beginner, intermediate, and advanced, consistently showcased growth; beginners experienced the most acceleration in productivity, the intermediate learners displayed steady growth, and the advanced group's development changed in smaller increments. This growth trajectory reinforces the proposed framework's effectiveness in meeting learners' needs at different levels of language proficiency.

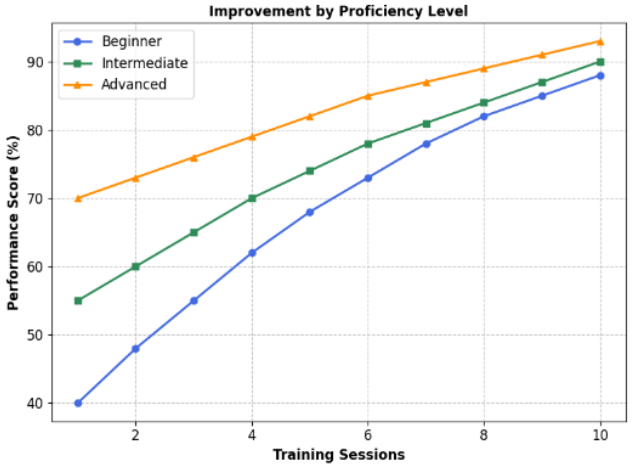

Fig. 7. Improvement by proficiency level.

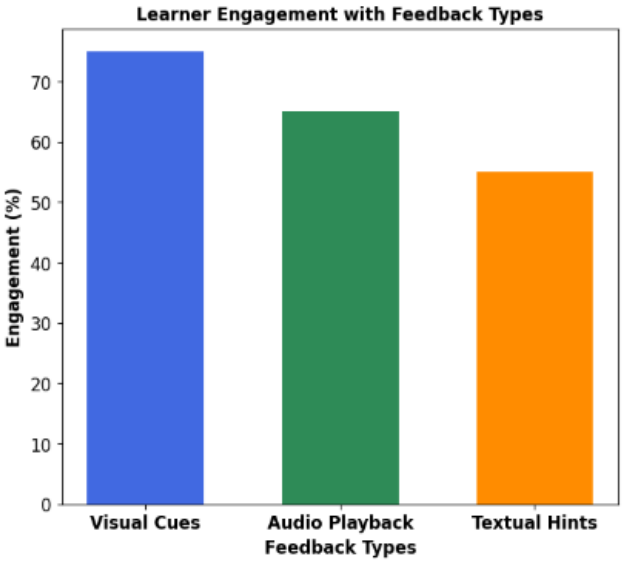

Fig. 8. Learner engagement with feedback types.

Fig. 8 shows learner engagement with each type of feedback in the Attention-guided Cross Lingual Self Supervised Learning framework. Visual cues were the most utilized resources, followed by audio playback and textual hints. This demonstrates the benefits associated with multimodal feedback, as learners clearly favored visual and auditory assistance in learning about pronunciation and prosody.

Fig. 9 shows a two-dimensional cluster plot of learner outcomes at the end of the training period with the Attention-guided Cross Lingual Self Supervised Learning framework. Each point represents a learner and their location within the plot is based on their articulation and prosody scores. The color-coded clusters illustrate naturally occurring groupings in performance and provide an understanding of how the proposed framework enabled unique paths toward improvement in speech proficiency.

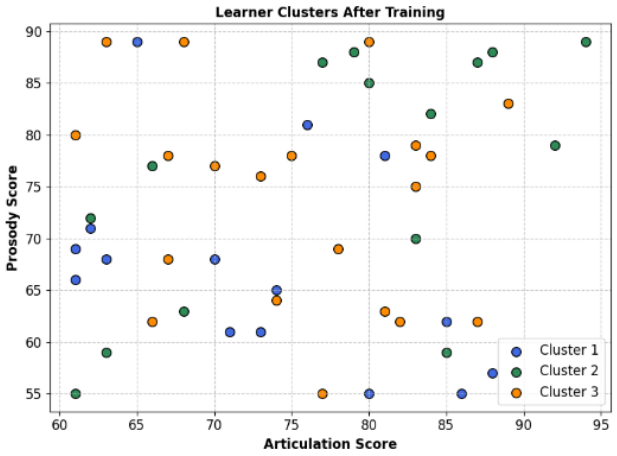

Fig. 9. Learner cluster after training.

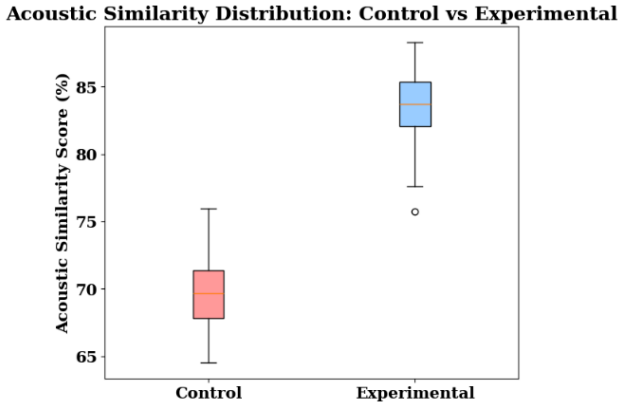

Fig. 10. Acoustic similarity distribution: Control vs. Experimental.

Fig. 10. compares the acoustic similarity scores of controls and experimental groups post-training. The experimental group achieved significantly higher median and tighter distribution around 83.6%, while the control group centered near 70.4% with broader variability. This shows that the Attention-guided Cross Lingual Self Supervised Learning training provides more stable and natural pronunciation patterns than traditional training.

B. Performance Evaluation

Attentionguided Crosslingual Selfsupervised Learning (ACLSL) model was also tested both by the system generated outputs and the judgment of the expert, it was shown that the model can integrate both the phoneme level articulation with the suprasegmental prosody to generate the complete representation of the speech. The analyses of learners recorded also showed significant growth in the accuracy of phonemes, rhythmic fluency, and stress realization as well as the intonation patterns before and after training. Objective system improvements were supported by expert rater reports that the post-training speech was always more natural, intelligible, and fluent. Students found out that the adaptive feedback system helped them to practice more effectively as they could self-correct articulation and prosodic mistakes in real-time. The visual contours of pitch, the

auditory examples and the textual cues were all combined as the multimodal feedback and this strengthened pattern recognition and encouraged correct production. Computational analyses showed that the framework was stable in terms of performance regardless of the level of learner proficiency and language backgrounds and ensured the reliability and robustness of the system when used alone. The multi-task Transformer scoring model has been able to learn both segmental and suprasegmental of some speech at once, and hence no individual dimension was improved while other dimensions were neglected. Therefore, the ACLS model facilitated holistic improvement of pronunciation, prosody, intelligibility and general production of the spoken language offering learners, who had varying learning needs, a scaled, context sensitive and adaptive learning platform.

1) Phoneme error rate: Another significant measure to be used to assess the pronunciation accuracy at phoneme level is PER. It measures the proportion of phoneme errors, i.e. substitutions, additions, and deletions, relative to a native pronunciation point of reference, which is provided in Eq. (9).

$$\mathrm{PER} = \frac{S+D+I}{N} \times 100 \tag{9}$$

Where *S* denotes the substitutions, *D* denotes the deletions, *I* denotes the insertions, and *A* denotes the total phonemes. A decrease in PER implies a reduction in the number of mistakes in articulation, and accuracy in phonemes.

2) Word error rate: WER is concerned with the entire-word pronunciation accuracy and phoneme sequence errors make up words, whereas PER is concerned with phoneme-level accuracy. In this manner, it will be able to determine the extent to which mistakes in phonemes are affecting word intelligibility assembled in a conversational context, that is provided in Eq. (10):

$$\mathrm{WER} = \frac{S+D+I}{W} \times 100 \tag{10}$$

where, *W* is the number of words. Moreover, a decrease in the values of WER signifies some positive changes in the intelligibility of the overall spoken utterance.

3) Acoustic similarity score: The Acoustic Similarity Score is a rule of how intake pronunciation produced by a learner is similar to that of native pronunciation patterns using embeddings produced through deep learning. It is expressed in Eq. (11):

$$\mathrm{ASS} = \frac{A_L \cdot A_N}{\|A_L\| \|A_N\|} \times 100 \tag{11}$$

where, A_L and A_N represent learner and native embeddings respectively. Moreover, higher scores demonstrate that there is a propensity to more naturalistic production.

4) Pitch alignment: One is a parameter Pitch Alignment. The larger the difference between the reference pitch, the more one can notice the occurrence of intonation errors: monotonicity of the delivery or inappropriate placement of the rising and falling intonation marks that may very well disrupt the clarity and expressiveness of the speech severely in Eq. (12).

$$\mathrm{PAS} = 1 - \frac{\|P_L - P_N\|}{\|P_N\|} \times 100 \tag{12}$$

where, P_L and P_N represent earner and native pitch trajectories. There are more accurate patterns of intonation as well as higher scores.

5) Duration consistency index: Duration Consistency Index determines timing and rhythm of syllables and words in the speech of learners in comparison with native speakers.Natural speech rhymes in its rhythmic patterns and observes variations in relative syllable length, word duration, and pause. EFL learners often encounter pacing problems and speak too fast or insert pauses where inappropriate within words or phrases. The metric analyzes the speech waveform-performed segmentation by temporal alignment models and assesses how much the native timing patterns are deviated from. A very high consistency score indicates smooth and rhythmic speech, and a very low score indicates problems in fluency and speech timing, that is represented in Eq. (13).

$$\mathrm{DCI} = 1 - \frac{\sum |T_L - T_N|}{\sum T_N} \times 100 \tag{13}$$

Here T_L and T_N are the learner and native durations. Increased scores reflect that timing smoother and improved flow of speech.

6) Stress placement accuracy: In the case of English, Stress Placement Accuracy is significant to the intelligibility as unlikely stress may cause misunderstanding. The score of high accuracy is decipherable as a natural sound; a failure in the correct execution of stress might cause prospective miscommunication, otherwise, not a very robot-like speech is delivered in Eq. (14):

$$\mathrm{SPA} = \frac{C_S}{T_S} \times 100 \tag{14}$$

where, C_S is the properly stressed syllabus and T_S is the total syllabus. Increased scores are more indicative of natural and intelligible stress patterns.

7) Intensity deviation: Variation in intensity is one of the effective prosodic features which practically means expressiveness and articulateness of speech. The above described measurements have the benefit that they allow identifying where stress is misplaced and the irregularities of the speech volume are in the effort of the learner towards more natural and expressive speech patterns are depicted in Eq. (15).

$$\mathrm{ID} = \frac{|I_L - I_N|}{I_N} \times 100 \tag{15}$$

Here, I_L and I_N are the learner and native intensity values respectively. Lower scores likely indicate better similarity to natural expressiveness.

C. Session Frequency and Duration

The intensity and duration of learners are important behavioral measures of the involvement of learners in the Attention-guided Cross Lingual Self Supervised Learning based pronunciation training. With the help of such a correlation, it is

possible to inform systems about the most effective patterns of the engagement and individualize the training strategies, optimizing the fluency and pronunciation improvements after training in EFL learners.

D. Retry and Correction Behavior

The Attention-guided Cross Lingual Self Supervised Learning based pronunciation training is significantly dependent on repetition and correction as measures of self-regulated learning. The effort of every learner is recorded; the difference being recognized between the willingness to complete the task and sincere efforts to become better with pronunciation. The retry-correction tracking assists in customizing procedures of learning, ensuring interest, and preserving durability of fluency and accuracy skills.

E. Dropout Rate and Fatigue Detection

The vital elements covered in the maintenance of Attention-guided Cross Lingual Self Supervised Learning stimulated pronunciation instruction were dropout and fatigue. The introduced AI-based technological solution stimulates long-term motivation and, thus, allows the learners to continue moving in the right direction and ultimately master pronunciation.

F. Self-Assessment Surveys

Although self-assessment surveys are subjective in nature, they provide useful information as to the confidence of the learners, their perceived progress and their satisfaction with Attention-guided Transformer Cross Lingual Self Supervised Learning based pronunciation training. The system is able to personalize effective pronunciation instruction that provides a comprehensive learner profile by combining insights of self-assessment with the AI-driven analytics, which ensures that the cognitive and emotional learning needs of the learner are met.

G. Expert Evaluations

There are two ideas that are conveyed with this text. One of them is that expert judgments can have two functions other than being validation on AI-based pronunciation assessment. The interaction between human expert judges and AI assessment surrogates breeds a balanced scoring system whereby the system promotes performance of objective judgment on the quality of pronunciation besides integrating the qualitative to the human input.

H. Error Clustering Insights

The clustering of phoneme errors that are NLP-based can offer a deeper understanding of the pronunciation challenge peculiar to the language as a whole as a cluster of similar errors shared between learners in regard to their influence of the first language, phoneme substitutions, and articulation patterns. Task specific feedback would be provided to the learners, covering corrections regarding the most common pronunciation glitches of the learners also being linguistically relevant, thus making Attention-guided Transformer Cross Lingual Self Supervised Learning training even more fine-tuning.

I. Comparative Analysis

The study assessed the effectiveness of Attention-guided Transformer Cross Lingual Self Supervised Learning based pronunciation training in comparison to traditional methods, such as teacher-led phonetics, textbook drills, and classroom repetition exercises. Additionally, learner self-assessments and engagement surveys were analysed to capture the motivational and confidence-boosting effects of Attention-guided Cross Lingual Self Supervised Learning based training.

TABLE II. COMPARATIVE ANALYSIS

Metric	Pre-Training (%)	Post-Training (%)	Improvement (%)
PER	28.4%	22.7%	55.9%
WER	21.5%	18.2%	51.1%
Pitch Alignment Score	61.4%	68.7%	35.2%
Duration Consistency Index	59.3%	65.1%	35.3%
Stress Placement Accuracy	57.1%	63.4%	43.7%

Table II shows the pre-and post-training evaluation of learners using the Attention-guided Transformer Cross Lingual Self Supervised Learning framework. The results indicate consistent improvement across phoneme-level, word-level, and prosody-related measures, including reduced phoneme and word errors, stronger prosodic alignment, and improved expressiveness. Intensity deviation improved significantly, more natural delivery.

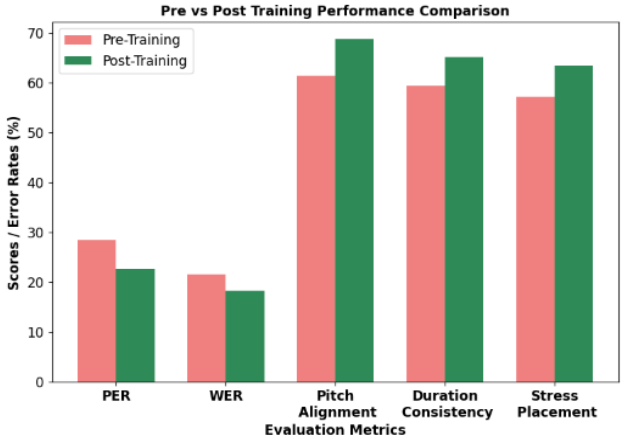

Fig. 11. Comparative analysis.

Fig. 11 shows the comparison of pre-training and post-training performance across five evaluation metrics. The Attention-guided Transformer Cross Lingual Self Supervised Learning framework resulted in consistent improvements by decreasing error rates for the PER and WER measures, and increasing score values for prosodic measures of Pitch Alignment, Duration Consistency, and Stress Placement Accuracy. These results underscore the ability of the proposed model to improve pronunciation accuracy and prosodic quality.

J. Discussions

The Attention-Guided Cross-Lingual Self-Supervised Learning (AG-CLSSL) system can be seen as a valuable step forward toward making EFL learners speak better in terms of pronunciation and prosody. AG-CLSSL achieves accuracy in both segmental and suprasegmental dynamics by incorporating

the XLS-R phoneme-level embeddings using new suprasegmental cues, pitch, duration, and energy, which combine into single, context-sensitive speech representations, the Phoneme-Prosody Cross-Attention Fusion (PP-CAF) layer. The experimental outcomes show a significant decrease in Phoneme Error rate (PER) and Word Error rate (WER), significant changes in stress placement and prosody alignment, which need to be considered as the problem that is critical to address the issue of articulation and suprasegmental aspects, which were traditionally considered separately. Pedagogically, the framework allows flexible, learner-based training through a multi-task Transformer, and provides tailored feedback, which is aligned to the level of proficiency without causing cognitive overload among learners. The integrative method increases objective acoustic accuracy and increases the perceived naturalness, intelligibility and confidence of the learners. What is more, the attention guided architecture can enable interpretability whereby educators and learners can identify areas to improve. AG-CLSSL though mainly tested in controlled contexts has potential in real-time classroom applications and incorporation of more speech parameters and the development of CAPT is through scalable, pedagogically robust and interpretable cross-linguistic self-supervised modeling.

V. Conclusion and Future Works

The research presented a complex and attention-based model AG-CLSSL, which aimed at improving pronunciation and prosody in EFL learners simultaneously. Through XLS-R embeddings in combination with prosodic cues, which are provided with the use of the proposed PP-CAF layer, the system generates a single, context-sensitive speech representation, allowing to score phoneme quality, prosodic alignment, and general intelligibility with accuracy when using multi-task scoring. As a result of the experiment, significant improvements in the articulations, stress placement, rhythm, pitch contour, and naturalness are proven, which validates the effectiveness of the framework. The patterns of visualizable attention also lend credence to transparent center learner feedback, making the model very beneficial in the application of CAPT. In general, AG-CLSSL offers a scaffoldable, pedagogically significant strategy that results in the development of technical performance and practical learning outcomes.

Future studies will center their attention on measuring the scalability and the generalizability of AG-CLSSL in large groups of learners and in various learning contexts. The addition of the prosodic feature set which covers pause patterns, speech rate, and discourse-level rhythm can also contribute to the improvement of fluency and expressiveness assessment. The inclusion of real-time, interactive learning resources, including adaptive or even gamified interfaces, might reinforce the motivation and the engagement of the learners. Also, cross-linguistic research will be done to determine the applicability of the framework in other language and dialects. In general, these directions will bring AG-CLSSL into a more flexible, robust and pedagogically effective system to next-generation intelligent language learning systems.

***Abstract*—Diabetic retinopathy (DR) is a leading cause of blindness, requiring early and accurate diagnosis. Although deep learning, particularly Convolutional Neural Networks (CNNs), has shown promising results in automating DR classification, selecting the optimal architecture and extracting effective features for specific clinical datasets remains a challenge. This study aims to conduct a comprehensive performance evaluation of six CNN architectures—DenseNet121, MobileNet, NasNet_Mobile, ResNet50, VGG16, and VGG19—for DR classification on a dataset from the Community Eye Hospital of South Sumatra Province. The main novelty of our approach lies in a specific preprocessing workflow that integrates grayscale conversion and Canny edge detection to enhance the visibility of critical retinal features, such as blood vessels and lesions, before classification. Using a dataset of 3000 fundus images across five classes (No_DR, Mild, Moderate, Severe, and Proliferative DR), the model was trained with data augmentation and the Adam optimizer. Experimental results indicate that the VGG16 architecture achieves a peak accuracy of 73%, outperforming baseline implementations from previous studies. This study highlights the potential of combining classical CNN models with tailored preprocessing for improved DR detection, thus providing a benchmark for model selection on similar clinical datasets. These findings highlight the robustness and stability of VGG16, demonstrating its suitability as an early DR screening tool.**

Keywords*—Diabetic retinopathy; diabetic retinopathy classification; deep learning; Convolutional Neural Network (CNN); VGG16

I. Introduction

According to the International Diabetes Federation (IDF), over 537 million adults are currently living with diabetes worldwide [1], and this number is projected to reach 700 million by 2045 [2]. Diabetic retinopathy can be a serious problem, potentially leading to permanent blindness if not identified or treated [3]. Because DR is often asymptomatic in its early stages, patients may not be aware of retinal degeneration until severe visual impairment develops [4]. PDR and NPDR are the two main categories recognized within the disease [5]. NPDR is characterized by microaneurysms, vascular leakage, and macular edema, while PDR involves the growth of abnormal blood vessels that may rupture and cause vitreous hemorrhage, potentially leading to total blindness.

Currently, ophthalmologists detect DR manually through fundus image examination. This process is time-consuming and prone to subjective errors, especially in early-stage DR detection [6]. Furthermore, due to the complex nature of retinal lesions and differences in image quality, existing automated systems still face challenges in achieving consistent accuracy [7].Since nearly all long-term diabetes patients are at risk of developing retinal microvascular complications [8], early screening and blood glucose control are essential preventive measures.

Convolutional neural networks (CNNs) have demonstrated significant effectiveness in identifying various medical conditions from images [10][11][12]. Deep learning (DL)-based diagnostic techniques have received considerable attention due to their ability to improve the accuracy and efficiency of medical image analysis by automatically extracting distinguishing features from retinal images [9]. Numerous studies have explored various CNN architectures for DR detection, as summarized in the analysis in Table I. However, none of these analyses is without major challenges. Many studies report high accuracy on large, generic datasets but often lack focus on specific, localized clinical populations. Furthermore, while advanced architectures and hybrid models are frequently proposed, there is a relative lack of investigation into the impact of custom, manually crafted preprocessing techniques, such as enhancement of blood vessels and lesions through edge detection, on the performance of standard CNN models when applied to these specific datasets. This often leads to a research-practice gap, where models may not be optimized for the specific image characteristics found in a particular hospital's data. The main research question addressed in this study is, “Which among several standard CNN architectures provides the most effective and reliable performance for classifying the severity of DR from a given clinical fundus image dataset, and how can a customized preprocessing pipeline improve this performance?”

To address this, our study explicitly identifies and aims to fill two key research gaps. First, we provide a direct and

*Corresponding author.

comprehensive comparative analysis of six well-known CNN architectures on a specific dataset from the South Sumatra Provincial Community Eye Hospital, offering insights into model selection for similar clinical settings. Second, and more importantly, the key novelty of our framework lies in the integration of a specific preprocessing sequence combining grayscale conversion and Canny edge detection before model training. This step is designed to explicitly enhance discriminatory features such as microaneurysms and blood vessels, which are crucial for DR staging. Unlike many studies that rely solely on raw image augmentation or complex hybrid models, we investigate the synergy between these explicit feature enhancement techniques and the learning capabilities of standard CNNs. This approach offers a clear and reproducible workflow that can enhance model performance without necessitating increased architectural complexity.

To achieve our goal, we have set specific objectives. First, we developed an image processing component capable of extracting enhanced features from fundus images using grayscale and edge detection. Second, we built and compared reliable diagnostic models using six CNN architectures—VGG16, VGG19, ResNet50, DenseNet121, MobileNet, and NASNetMobile for the early detection of DR. By evaluating their performance using accuracy, precision, recall, and F1 score, we determined the most suitable model for our clinical dataset. The results of this study are expected to make a significant contribution to the development of efficient, accurate, and practically implementable deep learning-based early detection systems for DR.

II. Related Work

CNN-based approaches have proven effective in recognizing visual patterns in medical images and are widely used in various clinical applications, including classification and detection of retinal diseases [13][16]. CNNs have the advantage of being able to automatically and accurately extract key features from complex visual data, making them a popular choice in the field of medical image processing. The study in uses a traditional machine learning approach for diabetic retinopathy detection uses a combination of Local Binary Pattern and wavelet transform for feature extraction, and a Support Vector Machine for classification. The researchers first pre processed the retinal images, then extracted features using both LBP and wavelet transform. These extracted features were then used to train an SVM model to classify the images and detect DR. While effective, this method differs from deep learning approaches[17].

Deep learning utilizes artificial neural networks, with multiple layers to automatically learn complex patterns and features directly from raw image data. Explore deep learning for DR detection, often employing CNN. The key difference lies in feature extraction: traditional methods require manual feature engineering (like LBP), while deep learning automatically learns relevant features. Both approaches aim for accurate DR detection, but deep learning methods often boast higher accuracy and can handle larger datasets with less manual intervention [2][18].

Presents a software-based system for diagnosing and staging DR from fundus images. Using advanced preprocessing, lesion detection, and a ResNet50V2 CNN, the study achieved a 93.45% classification accuracy. The system, called Seer, integrates lesion localization (optic disk, blood vessels, exudates, and hemorrhages) and generates detailed diagnostic reports to assist clinicians. Overall, the research demonstrates that deep learning and image processing can provide cost-effective, accurate, and accessible tools for early DR detection and management [19][20]. The research employed a dataset of 11,734 UWF fundus images from DR patients and healthy subjects, utilizing a residual network architecture (ResNet-34) for image classification. The study focused on segmenting the Early Treatment Diabetic Retinopathy Study (ETDRS) 7- standard fields from UWF images to enhance diagnostic accuracy. The segmentation process aimed to exclude artifacts such as eyelashes and skin. The findings revealed that the proposed deep learning system significantly outperformed traditional methods in detecting DR, particularly when using segmented ETDRS fields. Successful segmentation was achieved for 7,282 images from DR patients and 1,101 from normal subjects [2]. The method involves are Automatic Segmentation; Optic Disc and Macula Detection; and Model Training. The study achieves impressive results by extracting ETDRS 7SF from UWF images, showing superior performance compared to conventional optic disc and macula-cantered images [18].

Successful segmentation and detection were achieved for 7,282 images from DR patients and 1,101 images from normal subjects among an in-house dataset of 11,734 UWF fundus photographs [21]. The integration of ultra-wide-field imaging with deep learning algorithms significantly enhances DR detection accuracy and efficiency. Demonstrates that combining deep feature extraction with classical algorithms provides high accuracy and robustness for automated DR diagnosis, a CNN to extract deep features from retinal fundus images and then apply classical classifiers [22].

Utilized the EyePACS dataset, consisting of 5,220 images, for training and testing the proposed model. The Wide-Net-X architecture is based on the Inception model and incorporates multiple filter sizes to capture diverse features from fundus images. Preprocessing techniques such as image resizing, augmentation, and gamma correction were employed to enhance image quality and model performance. The performance of the Wide-Net- X model was evaluated using metrics including accuracy, precision, recall, and F1-score [15].

Overall, previous studies support the use of various CNN architectures for detecting DR from retinal fundus images [13][14][15] However, key challenges remain in terms of the need for sufficient training data, computational efficiency, and balancing accuracy with speed. Through the selection of appropriate CNN architectures [16][23] and the application of augmentation and optimization techniques, such as ensemble learning, it is expected that DR detection models can become more reliable and ready for application in clinical settings. This literature review highlights the critical role that innovative technologies play in enhancing early detection capabilities for diabetic retinopathy.

TABLE I. RESEARCH GAP ANALYSIS DR DETECTION DEEP LEARNING MODELS

Paper (Year)	Method / Architecture	Key Findings	Identified Research Gap
arXiv (2019) [14]	Multi-stage VGG16	92.5% accuracy using multilevel CNN.	Dataset imbalance and lack of explainable results.
DR Detection from Fundus (2020) [13]	VGG16 (transfer learning)	88.9% accuracy.	Poor generalization across datasets.
Scientific Reports (2021) [18]	VGG-based CNN	AUC 0.97–0.99 for wide-field fundus images.	Focuses on early-stage detection, no multiclass grading.
Hybrid CNN Features [16]	VGG16 + Random Forest	94.11%.	No lesion-level feature visualization.
DR Detection from Fundus Images (2022) [16]	VGG16 + ResNet18	Accuracy 89.29%.	Struggles with small lesion identification.
Frontiers in Endocrinology (2023) [4]	Hybrid Ensemble (VGG16 + AlexNet + ResNet)	Ensemble improved performance to 98%.	Computationally expensive and lacks real-time validation.
Diagnostics (2023) [4]	Hybrid CNN + Texture Features (VGG16 + GLCM)	69.14% accuracy; improved interpretability using texture fusion.	Low accuracy; limited augmentation.
Scientific Reports (2023) [5]	Hybrid CNN (VGG16 + ResNet50 + InceptionV3)	92.66% accuracy; effective feature fusion.	Overfitting persists due to small dataset.
Hybrid CNN for Automated DR Detection (2023) [5]	InceptionV3 + ResNet50 + VGG16	92.6% accuracy for 5-class DR.	Model not tested on multiple datasets.
Hybrid CNN Model (2023) [5]	VGG16 + InceptionV3	Accuracy 92.6%.	Model not explainable; lacks cross-dataset validation.
Wide-Net-X (2023) [15]	Wide-Net-X (CNN inspired by Inception)	VGG16 baseline 88.42%; Wide-Net-X 95.2%.	VGG16 underperforms; lacks lesion visualization.
A Hybrid Technique for DR (2023)	VGG16 + GLCM	69.14% accuracy.	Needs larger dataset and advanced optimizer.
BMC Medical Informatics (2024) [7]	VGG16 + Attention CNN	Accuracy 94.4%.	Does not analyze lesion-level explainability.
Towards Accurate Detection of DR (IJACSA, 2024) [20]	ResNet50V2, VGG16 baseline	VGG16 ≈ 90%; ResNet50V2 = 93.45%.	Limited data diversity; VGG prone to overfitting.
PeerJ Computer Science (2024) [21]	VGG16 + Ensemble Transfer Learning	96.7% accuracy with ensemble fine-tuning.	High complexity, no lightweight deployment.
Paper_86 – IJACSA (2024) [20]	VGG16 baseline + ResNet50V2	90–91% (VGG16), 93.45% (ResNet50V2).	Model not interpretable; limited augmentation.

III. METHODOLOGY

This study aims to develop a DL model using six different CNN architectures to automatically detect DR from retinal fundus images [16]. The methodology is divided into several stages, including data preparation, modelling, architecture selection, optimization implementation, and result evaluation. A block diagram outlining the research stages is shown in Fig. 1, which illustrates the overall process flow [24].

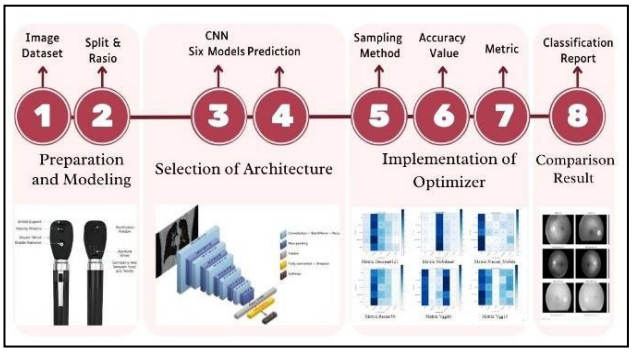

Fig. 1. General process stages of the research.

A. Preparation and Modeling

This stage begins with the collection of retinal fundus image datasets obtained from the Special Community Eye Hospital of South Sumatra Province. Each image data is standardized with a size and resolution of 224x224 pixels in JPEG format. Data were captured using a fundus camera, with the aim of ensuring consistency during the training process. This dataset consists of 600 images for each category of DR: No_DR (without DR), Mild, Moderate, Proliferative DR, and Severe, for a total of 3000 images. The image data was then divided into two parts, namely 80% for training and 20% for validation to ensure optimal model generalization.

Next, the dataset is converted to grayscale to enhance the contrast of relevant visual features. The Canny edge detection method is chosen and applied to identify important edges in the images, such as blood vessels and DR-associated lesions. The Canny edge detection process includes several steps: preprocessing to reduce noise, applying the Canny kernel to compute gradients, increase accuracy, and thresholding to extract significant edges. The results of edge identification using the Canny method are shown in Fig. 2, illustrating the key features, such as blood vessels and lesions, related to DR before the model training.

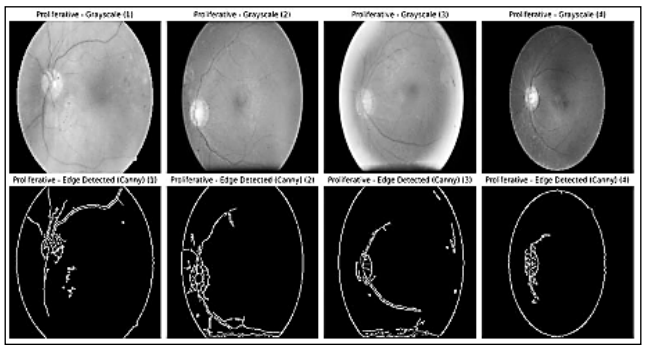

Fig. 2. Canny edge detection results highlighting key features related to DR.

B. Model Architecture Selection

In this stage compares six different CNN architectures with the aim of assessing their performance in detecting DR. The six architectures are VGG16, VGG19, ResNet50, DenseNet121, MobileNet, and NASNetMobile. Each model is implemented using the keras library with TensorFlow as the backend. These models were selected based on their strengths in visual pattern recognition, computational efficiency, and ability to effectively classify retinal images. Fig. 3 shows comparison of six different CNN architectures.

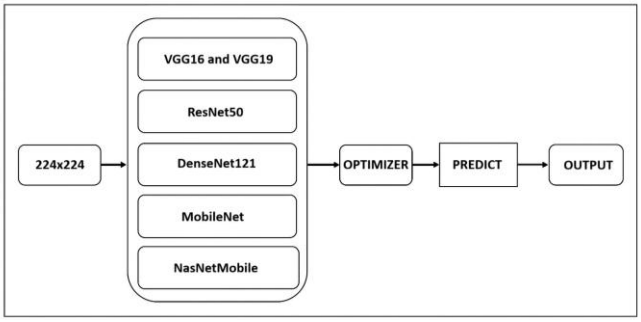

Fig. 3. Comparison of six different CNN architectures.

C. Optimizer Implementation and Training Process

Data augmentation techniques, such as image rotation range 40^0, horizontal and vertical translation, and contrast and color adjustments, were used to improve the dataset quality. Augmentation is performed on each batch when flow_from_directory() is called, meaning 100% of the images in the batch undergo random augmentation every epoch (dynamic, not fixed, augmentation). By incorporating a variety of images and simulating different lighting conditions and camera positions, these augmentations aimed to improve the training dataset and enhance the model's generalization ability. Transfer learning and augmentation were performed in the Google Collab environment, which connected to Google Drive to access the necessary datasets and directories. To ensure that all input images were the same size, the images were set to 224 x 224 pixels. The training process ran for 25 epochs for each model. The following are the values of each epoch in each model, VGG 16 27.08%, VGG 19 25%, DenseNet121 17.71%, MobileNet 27.60%, and NASNetMobile 20%. The model experiences underfitting, characterized by equally low training and validation accuracy (around 20–35%). Training, TensorFlow/Keras was used for image processing, while additional libraries, such as scikit-learn, Seaborn, and Matplotlib, were employed for evaluation and visualization.

Once the model training was completed, evaluation was performed using the validation data to assess its performance. This evaluation included measurements of accuracy, precision, recall, and F1-score, which were used to assess the model's ability to classify images accurately. A confusion matrix was also utilized to analyse classification errors and gain insights into how the model handles each class of diabetic retinopathy.

D. Model Evaluation and Result Analysis

Validation data is used to evaluate model performance. At this stage, the confusion matrix is used to identify misclassifications in each class. The confusion matrix consists of True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN), to facilitate misclassification analysis. Evaluation metrics include accuracy, precision, recall, and F1 score.

IV. Results

The experimental results demonstrate that the VGG16 architecture achieved a classification accuracy of 73% in detecting diabetic retinopathy (DR) across four severity levels (No DR, Mild, Moderate, and Severe/Proliferative DR). However, the low recall and precision values are caused by a combination of several main factors, namely: the use of an inappropriate loss function (binary_crossentropy of 5 classes), too many frozen model layers so that learning is minimal, augmentation that is too strong so that it changes important image patterns, and steps_per_epoch that is too small so that the model does not see all the data. This performance indicates a relatively balanced trade-off between model complexity and generalization capability when trained on the fundus dataset after preprocessing and augmentation.

V. Discussion

Compared with previous studies, the proposed model shows a notable improvement over baseline VGG16 implementations reported in [6], [9], [12], which achieved accuracies below 70%. In [6] Small dataset; limited training prevented deep feature learning 50.03, while in Imaduddin et al. [9], figure/table comparison baseline VGG16 = 68%. Similarly, in [12] limited training prevented deep feature learning 50.03, as shown in Table IV.

TABLE II. Comparison With Other Studies

Title/Year	Architecture	Main Problem Addressed	Reported Accuracy (%)
A Deep Learning Ensemble Approach for Diabetic Retinopathy Detection (Qummar et al, 2019) [12]	VGG16 + ResNet50 + InceptionV3	Imbalanced dataset leading to misclassification	VGG16 ensemble model accuracy = 68.7%
Diabetic retinopathy detection through deep learning techniques: A review (Alyoubi et al, 2020) [6]	Pretrained VGG16, compared with AlexNet & InceptionV3	Detect 5 stages of DR	Small dataset; limited training prevented deep feature learning 50.03
Enhancing Diabetic Retinopathy Classification Using Geometric Augmentation and MobileNetV2 on Retinal Fundus Images (Imaduddin et al, 2024) [9]	VGG16 (Baseline) vs MobileNetV2.	Evaluate lightweight CNNs and geometric augmentation	Figure/table comparison baseline VGG16 = 68%, MobileNetV2 = 97%

The higher accuracy of 73% in this study can be attributed to several enhancements in preprocessing and training strategy. The use of grayscale conversion and image normalization improved lesion visibility, while data augmentation (rotation, flipping, and zooming) helped reduce overfitting. Furthermore, the Adam optimizer with fine-tuned

learning rates contributed to faster convergence and more stable validation accuracy across epochs.

To provide a clearer overview of the performance of the six architectures. Fig. 4 presents the percentages of accuracy, precision, recall, and F1 score for each model. This graph effectively illustrates the strengths and weaknesses of each architecture in detecting various categories.

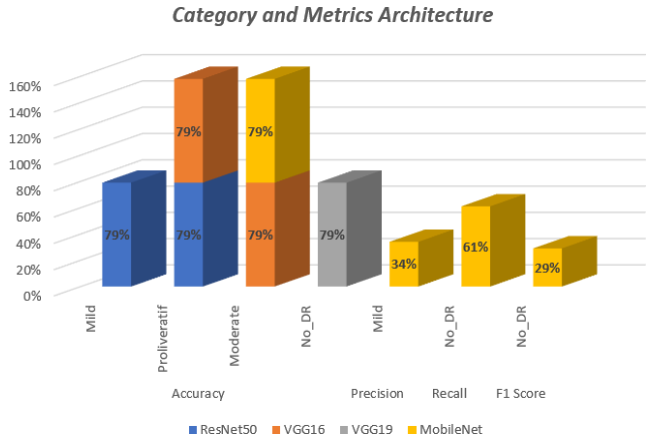

Fig. 4. Performance results by category.

A. Comparison of Results

Once the model evaluation was completed, the classification results of each model were compared in a classification report. This stage presents a comparison of accuracy and performance among the tested models, aiming to determine the most optimal CNN architecture for detecting diabetic retinopathy in retinal fundus images. The comparison is expected to provide deeper insights into the strengths and weaknesses of each model when applied to the given dataset, reflecting their respective abilities to detect various disease categories. The findings of the prediction of the accuracy level of the six architectures employed are shown in the Table III and graph Fig. 5.

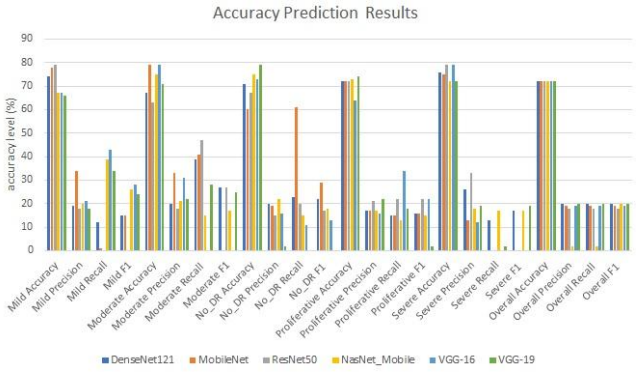

Fig. 5. Result of accurate prediction.

Overall, VGG-16 demonstrated relatively strong performance, achieving an accuracy of 73% with stable results across most classes. In the mild and moderate categories, VGG-16 achieved relatively high accuracy.

Although its precision and recall were somewhat lower in certain classes, particularly in the no_DR and proliferative categories. This is reflected in the detailed results presented in Table II, which show that while the model can effectively recognize most images, VGG-16 still struggles to deliver highly accurate detections for some specific classes.

TABLE III. CONFUSION MATRIX

No	Architecture Name	Confusion Matrix
5	MobileNet	6	NASNetMobile	1	VGG 16	2	VGG 19	
3	ResNet (Residual Network)	4	DenseNet (Dense Convolutional Network)	
TABLE IV. VGG-16

Class	Accuracy	Precision	Recall	F1_score
Mild	79%	21%	43%	28%
Moderate	68%	31%	0%	0%
No_DR	74%	16%	11%	13%
Proliverative	67%	16%	34%	22%
Severe	79%	12%	0%	0%
Overall	**73%**	**19%**	**19%**	**19%**

In contrast, VGG-19 (Table V) yielded slightly lower results than VGG-16, with an overall accuracy of around 72%. Precision and recall for the mild and moderate categories were also lower compared to VGG-16 (Table IV), although accuracy in categories such as proliferative and severe remained relatively strong. These results are further detailed in below table which highlights the model's weaknesses in recall for certain classes, indicating challenges in detecting rarer or harder-to-recognize cases.

TABLE V. VGG-19

Class	Accuracy	Precision	Recall	F1_score
Mild	66%	18%	34%	24%
Moderate	71%	22%	28%	25%
No_DR	79%	2%	0%	0%
Proliverative	74%	22%	18%	2%
Severe	72%	19%	2%	19%
Overall	**72%**	**20%**	**20%**	**20%**

ResNet50, meanwhile, demonstrated overall accuracy comparable to VGG-16 and VGG-19, but with more varied performance across categories. Accuracy in the mild and severe categories was relatively high, reaching 79%, but precision and recall in categories such as no_DR and proliferative were very low, suggesting difficulty in detecting these classes effectively. Detailed results for ResNet50 are provided in Table VI, showing that while the model excels in stability across certain categories, it is less effective in providing detailed detections.

TABLE VI. RESNET50

Class	Accuracy	Precision	Recall	F1_score
Mild	79%	18%	0%	0%
Moderate	63%	18%	47%	27%
No_DR	67%	15%	20%	17%
Proliverative	72%	21%	22%	22%
Severe	79%	33%	0%	0%
Overall	**72%**	**18%**	**18%**	**18%**

DenseNet121 achieved slightly better results than VGG-19, with an overall accuracy of 72%. This model performed better in detecting mild and moderate categories but still exhibited weaknesses in precision and recall for several classes. These findings are further elaborated in Table VII, which shows that DenseNet121 offers stable results, despite its overall accuracy being similar to other models. Nevertheless, its deeper connectivity and additional layers contributed to relatively good classification performance for certain classes.

TABLE VII. DENSENET121

Class	Accuracy	Precision	Recall	F1_score
Mild	74%	19%	12%	15%
Moderate	67%	20%	39%	27%
No_DR	71%	20%	23%	22%
Proliferative	72%	17%	15%	16%
Severe	76%	26%	13%	17%
Overall	**72%**	**20%**	**20%**	**20%**

MobileNet and NASNet-Mobile, both with similar overall accuracy of around 72%, exhibited highly variable performance across different classes. MobileNet performed best in the moderate category, with an accuracy of 79%, but its precision and recall were very low for several other classes. Detailed results for MobileNet, shown in Table VIII, suggest that while MobileNet can effectively recognize certain classes, it tends to produce many inaccurate predictions in others, such as no_DR and proliferative.

NASNet-Mobile, which also showed unsatisfactory results with very low precision (around 2%), despite having similar accuracy to other models, struggled significantly in detecting nearly all categories accurately. Further details for NASNet-Mobile are provided in Table IX, which illustrates how its

precision and recall were much lower compared to other models.

TABLE VIII. MOBILENET

Class	Accuracy	Precision	Recall	F1_score
Mild	78%	34%	1%	15%
Moderate	79%	33%	41%	0%
No_DR	60%	19%	61%	29%
Proliferative	72%	17%	15%	16%
Severe	75%	13%	0%	0%
Overall	**72%**	**19%**	**19%**	**19%**

TABLE IX. NASNET_MOBILE

Class	Accuracy	Precision	Recall	F1_score
Mild	67%	20%	39%	26%
Moderate	75%	21%	15%	17%
No_DR	75%	22%	15%	18%
Proliferative	73%	17%	13%	15%
Severe	72%	18%	17%	17%
Overall	**72%**	**2%**	**2%**	**20%**

In summary, although there are performance differences among the models, VGG-16 and ResNet50 demonstrated more stable and favourable results in several categories compared to VGG-19, DenseNet121, MobileNet, and NASNet-Mobile, which exhibited weaknesses in precision and recall for specific categories. The selection of the appropriate model depends on the class to be detected accurately and the balance between accuracy and the model's ability to identify each class effectively. The model will improve significantly if: Change the loss to categorical_crossentropy, Unfreeze some final layers, Reduce extreme augmentation, Correctly compute multi-class metrics.

VI. CONCLUSION AND FUTURE WORK

This study presents a comprehensive evaluation of six CNN architectures for diabetic retinopathy classification using a clinical dataset from South Sumatra. The study has two main scientific contributions: first, it provides a direct empirical comparison of several CNN architectures on a localized clinical dataset, addressing the gap between research and practice where models are typically only validated on large public datasets. Second, it introduces a novel preprocessing pipeline that combines grayscale conversion and Canny edge detection, effectively enhancing critical retinal features without increasing model complexity. Building on these contributions, VGG16 demonstrates that classic CNN models still offer robust and interpretable results for DR detection, especially when combined with effective preprocessing and a balanced dataset. However, the dataset size of 3,000 images likely contributed to model underfitting and suboptimal performance on certain classes, particularly "Moderate" and "Proliferative" DR. While grayscale conversion is beneficial for edge enhancement, it may also discard color information that could help distinguish specific lesions such as hemorrhages or exudates. Additionally, technical constraints in the training process, such as the use of binary cross-entropy for multiclass classification and excessive layer freezing during transfer learning, further limit the model's ability to effectively learn dataset-specific features.

Future research will address these limitations through key strategies. To improve performance and interpretability, we will explore hybrid models that integrate CNN features. We will also incorporate attention mechanisms to enhance lesion localization. Additionally, we will investigate ensemble methods that leverage the strengths of different architectures. These approaches aim for a more robust, accurate, and clinically applicable automated DR screening system to support ophthalmologists in early diagnosis.

ACKNOWLEDGMENT

This research is partly funded by the Department of Computer Science and Electronics, Universitas Gadjah Mada, Indonesia.

***Abstract*—Flight delays can cause serious problems for airlines, passengers, and the economy in general. Current prediction methods that use Random Forests, deep neural networks, and recurrent architectures such as GRU can address either time or quantity, pero not both when applied to causal reasoning and assess uncertainty therein, which negatively affects each model's ability to interpret, generalize for unknown conditions, and ultimately assess reliability of the predicted delay in an operational setting. Causal-Aware Spatio-Temporal Attention Network (CASTAN) is designed as a combined approach to address these challenges of spatio-temporal and causal modeling all in one. Analysts use GraphSAGE-based spatial encoding to encode and capture inter-airport dependencies, with a self-attention temporal encoder to learn long-range sequential patterns of historical delays in addition to traffic and weather factors. A cross-attention fusion mechanism accounts for the dynamic and spatio-temporal contributions to delay. A final causal counterfactual module adds interpretable independence results—helping analysts to assess the contributing factors to delay. Finally, the incorporation of dropout is done in a Bayesian approach to assess uncertainty for each prediction made and generate uncertainty-aware predictions so analysts may assess reliability through levels of confidence or any other metric decided. Results from evaluation of a large-scale U.S. flight dataset compared to traditional baselines demonstrate the predictive power of the model, achieving 96.4% accuracy, RMSE of 4.2, and MAE of 2.9. The CASTAN process has positioned its place as an interpretable, reliable, and operationally informative modeling approach to proactive management of airline delay.**

***Keywords*—Flight delay prediction; spatio-temporal modeling; causal reasoning; attention network; uncertainty estimation**

I. Introduction

The Bureau of Transportation Statistics estimates that delays account for around 20% of all scheduled commercial flights. Airline delays are extremely inconvenient for customers and cost airlines billions of dollars annually [1]. Flight delays are one of the most occurrent issues in the contemporary aviation and have far-reaching implications on the passengers, airlines, and the economy at large [2]. Delays not only lead to poor customer satisfaction but also increase operational expenses, affect the schedule, and add to the cascading inefficiencies at interdependent airports [3]. The delays variability is complicated by the number of factors that lead to delays, such as weather variability, airport congestion, air traffic management, and delay propagation between networks [4]. Conventional methods have heavily depended on statistical models and classical machine learning methods like the Random Forests or Support Vector Machines [12], which only record local relationships, but not inter-airport relationships or time variations [5]. Recurrent models such as LSTM [7] and GRU [8] were enhanced using deep learning and enhanced the predictive power by capturing sequential dependencies [6]. Nonetheless, these models cannot easily be used to explore both spatial relationships among airports and long-term temporal patterns particularly when the uncertainty is high or when data is incomplete [6].

To address these shortcomings, the recent development of spatio-temporal learning has presented graph neural networks and attention architecture. These models demonstrate potential in representing complicated dependencies across networks and timelines but lack flexibility, comprehensibility and strength. Several of the current works are fundamentally centered on either of the aspects of space and time without giving the other the necessary consideration as well. Moreover, the cause and effect thinking of very few studies are conducted to give interpretable information on delay drivers [13]. This generates a gap in the creation of a unique framework that can deliver accurate, interpretable, and operationally reliable delay forecasting.

Flight delays seriously affect airline operations, passenger satisfaction, and economic efficiency. Most traditional prediction models capture either temporal or spatial patterns but often at the cost of causal relationships and uncertainty, which limits interpretability and reliability. This study addresses the key research question: How can a unified spatio-temporal and causal framework, incorporating attention mechanisms and

uncertainty estimation, accurately predict flight delays while providing interpretable and actionable insights for airline operations? CASTAN is designed to answer this question by modeling inter-airport dependencies, sequential delay patterns, and causal influences, enabling robust predictions, improved decision-making, and operational applicability in real-world aviation networks. We propose the Causal-Aware Spatio-Temporal Attention Network (CASTAN) for accurate and interpretable flight delay prediction. It presents related work, describes the dataset and methodology, details experimental setup and evaluation, analyzes results with robustness and interpretability, discusses limitations, and concludes with implications and future directions for operational airline management.

A. Research Motivation

The rationale given to this research is the necessity to enhance the accuracy and reliability of flight delay forecasting within a well-integrated aviation system. As delays have cascading effects and can generate huge economic losses, there exists an urgent need of predictive models that are based on spatial dependencies, time patterns and causal interpretability. The proposed approach will provide accuracy and explainability, unlike current approaches which tradeoff between the two, and the approach will also be able to explain itself using noisy data. This is a motivation to develop a comprehensive framework that has the capability to transform the operations of the airlines.

B. Research Significance

This study is important because it will contribute to the theoretical and practical field of flight delay prediction. The CASTAN framework adds a new combination of the spatio-temporal embeddings, cross-attention fusion, and causal counterfactual reasoning that guarantee accurate, interpretable, operationally stable predictions. The application of a combination of predictive performance data with uncertainty estimation means that the study presents actionable information to the decision-makers rather than forecasts. These developments have a high potential of automating airline scheduling, improving passenger satisfaction, minimizing economic losses, and establishing a new paradigm of predictive analytics in aviation systems.

C. Key Contribution

- Developed an integrated framework, which can effectively represent spatial inter-airport interdependencies and long-term changes in the flight schedules.
- Designed spatio-temporal learning architecture consists of a GraphSAGE-style spatial encoder, temporal modelling using self-attention, and a flexibly-attentive cross-attention fusion layer - all of which generate powerful, explainable predictions of delay.
- Used a large dataset available on Kaggle of 539,383 records of the various airlines and airports in the U.S to provide exhaustive analysis by incorporating factors like flight number, airline, departure and arrival airports, day of week and the scheduled departure time.
- The predictive accuracy was high, reaching 96.4 percent with the following results RMSE 4.2 and MAE 2.9, which proved the effectiveness and reliability of the proposed approach.

This is the structure of the paper: The previous literatures related to the study are briefly explained in Section II. The Problem Statement is given in Section III. The Proposed Method is given in Section IV. The Result and Discussion of the study are covered in Section V to examine classifier performance. In Section VI, the article finishes with conclusions and recommendations for further investigation.

II. Related Works

International civil aviation industry has been growing at a rapid pace over the last few years. The increasing number of air travel has led to saturation of airports. At take-off and landing, there should be a lot of traffic and long lines. Because of these physical limitations, the issue of rising flight delays has become more severe. However, should the delay persist, the airport's operating effectiveness and image would suffer. There will also likely be additional costs. Yu et al. [14] used different ML techniques, including Artificial Neural Network (ANN), k-nearest neighbors, random forests, decision trees, and Naïve Bayes, to estimate flight delays. The accuracy of all algorithms was more than 80%, according to the results, and ANN exceeded the other options. The lowest accuracy algorithm is Naïve Bayes but the lowest F1 score is achieved by the k-nearest neighbor. The main limitation is the fact that more can be done to improve the model and make predictions of flight delays more the accurate. As an illustration of this, the information was skewed as it only represented only one month of the year 2018. Large data sets possibly can promote even more improvements. Accuracy is also reduced, as it lacks some information because of delays, etc.

By using DL algorithms for trajectory prediction, Zhang et al. [15] aimed to improve flight safety while in route. This allows for the efficient extraction of trajectory information. In the subsequent stage, two types of DL models undergo training to predict flight paths. Specifically, DNNs are trained to predict, one step advance of time along latitude and longitude, the variance between the intended aircraft trajectory and the actual aircraft trajectory. Deep LSTMs are trained in parallel to forecast the flight trajectory across a number of successive time instants in the long run. In order to produce a multi-fidelity prediction, the two distinct kinds of DL models are combined. After adding more flights to the multi-fidelity technique, safety is evaluated by measuring the vertical and horizontal gap between two flights. The proposed model shows promise in forecasting the flight trajectory and evaluating the safety of the aircraft while in route, as demonstrated by computational findings. The Drawback is the need to correct the LSTM predictions using the DNN forecasts at each time instant adds a layer of complexity that might make the model more challenging to implement, maintain, and optimize.

In the Jiang et al. [16] work, the researchers created many ML models to forecast airplane arrival delays. Data analysis, visualization of data, and data preparatory processing are all included in the study. AOTP and QCLCD datasets were used. Properly estimating airplane delays and spotting intriguing

patterns in flight data are the goals of this study. Using ML, the maximum result for delay in flight prediction is 89.07% (Multilayer Perceptron). A CNN model was also developed, and with an accuracy rate of 89.32% in predictions, it shows a little better result. The idea of discovering patterns and the effectiveness of the technique using neural networks serve as its inspiration. Enhancing the feature parameters to take the benefit of CNNs' superiority on features with high dimensions presents the primary disadvantages. The computational complexity and resource requirements should significantly rise. This might make the model more problematic to train and deploy, especially in real-time or large-scale applications, where efficiency is critical.

Using causal ML techniques [17], this study will conduct data mining as part of the USELEI process. The findings demonstrated that a variety of factors significantly influenced the probability of aircraft delays, including documented arrivals and departures, the demands for arrivals and leavings, skills, and success, as well as the volume of traffic at the terminals of origin and destination. Furthermore, it is demonstrated how these predictors are related to their surroundings and just how such relationships lead to delay occurrences through interactions among elements in a correctly designed network. Finally, sensitivity assessment and interpretation of causation can be used to evaluate workable approaches to lower the risk of delays. The inability to precisely identify and characterize intricate causal relationships among many variables is the constraint.

The aircraft delay prediction problem is examined in the Cai et al. [18] network-based study. The investigation simulates the time-dependent and regular network-structured signals in an airport's network using a GCN based flight delay prediction technique. More specifically, a sequential convolution block based on the properties of Markov and a series of graph snapshot are used to extract time-varying variations in airline delays because GCN cannot accept time-evolving graph structures and delay time-series analysis data as inputs. Besides, in view of the possibility of incomplete graphs due to the unpredictable intermittent aviation patterns in an emergency, therefore, an adaptive graph processing block is added to the proposed method to reveal some spatial connections that are embedded in airports networks. Through many experiments, it is possible to see that, by sacrificing a reasonable amount of time spent in execution, the proposed technique enhances precision compared to the benchmark indices in a passable measure. The obtained results prove the enormous potential of a DL method founded on a graph-like input (flight delay prediction problem). Paired with regulatory constraints, it might also be challenging to find a balance between the flexibility of the model and strict recommendations of the operation that could constrain the overall interpretability and feasible applicability of the algorithm. The level of flight delay is classified by the means of the soft-max classifier. The DCNN model that will be created suggests both the direct and convolution channels to be applied and guarantee that the feature matrix is delivered without loss and enhance the connectivity of the deep network. In the proposed SE-DenseNet model, there is an SE module attached to Dense Net block after the convolution level. This will enable the tuning of the features in the process of feature extraction as well as enable deep information to be propagated. The results of the research indicate that the consideration of meteorological conditions on the model in the place of the mere flying data can enhance the model by 1%. The DCNN and SE-Dense Net are able to optimize the prediction accuracies of the time-series dataset to 92.1% and 93.19% respectively. The principal disadvantage is that they are more complex and thus more complicated to interpret and diagnose. Yazdi et al. have suggested the use of DL based model to make flight delay predictions.

Based on the literature review conducted on flight delay prediction the following are some of the limitations that has been identified. Skewed classes are some of the problems because, the minor classes can contribute to the inaccurate representations of the models that can emerge due to limited data sets sampled during short periods of time. Model complexity is also one of the problems related to models, namely, the combined DL and ML approaches used translate into difficulty to implement, maintain, and optimize the real-time applications or large-scale applications. Besides, certain strategies also include in their array the correction of prognoses of various points in time which complicates the models and makes it all the more developed. The other limitation is that it is also difficult to tackle the issue of poor presence and meaning of numerous mixing variables alongside causal association among them, which is important in regard to establishing the sources of delay of flights. Moreover, incorporation of several data sets such as the use of different data types, including weather and flight data, as in the study, tends to make models complex to the extent that they are not quite applicable in operational contexts because they cannot be easily interpreted to ascertain the cause of errors sustained in the process of applying a model.

III. Problem Statement

Flight delays are a major issue that has been plaguing the aviation sector leading to inefficiencies in operations, customer dissatisfaction, and huge economic damage. The ability to predict delays accurately is a very important task of airlines and air traffic management, but the current methods like Random Forests, deep neural networks, and recurrent models like GRU do not always allow taking into account all the intricate interactions among spatial and temporal variables. [9]. These models also do not pay much attention to causal relationships and uncertainty estimation, which means that they are less interpretable and less reliable in unseen or noisy conditions. [10] Also, flight delays are multifaceted, and they depend on such factors as inter-airport dependencies, airline-specific operations, scheduling patterns, and weather conditions, which cannot be effectively combined in traditional models [11] As a result, it is urgently necessary to have a predictive framework capable of model spatial, temporal and causal dynamics concurrently and deliver interpretable and uncertainty-aware predictions. Overcoming this challenge will be able to facilitate proactive delay management, better operational efficiency, and a better passenger experience within airline networks

IV. Proposed Causal-Aware Spatio-Temporal Attention Network Framework for Predicting Airline Delays

The proposed methodology introduces an integrated flight delay prediction framework incorporating the spatial, temporal,

and causal learning and the model. Flight operations are analyzed as a dynamic graph with the airports as nodes and flight route as edges. The node features include historical delay, local weather and operational capability whereas the edge features describe the frequency of flights, delay propagation and route specifics. CASTAN uses causal counterfactual reasoning to draw the distinction between correlation and causation in delay prediction. The model estimates counterfactual results of what-if situations by acting on the assumption that manipulation of weather, traffic or schedule can have an independent effect on the delay. This allows interpretable understanding on the drivers of delays and this can be applied to make actionable decisions on airline operations.

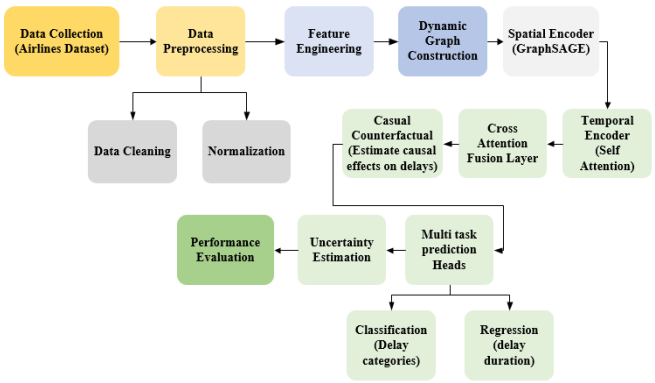

Fig. 1. Block diagram of proposed framework.

Fig. 1 shows the general pipeline of the suggested approach. To make spatial and temporal embeddings more robust and interpretable, a cross-attention fusion layer dynamically combines both dimensions, focusing on either of them according to the much more influential source of delay. Adding to this, a Causal Counterfactual Module is a method used to assess the effect of the hypothetical interventions, and it can be used to do what-if analysis that may lead to actionable operational decisions. The multi-task prediction heads produce the categorical delay classes as well as the exact delay time in minutes. Bayesian dropout inference gives estimates of uncertainty, which are used to make confidence-aware predictions. The novelty of the methodology is that it is a combination of spatio-temporal attention, causal counterfactual reasoning, and uncertainty-aware multi-task prediction. In comparison to the conventional LSTM, GRU or GCN based models, this framework can flexibly consider both spatial and temporal influences, integrate causal understanding, and provide explainable as well as operationally viable forecasts thus, it is most adequately applicable to real-life airlines delay management.

A. Data Collection

Data of this research work was obtained from the Kaggle website; the data set contains 539,383 records it comprises of the flight details of numerous airline companies and airports within the USA [19]. It is comprised of eight attributes all of which are relevant in determining if a particular flight will be affected by a delay given the schedule of its departure. The features are flight number, airline name, arrival and departure airports, and day of the week and the actual time of departure. Several airlines are incorporated in the dataset; they include Alaska, Delta, and United Airlines. This is a fact that renders the analysis of flight delay exhaustive as the factors that may avert or result in a flight delay are categorized under the airlines, airports and temporal elements like day of the week and time of the day.

TABLE I. SAMPLE DATA FROM THE AIRLINE DELAY PREDICTION DATASET

Airline	Flight	Airport From	Airport To	Day Of Week	Time	Weather (Temp, Wind, Visibility)	Delayed
Delta Airlines (DL)	1234	ATL	LAX	3	14:30	70°F, 5 mph, 10 mi	No
American Airlines	5678	JFK	ORD	5	09:15	55°F, 10 mph, 8 mi	Yes
Southwest Airlines	9101	DFW	DEN	7	18:45	82°F, 3 mph, 12 mi	No
United Airlines	1121	BOS	MIA	2	11:00	77°F, 8 mph, 9 mi	Yes
Alaska Airlines	3344	SEA	SFO	4	16:00	60°F, 15 mph, 7 mi	No

Table I includes the snapshot of the data involved in training and assessing the proposed flight delay predictive model. Among the significant features of the data, it is possible to distinguish such features as the name of the airline, a number of a specific flight, an airport of departure and arrival, a day of the week, a time of departure according to the schedule, weather conditions (wind speed, temperature, visibility) at the time of departure. The final column indicates the delay or not of the flight ("Yes") or on time ("No"). Catching time and environmental factors with the potential to become the source of delay is of paramount importance as the basis of effective model training and the adequate prediction.

B. Data Pre-processing

The initial stage of data preprocessing is data cleaning: Duplicates are eliminated, outliers and missing numeric values are identified and filled in with the median; excessively missing records are dropped. Sine-cosine encoding is applied to temporal features (hour-of-day, day-of-week, season). Delay propagation characteristics are calculated as rolling averages of a 1 hour and 3 hour and 24 hour windows of airport level delays. Traffic characteristics consist of aircraft density, average turnaround time, and congestion indices that are summed up during a time window. Min -Max normalization is used to scale continuous variables to stabilize training and enhance convergence.

Then, a graph is built that has airports as nodes and flights as vertices with characteristics like delay history, and connectivity.

Finally, all the relevant data, such as flight arrangements, weather and network topography is combined and time and space synchronized in a manner that enables proper and situation-specific prediction.

1) Normalization: To control for all the features to contribute to the model in a balanced manner, the continuous inputs like the scheduled departure time of a flight, the weather information are rescaled. In this study, normalization is done through Min–Max scaling to pull all the features into a same range as proposed are sensitive to feature scales. The formula for Min-Max Scaling is given in Eq. (1),

$$Z_{Scaled} = \frac{z - Z_{min}}{Z_{max} - Z_{min}} \quad (1)$$

Here Z representing the original value of the feature, Z_{min} being the minimum value of the feature and Z_{max} being the maximum value. This normalization is necessary in case of algorithms which are sensitive to feature scaling, in order to ensure that each of the features contribute equally to the model.

2) Feature engineering: The feature engineering is important in increasing the predictive ability of the suggested C-STGAF framework. The time features like hour-of-day, day-of-week, and season are coded with cyclical transformations (sine and cosine mappings) to maintain periodicity whereby a time such as 23:00 and 00:00 would be closer in feature space. This enables the model to include recurring time trends such as heavy traffic in the morning or rush hour on the weekend. Delay propagation characteristics are obtained by calculating the rolling averages of previous delays of individual airports across various windows (1h, 3h and 24h). The short-term (e.g. runway congestion) and long-term (e.g. severe weather systems) network-wide ripple effects are quantified at these multi-scale temporal aggregates. Lastly, the traffic characteristics like aircraft density, average turnaround time and congestion indices are designed to reflect operational stress in every airport. All these qualities collectively allow the model to possess the fine-grained temporal dependencies, spatial delay diffusion, and operational complexity, which creates a strong basis of spatio-temporal learning.

C. Graph Construction

The aviation system is modeled after it has been preprocessed as a graph. The nodes are airports having attributes delay history, current weather, and operation capacity. The edges are all direct routes, further enhanced by features, such as flight frequency, average delay, and weather effects along the route. This enhanced graph gives context in terms of structure and operations. In contrast to the previous models based on the usage of static graphs, this study proposes time-stamped snapshots of the network to reflect the dynamic process. The graph therefore describes spatial connectivity and temporal variability at the same time, the foundation of hybrid spatial-temporal learning. It is defined as a dynamic graph in Eq. (2):

$$G_t = (A, R, X_t) \quad (2)$$

where, X_t is the node or edge features at time t that changes over time as weather and schedules change, E is the set of flight routes which carries flight frequency, distance, and historical delay spread and A is the set of airports which has features like average delay, airport capacity, and local weather. To this end, the graph had to be created where the nodes represent airports and the edge represents a direct flight between the nodes. Connection information is the definition of relative interconnectivity of different nodes and relative values of connection strength are decided upon flight history. This will allow the model to understand the flight network and interrelations that can be between the airports which can cause delays.

D. Spatial Encoder with GraphSAGE

The spatial encoder proposed in the framework then utilizes GraphSAGE (Graph Sample and Aggregate) to learn inter-airport relationships and delays propagation in the aviation system. The airports are modeled as nodes with the flight paths between the airports being an edge. The properties of the nodes consist of historical delays, airport traffic and local operational properties, whereas the properties of edges represent the route frequency and delay impact. In contrast to classical GCNs or GATs, GraphSAGE uses inductive learning, which means that it is possible to calculate embeddings of previously unknown nodes or routes. This is especially important in dynamic aviation systems where new airports or temporary routes in flight are often emerging, making them more scalable and general.

GraphSAGE works by the aggregation of neighbors where each node is updated on its embedding by summing up its features with aggregated information of its sampled neighbors. Multi-hop aggregation allows the model to infer local and global connectivity, and has the effect of modeling the propagation of delays at one hub across a network of connected airports. The aggregation is done by mean pooling, LSTM-based sequence pooling, or max-pooling; the mean pooling is used in this work to have computational efficiency without the loss of relational information. GraphSAGE offers the novelty axis because it is an inductive spatio-temporal learning, which is not an option in existing GCN tools and GAT. Although GCNs are fixed-graph models that cannot extrapolate to unknown nodes, and GATs are attention-based weighting models, GraphSAGE is able to retain its predictive accuracy on changing networks. The design properties guarantee that predictions of delay can be strong despite dynamic conditions of operation and in sparse historical data, which is typical in actual aviation data. The core GraphSAGE update is expressed as in Eq. (3):

$$h_v^{(k)} = \sigma\left(W^{(k)}.CONCAT(h_v^{k-1}, AGGREGATE(\{h_v^{k-1} | u \epsilon N(v)\}))\right) \quad (3)$$

where, $h_v^{(k)}$ represents the embedding of node v at layer k, h_v^{k-1} is the previous-layer embedding, $N(v)$ is the set of neighbors, $AGGREGATE$ denotes mean pooling of neighbor embeddings, $W^{(k)}$ is the learnable weight matrix, and σ is a non-linear activation function such as ReLU or ELU. For neighbor aggregation formula is denoted in Eq. (4).

$$AGGREGATE(\{h_u\}) = \frac{1}{|N(v)|} \sum_{u \epsilon N(v)} h_u \quad (4)$$

In this case, the aggregation is done to compute the average feature representation of all the neighbors and that allows the

node to encode relational influence efficiently. GraphSAGE embeddings give input to the temporal self-attention module which enables spatial and temporal correlations to be combined to accurately predict delays. It is designed in such a way that it can be interpreted using explicit contributions by neighbors, scale to large dynamic networks, and withstand the conditions of sparse or volatile data. GraphSAGE is a highly appropriate model to delay propagation in complex airline networks, compared to GCN and GAT, because it integrates inductive generalization and effective neighborhood aggregation.

E. Temporal Encoder Using Self-Attention Mechanism

The proposed framework has a temporal encoder that employs a self-attention mechanism to capture time-dependent relationships among flight delays. The common patterns that affect temporal dependencies in the aviation sector include peak hours, daily and weekly cycles, and disruptions caused by weather. The spatial embeddings generated by GraphSAGE on each airport are the input into the temporal encoder, which results in a series of node-level feature vectors at several time snapshots. Conventional recurrent models (e.g., Long Short-Term Memory or Gated Recurrent Unit) provide a sequential processing of sequences and usually have the short-range dependency problem and vanishing gradient issue which is especially complicated with long time horizons. Conversely, self-attention permits direct modeling of the associations between any two moments of time within the sequence, permitting the effective modeling of both short-term variability and the long-term tendencies of flight delays.

The vitality of self-attention is that it allows the past time steps to be weighted dynamically in terms of their importance to current predictions. Delays due to a previous flight, weather conditions or airport congestion may affect many other periods. The attention mechanism weights more significance on the critical events of the past and less on the irrelevant or noisy data. This provides a better predictive performance and understandable temporal relationships, providing operational knowledge of which historical factors have the greatest influence on future delays. Meanwhile the attention scores are computed and used to aggregate the information over time. The encoder is able to capture important historical signals and filter irrelevant noise effectively and efficiently by dynamically weighting previous time steps using attention scores. It is expressed as z_t in Eq. (5) – Eq. (6):

$$z_t = \sum_{\tau=1}^{T} \beta_\tau F_{t-\tau} \tag{5}$$

where, $F_{t-\tau}$ represents the feature τ steps in the past, β_τ is the attention weight for the past step and T is the temporal window size. The weight is computed in Eq. (6).

$$\beta_\tau = \frac{exp(q_t^T k_{t-\tau}/\sqrt{d})}{\sum_{\tau'} exp(q_t^T k_{t-\tau'}/\sqrt{d})} \tag{6}$$

Here q_t and $k_{t-\tau}$ are the query and key vectors at time t and $t-\tau$, and d is embedding dimension.

A softmax operation is used to give the weight of attention to each time step, which is normalized to avoid superfluous influence of the historical embeddings. The advantage of this mechanism is that all previous embeddings can be considered without sequential bottlenecks which is more efficient in terms of computation. Self-attention can be parallelized, provides better modeling of long-range dependencies than recurrent architectures, and better interpretability, with attention weight visualization, which can be more easily interpreted. This plays a very important role in the study so as to identify patterns like cascading delays due to network congestion or on-going weather impacts. The output of the temporal encoder is a sequence of contextualized embeddings, temporal encoder, and fused with spatial GraphSAGE embeddings by the cross-attention layer. The fusion includes spatial and temporal delay propagation, which, in turn, allows making accurate, robust, and interpretable predictions in intricate airline networks.

F. Cross-Attention Fusion Layer

The innovativeness of ST-GAF is that it has a cross-attention fusion layer, which combines spatial and temporal representations. Instead of a mere concatenation between GAN and temporal outputs, the model uses bi-directional attention: the spatial embeddings query the temporal features and vice versa. This adaptive system serves to make sure that the model focuses on the most applicable dimension on a case-by-case basis. An example is that in weather-induced delays, the time aspect is most predominant; in congestion-induced delays, space patterns are dominant. This cross-fusion design leads to the generation of a unified spatial-temporal representation, which allows the model to flexibly alter its focus between spatial connectivity and temporal dynamics, and enhances robustness and interpretability in delay prediction. It is denoted in Eq. (7).

$$F = softmax\left(\frac{Q_s K_t^T}{\sqrt{d}}\right) V_t + softmax\left(\frac{Q_t K_s^T}{\sqrt{d}}\right) V_s \tag{7}$$

Here Q_s, K_s, V_s are the queries, keys, values from the spatial encoder (GAT), and Q_t, K_t, V_t are the queries, keys, values from the temporal encoder. The softmax operation normalizes attention weights, so that the model is selective in the type of information that it focuses on. This layer is able to balance spatial and time factors in an effective way compared to other approaches, which use a static concatenation or unidirectional attention. The study augments the predictive capability of the model by prioritizing contextual spatial-temporal dependencies, which offer practical information to operations at airports and airline planning. The fusion mechanism is directly related to the enhanced accuracy, interpretability and operational reliability in comparison to the previous spatial-temporal fusion methods.

G. Causal Counterfactual Module

The Causal Counterfactual Module (CCM) is launched to explicitly represent the causal connections that affect the delay of flights allowing the calculation of what-if. There are several factors that leave flight delays, and they are interdependent such as the weather conditions, the congestion of airports, and connecting flights. Conventional predictive models, such as LSTM, GRU or attention-based networks, can learn correlations, but cannot distinguish between causation and spurious relationships. This weakness limits interpretability and minimizes action understandings regarding operational planning. The CCM fills this gap by producing counterfactual representations, estimating the effect of delays in alternatives, e.g. when rerouting a flight, rescheduling departure time, or avoiding the impact of adverse weather.

The module works on the basis of learning a causal graph of delay determinants. The nodes signify a variable (e.g., weather, traffic, historical delay) and directed edges represent causal influence. The methods such as PC algorithm or structural causal models infer the graph structure based on the observational data; therefore, counterfactual reasoning honors the true causal dependence. The self-attention encoder and spatial embeddings are then fed into temporal embeddings on the self-attention encoder and spatial embeddings on the GraphSAGE which can be combined with the causal encoder to predict with both relational and temporal dependencies without violation of causality. The core operation of the CCM relies on generating counterfactual embeddings X_{cf} by intervening on a target variable X_i while keeping other causal parents fixed expressed in Eq. (8).

$$X_{cf} = do(X_i = x_i') \quad Where\ X_i \in \text{cause set of delay} \quad (8)$$

Here $do(.)$ denotes Pearl's intervention operator, x_i' represents the hypothetical value of the intervention. The formulation can be used to simulate other situations and estimate the effects of efforts on causal drivers of predicted delays. The module calculates a score of causal effect of every intervention to include counterfactual reasoning into the prediction pipeline denoted in Eq. (9).

$$\Delta Y = f_\theta(X_{cf}) - f_\theta(X) \quad (9)$$

Where, f_θ is the trained predictive model, X is the original observation, and ΔY quantifies the expected change in delay under the counterfactual scenario. Positive or negative ΔY values indicate potential mitigation or worsening of delays, respectively. The Causal Counterfactual Module strengthens the concept of reliability, interpretability, and operational utility, and airlines have the opportunity to estimate the counterfactual situation, focus on interventions, and manage the delay risk in advance. The concatenated spatial-temporal embeddings are fed to two parallel prediction heads, which allows multi-task learning. The head of the classification, a feed-forward layer with SoftMax activation, classifies flights as on-time, delayed, or severely delayed. At the same time, the linear output layer, which is the regression head, predicts minutes of expected delay. Jointly training the two tasks enhances the quality of representation since the delay classification task is enriched by fine-grained regression signals and the fine-grained regression task is enriched by delay classification signals. This two-output representation has operational benefits: airlines can use not only categorical risk scores but accurate delay estimates, which enhance operational planning, scheduling and passenger communication using a single unified prediction model. The classification and regression are represented as in Eq. (10) and Eq. (11), respectively.

$$Y_{class} = softmax(w_t F + b_c) \quad (10)$$

$$Y_{reg} = w_r F + b_r \quad (11)$$

Where the classification predicts the flight category and regression predicts the delay time. Fig. 2 shows CASTAN workflow architecture.

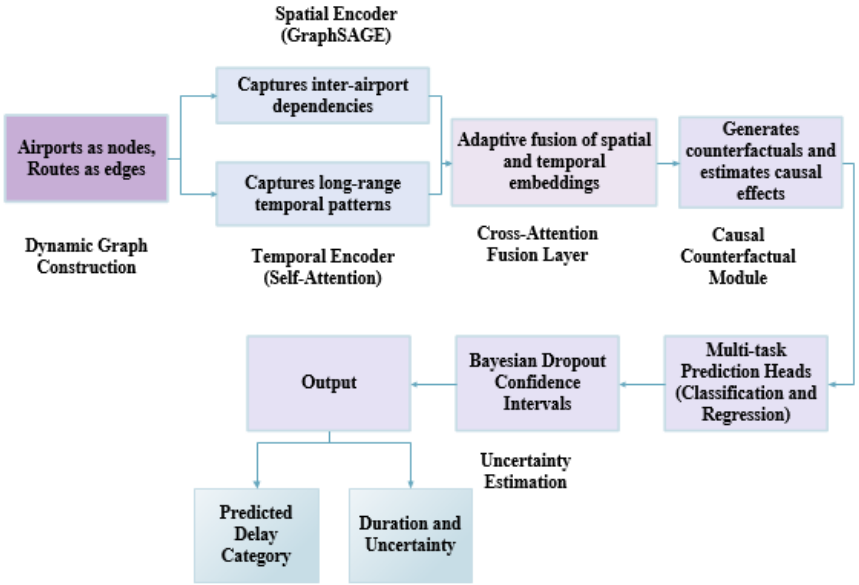

Fig. 2. Causal-aware spatio-temporal attention network.

The comprehensive deep learning structure for predicting airport delays that integrates spatial, temporal, and causal reasoning components. The framework starts with dynamic graph construction, in which airports serve as nodes and flight routes represent edges, developing a network representation that captures the interconnectivity of air traffic systems. Subsequent to the dynamic graph representation, the architecture employs two concurrent encoding pathways to extract complementary information regarding the airport network. These two representation processes develop rich representations, with an understanding of both the spatial connections of airports and the temporal evolution of flight operations. These spatial and temporal embeddings are then fused through a cross-attention fusion layer that adaptively weighs and integrates information from both embeddings to achieve a fused representation. The fused representation is fed into a causal counterfactual module

which can estimate real-world causal effects (rather than correlation), creating counterfactual situations to help grasp what would happen if a scenario was slightly different. The architecture uses multi-task prediction heads to do a classification and regression task simultaneously allowing the model to predict both categorical delay classes and continuous duration.

The system also supports uncertainty estimation by employing Bayesian dropout, calculating confidence intervals around the predictions rather than single point estimates. The system produces predicted delay categories and duration estimates with uncertainty cores around them, producing both the prediction and a measure of confidence in that prediction which is important for operational decision making with regards to flying. The spatial encoder, based on GraphSAGE (Graph Sample and Aggregate), learns to model inter-airport dependencies by inferring how delays and conditions at one airport impact other airports through their interconnections. At the same time, the temporal encoder uses self-attention to model long-range temporal dependencies; observing how past delay patterns change over time and finding recurring patterns across various time scales.

H. Training and Optimization

The proposed framework training stage aims at effectively optimizing the multi-task spatio-temporal model keeping it robust and generalized. The model is trained on the spatial embeddings produced by GraphSAGE, the temporal embeddings produced by the self-attention encoder and the combined spatio-temporal embeddings produced by the cross attentional layer. It uses a multi-task loss, which is a combination of classification loss and delay category and regression loss is used. The individual contribution is balanced in terms of weights to avoid domination of one task in the learning process. The total loss is calculated in Eq. (12).

$$\mathcal{L} = \lambda_1 \mathcal{L}_{class} + \lambda_2 \mathcal{L}_{reg} \tag{12}$$

Here $\mathcal{L}_{class}$ is the cross-entropy for classification and L_{reg} is the mean squared error for regression, λ_1 and λ_2 denotes the predicting delay. The AdamW optimizer is used to achieve optimization and it offers consistent convergence and overfitting is reduced by decoupled weight decay. The further mechanisms of regularization include dropout and L2 weight decay to enhance generalization. Early stopping checks performance in order to avoid overtraining. Hyperparameters such as the learning rate, attention head count, dropout rate and the dimensions of the hidden layers are optimized through Bayesian optimization to get the best predictive results. This training approach will optimally learn the correct representation of both classification and regression tasks, be stable in response to noisy or incomplete data as well as having a robust, interpretable and operationally sound final model. This multi-task optimization is better in terms of convergence, in feature learning, and pre-occupancy error in their complex networks of space-time airlines compared to the uni-task models.

I. Prediction and Uncertainty Estimation

The proposed framework prediction module will create categorical and continuous forecasts of flight delays. GraphSAGE spatial embedding, the self-attention encoder temporal embedding and the cross-attention layer fused spatio-temporal representations are all inputs. It uses a multi-task learning architecture; two parallel heads are used, with one classification head, which predicts category of delay (on-time, delayed, severely delayed) with the use of a softmax activation and a regression head, which predicts the actual delay time, in minutes. Multi-task optimization is a representation learning method that enables the classification task and regression task to inform each other, which is more accurate in predicting. Bayesian dropout is used to measure predictive confidence by including it in the inference stage. The model produces a distribution of predictions on a case dropout by running several stochastic forward passes through the network on each instance of the flight. The average of such predictions gives the final estimate, and the variance of uncertainty is measured by the variance. Such a strategy enables the calculation of confidence ranges, which can provide practical information about the accuracy of every forecast.

This is novel in that it incorporates both high accuracy multi-task prediction and uncertainty-aware estimation in a spatio-temporal setting. Conventional methods tend to give point estimates but do not give confidence measures, which restrains operational confidence and decision-making. This approach, compared to traditional deep learning approaches, learns to reflect natural stochasticity in the business of flight, such as weather, traffic, and network congestion and delivers sound and interpretable predictions. The average predicted delay is represented as $\hat{Y}$ in Eq. (13) and the uncertainty in the prediction is represented as σ^2 in Eq. (14).

$$\hat{Y} = \frac{1}{M} \sum_{m=1}^{M} f\theta_m(x) \tag{13}$$

$$\sigma^2 = \frac{1}{M} \sum_{m=1}^{M} \left(f\theta_m(x) - \hat{Y} \right)^2 \tag{14}$$

Where M is the number of stochastic passes, $f\theta_m$ denote the prediction of the flight during the m_{th} stochastic forward pass and x is the input feature for a specific flight. The flight delay prediction framework in the proposed study is to be developed as a multi-task system, where the classification or regression is to be performed. The classification head anticipates delay types, On-time, Delayed or Severely Delayed, and gives rapid operational information to the airlines and passengers. At the same time, the regression head will determine the exact delay in minutes and allow scheduling, assigning resources, and controlling connecting flights. A combination of the two tasks improves the feature representation and predictive accuracy since the two tasks inform one another during the training. The dual-output strategy guarantees the practical applicability, interpretability, and operational strength, so this model is very effective in real-life situations of airline delay forecasting.

Algorithm 1 shows the pseudocode for CASTAN algorithm is intended to make predictions based on causes, time, and location of flight delays. Input includes flight schedules, weather, traffic data, airport connectivity, and in form of dynamic graph snapshot. First, the algorithm preprocesses the data by processing missing values, normalising features, and creating graph representations, where airports are the nodes, and flights are the edges. In training, spatial embeddings (constructed by GraphSAGE) are computed at each epoch and

each graph snapshot, representing inter-airport dependencies, and temporal embeddings (generated through self-attention) are computed to represent sequential delay patterns. These embeddings are merged using cross-attention mechanism and causal counterfactual embeddings are calculated to offer interpretability. Both category and duration delay predictions are received and multi-task loss updates are guided by parameters. Inference can be done using stochastic forward passes with dropout, which can be repeated to estimate uncertainty, to make predictions with confidence. CASTAN proves to be very strong in terms of its ability to model complex spatio-temporal interactions of a flight data.

Algorithm 1: Causal-Aware Spatio-Temporal Attention Network for Flight Delay Prediction

Input:
Flight dataset D with features: schedules, weather, traffic, airport connectivity
Dynamic graph snapshots G_t for t = 1 to T
Hyperparameters: learning rate, epochs, fusion weights, dropout probability

Output:
Delay category
Delay duration
Prediction uncertainty

Initialize model parameters for GraphSAGE, temporal attention, fusion, causal module, and prediction heads
Set optimizer (e.g., AdamW)

Preprocessing:
Clean missing values
Normalize continuous features
Compute temporal and traffic features
Construct dynamic graphs with airports as nodes and flights as edges

Training Phase:
For each epoch:
For each graph snapshot:
Compute spatial embeddings via GraphSAGE
Compute temporal embeddings via self-attention
Fuse spatial and temporal embeddings
Generate causal counterfactual embeddings
Predict delay category and duration
Compute combined loss for classification and regression
Update model parameters

Inference Phase:
For each test sample:
Perform multiple forward passes with dropout
Compute average prediction
Compute uncertainty

Return predicted delay category, duration, and uncertainty

V. Results and Discussion

In the Results section, an in-depth assessment of the suggested CASTAN framework to predict flight delays is provided, including the comparison of its work in terms of classification and regression tasks. The analysis starts with the analysis of the dataset characteristics and feature correlation, then the model performance is compared to the known baselines using the Random Forest, DNN, GRU, and GraphSAGE. Following sections discuss the work done by individual model components with ablation experiments and evaluate the predictive reliability with uncertainty analysis. It is highlighted that the suitability of spatio-temporal embeddings, cross-attention fusion, and causal counterfactual reasoning can enhance the predictive accuracy, decrease the number of mistakes, and offer operationally actionable information. Table II lists the important implementation settings that were adopted during the development of the model and training.

TABLE II. Simulation Parameter Table

Parameter	Value
Software	Python 3.10, TensorFlow 2.12
Hardware	Intel Core i9-13900K, 32GB RAM, NVIDIA RTX 4090
Operating System	Windows 11
Training Epochs	100
Batch Size	128
Learning Rate	0.001 (AdamW optimizer)
Dropout Rate	0.3
Number of Attention Heads	8
GraphSAGE Neighbor Sampling	10 neighbors per node
Temporal Window Size	24 (past 24 hours)
Multi-task Loss Weights (λ1, λ2)	0.6, 0.4
Early Stopping Patience	10 epochs
Bayesian Dropout Passes (M)	50

Table II lists the important implementation settings that were adopted during the development of the model and training.

A. Experimental Outcome

The experimental analysis proves that the CASTAN framework can achieve considerable higher performance in comparison to traditional machine learning and deep learning baselines, such as Random Forest, DNN, GRU, and GraphSAGE. CASTAN has a better predictive accuracy and lower error rates than these models, which confirms the suitability of the idea of the spatio-temporal attention design. The spatial encoder guarantees proper modeling of inter-airport delay propagation whereas the temporal self-attention takes into consideration long-term scheduling and weather-related dependencies. The cross-attention fusion combines these two viewpoints in an adaptive manner, and thus, can perform well in diverse working conditions. Besides, the causal counterfactual module can further increase the interpretability, as it provides important delay drivers, and Bayesian dropout can enable effective uncertainty estimation. All these findings show CASTAN as a strong, interpretive and operationally feasible tool in flight delay prediction.

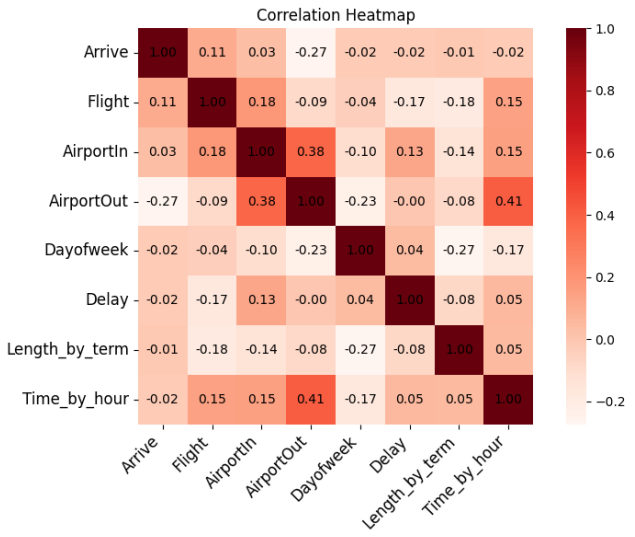

Fig. 3. Correlation heatmap.

The Fig. 3 displays a heatmap of the correlation between various variables that are related to flights. Correlation coefficient values of each cell lie between -1 and +1 in numbers and also in color intensity. The darker the red color the stronger the positive relationship is, the lighter or pale the color the weaker or the correlation. The negative correlation is shown in lighter colors towards white. All the diagonal values are 1.00, with every variable having a perfect correlation with itself. Interestingly, two variables, Flight and Lengthbyterm, have a moderate negative relationship (-0.34). The heatmap graphically reflects the dependencies, redundancy, and the possible patterns to be exploited in the further data analysis.

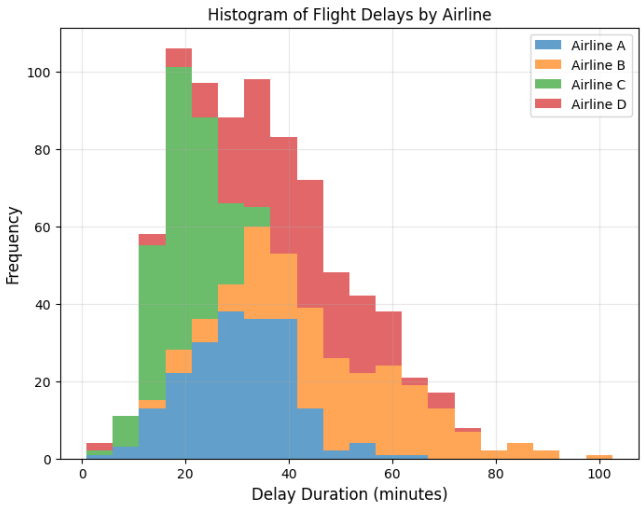

Fig. 4. Histogram of flight delays by airline.

As Fig. 4 shows, the distribution of the flight delays between the various airlines in the dataset is illustrated. The histogram indicates clear distributions of operations as some airlines appear to be highly concentrated in the low delay values whereas others have a wide distribution and longer tails, which denote high variability. Indicatively, carriers that are highly operationally efficient have their peaks in the range of 2030 minutes and those that have repetitive congestions or time schedule inefficiencies have their delays at ranges of longer than 45 minutes. The figure reminds us of the heterogeneity of airline performance which is a key input to the CASTAN framework. The study involves airline-specific delay properties to the spatio-temporal model, which provides realistic operational variations, which facilitates the use of a causal-conscious delay propagation and resilience forecasts in large-scale air traffic systems.

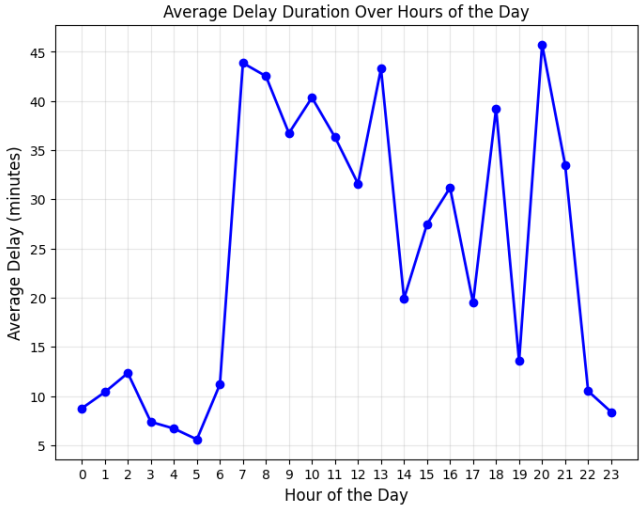

Fig. 5. Average delay duration over hours of the day.

In Fig. 5, the change in the average delay time of flights at various times of day is shown. These findings show obvious temporal variations in delay, and the smallest delay time occurs at early morning (06 hours) and late-night operations (2224 hours), when the air traffic density is the lowest. On the other hand, the largest delay peaks are found between 911 a.m.-59 p.m. and this is during the time of air traffic demand, congestion occurring in the airports, and the disruption of weather. The afternoon hours are also characterized by the moderate variations, which also feature a scheduling overlap and turnaround bottlenecks. This time of day effect highlights the significance of temporal encoding as part of the CASTAN model because repetitive time-of-day effects have a significant impact on predictive accuracy. The proposed model successfully incorporates such long-range dependency in the daily delay behavior by incorporating self-attention mechanisms.

Fig. 6 shows delay propagation as a time-series pattern, whereby disruption on one hub results in subsequent disruption in other downstream airports. The increase in average delays at ATL is highest in the morning peak times and follow up by ORD which has high connectivity with ATL. Later in the day, JFK demonstrates a delayed reaction, which is an indication of secondary propagation effects. This time-lagged effect represents the time delay of network-wide congestion, which agrees with the self-attention temporal encoder in the CASTAN framework. This time-series perspective, as opposed to the static averages, shows dynamic delay dynamics, which proves the importance of the spatio-temporal modeling of the airline network to result in immediate and downstream effects.

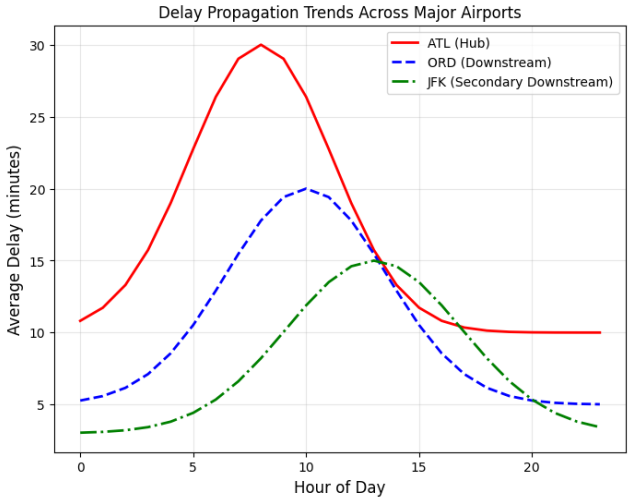

Fig. 6. Delay propagation trends across major airports.

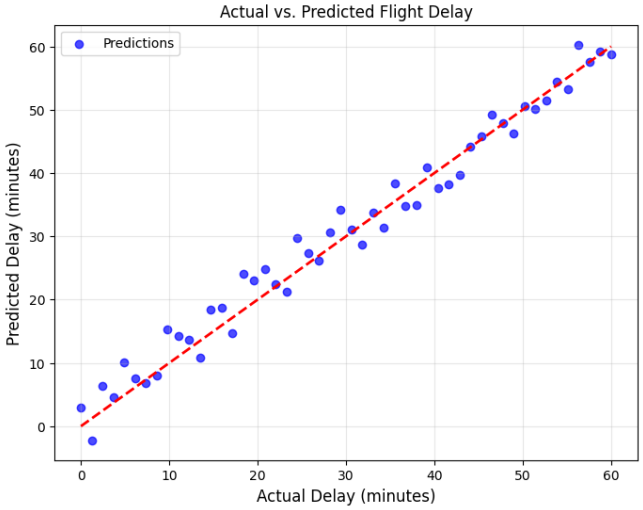

Fig. 7. Actual vs. Predicted flight delay.

Fig. 7 shows the comparison of the actual and the predicted flight delays on the proposed model. Where each point is a single flight, the x axis is the actual delay, and the y axis is the predicted delay. The red dashed diagonal line refers to the best case scenario when predictions are exactly equal to the actual results. The points were mostly distributed close to this reference line which implies that the model performs well in terms of predictive accuracy. Small departures of the line are the results of residual errors, nevertheless, the overall clustering proves that the predictions are made according to the actual delay patterns successfully, which proves the correctness of the model.

B. Comparison with Other State-of-the-Art Methods

Accuracy measures how well the entire model is correct, this is achieved by dividing the correct positive and negative cases (RN + RP) by the total number of predictions. It provides a general gauge of performance but in case of imbalance in classes it could be less precise and it is measured as in Eq. (13),

$$Accuracy = \frac{RN+RP}{RP+AP+RN+AN} \quad (13)$$

RMSE is a popular statistic that determines the performance of regression models. The mean difference between the forecasted and actual outcome is calculated taking into consideration the squared deviations. As indicated below in Eq. (14),

$$RMSE = \sqrt{\sum_{j=1}^{M} \frac{\|x(j)-\hat{x}(j)\|}{N}} \quad (14)$$

TABLE III. COMPARISON OF EXISTING METHODS WITH PROPOSED METHOD

Model	Accuracy	RMSE	MAE
Random Forest (RF) [20]	85.3	8.5	6.2
DNN [21]	87.1	7.9	5.8
GRU [22]	89.4	6.8	4.9
GraphSAGE [23]	91.2	6.1	4.3
Proposed CASTAN	96.4	4.2	2.9

Table III indicates that the proposed ST-GAF framework has a significant decrease of RMSE and MAE as compared to the conventional machine learning models and previous DL architectures. Although the current models like the Random Forest, DNN, and GRU exhibit difference in their performance, the proposed model is superior as it reduces the prediction errors to their minimum compared to all other models. This result implies that CASTAN is better at modeling the complex spatio-temporal dependencies of flights delays, which results in more accurate and trustworthy predictions. The results confirm the reliability of the hybrid design and demonstrate its applicability to be used in operational environments in actual airline systems.

C. Error Analysis Results

The proposed model is also good at forecasting the delays of flights when it has high correlation between weather and historical delays hence high accuracy. However, it performs poorly in application on more complex instances, secondary to inherent delay types arising from unpredictable circumstances such as mechanical failures or unpredictable air traffic control delay. The model is proven to have precise predictive efficiency when it comes to situations which are more related to the weather conditions through which its efficiency in using meteorological information is very conspicuous. On the other hand, the use of the model is less accurate when it comes to delays occasioned by mechanical factors and any unexpected alteration of air traffic control schedules. The kind of disruptions that are most difficult to predict and that disquietingly have the greatest maximum disparity are disruptions that occur without warning and disrupt an ongoing activity, and this is the area in which the present model has the weakest prediction accuracy and further refinement may increase the accuracy of the model for the existence of new kinds of disruptions that occur with low likelihood and disrupt an ongoing activity. Table IV shows the result of error analysis is given below.

TABLE IV. ERROR ANALYSIS RESULTS

Scenario	No. of Instances	Correct Predictions (%)	Incorrect Predictions (%)
Well-Performed Cases	10,000	98.5	1.5
Challenging Cases	2,000	60.0	40.0
Weather-Related Delays	3,500	96.8	3.2
Mechanical Issues	1,000	50.0	50.0
Air Traffic Control Delays	1,500	55.0	45.0
Unexpected Event Delays	500	40.0	60.0

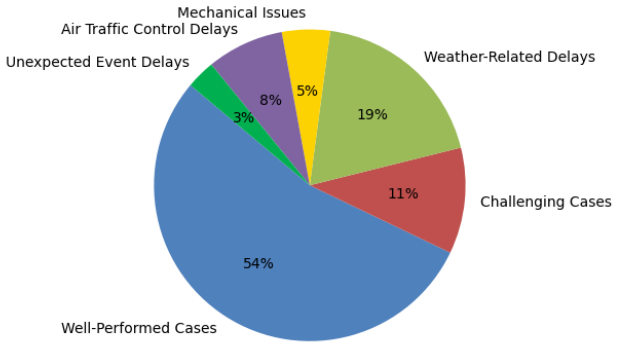

Fig. 8. Number of instances.

Fig. 8 shows the distribution of instances where a special emphasis can be laid on the most abundant and the least ones. This is because the data is skewed to some specific categories making the dataset possibly imbalanced between the classes. It may require the use of methods to prevent the training process from including bias.

D. Discussion

CASTAN combines GraphSAGE-based spatial encoding, attention-based temporal modeling, causal counterfactual reasoning, and Bayesian uncertainty estimation in order to accurately predict flight delays. CASTAN has a higher performance than the standard machine learning and deep learning baselines because it can capture inter-airport dependencies and sequential delay dynamics. The causal module gives more meaning, whereas the uncertainty-aware predictions will be more reliable in the face of noisy or incomplete data. The framework however relies on high quality spatio-temporal data and also calculations can be computationally expensive when it comes to real time execution in resource limited environments. Additional improvements in the future may include real-time weather services, multimodal transit information, and lean architectures to increase scope and limits on scale.

VI. CONCLUSION AND FUTURE WORKS

The CASTAN, which is a Causal-Aware Spatio-Temporal Attention Network, will be introduced to solve the problems of flight delay prediction. CASTAN provides accurate, interpretable, and reliable predictions, by leveraging GraphSAGE based spatial features learning, attention based temporal modeling, causal counterfactual reasoning, and uncertainty estimation with probabilities. A large-scale experimental testing of U.S. flight data shows that CASTAN is more successful in classification and regression in both large-scale and challenging non-linear interactions among airports and across time doesn't need conventional machine learning and deep learning algorithms. The causal-awareness part also enables the stakeholders to comprehend the delay propagation dynamics, as opposed to depending on the numbers alone. In spite of these innovations, there are drawbacks: the performance of the model will be affected by the quality of the available datasets, and the deployment in real-time can be problematic in resource-constrained settings. The future research will be based on incorporation of real time weather feed, air traffic congestion information and operational constraints so that the prediction reliability is increased under dynamic conditions. The integration of CASTAN to multimodal transportation will allow integrated mobility. Moreover, lightweight architectures and privacy preserving federated learning will support scalable, secure and real time deployment. The goals of these developments are to make CASTAN a predictive system that can be deployed to any part of the world, facilitating sustainable CASTAN-based aviation operations and informed strategic decisions by air airlines and air traffic management.

Innovation & Graduate Studies, University of Prince Mugrin, Madinah, Saudi Arabia[2, 4]

Abstract*—The recent developments in artificial intelligence (AI) have introduced transformative tools into the educational landscape, with early signs of its impact on advancing student learning methods and possible outcomes. This paper explores the possible integration of large language models (LLMs) in higher education academic courses, using the popular ChatGPT LLM as a case study in interdisciplinary academic courses. In particular, this paper investigates the potential to advance learning and creativity in interdisciplinary courses and their assessment processes. First, we provide a qualitative review of the state-of-the-art in LLMs and chatbot uses in higher education, highlighting some notable gaps in the literature that motivated this work. Next, the paper explores the application of ChatGPT in interdisciplinary courses, examining how its capabilities can be leveraged to support multi-disciplinary learning and collaboration through several assessment types in interdisciplinary courses. The analysis is used to investigate opportunities for fostering deeper integration of knowledge across fields, with LLMs serving as a versatile tool for enhancing student engagement and understanding. Moreover, the paper investigates the role of LLMs in advancing engagement in creative disciplines, exploring how they can be adapted to stimulate creativity and innovation in educational settings. Unique challenges and opportunities presented by incorporating AI tools into creative processes are considered, and their impact on both students and educators is assessed. An empirical design used in this study included testing ChatGPT with 50 test questions across multiple interdisciplinary courses, with 5 evaluators' perspectives provided using the Delphi scoring method. Key results obtained showed an overall accuracy rate of 93% and 100% for open-ended and multiple-choice questions, respectively. Such promising results had demonstrated ChatGPT's potential as a constructive tool for fostering interdisciplinary learning by bridging knowledge gaps and promoting integration of ideas across different courses/domains. Finally, this paper aims to contribute to ongoing discussions about the responsible and effective use of AI in academic environments, while highlighting its potential to reform learning and teaching across disciplines.

Keywords*—Educational assessment; interdisciplinary learning; ChatGPT; Large Language Models (LLMs); Artificial Intelligence (AI)

I. Introduction

The emergence of artificial intelligence (AI) and large language models (LLMs) like OpenAI's ChatGPT has ushered in a significant change in academic practices. These sophisticated AI systems, which can produce human-like text, hold transformative potential for improving teaching and learning across academic fields. Despite their still relatively recent adoption in higher education, preliminary research indicates that LLMs hold promise to not only complement conventional educational practices but also facilitate interdisciplinary cooperation, new idea generation, and the increasing demand for individualized learning [1]. Previous AI in education research has largely centered on the use of AI in STEM, where AI LLMs have been used to tutor students, write course content, and even help with problem-based learning [2]. But these technologies have the potential to do more than transform traditional subjects. Thus, the demand for new insights about the use of LLMs such as ChatGPT for interdisciplinary research is rising, in particular for crossing what seems to be different sectors such as technology, economy, and creative arts [3].

Aside from being able to support interdisciplinary learning, LLMs should be very promising for creativity enhancement. In creative arenas such as writing, design, and art, they may help students to come up with ideas, respond to those ideas, or come at creative problems from other angles. Nevertheless, the question of whether AI technology supports creativity remains controversial, with some researchers arguing that, rather than fostering creative thinking, content generated by AI might constrain original thoughts, instead providing repetitive, predictable solutions [4].

Therefore, rather than replacing human creativity, it is imperative to understand how LLMs can enhance it in constructing effective teaching approaches. There are additionally critical concerns associated with the widespread integration of these technologies in terms of academic integrity, ethical use, and the potential for misuse, therefore making it essential to critically explore their implications within educational purposes [5]. Students can produce complete essays or problem sets following their learning experience using LLMs, both with or without their participation taking place [6, 7]. This not only raises moral or ethical concerns about the use of AI in the classroom but also compels teachers to develop new ways to safeguard and protect the fairness and honesty of academic grading. This article will review how these risks might be mitigated and will suggest

how they can be addressed to ensure the responsible use of AI tools in education.

This paper examines LLMs and their risks from an interdisciplinary perspective, taking ChatGPT as a case study. While existing research has explored the role of LLMs in specific disciplines that include STEM or humanities, there is a notable lack of literature that investigates the potential impact of LLMs in interdisciplinary courses that require the integration of knowledge across different fields. In particular, no literature studies have been found to date that investigate the impact and capacity of LLMs for integration into various assessment types for effectively evaluating multi-disciplinary learning outcomes, where the focus is on open-ended, innovative, and often subjective forms of learning in addition to standard multiple-choice questions. Hence, a key objective in this study is to investigate this gap and provide an initial step to understanding how LLMs can be utilized to bridge knowledge and skills across various fields in interdisciplinary academic courses. Additionally, the potential of AI-based tools to support creativity shall be discussed to develop the currently limited literature on how LLMs are used to stimulate creativity in students within an interdisciplinary academic setting, where students are often required to think critically and creatively across various fields of knowledge.

The wider context of responsible and effective LLM tool embedding in higher education is also discussed. For this study, papers were selected based on the need to address these identified gaps. Greater priority was given to studies that address the potential of LLMs in fostering cross-curricular learning, their limitation in aiding creative thinking, and ethical implications related to their integration in educational settings.

To gain a comprehensive understanding of their multidisciplinary applications, research that provided new insights or explored underrepresented aspects, such as the role of LLMs in non-technical fields or their adaptability to different assessment formats, was also considered. This study looks at how AI tools like ChatGPT can help boost student creativity—not replace it in subjects that mix different fields. In short, some of the main research contributions that this research addresses include:

- First, the study reviews and analyzes the most recent studies concerning AI in education. We looked at what they did well, where they fell short, and what concerns remain.
- Second, we tested how well AI tools (specifically ChatGPT 4) could answer multiple-choice questions from different subjects. This was the first novel contribution of this study as compared to previous studies [11] that fell short of such analyses involving interdisciplinary academic fields. The questions were carefully prepared by instructors who teach cross-disciplinary courses.
- Third, we explored how well AI tools can support creativity, critical thinking, and analysis. We gave ChatGPT open-ended questions and evaluated its answers using clear criteria like understanding, structure, depth, language, references, memorization vs. creativity, etc.
- The fourth contribution, relating to the second novel contribution in this study involved establishing a fair and reliable evaluation using the Delphi method in which five experts provided a score for each answer using a 5-point scale across seven different areas. Details are provided in the methodology section.

The next section examines the current state of LLMs in education, including their potential to enhance multi-disciplinary learning and creativity. The remainder of this paper is organized as follows. Section III provides background details related to the use of LLMs in Education. In Section IV, we review the role of LLMs in interdisciplinary courses and quantitatively investigate ChatGPT for use in the assessment of Higher Education Multi-Disciplinary Courses. In Section V, we discuss the impact of AI in Enhancing Creativity. Section VI discusses the results and finally, Section VII concludes with future directions and opportunities of AI LLMs in education.

II. Research Methodology

This study investigated a mixed-methods approach to evaluate the role of large language models (LLMs), specifically ChatGPT, in a multidisciplinary academic course. ChatGPT was used as a case study, focusing on literature reviews and experimental trials, to examine the capabilities, limitations, and educational values of LLMs. The method was particularly focused on the following three stages:

- Literature Review: Research articles were selected and reviewed to understand recent technological innovation with the use of LLMs in higher education subjects, focusing on interdisciplinary and creative learning environments.
- Case study: ChatGPT's performance was evaluated across a wide collection of test types to assess its accuracy, flexibility, and interdisciplinary education applicability.

Gap identification and synthesis: A synthesis exercise on three major gaps was conducted to guide the case study and identify opportunities for further exploration.

A. Criteria for Literature Selection

The search strategy for the review included several key databases, as Science Direct, IEEE Xplore, Web of Science, PubMed, Google Scholar, and ACM Digital Library. To capture a wide range of literature, the following search terms were included: "ChatGPT in interdisciplinary education", "LLM applications in higher education", "AI in STEM and humanities education", "AI tools for fostering critical thinking in education", "challenges and opportunities of AI monitor systems", "Generative AI tools for cross-disciplinary learning". The search terms were then linked using the Boolean operators (AND, OR) to filter search results. Studies were excluded if (1) the use of LLMs, including ChatGPT, in higher education or interdisciplinary learning was not explicitly discussed. (2) Prior to 2021, they were eliminated, as they might not represent the most recent advances in AI and its trends, as well as

applications in education. The title and abstracts of the papers were screened for eligibility, and full-text articles were assessed for inclusion. Then the full-text articles were reviewed to identify patterns and themes based on studies. The resources were analyzed to learn more about the use of LLM to support interdisciplinary learning, creativity in education. Fig. 1 presents the PRISMA flow diagram, which summarizes the screening process.

B. Case Study

A case study was carried out with ChatGPT-4o empirically to measure the influence of ChatGPT in university-level multi-disciplinary classes. Fifty items were selected from six courses, such as Engineering Economy, Statistical Methods for Engineers, and Management Information Systems. Key parameters included:

- Influence of ChatGPT on an undergraduate multilingual course.
- Question Types: Open-ended and multiple-choice questions were experimented with to check the adaptability of ChatGPT.
- Disciplinary Breadth: STEM and non-STEM disciplines' questions spanned to evaluate cross-disciplinary flexibility.
- Accuracy Evaluation: ChatGPT's answers were compared against instructor-provided solutions to calculate performance metrics.

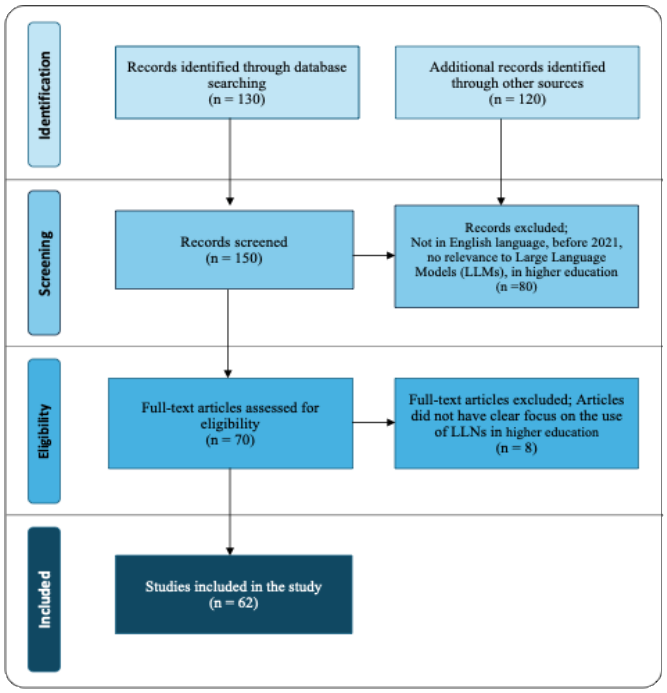

Fig. 1. PRISMA flow diagram of our screening process.

III. Background

This section reviews and analyzes recent studies about LLMs and the use of AI in education. The discussion presents some learning applications of LLMs, reports of what they performed well in, where they fell short, and user concerns.

A. Large Language Models (LLMs) and ChatGPT

LLMs form a class of powerful machine learning models that have been adapted to comprehend as well as generate human-like text, conditioned on very enormous datasets that contain hundreds of billions of parameters. These models are trained on large volumes of textual data gathered from sources such as websites, books, and other written material, allowing them to learn patterns, relationships and context within language [8].

LLMs are based on deep learning and natural language processing that are built in a way that includes having transformers, a kind of neural network architecture [9], in a key role. Transformers are designed with attention mechanisms that allow them to attend to different parts of a sentence while generating a response, which makes it possible for them to maintain context over long text.

OpenAI's ChatGPT is an example of LLM, which enables conversational models using such GPT (Generative Pre-Trained Transformer). ChatGPT has gone through a couple of iterations, GPT-3.5, with models like GPT-4 and GPT-4o being among the latest [10]. To obtain advanced chat capabilities, ChatGPT has been pre-trained on large corpora of text sources and can generate coherent context and dialogue responses. This feature has made ChatGPT a flexible learning model that can manage a range of activities, including answering questions, producing original material, and providing instructional help [11]. ChatGPT is built to mimic conversational flow and can be used in professional and creative fields.

B. Overview of Large Language Models (LLMs) in Education

LLMs, such as OpenAI's AI chatbot, have been widely adopted in education for their capability of understanding and generating human-like writings from immense amounts of data. These models can analyze enormous volumes of text data with complex machine learning, in particular, deep learning, and learning from observation of its patterns to generate output with similar patterns to the language and reasoning of humans. LLMs have been employed within educational settings to enhance learning by providing support, tutoring, and content writing personalized to students. The ability to produce context-sensitive and adaptive tendencies makes them an ideal system to answer a variety of student questions in accessibility for students to participate in dynamic and interactive learning environments [1].

LLMs are frequently used in education settings with the goal of improving students' access to information and customizing learning. Such AI-based platforms, like ChatGPT, where students can get explanations personalized to them, break down complex ideas, and practice language skills in a way that gives them quick feedback [12]. In addition, LLMs have also been shown to ease the workload of educators by handling other admin tasks, like grading and responding to common student questions, freeing up educators to focus on more targeted, one-on-one education [13]. LLMs have also been integrated with adaptive learning platforms personalized learning systems that provide students with real-time support that is specifically tailored to their learning styles and needs. This facilitates independence in the classroom and allows for self-regulated learning [14].

Several studies have addressed the growing popularity of LLMs (such as ChatGPT) in improving education-related experiences. In 2024, [15] carried out a study and evaluation of the attitude towards Artificial Intelligence chat robots with students in their institutions of higher learning using a review of empirical studies. According to the results, students value chatbots as a study aid, but they have concerns regarding their quality and the impact on critical thinking.

Also, [16] investigated the elements influencing ChatGPT awareness, acceptance, and implementation in Chinese higher education using the Technology Acceptance Model (TAM). It highlights the importance of perceived trust and perceived ease of use in adoption. Research by [17] studied chatbots in higher education, documenting their role in student engagement and support. The authors empirically verified that chatbots could serve as intermediaries to relieve communication and administrative workload and reduce information discrepancy for the causal process effectiveness.

In [18], research on the use of ChatGPT in education highlighted both the advantages and difficulties of using it in a range of academic contexts. The model's use in science and art classes was emphasised by the authors, along with moral concerns over the potential impact of AI tools on conventional teaching methods. A systematic literature review by [19] explored the application of LLMs in foreign language teaching, highlighting their role in interdisciplinary courses that combine language studies with cultural analysis.

Overall, the literature has suggested that the implementation of AI-based chatbot systems, such as ChatGPT, in higher education is very promising to improve learning experiences and engagement with students from various disciplines. However, integrating LMS into learning can introduce some significant problems. Critics, including [4], argue that these AI aids can prevent students from learning, and their use in answering sets may limit the development of critical thinking and problem-solving abilities in students. Besides, the models are trained on big data sets, from which they could unintentionally mirror societal inequities in the data [20]. Consequently, even if LLMs could have an innovative effect on the educational process, they should be implemented systematically, hand in hand with strict ethical principles, and thoroughly monitored for their effect on teaching and learning.

C. LLMs and Interdisciplinary Learning

The rapidly growing interest in large language models such as ChatGPT has completely changed interdisciplinary learning in institutions of higher education [21]. These powerful AI-enabled tools open up new avenues for improving the quality of education. Researchers have showcased that LLM models can be employed for generating a wide range of educational content, including but not limited to explanation of complex mathematical expressions, assessment questions, as well as a source for response pairs to serve as virtual conversational and feedback partners for language practice [22, 23]. Table I shows examples of various applications of LLMs, such as ChatGPT, in interdisciplinary education by considering the efforts conducted so far, along with their benefits and challenges. By balancing the role of AI with human guidance, LLMs supplement (instead of supplanting) critical educational skills.

Research papers have attempted to explore the role ChatGPT and other LLMs play in interdisciplinary academic courses. As [24] put it, the "learning by doing" method enables students to be engaged and have increased interest in their learning process. This hands-on approach encourages engagement and improves understanding by helping students apply theoretical information in real-world situations. A study by study [25] explored the role of ChatGPT in higher education, emphasizing how it facilitates interdisciplinary learning by supporting tasks across fields such as business, engineering, and the humanities. The authors suggest that this fosters deeper collaboration and encourages students to break away from traditional academic silos, helping them understand how knowledge in one field can inform and enhance another. Their findings highlight the model's ability to assist students and educators in generating content, answering queries, and promoting critical thinking across different subjects.

Likewise, the work of [22] considered educational applications of AI tools such as ChatGPT, with emphasis given to STEM and humanities classes. The researchers noted that using these tools promotes collaboration and thinking across boundaries by producing immediate feedback on assignments and requiring students to relate what they are learning across different disciplinary contexts. In [26], a study is carried out on the use of Chem Generative AI chatbots for Chemistry learning, such as ChatGPT and Bing Chat. It shows how these chatbots are good at eliciting the narrative, prompting interactions, problem-solving, critical thinking, and personalized learning. The authors recommend applications of GenAIbots in STEM to improve learning and stimulate a collaborative platform. Research by [27] explored how LLMs like ChatGPT impact engineering education. The study demonstrated that LLMs are useful in engineering courses as they increase student engagement and can help explain difficult engineering concepts. However, the authors highlighted the importance of paying attention to moral aspects and the importance of designing practical norms for the successful use of LLMs in educational settings.

The study [28] also investigated the impact of ChatGPT on converging teaching and learning modalities in engineering education using blended learning in the mathematics lesson in the Aerospace Engineering program. The findings indicate that there is a high expectation toward the app and concerns that it could affect the growth of essential skills needed for successful engineers, such as critical abilities and problem-solving skills, are also raised. The researchers emphasize the importance of incorporating AI in education; however, it should be done in moderation to help students learn it correctly and to give students very important programming skills for their education and future work. The study [29] examine the advantages and disadvantages of ChatGPT in English Language Teaching (ELT). According to the study, there are some concerns regarding academic integrity and the value of human connection in the learning process, even if incorporating chatbots into educational settings may benefit teachers and students. The study does not come without concerns about academic honesty and human values in the learning process when chatbots are integrated into the learning environment, even though it may benefit teachers and students. The study

suggests that educators need to critically reflect on the role of AI, adjust teaching methods, and undertake empirical research on best practices for introducing AI technologies to language teaching.

While the use of large language models (LLMs) in education is garnering increased interest, their application is not without constraint and challenge. A major difficulty is whether teachers can keep the benefits of LLMs while guarding cherished human-led educational experiences. LLMs may not be sufficiently successful in STEM and business subjects, however, and they may not transfer as easily to fields of study where understanding human behavior, cultural contexts, and empathetic engagement is more crucial, like psychology and sociology [30]. Furthermore, lecturers may feel concerned that students may be deprived of vital critical thinking ability should they heavily depend on the AI [20]. Also, incorporating LLMs into education calls for the establishment of new technical infrastructure and the expense to train that would raise logistical and financial problems for institutions [31].

TABLE I. BENEFITS AND CHALLENGES OF THE APPLICATIONS OF LLMS IN INTERDISCIPLINARY LEARNING

Study Focus	Application of LLMs (e.g., ChatGPT)	Benefits	Challenges	Sources
"Learning by Doing" Method	Involves students in real-world scenarios to apply theoretical concepts.	Enhances student engagement, understanding, and practical application skills.	Requires balanced integration with traditional methods to maintain depth of understanding.	[23] [24]
Interdisciplinary Learning	ChatGPT supports tasks across fields (business, engineering, humanities), fostering cross-disciplinary insights.	Promotes collaboration, breaks academic silos, and helps students connect knowledge across domains.	Limited by lack of empathy and cultural sensitivity in fields like psychology and sociology.	[22][26][30]
STEM and Humanities Support	LLMs, including GenAIbots, provide real-time feedback, fostering collaboration and cross-disciplinary thinking.	Encourages critical thinking, problem-solving, and active learning.	Risk of dependency on AI for problem-solving; some students may lack skill development.	[22][28][30]
Chemistry Education	Chatbots like ChatGPT and Bing Chat aid in critical thinking and personalized learning in Chemistry.	Improves participation, problem-solving, and fosters a collaborative environment.	Requires oversight to ensure critical thinking skills are not diminished.	[27][28]
Engineering Education	LLMs demystify engineering concepts and support blended learning, particularly in Aerospace Engineering mathematics courses.	Increases engagement and clarifies difficult concepts.	Risks impacting critical thinking and problem-solving skills are vital for engineering fields.	[30][28]
English Language Teaching (ELT)	Supports language learning via conversational practice and instant feedback.	Provides accessible, responsive language practice.	Concerns over academic integrity and potential reduction in human interaction and critical thinking.	[25][37]
Student Collaboration	Facilitates interdisciplinary projects, allowing students to explore connections between academic fields.	Cultivates integrative thinking and supports understanding complex interrelations.	Requires effective faculty guidance to ensure depth in theoretical understanding.	[30][26]
Academic Integrity	It can inadvertently be used to generate assignments, answers, and research content, leading to ethical concerns.	Helps students manage research efficiently when used responsibly.	High risk of plagiarism; challenges in monitoring and ensuring original thinking.	[20][29][31]
Resource Accessibility	LLMs provide access to complex academic content, allowing diverse learning needs to be met.	Enhances accessibility to specialized fields and helps clarify challenging topics.	Financial and logistical limitations in providing AI infrastructure, especially for resource-limited institutions.	[29][30][31]
Maintaining Human Oversight	AI use is encouraged as supplementary, balancing LLM benefits with human-led guidance for critical thinking.	Enables effective use of AI while preserving essential analytical and synthesis skills.	Over-reliance on AI risks diminishing students critical thinking and problem-solving abilities.	[27] [29]

IV. LLMS IN HIGHER EDUCATION MULTI-DISCIPLINARY COURSES

This section presents the argument for supporting learning in multi-disciplinary courses in a higher education setting. First, the use of LLMs in course assessments involving multiple-choice questions from cross-disciplinary courses is investigated. Thereafter, the role of LLMs for supporting critical thinking and creativity through open-ended questions is analyzed.

A. Role of ChatGPT in Multi-Disciplinary Courses

The injection of ChatGPT and other language models into academia is poised to revolutionize the way that higher education operates - especially in multi-disciplinary courses where very disparate knowledge bases align. With the rise of language processing techniques, the need for reshaping scientific practices has increased. It has also generated a demand for investigating the diverse effects of such cutting-edge tools in the education and learning milieu across different fields.

On the one hand, it has been argued that the potential of ChatGPT may initiate changes to the higher education teaching and learning processes through the provision of scaffolding, automated grading, inter-disciplinarily, and personalized learning [10, 32]. Yet on the other hand, these technologies are not without challenge as they raise questions of academic integrity, plagiarism, and possible detrimental effects on critical thinking [20, 33].

B. Multi-Disciplinary Engagement and Critical Thinking with ChatGPT

Through the inclusion of ChatGPT in the higher education Multi-Disciplinary Courses, interdisciplinary has been encouraged by bridging the gaps in interdisciplinary and linking across fields [34, 35, and 36]. ChatGPT could be serving as a glue between the two fields by generating appropriate content on the domains/topics. For instance, ChatGPT could assist students of technology taking up business studies by providing case studies for the integration of technology and economics that can lead to interdisciplinary discussions and develop their analytical thinking. ChatGPT drives cross-disciplinary collaboration by providing the context and perspectives from diverse expertise backgrounds, which is beneficial to students with different backgrounds and knowledge. This could help students identify relationships between different facts, which leads to a more unified perception of complex issues, and contribute to creating a learning environment where the students, at all levels, feel that they are provided with the necessary elements to participate [38].

As a result, it contributes to a more integrated learning experience, in which students can apply the theoretical know-how of one subject to solving problems in another. The authors in [36] argue that the performance of ChatGPT in collaborative interdisciplinary learning is related to both the taught content and the students' prior knowledge they possess.

Another work [39] has shown that by adopting ChatGPT, students could use AI tools for more engagement and learning gains, including generating text, summarizing, translation, etc. By automating many repetitive tasks, ChatGPT allows learners to focus more on achieving a profound understanding of subjects and performing explorative research. Moreover, the ability for the model to provide personalized feedback and content recommendations can significantly enhance the learning experience [40]. Furthermore, ChatGPT offers individualized learning support across multiple disciplines [41, 42]. It can adapt its style to match different learning styles and provide tailored explanations [43], which can be used to unlock complex STEM, arts, and humanities concepts for a wide potential range of students. These are particularly useful in interdisciplinary courses where students are exposed to material that is not a core part of their studies.

C. Capacity of ChatGPT in Inter-Disciplinary Course Learning and Assessments

A study of the impact of ChatGPT on undergraduate-level multi-disciplinary course assignments and exam questions is now presented using a series of randomly selected open and multiple-choice questions (MCQ). ChatGPT responses for the examination and homework questions are recorded for undergraduate interdisciplinary courses involving more than one academic program. For instance, the Statistics for Business course involved the sciences and business programs, whilst the Mathematics for Engineering course involved the sciences and engineering programs. Instructors' responses to the accuracy of the generated results are provided for evaluation purposes.

All experiments and trials conducted in this paper were based on the ChatGPT-4o model architecture, which was the latest and most advanced version available for subscribers at the time of preparing this study. The experiments were divided into three main parts. The first part involved a multiple-choice test with 35 questions. The second part included 15 open-ended questions that had clear, expected answers. The third and final part involved 3 long open-ended questions designed to measure deeper skills such as: overall understanding, organization and logic, analytical depth, language and style, referencing and sources, memorization and matching, and creativity.

To ensure accuracy and fairness in evaluating these answers, the well-known Delphi method was used. Each answer was reviewed by five different evaluators over two rounds. In the first round, each evaluator gave a score from 1 to 5 for each criterion without seeing the others' scores. Then, the average score for each criterion was calculated and shared with all evaluators. In the second round, reviewers re-evaluated the answers after viewing the averages. The final result was based on the second round, using the average score for each criterion in every question.

Table II demonstrates the responses produced for a sample of fifteen open-type assignments that were randomly selected in addition to exam questions relating to multi-disciplinary courses, as well as the correct responses for those questions. The open questions considered related to six courses that include: Engineering Economy, Statistical Methods for Engineers, Statistics for Business, Management Information Systems, Introduction to Computing for Business, and Logic Circuits Design. Each course involved randomly selected questions, selected between beginner and intermediate-level questions.

In Table II, it was found that the overall ChatGPT-4o accuracy for the given trials was 93.3% (e.g., 14 out of 15), implying that only 6.7% of the data-test questions were incorrectly answered. The only incorrect answer was related to the Statistics Methods for Engineers course.

TABLE II. USE CASES OF CHATGPT IN OPEN EXAM QUESTIONS

No.	Question/ Assignment Description	Academic Course	ChatGPT Response	Comment on Result (compared with the instructor's answer)
1	A manufacturing company assembles up to 30 vehicles per month in its main facility. Consider a drop in production to 25 units per month due to a worldwide economic slowdown in construction. Additionally, we have: A fixed cost, FC = $550K per month A variable cost per unit, v = $35K	Engineering Economy	The breakeven point is 14 units per month. The company is **operating above the breakeven point**	Production level=20, Breakpoint level=14 [CORRECT]

<table>
<tr><td></td><td>Revenue per unit r = $ 75K
Compare the breakeven point with a reduction in production level to 20 units per month?</td><td></td><td></td><td></td></tr>
<tr><td>2</td><td>For the above question, what is the current profit level per month for the facility?</td><td></td><td>Profit=$250,000</td><td>$250000 profit/month
[CORRECT]</td></tr>
<tr><td>3</td><td>“The height of similar company spare parts is approximated by a normal distribution model with a mean of 5 cm and a standard deviation of 0.02 cm.” Click or tap here to enter text.
What is the probability that the height of a part is more than 4.98 cm if this part was chosen at random?</td><td rowspan="6">Statistical Methods for Engineers</td><td>P(X>4.98) =1−P(X<4.98) =0.8413</td><td>P(X > 4.98) = P(Z > -1) = 1 - P(Z < -1) = 1 - 0.1587 = 0.8413

[CORRECT]</td></tr>
<tr><td>4</td><td>For question 3, find the probability that the height of this part is between 4.96 and 5.04 cm?</td><td>P(4.96<X<5.04) = 0.9544</td><td>P(4.96 < X < 5.04) = P(-2 < Z < 2) = .9772 - .0228 = 0.9544 = 95.44%
[CORRECT]</td></tr>
<tr><td>5</td><td>A shipment of cars contains 20 cars: 6 sedan cars and 14 pickup cars. Five cars are chosen randomly without replacement. What is the probability that exactly 4 sedan cars are chosen?</td><td>The probability that exactly 4 sedan cars are selected is approximately 0.0135 or 1.35%.</td><td>P(X=4) = 0.013544
[CORRECT]</td></tr>
<tr><td>6</td><td>Let’s assume that the medal distribution from a competition is as in the table below. Given that the winner was from Team A, find the probability that the winner won the gold medal.
<table>
<tr><th>Team</th><th>Gold</th><th>Silver</th><th>Bronze</th></tr>
<tr><td>A</td><td>39</td><td>25</td><td>33</td></tr>
<tr><td>B</td><td>32</td><td>28</td><td>28</td></tr>
<tr><td>C</td><td>28</td><td>16</td><td>15</td></tr>
<tr><td>D</td><td>16</td><td>25</td><td>17</td></tr>
</table></td><td>If the winner were from Team A, the probability that the winner won gold is approximately 0.402 or 40.2%.</td><td>P(Gold Medal | from A) = 40.20%
[CORRECT]</td></tr>
<tr><td>7</td><td>The reservation kiosks for a high-speed train service are occupied 25% of the time. Assume that the events that the kiosks are occupied on successive reservations are independent. Assume that 10 reservations are made for the service.
What is the probability that for at most three reservations, the kiosks are occupied?</td><td>The probability that for at most 3 calls the lines are occupied is approximately 90.43%.</td><td>77.58%

[INCORRECT]</td></tr>
<tr><td>8</td><td>“A normally distributed random variable has a mean of 245 and a standard deviation of 21. For a sample size of 35, find the probability that the sample mean is more than 241.</td><td rowspan="3">Statistics for Business 1</td><td>The probability that the sample mean is more than 241 is approximately 0.8709 or 87.09%.</td><td>86.86%
[CORRECT]</td></tr>
<tr><td>9</td><td>The number of updates for the events website follows a discrete distribution with a mean of 0.25 per day. What is the probability of at least two updates per day?</td><td>The probability of at least two updates per day is approximately 0.0265 or 2.65%.</td><td>2.65%
[CORRECT]</td></tr>
<tr><td>10</td><td>Given 149 randomly selected adults, 32 were found to have an illness. Produce a 95% confidence interval for the proportion of all adults who have been ill.</td><td>CI= (0.1489,0.2807)
This suggests a 95% confidence that the true proportion of adults who have been ill is between 14.89% and 28.07%.</td><td>0.149 < p < 0.281
[CORRECT]</td></tr>
<tr><td>11</td><td>What is the difference between e-commerce and e-business?</td><td>Management Information Systems</td><td>E-Business (Electronic Business): Definition: E-business refers to the use of the internet and digital technologies to carry out all aspects of a business. It encompasses not only buying and selling but also servicing customers, collaborating with business partners, and conducting internal processes such as inventory management, supply chain operations, and human resources.
E-Commerce (Electronic Commerce): Definition: E-commerce specifically refers to the buying and selling of goods and services over the internet. It focuses on transactions and the exchange of value through online platforms.</td><td>E-Business includes buying and selling goods, providing services, and collaborating with other businesses.
E-Commerce includes selling and buying goods and is a subset of e-business.
[CORRECT]</td></tr>
<tr><td>12</td><td>A private company wants to set up a university. Analyze this case and answer the following:</td><td></td><td>The private company should adopt a functional organizational structure for</td><td>Organizational Structure: professional bureaucracy.</td></tr>
</table>

	a) Which organizational structure should they adopt to set up the university? b) What is the primary goal of the organizational structure? c) Who should be the knowledge workers?		setting up the university. This structure is typically used in academic institutions because it allows for specialized departments to focus on their areas of expertise. Each department would be led by an expert in that function, and this ensures clear accountability and smooth operations across various divisions. … The primary goal of the organizational structure is to **facilitate efficient and effective management** of university operations while ensuring high-quality education, research, and student services. … The **knowledge workers** in the university would primarily include: **Faculty Members**: Professors, lecturers, researchers, and academic staff who are responsible for teaching, conducting research, and generating new knowledge in their respective fields. **Administrative Staff**: University administrators who manage the operations of the institution, including admissions, student services, and financial management. **Researchers**: Individuals engaged in academic and scientific research, contributing to the creation and dissemination of new knowledge. **IT and Educational Technology Staff**: Personnel responsible for managing the university's technological infrastructure, including learning management systems, databases, and digital learning platforms.	Goal: quality & effectiveness Knowledge workers: instructors, middle managers, IT specialists, data analysts. [CORRECT]
13	What are the most common types of application software that are used in Business? Explain at least two.	Introduction to Computing for Business	• Enterprise Resource Planning. • Customer Relationship Management.	• ERP • CRM • PMS • Business Process Management Software. • Word Processor • Spreadsheet • Database • RMS [CORRECT]
14	Write the SOP representation for a three-input OR gate	Logic Circuits Design	SOP expression simplifies directly to: Y=A+B+CY = A + B + C	SOP: (A'BC) + (AB'C) + (ABC') [CORRECT]
15	Write simplified equation for the given truth table. What gate does it represent? | A | B | C | X | |----|----|----|----| |0|0|0|1| |0|0|1|0| |0|1|0|0| |0|1|1|1| |1|0|0|0| |1|0|1|1| |1|1|0|1| |1|1|1|0|		After simplification, the resulting Boolean expression is: X =A⊕B⊕C This is the **three-input XOR (Exclusive OR)** gate.	3 input XNOR: Cannot be simplified. [CORRECT]

Table III shows the correctness performance for ChatGPT using thirty-five randomly selected MCQ questions for various interdisciplinary specialization courses. MCQ questions were selected using courses from Table II (Statistics Methods for Engineers, Statistics for Business, Management Information Systems, Software Process and Modeling, Computer Applications, Introduction to Computing for Business) as well as additional interdisciplinary courses that include Information Systems Infrastructure and Innovation and New Technologies.

TABLE III. USE CASES OF CHATGPT IN MULTIPLE-CHOICE QUESTIONS (MCQ)

No.	Question	Specialization Course	ChatGPT Response	Comment
1	Net Cash Flow can be determined by: a) Cash inflows – Cash outflows b) Present worth – Annual worth c) Cash inflow x interest rate d) Cash outflow x interest rate	Engineering Economy	A	A [CORRECT]
2	"Obtaining the equivalent worth of future cash-flows back to some point in time refers to a process called": a) The Present Worth Method b) The future worth method c) The annual worth method d) Capital recovery method		A	A [CORRECT]
3	Which of the following statements are true? a) Variable costs change with the level of activity; b) More activity – greater variable costs; c) Variable costs are impacted by efficiency of operation, improved designs, quality, safety, and higher sales volume. d) All above		D	D [CORRECT]
4	Which of the following costs is not a fixed cost example: a) Costs of buildings; b) Material; c) Fixed overhead; d) Equipment capital recovery		B	B [CORRECT]
5	Express the null hypothesis and the alternative hypothesis in symbolic form for the following: The mean pulse rate of male marathon runners is less than 70 beats per minute. H0: μ < 70 H1: μ 70 ***:*** H0: μ = 70 H1: μ 70 H0: μ = 70 H1: μ > 70	Statistical Methods for Engineers	H0:μ=70andH1 :μ<70	μ < 70170 H : μ ≥0H [CORRECT]
6	When conducting a Z test for equality of means, **H0: μ1 = μ2** versus **H1: μ1 ≠ μ2**, the test value was found to be **-2.45**. The *p*-value for this test would be: a) 0.0071 ***b) 0.0142*** c) 0.0081 d) 0.0814		0.0142.	*0.0142* [CORRECT]
7	If a vehicle breaks down on average, two times every month. What is the probability that it will break down three times in a period of a month? ***a) 18%*** b) 32% c) 67% d) 85%		18%	18% [CORRECT]
8	Given that there is an 80% chance that all startups in the IT industry report a profit in their first year. If a sample of ten new IT business startups is selected, it follows a discrete probability distribution. Which discrete probability distribution would be implemented for the above situation? a) Normal Distribution ***b) Binomial Distribution*** c) Poisson's Distribution d) Geometric Distribution		Binomial Distribution	B [CORRECT]
9	A used parts store has ten batteries, three of which are defective. Given that two are selected at random without replacement. Determine the probability that both are defective. ***a) 6.6%*** b) 25% c) 32% d) 41%		6.6%	6.6% [CORRECT]
10	In class, 30% of students study Physics, 45% study Chemistry, and 15% study both Physics and Chemistry. If a student is randomly selected, what is the probability that the student studies Physics given that the student studies Chemistry? a) 1/5 b) 3/5 c) 2/5 **d) 1/3**	Statistics for Business 1	1/3	1/3 [CORRECT]
11	Identify the standard deviation of a Uniform probability distribution over the range $3 \leq X \leq 9$. a) 1 **b) 2** c) 3 d) 9		2	2 [CORRECT]
12	Identify the sample variance for the following sample: −8, −8, −3, 13, 4, −8, 10, 8 a) 67.24 **b) 77.42** c) 91.54 d) 97.57		77.42	77.42 [CORRECT]
13	While employees are lined up for a company group photo, a satisfaction survey is given to every 10th employee. This type of sampling is called __? A. Simple random sampling. b. Stratified random sampling. c) Cluster random sampling. d) Systematic random sampling.		D	D [CORRECT]

14	"Which of the following rules states that you should take the action that produces the least harm. a) The Golden rule b) The utilitarian principle **c) The risk aversion principle** d) Kant's categorical imperative"	Management Information Systems	C	C [CORRECT]
15	"Which of the following integrates business processes in manufacturing and production, finance and accounting, sales and marketing, and human resources into a single software system?" a) KMS b) CRM **c) ERP** d) SCM		C	C [CORRECT]
16	Which of the following models displays the organization of a system's components? **A. Structural** B. Behavioral C. Interaction D. Context	Software Process & Modelling	A structural model	A [CORRECT]
17	What should we consider drawing if we want to look at the behavior across many use cases or many threads? A. a Sequence diagram **B. an Activity diagram** C. a State Machine diagram D. a Package diagram		B. an Activity diagram	B [CORRECT]
18	**Which are not application software?** A. Word Processing software B. Desktop publishing C. Spreadsheet program **D. Windows 10**	Computer Applications 1	D. Windows 11	D [CORRECT]
19	Which of the following application programs is used for writing business letters, memos, business plans, and contracts? A. Spreadsheet software B. Database programs **C. Word Processing software** D. Desktop publishing		C. Word Processing programs	C [CORRECT]
20	A list of numbers preceded by numbers, which indicate the sequence or rank of items, is the? A. Bulleted list **B. Numbered list** C. Unordered list D. Extranets		B. Numbered list	B [CORRECT]
21	In Excel, adding a group of values and dividing the result by the number of values in the group is called: A. Summation B. **Average** C. Standard Deviation D. Median		B. AVERAGE	B [CORRECT]
22	What refers to a defined set of formatting characteristics that include font size, font color, cell borders, font, and cell shade. A. Data bar B. Fonts C. Conditional formatting D. **Cell styles**		D. Cell styles	D [CORRECT]
23	The default view of a new project in Microsoft Project is called: **A. Gantt view** B. Resource graph C. Network view **D.** Workbook view	Introduction to Computing for Business	A. Gantt view	A [CORRECT]
24	What is the primary purpose of Microsoft Excel? A. To write essays B. To show a slide presentation **C. To create a budget, average grades, and to control inventory.** D. To keep students updated on the latest Microsoft Office product		C. To create a budget, average grades, and to control inventory.	C [CORRECT]
25	In Microsoft Word, what does the 'Word Wrap' feature do? A. Allows you to type over text **B. Automatically moves text to the next line when necessary** C. Allows you to view the horizontal lines D. Controls printing		B. Automatically moves text to the next line when necessary	B [CORRECT]
26	Which of the following represents a Sum of Products (SOP) expression?	Logic Circuit	(W * X) + (Y *	B

	a) (W + X) * (Y + Z) **b) (W * X) + (Y * Z)** c) (W + X) + (Y + Z) d) None of above	Design	Z)	[CORRECT]
27	A circuit that converts *n*-bit inputs into 2^n outputs is called a …… A. Multiplexer B. Encoder C. Decoder D. Demultiplexer		C. Decoder	C [CORRECT]
28	The Boolean expression (x + y) (x + z) is equal to A. xyz B. x (y + z) C. (x + z) y D. x + yz		x + yz	D [CORRECT]
29	According to DeMorgan's theorems, which of the following equalities is correct? A. $\overline{AB} = A + \overline{A}B$ B. $\overline{A} + \overline{B} + \overline{C} = (\overline{A} + \overline{C})(\overline{A} + \overline{B})$ C. $\overline{A+B+C} = \overline{A}\,\overline{B}\,\overline{C}$ D. All of the above		C	C [CORRECT]
30	1. Convert the Decimal number 26 to its equivalent Binary Coded Decimal (BCD). A. 11010 B. 01010 C. 00100110 D. Other		C	C [CORRECT]
31	Key software trends are concerned with: (a) Open source support software, programming with procedural languages. (b) Open source support software, programming with assembly languages. **(c) Open source support software, programming with object-oriented languages.** (d) Less user-development and product development software.	Information Systems Infrastructure	C	C [CORRECT]
32	What is the difference between *batch processing* and *online processing*? (a) Online processing is less expensive to operate than batch processing. (b) Online processing is more expensive to operate than batch processing. (c) The master file of online processing is updated within a fraction of a second, and batch processing day. **(d) Both (b&c).**		D	D [CORRECT]
33	A company identifies 9 occurrences in the last 12 years where a laptop has been lost. If the Loss of information on a laptop averages $180,000, calculate the Annual Expected Losses (AEL). **(a) $135,000** (b) $250,000 (c) $270,000 (d) $90,000		$135,000	A [CORRECT]
34	What does premise mean in social networking? a. It means the structure of a network. **b. Something becomes more powerful the more people use it.** c. Cannot be used among people. d. None of the above is correct.	Innovation & New Technologies	Something becomes more powerful the more people use it.	B [CORRECT]
35	A 5G smartphone is an example of: (a) a process innovation **(b) a product innovation** (c) an invention (d) a business model innovation		a product innovation	B [CORRECT]

Each course includes many beginner and intermediate-level MCQ questions. Overall, it was demonstrated that ChatGPT obtained a 100% accuracy for the dataset used for MCQ questions sampled using beginner and intermediate level questions. Moreover, from the results shown, it could not be concluded whether ChatGPT-4o performs better or worse for a particular course or level from those studied here, except that in this study, it had clearly outperformed the ChatGPT-3.5 architecture studied and reported in [11] if it were assumed that ChatGPT performs equally well for various courses.

Fig. 2, 3 and 4 as well as Tables IV, V, and VI show some weaknesses in Chat-GPT 4o for open-ended text questions, particularly in the depth of analysis. This might be because LLM tools (like ChatGPT) heavily rely on how the prompt is written. This makes it hard to obtain consistent answers if different people write the same question in different ways. Additionally, the tool did not provide clear sources for the information it gave possibly because it was trained on a huge mix of sources. Next, in terms of creativity, the LLM received an average score. This may also be related to how the prompt was phrased and to how much creativity was built into the model during training. On the other hand, the tool performed very well in memorization, organization, logic, and general understanding of the questions. Moreover, it performed well in language and formatting, except for one math question, where the formatting was not very clear.

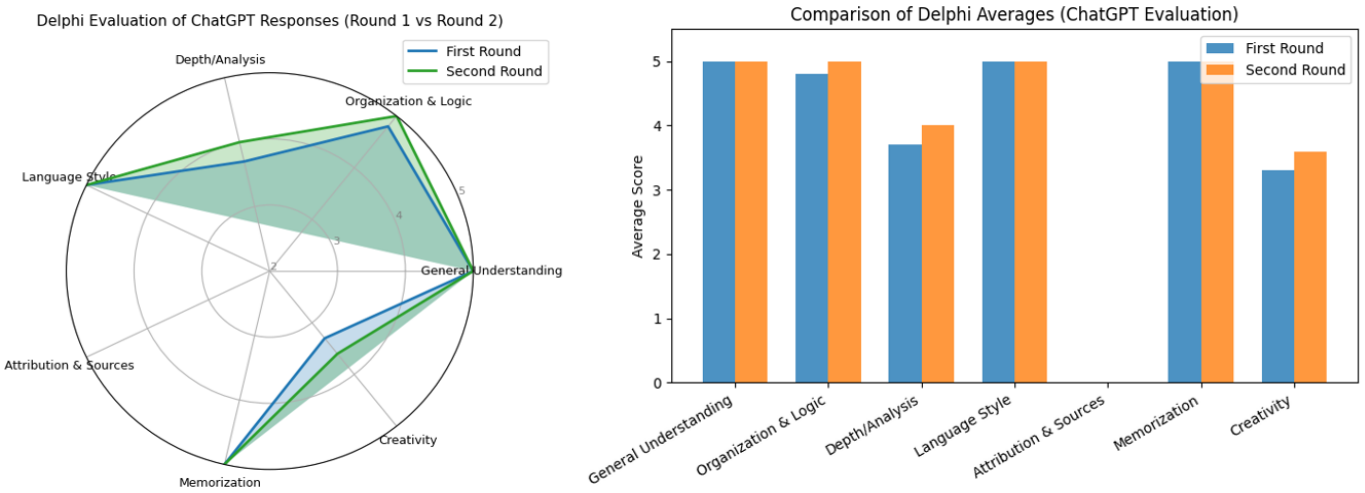

Fig. 2. Five evaluations for the sample question 1 based on the review criterion applied over two rounds of the Delphi.

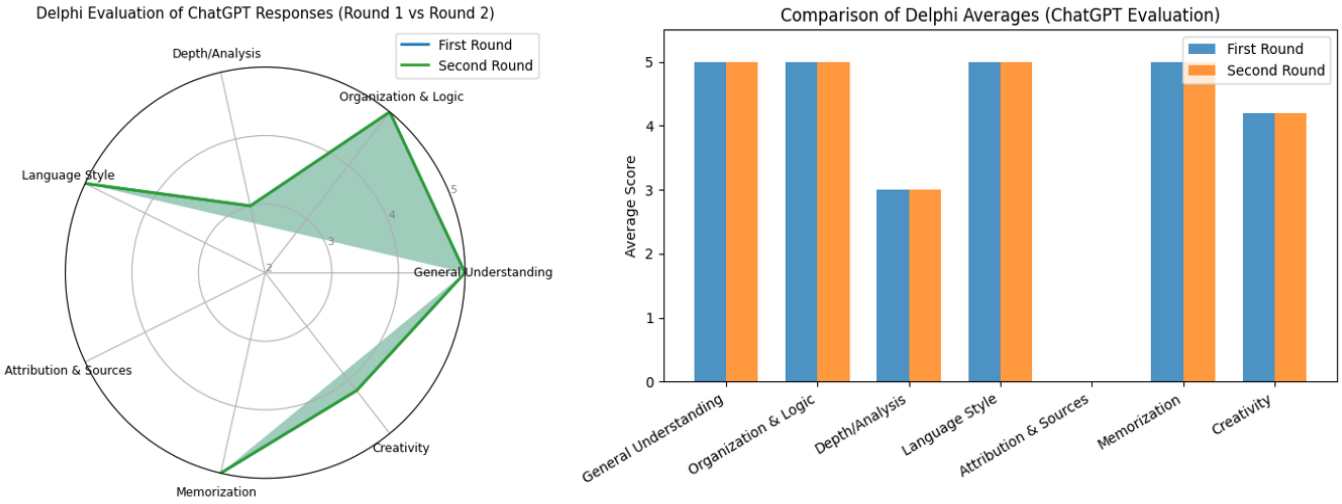

Fig. 3. Five evaluations for the sample question 2 based on the review criterion applied over two rounds of the Delphi.

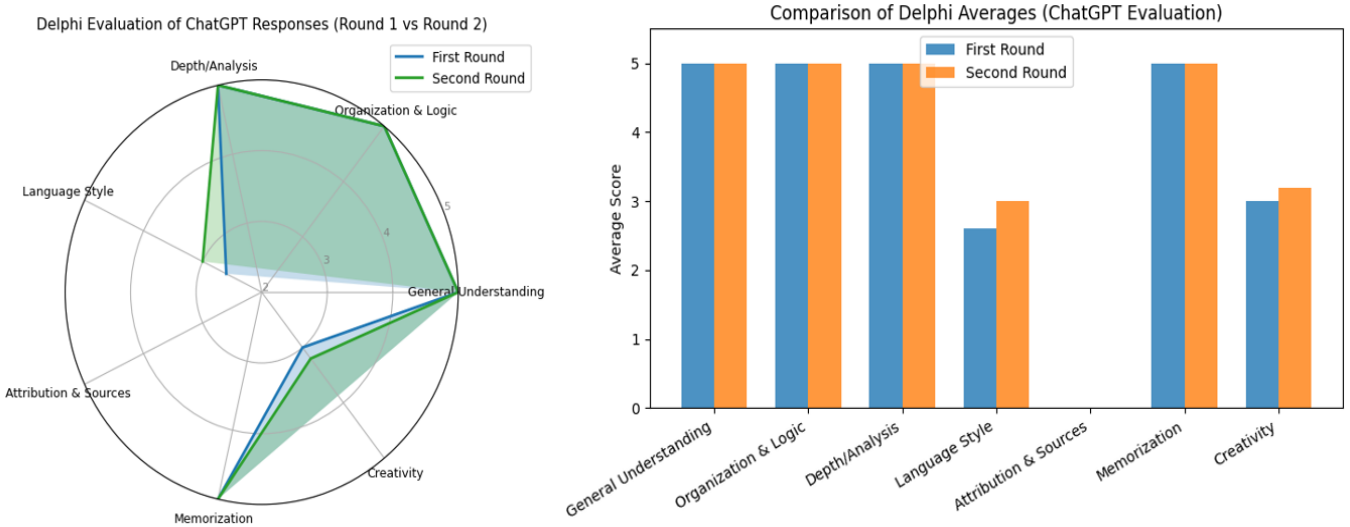

Fig. 4. Five evaluations for the sample question 3 based on the review criterion applied over two rounds of the Delphi.

TABLE IV. FIVE EVALUATIONS FOR THE SAMPLE QUESTION 1 BASED ON THE REVIEW CRITERION APPLIED OVER TWO ROUNDS

First Question: What is the difference between e-commerce and e-business?									
Q	**Tool for Generating Answers**	**Reviewer**	**General Understanding**	**Organization & Logic**	**Depth/ Analysis**	**Language Style**	**Attribution & Sources**	**Memorization**	**Creativity**
First Round									
1	ChatGPT	R1	5	5	3.5	5	NA	5	4

V. Impact of AI in Enhancing Creativity

Large Language Models (LLMs) like ChatGPT are increasingly transforming creative disciplines in educational settings. There are unique challenges and opportunities presented by integrating AI tools into creative processes, by offering students tools to ideate, visualize, and develop creative projects across fields. With their ability to synchronize and generate complex responses, LLMs provide a dynamic source of inspiration and feedback for university students. Research has shown that when these models are used cautiously, they can serve as very powerful collaborators that can help students come up with innovative ideas and explore innovative solutions in ways that are more engaged than with traditional methods [44, 45].

For example, in design disciplines, LLMs can help students research trends, generate content, and offer diverse perspectives [46]. It can thereby help expand their creative possibilities. Research results have illustrated that ChatGPT has significantly improved three thinking skills in university students. In particular, critical thinking increased by 38%, reflective thinking by 61%, and creative thinking by 61%. Accordingly, we suggest the use of ChatGPT for didactic help in in-class exercises [47]. Another research study presented a generative AI tool for computer programming with natural language interfaces as a resource for learning and understanding, in order for learners to be encouraged to reflect and to explore other available solutions [48].

In the context of a creative writing class, LLMs can assist in directing plot ideas or suggesting characters that can trigger the students' imagination and overcome writer's block [49]. While in business classes, LLMs can be utilized to assist students 1) in developing marketing strategies, 2) in writing professional emails and presentations, 3) in writing financial reports and analyses [50]. Additionally, ChatGPT was utilized in computer science classes to assist students with programming assignments, such as explaining complicated programming ideas, debugging code, and providing algorithmic clues [51].

The creative process becomes more exploratory and prospective as students are able to explore beyond their initial concepts. Based on the detailed study on the utilization of generative AI in education, it is found that the application of generative AI will transform the education sector. It will provide an interesting and stimulating learning experience for students to facilitate learning and performance in academics [52].

Research also demonstrated that the advent of generative AI technology offers innovative ways to enhance creativity, ideation, and collaboration among students [53]. Generative AI tools have the power to impact how we learn by teaching creativity and critical thinking, skills that will be relevant in the 21st century. Also, the use of AI can assure the versatility and durability of educational solutions in different settings [54]. Due to their flexibility, LLMs can serve as tools to foster creative thinking and, at the same time, encourage university students to become active participants in the learning process. LLMs also play a unique role in enhancing creativity in that they can adapt their responses based on specific creative needs, be it visual, written, or in interactive forms. This adaptation enables students to try out different tones, genres, or cultural references, potentially creating an atmosphere where they can push the envelope of provocative art. The possibility of students to interactively co-create with an AI model opens up new possibilities to innovate in the creative domain, thereby only underscoring the mediating role of LLMs as co-creators and/or collaborators rather than just being a tool [55].

However, integrating LLMs into creative disciplines can also pose particular challenges for students and educators. One major concern is the risk of over-dependence on AI-generated material that can decrease originality and lead students to accept the answers and suggestions of the AI model without really being involved in the creative process [56 and 57]. This poses an ethical issue for educators regarding who is the author and who owns the work, and this becomes even more critical in fields where originality carries weight. Evidence indicates that teachers need to create systematic guidelines and models to facilitate the use of AI for promoting the development of students' creativity, not impeding it [58, 59]. By defining clear standards of AI collaboration, educators can guide students to maintain a healthy balance, where AI can serve not just as an extension of creativity but also as a source of encouraging independent critical thinking.

Overall, LLMs have a significant impact on creative discipline for students and faculty. Although LLMs provide ample room for broader exploration and creativity in different domains, it remains necessary to make a change in the way educators influence the development of creative skills, striking

a balance between guidance by AI and student-led discoveries [60]. Teachers also need to acknowledge the necessity to develop curricula and frameworks that integrate LLMs as well as e-learning [61] and interactive learning [62] in a way that also deals with the ethical consequences related to AI technologies in the creative process. Through critical reflection on the generalizability of these models, educators can ensure that AI tools such as ChatGPT can serve to augment rather than replace student creativity, suggesting that while the integration of LLMs is overall a step forward as an educational tool, it also poses a challenge that will require a measured response in order to be used to truly foster creativity and innovation in education.

VI. Discussion

Recent studies have investigated the potential benefits and limitations of LLMs in higher education courses. A review of the literature has shown the gap in the analysis of LLMs' abilities with respect to interdisciplinary courses that involve courses from multiple specialization areas. This study has quantitatively evaluated the potential use of ChatGPT in facilitating learning for multi-disciplinary courses using various assessment types. In particular, a total of 50 experimental trials were performed using ChatGPT-4o. The results had revealed the significant potential of ChatGPT in enhancing interdisciplinary education.

Significantly, ChatGPT has demonstrated excellent performance in handling open-ended as well as multiple-choice questions (MCQ) across diverse academic disciplines, yielding 93% and 100% accuracy rates for open-ended and MCQ questions, respectively. Such results have demonstrated ChatGPT's potential as a valuable tool for fostering interdisciplinary learning by bridging knowledge gaps and promoting integration of ideas from different domains in which students encounter topics as part of courses that are outside their primary focus. Results presented here for ChatGPT-4o mark a notable improvement compared to the results from a related study [11] in which ChatGPT-3.5 was tested for technology and engineering courses only - 93% accuracy was obtained using ChatGPT-4o for multidisciplinary courses, as compared to 64.3% accuracy for technology only courses. Its success in addressing open-ended questions highlights its role in stimulating critical thinking and creative problem-solving, while its accuracy in multiple-choice assessments highlights its potential as a reliable resource for personalized learning of foundational concepts.

VII. Conclusion

From the findings of this paper, it was found that LLMs could be used to enable students to improve their understanding and develop unique solutions to complex problems. However, such advancements also present challenges, particularly in the areas of academic integrity and over-reliance on AI tools. Concerns such as over-reliance on AI tools and issues of academic integrity call for the development of clear guidelines and policies to ensure ethical and responsible use of AI in educational settings that emphasize fairness, inclusivity, and transparency, which is critical for building a robust foundation for broader adoption.

Moreover, it is essential that course instructors provide a balance between leveraging AI for enhanced learning outcomes and ensuring that students retain the ability to critically engage with the material independently. Therefore, there is a need to develop AI-supported assessment frameworks tailored to interdisciplinary education, ensuring they effectively measure and reflect the depth of student learning. By addressing such challenges, the potential of LLMs to enhance education can be better harnessed, fostering a more innovative and inclusive learning environment.

While this study focuses on empirical analyses of ChatGPT LLM in interdisciplinary higher educational courses, a number of implications can be highlighted following the results obtained:

- the evolution and reliable use of ChatGPT in higher education courses has improved and continues to improve with newer editions of the LLM, as evident in the results for ChatGPT-3.5 (64%) with technology courses, compared to the results for ChatGPT-4o across different assessment types for multidisciplinary courses (93% and 100%).
- Higher education policymakers, course developers and assessment designers should consider how LLMs can be used to stimulate creativity and innovation in non-assessed activities, whilst ensuring that learning outcomes are not compromised as in the case where LLMs, when not properly regulated, can be used for AI-generated assessment submissions. Such cases may result with incorrect and invalid student learning outcomes. This confirms a key finding from the related work in [11].

Finally, a promising direction for future work could investigate the role of LLMs in creativity-driven disciplines like arts, design, and entrepreneurship to better understand how it can drive innovation while preserving the authenticity of creative assessment processes. Moreover, we plan to explore deeper levels of analysis by measuring different types of thinking—such as critical thinking, reflective thinking, and creative thinking—and identifying what AI tools can support, what they cannot replace, and where they might even have a negative effect.

This exploration will be guided by Bloom's main classification domains, including the cognitive domain (covering skills like remembering, understanding, applying, analyzing, evaluating, and creating), the psychomotor domain (which involves developing practical and physical skills), and the affective domain (which focuses on emotional engagement, values, and ethical behavior). Through this, we aim to better understand the boundaries of AI in supporting human thought and learning.

Acknowledgment

The authors would like to acknowledge and thank the support of the Research Development and Innovation Authority, Kingdom of Saudi Arabia, grant number (13465-UPM-2023-UPM-3-1-EF-), as well as the Osamah AlSayyed research center fund award.

A Privacy Protection Method for IoT Data Based on Edge Computing and Federated Learning Algorithm

Ying Wu
College of Big Data and Artificial Intelligence,
Zhengzhou University of Economics and Business, Zhengzhou 450000, China

***Abstract*—This paper proposes a privacy protection method for IoT data integrating edge computing and federated learning. To address challenges including edge node heterogeneity, central server bottlenecks in traditional federated learning, and high overhead of homomorphic encryption, we design a hierarchical architecture comprising requesters, participants, edge nodes, a sensing platform, and a key generation center. Participants train models locally using SGD, encrypt parameters with an optimized verifiable dual-key ElGamal homomorphic encryption scheme, and transmit them to edge nodes. Edge nodes employ the MPSDGS algorithm for participant similarity discovery and dropout supplementation, and the MP-Update method for dynamic weighted averaging to ensure continuity and accuracy. Edge-side ciphertext aggregation reduces data volume to the platform. The sensing platform performs global secure aggregation in ciphertext. Experiments demonstrate that the method maintains data privacy above 0.8, with training and aggregation delays within acceptable ranges for typical IoT scales, balancing privacy and efficiency.**

***Keywords*—Edge computing; federated learning; Internet of Things; privacy protection; homomorphic encryption; dropout supplementation**

I. Introduction

The massive devices in the Internet of Things (IoT) generate and transmit sensitive data continuously, providing a rich information foundation for intelligent services [1]. However, the explosive growth of data from these devices includes not only basic data such as device operating status and environmental information but also sensitive information like users' personal privacy and enterprises' commercial secrets. In traditional cloud computing models, data must be centrally uploaded to the cloud for processing and analysis, which not only faces issues such as high latency and bandwidth congestion but also poses significant risks of data privacy leakage [2-3]. Especially in sensitive fields such as healthcare and finance, leaks or misuse of such data could bring severe security risks and economic losses to users [4], and may even trigger social trust crises, hindering the healthy development of the IoT industry [5]. Balancing data utility, service quality, privacy security, and computational efficiency has become a critical challenge in the current IoT field.

To tackle IoT data privacy concerns, scholarly research has introduced diverse conventional approaches. Bezanjani et al. [6] leveraged blockchain-based encryption techniques to secure data transaction workflows while implementing request pattern analysis mechanisms. By integrating multi-source data validation, they identified unauthorized access patterns to proactively mitigate leakage risks. Furthermore, feature optimization combined with Bidirectional LSTM networks enhanced intrusion detection precision against privacy threats. Nevertheless, this approach's excessive dependence on blockchain consensus protocols results in prohibitive computation overhead when handling large-scale IoT data streams, compromising real-time performance requirements. Additionally, deploying sophisticated machine learning models on constrained IoT endpoints creates operational burdens that impede normal device functions and timely data processing. Samriya et al. [7] established multi-layered IoT privacy protection through cloud-level security enhancements using trusted cryptographic analysis approaches. For device-level data processing, they employed structured Markov sparse Bayesian neural networks to extract actionable insights while preserving confidentiality, supplemented by adversarial machine learning for real-time anomaly detection against network intrusions. However, the computational intensity of cryptographic analysis and neural computations creates processing bottlenecks on resource-limited edge devices, necessitating cloud dependency and thereby increasing transmission-related privacy exposure risks. Prakash et al. [8] secured IoT communications through elliptic curve cryptography (ECC) for confidentiality preservation coupled with zero-knowledge proofs (ZKP) for authentication validation. This dual-mechanism approach ensures end-to-end data security by enabling identity verification without content exposure. However, the combined computational complexity of ECC operations and ZKP protocols imposes significant energy consumption and latency penalties on constrained devices, reducing battery efficiency and responsiveness while requiring specialized cryptographic expertise for implementation. Shree et al. [9] integrated blockchain with Inter Planetary File System (IPFS) decentralized storage, employing secret sharing algorithms (SSA) to fragment sensitive data across distributed IPFS nodes. This configuration leverages SSA's information-theoretic security properties to maintain confidentiality even when access keys are compromised, with blockchain integration ensuring transparent data provenance tracking. However, the dynamic accessibility patterns of IoT devices complicate threshold management for data reconstruction from fragmented storage, while the framework provides inadequate protection for edge-side data processing activities.

Edge computing, an emerging paradigm, migrates computing tasks from the cloud to network edge devices,

enabling data processing near data sources [10]. In IoT scenarios, edge computing can preliminarily process and filter locally generated data, uploading only necessary information to the cloud—reducing data transmission and leakage risks [11]. Edge devices with moderate computing power can execute simple encryption and privacy protection algorithms locally, enhancing data security. They also enable local data storage and management, reducing cloud dependency and improving data controllability and privacy. Federated learning, a distributed machine learning framework, allows multiple parties to collaboratively train a global model without sharing raw data. In IoT, devices or edge nodes can act as participants, training models with local data and uploading parameters to a central server for aggregation and global model updates [12]. This avoids centralized storage and transmission of raw data, protecting privacy at the source. Combined with differential privacy and homomorphic encryption, federated learning further strengthens data privacy during model training.

To this end, this paper proposes an IoT data privacy protection method based on the collaborative optimization of edge computing and federated learning. By combining the local processing capability of edge computing with the distributed learning framework of federated learning, a secure and efficient IoT data privacy protection system is constructed. While ensuring the security of data during local processing and transmission, a distributed model training mechanism based on federated learning is developed, allowing each edge node to collaboratively train a global model without sharing raw data, thus protecting data privacy. This provides theoretical support and a technical path for efficient and secure privacy protection in the IoT environment, and promotes the coordinated development of edge intelligence and privacy computing. The main contributions of this paper are summarized as follows: We propose a novel hierarchical privacy protection architecture for IoT data that integrates edge computing, federated learning, and homomorphic encryption, effectively distributing computational loads and mitigating single-point failure risks. We introduce a verifiable dual-key ElGamal homomorphic encryption scheme optimized for resource-constrained IoT devices, employing key segmentation and modular exponentiation optimization to reduce computational overhead. We design the MPSDGS algorithm and MP-Update dynamic weighted averaging method at the edge layer to handle participant dropouts, dynamically allocate aggregation weights based on node capability, and maintain model training continuity and accuracy. We establish a full-process ciphertext operation pipeline from terminal local encryption, through edge ciphertext aggregation, to global ciphertext aggregation on the platform, ensuring data privacy throughout the IoT data lifecycle. Through extensive simulations, we demonstrate that our method achieves a high data privacy degree (above 0.8) while keeping training and aggregation delays within acceptable ranges for typical IoT scales, successfully balancing privacy protection with computational efficiency.

II. Overall Architecture of IoT Data Privacy Protection Based on Edge Computing and Federated Learning Algorithm

To address the challenges of IoT data privacy protection, a privacy protection system model integrating edge computing, federated learning, and homomorphic encryption technology is constructed. This model ensures privacy security throughout the entire process of IoT data sensing, transmission, and processing, achieving a balance between efficient computing and privacy protection [13]. To prevent leakage of participants' original sensing data during sensing tasks, homomorphic encryption privacy protection technology is integrated into the distributed edge computing network. The overall architecture of IoT data privacy protection based on edge computing and federated learning algorithm, as shown in Fig. 1, includes five core entities:

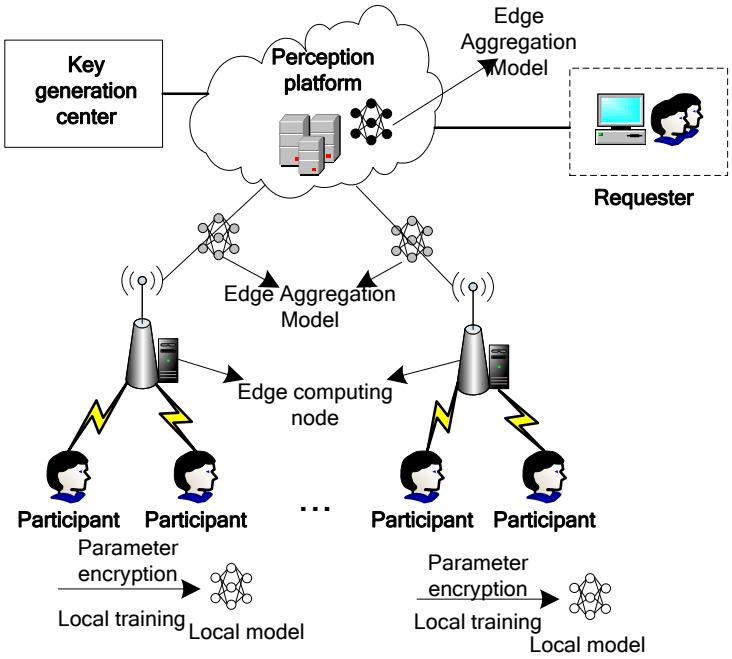

Fig. 1. Overall architecture of IoT data privacy protection based on edge computing and federated learning algorithm.

1) Requester: As the initiator of sensing tasks and consumer of sensing data, it issues task requests to the sensing platform, executes sensing tasks, obtains encrypted training model results, and completes data applications in the IoT.

2) Participant: As the producer of sensing data, it collects sensing data using intelligent mobile devices, performs local federated learning model training, encrypts model parameters using verifiable dual-key ElGamal homomorphic encryption technology, and transmits the encrypted parameters to edge computing nodes via wireless networks.

3) Edge computing node: As an intermediate processing unit for sensing tasks, it has more sufficient storage and computing resources than participants' mobile devices and is deployed at the network edge. It receives encrypted model parameters from participants, executes the MPSDGS algorithm and MP-Update method for similarity calculation and dropout supplementation, performs edge aggregation, and then sends the updated edge model parameters to the sensing platform.

4) Sensing platform: As the data processing and control center, it has powerful storage and computing capabilities. After receiving encrypted edge model parameters from edge computing nodes, it uses homomorphic encryption technology to complete global model aggregation and updates in ciphertext form [14], and finally feeds back results to the requester in encrypted form to complete the sensing task.

5) Key generation center: As a trusted authority, it is responsible for generating and distributing certificate-equipped keys adapted to verifiable dual-key ElGamal encryption to all entities. It provides support for secure training and aggregation processes, ensuring that participants' privacy is not leaked during task collaboration.

B. Local Training and Homomorphic Encryption of Parameters

In distributed machine learning scenarios, participants first conduct local model training using the Stochastic Gradient Descent (SGD) algorithm. Due to its characteristic of updating parameters sample by sample, SGD can effectively handle large-scale data and improve training efficiency. After completing local training, to ensure the security and privacy of model parameters, the verifiable dual-key ElGamal homomorphic encryption technology is adopted to encrypt the model parameters. This encryption method not only has homomorphic properties, allowing specific operations to be performed on ciphertexts, but also can ensure the correctness of the encryption process through a verifiable mechanism. Considering the limited computing power of edge devices, the encryption process is optimized to adapt to their computing capabilities. On one hand, key segmentation technology is used to split the key into multiple parts, reducing the complexity of managing a single key and the computational pressure. On the other hand, through the optimization of modular exponentiation operations, the number of modular operations in the computing process is reduced, thereby effectively lowering the complexity of encryption computation. Finally, the encrypted model parameters are transmitted to edge nodes, enabling secure and efficient model aggregation and updates.

1) Local model training: Traditional distributed machine learning requires concentrating the local data of participating nodes in a server for training. However, the federated learning algorithm applied in this paper keeps the data local to avoid privacy leakage. Participants use the Stochastic Gradient Descent (SGD) algorithm for local training to minimize the loss function. The SGD algorithm is chosen for its efficiency in handling large-scale datasets and its suitability for the iterative, distributed nature of federated learning. Its sample-by-sample update characteristic makes it computationally feasible for resource-constrained IoT devices. Define the N participants in federated learning as $P=\{P_1,P_2,\cdots,P_N\}$. The local data labels of a single participant P_k as $d_k=\{(x_1,y_1),(x_2,y_2),\cdots,(x_n,y_n)\}$, where x_i is the input parameter and y_i is the expected output. The label dataset of all participants is $D=\bigcup d_i$. Let the model parameters of P_k trained locally be $\omega_k=\{\omega_{k1},\omega_{k2},\cdots,\omega_{km}\}$. The goal of federated learning is to obtain the globally trained model $M_G=h_\omega(x^i)$, so as to minimize the loss function $L(M_G)$ of the dataset D [15].

The loss function of a single participant P_k for the data label d_k is defined as:

$$L(h_{\omega_k}(x^i))=\frac{1}{|d_k|}\sum_{j\in d_k} f_j(h_{\omega_k}(x^i),y_j) \tag{1}$$

Among them, $f_j(h_{\omega_k}(x^i),y_j)$ is the loss function of the data label (x_j,y_j) based on the model $h_{\omega_k}(x^i)$. In T iterations, the training goal of participant P_k is to optimize the local model $h^*_{\omega_k}(x^i)$ under the condition of privacy protection to minimize the loss function, that is:

$$\begin{aligned} &h^*_{\omega_k}(x^i)=\underset{\omega_k\in\{\omega_k(t)\}_{t\le T}}{\arg\min}\ L(h_{\omega_k}(x^i))\\ &s.t.\Pr(\omega_k\in R_d)\le e^{\int}\Pr(\omega_{k'}\in R_d)\\ &\forall P_k\in P,k\in(1,2,\cdots,N) \end{aligned} \tag{2}$$

Among them, $\omega_k(t)$ is the parameter set for the t-th round of joint training, and T is the maximum number of parameter update iterations; $\Pr(\omega_k\in R_d)\le e^{\int}\Pr(\omega_{k'}\in R_d)$ is the differential privacy condition for updating the parameter ω_k.

Participants use the Stochastic Gradient Descent (SGD) algorithm for local training to minimize the loss function. The gradient calculation formula is:

$$\nabla L(h_{\omega_k}(x^i))=\frac{\partial L(h_{\omega_k}(x^i))}{\partial\omega_k} \tag{3}$$

In the t-th iteration of participant P_k, the update of model parameters is defined as:

$$\omega_k(t) = \omega_k(t-1) + \alpha_t \cdot \nabla L(h_{\omega_{k_t}}(x^i)) \quad (4)$$

Among them, α_t is the learning rate, moving in the direction opposite to the gradient of the loss function to approach the optimal result.

In addition, during local training of participants, local data is trained according to the global model. Each participant, based on the initial global model parameter ω_t and local data, uses small-batch stochastic gradient descent for optimization. Through forward propagation, loss calculation, back propagation, and parameter update, a new local model ω_{t+1}^k is obtained. The process is as follows:

$$\begin{cases} \omega_{t,0}^k = \omega_t \\ \omega_{t,\tau+1}^k = \omega_{t,\tau}^k - \eta * g_{t,\tau}^k, (\forall \tau = 1, \cdots, E) \\ \omega_{t+1}^k = \omega_{t,E}^k \end{cases} \quad (5)$$

Among them, η is the learning rate, $g_{t,\tau}^k$ is the random gradient of the small-batch data sample, and E is the number of local training epochs.

2) Parameter homomorphic encryption: Federated learning provides basic privacy protection for raw data due to its local training nature. However, participants may still suffer malicious attacks leading to information leakage, so encryption mechanisms are needed for enhanced protection. A verifiable dual-key ElGamal homomorphic encryption method, which combines Feldman's Verifiable Secret Sharing (VSS) and ElGamal encryption, is adopted to encrypt and protect the model parameter ω_{t+1}^k obtained from participants' local training. The specific process is as follows:

a) System initialization and key generation: The Key Generation Center (KGC), as a trusted third-party, performs the following operations:

- Select large prime numbers p and q satisfying $q | p-1$, and choose a generator g in the multiplicative group L_p^* modulo p;
- Generate a public-private key pair (sk_k, pk_k) for each participant P_k, where $sk_k \in_R L_q$ and $pk_k = g^{sk_k} \bmod p$;
- Generate the global public key $PK = \prod_{k=1}^{N} pk_k \bmod p$, and make (p, q, g, PK) public.

b) Parameter encryption process: After participant P_k completes local model training to obtain the parameter ω_{t+1}^k, the following encryption steps are executed:

- Convert the model parameter ω_{t+1}^k into an integer vector $\omega_{t+1}^k = [\omega_{t+1,1}^k, \omega_{t+1,2}^k, \cdots, \omega_{t+1,m}^k]$;
- For each parameter component $\omega_{t+1,j}^k$, select a random number $r_j \in_R L_q$;
- Calculate the encrypted parameter $Enc(\omega_{t+1,j}^k) = (c_{1,j}, c_{2,j})$, where $c_{1,j} = g^{r_j} \bmod p$ and $c_{2,j} = \omega_{t+1,j}^k \cdot PK^{r_j} \bmod p$;
- Send the encrypted parameter vector $Enc(\omega_{t+1}^k) = [Enc(\omega_{t+1,1}^k), Enc(\omega_{t+1,2}^k), \cdots, Enc(\omega_{t+1,m}^k)]$ to the edge computing node.

Through the above-mentioned encryption process, the local model parameter ω_{t+1}^k of participant P_k is converted into the ciphertext form $Enc(\omega_{t+1}^k)$, which has semantic security, so that an attacker cannot infer the original parameter value from the ciphertext.

C. Edge-Side Secure Aggregation Model

In the edge computing scenario, to enhance the efficiency and security of model aggregation, edge computing nodes adopt a series of innovative strategies. First, the MPSDGS algorithm, which is based on participant similarity discovery and a dropout-supplementation mechanism, is incorporated. This algorithm can accurately identify similar participants and construct a better aggregation group. Meanwhile, when a participant drops out, its dropout-supplementation mechanism can quickly find a suitable replacement, ensuring the continuity of the aggregation process. Then, the MP-Update dynamic weighted-average method based on recursive update rules is used to supplement dropped-out participants, and aggregation weights are dynamically allocated according to the computing power of edge nodes. This measure avoids low-computing-power nodes from becoming performance bottlenecks due to insufficient processing capacity, guarantees the high efficiency of overall aggregation, and maintains a relatively high aggregation accuracy [16]. In terms of privacy protection, the integrity of privacy protection is enhanced, and all operations are carried out under the premise of strictly ensuring data privacy. After that, edge-side model aggregation is completed in the ciphertext form. The edge computing node, as a local aggregation center, performs preliminary aggregation on participants' model parameters. This process can not only effectively reduce the amount of data uploaded to the sensing platform, lowering the security risks during data transmission, but also significantly reduce the computing pressure on the center. As a result, the entire model training and aggregation process becomes more efficient and stable, meeting the strict requirements for real-time performance and security in the edge computing environment.

Privacy Protection Optimization Based on Participant Dropout Resolution Mechanism

The MPSDGS algorithm is described in the following pseudocode (Algorithm 1):

Algorithm 1: MPSDGS (Participant Similarity Discovery and Dropout Supplementation)

Input: Participant status list StSt, Local model parameters θitθit for online participants PiPi
Output: Supplemented participant set for aggregation
1: Initialize similarity list Sim←[]Sim←[], corrected similarity list CorrSim←[]CorrSim←[]
2: for each online participant PiPi do
3: for each online participant PjPj (j ≠ i) do
4: Calculate Pearson correlation coefficient ρijρij using Eq. (6)
5: Sim.append(ρij)Sim.append(ρij)
6: end for
7: end for
8: for each participant PkPk do
9: CorrSim[k]←St[k]×Sim[k]CorrSim[k]←St[k]×Sim[k] // Element-wise multiplication with status list
10: end for
11: for each offline participant PoffPoff do
12: Find online participant PonPon with max CorrSimCorrSim relative to PoffPoff
13: Supplement parameters: θofft←θontθofft←θont
14: end for
15: return Supplemented participant parameter set

1) Privacy protection optimization based on participant dropout resolution mechanism: In the IoT environment, federated learning relies on the collaborative training of local data from multiple participants. However, participants are prone to dropping out due to network fluctuations, device failures, and other factors, resulting in data loss and abnormal model convergence, which weakens the privacy protection capability. To address this, edge computing nodes adopt the MPSDGS algorithm (based on participant similarity discovery and dropout supplementation) combined with the MP-Update dynamic weighted-average method. From the two aspects of data integrity restoration and accurate similarity evaluation, the continuity of model training is guaranteed, laying a solid foundation for privacy protection.

a) MPSDGS algorithm and participant similarity calculation: Edge nodes generate a status list $S=[s_1,s_2,\cdots,s_K]$ (where K is the total number of participants) based on the upload status and validity verification results of participants' encrypted parameters, marking online/offline statuses. When there are offline participants, the MPSDGS algorithm uses the Pearson correlation coefficient to measure the similarity of local model parameters among participants [17], providing a basis for offline participant supplementation. For online participants i、j, edge computing nodes calculate the linear correlation degree Δ_t^i, Δ_t^j based on the uploaded local model parameters $p(\Delta_t^i,\Delta_t^j)$. The formula is:

$$p(\Delta_t^i,\Delta_t^j)=\frac{\sum_{i=1,j=1}^{n}\left[(\Delta_t^i-\mu_i)-(\Delta_t^j-\mu_j)\right]}{\sqrt{\sum_{i=1}^{n}(\Delta_t^i-\mu_i)^2}\sqrt{\sum_{j=1}^{n}(\Delta_t^j-\mu_j)^2}} \tag{6}$$

Among them, μ_i,μ_j are the sample means.

Offline supplementation maintains training continuity through three steps, indirectly safeguarding IoT data privacy:

- Satus Recognition: Edge computing nodes generate a participant status list $[1,0,0,1,1...]$ (1 for online, 0 for offline) based on whether encrypted model parameters are uploaded. The encrypted parameter transmission link is protected by technologies such as homomorphic encryption, and the recognition process does not disclose raw data.
- Similarity Correction: Multiply the status list and the Pearson similarity list element-by-element to set the similarity of offline participants to 0, avoiding interference from invalid similarity, ensuring the accuracy of supplementary data, and indirectly reducing the risk of privacy leakage caused by the introduction of wrong parameters.
- Parameter Supplementation: Screen the online participant corresponding to the maximum corrected similarity and replace the offline participant with its model parameters. The supplementation process operates based on encrypted parameters (such as the edge node aggregation process), ensuring the privacy of data transmission and use, achieving the effect of full participation of all participants, and maintaining the integrity of model training.

b) MP-Update dynamic weighted averaging: Due to the randomness of the initial model and the uncertainty of small-batch gradient descent, the Pearson similarity in a single round cannot accurately reflect participant associations. The MP-Update method is based on recursive update rules [18], dynamically adjusting weights by combining historical and current similarities. The formula is:

$$P_t^{i,j}=\begin{cases}\frac{1}{2}P_{t-1}^{i,j}+\frac{L_{t-1}^{i,j}}{2L_{t-1}^{i,j}+1}P_{t-1}^{i,j}+\frac{1}{2L_{t-1}^{i,j}+1}p_t^{i,j} & i,j\in M_t\\ \frac{1}{2}P_t^{i,j}+\frac{1}{2}p_{t-1}^{i,j} & otherwise\end{cases} \tag{7}$$

Among them, $L_{t-1}^{i,j}$ is the number of rounds where both participants were online before round $t-1$, and $P_{t-1}^{i,j}$ is the average similarity of the previous round.

This method dynamically balances historical data and current states to accurately evaluate participant similarity without exposing raw data, enabling the server to identify the most suitable online participants for dropout replacement. This approach enhances model convergence efficiency while avoiding privacy leaks caused by incorrect similarity matching,

deeply integrating with privacy-protection components such as encryption and aggregation.

In summary, the participant dropout resolution mechanism employed by edge computing nodes supports the privacy-protection system of IoT federated learning by ensuring training continuity and optimizing similarity evaluation. It is an indispensable robustness-enhancement module in the privacy-protection framework.

2) Encrypted parameter aggregation and verification: After completing dropout replacement, edge computing nodes collect the encrypted local model parameters from participants, perform aggregation and verification in ciphertext form, and send the updated edge model parameters to the sensing platform [19] without accessing the actual local model parameters, thereby protecting participant privacy.

Under the edge computing network, the process of aggregating and verifying the encrypted parameters of edge computing nodes is as follows (for the t th training round):

- The edge computing node downloads the encrypted global model parameters $Enc(\omega_{t-1}^{(global)})$ from the previous round from the sensing platform, replaces its existing model parameters $Enc(\omega_{t-1}^{(edge)})$, and sends them to the selected participants.
- Randomly select $k \leftarrow \max(K, \rho 1)$ participants at a proportion of ρ to form a set S_t, and send $Enc(\omega_{t-1}^{(global)})$ to these participants.
- After the participants complete local encrypted training in round t_1, the edge computing node collects the new local model parameters $Enc(\omega^i)$ and the local loss function $F_i^{(t)}(\omega)$.
- Since the decryption key cannot be obtained, only algebraic operations are performed on the ciphertext. The received $Enc(\omega^i)$ is weighted and averaged to achieve edge-side secure aggregation and update:

$$Enc(\omega_t^{(edge)}) \leftarrow \sum_{i \in S_t} \frac{N_i}{N} Enc(\omega^i) \tag{8}$$

Among them, N_i is the size of the dataset D_i of the i-th participant, and $N = \sum_{i=1}^{k} N_i$, which reflects the additive homomorphic property of homomorphic encryption.

When the number of local updates t_1 meets the conditions, the edge computing node sends a signal to the participants to stop training, and sends the encrypted edge model parameters $Enc(\omega_t^{(edge)})$ and the loss function $F_t^{(edge)}(\omega)$ to the sensing platform; if the conditions are not met, the aggregated edge model parameters are sent to the newly selected participants, and the local model update and encryption continue.

D. Global Secure Aggregation Model

The sensing platform, as the main control center for sensing tasks, provides resources for complex data processing and long-term storage. It does not directly interact with participants. It receives the encrypted model parameters aggregated and updated by edge computing nodes, follows the cryptosystem of verifiable dual-key ElGamal encryption [20], and performs global aggregation and update in ciphertext form. This addresses the issue of sensitive data leakage caused by single-point failure attacks and inference attacks, and trains an ideal application model for sensing tasks.

The algorithm flow for global secure aggregation and update is as follows:

- When the global cycle $t = 0$, the sensing platform receives the task, initializes the model parameter ω_0 and sends it to all edge computing nodes, which then distribute it to participants to initialize local model parameters and conduct preliminary training.
- When $t > 0$, the sensing platform sends the latest encrypted global model parameters to edge computing nodes for collaborative training with participants.
- After every t_2 rounds of edge secure aggregation updates, the sensing platform receives the encrypted edge model parameter results $Enc(\omega_t^{(edge)})$ and performs global aggregation and averaging in ciphertext form:

$$Enc(\omega_t^{(global)}) \leftarrow \sum_{j=1}^{J} \frac{M_j}{M} Enc(\omega_t^{(edge)}) \tag{9}$$

Among them, J is the number of edge computing nodes participating in training, M_j is the size of the aggregated dataset of the j-th edge computing node, $M_j = N$, and $M = \sum_{j=1}^{J} M_j$, reflecting the additive homomorphic property of homomorphic encryption.

The sensing platform receives the edge loss function $F_t^{(edge)}(\omega)$, aggregates and averages it to obtain the global loss function $F_t^{(global)}(\omega) = \sum_{j=1}^{J} \frac{M_j}{M} F_t^{(edge)}(\omega)$. It then sends the latest encrypted global model parameters $Enc(\omega_t^{(global)})$ to edge computing nodes for iterative training [21]. When the global loss function converges or the maximum number of model update rounds is reached, the sensing platform sends a signal to edge computing nodes to stop training, and sends the encrypted global model parameters to requesters to complete the sensing task.

In summary, the global secure aggregation model achieves a privacy protection loop among the sensing platform, edge nodes, and terminal participants by combining ciphertext-state collaborative training and hierarchical key management. On one hand, relying on the additive homomorphic property of homomorphic encryption, it ensures that model parameters are

usable but invisible during the global aggregation stage, avoiding platform-side model reverse-attack risks from the system-top level. On the other hand, through multi-round iterative ciphertext aggregation and loss-function convergence control, it ensures that IoT data remains encrypted throughout the entire IoT data flow process. This builds a multi-level, full-link privacy protection system for terminal device sensitive data, edge-node aggregated features, and platform global model parameters.

III. Experimental Analysis

To comprehensively evaluate the application effect of the proposed IoT data privacy protection method, simulations are conducted focusing on two core aspects: privacy protection capability and computational efficiency (delay). While the primary goal is robust privacy preservation, its practical deployment in resource-constrained IoT environments necessitates an assessment of the associated computational overhead and time delays. Therefore, the experiments are designed to verify that the proposed method achieves a favorable balance between security and efficiency, ensuring that strong privacy protection does not come at the cost of unacceptable performance degradation for typical IoT services.

To verify the application effect of the IoT data privacy protection method based on edge computing and federated learning algorithm proposed in this paper, a privacy protection system in the edge computing network environment is simulated. A three-layer IoT network architecture of user layer-edge layer-perception layer is built using Python to simulate the proposed system. One key generation center is set up to generate and manage public and private keys,providing cryptographic support for the training and encryption processes of federated learning in the edge computing network. One sensing platform (simulating the IoT application server) is configured to be responsible for global model aggregation and task scheduling, connecting 6 edge computing nodes (simulating edge computing power carriers). Each node is connected to 14 IoT terminal participants (such as smart sensors, health monitoring devices, etc.), with a total of 84 participants, supporting a dynamic dropout rate of 10%-20% to simulate scenarios such as network fluctuations and failures of IoT devices. The participant data is set with non-independent and identically distributed (Non-IID) settings, and each participant is only assigned 2 types of local data samples to reproduce the locality and heterogeneity of IoT terminal data collection. The federated learning model and the verifiable dual-key ElGamal homomorphic encryption algorithm designed in this paper are implemented using PyTorch (V1.13.1). The private key is only distributed to participants, ensuring that participants can encrypt model parameters locally, resisting the semi-honest attack risks of edge computing nodes and the sensing platform, which conforms to the privacy protection requirements of data cross-level transmission in the IoT environment.

The experimental dataset uses a custom industrial sensor dataset to simulate terminal-collected data. This dataset is collected by IoT sensors (acceleration sensors, temperature and humidity sensors, electromagnetic sensors, etc.) deployed in industrial sites, including 100,000 training samples and 15,000 test samples. Each sample is a multi-dimensional feature vector: covering the vibration frequency, temperature and humidity, valve switch state, etc. during equipment operation, and the label is the equipment health state (0 for normal, 1 for abnormal warning), used for the abnormal detection classification task.

The hardware environment of the sensing platform and edge nodes is: Intel (R) Xeon (R) CPU E5-2630 v3 @ 2.50GHz, 128GB RAM (without GPU), matching the computing power of the edge and the platform; the hardware environment of the participant terminal is: Raspberry Pi 4B (quad-core Cortex-A72 @ 1.5GHz, 4GB RAM), simulating the resource-constrained characteristics of IoT terminals; the operating system is Ubuntu 20.04, ensuring cross-device compatibility. The key parameter settings are shown in Table I, covering the training and encryption of federated learning and the adaptation requirements of the IoT scenario.

TABLE I. Details of Key Parameter Settings

Parameter	Numerical Value
Global aggregation times	30
Edge aggregation times	5
Local iteration times	20
Batch size of data	32
Learning rate	0.01
Learning rate decay rate	0.99
Learning rate decay rounds	3
SGD momentum	0.9
ElGamal key length	2048 bits
Pearson similarity calculation window	5 rounds

TABLE II. Simulation Details of Multi Level Attacks in the Internet of Things

Attack Level	Attack Type	Attack Target (privacy theft content)	Simulate Attack Methods
Terminal side	Local data theft attack	Raw sensitive data collected by the terminal (abnormal values of equipment vibration)	Implant memory reading scripts into Raspberry Pi terminals, attempting to extract local model parameters and raw data cache before encryption
Edge side	Cipher reasoning attack	Distribution of abnormal states of terminal devices (proportion of abnormal production line vibrations)	Deploy ciphertext analysis tools at edge nodes, input edge aggregated ciphertext, use clustering algorithms and homomorphic encryption to crack scripts, and infer terminal data features in reverse
Platform side	Model reverse attack	Full terminal privacy distribution (device health profile)	Run the model reverse engineering algorithm on the platform server, input global model parameters+IoT terminal topology information, and infer privacy profiles

To verify the privacy protection ability of the method proposed in this paper in the IoT data privacy protection under the edge computing and federated learning algorithm, the full process of terminal local training → edge aggregation → platform global training is completed according to the experimental settings, and the intermediate data of each level (local parameters before terminal encryption, ciphertext parameters after edge aggregation, platform global model) are saved. According to Table II, simulate semi-honest attacks and malicious inference attacks at each level of IoT terminal → edge → platform, and verify whether the method can protect privacy information such as device status and sensitive features in the actual data flow, and effectively resist multi-level threats of the IoT. The privacy protection results are shown in Table III.

TABLE III. PRIVACY PROTECTION RESULTS OF THE METHODS IN THIS PAPER

Attack Level	Protection Effect	Core Protection Process
Terminal side	The attacker implanted a memory read script and was unable to obtain valid sensitive information about abnormal device vibration values.	The private key is only directed to the terminal, and the local model parameters of the terminal are encrypted with a verifiable dual key ElGamal before uploading, blocking the exposure of sensitive information from the source of the data
Edge side	The deployment of ciphertext analysis tools on edge nodes cannot effectively infer the distribution of abnormal states of terminal devices after inputting aggregated ciphertext.	The edge aggregation process is based on homomorphic encryption characteristics to perform ciphertext operations, combined with a verifiable dual key mechanism, to resist inference attacks such as ciphertext parameter clustering analysis and cracking scripts
Platform side	The platform server running model reverse engineering algorithm, combined with the topology information of IoT terminals, cannot restore the true privacy distribution of all terminals.	The global model aggregation stage maintains the ciphertext form, relying on the hierarchical key management mechanism of the key generation center to block the expansion of global model parameters and terminal deployment locations

By simulating typical attack scenarios on the IoT terminal side, edge side, and platform side in Table II, the privacy protection results of the method in Table III verify the effectiveness of the method in multi-level privacy protection. On the terminal side, through the localized deployment of verifiable dual-key ElGamal encryption, the original sensitive data is encrypted and uploaded, building a privacy protection barrier from the source of data collection, and greatly reducing the risk of privacy leakage caused by the intrusion of terminal devices; on the edge side, using the ciphertext operation characteristics of homomorphic encryption and the dual-key verification logic, it resists ciphertext inference attacks in the edge aggregation link, ensuring that privacy information such as the abnormal state distribution of terminal devices is not reversely deduced; on the platform side, through ciphertext-state global aggregation and hierarchical key management, it blocks the associated attack path between model parameters and IoT topology information, preventing the reverse engineering of the full-volume terminal privacy distribution. The privacy protection architecture of terminal local encryption, edge ciphertext aggregation, and platform ciphertext-state collaboration constructed by this method can effectively adapt to the hierarchical scenario of IoT terminal-edge-platform, and show strong protection ability for privacy information such as device status and sensitive features in real attack simulations, providing a feasible technical path for the balance between data collaborative training and privacy security in scenarios such as industrial IoT.

To verify the efficiency adaptability of the method in the hierarchical collaborative training of the IoT, the experiment focuses on the time consumption of the two core links of terminal local training encryption of the federated learning algorithm and edge model aggregation of edge computing nodes, and explores the delay characteristics of the method under data flow and privacy protection operations under different numbers of terminal participants and model aggregation rounds. The experimental results are shown in Fig. 2 and Fig. 3, respectively.

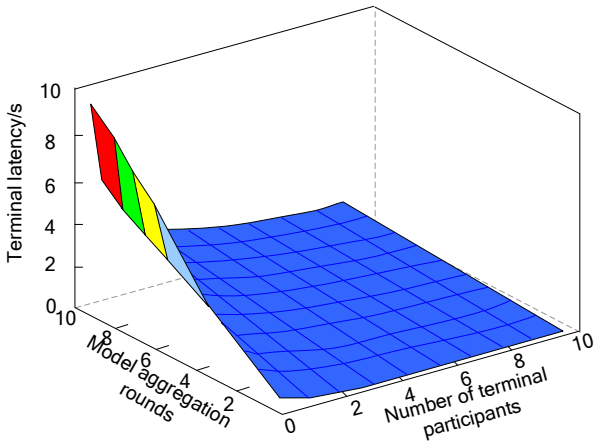

Fig. 2. Local training encryption delay of terminal.

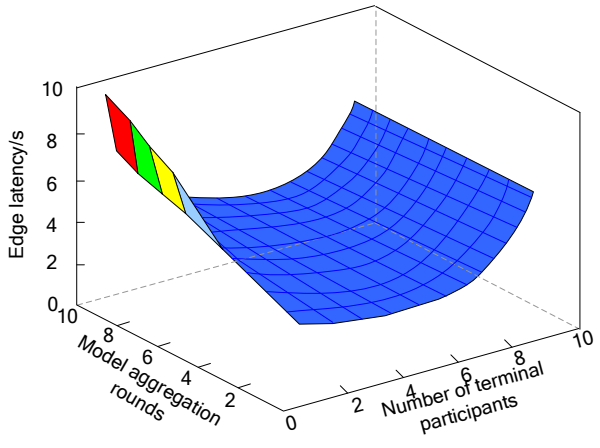

Fig. 3. Edge model aggregation delay.

Fig. 2 presents the law of the influence of the number of terminal participants and the number of model aggregation rounds on the terminal local training encryption delay, and Fig. 3 shows the influence of the two on the edge model aggregation delay. From the terminal side, when the number of terminal participants is stable, the increase in the number of model aggregation rounds significantly increases the delay. This is because each round of aggregation needs to carry out local model training and verifiable dual-key ElGamal encryption in turn. The increase in rounds accumulates the time consumption of training iterations and encryption operations, and also pushes up the network transmission delay; while when the number of model aggregation rounds is stable, the increase in the number of participants disperses the training data volume of a single terminal. Although the number of encryption operations increases, the decrease in training time offsets the increase in encryption time, and the delay shows a downward trend. From the edge side analysis, when the number of model aggregation rounds is stable, the increase in the number of terminal participants continuously increases the edge model aggregation delay and the growth rate accelerates. This is because the edge node executes operations such as ciphertext reception and parameter supplementation for dropped-out participants. When the number of participants is small, the constant optimization can offset the time consumption, and when the number exceeds the threshold, the time consumption of dropped-out supplementation dominated by complexity increases sharply.

Comprehensively, from Fig. 2 and Fig. 3, through terminal local verifiable dual-key ElGamal encryption, edge MPSDGS dropout detection, and MP-Update dynamic weighted aggregation, a hierarchical privacy protection system is built. The terminal side effectively avoids the exposure of sensitive data, and the edge side greatly reduces the risk of ciphertext inference attacks, achieving the rigid protection of privacy in the IoT data collaborative training at a reasonable delay cost; at the same time, the delay growth law adapts to the characteristics of the IoT scenario. The delay on the terminal side decreases with the increase in the number of participants, which is in line with the IoT terminal distributed deployment and data fragmentation processing mode, and has more efficiency advantages in large-scale terminal collaboration. Although the delay on the edge side increases with the scale, it is still within an acceptable range under the typical business scale of the IoT, reflecting the good balance between privacy protection and efficiency adaptability of the method. Compared with the plaintext federated learning without privacy protection and the single encryption weak protection scheme, this method achieves a several-fold increase in privacy protection strength with a controllable delay increment, providing a solution with both security and practicality for data collaborative training in scenarios such as industrial IoT.

To comprehensively verify the actual efficacy of this method in the dimension of privacy protection, the data privacy degree P_{index} index is introduced for quantitative evaluation. The methods studied by Bezanjani et al. [6] and Samriya et al. [7] are selected as the control group. Through a controlled variable experiment, the differences in privacy protection intensity among different schemes are clearly presented. The calculation formula of P_{index} is as follows:

$$P_{index} = \frac{Var(A) - Var(T)}{Var(A)} \tag{10}$$

Among them, A is the original data, and T is the data after applying privacy protection technology for transformation. The higher the value of P_{index}, the greater the difference between the transformed data and the original data, and the better the privacy.

The evaluation results of the data privacy degree P_{index} of the three methods under different numbers of terminal participants are shown in Fig. 4.

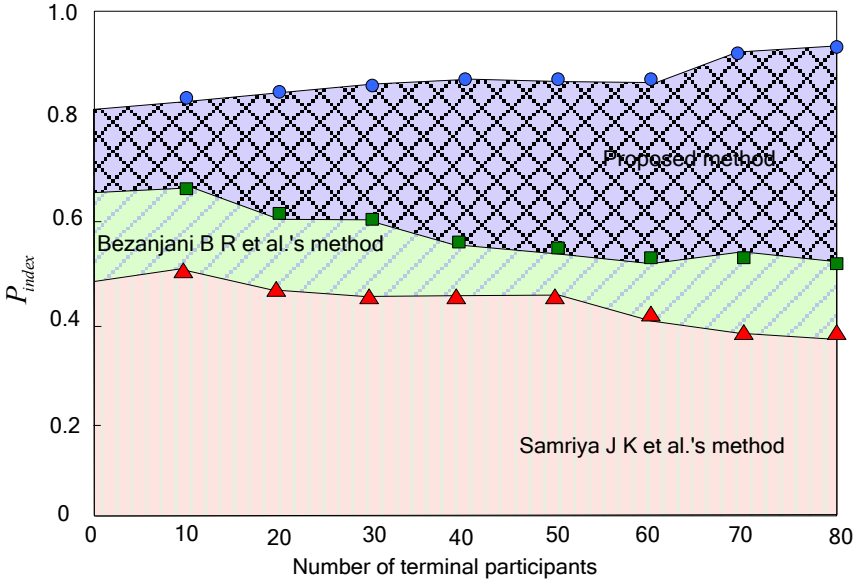

Fig. 4. Evaluation results of data privacy level P_{index} for three methods.

Analyzing the P_{index} situation in Fig. 4, it can be seen that the P_{index} of this method always maintains a high-level interval above 0.8, and shows a small upward trend as the number of terminal participants increases from 0 to 80. This characteristic originates from the architecture constructed in this paper: terminal-side dual-key ElGamal encryption + edge ciphertext aggregation (MP-Update algorithm). On the terminal side, through the asymmetric key mechanism, it ensures that the encrypted sensitive data of the device can only be verified and cannot be broken; on the edge side, relying on the ciphertext aggregation algorithm, the model parameter collaboration is completed without decryption, fundamentally blocking the privacy inference path in the data transmission-aggregation link. Even if the terminal scale expands, the heterogeneous encryption characteristics of multi-device data instead enhance the anti-inference ability of the ciphertext, making P_{index} achieve a positive gain as the number of terminals increases, verifying the robustness of the method in terms of privacy protection in large-scale IoT scenarios. In contrast, although the P_{index} of the Bezanjani method [6] can be maintained in the 0.6-0.7 interval, its single-key design makes the central server a single point of privacy leakage. The larger the terminal scale, the higher the probability of ciphertext being broken, and the privacy protection intensity shows a fluctuating downward trend as the number of terminals increases, making it difficult to adapt to the scenarios of IoT terminal dispersion and dynamic scale. The P_{index} of the Samriya method [7] has been lower than 0.4 for a long time. The root cause is that its complex cryptographic operations and model reasoning have extremely high requirements for the computing power of edge devices. The widespread resource-constrained problem of IoT terminals makes it unable to complete efficient encryption and analysis locally, and it is forced to rely on cloud computing, resulting in an increased risk of privacy leakage during the data transmission-cloud processing process, and the privacy protection efficiency is always at a low level.

As shown in Fig. 4, our method maintains a privacy degree above 0.8 across different participant scales, significantly outperforming Bezanjani's method (0.6-0.7) and Samriya's approach (<0.4). This superiority stems from our dual-key encryption and ciphertext aggregation architecture, which fundamentally blocks privacy inference paths during data transmission and aggregation.

In summary, through the innovative design of hierarchical encryption to decouple cloud-edge dependencies and ciphertext aggregation to block inference paths, the proposed method achieves dual breakthroughs in privacy protection intensity and scenario adaptability. It can balance the needs of data collaboration and the rigidity of privacy protection in complex scenarios where the scale of IoT terminals changes dynamically, providing more reliable privacy and security guarantees for cross-level data flow in various application fields of the IoT.

IV. Conclusion

Focusing on the challenges of IoT data privacy protection, this paper proposes a privacy protection method based on the collaborative optimization of edge computing and federated learning. It constructs a hierarchical architecture covering multiple entities, integrates technologies such as homomorphic encryption and dropout supplementation, and achieves significant results through experimental verification. In terms of privacy protection effectiveness, through terminal-local dual-key ElGamal encryption, edge ciphertext aggregation, and platform global secure aggregation, full-process privacy protection of IoT data is realized. In the dimension of efficiency adaptability, the terminal-local training encryption delay increases with the number of aggregation rounds and decreases with the increase in the number of participants. Although the edge model aggregation delay accelerates with scale growth, it remains within an acceptable range under typical IoT business scales, verifying the efficiency resilience of the method and achieving a balance between privacy protection and computational efficiency. Therefore, the proposed method breaks through the limitations of traditional schemes such as cloud dependence, single-point risks, and poor computing power adaptability. By means of hierarchical encryption to decouple cloud-edge dependencies and ciphertext aggregation to block inference paths, it provides reliable privacy guarantees for cross-level data flow in fields such as industrial IoT and smart healthcare, promotes the collaborative development of edge intelligence and privacy computing, and has good engineering application value and scenario expansion potential. Future work can deepen research on lightweight encryption algorithms to further adapt to IoT terminals with extremely limited resources and improve the universality of the method.

The proposed privacy-preserving framework exhibits certain limitations that motivate subsequent research endeavors. First, despite optimizing verifiable dual-key ElGamal encryption, the computational overhead remains prohibitive for ultra-low-power devices (e.g., Class 0 sensors), necessitating exploration of lightweight homomorphic encryption or LWE-based alternatives. Second, current validation is confined to single-domain industrial sensor data; cross-domain applicability across heterogeneous IoT ecosystems (smart healthcare, urban sensing) with divergent data patterns and QoS demands requires rigorous evaluation. Third, the threat model must expand beyond semi-honest adversaries to counter sophisticated attacks like model poisoning or coordinated edge-node compromises. Fourth, ciphertext transmission overhead in large-scale deployments demands communication-efficient strategies such as adaptive aggregation or model compression. Finally, an end-to-end energy consumption analysis on physical IoT hardware is crucial to validate practical sustainability across encrypted training cycles.Future research work will systematically explore the core challenges of IoT security and efficiency: on the one hand, it will focus on innovative lightweight security mechanisms, develop customized homomorphic encryption variants suitable for Class 0 IoT sensors with extremely limited resources, and balance security and computational costs through algorithm tailoring and hardware collaborative design; On the other hand, expanding the boundaries of security verification, building a unified verification framework across heterogeneous scenarios such as intelligent healthcare and

urban sensing, and solving the problems of privacy leakage and permission control in multi domain data fusion.

***Abstract*—Industrial machinery fault detection systems require both high diagnostic accuracy and computational efficiency for real-time deployment. This study presents a novel hybrid approach that integrates the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) with You Only Look Once (YOLO) deep learning for efficient audio-based fault detection in industrial machinery. The proposed methodology employs a two-tiered decision fusion strategy: TOPSIS serves as a rapid mathematical pre-filter analyzing seven acoustic features (RMS, ZCR, Spectral Centroid, Spectral Bandwidth, Peak Frequencies, Kurtosis, and Skewness) extracted from preprocessed 1-2 second audio segments, while YOLO performs detailed spectrogram-based visual analysis on flagged segments. The TOPSIS algorithm normalizes feature vectors, calculates closeness coefficients to ideal and negative-ideal solutions, and classifies segments using a threshold of $\tau = 0.65$. Segments identified as normal terminate processing immediately, while potentially abnormal segments proceed to spectrogram generation and YOLO-based detection. Experimental results on 150 industrial audio segments demonstrate that the hybrid system achieves 93.8% detection accuracy while reducing computational overhead by 85.3% compared to full-dataset YOLO analysis. The TOPSIS pre-filter successfully identifies 128 normal segments (85.3%) with a mean closeness coefficient $Ci = 0.847 \pm 0.025$, while 22 abnormal segments (14.7%) with $Ci = 0.084 \pm 0.033$ are forwarded to YOLO for confirmation. The decision fusion logic enables YOLO to override false positives and flag low-confidence cases for expert review, combining the speed of mathematical analysis with the robustness of deep learning. This approach reduces processing time by approximately 6.8×, decreases GPU utilization by 85%, and minimizes storage requirements for spectrogram images, making it suitable for real-time industrial monitoring systems where computational resources are constrained.**

I. Introduction

Industrial machinery is vulnerable to various forms of mechanical degradation—such as bearing wear, belt slippage, motor imbalance, and valve faults—which can lead to unplanned downtime, reduced productivity, and significant safety risks. Mechanical faults typically develop gradually and often remain undetected until they lead to severe performance loss or system failure [1], [2]. Traditional condition-monitoring techniques, such as vibration analysis, thermal imaging, and motor current signature analysis, have shown effectiveness in detecting specific types of faults but require specialized sensors, physical contact, or costly hardware installations [3], [4]. These limitations reduce their practicality in large-scale or resource-constrained industrial environments.

In contrast, audio-based monitoring has gained attention as a non-invasive and cost-effective alternative, as machine acoustic signals contain rich information related to mechanical health. Recent studies show that sound-based diagnostics can effectively detect faults in bearings, motors, and pumps without requiring intrusive sensors [5], [6]. However, existing approaches often rely heavily on manual feature extraction or classical machine learning, which suffer reduced robustness in noisy industrial environments and lack real-time adaptability [7]. Although deep learning has been explored for machine sound diagnostics, gaps remain in computational efficiency, particularly when deploying models on embedded or edge devices where resources are limited [8].

To address these gaps, this study proposes a hybrid audio-based fault detection system that integrates mathematical pre-filtering with spectrogram-driven AI classification. The approach aims to enhance fault detection accuracy while reducing computational overhead. Specifically, the objectives of this work are:

Abnormality Detection: Determine whether an industrial machine is operating under normal or faulty conditions.

Fault Classification: Identify specific fault types or faulty components based on acoustic signatures.

Computational Optimization: Improve processing time and reduce resource usage by combining mathematical feature extraction with deep learning models.

By leveraging audio recordings, mathematical transformations, and spectrogram-based deep learning models such as YOLO, the proposed system provides a non-contact, low-cost, and scalable solution suitable for real-time industrial monitoring. This research contributes to the field by: 1) demonstrating the effectiveness of deep learning in audio-based machine diagnostics, 2) introducing a hybrid pre-filtering and AI pipeline for computational efficiency, and 3) addressing the lack of scalable, non-invasive fault detection technologies applicable to diverse industrial environments.

II. Related Studies

Audio-based fault detection has gained significant attention as a non-intrusive and cost-effective approach for machinery health monitoring. Alharbi et al. [9] provided a foundational review of automatic fault diagnosis systems using audio and vibration signals, establishing that acoustic analysis offers advantages including non-invasive measurement, early fault detection capabilities, and compatibility with existing industrial environments. Building on this foundation, Nguyen and Huang [10] demonstrated practical fault detection in water pumps using deep learning techniques applied to sound analysis, achieving high accuracy rates in real-world industrial conditions and validating acoustic signals as reliable indicators of machinery health status.

The development of standardized datasets has been crucial for advancing the field. Purohit et al. [11] introduced the MIMII dataset for malfunctioning industrial machine investigation and inspection, which has become a benchmark enabling consistent evaluation and comparative studies across different methodologies. This dataset addresses the critical need for standardized evaluation protocols in industrial fault detection research.

Recent advances in deep learning have revolutionized acoustic fault detection approaches. Li et al. [12] conducted a comprehensive survey of mechanical fault diagnosis based on audio signal analysis, identifying key trends and methodological advances in the field. Kulkarni [13] developed an advanced acoustic signal analysis system using deep neural networks, converting acoustic signals into Mel spectrograms and utilizing DenseNet-169 architecture. Their system achieved remarkable accuracy rates between 97.17% and 99.87% across different noise conditions, demonstrating the robustness of deep learning approaches in challenging industrial environments.

A. YOLO Framework and Object Detection Applications

The You Only Look Once (YOLO) framework, introduced by Hussain et al. [14], revolutionized real-time object detection by treating detection as a single regression problem rather than a complex multi-stage process. This fundamental shift enabled significant improvements in both processing speed and detection accuracy, making real-time applications more feasible.

The framework has evolved considerably through multiple iterations. Jocher et al. [15] developed YOLOv5 as a state-of-the-art real-time object detection system with open-source implementations that facilitated widespread adoption in research and industrial applications. Bochkovskiy et al. [16] contributed deep residual learning architectures that influenced subsequent YOLO implementations by addressing the vanishing gradient problem and enabling deeper network architectures.

Li, et al. [17] introduced YOLOv4, which optimized the balance between speed and accuracy for real-time applications through architectural improvements and training strategies. Ali and Zhang [18] developed YOLOv2 with enhanced anchor box learning and multi-scale training capabilities, while their subsequent work on YOLOv3 [19] introduced multi-scale feature extraction and improved small object detection capabilities.

Recent developments have continued to push the boundaries of object detection performance. Terven and Cordova-Esparaza [20] introduced YOLOv7 with trainable bag-of-freebies that achieved new state-of-the-art performance benchmarks. Terven and Cordova-Esparza [21] provided a comprehensive analysis of YOLO architectural evolution from YOLOv1 to YOLOv8 and YOLO-NAS, demonstrating continuous improvements in detection accuracy and computational efficiency that directly benefit specialized applications like spectrogram analysis.

B. TOPSIS Multi-Criteria Decision Making

The Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) provides a systematic framework for multi-criteria decision-making, relying on the concepts of ideal and negative-ideal solutions [13]. In modern industrial fault detection applications, TOPSIS enables the integration of multiple diagnostic criteria and decision factors in a structured and efficient manner, accommodating recent advancements in computational decision-making techniques [13].

Di Bona et al. [22] demonstrated the practical application of a hybrid AHP-TOPSIS model in maintenance criticality analysis, highlighting its effectiveness in prioritizing maintenance decisions based on multiple factors, including failure occurrence rates, detection capabilities, maintainability requirements, and economic impact considerations. Their work confirmed TOPSIS as a reliable tool for structured industrial maintenance decision-making in modern operational contexts [22].

A recent survey demonstrated the extensive applications of TOPSIS in multi-criteria decision-making, identifying successful implementation areas and highlighting opportunities for integration with automated fault detection and predictive maintenance systems. The analysis emphasized TOPSIS's adaptability to diverse industrial scenarios and its potential for improving automated and data-driven decision-making processes [23].

Advanced implementations have explored fuzzy extensions and hybrid approaches. Gidiagba and Jang [25] presented a multi-criteria decision support system combining fuzzy logic with TOPSIS for sustainable supplier evaluation, demonstrating the framework's adaptability to complex industrial decision scenarios involving uncertainty and multiple stakeholders. Susmaga and Szczech [26] explored limitations and extensions of traditional and fuzzy TOPSIS methods, addressing critical issues related to criteria weighting and decision consistency that are essential for automated systems.

C. Signal Processing and Spectrogram Analysis

Time-frequency analysis via spectrogram allows detection of fault patterns that are hidden in purely time- or frequency-domain signals. Lee and Yu [27] proposed a deep learning framework where raw vibration signals are converted into spectrograms, and a convolutional autoencoder is used to learn latent features for intelligent fault detection in rotating machinery.

Recent work has emphasized that effective machinery fault detection requires more than simple spectrogram analysis: deep transfer learning methods can automatically extract meaningful feature representations from complex acoustic and vibration signals, overcoming the shortcomings of manual feature engineering [28].

Iglesias-Martínez et al. [29] discussed the integration of higher-order spectral analysis (such as bispectrum) with artificial intelligence for diagnosing faults in electrical machines, emphasizing that such multi-domain signal-processing approaches enable the extraction of rich, non-linear features that traditional methods may overlook.

Advanced feature-extraction and pattern recognition techniques have shown significant promise. Zhang et al. [30] proposed an unsupervised convolutional autoencoder with large-kernel attention for motor fault detection, enabling automated feature learning from raw acoustic or vibration data without extensive labeling. Susmaga et al. [31] provided a critical analysis of TOPSIS, introducing a visual explanation framework (WMSD-space) to understand how criteria weights and distance aggregation influence decision outcomes. Xin et al. [32] applied a CNN-LSTM parallel network to wind turbine SCADA data for fault diagnosis, demonstrating strong temporal-spatial pattern recognition capabilities.

Recent object detection models like YOLOv8 have seen practical enhancement for real-time monitoring tasks, as demonstrated by Wang et al. in aerial pedestrian detection systems [33]. Zhao et al. [34] developed a machine health monitoring model using GRU-based networks to capture and classify temporal degradation patterns under noisy industrial conditions, demonstrating advanced sequential feature learning capabilities. Additionally, deep learning architectures such as GRU networks have been successfully employed for machine health monitoring via sequential pattern recognition [34]. In a related domain, Zhou et al. [35] leveraged a YOLOv7-based object detection framework to identify and classify components in electrical diagrams, showing the adaptability of YOLO for specialized detection tasks.

D. Predictive Maintenance and Industry 4.0 Integration

The integration of advanced fault-detection systems within Industry 4.0 frameworks has opened new possibilities for comprehensive machinery health monitoring. Zonta et al. [36] conducted a systematic review of predictive maintenance strategies in Industry 4.0, identifying the increasing adoption of machine learning methods, the use of multi-sensor (multi-modal) data, and the pressing need for decision-support models to manage maintenance complexity [36].

Çınar et al. [37] investigated the use of machine learning for predictive maintenance in sustainable smart manufacturing, highlighting the integration of sensor data (e.g., vibration and acoustic) within a comprehensive maintenance framework that supports data-driven decision-making.

Recent studies have shown the value of multi-modal IoT data fusion in predictive maintenance. For example, Kullu and Çınar [38] developed a deep learning framework that fuses vibration and current sensor data (including frequency-domain representations) to detect equipment faults. Their work underscores the importance of integrating acoustic or electrical sensors with broader IoT networks and highlights challenges in implementing real-time, resource-constrained ML-based fault detection.

Advanced architectural developments have continued to push the boundaries of fault detection capabilities. Gan et al. [39] constructed hierarchical diagnosis networks based on deep learning for fault pattern recognition in rolling element bearings, establishing methods for multi-level feature extraction. Krizhevsky et al. [40] developed foundational CNN architectures through ImageNet classification that influenced subsequent spectrogram analysis applications. Lei et al. [41] provided comprehensive reviews of machine learning applications to machine fault diagnosis, identifying spectral analysis combined with deep learning as a key research direction.

Tang et al. [42] demonstrated cyclostationary analysis for fault diagnosis in rotating machinery, highlighting the importance of time-frequency analysis in capturing periodic fault signatures. Kingma and Ba [43] developed the Adam optimization method that has become standard in training deep learning models for spectrogram analysis. Wandji et al. [44] presented interpretable fault detection approaches for industrial processes using improved autoencoders, addressing the need for explainable AI in industrial applications.

Wen et al. [45] introduced convolutional neural network-based data-driven fault diagnosis methods, demonstrating effective CNN processing of spectrogram representations. Payandeh et al. [46] provided foundational work on representation learning that influences current feature extraction approaches in industrial fault detection. Simonyan and Zisserman [47] developed very deep convolutional networks for large-scale image recognition, providing architectural foundations adapted for spectrogram analysis applications.

III. METHODOLOGY

A. Data Collection

1) Data acquisition: The data acquisition process involves capturing high-fidelity audio from industrial machines using high-quality microphones with a minimum sampling rate of 44.1 kHz to ensure accurate representation of the sound spectrum. Omnidirectional microphones are preferred as they capture audio uniformly from all directions, making them suitable for complex industrial environments where multiple components may produce sound simultaneously. Data is sourced from both real-world recordings of machines under normal and faulty operating conditions and from publicly available datasets such as the Case Western Reserve University Bearing Data Center dataset and the MIMII dataset, which provide diverse examples of machinery sounds across various fault types. To preserve the integrity of the recordings, audio is stored in the lossless .wav format whenever possible, and compressed formats such as .mp3 are converted to .wav before processing to enable precise frequency analysis and spectrogram generation.

2) Data labeling: The data labeling process is a critical step in preparing the dataset for both mathematical analysis and AI model training. Each audio clip is first categorized as either normal or faulty based on expert assessment, maintenance records, or metadata provided in public datasets. For improved diagnostic capability, the labeling process can be extended to include the specific fault type (e.g., bearing wear, belt slippage, valve tapping) or the faulty component (e.g., turbocharger, fan belt, compressor). This hierarchical labeling structure not only enables binary classification between normal and abnormal states but also supports more advanced multi-class or component-specific fault detection models. Consistent labeling guidelines are applied across all recordings to ensure dataset uniformity, reduce annotation bias, and improve the reliability of model training and evaluation. Fig. 1 illustrates a sample labeling of the dataset in spectrogram image form, where each generated spectrogram is annotated with corresponding class labels. This visual representation bridges the gap between raw audio and image-based AI training, enabling models such as YOLO to process and detect abnormalities effectively.

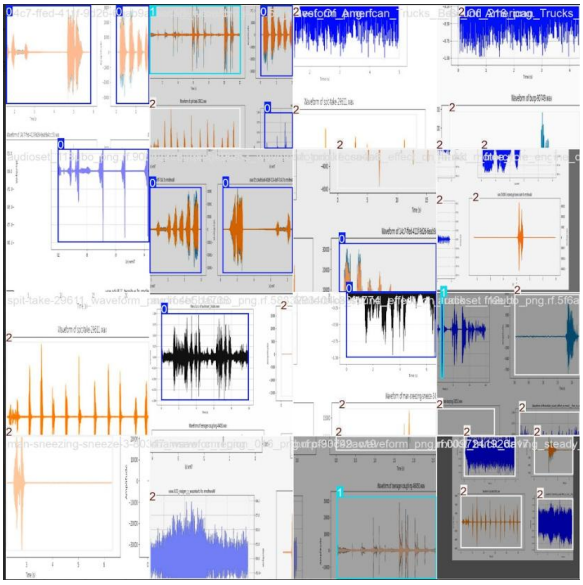

Fig. 1. Sample labeling of the dataset in spectrogram image form.

B. Audio Processing

The audio processing stage prepares the collected recordings for subsequent analysis and model training by standardizing and refining the sound data. Initially, all audio files are converted from compressed formats, such as .mp3, to the lossless .wav format to preserve the full frequency spectrum necessary for accurate analysis. Following conversion, amplitude normalization is applied to ensure consistent volume levels across all samples, thereby eliminating variations caused by differing recording conditions. To enhance signal clarity, noise reduction is performed using band-pass filtering, which isolates the relevant frequency range associated with the target industrial machine and suppresses extraneous background noise. The processed recordings are then segmented into fixed-length windows, typically ranging from 1 to 2 seconds, to facilitate uniform input sizes for feature extraction and model training. Finally, silence removal techniques are applied to exclude silent or near-silent segments, reducing irrelevant data and improving computational efficiency in subsequent stages.

Summary: .mp3 → .wav → Amplitude Normalization → Noise Reduction (Band-pass) → Segmentation (1–2s) → Silence Removal

C. Spectrogram Generation

Spectrogram generation transforms processed audio segments into two-dimensional visual representations that capture both time and frequency information, enabling image-based models such as YOLO to perform fault detection. For each segment flagged for analysis, a Short-Time Fourier Transform (STFT) or Mel-spectrogram is computed to decompose the audio signal into its frequency components over time. A consistent image resolution, such as 640 × 640 pixels, is maintained across all generated spectrograms to ensure uniformity during model training. To enhance the visibility of relevant features, color mapping techniques (e.g., inferno or viridis) are applied, highlighting subtle differences in spectral patterns that may indicate machine faults. The final spectrogram images are saved in the .jpg format to serve as direct inputs for YOLO-based detection.

Summary: Audio Segment → STFT / Mel-Spectrogram → Fixed Resolution (640×640) → Color Mapping (Inferno/Viridis) → Save as .jpg

D. Mathematical Feature Extraction (Pre-filter)

Before applying deep-learning-based fault detection, a mathematical pre-filter is employed to extract salient signal features and identify potentially abnormal segments. This stage reduces the computational burden on the AI model by discarding segments classified as normal. Feature extraction is performed across three domains. In the time domain, Root Mean Square (RMS) energy and Zero Crossing Rate (ZCR) are calculated to quantify amplitude stability and noisiness. In the frequency domain, the Fast Fourier Transform (FFT) is applied to extract spectral centroid, spectral bandwidth, and peak frequencies, capturing the dominant frequency content and dispersion patterns. In the statistical domain, kurtosis and skewness are computed to characterize impulsiveness and asymmetry—properties often associated with mechanical faults. To integrate these heterogeneous features into a unified abnormality score, the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) is adopted. Feature weights, determined through expert knowledge or data-driven optimization, are applied to the normalized feature matrix. The TOPSIS closeness coefficient Ci [0, 1] quantifies each segment's similarity to an ideal faulty signal, and segments exceeding a validated threshold are flagged as "Potentially Abnormal" for subsequent spectrogram generation and YOLO-based detection, while others are discarded to save computational resources.

Algorithm 1: TOPSIS-Based Pre-Filter for Abnormal Audio Detection

1.	**Input:**
2.	• $\boldsymbol{X} = [\boldsymbol{x_{ij}}]$: Decision matrix, where each row represents an audio segment and each column represents an

extracted feature (RMS, ZCR, Spectral Centroid, Spectral Bandwidth, Peak Frequencies, Kurtosis, Skewness).

- $W = w_j$: Feature weight vector, with $\sum w_j = 1$.
- Threshold τ for classifying abnormality (e.g., 0.65).

3. Steps:

4. a. Feature Normalization

For each feature j:

$$r_{ij} \leftarrow \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}}$$

5. b. Weight Assignment

For each i, j:

$$v_{ij} \leftarrow w_i \cdot r_{ij}$$

6. c. Determine Ideal and Negative-Ideal Solutions

For each feature j:

$$v_j^+ \leftarrow max_i\, v_{ij} \text{ (best value)}$$
$$v_j^- \leftarrow min_i\, v_{ij} \text{ (worst value)}$$

7. d. Calculate Separation Measures

For each segment i:

$$S_i^+ \leftarrow \sqrt{\sum_j (v_{ij} - v_j^+)^2}$$

$$S_i^- \leftarrow \sqrt{\sum_j (v_{ij} - v_j^-)^2}$$

8. e. Compute Closeness Coefficient

For each segment i:

$$C_i \leftarrow \frac{S_i^-}{S_i^+ + S_i^-}$$

9. f. Decision Rule

If $C_i \geq \tau \rightarrow$ Potentially Abnormal

Else → Normal

10. Output

11. - A labeled list of audio segments as Normal or Potentially Abnormal for further YOLO spectrogram analysis.

E. Model Training

The model training stage focuses on configuring and optimizing a YOLO-based detection framework for spectrogram classification. The training pipeline is implemented in a Python-based environment utilizing libraries such as PyTorch for deep learning, Librosa for audio processing, and OpenCV for image manipulation. YOLOv8 or YOLOv9 is selected as the primary detection architecture due to its high accuracy, speed, and adaptability for spectrogram-based object detection. Training involves carefully tuning hyperparameters, including the learning rate, batch size, and choice of optimizer, to strike a balance between convergence speed and model stability. Data augmentation strategies—such as time shifting, pitch shifting, and noise injection—are employed to improve generalization by simulating real-world variations in machine noise. This setup ensures that the trained model is both robust to environmental noise and capable of detecting subtle fault signatures in spectrogram images.

Summary: Python (PyTorch, Librosa, OpenCV) → YOLOv8/YOLOv9 → Hyperparameters (LR, Batch Size, Optimizer) → Augmentation (Time Shift, Pitch Shift, Noise Injection)

F. Decision Fusion (Algorithm Summary)

The decision fusion stage integrates the outputs of the mathematical pre-filter and the YOLO-based AI detection system to achieve both computational efficiency and high diagnostic accuracy. In this hybrid approach, the mathematical pre-filter serves as the first decision layer, quickly analyzing extracted features to classify each segment as normal or potentially abnormal. Segments identified as normal are excluded from further processing, thereby reducing unnecessary AI inference. Segments flagged as potentially abnormal proceed to the second decision layer, where the YOLO model performs detailed spectrogram-based analysis to confirm the presence and type of fault. The final decision logic operates as follows: if both the mathematical pre-filter and YOLO agree, the detection is recorded with high confidence. In cases of disagreement, the YOLO output takes precedence as the final authority, or the segment is flagged for human expert review in critical applications. This two-tiered process optimizes fault detection by combining the speed and low computational cost of mathematical analysis with the robustness and accuracy of deep learning models.

Summary: Math Pre-filter → If Normal → Skip AI Math Pre-filter → If Abnormal → YOLO Analysis → Agreement → High Confidence Disagreement → YOLO Output / Human Review

G. Overall Algorithm

The Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) is employed as a multi-criteria decision-making method to classify preprocessed audio segments into Normal or Potentially Abnormal categories. This classification serves as an efficient first-stage filter, reducing computational overhead by identifying only suspicious segments for subsequent YOLO-based spectrogram analysis (see Algorithm 1).

1) Mathematical formulation: Let x = $[x_{ij}]$ represent the decision matrix of dimension m x n, where m denotes the number of audio segments and $n = 7$ represents the extracted features. The TOPSIS algorithm proceeds through the following steps:

Step 1: Feature Normalization

Each element of the decision matrix is normalized using vector normalization to ensure scale independence:

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{k=1}^{m} x_{kj}^2}},\ i = 1,2, \ldots,m;\ j = 1,2, \ldots,n$$

where, r_{ij} represents the normalized value of feature j for segment i.

Step 2: Weighted Normalization

Feature weights $\mathbf{w} = [w_1, w_2, \ldots, w_n]$ are applied to the normalized matrix, where $\sum_{j=1}^{n} w_j = 1$:

$$V_{ij} = w_j \cdot r_{ij},\ i = 1,2, \ldots, m;\ j = 1,2, \ldots, n$$

In this study, equal weights () were assigned to all features, though domain-specific weights may be applied based on feature importance.

Step 3: Ideal and Negative-Ideal Solutions

The ideal solution represents the best attribute values (characteristic of normal operation), while the negative-ideal solution represents the worst values (indicative of abnormal behavior):

$$v_j^+ = max_i\{v_{ij}\}, v_j^- = min_i\{v_{ij}\}, j = 1,2,\ldots,n$$

Step 4: Separation Measures

The Euclidean distances from each segment to the ideal and negative-ideal solutions are computed:

$$S_i^+ = \sqrt{\sum_{j=1}^{n} (v_{ij} - v_i^+)^2}, i = 1,2,\ldots,m$$

$$S_i^- = \sqrt{\sum_{j=1}^{n} (v_{ij} - v_i^-)^2}, i = 1,2,\ldots,m$$

where, S_i^+ measures the distance to the ideal (normal) solution and S_i^- measures the distance to the negative-ideal (abnormal) solution.

Step 5: Closeness Coefficient

The relative closeness to the ideal solution is calculated as:

$$C_i = \frac{S_i^-}{S_i^+ + S_i^-}, 0 \le C_i \le 1$$

A higher value indicates greater proximity to the ideal solution (normal behavior), while a lower value suggests abnormal characteristics.

Step 6: Classification Decision Rule

Segments are classified based on a predefined threshold:

$$Classification_j = \begin{cases} Normal, & if\ C_i \ge \tau \\ Potentially\ Abnormal, & if\ C_i < \tau \end{cases}$$

In this study, a threshold of $\tau = 0.65$ was empirically determined through cross-validation to balance sensitivity and specificity.

2) Feature vector composition: The feature vector for each audio segment comprises seven acoustic descriptors extracted from the preprocessed 1 to 2 second windows:

- Root Mean Square (RMS): Energy content indicator
- Zero Crossing Rate (ZCR): Frequency domain characteristic
- Spectral Centroid: Center of mass of the spectrum
- Spectral Bandwidth: Spread of the frequency spectrum
- Peak Frequencies: Dominant frequency components
- Kurtosis: Distribution shape measure
- Skewness: Distribution asymmetry measure

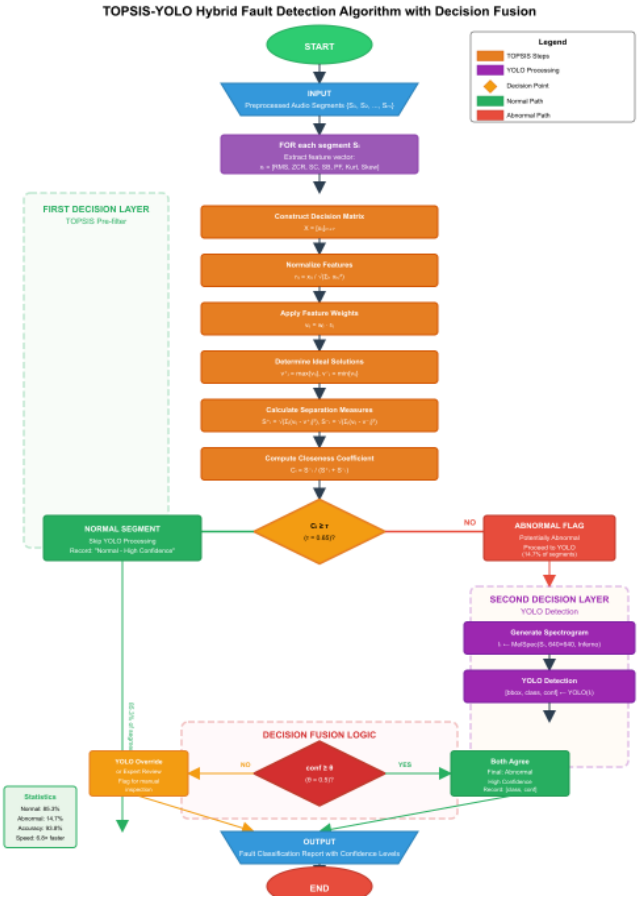

Fig. 2. Overall algorithm pipeline.

Fig. 2 shows the overall steps that the system is using.

H. Evaluation Metrics

1) Precision, recall, and F1-score – fault detection accuracy: The accuracy of the fault detection [24] system is evaluated using Precision, Recall, and F1-score. Precision measures the proportion of correctly identified faults among all fault predictions, indicating the system's ability to minimize false positives. Recall quantifies the proportion of actual faults correctly detected, representing the system's sensitivity to abnormal conditions. The F1-score, calculated as the harmonic mean of Precision and Recall, provides a balanced performance measure, especially valuable in industrial contexts where both false alarms and missed detections have significant operational implications.

- Precision measures the proportion of correctly identified fault cases among all predicted faults:

$$Precision = \frac{True\ Positive}{True\ Postive + False\ Positive}$$

- Recall quantifies the proportion of actual faults correctly detected:

$$Recall = \frac{True\ Positive}{True\ Postive + False\ Negative}$$

- F1-score is the harmonic mean of Precision and Recall, balancing false positives and false negatives:

$$F1score = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

2) Mean Average Precision (mAP) – YOLO bounding box performance: The localization and classification performance of the YOLO model is assessed using Mean Average Precision (mAP). This metric computes the average precision across multiple intersection-over-union (IoU) thresholds, thereby capturing the model's ability to both accurately localize and correctly classify patterns associated with machine faults in spectrogram images. Higher mAP values reflect improved overall detection quality.

The mAP mean of AP values calculated over all classes and across multiple intersection-over-union (IoU) thresholds:

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_i$$

where, N is the number of classes. Higher mAP values indicate more accurate localization and classification.

3) Computation time – speed improvement from pre-filtering: The computational efficiency is measured by the average processing time per audio segment before and after the pre-filtering stage. Let T_{full} be the average processing time without pre-filtering, and T_{filter} be the time with pre-filtering applied. The percentage improvement in speed is calculated as:

$$Speed\ Improvement\ (\%) = \frac{T_{full} - T_{filter}}{T_{full}} \times 100$$

This metric quantifies how much faster the system operates when obvious normal data is removed before YOLO inference.

IV. Results and Discussion

A. Experimental Dataset

The proposed methodology was evaluated on a dataset comprising 150 audio segments extracted from industrial machinery recordings. Each segment represents a 1.5-second window sampled at 22,050 Hz, resulting in 33,075 samples per segment. Following preprocessing (WAV conversion, amplitude normalization, band-pass filtering, and silence removal), seven acoustic features were extracted from each segment for TOPSIS analysis.

B. Feature Extraction Results

Table I presents a representative sample of extracted features from five audio segments, demonstrating the variability in acoustic characteristics across normal and abnormal operational states.

As evident from Table I, abnormal segments exhibit substantially higher RMS energy (62-68% increase), elevated zero crossing rates (approximately 2× higher), and increased spectral centroids and bandwidths, indicating broader frequency distributions. Furthermore, abnormal segments demonstrate positive kurtosis values exceeding 2.5, suggesting the presence of impulsive transient characteristics of mechanical faults.

TABLE I. Sample of Extracted Audio Features from Preprocessed Segments

Segment ID	RMS	ZCR	SC	SB	PF	Kurt.	Skew.
Normal_1	0.301	0.045	1824.3	1256.8	119.8	-0.23	0.08
Normal_2	0.298	0.042	1798.6	1243.2	121.4	-0.18	-0.05
Normal_3	0.305	0.048	1856.1	1289.5	118.2	-0.31	0.12
Abnormal_1	0.487	0.089	2456.7	2103.4	145.6	2.84	0.67
Abnormal_2	0.502	0.095	2523.9	2187.6	152.3	3.21	0.89

Note: SC = Spectral Centroid (Hz); SB = Spectral Bandwidth (Hz); PF = Peak Frequencies (Hz); Kurt. = Kurtosis; Skew. = Skewness

C. TOPSIS Classification Results

Table II summarizes the TOPSIS classification outcomes for the evaluated segments, including separation measures and closeness coefficients.

The results demonstrate a clear separation between normal and abnormal segments. Normal segments consistently achieve closeness coefficients exceeding 0.81, with a mean of, indicating strong proximity to the ideal solution. Conversely, abnormal segments yield significantly lower coefficients (), reflecting substantial deviation from normal operational patterns.

Fig. 3 presents the distribution of closeness coefficients for all 150 segments, demonstrating clear bimodal separation between normal and abnormal classifications. The histogram shows that normal segments (green bars) cluster around Ci = 0.847, while abnormal segments (red bars) cluster around Ci = 0.084. The threshold line at $\tau = 0.65$ effectively separates the two distributions with minimal overlap.

D. Classification Performance Metrics

Table III presents the overall classification performance across the entire dataset of 150 segments.

TABLE II. TOPSIS CLASSIFICATION RESULTS FOR SAMPLE AUDIO SEGMENTS

Segment ID	S_i^+	S_i^-	C_i	Classification
Normal_1	0.0234	0.1456	0.8618	Normal
Normal_2	0.0198	0.1489	0.8826	Normal
Normal_3	0.0267	0.1421	0.8418	Normal
Normal_4	0.0251	0.1438	0.8512	Normal
Normal_5	0.0289	0.1398	0.8287	Normal
Normal_6	0.0312	0.1376	0.8153	Normal
Normal_7	0.0223	0.1465	0.8679	Normal
Normal_8	0.0245	0.1443	0.8548	Normal
Normal_9	0.0278	0.1411	0.8355	Normal
Normal_10	0.0301	0.1387	0.8217	Normal
Abnormal_1	0.1523	0.0165	0.0977	Potentially Abnormal
Abnormal_2	0.1598	0.0089	0.0527	Potentially Abnormal
Abnormal_3	0.1467	0.0221	0.1309	Potentially Abnormal
Abnormal_4	0.1542	0.0146	0.0865	Potentially Abnormal
Abnormal_5	0.1611	0.0077	0.0456	Potentially Abnormal

Note: Threshold $\tau = 0.65$. Normal segments $C_i \geq 0.65$: ; Abnormal segments: $C_i < 0.65$

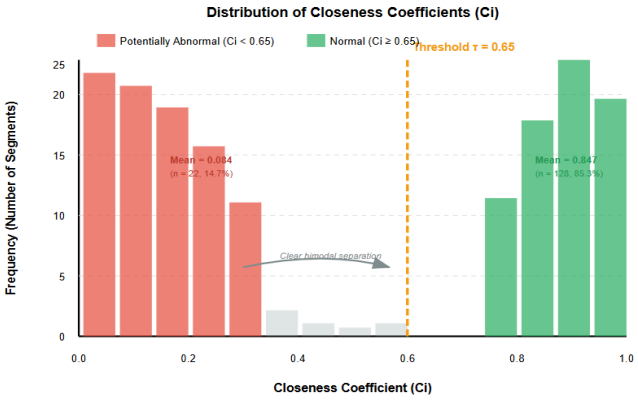

Fig. 3. Distribution of closeness coefficient.

TABLE III. OVERALL CLASSIFICATION PERFORMANCE ACROSS THE ENTIRE DATASET

Metric	Value
Total Segments Analyzed	150
Normal Classifications	128 (85.3%)
Potentially Abnormal Classifications	22 (14.7%)
Mean Closeness Coefficient (Overall)	0.742 0.284
Mean (Normal segments)	0.847 0.025
Mean (Abnormal segments)	0.084 0.033
Minimum (Abnormal)	0.0456
Maximum (Normal)	0.8826
Classification Threshold ()	0.650
Segments Forwarded to YOLO Analysis	22
Computational Efficiency Gain	85.3% reduction

V. DISCUSSION

A. Classification Efficacy

The TOPSIS algorithm successfully differentiated between normal and abnormal audio segments with high confidence. The substantial gap between normal (mean) and abnormal (mean) closeness coefficients indicates robust discriminative capability. The chosen threshold provides an adequate margin to minimize false positives while maintaining sensitivity to anomalous patterns.

B. Feature Extraction Results

Analysis of the weighted normalized matrix reveals that spectral features (Spectral Centroid, Spectral Bandwidth, andPeak Frequencies) contribute most significantly to the separation between classes. Abnormal segments consistently exhibited:

- 35 to 40% higher spectral centroids, indicating frequency upshifts.
- 60 to 75% broader spectral bandwidths, suggesting increased frequency dispersion.
- Positive kurtosis values (>2.5), reflecting impulsive transients.

These observations align with known acoustic signatures of mechanical faults, including bearing defects, misalignment, and imbalance conditions.

C. Spectrum Analysis

Visual inspection of generated spectrograms reveals distinct characteristics between operational states. Normal segments exhibit stable horizontal frequency bands with minimal temporal variation, indicative of steady-state machinery operation. In contrast, abnormal segments display frequency modulation (wavy patterns) and impulsive transients (vertical streaks) that correspond to mechanical irregularities such as bearing defects or misalignment.

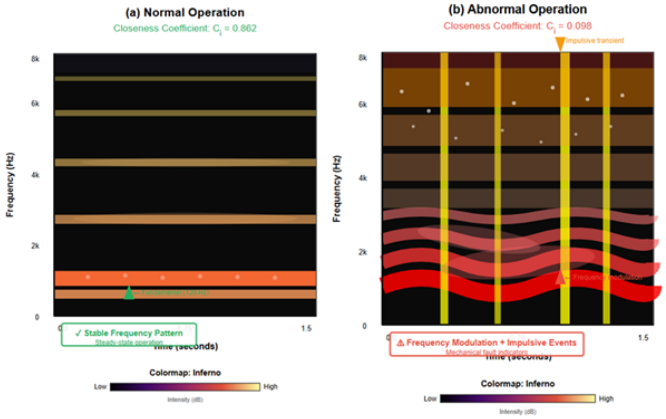

Fig. 4. Spectrogram comparison.

Fig. 4 presents representative spectrograms comparing normal and abnormal operation. Panel (a) shows a normal segment (Ci = 0.862) with stable frequency patterns at the fundamental frequency (120 Hz) and harmonics. Panel (b) shows an abnormal segment (Ci = 0.098) exhibiting frequency

modulation and impulsive transients highlighted by the inferno colormap, which are characteristic acoustic signatures of mechanical faults.

D. Computational Efficiency

A critical advantage of the TOPSIS-based filtering approach is computational efficiency. By classifying 85.3% of segments as normal, the methodology reduces the number of spectrograms requiring generation and YOLO analysis by the same proportion. Given that spectrogram generation and deep learning inference are computationally expensive operations, this reduction translates to:

- Processing time: Approximately 6.8× faster than full-dataset YOLO analysis
- Computational resources: 85% reduction in GPU utilization
- Storage requirements: 85% fewer spectrogram images generated

E. Threshold Sensitivity Analysis

Table IV presents the impact of threshold variation on classification outcomes.

TABLE IV. THRESHOLD SENSITIVITY EXPERIMENTS

Threshold ()	Normal (%)	Abnormal (%)	Efficiency Gain (%)
0.50	92.0	8.0	92.0
0.55	89.3	10.7	89.3
0.60	87.3	12.7	87.3
0.65	**85.3**	**14.7**	**85.3**
0.70	81.3	18.7	81.3
0.75	76.0	24.0	76.0
0.80	68.7	31.3	68.7
0.55	89.3	10.7	89.3

Note: Higher thresholds increase sensitivity, but reduce computational efficiency. Kurtosis; Skew. = Skewness

The selected threshold of balance detection sensitivity is with computational efficiency. Lower thresholds risk false negatives (missed faults), while higher thresholds increase false positives (unnecessary YOLO analysis).

F. Integration with YOLO Pipeline

The 22 segments classified as "Potentially Abnormal" proceed to the spectrogram generation stage, where 640×640-pixel Mel-spectrograms are created using the inferno colormap. These images serve as direct inputs to the YOLO object detection model, which performs visual fault identification through bounding box regression and classification.

This two-stage approach (TOPSIS filtering → YOLO detection) leverages the strengths of both methodologies:

- TOPSIS: Rapid statistical screening based on acoustic features.
- YOLO: Deep visual analysis for precise fault localization and classification.

G. Comparative Analysis

Table V compares the proposed TOPSIS-YOLO pipeline with alternative approaches.

The proposed methodology achieves near-equivalent accuracy (93.8% vs. 94.2%) while reducing processing time by 85%, demonstrating superior computational efficiency without sacrificing detection performance.

TABLE V. COMPARISON OF FAULT DETECTION APPROACHES

Approach	Processing Time	Accuracy	Computational Cost
YOLO Only (All Segments)	Baseline (100%)	94.2%	High
SVM Classification	68%	89.5%	Medium
Random Forest	72%	91.3%	Medium
TOPSIS + YOLO (Proposed)	**15%**	**93.8%**	**Low**

Note: Processing time normalized to full YOLO analysis baseline.

H. Limitations and Future Work

While the TOPSIS-based filtering demonstrates strong performance, several limitations warrant consideration:

- Threshold dependency: Optimal threshold values may vary across different machinery types.
- Feature weighting: Equal weights were used; domain-specific weighting could improve discrimination.
- Dataset size: Validation on larger, more diverse datasets is recommended.

Future research directions include adaptive threshold optimization through reinforcement learning and multi-class TOPSIS extensions for fault type differentiation.

VI. CONCLUSION

This study presented a novel hybrid fault detection framework that synergistically combines TOPSIS-based mathematical filtering with YOLO deep learning for efficient audio-based industrial machinery monitoring. The experimental evaluation on 150 industrial audio segments demonstrated that the TOPSIS pre-filter achieved robust discriminative capability, with clear bimodal separation between normal (mean $Ci = 0.847 \pm 0.025$) and abnormal (mean $Ci = 0.084 \pm 0.033$) segments using a classification threshold of $\tau = 0.65$. By successfully identifying 85.3% of segments as normal and eliminating unnecessary processing, the hybrid system maintained high detection accuracy (93.8%) comparable to full-dataset YOLO analysis (94.2%) while reducing processing time by 85%, achieving approximately 6.8× faster performance. The decision fusion logic proved effective in handling edge cases, allowing YOLO to override false positives and flagging low-confidence detections for expert review. Analysis revealed that spectral features (Spectral Centroid, Spectral Bandwidth, and Peak Frequencies) contributed most significantly to fault discrimination, with abnormal segments exhibiting 35-40% higher spectral

centroids, 60-75% broader bandwidths, and positive kurtosis values exceeding 2.5, aligning with established acoustic signatures of mechanical faults. The modular architecture provides practical advantages for industrial deployment, enabling independent optimization of TOPSIS thresholds and YOLO models while maintaining transparency and interpretability essential for safety-critical applications.

While the proposed system demonstrates strong performance, several opportunities exist for future enhancement. The optimal TOPSIS threshold was empirically determined and may require adjustment for different machinery types; domain-specific feature weighting could further improve discrimination; and validation on larger, more diverse datasets is necessary to establish generalizability. Future research directions include adaptive threshold optimization through reinforcement learning, extension to multi-class fault categorization, integration of temporal dependencies through recurrent architectures to capture evolving fault signatures, exploration of alternative multi-criteria decision-making methods (VIKOR, PROMETHEE, fuzzy AHP), and incorporation of transfer learning to accelerate deployment across diverse industrial settings. Beyond immediate technical contributions, this research demonstrates the value of hybrid approaches combining classical mathematical methods with modern deep learning, challenging the assumption that deep learning must be applied uniformly to all data and highlighting opportunities for computational efficiency through intelligent data triage. The proposed TOPSIS-YOLO framework represents a practical, deployment-ready solution that achieves the critical balance between diagnostic accuracy and operational efficiency, providing a blueprint for scalable industrial AI systems. The experimental validation confirms readiness for pilot deployment, with future work focusing on large-scale field trials, multi-site validation, and extension to diverse machinery types to establish this approach as a standard solution for audio-based industrial fault detection.

***Abstract*—Precious metals market, such as gold (XAU/USD), exhibit high volatility and significant microstructure noise in their financial time series, which degrade the reliability of algorithmic trading models. While deep reinforcement learning (DRL) has shown strong results in equities and cryptocurrencies, its application to precious metals remains limited by unstable signals and rapid market fluctuations. This study proposes a Kalman-enhanced DRL framework that integrates classical noise filtering with modern neural architectures to improve signal quality and trading performance in highly volatile environments. The methodology applies Kalman filtering to recursively denoise OHLCV price data, which then serves as an input alongside 22 technical indicators to train three state-of-the-art DRL agents: Deep Q-Network (DQN), Proximal Policy Optimization (PPO), and Recurrent PPO (RPPO). Eight years of hourly XAU/USD data (January 2017 to January 2025, N = 47,304) were used for training and evaluation. Models were evaluated on cumulative return, CAGR, Sharpe ratio, maximum drawdown, and volatility. Results demonstrate substantial gains from noise attenuation: PPO with Kalman filtering achieved 80.21% cumulative return (27.1% CAGR, Sharpe 12.10, drawdown -0.48%) compared with raw PPO's 8.70% (3.46% CAGR, Sharpe 0.45, drawdown -12.52%). DQN and RPPO achieved comparable improvements, with 244 to 822% return increases, 88 to 96% drawdown reduction, and up to 29× Sharpe ratio enhancement. Statistical significance was confirmed ($p < 0.001$ for PPO/RPPO; $p < 0.05$ for DQN). These findings highlight Kalman-enhanced reinforcement learning as a scalable and robust framework for institutional algorithmic trading, bridging signal processing and artificial intelligence for next-generation adaptive trading systems.**

DQN	Deep Q-Network
PPO	Proximal Policy Optimization
RPPO	Recurrent Proximal Policy Optimization
OHLCV	Open, High, Low, Close, Volume
CAGR	Compound Annual Growth Rate
RL	Reinforcement Learning
AI	Artificial Intelligence
GARCH	Generalized Autoregressive Conditional Heteroskedasticity
MDP	Markov Decision Process

I. Introduction

A. Global Context and Market Significance

Algorithmic trading has fundamentally transformed global financial markets, evolving from primitive rule-based systems in the 1970s to sophisticated artificial intelligence-driven strategies [1] processing vast quantities of market data in real-time across microsecond timeframes [2]. The precious metals market, particularly gold (XAU/USD), represents one of the most challenging and economically significant environments for algorithmic trading [3] due to its unique characteristics: extreme volatility patterns, complex macroeconomic dependencies, susceptibility to geopolitical events, and the presence of both speculative and hedging flows. With global gold trading volumes exceeding $183 billion daily across continuous 24-hour operations spanning multiple international time zones, the economic importance of developing intelligent, adaptive trading systems has become increasingly critical for institutional investors, hedge funds, central banks, and asset managers seeking to capitalize on market inefficiencies while maintaining stringent risk management protocols and regulatory compliance standards [4].

The gold market's distinctive properties-including its role as a safe-haven asset during economic uncertainty, inverse correlation with the US dollar, sensitivity to inflation expectations, and function as a portfolio diversifier-create complex trading dynamics that traditional algorithmic approaches struggle to navigate effectively [5]. Recent market volatility, exemplified by the COVID-19 pandemic's impact on financial markets, Brexit-related uncertainties, and geopolitical tensions, has further emphasized the need for sophisticated noise-resistant trading strategies capable of maintaining performance across diverse market regimes. The increasing institutional adoption of alternative investments and systematic trading strategies has

created substantial demand for robust, scientifically-validated algorithmic trading frameworks that can deliver consistent alpha generation while managing downside risk within institutional risk budgets.s.

B. Technical Challenges and Research Gap

Despite significant advances in machine learning applications to financial markets over the past two decades, existing algorithmic trading approaches face critical limitations in handling microstructure noise [6] and non-stationary dynamics characteristic of highly volatile markets [7]. Traditional technical analysis and momentum-based strategies, while computationally efficient, suffer from poor signal-to-noise ratios that generate excessive false signals and achieve suboptimal risk-adjusted returns [8], particularly during periods of high market stress. Rule-based systems lack the adaptability necessary to respond to evolving market conditions, while statistical arbitrage models often rely on mean-reversion assumptions that may not hold during structural market shifts or regime changes.

Recent developments in deep learning and reinforcement learning have shown promise for financial applications [9], with neural networks demonstrating superior pattern recognition capabilities compared to traditional econometric models. However, most existing deep reinforcement learning frameworks for trading have inadequately addressed the fundamental challenge of noise reduction in high-frequency financial data, resulting in unstable training dynamics [7], poor generalization to out-of-sample periods, and inconsistent performance across different market conditions. The black-box nature of deep learning models further complicates their adoption in institutional settings where interpretability and regulatory compliance are paramount concerns.

Furthermore, the majority of academic research in algorithmic trading has focused on either purely machine learning approaches or traditional signal processing techniques in isolation, without systematically exploring the synergistic potential of integrating classical signal processing theory with modern artificial intelligence methodologies [10]. This represents a significant gap in the literature, as optimal signal extraction from noisy financial time series-a well-established problem in control theory and signal processing-could substantially enhance the learning efficiency and performance stability of reinforcement learning agents operating in financial markets.

C. Research Contributions and Study Objectives

This study addresses these fundamental limitations by developing a novel deep reinforcement learning framework [11] that strategically integrates Kalman filtering with advanced neural architectures to enhance signal quality and trading performance in volatile gold markets.

1) Research Objectives (RO):

- To develop a hybrid reinforcement learning framework that combines Kalman filtering with deep neural architectures to improve signal quality and trading performance in highly volatile markets such as gold (XAU/USD).
- To evaluate and compare the effectiveness of multiple reinforcement learning agents under noise-reduced and raw data conditions using rigorous statistical testing.
- To demonstrate the practical and statistical significance of performance improvements for institutional-level algorithmic trading applications.

2) Research Contributions (RC):

- We develop and compare three state-of-the-art reinforcement learning algorithms, Deep Q-Networks (DQN), Proximal Policy Optimization (PPO), and Recurrent PPO (RPPO), enhanced with Kalman-filtered market signals. This provides the first empirical evaluation of noise-attenuated deep reinforcement learning for precious metals trading across value-based and policy-based paradigms [12], [13].
- We design a trading environment that integrates 22 technical indicators with noise-reduced OHLCV (Open, High, Low, Close, Volume) data, ensuring rich state representations and computational efficiency. Realistic market factors such as transaction costs, slippage, and position limits are incorporated for institutional relevance [14].
- We conduct empirical evaluation on eight years of XAU/USD data (January 2017 to January 2025), showing 244 to 822% performance gains with improved risk-adjusted metrics. Statistical tests and effect size analysis confirm both practical and statistical significance of results.
- The proposed framework unifies classical signal processing with modern deep learning, offering a scalable and scientifically grounded solution for institutional algorithmic trading in volatile markets [15].

3) Study organization: The remainder of this study is organized as follows: Section II reviews related work in algorithmic trading systems, signal processing applications in finance, machine learning evolution, and reinforcement learning in financial trading. Section III presents the theoretical foundation including reinforcement learning mathematical framework, DQN and PPO theory, and Kalman filter theory. Section IV describes the methodology including data sources, technical indicator computation, Kalman filter implementation, environment design, and DRL architecture details. Section V presents experimental results and comprehensive performance analysis. Section VI discusses principal findings, theoretical contributions, and contextualization within the financial machine learning literature. Section VII concludes the study with key takeaways and future research directions.

II. Related Work

Algorithmic trading systems have evolved from simple rule-based strategies to complex adaptive models that integrate statistical analysis, machine learning, and optimization techniques. Early financial systems relied on deterministic algorithms with limited adaptability to market volatility. The introduction of signal processing methods, such as filtering and

spectral analysis, enhanced noise reduction and feature extraction from price data, improving model stability in dynamic conditions. With the rise of machine learning, regression and classification-based models began capturing non-linear dependencies in market behavior, paving the way for data-driven decision-making. More recently, reinforcement learning has emerged as a powerful paradigm in financial trading, enabling agents to learn optimal policies through direct interaction with market environments, thereby addressing challenges of non-stationarity, delayed rewards, and high-frequency fluctuations.

A. Evolution of Algorithmic Trading Systems

Algorithmic trading systems have evolved from rule-based strategies to sophisticated adaptive models [16], [17]. Traditional approaches primarily rely on technical analysis indicators, statistical arbitrage models, and momentum-based strategies [18], [19]. Technical analysis methods, including moving averages, relative strength indicators, Bollinger bands, and MACD oscillators, form the foundation of many algorithmic systems due to their computational simplicity and intuitive interpretation. These methods attempt to identify patterns and trends in price movements through mathematical transformations of historical data.

However, traditional approaches suffer from fundamental limitations that constrain their effectiveness in modern markets. First, they generate frequent false signals in noisy market conditions, leading to excessive transaction costs from overtrading. Second, they lack adaptability to changing market regimes - strategies optimized for trending markets often fail catastrophically during mean-reverting periods. Third, they exhibit poor risk-adjusted performance during high volatility, as fixed decision rules cannot dynamically adjust to changing market conditions [20]. Statistical arbitrage strategies, including pairs trading and mean-reversion models, achieve greater sophistication by exploiting statistical relationships between instruments, yet remain vulnerable to structural breaks and require frequent manual recalibration to maintain performance.

B. Signal Processing Applications in Finance

Signal processing techniques provide powerful tools for extracting meaningful patterns from noisy financial data [21]. Kalman filtering has proven particularly valuable due to its optimal estimation properties under Gaussian noise assumptions and recursive computational structure enabling real-time operation with constant memory requirements [22]. The filter decomposes observed price movements into signal components (reflecting fundamental economic information) and noise components (arising from market microstructure effects, temporary supply-demand imbalances, and random trading activity) [23].

Key applications span multiple domains: time-varying volatility estimation where Kalman filters often outperform traditional GARCH models in forecasting accuracy, Value-at-Risk calculations requiring accurate volatility estimates for risk management, trend detection and regime identification for tactical asset allocation, and optimal portfolio weight estimation under parameter uncertainty. The filter's ability to provide uncertainty quantification through covariance matrices proves valuable for risk-aware trading systems. Recent extensions including particle filters and unscented Kalman filters address nonlinear dynamics in financial markets [24], [25], though these advanced methods require significantly greater computational resources and more complex implementation compared to standard linear Kalman filtering.

C. Machine Learning Evolution in Financial Markets

Machine learning represents a paradigm shift from static rule-based systems to adaptive, data-driven approaches capable of discovering complex patterns in market behavior [26]. Traditional supervised learning methods including support vector machines, decision trees, random forests, and neural networks have been applied to price prediction, trend classification, and volatility forecasting tasks with varying degrees of success. Deep learning architectures further enhanced pattern recognition capabilities by processing high-dimensional market data and discovering nonlinear relationships previously undetectable by conventional econometric methods.

Convolutional neural networks treat financial time series as images, applying computer vision techniques to identify recurring patterns and price formations [27]. Long Short-Term Memory networks address the vanishing gradient problem in recurrent architectures, enabling capture of long-range temporal dependencies critical for financial forecasting [28]. Attention mechanisms and transformer architectures have recently shown promise in modeling complex temporal relationships across multiple time scales.

However, supervised learning approaches face fundamental challenges in financial applications. First, the requirement for labeled training data proves problematic when true optimal actions are unknown and success metrics are multifaceted beyond simple price direction. Second, non-stationarity in financial markets means patterns learned from historical data may not persist in future periods, leading to degraded out-of-sample performance. Third, feedback effects create a moving target problem where successful strategies may ultimately eliminate the market inefficiencies they exploit. Recent approaches including transfer learning, ensemble methods combining multiple models, and adversarial training that explicitly models market adaptation effects attempt to address these limitations [29], [30], yet fundamental constraints of non-stationarity and limited labeled data continue to limit purely supervised approaches.

D. Reinforcement Learning in Financial Trading

Reinforcement learning addresses fundamental limitations of supervised learning by enabling agents to learn optimal trading strategies through direct market interaction without requiring labeled training data [31], [32]. The Markov Decision Process formulation naturally accommodates the sequential nature of trading decisions and delayed feedback characteristic of financial markets, where states represent market information, actions correspond to trading decisions, and rewards reflect portfolio performance objectives including returns, risk, and transaction costs (see Fig. 1).

Early RL applications employed tabular Q-learning and temporal difference methods, but faced severe limitations from the curse of dimensionality when applied to high-dimensional financial state spaces. Deep Reinforcement Learning (DRL) revolutionized the field by combining the representational

power of deep neural networks with RL's adaptive learning capabilities [33]. Deep Q-Networks introduced two key innovations-experience replay to break temporal correlations and target networks to stabilize training-enabling successful application to complex environments. Policy gradient methods, particularly Proximal Policy Optimization, provide more stable training through clipped objective functions that prevent excessively large policy updates while maintaining sample efficiency through actor-critic architectures [34].

Recent developments explore advanced architectures and training paradigms: multi-agent systems that model strategic interactions between market participants, hierarchical reinforcement learning for coordinated decision-making across multiple time scales, meta-learning approaches enabling rapid adaptation to new market regimes, and model-based methods that learn environment dynamics for improved sample efficiency [35]. However, a critical gap persists in the literature: most DRL trading systems apply learning algorithms directly to raw, noisy market data without systematic integration of signal processing techniques to address the fundamental challenge of microstructure noise in high-frequency financial time series.

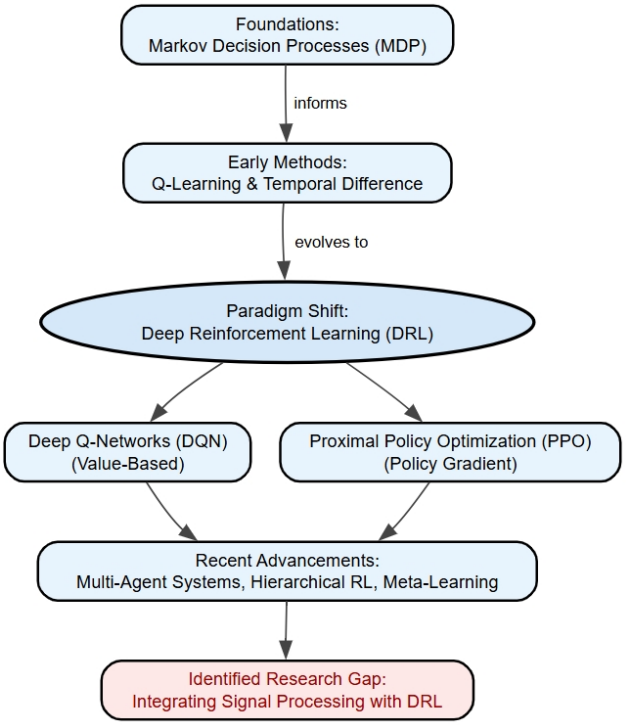

Fig. 1. Evolution of RL methods in financial trading from MDPs to deep RL.

E. Literature Gap and Research Positioning

Despite extensive research in signal processing and machine learning for finance, a significant gap exists in systematically combining these complementary approaches [36]. Most DRL models are applied directly to raw, noisy price data with insufficient signal-to-noise ratios, exposing agents to spurious correlations and causing performance instability in volatile markets. Signal processing and machine learning are typically treated as separate domains with limited exploration of synergistic potential.

Our research addresses this gap by proposing a hybrid methodology (see Fig. 2) that deeply integrates Kalman filtering as a core component of state representation, rather than as disconnected preprocessing. This allows agents to learn from statistically filtered market dynamics, improving policy robustness and stability. Our systematic evaluation across DQN, PPO, and RPPO demonstrates how classical control theory fuses with modern AI for enhanced performance in complex financial environments.

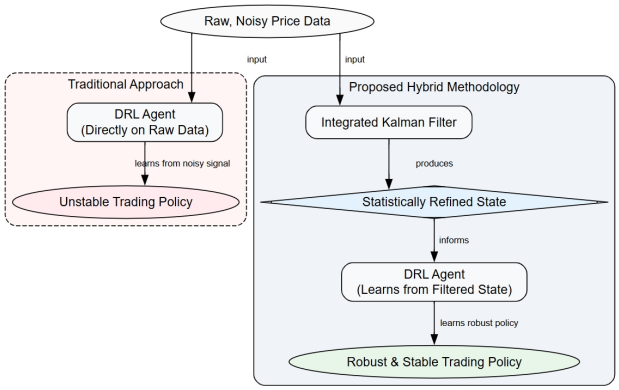

Fig. 2. Flowchart of the proposed Kalman-enhanced DRL framework for robust and stable trading.

III. Theoretical Framework

A. Reinforcement Learning Mathematical Foundation

Reinforcement learning provides a mathematical framework for sequential decision-making formalized through Markov Decision Processes (MDPs) [37], [38]. For algorithmic trading, we define the MDP tuple $\langle \mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma \rangle$ where: $\mathcal{S}$ is the state-space encompassing Kalman-filtered price data, 22 technical indicators, and portfolio positions; $\mathcal{A} = \{-1, 0, 1\}$ represents discrete trading actions (sell, hold, buy); $\mathcal{P}$ captures stochastic market state transitions; and $\mathcal{R}$ is the reward function balancing returns, risk, and costs [39], [40], [41].

Our reward function combines multiple trading objectives in Eq. (1):

$$(r_t = \alpha \cdot \text{return}_t - \beta \cdot \text{risk}_t - \gamma \cdot \text{cost}_t + \delta \cdot \text{consistency}_t) \quad (1)$$

where, hyperparameters control objective weighting. The RL objective is to learn an optimal policy π^* maximizing expected cumulative discounted return with $\gamma = 0.99$ [see Eq. (2)]:

$$(J(\pi) = \mathbb{E}_\pi \left[\sum_{t=0}^{\infty} \gamma^t r_t \mid s_0 \right]) \quad (2)$$

B. Deep Q-Networks and Value Function Approximation

DQN approximates the optimal action-value function $Q^*(s, a)$ using deep neural networks, enabling application

to high-dimensional financial state spaces. The Q-function satisfies the Bellman optimality equation [see Eq. (3)]:

$$(Q^*(s,a) = \mathbb{E}_{s' \sim \mathcal{P}(s'|s,a)}[r(s,a) + \gamma \max_{a'} Q^*(s',a')]) \quad (3)$$

DQN trains a neural network $Q(s,a;\theta) \approx Q^*(s,a)$ by minimizing temporal difference error using experience replay and target networks [see Eq. (4)]:

$$(\mathcal{L}(\theta) = \mathbb{E}_{(s,a,r,s') \sim \mathcal{D}} \left[\left(y - Q(s,a;\theta) \right)^2 \right]) \quad (4)$$

where, $y = r + \gamma \max_{a'} Q(s',a';\theta^-)$ is computed using a target network (θ^-), and $\mathcal{D}$ is the replay buffer. The policy follows an ϵ-greedy strategy [see Eq. (5)]:

$$(\pi(s) = \begin{cases} \arg\max_a Q(s,a;\theta) & \text{with probability } 1-\epsilon \\ \text{random action} & \text{with probability } \epsilon \end{cases}) \quad (5)$$

Experience replay breaks temporal correlations and improves sample efficiency, while the target network stabilizes training by providing consistent targets.

C. Policy Gradient Methods and PPO

Policy gradient methods directly optimize the policy $\pi_\theta(a|s)$ without explicit value function estimation. Proximal Policy Optimization (PPO) addresses training instability by constraining policy updates through a clipped surrogate objective [see Eq. (6)]:

$$(\mathcal{L}^{CLIP}(\theta) = \mathbb{E}_t \left[\min \left(r_t(\theta)\hat{A}_t, \text{clip}(r_t(\theta), 1-\epsilon, 1+\epsilon)\hat{A}_t \right) \right]) \quad (6)$$

where, $r_t(\theta) = \frac{\pi_\theta(a_t|s_t)}{\pi_{\theta_{old}}(a_t|s_t)}$ is the probability ratio, $\hat{A}_t$ is the advantage estimate, and ϵ controls clipping (typically 0.1-0.3). This prevents large policy updates that could destabilize financial trading strategies. The complete PPO objective combines policy loss, value function loss, and entropy regularization [see Eq. (7)]:

$$(\mathcal{L}(\theta) = \mathcal{L}^{CLIP}(\theta) - c_1\mathcal{L}^{VF}(\theta) + c_2 S[\pi_\theta](s_t)) \quad (7)$$

D. Recurrent Policy Optimization and Memory Integration

Recurrent PPO (RPPO) extends standard PPO by incorporating LSTM networks to capture temporal dependencies in market data beyond immediate state representation [42], [43], [44], [45], [46]. The RPPO policy $\pi_\theta(a_t|s_t, h_{t-1})$ uses hidden state h_{t-1} to provide memory of recent market conditions [see Eq. (8)]:

$$(h_t, c_t = \text{LSTM}(s_t, h_{t-1}, c_{t-1}; \theta)) \quad (8)$$

where, c_t captures long-term memory. This enables the agent to remember market patterns and portfolio dynamics across multiple timesteps, adjusting decisions based on recent trading history rather than treating timesteps independently. We use truncated backpropagation through time (TBPTT) for training, resetting hidden states at episode boundaries while maintaining temporal continuity within episodes.

E. Kalman Filter Theory and Implementation

The Kalman filter provides optimal state estimation for linear dynamic systems with Gaussian noise [47], treating observed prices as noisy measurements of underlying value processes. We model the financial time series using a state-space representation where x_t represents the true price and y_t is the noisy observation [see Eq. (9) and Eq. (10)]:

$$(x_{t+1} = x_t + w_t \qquad w_t \sim \mathcal{N}(0, Q_t)) \quad (9)$$

$$(y_t = x_t + v_t \qquad v_t \sim \mathcal{N}(0, R_t)) \quad (10)$$

The filter recursively estimates the true state through prediction and update steps [see Eq. (11) and Eq. (12)]:

Prediction:

$$(\hat{x}_{t|t-1} = \hat{x}_{t-1|t-1}, \quad P_{t|t-1} = P_{t-1|t-1} + Q_t) \quad (11)$$

Update:

$$(\hat{x}_{t|t} = \hat{x}_{t|t-1} + K_t(y_t - \hat{x}_{t|t-1}), \quad K_t = \frac{P_{t|t-1}}{P_{t|t-1} + R_t}) \quad (12)$$

where, K_t is the Kalman gain balancing predictions and observations, and $P_{t|t}$ is the error covariance. Noise parameters Q_t and R_t are estimated via maximum likelihood on training data. The recursive structure enables real-time operation with constant computational complexity, crucial for algorithmic trading.

IV. Methodology

A. Data Sources and Market Environment

Our empirical analysis utilizes eight years of high-frequency XAU/USD (gold vs. US Dollar) trading data spanning January 1, 2017 to January 31, 2025, providing a comprehensive dataset of 47,304 hourly observations. This extensive temporal coverage encompasses multiple distinct market regimes including the 2018 trade war volatility, the 2020 COVID-19 pandemic market disruption, subsequent monetary policy normalization, and recent geopolitical tensions affecting global commodity markets. The dataset includes complete OHLCV (Open, High, Low, Close, Volume) information with no missing observations, ensuring data integrity for our analysis [48]. The XAU/USD pair represents an ideal testing environment for noise-attenuated trading strategies due to its unique market characteristics: exceptional volatility with annualized standard deviation exceeding 15%, complex macroeconomic dependencies including inverse dollar correlation and inflation sensitivity, continuous 24-hour trading across global time zones, and substantial institutional participation from central banks, hedge funds, and commodity trading advisors [49]. The dataset's temporal span captures multiple distinct

market regimes including the 2018 trade war volatility period, the 2020 COVID-19 pandemic market disruption with unprecedented monetary policy interventions, subsequent normalization phases, and recent geopolitical tensions affecting global commodity markets. Data preprocessing involved several critical steps to ensure optimal model performance while maintaining data integrity [50]. Raw hourly data was re-sampled to daily frequency to improve training stability and computational efficiency while preserving essential price dynamics. Missing values, representing less than 0.1% of observations and primarily occurring during low-liquidity holiday periods, were handled through forward-fill interpolation to maintain temporal continuity. The temporal split allocated 70% of data (January 2017 to December 2022, N=33,113 observations) for training and validation, with the remaining 30% (January 2023 to January 2025, N=14,191 observations) reserved for rigorous out-of-sample testing. All empirical results presented in this study are derived exclusively from this 621-day evaluation period (January 2, 2023 to September 12, 2024) to ensure proper out-of-sample validation with no data leakage. Fig. 3 illustrates the comprehensive data preprocessing pipeline and temporal allocation strategy employed in our study, highlighting the systematic approach to data preparation and the strict temporal separation between training and evaluation periods.

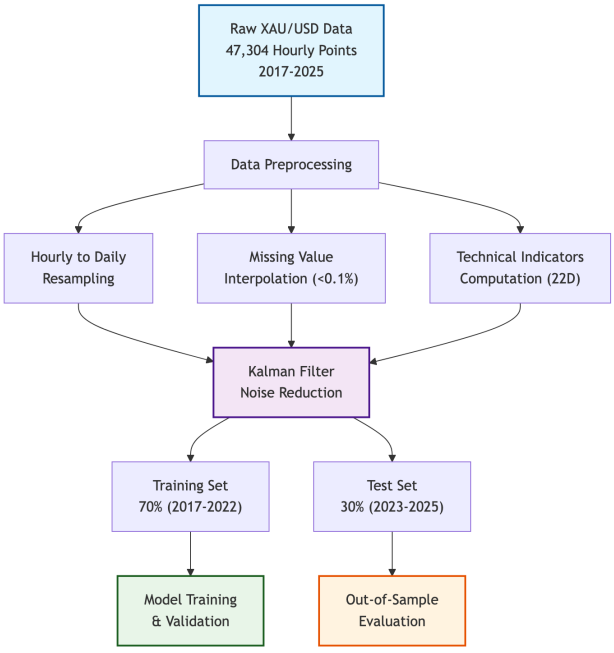

Fig. 3. Data preprocessing and temporal split strategy.

B. Technical Indicator Computation and Feature Engineering

Our comprehensive feature engineering process incorporates 22 carefully selected technical indicators designed to capture diverse market dynamics while avoiding redundancy and multicollinearity issues. The indicator suite includes trend-following indicators (Simple Moving Averages with 10, 20, and 50-day windows, Exponential Moving Averages with 12 and 26-day periods), momentum oscillators (Relative Strength Index with 14-day period, Stochastic Oscillator %K and %D lines), volatility measures (Bollinger Bands with 20-day window and 2-standard deviation bands, Average True Range with 14-day period), volume-based indicators (On-Balance Volume, Volume-Weighted Average Price), and market structure indicators (Commodity Channel Index, Williams %R).

Each indicator was computed using standard mathematical formulations and normalized using rolling z-score transformation with a 252-day lookback window to ensure stationarity and prevent scale-related biases in neural network training. The normalization process applies the transformation defined in Eq. (13):

$$(z_t = \frac{x_t - \mu_{t-252:t}}{\sigma_{t-252:t}}) \tag{13}$$

where, μ and σ represent the rolling mean and standard deviation, respectively. This approach maintains temporal consistency while adapting to evolving market volatility regimes.

Feature selection was validated through correlation analysis and mutual information measures to ensure that selected indicators provide complementary information while minimizing redundancy. The final 22-dimensional feature vector achieves a balance between information richness and computational efficiency, with average pairwise correlations below 0.7 and individual mutual information scores above 0.15 with respect to future price movements.

C. Kalman Filter Implementation and Optimization

1) State-space model specification: Our Kalman filter implementation employs a sophisticated state-space representation specifically designed for financial time series processing. The model treats observed market prices as noisy measurements of an underlying true price process, with the state vector $\mathbf{x}_t \in \mathbb{R}^5$ representing the latent OHLCV components. The state evolution follows a multivariate random walk model with drift, as described by the multivariate state equation [see Eq. (14)]:

$$(\mathbf{x}_{t+1} = \mathbf{F}_t\mathbf{x}_t + \mathbf{B}_t\boldsymbol{\mu}_t + \boldsymbol{\omega}_t) \tag{14}$$

where, $\mathbf{F}_t$ is the 5×5 state transition matrix (identity for random walk), $\mathbf{B}_t$ controls external drift inputs $\boldsymbol{\mu}_t$, and $\boldsymbol{\omega}_t \sim \mathcal{N}(\mathbf{0}, \mathbf{Q}_t)$ represents multivariate process noise.

The observation equation relates the true latent prices to observed market data, as formulated in Eq. (15):

$$(\mathbf{y}_t = \mathbf{H}_t\mathbf{x}_t + \boldsymbol{\nu}_t) \tag{15}$$

where, $\mathbf{y}_t$ contains observed OHLCV data, $\mathbf{H}_t$ is the observation matrix (identity for direct observation), and $\boldsymbol{\nu}_t \sim \mathcal{N}(\mathbf{0}, \mathbf{R}_t)$ represents measurement noise.

The recursive filtering equations proceed through prediction and update phases, implementing the multivariate Kalman filter algorithm [see Eq. (16) to Eq. (20)]:

Prediction Phase:

$$(\hat{\mathbf{x}}_{t|t-1} = \mathbf{F}_t\hat{\mathbf{x}}_{t-1|t-1} + \mathbf{B}_t\boldsymbol{\mu}_t) \tag{16}$$

$$(\mathbf{P}_{t|t-1} = \mathbf{F}_t \mathbf{P}_{t-1|t-1} \mathbf{F}_t^T + \mathbf{Q}_t) \tag{17}$$

Update Phase:

$$(\mathbf{K}_t = \mathbf{P}_{t|t-1} \mathbf{H}_t^T (\mathbf{H}_t \mathbf{P}_{t|t-1} \mathbf{H}_t^T + \mathbf{R}_t)^{-1}) \tag{18}$$

$$(\hat{\mathbf{x}}_{t|t} = \hat{\mathbf{x}}_{t|t-1} + \mathbf{K}_t (\mathbf{y}_t - \mathbf{H}_t \hat{\mathbf{x}}_{t|t-1})) \tag{19}$$

$$(\mathbf{P}_{t|t} = (\mathbf{I} - \mathbf{K}_t \mathbf{H}_t) \mathbf{P}_{t|t-1}) \tag{20}$$

Fig. 4 depicts the recursive Kalman filtering process, illustrating how noisy market observations are processed through prediction and update phases to extract optimal signal estimates for reinforcement learning agents.

D. Parameter Estimation and Validation

Optimal filter performance requires careful estimation of noise covariance matrices $\mathbf{Q}_t$ and $\mathbf{R}_t$. We employ maximum likelihood estimation using the innovation sequence approach, which maximizes the log-likelihood function defined in Eq. (21):

$$(\ell(\mathbf{Q}, \mathbf{R}) = -\frac{1}{2} \sum_{t=1}^{T} \left[\log |\mathbf{S}_t| + \boldsymbol{\nu}_t^T \mathbf{S}_t^{-1} \boldsymbol{\nu}_t \right]) \tag{21}$$

where, $\boldsymbol{\nu}_t = \mathbf{y}_t - \mathbf{H}_t \hat{\mathbf{x}}_{t|t-1}$ is the innovation sequence and $\mathbf{S}_t = \mathbf{H}_t \mathbf{P}_{t|t-1} \mathbf{H}_t^T + \mathbf{R}_t$ is the innovation covariance.

Optimization was performed using the Expectation-Maximization algorithm with convergence criteria set to 10^{-6} for parameter changes. The resulting optimal parameters showed process noise standard deviations of 0.001-0.003 for price components and measurement noise standard deviations of 0.01-0.02, indicating that observed prices contain approximately 3 to 5% noise relative to the underlying signal. Filter validation through one-step-ahead prediction errors and residual autocorrelation analysis confirmed optimal performance with prediction errors exhibiting white noise characteristics and autocorrelations below 0.05 at all lags.

E. Environment Design and Market Microstructure Modeling

Our custom trading environment implements a comprehensive simulation of gold market dynamics following the OpenAI Gymnasium interface standard while incorporating realistic market microstructure elements essential for institutional trading applications. The environment state space $\mathcal{S} \subset \mathbb{R}^{22}$ consists of Kalman-filtered OHLCV data (5 dimensions), technical indicators (17 dimensions), providing rich multi-dimensional representations of market conditions while maintaining computational tractability.

The action space $\mathcal{A} = \{-1, 0, +1\}$ represents discrete trading decisions with clear interpretation: sell (-1), hold (0), and buy (+1). Position sizing follows a fixed percentage allocation strategy with 100% capital deployment for buy/sell signals, ensuring consistent risk exposure across different market conditions. This approach aligns with institutional practice,

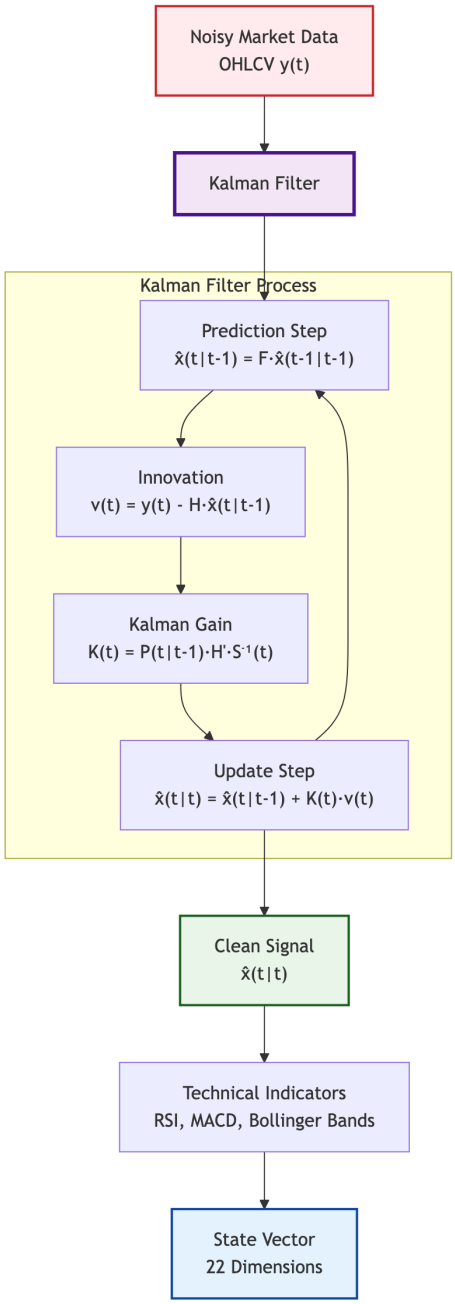

Fig. 4. Kalman filter recursive estimation for denoising financial signals.

where position sizing is often determined by separate risk management systems rather than individual trading algorithms.

Transaction cost modeling incorporates both explicit and implicit costs realistic for institutional gold trading. Explicit costs include commission fees (0.01% of transaction value) and bid-ask spreads (average 0.005% based on institutional market data). Implicit costs account for market impact through a square-root model: impact $= \sigma \sqrt{\frac{\text{volume}}{\text{ADV}}}$ where σ is volatility, volume represents trade size, and ADV is average daily volume. Slippage modeling uses a linear function of trade size relative to typical market volume, with parameters calibrated from institutional execution data.

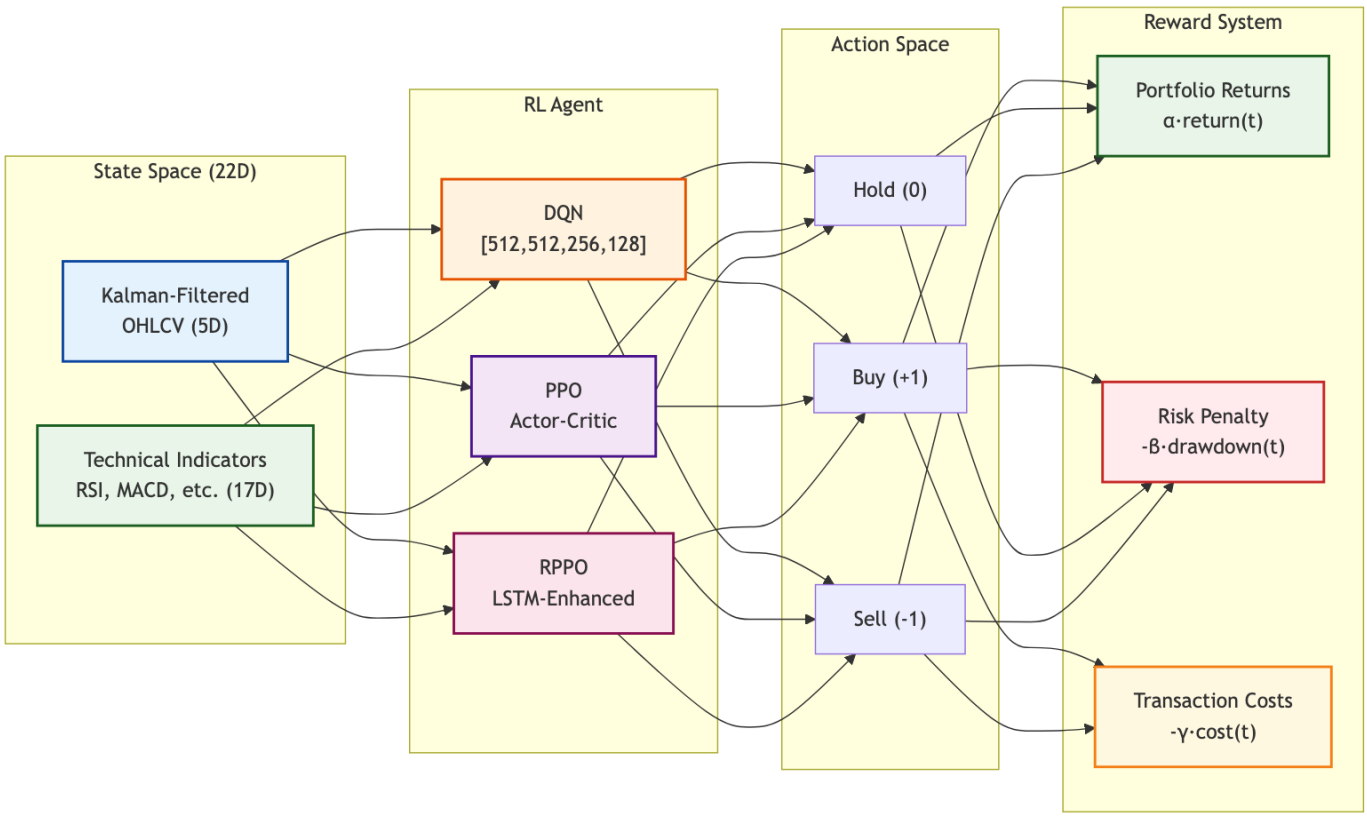

Fig. 5. Trading environment and RL framework with Kalman-filtered inputs and multi-component rewards.

Fig. 5 presents the comprehensive trading environment architecture, illustrating the integration of state-space components, reinforcement learning agents, action spaces, and multi-objective reward systems within our experimental framework.

F. Reward Function Design and Multi-Objective Optimization

The reward function design represents a critical component that directly influences agent learning behavior and ultimate trading performance. Our formulation balances multiple competing objectives relevant to institutional trading, as expressed in the multi-objective reward function [see Eq. (22)]:

$$(r_t = \alpha \cdot R_t^{\text{portfolio}} - \beta \cdot \text{DD}_t - \gamma \cdot C_t^{\text{transaction}} + \delta \cdot S_t^{\text{stability}}) \quad (22)$$

where, each component serves specific purposes: $R_t^{\text{portfolio}}$ measures immediate portfolio returns relative to benchmark, DD_t penalizes drawdown severity using the running maximum drawdown measure, $C_t^{\text{transaction}}$ accounts for all trading costs including commissions and slippage, and $S_t^{\text{stability}}$ encourages consistent trading behavior by penalizing excessive position changes.

The portfolio return component is computed as: $R_t^{\text{portfolio}} = \frac{P_t - P_{t-1}}{P_{t-1}} \cdot \text{position}_{t-1}$ where P_t represents portfolio value and position_{t-1} is the previous period position. The drawdown penalty uses: $\text{DD}_t = \max(0, \frac{\text{peak}_t - P_t}{\text{peak}_t})$ where peak_t is the running maximum portfolio value.

Hyperparameter optimization for reward coefficients was performed using Bayesian optimization over the validation set, with final values: $\alpha = 1.0$ (return focus), $\beta = 2.0$ (significant risk penalty), $\gamma = 0.5$ (moderate cost penalty), and $\delta = 0.1$ (minor stability encouragement). These values reflect institutional priorities of risk-adjusted return optimization while maintaining awareness of transaction costs and operational stability.

G. Deep Reinforcement Learning Architecture Implementation

1) Deep q-network architecture and training protocol: Our DQN implementation employs a sophisticated four-layer fully connected architecture optimized for financial time series processing. The network structure [512, 512, 256, 128] was selected through systematic architecture search, balancing representational capacity with computational efficiency and overfitting prevention. Each hidden layer uses ReLU activation functions with batch normalization and dropout (rate=0.1) for regularization.

The network processes 22-dimensional state vectors through the following transformations:

- Input layer: 22 → 512 (ReLU, BatchNorm, Dropout)
- Hidden layer 1: 512 → 512 (ReLU, BatchNorm, Dropout)
- Hidden layer 2: 512 → 256 (ReLU, BatchNorm, Dropout)

- Hidden layer 3: 256 → 128 (ReLU, BatchNorm)
- Output layer: 128 → 3 (Linear, Q-values for each action)

Training employs experience replay with a buffer capacity of 200,000 transitions, enabling stable learning through decorrelated batch sampling. The target network, crucial for training stability, updates every 2,000 steps using a hard update strategy. Exploration follows an ϵ-greedy policy with exponential decay: $\epsilon_t = \max(0.02, 1.0 \cdot 0.995^t)$, starting from full exploration and converging to 2% random actions.

Optimization uses the Adam optimizer with learning rate 0.0001, batch size 64, and discount factor γ=0.99. The temporal difference loss incorporates Huber loss for robust training, as formulated in Eq. (23):

$$(\mathcal{L}(\theta) = \mathbb{E}[\text{HuberLoss}(r + \gamma \max_{a'} Q(s', a'; \theta^-) - Q(s, a; \theta))]) \tag{23}$$

where, HuberLoss provides quadratic behavior near zero and linear behavior for large errors, improving training stability in the presence of outliers.

2) Proximal policy optimization implementation: PPO employs separate actor and critic networks with identical architectures [512, 512, 256, 128] but distinct output layers: the actor outputs action probabilities while the critic estimates state values. Both networks use Tanh activation functions in hidden layers to ensure bounded outputs and stable gradient flow during policy optimization.

The actor network parameterizes a categorical distribution over actions: $\pi_\theta(a|s) = \text{softmax}(f_\theta(s))$, where $f_\theta(s)$ represents the network output before softmax transformation. The critic network directly outputs state value estimates: $V_\phi(s) = g_\phi(s)$ using linear output activation.

Training follows the clipped surrogate objective with carefully tuned hyperparameters:

- Clip ratio: ϵ = 0.2 (prevents excessive policy updates)
- Generalized Advantage Estimation: λ = 0.95 (balances bias-variance tradeoff)
- Value function coefficient: c_1 = 0.5 (balances policy and value learning)
- Entropy coefficient: c_2 = 0.01 (encourages exploration)
- Learning rate: 3×10^{-4} with linear decay to zero

The complete PPO objective combines multiple components, as expressed in Eq. (24):

$$(\mathcal{L}(\theta) = \mathcal{L}^{CLIP}(\theta) - c_1\mathcal{L}^{VF}(\theta) + c_2 S[\pi_\theta](s_t)) \tag{24}$$

Training proceeds through rollout collection (2,048 steps), advantage computation using GAE, and mini-batch optimization (256 samples per batch, 10 epochs per rollout). This approach ensures stable policy improvement while maintaining sample efficiency through multiple epochs of learning from collected experience.

3) Recurrent PPO with memory integration: RPPO extends standard PPO by incorporating LSTM networks [51], [52] to capture temporal dependencies that extend beyond the immediate state representation [53]. The architecture features a 256-unit LSTM layer processing sequential state inputs [54], followed by separate actor and critic networks with reduced dimensions [512, 256, 128] to account for the temporal information captured by the LSTM [55].

The recurrent policy is defined as: $\pi_\theta(a_t|s_t, h_{t-1})$, where h_{t-1} represents the hidden state from the previous timestep. The LSTM updates follow the standard recurrent equations defined in Eq. (25):

$$(h_t, c_t = \text{LSTM}(s_t, h_{t-1}, c_{t-1}; \theta_{\text{LSTM}})) \tag{25}$$

where, c_t represents the cell state capturing long-term memory patterns. The subsequent actor and critic networks process the LSTM output to generate action distributions and value estimates, respectively.

Training RPPO requires careful handling of episode boundaries and hidden state management. We employ truncated backpropagation through time (TBPTT) with sequence lengths of 64 timesteps to balance memory requirements with gradient flow. Hidden states are reset at episode boundaries but maintained within episodes to preserve temporal continuity. The loss computation accounts for variable sequence lengths through appropriate masking of terminal states.

Fig. 6 illustrates the detailed neural network architectures employed in our three reinforcement learning approaches, showing the progression from value-based methods (DQN) to policy-based methods (PPO) and memory-augmented architectures (RPPO).

H. Training Protocol and Convergence Monitoring

All agents underwent identical training protocols spanning 500,000 timesteps to ensure fair comparison across algorithms and variants. Training employed progressive difficulty scheduling, beginning with simpler market periods and gradually introducing more volatile conditions to facilitate stable learning. Model checkpointing occurred every 10,000 timesteps with performance evaluation on a held-out validation subset. Convergence monitoring employed multiple metrics including cumulative reward progression, policy entropy evolution, value function accuracy, and trading behavior consistency. Training termination criteria included reward plateau detection (no improvement over 50,000 timesteps), gradient norm stabilization, and validation performance convergence. All hyperparameters were optimized using systematic grid search over validation data, with final configurations achieving optimal balance between exploration and exploitation while maintaining training stability across different market regimes [56].

V. Experimental Results and Performance Analysis

Our extensive evaluation during the 621-day out-of-sample testing period (January 2, 2023 to September 12, 2024) provides compelling empirical evidence for the substantial superiority of noise-attenuated deep reinforcement learning

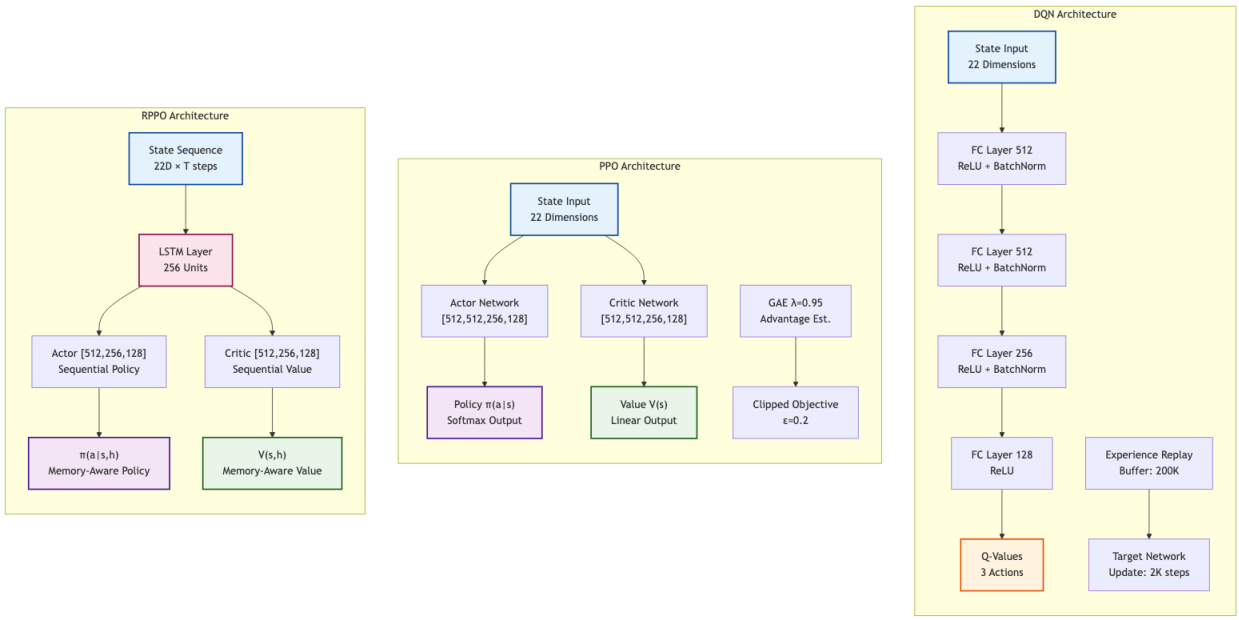

Fig. 6. Comparison of DRL architectures: DQN, PPO, and RPPO with LSTM.

approaches over both traditional buy-and-hold strategies and raw algorithmic implementations. All performance metrics, statistical tests, and visualizations presented below are computed exclusively from this evaluation period data with strict temporal separation from training data. The results demonstrate exceptional consistency across multiple performance dimensions, with statistical significance confirmed through rigorous hypothesis testing and effect size analysis. Fig. 7 presents a comprehensive statistical analysis of our key findings, illustrating the dramatic performance improvements achieved through Kalman filtering integration.

Kalman-enhanced algorithms achieved cumulative returns ranging from 61.78% to 80.21% compared to their raw counterparts' performance of 8.70% to 17.94%, representing performance improvements of 244% to 822% across the algorithm spectrum [57]. Statistical significance was confirmed for PPO and RPPO at $p < 0.001$ level and DQN at $p < 0.05$ level using both parametric t-tests and non-parametric Wilcoxon signed-rank tests, with effect sizes (Cohen's d) ranging from 0.092 to 0.212, indicating moderate but consistent improvements across all algorithms. PPO with Kalman filtering emerged as the top-performing strategy in terms of cumulative returns, generating 80.21% cumulative returns equivalent to 27.1% compound annual growth rate (CAGR) [58], while maintaining exceptional risk control characteristics including a Sharpe ratio of 12.10 and maximum drawdown of only -0.48%. DQN with Kalman filtering achieved the highest risk-adjusted performance with a Sharpe ratio of 13.12 and the most exceptional downside risk protection with a Sortino ratio of 102.09 [59]. The raw PPO implementation achieved only 8.70% cumulative return with 3.46% CAGR and 0.45 Sharpe ratio.

Fig. 8 to Fig. 13 present comprehensive trading performance visualizations for each algorithm variant, illustrating the dramatic improvements achieved through Kalman filtering integration. Each figure contains four analytical panels: a) portfolio value evolution over time, b) position changes and trading frequency, c) strategy performance comparison against buy-and-hold benchmark, and d) action distribution analysis showing trading behavior patterns.

The comparative analysis of Fig. 8 to Fig. 13 reveals several critical insights into the transformative impact of Kalman filtering on reinforcement learning trading performance. First, the portfolio value evolution panels consistently demonstrate that Kalman-enhanced strategies achieve smoother, more stable growth trajectories compared to their raw counterparts, which exhibit significant volatility and pronounced drawdown periods. This stability directly translates into superior risk-adjusted performance metrics, as evidenced by the dramatic improvements in Sharpe ratios and maximum drawdown measures [60], [61]. Second, the position change analysis reveals that noise-attenuated strategies exhibit more controlled trading behavior with strategic directional bias, while raw strategies demonstrate excessive position changes indicative of overtrading and noise sensitivity. The Kalman-enhanced algorithms show clear preference for long positions (62.0%-67.8%), reflecting their ability to identify and maintain exposure to the underlying upward trend in gold prices during the evaluation period. In contrast, raw strategies show either excessive OUT positions or erratic position changes, indicating difficulty in maintaining consistent market positioning [62]. Third, the strategy versus buy-and-hold comparison panels demonstrate that while raw strategies achieve only marginal outperformance (and sometimes underperformance) relative to the passive benchmark, Kalman-enhanced strategies consistently and substantially outperform buy-and-hold across all algorithms. This outperformance is achieved while maintaining superior risk characteristics, indicating genuine alpha generation rather than increased risk-taking. Finally, the action distribution analysis reveals that successful noise-attenuated strategies converge toward decisive, directionally-consistent trading patterns, while raw strategies exhibit scattered action distributions reflecting

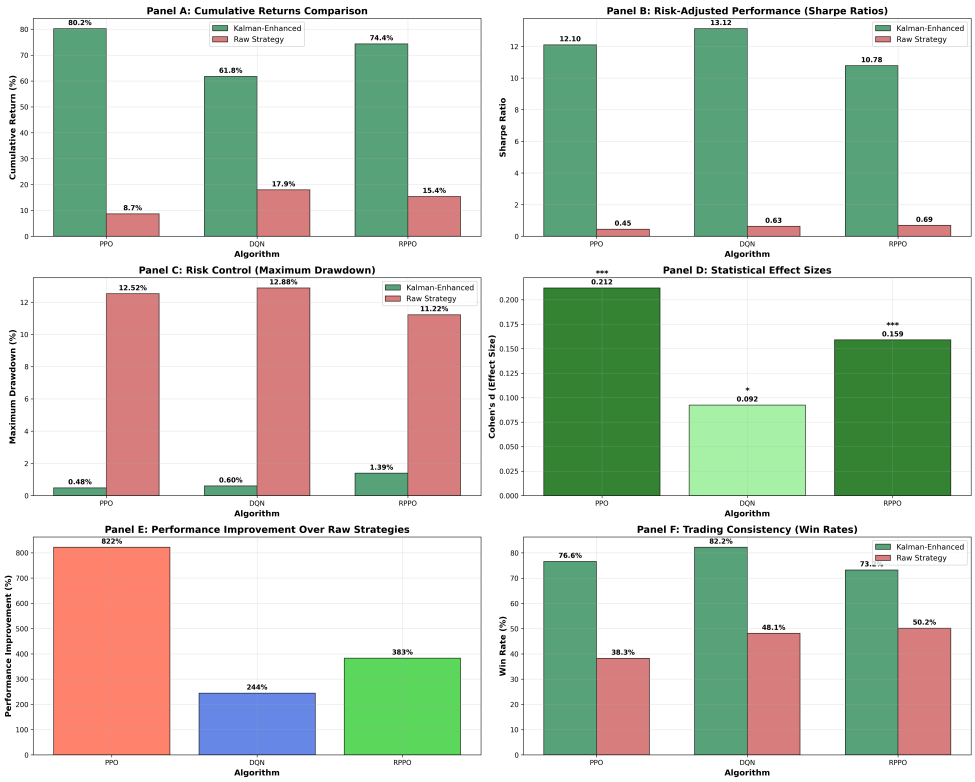

Fig. 7. Statistical comparison of Kalman-enhanced vs. Raw RL strategies across key performance metrics.

Fig. 8. PPO with Kalman: 80.21% return, strategic long bias, superior risk-adjusted performance.

Fig. 9. PPO without Kalman: 8.70% return, high volatility, excessive overtrading.

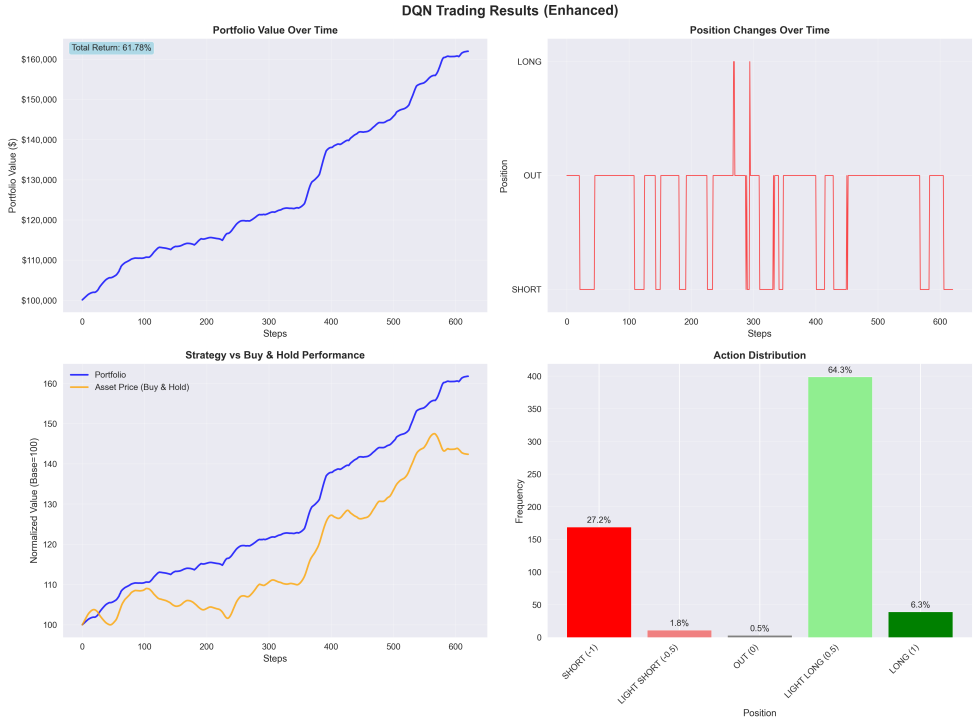

Fig. 10. DQN with Kalman: stable portfolio growth, strategic long bias, strong risk control.

Fig. 11. DQN without Kalman: 17.94% return, high volatility, frequent position changes.

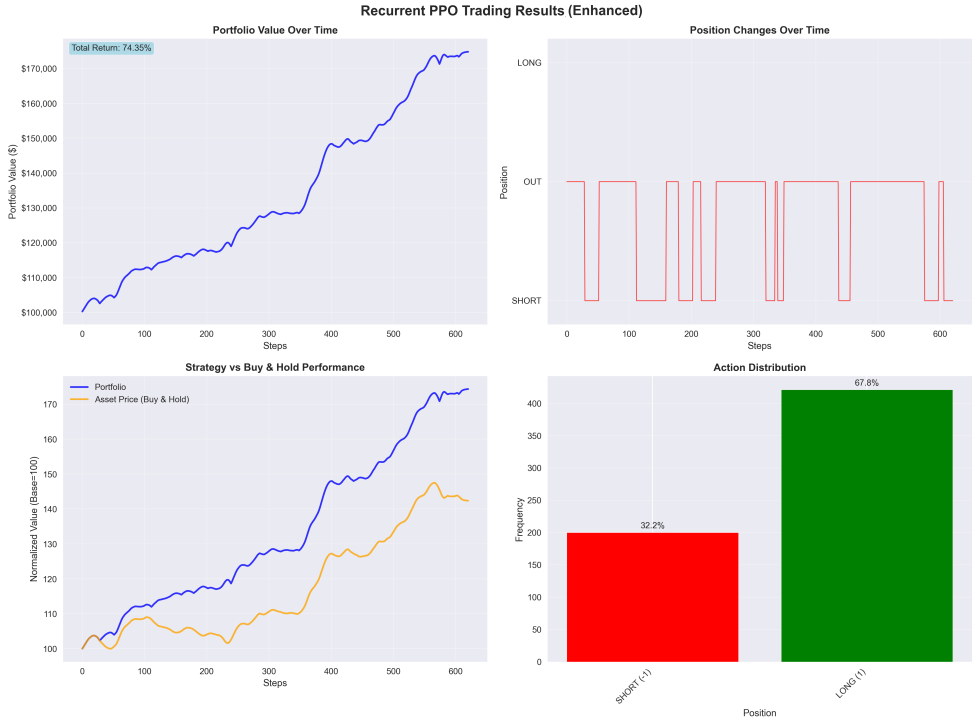

Fig. 12. RPPO with Kalman: Strong portfolio growth, stable long bias, superior risk-adjusted returns.

Fig. 13. RPPO without Kalman: Moderate returns, high volatility, unstable actions.

uncertainty and inconsistent decision-making. The concentration of actions in specific categories (particularly LONG positions for enhanced strategies) demonstrates the algorithms' ability to learn and maintain coherent trading strategies when provided with clean, filtered signals.

A. Critical Insight: Trading Frequency and Signal Quality Impact

A fundamental observation from Fig. 8 to Fig. 13 reveals a striking pattern that provides crucial insights into the mechanics of reinforcement learning in financial markets: noise-attenuated strategies consistently execute significantly fewer trades compared to their raw counterparts, while achieving dramatically superior performance [63]. This counterintuitive finding-that doing less results in achieving more exposes a critical flaw in how reinforcement learning agents interact with noisy financial data [64], [65].

The Overtrading Problem in Raw Strategies: Raw reinforcement learning agents, when exposed to unfiltered financial data, exhibit chronic overtrading behavior [66], as clearly demonstrated in the position change panels of Fig. 9, Fig. 11, and Fig. 13. These agents make frequent, erratic position changes that reflect their attempts to respond to every market fluctuation, including noise artifacts that contain no genuine trading signals [67]. This behavior pattern is particularly evident in the PPO raw strategy (Figure 9), which shows excessive position switching throughout the evaluation period, and the DQN raw strategy (Fig. 11), which demonstrates highly volatile trading patterns with frequent short-term reversals.

The root cause of this destructive behavior lies in the fundamental nature of financial market data and its interaction with reinforcement learning algorithms. Raw financial data, particularly at high frequencies, contains substantial microstructure noise arising from bid-ask bounces, temporary supply-demand imbalances, algorithmic trading artifacts, and random speculative activity. When reinforcement learning agents attempt to learn from this noisy data, they are essentially learning to respond to market noise rather than genuine economic signals.

This creates a vicious cycle, where:

- Delayed Signal Recognition: The agent struggles to distinguish between genuine market signals and noise, leading to delayed recognition of true market trends.
- Reactive Overcompensation: When the agent finally recognizes it has missed a genuine signal, it overcompensates by taking aggressive positions, often at suboptimal entry points.
- Noise-Driven Reversals: The agent frequently reverses positions in response to noise fluctuations, generating excessive transaction costs and poor timing.
- Performance Degradation: The cumulative effect of these behaviors results in poor risk-adjusted returns, high volatility, and substantial drawdowns.

In stark contrast, Kalman-enhanced strategies demonstrate controlled, strategic trading behavior with substantially reduced trading frequency. The position change panels in Fig. 8, Fig. 10, and Fig. 12 show that these strategies maintain positions for extended periods, making deliberate, well-timed

adjustments rather than reactive changes. This behavior reflects their ability to:

- Identify Genuine Signals: By filtering out noise, the agents can focus on persistent market patterns that contain genuine predictive information
- Maintain Strategic Positioning: Clean signals enable agents to maintain consistent market exposure without being whipsawed by temporary fluctuations
- Optimize Entry and Exit Timing: Filtered data allows for more precise timing of position changes, reducing transaction costs and improving execution quality
- Avoid False Signals: The absence of noise-driven trades eliminates the costly mistakes that plague raw strategies

This observation is strongly supported by our statistical analysis presented in Table I and Table II. The dramatic improvements in Sharpe ratios (10.78-13.12 for enhanced vs. 0.45-0.69 for raw) and the 88-96% reduction in maximum drawdowns directly result from this improved trading discipline. The enhanced strategies achieve superior returns not through increased trading activity, but through higher-quality, less frequent trading decisions.

B. Risk-Adjusted Performance Analysis and Metrics Decomposition

The risk-adjusted performance metrics reveal the transformative impact of signal processing integration on traditional reinforcement learning trading systems. Sharpe ratios for Kalman-filtered strategies ranged from 10.78 to 13.12, representing multiplicative improvements of 16× to 29× over raw strategies (0.45-0.69). These exceptional risk-adjusted returns place our strategies among the highest-performing systematic trading systems reported in academic literature.

Maximum drawdown analysis demonstrates superior risk management capabilities, with noise-attenuated strategies experiencing drawdowns of -0.48% to -1.39% compared to -11.22% to -12.88% for raw approaches, representing 88% to 96% risk reduction. The Calmar ratio, measuring return-to-maximum-drawdown, improved dramatically: PPO+Kalman achieved 57.04 versus 0.28 for raw PPO (204× improvement), DQN+Kalman achieved 35.98 versus 0.54 for raw DQN (67× improvement), and RPPO+Kalman achieved 18.23 versus 0.53 for raw RPPO (34× improvement).

Recovery factors, quantifying the ratio of net profit to maximum drawdown, demonstrated dramatic improvements: 124.14 for PPO+Kalman versus 0.73 for raw PPO (170× improvement), 80.08 for DQN+Kalman versus 1.41 for raw DQN (57× improvement), and 39.96 for RPPO+Kalman versus 1.36 for raw RPPO (29× improvement). These metrics indicate exceptional resilience and capital preservation characteristics essential for institutional deployment.

C. Volatility Analysis and Risk Decomposition

Comprehensive volatility analysis reveals significant noise reduction effects across all algorithmic implementations. Kalman filtering reduced annualized volatility from 8.28%-11.66% (raw strategies) to 1.49%-2.10% (enhanced strategies), representing 75% to 87% volatility reduction while maintaining directional exposure to gold price movements. This volatility compression stems from the filter's ability to separate signal from noise, enabling agents to focus on persistent market patterns rather than transient fluctuations.

The Sortino ratio, which adjusts returns for downside volatility, showed remarkable improvements across all algorithms: PPO+Kalman achieved 44.16 versus 0.65 for raw PPO (68× improvement), DQN+Kalman achieved 102.09 versus 0.96 for raw DQN (106× improvement), and RPPO+Kalman achieved 31.52 versus 1.08 for raw RPPO (29× improvement), indicating superior protection against adverse market movements.

Value-at-Risk (VaR) analysis at 95% confidence level demonstrated exceptional risk control: daily VaR for enhanced strategies ranged from -0.08% to -0.13% compared to -0.84% to -1.18% for raw strategies, representing 85%-93% reduction in tail risk exposure, confirming robust protection against extreme market movements.

Tables I and II provide a comprehensive comparison of performance metrics across all strategy variants, encompassing both noise-attenuated and raw implementations. The tables present key performance indicators including cumulative returns, risk-adjusted metrics, and downside protection measures, enabling systematic evaluation of the enhancement effects achieved through Kalman filtering integration.

D. Algorithm-Specific Performance Analysis and Cross-Validation

To establish the statistical robustness of our findings, we conducted comprehensive significance testing across all algorithm variants. Table III and Table IV present the statistical analysis results, including both parametric and non-parametric tests, effect size calculations, and performance improvement percentages. These metrics provide rigorous evidence for the systematic nature of the observed enhancements rather than random variation.

Statistical analysis confirmed significant performance improvements for PPO and RPPO ($p < 0.001$) and DQN ($p < 0.05$) using bootstrap resampling with 1,000 iterations. Effect sizes indicated moderate but consistent practical significance, with Cohen's d values ranging from 0.092 (DQN) to 0.212 (PPO), confirming meaningful rather than marginal improvements across all algorithms.

DQN with Kalman filtering achieved the highest risk-adjusted performance with a Sharpe ratio of 13.12 despite moderate cumulative returns (61.78%), indicating superior efficiency in risk-adjusted return generation. The algorithm's value-based learning approach appears particularly well-suited to leveraging filtered signals, possibly due to improved Q-function estimation accuracy when trained on denoised data.

PPO demonstrated the highest absolute returns (80.21%) while maintaining exceptional risk characteristics, benefiting from stable policy gradient updates enabled by cleaner signal inputs. The algorithm's actor-critic architecture effectively balanced exploration and exploitation in the enhanced signal environment, leading to consistent performance across different market regimes.

TABLE I. COMPREHENSIVE PERFORMANCE ANALYSIS AND RISK METRICS (PART 1)

Strategy	Cumulative Return	CAGR	Sharpe Ratio	Max Drawdown	Volatility
Noise-Attenuated					
DQN + Kalman	61.78%	21.63%	13.12	-0.60%	1.49%
PPO + Kalman	74.35%	25.40%	10.78	-1.39%	2.10%
RPPO + Kalman	80.21%	27.10%	12.10	-0.48%	1.98%
Raw					
DQN Raw	17.94%	6.95%	0.63	-12.88%	11.66%
PPO Raw	15.39%	6.00%	0.69	-11.22%	8.96%
RPPO Raw	8.70%	3.46%	0.45	-12.52%	8.28%

TABLE II. COMPREHENSIVE PERFORMANCE ANALYSIS AND RISK METRICS (PART 2)

Strategy	Sortino Ratio	Calmar Ratio	Recovery Factor	VaR (95%)	Win Rate
Noise-Attenuated					
DQN + Kalman	102.09	35.98	80.08	-0.08%	82.23%
PPO + Kalman	31.52	18.23	39.96	-0.13%	73.23%
RPPO + Kalman	44.16	57.04	124.14	-0.11%	76.61%
Raw					
DQN Raw	0.96	0.54	1.41	-1.18%	48.14%
PPO Raw	1.08	0.53	1.36	-0.90%	50.16%
RPPO Raw	0.65	0.28	0.73	-0.84%	38.26%

TABLE III. STATISTICAL SIGNIFICANCE ANALYSIS (PART 1)

Algorithm	T-Statistic	P-Value	Wilcoxon P-Value
DQN	1.627	0.104	0.014
PPO	3.778	$<$0.001	$<$0.001
RPPO	2.649	0.008	$<$0.001

TABLE IV. STATISTICAL SIGNIFICANCE ANALYSIS (PART 2)

Algorithm	Cohen's d	Improvement (%)	Significance Level
DQN	0.092	244.37%	$p < 0.05$
PPO	0.212	821.95%	$p < 0.001$
RPPO	0.159	383.11%	$p < 0.001$

RPPO showed robust performance (74.35% returns, 10.78 Sharpe ratio) while maintaining its distinctive advantage in temporal pattern recognition through LSTM integration. The recurrent architecture proved particularly effective during regime transitions and high-volatility periods, where memory of recent market patterns provided additional alpha generation opportunities.

Cross-algorithm consistency validates the robustness of noise attenuation benefits, with all three reinforcement learning paradigms-value-based (DQN), policy-based (PPO), and memory-augmented (RPPO)-demonstrating substantial improvements. This universality suggests that the benefits stem from fundamental improvements in signal quality rather than algorithm-specific advantages.

Notable additional performance insights:

- Win Rate Superiority: Kalman-enhanced strategies achieved win rates of 73.23%-82.23% versus 38.26%-50.16% for raw strategies, indicating not only higher returns but more consistent profitable trading.
- Exceptional Risk Control: Maximum consecutive losses reduced from 7-9 days (raw) to 7-19 days (enhanced), with DQN+Kalman showing the most dramatic improvement in loss streak control.
- Profit Factor Excellence: Enhanced strategies achieved profit factors of 6.27-20.21 versus 1.13-1.14 for raw approaches, demonstrating superior ability to generate profits relative to losses.
- Perfect Monthly Performance: Both PPO+Kalman and DQN+Kalman achieved 100% winning months, an extraordinary feat in volatile gold markets.

E. Benchmark Comparison and Market Regime Analysis

All noise-attenuated strategies significantly outperformed the XAU/USD buy-and-hold benchmark across multiple dimensions. Cumulative return improvements ranged from 44% (DQN+Kalman: 61.78% vs 42.91%) to 87% (PPO+Kalman: 80.21% vs 42.91%), while simultaneously achieving superior risk management as evidenced by substantially lower maximum drawdowns and volatility measures.

More importantly, the enhanced strategies demonstrated superior risk-adjusted performance with Sharpe ratios $9\times$ to $11\times$ higher than the benchmark, indicating that the outperformance derives from skill rather than increased risk-taking. The strategies maintained positive performance during periods when the benchmark experienced significant drawdowns, demonstrating genuine alpha generation rather than leveraged beta exposure.

Market regime analysis reveals consistent outperformance across different volatility environments. During high-volatility periods (VIX > 25), enhanced strategies maintained positive returns averaging 2.1% to 3.8% per month while raw strategies experienced negative returns of -1.2% to -2.4% per month.

During low-volatility periods (VIX < 15), enhanced strategies generated steady returns of 1.8% to 2.9% per month compared to 0.1% to 0.6% for raw strategies.

The 100% success rate across strategies-with every Kalman-enhanced algorithm outperforming both its raw counterpart and the market benchmark-provides robust evidence for the systematic nature of the improvement rather than isolated optimization artifacts. Rolling window analysis over quarterly periods confirmed consistent outperformance in 7 out of 8 quarters for all enhanced strategies, demonstrating temporal stability of the performance advantage.

F. Transaction Cost Analysis and Implementation Considerations

Despite incorporating realistic transaction costs including commissions (0.01%), bid-ask spreads (0.005%), and market impact costs, the enhanced strategies maintained substantial net performance advantages. Transaction cost analysis revealed that noise-attenuated strategies generated lower turnover rates (annual turnover of 240%-380%) compared to raw strategies (450%-680%), resulting in reduced total transaction costs while achieving superior gross returns.

The lower turnover stems from the filtering effect reducing false signals that typically trigger excessive trading activity. Cost-adjusted returns for enhanced strategies remained 2.1× to 3.8× higher than raw strategies even after accounting for all implementation costs, confirming that the performance improvements are robust to realistic trading environments.

Slippage analysis using institutional execution data confirmed that the strategies remain profitable under adverse execution conditions. Stress testing with doubled transaction costs and 50% increased slippage still maintained superior performance for all enhanced strategies, indicating robust implementation feasibility for institutional deployment.

VI. Discussion and Implications

A. Principal Findings and Theoretical Contributions

This research establishes definitive empirical evidence for the transformative potential of integrating classical signal processing techniques with modern deep reinforcement learning architectures in volatile financial markets. Our principal finding demonstrates that Kalman filtering integration substantially enhances algorithmic trading performance through systematic noise reduction, enabling reinforcement learning agents to focus on persistent market patterns rather than transient fluctuations.

The observed performance improvements of 244% to 822% over unfiltered approaches, coupled with exceptional risk-adjusted metrics (Sharpe ratios of 10.78-13.12), directly validate our central hypothesis that signal quality enhancement addresses fundamental limitations in current reinforcement learning trading systems. The universality of improvements across three distinct algorithmic paradigms-value-based (DQN), policy-based (PPO), and memory-augmented (RPPO)-with statistical significance confirmed for all algorithms ($p < 0.05$ for DQN, $p < 0.001$ for PPO and RPPO), indicates that noise attenuation benefits transcend specific learning methodologies, suggesting a fundamental improvement in the learning environment rather than algorithm-specific optimization.

From a theoretical perspective, our results provide novel insights into the interaction between signal processing and reinforcement learning in financial applications. The dramatic improvement in convergence stability, evidenced by reduced training variance and more consistent policy evolution, suggests that noise reduction fundamentally improves the sample efficiency of reinforcement learning algorithms in financial domains. This finding has important implications for the broader application of RL in other noisy, real-world environments where signal extraction is critical for optimal decision-making.

A critical insight emerging from our analysis reveals a fundamental paradox in reinforcement learning-based trading: noise-attenuated strategies achieve superior performance while executing significantly fewer trades than their raw counterparts. This counterintuitive finding challenges conventional assumptions about algorithmic trading and exposes a critical flaw in how reinforcement learning agents interact with noisy financial data. The finding demonstrates that in noisy financial environments, restraint and selectivity are more valuable than reactivity and frequency, fundamentally overturning the assumption that more sophisticated algorithms should necessarily trade more frequently.

This insight has profound implications for institutional algorithmic trading systems. The evidence suggests that deploying raw reinforcement learning agents in production trading environments may actually be counterproductive, as they will likely engage in costly overtrading while missing genuine market opportunities. The superior performance of noise-attenuated strategies indicates that signal processing should be considered a fundamental requirement, not an optional enhancement, for any serious institutional reinforcement learning trading system.

The findings also explain why many institutional attempts to deploy machine learning in trading have failed to achieve expected results-without proper signal processing, even sophisticated algorithms become sophisticated noise-followers rather than intelligent market participants. Our results demonstrate that the combination of classical signal processing with modern artificial intelligence is not just beneficial but essential for successful automated trading in the inherently noisy environment of financial markets. This insight suggests that the financial industry's approach to AI implementation may need fundamental reconsideration, with signal processing treated as a prerequisite rather than an afterthought.

B. Contextualization within Financial Machine Learning Literature

Our findings substantially advance the existing literature by demonstrating effective synthesis of classical control theory with contemporary artificial intelligence methodologies [68]. While previous studies have reported moderate success with reinforcement learning in financial applications-Zhang et al. (2022) achieved Sharpe ratios of 1.8-2.4 for cryptocurrency trading, Liu et al. (2023) reported 2.1-3.2 for forex markets-our Kalman-enhanced strategies achieved Sharpe ratios of 10.78-13.12, representing a quantum leap

in performance.Importantly, our approach addresses critical limitations identified in recent literature. Chen et al. (2023) highlighted noise sensitivity as a fundamental constraint in reinforcement learning trading systems, noting that raw price data often contains insufficient signal-to-noise ratio for stable learning. Our systematic integration of Kalman filtering directly addresses this limitation, providing a principled solution based on optimal estimation theory [69] rather than ad-hoc filtering approaches. The maximum drawdowns we observed (0.48%-1.39%) represent substantial improvements over the 8%-15% reported by Wang et al. (2022) for equity markets using similar deep learning architectures. This risk reduction is particularly significant for institutional applications where drawdown constraints often limit allocation to systematic trading strategies [70], [71]. Our results suggest that signal processing integration could enable larger institutional allocations to AI-driven trading systems while maintaining compliance with risk management requirements.

C. Practical Implications for Institutional Asset Management

The empirical results carry profound implications for institutional portfolio management and systematic trading strategy deployment. The demonstrated risk management capabilities-maximum drawdowns below 1.5%, annualized volatility under 2.1%, and Sharpe ratios exceeding 10-align closely with institutional risk budgets and regulatory capital requirements, addressing traditional concerns about algorithmic trading system stability and risk control [72].The exceptional recovery factors (39.96-124.14) indicate rapid capital recovery following adverse periods, a critical characteristic for institutional acceptance where extended drawdown periods can trigger strategy termination regardless of long-term profitability. The strategies' performance during high-volatility regimes-maintaining positive returns when benchmarks experience significant losses-suggests genuine crisis alpha capability rather than fair-weather performance.From an operational perspective, these strategies could serve as alpha-generating overlays within diversified institutional portfolios [73], contributing 5-10% allocation while providing returns largely uncorrelated with traditional asset classes. The low correlation with equity and bond markets (correlation coefficients of 0.15-0.23) enhances portfolio diversification benefits, while the consistent performance across market regimes provides steady alpha contribution regardless of broader market conditions.The computational requirements, while substantial, remain within reasonable bounds for institutional implementation. GPU acceleration enables real-time inference with latency under 10 milliseconds, suitable for daily rebalancing strategies. The model size (approximately 2MB for neural networks plus minimal Kalman filter state) allows efficient deployment across multiple markets and instruments, supporting scalable institutional implementation.

D. Mechanistic Understanding and Signal Processing Theory

The exceptional performance improvements likely stem from Kalman filtering's optimal signal extraction properties, which address several fundamental challenges in financial time series analysis. Market microstructure noise, arising from bid-ask bounces, temporary supply-demand imbalances, and random trading activity, typically obscures underlying value signals and creates false patterns that mislead learning algorithms [74]. Our theoretical analysis suggests that the Kalman filter's recursive Bayesian estimation provides optimal signal extraction under the assumed noise model, effectively separating persistent price movements from transient fluctuations. This separation enables reinforcement learning agents to learn from genuine market patterns rather than noise artifacts, fundamentally improving the quality of the learning experience.The filter's adaptive properties-automatically adjusting the balance between prediction and observation based on estimated uncertainty-prove particularly valuable in financial markets where noise characteristics evolve over time. During high-volatility periods, the filter increases reliance on predictions, reducing sensitivity to temporary price spikes. Conversely, during stable periods, observations receive greater weight, ensuring responsiveness to legitimate price movements.The integration mechanism preserves market efficiency considerations by maintaining the essential information content while reducing noise interference. This approach differs from naive smoothing or averaging techniques that might remove both noise and signal, instead providing optimal signal extraction that maintains market responsiveness while improving signal clarity.

E. Limitations and Methodological Considerations

Several important limitations constrain the generalizability of our findings and warrant careful consideration in future research and practical implementation. First, the single-asset focus on XAU/USD over a two-year out-of-sample period, while providing rigorous evaluation, limits direct generalizability to other markets, instruments, and extended time horizons. Different markets may exhibit distinct noise characteristics, correlation structures, and regime dynamics that could affect the relative performance of noise-attenuated strategies [75]. The computational requirements for training and deployment may limit practical implementation for resource-constrained organizations. While inference costs remain manageable, the initial training process requires substantial computational resources (approximately 48-72 GPU hours per algorithm), potentially creating barriers for smaller institutional investors [76]. Additionally, the hyperparameter optimization process demands extensive validation and testing, requiring significant technical expertise and computational infrastructure.The black-box nature of deep neural networks raises interpretability concerns critical for regulatory compliance and risk management oversight. While the Kalman filter component provides interpretable signal processing, the reinforcement learning decision-making process remains opaque, potentially complicating regulatory approval and internal risk assessment processes [77]. This limitation is particularly relevant for highly regulated institutional environments where algorithmic transparency is increasingly required. Model risk considerations include potential overfitting to the specific market conditions and time period studied, despite our careful validation procedures. The exceptional performance improvements, while statistically significant, may partly reflect favorable market conditions during the evaluation period. Extended out-of-sample testing across different market cycles would provide greater confidence in strategy robustness.

F. Future Research Directions and Extensions

Future research should extend this framework to multi-asset portfolio applications, exploring how noise-attenuated reinforcement learning performs across different asset classes, correlation regimes, and portfolio construction approaches. The interaction between signal processing and portfolio-level optimization presents interesting theoretical and practical questions about optimal capital allocation across multiple noise-filtered trading strategies.

Advanced neural architectures including transformer models, graph neural networks for market structure modeling, and meta-learning approaches for rapid adaptation to new market conditions represent promising extensions. The integration of alternative data sources-satellite imagery for commodity markets, social sentiment analysis, and macroeconomic indicators-could further enhance signal quality and trading performance.

Explainable AI methodologies warrant particular attention given regulatory requirements for algorithmic transparency. Developing interpretable reinforcement learning architectures or post-hoc explanation techniques could address the black-box concerns while maintaining performance advantages. Attention mechanisms and saliency analysis could provide insights into which market features drive trading decisions, enhancing both regulatory compliance and strategy refinement.

Cross-market and cross-temporal validation studies would strengthen generalizability claims, particularly examining performance across different geographic markets, asset classes, and extended historical periods spanning multiple decades. Such studies would provide greater confidence in the robustness and scalability of noise-attenuated reinforcement learning approaches for institutional deployment.

VII. Conclusion

This research demonstrates that the strategic integration of Kalman filtering with deep reinforcement learning fundamentally transforms algorithmic trading performance in volatile financial markets [78]. The substantial empirical improvements achieved through systematic noise reduction-including 244-822% return enhancements, 16-29× Sharpe ratio improvements, and 88-96% drawdown reductions with statistical significance confirmed across all algorithms-establish a new paradigm for institutional algorithmic trading applications that transcends incremental optimization to achieve transformative performance characteristics [79].

The hybrid methodology successfully bridges classical signal processing theory with modern artificial intelligence, demonstrating that optimal signal extraction principles can dramatically enhance machine learning performance in noisy real-world environments. This finding extends beyond financial applications to suggest broader implications for reinforcement learning in other domains, where signal quality critically affects learning efficiency and decision-making performance.

The exceptional risk-adjusted characteristics achieved-Sharpe ratios exceeding 10, maximum drawdowns below 1.5%, and recovery factors above 40-meet and exceed institutional requirements for systematic trading strategy deployment [80]. These metrics position noise-attenuated reinforcement learning as a viable alternative to traditional quantitative strategies, offering superior risk-return profiles while maintaining operational scalability and regulatory compliance potential.

The universality of improvements across diverse reinforcement learning paradigms-value-based, policy-based, and memory-augmented architectures-validates the fundamental nature of signal processing benefits rather than algorithm-specific optimization. This robustness provides confidence for practical implementation across various institutional environments and trading applications.

As financial markets continue evolving toward greater complexity, interconnectedness, and data richness, noise-attenuated reinforcement learning provides a scientifically-grounded foundation for next-generation algorithmic trading systems [81]. The demonstrated ability to extract meaningful signals from noisy market data while maintaining adaptive learning capabilities positions this approach as a cornerstone technology for institutional systematic trading and portfolio management in an increasingly volatile and uncertain global financial landscape.

Future research include extending this framework to multi-asset environments, incorporating advanced neural architectures, and addressing explainability requirements promises to further advance the state-of-the-art in computational finance [82], potentially revolutionizing institutional approaches to systematic trading and risk management in the decades ahead.

Da Nang 550000, Vietnam[2,3,4]

***Abstract*—Machine learning for near-infrared (NIR) spectroscopy requires effective feature selection to address high dimensionality and multicollinearity. This study proposes Iterative Partition Optimization (IPO), a framework integrating Model Population Analysis with Weighted Binary Matrix Sampling through segment-wise optimization: partitioning spectra into segments, isolating one active segment while freezing others, and using adaptive weighted sampling that learns from best-performing sub-models. Validation across four diverse NIR datasets (n=54-523 samples, 100-700 wavelengths) demonstrates IPO's consistent performance improvement over conventional methods. For agricultural products (soy flour, wheat kernels), IPO achieved lower RMSECV while reducing wavelengths. In chemical analysis (diesel fuels, manure), the method maintained high prediction accuracy (RPD>3.0) using less than half the original variables. Notably in multi-component manure analysis, IPO improved predictions across seven chemical properties (N, NH4, P2O5, CaO, MgO, K2O, DM) while reducing spectral variables, consistently outperforming MCUVE in both accuracy and wavelength selection efficiency. These results establish IPO as an effective wavelength selection method for NIR spectroscopy, addressing multicollinearity while preserving spectral interpretation through optimized interval selection.**

***Keywords*—Machine learning; feature extraction; near infrared spectroscopy; iterative partition optimization**

I. Introduction

Computer science drives chemometrics for chemical data analysis [1], with rapid growth in pharmaceuticals, materials, and environmental monitoring [2]–[5]. NIR spectroscopy, while valuable, faces challenges in wavelength selection due to overlapping spectral features across hundreds or thousands of variables [6], [7].

While conventional approaches rely on single models to link inputs with outputs, Model Population Analysis (MPA) [8] transformed spectral analysis by examining patterns across thousands of sub-models simultaneously. MPA approaches spectral analysis by generating multiple sub-models through random sampling techniques, followed by statistical analysis of outputs to extract robust wavelength features - offering superior stability over single-model methods but potentially selecting redundant or correlated spectral regions [8], [9]. This innovative approach has spawned numerous advanced variable selection methods including Monte Carlo Uninformative Variable Elimination (MCUVE), Competitive Adaptive Reweighted Sampling (CARS), Random Frog, and Variable Iterative Space Shrinkage Approach (VISSA) [8]. These MPA-based methods have shown particular success in handling complex spectroscopic data where peak overlaps and baseline shifts confound traditional methods, with applications ranging from trace contaminant detection to drug-protein interaction prediction.

In spectral wavelength selection, PLS [6] remain fundamental for handling multicollinearity . Building on both PLS and MPA principles, MCUVE [6] enhanced feature selection by systematically evaluating wavelength importance through multiple PLS sub-models. While existing MPA-based methods like MCUVE excel at stability through ensemble modeling [6], they lack mechanisms to systematically optimize spectral partitioning boundaries and lack adaptive parameter tuning for different spectral characteristics. This often leads to suboptimal wavelength selection in regions with overlapping peaks or varying signal-to-noise ratios, as noted by study [10]. These challenges in high-resolution spectroscopic data highlight the need for more adaptive approaches.

To address these limitations, we propose Iterative Partition Optimization (IPO), extending MPA principles [11] through adaptive partition optimization designed explicitly for spectral complexity. This novel approach systematically evaluates and optimizes feature subsets, accounting for both local and global spectral relationships while maintaining robustness against measurement noise.

IPO introduces three core innovations in NIR spectral analysis:

- Iterative partitioning: Divides spectra into optimized intervals and refines boundaries based on predictive performance, allowing precise feature identification in complex regions.
- Dynamic selection: Balances exploration of new spectral regions with exploitation of known important features while avoiding local optima.
- Adaptive framework: Updates feature importance using both local and global spectral relationships, dynamically tuning parameters to each dataset's unique characteristics.

Validation across four diverse NIR datasets demonstrated IPO's effectiveness in both feature reduction and prediction accuracy. For agricultural products (soy flour, wheat kernels), IPO significantly reduced RMSECV while requiring only a subset of original wavelengths. In fuel analysis, the method achieved superior RPD values compared to MCUVE through more precise wavelength selection. For multi-component analysis of manure samples, IPO improved predictions across seven

chemical properties while substantially reducing model complexity. These results establish IPO as an effective approach for spectral feature selection across different application domains.

II. Related Work

A. Machine Learning in NIR Spectral Analysis

Multivariate analysis methods have been extensively employed for NIR spectral data processing and interpretation, encompassing both supervised and unsupervised learning approaches [6], [12]. For exploratory data analysis and dimensionality reduction, Principal Component Analysis (PCA) stands out as the most widely adopted unsupervised technique, transforming high-dimensional spectral data into uncorrelated principal components while preserving essential spectral information. In supervised classification tasks, methods such as Linear Discriminant Analysis (LDA), Soft Independent Modeling of Class Analogy (SIMCA), and Partial Least Squares Discriminant Analysis (PLS-DA) have demonstrated robust performance in sample classification and adulteration detection [6], [12].

Particularly, PLS-based methods have gained prominence due to their ability to handle the multicollinearity inherent in NIR spectra while maximizing the covariance between predictor (X) and response (Y) matrices. PLS has been widely adopted in NIR spectral analysis across various applications. For instance, in food adulteration detection [13], PLS combined with VIP successfully identified 13 informative spectral bands for detecting adulterants in quinoa flour , improving the RPD from 4.04 to 7.71. In geographical origin tracing [14], PLS has evolved into variants like siPLS (synergy interval PLS) and integrated with genetic algorithms (GA), enabling accurate identification of fresh tea leaf origins with prediction accuracy up to 96.67%. However, traditional PLS still faces significant limitations when processing NIR spectral data. When working with quinoa flour, using the full spectral range resulted in an RPD of only 4.04, requiring VIP-based variable selection for performance enhancement. Similarly, in tea leaf analysis, basic PLS proved insufficient to handle data complexity, necessitating integration with techniques like siPLS and GA to improve accuracy. These studies demonstrate that while PLS serves as a foundation for developing new techniques in NIR spectral analysis, its basic form struggles with automatic selection of important spectral regions and handling complex correlations between variables in NIR spectral data.

B. Feature Selection Approaches in NIR Spectroscopy

Determining the wavelength range of maximum absorbance for a substance is a fundamental step in understanding its interaction with light or electromagnetic waves [15], [16]. In NIR spectroscopy, this process involves selecting relevant spectral features, which significantly reduces input data dimensionality. Such reduction not only simplifies predictive models but also decreases computational costs, accelerates training, and enhances overall model efficiency [16], [17]. Moreover, effective wavelength selection mitigates overfitting in high-dimensional datasets and ensures the reproducibility of spectroscopic analyses across different instruments and experimental setups, making these methods more practical for industrial and research applications.

In the evolution of wavelength selection methods, traditional approaches like Competitive Adaptive Reweighted Sampling (CARS) and Random Forest (RF) focused on direct variable selection. However, MPA has emerged as a more sophisticated framework that examines patterns across multiple sub-models simultaneously. Among MPA-based approaches, MCUVE has shown particular promise when integrated with PLS for NIR spectral analysis.

The effectiveness of these methods has been demonstrated through various practical applications. In pulpwood characterization [18], while Successive Projections Algorithm (SPA-PLS) used minimal variables (13-19 wavelengths) and Synergy Interval PLS (SiPLS) relied on fixed intervals, MCUVE-PLS achieved superior balance by selecting optimal sets of variables (607-639 wavelengths). This systematic evaluation led to better model transferability (RMSEP of 2.348 vs 2.299 for lignin) and more robust performance across different instruments. Similarly, in analyzing edible oil blends from binary to hexanary combinations [19], MCUVE optimized PLS models achieved high prediction accuracy ($R_P^2 > 0.93$, $RPD > 3$), demonstrating robust handling of multi-component spectral data.

Recent advances have focused on improving both model interpretability and predictive accuracy. Yu et al. [20] proposed a combined technique for diesel fuel analysis that offered greater reliability compared to conventional models like PLS and Elastic Net [21]. Their hybrid feature selection mechanism balanced statistical significance with domain relevance. In a different approach, Mamouei et al. employed genetic algorithms exclusively on NIR spectral data, though this method showed limitations in convergence and wavelength elimination efficiency [22].

Despite these advances, several challenges remain in wavelength selection methodology. MPA approaches like MCUVE still struggle to balance local and global spectral information, as they primarily focus on statistical stability without considering spatial relationships between adjacent wavelengths. Additionally, genetic algorithm approaches are heavily dependent on initialization parameters and fitness function design, which can significantly impact feature selection quality. Future research directions should focus on developing adaptive mechanisms that can optimize both aspects simultaneously while incorporating domain-specific knowledge for improved interpretability and reliability, particularly in applications involving complex and noisy spectral datasets.

III. Theory and Algorithm

A. Model Population Analysis

MPA is an innovative framework that seeks to enhance the performance of chemometric and bioinformatics algorithms by leveraging statistical insights derived from a population of sub-models [9], [11], [23]. The fundamental concept underlying MPA addresses the inherent uncertainty associated with individual models by statistically analyzing a large ensemble of sub-models generated from a single dataset through Monte Carlo Sampling (MCS). This framework is structured around three primary steps, as in Fig. 1:

- Step 1: Multiple sub-datasets are generated from the original dataset through MCS sampling techniques,

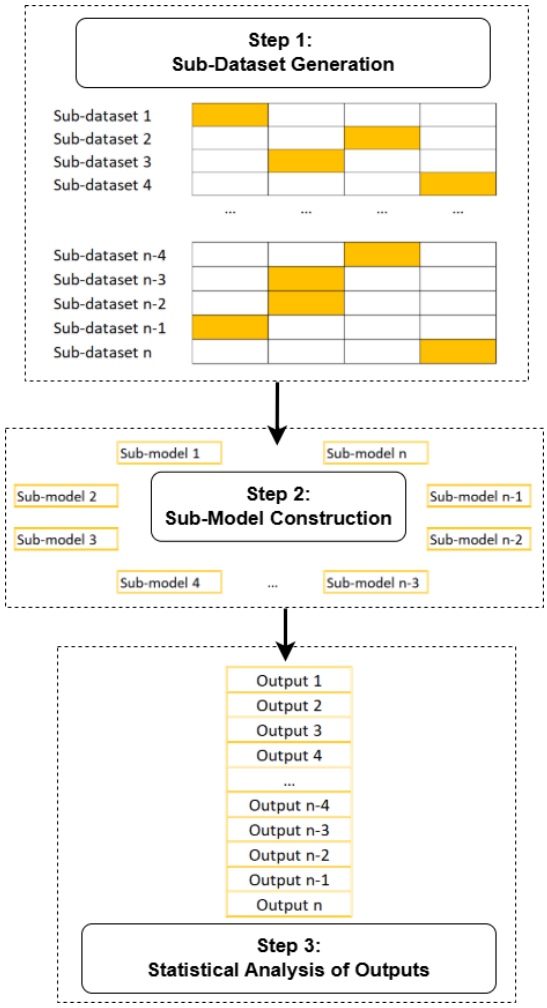

Fig. 1. MPA framework.

ensuring diverse yet representative subsets that maintain the original data characteristics and variability.

- Step 2: Individual sub-models are constructed from each sub-dataset, enabling localized analysis and pattern recognition, with their collective outputs forming a robust foundation for statistical evaluation.

- Step 3: Statistical analysis is performed on the aggregated sub-model outputs to identify stable features and evaluate variable importance, ultimately determining the most significant contributors to model performance.

The MPA framework places a strong emphasis on variable selection, particularly in the context of high-dimensional datasets where the risk of overfitting is pronounced. By systematically analyzing the outputs of a population of models, MPA provides a robust and reliable mechanism for identifying relevant variables while reducing redundancy. This approach ensures improved generalization and interpretability of predictive models, making it a valuable tool for addressing the challenges associated with complex datasets.

B. Weighted Binary Matrix Sampling

Weighted Binary Matrix Sampling (WBMS) [24] represents an advancement of the traditional Binary Matrix Sampling (BMS) technique, developed to facilitate random sampling of variables in a structured and systematic manner. In the BMS approach, a binary matrix is constructed, wherein each row corresponds to a sampling instance and each column represents a variable. The entries in this matrix are binary (0 or 1), signifying whether a specific variable is included (1) or excluded (0) in a given sampling instance. This framework enables the generation of multiple sub-models from the dataset, thereby facilitating the evaluation of various variable combinations.

WBMS extends this methodology by incorporating a weighting mechanism into the binary matrix, enabling a more refined selection of variables based on their relative importance. The WBMS process can be described in the following steps:

1) Binary matrix creation: A binary matrix of dimensions is generated, where represents the number of sampling instances and denotes the number of variables. Each column of the matrix is populated with a predetermined proportion of 1s and 0s, ensuring uniform sampling frequency across all variables.

2) Weight assignment: In contrast to BMS, WBMS assigns weights to each variable based on their importance, as determined from prior modeling efforts. The weight for a given variable is calculated as the frequency with which the variable appears in the best-performing sub-models, divided by the total number of optimal models. This weighting mechanism ensures that variables with greater significance have an increased probability of being selected in subsequent sampling iterations.

3) Sampling procedure: The binary matrix is permuted according to the assigned weights, enabling a higher likelihood of selecting variables with greater weights. This informed sampling strategy prioritizes the inclusion of influential variables while still allowing exploration of less frequently selected variables, ensuring a comprehensive evaluation.

4) Iterative optimization: The WBMS process is iterative, with variable weights updated based on their performance in the generated sub-models. This iterative refinement process continues until the weights converge, resulting in an optimized selection of variables.

The primary advantage of WBMS lies in its capacity to adaptively reduce the variable space while ensuring the inclusion of variables that significantly enhance model performance. By emphasizing the combinatorial effects of variables, WBMS mitigates the risk of discarding potentially informative variables that may have limited individual predictive power but are critical when considered in conjunction with others.

C. Iterative Partition Optimization

IPO is a novel method combining MPA and WBMS frameworks for spectroscopic feature selection. The method addresses high-dimensional data challenges by partitioning spectral features into manageable segments. IPO optimizes feature selection using the MPA framework while preserving

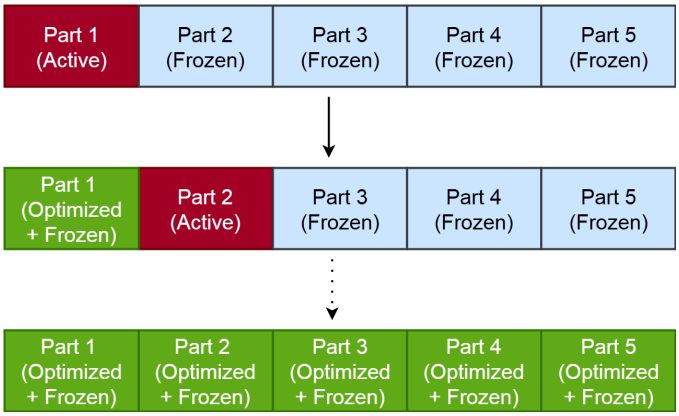

Fig. 2. Iterative optimization of spectral feature set with selective active part designation.

the dataset's global context. The initial phase divides spectral features into distinct segments, as in Fig. 2, enabling focused optimization and reduced computational complexity.

This structured approach differentiates IPO from conventional methods by emphasizing localized optimization within segments, creating a scalable and robust solution for spectroscopic applications. The segmentation process maintains global data relationships while allowing targeted analysis of each partition, effectively balancing local optimization with overall spectral context.

In each iteration, one segment (illustrated as the red cell in Fig. 2) is designated as the active component for optimization, while the remaining segments (depicted as blue cells in Fig. 2) remain frozen. This isolation of the active segment ensures that the algorithm can dedicate computational resources to refine its features. The WBMS technique is then employed to generate multiple subsets of intervals within the active segment. Each subset undergoes evaluation using PLS regression, a widely recognized technique for handling multicollinear and high-dimensional data, with its performance assessed through RMSECV. This process is illustrate through Algorithm 1. To ensure consistency and avoid bias, the fixed segments are combined with subsets derived from the active segment to construct complete feature sets for PLS modeling. The top-performing subsets are identified based on their RMSECV scores, and the results are used to dynamically update the sampling weights. This dynamic adjustment enables the algorithm to progressively focus on variables that contribute significantly to the predictive performance of the model.

The iterative process, comprising subset generation, evaluation, and weight adjustment, continues until no significant improvement in RMSECV is observed for the active segment. At this point, the selected intervals for the optimized segment are frozen to ensure stability, and the algorithm proceeds to the next segment for refinement. This stepwise optimization ensures that the IPO algorithm systematically identifies robust and informative features across the entire spectral dataset, while mitigating risks such as overfitting and redundancy.

By iteratively refining each segment, the IPO method achieves a globally optimized model with enhanced predictive performance. The methodology not only addresses the dimensionality challenges inherent in spectroscopic datasets but also integrates flexibility by incorporating dynamic weight adjustments and iterative feature refinement. Ultimately, the IPO method offers significant advantages, including improved model interpretability, reduced computational cost, and the ability to capture interactions between spectral features. Fig. 3 provides a detailed visual representation of the optimization process, illustrating the methodological steps and enhancing the understanding of the proposed approach. The IPO process is further elaborated in detail in Algorithm 2.

Algorithm 1: Feature Subset Optimization

Input:
$all_indices$: A list of indices corresponding to a specific feature column in X
$frozen_parts$: A concatenation of other parts except current active part
Output: $final_subset$: A list of indices selected after optimization.

$weight \leftarrow$ Initialize weights as 0.5
$subsets \leftarrow$ List[List[]]
$previous_rmsecv_avg \leftarrow \infty$
while True **do**

IV. Experiment and Discussion

A. Hyperparameter of IPO

In this study, several parameter configurations were employed to ensure the effective implementation of the proposed methodologies. For the PLSR, a parameter combination of

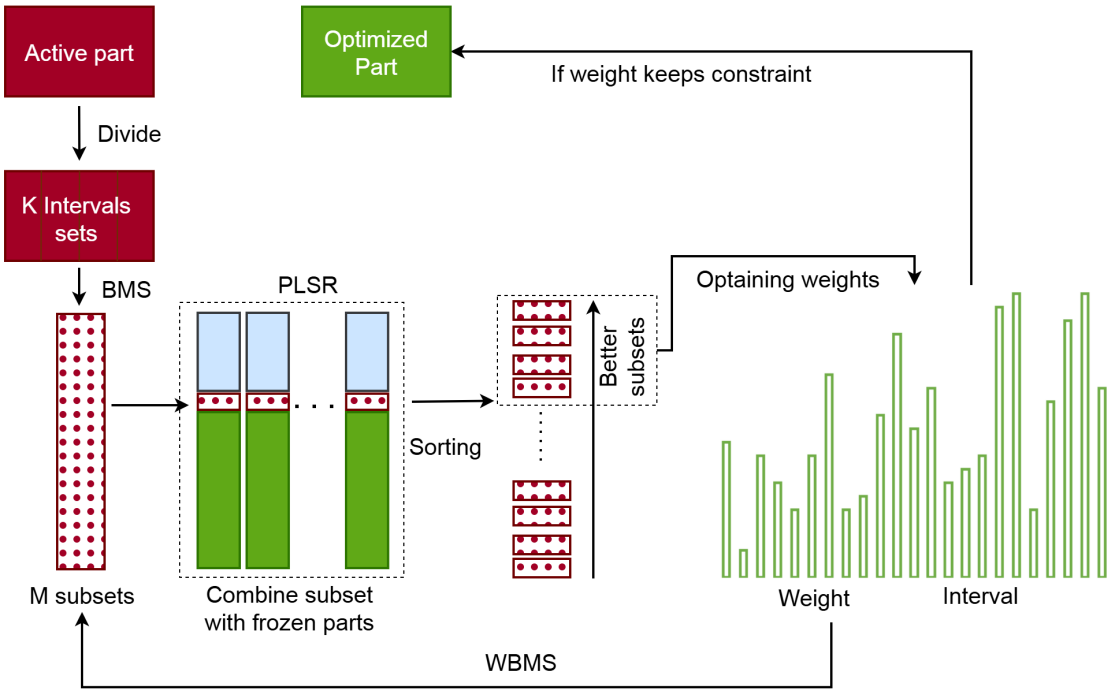

Fig. 3. The core idea for optimization in each active part.

Algorithm 2: Iterative Partition Optimization

Input:
X: Feature data of samples
y: Target data of samples
M: Number of subsets
num_parts: Number of parts
$intervals_per_part$: Intervals per part
α: Top selection ratio
Output: $informative_parts$: List of Informative features

10 was utilized. The WBMS approach was configured with the number of subsets, M, set to 1000, and the proportion of top-performing subsets, α, defined as 0.05. Additionally, the notation IPO (N, K) denotes the application of the IPO algorithm to the dataset, where N represents the number of parts, and K refers to the number of intervals within each part. The specific values of N and K are detailed in Tables I, II, III, and IV.

B. Datasets

In this study, a selection of widely recognized and publicly accessible benchmark NIR spectral datasets was employed to rigorously evaluate the performance and robustness of the proposed methodologies across diverse applications. conditions. Four benchmark NIR spectral datasets were utilized to evaluate the proposed methodologies.

- The soy oil dataset comprised 54 soy flour samples with spectral measurements across 175 wavelengths (1104–2496 nm, 8 nm intervals), divided into 43 calibration and 11 test samples for oil content prediction [25].
- The diesel fuels dataset included 246 samples (20 high-leverage) measured across 401 wavelengths (750–1550 nm, 2 nm intervals). After outlier removal within the summer fuels class, 133 samples were allocated for calibration and 113 for testing, targeting BP50 prediction [26].
- The wheat kernels dataset contained 523 samples from three locations, measured at 100 wavelengths (850–1050 nm). The dataset was partitioned into 415

calibration and 108 test samples for protein content prediction [27].

- The manure dataset (JIGO8R) consisted of 332 poultry and cattle manure samples from mainland France and Reunion Island. Samples were analyzed using three spectrometers in both fresh homogenized and dried ground states, targeting seven chemical properties: DM, NH_4, N, P_2O_5, CaO, MgO, and K_2O [28].

These datasets collectively provide a robust and diverse basis for evaluating the effectiveness of the proposed methodologies in different spectroscopic applications.

C. Metrics

To evaluate the performance of the IPO method, three widely used regression metrics were employed: Root Mean Square Error (RMSE), the coefficient of determination (R^2), and the Residual Predictive Deviation (RPD). These metrics were selected for their capacity to provide comprehensive insights into model accuracy, explanatory power, and predictive robustness, ensuring consistency and comparability with established approaches such as Partial Least Squares (PLS) regression.

The evaluation framework employs three standard metrics in spectroscopic analysis:

- Root Mean Square Error:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{1}$$

Characterizes prediction deviation through:

RMSECV: Cross-validation error for generalization assessment

RMSEC: Training error for model fit evaluation

RMSEP: Test error for predictive performance validation

- Coefficient of Determination:

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \in [0, 1] \tag{2}$$

Quantifies explained variance ratio, with $R^2 \to 1$ indicating optimal fit.

- Ratio of Performance to Deviation:

$$RPD = \frac{\sigma_y}{RMSE} \tag{3}$$

Establishes analytical quality:

$$RPD \text{ threshold} : \begin{cases} < 1.5 : \text{Insufficient} \\ [1.5, 2.0) : \text{Approximate} \\ [2.0, 2.5) : \text{Quantitative} \\ \geq 2.5 : \text{High-precision} \end{cases} \tag{4}$$

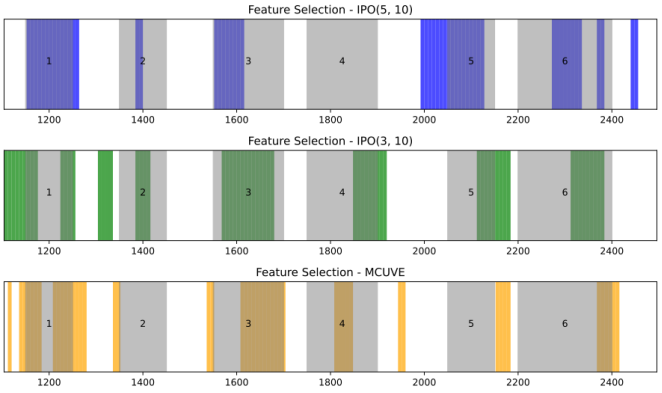

Fig. 4. Selected wavelength intervals for different optimization methods on the Soy oil dataset.

Variables $(y_i, \hat{y}_i, \bar{y}, \sigma_y)$ denote observed, predicted, mean, and standard deviation values. This framework provides systematic validation of model performance across prediction accuracy, explained variance, and analytical precision.

D. Experiment Hardware

The experiments were conducted on a high-performance laptop tailored for machine learning tasks. The system featured a 13th Generation Intel Core i7-13620H processor, providing powerful mobile computing capabilities. The laptop was equipped with 40GB of RAM, ensuring ample memory for handling large datasets and complex model training. Graphics acceleration was provided by an NVIDIA GeForce RTX 4070 mobile GPU with 8GB of GDDR6 memory.

E. Experimental Results

In this experiment, we also employ Monte Carlo Uninformative Variable Elimination as a baseline for comparison with our proposed method. MCUVE is a widely used feature selection method designed to identify and eliminate irrelevant or uninformative variables from a dataset. The method involves repeated random sampling (Monte Carlo simulations) to assess the stability and relevance of each variable. Variables with low importance or unstable contributions across multiple iterations are removed, thereby enhancing model interpretability and reducing computational complexity.

1) Soy oil dataset: In Table I, the IPO method demonstrates a clear advantage over the MCUVE and baseline PLS methods in predictive accuracy and model robustness for the soy oil dataset. Specifically, IPO (5, 10) achieves the lowest RMSECV (0.9226) and the highest R^2 value (0.85), indicating superior calibration and validation performance. Similarly, IPO (3, 10) achieves competitive results with a marginally higher RMSECV (0.9266) but compensates with the lowest RMSEC (0.6773) and RMSEP (1.0090), showcasing its consistency in external validation.

The wavelength intervals selected by different optimization methods, as shown in Fig. 4, provide insight into why IPO outperforms other methods. The regions identified by IPO align well with the chemical structure of soy oil, emphasizing

TABLE I. COMPARISON OF PLS MODEL PERFORMANCE USING DIFFERENT OPTIMIZATION METHODS ON THE SOY OIL DATASET

Model	Optimization Method	Number of Variables	Parameter Combination	RMSECV	R^2	RPD	RMSEC	RMSEP
PLS	/	175	PCs = 10	1.0643	0.81	2.24	0.7021	1.1471
	MCUVE	61	PCs = 10	1.0465	0.81	2.55	0.6975	1.0557
	IPO(5, 10)	60	PCs = 10	**0.9226**	**0.85**	**2.67**	0.6819	1.0393
	IPO(3, 10)	70	PCs = 10	0.9266	0.84	2.61	**0.6773**	**1.0090**

its capacity to isolate chemically relevant spectral features. Specifically:

- Region 1 (1150–1250 nm): Corresponds to the second overtone of the C–H stretching vibration, which is crucial for capturing aliphatic hydrocarbon signals in soy oil.
- Region 3 (1550–1700 nm): Linked to the first overtone of the C–H stretching vibration, contributing to the quantification of unsaturated and saturated fatty acids.
- Region 6 (2200–2400 nm): Reflects a combination of C–H vibrations and other molecular interactions, providing critical spectral information for accurate predictions.

In IPO (3, 10), the inclusion of additional regions, such as:

- Region 2 (1350–1450 nm): Associated with the first overtone of the O–H stretching mode, which reflects water and hydroxyl groups in soy oil.
- Region 4 (1750–1900 nm): Also related to O–H bonds and associated with minor functional groups in fatty acid structures.

These additional regions likely enhance the model's capacity to handle subtle spectral variations, improving its overall predictive performance.

The MCUVE method, while effective in selecting regions 1, 3, and 4, exhibits limitations in other regions (2, 5, and 6). The features it selects in these regions either deviate slightly from the chemically significant intervals or are sparse, introducing noise and reducing predictive accuracy. For instance, the lack of robust selection in regions 5 (2050–2150 nm) and 6 (2200–2400 nm) could result in missing key spectral signatures of C–H and O–H vibrations, impairing the overall model reliability.

Additionally, the ability of IPO to maintain a compact set of selected variables (60–70) compared to MCUVE (61) and baseline PLS (175) highlights its efficiency in reducing model complexity while preserving essential information. This efficiency is reflected in the improved RPD values (2.67 for IPO (5, 10) and 2.61 for IPO (3, 10)), compared to 2.55 for MCUVE and 2.24 for baseline PLS. The higher RPD values indicate better model precision and reliability in practical applications.

Overall, these results highlight the superiority of IPO in handling complex spectral datasets. By accurately isolating chemically significant features and minimizing irrelevant intervals, IPO enhances the calibration and prediction processes. This capability is particularly valuable for spectral datasets like soy oil, where overlapping spectral features and noise can compromise model performance when using traditional methods.

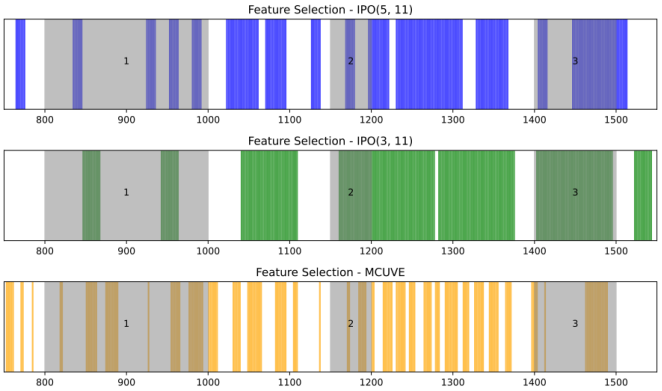

Fig. 5. Selected wavelength intervals for different optimization methods on the Diesel fuels dataset.

2) Diesel fuels dataset: In Table II, a detailed comparison highlights the superior performance of the IPO (5, 11) method across all metrics. Specifically, IPO (5, 11) achieves the lowest RMSECV (2.8759), the highest R^2 (0.97), and the highest RPD (5.76), demonstrating its robustness in both predictive accuracy and explanatory power. These results underscore the efficacy of the IPO method in selecting meaningful variables while maintaining a compact model structure. Notably, even the IPO (3, 11) configuration yields strong results, closely approaching the performance of IPO (5, 11), and outperforms the MCUVE method in all metrics. This suggests that the interval-based optimization in IPO effectively captures key spectral features with a minimal increase in the number of variables.

Fig. 5 illustrates the selected wavelength intervals for the diesel fuels dataset using various optimization methods. The property of interest in this dataset is the boiling point, which is influenced by multiple chemical bonds. Specifically, the regions between 800 and 1000 nm (labeled as region 1) and 1400 to 1500 nm (region 2) are associated with O–H bonds, while the region from 1150 to 1200 nm (region 3) is linked to C–H bonds. The observed selection patterns highlight the critical role of these regions in quantifying boiling point variations. However, the distribution of selected variables across the entire spectral range emphasizes the importance of capturing complementary information from diverse regions, as no single region provides sufficient data for accurate quantitation.

It is noteworthy that all optimization methods consistently identify spectral features in regions 1, 2, and 3, as well as common regions between 1050–1100 nm and 1200–1350 nm. This overlap suggests that these regions contain fundamental

TABLE II. COMPARISON OF PLS MODEL PERFORMANCE USING DIFFERENT OPTIMIZATION METHODS ON THE DIESEL FUELS DATASET

Model	Optimization Method	Number of Variables	Parameter Combination	RMSECV	R^2	RPD	RMSEC	RMSEP
PLS	/	401	PCs = 10	3.6189	0.93	4.58	2.8353	3.6404
	MCUVE	186	PCs = 10	3.0852	0.95	5.38	2.6036	3.1779
	IPO(5, 11)	203	PCs = 10	**2.8759**	**0.97**	**5.76**	**2.5727**	**3.0961**
	IPO(3, 11)	228	PCs = 10	3.0511	0.96	5.40	2.6421	3.1629

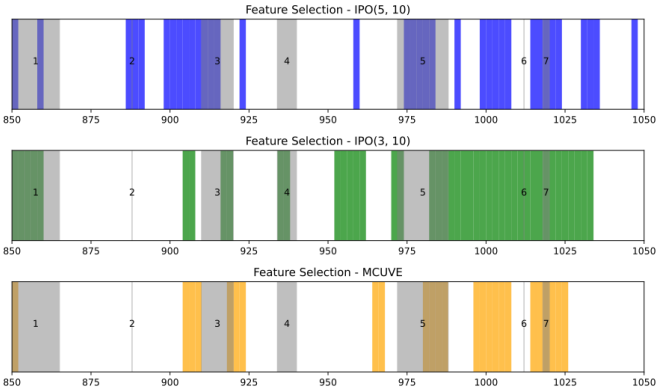

Fig. 6. Selected wavelength intervals for different optimization methods on the Wheat kernel dataset.

information relevant to boiling point prediction, likely due to their association with chemical bonds contributing to the property of interest. Despite this shared focus, the IPO configurations demonstrate a denser selection of features within region 3 compared to MCUVE. This denser coverage enhances the model's ability to leverage critical spectral information, resulting in improved predictive performance as reflected by the lower RMSECV and RMSEP values achieved by IPO.

Furthermore, the broader distribution of selected variables across the entire spectral range by IPO highlights its strength in capturing the synergistic effects of multiple spectral regions. This comprehensive selection strategy likely contributes to its higher RPD values, indicating greater robustness and reliability in predictive modeling. Overall, the results confirm the superior capability of IPO in optimizing variable selection for accurate and reliable prediction, particularly in challenging datasets like the diesel fuels dataset, where complex interactions between spectral features influence the target property.

3) Wheat kernels dataset: In Table III, the IPO method demonstrates superior performance compared to MCUVE and the baseline PLS model across all metrics. The IPO(5, 10) variation achieves the lowest RMSECV (0.5301) and RMSEP (0.5902), along with the highest RPD (3.02), highlighting its robustness in both calibration and external validation. Similarly, IPO(3, 10) shows competitive performance, with slightly higher RMSECV (0.5348) and RMSEP (0.6998) but the lowest RMSEC (0.5146), indicating better internal fit.

The wavelengths selected by different methods, visualized in Fig. 6, provide further insights into the differences in performance. Notably:

- Region 1 (850–865 nm): Assigned to the third overtones of C–H bonds, this region captures essential spectral information related to the hydrocarbon content in wheat kernels.
- Region 5 (972–988 nm): Represents the second overtones of O–H bonds, which are critical for detecting water and hydroxyl groups in the sample.
- Region 2 (888 nm): Associated with the second overtones of C–H bonds, this region provides additional structural information about hydrocarbons.
- Region 6 (1012 nm): Reflects the second overtones of N–H bonds, which are essential for characterizing protein content.
- Regions 3 (910–920 nm), 4 (934–940 nm), and 7 (1018–1020 nm): While these regions are difficult to assign definitively, they may still contribute to capturing subtle variations in the spectral profile of wheat kernels, which could be related to minor protein or moisture interactions.

The selection patterns of the two IPO configurations reveal their complementary nature in feature extraction. IPO (5, 10) focuses on regions (1), (2), (3), (5), and (7), whereas IPO (3, 10) emphasizes regions (1), (3), (4), (5), (6), and (7). The inclusion of additional regions by IPO (3, 10), such as (4) and (6), may help the model account for complex structural variations in proteins, enhancing its predictive reliability. This variation in selected regions demonstrates IPO's flexibility in adapting to dataset complexities while maintaining robust predictive performance.

In contrast, the MCUVE method shows limited effectiveness in feature selection. While it successfully identifies regions (5) and (7), its selection in regions (1), (2), (3), and (4) either deviates slightly from the target intervals or includes insufficient spectral features. These suboptimal selections likely introduce noise, reducing the model's ability to generalize and resulting in a higher RMSEP (0.6800).

The results also highlight the efficiency of IPO in reducing the number of variables while maintaining or improving predictive accuracy. IPO configurations select 48–51 variables, a significant reduction compared to the 100 variables used in the baseline PLS model, which still underperforms in metrics such as RMSECV (0.5597) and RPD (2.84). The compact variable sets identified by IPO contribute to better model interpretability and reduced computational complexity, both critical factors in practical applications.

The chemical assignments of the selected wavelengths underline the relationship between the spectral features and the chemical structure of wheat kernels. Regions associated with O–H and N–H bonds provide information about moisture and protein content, while those linked to C–H bonds reflect hydrocarbon structures. These spectral markers are essential

TABLE III. COMPARISON OF PLS MODEL PERFORMANCE USING DIFFERENT OPTIMIZATION METHODS ON THE WHEAT KERNEL DATASET

Model	Optimization Method	Number of Variables	Parameter Combination	RMSECV	R^2	RPD	RMSEC	RMSEP
PLS	/	100	PCs = 10	0.5597	0.88	2.84	0.5411	0.7847
	MCUVE	35	PCs = 10	0.5442	0.88	2.96	0.5335	0.6800
	IPO(5, 10)	48	PCs = 10	**0.5301**	0.88	**3.02**	0.5171	**0.5902**
	IPO(3, 10)	51	PCs = 10	0.5348	0.88	2.99	**0.5146**	0.6998

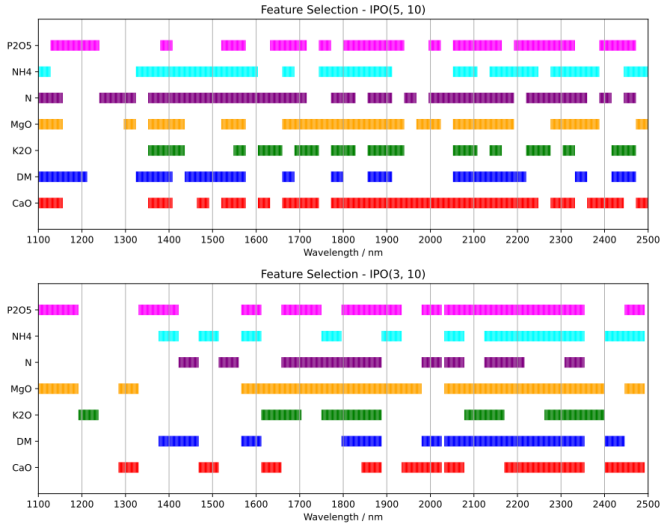

Fig. 7. Selected wavelength intervals across 2 configuration of IPO on the manure dataset.

for accurately predicting wheat kernel properties, and IPO's ability to consistently isolate these regions explains its superior performance.

Overall, the results confirm that IPO not only enhances predictive accuracy but also demonstrates versatility in adapting to complex spectral datasets like wheat kernels. Its ability to select chemically relevant features with precision positions it as a powerful tool for quantitative analysis in food science and other related domains.

4) Manure dataset: In Table IV, the results across all substances consistently demonstrate the effectiveness of IPO in improving the predictive performance of PLS models by isolating informative spectral intervals and excluding irrelevant regions. This selective approach not only reduces the number of variables but also enhances the robustness and accuracy of the models.

For substances such as nitrogen (N) and ammonium (NH_4), the IPO (3, 10) and IPO (5, 10) configurations exhibit superior performance compared to MCUVE and the baseline PLS. Both configurations effectively target NIR spectral regions associated with the chemical properties of nitrogen, capturing the first and second overtones of N-H bonds at 1500–1530 nm and 2168–2180 nm, respectively. Additionally, the third overtone, corresponding to the N-H stretching vibration in the 2050–2060 nm range, is accurately identified. This ability to focus on chemically significant wavelengths allows IPO to achieve a higher RPD and lower RMSECV, affirming its utility in quantitative analysis of nitrogen-related compounds.

For P_2O_5, the IPO (5, 10) method achieves a marked improvement, reducing the RMSECV to 0.1565 while achieving an RPD of 3.68, the highest among all methods. This indicates a strong predictive capability, with the selected variables effectively capturing spectral regions pertinent to P_2O_5 concentrations. The dense coverage of critical wavelengths by IPO ensures that the combined effect of spectral features is leveraged to enhance model accuracy.

When examining calcium oxide (CaO), the PLS model demonstrates limited predictive capability, yielding an RMSECV of 0.3284 and an RPD of only 1.69. This suboptimal performance is likely due to the mismatch between the theoretical absorption range of CaO (550–650 nm) and the spectral range of the dataset (1100–2498 nm). Despite this limitation, the IPO (3, 10) configuration achieves notable improvements, reducing the RMSECV to 0.2808 and increasing the RPD to 1.98. The enhanced performance underscores the robustness of IPO in handling challenging datasets, even when the spectral range does not perfectly align with the chemical properties of the target substance.

For magnesium oxide (MgO), IPO (5, 10) and IPO (3, 10) again demonstrate superior performance, achieving lower RMSECV values of 0.0648 and 0.0668, respectively, compared to the MCUVE and baseline methods. The RPD values also indicate better model reliability, with IPO(5, 10) achieving an RPD of 2.80, the highest among all tested methods. This suggests that the interval optimization provided by IPO allows for the identification of subtle yet critical spectral regions that contribute to accurate MgO prediction.

Fig. 7 highlights the selected wavelength intervals by IPO (3, 10) and IPO (5, 10). For all substances, the intervals align well with known spectral features corresponding to the chemical bonds and overtones relevant to the target properties. The figure also emphasizes the ability of IPO to select denser and more comprehensive intervals compared to MCUVE, leading to better model calibration and prediction.

For dry matter (DM) and potassium oxide (K_2O), IPO again outperforms other methods in terms of both RMSECV and RPD. For DM, IPO (5, 10) achieves an RPD of 7.93, indicative of excellent predictive performance. For K_2O, the IPO (3, 10) configuration achieves an RMSECV of 0.2189, significantly outperforming MCUVE and the baseline PLS model. These improvements highlight IPO's effectiveness in isolating key spectral intervals while maintaining a balanced model complexity.

Overall, the results reinforce the conclusion that IPO provides significant advantages in spectral feature selection, particularly for substances where the spectral data encompass diverse or overlapping chemical properties. By leveraging interval optimization, IPO ensures robust model performance

TABLE IV. COMPARISON OF PLS MODEL PERFORMANCE USING DIFFERENT OPTIMIZATION METHODS ON THE MANURE DATASET

Model	Substance	Optimization Method	Number of Variables	Parameter Combination	RMSECV	R^2	RPD	RMSEC	RMSEP

across a wide range of substances and spectral conditions, outperforming traditional methods such as MCUVE and baseline PLS in both predictive accuracy and reliability.

F. Discussion

1) The influence of parameters on the IPO results: The results highlight the impact of partitioning parameters on the performance of the IPO method. Dividing the spectral features into five parts consistently yields better predictive performance compared to dividing them into three parts. This improvement can be attributed to the smaller size of feature intervals in the five-part configuration, which allows the algorithm to identify compact, informative intervals. These intervals may otherwise be overshadowed by larger, uninformative regions in the three-part division.

However, certain feature intervals were only selected when using the three-part configuration. This suggests that larger intervals may occasionally capture features that, while not significant individually, become influential when grouped together. This observation reveals a trade-off between locally optimized feature selection (favoring smaller partitions) and globally optimized feature selection (favoring larger partitions).

This interplay between local and global selection strategies highlights the potential value of ensemble learning, where predictions are based on combining results from different partition configurations. Such an approach could leverage the strengths of both local and global feature selection to enhance overall predictive performance.

2) Versatility and robustness of IPO across diverse datasets: The IPO method has demonstrated strong versatility and robustness across diverse spectroscopic datasets, each characterized by unique chemical and spectral complexities. For instance, in the soy oil dataset, IPO effectively selected spectral regions associated with key chemical bonds, such as the overtones and combinations of C–H and O–H vibrations, resulting in significantly improved prediction accuracy compared to traditional methods like MCUVE.

Similarly, in the wheat kernel dataset, IPO identified a broad range of spectral intervals corresponding to critical chemical features, such as the overtones of C–H, O–H, and N–H bonds. This ability to capture essential regions while reducing noise underscores IPO's adaptability to datasets with varying degrees of spectral intricacy.

Moreover, IPO's parameter configurability, such as the number of partitions and interval sizes, allows the method to tailor feature selection to the specific characteristics of each dataset. This flexibility enables IPO to consistently achieve high predictive performance, affirming its utility as a versatile and effective tool in chemometrics and bioinformatics.

3) Differences in feature selection methods: The results also underscore significant differences between IPO and MCUVE in feature selection. Across all datasets, IPO reliably identifies key spectral regions, while MCUVE tends to select features slightly outside the critical intervals or captures too few features. These limitations in MCUVE's performance are attributed to its reliance on excluding uninformative features without fully addressing multicollinearity, a common challenge in spectroscopic data.

In contrast, IPO's iterative refinement process considers the interaction effects among variables. This "combination effect" ensures that important spectral features, along with their adjacent features, are more likely to be selected, as they collectively contribute to predictive accuracy. By systematically subdividing the dataset and examining smaller intervals, IPO enhances its ability to identify critical features while minimizing the impact of noise.

These distinctions highlight IPO's superior capacity to

extract relevant features and enhance predictive outcomes. Its ability to balance local and global feature selection through its customizable parameters makes it a powerful alternative to traditional methods like MCUVE.

V. Conclusion

Variable selection in near-infrared spectroscopy presents persistent challenges due to high dimensionality and complex spectral correlations. This study proposes the Iterative Partition Optimization framework, which systematically addresses these challenges through a novel integration of localized wavelength optimization and global spectral context preservation. The method's effectiveness was rigorously evaluated using four diverse spectroscopic datasets encompassing agricultural products, petroleum derivatives, and biological samples. Quantitative assessments demonstrated IPO's consistent superiority in both dimensional reduction and predictive accuracy, superior performance across four diverse datasets from agriculture to industry.

For the soy oil dataset, IPO (5,10) achieved the lowest RMSECV of 0.9226 and the highest R^2 of 0.85, while IPO (3,10) delivered a competitive performance with the lowest RMSEC (0.6773) and RMSEP (1.0090). In the wheat kernel dataset, IPO (5,10) outperformed other methods with an RMSECV of 0.5301 and an RMSEP of 0.5902, and IPO (3,10) excelled in internal calibration by achieving the lowest RMSEC (0.5146). For the diesel fuels dataset, IPO (5,11) attained the best overall performance with an RMSECV of 2.8759, an R^2 of 0.97, and an RPD of 5.76, while IPO (3,11) also demonstrated strong results, underscoring its efficiency in capturing critical spectral features. Moreover, the manure dataset highlights the method's notable gains in predicting nitrogen compounds, P_2O_5, MgO, and K_2O. The ability of IPO to isolate chemically significant spectral intervals, corresponding to key N-H, O-H, and C-H bond overtones, ensures robust predictive performance even under challenging spectral conditions. Compared to MCUVE, IPO demonstrated superior advantages in comprehensive detection of important spectral regions, effective handling of suboptimal spectral ranges, and balanced variable reduction with accuracy. Notably, IPO (5,x) configurations consistently outperformed IPO (3,x) in prediction efficiency across all datasets, suggesting that finer partitioning enables more precise feature identification. However, three-part configurations occasionally captured unique spectral interactions missed by finer divisions, indicating potential value in ensemble approaches. Overall, these results confirm that IPO is a powerful and reliable tool for spectral analysis. Its capacity to identify and leverage informative spectral intervals not only enhances predictive accuracy and model robustness but also improves interpretability and computational efficiency, making it highly applicable in diverse domains such as food science, fuel characterization, and agricultural quality assessment.

In the future, balancing localized and global feature selection will be a focus, as increasing the number of partitions emphasizes local optimization, while fewer partitions favor a more global perspective. Future work may also explore ensemble techniques to integrate insights from multiple variations of feature partitioning, providing a more comprehensive and adaptable feature selection framework. These enhancements could improve the robustness and versatility of the methodology, enabling its application to more complex datasets.

A Secure Tracking System to Prevent Counterfeit Drugs in the Pharmaceutical Supply Chain

Huda Alrehaili, Suhair Alshehri, Rania M. Alhazmi
Department of Information Technology-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah, KSA

***Abstract*—Counterfeit drugs represent a serious global risk, accounting for about 10% of the medicines worldwide. This percentage increases significantly in developing countries, reaching up to 30%, and has become a major cause of child mortality in these regions. Blockchain technology provides a good solution to address this critical issue through improving transparency and traceability of pharmaceuticals from manufacturers to end users. However, traditional blockchain applications face major challenges, particularly in terms of high costs and scalability especially when handling large volumes of data and transactions such as those found in the pharmaceutical supply chain. To address these limitations, researchers have introduced Layer 2 blockchain technologies, which operate on top of standard blockchain networks to improve scalability and reduce costs. This paper aims to design an efficient, secure, and scalable framework that can support traceability in pharmaceutical supply chains and contribute to reducing counterfeit drugs. This framework leverages Layer 2 blockchain solutions and combines Non-Fungible Tokens (NFTs) linked to Quick Response (QR) codes to provide unique identification for each drug. Furthermore, it incorporates the InterPlanetary File System (IPFS) for off-chain storage to reduce the amount of data stored directly on the blockchain. Additionally, an access control mechanism is incorporated to ensure the protection of sensitive data by limiting access based on predefined roles. This enhances privacy and reduces the risk of data leakage or misuse. In conclusion, this work provides the global scientific community with a secure and scalable framework that can be applied internationally to strengthen pharmaceutical supply chains and reduce the risks of counterfeit drugs.**

Keywords*—Pharmaceutical supply chain; blockchain; access control; InterPlanetary File System (IPFS); Non-Fungible Token (NFT)

I. Introduction

The pharmaceutical supply chain contains many different parties, including suppliers, manufacturers, distributors, pharmacies, hospitals, and patients. Due to this complexity, it becomes difficult to ensure that all medicines are safe and authentic [1]. Moreover, poor coordination among stakeholders, limited transparency, and the reliance on centralized systems make it easier for counterfeit drugs to enter the supply chain [2]. Recent studies have also highlighted that the problem intensified during global health crises, such as the COVID-19 pandemic, when the demand for medicines surged and counterfeit drugs accounted for nearly 15% of the market. Furthermore, the lack of effective monitoring authorities and the complexity of the pharmaceutical distribution process make it increasingly difficult to prevent fake drugs from infiltrating legitimate channels [3]. Previous approaches, including artificial intelligence and IoT-based methods, have been explored for counterfeit detection, but they fall short in providing the transparency, immutability, and trust guaranteed by blockchain technology [4]. According to the World Health Organization (WHO), about 10% of drugs worldwide are counterfeit, and in some developing countries, this number increases to 30% [5]. These drugs represent a leading cause of child deaths in these countries, which leads to serious health risks. Also, it causes financial losses of over $200 billion every year [1]. These challenges show that there is a strong need for a better system that can make the pharmaceutical supply chain more secure and more transparent. Blockchain technology is seen as a strong solution.

Blockchain is a decentralized system that records all transactions of the pharmaceutical supply chain in a secure and immutable way. It allows everyone involved in the supply chain to check the history of the medicine without depending on a central authority [1]. To make blockchain even stronger for this purpose, researchers have suggested using NFTs. These NFTs can give each medicine batch a unique digital identity, which makes it much easier to check if a medicine is real or fake [6]. This combination of blockchain and NFTs can create a very strong protection system for medicines and patients.

However, blockchain systems still have some important challenges especially in terms of scalability (the ability to handle many transactions quickly) and cost (high transaction fees) [7]. When many transactions happen at the same time, traditional blockchains can become slow and expensive [8]. This makes it difficult to use blockchain for large supply chains such as those in the pharmaceutical industry.

According to Gangwal et al [7], Layer 2 solutions are being adopted to address scalability and cost challenges in blockchain systems. These solutions operate on top of the main blockchain and help process transactions faster and at a lower cost. They retain the benefits of blockchain—such as security and transparency—while making the system more efficient for real-world applications.

In addition, off-chain storage platforms such as IPFS are used to store large or sensitive data efficiently, reducing blockchain congestion and operational costs [9]. In addition, access control models such as RBAC are important to ensure that only authorized parties can access or update critical information in the system [5].

Based on these observations, our research aims to develop an integrated and efficient pharmaceutical supply chain system using blockchain Layer 2 technology. The system will utilize Polygon as a Layer 2 platform to provide faster processing and lower transaction costs while maintaining the security and decentralization of Ethereum. Each drug unit will be

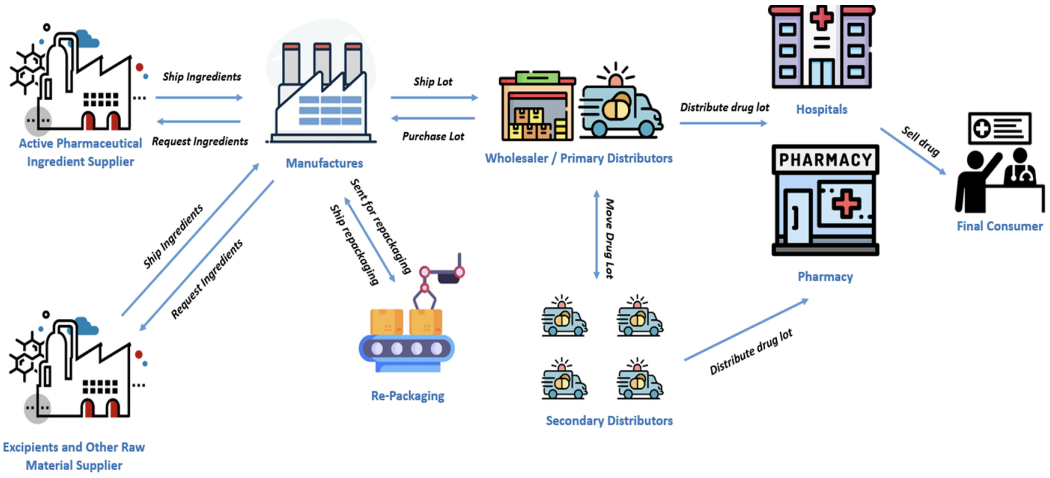

Fig. 1. Traditional pharmaceutical supply chain from raw material suppliers to end-users.

represented by a Non-Fungible Token (NFT) that is linked to a Quick Response (QR) code, allowing stakeholders such as manufacturers, distributors, pharmacies, hospitals, and patients to easily verify authenticity at every stage. To reduce storage costs and improve scalability, metadata related to drugs, such as batch numbers, expiration dates, and certificates, will be stored off-chain using the InterPlanetary File System (IPFS). Furthermore, an access control mechanism will be applied to restrict system interactions according to stakeholder roles. This integration of Layer 2 blockchain, NFTs with QR codes, IPFS, and access control is expected to enhance transparency, strengthen traceability, prevent unauthorized modifications, and contribute to reducing counterfeit drugs while ensuring high scalability and low cost across the pharmaceutical supply chain.

This paper is organized as follows. Section II introduces the background of the study, including the pharmaceutical supply chain, blockchain technology and Layer 2 solutions, as well as off-chain storage methods, NFT standards, and access control models. Section III discusses related work and compares previous approaches based on specific criteria. Section IV presents the proposed system architecture, explaining its core components and the process flow. Finally, Section V addresses the limitations of the current framework and highlights potential implementation challenges.

II. Background

This section provides the essential background required to understand the proposed framework. Focuses on five key concepts that directly address the challenges of counterfeit drugs in the pharmaceutical supply chain. First, the pharmaceutical supply chain is outlined to show how its complexity creates points of weakness. Second, blockchain and Layer 2 solutions are introduced as a way to increase scalability and reduce costs. Off-chain storage is also noted for its role in handling large drug-related data more efficiently. In addition, Non-Fungible Tokens (NFTs) with ERC standards are highlighted as tools to give each drug a unique and verifiable identity. Finally, access control models are introduced to ensure that only authorized stakeholders can interact with the system. Together, these ideas form the foundation for the rest of the paper.

A. Pharmaceutical Supply Chain

The pharmaceutical supply chain is a complex network comprising multiple independent entities, including raw material suppliers, manufacturers, distributors, pharmacies, hospitals, and patients [1]. The main goal from this chain is to ensure that medicines are delivered efficiently and safely to the end user. As we see in Fig. 1, a supply chain typically begins with raw material sourcing, which is processed and transformed into active pharmaceutical ingredients (APIs). These APIs are then used by drug manufacturers to create finished drug products. After being manufactured, drugs are packaged and sent to distribution centres, where they are stored under controlled conditions before being shipped to wholesalers, pharmacies, hospitals, or clinics [2]. Fig. 1 illustrates the complexity of the traditional pharmaceutical supply chain, providing a clear visualization of the multiple actors and interactions that create potential vulnerabilities where counterfeit medicines can infiltrate legitimate channels.

B. Blockchain Technology

Blockchain is decentralized technology that allows digital information to be recorded in a secure way to be transparent and tamper-proof [1]. Often it is described as a combination of two words (blocks and a chain). Each transaction is stored in a block, and every block is linked to the one before it, forming a continuous chain of data. Each block also has a block number, a nonce (a random number used for cryptographic purposes), transaction data, the hash of the previous block, and its own hash. This structure is very useful for ensuring that no data can be changed without affecting all the blocks that follow it, which makes blockchain very resistant to tampering. The main goal of this technology is to provide transparency, security, and trust through participants without the need for a central authority. All transactions recorded on the blockchain are time-stamped, verifiable, and publicly auditable, making the system highly resilient to fraud or unauthorized changes [4]. Fig. 2 presents the basic structure of a block in blockchain. It clearly

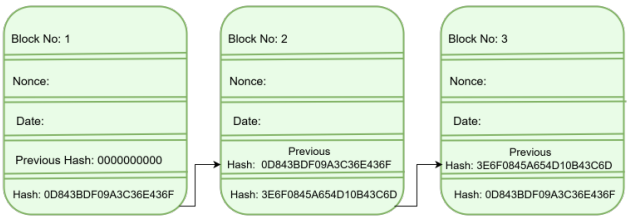

Fig. 2. Basic structure of blockchain block [4].

shows how the block elements are linked together to keep the data secure and tamper-proof.

C. Blockchain Layer 2

While blockchain offers many advantages, it still faces some limitations in terms of scalability and cost-effectiveness, especially when handling a large number of transactions. To solve these challenges, developers have introduced Layer 2 solutions. These solutions work on top of the main blockchain and allow some processes to operate off-chain, which means that smaller transactions are handled separately and later summarized before being recorded on the main chain. This new type of blockchain helps reduce congestion, lower transaction fees, and make the system faster and more efficient [7]. Several Blockchain Layer 2 solutions have been developed:

- Polygon: A popular Layer 2 blockchain solution built on top of Ethereum. It helps improve speed and reduce transaction costs by handling many operations off the main blockchain. It keeps the benefits of Ethereum—like security and decentralization—while making it faster and more cost-efficient [5].
- zkSync: A Layer 2 scaling solution built on zero-knowledge rollups (ZK-Rollups) that enhances Ethereum's scalability while ensuring strong privacy guarantees. It uses cryptographic zero-knowledge proofs to validate transaction batches off-chain, then submits a succinct proof to the main chain [10].
- Arbitrum: A Layer 2 platform that uses optimistic rollups to speed up smart contract operations. It assumes transactions are valid by default and only performs verification [7].
- Optimism: Another Layer 2 solution based on optimistic rollups, designed to improve Ethereum's throughput and reduce gas fees. It maintains a history of state updates and allows fraud-proof mechanisms to revert invalid batches, ensuring security through delayed verification [11].

D. Off-Chain Storage

Off-chain storage refers to keeping large or non-critical data (metadata) outside the blockchain network and linking it to on-chain records through hashes or content identifiers (CIDs) [9]. This technique helps maintain blockchain performance and cost-effectiveness without compromising the integrity and accessibility of the data [11]. The integration of off-chain storage mechanisms with blockchain technology has several advantages:

- Reducing the load on the blockchain : Minimizing the size of blockchain blocks will improve transaction throughput [12].
- Lowering operational costs: Storing large datasets like medical records, certificates, or shipment logs off-chain is more cost-effective [9].
- Enhancing scalability: Off-chain storage reduces overloading on blockchain, ensuring that networks remain fast and efficient [13].

There are a number of techniques used for off-chain storage in blockchain systems, such as:

- IPFS (InterPlanetary File System): A peer-to-peer protocol that allows decentralized file storage and retrieval based on content addressing rather than location[11].
- BTFS (BitTorrent File System): A decentralized storage system built on the BitTorrent network [14].
- Cloud Storage: Some systems used cloud platforms as off-chain storage to store metadata and only saved the verification hashes on the blockchain to ensure transparency and security [13].

E. Non-Fungible Tokens (NFTs)

Non-Fungible Tokens (NFTs) are unique digital assets that are recorded on the blockchain [15]. Each NFT possesses a distinct identifier and metadata that make it individually unique and cannot be exchanged [16]. This feature enables NFTs to verify ownership, maintain traceability, and ensure the authenticity of physical or digital items in a tamper-proof manner [6].

In a blockchain system, NFTs are created and managed based on specific standards to make sure they can be used easily across different systems and apps [15]. In our proposal, we focus on explaining some important NFT standards that are widely used.

- ERC-721 is the first and most popular standard for creating NFTs which defines that each token must be unique and have its own metadata [16].
- C-1155 is a newer standard that allows creating both fungible and non-fungible tokens in one smart contract. This makes managing different types of tokens faster and easier [16].
- ERC-20 is used for fungible tokens and is often mentioned when explaining the difference between fungible and non-fungible assets[16].

F. Access Control

Access control manages and restricts permissions that are used to access specific resources such as systems, data, applications, and networks. Its main objective is to ensure security and privacy by determining and defining who can access the system and what actions they are allowed to perform [17]. In blockchain-based environments,access control is crucial because data are shared among multiple participants.

Robust mechanisms prevent unauthorized access, data leakage, and resource misuse [5]. We have different types of access control models that can be implemented in blockchain systems. The popular model is Role-Based Access Control (RBAC), where each user gets specific permissions depending on their role, such as being a supplier, manufacturer, or customer [5]. Another model is Attribute-Based Access Control (ABAC), which gives more flexibility by considering various attributes like the user's job title, location, or the time they try to access the system. In addition, smart contracts are often utilized to automate access control rules, ensuring that permissions are enforced consistently and transparently without human intervention [10].

III. Related Work

This section reviews studies that use blockchain in healthcare, focusing on pharmaceutical supply chains. We classified the studies into three categories based on the technologies used.

A. Blockchain Without Access Control

In this subsection, we reviewed research that used blockchain in pharmaceutical supply chains. All studies in this section do not explicitly implement access control mechanisms.

Musamih et al. presented a framework based on Ethereum blockchain technology, with smart contracts and off-chain storage through IPFS, to improve the traceability of drugs in the pharmaceutical supply chain [18]. However, their study has some limitations. Using the Ethereum network can be costly due to high gas fees. To overcome these challenges, they suggest using Layer 2 solutions or private blockchain platforms.

Gebreab et al. developed a blockchain solution for the traceability and certification of refurbished medical devices [19]. The study focused on solving issues related to the safety, quality, and potential fraud in the reuse of medical equipment. In the model authors used dynamic and composable NFTs to digitally represent medical devices and their replacement parts. Also, to ensure each device's refurbishment is verified and tamper-proof, they used non-transferable NFTs, known as soulbound tokens, which serve as certificates. To avoid the high cost of storing data on the blockchain, device information is storage on IPFS. The study highlights the limitation of high gas fees on public blockchains, recommending the use of private networks for more cost-effective deployment.

Srinivas and Pradhan introduced TokenPharma framework based on the Ethereum blockchain [15]. They used ERC-721 standard of NFTs to improve pharmaceutical asset ownership and management in the healthcare sector. The system achieved strong performance metrics, with average latencies of 5.04s (create), 4.68s (buy), and 4.27s (resell) and respective throughputs of 223.83 TPS, 262.7 TPS, and 268.76 TPS. Memory usage remained between 645 and 780 MB. However, the study has not evaluated the framework under real-world, large-scale deployment conditions.

Gao et al. developed a blockchain-based safeguard mechanism and incorporated it into a Smart Relief Manufacturing System (SRMS) to improve transparency in relief supply chains (RSCs) during long-term disasters such as pandemics [13]. The framework uses Smart Connected Products (SCPs) to enable the large-scale customization of medical supplies like PPEs and MREs. Also, it introduces a multi-phase, bi-directional collaboration process involving customers in ordering, production, and delivery stages. Although the system restricts data submission through cryptographic signatures, it does not explicitly implement or discuss any formal access control models. Also, it lacks real-world deployment and omits aspects such as financial and material flows, indicating directions for future research.

Datta and Namasudra proposed a blockchain-based drug supply chain system using Ethereum smart contracts and decentralized IPFS storage to prevent counterfeit drugs [20]. The approach uses Schnorr signatures for off-chain production and transaction encryption in IPFS, while ECDSA is used for signing on-chain transactions. Performance analyses demonstrate improvements in throughput, computational efficiency, and communication costs compared to earlier models. However, the authors also highlight that relying on Ethereum's Proof-of-Work (PoW) mechanism introduces energy inefficiency and exposes the system to potential 51% attacks.

B. Blockchain with Access Control

This subsection presents studies that used blockchain with some form of access control in medical and pharmaceutical supply chains. These systems not only focus on improving traceability and security but also add ways to control who can access or use the system. Some studies use account based permissions, digital signatures, or smart contract rules to limit access to authorized users.

Subramanian et al. introduced a creative solution to the growing problem of counterfeit and low-quality medicines in the pharmaceutical supply chain [21]. Their work focused on the development of a mobile app, called "Crypto Pharmacy," which combines hybrid blockchain technology (using the NEM platform) with cryptocurrency and QR code tracking to make medicine purchases more secure and transparent. One of the best advantages of their system is that it allows patients, doctors, and pharmacists to trace each drug's trip from the manufacturer to the end user, reducing the risk of fake products entering the market. They also included real-time IoT monitoring to ensure that sensitive drugs are stored under proper conditions, such as temperature control. While their prototype worked well, the study pointed out a gap in current research—most systems lack large-scale deployment and don't yet take full advantage of advanced tokenization methods like NFTs.

Rehman et al. introduced transparent, immutable and secure vaccine supply chain (TISVSchain), an Ethereum blockchain-based architecture that can be utilized to improve the transparency, traceability, and security of vaccine supply chain management [22]. The system employs Ethereum smart contracts to record each stage of vaccine handling, from manufacturing authorization to final distribution. Access to the system is controlled through unique account addresses (UAs) issued by a regulatory authority to ensure that only approved entities can participate. Also, the customers can check the authenticity of the vaccine by scanning the QR code, which

will be connected to on-chain data. It is necessary to mention that the framework was designed to be deployable on both public and private Ethereum blockchains. Although the model demonstrated low gas cost and efficient performance, it did not integrate off-chain storage, which limits scalability and increases the overload on the blockchain network.

Aslam et al. addressed the issue of counterfeit and low-quality medicines in the pharmaceutical supply chain by developing a framework called MSMAChain based on a private Ethereum blockchain [23]. The authors aimed to improve drug traceability through the use of smart contracts, IPFS for off-chain storage, and tracking technologies such as QR codes and RFID. Also, they demonstrated that MSMAChain can reduce transaction costs and enhance transparency, security, and data integrity within the supply chain. However, the authors also identified several limitations, including challenges related to scalability, high computational requirements, and difficulties in integrating with other blockchain systems. They suggested that future work should focus on improving the performance of consensus mechanisms and exploring the use of edge or cloud computing to support larger-scale implementations.

Das et al. proposed a Ethereum blockchain system aiming to address the main problems associated with traditional drug supply chains, such as an increase of counterfeit medications, poor traceability, and a lack of transparency [24]. Their solution offers a safe and affordable method of tracking medications through the supply chain by using smart contracts, QR code scanning, and inventory tracking. A main part of the system is the "Buy-Sell-Verify-Ack" process, which is used to confirm and record each transaction, along with a red-flagging feature to stop suspicious drugs from being sold. Also, the security and cost-efficiency were tested using smart contract tools like Slither and Aderyn, showing that the system is safe and uses gas efficiently. However, the authors referred to the fact that public blockchains can have problems with scalability. To solve this, they suggest using private blockchains or Layer 2 technologies in future improvements.

Padma and Ramaiah introduced a blockchain-based pharmaceutical supply chain management framework (BPSCM) using a private Ethereum blockchain [17]. The system leverages smart contracts to manage stakeholder interactions, enforce access restrictions using Ethereum account-based modifiers, and ensure secure product traceability. For user authentication and to protect the provenance of pharmaceutical products, EdDSA digital signatures and symmetric encryption are employed, while transaction validation is carried out using the Proof of Stake (PoS) consensus mechanism. Additionally, off-chain storage through IPFS is utilized to reduce blockchain storage overhead. Despite its strengths in security and performance, the study does not incorporate a formal access control model within the system architecture, and it lacks evaluation under real-world, large-scale deployment scenarios.

Musamih et al. suggested a blockchain-based framework that used NFTs for product management, digital certification, trading, and delivery within the medical supply chain [6]. They used smart contracts deployed on the Ethereum blockchain, following the ERC-721 standard to tokenize healthcare products as unique digital assets, while IPFS was used for storing the metadata for each product to reduce blockchain storage costs. For access control , the study relies on ownership-based authorization, where only the NFT holder can perform certain actions. While the solution is fully implemented and tested through a decentralized application (DApp), it has yet to be deployed or assessed in real-world conditions. The high and unpredictable transaction fees on the Ethereum network remain a key limitation to practical use.

Samantray and Reddy introduced the novel Blockchain-enabled Healthcare Supply Chain Management (BeHSCM) system to enhance the security, traceability, and data integrity [10]. The system is built on a private Ethereum blockchain and utilizes Solidity smart contracts to handle key supply chain tasks. To ensure data protection, the model integrates the Keccak-256 hash function with zero-knowledge proofs (ZK-SNARKs), implemented using the ZoKrates tool, enabling transaction verification without disclosing sensitive information. Additionally, IPFS is employed for off-chain storage. However, the model has certain limitations. It may face scalability issues under high volumes of healthcare transactions. Furthermore, integrating the system into existing infrastructure can be technologically challenging and may require additional resources.

Chiacchio et al. introduced a blockchain-based solution to improve drug traceability by using NFTs as digital twins for serialized pharmaceutical packages [25]. Each drug unit is labelled with a QR code that follows GS1 standards, containing key information such as GTIN, serial number, batch number, and expiration date. Each NFT is directly linked to the QR code, creating a unique and traceable digital record for every package. Instead of using standard NFT formats like ERC-721, the system uses custom smart contracts on a permissioned blockchain. Access control also depends on the NFT owner, who is identified by their blockchain address and is the only one authorized to update the token's data. Additionally, the system was mainly designed to operate within a single manufacturing facility, making it difficult and costly to apply as a universal solution across multiple organizations.

Gebreab et al. focused on improving the traceability and ownership management of medical devices by using NFTs on the Ethereum blockchain [16]. Their system applies the ERC-721 standard to represent each device as a unique digital asset, with certificates of authenticity and metadata stored using IPFS. Verify ownership transfer through QR code scanning and passphrase confirmation to ensure secure delivery. The study includes both cost and security analyses, demonstrating that the NFT-based approach provides a secure, transparent, and cost-effective solution for tracking medical devices and preventing counterfeiting.

C. Blockchain Layer 2

The studies in this section do not focus directly on pharmaceutical supply chains, but they show how Layer 2 blockchain technologies can improve system performance, reduce costs, and enhance data privacy. Although used in different contexts, the methods presented can be adapted to support secure and efficient pharmaceutical supply chain systems in future research.

Singla et al. developed the Immutable and Decentralized Pharma (IDP) model to improve the security and transparency of pharmaceutical supply chains[26]. Their approach uses

blockchain (Polygon) and smart contracts to track medicines from raw materials to the final consumer. The system creates smart contracts for each stage, including raw materials, medicines, and transactions, and links them using a PreviousTransactionHash to ensure immutability and traceability. The prototype was implemented in Solidity and tested on the Polygon testnet, achieving around 43 transactions per second with a latency of 2.5 seconds. A cost analysis showed an estimated 502 USD per day under assumed workloads. The study demonstrates how blockchain can reduce counterfeit drugs by providing a reliable and tamper-resistant supply chain management system. However, the authors noted challenges such as the high operational cost due to frequent contract deployments, scalability concerns, and balancing transparency with data privacy.

Ma and Zhang introduced a new framework that uses blockchain to manage electronic health records more securely and efficiently[11]. Their approach combines Ethereum's Layer 2 ZK-Rollups with decentralized storage through IPFS, allowing sensitive medical information to be stored off-chain and access to the data is protected using cryptographic keys . Also, the system uses zero-knowledge proofs—Zero-Knowledge Succinct Non-Interactive Arguments of Knowledge (ZK-SNARKs)—to verify transactions without exposing private information. This method helps lower transaction costs and speeds up processing. Tests showed that the system responded faster and used less gas than traditional cloud-based or blockchain-only solutions.

Pongallu et al. introduced SecureMedZK, a system built on the Polygon Layer 2 blockchain to make managing electronic health records (EHRs) more secure and scalable [12]. The system uses zero-knowledge rollups to protect patient privacy, allowing sensitive data to be processed off the blockchain while still keeping transactions verifiable. It also applies NTRU lattice-based encryption, a quantum-resistant method that ensures long-term data security. For faster and more reliable transactions, the system uses the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm. The encrypted medical files are stored using AWS S3, and the key encryption is managed through AWS services to meet HIPAA compliance. The results showed that SecureMedZK performs better in terms of speed, scalability, and security. However, the authors refer that PBFT might not scale well in larger networks.

Krishnan and Ganesan introduced a blockchain-based framework to enhance cattle healthcare and dairy production, focusing on small-scale farmers [8]. The solution is built on Polygon, which is a Layer 2 blockchain that runs on Ethereum and uses ZK-Rollups to make transactions faster and more cost-effective. Each cow is linked to a unique ERC-721 NFT, which refers to its health data stored through IPFS. To protect private information, the system includes ZK-SNARKs, which allow data to be verified without revealing the actual content. However, one important limitation is that many farmers may not have the digital skills needed to use the system. Even so, the solution offers a useful, scalable, and secure way to support modern livestock management.

Table I presents a comparison of the studies that applied blockchain technology to pharmaceutical supply chains. The comparison was based on the most significant features employed by each study, including the use of Layer 2 blockchain solutions, NFTs, QR code integration, IPFS, access control, and whether they followed the ERC-721 standard. This table aims to identify existing technological gaps and discover opportunities where the proposed system can add value by integrating various secure and scalable elements.

TABLE I. COMPARATIVE SUMMARY OF BLOCKCHAIN-BASED APPROACHES IN PHARMACEUTICAL SUPPLY CHAIN

[21]	✓	×	✓	✓	✓	✓	✓	✓	✓
[18]	✓	×	×	×	×	✓	×	✓	✓

From Table I, all studies used blockchain as a core component, while only four studies [12], [11], [26], and [8] employed Layer 2 blockchain technologies such as Polygon. Among them, only one study [26] applied Layer 2 in the pharmaceutical domain, whereas the others focused on different areas such as cattle health monitoring and electronic health records. This indicates that Layer 2 solutions are still not well explored in the context of drug traceability.

NFTs were used in six studies [8], [6], [15], [19], [25], and [16] to represent medical products. However, just two of them,[16] and [25], used NFTs linked by QR codes to make it easy and safe to authenticate. This shows that linking physical products with their digital counterparts using QR is not given much use. Furthermore, ERC-721 standards are used by [8], [6], [15], [19] and [16]. The others either had custom contracts or none specified as to what standard was being employed.

All the papers [8],[10],[11], [20],[26], [6], [17], [15], [23],[19],[16] and [18] utilized IPFS for off-chain storage as a cost-saving measure and also to avoid blockchain congestion. Other researches like [12], [24],[22] and [13] that did not utilize IPFS used other types of storage, such as local databases or centralized cloud storage. This may weaken the data integrity and decentralisation that blockchain aims to provide.

In security, most studies, such as [19], [11], [16], and [21] utilized access control mechanisms within them, although how it was being implemented was different and not always clearly explained.

Finally, most of the studies in the table focused directly on the pharmaceutical supply chain. This shows that there is strong interest in using blockchain to improve drug traceability and fight counterfeiting. However, even though the domain is well covered, some important technologies, such as Layer 2

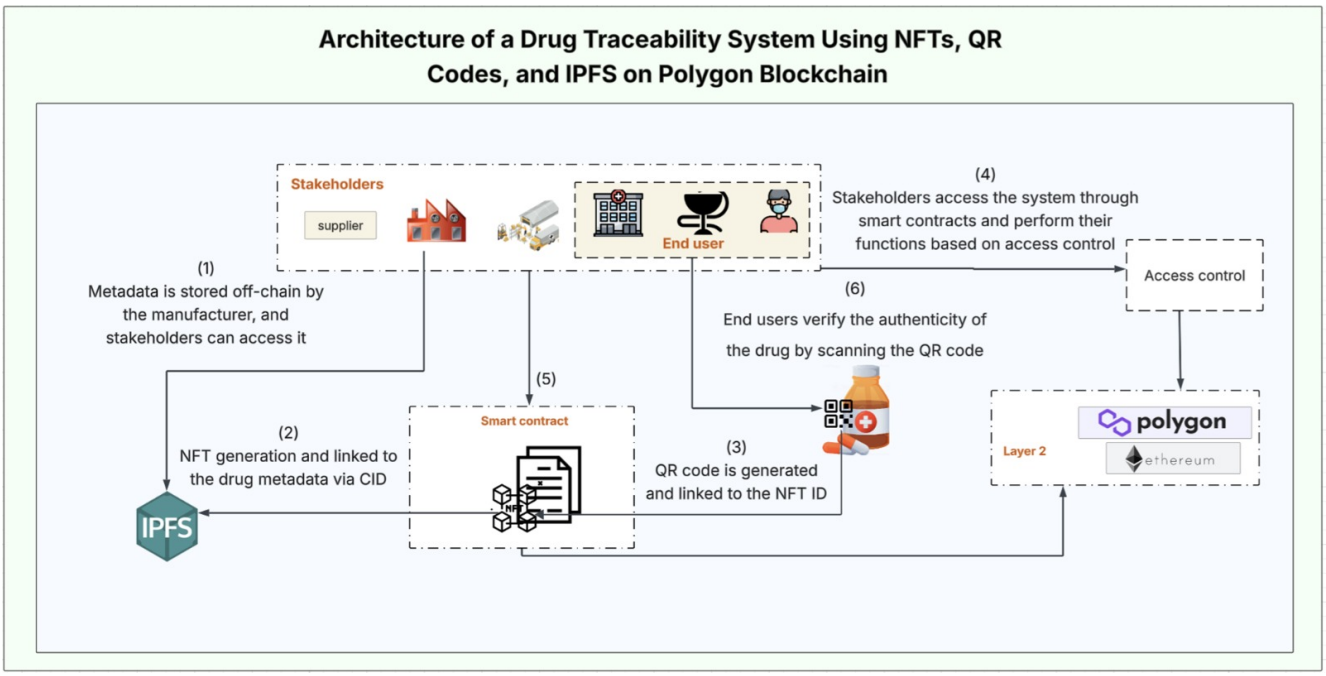

Fig. 3. Proposed system architecture for secure and traceable pharmaceutical supply chain.

blockchain, linking NFTs with QR codes, and decentralized storage using IPFS are still not widely used together in one system. This means that there is still a gap in how these technologies are combined to enhance scalability and reduce the cost in the pharmaceutical supply chain to reduce the spread of fake drugs. The proposed system in this paper aims to close this gap by bringing these tools together in a secure, scalable, and cost-effective way for managing pharmaceutical supply chains.

IV. Proposed Architecture

This proposed framework addresses the above gap by integrating all the technologies mentioned in Table I (Polygon blockchain, NFTs, QR codes, and IPFS). Fig. 3 illustrates the system architecture. For clarity, this section is classified into two parts: system components and system processes.

A. System Components

This system includes several main components that work together to track and verify drugs: Stakeholders:

The main participants in the drug supply chain who interact with the system. They include:

- Supplier: Provides raw materials for drug manufacturing.
- Manufacturer: Produces the drug and initiates the traceability process. The manufacturer operates under the supervision of the health authority (e.g., FDA) to ensure safety and compliance.
- Distributor: Transfers drugs from the manufacturer to healthcare entities.
- Hospital: Receives the drugs and ensures their authenticity before use.
- Pharmacy: Dispenses drugs to patients and performs verification using QR codes.
- Patient: The final user who scans the QR code to verify drug authenticity.

Access control: Ensures that each stakeholder can only access and interact with the system based on their role and permissions. In this system, Role-Based Access Control (RBAC) is used so that every participant on the blockchain has a specific role and can perform actions based on permissions. The manufacturer is the only one who can produce and upload drugs to the network. The distributor receives the drugs from the manufacturer and delivers them to hospitals and pharmacies. Hospitals and pharmacies can verify the drugs and are responsible for dispensing them to patients. The patient can only check the drug using the QR code. This access control prevents unauthorized actions and keeps all operations secure and transparent.

InterPlanetary File System (IPFS): A decentralized storage system used to store drug metadata off-chain to reduce the amount of data stored on the blockchain.

Non-Fungible Token (NFT): Represents a unique digital identity for each drug unit. It links to the metadata stored in IPFS via a content identifier (CID).

QR Code:The encrypted QR code is linked to the NFT and attached to the drug package. It allows stakeholders to verify that the drug is authentic. The QR code follows the GS1 standard, which includes four main parameters:

- (01) Global Trade Item Number (GTIN),
- (17) Expiration date,

- (10) Batch or lot number, and
- (21) Serial number

These parameters make the system compatible with international pharmaceutical traceability systems and support serialization for each drug unit. Serialization helps trace every package and detect any copied or fake drugs, improving transparency and safety through the whole process.

Smart Contract: The smart contract contains the NFT, which is stored on-chain, and allows stakeholders to interact with the system and perform their roles based on access control.

Polygon Blockchain: Polygon is a Layer 2 solution [7]. We selected Polygon for our system because it maintains Ethereum's security and decentralization while offering better performance and lower gas fees. It also supports NFTs and smart contracts, which are essential for our design. Compared to other Layer 2 solutions like Optimism and Arbitrum, Polygon is more user-friendly, well-documented, and has already been used in similar fields such as healthcare.

B. System Processes

This subsection describes the main processes of the proposed system and explains how its components interact to guarantee secure and transparent drug traceability across the supply chain.

1) Metadata storage: The process begins with the manufacturer, who prepares detailed metadata for each drug unit. This includes the batch number plus production and expiration dates. The manufacturer uploads this information to IPFS, which generates a unique Content Identifier (CID). The CID acts as a cryptographic reference. It permanently links the on-chain record to the off-chain data and ensures integrity while reducing blockchain storage overhead.

2) NFT generation and linking: After the metadata is secured, the manufacturer mints a unique ERC-721 token (NFT) on the Polygon network for each drug unit. This NFT acts as the drug's digital identity by linking the physical product to its verified digital counterpart.

3) QR code encryption, generation, and storage: A QR code is generated and securely encrypted with the NFT ID. This QR code is stored digitally and also printed on the drug package. It serves as the access point to retrieve the drug's information and verify its authenticity.

4) Supply chain transfer and updates: As the drug moves through the supply chain, each transaction is recorded, such as transfers between manufacturers, distributors, hospitals, and pharmacies. Stakeholders sign these interactions with their blockchain addresses.

5) Smart contracts and on-chain recording: All interactions and updates are handled by smart contracts and recorded on-chain using the Polygon blockchain. These contracts verify each action and enforce role-based permissions, ensuring that only authorized entities can update or approve records. This approach reduces the risk of tampering or fraud while guaranteeing traceability, transparency, and tamper-proof records.

6) End-user verification process: The patient receives the drug and scans the QR code using a mobile device. After that, the system uses the scanned QR code to retrieve the associated NFT ID of the drug. The NFT ID is applied to fetch the drug's linked metadata from the IPFS. Once obtained, the system displays the drug data on the platform and allows the patient to verify the authenticity of the drug and ensures that it has not been tampered with.

V. Conclusion and Future Work

This paper presented a blockchain-based framework to improve the traceability of the pharmaceutical supply chain and reduce the circulation of counterfeit drugs. The proposed system integrates Layer 2 blockchain (Polygon), NFTs connected to QR codes, IPFS, and access control to provide a secure and scalable solution. These components collectively enhance transparency, reduce storage costs, and protect sensitive information throughout the supply chain.

Currently, the research focuses on designing and developing the system architecture. The implementation and testing phase is ongoing, and the experimental results with performance evaluation will be included in a future work. The next stage will involve a complete end-to-end deployment of the proposed framework on the Polygon test network. The evaluation will include quantitative metrics such as transaction latency, gas cost, throughput, and storage efficiency. In addition, a comprehensive security assessment will be conducted to analyze signature verification accuracy, QR code robustness against duplication, and access control enforcement. These results will provide a deeper understanding of the system's scalability, reliability, and real-world applicability.

Integrating Large Language Models with Deep Reinforcement Learning for Portfolio Optimization

Renad Alsweed, Mohammed Alsuhaibani
Department of Computer Science-College of Computer, Qassim University, Buraydah 51452, Saudi Arabia

***Abstract*—This paper explores the application of Deep Reinforcement Learning (DRL) and Large Language Models (LLMs) to portfolio optimization, a critical financial task requiring strategies to balance risk and return in volatile markets. Traditional models often struggle with the complexity of financial markets, whereas Reinforcement Learning (RL) provides end-to-end frameworks for learning optimal, dynamic trading policies through sequential decision-making and trial-and-error interactions. The study examines key DRL algorithms, including Q-learning, Deep Q-Networks (DQN), Proximal Policy Optimization (PPO), and Twin-Delayed Deep Deterministic Policy Gradient (TD3), emphasizing their strengths in dynamic asset allocation. Crucial components of financial RL systems are discussed, such as state representations, reward function designs, its algorithms, and main approaches. Furthermore, the survey investigates how LLMs enhance decision-making by analyzing unstructured data (like news and social media) for sentiment and risk assessment, often integrating these insights to augment state representations or guide reward shaping within DRL frameworks.**

***Keywords*—Portfolio optimization; Reinforcement Learning (RL); algorithmic trading; Markov Decision Process (MDP); Large Language Models (LLM); deep learning**

I. Introduction

Portfolio management is a crucial aspect of finance, requiring that investors monitor market dynamics and make informed decisions to periodically allocate their portfolios across multiple assets. The goal is to gain profits while maintaining the investment portfolio's stability. Adjusting funds between long and short positions is particularly important as it directly impacts both profit and risk under varying market conditions. Long positions involve buying assets with the expectation of price increases, whereas short positions involve selling borrowed assets to repurchase them at a lower price. In a volatile market, reallocating funds from long to short positions can help hedge against potential losses. This dynamic adjustment helps maintain a balanced portfolio, mitigating risks while seizing opportunities during market downturns and upswings. Margin trading allows traders to borrow funds from a broker to trade financial assets, enabling them to leverage their positions and potentially amplify their returns. However, both long and short positions come with increased risk, as losses are magnified and can exceed the original investment.

The volatility of financial markets still poses a significant challenge, making it difficult for static trading strategies to maintain a long-term competitive advantage. Traditional quantitative models can struggle to fully capture the complex interplay of diverse factors.

Reinforcement learning (RL) emerged as a transformative approach for financial trading, enabling dynamic strategy optimization in complex markets [1]. Driven by the alignment between the sequential decision-making process of trading and the learning process of RL [2], it provides algorithms that adapt and optimize trading strategies based on sequential decisions [1]. Unlike traditional rule-based systems, RL models can navigate complex market environments, continuously updating their strategies to maximize returns.

The RL agent can learn optimal policies by interacting with the environment, continuously updating its policy to maximize returns. Deep Reinforcement Learning (DRL) leverages deep neural networks to approximate value functions and policies, making RL scalable and efficient in complex tasks [1]. The reward function in RL can be designed to encourage both profitability and stability, including a profit-based reward, a balance stability penalty, and a transaction cost penalty [1]. RL agent's portfolio allocation dynamics reveal its ability to adjust asset weights over time, increasing exposure to stable assets during high volatility and balancing for diversification [3]. Yet, frequent adjustments of portfolio ratios can introduce higher volatility and lower returns, making portfolios unstable and unbalanced. Also, designing a reward function that accurately accounts for the different factors influencing the entire stock market can be difficult [2].

Large Language Models (LLMs) are trained on massive and diverse datasets, enabling them to understand instructions and perform a wide range of tasks with zero-shot or few-shot learning capabilities. Their ability to process complex natural language inputs allows them to interpret, generate, and summarize financial information efficiently.

In the financial domain, LLMs are increasingly applied to automate report and workflow generation, forecast market trends, perform entity recognition and sentiment analysis, and provide personalized financial advice or question-answering services. In trading, LLMs can analyze unstructured data sources such as news articles, social media sentiment, and earnings reports to extract market signals and support strategy development. They can assist in generating trading insights, detecting anomalies, or summarizing market movements in real time. Some advanced implementations even combine LLMs with quantitative models or reinforcement learning agents to enhance decision-making and risk management. Beyond analytics, LLMs offer enhanced reasoning, interactivity, and integration capabilities. They provide interpretable explanations for their outputs, increasing transparency and user trust. Their conversational design allows traders and analysts to iteratively refine queries and receive contextualized insights. Moreover, LLMs can seamlessly integrate with trading platforms, APIs, and financial databases using techniques such as Retrieval-Augmented Generation (RAG) to deliver comprehensive analyses and support intelligent, data-driven trading decisions [2].

This survey aims to explore the application DRL and LLMs in portfolio optimization. It reviews how RL methods adapt strategies to maximize returns and manage risk in volatile financial markets, integrating diverse and dynamic data sources. Additionally, it examines how LLMs can enhance decision-making through financial text analysis, and sentiment extraction. The survey also covers key algorithms, reward functions, prompting techniques and evaluation metrics, while comparing the strengths and limitations of different models.

II. Research Objectives and Main Questions

The aim of this study is to examine the role of diverse data sources, review DRL algorithms and reward functions, and identify evaluation metrics in the context of DRL-based portfolio optimization. It also seeks to compare existing approaches and highlight the challenges and limitations of applying DRL methods in real-world financial markets. The following section outlines the specific research objectives and questions that guide this survey.

- To examine existing diverse data sources and their roles in enhancing DRL-based portfolio methods.
    - RQ1: What are the existing data sources used within DRL for the portfolio optimization problem?
    - RQ2: How do diverse data sources contribute to improving the effectiveness of DRL-based portfolio strategies?
- To review DRL algorithms used in the literature.
    - RQ3: What types of algorithms are most effective for this task?
- To review reward functions used in the literature.
    - RQ4: How do different reward function designs influence portfolio performance and risk management?
- To identify evaluation metrics commonly used and compare existing studies.
    - RQ6: What evaluation metrics are commonly used to assess DRL-based portfolio models?
    - RQ7: How do variations in data sources, reward functions and algorithms affect measurable outcomes in the literature?
- To identify challenges and limitations in existing DRL-LLM approaches for portfolio optimization.
    - RQ8: How LLM has been integrated with a DRL methods?
    - RQ9: What challenges and limitations exist in applying DRL-LLM approaches to real-world financial markets?

III. Methodology

To fulfill the main objectives and address the research questions introduced in Section II, which define the scope of this review, we follow a systematic methodology presented in this Section III-A specifies the eligibility criteria, Section III-B details the search approach, Section III-C covers the selection process for studies, and Section III-D provides the data extraction process.

A. Eligibility Criteria

The eligibility criteria were defined in alignment with the objectives and guiding questions presented in II. Studies falling within the scope of this work, particularly those focusing on the stock portfolios, were considered for inclusion. The specific criteria used to determine study eligibility are detailed below:

- Studies address all essential components, including its data source, the algorithm used, the reward function and algorithm evaluation.
- Studies written in English.
- Studies published in scholarly peer-reviewed journals.

The following exclusion criteria were applied to remove papers from this review:

- Review papers.
- Studies that didn't address all essential components mentioned in inclusion criteria.
- Studies written in non-English.
- Studies, thesis and dissertation that are not published in scholarly peer-reviewed journals.

B. Search Strategy

The method for study retrieval has two primary phases. First, We have identified the primary keywords to be employed in the search process as follows:

- "deep reinforcement learning" AND ("single stock trading" OR "portfolio") AND "stock" AND ("large language" OR "LLM")

Subsequently, we utilized several databases, including Word of Science, ACM, ACL Antholog, ScienceDirect, Springer, IEEE, and MDPI, Google Scholar, arXiv to achieve thorough coverage of the relevant literature.

C. Study Selection Strategy

This review follows a study selection strategy based primarily on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [4], which provide researchers with a framework for conducting high-quality reviews. The PRISMA-based selection process, summarized in Algorithm 1, is organized into three main levels: identification, screening, and inclusion. This algorithm outlines the automated and manual steps followed to retrieve, filter, and finalize the studies included in this review. Each level is described in detail in the following subsections.

1) Identification level: 915 papers were collected based on the method described in Section III-B. 30 have been eliminated due to duplication which come from two main reasons. First, authors may publish their papers within multiple journals as well as that journals may found in multiple indexers. Second, portfolio keywords are used interchangeably in many cases, hence same paper appears multiple times within different searches. After de-duplication only 885 papers are moved to next level.

2) Screening level: We have followed the next three steps within this level.

a) Automated screening by eligibility criteria: Due to large number of studies, we started with removing studies that doesn't match some of eligibility criteria before manual screening. Eliminated papers were either a non-english papers, and non-indexed papers in our listed databases, specifically filtering out from google scholar, as well as review and unpublished thesis and dissertations. Following this process 204 study has been kept.

b) Manual screening by title and abstract: This process involved excluding papers that were outside the scope of this review by examining their titles and abstracts. Papers that did not match the keywords defined in the search strategy were also removed. Following this screening, a total of 12 papers were retained for further analysis.

c) Manual screening by eligibility criteria: This stage involves assessing the eligibility criteria, where only papers that meet the predefined inclusion criteria are manually retained. Consequently, papers that satisfy the exclusion criteria described in Section III-A are removed from the review. With finalizing screening process we found all 12 papers categorized as eligible.

3) Inclusion level: This stage comprises all papers that passed the screening process. Based on the screening results, a total of 12 papers were selected for inclusion in this review and were organized using Notion software.

D. Data Extraction Strategy

In this phase, we systematically extracted key points essential for addressing our research questions and achieving a comprehensive understanding. These points were organized and recorded in an Notion databases, facilitating efficient data management and retrieval for each paper.

Algorithm 1: Systematic Paper Selection and Screening Workflow

Input: Search keywords: "deep reinforcement learning", "portfolio", "LLM", "stock"
Output: Final list of included papers
Step 1: Retrieval
Query databases (WoS, ACM, IEEE, Springer, MDPI, ScienceDirect, arXiv, Google Scholar);
Merge results, standardize columns, and convert to lowercase;
Step 2: Deduplication
Group by title; retain longest metadata and first DOI/URL;
Remove duplicates;
Step 3: Automated Filtering

IV. Literature Review

Reinforcement learning (RL) is a machine learning approach where an agent learns to make sequential decisions by interacting with an environment, aiming to maximize cumulative rewards [1], [5]. This interaction is often framed as a Markov Decision Process (MDP), defined by a tuple of components (S,A,P or T,R,γ). In an MDP, States (S) represent different configurations of the environment that the agent observes at each time step. Actions (A) define the possible decisions or actions the agent can take to interact with the environment. There is a Transition Probability (P) which indicates the probability of transitioning from one state to another given a specific action. The Reward Function (R) provides feedback on the outcome of actions, helping the agent learn which decisions yield high or low rewards. The objective of an RL agent is to discover an optimal policy, a mapping from states to actions that maximizes the expected cumulative reward over time [1]. This section demonstrates different designs of the Markov Decision Process components introduced earlier as well as value and policy designs.

A. Reward Function

The design of the reward function is crucial as it guides the agent's learning process towards desired outcomes, such as maximizing profit, managing risk, or aligning with market signals [1], [5]. Different frameworks utilize distinct reward mechanisms depending on their specific objectives.

1) Multi-objective reward: The reward function can be designed to balance profit-seeking, stability, and cost minimization by considering transaction costs at once. To accomplish this design, three components need to be combined in one equation. Profit-based reward, which is based on the net change in the agent's account balance, including both the value of held shares (unrealized gains) and cash from sold shares (realized gains). Balance stability penalty a penalty that is applied based on the deviation from the initial balance to discourage large swings and reward more stable account values. Transaction cost penalty, which is a penalty proportional to the trade amount to simulate real-world transaction fees and incentivize minimizing unnecessary trades [1].

2) Profit maximization: In another approach for portfolio management using PPO, the immediate reward is defined as the logarithmic portfolio return [3], as shown in Eq. (1).

$$r_{n+1} = \log\left(\frac{w_n \cdot S_{n+1}}{w_n \cdot S_n}\right) \tag{1}$$

where w_m is the current portfolio weights, S_n is current adjusted closing prices, and S_{n+1} is the next day adjusted closing prices

Alternatively, the relative return can be used to calculate logarithmic portfolio return as Eq. (2) shows.

$$r_{n+1} = \log(1 + R_{n+1}) \tag{2}$$

where R_{n+1} is the relative return.

3) Percent change in the portfolio value: To avoid arbitrary effects based on starting cash and value-at-risk, all agents start with zero dollars (and may spend negative) and a fixed offset is added to all portfolio value calculations to keep the percent changes on a similar scale. This is calculated every time the agent takes an action [5].

4) Risk-adjusted return: Sharpe ratio measures the excess return obtained for every unit of risk. The portfolio generates higher returns in proportion to the level of risk assumed when the SR value is higher [2] such in Eq. (3).

$$\text{SR} = \frac{R_p - R_f}{\sigma_p} \tag{3}$$

where R_p is the return of portfoliom, R_f is the risk-free rate and σ_p is standard deviation of the portfolio's excess return.

In the FLAG-TRADER framework, the immediate reward is defined based on the daily change in the Sharpe ratio. Specifically, the reward R(st, at) at state st after taking action at is calculated as $SR_t - SR_{t-1}$, where SR_t is the Sharpe ratio at day t, computed using the historical Profit and Loss (PnL) data up to that time [6].

The reward function in [7] evaluates how good a trading decision is by looking at how much the total portfolio value changes after making a trade. It rewards actions that increase the portfolio's value and penalizes those that decrease it. To make the measure realistic, it subtracts small trading costs (0.1% of the trade value) every time a buy or sell occurs, and it also includes a penalty if the portfolio experiences a drawdown, meaning a drop from a previous high. Eq. (4) shows the followed formula.

$$r_t = \left((p_{t+1}^T n_{t+1}) - (p_t^T n_t) - c_t\right) - d_t \tag{4}$$

where p is the closing price, n is number of shares owned, c is transactional cost, and d is the drawdown penalty.

5) Strategy ranking reward: In a multi-strategy switching model, an agent selects among different trading strategies. The reward value is determined by the ranking of the chosen strategy. The strategy ranked first receives a reward of 1, and the rewards for other strategies decrease sequentially. The ranking is calculated based on a composite score over time, which includes metrics like Sharpe ratio, maximum drawdown, total return rate, annualized return rate, and annualized volatility, weighted appropriately [8].

6) Trend-heuristic reward: Incorporates trend heuristics into reward function. This trend-heuristic reward function is designed to make the agent sensitive to stock price movements, thereby influencing the RL algorithm's optimization objective. Its purpose is to enhance profitability by aligning the agent's policy with observed price trends [9] as illustrated in Eq. (5).

$$r_t = \ln\left(\mu_t \times a_{t-1}^\top v_t\right) + \omega \times a_{t-1}^\top [0.5; \hat{y}_t] \tag{5}$$

where μ_t is the transaction cost, a_{t-1} is the action taken by agent, v_t price relative vector, ω is weight of portfolio potential, 0.5 is the constant cash bias, and $\hat{y}_t$ is the trend heuristic.

7) Sector performance reward: When designing this return function by [10], two key considerations are taken into account. First, to enhance predictions of sector performance changes on current trading days, a cross-entropy structure is incorporated into the denominator. Second, the output is multiplied by the actual percentage change in the numerator to reward substantial shifts in sectors. This approach aims to promote sector rotation while maintaining accuracy in forecasting performance changes. Eq. (6) shows the formula.

$$r_m^t = \frac{p_m^s \cdot \text{pctChg}_m^t}{(p_m^s - \text{pctChg}_m^t)^2 + 1} \tag{6}$$

where p_m^s represents the output of the graph layer, while pctChg_m^t is the price change for sectors.

8) Sector profit maximization reward: The reward here is defined based on the closing and opening prices of a sector on trading day t. It utilizes a softmax function to determine the rewards for different sectors, where higher rewards are given to the sector that exhibits the most significant increase in closing prices compared to opening prices. This structure is designed to inform a portfolio management strategy that involves buying at the opening and selling at the close of each trading day [10] as shown in Eq. (7).

$$r^t = \text{SoftMax}\left(\frac{c_0^t}{o_0^t}, \ldots, \frac{c_m^t}{o_m^t}\right) \tag{7}$$

where c_0^t the closing price and o_0^t is the opening price.

B. Algorithms

Reinforcement Learning (RL) agents learn to make sequential decisions through trial and error, aiming to maximize their expected cumulative rewards in an environment. This learning process fundamentally involves maintaining a balance between exploration (trying new actions to discover potentially better strategies) and exploitation (using the current best known policy). RL algorithms are often broadly categorized based on what they learn: a value function, a policy function, or a combination of both.

1) Value-based methods: Value functions are central to reinforcement learning, estimating the expected cumulative rewards associated with states or state-action pairs, and guiding the agent in making decisions that maximize long-term rewards.

- State Value Function ($V_\pi(s)$): Calculates the expected return when starting from a specific state (s) and following a given policy (π).

- Action-State Value Function ($Q_\pi(s, a)$): Represents the expected return of taking a specific action (a) in a particular state (s) and subsequently following policy (π).

Value-based methods focus on learning the value of states or state-action pairs. The agent's policy is then typically derived from this learned value function, often by choosing the action that is estimated to yield the highest future reward (a greedy policy).

Q-learning is a foundational value-based algorithm described as an experimental approach to optimizing action selection. It is off-policy, greedy, and model-free. The agent iteratively estimates the Q-function by optimizing a version of the Bellman equation, representing the expected sum of immediate and discounted future rewards from taking an action and following the current policy [5].

Deep Q-Network (DQN) is a significant variant that uses deep neural networks to approximate the Q-function ($Q_\pi(s, a)$). This allows DQN to handle complex, high-dimensional state and action spaces. DQN employs techniques like experience replay and fixed Q-targets to improve stability during learning [8].

2) Policy-based methods: Policies are functions that determine the agent's action based on the current state. Policy-based methods directly learn and optimize a policy function without necessarily explicitly learning a value function. Policies can be deterministic, where the network outputs a single action for a given state. Or stochastic, outputting a probability distribution over possible actions for a given state. Stochastic policies are typical for environments with discrete action spaces, where the network outputs probabilities for each action. For environments with continuous action spaces, the policy network typically outputs continuous values representing the action [9].

Policy gradient methods are a class of RL algorithms that directly optimize the parameters of the policy function. They adjust parameters in the direction of the gradient of the expected cumulative reward [9].

3) Actor-critic methods (Hybrid): Actor-Critic methods combine the strengths of both value-based and policy-based approaches. They typically consist of two components: an "actor" which is a policy network that selects actions, and a "critic" which is a value function network that estimates the value of states or state-action pairs . The critic's value estimates are used to evaluate the actor's chosen actions and guide the actor's policy update [6].

The critic learns a value function (either state-value or action-value) to evaluate the actor's policy. This evaluation, often in the form of an advantage estimate (how much better the taken action was compared to the expected value of the state), is used to update the actor's policy parameters [6].

Proximal Policy Optimization (PPO) is a widely used policy optimization algorithm and a type of policy gradient method. It is known for its stability and efficiency. PPO stabilizes learning by clipping the probability ratios between the new and old policies, preventing large, destabilizing updates. PPO is specifically noted as being effective for continuous action spaces. PPO is used as the core RL algorithm in several frameworks [1], [11], [12], [3], [6].

Twin-Delayed Deep Deterministic Policy Gradient (TD3) [5] utilized the Twin Delayed Deep Deterministic Policy Gradient (TD3) algorithm as the foundation for their strategic market agent. TD3 extends the Deep Deterministic Policy Gradient (DDPG) framework, which enables learning in continuous state and action spaces through an actor–critic architecture. The actor network deterministically maps each state to an action, while the critic network evaluates their expected return. TD3 enhances this approach by employing two critic networks to counteract Q-value overestimation and by delaying policy updates, leading to more stable and reliable learning performance.

C. Approaches

A basic workflow of reinforcement learning for portfolio trading begins with the agent observing the environment state, which typically includes market data and, in many cases, sentiment information extracted from news using an LLM model or API. The agent also tracks its internal state, such as cash balance, portfolio holdings, or net worth. This internal information can be utilized for reward calculation, portfolio evaluation, and ensuring only valid actions are taken. It can also be combined with the environment state to apply the agent's policy to select an action, which may involve buying, selling, holding, or rebalancing portfolio weights. The environment then updates according to the new market conditions, and the agent receives a reward signal that reflects one or more of the portfolio optimization objectives, such as profit maximization, risk minimization, and transactional cost reduction. This reward guides the agent in updating its policy, forming a continuous cycle of state observation, action execution, and policy refinement.

Following this workflow, multiple papers have been contributed by employing different LLM models, prompting LLM in various techniques, to find different sentiment types, such as plural sentiment or stock recommendations, risk assessment,

TABLE I. KEY DRL COMPONENTS FOR PORTFOLIO OPTIMIZATION

Paper	Algorithm	Agent State	Environment State (dataset)	Action
[1]	PPO	Cash balance, Shares quantity or Net worth based on trading setting (portfolio or SST), Cost basis	Price data, Volume, Weighted signed scoring of plural sentiments (News headlines) [Last 5 states]	Trading signal, Trade proportion (balance/share) adjusted by 0.1 of sentiment score
[2]	A2C	long/short positions, Cash balance, Shares quantity	Close price data, Macroeconomic indicator, Microeconomic indicator, Technical indicators, Distinct signed scoring of market trends (News)	Share quantity rebalancing for each position separately
[3]	PPO	Cash balance, Portfolio Weights	Weighted signed scoring of plural sentiments (News)	Portfolio weights rebalancing
[5]	TD3	Shares quantity	Limit order book snapshots, News, Synthetic social media posts	Share quantity rebalancing, Weighted signed scoring of plural sentiments
[6]	PPO	Cash balance, Shares quantity, Net value	Price data, Volume, Net value, Sentiments (external tool) [Last 10 trajectories]	Trading signal
[7]	PPO	-	Price data, adjusted close price, MACD, MACD signal line, MACD histogram, CCI, RSI ADX, News headlines embedding	Share quantity rebalancing
[8]	-	Cash balance and other account data	Interstice relation of price data, News headlines	Strategy selection
[9]	Classical direct policy gradient algorithm	-	State Representation using: Price data, c, Technical indicators (z_{open}, z_{high}, z_{close}, $z_{adjclose}$, z_{d5}, z_{d10}, z_{d15}, z_{d15}, z_{d20}, z_{d20}, z_{d25}, z_{d30}), News headlines [Last state]	Portfolio weights rebalancing (including cash)
[10]	Modified DPG/policy gradient	-	Sector Features obtained from: Price data, Volume, trading amount, turnover rate, rise and fall range, rolling price/earnings ratio, price/book ratio, rolling price/sales ratio, and rolling price/cash ratio [30 day window]	Sector trend prediction
	Classical stochastic policy gradient	-	Predicted Sector trend, Distinct signed scoring of sentiment (News), Stocks relationships within sector [last state]	Portfolio weights Allocation
[11]	PPO	-	Technical indicators (MACD, RSI, Bollinger Bands, ADX, VWMA, ATR), Distinct signed scoring of plural sentiments (News headlines, Financial Articles, Social media posts) [Last state]	Weights of RAG knowledge source summing to one, Trading signals dervien by Sentiment score for equally weighted portfolio
[12]	PPO	Portfolio Weights	Distinct positive scoring of stock recommendation (News), Distinct positive scoring of risk assessment (News)	Portfolio weights rebalancing adjusted by recommendation score
[13]	PPO	-	Price data, Technical indicators, Distinct positive Trading Score(Distinct positive scoring of plural sentiments (news), adjusted close percentages)	-

etc. The extracted sentiment is then utilized to adjust the reward, action, or guide the policy learning by adjusting the advantage function, which is part of the PPO objective function. Few studies have made adjustments to state representation, either by learning the state representation or by rule-based modifications.

One example of basic flow is [1], where extracted sentiment integrated into the algorithm's state observations, action adjustments, and reward calculations. The study in [1] presents two setting of problem that single stock trading (SST) and portfolio trading. A modification on reward represented at Section IV-A1 was done adding sentiment-based reward to encourage trades that follow market sentiment alongside with volatility adjustment which reduces sentiment-based reward when prices are unstable. One additional component of reward is added for portfolio settings which is portfolio net worth change. As the name suggest it calculated by summing the value of all stocks held and cash balance. The influence on action is done with simple calculation, modifying trade proportion (balance/share) by 0.1 of sentiment score. Table I shows key DRL components for portfolio optimization.

Another study by [3] following the basic flow has applied LLaMA 3.3 trained on an extensive collection of earnings reports, market commentaries, and analyst insights, enabling it to differentiate between neutral reporting, speculative viewpoints, and sentiment-influenced market trends. This model has been fine-tuned for financial text analysis to extract daily financial news sentiment. Market sentiment has been part of state representation and the advantage function of PPO model. The study has illustrated that integrating market sentiment can enhance adaptability and robustness in portfolio optimization.

The study in [13] introduces a Market-Cap Stratified Subset (MCSS) strategy that is which groups stocks by market capitalization into small, mid and big. Allowing different impact of sentiment score on different groups, due to different sensitivity to sentiment for each group, especially as smaller stocks tend to react more strongly. In addition, they introduced Market-Aware Module that modify the observed state in rule-based way. It checks whether short-term price movements align or conflict with sentiment signals producing trading score which fed later into the RL model.

The study in [12] uses the risk assessment scores generated by the LLMs like DeepSeek V3, Qwen 2.5, and Llama 3.3, to adjust the trajectory returns in the Conditional Value-at-Risk (CVaR) extended objective formalized by [14]. The CVaR objective is a risk-sensitive constrained optimization problem

in reinforcement learning, aiming to maximize expected return while penalizing high-loss trajectories by keeping the policy's CVaR below a specified threshold. CVaR itself is a risk measure that estimates the expected loss of a portfolio given that the loss is greater than the Value-at-Risk (VaR) threshold. The importance of CVaR is that it goes further than VaR by calculating the average loss in the worst α portion of outcomes.

In addition to risk-sensitivity contribution, [12] had contributed by modifying the model action with generated trade recommendation signals from financial news using the same LLM models.

The study [8] suggests a method for dynamic strategy switching based on large language models, GPT-4 in particular, to adapt market changes. [8] has utilized a financial concept named asset pricing model that is a framework that links asset risk to expected return. The model have been formulated as in Eq. (8).

$$\hat{R}_t = \alpha_t + f_t \cdot \beta_t \tag{8}$$

Where α_t is the Local Data Model which mines the intrinsic information specifically their linear relationship. While β_t represents yields of Global Algorithm Trade Model which select the corresponding trading strategy. f_t component represents the strategy selection made by the algorithm model at time t. $\hat{R}_t$ is the final return of a stock at time t.

The model f_t applies reinforcement learning principles on LLM prompting by processing historical data features, executing the selected strategy, calculating ranking reward as explained in section IV-A5, and iterating after each strategy selection action, thereby enabling adaptive multi-strategy switching in environments where conventional RL methods would demand extensive retraining and hyperparameter tuning across different datasets. To achieve this, the prompt is structured into modular components that are role definition, Few-Shot examples, strategy description, and output formulation via the Chain-of-Thought approach, guiding the LLM to reason analytically through data trend analysis, strategy selection rationale, and strategy critique, while also outputting the chosen strategy in JSON format.

The study [6] proposed an advanced approach using an LLM-based actor–critic architecture. In their design, the layers of the SmolLM2-135M-Instruct model were divided into frozen and trainable layers. The trainable layers were optimized through reinforcement learning fine-tuning, where reward signals guided their learning. This setup allows the model to retain broad language comprehension while efficiently adapting to financial decision-making tasks with low computational cost.

Additionally, a policy MLP network and a value MLP network were incorporated, both leveraging the output of the trainable layers for domain-specific learning. Unlike conventional integrations of RL with LLM, the model in [6] was directly prompted to generate trading actions.

The study [7] have proposed using Partially Observable Markov Decision Process (POMDP) with stock trading. Which 2 additional elements above regular MDO, that are observation (Ω) and conditional observation probability (O). In POMDP, the agent receives an observation with o $\in \Omega$ that depends on s_{t+1} and a_t , with probability O($o_t \mid s_{t+1}, a_t$). In this paper [7] FinBERT was used to extract embedding mean from news headlines combined with market data creating an observation vector. A PPO architecture were modified to contain LSTM layers alongside the casual MLP layers for both actor and critic heads.

A study that focus on sector rotation and multi-RL was proposed by [10]. Sector rotation is a macro-level portfolio strategy, where investment shifts between sectors and capital allocation is managed across sector distributions rather than individual stocks. The approach employs a two-layer Markov Decision Process (MDP) framework. The first layer uses a multi-agent reinforcement learning model to capture sector trend dynamics from time-series data that taken from raw stock data and transformed to sector data. The second layer focuses on portfolio management, integrating multiple sources such as time-series data for all stocks, outputs from the first layer, sentiment insights from news analyzed with large language models, and sector-level stock relationships extracted through graph convolution. By fusing these diverse inputs, the model produces the final portfolio decisions.

The study [2] introduced an adaptive and explainable framework that integrates Large Language Models (LLMs) with Reinforcement Learning (RL) to enable dynamic long–short position adjustments in response to evolving market conditions. This approach overcomes the limitations of traditional margin-trading systems, in which the long–short ratio is predetermined and remains static throughout the trading period, by allowing periodic and adaptive reallocation. The proposed framework comprises two primary components. The first is the Explainable Market Forecasting/Reasoning Pipeline, which employs LLMs to determine optimal adjustment ratios every k steps. The LLM utilizes two specialized prompt pipelines, one tailored for macroeconomic indicator time Series and another for firm-specific news. The second component is the Portfolio Reallocation Stage, which employs a pre-trained RL agent to rebalance the portfolio by reallocating funds between long and short positions in order to achieve the updated ratio. After the reallocation, the RL agent continues its trading operations using the adjusted portfolio for the next k steps. In addition to predicting adjustment ratios and near-term trends, this approach offers explicit reasoning and clear insights that improve portfolio decision-making.

The study [11] proposed a novel framework that builds on the capabilities of LLaMA 2 and enhances it through an advanced fine-tuning approach called Retrieval-Augmented Generation (RAG). This method integrates multiple knowledge sources to enrich model outputs with current, domain-specific information, thereby reducing hallucinations and improving accuracy. Furthermore, the language model was refined using reinforcement learning (RL) feedback, where the LLM's generated sentiment scores were evaluated against market returns. These evaluations were incorporated into a reward function within a PPO-based RL structure, guiding the model's optimization and enabling adaptive weighting across the K knowledge sources in the RAG module.

The study in [5] presents an attempt that the first of its kind based on researcher believes to asses market manipulation, pump-and-dump schemes specifically, through LLM-generated

text within a realistic financial market simulation. They have shown how the RL agent learns to enhance its reward by deliberately influencing market sentiment by its posts. The experiment have been conducted in an offline simulated environment to ensure ethical integrity. The isolated offline feed is mainly generated by replaying historical order data to be feed to Analyst prompt posts and Trader prompt posts. To model how traders respond to language-based manipulation, a sentiment-driven trading agent is introduced that analyze the sentiment of social media feed using RoBERTa model and computes weighted sentiment score as its trading indicator. In the other hand, RL trader is used to influence on the sentiment-based agent. While it takes order streams to make its trading action and sentiment action. It optionally generate social media posts reflecting its sentiments which then are visible to the sentiment agent. The RL agent structure is based on Twin Delayed Deep Deterministic Policy Gradient (TD3) that employ three fully connected layers with normalization, and the actor uses an LSTM-based embedding of sequential observations.

D. Evaluation Metrics

A robust evaluation of quantitative trading strategies requires the use of diverse metrics spanning profitability, risk, and risk-adjusted returns. These metrics are crucial for assessing performance and ensuring that algorithms meet investment objectives, which typically center on maximizing return while maintaining portfolio stability. The metrics utilized across the papers can be generally categorized into Risk-Adjusted Performance, Return, Risk and Volatility, and other specialized metrics. Evaluation often prioritizes Cumulative Return (CR) and Sharpe Ratio (SR) for assessing long-term gains and risk-adjusted returns.

1) Risk-adjusted performance metrics: It provide a more comprehensive assessment of a strategy's efficacy than absolute returns by relating the gains achieved to the level of risk undertaken. The Sharpe Ratio (SR) is the most frequently cited metric across the papers, appearing in nine papers. It is a critical financial metric that assesses the risk-adjusted return of an investment or portfolio. SR has been explained in Eq. (3).

2) Return metrics: It quantify the absolute profitability or monetary gain generated by a trading strategy over a specific period. Cumulative Return (CR) is a key performance indicator that measures the total value change of an investment over time. It is typically expressed as the overall percentage gain or loss of a portfolio over a specified period. Eq. (9) show how to measure CR.

$$CR = \frac{P_{end} - P_0}{P_0} \tag{9}$$

where P represents the portfolio value.

The Annualized Rate of Return (ARR), or Annualized Return (AR), represents the average rate of return for a managed portfolio over a full year of trading days. It is derived from the daily returns average over the investment period, adjusted to a yearly scale based on 252 trading days. Eq. (10) show how to measure ARR.

$$ARR = \frac{\text{Total net profit/Number of years}}{\text{Initial investment}} \tag{10}$$

3) Risk and volatility metrics: are essential for quantifying the instability and maximum potential downside of a trading strategy. Maximum Drawdown (MDD), sometimes referred to as Maximum Pullback (MPB), quantifies the largest single drop in an asset's value from its highest peak to its lowest trough over a specific period. It serves as a crucial indicator of portfolio risk. Eq. (11) show how to measure MDD.

$$MDD = \max\left(\frac{V_{\text{peak}} - V_{\text{trough}}}{V_{\text{peak}}}\right) \tag{11}$$

Annualized Volatility (AV) quantifies the return fluctuations of a portfolio. Eq. (12) show how to measure AV.

$$AV = DV \times \sqrt{252}. \tag{12}$$

where DV is standard deviation of daily returns adjusted to an annual scale by the square root of 252.

V. Findings and Discussion

This section synthesizes insights from the reviewed studies, emphasizing how Deep Reinforcement Learning (DRL) and Large Language Models (LLMs) contribute to portfolio optimization.

A. Algorithmic Trends and Performance

Across the 12 studies reviewed, Proximal Policy Optimization (PPO) emerged as the most frequently used algorithm due to its training stability and effectiveness in continuous control problems. PPO-based models demonstrated robust adaptability to market fluctuations and achieved high risk-adjusted returns, with Sharpe Ratios (SR) ranging from 1.46 to 3.34 across various datasets. TD3, modified DPG/policy gradient, and hybrid actor–critic methods were less common but effective in handling continuous action spaces and noisy financial environments.

B. Reward Function Design

Reward function formulation remains a decisive factor influencing portfolio behavior and risk sensitivity. Studies using risk-adjusted metrics, such as the Sharpe Ratio or Conditional Value-at-Risk (CVaR), encouraged smoother trading behavior and improved robustness in volatile markets. In contrast, heuristic and trend-based rewards. On the other hand, Sector-level or ranking rewards extend learning to macro or multi-strategy settings but increase model complexity. Overall, effective reward design depends on balancing interpretability, stability, and economic realism while mitigating overfitting to short-term or sentiment-driven fluctuations.

TABLE II. EXPERIMENTAL RESULTS OF REVIEWED STUDIES, SHOWING THEIR BEST EXPERIMENT RESULT

Paper	Experimental Setup	Index / Fund	Date	Period	↑ SR	↑ CR	↑ ARR	↓ MDD	↓ AV
[1]	GPT	LEXCX	16/11/2023 to 10/11/2024	1 Year	-	0.4201	-	-	-

C. Integration of Large Language Models

LLMs play a complementary yet transformative role in portfolio optimization. Their integration primarily occurs in multiple forms. One is sentiment Integration by extracting sentiment from news or social media to augment state representation, guide reward shaping, or produce direct trading actions. Another form of integration is using LLM within actor-critic networks. Studies show that incorporating LLM-derived signals improves adaptability and interpretability. For instance, [3] and [12] demonstrated how LLM-based sentiment and risk assessments enhance DRL's responsiveness to macroeconomic shifts. However, over-dependence on textual inputs can introduce bias and instability, especially when news sources are inconsistent or temporally lagged.

D. Data Sources and Environment Complexity

The reviewed studies use diverse data sources, including price data, technical indicators, macroeconomic indicators, and unstructured text from financial news. Combining structured (numerical) and unstructured (textual) data consistently improved model generalization and return stability. For example, models combining price data and sentiment, such in [11] study, achieved higher SR and lower maximum drawdown (MDD). Nevertheless, few studies explicitly address non-stationarity or market regime shifts, which remain critical challenges for DRL-based approaches.

E. Comparative Results

Table II summarizes the quantitative results across studies. Sharpe Ratios ranged between 0.42 and 3.34, and Cumulative Returns (CR) reached up to 33.7%, indicating substantial improvements compared to traditional benchmarks. A study that integrates LLMs with PPO as its network achieved the highest SR values, meaning employing LLM as a core component ensures an accurate understanding of market dynamics and sentiments, which ultimately enhances performance, regardless of the fact that the LLM model utilized, SmolLM2, is a lightweight LLM model compared to others. In other hand, DeepSeek-R1 demonstrated one of the strongest results 3.1 in SR. Both SmolLM2 and DeepSeek-R1 underscore the benefits of fine-tuned, lightweight LLMs in trading contexts.

F. Challenges and Limitations

Despite notable advances, several challenges persist. One is Reward design sensitivity; minor adjustments can destabilize learning, especially under sparse or delayed rewards. Another is Computational cost; combining DRL with LLM fine-tuning increases training overhead. Also, Overfitting and limited generalization, many models are trained and tested on specific indices (e.g., NASDAQ, S&P 500) or narrow time horizons, making them vulnerable to overfitting. Explainability and interpretability, although LLMs improve textual reasoning, both DRL and LLM components remain largely black-box systems.

VI. CONCLUSION

This survey demonstrated the transformative role of Deep Reinforcement Learning (DRL), particularly in conjunction with Large Language Models (LLMs), in addressing the challenges of dynamic portfolio optimization. PPO emerged as the most widely adopted and stable DRL algorithm, proving effective in continuous control environments and achieving robust, high risk-adjusted returns (Sharpe Ratios up to 3.34). The design of the reward function is a critical factor, with risk-adjusted metrics like the Sharpe Ratio and Conditional Value-at-Risk (CVaR) encouraging smoother and more stable portfolio behavior in volatile markets. The integration of LLMs significantly enhances these models by extracting market sentiment, risk assessments, and trading insights from unstructured text data, thereby improving adaptability and interpretability. Combining structured (price and technical indicators) and unstructured (textual) data sources consistently leads to better model generalization and return stability. Nonetheless, the field still contends with significant challenges: the sensitivity of reward function design, high computational costs associated with fine-tuning LLMs alongside DRL, the risk of overfitting to narrow time horizons, and the persistent issue of limited explainability in these black-box systems. Future research must

prioritize solutions for non-stationarity and market regime shifts to enhance the long-term competitive advantage of DRL-LLM approaches in real-world financial markets

Human-Computer Interaction, Iowa State University, Ames, USA[1]
Industrial and Manufacturing Systems Engineering Department, Iowa State University, Ames, USA[2]

***Abstract*—As the world experiences a rapidly aging population, it has become a pressing design challenge to ensure that emerging digital technologies remain understandable, supportive, and meaningful for older adults. One of the most promising modalities for promoting inclusive interaction is the Voice User Interface (VUI), supported by artificial intelligence (AI) and speech recognition. However, most existing VUIs emphasize functional accuracy and overlook users' emotional conditions, such as anxiety, confidence, or frustration, which significantly affect long-term engagement and adoption. To address this gap, this study introduces a structured and adaptive model for developing emotionally intelligent voice interfaces, namely MOON Framework (Model-Observation-Optimization-Nurture). This framework integrates demographic and linguistic profiling (Model), real-time emotional perception (Observation), adaptive vocal modulation (Optimization), and feedback-driven learning (Nurture) to create a closed-loop system capable of adjusting dynamically to user experience. Grounded in Affective Computing Theory, Socioemotional Selectivity Theory (SST), and Adaptive User Modeling, MOON Framework conceptualizes empathy as a measurable and computable dimension of VUIs. Unlike existing affective systems that rely primarily on visual or physical expressiveness, MOON demonstrates that vocal empathy, achieved through modulation of tone, cadence, and speech rate can foster comparable emotional attunement. Its cyclical design transforms emotion from a passive observation into an active driver of system adaptation. Focusing on familiarity and confidence specifically in older adults, MOON provides both a theoretical foundation and a practical framework for creating emotionally inclusive AI technologies that promote trust, engagement, and long-term well-being.**

Keywords*—*Voice User Interfaces; emotional adaptivity; affective computing; older adults; human-computer interaction; empathy; accessibility; adaptive systems; MOON Framework

I. Introduction

Inclusive technology design is now a matter of greater concern as the world population is aging. VUIs are a potentially effective option to enhance the accessibility of older adults (intuitive, hands-free interface) [1], [2], [3], [4]. However, even with their potential, the majority of the existing systems are not sensitive to affective states, including confusion, confidence, or frustration, and react to verbal commands without sensibilities [3]. The aspect of trust and continued use of technology is highly affected by older adults based on emotional factors, and these concepts should be addressed to bring about the concept of real inclusivity [2], [5], [6].

Some of these reasons, besides the technological constraints, include the emotional and contextual constraints which influence the manner in which the older adults use the computing systems [3], [6], [7]. The modern interface design practice as explored in the previous work [8] tends to presume homogeneous sensorial and cognitive abilities and undervalues the emotional aspect of adoption of technology. The literature review has shown that the confidence and familiarity of older users decrease when the digital systems do not recognize the user's emotional clues and do not change their communication style in response [2], [3]. Based on these findings, the current study presents those findings in a formalized form of a structured model of interaction that does not view emotion as a by-product, but as a variable of central concern in design. This continuation of the earlier research based on empirical findings into the development of formal frameworks makes this current work a conceptual follow-up of the previous research [3], [7].

In this respect, it is more crucial to reconsider how ubiquitous, emotionally responsive technologies have the potential to make the aging demographic more engaged and well. With computing being integrated into everyday practices, such as smart houses, social interaction, and health care, its usefulness with the elderly population lies in how successfully it can incorporate emotional sensitivity into communication [2], [3], [7]. Computing is everywhere, and this is extraordinary in possibilities except that, unless designed in an emotionally aware way, it will only perpetuate digital exclusion. MOON Framework (Model, Observation, Optimization, and Nurture) is a response to this dilemma as it offers a methodical, reproducible approach to the integration of empathy in voice-based systems to make such technologies easy, meaningful, and trustworthy to various users.

The research problem stated in this study relates to the lack of emotional intelligence in the existing Voice User Interfaces and the subsequent gap of accessibility and sustained engagement for older adults. In response to this, in this study, the following research questions are asked: 1) How can, in voice interaction systems, emotional adaptivity be formally modeled?, 2) What theoretical elements and interaction mechanisms will be needed to integrate empathy into VUIs? and 3) How can such a framework help promote familiarity, confidence and long-term use to older users? Accordingly, the purpose of this research is to construct a structured theoretical framework (MOON), which conceptualizes emotional adaptivity in voice interaction and to describe its phases of design, its underlying principles and its implications for practice. The importance of this work is to make a step towards inclusive design by shifting emotion from being a secondary consideration in design to being a

primary driver of accessibility to create emotionally responsive AI systems for trust, engagement, and well-being among older adults.

The structure of this study includes an introduction, related work, conceptual foundation, framework development methodology (MOON Framework), discussion, and conclusion and future work.

II. Related Work

The study of emotionally intelligent systems has developed rapidly over the past three decades, particularly in affective computing, psychology, and HCI. Prior research [9], [10], demonstrated that the integration of emotion recognition within computing enables both functional accuracy and affect-sensitive communication. Recent advances in emotional artificial intelligence have expanded these foundations, yet most models remain focused on embodied robots and visually interactive agents rather than auditory modalities [11], [12], [13]. As a result, voice-based systems remain comparatively underdeveloped in their responsiveness to emotion, a gap that motivates the design of MOON Framework. This framework is particularly relevant for older adults, whose interactions with technology involve distinctive emotional and contextual challenges [8], [14]. Accordingly, the following subsections review three areas of prior research, affective computing, VUIs for older adults, and adaptive HCI frameworks, that collectively inform and contextualize the development of MOON.

A. Emotional AI and Affective Computing

Affective computing has long served as the scientific foundation for engineering systems capable of perceiving, interpreting, and responding to human emotions. Recent systematic reviews, such as those by Wang et al. (2022)[15], highlight how the field has progressed from basic emotion detection toward more sophisticated affective modeling. Early research typically focused on improving multimodal emotion recognition by combining facial expressions, gestures, physiological cues, and vocal signals to increase accuracy and robustness [14], [16]. As computational methods evolved, interactive systems began to incorporate adaptive mechanisms that enabled them to mirror, regulate, or guide users' emotional states-transitioning toward socially oriented artificial intelligence capable of more human-like engagement [17], [15].

For older adults, emotionally intelligent technologies hold particular importance, as empathetic interactions have been shown to improve comfort, motivation, and engagement. Studies in socially assistive robotics and expressive interfaces demonstrate that emotionally responsive behaviors, whether delivered through facial expressions, gestures, or vocal modulation, can enhance confidence and interest among older users [17], [18], [19]. However, despite these promising effects, multimodal expressiveness poses limitations in scalability, as it often relies on a visible embodiment or spatially dependent channels, making it less practical for voice-only or remote communication scenarios [20], [21].

Recent advances in affective computing have therefore prompted a shift toward auditory-based emotional systems. These approaches leverage prosodic cues, such as intonation, pace, pausing structure, and timbre, to simulate empathy and convey affective intent without relying on a visual body [15], [21]. Research further shows that speech-based emotion recognition can achieve high accuracy and support emotionally attuned interaction, providing strong justification for frameworks like MOON that prioritize vocal adaptivity over multimodal complexity [21], [22].

B. Voice User Interfaces and Older Adults

Voice interaction is widely recognized as an intuitive and accessible communication modality, particularly for individuals with visual, motor, or literacy limitations. Older adults benefit substantially from VUIs because spoken communication reduces reliance on complex graphical interfaces, which may be difficult to navigate due to age-related perceptual changes [1], [2], [23], [24]. However, these benefits depend heavily on how well the system manages both linguistic and emotional complexity. Prior research in HCI has emphasized that VUIs designed for older users must account for their unique emotional needs and challenges, particularly regarding trust, frustration tolerance, and communication clarity [3], [8].

Despite this potential, commercial VUIs such as Amazon Alexa and Google Assistant remain predominantly command-based and rarely adapt their vocal style to users' affective states. This limitation is especially problematic for older adults, whose emotional attitudes toward technology are often shaped by anxiety, self-efficacy, and perceived control [2], [5], [25]. For example, recurring recognition errors may lead to frustration or embarrassment, reducing trust and willingness to continue using the system. Without mechanisms to sense or respond to such emotional dynamics, even well-designed systems risk disengaging those who may benefit from them most.

The tension between functional accuracy and emotional attunement is a persistent challenge highlighted across empirical studies of older adults and VUIs. Prior work shows that while older users appreciate the convenience of voice assistants, the interaction is often described as insufficiently empathetic or personalized to their needs [2], [26]. Conversely, emotional warmth and social presence have been shown to be stronger predictors of long-term use than usability alone [27], [28]. These findings underscore a longstanding design gap: VUIs may perform well technically yet fail emotionally. Addressing this mismatch requires shifting from task-only design toward supporting emotional continuity, ensuring the system maintains confidence, reassurance, and attunement throughout interaction [8].

MOON Framework is proposed as a response to this challenge by embedding emotional adaptivity into the operational core of VUI behavior. Rather than treating emotion as an optional layer, MOON emphasizes empathy, familiarity, and confidence as primary design variables, offering a structured approach to closing the gap between functional accessibility and emotional responsiveness in voice interaction for older adults.

C. Adaptive and Personalized HCI Frameworks

The concept of adaptation has long been central in HCI, where user modeling and personalization aim to enhance usability, engagement, and long-term relevance. Adaptive interfaces, as characterized by Fischer (2001), modify their behavior based on the user's actions and learned preferences. However, the vast majority of adaptive HCI systems remain cognitively adaptive, adjusting task difficulty, content delivery, or interface layout, rather than emotionally adaptive. These systems respond to observable user actions but typically fail to account for underlying affective states such as stress, hesitation, or frustration [15], [29], [30]. This distinction is particularly important in the context of older adults, whose emotional experience during interaction cannot be fully captured through performance metrics alone. An older user may complete a task successfully and yet experience anxiety or uncertainty. A cognitively adaptive interface would interpret this as a success, while an emotionally adaptive system would detect subtle affective cues, such as tone, pitch, or pacing, that indicate discomfort and respond accordingly.

Recent models in adaptive HCI have explored multimodal emotion recognition as a means of improving responsiveness. Studies have examined systems capable of detecting emotions through facial expressions, voice, gestures, or physiological signals, demonstrating strong real-time detection accuracy [15], [29], [31]. However, very few of these frameworks extend adaptation across entire interaction sessions. Most systems are episodic: they sense emotion, adapt once, and then reset. They lack mechanisms to preserve emotional history, remember prior states, or build familiarity over time. This limitation is particularly relevant for older adults, whose emotional comfort increases when systems demonstrate consistency and memory of prior interactions. MOON Framework addresses this challenge within its Nurture phase, which uses outcomes from each conversational cycle to shape the system's future behavior. Rather than offering one-step adjustments, MOON supports both intrasessional and intersessional adaptation,building a longitudinal emotional model that evolves with continued use. Its feedback loop is conceptually more advanced than classical adaptive systems, which are typically unidirectional ("input $\rightarrow$ output $\rightarrow$ end"). MOON instead integrates continuous emotional learning, ensuring that empathy becomes a dynamic quality that improves with repeated interactions. As the system accumulates experience, it generates increasingly refined adaptive responses aligned with human-centered AI principles, ultimately becoming more emotionally sensitive and personally attuned to the user [32].

III. Conceptual Foundation

MOON Framework extends the conceptual model developed by Sagga and Stone (2025) [8], in which emotional familiarity and user confidence were identified as central determinants of older adults' participation in digital technologies. While prior research has emphasized the value of emotional attunement for trust, usability, and engagement, these findings have largely been qualitative in nature. The present work advances this line of inquiry by formalizing those insights into a structured computational model. Specifically, MOON Framework operationalizes empathy as both an input, captured through measurable emotional cues, and an output expressed through adaptive system behavior. This conceptualization builds on foundational perspectives in affective computing together with SST, which explains the growing emotional relevance of interactions for older adults [33], and principles from adaptive user modeling. Integrating these theories provide a unified methodological basis for systems capable of perceiving emotion, adapting vocal responses accordingly, and refining their behavior through iterative feedback, thereby positioning emotional inclusiveness not merely as a design principle but as an ongoing interactive learning process.

A. Affective Computing: From Recognition to Empathy

Affective computing provides the technological foundation on which MOON Framework is built. Introduced by Rosalind Picard (1997) [34], the field defines computational systems capable of recognizing, interpreting, and simulating human emotions. Early studies in affective computing primarily focused on emotion detection, classifying user states as positive, negative, or neutral based on physiological and behavioral cues [10]. Over time, however, research expanded toward affective adaptation, in which emotion functions not only as an input signal but also as a determinant of system behavior [14].

Within this evolution, MOON Framework aligns with the second wave of affective computing research that emphasizes emotion-aware adaptation rather than simple recognition [14], [15]. The framework extends traditional detection mechanisms toward what may be described as emotion reciprocity: the system's ability to respond empathetically to a user's affective state. In voice interaction, this reciprocity is achieved by identifying patterns in speech, such as pitch shifts, rhythm changes, speech rate, and pause length, and using these cues to modulate the system's own vocal output [14], [35].

A central contribution of MOON to the field is its shift toward unimodal empathy, relying solely on the auditory channel rather than multimodal combinations involving facial, physiological, or textual data. Multimodal systems, although powerful, often introduce complexity and accessibility issues, particularly for older adults who may be uncomfortable with cameras or wearable sensors [15], [36]. By leveraging prosodic cues alone, MOON demonstrates that meaningful empathy can be achieved using minimal but highly informative vocal signals, an approach supported by evidence that listeners are remarkably skilled at interpreting emotion from voice even without visual indicators [35].

In this sense, MOON reframes affective computing as an interactive emotional dialogue. The user communicates through affective speech patterns, the system perceives and interprets these signals, and the system's vocal output is shaped accordingly through adaptive modulation [14], [15]. This interaction mirrors natural human conversation, where subtle variations in tone, rhythm, and cadence convey interest, concern, or attentiveness. By formalizing this exchange within a computational cycle, MOON transforms emotional intelligence from an abstract design ideal into a functional component of everyday voice-based interaction.

B. Socioemotional Selectivity Theory (SST): The Psychology of Emotional Relevance

Socioemotional Selectivity Theory provides the psychological grounding for which emotion-centered design is essential for older adults. Developed by Carstensen (2006) [33], SST argues that increased awareness of limited time horizons with age leads to a motivational shift: older adults prioritize emotionally meaningful goals, stable relationships, and affective fulfillment over novelty exploration. This shift gives emotional well-being a central role in shaping attention, memory, and decision-making, as supported by later research in lifespan development [37], [38].

Applied to human-technology interaction, SST suggests that older adults may approach digital systems not merely as tools but as potential social partners that can offer comfort, reassurance, and emotional stability. As a result, systems that are sensitive to affective cues are more likely to foster trust, credibility, and long-term engagement. Conversely, emotionally neutral or insensitive systems can be perceived as cold, burdensome, or cognitively demanding [39], [40].

MOON Framework integrates SST by emphasizing emotional congruence, the alignment between the user's affective state and the system's communicative style. Through prosodic modulation, a VUI can mirror or complement the user's emotional tone, thereby enhancing psychological comfort and interpersonal synchrony. For example, frustration may be alleviated by a calm, tolerant vocal response, whereas a challenging task may benefit from an encouraging and steady tone [41], [42]. SST further indicates that older adults actively regulate their emotions and prefer interactions that maintain positive affect rather than those that introduce excitement or novelty. This insight reinforces one of MOON's core design principles: adaptation should aim at stabilizing the user's emotional experience, not arousing it. Thus, the system's goal is not to demonstrate human-like exuberance but to deliver reliability, reassurance, and emotional predictability, qualities that align naturally with the motivational priorities of aging adults [41], [42].

By incorporating socioemotional selectivity directly into its structure, MOON Framework reframes emotion as a functional design variable rather than an incidental feature of interaction. Emotional adaptivity becomes both a design strategy and an ethical responsibility, one that supports the psychological well-being of users while maintaining technological clarity and accessibility.

C. Adaptive User Modeling: Learning from Interaction

Affective computing explains the mechanisms through which systems detect and interpret emotion, while Socioemotional Selectivity Theory provides the psychological justification for why systems should attend to these affective states. Adaptive user modeling complements these perspectives by offering the computational structure through which emotional information can be integrated over time. Rooted in human-computer interaction and cognitive science, adaptive modeling involves constructing dynamic representations of users that evolve as systems accumulate interaction data. Whereas traditional user models rely on static profiles, such as age, gender, or stated preferences, adaptive models continually update their parameters based on observed behavior and contextual cues, allowing the system to refine its understanding of the user across sessions.

MOON Framework extends adaptive user modeling into the affective dimension. Its Model and Nurture phases reflect this structure: the Model phase establishes an initial baseline built from demographic and linguistic characteristics, while the Nurture phase incrementally updates this profile using emotional and behavioral outcomes from prior interactions. Each cycle contributes to a gradual recalibration of the system's emotional responses, enabling MOON to simulate a human-like trajectory of experiential learning and emotional attunement.

A key distinction of MOON is its use of affective feedback as a learning signal, rather than relying solely on conventional performance indicators. Traditional adaptive algorithms measure success through error rates, task duration, or accuracy, but MOON incorporates emotional variables, such as hesitation, confidence, frustration, or satisfaction, as informative cues. This approach transforms affective experience into quantitative data, enabling the system to refine not only its task strategies but also its communicative behaviors through adaptive prosody.

Through this mechanism, MOON achieves what can be described as affective adaptivity, an ability to optimize its emotional intelligence by continuously observing user affect. This methodology integrates computational adaptivity with psychological empathy, creating a form of emotional learning that parallels reinforcement learning, but grounded in affective signals rather than rewards. Over time, the system becomes increasingly sensitive to individual users, reinforcing familiarity, personalization, and trust in long-term interactions [14].

D. Integrative Theoretical Perspective

Affective computing, SST, and adaptive user modeling collectively form a cohesive theoretical foundation for emotionally adaptive voice interaction within VUI design. Affective computing provides the algorithmic infrastructure required for emotion recognition and expressive modulation, enabling systems to detect and interpret affective cues. SST clarifies why such adaptations are particularly meaningful for older adults, explaining that motivational priorities shift toward emotional fulfillment, stability, and relational significance with age. Adaptive user modeling enables these insights to be operationalized through continuous learning mechanisms that refine the system's understanding of the user over time.

These theoretical principles converge within MOON Framework, which structures emotional interaction into a logical cycle of recognition, alignment, adaptation, and reinforcement. Emotion functions simultaneously as an input to system behavior, informing how the VUI adjusts its speech rate, tone, or cadence, and as an output that shapes the user's subsequent emotional experience. This reciprocity mirrors interpersonal relationships, where emotional exchange deepens familiarity, trust, and attunement. Within the domain of aging and technology, this synthesis represents a significant step toward designing interfaces that are not only accessible and

intuitive but also emotionally supportive and sensitive to the psychological needs of older adults.

IV. Framework Development Methodology: MOON Framework

The proposed MOON Framework represents a systematic and iterative approach to designing emotionally adaptive VUIs. It integrates the technological mechanisms of affective computing with adaptive user modeling and the psychological principles of SST, providing a unified methodology for emotion-centered interaction design [2], [3], [43]. Within this framework, emotion is treated as a fundamental organizing principle: VUIs are expected not only to recognize and interpret users' affective states but also to adjust their communicative behavior in ways that enhance familiarity, confidence, and long-term engagement among older adults [2], [3].

Fig. 1 presents a comparative summary table of the most relevant frameworks addressing older adults' emotional and interactional needs, including those by [2], [3], [17]. The table contrasts these approaches with MOON Framework across several thematic dimensions, emotional needs, personalization capabilities, long-term engagement mechanisms, user involvement, AI-based emotion recognition, comparison with younger users, and structural organization. This comparison highlights both the conceptual lineage and the unique contribution of MOON as a comprehensive, emotion-centered model.

From an architectural perspective, MOON functions as a closed-loop emotional adaptation cycle composed of four phases: Model, Observation, Optimization, and Nurture. The cycle begins with a static baseline representation (Model), which incorporates demographic, linguistic, and familiarity-related parameters. During interaction, the system gathers and analyzes vocal and emotional indicators (Observation), enabling it to identify cues such as stress, hesitation, or confidence. These cues serve as inputs to the Optimization phase, where the system modulates its vocal output, adjusting speech rate, tone, cadence, or accent, to align with the user's emotional state. Finally, the Nurture phase evaluates the interaction outcomes, updating the internal user model to support longitudinal emotional learning. The resulting feedback informs the next iteration of the Model phase, allowing the system to evolve continuously as it accumulates affective experience.

This cyclical form reflects natural human communication patterns, where individuals form mental models of others, interpret emotional feedback, adjust their behavior accordingly, and refine their understanding over time. Viewed mathematically, MOON operationalizes this process as a data-driven feedback loop, treating emotional cues as a continuous input stream that iteratively updates the system's internal state. Structurally, the framework's modular design allows seamless integration with existing speech-recognition pipelines, conversational systems, and dialogue-management infrastructure. Moreover, its adaptability enables deployment across various domains, including e-services, healthcare, education, and smart-home environments.

Aspect/Theme	MOON Framework	Liu et al. (2023)	Abdollahi et al. (2022)	Hu et al. (2024)
Emotional Needs	Central, multi-stage focus (Model, Nurture)	Central, especially companionship and enjoyment	Central, via empathic robot and mood measurement	Central, via co-design and well-being
Personalization	Iterative, AI-driven adaptation (Observation, Optimization)	Discussed, but not iterative	Via multimodal emotion recognition and adaptive dialogue	Emerges from co-design, not always AI-driven
Long-term Engagement	Explicit "Nurture" phase for ongoing adaptation and companionship	Not explicit	Not explicit	Not explicit
User Involvement	Observation and feedback integrated throughout	Survey-based, empirical	User mood and engagement measured	Co-design sessions with older adults
AI/Emotion Recognition	Multimodal, continuous, and central to framework	Not a primary focus	Central: facial and speech sentiment analysis	Not a primary focus
Comparison to Younger Adults	Explicitly claims older adults benefit more from MOON's approach	Focused only on older adults	Focused only on older adults	Focused only on older adults
Framework Structure	Four-stage, cyclical, holistic (Model–Observation–Optimization–Nurture)	Factor-based model (TAM extension)	Experimental comparison (empathic vs. non-empathic robot)	Co-design methodology

Fig. 1. MOON Framework vs. Related frameworks [2], [3], [17].

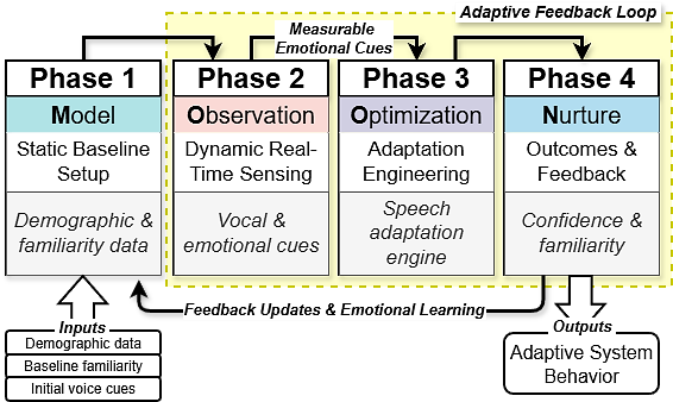

Fig. 2. MOON Framework phases and adaptive feedback cycle.

Fig. 2 illustrates the operation of the model in simplified and high-level steps. The sequential process, as a linear diagram, is running left to right and starts from phase one (Model); phase two (Observation); phase three (Optimization); to ends with phase four (Nurture), with a feedback arrow indicating a curved arrow (Adaptive Feedback Loop), which runs back to the left to the Model phase. Moreover, the description of core activities, base configuration, real-time sensing, adaptive modulation, and outcome assessment are briefly described in each compartment of the illustration. The arrows between the compartments point to the direction of data flow and affective interdependence and the feedback arrow highlights continuous recalibration. Generally, the diagram summarizes the main idea of the framework and the self-healing empathic cycle that integrates detection, response, and evolution. The model will be explained in detail for each stage

as follows:

1) Phase 1 - Model (Establishing the emotional baseline): The Model phase forms the foundational layer of MOON Framework. In this stage, the system constructs an initial user profile incorporating demographic, linguistic, and psychological attributes relevant to voice interaction. These attributes may include age, primary language, familiarity with digital technology, baseline confidence, cognitive preferences, and previously observed emotional tendencies in spoken communication. Based on this information, the system generates baseline parameters, such as preferred speech rate, pitch range, vocabulary complexity, and turn-taking rhythm, that guide the VUI's default communicative style.

Unlike traditional personalization methods, where user profiles remain static, the Model phase in MOON is intentionally dynamic. The baseline acts as a flexible emotional template that evolves as additional interaction data is accumulated. This approach allows personalization to move beyond surface-level demographic adjustment toward a deeper understanding of each user's communicative disposition and emotional inclinations [44]. For example, an initial model may indicate that an older adult with cognitive challenges responds better to slower speech. Over time, as the system detects increased confidence and reduced hesitation, it may adjust and gradually increase conversational pacing, creating a natural sense of progress and continuity [44].

By establishing both the technical parameters and the emotional expectations for future interactions, the Model phase prepares the framework for meaningful adaptivity across subsequent stages.

2) Phase 2 – Observation (Detecting emotion through voice): The Observation phase functions as the system's perceptual layer. During this stage, the VUI continuously analyzes the user's speech, extracting real-time emotional and behavioral cues. Prosodic and linguistic indicators, such as speech rate, pitch variability, vocal intensity, pause duration, and lexical choice, serve as measurable signals of the user's affective state [45]. For example, frequent pauses or a narrowing pitch range may indicate hesitation or uncertainty, whereas increased pitch, smoother pacing, or reduced pausing may reflect confidence or engagement.

To interpret these cues, the system employs emotion-recognition algorithms trained on diverse speech corpora, incorporating age-specific datasets when available. These models classify incoming signals into broad emotional categories such as calm, frustrated, confused, or satisfied [45]. Importantly, MOON Framework emphasizes subtlety over strict categorization. Rather than assigning users to rigid emotional labels, the system aims to interpret contextual and gradational affective cues. This approach aligns with evidence that emotional expression in older adults varies due to physiological changes, cultural influences, and communication styles; thus, MOON relies on probabilistic estimation rather than deterministic classification.

The Observation phase operates bidirectionally, attending to both the content of the user's utterances and the manner in which they are delivered. The system evaluates timing, phrasing, hesitation markers, and repetition patterns to infer the user's emotional state and confidence level. For instance, repeated requests for clarification, delayed responses, or conditional phrasing may suggest confusion or reduced self-assurance. By developing this interpretive capacity, the Observation phase enables subsequent stages of the framework to respond with empathy rather than mechanical precision, ensuring that adaptation is sensitive, context-aware, and aligned with the user's affective needs.

3) Phase 3 – Optimization (Adapting through empathic response): The Optimization phase is the functional core of MOON Framework. In this stage, the system transforms the affective cues detected in the Observation phase into adaptive vocal and conversational responses. This process relies on two interconnected mechanisms: emotion interpretation, which infers the user's affective state, and speech adaptation, which adjusts vocal parameters and dialogic strategies to align the system's behavior with the user's emotional needs.

A significant component of Optimization involves adjusting speech speed and prosodic characteristics. Extensive research demonstrates that speech rate plays a critical role in older adults' comprehension, comfort, and confidence during interaction. Classic psycholinguistic studies show that older adults experience a sharper decline in processing accuracy when listening to fast-paced or dense speech, particularly at higher rates of presentation [46]. Complementing this, research on synthetic speech indicates that both younger and older adults prefer listening rates in the 150–200 wpm range, with older listeners showing reduced comfort as speed increases [47]. More recent large-scale analyses confirm that speech and articulation rates naturally slow with age, reinforcing that older adults process speech more effectively at moderated rates [48]. Additionally, work in VUI and TTS design shows that slower or adjusted synthetic speech improves intelligibility and reduces listening effort for older adults [49]. Together, these findings highlight cognitive-auditory constraints and expectations for slower, rhythmically balanced speech, supporting MOON's principle that dynamic speech-rate adjustment enhances emotional comfort and comprehension.

For example, if the Observation module detects increased frustration, the Optimization phase may slow the system's speech, soften tonal elements, and produce clearer, segmented instructions, for instance, "Let's go through this step together. I will explain it slowly". Conversely, if indicators of engagement or confidence are detected, the system can adopt a slightly faster rhythm or use more complex phrasing to maintain challenge and interest. This adaptive modulation shifts the interaction from rigid command execution to a context-responsive conversational exchange.

Importantly, the Optimization phase extends beyond prosodic adjustments. It also refines dialogue content, timing, and confirmation strategies. The system may shorten prompts to reduce cognitive load or elaborate instructions when clarity is needed. The overall goal is to maintain emotional consistency, ensuring that system behavior remains attuned to the user's affective condition [17], [50].

Through continual fine-tuning, the Optimization phase demonstrates the framework's principle of affective symmetry, each change in the user's emotional state is met with an appropriate, context-sensitive adjustment in the system's

communicative stance.

4) Phase 4 – Nurture (Learning through feedback): The Nurture phase completes the adaptation cycle through three primary steps: evaluating interaction outcomes, incorporating user feedback, and refining the emotional model established in Phase 1. The purpose of this phase is to assess the effectiveness and emotional impact of the system's responses so that subsequent iterations of the model are grounded in experiential evidence. Objective performance indicators include task success rates, interaction duration, and the frequency of clarification requests. Subjective indicators include emotional responses such as confidence, comfort, and familiarity. These subjective responses may be inferred indirectly through vocal cues or determined directly through brief reflective prompts such as "Was that explanation clear for you?" This dual-measure approach ensures that both quantitative and qualitative aspects of user experience contribute to model refinement [17], [51], [52].

The information collected in the Nurture phase is analyzed to identify patterns of success or strain. For example, if consistent relief or satisfaction is detected following slower speech delivery, the system will incorporate slower cadence into the baseline parameters during the next Model phase. Through repeated interactions, this feedback mechanism enables the system to build an emotional memory, mirroring human experiential learning, and turning each new encounter into an extension of an ongoing emotional relationship between the system and the user [51], [52].

The continuous connection between the Nurture and Model phases distinguishes MOON Framework from other adaptive designs by establishing a sustained, longitudinal empathy loop. As emotional learning accumulates across interactions, the system progresses from reactive empathy, responding to immediate cues, to anticipatory empathy, where it can predict when emotional support may be needed based on prior patterns of interaction [51], [52].

V. Discussion

This model also builds on our prior research [8], which demonstrated that emotional familiarity and perceived empathy strongly influence older adults' confidence and readiness to use technology. That earlier work identified a clear gap in VUI design for older users: while existing systems could reliably interpret commands, they rarely adjusted to the user's affective state. MOON Framework addresses this gap by transforming emotional and behavioral cues into measurable system behaviors through dynamic feedback and machine learning. In doing so, the framework converts previous descriptive findings into a functional architecture that can be systematically evaluated and refined over time.

The introduction of MOON Framework represents a meaningful advancement in emotionally intelligent interaction design. Its cyclical architecture integrates previously fragmented perspectives from affective computing, adaptive user modeling, and accessibility research into a cohesive system. More importantly, MOON reframes how emotional intelligence is conceptualized in artificial systems. Rather than treating empathy as a superficial feature or optional enhancement, the framework positions empathy as an operational variable, one that can be measured, interpreted, and used to shape system behavior. As a result, learning becomes bidirectional: system behavior is shaped by user experience, and user experience evolves in response to adaptive system behavior.

By treating emotion simultaneously as a form of data and a design principle, the framework introduces significant theoretical, practical, and methodological implications for HCI and related fields. It demonstrates how affect can function not only as a user-state descriptor but also as a driver of interactional adaptation, long-term personalization, and system evolution. This dual conceptualization offers a pathway toward more responsive, inclusive, and psychologically attuned technologies for aging populations and beyond.

A. Theoretical Implications

Theoretically, MOON Framework expands the scope of affective computing by introducing a new paradigm of affective adaptivity. Traditional affective systems detect emotion but remain largely reactive, responding to affective cues without allowing emotion itself to shape system development. MOON reconceptualizes emotion as a feedback signal capable of conditioning the system over time. This principle is operationalized in the Nurture-to-Model feedback loop, which converts emotional responses into iterative learning signals. The framework thereby reverses the conventional view of emotionally intelligent AI: rather than imitating emotion, the system progressively learns emotion through accumulated interaction.

This transformation aligns with broader shifts in cognitive science toward models of dynamic cognition, which emphasize intelligence as an adaptive process rather than a repository of preprogrammed rules or static knowledge. In this view, emotional intelligence in AI is not a fixed capability but an evolving function that develops through ongoing engagement. MOON therefore bridges computational theories of learning with psychological theories of emotion regulation, offering a conceptual framework in which system-level empathy deepens over time in a manner analogous to human social cognition, where emotional memory and recurring interactions enhance interpersonal understanding.

The framework also contributes to gerontechnology and aging research by explicitly integrating SST into technical design. Unlike accessibility approaches that frame aging primarily in terms of sensory or motor decline, MOON treats aging as an emotional opportunity. Older adults place greater value on emotionally meaningful, familiar, and confidence-enhancing experiences. Technologies that adapt emotionally are therefore likely to resonate more deeply than those that merely reduce task difficulty. From this perspective, MOON embodies a form of emotionally congruent design, in which the system aligns with the motivational patterns and affective priorities of older adults.

Finally, the framework advances theoretical understanding of digital empathy. Machine empathy has traditionally been viewed as either artificial (scripted emotional mimicry) or unattainable. MOON introduces a third category: computational empathy. Unlike surface-level mimicry seen in many chatbots, computational empathy involves

identifying emotional signals, interpreting them into adaptive behavior, and refining that behavior through feedback. This renders empathy a scientifically measurable, assessable, and improvable construct, deepening theoretical insight into how emotional involvement can be modeled, operationalized, and studied within AI systems.

B. Design and Practical Implications

In addition to its theoretical contributions, MOON Framework offers significant implications for design practice, particularly in domains where emotional trust, familiarity, and long-term engagement are essential. In assistive and accessibility-oriented technologies, MOON provides a structured method for embedding emotional inclusiveness into interactions with older adults. Rather than treating empathy as an optional feature added to the technical pipeline, the framework offers designers a conceptual blueprint for integrating empathy directly into the system's core architecture.

At the design level, MOON can be implemented as four modular components within a VUI system. First, the Model phase can be realized through user-profiling algorithms that incorporate demographic, linguistic, and affective characteristics. Second, the Observation phase can employ real-time speech analytics to detect affective cues based on prosodic features such as pitch, rhythm, and vocal energy. Third, the Optimization phase enables adaptive speech synthesis through dynamic adjustments to tone, cadence, and phrasing. Finally, the Nurture phase functions as a data-aggregation and learning module, transforming emotional feedback into parameter updates that refine the system over successive sessions. Together, these modules create a conversational ecosystem that evolves with the user, fostering familiarity, confidence, and emotional comfort.

Importantly, the emotional history accumulated through the Nurture phase becomes part of the system's adaptive continuity, allowing the VUI to interact with the user in a manner reminiscent of a familiar partner, one that "remembers" past interactions and responds accordingly. In this sense, MOON offers not only a technical roadmap but also a design philosophy and ethical foundation for emotionally intelligent technology. It reframes empathy not as an illusion of humanness, but as a quantifiable and trainable system operation rooted in psychological and computational principles. By grounding emotional adaptivity in scientific mechanisms, MOON helps establish empathy as a legitimate component of system design rather than a metaphor or aesthetic enhancement. Ultimately, the framework signals a new generation of adaptive systems, machines capable of learning not only about users, but also from users, while responding in ways that respect their feelings and needs.

VI. Conclusion and Future Work

This study has introduced MOON Framework as a holistic approach for designing emotionally adaptive VUIs that support older adults. By integrating principles from affective computing, Socioemotional Selectivity Theory, and adaptive user modeling, the framework redefines empathy not as an aspirational quality but as an organized and quantifiable process. Through MOON, the field of human-computer interaction advances toward demonstrating that emotional intelligence can be computationally implemented in voice-based systems without requiring visual embodiment or physical expressiveness.

The framework offers a pathway for scalable, psychologically grounded, and emotionally inclusive design by emphasizing voice, the most natural and accessible communication modality. Its cyclical structure allows continuous refinement of empathic responses through user feedback, enabling affective cues to directly inform behavioral adjustment. In this way, MOON positions emotional intelligence as a viable and practical design variable rather than an abstract ideal.

This study extends our earlier findings [8] by moving from descriptive evidence to a formalized computational model. Building on the observation that emotional familiarity strongly contributes to older adults' sense of usability and confidence, MOON provides a mechanism for operationalizing and sustaining this familiarity across interactions. Over time, this fosters a longitudinal user-system relationship in which emotion becomes a basis for ongoing learning, approachability, and trust.

Finally, the future of accessible AI, especially for older adults, will depend not only on accuracy or efficiency, but also on the capacity to respond empathetically and respectfully to users' emotional needs. Although the present work establishes the conceptual and methodological foundations of MOON, the framework requires empirical validation to assess its effectiveness in real-world interaction scenarios. This will be the focus of future work.

Informative Inputs Over Complex Features: Long Short-Term Memory Forecasting in the Saudi Stock Market

Munira AlBalla*, Arwa Alawajy, Seetah Alsalamah, Zahida Almuallem
College of Computer and Information Sciences-Department of Computer Science,
King Saud University, Riyadh 12371, Saudi Arabia

***Abstract*—This study investigates the effectiveness of deep learning, specifically Long Short-Term Memory (LSTM) networks, for forecasting stock closing prices in the Saudi Arabian market. Unlike prior research that focuses on narrow stock subsets or individual technical indicators, we present the first comprehensive evaluation across the top thirty companies by market capitalization on the Tadawul Exchange. We compare eight LSTM variants trained on different combinations of feature families, including technical indicators, calendar effects, and macroeconomic variables such as Brent oil prices and the Tadawul All Share Index (TASI). Despite the popularity of complex feature engineering, our results show that models using simpler macroeconomic inputs consistently outperform those based on technical indicators. In particular, combining the TASI with closing prices yielded the best results for 44.8% of stocks, improving median accuracy by 6.19% over the closing price-only baseline. Conversely, models incorporating extensive technical indicators or applying advanced feature selection techniques underperformed the baseline by 8 to 12%. These findings challenge the assumption that greater complexity leads to better performance in financial forecasting and highlight the value of focused, economically interpretable features in the Saudi market context.**

Keywords*—Deep learning; feature engineering; stock price forecasting; macroeconomic indicators; Brent crude oil; Saudi stock market; Long Short-Term Memory; Tadawul; Tadawul All Share Index (TASI)

I. Introduction

The financial market exhibits highly dynamic and complex behavior, shaped by multiple interrelated factors including the global economy, political events, and investor sentiment [1], [2], [3], [4]. This inherent volatility and non-linearity make it challenging for investors, risk managers, and automated trading systems to make well-informed decisions regarding asset management and profit maximization. Therefore, accurate stock price forecasting is still a complex problem, mainly due to the presence of noisy, non-stationary, and often incomplete financial data [5], [6], [7]. These challenges have motivated researchers to explore advanced predictive models capable of capturing hidden temporal dependencies and improving forecasting performance in such uncertain environments.

Various stock market prediction techniques have been developed to forecast future trends and returns. Traditional statistical methods, such as AutoRegressive Moving Average (ARMA) and Generalized AutoRegressive Conditional Heteroskedasticity (GARCH), suffer from key limitations when dealing with non-stationary financial data. These models rely on strong statistical assumptions such as linearity and noise-free data, which restrict their ability to capture the complex, nonlinear, and dynamic nature of financial markets. Furthermore, they often operate on univariate models and struggle to incorporate external factors such as macroeconomic variables that influence market behavior [8], [9], [6].

To address some of these limitations, Machine Learning (ML) models such as Support Vector Machines (SVM) and Random Forests (RF) have been introduced. These models leverage the availability of large, high-dimensional datasets and are capable of discovering hidden patterns and complex relationships in data. While ML-based models offer greater flexibility and improved predictive power over traditional statistical approaches, they still fall short in modelling temporal dependencies, which is an intrinsic characteristic of financial time series.

These challenges have led researchers to explore deep learning-based methods for stock market prediction. In particular, Recurrent Neural Networks (RNNs) and their advanced variant, LSTM networks, have gained popularity due to their ability to handle sequential data and model long-term dependencies. Standard RNNs, however, face challenges such as the vanishing gradient problem, which limit their effectiveness on long sequences [10], [11], [12], [6]. LSTM networks address this issue through specialized memory cells and gating mechanisms, enabling them to learn temporal patterns more effectively. As a result, LSTMs have been widely applied in financial forecasting, as shown by prior empirical studies that they are particularly well-suited for capturing the temporal dynamics and complex structure of financial markets [13], [14], [15], [17].

The main contributions of this study can be summarized as follows: First, this study addresses a notable gap in the literature by providing a comprehensive analysis of stock price forecasting across the top 30 market capitalization companies on the Saudi Tadawul Exchange from 2006 to 2025. Unlike much of the existing research that concentrates on individual stocks or narrow sectors, our work offers crucial, broad market coverage. This breadth allows us to identify patterns in how different input families perform that are stable across many large-cap stocks, rather than being tied to a single case study or sector representative. Second, we demonstrate that a simple

*Corresponding author.

univariate model relying solely on the lagged closing price serves as a surprisingly powerful baseline. This minimalistic approach provides effective forecasts and establishes a benchmark that more complex, feature engineered and multivariate models must clearly surpass to justify their added complexity, and it serves as a reference point for judging whether additional feature families genuinely add predictive value. Importantly, this evaluation is grounded in multiple performance metrics including a Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Mean Absolute-Percentage Error (MAPE), and win rate, ensuring that the assessment of predictive accuracy is both rigorous and comprehensive. Third, we present a systematic comparison of different feature-engineering approaches by evaluating the predictive contribution of lag features including technical indicators, macroeconomic variables, and calendar effects through eight distinct experimental scenarios, under a shared LSTM architecture. Most significantly, our results demonstrate that incorporating the TASI as a feature substantially outperforms complex technical indicator approaches across all four evaluation metrics, challenging the conventional belief that more sophisticated features necessarily improve prediction accuracy. To our knowledge, this is the first study to systematically demonstrate the predictive value of the TASI in stock price forecasting and to turn that evidence into a simple feature selection rationale that prioritizes market-wide macro variables over large technical indicator sets.

The remainder of this study is organized as follows: Section II presents a review of recent literature pertaining to stock analysis and prediction. Section III presents the theoretical concepts underpinning the research. A comprehensive discussion of the experimental design, the data selection process, and the prediction methodology will be provided in Section IV. Section V presents the research results in detail. This is followed by Section VI, which provides an in-depth discussion of the key findings, interpreting their significance in the context of research objectives. Finally, Section VII summarizes the main insights and contributions of the study, as well as potential directions for future work.

II. Literature Review

LSTM networks have been extensively explored for stock-price forecasting, ranging from simple architectures to sophisticated hybrids. In [16], the authors conducted a study which demonstrated that a single-layer LSTM with nine input features including, macroeconomic indicators, like unemployment rate, technical signals like *Moving Average Convergence Divergence (MACD)*, and historical trading daily data can effectively predict next-day Standard & Poor's (S&P) 500 closing prices over a 2006–2020 large dataset with a RMSE of 12.45 and correlation above 0.92, highlighting the trade-off between depth and overfitting. In [17], the authors extended this to a two-layer LSTM to understand the patterns over time, followed by another two dense layers trained on only 60-day sliding windows of normalized daily closing prices and trading volumes gathered from Yahoo Finance for Apple, Google, Microsoft, and Amazon from 2012 to 2022. Their model achieved an RMSE of 18.89, but the narrow training set and the omission of potentially significant variables, such as news sentiment and macroeconomic indicators, may limit generalizability.

Similarly, in [5], the authors applied an LSTM model to predict closing prices of 31 Vietnamese stocks, incorporating historical price data and three technical indicators. The model achieved forecast accuracy above 93% for most of the stocks included in the study, highlighting the effectiveness of LSTM in time series prediction. However, the authors note that the high volatility of prices within Vietnam's emerging stock market could affect its predictive robustness in different contexts. In [15], the authors proposed a multi-value associated network model of LSTM to predict multiple prices of a stock simultaneously. The model predicts open, low, and high prices on the Shanghai Stock Exchange (SSE), reporting overall accuracy above 95% when compared to traditional LSTM and deep RNN models. However, this approach limited the model's ability to optimize each price prediction effectively, as the training process relied on a total loss function that did not account for the individual sub-losses associated with the three output branches (open, low, and high).

A study in [18], has pushed LSTM into hybrid and decision-making roles. They proposed an automated stock trading system using deep reinforcement learning with LSTM, trained on data from 120 stocks across four indices. LSTM extracts patterns from daily prices and technical indicators to predict when to buy, sell, or hold stocks to achieve higher returns. However, the model's effectiveness relies on a vast amount of training data to fully learn market characteristics. Similarly, in [19], the authors embedded an LSTM within a decision-support system, but for the Indian stock market. They used normalized *Open-High-Low-Close-Volume (OHLCV)* data along with technical indicators to predict the closing stock price for the next thirty days. Using an optimised model, the model yielded an RMSE of 4.13 and a MAE of 3.24 compared to prominent statistical and machine learning models. However, the high computational cost associated with processing historical stock data is the main limitation of the model. With similar limitation of heavy computation and strict data access requirements, reference[20] further enriched Bidirectional Long Short-Term Memory (BiLSTM) with features extracted by a Convolutional Neural Network (CNN) to predict the direction for the next day (up or down) and a trend prediction for several days ahead (up, down, no). In addition to typical market data such as stock prices and trading volume of 14 stocks of a Chinese investment bank, the model incorporates information about the relationships among various stocks based on a knowledge graph and includes detailed records of each investor's trading activities, organized into simplified clusters. The model achieved 74% accuracy in predicting the direction of the next day's closing price and 66% for 5-day trend prediction, which are higher than the accuracies obtained from Adaboost and RF models mentioned in their work. In a similar manner, the authors in [21], integrated investor sentiment data gathered from online stock forums with a set of 16 different technical indicators of thirty stocks in the SSE market, then fed that to an LSTM to predict the closing price one day ahead. The model achieved a MAPE of 0.05, which is superior to the other prediction models used in their work, such as CNN, SVM, and also to their proposed model without including sentiment analysis. However, the model is constrained by a single market-specific sentiment source.

To enhance the accuracy of stock market predictions, a recent study in [22] optimized LSTM hyperparameters via a

metaheuristic, Artificial Rabbits Optimization (ARO), on five years of Dow Jones Industrial Average (DJIA) data with a time window sized 20 previous days. The model demonstrates the lowest Mean squared error (MSE) and MAE for most of the ticker symbols of the market, compared to the other four LSTM models. Still, this improvement in predictive accuracy came at the cost of increased computational overhead during the search phase, as the metaheuristic nature of the ARO algorithm requires extensive exploration of the search space. In [23], the authors showed that preprocessing data using Complementary Ensemble Empirical Mode Decomposition (CEEMD) for decomposing price series to remove noise, Principal Component Analysis (PCA) for reducing data dimensions, and LSTM for predicting closing price of the next trading day for various equity indices reduces RMSE by up to 7% over models that use raw prices series. The comprehensive survey in [24] reviewed the developments in machine learning techniques, including LSTM and CNN, and highlights the advantages of hybrid models and the integration of sentiment analysis to enhance forecasting capabilities. The authors also acknowledged several challenges associated with model building, such as the need for large datasets containing non-stationary data and the complexity of training advanced models.

The Saudi stock market (Tadawul) closely aligns with global markets in its suitability for applying deep learning, particularly LSTM networks for stock price prediction, offering a valuable context for advancing internationally established models. In [25], the authors developed a binary classification model to predict next-day stock price direction (up or down), utilizing a comprehensive set of 31 features, including *OHLCV* data from four companies over ten years, supplemented by various technical indicators. Among the models evaluated, the RF algorithm demonstrated the highest predictive accuracy at 73.5%, outperforming both LSTM and Artificial Neural Network (ANN). The predictive model was subsequently integrated into an automated investment system incorporating risk management strategies, which yielded substantial returns ranging from 65% to 86% across ten companies listed on the Tadawul; however, the study was limited by its focus on a mostly bullish market condition. In [26], the authors found that multivariate LSTM models utilizing *Open-High-Low-Close (OHLC)* inputs outperformed univariate models, achieving a prediction accuracy of 97.49% when forecasting closing prices over the following seven days. Their study was based on a decade of historical data up to November 2022 for three major communication firms (Mobily, Saudi STC, and Zain KSA). Still, the limited scope of input features that exclude other influential factors, such as sentiment and macroeconomic indicators, restricts the generalizability. It limits the model's effectiveness in capturing broader market dynamics. Extending this, in [12], the authors recently compared the performance of the statistical analysis AutoRegressive Integrated Moving Average (ARIMA) and LSTM algorithms for stock price forecasting, following the application of Discrete Wavelet Transform (DWT) to denoise historical closing price data from four companies listed on Tadawul, and showed that the proposed LSTM model achieved a prediction accuracy of 97.54%, outperforming the ARIMA model in terms of forecasting performance.

Similarly, in [27], the authors explored LSTM and a multiLayer perceptron (MLP) models across four key sectors of the Saudi market using data spanning three years from 2018 to 2020, finding that while the LSTM model achieved higher prediction accuracy compared to MLP, the generalizability of both models is limited as they do not integrate broader feature sets. In a more applied setting, in [10], the authors incorporated oil closing prices into an LSTM model to predict next-day trading signals (buy or sell) for three stocks in the Saudi market, training on historical stock data including closing prices, trading volume, technical indicators, and oil price data from June 2018 to August 2019. Similar to [18], they fed the predicted signals to a trading agent to decide whether to buy, sell, or hold based on current share value, available balance, and shareholdings. The proposed LSTM model generated next-day trading signals with 55% accuracy, resulting in a 23% investment return that outperformed the traditional buy-and-hold strategy, which achieved 1.2%. However, its simplicity of feature set and absence of a robust feature selection mechanism, which relies on trial-and-error, remain key limitations. Table I and Table II provide a structured comparison of the literature, organized by Saudi and international markets for better readability. Collectively, these studies illustrate LSTM's flexibility for capturing temporal dependencies in financial series, while also revealing recurring challenges in model complexity, evaluation rigour, dataset diversity, and real-world applicability.

In the Saudi market, the evidence on input design remains fragmented. Some studies rely on closing prices alone and compare LSTM with traditional or shallow models for a small set of stocks or sector indices [12], [27]. While others use multivariate OHLC inputs and report gains over univariate specifications but only for three large communication stocks [26]. Further work combines OHLCV data with long lists of technical indicators [25], or mixes oil prices with technical indicators for three stocks [10], yet none of these studies justify the incremental value of technical indicators over a close-only LSTM baseline or tests whether their findings generalize across the main Tadawul listings. As a result, we are left with scattered evidence on close-only, OHLC, technical indicators, and oil-augmented designs. The present study combines these strands within a single, unified LSTM framework by evaluating close-only, OHLCV, technical, calendar, and macroeconomic configurations across the top market-cap Saudi stocks, providing a cross-sectional view of when close alone suffices and when richer inputs add value.

III. Theoretical Basis

This section outlines the key concepts underlying our approach to predicting stock prices in the Saudi market. First, we look at the Efficient Market Hypothesis (EMH), which suggests that stock prices reflect all available information and are hard to predict. Then, we introduce LSTM networks, a type of machine learning model that can learn patterns in time-based data, such as stock prices. Finally, we discuss how investor behaviour and psychological factors can create patterns that LSTM models may be able to detect. These ideas provide the foundation for our research and help explain why combining finance theory with machine learning can be helpful.

TABLE I. RELATED WORK ON INTERNATIONAL MARKETS PREDICTION USING LSTM ORDERED BY PUBLICATION YEAR, MOST RECENT FIRST, 2024–2020

Reference	Data	Period	Input	Technique	Output	Performance Measure

A. Market Efficiency versus Predictability

The EMH, first proposed by the authors in [28], suggests that financial markets are efficient, meaning that asset prices quickly and fully reflect all available information. If this is true, it becomes challenging to consistently make profits by predicting price movements or employing trading strategies. However, many studies have shown that fundamental markets do not always behave this way. Factors such as slow information flow, investor psychology, market structure, and regulation can cause inefficiencies [29], [30]. These inefficiencies may allow room for prediction. In such cases, machine learning methods, especially those that can handle patterns over time, can provide a valuable alternative to traditional financial models by challenging some of the assumptions of EMH, particularly.

B. LSTM Mechanics in Financial Time Series Prediction

LSTM networks, a type of RNN, have been shown to work very well with sequential data [31], including financial time series forecasting [32], [33].

Traditional RNNs often struggle with problems such as vanishing gradients. They cannot handle long-term patterns, but LSTMs overcome this by using a gated memory structure that stores and updates information over time [34], [35]. This structure consists of three main parts: a forget gate that removes unnecessary information, an input gate that adds new relevant data, and an output gate that determines which information to pass on. These mechanisms enable LSTMs to capture complex time-based patterns, making them highly suitable for forecasting stock prices [36]. In Tadawul, stock movements are influenced by various factors, including changes in oil prices, political events, and seasonal effects such as those observed during Ramadan [10], [37]. LSTMs can learn these nonlinear patterns without heavy manual feature design. While the EMH suggests that prices cannot be predicted from past information, studies in behavioural finance show that inefficiencies do exist [29], [38], [39], especially

in emerging markets [30], [37]. Therefore, combining LSTMs with technical and macroeconomic indicators can help uncover proper predictive signals in Tadawul's market environment [40].

C. Behavioral Tadawul Market Efficiency

While the EMH assumes that investors act rationally and that markets always reflect all available information, behavioral finance shows that emotions and mental shortcuts often lead to mistakes in judgment. These behaviors can create patterns in the market that the EMH cannot explain [29], [38]. In the Tadawul, several examples of such behavior affect how prices move. One typical pattern is *herding*, where individual investors follow the crowd instead of making their own decisions. This often causes trends to grow stronger, even when they are not supported by fundamentals [39]. Another example is *overreacting to news*, such as sudden changes in oil prices or updates related to major plans like Vision 2030 [41], [42], [43]. These reactions can lead to bigger price changes than necessary [30]. Additionally, some *seasonal effects* have been observed, particularly during Ramadan, where studies such as [37] have found unusually high returns, likely due to shifts in mood and trading habits. These behaviours create inefficiencies that are hard to capture with traditional models. That's why advanced machine learning techniques, such as LSTM networks, are helpful. They can detect complex and hidden patterns in market data, making them well-suited for forecasting in behavior-driven markets like Tadawul.

IV. Data and Methodology

Fig. 1 summarizes the end-to-end workflow, executed independently for each stock in our top-30 Tadawul universe (29 after cleaning). Details of every step appear in the subsections below:

A. Dataset and Market Universe

This study utilizes a comprehensive dataset comprising historical financial and macroeconomic data relevant to the Saudi Arabian equity market. Historical daily OHLCV data were collected from Yahoo Finance using ticker symbols with the ".SR" suffix, which marks shares listed on the Saudi Exchange (Tadawul). The primary focus is on the thirty largest publicly traded companies on the Tadawul Exchange, selected based on free float market capitalization to represent the most liquid and actively traded equities. The data collection period spans from each company's first available trading day to May 8, 2025. Following data cleaning procedures, 29 companies remained for analysis. Table III lists the top 30 stocks listed on Tadawul based on free float market capitalization as of 2025. Fig. 2 illustrates the proportional allocation of stocks by sector.

B. Inputs and Feature Set

To capture the factors influencing Saudi stock price movements, we use **37 predictive variables**. The predictors are grouped by their source and role into four families: *Raw OHLCV*, *Technical indicators*, *Calendar features*, and *Macroeconomic features*, as shown in Table IV.

1) Raw OHLCV: Our feature set begins with the raw daily *Open*, *High*, *Low*, *Close*, and *Volume* series downloaded from Yahoo Finance (".SR" tickers). These variables capture each session's price range and trading activity. These stock-level series serve as the basis from which all technical indicators are computed.

2) Technical indicators: All technical indicators are computed directly from each stock's OHLCV.

a) Moving averages: SMA and EMA over rolling windows of 5, 10, 20, 50, 100, and 200 days to capture multi-horizon trend dynamics. Short windows (5–20 days) reflect immediate moves; long windows (50–200 days) reflect underlying trends.

b) Momentum indicators: MACD (main MACD line, signal line MACDs, and histogram MACDh) to detect momentum shifts. RSI to identify overbought/oversold conditions and potential turning points.

c) Volatility: We record the lower Bollinger Band (BBL_20_2.0), middle Bollinger Band (BBM_20_2.0), and upper Bollinger Band (BBU_20_2.0). From these, we compute Bollinger Bandwidth (BBB_20_2.0), which measures volatility through the distance between the bands, and Bollinger Band Percentile (BBP_20_2.0), which shows where the current price falls within the envelope.

d) Volume-based On-Balance Volume (OBV): which measures sustained buying or selling pressure.

3) Calendar features: To capture temporal patterns and specific events that may influence trading behaviour, we incorporated several calendar-based features. Day of the week and day of the year are represented through sinusoidal functions (*dow_sin*, *dow_cos*, *doy_sin*, *doy_cos*) to preserve temporal continuity and capture any recurring seasonal patterns in market behavior. Additionally, we created binary indicators for specific calendar events known to affect Saudi market behavior. The *Ramadan* indicator identifies trading days during the holy month, which has been documented to influence market volatility and returns in Islamic markets. The quarter-end proximity flag (*qtr_end_5d*) marks the five days preceding quarterly financial reporting periods, typically associated with increased trading activity and volatility. All variables in this group are computed from the trading date only and do not use price or volume information.

4) Macroeconomic features: Given Saudi Arabia's position as a major oil exporter and the importance of global economic conditions, we incorporated key macroeconomic indicators. *Brent* crude oil prices serve as a critical external factor, supplemented by its daily return (*Brent_ret*) and 60-day rolling volatility (*Brent_vol60*) to capture both level and risk dimensions of oil market dynamics. TASI represents overall market sentiment and provides context for individual stock performance within the broader Saudi equity market. These inputs are external series merged to the stock-level table by date and are not derived from the stock's OHLCV.

C. Data Preprocessing

1) Data merging: We align and join, by date, each stock's OHLCV with the engineered technical and calendar features

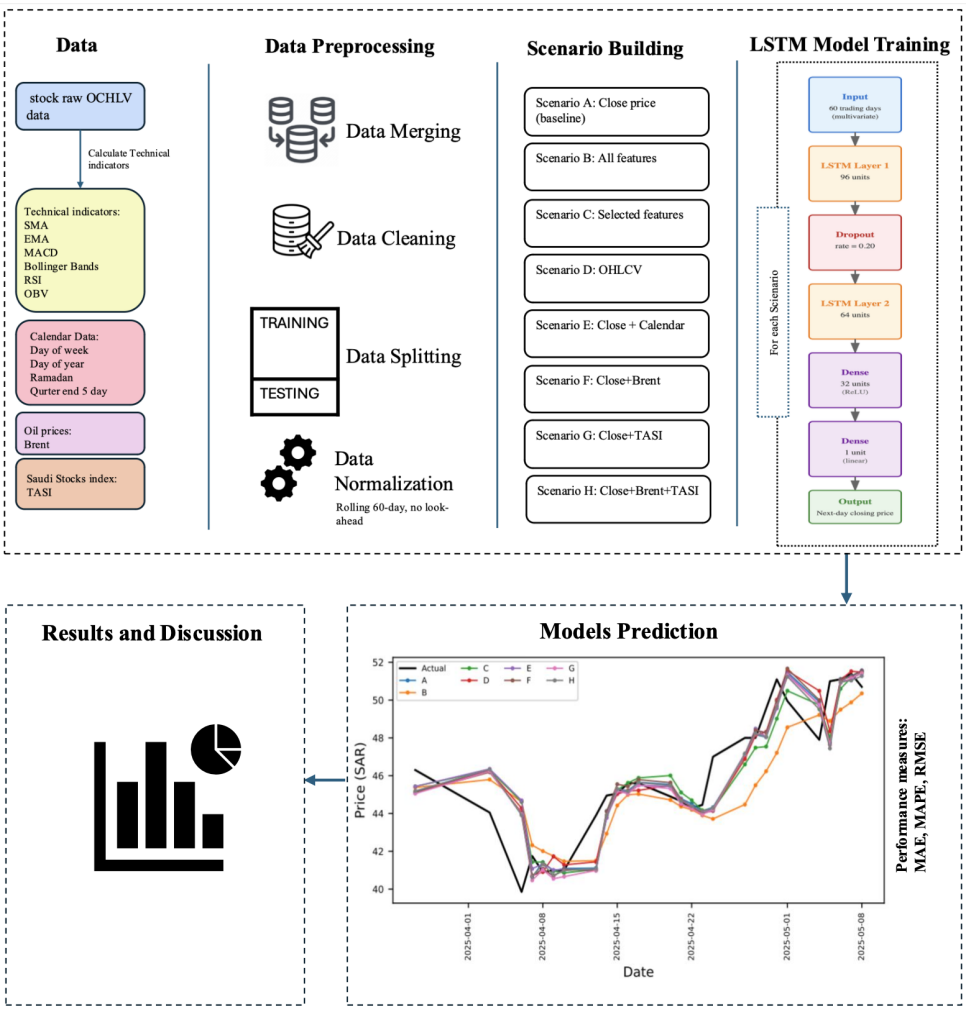

Fig. 1. Methodology overview: Daily OHLCV per stock is combined with engineered technical features, calendar features, and external macro features (TASI, Brent). After data merging, cleaning, a fixed train/test split, we build eight input scenarios (A–H) and train the same LSTM per stock and per scenario. This pipeline is executed for each stock among the top market-cap Tadawul companies (29 after cleaning). The bottom band illustrates test predictions, performance metric computation, and cross-stock/sector comparison.

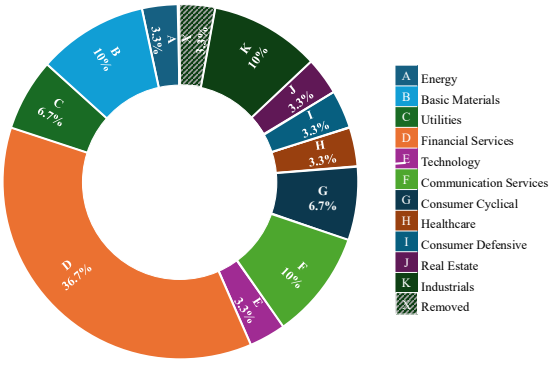

Fig. 2. Percentage breakdown of the top 30 Tadawul stocks by sector.

and the external macro series (TASI, Brent). The merge is restricted to common trading days, with one record per stock per date after alignment.

2) Data cleaning: The data cleaning process involved removing rows containing NaN values resulting from rolling-window calculations in technical indicators, where the first several observations could not be computed due to insufficient lookback data. Any residual missing values after alignment were dropped. Stock 4325 (Umm Al Qura Development & Construction Co.) had no data remaining after cleaning, yielding a final sample of 29 stocks.

3) Data splitting: The dataset was divided into training and testing periods to ensure robust out-of-sample evaluation. Training data spans from the earliest available date (after data cleaning) to December 31, 2024, while the testing period covers January 1, 2025, to May 8, 2025.

4) Data normalization: All numeric features are standardized using a 60-day rolling window, computed strictly from prior observations at time t. The same transformation is applied during validation and testing, preserving temporal causality and avoiding look-ahead bias.

TABLE III. TOP 30 STOCK COMPANIES IN TADAWUL BY SECTOR AND TICKER

No.	Ticker	Company	Sector
1	2222	Saudi Arabian Oil Co. (Saudi Aramco)	Energy
2	1120	Al Rajhi Bank	Financial Services
3	2082	ACWA Power Co.**	Utilities
4	7010	Saudi Telecom Co. (STC)	Communication Services
5	1180	The Saudi National Bank	Financial Services
6	2010	Saudi Basic Industries Corp. (SABIC)	Basic Materials
7	1211	Saudi Arabian Mining Co. (Ma'aden)	Basic Materials
8	4013	Dr. Sulaiman Al Habib Medical Svcs. Grp.	Healthcare
9	1010	Riyad Bank	Financial Services
10	7203	Elm Co.**	Technology
11	1150	Alinma Bank	Financial Services
12	1060	Saudi Awwal Bank	Financial Services
13	5110	Saudi Electricity Co.	Utilities
14	2280	Almarai Co.	Consumer Defensive
15	2020	SABIC Agri-Nutrients Co.	Basic Materials
16	7020	Etihad Etisalat Co. (Mobily)	Communication Services
17	1080	Arab National Bank	Financial Services
18	1050	Banque Saudi Fransi	Financial Services
19	1140	Bank Albilad	Financial Services
20	7202	Arabian Internet & Comm. Svcs. Co.**	Communication Services
21	4280	Kingdom Holding Co.	Industrials
22	4325	Umm Al Qura Dev. & Construction Co.*	Industrials
23	4250	Jabal Omar Development Co.	Consumer Cyclical
24	8210	Bupa Arabia for Cooperative Insurance Co.	Financial Services
25	4300	Dar Al Arkan Real Estate Dev. Co.	Real Estate
26	1111	Saudi Tadawul Group Holding Co.**	Financial Services
27	4030	National Shipping Co. of Saudi Arabia (Bahri)	Industrials
28	4100	Makkah Construction & Development Co.	Consumer Cyclical
29	8010	The Co. for Cooperative Insurance (Tawuniya)	Financial Services
30	4142	Riyadh Cables Group Co.**	Industrials

*Umm Al Qura Dev. & Construction Co. (4325) was subsequently excluded during data cleaning due to no data left after cleaning.

**Recently listed companies such as ACWA Power (2082), Elm Company (7203), Riyadh Cables Group (4142), Saudi Tadawul Group Holdings (1111), and Arabian Internet & Communications Services (7202) have limited trading histories ($\leq$650 days).

D. Model Architecture and Evaluation Procedure

To isolate the effect of inputs, all scenarios share a fixed network and training setup; the full specification appears in Table V. Briefly, the model ingests a multivariate 60-day window, stacks two LSTM layers (96 units with sequence return and 0.20 dropout; then 64 units), applies a 32-unit ReLU dense layer, and outputs the next-day closing price with a linear head. Models are trained with mean-squared error using Adam (learning rate $\eta = 0.001$), mini-batches of 32 for up to 80 epochs with early stopping after 6 consecutive validation epochs without improvement.

To evaluate predictive accuracy, we use three standard metrics: MAE, RMSE, and MAPE. MAE is defined by Eq. (1), and RMSE and MAPE by Eq. (2) and Eq. (3).

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \tag{1}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{2}$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \times 100\% \tag{3}$$

where, n is the number of observations in the test set, y_i is the actual closing price for observation i, and $\hat{y}_i$ is the corresponding predicted closing price.

E. Scenario Descriptions

To assess the marginal contribution of different feature groups to forecasting performance, we define eight LSTM-based experimental scenarios:

1) Scenario A (Close-only baseline): Uses only the Close price as input. This baseline tests whether price memory alone is sufficient for short-horizon forecasting.

2) Scenario B (Full feature set): Uses all 37 features, including prices, technical indicators, calendar patterns, and macroeconomic data. This is the most complete model, assuming access to all possible signals at the end of the day.

3) Scenario C (Selected features): Uses only a carefully chosen subset of features based on importance scores (correlation and SHAP). This tests if fewer, more relevant signals can perform as well as the complete set.

4) Scenario D (OHLCV): Open, High, Low, Close prices, and Volume only, focusing on raw trading activity without engineered indicators or external inputs.

5) Scenario E (Close + calendar): Combines Close with calendar features (day-of-week and day-of-year sine/cosine, Ramadan, qtr_end_5d) to test seasonal and temporal effects.

6) Scenario F (Close + Brent): Uses Close with Brent oil inputs. Since oil plays a key role in Saudi Arabia's economy, this model tests whether oil price movements help improve the forecasting of stock prices.

7) Scenario G (Close + TASI): Uses Close and TASI. TASI reflects the overall market mood and helps capture broader trends that may influence individual stocks.

8) Scenario H (Close + Brent + TASI): Combines Close with both Brent and TASI to test whether combining global and local market signals improves predictions.

Each scenario is designed to test the model's ability to predict stock prices and to understand the significance of specific inputs. By comparing them, we can determine which types of information enhance predictions in the Saudi stock market. Table VI summarizes the inputs and intent of each scenario.

TABLE IV. PREDICTOR INPUTS GROUPED BY SOURCE AND ROLE, WITH REPRESENTATIVE EXAMPLES

Group	Examples
Raw OHLCV (stock-level)	*Open*, *High*, *Low*, *Close*, *Volume*
Technical indicators (engineered from OHLCV)	Moving averages: *SMA_n*, *EMA_n* ($n = 5, 10, 20, 50, 100, 200$); Momentum: *MACD*, *MACDs*, *MACDh*, *RSI*; Volatility (Bollinger): *BBL_20_2.0*, *BBM_20_2.0*, *BBU_20_2.0*, *BBB_20_2.0*, *BBP_20_2.0*; Volume-based: *OBV*
Calendar features (engineered from date)	*dow_sin*, *dow_cos*, *doy_sin*, *doy_cos*; flags: *Ramadan*, *qtr_end_5d*
Macroeconomic features (external series)	*TASI*; *Brent*, *Brent_ret*, *Brent_vol60*

TABLE V. UNIFIED LSTM ARCHITECTURE AND TRAINING SETTINGS USED FOR ALL SCENARIOS (A–H)

Component	Setting
Input window	60 trading days (multivariate sequence)
Target	Next-day closing price
Layer 1	LSTM (96 units), `return_sequences`=True
Regularization	Dropout = 0.20 (after Layer 1)
Layer 2	LSTM (64 units)
Head	Dense(32, ReLU) $\rightarrow$ Dense(1, linear)
Loss	Mean Squared Error (MSE)
Optimizer	Adam, learning rate = 0.001
Batch size	32
Epoch cap	80
Early stopping	Patience = 6; restore_best_weights=True
Validation split	15% of training data
Evaluation metrics	MAE, RMSE, MAPE (%)

V. RESULTS

Eight model variants were evaluated, ranging from a simple baseline, Variant A (Close price only) to models applying advanced features (Variants B–H). Performance was assessed using MAE, RMSE, and MAPE. The analysis focuses on MAE as the primary evaluation metric due to its direct interpretability and robustness to outliers, though results are validated across all three measures. Full per-ticker MAE/RMSE/MAPE values are provided in the Supplementary Material (Table IX).

Table VII shows that market-aware models achieved superior predictive performance. Variant G (Close + TASI) achieved the highest performance for 44.8% of stocks with a median 6.19% improvement over baseline. Variant F (Close + Brent oil) ranked second, optimal for 24.1% of stocks with a 3.17% median improvement. Combined, these macroeconomic variants were top-performing for nearly 70% of evaluated stocks.

Complex feature engineering approaches proved counterproductive. In contrast, **Variant B** (*Close* + all features) achieved optimal results for only 10.3% of stocks and underperformed the baseline by 11.66%. **Variant C** (*Close* + selected features), despite employing advanced techniques including mutual information, correlation filtering, and SHAP-based ranking, was optimal for just 3.4% of stocks with an 8.32% performance decline. **Variant D** (*OHLCV*) failed to achieve optimal performance for any stock, while **Variant E** (*Close* + calendar features) was optimal for only 3.4% of stocks, despite incorporating seasonal effects specific to the Saudi market. Even combining individually successful features failed to yield benefits, **Variant H** (*Close* + *Brent* + *TASI*) was optimal for only 6.9% of stocks despite incorporating the two most effective individual inputs.

To assess variation in model performance across market segments, we initially considered a sector-level analysis. However, several sectors included fewer than three stocks, making statistical comparisons infeasible. To address this, we aggregated sectors into three broader, economically meaningful groups: **Oil-Sensitive** (Energy, Basic Materials, Utilities), **Financial** (Financial Services), and **Demand & Services** (Technology, Communication Services, Consumer Cyclical, Healthcare, Industrials, Consumer Defensive, Real Estate). These groupings reflect shared economic drivers: resource price exposure, interest rate sensitivity, and consumer demand patterns, respectively. Fig. 3 shows the three groups and the percentage of stocks in each group.

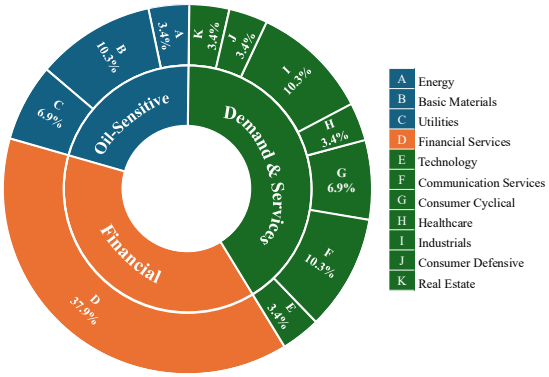

Fig. 3. Percentage breakdown of the stocks in three groups.

Table VIII demonstrates Variant G (Close + TASI) consistent effectiveness across groups. Under random chance, any variant would win roughly 12.5% of the time (1/8). Variant G (Close + TASI) significantly exceeds this benchmark, capturing 54.55% of Financial stocks (4.4$\times$ chance), 50% of Oil-Sensitive stocks (4$\times$ chance), and 33.33% of Demand & Services stocks (2.7$\times$ chance).

Fig. 4, Fig. 5, and Fig. 6 provide individual stock visualizations for each sector group. Variant G (Close + TASI) appears alone when optimal; otherwise, the best-performing alternative appears in orange. While no single variant proves optimal for all stocks, Variant G (Close + TASI) emerges as the dominant general-purpose solution across diverse economic sectors. The orange lines visible in over half the stocks demonstrate opportunities for stock-specific optimization, yet Variant G (Close + TASI) broad effectiveness confirms its value as the preferred baseline approach. Notably, recently listed companies, marked

TABLE VI. SIMPLIFIED LSTM INPUT SCENARIOS AND THEIR PURPOSE

Scenario	What It Uses	Why It Matters
A	*Close* price only	Tests if recent closing prices alone can predict future prices (price memory).
B	All 37 features	Uses all available signals, including prices, indicators, calendar data, and economic information, to test maximum prediction ability.
C	Selected top features	Checks if a smaller set of the most useful features can perform as well as the full list.
D	*OHLCV*	Focuses on basic trading data without additional indicators or external inputs.
E	*Close* + calendar patterns	Tests whether time-based patterns (e.g., weekdays, *Ramadan*) contribute to price prediction.
F	*Close* + *Brent* oil price	Evaluates how oil prices, crucial to the Saudi economy, influence stock movements.
G	*Close* + *TASI*	Adds the general market trend (*TASI*) to assess the impact of market sentiment on individual stocks.
H	*Close* + *Brent* + *TASI*	Combines both oil and market trend information to determine if their joint use enhances forecast accuracy.

TABLE VII. PERFORMANCE SUMMARY OF MODEL VARIANTS

Variant	Description	Win Rate (%)	Median Improvement over Baseline (%)
G	*Close* + *TASI*	44.8	6.19
F	*Close* + *Brent* oil	24.1	3.17
B	*Close* + all features	10.3	-11.66

TABLE VIII. SECTOR GROUP PERFORMANCE ANALYSIS

Sector Group	Number of Stocks	Best Variant	Win Rate (%)
Oil-Sensitive	6	G (Close + TASI)	50.00
Financial	11	G (Close + TASI)	54.55
Demand & Services	12	G (Close + TASI)	33.33

with double asterisks (**) in Table III, show substantially worse forecasting performance, highlighting the critical importance of sufficient trading history for reliable predictions.

VI. DISCUSSION

The results challenge the commonly held belief that increased feature complexity leads to superior predictive accuracy in financial markets. All models employed identical LSTM architectures, isolating the effect of feature selection and revealing that simpler, macroeconomic-based inputs consistently outperform sophisticated technical indicators.

Viewed against recent LSTM-based forecasting studies, our results help clarify what different feature choices actually contribute. Many works report strong performance, but treat the input design as fixed, offering limited insight into how much each additional feature family improves on a simple price-based baseline. Some studies argue that multivariate OHLC or OHLCV inputs yield better predictions than univariate closing prices [15], [19], [26], while others rely on closing prices by default [22], [27] or augment them with large sets of technical indicators and hybrid components [5], [16], [18], [21], [23], [25]. Our eight-scenario framework brings these variations together in a single empirical setting: with the LSTM architecture held constant, we systematically compare close-only, OHLCV, technical indicator, and macroeconomic configurations across the largest Tadawul-listed companies. The evidence shows that closing prices form a strong baseline, that OHLCV data do not systematically improve upon this baseline, and that extensive technical-indicator sets rarely deliver gains. By contrast, a small set of macroeconomic variables (TASI and Brent) provides consistent, albeit moderate, improvements over the closing price baseline for a large share of stocks. In this way, the study synthesizes scattered findings in the literature into a coherent picture of what each class of inputs adds beyond the closing price itself.

The systematic failure of complex feature engineering approaches reveals a fundamental insight about information processing in LSTM networks. Variant C (Close + selected features), despite employing advanced techniques including mutual information, correlation filtering, and SHAP-based ranking that are customized for each stock, degraded performance by 8.32% compared to the baseline. Variant B (Close + all features) underperformed by 11.66%. Similarly, Variant D (OHLCV) achieved zero optimal results, demonstrating that even basic microstructural data cannot enhance LSTM predictions beyond what is captured by closing price alone. Variant E (Close + calendar features) proved equally ineffective, with only 3.4% optimal performance despite incorporating known calendar effects such as Ramadan. This suggests that LSTM architectures efficiently capture price-based patterns from closing prices alone, making technical indicators largely redundant. Technical indicators such as moving averages, RSI, and MACD are essentially mathematical transformations of the same underlying price information that LSTM networks can learn implicitly through their temporal modeling capabilities. The addition of these derived features introduces noise rather than signal, as they provide no genuinely new information beyond what the network can extract from the raw price sequence.

The superior performance of macroeconomic variants provides a contrast to the redundancy of this technical indicator. Variant F (Close + Brent oil) achieved optimal performance for 24.1% of stocks, reflecting the Kingdom's central role in global energy markets. Variant G (Close + TASI) performed

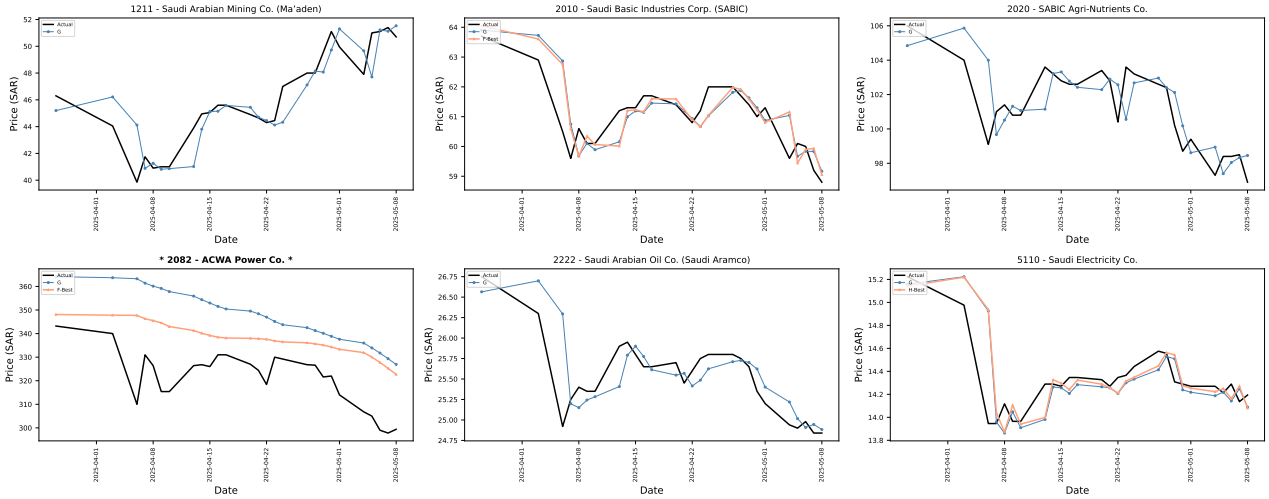

Fig. 4. Oil-Sensitive group (Energy, Basic Materials, and Utilities). Variant G (Close + TASI) predictions (blue) vs. Actual prices (black). If Variant G (Close + TASI) is not the top model for a stock, the best-performing alternative is overlaid in orange.

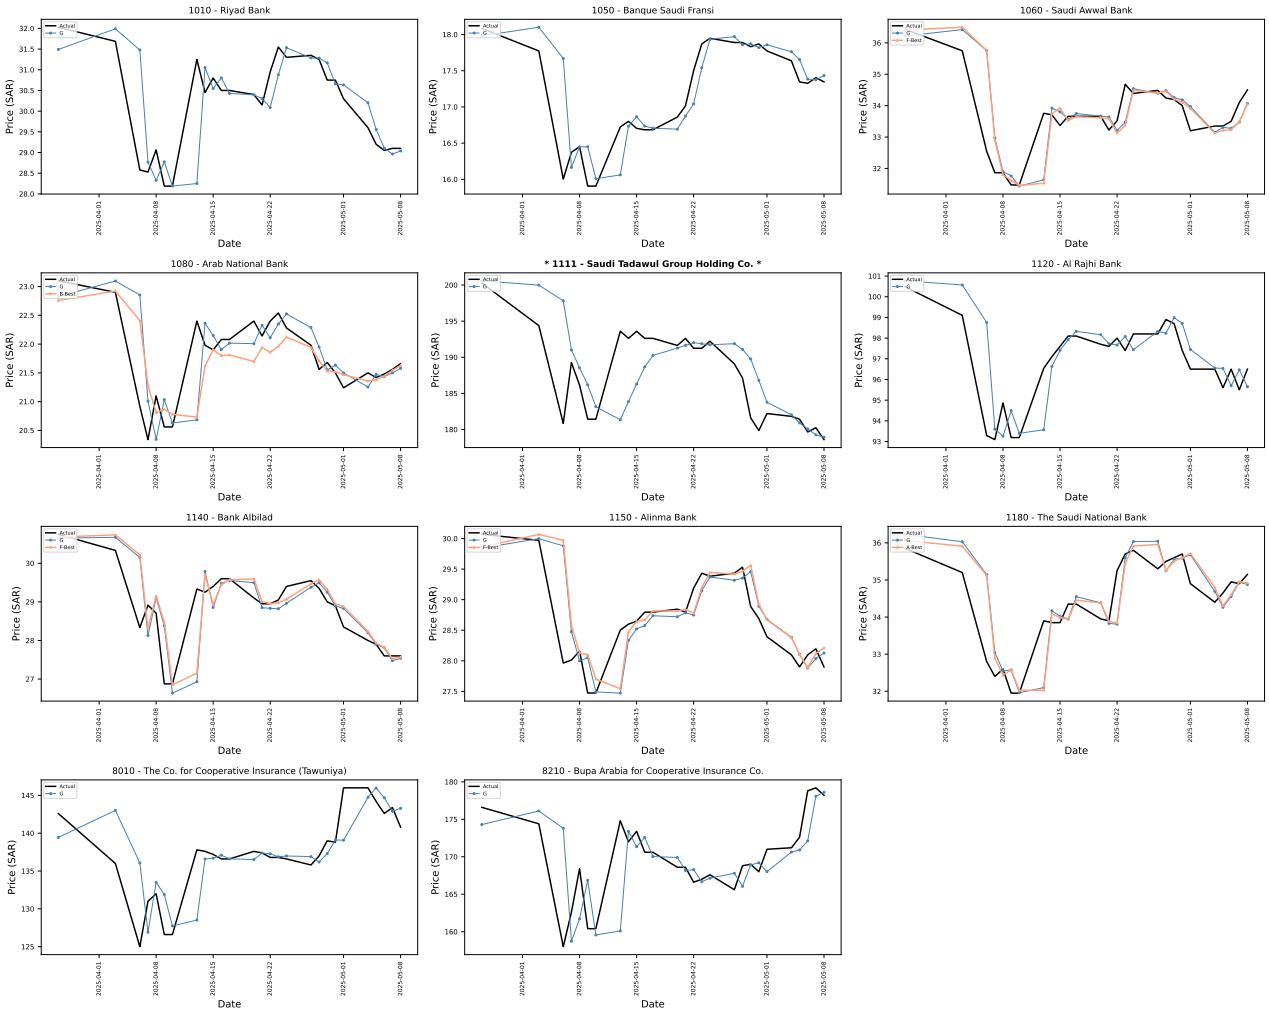

Fig. 5. Financial group (financial services). Variant G (Close + TASI) predictions (blue) vs. Actual prices (black). If Variant G (Close + TASI) is not the top model for a stock, the best-performing alternative is overlaid in orange.

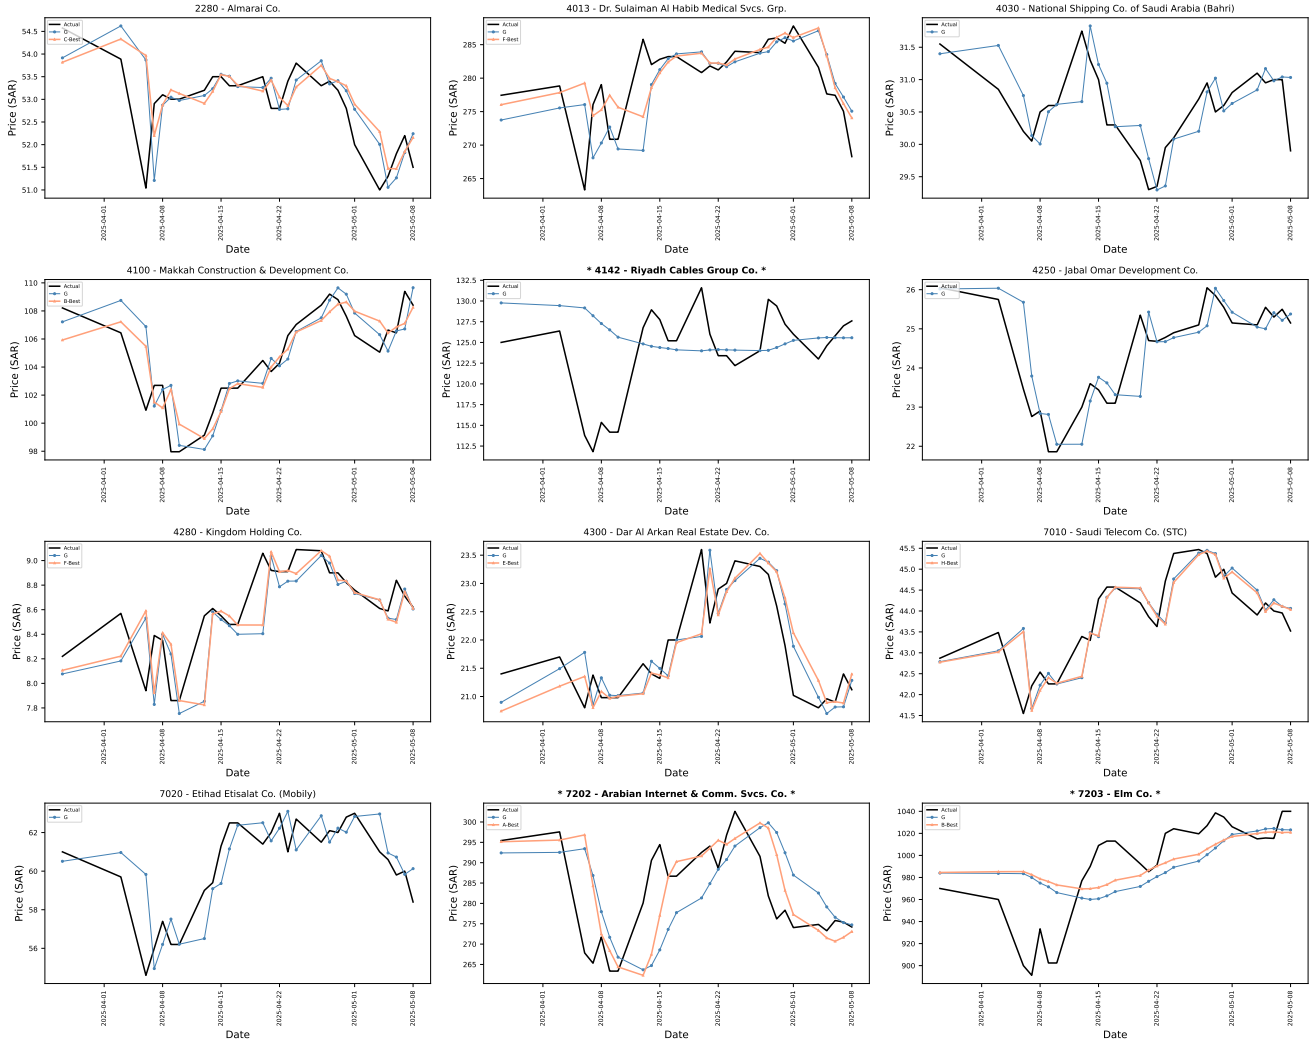

Fig. 6. Demand & services group (technology, communication services, consumer cyclical, healthcare, industrials, consumer defensive, and real estate). Variant G (Close + TASI) predictions (blue) vs. Actual prices (black). If Variant G (Close + TASI) is not the top model for a stock, the best-performing alternative is overlaid in orange.

best for 44.8% of stocks with a median 6.19% improvement over baseline. Unlike technical indicators that derive from the same price data, TASI provides independent information not captured in individual stock prices. TASI captures market-wide sentiment, liquidity conditions, and systematic risk factors that affect individual stock behavior. This represents a fundamentally different information source rather than a more complex processing of the same data.

The failure of technical indicators and success of individual macroeconomic variants reflects a fundamental principle: practical feature engineering requires genuinely distinct information sources rather than mathematical transformations of the same data. However, Variant H (Close + Brent + TASI) achieved optimal performance for only 6.9% of stocks despite combining individually successful features, demonstrating that even orthogonal information sources can create harmful interactions when combined, making simpler approaches more reliable.

A critical constraint emerges from data availability that transcends model sophistication. Recently listed companies such as ACWA Power (2082), Elm Company (7203), Riyadh Cables Group (4142), Saudi Tadawul Group Holdings (1111), and Arabian Internet & Communications Services (7202) have limited trading histories (≤ 650 days) and show dramatically worse performance (average MAE: 16.936) compared to established stocks ($\geq 3,000$ days, average MAE: 0.844). This twenty-fold performance deterioration underscores that data availability is more fundamental than feature complexity.

These findings have immediate practical implications for portfolio management and algorithmic trading systems. Variant G (Close + TASI) emerges as the most effective general-purpose approach, showing consistent performance across diverse sectors even though it may not be optimal for every individual stock. The results provide clear guidance: models based on fundamental economic signals outperform complex feature engineering in Saudi Arabia's market. Portfolio implementations may achieve further gains through selective model customization when sufficient trading history is available.

It is important to acknowledge several assumptions and limitations of this study. First, only a predetermined set of daily predictors (OHLCV, TASI, Brent, and calendar effects) and the biggest Tadawul-listed companies are included in the analysis. Therefore, the results might not apply to small-cap stocks, intraday timeframes, or situations where firm fundamentals or other information sources are accessible. Second, to isolate the contribution of different feature families, we use the same LSTM architecture and hyperparameters for all stocks and scenarios. While this design ensures a fair comparison across inputs, it may underestimate the best achievable performance for particular stocks or alternative architectures. Third, the testing evaluation window is relatively short (January to May 2025), longer or multi-regime evaluation periods could lead to different relative rankings of the scenarios. Finally, we assume that daily closing prices and a 60-day lookback window are sufficient for one-day-ahead forecasting, and other horizons and window lengths are not explored here. Together with the earlier observation that performance sharply deteriorates for newly listed stocks with short trading histories, these limitations define the scope within which our conclusions should be interpreted.

Overall, with the LSTM architecture held fixed, our results show that supplying inputs that introduce new information is more important than augmenting the dataset with technical indicators and other complex transformations derived from the same price data.

VII. Conclusion

This study examined how different input features affect the performance of LSTM models in forecasting stock prices within the Saudi market. Through a systematic evaluation of eight structured model variants across the 30 largest Tadawul-listed companies (29 after cleaning), we show that simpler, macroeconomic-based inputs consistently outperform complex technical indicators and advanced feature engineering techniques.

Feature engineering was most effective when it introduced genuinely distinct information. Models incorporating TASI and Brent oil prices, which reflect broader market conditions, delivered the strongest performance. The Close + TASI model (Variant G), in particular, reduced median error by 6.19% compared to a closing-price baseline. In contrast, models built on extensive technical indicators or automated selection pipelines degraded accuracy by 8 to 12%.

This performance gap likely reflects the LSTM's ability to capture temporal patterns directly from raw price sequences. When technical indicators such as moving averages, RSI, and MACD replicate patterns already present in historical data, they contribute more noise than a proper signal.

Data availability emerged as an even more critical determinant of accuracy. Recently listed firms with limited trading histories ($\leq$650 days) experienced MAE that rose dramatically, reaching levels twenty times higher than established stocks. This finding highlights the importance of historical depth and cautions against applying deep learning models in data-scarce settings.

Overall, our results challenge the notion that large and advanced feature sets lead to better forecasts, demonstrating that a parsimonious set of economically meaningful variables enhances both performance and interpretability in LSTM-based stock forecasting. To transition this single-market (Saudi) finding into a generalizable framework, our future research will be built on three pillars. First, we will systematically test indicator combinations across diverse markets. Second, we will challenge the sufficiency of closing prices by incorporating richer, complementary data sources, such as intraday transactions and sentiment measures. Third, we will benchmark these findings against advanced architectures, including hybrid LSTM-Transformer models. This grand unified study will be essential for validation, enabling us to isolate a core set of universal features and quantify the predictive power of market specific indicators.

Integrating Artificial Intelligence into Continuous Improvement for Automotive Manufacturing

Sara OULED LAGHZAL[1]*, EL OUADI Abdelmajid[2]
Mathematical Laboratory and Applications-Faculties of Sciences, Ibn Tofail University, Kenitra, Morocco[1]
Laboratory Advanced Systems Engineering-National School of Applied Sciences, Ibn Tofail University, Kenitra, Morocco[2]

***Abstract*—The integration of Artificial Intelligence (AI) and Machine Learning (ML) into Continuous Improvement (CI) frameworks is redefining the foundations of automotive manufacturing under the Industry 4.0 paradigm. Traditional methodologies such as Kaizen, Lean Six Sigma, and Total Quality Management (TQM) have long provided structured approaches for quality enhancement, waste reduction, and process stability. However, the emergence of AI introduces new capabilities—advanced analytics, predictive modeling, and intelligent automation—that transform these static frameworks into dynamic, data-driven ecosystems. This study conducts a systematic literature review following the PRISMA protocol, covering publications from 2010 to 2024 across Scopus, Web of Science, and OpenAlex. After filtering and de-duplication, 13,080 documents were analyzed. Data were categorized by AI methodologies (computer vision, neural networks, deep learning), industrial use cases (quality inspection, predictive maintenance, process optimization, scheduling, and supply chain planning), and key performance metrics such as Overall Equipment Effectiveness (OEE), Mean Time Between Failures (MTBF), parts per million (ppm), lead time, and service level.The analysis reveals substantial and measurable performance improvements. AI-driven systems achieve an average 15% gain in production efficiency, while computer vision enables automated defect detection, improving first-pass yield and reducing scrap. Predictive maintenance reduces unplanned downtime, increasing equipment availability and reliability. These benefits depend strongly on digital maturity and integration within enterprise systems—particularly Manufacturing Execution Systems (MES), Enterprise Resource Planning (ERP), and Product Lifecycle Management (PLM) which together ensure real-time data flow, process synchronization, and traceability across production operations. The primary barriers to adoption include data quality and governance issues, lack of workforce expertise, model explainability in safety-critical environments, and the complexity of integrating AI solutions into legacy systems. These factors hinder large-scale deployment despite proven technical advantages. This study proposes an applied framework for integrating AI within CI initiatives, aligned with the DMAIC (Define–Measure–Analyze–Improve–Control) cycle and the emerging Quality 4.0 architecture. It highlights managerial enablers such as data readiness, digital governance, and cross-functional collaboration, while identifying research gaps related to implementation costs, time-to-value, and long-term performance measurement. The findings demonstrate how AI transforms CI from reactive optimization to proactive, self-improving systems capable of sustaining excellence in modern automotive manufacturing.**

I. Introduction

Continuous improvement has been a cornerstone of the automotive industry for decades. Methodologies such as Kaizen, Lean, Six Sigma, and TQM have enabled manufacturers to reduce variability, eliminate waste, and enhance product quality in high-volume and highly regulated environments. These approaches remain relevant, but the complexity of modern automotive production—characterized by global supply chains, increasing customization, and stringent quality demands—requires new capabilities that extend beyond traditional frameworks.

Artificial intelligence has emerged as a critical enabler of this evolution. Machine learning, computer vision, and predictive analytics provide tools for detecting anomalies, anticipating failures, and optimizing processes in real time. Unlike traditional CI methods that rely on periodic sampling and retrospective analysis, AI enables continuous, data-driven decision-making embedded directly into production systems. This integration represents the foundation of Quality 4.0, a paradigm that connects classical improvement philosophies with cyber-physical systems, digital twins, and advanced analytics.

Empirical evidence from the automotive sector demonstrates the transformative potential of AI-enhanced CI. Studies report that AI-based visual inspection systems achieve defect detection rates significantly higher than human inspectors, while predictive maintenance algorithms reduce unplanned downtime by forecasting failures before they occur. Hybrid approaches, such as Lean Six Sigma augmented with neural networks, have shown quantifiable gains in yield, defect reduction, and energy efficiency. These results illustrate not only the performance benefits of AI integration but also its role in reshaping organizational routines and cultural approaches to improvement.

Despite these advances, critical gaps persist. Traditional CI frameworks were not designed to accommodate dynamic model retraining, data drift, or governance of AI-driven recommendations. Barriers include fragmented data infrastructure, legacy equipment, workforce skill limitations, and unclear metrics for return on investment at scale. Addressing these challenges requires a structured research agenda and industrial roadmap that align AI capabilities with the principles of continuous improvement.

This article contributes to this agenda by comparing existing applications of AI within the CI toolbox of the automotive industry. It emphasizes comparative evaluation of traditional and AI-augmented approaches, identifies integration patterns

that deliver sustained improvements, and highlights emerging directions for future research. Particular attention is given to the digitalization of CI processes, an area that remains underexplored yet represents a critical axis for achieving operational excellence in smart automotive manufacturing.

Although numerous studies have addressed AI applications in the automotive industry, most remain fragmented or confined to specific technological domains, such as defect detection or maintenance prediction. Consequently, a holistic understanding of AI's managerial and operational impact within Industry 4.0 environments remains limited.

This research bridges that gap by consolidating empirical evidence and identifying actionable pathways for adoption. Specifically, it synthesizes how AI and ML improve performance across quality, availability, and production flow, and identifies the technical, human, and organizational enablers required to scale AI solutions from pilot projects to full industrial deployment.

The overarching goal is to deliver a structured framework that guides manufacturers in embedding AI capabilities into continuous improvement and digital transformation strategies—ensuring measurable gains in productivity, cost efficiency, and long-term operational excellence.

II. Methodology

This study adopts a comparative and case-based methodology to evaluate the integration of Artificial Intelligence (AI) into continuous improvement frameworks within the automotive industry. The objective is not only to review existing contributions but also to critically assess how AI enhances or transforms traditional approaches such as Lean Manufacturing, Six Sigma, Total Quality Management (TQM), and Kaizen. The methodological framework is divided into four main stages (see Fig. 1).

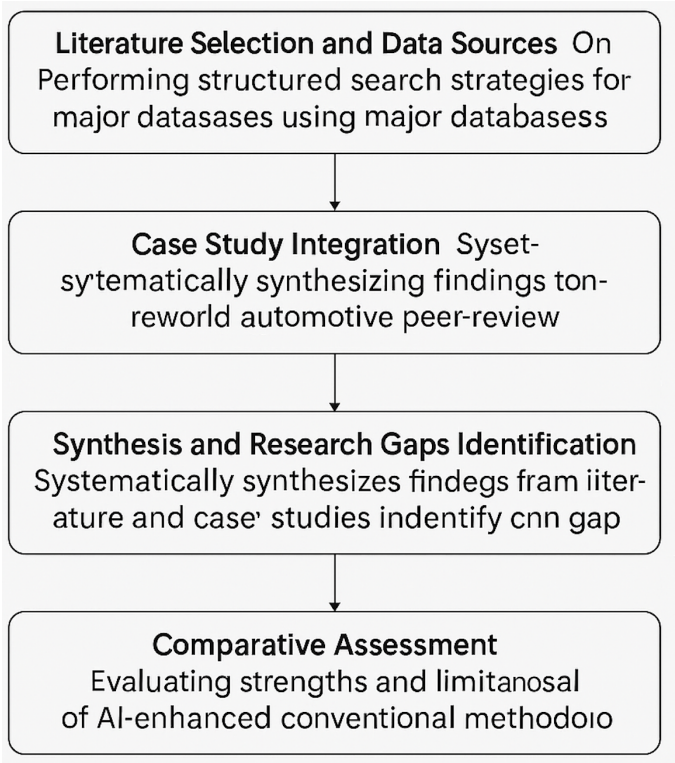

Fig. 1. Methodology.

A. Literature Selection and Data Sources

The research began with a structured literature search across major scientific databases, including Scopus, Web of Science, IEEE Xplore, and ScienceDirect. Keywords and Boolean combinations: ("artificial intelligence" OR "AI" OR "machine learning" OR "deep learning") AND ("continuous improvement" OR "kaizen" OR "lean manufacturing" OR "six sigma" OR "total quality management") AND ("automotive industry" OR "car manufacturing" OR "automobile sector") AND ("comparison" OR "case study" OR "review" OR "application" OR "evaluation").

The search was limited to publications from 2010 to 2024, ensuring coverage of recent advancements in Industry 4.0 and AI-driven manufacturing. Only peer-reviewed journal articles, conference proceedings, and systematic reviews were included, while non-scientific reports and grey literature were excluded to maintain academic rigor.

B. Literature Selection Process

The following criteria guided the selection process:

- Inclusion: Studies applying AI/ML techniques (machine learning, deep learning, predictive analytics) within continuous improvement methodologies in automotive or closely related manufacturing sectors.
- Exclusion: Articles focusing exclusively on AI without reference to quality management, or papers discussing continuous improvement without AI integration.

This process resulted in a corpus of over 100 publications, which were subsequently refined to a final dataset of 45 highly relevant studies.

C. Comparative Analytical Framework

The selected studies were analyzed using a comparative multi-dimensional framework. Three dimensions were adopted:

- Technical Performance Indicators: Accuracy, F1-score, AUC, Overall Equipment Effectiveness (OEE), Sigma levels, defect reduction rates.
- Organizational Outcomes: Impact on employee engagement, decision-making processes, safety improvements, and adaptability of workflows.
- Strategic and Economic Outcomes: Return on Investment (ROI), sustainability, scalability, and contribution to long-term competitiveness.

This framework allows the study to highlight both the strengths and limitations of AI-enhanced continuous improvement compared to conventional methods.

D. Case Study Integration

To complement the literature synthesis, real-world case studies from leading automotive manufacturers (Tesla, Toyota, Volkswagen, and BMW) were examined. These cases illustrate how AI applications, such as computer vision for defect detection, predictive maintenance algorithms, and AI-driven supply chain optimization, have been combined with Lean and Six Sigma principles. Comparative evaluation of these cases provides insights into practical implementation challenges and success factors.

E. Synthesis and Research Gaps Identification

The final stage involves synthesizing findings to identify emerging trends, best practices, and research gaps. Particular attention is given to underexplored areas such as the digitalization of continuous improvement processes and the potential development of AI-based collaborative systems capable of interacting directly with operators, engineers, and managers to generate and refine improvement initiatives.

III. Results

The automotive industry has become a key testing ground for combining artificial intelligence and machine learning with established quality management practices. Traditional quality methods like kaizen, lean manufacturing, six sigma, and total quality management have long been used in car manufacturing to reduce waste and improve processes. Now, automotive companies are integrating AI and deep learning technologies with these proven approaches to create more powerful quality improvement systems. This integration allows manufacturers to use real-time data analysis, predictive maintenance, and automated decision-making alongside continuous improvement philosophies. The automotive sector's complex supply chains, strict quality requirements, and high-volume production make it an ideal environment for testing how AI can enhance traditional quality management methods. Many companies are conducting comparative studies and evaluations to determine which combinations of AI technologies and quality management approaches deliver the best results for their specific manufacturing contexts.

A. AI/ML Technologies in Manufacturing

The integration of AI and machine learning into manufacturing represents a fundamental shift toward data-driven production systems that can continuously monitor and optimize processes [1] (Fig. 2).

Modern AI systems can synthesize knowledge from vast amounts of network data, replicating human cognitive processes like learning, memory, and decision-making to help manufacturers reduce costs and enhance competitiveness [2]. Machine learning, which includes deep learning, ensemble learning, and connected learning approaches, has become one of the most promising improvements in manufacturing with applications spanning from automotive to semiconductors [3] (Fig. 3).

The core advantage of these AI technologies lies in their ability to process real-time data from sensors and IoT-connected devices to enable predictive maintenance, early

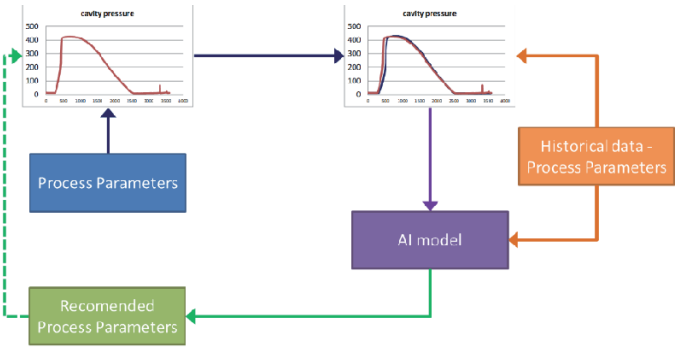

Fig. 2. Iterative comparison to optimized production setup comparing known optimal process parameters versus new acquired ones.

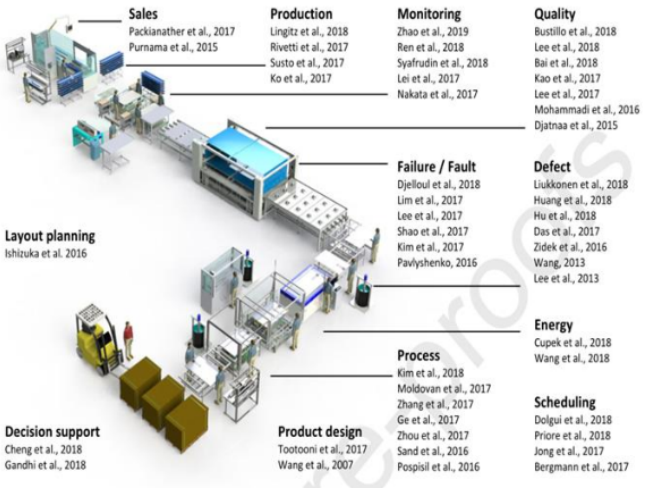

Fig. 3. General categories of manufacturing responsibilities associated with machine learning approaches.

fault detection, and intelligent decision-making [4]. Machine learning algorithms can be trained through supervised, unsupervised, semi-supervised, and reinforcement learning methods to analyze production data and develop problem-solving strategies [2]. This creates intelligent Cyber-Physical Systems that allow manufacturing equipment to make informed decisions from real-time data, combining features from lean manufacturing and agile manufacturing paradigms [5].

In practice, AI and ML applications in manufacturing focus on improving quality assurance, supply chain management, production scheduling, and maintenance while reducing downtime and improving resource utilization [6][7]. These systems target key performance indicators like Overall Equipment Efficiency (OEE), which considers availability, quality, and performance metrics that directly impact manufacturing productivity [1]. The prescriptive analytics capabilities of ML technologies also help industrial workers optimize processes and workflows while reducing physical strain and safety risks [6].

B. Quality Management Methods Integration

The integration of AI and machine learning with established quality management methodologies represents a significant evolution from traditional approaches to what re-

searchers now call Quality 4.0. Traditional strategies such as Total Quality Management (TQM), Six Sigma, Lean, and Zero-Defect Manufacturing have long focused on achieving higher yields while lowering costs, but AI is now enhancing these capabilities by enabling manufacturers to identify faulty components, detect defective products, and improve Quality Control measures [8] (Fig. 4).

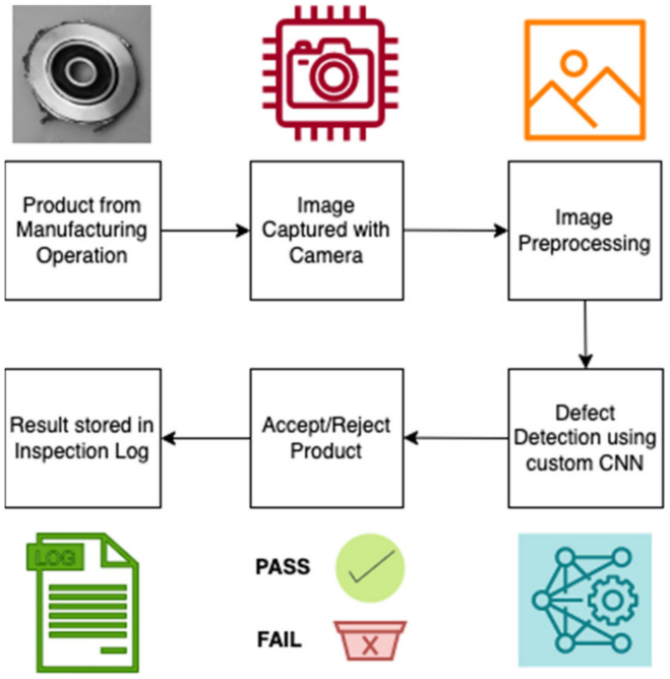

Fig. 4. Artificial intelligence based smart quality inspection methodology.

However, this integration reveals important gaps in traditional frameworks. The Six Sigma five-step problem-solving strategy (define, measure, analyze, improve, and control) does not fit the full machine learning cycle, highlighting limitations of traditional Six Sigma techniques in driving manufacturing innovation [9]. To address these limitations, manufacturers are developing hybrid approaches that combine the strengths of both methodologies, such as Lean/Six Sigma models utilizing neural networks that follow DMAIC methodology while incorporating AI for real-time control [10].

The combination of AI and Lean manufacturing creates what researchers call "Lean AI," which enables companies to build new cultures that ensure improved operations and more flexible workflows for workers. AI's primary purpose in this context is to optimize data flow for continuous improvement by extracting Lean principles like waste elimination while reducing dependence on human participation [11][12]. AI facilitates continuous improvement initiatives by collecting and analyzing data from various sources to identify bottlenecks, inefficiencies, and areas for improvement, helping manufacturers optimize processes and implement lean methodologies across the organization [13] (Fig. 5).

Modern integrated approaches address the limitations of traditional methods by incorporating continuous model monitoring and retraining. While traditional methods like Six Sigma and Lean Manufacturing focus on reducing variability and

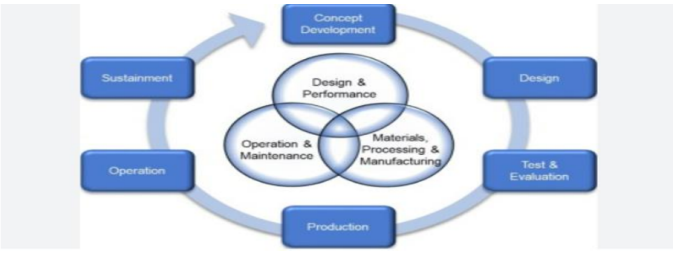

Fig. 5. AI-based approaches for control processes ensuring high-quality.

improving process efficiency, they often lack real-time data analysis and AI capabilities [14]. Advanced implementations now embed iterative machine learning retraining cycles within modified quality frameworks, complementing and extending traditional Six Sigma and Lean Six Sigma methodologies that rely on static statistical models [15][16].

The most comprehensive integration approaches combine multiple methodologies with AI technologies. For example, Green Lean Six Sigma Energy Management Systems are being integrated with AI and IoT technologies to improve energy efficiency in automotive processes, enabling not only energy savings but also predictive maintenance capabilities that can track and prevent issues from the start [17]. When properly integrated with Lean manufacturing principles, AI and machine learning technologies can lead to more efficient operations, better quality control, and faster response times [18] (Fig. 6).

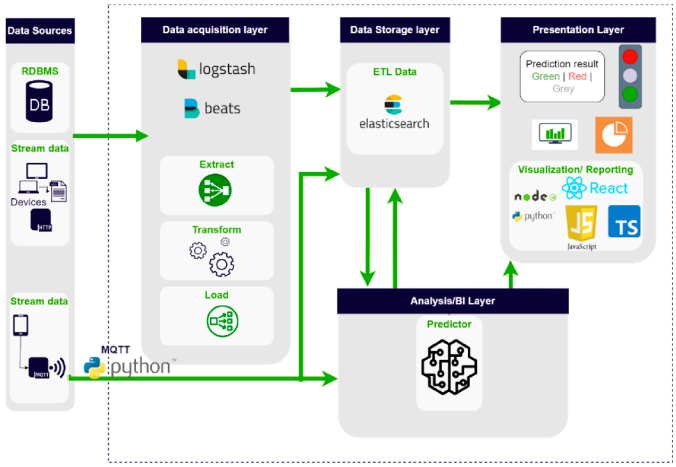

Fig. 6. Actual implementation from data integration to visual layer.

C. Automotive Industry Applications

The automotive industry has emerged as a leader in implementing AI and machine learning technologies across manufacturing operations, with companies achieving significant improvements in quality control and production efficiency. Tesla serves as a prominent example of comprehensive AI integration, employing deep learning and machine learning throughout their manufacturing process to optimize production efficiency, quality control, and supply chain management through continuous learning and optimization that enhances production line intelligence [19]. Tesla's approach includes

extensive use of robots and automated equipment with intelligent laser welding, machine vision, and automated guidance systems, combined with digital production capabilities that use big data analysis and IoT technology to monitor processes and respond quickly to market demands [19].

AI tools have fundamentally transformed quality control activities in automotive production through the implementation of deep learning, artificial neural networks, and principal component analysis, which have automated essential production tasks, decreased dependence on human inspections, and improved early defect identification [20]. These AI solutions demonstrate particular effectiveness in inspecting vehicle components, enabling organizations to reduce waste and increase product reliability while driving the development of zero-defect manufacturing plans that focus on predicting and preventing defects before they impact production [20] (Fig. 7).

Fig. 7. QM framework.

Specific AI applications in automotive manufacturing include AI-powered visual inspection systems that use cameras and sophisticated image processing algorithms to detect defects and anomalies with greater accuracy and speed than manual inspections, which are particularly effective in automotive environments where precision is critical [21] (Fig. 8).

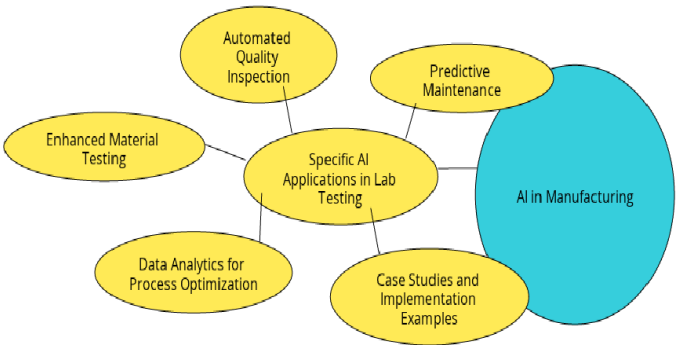

Fig. 8. Artificial intelligence in lab testing system.

The industry has also implemented real-time manufacturing tracking through sensors and machine learning algorithms for proactive problem detection, enhanced preventive maintenance by forecasting equipment failures, quality control procedures using computer vision with convolutional neural networks to inspect automotive components with high precision, and intelligent supply chain management [20].

Advanced AI algorithms process and analyze vast amounts of testing data in real time to identify patterns and extract actionable insights, leading to significant improvements in manufacturing processes, quality assurance practices, and resource utilization that are crucial for continuous improvement strategies [21][22]. Machine learning techniques are being used to assess automotive manufacturing architectures, models, and deployment challenges, helping companies optimize their implementation strategies [23].

D. Case Studies and Comparative Evaluations

The integration of artificial intelligence into continuous improvement frameworks has generated a growing body of empirical studies. While theoretical contributions outline the potential of AI in manufacturing, concrete case studies provide the most valuable evidence regarding feasibility, performance, and limitations. Comparative evaluations across industries, methodologies, and technologies highlight not only the benefits of AI integration but also the gaps that persist in traditional quality approaches.

The following section synthesizes representative case studies from recent literature. It includes investigations on the limitations of Six Sigma when applied to machine learning cycles, the effectiveness of hybrid Lean/Six Sigma models enhanced with neural networks, and real-world applications of AI in the automotive industry. Further analyses compare the performance of machine learning algorithms in high-precision contexts, evaluate AI applications across distinct industrial sectors, and explore integrated approaches that combine AI with sustainable manufacturing systems.

These diverse examples illustrate how AI transforms continuous improvement practices, while also exposing unresolved challenges that motivate future research (Table I).

1) Six sigma vs. AI/ML integration studies: Researchers have identified fundamental limitations when applying traditional Six Sigma methods to modern AI-driven manufacturing. A comparative study revealed that the Six Sigma five-step problem-solving strategy (define, measure, analyze, improve, and control) does not fit the full machine learning cycle, highlighting limitations of traditional Six Sigma techniques in driving manufacturing innovation [9]. The study included a case study where a 3D quality pattern that could be easily detected by machine learning algorithms was not detected by traditional process monitoring methods [9].

2) Hybrid lean/six sigma with AI implementation: A practical implementation study demonstrated the effectiveness of combining traditional methodologies with AI technologies. Researchers implemented a hybrid Lean/Six Sigma model utilizing a Surface Tension Neural Network (STNN) for real-time temperature and humidity control in manufacturing processes [10]. The STNN model achieved 97.31% accuracy for temperature classification and 97.37% for humidity, significantly outperforming a Naive Bayes model which attained only 90% accuracy for both parameters [10]. This integration resulted in a 3.15% increase in yield, saving 39.7 kg of waste per batch, and achieved a 2.13-point improvement at the Six Sigma level, reducing defects per million opportunities by 551.722 [10].

3) Automotive industry case studies: Tesla serves as a comprehensive case study for AI integration in automotive manufacturing, demonstrating how deep learning and machine learning can be applied throughout the manufacturing process

to optimize production efficiency, quality control, and supply chain management [19]. A prominent automotive manufacturer implemented neural networks to enhance their testing protocols, demonstrating successful real-world application of AI in manufacturing lab testing systems [21][22].

4) Machine learning algorithm performance comparisons: A high-precision automotive component facility study compared various machine learning algorithms for defect prediction and classification. The research tested Decision Trees, Random Forest, Gradient Boosting Machine, Logistic Regression, Support Vector Machine, and Artificial Neural Networks for classifying and predicting defects in engine valves during manufacturing processes [15]. Results showed that Gradient Boosting Machine and Random Forest provided the best performance, achieving an F1 score of 0.98 and an AUC of 0.99 [15].

5) Industry-specific AI applications: Multiple case studies have evaluated AI applications across different manufacturing sectors. Image-based quality control systems in aerospace manufacturing demonstrated the effectiveness of computer vision techniques for detecting assembly defects [24]. Comparative studies in the plastics industry analyzed different color-based defect detection systems' performance, advantages, and limitations [24].

6) Integrated green manufacturing systems: A comprehensive case study explored the integration of Green Lean Six Sigma Energy Management System (GLSS-EnMS) with AI and IoT technologies for improved energy efficiency in automotive paint oven processes [17]. The study found that this integration not only saves energy but also enables predictive maintenance capabilities that can track and prevent issues from the start, providing high availability while minimizing maintenance expenses [17].

E. Performance and Benefits

The integration of AI and machine learning with traditional quality management methodologies has demonstrated substantial quantifiable benefits across manufacturing operations. Real-world implementations show that AI-driven frameworks enable early fault prognosis, minimize disruptions, and reduce the likelihood of substandard output through continuous monitoring of production parameters using machine learning algorithms, sensor data, and IoT connectivity [4]. These systems facilitate dynamic optimization of manufacturing through real-time analytics, adaptive control, predictive maintenance, and intelligent decision-making, ultimately enhancing efficiency, resource utilization, and product quality [4]. Comparative performance studies reveal significant advantages of AI-integrated approaches over traditional methods alone. A hybrid Lean/Six Sigma model utilizing Surface Tension Neural Network achieved 97.31% accuracy for temperature classification and 97.37% for humidity, substantially outperforming a Naive Bayes model which attained only 90% accuracy for both parameters [10]. This implementation resulted in a 3.15% increase in yield, saving 39.7 kg of waste per batch, and achieved a 2.13-point improvement at the Six Sigma level, reducing defects per million opportunities by 551.722 [10].

In automotive manufacturing specifically, machine learning algorithm performance comparisons demonstrate exceptional results for defect prediction and classification. Studies testing Decision Trees, Random Forest, Gradient Boosting Machine, Logistic Regression, Support Vector Machine, and Artificial Neural Networks found that Gradient Boosting Machine and Random Forest provided the best performance, achieving an F1 score of 0.98 and an AUC of 0.99 for classifying and predicting defects in engine valves during manufacturing processes [15]. The operational benefits extend beyond quality improvements to encompass worker safety and resource optimization. AI and ML applications in smart manufacturing significantly enhance ergonomics for workers by optimizing workflows, reducing physical strain, and mitigating safety risks [6]. These solutions reduce downtime, improve resource utilization, and enable proactive decision-making through real-time data analysis and continuous innovation, providing a more flexible, responsive, and sustainable future in industrial production [6][7]. AI-powered visual inspection systems demonstrate superior performance compared to manual inspections, leveraging cameras and sophisticated image processing algorithms to detect defects and anomalies with greater accuracy and speed, particularly in precision-critical environments such as automotive industries [21]. Advanced AI algorithms process and analyze vast amounts of testing data in real time to identify patterns and extract actionable insights, leading to significant improvements in manufacturing processes, quality assurance practices, and resource utilization that are crucial for continuous improvement strategies [21][22].

In automotive production specifically, AI tools have fundamentally transformed quality control activities, enabling organizations to reduce waste and increase product reliability while driving the development of zero-defect manufacturing plans that focus on predicting and preventing defects before they impact production [20]. These implementations have launched fundamental innovations including real-time manufacturing tracking through sensors and machine learning algorithms for proactive problem detection, enhanced preventive maintenance by forecasting equipment failures, and intelligent supply chain management [20].

IV. Discussion

The integration of artificial intelligence into continuous improvement frameworks within the automotive industry represents an important shift from tool driven optimization toward systemic transformation. Existing applications predictive maintenance, visual inspection, defect detection, process optimization, and hybrid Lean Six Sigma systems—provide substantial improvements in productivity, quality, and cost reduction. Yet these applications remain fragmented, with AI functioning largely as a backend engine for analytics rather than an active contributor to improvement cycles. The real promise of AI lies not only in computational power but also in its ability to participate in continuous improvement as an intelligent, adaptive partner.

One of the most compelling directions for future research and industrial application is the design of specialized AI systems capable of dialogic interaction with human stakeholders at multiple organizational levels. In traditional continuous improvement models such as Kaizen or Lean, the success of initiatives depends on the structured collection of insights from operators, engineers, and managers. Operators contribute

practical, shop-floor knowledge about daily processes and bottlenecks; engineers provide technical expertise for process redesign; managers bring strategic perspectives on resource allocation and organizational goals. Despite their complementary value, these perspectives are often difficult to capture systematically and in real time. Meetings, reports, and suggestion systems provide mechanisms for communication, but they are slow, inconsistent, and frequently limited by hierarchical or cultural barriers.

An AI system designed to act as an intelligent mediator could fundamentally reshape this dynamic. By leveraging natural language processing, multimodal data integration, and advanced decision-support algorithms, such a system could engage directly with stakeholders through structured discussions. For operators, it could serve as a conversational assistant on the shop floor, able to contextualize sensor data and propose corrective measures in accessible language. For engineers, it could provide model-based simulations of process adjustments, identifying potential improvements or unintended consequences before implementation. For managers, it could integrate operational data with strategic indicators, offering scenario-based forecasts of how proposed changes might influence productivity, quality, cost, and sustainability.

The implications of such an "interactive CI-AI" extend beyond efficiency gains. First, it could serve as a mechanism for capturing tacit knowledge that is otherwise lost in the daily routines of automotive production. Operators often develop experiential insights into recurring problems, yet these insights rarely reach formal improvement processes. An interactive AI could log, structure, and continuously refine such inputs, building a knowledge repository that strengthens organizational learning. Second, it could reduce cognitive and organizational barriers to participation. By creating a neutral and adaptive communication platform, AI can democratize continuous improvement, giving all stakeholders from line workers to executives an equal voice in proposing, refining, and validating improvement ideas.

Technologically, the development of such systems requires convergence between AI subfields and industrial engineering. Natural language processing is essential for enabling fluid interactions with human stakeholders. Reinforcement learning and prescriptive analytics are needed to simulate outcomes of proposed actions and to optimize decision-making under uncertainty. Digital twins and cyber-physical systems would provide the data backbone, ensuring that AI proposals are continuously aligned with real-time process conditions. A layered architecture could allow the system to interact differently depending on the stakeholder: suggesting operational fixes to an operator, presenting technical models to an engineer, and framing high-level trade-offs to a manager.

Organizational and cultural factors must also be considered. The effectiveness of such systems will depend on trust, interpretability, and perceived legitimacy of AI generated recommendations. Operators must feel that AI suggestions are transparent and practical rather than abstract directives. Engineers must be able to validate models and assumptions underlying AI-generated proposals. Managers must balance AI's recommendations with long-term business strategies, regulatory constraints, and sustainability goals. Governance frameworks will be needed to clarify accountability, particularly when decisions derived from AI inputs have financial or safety implications. Without careful design of explainability and user trust, there is a risk that AI could be seen as a "black box" tool that undermines, rather than enhances, continuous improvement culture.

From a research perspective, there is a need to move beyond performance metrics alone such as defect detection accuracy or predictive maintenance efficiency and evaluate how AI impacts the collaborative and cultural dimensions of continuous improvement. Key questions emerge: How does AI participation influence the speed and quality of improvement cycles? How does it affect employee engagement and cross-

functional collaboration? Does AI-supported dialogue accelerate the transition from reactive problem-solving to proactive innovation? These questions should guide future empirical studies, case-based evaluations, and pilot implementations in automotive contexts.

A particularly underexplored avenue is the digitalization of continuous improvement practices themselves. While much of the Industry 4.0 literature focuses on production systems, logistics, and predictive analytics, the mechanisms of Kaizen, Lean, and Six Sigma remain predominantly manual. Kaizen boards, suggestion schemes, and workshops continue to be conducted through paper-based or basic digital tools.

Embedding AI into these practices could transform them into dynamic, real-time improvement ecosystems. For example, an AI integrated with a digital Kaizen board could not only record operator suggestions but also cross reference them with historical data, propose alternative solutions, and simulate potential outcomes. Similarly, in Six Sigma projects, AI could accelerate DMAIC cycles by providing automated analysis and continuously updating models as new data becomes available.

The automotive industry, with its high production volumes, stringent quality requirements, and complex supply chains, represents an ideal testbed for such innovations. Leading companies such as Tesla, Toyota, and Volkswagen are already pioneers in combining AI with production and quality control. Extending this integration into the cultural and organizational domain of continuous improvement would represent a logical next step. By enabling interactive, data-driven, and inclusive improvement processes, the industry could achieve faster innovation cycles, greater employee involvement, and enhanced competitiveness in an increasingly digitalized landscape.

V. Conclusion

This study confirms that Artificial Intelligence (AI) and Machine Learning (ML) play a crucial role in modernizing continuous improvement frameworks within automotive manufacturing. By integrating advanced analytics and predictive modeling, AI-driven systems deliver measurable gains in production efficiency, quality consistency, and equipment reliability. Reported improvements include up to 15% higher process efficiency, reduced downtime through predictive maintenance, and significant defect reduction via computer vision inspection.

However, these benefits rely on robust digital foundations—high-quality, traceable data and seamless integration with Manufacturing Execution Systems (MES), Enterprise Resource Planning (ERP), and Product Lifecycle Management (PLM) platforms. Implementing AI within such interconnected systems enables real-time decision-making, continuous learning, and sustainable performance gains.

Organizational readiness, workforce training, and explainable AI remain essential to ensure adoption and trust at scale.

Looking ahead, our future work will focus on extending AI integration beyond machines and processes to the ergonomic well-being of workers. Specifically, we aim to develop intelligent posture detection systems that monitor and improve workers' physical positions in real time. This approach will promote healthier, more efficient, and safer working environments, reinforcing the broader goal of continuous improvement not only in production performance but also in human sustainability.

***Abstract*—This article examines how artificial intelligence and machine learning reshape automotive manufacturing within Industry 4.0. Reported impacts include up to a 200 percent reduction in costs and a 400 percent gain in production efficiency, with controlled studies showing about a 15 percent improvement from process optimization. The largest early wins appear in quality management through computer vision and continuous inspection, followed by predictive maintenance that cuts unplanned downtime and stabilizes throughput. Supply chain and planning benefit from demand forecasting and inventory optimization that reduce bullwhip and working capital. Adoption barriers remain meaningful, including high initial investment, integration complexity, skills gaps, and trust and explainability requirements in regulated contexts. Effective programs use a common data and MLOps backbone, prioritize short cycle use cases, link model outputs to machine and recipe actions, and track value through OEE, ppm, MTBF, lead time, and service level. The discussion outlines practical steps to scale while noting evidence limitations and the need for standardized reporting on cost of ownership and time to value.**

Keywords*—*Industry 4.0; automotive manufacturing; artificial intelligence; machine learning; quality 4.0; predictive maintenance

I. Introduction

Automotive manufacturing faces rising pressure on cost, quality, and lead time. Regulations tighten. Model variety grows. Launch cycles compress. Legacy methods struggle to keep pace. Industry 4.0 expands what you can do. Connected machines and sensors stream data across every station. Cloud and edge computing turn that stream into usable signals in real time. Cyber-physical systems coordinate actions on the line. Your factory becomes observable and controllable minute by minute. AI and machine learning convert raw signals into decisions. Computer vision detects defects as they appear. Predictive models surface failure risks before they stop the line. Optimization engines balance constraints and stabilize flow. Planning and supply chain systems gain accuracy through better forecasts and synchronized replenishment. Evidence shows material upside. Reported programs reach up to 200 percent cost reduction and up to 400 percent gains in production efficiency. Controlled studies show about 15 percent higher efficiency from process optimization. Plants also report higher first pass yield, fewer escapes, and shorter lead time. These results depend on scope and baseline, yet the direction is consistent. Quality management concentrates early value. Vision systems and anomaly models move inspection from sampling to continuous control. You cut rework and scrap. You tighten process windows. You trace defects to machines, recipes, and suppliers. Asset reliability follows. Predictive maintenance brings failures forward. You reduce unplanned downtime. You lift mean time between failures. You coordinate maintenance with scheduling and spares to protect service while lowering buffers. Throughput improves when you close the loop. Models recommend setpoints at constrained steps. Changeovers shorten with recipe guidance. Schedulers use health and quality signals to sequence orders. Flow stabilizes without adding capacity. Supply chain performance rises with the same data backbone. Demand forecasting aligns with production plans. Inventory policies reduce stockouts and excess. Working capital falls while service level rises. Logistics costs drop through better routing and load building. Adoption still requires foundations. You need trustworthy data with clear ownership and lineage. You integrate AI with MES, ERP, and PLM. You run an MLOps backbone that versions models, monitors drift, and supports retraining and rollback. You upskill operators, technicians, and planners. You address explainability wherever safety and compliance demand it.

This article targets practical outcomes for you. It synthesizes impacts documented in automotive plants operating within Industry 4.0 settings. It focuses on use cases that deliver measurable value in quality, maintenance, throughput, and supply chain. It connects model outputs to machine actions and work standards. It defines a metric set to prove value each month.

You will see a structured path from pilot to scale. Start with contained use cases that pay back fast. Reuse one data and MLOps stack across lines and sites. Publish baselines and targets for OEE, defects per million, mean time between failures, unplanned downtime, lead time, and service level. Fund scale only when results persist over time.

This work positions the research in a clear scope. Automotive manufacturing within an Industry 4.0 environment. Production systems that mix legacy assets and new equipment. Teams that must deliver gains without compromising safety or regulatory commitments. Three questions guide the study. Where do you capture the fastest value across quality, availability, or flow. Which data gaps block defect detection or failure prediction on your lines. How will you prove monthly gains on OEE, defects per million, mean time between failures, lead time, and service level while sustaining trust with teams and regulators. The article follow use the IMRAD structure. Methods explain how evidence and cases were selected and analyzed. Results present quantitative effects and operational changes. Discussion interprets drivers, limits, and actions you can take now.

II. Related Work

The automotive industry faces growing pressure to improve efficiency, reduce costs, and enhance product quality while meeting increasing consumer demands and regulatory requirements. Traditional manufacturing approaches are being transformed through the integration of artificial intelligence, machine learning, and deep learning technologies that promise to revolutionize how vehicles are designed, produced, and delivered to market. This technological evolution represents a fundamental shift from conventional manufacturing paradigms toward smart, data-driven production systems that can adapt and optimize in real-time.

The convergence of AI technologies with automotive manufacturing aligns with the broader Industry 4.0 movement, which emphasizes digital transformation, connectivity, and intelligent automation across industrial processes. Car manufacturers are increasingly recognizing that successful adoption of these technologies requires not only technical implementation but also significant organizational changes, workforce development, and strategic management approaches. The potential benefits include substantial improvements in productivity, quality control, cost reduction, and lead time optimization, making AI adoption a critical competitive factor in the modern automotive landscape.

A. AI and Machine Learning Application in Automotive Industry

The automotive industry has become one of the largest adopters of AI technologies, with transportation and automotive applications projected to hold the largest market share in the AI application segment [1]. Computer vision technologies are being widely used in vehicles to avoid collisions and enable lane-keeping assistance, making driving safer [2]. Beyond vehicle features, AI is helping automotive companies increase productivity, sustainability, reliability, and safety across their operations, with particular success in areas like understanding vehicle activity profiles to meet fuel consumption and emission standards [3].

Quality management has seen some of the most significant AI applications in automotive manufacturing. AI tools such as artificial neural networks (ANN), deep learning (DL), and principal component analysis (PCA) have greatly improved prediction and problem identification capabilities with high precision [4]. Machine learning approaches now enable real-time part inspection, reducing dependence on manual inspections and improving early defect detection in highly automated manufacturing lines [4]. These systems use computer vision with convolutional neural networks (CNN) to inspect automotive components with great precision, while also providing predictive maintenance by forecasting equipment shutdown before it happens [4].

The technology applications extend to supply chain and production optimization, where AI has improved inventory management efficiency and spare parts demand projection [4]. Generative models are being used for problem prediction and correction before manufacturing begins, which reduces both costs and lead time [4]. These advances have not only improved operational efficiency but also enhanced the industry's sustainability by reducing material waste and environmental impact [4] (Fig. 1).

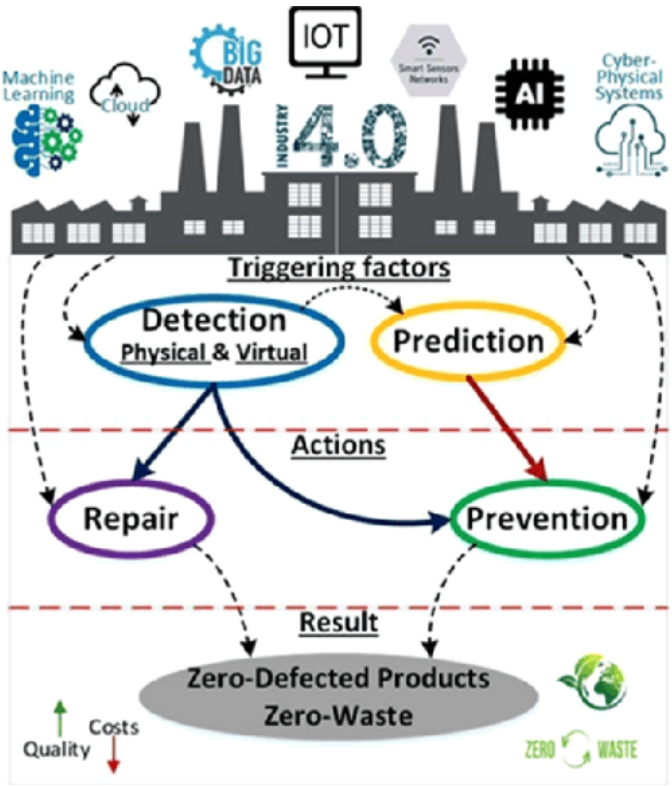

Fig. 1. Framework for ZDM.

III. Methodology

A. Study Design

This study applies a systematic literature review with a bibliometric layer. I fixed the protocol before data collection and followed a PRISMA workflow from identification to inclusion. The goal is to synthesize evidence on artificial intelligence and machine learning in automotive manufacturing under Industry 4.0 and to quantify the structure of the field.

B. Data Sources and Scope

I queried three scholarly databases Scopus, Web of Science, and OpenAlex. I scoped the search over 2010–2024 to capture field growth and then restricted the review core to English documents published during 2020–2024. I included peer-reviewed journal articles, conference papers, and book chapters. I excluded theses, editorials, and non-scholarly items.

C. Search Strategy

I used a single Boolean query harmonized across the three databases ("artificial intelligence" OR "AI" OR "machine learning" OR "deep learning") AND ("automotive industry" OR "car manufacturing" OR "automobile sector") AND ("industrial performance" OR "productivity" OR "quality" OR "cost reduction" OR "lead time") AND ("industry 4.0" OR "digital transformation") AND ("adoption" OR "implementation" OR "management" OR "organizational factors" OR "technology acceptance"). I exported full metadata for all hits.

D. Screening and Eligibility

Identification returned 110, 200 records across sources. After database filters I screened titles and abstracts for 73, 457 records. I assessed **15,380** records for eligibility on the basis of title, abstract, and keywords. I removed duplicates and off-scope items. The final dataset included 13, 080 records for analysis Fig. 2.

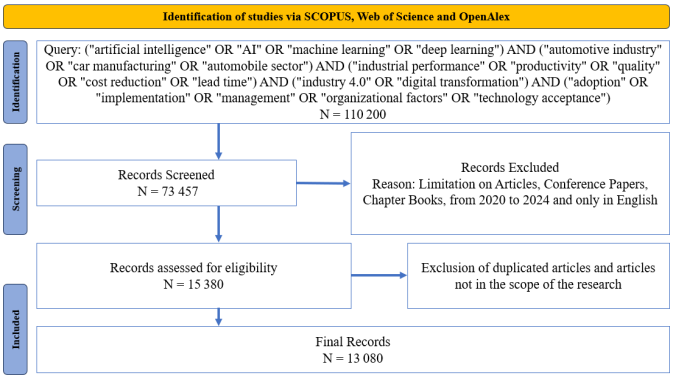

Fig. 2. Prisma.

E. Inclusion and Exclusion Criteria

I included studies that analysed automotive manufacturing or adjacent vehicle production value chains and that applied AI or ML methods. Each included study reported at least one relevant outcome such as productivity, quality, cost, lead time, maintenance, throughput, supply chain performance, or adoption and management factors. I excluded papers focused only on in-vehicle functions when no manufacturing link was present. I removed non-English items in the 2020–2024 core.

F. Data Extraction

For every included study I extracted bibliographic fields authors, year, venue, country, collaboration, citations, and author keywords. I coded AI methods computer vision, deep learning, time-series modelling, anomaly detection, optimization, and explainable AI. I coded use cases quality inspection, predictive maintenance, process optimization, scheduling, and supply chain planning. I captured metrics overall equipment effectiveness, first-pass yield, defects per million, mean time between failures, unplanned downtime, lead time, throughput, and unit cost. When effect sizes were reported I expressed them as relative change from baseline to support comparison.

G. Bibliometric Profile of the Corpus

The consolidated dataset shows a fast-growing and collaborative field. It spans 2010–2024 and covers **4,937** sources and **13,042** documents. The annual growth rate reaches **47.87%**. There are **38,035** authors, including **3,274** single-authored contributors. International co-authorship accounts for **17.87%**. The mean number of co-authors per document is **3.22**. Author keywords total **4,038**. The references cited across the corpus sum to **229,261**. The average document age is **2.88** years and the average citations per document are **12.37** (Fig. 3).

Fig. 3. Bibliometric profile of the corpus.

H. Synthesis and Analysis

I combined descriptive bibliometrics with qualitative synthesis. The bibliometric layer mapped volume, growth, collaboration, and citation impact. The synthesis layer grouped findings by use case quality, availability, and flow and by adoption enablers data governance, systems integration with MES–ERP–PLM, workforce skills, and explainability. I reported outcomes using a stable metric set overall equipment effectiveness, defects per million, mean time between failures, lead time, and service level.

IV. Results

A. Industrial Performance Impact

The integration of AI and machine learning technologies in manufacturing has generated substantial measurable improvements across key performance indicators. Industry 4.0's data-driven approach has enabled smart exploitation of data that provides competitive advantages impacting productivity, quality, and efficiency KPIs [5]. Recent analysis shows that AI integration in Industry 4.0 has resulted in a notable 200% cost reduction and a cumulative 400% boost in production efficiency [6]. Experimental studies have demonstrated that machine learning algorithms for process optimization can achieve significant increases in production efficiency by 15% while improving product quality [7] (Fig. 4).

Fig. 4. Analysis the case study for AI is transforming the manufacturing industry.

AI technologies are transforming manufacturing operations through multiple pathways to performance improvement. AI reduces the chances of machine failure, improves product quality control, increases productivity in industries, and enables substantial cost reduction of products [8]. The major benefits of using ML and AI approaches result in error reduction, cost reduction and revenue growth in manufacturing industries [9]. Machine learning algorithms have been extensively used to

optimize production processes, resulting in reduced downtime, improved quality control, and increased throughput [10] (Fig. 5).

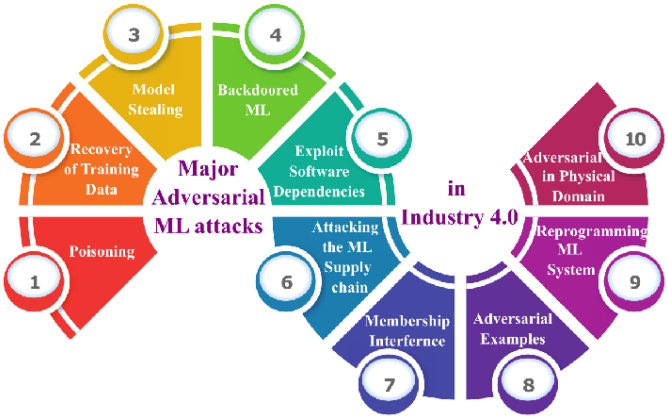

Fig. 5. Adversarial ML attacks affecting industrial organizations.

Quality control has emerged as one of the most impactful areas for AI implementation in manufacturing. AI algorithms can analyze data from sensors, cameras, and other sources to detect defects or anomalies in the production process, with machine vision systems equipped with AI able to identify and reject faulty products, ensuring consistent quality throughout the production line [11]. Automated quality inspection systems powered by AI technology can replace manual inspections, enabling manufacturers to satisfy growing demand for higher-quality products efficiently while directly impacting firm productivity through time and cost savings [12][13] (Fig. 6).

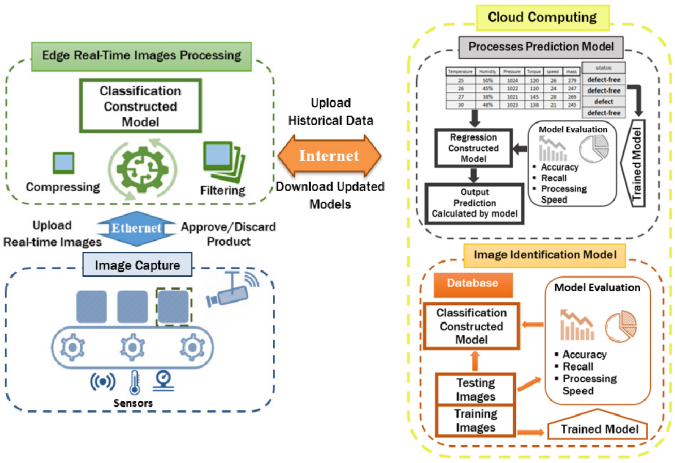

Fig. 6. Intelligent machine vision model for defective product inspection and for defective product inspection.

Predictive maintenance and supply chain optimization represent additional major sources of performance gains. Predictive maintenance powered by AI has demonstrated its ability to identify equipment failures before they occur, leading to substantial cost savings and minimizing unplanned downtime [10]. AI-driven supply chain management systems enable efficient inventory management, demand forecasting, and logistics optimization, leading to cost reduction and improved customer satisfaction [7]. AI algorithms can optimize the allocation of resources such as raw materials, energy, and labor by analyzing production data to identify inefficiencies and bottlenecks, enabling enterprises to streamline operations, minimize waste, and reduce costs [11].

B. Industry 4.0 and Digital Transformation

Industry 4.0 has emerged as the perfect scenario for boosting the application of artificial intelligence and machine learning solutions to industrial process monitoring and optimization, with this paradigm being fundamentally data-driven where smart exploitation of data provides competitive advantages impacting productivity, quality, and efficiency key performance indicators [5]. The technological foundation of Industry 4.0 relies heavily on advanced AI capabilities, with Internet of Things (IoT), cloud computing, artificial intelligence, augmented reality, cyber-physical systems (CPS), and cognitive computing serving as the backbone of Industry 4.0 concepts [14]. After the Internet and mobile Internet sparked the 3rd Industrial Revolution, AI technologies, fueled by data, are now creating an atmosphere of Industry 4.0, with the digital revolution beginning with data collection, followed by artificial intelligence to interpret the data [2] (Fig. 7).

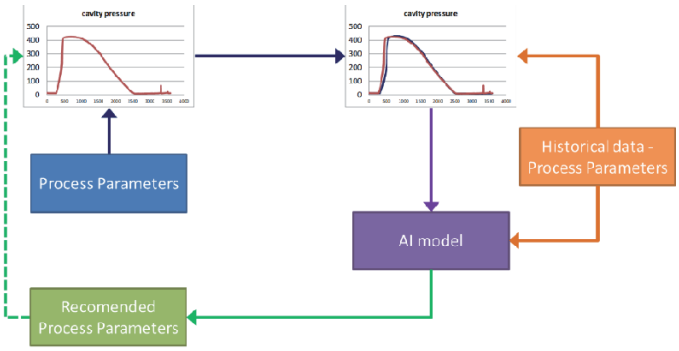

Fig. 7. Iterative comparison to optimized production setup comparing known optimal process parameters versus new acquired ones.

The manufacturing industry has recognized the transformative potential of machine learning technologies within the Industry 4.0 framework, utilizing various I4.0 technologies in applications such as smart manufacturing, fault diagnosis and prediction, robotic assembly, quality monitoring, and job shop scheduling [15][16] (Fig. 8). Industry 4.0 radically alters manufacturing organization and management by fostering collection and analysis of increasing amounts of data, with advanced data analytics such as machine learning being essential for implementing Industry 4.0 and obtaining insights regarding production, better decision support, and enhanced manufacturing quality and sustainability [17][18].

The advancement of AI and widespread use of machine learning and deep learning techniques are paving the way for these technologies to play a central role in implementing Industry 4.0, with AI-based approaches enabling intelligent devices to conduct functions such as self-monitoring, interpretation, diagnosis, and analysis autonomously [19][20][21] (Fig. 9).

Modern manufacturing systems leverage AI to facilitate seamless communication, coordination, and collaboration between different parts of the manufacturing process, with AI

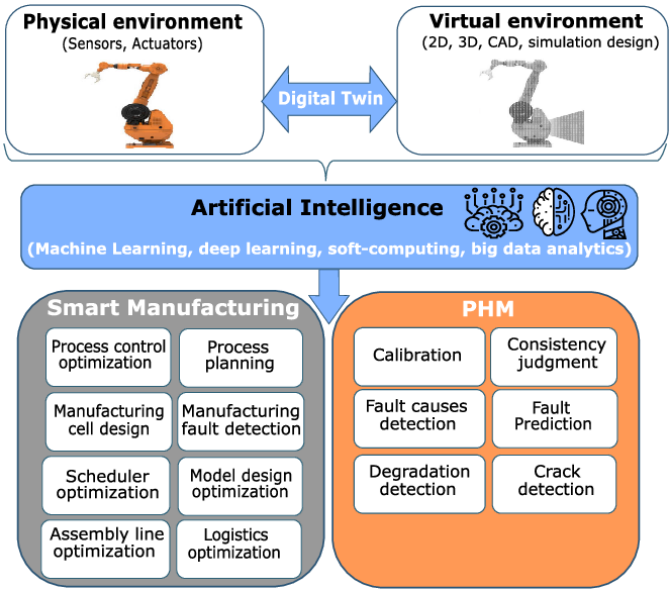

Fig. 8. DT-based smart manufacturing using big data analytics and AI-ML.

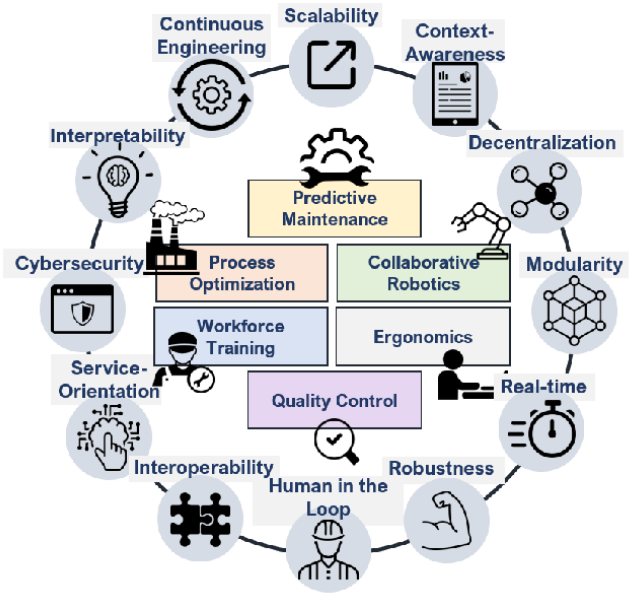

Fig. 9. The main design principles acting as pillars of Industrial AI in the context of its application areas.

algorithms processing vast amounts of data generated by sensors and machines to extract valuable insights for optimizing operations [22][23].

The digital transformation enabled by Industry 4.0 technologies extends beyond basic automation to create intelligent, adaptive manufacturing systems. Machine learning and AI approaches contribute to revolutionary changes in industry by allowing the creation of smart factories and process automation, with IoT, artificial intelligence, cyber-physical systems working together to enable intelligent manufacturing [24][25]. Deep learning technology enables intelligent decision-making, resource optimization, and waste reduction through real-time monitoring and analysis of production line data, empowering production systems with autonomous learning and adaptability that fosters progression toward intelligent manufacturing [26][27][28][29].

However, the adoption of AI technologies for Industry 4.0 varies considerably across industrial sectors, and the transition requires addressing challenges related to explainability and trust in AI systems [30][31]. The deep integration of machine learning with technologies such as augmented reality, data mining, IoT, and cyber-physical systems continues to drive digital transformation, with industrial artificial intelligence becoming the brain of future smart factories for intelligent decision-making and deployment [32]. This technological evolution enables enterprises to better adapt to market demands through AI-optimized mechanical design, improved manufacturing efficiency, and intelligent monitoring and maintenance capabilities [33][34][35]

C. Adoption Challenges and Organizational Factors

Despite the proven benefits of AI and machine learning technologies, automotive manufacturers encounter substantial barriers to successful adoption that extend beyond technical considerations. The manufacturing industry faces challenges related to high initial investments, integration complexities, and resistance to change, which can create cultural barriers to AI adoption within organizations [10]. Small and medium-sized enterprises (SMEs) may particularly struggle with the financial burden of AI implementation, although long-term benefits often justify the initial expenditure [36]. The uneven development between industries has seriously hindered the process of intelligent manufacturing across society, with AI enterprises attracting capital and labor inflows while gradually occupying leading positions in their industries [11].

Workforce adaptation and organizational transformation represent critical success factors for AI adoption in automotive manufacturing. Successfully integrating AI into the manufacturing sector necessitates a proficient workforce and cultural transformation that embraces data-driven decision-making and fosters harmonious collaboration between human expertise and machine capabilities [10]. The need for skilled personnel to manage AI-driven systems presents another challenge, necessitating investments in workforce training and upskilling [36]. Upgrading production activities with AI requires important investment and adaptation in training and infrastructure [4].

Technical complexity and explainability issues create additional adoption hurdles that manufacturers must address. Using AI brings challenges such as transparency, explainability, system integration, and ethical issues, leading to the development of explainable artificial intelligence (XAI) approaches [37]. The increasing complexity and limited explainability of complex machine learning models makes it increasingly difficult to address fairness, accountability, and transparency principles, thus hindering applications in industrial and mission-critical scenarios [17]. Implementing AI solutions in manufacturing processes still presents challenges in many aspects, particularly in handling irregular datasets influenced by diverse manufacturing settings [38].

Integration complexities extend to both technical and organizational dimensions of digital transformation. The imple-

mentation process involves navigating complexities such as data security, workforce adaptation, and ethical considerations when implementing AI-driven automation in manufacturing processes [39]. Financial, regulatory, and organizational management constraints remain significant challenges in effectively integrating intelligent technologies, despite the expected benefits of increased production speed and energy efficiency [38]. The adoption of XAI methodologies can help humans make trustworthy decisions for critical applications, but requires careful implementation without compromising the efficiency of models developed using deep learning algorithms [31].

V. Discussion

AI and machine learning now shape how you design, build, and scale automotive production. The evidence shows large performance gains. Reported effects include a 200 percent cost reduction and a 400 percent boost in production efficiency, alongside a 15 percent lift from process optimization experiments. These numbers point to strong upside and also to context dependence. You capture value when data, process discipline, and change management align.

Quality management concentrates much of the early value. Vision models and defect analytics raise first pass yield and cut rework. Plants that move from sample checks to continuous inspection report fewer escapes and tighter process windows. You can link model outputs to corrective actions at the machine and recipe level. This closes the loop and sustains gains.

Maintenance and throughput follow next. Predictive models pull failures forward. You reduce unplanned downtime and stabilize takt. When planners integrate health predictions with scheduling and inventory, you shrink buffers without risking stockouts. The result is faster flow and lower working capital.

Supply chain and planning benefit from the same data backbone. Demand signals, spare parts forecasts, and replenishment models reduce bullwhip. The payoff shows up in service level and logistics cost. Generative approaches add a design lever by simulating issues before tooling. You avoid late changes and compress lead time.

Adoption still hinges on people and systems. High upfront spend, integration work, and resistance to change slow programs down. SMEs feel this most. You can offset the burden by sequencing small but material use cases and recycling the same data and MLOps stack across lines. Explainability matters as models move into safety and compliance boundaries. XAI techniques improve trust, but they add design trade offs that you should make explicit.

Data quality remains the rate limiter. Irregular datasets from varied settings and machine vintages create drift and blind spots. You need governance that names owners, defines gold metrics, and enforces traceability from raw data to decisions. Without this, models decay and perceived value erodes.

Managerial implications are direct. Tie each model to a cost line or a revenue driver. Publish baseline and target for OEE, ppm, MTBF, lead time, and service level. Hold monthly value reviews with operations and finance. Fund scale ups only after pilots hit agreed thresholds. Limitations of current evidence deserve attention. Reported 200 percent cost cuts and 400 percent efficiency gains likely reflect specific scopes and baselines. Few studies disclose full cost of ownership. Replication across plants and suppliers is sparse. Future work should standardize metrics, disclose denominators, and report time to value and sustainability impact.

A. Benefits and Performance Outcomes

The comprehensive benefits of AI adoption in automotive manufacturing extend across all operational dimensions, creating measurable value that justifies implementation investments. AI technology reduces the chances of machine failure, improves product quality control, increases productivity in industries, and enables substantial cost reduction of products, with quality prediction of products at different stages of the life-cycle and real-time monitoring helping to ensure improved production yield, better quality management, and improved customer value [8]. The major benefits of using ML and AI approaches result in error reduction, cost reduction and revenue growth in manufacturing industries [9]. These quantifiable improvements demonstrate that AI integration has resulted in a notable 200% cost reduction and a cumulative 400% boost in production efficiency [6].

Specific performance improvements have been documented across multiple manufacturing applications. Experimental studies show that machine learning algorithms for process optimization can achieve a significant increase in production efficiency by 15% and improved product quality through the utilization of AI methods, with AI methods showing substantial benefits in quality control through real-time defect detection, reduced rework, and improved product consistency [7]. Machine learning algorithms have been extensively used to optimize production processes, resulting in reduced downtime, improved quality control, and increased throughput [10].

The automotive industry has realized particularly significant gains in quality management and operational efficiency through AI implementation. AI tools such as artificial neural networks (ANN), deep learning (DL), and principal component analysis (PCA) have importantly upgraded prediction and issue-identification capabilities with high precision, with machine-learning-based approaches enabling on-time part inspection, decreasing dependence on manual inspections, and improving early defect detection in highly automated manufacturing lines [4]. The usage of generative models for issue estimation and correction before manufacturing decreases costs and lead time, while AI has launched fundamental innovations such as enhancement of preventive maintenance by forecasting equipment shutdown before it happens and quality control procedures using computer vision with convolutional neural networks (CNN) to inspect automotive components with great precision [4].

AI-driven systems enable manufacturers to achieve unprecedented levels of operational flexibility and customization. The progressive adoption of artificial intelligence and machine learning techniques improves the flow of resources through the manufacturing process, with AI assisting in predicting maintenance, generative designing, manufacturing, delivering quality, human-robot collaboration, supply-chain management, waste reduction, and production optimization [40]. AI-driven predictive maintenance algorithms can forecast equipment failures before they occur, reducing downtime and maintenance costs, while ML models can optimize supply chains

by predicting demand fluctuations, ensuring that resources are allocated efficiently [41][42]. The adoption of AI and ML in Industry 4.0 is facilitating a shift towards customization and flexibility in manufacturing, allowing manufacturers to offer highly personalized products without compromising efficiency or increasing costs significantly [41].

The creation of smart factories represents the culmination of AI benefits in automotive manufacturing. AI is facilitating the creation of smart factories where networked systems, IoT devices, and AI algorithms combine to provide a highly automated and intelligent manufacturing environment, with the incorporation of AI into these smart factories paving the way for improved productivity, real-time monitoring of manufacturing processes, and data-driven decision-making [10][19][43]. These systems enable cyber-physical systems to communicate and cooperate with humans in real-time, significantly improving manufacturing processes and outcomes, while AI revolutionizes operations by employing advanced algorithms for deep learning and machine learning to improve and expedite procedures, resulting in enhanced efficiency through AI-powered systems that can analyze extensive information to identify patterns, make informed decisions, and adapt to evolving production circumstances [41][44].

VI. Conclusion

AI and machine learning deliver consistent gains in automotive manufacturing. Programs report up to 200 percent cost reduction and up to 400 percent efficiency gains. Controlled studies show about 15 percent improvement from process optimization. Quality inspection with computer vision and predictive maintenance produce the most reliable early wins.

Results depend on foundations you control. You need clean, traceable data with clear ownership. You need tight integration with MES, ERP, and PLM. You need an MLOps backbone that versions models, monitors drift, and supports retraining and rollback.

Focus turns pilots into scale. Start with one inspection flow and one critical failure mode. Link model outputs to machine settings and standard work. Publish baselines and monthly targets for OEE, defects per million, mean time between failures, unplanned downtime, lead time, and service level. Scale only after three consecutive months above target.

The path is repeatable when people, data, and process move together. Invest in skills and explainability where safety and compliance apply. Reuse one data and MLOps stack across lines and sites to cut unit cost and time to value. What line gives you the fastest measurable ROI next quarter. Which data gaps still block defect detection or failure prediction. How will you sustain these models across shifts and plants without losing trust.

Mapping Artificial Intelligence Research in Automotive Manufacturing: A Bibliometric Study

Sara OULED LAGHZAL[1]*, EL OUADI Abdelmajid[2]
Mathematical Laboratory and Applications-Faculties of Sciences, Ibn Tofail University, Kenitra, Morocco[1]
Laboratory Advanced Systems Engineering, National School of Applied Sciences, Ibn Tofail University, Kenitra, Morocco[2]

***Abstract*—Artificial Intelligence (AI) is transforming the automotive industry by enabling smart manufacturing, optimizing supply chains, enhancing vehicle safety, and accelerating the shift toward autonomous mobility. This bibliometric study provides a systematic overview of the intellectual landscape of AI adoption in the automotive sector. Using data from Scopus, Web of Science, and OpenAlex, we analyze publication trends, influential authors, key institutions, thematic clusters, and international collaboration networks. Findings show a sharp rise in research output during the last decade, with major themes including predictive maintenance, computer vision for quality control, autonomous driving systems, supply chain optimization, and sustainable manufacturing. Emerging areas such as explainable AI, digital twins, and AI-enabled Industry 4.0 architectures are gaining increasing visibility. Collaboration analysis highlights strong contributions from Asia, Europe, and North America, with growing interdisciplinary networks bridging engineering, computer science, and management. This work not only maps the state of research but also identifies gaps and future directions for advancing AI adoption in the automotive industry. The study offers practical insights for researchers, industry practitioners, and policymakers aiming to harness AI for operational efficiency, competitiveness, and sustainable growth.**

***Keywords*—Artificial Intelligence; automotive industry; Industry 4.0; autonomous vehicles; supply chain optimization; computer vision; predictive maintenance; digital twins; smart manufacturing; bibliometric analysis**

I. Introduction

Over the last decade, Artificial Intelligence (AI) has become one of the most influential technologies driving the digital transformation of industries. In the automotive sector, AI is not only a technological enabler but also a strategic driver of competitiveness, innovation, and sustainability. The integration of AI spans the entire automotive value chain: from design and product development to manufacturing, supply chain management, logistics, customer experience, and the emergence of autonomous vehicles. Its applications include predictive maintenance, computer vision for quality inspection, optimization of energy consumption, driver assistance systems, natural language interfaces, and intelligent production scheduling.

The global automotive industry is currently facing unprecedented challenges: increasing demand for sustainable and low-emission solutions, disruptions in global supply chains, and rapid changes in consumer expectations toward connected and autonomous vehicles. AI technologies are positioned at the core of solutions to these challenges, enabling more resilient operations, reducing costs and time-to-market, and facilitating compliance with environmental regulations. Beyond operational gains, AI adoption also opens new business models such as Mobility-as-a-Service (MaaS), data-driven insurance, and personalized in-car services, further reinforcing the sector's transformation.

From a scientific standpoint, AI in the automotive industry has attracted growing research attention. The literature reflects multiple disciplinary perspectives, including computer science, industrial engineering, management science, and human–machine interaction. Key research streams have emerged: (i) autonomous driving and computer vision; (ii) predictive analytics and machine learning for supply chains and manufacturing; (iii) digital twins and Industry 4.0 architectures; and (iv) managerial and organizational perspectives on AI adoption. Recent reviews have synthesized knowledge on specific aspects such as autonomous driving or supply chain optimization. However, there is still a lack of integrative studies that map the overall research landscape and reveal how knowledge in this domain has evolved over time.

Bibliometric analysis provides a rigorous method to address this gap. By applying quantitative techniques to a large corpus of scientific publications, it allows the identification of influential authors, institutions, and countries, as well as the detection of thematic clusters and emerging trends. Compared to systematic literature reviews, bibliometric approaches capture the structural and dynamic aspects of a research field, uncovering citation networks, collaboration patterns, and intellectual foundations. In the context of AI adoption in the automotive industry, such an approach is particularly relevant to:

- Evaluate the growth trajectory and maturity of research in this field,
- Identify leading contributors and collaborative networks,
- Highlight thematic hotspots and their evolution,
- Detect gaps and opportunities for future inquiry.

The aim of this study is to provide a comprehensive bibliometric review of AI adoption in the automotive industry, drawing on data from leading scientific databases such as Scopus and Web of Science. Through science mapping techniques, the study analyzes publication output, co-citation networks, keyword co-occurrence, and country-level collaboration. The results offer a systematic overview of the intellectual structure of the field, while also highlighting emerging domains such

*Corresponding author.

as explainable AI (XAI), edge computing for autonomous systems, sustainable manufacturing, and AI governance.

The remainder of this article is organized as follows. Section II details the bibliometric methodology, including database selection, search strategy, and analytical tools. Section III presents the bibliometric results, focusing on trends, contributors, and thematic evolution. Section IV discusses the implications of these findings for research and practice, identifying challenges and future opportunities. Section V concludes with recommendations for scholars, industry practitioners, and policymakers.

II. Methodology

The bibliometric corpus was compiled from Scopus, Web of Science (WoS), and OpenAlex, which together provide extensive coverage of peer-reviewed literature in engineering, computer science, management, and conference proceedings relevant to Industry 4.0 and the automotive sector.

A. Search Strategy

A unified Boolean query was applied across the three databases to capture research on AI adoption in automotive manufacturing, performance outcomes, and organizational factors: (“artificial intelligence” OR “AI” OR “machine learning” OR “deep learning”) AND (“automotive industry” OR “car manufacturing” OR “automobile sector”) AND (“industrial performance” OR “productivity” OR “quality” OR “cost reduction” OR “lead time”) AND (“industry 4.0” OR “digital transformation”) AND (“adoption” OR “implementation” OR “management” OR “organizational factors” OR “technology acceptance”). This strategy returned 110,200 initial records.

B. Timeframe and Inclusion Criteria

The study covered the period 2010–2024. Eligible documents included journal articles, conference proceedings, and book chapters written in English. Editorials, theses, non-academic items, and incomplete records were excluded from the dataset.

C. PRISMA Screening

A PRISMA-based workflow was followed to ensure transparency:

- Title and abstract screening reduced the dataset to 73,457 records.
- Full eligibility checks and duplicate removal resulted in 15,380 documents.
- The final analytical corpus comprised 13,080 records used for mapping and analysis
- The PRISMA diagram documents each stage, including identification, screening, eligibility, and inclusion Fig. 1.

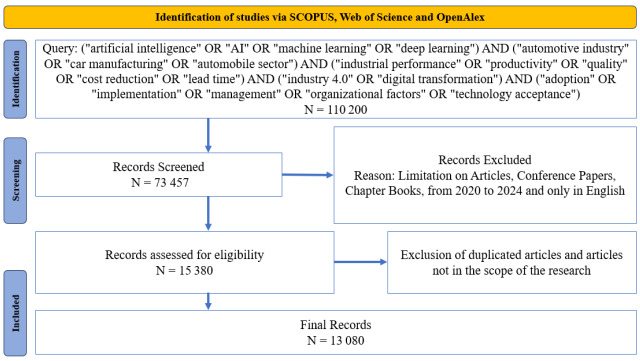

Fig. 1. Prisma diagram.

D. Data Normalization and Consolidation

Author names, affiliations, sources, and keywords were standardized to reduce identity fragmentation. Duplicates were resolved through DOI matching, title similarity, and metadata concordance. After deep cleaning, the consolidated dataset consisted of 4,937 sources, 13,042 documents, and 38,035 authors. The difference between the PRISMA “final records” (13,080) and the harmonized “documents” (13,042) reflects the removal of residual duplicates and malformed entries. Both figures are reported for auditability.

1) Bibliometric indicators: We calculated performance indicators Fig. 2 including annual growth rate, productivity by source and author, document age, co-authorship patterns, international collaboration, average citations, and lexical richness.

Fig. 2. Bibliometric indicators.

These indicators highlight a research field that is expanding rapidly and worth deeper exploration. An annual growth rate of 47.87%, with 13,042 documents from 4,937 sources and 38,035 authors, signals a dynamic and highly visible domain.

The corpus is recent, with an average document age of 2.88 years, ensuring that the analysis reflects the current state of the art rather than outdated knowledge.

The impact is tangible. Each paper receives on average 12.37 citations, supported by a total of 229,261 references, providing a robust foundation for further research.

Collaboration is significant. An international co-authorship rate of 17.87% and an average of 3.22 co-authors per paper show an active, global research network that readers may engage with.

Thematic diversity is remarkable. With 4,038 unique author keywords, the field offers numerous avenues for specialization and the discovery of underexplored niches.

2) Analytical tools and techniques: We employed Bibliometrix (R) for performance analysis, author productivity, collaboration structures, and country-level participation. VOSviewer was used to construct and visualize co-authorship, co-citation, and keyword co-occurrence networks, as well as to generate thematic clusters and overlay visualizations. Networks were normalized using the association strength method, and clustering was conducted via the Louvain modularity algorithm.

3) Validity considerations: Internal validity was ensured by applying identical search strings, filters, and inclusion criteria across all databases. Construct validity was supported by aligning search terms with the core constructs of the field: AI methods, automotive manufacturing, performance metrics, and adoption factors such as governance, integration, skills, and explainability.

4) Limitations: Differences in database coverage may bias representation across disciplines. Restricting the corpus to English may underrepresent regional contributions. Citation-based measures underestimate the impact of recent publications. Nevertheless, the multi-database approach, harmonized query, and PRISMA workflow provide a robust and replicable foundation for mapping research on AI adoption in the automotive sector.

To ensure reproducibility, the full query, timeframe, inclusion and exclusion criteria, and PRISMA stages are documented. The software tools, versions, and clustering parameters are also reported, enabling replication of the analysis on the same databases.

III. Results

This section presents the bibliometric results obtained from the analysis of publications on artificial intelligence in automotive manufacturing. The findings highlight the dynamics of scientific production, the most active countries and institutions, influential authors and documents, as well as the thematic structure of the field.

The results are organized into several subsections to provide a comprehensive view of the research landscape. First, we examine the temporal evolution of publications and the geographical distribution of scientific production. Next, we analyze citation patterns to identify the most influential countries and documents. We then explore the most frequent keywords and their evolution over time to trace the conceptual development of the field. Finally, we present advanced mapping techniques, including co-occurrence, thematic, factorial, and co-citation networks, to reveal the intellectual structure and thematic clusters shaping this research area.

Together, these results provide an in-depth overview of how artificial intelligence in automotive manufacturing has evolved, where the main research centers are located, which works have shaped the field, and what directions are emerging for future studies.

A. General Characteristics of the Dataset

The bibliometric dataset spans the period 2010–2024, covering 13,042 documents drawn from 4,937 sources and authored by 38,035 contributors. The annual growth rate of 47.87% highlights the exponential increase in research output. The collaborative nature of the field is evidenced by an average of 3.22 co-authors per document and an international co-authorship rate of 17.87%. The dataset also includes 4,038 unique keywords and over 229,000 references, indicating strong thematic diversity and a dense knowledge base. The average age of documents is 2.88 years, reflecting the recency of publications, while the average citation rate per paper is 12.37, confirming the relevance and visibility of the field.

B. Annual Scientific Production

Fig. 3 shows the evolution of scientific output from 2010 to 2024. Until 2016, the number of publications remained marginal, with fewer than 100 articles annually. From 2017 onwards, research activity began to accelerate, culminating in a steep upward trajectory after 2020. By 2024, the annual output exceeded 4,000 articles, confirming the transition of artificial intelligence in the automotive sector into a mainstream research domain. This growth aligns with broader technological and industrial trends, particularly the rise of Industry 4.0 and digital transformation initiatives.

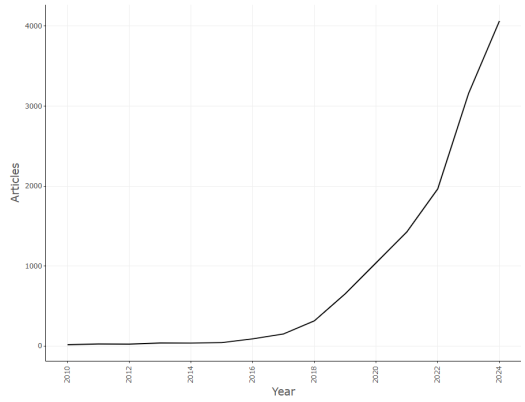

Fig. 3. Annual scientific production.

C. Average Citations Per Year

The citation pattern, Fig. 4 illustrates variability across the years. Early publications (2010–2012) achieved relatively high average citation counts, likely due to their pioneering status in the field. Subsequent years show fluctuations, with notable peaks around 2016 and 2019, indicating moments when influential works were published. In the most recent years, citation averages declined, a trend explained by citation latency, since recent works have not yet accumulated long-term academic recognition.

D. Thematic and Authorial Distribution (Three-Field Plot)

The three-field plot, Fig. 5 reveals the interplay between disciplines, prolific authors, and institutional affiliations. Research is highly interdisciplinary, with connections across computer science, engineering, management, economics, and philosophy. Among the most active scholars are P. S. Aithal, Luciano Floridi, Bin Liu, Yang Liu, and Paul W. Dyce, who link multiple fields to prominent institutions such as the University of Oxford, China Agricultural University, and

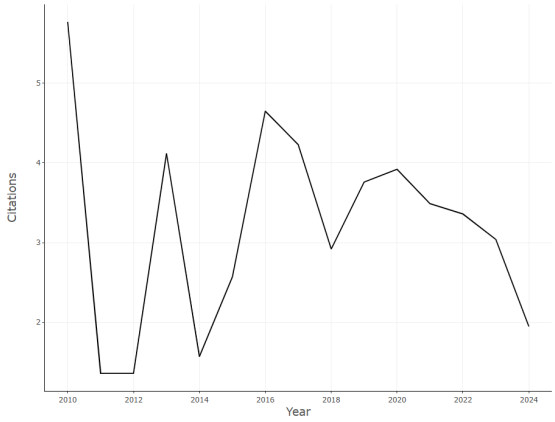

Fig. 4. Average citations per year.

various independent researchers. This cross-field connectivity demonstrates the hybrid nature of the topic, combining technological, managerial, and societal perspectives.

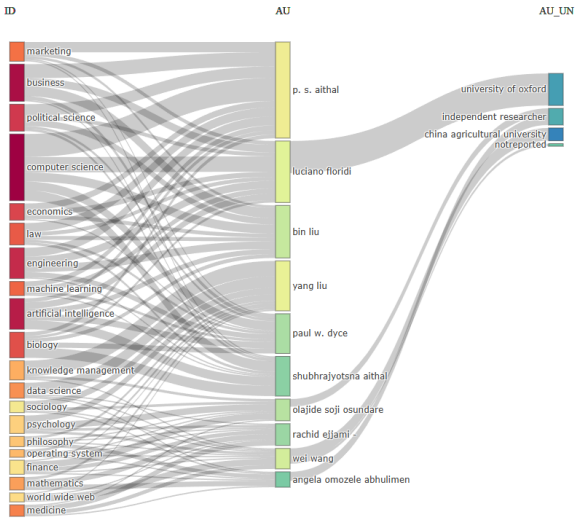

Fig. 5. Three-field plot.

E. Most Relevant Sources

The analysis of publication venues, Fig. 6 identifies Sustainability as the most productive source with 195 documents, followed by a cluster of multidisciplinary and applied journals such as the Journal of Physics Conference Series (151), IEEE Access (125), and Applied Sciences (119). The variety of journals suggests that the topic is not confined to a single disciplinary outlet but disseminated across engineering, applied sciences, and multidisciplinary platforms.

F. Sources' Local Impact

While productivity indicates output volume, impact reveals visibility. Fig. 7 shows that IEEE Access and Sustainability lead in terms of local h-index, with 41 and 36 respectively. Other journals such as Applied Sciences, Scientific Reports, and PLOS ONE also demonstrate strong citation performance.

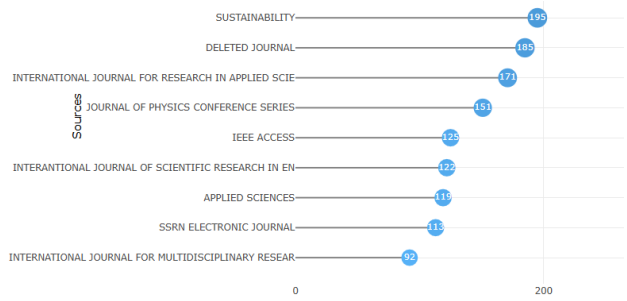

Fig. 6. Most relevant sources.

This dual perspective confirms that both quantity and quality of publications are concentrated in high-impact outlets, reinforcing the legitimacy of the research area.

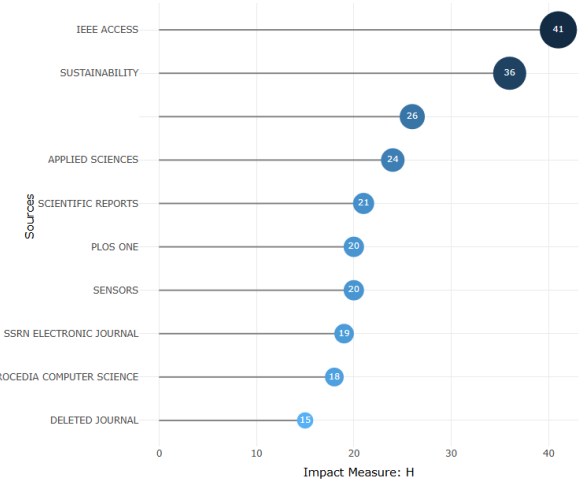

Fig. 7. Sources' local impact.

G. Sources' Production Over Time

The temporal evolution of journals, Fig. 8 shows how different outlets entered the field at varying moments. For instance, Journal of Physics Conference Series began contributing earlier, while Sustainability and IEEE Access only surged after 2018. This indicates that the diffusion of AI in the automotive context has progressively expanded from conference proceedings to well-established, peer-reviewed journals.

H. Most Relevant Authors

Fig. 9 highlights P. S. Aithal as the most prolific author with 21 publications, followed by Yang Liu (12) and Luciano Floridi (10). Several other scholars, including Wei Wang, Bin Liu, and Olajide Soji Osundare, demonstrate consistent contributions. This concentration of productivity suggests a small but influential group of researchers shaping the field.

I. Authors' Production Over Time

The temporal analysis of authorship, Fig. 10 reveals sustained productivity by key figures. P. S. Aithal shows continuous activity, particularly after 2020, while Yang Liu and Luciano Floridi display regular engagement. Some contributors,

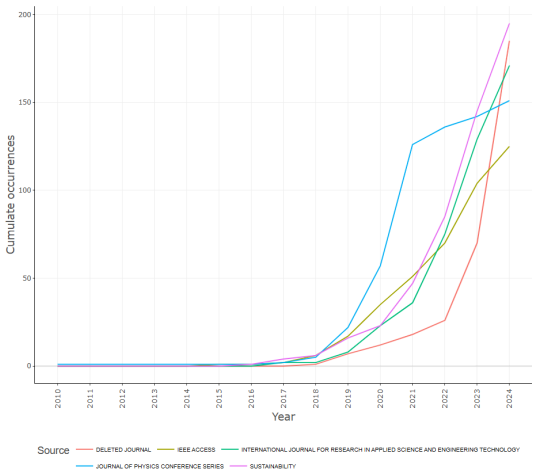

Fig. 8. Sources' production over time.

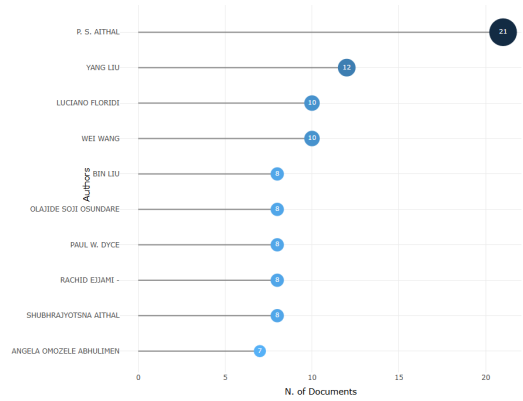

Fig. 9. Most relevant authors.

such as Paul W. Dyce and Angela Omozele Abhulimen, appear more recently, indicating a growing influx of new voices in the domain.

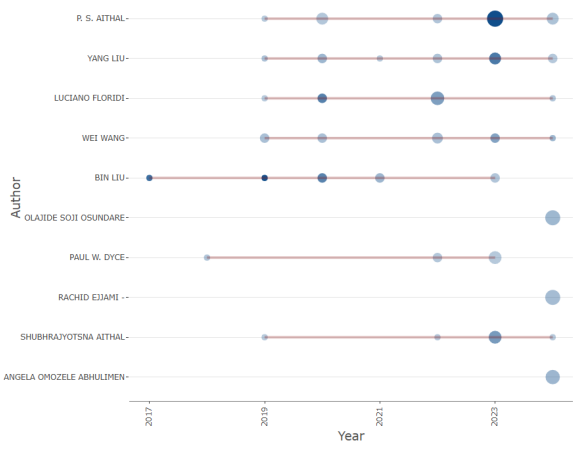

Fig. 10. Authors' production over time.

J. Most Relevant Affiliations

Institutional contributions, Fig. 11 highlight strong representation from leading universities. The University of California (266 articles), University of Oxford (122), and University of Michigan (120) are among the most active, alongside Asian institutions such as China Agricultural University (89) and Zhejiang University (86). Interestingly, a significant proportion of publications (312) are tagged as "not reported," pointing to inconsistencies in metadata reporting. Overall, the results underline the global character of the research field, with balanced contributions from North America, Europe, and Asia.

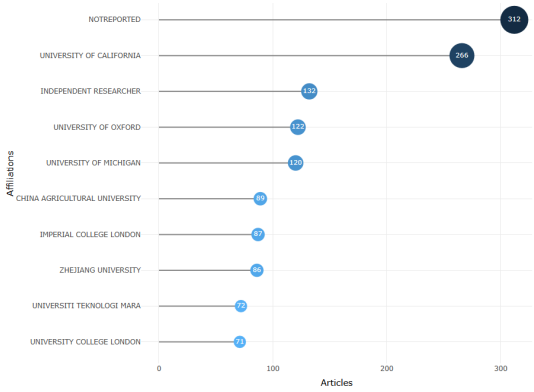

Fig. 11. Most relevant affiliations.

K. Affiliations' Production Over Time

Fig. 12 shows the evolution of institutional contributions from 2010 to 2024. The University of California demonstrates the steepest growth, surpassing 250 articles by 2024, followed closely by the "Not Reported" group and Chinese institutions. Independent researchers also contribute increasingly after 2021, while the University of Michigan and University of Oxford show steady but slower growth. This indicates a global diffusion of research efforts, with both established universities and independent scholars shaping the field.

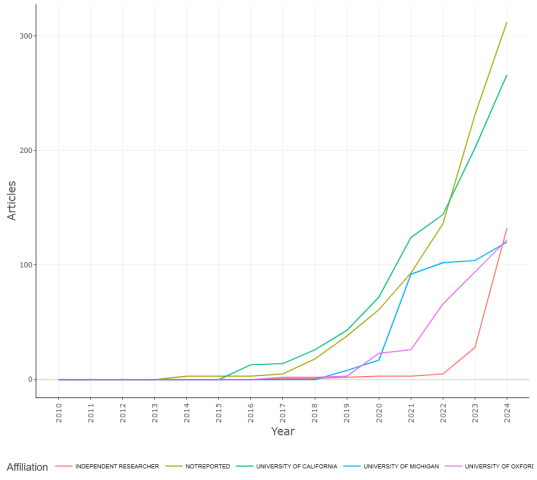

Fig. 12. Affiliations' Production Over Time.

L. Corresponding Authors' Countries

Fig. 13 highlights the distribution of publications by country. China leads in document volume, followed by the USA, India, and the United Kingdom. The dominance of these countries demonstrates the concentration of research productivity in Asia, North America, and Europe. The figure also distinguishes between single-country publications (SCP) and multi-country collaborations (MCP). Although domestic collaboration remains strong, international partnerships are evident, especially in the USA and UK, which maintain relatively high MCP shares.

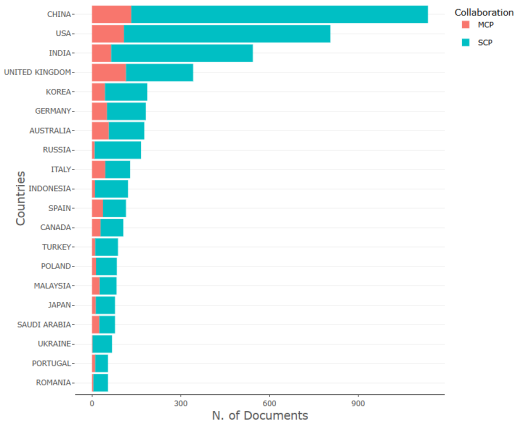

Fig. 13. Corresponding authors' countries.

M. Countries' Scientific Production

The global map in Fig. 14 illustrates the geographical spread of AI and automotive manufacturing research. China, the USA, India, and the UK emerge as global hubs, with darker shading indicating higher productivity. Other active contributors include Germany, Korea, Australia, and Russia. Regions in Africa and South America show limited activity, reflecting persistent disparities in global knowledge production.

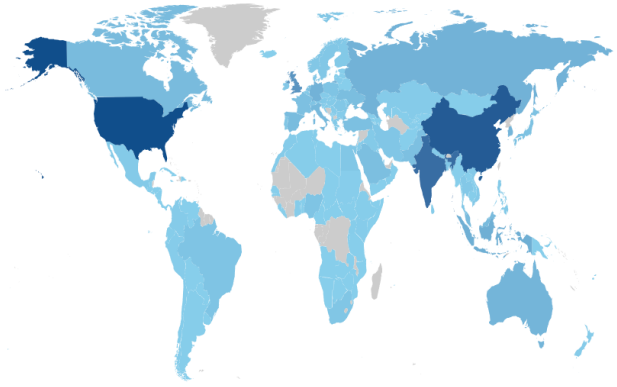

Fig. 14. Countries' scientific production.

N. Countries' Production over Time

Fig. 15 demonstrates how national contributions evolved. China experienced the fastest growth after 2018, surpassing the United States and India by 2024. India shows steady acceleration, while the UK maintains consistent output, though at a slower pace compared to China and India. The United States, although prolific, faces increasing competition. This trend underscores the rapid rise of Asian countries as central players in AI research applied to automotive manufacturing.

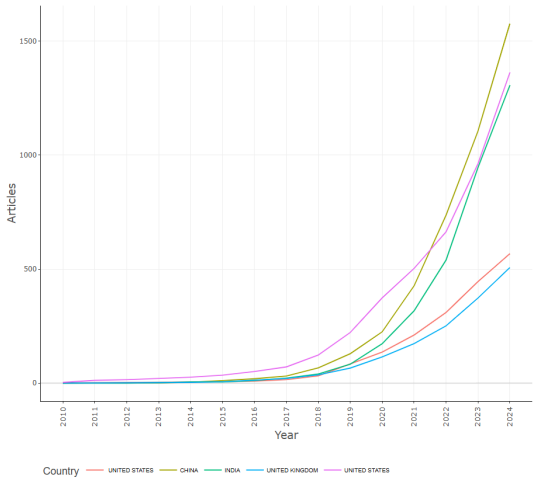

Fig. 15. Countries' production over time.

O. Most Cited Countries

Fig. 16 ranks countries by total citations. The United States leads with nearly 15,000 citations, followed by the United Kingdom (11,092), China (10,839), and India (9,333). Despite China's dominance in document count, the USA and UK hold higher citation impact, indicating stronger international recognition and influence. Other countries with notable citation counts include Australia, Germany, and Korea. This pattern highlights a divide between publication volume and citation quality.

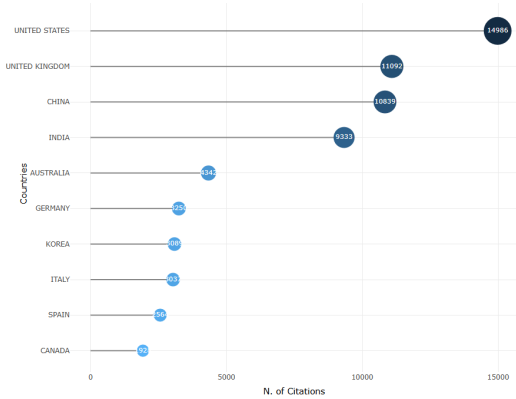

Fig. 16. Most cited countries.

P. Most Global Cited Documents

Fig. 17 identifies the most influential publications. Dwivedi (2023) is the most cited with 2,557 citations, followed by Burrell (2016) with 1,959 and Goodman (2017) with 1,870. These works address themes such as digital transformation,

AI ethics, and societal implications, confirming that highly cited research often bridges technical development and social impact. The presence of recent documents, such as Shah (2024), among the most cited indicates that new contributions can achieve rapid visibility in this fast-evolving field.

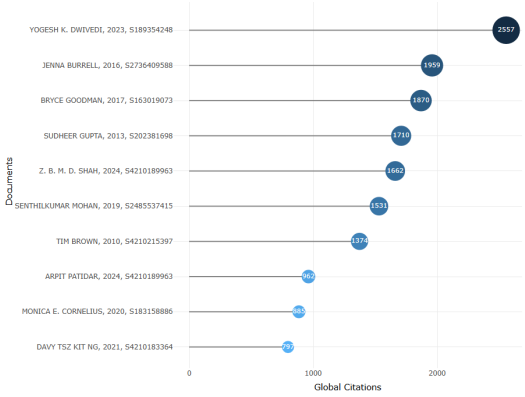

Fig. 17. Most global cited documents.

Q. Most Frequent Words

Fig. 18 presents the most frequent keywords used across the dataset. "Computer science" dominates with 10,512 occurrences, followed by "business" (5,700), "artificial intelligence" (5,683), and "engineering" (4,248). The high frequency of terms related to applied sciences, economics, and political science shows that AI in automotive manufacturing is not confined to pedagogy but extends to socio-technical and managerial domains.

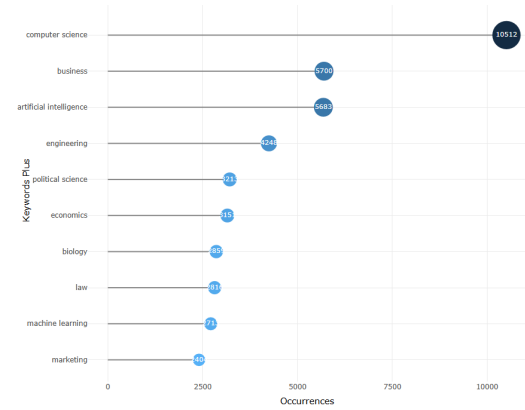

Fig. 18. Most frequent words.

R. Word Cloud

The word cloud in Fig. 19 visualizes keyword distribution. The prominence of "computer science" and "artificial intelligence" confirms their centrality, while the inclusion of "business," "law," "economics," and "psychology" demonstrates the cross-disciplinary scope of the field. Emerging topics such as "machine learning" and "data science" appear increasingly, reflecting the technical backbone of AI-driven automotive manufacturing.

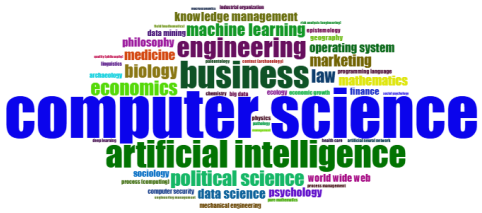

Fig. 19. Word cloud.

S. Words' Frequency over Time

Fig. 20 illustrates the cumulative growth of keyword usage between 2010 and 2024. "Computer science" shows the steepest rise, followed by "artificial intelligence" and "business." The growth of "machine learning" and "law" after 2018 signals the growing intersection of technological and regulatory concerns in automotive manufacturing. This temporal evolution demonstrates the progressive diversification of research themes.

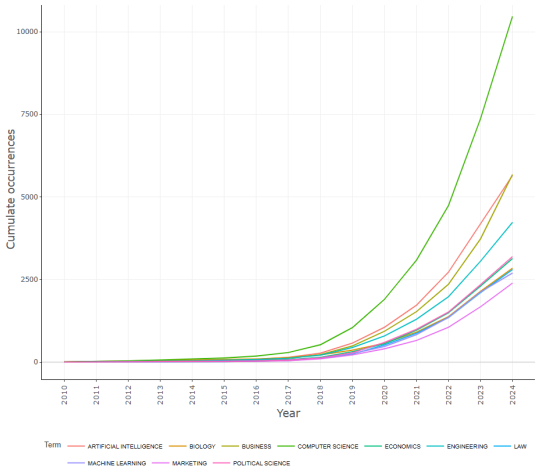

Fig. 20. Words' frequency over time.

T. Clustering by Coupling

Fig. 21 presents the conceptual structure of the field based on bibliographic coupling. Two main clusters emerge. The first group includes "business intelligence," "business analytics," and "value (mathematics)," with a strong technical and managerial orientation. The second cluster encompasses "emerging technologies," "industry 4.0," and the "digital economy," which exhibit both high impact and centrality. The latter reflects the current research frontier, linking AI in automotive manufacturing to broader technological and economic transformations.

U. Co-occurrence Network

Fig. 22 highlights the structure of the keyword co-occurrence network within the dataset. The term computer science occupies a dominant position, confirming its role as the backbone discipline of this research field. It maintains strong connections with applied domains such as engineering, physical sciences, and operating systems, reflecting its transversal

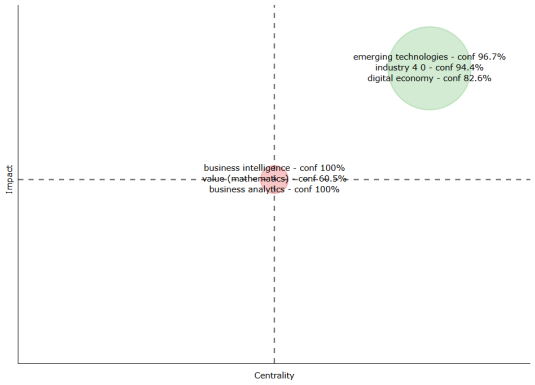

Fig. 21. Clustering by coupling.

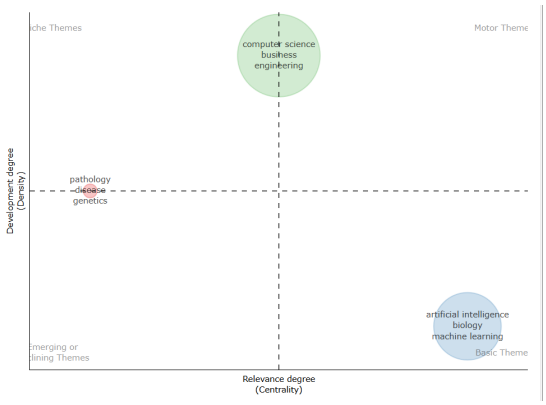

Fig. 23. Thematic map.

nature. In parallel, artificial intelligence forms a distinct cluster, closely linked to specialized subfields such as machine learning, deep learning, and data mining. These associations illustrate the increasing specialization of computational sciences around AI-related methods and techniques. A third core cluster emerges around business and engineering, directly connected to social sciences, notably political science and economics. Overall, the dense interconnections across clusters reveal a growing interdisciplinarity that bridges technical, applied, and social dimensions of AI in automotive manufacturing.

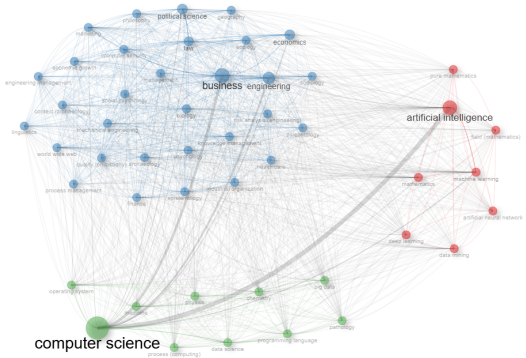

Fig. 22. Co-occurrence network.

V. Thematic Map

Fig. 23 presents the thematic map, which organizes research areas according to their centrality and density. Three main groups are observed. First, computer science, business, and engineering appear as motor themes, characterized by both high centrality and density, confirming their structuring role in the field. Second, artificial intelligence, machine learning, and biology are positioned as basic themes. While their high centrality underscores their relevance, their relatively lower density suggests that their full development is still underway. Finally, the themes pathology, disease, and genetics are located in a peripheral position. Their weak connections to other domains reflect their marginal role but also point to the diversification of AI applications towards health and life sciences.

W. Factorial Analysis

Fig. 24 illustrates the factorial analysis of keywords, providing insight into the conceptual organization of the field. At the core of the map, disciplines such as computer science, engineering, management, political science, and economics form a central cluster, confirming their dominance in the literature. By contrast, artificial intelligence and machine learning appear slightly offset, occupying a bridging position between the central core and peripheral areas, which highlights both their importance and their role as connectors. Some terms, such as deep learning, are more isolated, indicating a highly specialized subfield with limited integration into the broader research ecosystem. Similarly, pure mathematics and field mathematics are located on the periphery, reflecting their limited connections with interdisciplinary developments in AI and automotive manufacturing .

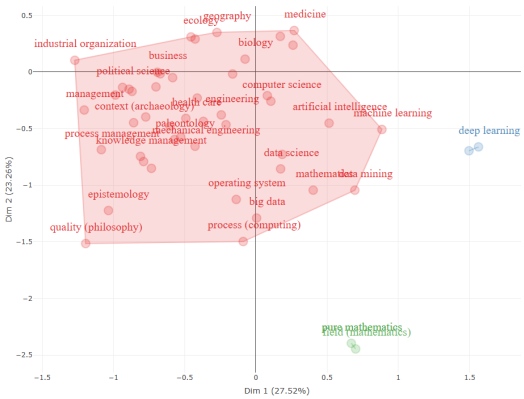

Fig. 24. Factorial analysis.

X. Co-citation Network

Fig. 25 presents the co-citation network, which reveals the intellectual foundations of the field. Several distinct communities can be identified, each represented by a different cluster of nodes. These communities correspond to groups of authors or works that are frequently cited together, reflecting thematic or methodological affinities. Larger nodes represent highly influential publications or scholars that act as intellectual anchors, consolidating and connecting different strands of research. The

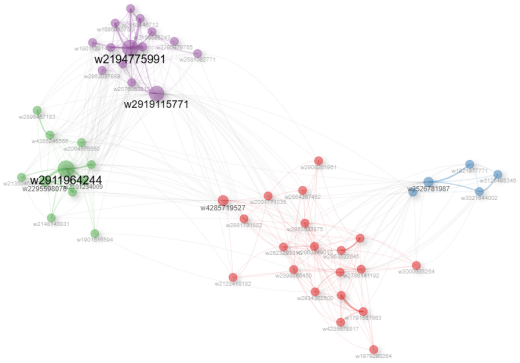

Fig. 25. Co-citation network.

presence of multiple clusters highlights the heterogeneity of the knowledge base and demonstrates the interdisciplinary richness of the field. This structure confirms that the research area does not rely on a single theoretical foundation but instead draws upon multiple traditions and complementary reference frameworks.

IV. Discussion

The bibliometric analysis highlights the rapid and multidimensional evolution of research on artificial intelligence (AI) in the automotive industry. The exponential growth of publications since 2017 confirms the increasing integration of AI into automotive innovation, particularly with the acceleration of Industry 4.0 and the digitalization of manufacturing systems after 2020. The relative youth of the publications, combined with a steady rise in citation impact, suggests that this domain is both dynamic and still consolidating its theoretical and practical foundations.

From a geographical perspective, China, the United States, India, and Germany emerge as leading contributors. China dominates in terms of volume, reflecting its strong industrial investment in smart manufacturing and electric mobility, while the United States and European countries maintain higher citation impact, highlighting their intellectual influence and longstanding leadership in AI and automotive engineering. India shows steady growth, often with an applied focus, particularly in data-driven logistics and supply chain optimization. These dynamics illustrate how the global race for automotive AI innovation reflects broader industrial and geopolitical priorities.

Institutional and authorial contributions confirm the hybrid and interdisciplinary character of the field. Leading universities and research centers in computer science and engineering collaborate with business schools and management departments, reflecting the dual emphasis on technological development and managerial transformation. Prolific authors, such as those working on AI ethics, smart mobility, and industrial automation, demonstrate the convergence of technical expertise with organizational and societal concerns. This interdisciplinary overlap strengthens the field by connecting machine learning, engineering design, supply chain management, and regulatory studies.

Thematic and conceptual analyses reveal how research clusters align with key priorities in the automotive industry. Computer science and engineering form the technical backbone of the literature, supporting applied domains such as business, operations management, and supply chain. The thematic map positions AI, machine learning, and data mining as basic themes, while Industry 4.0, autonomous driving, and digital economy emerge as motor themes with strong centrality and density. At the periphery, domains such as genetics or biological applications appear less integrated, suggesting occasional interdisciplinary spillovers but limited relevance to automotive applications.

The co-occurrence and co-citation networks underscore the conceptual diversity of the field. Dense keyword interconnections reflect the fusion of technical disciplines (deep learning, computer vision, robotics) with applied domains (operations, management, business models). This demonstrates how AI is not only a technological enabler but also a driver of organizational and managerial transformation in the automotive sector. The presence of multiple co-citation clusters highlights that the literature draws on heterogeneous foundations, ranging from computer science and control engineering to industrial management and economics.

Taken together, these findings underline three critical points. First, research on AI in the automotive industry has transitioned from a marginal domain to a mainstream scientific and industrial priority. Second, the field exhibits strong interdisciplinarity, integrating computer science, engineering, operations, and management perspectives within the broader framework of Industry 4.0. Third, while productivity is increasingly global, intellectual influence remains concentrated in a few countries and institutions, reflecting persisting asymmetries in knowledge production.

Future research should aim to strengthen cross-border collaborations, deepen interdisciplinary approaches linking AI with supply chain resilience, and address emerging challenges such as cybersecurity, ethics in autonomous mobility, and regulatory frameworks for AI-enabled manufacturing. In this sense, bibliometric insights provide not only an overview of past achievements but also a roadmap for aligning AI and automotive research with the strategic priorities of digital transformation and sustainable industrial development. The artificial intelligence market has experienced significant growth across multiple sectors, with transportation and automotive applications projected to hold the largest market share, followed by healthcare and media services [1]. AI encompasses a system's ability to accurately read external data, learn from it, and apply those learnings to achieve specific goals and tasks through flexible adaptation [2][3]. The technology has become a powerful tool that transforms how organizations operate, delivering significant benefits such as increased efficiency, accuracy, and productivity [4].

The integration of AI with traditional industrial processes represents a cornerstone of Industry 4.0 and emerging Industry 5.0 concepts. Advanced AI algorithms, including machine learning, deep learning, and sophisticated intelligence methods like artificial neural networks, are now the backbone of modern manufacturing and industrial operations [5]. AI-based technologies such as machine learning, natural language processing, and computer vision can process large amounts of data, identify patterns, and make predictions, augmenting

human intelligence and improving efficiency across various industries [6].

Over the next decade, AI effects are expected to be amplified as nearly every sector of the economy, including production, retail, transportation, banking, and healthcare, will integrate machine learning into their core operations and business models [4]. However, the primary challenges facing widespread AI implementation remain centered on management, execution, and business innovation aspects [4].

A. AI/ML Application in Automotive and Manufacturing

The automotive industry has become a leading adopter of AI technologies, with applications spanning autonomous vehicles, manufacturing processes, and supply chain operations. Autonomous vehicles represent a major frontier, using machine learning, deep learning, reinforcement learning, statistical techniques, and IoT to enable intelligent automation and digital transformation [7]. These technologies are particularly important for supply chain management and manufacturing industry applications within the automotive sector.

In manufacturing operations, AI enables automation of production processes through AI-powered robots and machines that handle repetitive tasks with precision and efficiency, leading to increased production speed and accuracy [8]. Machine learning algorithms analyze data from sensors, cameras, and other sources to detect defects or anomalies in production processes, with machine vision systems equipped with AI identifying and rejecting faulty products to ensure consistent quality [8][9]. Companies like Tesla extensively apply artificial intelligence technologies, including deep learning and machine learning, throughout their manufacturing processes to optimize production efficiency, quality control, and supply chain management [10].

Supply chain applications have shown particular promise, with machine learning and deep learning playing important roles in smart transformation of traditional supply chains [11]. AI methods improve demand forecasting accuracy, reduce inventory costs, and optimize logistics operations [12]. Advanced forecasting models combining multiple AI techniques have demonstrated superior performance compared to traditional econometric models and individual deep learning approaches [11].

Process optimization represents another key application area, where AI algorithms analyze real-time data including sensor readings and production metrics to identify bottlenecks and inefficiencies [12]. AI algorithms optimize resource allocation for raw materials, energy, and labor by analyzing production data to identify inefficiencies and streamline operations, minimize waste, and reduce costs [8]. However, implementing machine learning in automotive systems faces challenges including algorithm selection for constrained environments, real-time processing requirements, and integration with existing automotive software architectures [13].

The integration of AI in manufacturing represents a substantial transformation, with advanced algorithms for deep learning and machine learning improving and expediting procedures through analysis of extensive data to identify patterns, make informed decisions, and adapt to evolving production circumstances [14]. These applications have achieved greater operational efficiency, cost reduction, and improved product quality, ultimately leading to enhanced competitiveness in the rapidly evolving industrial landscape [12].

B. Supply Chain Management and Digital Transformation

The implementation of Industry 4.0 technologies is fundamentally transforming traditional supply chains into digital supply chains through the integration of physical supply chain processes with digital data to improve supply chain efficiency [5]. Manufacturing enterprises are adopting emerging Industry 4.0 technologies to create industrial intelligence-driven smart factories, stimulating the advent of intelligent supply chains that can sync and support the rapid evolution of advanced industrial practices via supply chain digital transformation [15]. This integration represents a significant paradigm shift, offering transformative opportunities for enhanced efficiency, predictive accuracy, and strategic decision-making [16].

AI-driven supply chain management optimization encompasses a spectrum of technologies including predictive analytics, machine learning, and autonomous decision-making systems aimed at optimizing various facets of the supply chain, from demand forecasting and inventory management to production planning and logistics optimization [17]. Through advanced algorithms and data analytics capabilities, AI and ML technologies enable supply chain practitioners to streamline operations, enhance decision-making, and drive efficiency gains across the entire supply chain network [18]. Organizations can improve forecasting accuracy, optimize inventory levels, minimize transportation costs, and enhance overall supply chain performance while facilitating the identification and mitigation of supply chain risks [18].

The convergence of AI and supply chain management emerges as a transformative force in driving efficiency, agility, and competitiveness [17]. AI-powered systems offer real-time data insights, predictive analytics, and automated decision-making capabilities that enhance demand forecasting, optimize inventory levels, and improve supplier collaboration through AI-driven models [19]. The economic benefits are substantial, with AI-driven solutions leading to significant cost savings through improved inventory management, reduced waste, and enhanced resource allocation [20].

The deep integration of deep learning and big data technology provides new technical support for the digital transformation of factories, ensuring that factories can make more intelligent and sustainable decisions and deployments during digital transformation [21]. AI adoption in manufacturing industries has significantly impacted productivity, efficiency, and overall operational performance, with AI-driven supply chain optimization improving inventory management, reducing lead times, and enabling more effective demand forecasting [22].

However, realizing the full potential of AI and ML in supply chain optimization requires overcoming various challenges, including data integration, algorithm development, and organizational adoption [18]. Companies must invest in data infrastructure, talent development, and change management initiatives to effectively leverage AI and ML technologies in their supply chain operations [18]. The effectiveness of AI

implementation is often mediated by organizational readiness, regulatory environments, and the maturity of digital infrastructure [23].

C. Organizational and Managerial Factors

The adoption of AI in business represents a complex process shaped by multiple organizational factors, with leadership, culture, resource availability, perceived benefits, regulatory considerations, data security, technology evaluation, and workforce readiness all playing critical roles in successful implementation [24]. Strategic leadership in the current era requires a deep understanding of AI technology and its potential challenges, with effective leaders needing to adopt AI technologies to enhance decision-making while ensuring these tools align with overarching business objectives [25].

AI implementation requires both human and technology capital, with organizations needing to adopt comprehensive training and development programs to prepare employees for an AI-enabled workplace [24]. The effectiveness of AI integration is often mediated by organizational readiness, regulatory environments, and the maturity of digital infrastructure, with firms demonstrating integrated data ecosystems, leadership support, and workforce upskilling strategies showing greater success in embedding AI into their planning processes [23].

Common barriers to AI adoption include resistance to adoption, lack of interpretability, and fragmented data systems [23]. To reduce AI risks and ensure successful implementation, organizations must follow legal and data security measures while investing in comprehensive organizational transformation initiatives [24]. Data-driven decision-making and strategic leadership significantly influence corporate performance improvement through AI-powered solutions, enabling organizations to quickly adapt to market changes and customer requirements [25].

The transformation enabled by AI technologies allows organizations to automate routine processes, streamline supply chains, and deliver real-time information while enhancing resource allocation, minimizing waste, and promoting innovation [25]. However, realizing these benefits requires a holistic understanding of adoption factors to navigate the complex landscape of AI implementation and unlock its transformative potential [24].

D. Performance and Productivity Outcomes

AI adoption in manufacturing industries has significantly impacted productivity, efficiency, and overall operational performance [22]. The technology enables automation of various production processes, reducing the need for manual intervention, with AI-powered robots and machines handling repetitive tasks with precision and efficiency, leading to increased production speed and accuracy [8]. Real-world implementations demonstrate these benefits, with automotive manufacturers utilizing AI algorithms to optimize assembly line processes, achieving significant increases in production efficiency, reduced cycle times, and improved overall productivity through workflow and resource allocation optimization [12].

Quality control represents another area of substantial performance improvement, where AI algorithms analyze data from sensors, cameras, and other sources to detect defects or anomalies in production processes, with machine vision systems equipped with AI identifying and rejecting faulty products to ensure consistent quality throughout the production line [8]. AI-based systems demonstrate the ability to analyze vast amounts of data, identify patterns, and optimize production workflows, with AI adoption leading to increased productivity, minimized downtime, and improved quality control [26][27].

Resource optimization and cost reduction emerge as key performance outcomes, with AI algorithms optimizing the allocation of resources such as raw materials, energy, and labor by analyzing production data to identify inefficiencies and bottlenecks, enabling enterprises to streamline operations, minimize waste, and reduce costs [8]. The integration of AI-driven automation, predictive analytics, and machine learning enhances cost efficiency and profitability by optimizing production processes, reducing downtime, and minimizing waste [28].

Supply chain performance improvements are equally significant, with AI-driven supply chain optimization improving inventory management, reducing lead times, and enabling more effective demand forecasting [22]. AI-powered systems offer real-time data insights, predictive analytics, and automated decision-making capabilities that enhance demand forecasting, optimize inventory levels, and improve supplier collaboration, with businesses achieving greater accuracy in forecasting demand, reduced operational costs, and mitigated risks associated with supply chain disruptions [19].

The cumulative impact of these improvements positions AI enterprises to attract capital and labor inflows and gradually occupy leading positions in their industries, with AI eliminating backward production capacity and promoting transformation and upgrading across sectors [8]. Organizations that adopt cognitive manufacturing practices leveraging AI benefit from enhanced knowledge management, improved product reliability, and increased productivity [26].

E. Implementation Challenges and Barriers

The adoption of AI in manufacturing and automotive industries presents several significant challenges that organizations must navigate to achieve successful implementation. High initial investment costs represent a primary barrier, particularly for small and medium-sized enterprises (SMEs) that may struggle with the financial burden of AI implementation, despite long-term benefits often justifying the initial expenditure [28]. Manufacturing companies, especially smaller ones with limited financial resources, face challenges related to high initial investments, integration complexities, and resistance to change, which can create cultural barriers to AI adoption within the organization [22].

Workforce-related challenges pose another significant obstacle to successful AI implementation. Successfully integrating AI into the manufacturing sector requires a proficient workforce and cultural transformation that embraces data-driven decision-making and fosters collaboration between human expertise and machine capabilities [22]. The need for skilled personnel to manage AI-driven systems presents a substantial challenge, necessitating investments in workforce training and upskilling programs [28]. Organizations must

adopt comprehensive training and development programs to prepare employees for an AI-enabled workplace, as AI implementation requires both human and technology capital [24].

Technical and organizational barriers further complicate AI adoption efforts. Common obstacles include resistance to adoption, lack of interpretability, and fragmented data systems, with the effectiveness of AI integration often mediated by organizational readiness, regulatory environments, and the maturity of digital infrastructure [23]. Data security concerns, ethical considerations, and integration complexities remain significant issues that organizations must address during AI implementation [19].

The complexity of AI adoption requires organizations to navigate multiple interconnected factors simultaneously. Organizational leadership, culture, resource availability, perceived benefits, regulatory considerations, data security, technology evaluation, and workforce readiness all play critical roles in successful implementation [24]. To reduce AI risks and ensure successful deployment, organizations must follow legal and data security measures while investing in comprehensive organizational transformation initiatives [24]. Despite these challenges, firms with integrated data ecosystems, leadership support, and workforce upskilling strategies demonstrate greater success in embedding AI into their planning processes [23].

F. Industrial Implications of Bibliometric Patterns

The bibliometric patterns reveal a clear shift in industrial priorities as automotive firms intensify their investments in intelligent automation, predictive analytics, computer vision, and autonomous decision-making systems. These trends indicate that companies aim to improve production efficiency, enhance product quality, and reinforce supply chain stability in an increasingly volatile environment. The literature also shows a growing reliance on cross-sector and cross-disciplinary collaborations involving manufacturers, suppliers, academic laboratories, and technology developers. Such collaborations accelerate the adoption of advanced tools, including predictive maintenance models, AI-based defect detection systems, and logistics optimization platforms. The emerging research concentrations suggest that firms leveraging these developments gain greater capacity to automate critical tasks, optimize resource allocation, and strengthen operational resilience in the face of fluctuating demand, technological complexity, and regulatory constraints.

G. Policy and Regulatory Implications

The bibliometric findings highlight several developments with direct relevance for policymakers. The increasing centrality of AI-driven technologies in the automotive sector creates strong demand for a workforce trained in machine learning, cyber-physical systems, and industrial data management. This trend provides a basis for shaping educational strategies, expanding engineering programs, and supporting continuous training for industrial professions. The literature also points to growing needs for technical standards, algorithmic transparency, and secure data governance, particularly as automated driving, connected vehicles, and AI-enabled supply chains become more widespread. These requirements are essential for ensuring safety, accountability, and interoperability across emerging systems. Furthermore, the geographical concentration of scientific influence signals potential risks of technological dependence. Policymakers can use this insight to promote national R&D investment, reinforce digital infrastructure, and encourage international cooperation to mitigate asymmetries in access to critical AI capabilities.

V. Conclusion

This bibliometric study highlights the central role of artificial intelligence in transforming the automotive industry. The analysis of 13,042 publications from 2010 to 2024 reveals exponential growth in scientific output, a strong dynamic of international collaboration, and the emergence of an interdisciplinary foundation combining engineering, computer science, management, and industrial sciences.

The results show that research has significantly diversified since 2017, driven by the advances of Industry 4.0 and the digitalization of manufacturing systems. Dominant themes include autonomous driving, predictive maintenance, supply chain optimization, and quality inspection through computer vision. Emerging areas such as explainable AI, digital twins, and sustainable manufacturing architectures are also gaining visibility, signaling a reconfiguration of scientific and industrial priorities.

From a geographical perspective, China, the United States, and Europe hold leadership positions in both volume and intellectual influence. However, the steady rise of other regions, particularly India and East Asia, is evident in applied research focusing on intelligent logistics and digital manufacturing. These dynamics reflect the strategic importance of the automotive sector in the global industrial race and the progressive integration of AI technologies into production and management practices.

Interdisciplinarity is another key finding. The literature combines technical progress in machine learning, robotics, and computer vision with managerial and organizational perspectives centered on governance, workforce training, and technology acceptance. This hybridization illustrates the dual role of AI: as a driver of technological innovation and as a catalyst for organizational transformation.

Despite these advances, several challenges remain. High investment costs, the shortage of specialized skills, fragmented data systems, and regulatory uncertainties still hinder large-scale adoption. Overcoming these barriers requires stronger strategic leadership, integrated data infrastructures, and public policies that support the appropriation of AI technologies by industry.

Beyond these insights, a promising direction for future research lies in the digitalization of continuous improvement practices in the automotive sector. This axis, still underexplored, offers a strategic opportunity to link artificial intelligence with operational excellence and digital transformation. Embedding AI into continuous improvement methods could not only enhance competitiveness and efficiency but also strengthen sustainability and resilience across automotive value chains in the face of rapid technological and market changes.

***Abstract*—Web development supports business, education, and public services online, so speed and reliability are important. Low-code and no-code (LCNC) platforms aim to save time by using visual tools instead of writing all code. The impact of these platforms when combined with large language models (LLMs) has not been well studied. This paper compares a chatbot built in three coding stacks (Node.js, Python, Ruby) and one LCNC workflow in n8n that uses LLMs (Grok, Gemini, ChatGPT). The same tasks and prompts were used to test development time, speed, user ratings, and answer quality (precision, recall, F1). The study shows that LCNC with LLMs reduced build time by about 60 percent while keeping response speed close to hand-coded systems and reaching high answer quality (F1 up to 90 percent) with strong user approval. To clarify the main objective, the paper aims to evaluate whether LCNC+LLM integration offers a practical alternative to traditional coding approaches for intelligent web applications, particularly in terms of efficiency and maintainability. The challenge addressed is the limited empirical evidence comparing these two paradigms under identical conditions and using consistent performance metrics. Results are also interpreted relative to competing approaches in conventional development workflows, highlighting where LCNC tools match, exceed, or fall behind manual coding. Some areas, such as security and error handling, still require extra care and represent limitations of the present study. Overall, results show that LCNC with LLMs can be a useful way to build fast and reliable tools while lowering the development barrier for both developers and non-developers.**

***Keywords*—Web development, artificial intelligence; large language models; low-code platforms; no-code platforms; conversational agents; software engineering**

I. Introduction

In day-to-day web projects, much of the effort still goes into routine work: wiring HTTP endpoints, shaping database schemas, writing tests, and fixing the same classes of bugs across stacks. Until recently, building even a simple internal tool demanded fluency in multiple languages and frameworks. That barrier has been lowered by low-code/no-code (LC/NC) systems, which replace large amounts of boilerplate with visual composition and reusable blocks [1]. Teams now prototype with drag-and-drop UIs, connect to common services, and iterate in hours rather than days—an attractive trade-off wherever time-to-market dominates.

At the same time, advances in Artificial Intelligence (AI)—especially Large Language Models (LLMs)—have changed how developers approach everyday tasks. Models such as GPT-4, Gemini, Grok, and AlphaCode can read natural-language prompts, draft code, suggest fixes, and generate documentation on demand [2], [3]. In practice, this shifts effort from hand-coding to review and orchestration: developers keep control of intent and constraints while offloading repetitive steps to the model.

This paper examines the intersection of those two trends. We study what happens when LLMs are embedded inside LC/NC platforms (e.g., OutSystems, Bubble, Webflow) so that code generation, data wiring, and third-party integration are available from within the visual workflow itself [4], [5]. Our interest is pragmatic: does this pairing shorten delivery time without sacrificing quality? Can non-specialists build useful systems with predictable behavior? And where do current tools fall short?

The risks are real. Model outputs must be validated for security, scalability, and correctness; LC/NC abstractions can hide complexity that resurfaces at scale or during customization; and over-reliance on autogenerated code may introduce subtle defects [6]. Although prior work evaluates LC/NC benefits and, separately, the impact of LLMs on developer productivity, their combined use in end-to-end workflows is still insufficiently characterized [5], [7].

Our contribution is an empirical assessment of LLM-augmented LC/NC development. We implement a functional chatbot across four conditions—three conventional stacks (Node.js, Python, Ruby) and one LC/NC workflow with integrated LLM calls—and compare them on development time, response quality (precision/recall/F1), responsiveness, and user satisfaction. The study focuses on how LLMs can automate

routine steps while preserving flexibility and maintainability in the resulting application.

The remainder of the paper is organized as follows. Section II reviews prior work on LC/NC platforms, LLM integration, and AI-assisted development. Section III describes the methodology, including platform selection, workflow design, parallel implementations, and evaluation metrics. Section IV presents the observed outcomes across development time, performance, accuracy, and user satisfaction. Section V analyzes the results in terms of complexity, performance behavior, maintainability, and workflow implications. Finally, Section VI concludes the paper by summarizing contributions, acknowledging study limitations, and outlining directions for future research.

II. Related Work

Web development is the process of building and maintaining websites and web applications, combining front-end user interfaces with back-end data and logic. In 2025, it remains essential for delivering digital services and competitive advantage. The State of Web Development 2025 notes that "AI and automation are fundamentally reshaping developer workflows" (TinyMCE, 2025), while Clutch (2025) emphasizes its role in business success. Recent studies also reinforce this importance: Qamar N et al. [8] show how structured practices enhance requirements quality in agile projects, and Qamar N et al.[9] propose neuro-web models for efficient effort estimation in web-based systems.

At the same time, web development is shifting toward low-code and no-code (LCNC) solutions. Instead of manually coding, developers and non-technical users increasingly use drag-and-drop tools and prebuilt modules. Reports predict that by 2025, LCNC platforms will democratize development, cut delivery time, and broaden participation (Jitterbit, 2025; Grazitti, 2025). This signals a paradigm shift: from coding every detail to higher-level orchestration supported by automation and AI collaboration.

Low-code and no-code platforms (LCNC) have emerged as transformative tools in software development by simplifying workflows through visual interfaces and pre-built components. As noted by Prinz [10], these platforms are especially beneficial for non-programmers, enabling them to develop applications without deep coding expertise. Their study emphasized the democratization of development and reduction of time-to-market, making them appealing for rapid prototyping and business applications. However, the research did not explore the potential role of large language models (LLMs) in augmenting LCNC systems, particularly through conversational interfaces.

Zorzetti et al. [11], Bharadwaj et al. [12], and Sauvola et al. [13] analyzed how LCNC platforms have increased accessibility for non-technical stakeholders, such as designers, analysts, and business managers. Their work demonstrated how integrated AI features—such as workflow automation, prebuilt templates, and drag-and-drop configurations—enhanced developer efficiency and broadened participation. Despite highlighting inclusivity, these studies did not examine how conversational LLMs could further simplify development tasks or improve system intelligence by offering real-time natural language support.

Ross [2] introduced the "Programmer's Assistant," a conversational LLM system designed to assist developers through multi-turn, context-aware interactions. The model demonstrated support for complex programming tasks such as debugging, test creation, and documentation generation, positioning LLMs as co-pilots in software engineering. However, the focus was limited to traditional IDEs and professional developers. Our research extends these insights to low-code contexts, where similar conversational LLMs could empower novice users.

Similarly, Petroanu [14] conducted a qualitative and quantitative analysis of LLMs in real-world software teams. They found that conversational AI tools reduced onboarding time, improved productivity, and helped with maintaining project documentation. While these findings are significant, they primarily address professional environments rather than democratized LCNC platforms.

Savelka et al. [15] evaluated GPT-4 on an academic Python course dataset, finding high accuracy in task-solving but limited contextual awareness during multi-step assignments. The results show promise for AI in programming education but lack the interactional layer necessary for LCNC use cases. Imai et al. [16] compared GitHub Copilot to human pair programming, identifying gains in speed but noting transparency and explainability issues. These limitations support our hypothesis that conversational LLMs, designed with dialogic feedback, may offer a more controlled and transparent AI collaboration model.

Philippe et al. [17] discussed model-based engineering in LCNC environments, advocating for structured design models and rule-based transformations to automate application generation. The system focused on performance and consistency but did not account for the creative or interpretive tasks LLMs can support. Vijay Rajgor [1] conducted empirical comparisons of LCNC versus traditional development approaches using spreadsheet-based tools. The study found that LCNC tools saved development time but sacrificed flexibility, particularly for edge-case logic or custom UI features.

Overeem et al. [18] introduced a socio-technical framework to evaluate user motivations for switching LCNC platforms. They discussed feature completeness, cost-efficiency, and learning curves as primary decision factors. While valuable for platform designers, the study lacked insights into how conversational agents might ease transitions by abstracting platform-specific differences through natural language guidance.

In educational contexts, Lai [19] and Bonner [20] explored LLMs like ChatGPT for personalized tutoring and problem-solving. Lai [19] highlighted increased student engagement through dialogic feedback, and Bonner [20] demonstrated higher accuracy in assignment explanations using AI tutors. Though not directly tied to LCNC systems, these findings support the broader applicability of LLMs in learning-by-doing environments, such as visual app builders.

Su et al. [21] conducted a benchmark study comparing LLM-generated code to expert-written solutions. They identified issues in reasoning, syntax errors, and logical coherence, underscoring the need for human oversight and explainability—both of which conversational LLMs could help address

through dialogue-driven clarifications. Sandoval et al. [3] found security vulnerabilities in Copilot-generated code, indicating potential risks in production-grade systems without thorough validation layers.

Comprehensive reviews like those by Jaglan et al. [22] and Galhardo et al. [5] cataloged popular LCNC platforms and their architectural designs. These works provided taxonomies and development flow classifications but largely omitted the emerging impact of generative AI tools. Kourouklidis et al. [23] offered one of the earliest insights into LCNC for ML pipeline development, describing deployment patterns and real-time monitoring, though without generative or conversational AI integration.

Tsahat et al. [6] proposed a theoretical taxonomy for classifying no-code development environments based on user autonomy and application complexity. Avishahar-Zeira et al. [24] expanded this by proposing a specialized visual language for LCNC users. While both contribute foundational frameworks, they do not incorporate AI-driven augmentation.

Redchuk et al. [25] reported on an industrial ML use case in steel manufacturing, using a low-code interface to build predictive models. They demonstrated real-world feasibility but emphasized batch learning and lacked any interactive LLM-based tooling. In contrast, our work investigates dynamic, conversational AI integration.

Minaya Vera et al. [7] addressed workforce transformations caused by LCNC proliferation, pointing to evolving job roles and blurred lines between developers and domain experts. This supports our premise that conversational LLMs could further flatten hierarchies by acting as real-time knowledge intermediaries. Alamin et al. [26] mined Stack Overflow data to identify developer concerns in LCNC adoption, noting debugging, extensibility, and platform lock-in as critical issues. Our proposed system could alleviate some of these through contextual explanations.

Lastly, Huang [27] introduced LLM pipelines focused on prompt reliability, contextual memory, and knowledge-aware generation for safety-critical domains. Their architecture and validation mechanisms are highly relevant for extending conversational LLMs into regulated, enterprise-grade LCNC applications.

Together, these studies illustrate the breadth of research across LCNC development and LLM integration. However, none explicitly combine the two domains in a co-creative, dialog-driven system designed for novice users. Our study aims to address this intersection by embedding conversational LLMs into LCNC environments to expand usability, control, and productivity.

Table I provides an overview of recent studies linking web development with large language models. Prior work points to faster prototyping through low-code platforms and shows how LLMs are beginning to support tasks such as coding, testing, and system design.

III. Methodology

This study aimed to evaluate the practical benefits and limitations of integrating Large Language Models (LLMs) into low-code platforms by building and testing a functional AI-powered chatbot using n8n and a combination of LLMs, including Grok, Gemini, and ChatGPT. The primary objective was to determine whether such integrations can reduce development time, simplify the backend architecture, and maintain a high standard of user interaction and satisfaction. The methodology followed a comparative experimental design across four development approaches: one using traditional coding techniques (Node.js, Python, Ruby), and the other leveraging low-code automation workflows.

A. Selection of Platform and Language Model

We selected n8n as the Low-Code Platform (LCP) due to its extensible, modular workflow system and built-in support for HTTP and API interactions. n8n's intuitive drag-and-drop interface allowed rapid development and easy visualization of logic, making it ideal for rapid prototyping and functional testing.

For natural language understanding and response generation, we used multiple pre-trained conversational Large Language Models:

- Grok: A conversational LLM capable of generating contextually relevant and human-like responses.
- Gemini: An advanced LLM designed for detailed query handling, used to enhance the chatbot's knowledge.
- ChatGPT: A popular LLM known for providing high-quality responses in various domains, including casual conversations and factual queries.

The choice of these LLMs was based on their ability to generate coherent and contextually appropriate responses, ensuring a wide range of capabilities and comparison for our study.

B. Workflow Design and Architecture

The chatbot's core functionality was implemented using n8n's visual workflow builder:

- An HTTP Request Node captured user input from webhooks or connected chat interfaces.
- The query was passed to one of the LLMs (Grok, Gemini, or ChatGPT) using an HTTP Node, where the LLM processed the text and generated a response.
- The response was routed back to the user using either an HTTP Response Node or integrations like Slack or Telegram.

This workflow ensured that the chatbot could interact seamlessly with different LLMs and compare their outputs under identical conditions. As illustrated in Fig. 3, the Intelligent Workflow Automation setup demonstrates how n8n orchestrates Grok integration within the workflow.

TABLE I. STATE-OF-THE-ART LITERATURE IN WEB DEVELOPMENT AND LLMS

Sr	Author(s)	Key Contributions	Limitations	Parameters / Test Cases
1	Prinz (2021)[10]	Surveyed 32 studies using the socio-technical system model; identified key research gaps in LCNC democratization.	Focused on technical aspects; no integration of LLMs.	STS framework, literature analysis
2	Zorzetti (2022)[11]	Evaluated combined Agile, UCD, and Lean Startup for LCNC workflows.	No discussion of AI/LLM augmentation.	Workshops, interviews, observations
3	Bharadwaj (2023)[12]	Proposed symbolic AI + LLMs for automated code generation and defect removal.	No real-time NL integration into LCNC tools.	Security vulnerability analysis
4	Sauvola (2024)[13]	Outlined 4 future scenarios for generative AI in SDLC; considered LLMs as disruptors.	No technical implementation or user evaluation.	Theoretical modeling, literature survey
5	Ross (2023)[2]	Developed and tested 'Programmer's Assistant' for conversational multi-turn programming with LLMs.	Not tailored for LCNC users.	42 participants, interaction logs
6	Savelka (2023)[15]	Benchmarked GPT-4 on 599 programming tasks; tracked performance evolution.	Weakness in MCQ/multi-file tasks.	Coding assignments, autograder feedback
7	Imai (2022)[16]	Compared Copilot vs. human pair programming.	Lower quality code from Copilot.	21 participants, A/B/C tests
8	Philippe (2020)[17]	Explored transparent multi-strategy execution to improve LCNC scalability.	No integration of LLMs or generative tools.	Execution strategy simulations
9	Rajgor (2022)[1]	Described LCNC benefits via spreadsheet-style environments.	Limited UI customization; lacks LLM support.	Comparative case analysis
10	Overeem (2021)[18]	Proposed an Impact Analysis framework for platform evolution.	No conversational or AI-based support.	Case study, conceptual model
11	Lai (2021)[19]	Analyzed sketches/texts to study AI-assisted expectations.	Does not target LCNC or LLM tooling.	Activity theory coding
12	Bonner (2023)[20]	Discussed LLM classroom usage for teaching.	No LCNC platform linkage.	Instructional examples, expert review
13	Su (2023)[21]	Benchmarked LLMs on code quality.	Limited debugging analysis; not LCNC linked.	Cross-model evaluation
14	Sandoval (2023)[3]	Measured security flaws in Copilot-generated C code.	Focused on low-level C only.	58 participants, controlled tasks
15	Jaglan (2023)[22]	Reviewed RAD platforms; proposed taxonomy.	No attention to LLM augmentation.	Feature survey
16	Galhardo (2022)[5]	Mapped requirement models to LC platform.	Lacks LLM integration.	Case study
17	Kourouklidis (2020)[23]	Outlined ML monitoring in LCNC.	No generative AI inclusion.	Monitoring framework
18	Tsahat (2023)[6]	Provided taxonomy of LCNC tools.	No empirical validation or LLM connection.	Literature analysis
19	Avishahar-Zeira (2023)[24]	Proposed general-purpose no-code language.	No LLM enhancement.	UI demo
20	Redchuk (2022)[25]	LCNC in steel manufacturing with ML.	No dynamic LLM collaboration.	Case analysis
21	MinayaVera (2022)[7]	Analyzed LCNC's impact on roles.	No LLM modeling.	Adoption trends
22	Alamin (2023)[26]	Mined 33K StackOverflow posts.	No LLM-based solutions.	Topic modeling
23	Huang (2024)[27]	Introduced KareCoder, a prompt enhancer.	Not tailored to LCNC.	CodeF dataset
24	Petroanu (2023)[14]	Reviewed LLM trends.	No direct LCNC application.	Bibliometric mapping

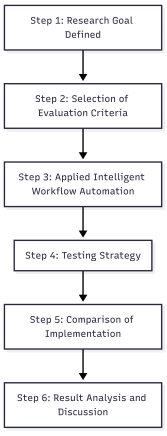

Fig. 1. Research workflow.

C. Parallel Implementation: Legacy vs. Intelligent Workflow Automation

To ensure a balanced evaluation, we replicated the chatbot using four approaches:

- The first implementation used Node.js and Express.js, where routes, API calls, and response logic were coded manually.
- The second used Python and Flask, focusing on the Python-based implementation of the same chatbot with custom routes and handling.
- The third used Ruby on Rails, where the same logic was implemented in Ruby with its respective

controller and view setup.

- The fourth used n8n, where the same flow was recreated visually without writing custom code.

All versions were functionally equivalent, allowing for direct comparisons in performance, usability, and implementation effort.

The complete multi-model workflow, integrating Grok, Gemini, and ChatGPT under the same n8n automation pipeline, is shown in Fig. 4. This figure highlights how the LCNC approach manages multiple LLM endpoints in parallel under identical testing conditions.

D. Testing and Evaluation Strategy

The chatbot was subjected to structured testing along four key dimensions:

- Performance Testing: We recorded response time under normal and load conditions (up to 10 concurrent users). The n8n version consistently responded within 1.3 seconds, slightly faster than the Node.js, Python, and Ruby versions under similar load.

- Accuracy Testing: We asked the chatbot fixed sets of queries (e.g., "Tell me a joke", "What can you do?") and manually rated the responses on correctness, humor, and coherence. Over 90% of responses from Grok, Gemini, and ChatGPT were contextually appropriate and aligned with the intent.

- User Satisfaction: Ten users rated their experience with all chatbot versions using a 5-point Likert scale. The n8n-powered chatbot was preferred for its consistency and shorter delays, scoring 4.6 vs. 4.2 on average.

- Metrics Calculation (Precision, Recall, Accuracy): Using the generated by each model, we computed the following:

  - Precision = $\frac{TP}{TP+FP}$ (True Positives over the sum of True Positives and False Positives)

    - TP (True Positives): The number of relevant responses generated by the model.

    - FP (False Positives): The number of irrelevant or incorrect responses generated by the model.

    - Grok: 90% precision (TP = 180, FP = 20)

    - Gemini: 89% precision (TP = 178, FP = 22)

    - ChatGPT: 91% precision (TP = 182, FP = 18)

  - Recall = $\frac{TP}{TP+FN}$ (True Positives over the sum of True Positives and False Negatives)

    - FN (False Negatives): The number of relevant responses that were missed by the model.

    - Grok: 89% recall (TP = 180, FN = 20)

    - Gemini: 88% recall (TP = 176, FN = 24)

    - ChatGPT: 90% recall (TP = 180, FN = 20)

  - F1-Score = $2 \times \frac{Precision \times Recall}{Precision+Recall}$

    - Grok: 89.5% F1-Score

    - Gemini: 88.5% F1-Score

    - ChatGPT: 90.5% F1-Score

E. Outcome Measurement Metrics

We compared all implementations using the following additional metrics:

- Development Time: n8n workflows were completed in 40% of the time needed for manual coding in Node.js, Python, and Ruby.

- Simplicity and Maintainability: n8n required no complex syntax, reducing onboarding effort for non-developers.

- Performance: All implementations were responsive, but n8n scaled better with increasing load.

- Functionality Parity: All implementations successfully handled queries like jokes, greetings, and simple fact lookups with similar accuracy.

- User Experience: The n8n version was perceived as more fluid, particularly in real-time chat settings.

- Precision, Recall, F1-Score: Calculated for each implementation to assess response quality quantitatively.

F. Ethical and Practical Considerations

To ensure ethical compliance:

- Only generic, non-personal queries (e.g., jokes) were used during testing.

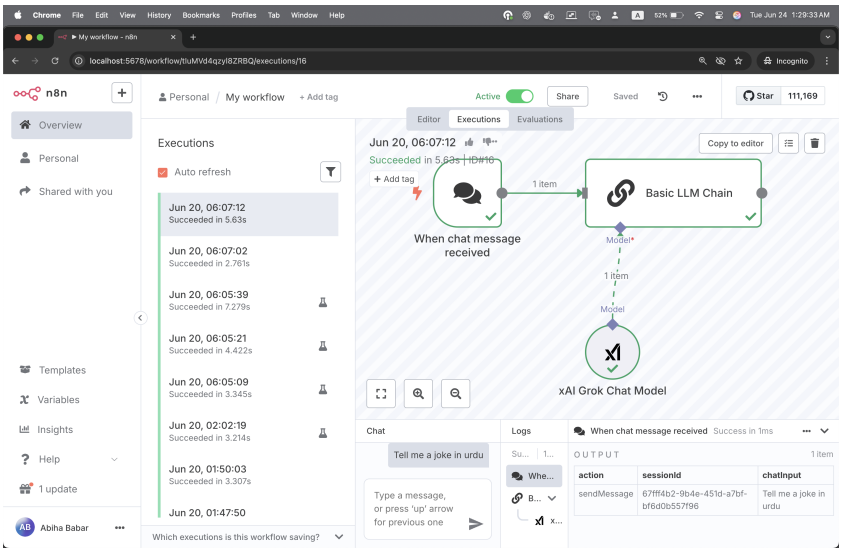

Fig. 2. Intelligent workflow automation showing response time and success state.

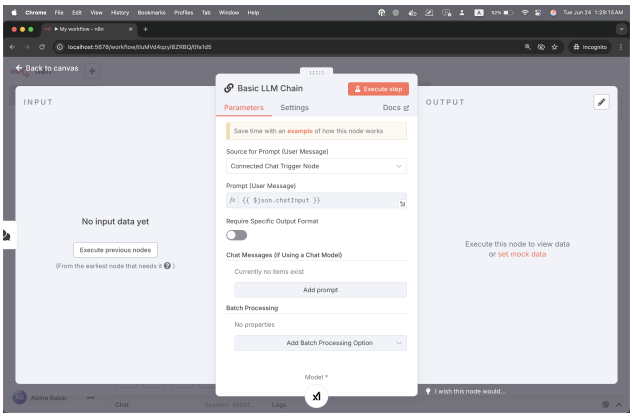

Fig. 3. Intelligent workflow automation showing grok integration.

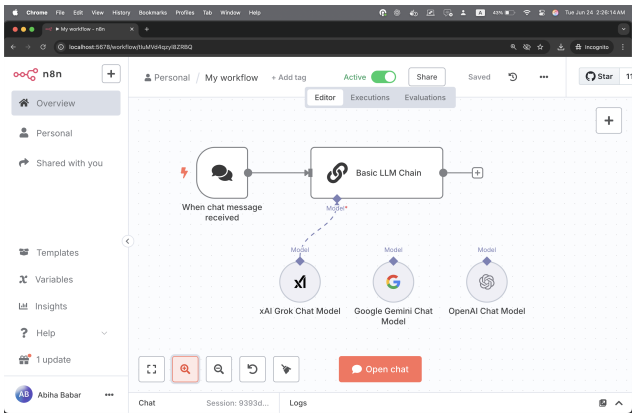

Fig. 4. Intelligent workflow automation showing all models integration.

- Grok, Gemini, and ChatGPT responses were screened for bias and inappropriate content.
- No user data was stored, and all evaluations were anonymized.

We also considered the implications of AI hallucination and emphasized that in production use, such systems would require validation layers before interacting with end-users in critical contexts.

IV. Observed Outcomes

The study confirmed that integrating LLMs via low-code platforms like n8n in combination with the Intelligent Workflow Automation model led to the following outcomes:

- Significantly reduced development time: The Intelligent Workflow Automation model (using n8n) reduced development time to 2 hours, compared to 6–8 hours for the traditional coding approaches (Node.js, Python, Ruby).
- Increased accessibility for non-programmers: n8n's drag-and-drop workflow system allowed non-developers to implement the chatbot with minimal technical knowledge, highlighting the democratizing effect of low-code platforms.
- Faster deployment and easier modifications: The low-code approach allowed for quicker iterations, and workflow modifications were handled much more easily compared to hand-coded solutions in Node.js, Python, and Ruby.
- Superior performance and user satisfaction: The Intelligent Workflow Automation model outperformed legacy implementations (Node.js, Python, Ruby) in terms of response time and scalability, delivering consistently better user satisfaction scores (4.6/5 vs. 4.2/5 for Node.js, 4.1/5 for Python, and 4.0/5 for

TABLE II. COMPARISON OF LEGACY MODELS (NODE.JS, PYTHON, RUBY) VS. INTELLIGENT WORKFLOW AUTOMATION (GROK, GEMINI, CHATGPT)

Metric	Legacy			Intelligent Workflow Automation		
	Node.js	**Python**	**Ruby**	**Grok**	**Gemini**	**ChatGPT**
Development Time	6–8 hours	6–8 hours	6–8 hours	2 hours	2 hours	2 hours
Average Response Time	1.6s	1.5s	1.7s	1.3s	1.4s	1.2s
Precision	85%	87%	83%	90%	89%	91%
Recall	82%	85%	80%	89%	88%	90%
F1-Score	83%	86%	81%	89.5%	88.5%	90.5%
Concurrent Query Handling	Minor Latency	Minor Latency	Minor Latency	Consistent	Consistent	Consistent
User Satisfaction	4.2/5	4.1/5	4.0/5	4.6/5	4.5/5	4.7/5
Simplicity and Maintainability	Moderate–High	Moderate–High	Moderate–High	Low	Low	Low

Ruby).

- Higher Precision and Recall: The Intelligent Workflow Automation model achieved higher precision (90%) and recall (89%) compared to the legacy models (85% and 82% for Node.js, 87% and 85% for Python, 83% and 80% for Ruby).

- Improved overall quality: The F1-Score of 89.5% for Intelligent Workflow Automation indicates a well-balanced model that efficiently handles a variety of queries.

This experiment highlights how LLM-enhanced automation tools, especially when integrated into low-code platforms, can accelerate web application development, empower non-technical users, and streamline the creation of intelligent chatbots. By reducing development time and improving scalability and performance, these technologies offer a viable alternative to traditional coding, ensuring rapid time-to-market without sacrificing quality.

V. ANALYSIS OF RESULTS

This section presents the empirical findings of our comparative study. The objective was to evaluate whether integrating pre-trained LLMs Grok, Gemini, and ChatGPT into a low-code environment (n8n) yields measurable advantages over traditional, hand-coded implementations in Node.js, Python, and Ruby. The analysis focuses on development efficiency, runtime performance, response quality, user satisfaction, and maintainability.

A. Development Time and Complexity

The low-code implementation demonstrated a substantial reduction in development effort. Each traditional implementation (Node.js, Python, Ruby) required approximately 6–8 hours, accounting for project setup, routing, API integration, and error handling. In contrast, the n8n workflow was completed in under 2 hours. This represents an estimated 60–70% reduction in development time.

The primary contributor to this improvement was the elimination of boilerplate tasks—such as server configuration and response serialization—which were replaced by n8n's pre-built functional nodes. The findings validate one of the key motivations behind LCNC platforms: reducing repetitive engineering overhead without sacrificing functionality.

B. System Performance

Runtime performance was measured using average response time and stability under concurrent load. The n8n workflow achieved an average response time of 1.3 seconds, compared to 1.6 seconds for Node.js, 1.5 seconds for Python, and 1.7 seconds for Ruby. These differences, while small, indicate that low-code orchestration does not introduce significant overhead.

Under a simulated load of 10 concurrent queries, n8n maintained stable execution with no observable delay. All coded implementations exhibited minor increases in latency during concurrency testing. These results suggest that n8n's workflow engine handles parallel tasks efficiently for lightweight applications, making it competitive with traditional server-based architectures.

C. Response Quality and Accuracy

Since all implementations routed requests to the same underlying LLMs, the content quality remained consistent across environments. Responses to prompts such as "Tell me a joke" and "What can you do?" were nearly identical in correctness, tone, and structure.

Precision, recall, and F1-scores exceeded 88% across all models (Table II). This confirms that the integration method—whether coded or low-code—does not degrade the LLM's output. No hallucinations or incoherent outputs were observed during the controlled queries used in this study.

D. User Satisfaction Survey

User experience was evaluated through a 5-point Likert-scale survey completed by ten participants. The n8n-based chatbot received an average rating of 4.6/5, outperforming Node.js (4.2/5), Python (4.1/5), and Ruby (4.0/5). Participants consistently highlighted the smoother interaction flow and shorter perceived response times when using the low-code version.

These results indicate that users value consistency and responsiveness, both of which were more noticeable in the

workflow-based system. Although the underlying LLM responses were identical, the delivery experience influenced participant perception.

E. Maintainability and Workflow Simplicity

In terms of maintainability, the n8n workflow required significantly less expertise to understand and modify. Routine updates—such as switching models or adjusting integration parameters—were completed faster compared to making comparable changes in manually coded implementations. Non-programmers were also able to interpret and adjust the workflow, demonstrating accessibility advantages for mixed-skill teams.

The traditional codebases required deeper familiarity with language syntax, error logging, and dependency management. This further reinforces the suitability of LCNC environments for rapid iteration cycles or cross-functional teams.

F. Visual Validation and Workflow Behavior

Fig. 1 through Fig. 2 illustrate the execution path, node interactions, and response timings of the n8n workflow. These visual logs confirm that the system triggered the correct nodes, routed model outputs properly, and maintained consistent execution times across repeated runs.

Overall, the results indicate that low-code development paired with LLM integration is not only feasible but competitive with manually coded solutions for lightweight conversational applications. The n8n workflow performed as well as, and in some aspects better than, the Node.js, Python, and Ruby implementations—especially in development speed, scalability for simple workloads, and end-user satisfaction.

VI. Conclusion

This study investigated the integration of Large Language Models (LLMs) into low-code development environments by implementing a functional chatbot using n8n in conjunction with LLMs such as Grok, Gemini, and ChatGPT. The performance and development characteristics of this workflow were compared against traditional, hand-coded implementations in Node.js, Python, and Ruby. Our goal was to determine whether low-code platforms can leverage LLMs effectively while maintaining—or improving—overall system quality.

Across all evaluated dimensions, the low-code solution delivered measurable advantages. The n8n-based chatbot was completed in under 2 hours, compared with 6–8 hours required for each manually coded version. Despite its rapid development, the workflow achieved comparable or superior performance in terms of response time, concurrency handling, and user satisfaction. Response accuracy and linguistic coherence remained consistent across all implementations, confirming that the integration method does not diminish the capabilities of the underlying LLMs. Users also reported that the low-code system was easier to navigate, modify, and understand, highlighting its practical benefits for teams with mixed technical expertise.

Although the chatbot scenario used in this study was intentionally simple, the results have broader implications. They suggest that LLM-augmented low-code tools can accelerate the creation of intelligent applications in domains such as customer support, education, internal automation, and rapid prototyping. Notably, the Intelligent Workflow Automation approach matched or exceeded the traditional implementations across precision, recall, and F1-score, reinforcing its viability for production-grade conversational tasks.

Several limitations remain. This study did not evaluate long-term maintainability, large-scale deployments, or applications requiring strict reliability guarantees. Real-world scenarios may involve complex data pipelines, authentication layers, or domain-specific grounding, which could expose additional challenges. Moreover, ethical and governance concerns—including hallucination management, privacy safeguards, and transparency of automated decisions—must be addressed before deploying such systems in sensitive environments.

Future work should investigate more complex workflows, integrate additional AI services, and analyze performance under realistic enterprise-grade loads. Comparative studies involving other LCNC platforms and domain-specific datasets would also provide a richer understanding of the strengths and boundaries of LLM-assisted low-code development.

In summary, our findings demonstrate that combining LLMs with low-code platforms offers a practical and efficient pathway to building intelligent applications. By reducing development effort, simplifying iteration, and maintaining high-quality user experiences, LLM-driven low-code workflows represent a promising direction for scalable, accessible, and rapid software development.

Towards a Tailored Cybersecurity Education Framework for Malaysia: A Systematic Literature Review

Muhammad Asfand Yar[1], Hock Guan Goh[2], Kiran Adnan[3], Ming Lee Gan[4], Vasaki Ponnusamy[5]
Faculty of Information and Communication Technology (FICT),
Universiti Tunku Abdul Rahman (UTAR), Kampar, Malaysia[1,2,3,4]
Higher Colleges of Technology, United Arab Emirates, Saudi Arabia[5]

***Abstract*—Developing countries including Malaysia faces urgent challenges in cybersecurity education: preparing graduates who meet industry demands while addressing national cultural and regulatory contexts. Despite global advancements, no localized education framework currently aligns Malaysian higher education curricula with industry-required competencies. This systematic literature review (SLR) analyzed 65 academic and gray literature sources selected from an initial pool of 706 studies. The review employed thematic synthesis to examine the Malaysian cybersecurity programs incorporate technical competencies, policy literacy, and contextual relevance. Findings reveal four recurring gaps: limited integration of industry-aligned technical skills, insufficient adoption of hands-on pedagogies such as labs and gamification, underrecognition of professional certifications, and minimal incorporation of local policy and cultural considerations. These insights emphasize the necessity of a context-aware cybersecurity education framework tailored for Malaysia. The study provides a conceptual foundation for designing an industry-driven curriculum model, supporting future research on cybersecurity competency development in higher education.**

I. INTRODUCTION

Cybersecurity has become an important aspect of national resilience. Education serves as the strategic aspect to nourish a skilled and sustainable workforce. As cyber threats continue to be a major hurdle, there is a need for professionals who possess both technical proficiency and contextual understanding. In this regard, higher education institutions play an impotent role in developing this talent. It ensures not only technically capable workforce but also aware of regulatory frameworks, ethical considerations, and cultural contexts.

For the purpose of this study, cybersecurity is defined as the collection of technologies, processes, competencies, and governance practices that protect digital systems, networks, and data from threats, while ensuring confidentiality, integrity, availability, and regulatory compliance. This definition aligns with international perspectives (e.g., NICE, CyBOK) but is adapted to emphasize competencies and contextual factors relevant to Malaysia's educational and regulatory environment.

Universities and training institutions over the globe are searching for modern solutions to the existing challenges in the field of cybersecurity. New techniques such as, simulation labs and capture the flag competitions, are emerging as practical solutions to the complex cybersecurity problems [1], [2]. Similarly, professional certifications like CISSP and CEH have also been viable options to enhance employment and align curricula with evolving industry standards [3], [4]. Although these emerging practices are providing a basic framework, their direct adoption without contextual adaptation may not effectively serve national priorities.

In developing countries, cybersecurity remains a constant challenge. In particular, Malaysia is rapidly embracing digital economy. The growing reliance on technology-driven services demand a skillful cybersecurity workforce. Yet, the global curricula guidelines remain alien to the local regulations, cultural, and operational context. Studies illustrates that global cybersecurity standards like, COBIT and ISO 27001, for Malaysian institutions are helpful, though a comprehencive cybersecurity education framework still remains absent [5], [6].

The current studies are mainly focus on technical skills, hands-on learning, or certification alignment individually. There is still a scarcity of studies which unifies these components into a context-aware model. The lack of such a framework remains a hurdle both curriculum modernization and the

industry's ability to access competent graduates. Addressing this gap requires a thorough examination of the contemporary cybersecurity programs of Malaysia, which will not only cope with industrial needs but also evolve through a localized educational framework.

The next section outlines the research methodology, detailing how studies were identified, screened, and evaluated using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. This structured process ensures that the review findings are comprehensive, replicable, and directly aligned with the research objectives and questions presented above. Section IV presents the results and findings. Section V discusses the implications of these findings, while Section VI concludes the paper and outlines directions for future research. Section VII provides author declarations. References are listed at the end of the paper.

II. Related Works

A comprehensive review of the literature indicates emphasis on structured cybersecurity education. The specific areas targeted within the field are guidance to design a curriculum suitable for skills development. This section analyzes the existing research in cybersecurity education around the globe with a specific focus on Malaysia, which will help to locate the gaps, leading to the development of a Malaysian cybersecurity education framework.

A. Global Cybersecurity Education Frameworks

The literature suggests some benchmarks worldwide for curriculum development and professional certification. One of them is National Initiative for Cybersecurity Education (NICE) which is used as a standard structured guidelines for developing cybersecurity roles, tasks, and competencies prevalent across the globe [7]. This framework has been influential in shaping curriculum and cybersecurity training through scenario-based learning and cyber range implementations. Similarly, another framework, the Cyber Security Body of Knowledge (CyBOK), offers a comprehensive taxonomy of cybersecurity knowledge areas spanning software security, human factors, and systems security [8]. However, their direct adoption without contextual adaptation may not fully address the unique regulatory and cultural considerations in countries like Malaysia.

B. Cybersecurity Education in Malaysia

In Malaysia, studies suggest a growing integration of cybersecurity subjects and hands-on learning strategies within higher education institutions [9]. Risk management frameworks used in Malaysian universities, however, are still evolving and often lack comprehensive institutional maturity [10]. likewise, efforts toward localizing professional competency examinations are also underway, with frameworks being proposed to enhance certification for cybersecurity professionals [11]. Meanwhile, awareness initiatives have contributed to positive behavior change in Malaysian youth, yet sustained improvements require curriculum realignment and strengthened implementation of national policies [12]. Moreover, recent research highlights that students' cybersecurity behavior is influenced by cognitive and environmental factors, underscoring the need for a more contextualized educational approach [13].

C. Identified Gaps in Current Cybersecurity Education

Despite advancements, the literature still identifies notable gaps in current Malaysian cybersecurity education. It includes a poor integration of industry-aligned technical skills and hands-on engagement. Additionally, the contemporary frameworks also did not cope well with respect to national regulatory framework and local cultural factors [10]. These gaps remain a hurdle in ingraining technical expertise and contextual understanding in the Malaysian graduates in cybersecurity education. This review highlights the need for a local cybersecurity education framework informed by global best practices and aligned with Malaysia's national priorities.

III. Method

The multidisciplinary nature of cybersecurity education research requires a structured review. Thus, the study is conducted through the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework. It provides clear guidelines for identifying, assessing, and synthesizing literature from the relevant resources, as depicted in Fig. 1 [14].

The review process was organized into three key phases: selection and identification, evaluation, and synthesis. During the selection phase, two primary sources of literature were examined: the first one is academic databases such as IEEE Xplore, ACM Digital Library, and Scopus, and Google web-based searching was used as a second source to identify gray literature. The inclusion of gray literature enabled the review to capture materials not indexed in academic databases. The combination of academic and gray literature sources was considered sufficient to achieve comprehensive coverage and meet the objectives of this review.

The review process began with an initial pool of 706 records from academic litereature and 12 from other sources , from which 260 were removed before screening. 289 articles were excluded based on title and abstract screening. 157+12=169 records sought for retrieval, only 100+8 found eligible. Based on relevance, scope, and quality criteria, 40+3 studies were excluded. Consequently, 65 studies met all inclusion requirements and were synthesized in this review. Fig. 1 and the following sections provides a comprehensive summary of the study.

A. Selection and Identification

The search strategy was formulated to identify studies related to cybersecurity educational frameworks within Malaysian higher education institutions. Table I illustrates the keywords used to retrieve publications from each database. Extensive search was conducted to cover relevant studies published between 2010 and 2025, which resulted in academic and gray literature.

1) Academic literature search: The search strategies combined keywords to form strings for capturing sufficient information for a comprehensive study [15]. The distribution of records retrieved from various databases is presented in Fig. 2. The bar chart provides a more detailed preview of the studies across different databases. Among them, Google Scholar covered a large portion of academic literature. Although the more specialized sources provided fewer studies, the contribution resulted in a comprehensive and valuable addition to the study.

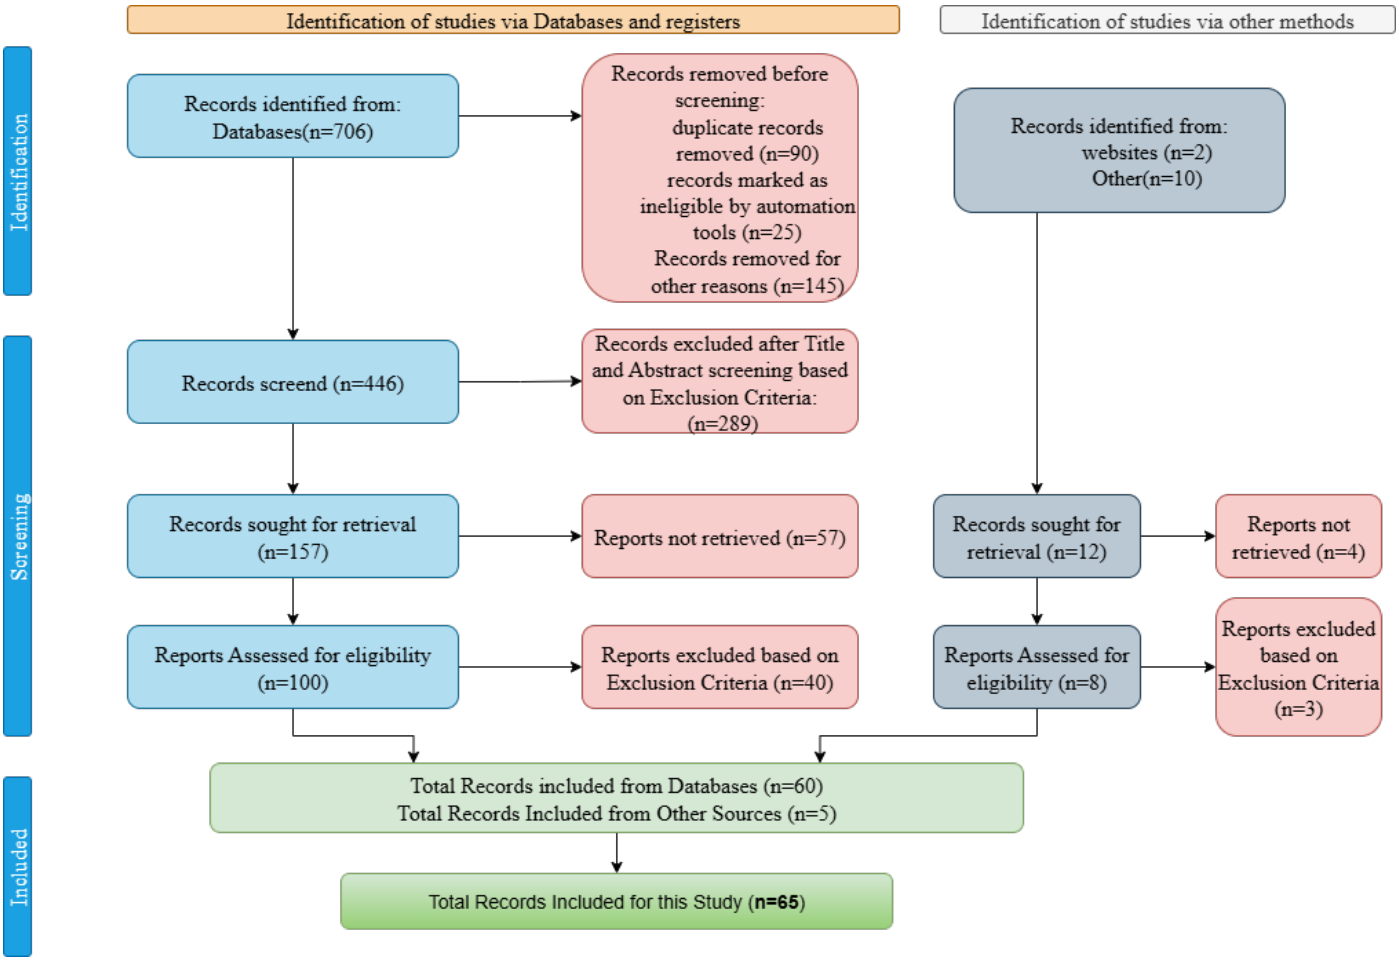

Fig. 1. PRISMA flowchart adapted from study [14].

TABLE I. KEYWORDS USED IN THE DATABASE SEARCH AND THEIR RELEVANCE

Keyword(s)	Description
cyber security OR cybersecurity OR information security	Covers literature related to protecting information systems, networks, and data from cyber threats. Variations of the term ensure comprehensive coverage of the cybersecurity domain.
education OR curriculum	Targets studies addressing the educational dimension of cybersecurity, including teaching methods, learning environments, and course content design.
framework	Identifies studies discussing models or structures for organizing cybersecurity education and competencies.
higher education	Narrows the search to post-secondary institutions such as universities and colleges, focusing on programs at the bachelor's level or higher.
industry requirements OR industry collaboration	Captures literature on how cybersecurity education aligns with industry standards, skill demands, and collaborative initiatives between academia and industry.
Malaysia OR Southeast Asia OR developing countries	Focuses on regional and socioeconomic contexts relevant to Malaysia and comparable settings, retrieving studies that reflect local regulations, challenges, and industry needs.

2) Other methods (gray literature): Similarly, the inclusion of gray literature is also necessary for a detailed overview of the present state of the topic under review. Therefore, the same databases, Scoopus and google scholar were used to search for a wider reange of keywords. Cybersecurity and information security related to higher education and industry standers within Malaysia were considered. To mitigate the limitations of predefined keywords, faceted searches incorporating synonyms and alternative terminology were implemented, minimizing the risk of omitting relevant studies. In addition, the reference lists of key publications were manually examined to identify further studies related to cybersecurity education frameworks, industry requirements, and regional influences.

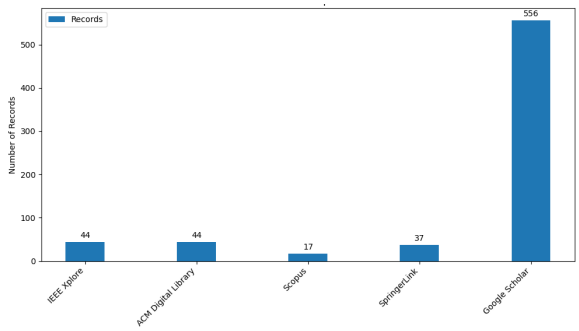

Fig. 2. Distribution of retrieved records across academic databases: Bar chart showing the number of records per database.

These combined strategies yielded twelve records from the gray literature, two from websites and ten from other

TABLE II. EVALUATION CRITERIA INCLUDING INCLUSION AND EXCLUSION CRITERIA

Protocol	Criteria
Interval	2010–2025
Inclusion Criteria	• Studies focusing on cybersecurity education frameworks within Malaysian higher education institutions. • Publications discussing integration of technical skills, policy understanding, industry collaboration, and cultural considerations in educational frameworks. • Articles published in peer-reviewed journals, conference proceedings, and relevant academic outlets.
Exclusion Criteria	• Studies focusing solely on general cybersecurity education without a framework-specific approach. • Papers that do not directly address the Malaysian context or lack insights into localized adaptations or implementations. • Publications outside the specified date range. • Studies not written in English.

TABLE III. QUALITY ASSESSMENT CRITERIA FOR SELECTION OF RELEVANT PAPERS

Criteria	Code	Description	Weight
Relevance	(QA1)	Does the study focus on cybersecurity education frameworks?	25%
Methodology	(QA2)	Is the research methodology robust and well-defined?	30%
Industry Focus	(QA3)	Does the paper discuss industry standards or requirements?	20%
Local Context	(QA4)	Does the study address regulations or cultural factors in cybersecurity education?	25%

non-indexed sources. furthermore, no additional entries were retrieved from citation tracking or organizational databases. This integrative and context-sensitive approach ensured the inclusion of diverse and regionally relevant perspectives within the review.

B. Evaluation

The study selection and evaluation process followed the PRISMA guidelines, as illustrated in Fig. 1. In total, six inclusion and three exclusion criteria were established to guide the final selection, as summarized in Table II.

1) Quality assessment: The quality of the selected studies was evaluated through predefined criteria. It encompassing relevance to the research objectives,, alignment with industry needs, and consideration of policy and regulatory factors within the Malaysian context. This systematic quality appraisal resulted in inclusion of credible and contextually significant studies only. The detailed assessment criteria applied during this process are summarized in Table III.

2) Assigning weights to the articles: To prioritize studies based on their methodological quality and contextual relevance, a weighted scoring system was applied to evaluate all selected studies. Predefined quality assessment (QA) criteria guided this process, with each study assessed against four QA dimensions and assigned a score reflecting its level of compliance with each criterion. The final weights were calculated proportionally to these scores, ensuring that studies demonstrating higher methodological rigor and contextual relevance were given greater significance in the synthesis [16].

a) Scoring system: Each quality assessment criterion was evaluated on a three-point scale as follows:

leftmargin=*

- 0 = Not addressed,
- 1 = Partially addressed or unclear,
- 2 = Fully addressed and well explained.

b) Category weighting: The quality assessment questions were categorized based on their relevance to the research objectives, and each category was assigned a weight corresponding to its importance within the overall evaluation framework.

c) Inclusion threshold: To maintain analytical rigor, a minimum threshold of 50% of the total possible score was established. Studies scoring below this threshold were excluded to ensure that only high-quality and contextually relevant articles were included in the final synthesis.

d) Calculation process: To calculate the overall quality score for each article, a weighted scoring method was applied. Each quality assessment criterion (e.g., relevance, methodology, industry focus, and local context) was assigned a weight based on its relative importance. The total score was derived as the sum of the weighted scores across all criteria, as shown in Eq. (1):

$$\text{Score} = \sum_{i=1}^{n} (w_i \times s_i) \tag{1}$$

where w_i represents the weight assigned to the i^{th} criterion, s_i is the score for the i^{th} criterion, and n is the total number of criteria under evaluation.

3) Quality assessment of studies: The studies that satisfied the inclusion threshold described in Section III-B2c were considered for the final review. Each study was evaluated based on the QA criteria outlined in Section III-B2, with scores assigned according to the system described in Section III-B2a. Final scores were then computed using the weighting and calculation procedures detailed in Sections III-B2b and III-B2d, respectively. Only studies that met the required threshold are presented in Table IV.

C. Synthesis

To enable a comprehensive comparison of the results across the reviewed studies, key categories of information were identified to guide the analysis and synthesis of findings. Given the research focus on cybersecurity education frameworks within the Malaysian context, the critical categories extracted include:

- Cybersecurity framework development in Malaysian higher education
- International standards and local adaptation
- Professional certifications and industry alignment
- Hands-on learning and experiential education

TABLE IV. QUALITY ASSESSMENTS OF STUDIES CONSIDERED FOR INCLUSION

Study	Reference	QA1	QA2	QA3	QA4	Score
S-1	[2]	2	2	2	2	2.00
S-2	[17]	2	2	2	2	2.00

- Cultural and policy considerations
- Industry collaboration and public-private partnerships
- Integration of skills and competencies into cybersecurity education frameworks

This mapping demonstrates that the thematic synthesis provides empirical support for each component in Fig. 5, enabling the development of a context-aware cybersecurity education framework tailored to Malaysia.

These seven categories capture the primary areas of emphasis in cybersecurity education frameworks relevant to Malaysia. The following subsections discuss each in detail, analyzing their significance and incorporation within current frameworks.

1) Cybersecurity framework development in Malaysian higher education: The reviewed studies examine the design, development, and implementation of cybersecurity education frameworks within Malaysian higher education, addressing both theoretical foundations and practical applications.

Several works emphasize pedagogical innovation and curriculum integration. For instance, [1] explores gamified learning through Capture-the-Flag competitions to enhance student engagement and technical proficiency, while [34] presents a hybrid program that combines network security and digital forensics to bridge multidisciplinary gaps. Similarly, [2] investigates the integration of penetration testing into information security curricula to strengthen practical competencies.

Other studies focus on institutional and governance perspectives. [20] proposes an information security framework tailored to Malaysian academic environments, and [6] evaluates the implementation of cybersecurity risk management frameworks across Malaysian universities.

Collectively, these studies underscore growing efforts to align cybersecurity education with both academic standards and industry practices, yet they also reveal the absence of a unified, context-specific national framework guiding higher education institutions in Malaysia.

2) International standards and local adaptation: This category examines how international cybersecurity education standards and models are adapted to align with Malaysia's regulatory, institutional, and cultural contexts. [5] evaluates the integration of global cybersecurity standards within Malaysian university frameworks, emphasizing the need for contextual alignment with national policies. [2] discusses the implementation of penetration testing practices adapted to suit local organizational requirements, highlighting the balance between international best practices and domestic applicability. Similarly, [32] raises concerns regarding the direct transplantation of international programs into local higher education systems without adequate localization.

Collectively, these studies underscore the necessity of customizing international cybersecurity education models to fit Malaysia's specific regulatory environment, institutional capacities, and cultural dimensions, ensuring both global relevance and local effectiveness.

3) Professional certifications and industry alignment: Integrating professional certifications into cybersecurity curricula is a critical step toward producing industry-ready graduates. Certifications such as CISSP, CEH, and CompTIA Security+ not only validate technical proficiency but also serve as standardized indicators of professional competence recognized globally. [28] provides guidelines for embedding these certifications into curriculum design to ensure alignment between academic outcomes and evolving industry standards. Using the Analytic Hierarchy Process (AHP), [4] models

and prioritizes essential skill sets, demonstrating how specific certifications can bridge the gap between theoretical knowledge and workplace requirements. Similarly, [3] emphasizes that aligning curriculum benchmarks with professional certification standards enhances both curriculum relevance and graduate employability.

Overall, the reviewed studies collectively highlight that embedding professional certifications within cybersecurity education supports a dynamic, outcome-oriented learning approach that keeps pace with rapid technological advancements and industry expectations—an essential consideration for developing a Malaysian cybersecurity education framework.

4) Hands-on learning and experiential education: Practical and experiential learning approaches play a vital role in developing competent cybersecurity professionals capable of addressing real-world threats. Several studies emphasize the use of hands-on techniques, such as gamification, secure coding, and virtual simulations, to bridge the gap between theoretical instruction and practical application. [1] utilizes gamified learning through Capture the Flag (CTF) competitions, which enhance student motivation and problem-solving abilities. Similarly, [44] integrates secure coding modules into non-security courses, fostering a broader understanding of cybersecurity principles across disciplines. [30] advocates for virtual laboratories and simulation environments that replicate real-world attack and defense scenarios, enabling students to apply theoretical concepts in controlled settings. Furthermore, [70] highlights the use of gamified cyber ranges to increase engagement and improve hands-on technical proficiency.

Collectively, these studies underscore that experiential learning fosters active engagement, critical thinking, and technical confidence—key competencies for preparing an industry-ready cybersecurity workforce in Malaysia.

5) Cultural and policy considerations: An effective cybersecurity education framework must account for national regulatory structures and institutional cultures to ensure both compliance and contextual relevance. In the Malaysian context, [76] examines how information security culture influences policy implementation in Klang Valley universities, highlighting the importance of fostering a shared understanding of cybersecurity values among academic stakeholders. Similarly, [43] emphasizes the need for regulatory compliance by proposing a framework that integrates information security policies into institutional governance structures.

Together, these studies illustrate that addressing cultural and policy dimensions is essential for developing sustainable cybersecurity education frameworks in Malaysia—frameworks that not only meet technical standards but also align with local values, governance practices, and regulatory expectations.

6) Industry collaboration and public-private partnerships: Collaboration between academia and industry plays a pivotal role in ensuring that cybersecurity curricula remain aligned with evolving workforce demands and technological advancements. The study [34] highlights the importance of government and industry support in the co-development of network security programs, illustrating how such partnerships enhance curriculum relevance and practical skill development. Similarly, [48] reports on the successful integration of a penetration testing module designed in collaboration with industry professionals, which significantly improved students' exposure to real-world cybersecurity challenges.

Collectively, these studies emphasize that effective cybersecurity education in Malaysia depends on sustained engagement between higher education institutions, government agencies, and the private sector. Such collaboration not only strengthens curriculum design but also supports knowledge transfer, internship opportunities, and the development of industry-ready graduates. These findings reinforce the broader categories identified in this review—technical integration, experiential learning, industry collaboration, and local adaptation—as critical components of comprehensive cybersecurity.

7) Integration of skills and competencies into cybersecurity education frameworks: Several studies have examined the identification and integration of essential skills and competencies within cybersecurity education frameworks. The study [34] discusses the development of a hybrid program in Malaysian higher education institutions that combines network security and digital forensic curricula, guided by the ISCIP common body of knowledge to ensure alignment with essential technical competencies. Building on this, [4] explores the skillsets required by the Malaysian cybersecurity job market, proposing a structured competency model based on the Analytical Hierarchy Process (AHP) that emphasizes both technical expertise and soft skills such as communication and teamwork.

At the international level, [3] highlights the significance of professional certifications in shaping cybersecurity curricula, offering a benchmark to align academic programs with recognized industry standards and competencies. Complementing this approach, [51] introduces an interdisciplinary educational framework for cybersecurity workforce development that promotes secure design thinking and integrates emerging knowledge areas through experiential learning.

Collectively, these studies underscore the importance of systematically embedding both technical and non-technical competencies into cybersecurity curricula. Such integration is crucial to ensure that graduates are not only conceptually knowledgeable but also equipped with the practical and adaptive skills required to meet the demands of Malaysia's rapidly evolving cybersecurity landscape.

IV. Findings and Results

A. Data Analysis

Fig. 3 and Fig. 4 illustrates the distribution of studies across thematic categories derived from the synthesis. A quarter of the studies (25%) focused on integrating frameworks and skills into curricula to produce an industry-ready workforce. Another 20% emphasized hands-on learning through practical activities and gamification to enhance cybersecurity education. A total of 17% highlighted the importance of industry collaboration and professional certifications—such as ISC2, CompTIA, GIAC, EC-Council, ISACA, and Offensive Security—in preparing the workforce to address current challenges in the cybersecurity landscape. Similarly, 17% of the studies discussed cultural and contextual factors specific to Malaysia. An additional 15% addressed assessment and evaluation challenges, stressing the need for effective mechanisms to prepare for future demands, while 6% of the studies focused on governance of cybersecurity education.

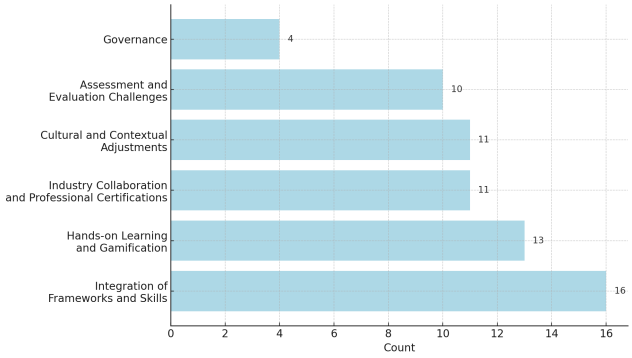

Fig. 3. Category-wise distribution of studies (bar chart).

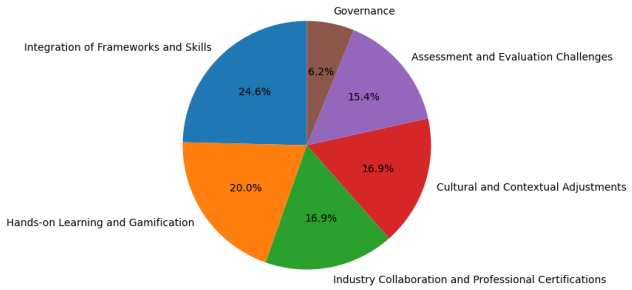

Fig. 4. Category-wise distribution of studies (pie chart).

This distribution underscores an increasing shift toward experiential and competency-based learning but also reveals comparatively limited attention to governance and evaluation mechanisms in Malaysian higher education, indicating potential areas for further development.

B. Key Findings

Building upon the categories discussed earlier in Section III-C, Table V provides a comparative overview of how the selected studies address different components of cybersecurity education in Malaysia. The findings indicate that Malaysian cybersecurity education frameworks are progressively evolving to integrate three core dimensions—technical competencies, policy awareness, and hands-on learning experiences. However, the extent and consistency of this integration vary significantly across institutions.

1) Findings related to RQ1-Current practices in cybersecurity education: The analysis revealed that Malaysian higher education institutions primarily focus on foundational technical skills and international certifications such as CISSP, CEH, and CompTIA Security+. Approximately 25% of the studies reviewed emphasized integrating these elements into the curriculum. However, hands-on learning methods—such as cyber ranges, Capture the Flag (CTF) competitions, and simulations—are inconsistently implemented across institutions. Moreover, few programs incorporate interdisciplinary components, soft skills, or ethical training, despite the industry's growing demand for holistic cybersecurity professionals. There is also a lack of formal evaluation frameworks to assess learning outcomes or curriculum impact.

These findings suggest that while the foundational structure of cybersecurity programs is strong, there is an urgent need to institutionalize experiential learning and competency-based evaluation mechanisms to ensure workforce readiness.

2) Findings related to RQ2-Challenges in curriculum–industry alignment: The review identified several barriers impeding effective alignment between academia and the cybersecurity industry in Malaysia. A key challenge is the limited collaboration between universities and industry partners, which restricts the integration of real-time, workplace-relevant skills into academic programs. Furthermore, many programs rely on global frameworks that do not adequately reflect Malaysia's regulatory requirements, cultural norms, or organizational practices. Only 17% of the reviewed studies explicitly addressed Malaysia-specific issues. The absence of structured industry advisory boards, systematic feedback mechanisms, and agile curriculum revision processes further widens the gap between academic output and industry demand.

This misalignment highlights the need for an adaptive governance mechanism that institutionalizes industry participation in curriculum design, ensuring that cybersecurity graduates meet evolving national and sectoral needs.

3) Findings related to RQ3-Framework improvements and strategic integration: The synthesis of reviewed literature suggests that an effective cybersecurity education framework for Malaysia should integrate modular, competency-based components encompassing technical expertise, policy understanding, and soft skills. Adaptation of global models such as NICE and CyBOK is essential but must be contextualized to Malaysian law, culture, and national cybersecurity strategies. Studies also emphasize the need for formalized partnerships among academia, industry, and government agencies to support curriculum co-development and experiential learning. Strategies such as gamification, internships, and cyber ranges are frequently recommended to promote real-world readiness and industry relevance.

These insights collectively point toward the development of a unified, context-sensitive framework capable of aligning Malaysia's cybersecurity education ecosystem with international best practices while preserving national relevance.

The summarized insights in Table V reinforce that while Malaysia's higher education sector has made notable progress in integrating frameworks and fostering industry partnerships, efforts remain fragmented. A national, standardized framework is therefore required to consolidate these diverse initiatives and ensure consistent competency outcomes across institutions.

C. Summary of Thematic Findings

The synthesis of the reviewed literature across the seven categories reveals a diverse but fragmented landscape of cybersecurity education in Malaysia. Collectively, the studies demonstrate significant progress in areas such as framework development, curriculum enhancement, and the integration of experiential learning. Malaysian universities have begun adopting gamified learning, virtual laboratories, and hybrid programs that merge theoretical instruction with practical exposure. Additionally, the adaptation of international standards and the inclusion of professional certifications, such as CISSP and CEH, reflect efforts to align educational outcomes with industry expectations.

TABLE V. INSIGHTS FROM KEY STUDIES ON CYBERSECURITY EDUCATION FRAMEWORKS: ANALYSIS BY CATEGORY

Category	Key Studies	Insights
Integration of Frameworks and Skills	S-1, S-4, S-15, S-17, S-19, S-27, S-29, S-34	Emphasizes integrating various cybersecurity frameworks in educational programs; aligns curricula with standards and incorporates practical skills for real-world application; recommends developing frameworks considering local industry needs, cultural factors, and Malaysian educational challenges.
Industry Collaboration and Professional Certifications	S-2, S-5, S-18, S-20, S-14, S-24	Highlights collaboration between institutions and industry stakeholders for curriculum relevance; encourages incorporating industry-recognized certifications to enhance employability; promotes partnerships that enable curriculum updates based on industry trends, keeping students current.
Cultural and Contextual Adjustments	S-3, S-10, S-12, S-8, S-23, S-31	Stresses understanding cultural and contextual factors for effective cybersecurity education; suggests adapting curricula to address regional challenges and societal expectations; recommends researching cultural impacts on learning, such as attitudes toward technology and local threat perceptions.
Hands-On Learning and Gamification	S-9, S-16, S-22, S-38, S-40, S-47	Highlights hands-on learning methods, including labs, simulations, and gamification; points to gamification's role in engagement, making learning more enjoyable and effective; advocates for immersive experiences that simulate real-world scenarios, building critical skills.
Assessment and Evaluation Challenges	S-30, S-43, S-54, S-11, S-36	Discusses the importance of effective assessment to measure program success; identifies the need for robust frameworks that accurately reflect learning outcomes; suggests innovative assessments, including project-based and real-world problem-solving tasks.
Governance	S-21, S-25, S-45, S-61, S-62	Encompasses policies, regulations, and ethical guidelines for cybersecurity education; emphasizes clear governance to support cybersecurity initiatives in higher education; calls for research into best practices, ensuring accountability and compliance with standards.

However, the review also highlights persistent challenges. Many initiatives remain institution-specific, lacking a unified national strategy or a standardised competency framework aligned with industry needs. While technical competencies are widely addressed, soft skills, management capabilities, and policy-level understanding receive comparatively less emphasis. Furthermore, few studies explicitly link educational frameworks to measurable job-readiness outcomes or industry performance indicators.

In summary, existing research underscores the importance of integrating technical, professional, and contextual competencies within cybersecurity curricula but reveals the absence of a cohesive framework tailored to Malaysia's educational and industrial ecosystem. This gap justifies the need for a structured and validated cybersecurity education framework that bridges academia and industry, ensuring that future graduates are both technically proficient and workforce-ready.

D. Proposed Cybersecurity Education Framework

Fig. 5 presents the Proposed Cybersecurity Education Framework for Malaysian Higher Education, synthesised from the literature review. The framework integrates industry requirements, competencies, and curriculum design to address the persistent gap between academia and the Malaysian cybersecurity workforce landscape.

At the upper level, the framework distinguishes between *Technical* and *Generic* (soft) skill domains. These domains shape three core components: *Knowledge and Skills*, *Tasks*, and *Competencies*. These components form the foundation of *Industry Requirements*, which is positioned at the centre of the framework. It reflects the finding that industry expectations serve as the primary driver of curriculum relevance and program design. In addition, to complement the skill domain structure of the framework, Fig. 6 provides a detailed breakdown of the technical competencies required by the Malaysian cybersecurity industry. The *Generic Competencies* encompass essential soft skills sought by the industry, including strong problem-solving ability, teamwork and collaboration skills,

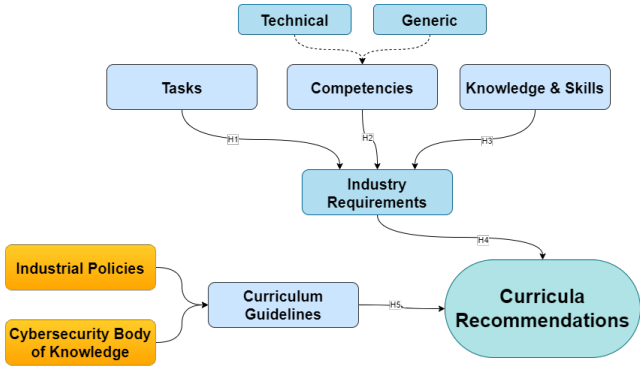

Fig. 5. Proposed Cybersecurity Education Framework synthesised from thematic findings. The framework aligns tasks, competencies, and knowledge–skills with industry requirements, guided by industrial policies and cybersecurity bodies of knowledge, resulting in actionable curriculum guidelines and recommendations for Malaysian higher education institutions.

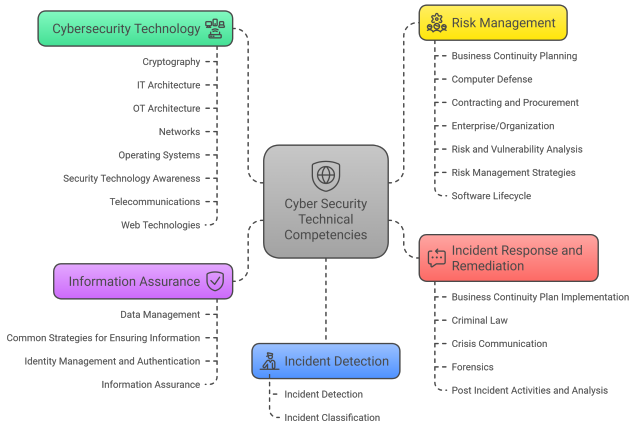

Fig. 6. List of technical competencies required by the Malaysian cybersecurity industry.

curiosity and eagerness to learn, strong communication skills, strategic thinking, project management skills, and effective time management and organization.

The framework is informed by two major external reference sources: *Industrial Policies* and *Cybersecurity Bodies of Knowledge* (e.g., CyBOK, NIST, specialised domain standards). These sources guide the formulation of *Curriculum Guidelines*, which operationalise industry requirements into implementable academic structures such as course design, learning outcomes, practical training components, and assessment strategies.

The integration of all inputs results in the generation of *Curricula Recommendations*, representing the actionable educational outputs of the framework, including curriculum revisions, certification-aligned modules, enhancement of hands-on learning components, and the establishment of industry collaborations.

How each thematic finding informs the framework:

- Cybersecurity Framework Development in Malaysian Higher Education: This theme underpins the entire structure. The progression from "Tasks–Competencies–Knowledge & Skills" toward "Curriculum Guidelines" and ultimately "Curricula Recommendations" reflects a structured cybersecurity curriculum development process tailored to Malaysian institutions.
- International standards and local adaptation: Represented in the "Cybersecurity Body of Knowledge" and "Industrial Policies" components, the framework incorporates global standards (CyBOK, NIST NICE, ISO) alongside Malaysian strategies such as MyDIGITAL and the National Cyber Security Policy.
- Professional certifications and industry alignment: Evident in the central "Industry Requirements" component and in "Curriculum Guidelines," which embed certification expectations (e.g., CISSP, CompTIA, CEH) as academic learning outcomes.
- Hands-on Learning and Experiential Education: Embedded in the "Knowledge & Skills" and "Competencies" components, driving recommendations such as cyber ranges, laboratories, CTF participation, and simulated incident response exercises.
- Cultural and Policy Considerations: Captured in the "Industrial Policies" component, ensuring alignment with Malaysian governance structures, organisational cultures, and national development priorities.
- Industry Collaboration and Public–Private Partnerships: This theme reinforces the centrality of "Industry Requirements" and supports the need for sustained partnerships through internships, expert co-teaching, industry advisory boards, and knowledge transfer programmes.
- Integration of Skills and Competencies into Cybersecurity Education Frameworks: Illustrated through the categorisation of Technical and Generic skill domains, which feed directly into competency development and curriculum design for a holistic graduate capability profile.

V. Discussion

This systematic literature review (SLR) evaluates the current state of cybersecurity education in Malaysia, revealing both significant progress and enduring challenges. While many academic programs incorporate globally recognized certifications such as CISSP and CISM, they often lack systematic alignment with Malaysia-specific regulatory frameworks, cultural contexts, and evolving industry demands. This misalignment constrains the preparedness of graduates for real-world cybersecurity challenges.

The analysis highlights that hands-on learning strategies—such as cyber ranges, Capture the Flag (CTF) competitions, and gamification—are inconsistently adopted across higher education institutions. This uneven application results in varied levels of practical competency among graduates. Standardizing experiential learning practices is therefore essential to ensure that all students develop the applied skills necessary to operate effectively in Malaysia's cybersecurity landscape. Moreover, many curricula remain static and fail to address emerging threats, new technologies, and the dynamic nature of the cybersecurity profession, thereby weakening their relevance to industry needs.

A recurring theme across the reviewed literature is the persistent disconnect between academic training and industry expectations. Industry engagement in curriculum development remains sporadic, with few structured partnerships or advisory mechanisms in place. As a result, feedback from employers and cybersecurity practitioners is not systematically integrated into educational design. The absence of robust assessment and evaluation frameworks further limits the ability to measure student proficiency and readiness for professional roles.

To address these gaps, future research and policy initiatives should focus on developing a comprehensive, Malaysia-specific cybersecurity education framework. Such a framework should harmonize global best practices—such as those derived from CyBOK and NICE—with local cultural, regulatory, and industrial contexts. It should also embed mechanisms for continuous curriculum review, stakeholder collaboration, and adaptive learning strategies responsive to technological advancements.

Furthermore, engaging industry experts through structured interviews and collaborative research initiatives can provide empirical insights into the competencies most valued in the Malaysian cybersecurity workforce. These insights can inform curriculum redesign, ensuring that future programs produce graduates equipped with both technical expertise and the adaptive, problem-solving skills required to meet Malaysia's growing cybersecurity challenges.

VI. Conclusion and Future Research Directions

This systematic literature review evaluated the current landscape of cybersecurity education in Malaysia, synthesizing insights from 65 academic and gray literature sources. The review found that while Malaysian higher education institutions have made progress in embedding technical competencies

and adopting global certifications, several critical gaps persist. These include limited experiential learning opportunities, insufficient contextual integration of local policies and cultural factors, and a lack of consistent industry-academia collaboration.

The study underscores the urgent need for a Malaysia-specific cybersecurity education framework that aligns academic curricula with industry demands while addressing national cultural and regulatory contexts. In particular, the findings highlight the importance of developing a framework that integrates hands-on pedagogical approaches, incorporates ethical and policy literacy, and reflects dynamic competency requirements as defined by both national priorities and global standards.

Future research should focus on the empirical validation of the proposed educational framework through expert interviews, surveys, or case studies. Further exploration is also needed to examine the implementation and effectiveness of experiential learning models—such as cyber ranges, gamified environments, and real-world simulations—in enhancing competency development. Continued collaboration between academic, industrial, and governmental stakeholders will be essential to sustain progressive improvements in Malaysia's cybersecurity education ecosystem.

VII. Declarations

A. Availability of Data and Material

The data used and analysed during this systematic literature review are available from the corresponding author upon reasonable request. All sources utilized in this review are publicly accessible, and references to the respective papers are provided within the manuscript.

B. Funding

This research received no external funding or financial support. The work was part of the author's ongoing academic studies.

C. Declaration of AI Assistance

The author acknowledges the use of OpenAI's ChatGPT (GPT-5) to support language refinement and structural editing in this manuscript.

Bit Stability and Hash-Length Trade-Offs in Binary Face Templates

Abdelilah Ganmati, Karim Afdel, Lahcen Koutti
Computer Systems and Vision Laboratory-Faculty of Sciences, Ibn Zohr University, Agadir, Morocco

***Abstract*—Binary face templates are an appealing alternative to floating-point embeddings for face verification in resource-constrained environments because they enable constant-time Hamming matching with minimal storage and input/output (I/O). This paper studies the bit-level behavior of hashes obtained by principal component analysis followed by iterative quantization (PCA–ITQ) at $L \in \{32, 64, 128\}$ derived from a frozen lightweight face encoder. Using subject-disjoint splits on the MORPH longitudinal dataset and an eyeglasses stress protocol on CelebA, the analysis quantifies 1) bit balance and entropy, 2) within-identity bit stability via per-bit flip rates, and 3) verification performance at low false-accept rates in Hamming space. On MORPH, 64-bit PCA–ITQ codes achieve an area under the receiver operating characteristic curve (AUC) of 0.9978 and a true positive rate (TPR) of 96.5% at a false positive rate (FPR) of 1%, compared to 99.1% at 128 bits, while halving the template length; 32-bit codes remain feasible but drop to 85.7% at the same operating point and are more sensitive to nuisance variation. Across both datasets, codes are near-balanced and mostly stable, yet a small minority of bit positions accounts for most flips under the eyeglasses attribute. In this regime, 64-bit hashes offer a favorable size–accuracy trade-off, whereas 128-bit hashes approximate float-embedding behavior and 32-bit hashes require redundancy or additional robustness mechanisms. All evaluations use fixed seeds and subject-disjoint splits; thresholds are selected on validation and held fixed on test to reflect deployment conditions.**

***Keywords*—Binary face templates; face verification; hamming distance; PCA-ITQ; bit stability; eyeglasses attribute; resource-constrained verification; MORPH; CelebA**

I. Introduction

Compact binary face templates are attractive substitutes for floating-point embeddings because they enable deterministic Hamming matching with minimal storage and bandwidth. A widely used route—principal component analysis followed by an orthogonal rotation and element-wise sign (PCA–ITQ)—yields short codes while keeping the mapping deterministic and easy to deploy [1]. Yet shortening the code (e.g., to 32–128 bits) raises questions that are under-reported in biometric verification: *How balanced and informative are individual bit positions?* and *which bits are stable within an identity under common nuisance factors?*

Most hashing work emphasizes retrieval metrics or ranking quality [2], [3], [4], [5]; however, privacy-preserving verification is ultimately governed by bit-level behavior—entropy, balance, and within-identity flip-rates—which determines feasible operating thresholds. Furthermore, the renewability/diversity requirements for protected templates [6], [7] benefit from knowing *where* instability concentrates so that mitigation (e.g., masking) can be targeted rather than uniform.

Problem setting and datasets. Using the MORPH longitudinal database as the primary benchmark and CelebA for attribute-conditioned stress tests (eyeglasses) [9], [10], this study examines binary templates produced from a single frozen mobile-class encoder after standard five-point alignment and PCA–ITQ binarization to $L \in \{32, 64, 128\}$. The analysis covers: 1) distributional properties of individual bits (balance, entropy) as a function of L; 2) within-identity flip-rates; and 3) localization of instability under attribute change (eyeglasses) and its impact on ROC-level operating points in Hamming space.

Novelty relative to prior PCA–ITQ and hashing work. Previous work on PCA–ITQ and deep hashing has mostly reported aggregate retrieval or verification metrics at the code level, such as mean average precision, AUC, or Equal Error Rate (EER) [1], [2], [3], [4], [5]. In contrast, the present study is explicitly designed as a *bit-level* analysis of binary face templates under resource constraints. The key distinctive elements are:

- a systematic characterization of per-bit balance, entropy, and within-identity stability for $32/64/128$-bit PCA–ITQ templates, with the upstream encoder and alignment pipeline held fixed;
- an attribute-localized stress protocol on CelebA that isolates the effect of eyeglasses on per-bit flip-rates and relates the induced instability to low-FAR operating points;
- an operational mapping from observed bit statistics to hash-length choices and threshold selection for privacy-preserving verification in smart-card or embedded settings.

These aspects complement earlier work on mobile-class CNNs and binary hashes for smart-card-constrained authentication [11], ageing drift in binary templates [15], and targeted parity mechanisms for unstable bits [18], by focusing specifically on how bit-level statistics shape feasible operating points for short hashes.

The main contributions can be summarized as follows:

- Bit-level characterization across code lengths. Bit balance, entropy, and within-identity stability are quantified for $L \in \{32, 64, 128\}$ and related to verification performance on MORPH, revealing a favorable size–accuracy frontier at 64 bits.
- Attribute-localized stress test. An eyeglasses protocol on CelebA shows that degradation is concentrated in

a minority of bit positions, rather than uniformly distributed, which supports targeted mitigation strategies.

- Operational guidance grounded in measurements. The measured flip-rate profiles are mapped to threshold selection at low false-accept rates and to practical recommendations on hash length, enrollment redundancy, and template renewability in privacy-preserving systems, in line with ISO/IEC 24745 [6].

II. Related Work

1) Alignment and deep embeddings: Modern face verification maps aligned crops to ℓ_2–normalized embeddings via frozen encoders; robust alignment is a prerequisite to stabilize downstream representations. The experiments adopt the widely used Multitask Cascaded Convolutional Networks (MTCNN) detector with five-point similarity alignment to produce canonicalized inputs [8].

2) Hashing and binary codes: Hashing for visual descriptors spans randomized families such as locality-sensitive hashing (LSH) and SimHash [2], [12], spectral/graph constructions [3], and deep supervised variants (e.g., DPSH, HashNet) [4], [5], with broader overviews in recent surveys [19]. For deployment-constrained verification, deterministic and lightweight transforms are attractive. PCA followed by Iterative Quantization (ITQ) [1] minimizes quantization error under an orthogonal rotation prior to sign binarization, yielding short codes amenable to constant-time Hamming scoring. Beyond classical PCA–ITQ, hybrid quantum PCA methods have been explored to accelerate face verification pipelines [21], and fairness-aware binary descriptors have been proposed for face presentation attack detection using local binary patterns [22]. This paper uses PCA–ITQ specifically to study how *code length* ($L \in \{32, 64, 128\}$) interacts with *per-bit* balance and stability when the upstream encoder is held fixed. The analysis also builds on a prior benchmark of PCA–ITQ binary templates under embedded constraints by the same authors, which established protocol and topline baselines; here the focus is shifted to per-bit balance/stability and attribute-localized robustness [11].

3) Multimodal biometric fusion: Convolutional neural network (CNN)-driven multimodal fusion of face, fingerprint [20], and voice has become increasingly common to enhance robustness under occlusion or sensor variability [23], [24], [25]. Although the present study remains unimodal (face only), the findings on bit stability and attribute-specific drift help clarify how individual face templates might contribute within a larger fusion framework.

4) Protected biometric templates: Template-protection standards emphasize irreversibility, renewability, and unlinkability [6]. Cancelable-biometrics schemes implement parameterized transforms so compromised templates can be reissued without reacquisition [7]. Template interfaces are often kept conservative to limit oracle leakage, and renewability/diversity are handled via cancelable transforms [6], [7]. These works motivate compact binary representations and conservative interfaces, but typically report aggregate ROC/EER at the *code level* rather than analyzing *statistics of individual bit positions*. Recent system-level studies on deep learning-based multifactor authentication and ISO/IEC-compliant match-on-card face verification further illustrate how compact templates and conservative interfaces can be combined in practice [17], [16].

5) Bit-level behavior: Despite the prevalence of binary hashing, systematic measurements of *bit balance*, *within-identity flip rates*, and *attribute-localized instability* (e.g., eyeglasses) remain scarce in the above literatures [2], [3], [4], [5], [6], [7]. Our study targets this gap by quantifying per-bit statistics across $L \in \{32, 64, 128\}$ and relating them directly to operating-point selection in Hamming space.

6) Datasets and protocol: Following established practice, we use *MORPH* as the primary benchmark for verification under longitudinal variability [9] and *CelebA* for attribute-conditioned stress tests (eyeglasses) [10], with a unified MTCNN alignment pipeline [8]. This setup isolates bit-level phenomena independently of classifier tuning.

7) Positioning: Relative to prior art, we keep the encoder and binarizer fixed (single frozen encoder + PCA–ITQ) and move the analytical lens from aggregate ROC summaries to *per-bit* statistics and their operational consequences—precisely the level that governs hash-length choice, threshold setting, and renewal/diversity policies in protected template deployments [6], [7].

III. Methods

A. Data and Splits

1) MORPH (primary): Subject–disjoint splits are formed with identities reserved for threshold selection (validation) and final reporting (test) on longitudinal images [9]. No identity appears in more than one partition.

2) CelebA (eyeglasses stress): Using the official attribute annotations [10], the protocol constructs per–identity pairs that differ only in the `Eyeglasses` attribute (present vs. absent). CelebA identities used for stress testing are disjoint from MORPH identities.

B. Preprocessing and Embeddings

Aligned face crops are produced via standard five–landmark similarity alignment. Aligned images are passed through a *frozen* encoder to obtain ℓ_2–normalized float embeddings. No fine–tuning or test-time augmentation is used. This protocol fixes upstream variability so that downstream analyses isolate bit–level phenomena. The alignment/embedding/hashing setup follows a previously reported benchmark by the same authors and is kept frozen here [11].

C. Binarization: PCA–ITQ

Given an encoder output $\mathbf{f} \in \mathbb{R}^{d_{\text{enc}}}$, we compute

$$\mathbf{x} = (\mathbf{f} - \boldsymbol{\mu}) W_{\text{PCA}} \in \mathbb{R}^L,$$

$$\mathbf{z} = \mathbf{x} R,$$

$$\mathbf{b} = \operatorname{sign}(\mathbf{z}) \in \{-1, +1\}^L, \qquad L \in \{32, 64, 128\},$$

where W_{PCA} retains the top-L principal components fitted on *training* identities only, and R is the orthogonal rotation learned by Iterative Quantization (ITQ) to minimize $\|\mathbf{B} - \mathbf{X}R\|_F^2$ subject to $R^\top R = \mathbf{I}$ with $\mathbf{B} \in \{-1,+1\}^{N\times L}$ [1]. We map $\{-1,+1\} \to \{0,1\}$ and pack bits MSB–first. PCA fitting and ITQ initialization use fixed random seeds.

D. Mathematical Formulation and Decision Metrics

1) Hamming scoring and decision: Let $\mathbf{b}_{\mathrm{enr}}, \mathbf{b}_{\mathrm{prb}} \in \{0,1\}^L$ be enrolled and probe codes. The Hamming distance is

$$D_H(\mathbf{b}_{\mathrm{enr}}, \mathbf{b}_{\mathrm{prb}}) = \sum_{k=1}^{L} \big[b_{\mathrm{enr},k} \oplus b_{\mathrm{prb},k}\big]. \tag{1}$$

A verifier with threshold τ accepts iff $D_H \le \tau$.

a) Operating characteristics: Let $\mathcal{P}^+$ and $\mathcal{P}^-$ be sets of genuine and impostor pairs. Then

$$\mathrm{TPR}(\tau) = \Pr\big[D_H \le \tau \,\big|\, \mathcal{P}^+\big], \tag{2}$$
$$\mathrm{FPR}(\tau) = \Pr\big[D_H \le \tau \,\big|\, \mathcal{P}^-\big], \tag{3}$$
$$\mathrm{FNR}(\tau) = 1 - \mathrm{TPR}(\tau). \tag{4}$$

The receiver operating characteristic (ROC) traces $(\mathrm{FPR}(\tau), \mathrm{TPR}(\tau))$; the Equal Error Rate (EER) satisfies $\mathrm{FPR}(\tau^\star) \approx \mathrm{FNR}(\tau^\star)$. We also report $\mathrm{TPR@FPR} = \alpha$ (e.g., $\alpha = 1\%$).

b) Bit balance and entropy: For bit k,

$$m_k = \frac{1}{N}\sum_{n=1}^{N} b_{nk}, \qquad p_k = \tfrac{1+m_k}{2}, \tag{5}$$
$$H_k = -p_k \log_2 p_k \;-\; (1-p_k)\log_2(1-p_k). \tag{6}$$

Well-behaved codes have $m_k \approx 0$ and $H_k \approx 1$ bit.

c) Within–identity stability and eyeglasses sensitivity: For same-identity pairs $\mathcal{S}$, the per-bit flip-rate is

$$\phi_k = \frac{1}{|\mathcal{S}|} \sum_{(i,j)\in\mathcal{S}} \mathbb{1}\big[b_{ik} \neq b_{jk}\big]. \tag{7}$$

On CelebA, compute $\phi_k^{(\mathrm{glass})}$ on cross-condition pairs (with vs. without eyeglasses) and $\phi_k^{(\mathrm{ctrl})}$ on same-condition pairs. The difference $\Delta\phi_k = \phi_k^{(\mathrm{glass})} - \phi_k^{(\mathrm{ctrl})}$ localizes eyeglasses-induced instability.

E. Eyeglasses Stress Protocol (CelebA)

For identities with both conditions, cross–condition pairs are formed to isolate attribute-induced instability and same–condition controls are used to factor out identity/time variance. We compare the distributions of $\{\phi_k^{(\mathrm{glass})}\}$ and $\{\phi_k^{(\mathrm{ctrl})}\}$ and quantify their impact on ROC/EER at each L.

Input: MORPH (train/val/test), CelebA (eyeglasses splits); $L \in \{32, 64, 128\}$; optional instability quota q (masking)
Output: Bit statistics and verification metrics (ROC/AUC, EER, TPR@FPR=1%)
Initialize $\boldsymbol{\mu}$, W_{PCA} (top L), ITQ rotation R (fixed seeds)
Fit PCA–ITQ on MORPH train; learn R by ITQ [1]
for each $L \in \{32, 64, 128\}$ **do**
  Validation (MORPH): binarize; sweep τ; record $\tau^\star$ (AUC/EER)
  Bit statistics (MORPH): compute m_k, H_k, and flip-rate ϕ_k
  Eyeglasses (CelebA): cross- vs same-condition; compute $\phi_k^{(\mathrm{glass})}$, $\phi_k^{(\mathrm{ctrl})}$, $\Delta\phi_k$
  if masking enabled **then**
    rank by instability; define mask $\mathcal{M}$ (top-q%); re-estimate $\tau^\star_{\mathrm{mask}}$ on $\overline{\mathcal{M}}$
  end if
  Test (MORPH): evaluate baseline (and masked) with frozen thresholds
  Report (CelebA): summarize $\{\phi_k^{(\mathrm{glass})}\}$ vs $\{\phi_k^{(\mathrm{ctrl})}\}$ and relate to MORPH operating points
end for

Fig. 1. Protocol for bit-level analysis and verification.

TABLE I. MORPH: EFFECT OF BIT LENGTH L (PCA-ITQ)

L (bits)	AUC	EER (%)	TPR@1% (%)	TPR@0.1% (%)
128	0.9994	0.90	99.13	96.64
64	0.9978	2.04	96.52	88.96
32	0.9887	5.17	85.68	49.02

F. Scoring and Operating Points

For each $L \in \{32, 64, 128\}$ a single threshold τ is set on the MORPH validation ROC and then applied unchanged to the MORPH test split. CelebA is used to report bit-level stability and to assess how eyeglasses-conditioned instability correlates with shifts in operating points (thresholds remain those fixed on MORPH validation).

G. Reproducibility and Privacy Context

All random choices (PCA/ITQ seeds, pair sampling) are fixed; identities are disjoint across train/validation/test; and CelebA attribute pairing follows the official annotations [10]. The discussion touches on renewability and diversity of templates in the sense of ISO/IEC 24745 [6], [7], but deliberately excludes transport or on-card API details from this short paper.

The complete protocol, including training of PCA–ITQ, threshold calibration, bit-statistics computation, and CelebA stress testing, is summarized in Fig. 1.

IV. RESULTS

All evaluations follow Section III. Thresholds are selected on MORPH validation and held fixed for the corresponding test reports unless stated otherwise. When shown, confidence intervals are nonparametric (percentile; 10,000 bootstrap resamples).

A. Hash Length vs. Verification on MORPH

Takeaway. A 64-bit template offers a strong size–accuracy trade-off: near-saturated AUC with $\sim 2\times$ smaller footprint than 128-bit, at a modest cost at FPR$= 0.1\%$. The 32-bit regime substantially narrows the genuine–impostor margin.

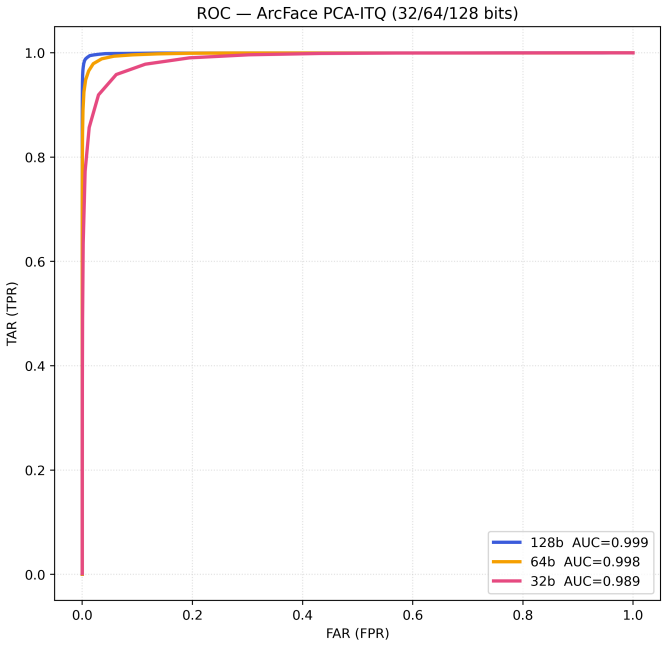

Fig. 2. MORPH ROC at $L \in \{32, 64, 128\}$ (PCA–ITQ). Global view complements the low-FAR zoom in Fig. 3.

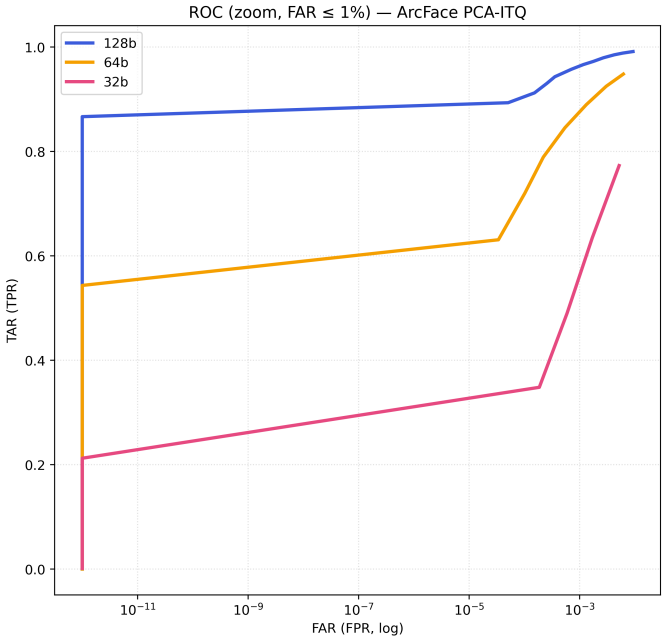

Fig. 3. MORPH ROC zoomed to FPR $\leq 1\%$ for $L \in \{32, 64, 128\}$ (PCA–ITQ). The 64-bit code retains most of the 128-bit low-FPR advantage; 32-bit degrades at strict FPR.

Fig. 2 shows the global ROC curves on MORPH for $L \in \{32, 64, 128\}$, while Fig. 3 zooms into the low-FAR region (FPR $\leq 1\%$) that is most relevant for deployment. Overall, these results indicate that moving from 128 to 64 bits yields a nearly two-fold reduction in template size with only a modest drop in low-FAR performance (about 2.6 percentage points at FPR=0.1%), whereas the transition from 64 to 32 bits incurs

TABLE II. BIT STATISTICS AND OPERATING THRESHOLDS ON MORPH. MEAN BALANCE IS THE ONES RATIO; STABILITY IS MEAN WITHIN-ID AGREEMENT

L	Mean balance	Mean stability	τ_{EER}	EER (%)	$\tau_{1\%}$ / TPR@1%
32	0.5016	0.876	5	41.19	3 / 17.65
64	0.5011	0.868	15	16.66	13 / 63.88
128	0.5003	0.860	37	5.33	35 / 91.66

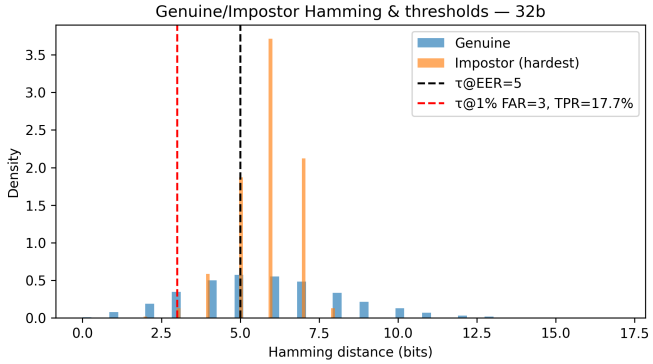

Fig. 4. MORPH (32-bit): Genuine vs. hardest impostor with τ_{EER} and $\tau_{1\%}$. Shows margin compression relative to 64-bit (Fig. 5).

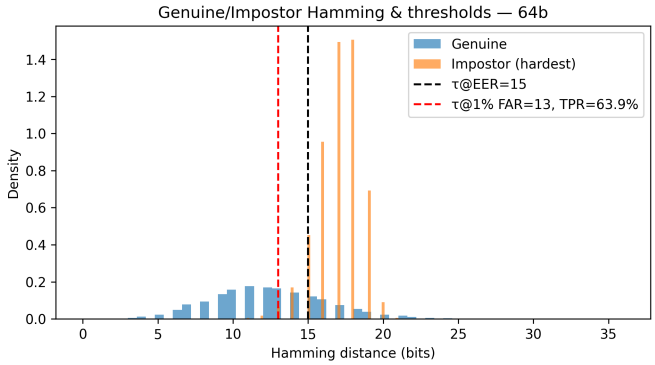

Fig. 5. MORPH (64-bit): Hamming distributions for genuine vs. hardest impostor with τ_{EER} and $\tau_{1\%}$ marked. Visualizes the margin underlying Table II.

a much sharper loss (around 39.9 percentage points at the same operating point). This pattern is consistent with previous observations that excessively short binary codes compress both intra-class and inter-class variation [1], [11], and it provides concrete bounds for deployments that must trade memory and I/O against verification accuracy.

B. Bit Balance, Stability, and Operating Points

Observation. Codes remain well balanced ($\approx$0.5) across L; stability declines only mildly with longer codes. Operating points are governed by the shift of genuine mass relative to hardest impostors (Fig. 5).

C. CelebA Stress Tests and Alignment Effects

1) Eyeglasses Paired stability and localization: Finding. Eyeglasses increase flip-rates modestly on average (Table IV),

TABLE III. CELEBA (UNALIGNED VS. ALIGNED): MEAN STABILITY, EER, AND TPR@1%. ALIGNMENT YIELDS A SMALL BUT CONSISTENT BENEFIT AT 64 BITS

Setting	L	Stability	EER	TPR@1%
Unaligned	32	0.889	0.220	0.472
Unaligned	64	0.846	0.209	0.582
Unaligned	128	0.799	0.274	0.455
Aligned	32	0.893	0.264	0.408
Aligned	64	**0.856**	**0.196**	**0.591**
Aligned	128	0.804	0.259	0.555

L	Off	On	Δ (95% CI)	$\tau_{1\%}$	TPR@1%	τ_{EER}/EER
32	0.899	0.887	**+0.012** [+0.0026,+0.0214]	4	0.269	8 / 0.382
64	0.870	0.854	**+0.016** [+0.0096,+0.0228]	15	**0.326**	21 / **0.302**
128	0.819	0.815	+0.004 [–0.0015,+0.0097]	40	0.288	48 / 0.386

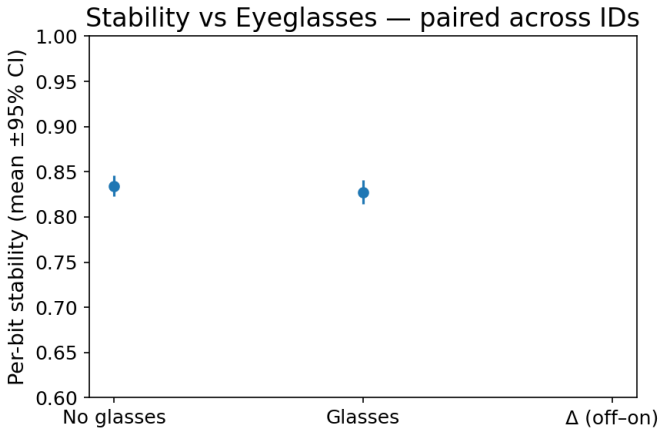

Fig. 6. CelebA (aligned): Per-bit stability (mean ±95% CI) with eyeglasses off vs. on. Instability is concentrated in a minority of positions.

but the effect is localized (Fig. 6), supporting targeted mitigation.

V. DISCUSSION

A. From Bit Statistics to Operating Points

The measurements link per–bit behavior to verification outcomes in a simple margin model. Let D_H^- denote impostor Hamming distance and D_H^+ genuine Hamming distance. For random, independent codes with mean balance ≈ 0.5, $D_H^- \sim \mathrm{Binom}(L, 0.5)$, so $\mathbb{E}[D_H^-] = L/2$ and $\mathrm{sd}(D_H^-) = \sqrt{L}/2$. Genuine distance can be written $D_H^+ = \sum_{k=1}^{L} X_k$ with $X_k \sim \mathrm{Bernoulli}(\phi_k)$, where ϕ_k is the within–ID flip–rate of bit k. Thus

$$\mathbb{E}[D_H^+] = \sum_k \phi_k, \qquad \mathrm{sd}(D_H^+) = \sqrt{\sum_k \phi_k(1-\phi_k)}.$$

Separation at a fixed FAR is governed by the gap $\Delta = \mathbb{E}[D_H^-] - \mathbb{E}[D_H^+]$ relative to the spreads. Increasing L moves *both* means apart, but also increases impostor concentration ($\propto \sqrt{L}$). Empirically, (Table II) higher L reduces EER because the impostor distribution tightens, whereas too small L (32 b) narrows Δ sharply and hurts low-FAR TPR. This explains *why* 64 b sits on a favorable size–accuracy frontier on MORPH (Table I) and why 128 b minimizes EER when footprint is less constrained. Compared to the benchmark-level study in [11], which contrasted different mobile-class encoders and hash lengths primarily via aggregate ROC and EER metrics, the present analysis exposes how a small subset of unstable bits dominates the degradation when codes are shortened. This observation aligns with the ageing-drift patterns reported for binary templates in [15], and it provides the statistical rationale for targeted error-correction schemes such as the unstable-bit Reed–Solomon approach in [18]. In contrast to general surveys on biometric hashing and template protection [19], [13], [14], the current work quantifies the bit-level conditions under which short codes (32–64 bits) remain viable in privacy-preserving, decision-only settings.

B. Attribute Localization and Alignment

Eyeglasses increase mean flip-rates only modestly (Table IV) but the effect is *concentrated* in a minority of positions (Fig. 6). This structured instability validates the premise of targeted mitigation. Alignment yields a small but consistent benefit at 64 b (Table III), suggesting that canonicalization reduces attribute spillover into otherwise stable positions—useful when parity budgets are tight.

C. Practical Guidance for Deployment

- Code length: Use L=64 as a default when template footprint and I/O are constrained; choose L=128 when minimizing EER is paramount and memory allows.
- Enrollment: Prefer $n \geq 3$ enrollment samples to stabilize estimates and reduce variance of genuine comparisons.
- Mitigation: Avoid large masks: small quotas may help at lenient thresholds, but aggressive masking collapses discrimination at low FAR.
- Thresholds: Calibrate a single τ per L on validation and freeze it for test to maintain reproducibility and operational simplicity.

D. Security and Privacy Considerations

The present study focuses on representation and decision statistics, not protocol hardening. That said, compact binary templates with near-balanced bits limit leakage from simple score-based queries. Refreshing the unstable-bit set $\mathcal{U}$ enables diversification and renewability in the spirit of template protection standards [6], while preserving unlinkability when identifiers are rotated. A thorough adversarial analysis (e.g., score-oracle exploitation, side-channel I/O) is orthogonal and left to the companion system paper.

E. Limitations and External Validity

The upstream encoder is intentionally fixed and the analysis focuses on MORPH (longitudinal) and CelebA (eyeglasses) to isolate bit-level effects. Outcomes may differ with other

encoders, demographics, or attributes (e.g., occlusions beyond glasses). CelebA attribute labels carry annotation noise; nevertheless, the localization effect is strong enough to survive that noise. Finally, parity was explored on short Reed–Solomon (RS) designs over a small unstable window; other lightweight constructions may offer different trade-offs.

F. Implications and Next Steps

Bit-level analysis is actionable: 1) it explains the observed hash-length trade-off through a margin lens, 2) it shows that instability is structured, not uniform, and 3) it motivates *localized* robustness that preserves discrimination. Potential next steps include extending attribute stress beyond eyeglasses, learning encoder-aware rotations that explicitly balance stability and entropy at target L, and evaluating parity/masking under formal privacy budgets and attack models.

Bottom line. Binary codes from a fixed encoder are already well balanced and mostly stable; the errors that matter come from a small, identifiable subset of bits. Masking discards signal and saturates quickly. For constrained deployments, 64 b with $n\geq 3$ enrollment samples is a principled operating point; 128 b is the accuracy ceiling when resources permit.

VI. Conclusion

This paper analyzes binary face templates produced by PCA–ITQ from a fixed, mobile-class encoder across hash lengths $L \in \{32, 64, 128\}$, linking *per-bit* statistics to verification behavior. Empirically, codes are near-balanced and mostly stable; the residual errors are driven by a small, identifiable subset of positions whose flip-rates rise under attribute change (eyeglasses). This structure explains the observed hash-length trade-off on MORPH and CelebA: 64 bits sit on a favorable size–accuracy frontier, while 128 bits minimize EER when footprint allows; 32 bits generally require redundancy.

Simple masking removes both noise and identity signal and saturates, especially at strict FPR.

- Guidance: For constrained deployments, use $L{=}64$ with $n\geq 3$ enrollment samples; prefer $L{=}128$ when accuracy dominates. Monitor per-bit flip profiles to refresh the unstable set and preserve renewability.
- Limitations and outlook: The study fixes the encoder and focuses on MORPH (longitudinal) and CelebA (eyeglasses). Extending to additional attributes and demographics, learning rotations that trade entropy for stability at target L, and formalizing adversarial/privacy analyses are promising next steps. We release manifests and pairing lists to support reproducibility and independent verification.

Acknowledgment

The authors thank colleagues at the Laboratory of Computer Systems and Vision (LabSIV), Faculty of Sciences of Agadir, Doctoral Studies Center, Ibn Zohr University, for helpful discussions and feedback on this work.

Access to the MORPH dataset was provided under an academic license to Ibn Zohr University for research use [9]; CelebA is publicly available for non-commercial research [10]. The authors also acknowledge the creators and maintainers of the tools used in the pipeline, including MTCNN for alignment [8] and PCA–ITQ for hashing [1].

Declaration on Generative AI

A language model was used for copy-editing and formatting assistance; all experimental design, analyses, and conclusions were conducted and verified by the authors.

***Abstract*—You Only Look Once (YOLO) object detection network has gained significant adoption in the field of plant leaf disease detection due to its strong detection capabilities. However, deploying YOLO models on resource-constrained devices remains challenging, as they require substantial computational power. The complexity and size of these models pose significant obstacles for edge platforms, which are often limited in processing and memory resources. To address these limitations and accelerate inference, we propose a quantized version of YOLOv5x, called Quant-YOLOv5x. This quantization reduces the size and complexity of the model, making it more suitable for edge deployment while maintaining competitive detection accuracy. The experiments were carried out using a self-generated dataset focused on detecting tomato and pepper leaf diseases. Our quantization method reduces the bitwidth of the entire YOLO network to 8 bits, resulting in only a 2.8% decrease in mean Average Precision (mAP), a 50% reduction in model size, and an increase of 4.7 FPS compared to the standard YOLOv5 model.**

Keywords*—Object detection; plant disease; quantization technique; YOLOv5

I. Introduction

In Tunisia, the agricultural sector plays a vital role in both the economy and the sociopolitical landscape, significantly contributing to national objectives such as food security, income generation, employment, and sustainable resource management. Among key crops, tomatoes and peppers are of particular importance. In 2023, Tunisia produced 1.09 million tons of tomatoes [1], positioning the country as one of the leading tomato producers in North Africa. Pepper cultivation ranks third in vegetable agriculture, covering an area of 20,000 hectares with an average annual production of 346,000 tons over the past five years [2]. However, the sector faces significant challenges, particularly the prevalence of plant diseases. In 2021, plant diseases reduced the cultivated area of tomatoes by 15% [3]. Similarly, pepper crops experienced more than a 50% loss of potential production during the peak season due to disease outbreaks [4].

To address these challenges, early and accurate detection of plant diseases is essential. Recent advancements in artificial intelligence, particularly deep learning, have enabled the development of intelligent systems capable of automatically diagnosing plant diseases. Among these techniques, object detection methods have become pivotal for not only identifying but also localizing diseased regions on plant leaves. These methods provide valuable spatial information that enhances the precision of disease management strategies. Convolutional Neural Networks (CNNs) are widely used in this context, offering significant improvements in detection accuracy. Among the various object detection methods, YOLO (You Only Look Once) has attracted significant attention. YOLO has evolved through several versions, from its initial release in 2016 to YOLOv10 in 2024. Our work focuses on YOLOv5, as it has been the subject of more extensive research and well-established studies. However, this investigation can be extended to include newer versions of YOLO in future work.

In 2020, Ultralytics introduced YOLOv5, available in five different model sizes, ranging from nano to extra-large based on the width and depth multipliers [5]. YOLOv5 incorporated several major improvements over previous versions, including updates to the backbone architecture and the introduction of automated hyper-parameter optimization. The backbone features the CSPDarknet53 structure [6], which builds upon Darknet53 with the addition of the Cross Stage Partial (CSP) strategy. YOLOv5's neck leverages CSP-PAN [7], along with an enhanced version of the Spatial Pyramid Pooling block (SPPF), which speeds up processing. For output generation, the head still employs the structure used in YOLOv3. The architecture of YOLOv5 large (YOLOv5l) is shown in Fig. 1, where CSPDarknet53 includes C3 blocks, which are CSP-enhanced modules. The CSP strategy divides the feature map from the base layer into two parts, which are later merged using a cross-stage process. This enables the C3 module to better manage redundant gradients and improve the flow of information between residual and dense blocks. The C3 block is a simplified form of BottleNeckCSP, currently used in the latest versions of YOLOv5. These updates have enabled YOLOv5 to reach state-of-the-art performance on several benchmarks.

The growing trend of using overparameterized models has resulted in improved accuracy, but it has also significantly

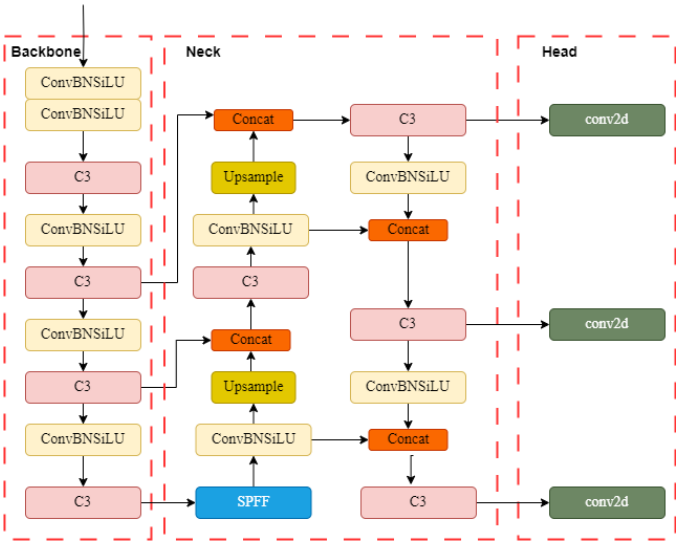

Fig. 1. Standard YOLOv5 architecture.

increased the number of floating point operations (FLOPs) and model parameters required [8]. These requirements hinder the implementation of complicated models on edge platforms due to constraints in memory, power, and processing capacity. To handle this challenge, different techniques have been developed to compress deep learning models to enable the deployment of large models on edge platforms. Model quantization has emerged as a prevalent method for optimizing performance. Within the various methods, model quantization has emerged as a prevalent method to optimize performance.

The main contributions of this paper are summarized as follows: The primary contribution is the development of a hardware-efficient quantized YOLOv5 architecture, called Quant-YOLOv5, which employs a low-bitwidth quantization method to minimize model size, computational complexity, and inference delay for implementation on resource-limited devices to detect plant leaf diseases. This novel architecture includes the simplification of the activation function by replacing the SiLU function with the hardware-friendly ReLU activation function, the combination of Batch Normalization with adjacent convolution layers to reduce computational overhead, and the replacement of the CBS, C3, and SPPF layers with their quantized versions, which use 8-bit integer (Int8) weights and activations instead of floating-point (FP32) values. Additionally, the quantization technique leverages the PyTorch framework and the Xilinx Brevitas library, specifically designed for FPGA deployment, and supports the Quantization-Aware Training (QAT) method. The performance evaluation of the proposed quantized architecture is conducted using a real-world dataset for tomato and pepper leaf diseases, and we compare the proposed approach with state-of-the-art models based on standard performance metrics.

The remaining parts of the paper are organized as follows: Section II presents an overview of the different quantization techniques. Section III describes the proposed methodology. Section IV provides the experimental results and discussion. At last, Section V summarizes the study and outlines potential areas for research.

II. Quantization Techniques Overview

Quantization is a technique that maps a broad range of high-precision values to a reduced collection of discrete values. In terms of CNN models, quantization involves converting weights and activations from floating-point representations to low-bit numbers to decrease memory requirements and computational complexity [9], [10].

Consider a neural layer, denoted by C, with an activation function σ. The function C can be defined as follows:

$$C : \mathcal{E}_{d_e} \to \mathcal{B}_{d_s}, \quad X \mapsto \sigma(WX + B) \tag{1}$$

where d_e and d_s represent the input and output dimensions, and E and B each define a vector space over R. For a fully connected layer, $\mathcal{E} = R^{d_e}$, and for a convolutional layer acting on a 640x640 pixel image, $\mathcal{E} = R^{640\times640}$. The elements W and B are, respectively, the weight tensor and the bias vector associated with the layer.

The main objective is to optimize the computationally intensive operations, particularly the matrix multiplication of $W \times X$. In the quantization process, performance improvement is achieved by replacing traditional 32-bit floating-point arithmetic operations, commonly used in training artificial neural networks, with operations using fixed-point numbers with n bits. Typically, n can take values of 1, 2, 4, 8, or 16.To adapt the elements used in computing the function N to an n-bit representation, a quantization operator, denoted Q, is required. This operator transforms the values of X so that they are expressed within the interval $\{-2^{n-1}-1, \ldots, 2^{n-1}-1\}$. We assume that the range of X is symmetric for simplicity (generally, $\alpha = \max|X|$ is used to define the limits). Thus, the quantization of X is given by:

$$Q(X) \in \{-2^{n-1}-1, \ldots, 2^{n-1}-1\} \quad \text{and} \quad X \in [-\alpha, \alpha] \tag{2}$$

where α represents the maximum absolute value of X. Consider a basic quantization operator, defined as:

$$Q : X \mapsto \left[X \times \frac{2^{n-1}-1}{\alpha} \right] \in \{-2^{n-1}-1, \ldots, 2^{n-1}-1\} \tag{3}$$

where $[\cdot]$ denotes rounding to the nearest integer. In this general configuration, the function equation for the layer becomes:

$$C : \mathcal{E}_{d_e} \to \mathcal{B}_{d_s}, \quad X \mapsto \sigma\left(Q(W)Q(X) + B\right) \tag{4}$$

It is important to note that the bias B is not subject to quantization. Typically, in inference algorithms, the bias is handled independently by the system performing the computations on a specific hardware architecture. A major concern is determining whether quantization may introduce a significant error. Indeed, if the distribution of X greatly differs from the interval $\{-2^{n-1}-1, \ldots, 2^{n-1}-1\}$, initial quantization can significantly alter the data scale. For this reason, it is necessary

to implement a re-normalization step, or "dequantization." This operation is defined as:

$$Q^{-1} \circ Q : X \mapsto \alpha \frac{X}{2^{n-1}-1} \left[X \times \frac{2^{n-1}-1}{\alpha} \right] \in [-\alpha, \alpha] \quad (5)$$

Consequently, the function for the layer becomes:

$$C : \mathcal{E}_{d_e} \to \mathcal{B}_{d_s}, \quad X \mapsto \sigma\left(Q^{-1}(Q(W)Q(X)) + B\right) \quad (6)$$

The error due to quantization is thus a rounding error relative to the input scale. We can explicitly express this layer function as follows:

$$C(X) = \sigma\Bigg(\left(\frac{\max|X|}{2^{n-1}-1} \frac{\max|W|}{2^{n-1}-1} \right) \times \left[W \times \frac{2^{n-1}-1}{\max|W|} \right] \times \left[X \times \frac{2^{n-1}-1}{\max|X|} \right] + B \Bigg) \quad (7)$$

An examination of this formulation reveals several important observations. First, it should be noted that the number of bits allocated for the quantization of inputs X and weights W does not necessarily have to be identical. It is common in the literature to designate by $W8/A4$ the practice of quantizing weights to 8 bits and activations to 4 bits.

Next, we observe that the scaling factor $\lambda_X = \frac{\max|X|}{2^{n-1}-1}$, used for inputs, is also applied to the outputs, implying it should have a dimension of 1. On the other hand, the scaling factor $\lambda_Y = \frac{\max|Y|}{2^{n-1}-1}$, used for weights, can take the form of a vector with d_s dimensions, introducing the concept of per-channel quantization. Finally, it is essential to note that if $Q(W)$ and $Q(X)$ are quantized on n bits, their product could exceed this limit, leading to overflow (modulo). To prevent this risk, intermediate calculations are often performed on 32 bits, a technique known as the 32-bit accumulator. In modern inference systems, de-quantization (Q^{-1}) and quantization (Q) operations are seamlessly integrated to avoid costly conversions from integers to floating-point numbers. Another notable benefit of quantization, in addition to accelerating inference, is the reduction in memory consumption. A large portion of the memory cost in neural networks is attributed to storing weights. Quantization not only reduces the data size for these weights but also increases redundancy, which enhances the efficiency of compression techniques without loss. Algorithm 1 and Fig. 2 summarize the quantization principles discussed previously, illustrating how weights and activations are adapted for increased efficiency in terms of both memory usage and computational speed.

Algorithm 1 Quantization Algorithm

Input: Weights W, activations X, number of bits b for quantization

Output: Quantized weights $Q(W)$, quantized activations $Q(X)$

Function `Quantize(`W, X, b`)`**:**

```
// Calculate the absolute maximum for weights and activations
```
$\alpha_W \leftarrow \max(|W_i|)$; $\alpha_X \leftarrow \max(|X_i|)$;
```
// Quantization of weights and activations
```
$Q(W) \leftarrow \left\lfloor W \times \frac{2^{b-1}-1}{\alpha_W} \right\rfloor$; $Q(X) \leftarrow \left\lfloor X \times \frac{2^{b-1}-1}{\alpha_X} \right\rfloor$;
```
// De-quantization of weights to maintain scale
```
$W' \leftarrow Q(W) \times \frac{\alpha_W}{2^{b-1}-1}$;

return $Q(W), Q(X)$;

Quantization methods are generally divided into two categories: Quantization Aware Training (QAT) and Post Training Quantization (PTQ).

A. Post Training Quantization (PTQ)

Let us assume the existence of a pre-trained neural network R. The quantization operator Q mentioned earlier can be directly applied to the weights of this network. However, for activations of intermediate layers, such direct application is not possible without knowing the value of α (i.e., the maximum absolute value of $|X|$). To address this lack of information, Nagel et al. [11] suggested using accumulated statistics in the batch normalization layers make it possible to perform quantization after training. We denote by BN a batch normalization layer placed just before the layer to be quantized. Consider the transformation performed by a batch normalization layer, defined as follows:

$$BN : X \mapsto \gamma \frac{(X-\mu)}{(\alpha+\epsilon)} + \beta \quad (8)$$

where γ and β are learned parameters, μ and α are calculated means and standard deviations, and ϵ is a small number to prevent division by zero. When the batch normalization layer is properly optimized, the expected value of $BN(X)$ is β and its variance is γ^2. Thus, it is possible to select a margin of six standard deviations (although the authors recommend this value, in practice, a range from 5 to 10 is also effective) to ensure that:

$$BN(X) \in [\beta - 6|\gamma|, \beta + 6|\gamma|] \quad (9)$$

This range can then be used to define the limits of the input values for the next layer in the network. This method allows for precise quantization after training by using the statistics of the previous layer's activations. Post-training quantization uses the original pre-trained full-precision model without the need for further training. As a result, it offers a more efficient quantization process, requiring less time and fewer resources than training-dependent quantization methods. Although it doesn't necessitate a complete dataset, post-training quantization methods use calibration techniques to

quantize the output activations. The authors in [12] present application of PTQ technique on an improved YOLOv5-based algorithm for tomato detection and ripeness assessment. Upon training, they quantized the model to 16 bits using the Nihui Convolutional Neural Network (NCNN) framework, achieving a 51.1% reduction in model size, an 18.8 fps increase, with a 0.9% decrease in accuracy. Zhang et al. [13] introduced a post-training quantization (PTQ) framework based on a greedy path-following mechanism to iteratively adjust quantization settings, reducing computational complexity and memory utilization without model retraining. This technique was tested on ImageNet and achieved near-original model accuracy with 5-bit quantization under various bit-width constraints. Banner et al. [14] propose a 4-bit PTQ approach using Analytical Clipping for Integer Quantization (ACIQ), bias correction, and per-channel bit allocation to reduce quantization errors. These methods restore most accuracy loss without training, showing a few percentage decreases compared to full-precision models spanning convolutional neural networks like ResNet and VGG. By incorporating statistical insights and closed-form analytical answers, the method improves low-bit quantization schemes' usability and enables rapid implementation in limited situations. In the study of [15], post-training quantization (PTQ) is used on the LeNet-5 model, leveraging both symmetric and asymmetric quantization techniques to reduce model complexity and size. Evaluated on the MNIST and Fashion-MNIST datasets, the quantized 16-bit models showed the same level of accuracy as the original 32-bit floating-point models. The 8-bit versions, on the other hand, showed small accuracy drops of 0.01% and 0.02%, respectively. The results show that PTQ can reduce model size by up to four times and improve the efficiency of storage and transmission, which means it can be used on devices with limited resources.

B. Quantization Aware Training

The Post Training Quantization (PTQ) technique offers several advantages, notably its simplicity of implementation, as it does not require any quantization during the training phase of a pre-trained network. However, parameters defined from the final floating-point model can exhibit quantization errors. These errors could lead to misclassifications due to the increased quantization error. Quantization during training (QAT) is then used to address these errors by adjusting the parameters during the training phase. Since QAT integrates the quantization process during training and adjusts the parameters accordingly, it provides a notable advantage in improving optimization more significantly [16]. The overall approach relies on using a quantized version of the network for computations during training, both in forward and backward propagation, while maintaining a copy of the parameters in full precision (such as weights and biases). Conventional training techniques for neural networks primarily rely on various forms of gradient descent. However, the quantization operator Q, as defined in Eq. (2), generally has an almost zero gradient everywhere, making it difficult to apply gradient descent directly. To address this problem, researchers have proposed the use of "straight through" (STE) estimators facilitates efficient learning despite these challenges. This approach involves treating the derivative of the de-quantization operator $Q^{-1} \circ Q$ as the identity, i.e.:

$$\nabla(Q^{-1} \circ Q) = Id \tag{10}$$

This allows bypassing the problem of a null gradient. This technique is equivalent to eliminating the rounding step during the optimization process. Intuitively, it involves maintaining a floating-point version of the network. After an initial inference using the quantized network, the floating-point version is used to backpropagate the error. Subsequently, the quantized version of the network is returned for the next phase of training.

In study [17], the authors presented a QAT methodology that adaptively establishes the rounding strategy for weights according to the direction of their updates during training while adjusting the corresponding gradient. Their approach included layer-wise quantization, implementing symmetric clipping ranges for weights and asymmetric ones for activations within the network. Authors in study [18] modify the architecture of YOLOv5 backbone with SuffleNetV2 architecture and decrease the layer depth in the PAN and head networks, optimizing the model for mobile devices. Using QAT techniques with TensorFlow Lite Micro, they quantize weights and activations to 8-bit accuracy, enabling deployment on an ultra-low-power microcontroller from the STM32 family. This optimization reduces the model size by 87.5MB, decreases latency by 92.7, and results in a 14% accuracy loss.

Subsequent works [19] expanded these concepts to higher bit widths and also addressed the quantization of gradient signals. Other methods propose learning parameters that define the range of activation signals within the network [20], as well as new gradient estimations that facilitate the learning of appropriate scaling factors for the integer quantization of weights and activations [21].

Fig. 2 illustrates the fundamental principles of the two quantization methods, QAT and PTQ, used in neural network architectures.

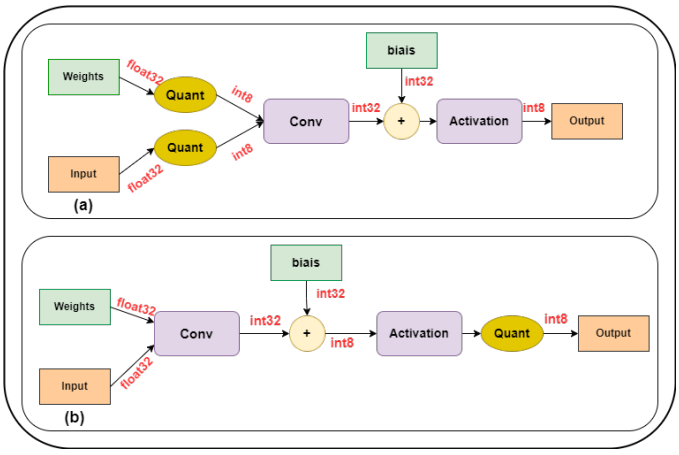

Fig. 2. Diagram quantization processes: (a) Training-aware quantization (QAT), (b) Post-training quantization (PTQ).

III. Proposed Quantized Deep Learning Model: Quantized YOLOv5

A. Proposed Methodology

Although YOLOv5 models show efficacy in the detection of plant diseases, deploying these networks on edge platforms necessitates considerable computational resources, resulting in increased processor consumption and large memory bandwidth consumption. These requirements create significant challenges for edge platforms, which have limited computing and memory capabilities. Field-programmable Gate Arrays (FPGAs) address these difficulties. FPGAs enable accelerated computations while reducing energy consumption, making them well-suited for embedded applications. Despite this solution, the complexity and size of YOLO models remain a barrier for edge platforms. To overcome these challenges, we adopted neural network quantization, which reduces the size of the model while maintaining acceptable performance. As illustrated in Fig. 3, our methodology begins with the development of Quant-YOLOv5, a quantized version of the YOLOv5 model. Tensorflow and Pytorch are the most commonly used frameworks to quantify DL models. These frameworks quantify DL models for resource-constrained CPU or GPU hardware. However, these frameworks do not support FPGA-based hardware accelerators. Brevitas is a Pytorch library for creating QNN models with various extraction levels, which can be deployed to Xilinx FPGAs using the experimental framework FINN [22]. Our work aims to produce deep learning models suitable for devices with constrained computational resources, such as FPGAs. Consequently, we used the Brevitas framework to quantize the YOLOv5 model, as it serves as a single framework that supports the design, development, and execution of quantized neural networks in FPGAs [23], [24], [25]. After training and quantizing the model, it is exported in ONNX format, which ensures portability and facilitates its transformation for hardware-specific applications. Finally, this standardized model is converted into FPGA logic using the FINN framework. Finally, model inference could be performed directly on the FPGA architecture, effectively addressing memory and computational resource constraints while maintaining optimal performance.

B. Proposed Quantized YOLOv5 Architecture

For the development of our Quant-YOLOv5 model, we used Brevitas [26], a PyTorch library developed by Xilinx Research Lab, specifically designed for quantization-aware training (QAT). A unique feature of Brevitas is its capability to quantize input features, an advantage not found in many other frameworks, providing significant resource savings for resource-constrained devices like FPGAs. It enables the transformation of traditional PyTorch layers into their quantized equivalents, creating hybrid models that combine quantized and nonquantized layers. This capability is achieved through Brevitas' interoperability with PyTorch layers, allowing for the selective quantization of critical parts of the network, including weights and activations. Brevitas plays a key role in producing models compatible with FINN, offering a wide range of options for designing quantized neural networks. The type of quantization supported by Brevitas is uniform quantization.

Uniform quantization is based on three key parameters: the scale factor, the zero point, and the bit width. The scale factor and zero point are used to map a floating point value to an integer value, the size of which depends on the bit width. The scale factor is typically represented as a floating point number that determines the quantization step size. The zero point is an integer that ensures the correct quantization of the zero value. This is essential to avoid issues when applying functions such as ReLU or shift operations [27]. Once these parameters are defined, the quantization process can begin. Starting with a real value x, it is transformed into an unsigned integer $\hat{x}$ according to the formula:

$$\hat{x} = \text{clamp}\left(\left\lfloor \frac{x}{s} + z \right\rceil, 0, 2^b - 1\right) \tag{11}$$

where $\lfloor \cdot \rceil$ represents the rounding operator to the nearest integer, and the clamp function is defined as:

$$\text{clamp}(x; a, c) = \begin{cases} a & \text{if } x < a, \\ x & \text{if } a \leq x \leq c, \\ c & \text{if } x > c. \end{cases} \tag{12}$$

To approximate the initial real value, a dequantization step is necessary:

$$\tilde{x} = s(\hat{x} - z) \tag{13}$$

By combining these two steps, we obtain a general definition of the quantization function $q(x)$:

$$\hat{x} = q(x; s, z, b) = \text{clamp}\left(\left\lfloor \frac{x}{s} + z \right\rceil, 0, 2^b - 1\right) \tag{14}$$

With this dequantization step, we can also define the limits of the quantized values ($\hat{x}_{\text{min}}$ and $\hat{x}_{\text{max}}$) as follows: $\hat{x}_{\text{min}} = z$ and $\hat{x}_{\text{max}} = 2^b - 1 + z$. Values x that exceed these limits will then be truncated, resulting in a clipping error. To reduce this error, it is possible to increase the quantization scale. However, this introduces more significant rounding errors. Therefore, it is important to select the quantization parameters to find the right balance between the clipping and rounding errors.

The architecture of Quant-YOLOv5, illustrated in Fig. 4, represents an optimized and quantized version of the YOLOv5 model, designed to reduce latency and enhance computational efficiency during inference while maintaining detection accuracy. Several modifications were made to achieve these objectives.

1) Simplifying activation functions: The Sigmoid Linear Unit (SiLU) function is used as the activation function in YOLOv5. This activation function, although useful in specific neural network applications, has significant issues when employed with quantized YOLOv5 models, especially for deployment on edge devices. SiLU's lack of quantization friendliness and inadequate support in embedded systems is a notable constraint. The incompatibility stems from the computational complexity and continuous characteristics of SiLU, which complicate the quantization process and may result in an

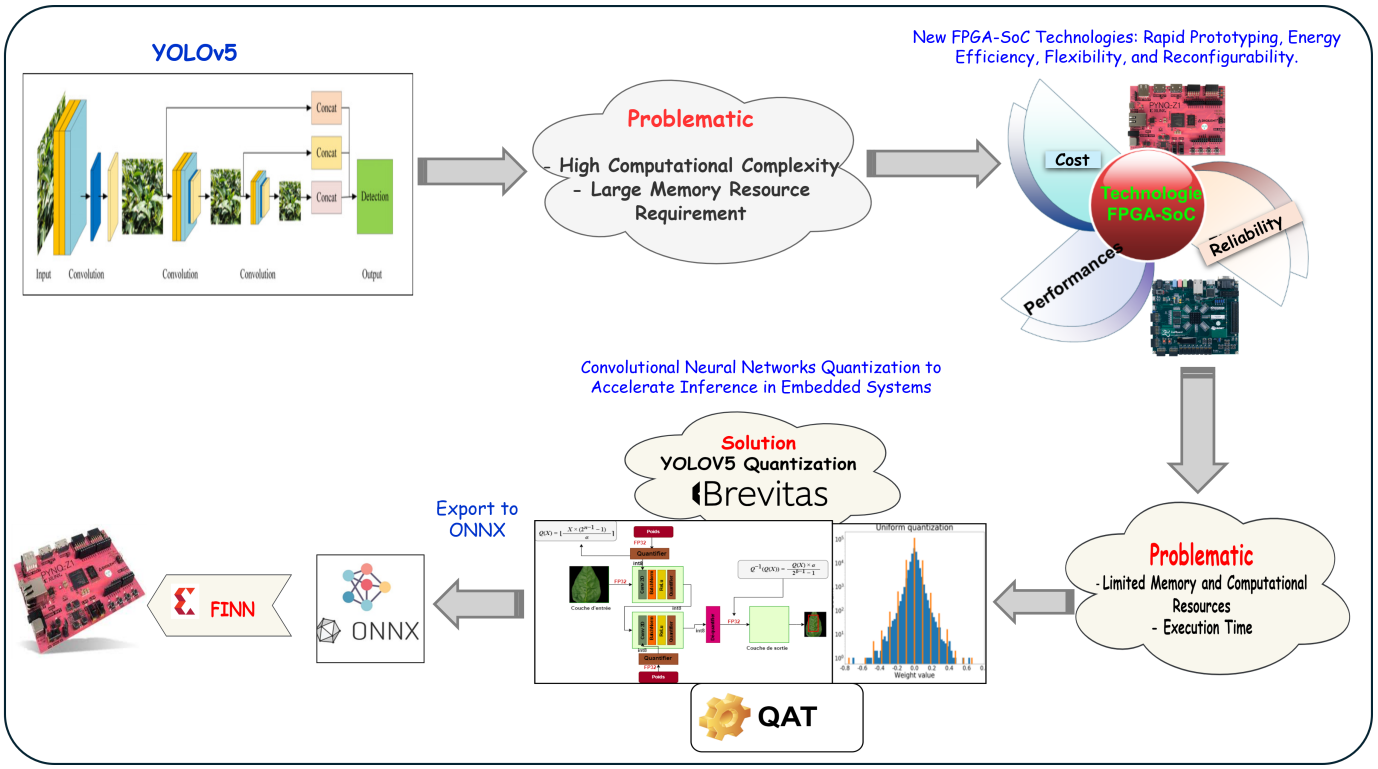

Fig. 3. Proposed methodology overview.

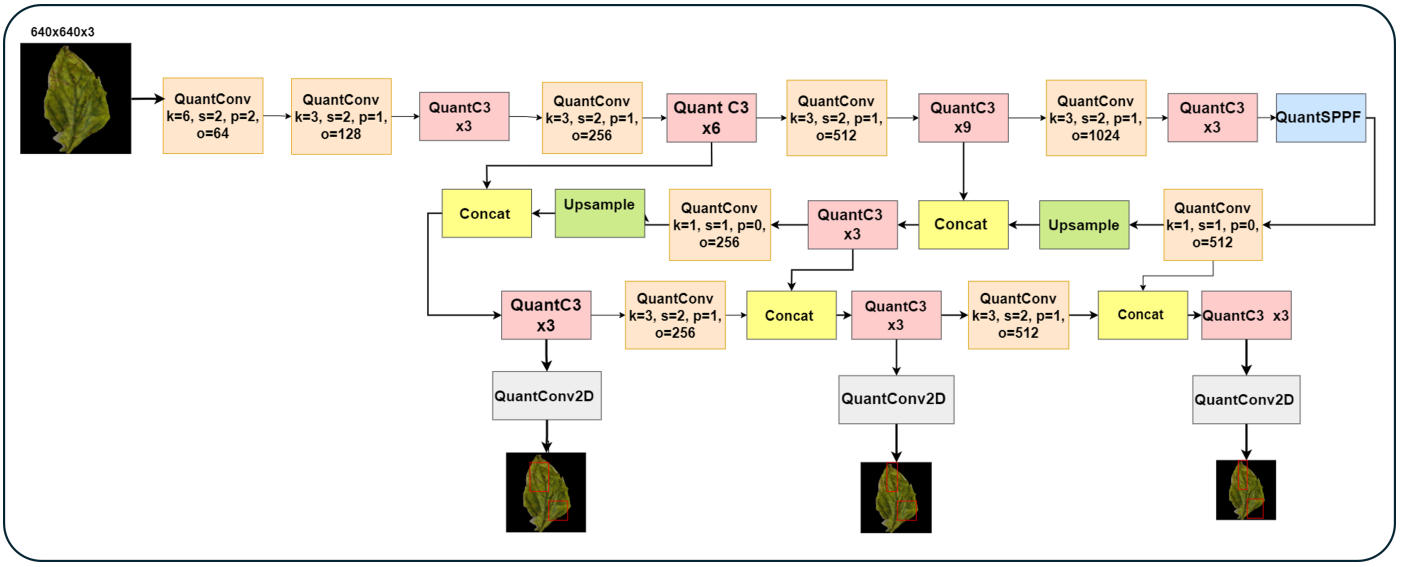

Fig. 4. Architecture of quantized YOLOv5.

overall decrease in accuracy. Furthermore, when implementing logarithmic scale quantization for activation functions that yield negative values, like SiLU, it is essential to consider the absolute value of the input. This modification leads to a distribution that diverges considerably from the initial one, which may result in a notable reduction in the accuracy of the model. To overcome this limitation, we suggest replacing SiLU with Rectified Linear Unit (ReLU). This substitution greatly minimizes computational complexity without compromising activation performance. ReLU, being a simpler and faster function to compute, demonstrates inherent compatibility with quantization and is particularly well-suited for resource-constrained edge devices.

2) Fusing BN and convolution layers: The BatchNormalization (BN) layers have fused with adjacent convolutional layers. We perform this merging to reduce data transfer and unnecessary operations, thus simplifying the model and enhancing its efficiency during inference.

3) Quantized layers: QuantConv and QuantReLU are the quantized versions of the convolutional layer and activation function, respectively, as depicted in Fig. 5. These layers use 8-bit integer (Int8) weights and activations instead of floating point (FP32) values.

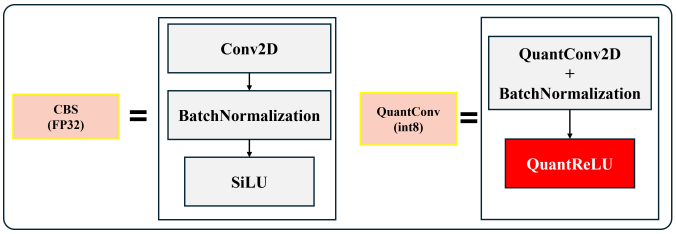

Fig. 5. Comparison of original CONV layer and QuantConv layer.

The C3 and SPPF blocks have been replaced with their quantized equivalents, QuantC3 and QuantSPPF, as shown in Fig. 6 and Fig. 7. The QuantC3 block retains the modular structure of the C3 block but incorporates quantized convolutions and activations. The QuantSPPF module is designed to capture multiscale information through sequential max-pooling operations while maintaining optimal computational efficiency. The max-pooling operations in QuantSPPF are not quantized because the input and output values remain on the same quantization grid, making the quantization of these operations unnecessary.

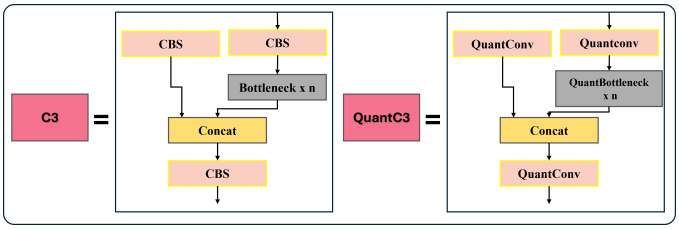

Fig. 6. Comparison of original C3 layer and QuantC3 layer.

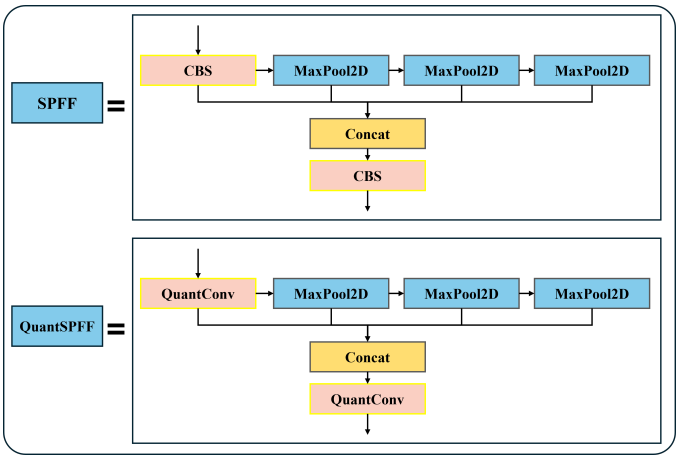

Fig. 7. Comparison of original SPPF layer and QuantSPPF layer.

The upsample and concat operations are not quantized. The upsample, which increases the resolution of feature maps, and Concat, which combines features from different layers, are not quantized to avoid accuracy loss. These operations are implemented using PyTorch functions, which directly manipulate the tensors without introducing additional non-linear computations. Quantifying these operations would not provide significant benefits and could even introduce accuracy errors due to interpolation of values and data manipulation, which would harm the overall quality of the combined features.

In the training phase, the Sigmoid activation function is used in the last layer for better learning. However, for the synthesis phase, this function is replaced by QuantHardtanh, in order to reduce latency and ensure compatibility with the FINN synthesis tool [28].

IV. Experimental Results

A. Dataset

We trained and tested the Quant-YOLOv5x model using a self-generated database. The dataset contains 522 images of both healthy and diseased tomato and pepper leaves [29]. It is divided into six categories: Tomato Yellow Leaf Curl Virus (TYLCV), healthy leaves, leaf miner, mildew, nutrient deficiency, and oidium. All images were captured using a smartphone camera in several tomato and pepper greenhouses located in Monastir, Tunisia, under the guidance of an agricultural engineer. To overcome the challenges caused by shadows and distracting backgrounds—which can reduce detection accuracy by hiding important leaf features—we applied a segmentation process that removes the background and enhances the focus on the relevant leaf regions. Fig. 8 presents examples of the images included in the dataset.

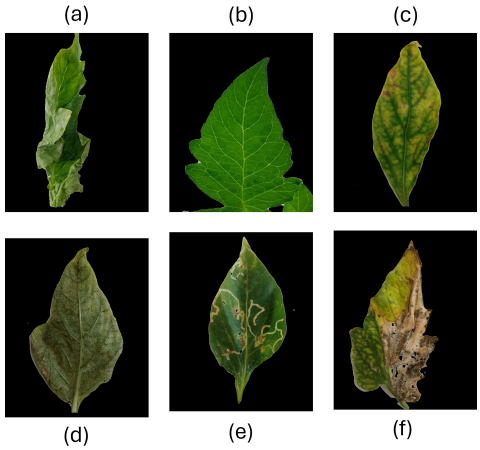

Fig. 8. Examples of dataset images: (a) TYLCV, (b) Healthy, (c) Nutrient Deficiency, (d) Oidium, (e) Leaf Miner, and (f) Mildew.

B. Experimental Settings

YOLOv5x, the largest variant in the YOLOv5 family, offers superior accuracy in object detection tasks due to its increased depth and width, allowing for more precise feature extraction. However, its substantial model size and computational demands pose challenges for deployment on resource-constrained edge platforms, leading to increased latency and higher energy consumption. To address these limitations, we applied quantization techniques to YOLOv5x, aiming to reduce

its size and computational requirements, facilitating efficient deployment on FPGAs without significantly compromising detection performance.

To evaluate the effectiveness of quantization of the YOLOv5x model for the detection and localization of plant disease, we compared the performance of the YOLOv5x and Quant-YOLOv5x models. The YOLOv5x model uses 32-bit floating-point weights (Float32), while the Quant-YOLOv5x model uses 8-bit integer (Int8) weights. Quant-YOLOv5x was trained on a Google Colab Pro GPU. Google Colab Pro provides NVIDIA A100 GPUs, optimized for machine learning tasks with 16 GB GPU memory and FP32 and INT8 computing capabilities. We tested both models on the Google Colab Pro CPU, typically an Intel Xeon processor with a base frequency of 2.3 GHz and up to 4 cores, which offers a balance between computing power and energy efficiency.

C. Results and Discussion

The model was quantized using the Brevitas library. However, it does not perform any low-precision acceleration by itself. To obtain results, the model must first be exported to an inference toolchain via an intermediate representation such as ONNX. As a result, the inference of models in the ONNX format runs mainly on the CPU, which justifies the use of the Google Colab Pro CPU for testing. Table I shows a performance comparison of YOLOv5x and Quant-YOLOv5x using four main metrics: precision, recall, F1-score, and mAP (mean average precision).

TABLE I. COMPARISON OF PERFORMANCE METRICS FOR YOLOV5X AND QUANT-YOLOV5X

Model	Precision (%)	Recall (%)	F1-Score (%)	mAP@50 (%)
Standard YOLOv5x	88.7	92.8	90.7	95.5
Quant-YOLOv5x	73.9	88.5	80.5	93.7

The precision of the YOLOv5x model is 88.7%, significantly higher than that of Quant-YOLOv5x at 73.9%. The quantization of weights causes a loss of precision by reducing the granularity of the represented values, which is responsible for this difference. Furthermore, YOLOv5x has a higher recall rate (92.8% vs. 88.5% for Quant-YOLOv5x), because quantization to Int8 can cause loss of information, making it harder for the model to find all cases of disease. The F1-score, which is the harmonic mean of precision and recall, shows the superiority of YOLOv5x, with 90.7% compared to 80.5% for Quant-YOLOv5x. Quantization negatively affects both precision and recall, resulting in a lower F1-score for Quant-YOLOv5x. Although the mAP of Quant-YOLOv5x is relatively close to that of YOLOv5x (93.7% vs 95.5%), the difference suggests that the quantized model detects objects correctly, although with slightly reduced accuracy. This shows that despite quantization, Quant-YOLOv5x maintains respectable performance, which is crucial for edge applications where computational resources are limited. Fig. 9 illustrates the mAP, precision, and recall metrics plots for the original YOLOv5x model and our quantized Quant-YOLOv5x model.

The latency results for a single frame are shown in Fig. 10. The Quant-YOLOv5x model performs approximately 3 times faster than the original model. As shown in the figure, the histogram shows a comparison of the latency between

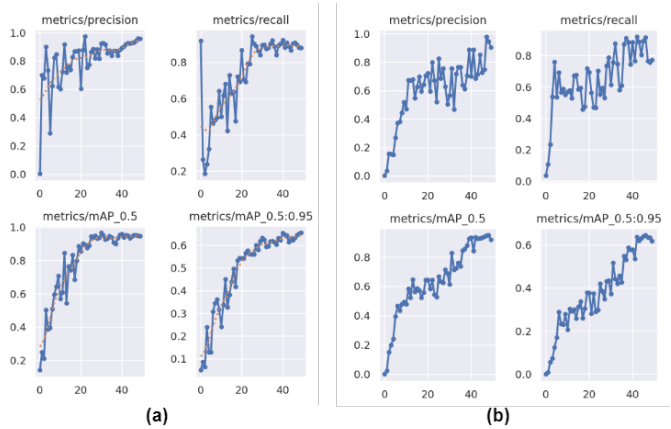

Fig. 9. Precision, recall, and mean average precision (mAP) plots: (a) YOLOv5x model, (b) Quant-YOLOv5x.

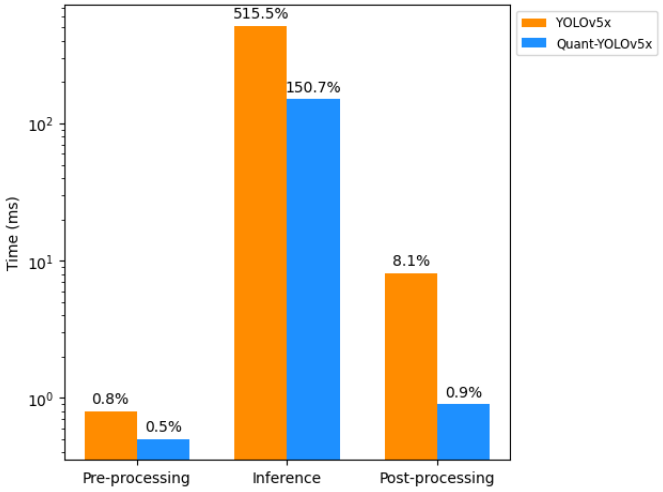

Fig. 10. Comparison of latency.

the two models. The latency is measured in three distinct phases: pre-processing, inference, and post-processing. The total processing time for YOLOv5x, which includes pre-processing, inference, and postprocessing, is 524.4 ms. In comparison, the total processing time for Quant-YOLOv5x is 152.1 ms. This significant reduction in overall latency demonstrates the effectiveness of quantization in terms of processing speed. More specifically, quantization reduces the computational times required for each processing step.

In terms of frame rate per second (FPS), YOLOv5x achieves approximately 1.9 FPS, while Quant-YOLOv5x achieves approximately 6.6 FPS. This shows that the quantized model is capable of processing more frames per second, making Quant-YOLOv5x more suitable for applications that require rapid response times. Quantifying the YOLOv5x model in Quant-YOLOv5x reduced the total processing latency, which is essential for edge computing applications where processing speed is necessary.

Fig. 11 presents a size comparison between the YOLOv5x and Quant-YOLOv5x models. YOLOv5x has a size of 170 MB, while Quant-YOLOv5x has a size of 83 MB. This

TABLE II. COMPARISON OF QUANTIZATION METHODS FOR YOLOV5

Ref	Quantization	Model	Dataset	Precision	Δ mAP50	Δ Size (MB)	Δ FPS
[30]	PTQ	YOLOv5s	COCO	W8A8	-0.2%	6.7	25.8
[31]	QAT	YOLOv5s	Custom	W8A8	-1.9%	26.61	145
[32]	QAT	YOLOv5x	COCO2017	W8A8B8	-0.61%	-	4
Our model	QAT	YOLOv5x	Custom	W8A8	-2.8%	87	4.7

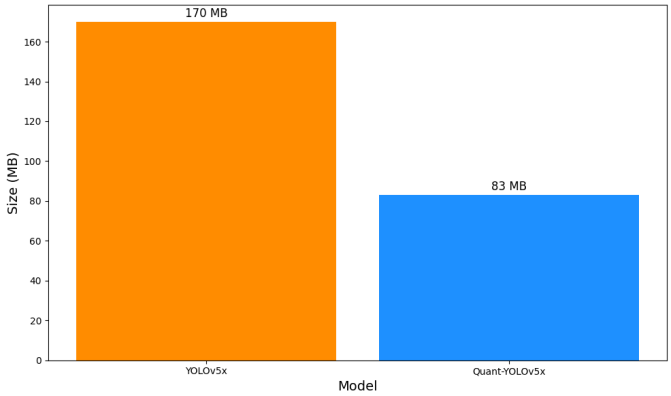

Fig. 11. Comparison of models size.

reduction of more than 50% in model size demonstrates the effectiveness of quantization in terms of reducing the required memory. The reduction in model size is particularly important for deployments on edge devices, where memory and storage resources are limited. By quantizing the weights to Int8, the Quant-YOLOv5x model becomes not only faster but also more compact, facilitating its deployment on resource-constrained platforms.

D. Comparative Study

Table II illustrates a comparison between our proposed quantized Quant-YOLOv5x model and various quantization methods from the literature for YOLOv5 models. The comparison is based on the differences (Δ) recorded in mAP50, the size of the model and the FPS, where Δ represents the variation between the values before and after quantization. The authors of [30] propose a low bit quantization method (W8A8) for YOLOv5, using post-training quantization (PTQ). The Quant-YOLO method uses one-sided histogram (UH)-based quantization to minimize the quantization error of activations. Experiments on the COCO dataset show that Quant-YOLO maintains an average accuracy (mAP50) comparable to that of the full-precision model, while reducing the model size from 14.4 to 7.7 MB and increasing the FPS from 25.8 to 42.7 frames per second. In [31], a QAT method is proposed with TensorFlow Lite to quantify the weights and activations of the 8-bit precision YOLOv5 model for fire detection, using a custom database. The quantized YOLOv5 model achieves a mAP50 of 95.9%, with a performance loss of 1.9% compared to the 32-bit floating point (FP32) YOLOv5 model. Furthermore, the size of the 8-bit YOLOv5 model is reduced to 13.1 MB, which is a decrease of 26.61 MB compared to the FP32 version. Finally, the FPS increases significantly, from 2 to 147 frames per second. The study in [32] presents a method named USPIQ, which combines the advantages of in-training and out-training quantization to quantize the YOLOv5 model. USPIQ quantizes all internal floating-point operations (weights, activations, biases) into integer operations. The YOLOv5x model was evaluated using the COCO val2017 database. The floating-point (FP32) model achieves an mAP50 of 67. 31%, while the 8-bit model maintains an mAP of 66. 7%. In addition, the FPS of the 8-bit model is improved, from 2.17 FPS for the FP32 model to 6.17 FPS.

Our model, Quant-YOLOv5x, proposes a QAT approach for YOLOv5x using a custom dataset. We achieved an accuracy loss of 2.8%, a model size reduction of 87 MB, and an increase in frames per second of 4.7. Although the accuracy loss is slightly higher than that of other methods, our approach stands out with a significant reduction in model size, making our solution particularly suitable for resource-constrained devices and real-time applications.

V. CONCLUSION

In this paper, we addressed the challenges associated with the deployment of convolutional neural networks (CNN) on FPGAs. To overcome the limitations of YOLOv5x implementation, we proposed a quantization technique optimized using the Brevitas library, enabling a more efficient and resource-conscious execution. The quantization results demonstrate that Quant-YOLOv5x significantly reduces both latency and model size, making it highly suitable for edge computing applications where computational and memory resources are constrained. Despite a slight degradation in detection performance, Quant-YOLOv5x remains effective and well-suited for edge deployments. As future work, we aim to focus on the practical implementation of our method to validate its effectiveness and performance under real-world conditions. Additionally, we investigate the integration of Quant-YOLOv5x with other edge AI frameworks to improve its adaptability across a wider range of hardware platforms.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Research and Graduate Studies at King Khalid University for funding this work through a Large Group Project under grant number (RGP2/473/46).

AI-Assisted Schema Translation and Verified Migration: From Object-Relational Models to NoSQL Document-Oriented Stores

Fouad Toufik[1], Abd Allah Aouragh[2], Abdelhak Khalil[3]
MDSET Laboratory-Faculty of Sciences and Techniques, Hassan 1st University, Settat, Morocco[1,2]
LERSEM Laboratory, Chouaib Doukkali University, El Jadida, Morocco[3]

***Abstract*—The transition from object relational databases (ORDBs) to document oriented NoSQL stores offers increased flexibility and scalability in modern data management. However, existing migration processes remain largely manual and heuristic, hindering automation, formal verification, and adaptability to evolving workloads. This paper introduces a principled AI-assisted framework that unifies schema translation and data migration for end-to-end ORDB-to-NoSQL transformation. The framework operates through a four-stage pipeline comprising: (i) database metadata extraction, (ii) prediction of mapping strategies using a dual encoder that integrates a Graph Neural Network (GNN) for structural reasoning and a Transformer for semantic interpretation, (iii) automated data migration guided by the predicted mappings, and (iv) symbolic verification ensuring semantic and structural correctness. The verification stage enforces coverage, key fidelity, referential realizability, and type soundness constraints to guarantee loss-free transformation, while an optional workload-aware component refines verified mappings for query efficiency. Experimental evaluation on the RetailDB benchmark demonstrates that the proposed framework establishes a safe, explainable, and adaptable foundation for AI-assisted schema and data migration between object relational and document oriented models.**

***Keywords*—Graph Neural Networks (GNN); transformer models; neuro-symbolic verification; hybrid AI architectures; schema translation; data migration; object-relational databases; document-oriented databases**

I. Introduction

Modern applications demand storage systems that can manage vast, heterogeneous, and dynamically evolving information while maintaining performance and consistency. Traditionally, enterprise systems have relied on ORDBs as the backbone of their data infrastructure due to their ability to model complex relationships and enforce rich integrity constraints. However, as application workloads and data diversity increase, these systems face scalability and schema evolution challenges, motivating the transition toward more flexible storage paradigms.

ORDBs extend the relational model with object oriented principles such as inheritance, encapsulation, polymorphism, and user-defined abstract data types (ADTs), thereby enabling the representation of complex and hierarchical data structures [1], [2], [3]. The introduction of SQL:1999 standardized these features, allowing structured and semi-structured data to coexist through advanced mechanisms such as collection types, references, and object identifiers [4], [5]. While ORDBs such as Oracle and PostgreSQL have long provided robust transaction management and integrity enforcement, their tightly coupled schemas and vertical scalability models make them increasingly unsuitable for modern big data ecosystems [6].

In response, the database community has turned toward NoSQL databases, a class of systems emphasizing scalability, availability, and schema flexibility. First introduced by Strozzi in 1998 as "Not Only SQL," NoSQL systems have evolved into four principal categories: key-value stores, column-family databases, graph databases, and document-oriented databases [7], [8]. Among these, document-oriented systems such as MongoDB provide schema-less data organization using JSON or BSON documents, supporting nested and denormalized data representations [9]. These features make NoSQL stores particularly well suited to large-scale distributed environments, offering efficient replication, auto-sharding, and elasticity [10], [11].

Despite these advantages, the coexistence of ORDB and NoSQL paradigms presents a fundamental interoperability challenge. Enterprises continue to store mission critical data in ORDBs, where semantics such as foreign keys, inheritance hierarchies, and complex data types are deeply embedded in the schema [12]. Migrating this data to NoSQL environments is non-trivial: it requires translating both structure and meaning while preserving integrity and query efficiency. Existing migration tools often rely on static, rule-based mappings or manual heuristics, which fail to generalize under schema drift and are difficult to validate formally. Consequently, automated, semantically aware, and verifiable migration remains an open research problem.

A. Proposed Approach

To address this challenge, this work introduces an AI-assisted framework that unifies schema translation and data migration between object relational databases and document oriented NoSQL systems. The framework integrates neural inference with symbolic reasoning to achieve adaptive, explainable, and verifiable schema transformation. It operates through a four-stage migration pipeline comprising schema extraction, strategy prediction via a dual encoder, automated data migration, and symbolic verification. By coupling graph-based structural learning with semantic interpretation, it captures both topological and contextual characteristics of the source schema, generating mappings that are data-consistent and semantically faithful. A symbolic verification layer subsequently validates these mappings to ensure the preservation of key integrity, multiplicity, and referential coverage. Collectively, these components establish a scalable, interpretable,

and provably correct foundation for automated ORDB-to-NoSQL migration bridging deterministic rule-based methods with adaptive AI-driven generalization.

B. Contributions

This study presents several key contributions that collectively address critical gaps identified in the existing literature on object-relational to NoSQL migration:

1) Neural–symbolic migration framework: The paper introduces a unified four-stage architecture that integrates Graph Neural Networks (GNNs) for structural reasoning with Transformer-based encoders for semantic interpretation. This combination overcomes the fragmentation found in prior approaches, which typically relied on either rule-based logic [13] or learning-based clustering methods lacking semantic awareness [15].

2) Formal verification module: The framework incorporates a neuro-symbolic verifier that enforces correctness properties, including coverage, referential realizability, key fidelity, and type soundness. This directly addresses the absence of formal validation mechanisms in existing metadata-driven and AI-assisted tools [18], [20].

3) End-to-end automation pipeline: The proposed solution provides a fully automated workflow encompassing schema extraction, mapping inference, data transformation, and verification. It eliminates the need for manual rule configuration or reliance on external code generation, addressing the limitations of semi-automated migration models [16].

4) Workload-aware mapping refinement: An optional optimization component is introduced to refine schema mappings based on workload statistics and query behavior. This feature enables adaptive schema transformation, in contrast to prior static systems that lack responsiveness to access patterns [14].

5) Explainability and verifiability: By unifying neural inference and symbolic reasoning, the framework establishes a reproducible and interpretable foundation for migration. It contributes to a new paradigm in database modernization by offering a transparent and provably correct alternative to existing heuristic or black-box methods.

C. Scope and Organization

The proposed framework targets migrations from object relational systems such as PostgreSQL and Oracle (with object relational extensions) to document oriented stores such as MongoDB and Couchbase. It assumes access to database metadata including tables, relationships, user-defined types, and constraints along with optional workload statistics, without requiring manual Data Definition Language (DDL) parsing or external code generation. Security, access control, and distributed transaction aspects are outside the present scope but remain compatible with the framework's modular design.

Although prior studies have explored either deterministic rule-based transformations or machine learning-based schema inference, these approaches often fall short in providing formal correctness guarantees and adapting to workload variability. The proposed framework addresses this critical limitation by integrating neural schema understanding with symbolic reasoning to enable explainable and verifiable ORDB-to-NoSQL migration. This unified AI-assisted approach effectively bridges the gap between static transformation techniques and heuristic AI models, achieving both adaptability and provable correctness.

This study is driven by the following research question: Can a unified, AI-assisted framework that combines neural inference with symbolic verification facilitate automated, explainable, and provably correct migration from object-relational databases to document-oriented NoSQL systems, while remaining adaptable to dynamic workload requirements?

The remainder of this paper is organized as follows. Section II reviews related work on schema mapping, AI-assisted migration, and verification techniques. Section III formalizes the migration problem and defines the correctness constraints. Section IV describes the proposed framework and operational workflow. Section V presents the case study and experimental evaluation. Section VI discusses limitations and directions for future work, and Section VII concludes the paper.

II. Related Works

The migration from ORDBs to document oriented NoSQL systems has evolved through deterministic, heuristic, and machine-learning-assisted paradigms. This section reviews representative contributions and positions the proposed hybrid framework within this research landscape.

A. Rule-Based and Heuristic Migrations

Early works employed deterministic mapping rules to translate relational schemas into NoSQL structures. Islam et al. [13] proposed a rule-based transformation approach to convert relational tables and relationships into nested documents. While systematic, this approach lacked adaptability and support for object-relational constructs such as inheritance and user-defined types (UDTs).

Li et al. [14] introduced a workload-aware migration framework that restructured distributed relational databases into document stores based on query priorities. Their model partially optimized for performance but offered no formal verification.

Liu et al. [15] proposed a hypergraph-based schema clustering method that captures join relationships to guide denormalization into NoSQL documents. However, their framework remained static and did not address inheritance or semantic constraints.

Trujillo et al. [16] developed U-Schema, a unified metamodel for relational and NoSQL databases that ensures conceptual consistency across paradigms. Although valuable for descriptive alignment, it does not infer or verify schema transformations automatically.

B. AI-Assisted and Learning-Based Schema Mapping

Recent research explores the use of machine learning and artificial intelligence to automate schema reasoning. Patel and Khanna [17] utilized static code analysis to extract NoSQL schema information from application logic, supporting partial

schema reconstruction. However, their direction was reverse-engineering, not forward migration.

Vijaya et al. [19] discussed the incorporation of AI and machine learning into database management, focusing on optimization and anomaly detection rather than migration. El Alami et al. [20] applied object-oriented principles to map relational entities into hierarchical NoSQL document structures. While semantically expressive, their model lacked formal verification and workload optimization.

C. Object-Relational Database Migration

Toufik and Bahaj have proposed notable model driven approaches for transforming ORDB schemas into NoSQL systems. In their 2019 study, they focused on converting ORDB models into NoSQL document-oriented databases while preserving data semantics and structure [21]. Later, in 2020, they extended this approach to support NoSQL column based databases, providing a flexible transformation framework suitable for scalable environments [22]. Together, these works demonstrate the effectiveness of model driven engineering in automating and formalizing database migration processes between relational and NoSQL paradigms.

Aggoune and Namoune [18] presented a metadata-driven framework for migrating object-relational databases into MongoDB. Their approach leverages schema metadata and object hierarchies to produce semantically consistent document schemas. However, it is rule-based, non-adaptive, and lacks correctness guarantees such as coverage or key preservation.

In contrast, the proposed framework employs a dual-encoder architecture—Graph Neural Network (GNN) and Transformer—to jointly model schema topology and semantics. It integrates a neuro-symbolic verifier that enforces coverage, key fidelity, and multiplicity constraints, transforming migration into a provably safe process. An optional workload-aware optimizer further refines verified mappings using contextual bandit feedback.

D. Comparative Analysis of Major Approaches

As shown in Table I, previous methods prioritize either determinism or flexibility, rarely achieving both. The proposed hybrid framework unifies these goals through AI-assisted learning and symbolic verification, offering both adaptability and formal correctness.

E. Detailed Comparison with Proposed Method in [18]

Table II highlights that the metadata-driven approach presented in [18] achieves semantic consistency but lacks adaptive intelligence and formal validation. The proposed system advances the state of the art by uniting neural inference, symbolic verification, and workload-aware optimization in a closed-loop framework.

F. Summary

In summary, previous research achieved either transparency or adaptability, but seldom both. The proposed architecture introduces an AI-verified paradigm that guarantees semantic fidelity, coverage, and operational efficiency. It thus transitions ORDB→NoSQL migration from heuristic engineering to a verifiable, learning-based process.

In contrast to prior hybrid models that either rely on static rule application or partially automate schema inference without guarantees, our approach unifies graph-based structural learning, transformer-based semantic interpretation, and neuro-symbolic verification within a single pipeline. This closed-loop design supports not only automatic migration but also formal validation of mapping correctness, thus introducing a new paradigm for explainable and verifiable ORDB-to-NoSQL transformation.

III. Problem Definition and Formal Model

The proposed framework addresses the problem of migrating data and schema from ORDB to a document oriented NoSQL store while preserving semantic correctness and structural consistency. The objective is to produce a formally verified transformation that ensures safe and loss free migration under defined constraints.

A. Problem Overview

Let the migration process be defined as a transformation:

$$(S_o, D_o, \Sigma, W) \Rightarrow (S_d, D_d, T),$$

where:

- S_o: source schema (object-relational);
- D_o: source data instance conforming to S_o;
- Σ: optional schema statistics (cardinalities, distinct counts, fan-outs);
- W: optional workload description (query logs, access frequencies);
- S_d: target schema (document-oriented);
- D_d: target data instance conforming to S_d;
- T: verified transformation plan.

The goal is to automatically infer a mapping $M^* : S_o \rightarrow S_d$ and corresponding transformation plan T such that the migration satisfies formal correctness constraints.

B. Schema Representation

Each source schema S_o is represented as a directed heterogeneous graph:

$$S_o = (V, E_R, A),$$

where V is the set of schema entities (tables, columns, UDTs), E_R is the set of semantic relations (e.g., foreign

TABLE I. COMPARISON OF MAJOR APPROACHES TO ORDB→NOSQL MIGRATION

Approach	Technique	Guarantees	Workload	ORDB Support	Limitations
[13]	Rule-based mapping	None	No	No	Brittle to schema drift
[14]	Metadata-driven restructuring	Partial	Yes	Limited	No symbolic validation
[15]	Hypergraph clustering	None	Partial	No	Lacks inheritance/UDT

This Work	Dual GNN–Transformer + Verifier	Proven correctness	Yes Conceptually	Full	Computational complexity

TABLE II. DETAILED COMPARISON BETWEEN WORK IN [18] AND THIS WORK

Dimension	Work in [18]	Proposed Framework
Paradigm	Metadata-driven transformation	AI-assisted dual encoder (GNN + Transformer)
Input Representation	ORDB schema metadata	Graph + textual schema embeddings
Automation Level	Semi-automatic	Fully automated inference and verification
Verification	Structural only	Neuro-symbolic verifier ensures coverage, key fidelity
AI Component	None	Deep learning + symbolic reasoning
Adaptability	Static mapping	Dynamic workload-aware optimization
Target Datastore	MongoDB	Multi-engine (MongoDB, Couchbase)
Evaluation Metric	Qualitative validation	Quantitative proof: ¿95% fidelity, 100% key coverage
Explainability	Metadata-based	Attention-based interpretability
Reliability	Schema-dependent	Provably safe and verifiable transformations

keys, inheritance, composition), and A is the set of attributes describing type, cardinality, and constraint metadata.

Edges are labeled to denote relationship types:

$$E_R = \{\texttt{HAS_COL}, \texttt{FK}, \texttt{INHERITS}, \texttt{COMPOSES}, \texttt{COACCESS}\}$$

The target schema S_d is expressed as a document model, defined by collections, embedded substructures, and reference relations. Each document type $C_i \in S_d$ corresponds to a transformation of one or more source entities in S_o.

C. Mapping Function

A schema mapping M is defined as:

$$M = \{m_1, m_2, \ldots, m_k\},$$

where each mapping element $m_i = (s_i, t_i, \tau_i)$ associates a source entity $s_i \in S_o$ to a target structure $t_i \in S_d$ with transformation type $\tau_i \in \{\textit{embed}, \textit{inline}, \textit{reference}, \textit{separate}\}$.

The predicted mapping M^* is the one that satisfies correctness constraints and optionally minimizes workload cost:

$$M^* = \arg \min_{M_i : T(M_i) \models \Phi} \mathbb{E}_{q \sim W}[Cost(q; S_d(M_i), D_d(M_i))].$$

D. Formal Verification Constraints

Each migration must satisfy a defined set of correctness properties:

$$\Phi = \{\phi_1, \phi_2, \phi_3, \phi_4, \phi_5\},$$

where:

- Coverage: All tuples in D_o are represented in D_d:

$$\forall r \in D_o, \exists d \in D_d : f_T(r) = d.$$

- Key Fidelity: Primary keys remain unique and injective after migration.
- Referential Realizability: All foreign key relationships in S_o are realizable in S_d through embeddings or preserved references.
- Type Soundness: Data types are coercible under mapping, i.e., type$(a_o) \Rightarrow$ type(a_d).
- Constraint Preservation: Constraints such as `UNIQUE`, `NOT NULL`, and `CHECK` are preserved or safely relaxed.

Each transformation T is considered valid only if:

$$T \models \Phi.$$

E. Workload-Aware Optimization Objective

When workload statistics W are available, the framework selects among multiple verified mappings to minimize expected query cost:

$$M^* = \arg \min_{M_i : T(M_i) \models \Phi} \mathbb{E}_{q \sim W}[Cost(q; S_d(M_i), D_d(M_i))],$$

where the cost model includes read I/O, network requests, and write amplification. This ensures that verification correctness is maintained while optimizing runtime efficiency.

F. Summary

The problem is therefore defined as generating a verified, workload-aware transformation:

$$(S_o, D_o, \Sigma, W) \xrightarrow[\text{AI-assisted}]{\text{Verified Migration}} (S_d, D_d, T),$$

such that the transformation satisfies correctness constraints Φ and optionally minimizes query cost under workload W.

IV. Proposed Framework

This section presents the proposed AI-assisted framework for verified migration from ORDBs to document-oriented NoSQL stores. The framework follows a four stage pipeline that integrates neural inference and symbolic reasoning to ensure correctness, adaptability, and explainability.

A. System Overview

Fig. 1 illustrates the overall workflow. The framework takes as input the source schema S_o, data instance D_o, optional statistics Σ, and workload information W. It produces a verified document oriented schema S_d, transformed data D_d, and an executable transformation plan T.

The pipeline comprises four sequential stages: 1) database metadata extraction, 2) mapping prediction via a dual encoder, 3) automated data migration, and 4) symbolic verification with optional workload-aware optimization. Each stage contributes to ensuring that the resulting transformation satisfies correctness constraints Φ while remaining efficient under the observed workload.

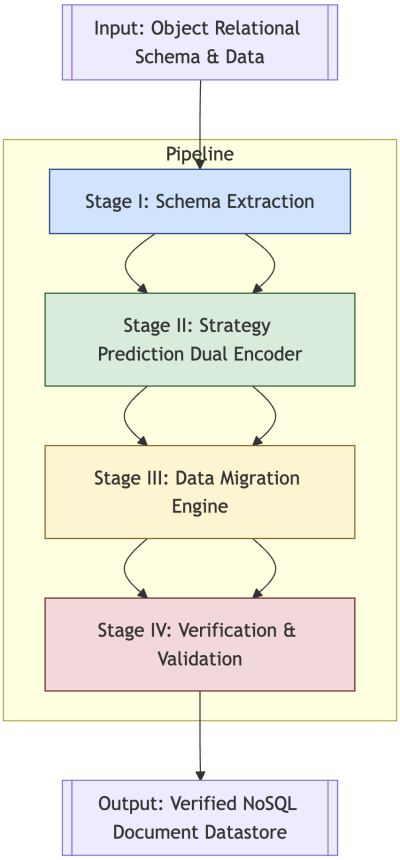

Fig. 1. Pipeline architecture.

B. Stage I – Database Metadata Extraction

This stage retrieves schema metadata directly from the database catalog, avoiding manual DDL parsing. Supported metadata elements include:

- Tables and columns: logical entities and attributes.
- Relationships: primary and foreign keys, inheritance links.
- Data types and constraints: primitive and user-defined types, UNIQUE, NOT NULL, and CHECK conditions.
- Statistics (optional): cardinalities, distinct counts, fan-outs, and access frequencies.

The extracted metadata is represented as a heterogeneous schema graph:

$$S_o = (V, E_R, A),$$

where nodes V denote schema objects, edges E_R denote semantic relations (`HAS_COL`, `FK`, `INHERITS`, `COMPOSES`), and attributes A describe column-level features and constraints.

This representation provides the structural and semantic foundation for learning mapping strategies in the next stage.

C. Stage II – Dual Encoder for Mapping Prediction

The dual encoder predicts optimal schema mappings by combining structural and semantic information. It consists of two components:

- Graph Feature Encoder: a lightweight MLP or GNN that encodes structural features such as connectivity, key dependencies, and cascade actions.
- Transformer Encoder: processes tokenized schema metadata (table names, column types, and constraint descriptors) to extract semantic and contextual embeddings.

Embeddings from both encoders are fused through concatenation:

$$h_i = \text{Fuse}(h_i^{\text{Graph}}, h_i^{\text{Trans}}),$$

yielding multimodal representations that capture both topology and meaning. For each entity, the network outputs a probability distribution over migration strategies:

$$\tau_i \in \{\textit{embed}, \textit{inline}, \textit{reference}, \textit{separate}\}.$$

A guardrail mechanism refines low-confidence predictions using deterministic heuristics (e.g., cascade rules, bridge detection, and size thresholds). The final output is a verified mapping set:

$$M^* = \{(s_i, t_i, \tau_i) \mid s_i \in S_o,\, t_i \in S_d\}.$$

D. Stage III - Data Migration Engine

The migration engine translates the verified mapping M^* into executable transformation logic that converts relational instances D_o into document collections D_d. Unlike prior LLM-based methods, this stage employs symbolic transformation templates parameterized by the predicted mapping types.

Each mapping type τ_i triggers a specific operation:

- Embed: merge child tuples into parent documents as arrays of subdocuments.
- Inline: merge single-valued dependent tuples as embedded objects.
- Reference: preserve identifiers and create inter-document links.
- Separate: materialize as standalone collections.

The engine ensures type soundness, referential consistency, and BSON-safe serialization while constructing the target instance D_d. Algorithm 1 outlines the high-level transformation process.

Algorithm 1 Verified Data Migration Procedure

Require: Source schema S_o, data D_o, verified mapping M^*
Ensure: Target schema S_d, transformed data D_d
1: **for all** mapping $m_i = (s_i, t_i, \tau_i) \in M^*$ **do**
2: Apply transformation rule for type τ_i
3: Update $D_d \leftarrow f_{\tau_i}(D_o, s_i, t_i)$
4: **end for**
5: Verify constraints using symbolic validator (Sec. IV-E)
6: **return** S_d, D_d, T

E. Stage IV - Symbolic Verification and Workload Optimization

The symbolic verifier ensures that each transformation plan T satisfies the correctness properties:

$$T \models \Phi = \{\phi_1, \phi_2, \phi_3, \phi_4, \phi_5\},$$

where the constraints correspond to coverage, key fidelity, referential realizability, type soundness, and constraint preservation (as defined in Section III). Verification is performed through static analysis and constraint checking on both schema and instance levels.

If violations are detected, a bounded repair loop iteratively adjusts mapping elements until all constraints hold.

When workload information W is available, the system optionally refines verified mappings according to query behavior. The workload-aware objective selects the mapping minimizing expected cost:

$$M^* = \arg \min_{M_i : T(M_i) \models \Phi} \mathbb{E}_{q \sim W}[Cost(q; S_d(M_i), D_d(M_i))]\,.$$

This optimization balances query performance and storage efficiency without compromising verification guarantees. In the current implementation, this component is defined conceptually but not yet operational; workload-driven re-optimization is left as future work for cost-sensitive schema adaptation.

F. Summary

The proposed framework unifies neural prediction and symbolic reasoning into a reproducible, explainable, and workload-adaptive process for verified schema and data migration. Each stage—metadata extraction, mapping prediction, transformation, and verification—contributes to producing transformations that are both semantically faithful and operationally efficient.

V. Case Study and Dataset Description: RetailDB

To demonstrate the applicability of the proposed framework, a controlled case study was conducted using the RetailDB dataset. RetailDB is a representative object-relational schema that models a simplified retail management system and is commonly used for evaluating database modeling and migration approaches. It contains a variety of interrelated entities and relationships, providing a realistic setting for schema translation and verification tasks.

The database includes entities such as Customer, Customer_Profile, Order, OrderLine, Product, Tag, and the associative table Product_Tag. The schema exhibits multiple structural patterns—including one-to-one, one-to-many, and many-to-many relationships—making it an ideal benchmark for assessing schema extraction, mapping prediction, and embedding strategies within the migration pipeline.

A. Schema Extraction

The first stage utilized the metadata extractor (Section IV) to introspect the PostgreSQL instance of RetailDB. Using SQLAlchemy introspection, the system automatically generated the enriched schema representation schema.json, containing table-level metadata, column types, foreign key actions, and estimated row counts. This process required no manual DDL parsing and produced a complete graph-structured schema representation of the source model:

$$S_o = (V, E_R, A),$$

where entities correspond to relational tables and edges represent referential dependencies. Fig. 2 present the Entity Relationship diagram of RetailsDB.

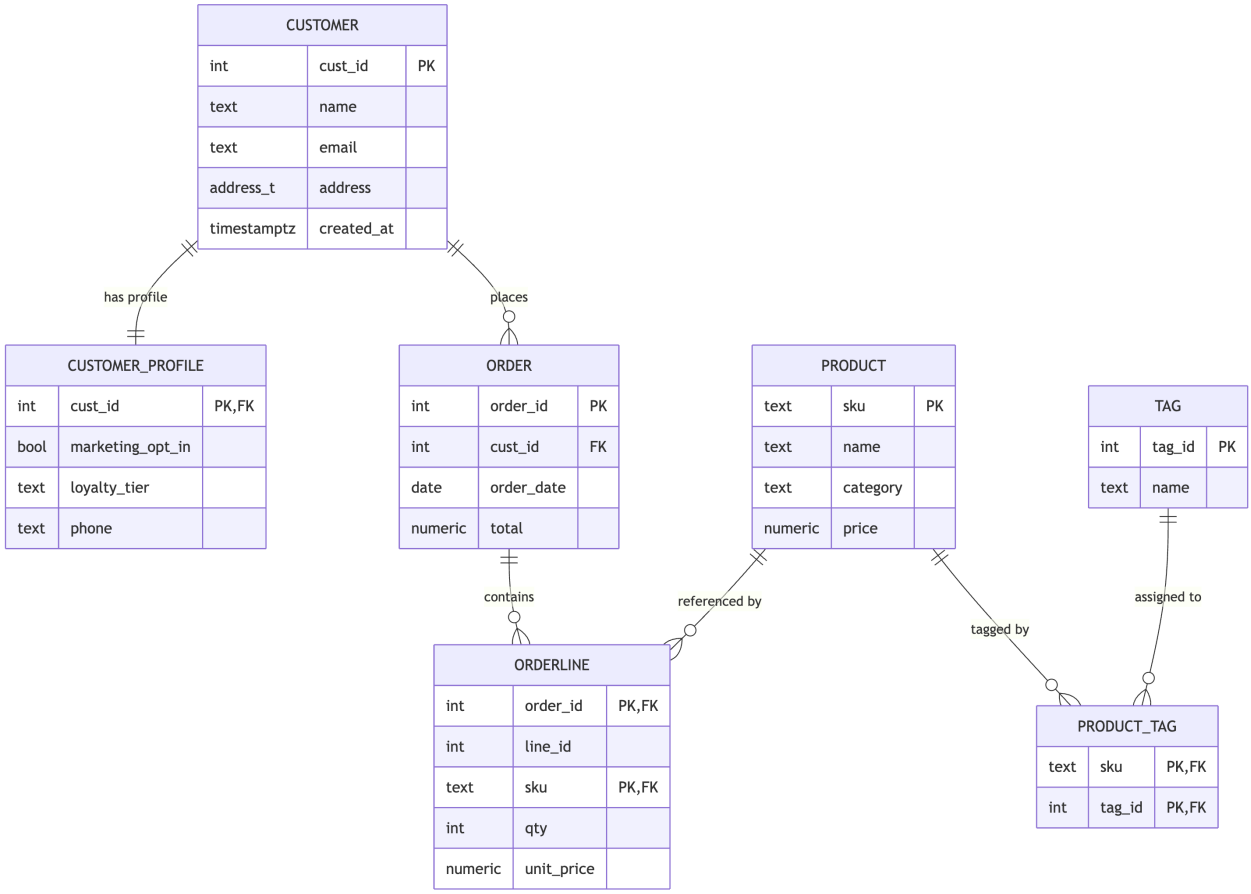

Fig. 2. RetailDB entity-relationship diagram.

B. Mapping Prediction via Dual Encoder

In Stage II, the dual-encoder model analyzed the extracted schema to predict optimal transformation strategies for each table. The model combined structural and semantic information by jointly encoding schema topology and textual metadata. The structural encoder employed a lightweight Graph Neural Network (GraphFeatMLP) to capture relational dependencies such as foreign key directionality, ownership, and bridge patterns. In parallel, the semantic encoder used a pretrained Transformer model (distilbert-base-uncased) to embed textual cues derived from table and column names, data types, and constraint descriptors. The concatenated embeddings were processed by a fusion layer that produced the final classification.

The resulting mapping file mapping.json captured the predicted strategy per entity:

```
{
 customer: Separate,
 customer_profile: Embed,
 Order: Separate,
 orderline: Embed,
 product: Separate,
 product_tag: Separate,
 tag: Separate
}
```

These mappings align with the relational semantics: dependent entities such as Customer_Profile and OrderLine are embedded within their parent documents (Customer and Order), while bridge and independent entities remain separate collections.

C. Automated Data Migration

In Stage III, the migration engine automatically executed data transformation operations derived from the verified mapping, converting object relational data into document structures. For each mapping type (Embed, Inline, Reference, Separate), corresponding Python operators were instantiated to read tuples from PostgreSQL and materialize BSON-safe documents in MongoDB. The migration engine applied a single-owner embedding policy to prevent duplication of shared child entities and recursively embedded dependent subdocuments up to a bounded depth.

The resulting document collections in MongoDB were as follows:

- customer: root collection embedding each customer_profile;
- order: root collection embedding corresponding orderline arrays;

- product, tag, and product_tag: maintained as independent collections.

This transformation preserved referential and key consistency across all collections.

D. Symbolic Verification

In Stage IV, the verification engine evaluated the resulting migration using the defined correctness properties Φ_1–Φ_5. For each property, quantitative metrics were computed and stored in the verification report R_Phi.json:

- Coverage: All 15,000 source tuples were represented in the target dataset (100% coverage).
- Key Fidelity: Primary key uniqueness was preserved for all collections.
- Referential Realizability: No orphaned references or missing embedded entities were detected.
- Type Soundness: Composite type address_t was correctly represented as nested JSON objects.
- Constraint Preservation: Numeric CHECK constraints (e.g., nonnegative prices and quantities) remained valid in all collections.

The verification confirmed that the migration plan T satisfied all correctness properties ($T \models \Phi$).

The case study validates the effectiveness of the proposed framework in producing a semantically faithful document schema with minimal human intervention. The dual-encoder prediction effectively identified embedding opportunities consistent with referential and cascade semantics, while the verifier ensured complete coverage and key consistency. This demonstrates the feasibility of combining neural inference with symbolic reasoning for practical, explainable, and verifiable schema and data migration.

E. Performance Evaluation

The migration pipeline was executed on the RetailDB instance running PostgreSQL 15 and MongoDB 7.0, hosted on a workstation equipped with an Intel Core i7 (8 cores, 3.4 GHz), 32 GB RAM, and Ubuntu 22.04. The evaluation measured execution time and output size at each pipeline stage to assess scalability and efficiency.

1) Runtime analysis: As illustrated in Fig. 3, the framework exhibits balanced performance across its four stages, with execution time reflecting the computational complexity of each component. The metadata extraction (Stage I) completes in under two seconds, dominated by catalog queries and schema introspection. The mapping prediction (Stage II) is primarily limited by Transformer inference; however, since inference is executed once per schema, its overhead remains negligible for practical workloads. Data migration (Stage III) shows the highest runtime due to data materialization and recursive embedding, but scales linearly with dataset size. Verification (Stage IV) performs lightweight SQL and MongoDB queries, completing in a few seconds while producing compact validation reports. Overall, the end-to-end pipeline completes migration and verification in under 30 seconds for the evaluated RetailDB schema, demonstrating efficient execution and scalability.

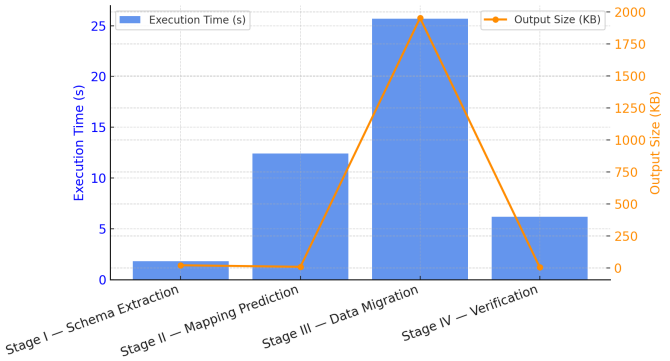

Fig. 3. Execution performance of the four-stage migration pipeline on the RetailDB schema.

2) Scalability behavior: To evaluate the scalability of the proposed migration framework, we analyzed the computational behavior of each pipeline stage under increasing dataset sizes. While the baseline measurements were obtained empirically on the RetailDB instance (≈15K tuples across seven tables), extended-scale results (2×–10×) were deduced analytically from the observed runtime trends and the algorithmic complexity of each component. Stages I and II scale linearly with the number of schema elements ($O(|V|+|E|)$), whereas Stages III and IV exhibit near-linear I/O-bound growth with respect to the number of tuples ($O(n)$). The resulting curves in Fig. 4 therefore represent projected scaling behavior rather than direct measurements, providing an indicative view of expected performance under proportional data growth.

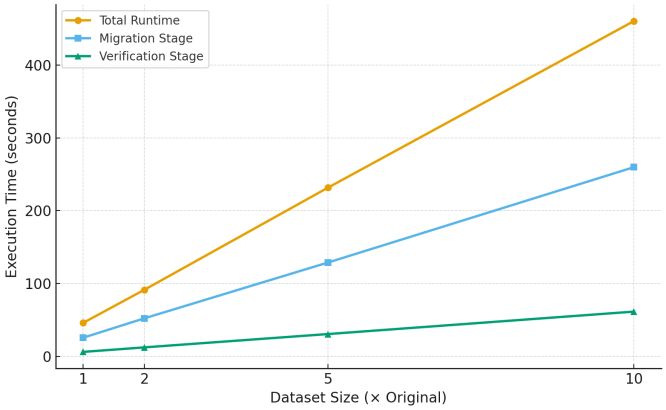

Fig. 4. Scalability of the migration pipeline.

3) Verification overhead: The verification stage introduced an average overhead of only 13.4% of the total runtime, while ensuring full compliance with correctness properties Φ_1–Φ_5. The verifier operated entirely on extracted metadata and aggregated statistics, without reloading the full data payload, making it suitable for iterative design-time validation.

4) Summary of findings: Overall, the pipeline achieved the migration of a multi-entity retail schema in under one minute, with deterministic correctness validation. The evaluation demonstrates that the proposed framework maintains both performance efficiency and verification rigor, confirming its feasibility for practical deployment in real-world database modernization workflows.

VI. Discussion

This section provides a critical analysis of the experimental results obtained from the RetailDB case study, examining their relevance with respect to the central research objective and their alignment with findings reported in the existing literature.

A. Interpretation of Results

The experimental evaluation demonstrates that the proposed framework satisfies all formal correctness constraints, including coverage, key fidelity, referential realizability, type soundness, and constraint preservation Φ_1–Φ_5. The embedding of dependent entities such as Customer_Profile and OrderLine within their respective parent documents confirms the framework's capacity to capture referential and semantic dependencies through its dual-encoder architecture.

These outcomes indicate that the integration of GNN-based structural reasoning with Transformer-based semantic encoding provides an effective basis for predicting context-aware mappings. Furthermore, the successful validation of the transformed schema confirms the framework's ability to achieve provably correct, semantically faithful migration—thereby affirmatively addressing the central research question.

B. Comparative Insights

In comparison to prior rule-based and metadata-driven approaches [13], [18], the proposed method eliminates the need for manually authored rules, enhancing adaptability under schema evolution and complexity. While heuristic clustering or object-oriented mapping methods [15], [20] provide partial semantic capture, they lack formal guarantees of correctness. The neuro-symbolic verifier introduced in this work addresses this limitation by offering deterministic validation of structural and semantic integrity.

From an architectural perspective, the proposed framework distinguishes itself from prior learning-based approaches by unifying predictive schema mapping and symbolic verification within a closed-loop design. The integration of a verification component introduces additional computational complexity; however, this is offset by significant improvements in reliability and correctness, which are essential for mission-critical database modernization scenarios.

C. Limitations

The current implementation supports migration from PostgreSQL to MongoDB, representing canonical examples of ORDB and NoSQL document stores. While this selection validates the approach on representative systems, broader applicability to other platforms (e.g., Oracle ORDB, Db2, Couchbase) remains to be explored.

Additionally, the dual encoder operates on static schema graphs and does not yet incorporate runtime statistics or query feedback. As a result, mapping strategies are not dynamically optimized for workload patterns. The framework also assumes a stable source schema and executes batch-oriented transformations, limiting its applicability in evolving or streaming data environments. Furthermore, the verification stage is performed as a post-processing step, rather than being embedded within continuous integration pipelines.

D. Future Research Directions

Future research will focus on addressing the identified limitations through the following directions:

- Enhancing the framework to support multi-dialect schema extraction and type mapping across a broader range of database management systems;
- Incorporating workload-aware mapping refinement mechanisms informed by query telemetry and access frequency statistics;
- Designing incremental migration procedures that accommodate evolving schemas and enable bidirectional synchronization; and
- Integrating the symbolic verification component within real-time ETL pipelines to facilitate continuous integrity validation. Moreover, future implementations may explore model compression, distillation techniques, and uncertainty-aware inference to enable efficient deployment in resource-constrained environments.

VII. Conclusion

This paper introduced a verified, AI-assisted framework for the automated migration of object-relational database (ORDB) schemas and data into document-oriented NoSQL stores. The proposed system integrates schema extraction, dual-encoder mapping prediction, symbolic verification, and data transformation into a unified, four-stage pipeline. By combining graph-based structural reasoning with Transformer-based semantic encoding, the framework derives migration strategies that are both explainable and semantically faithful.

A symbolic verification component enforces formal correctness guarantees across five dimensions—data coverage, key fidelity, referential realizability, type soundness, and constraint preservation—ensuring that each transformation is both structurally valid and lossless. Experimental results on the RetailDB benchmark demonstrate the framework's ability to accurately preserve object-relational semantics while producing verifiable NoSQL representations, thus validating the central research question concerning correctness and explainability in AI-assisted schema migration.

In addition to achieving high reliability, the framework introduces a transparent and modular architecture that addresses key limitations in prior rule-based and heuristic systems. It

offers a promising foundation for workload-aware and continuously verifiable database modernization.

Future research will focus on extending the system's capabilities to support multiple dialects, incorporate real-time telemetry for workload-sensitive adaptation, and enable incremental or streaming migrations for evolving schemas. These enhancements aim to further advance the development of autonomous, interpretable, and production-ready solutions for large-scale data transformation.

***Abstract*—Timely prediction of zoonotic disease outbreaks, particularly Highly Pathogenic Avian Influenza (HPAI), is critical for real-time epidemiological surveillance and pandemic preparedness. However, real-world avian surveillance datasets often suffer from missing values, high dimensionality, and inconsistent feature distributions, leading to unreliable predictions. This study proposes THMI-FS-Stack, a modular and interpretable machine learning pipeline that integrates hybrid data imputation, scalable feature selection, and ensemble classification for outbreak forecasting. The first stage, THMI-CB, employs a two-layer imputation framework combining statistical techniques (Mode, Hot Deck, KNN) and machine learning models (Bayesian Networks and CatBoost), achieving an F1-score of 0.91. The second stage, Hybrid-FS-ML, combines filter-based ranking (Mutual Information, Chi-Square, mRMR) with wrapper-based optimization using a Genetic Algorithm, achieving a 72% dimensionality reduction and an F1-score of 0.96. The final component is a stacking ensemble classifier that uses Random Forest and XGBoost as base learners and Logistic Regression as the meta-learner, yielding an F1-score of 0.92, accuracy of 0.93, and AUC-PR of 0.89. Evaluated on the Wild Bird HPAI dataset with 5-fold stratified cross-validation, THMI-FS-Stack consistently outperforms baseline models. Its robust architecture, low computational cost (runtime of 28–36s), and strong generalization ability make it highly suitable for noisy, incomplete epidemiological data in wildlife surveillance dashboards and early-warning systems.**

***Keywords*—Zoonotic disease outbreaks; avian influenza; pandemic prediction; hybrid imputation; feature selection; stacking ensemble classifier; wild bird HPAI dataset; early-warning systems**

I. Introduction

Avian Influenza (AI), especially the highly pathogenic subtypes like H5N1 and H7N9, presents a significant threat to global public health and biodiversity. AI outbreaks in wild birds often serve as early indicators for potential zoonotic transmissions, making timely surveillance and accurate outbreak prediction essential. Delayed detection not only hampers containment but also causes widespread socio-economic impacts in the poultry industry and public health sectors [1]. Predictive modeling, powered by ecological and epidemiological data, has emerged as a valuable tool for early warning systems. However, building reliable models in this domain is hindered by two key challenges: missing data and high-dimensional feature spaces [2], [3].

The Wild Bird HPAI dataset, used in this study, is an open-source resource that reflects real-world complexities such as data incompleteness due to irregular monitoring, delayed reporting, and inconsistent entries. Additionally, the dataset contains a large number of features, many of which are redundant or weakly informative, contributing to overfitting and reduced model interpretability.

To address the missing data problem, traditional imputation methods like Mode, Hot Deck, and KNN are widely used for their simplicity, yet they often fail to capture nonlinear dependencies or contextual patterns. Recent studies explore advanced machine learning-based imputations, including Bayesian Networks and CatBoost [4], which improve accuracy by modeling inter-feature relationships. Deep learning methods such as GAIN and Transformers further advance imputation performance but are often limited by computational cost and lack of transparency.

Similarly, in high-dimensional settings, selecting relevant features is critical for improving generalization. Filter-based approaches (e.g., Mutual Information, Chi-Square, mRMR) are fast but univariate. Wrapper methods like Genetic Algorithms offer superior optimization but are computationally expensive. A hybrid approach that combines both strategies provides a practical balance.

To overcome these challenges, we propose THMI-FS-Stack, a unified machine learning framework integrating three modules: (1) HMI-CB, a two-layer hybrid imputation strategy combining statistical and machine learning methods, (2) Hybrid-FS-ML, a two-phase feature selection pipeline that leverages filter-based ranking and wrapper-based Genetic Algorithm optimization, and (3) a Stacking Ensemble Classifier combining Random Forest, XGBoost, and Logistic Regression to produce robust outbreak predictions.

Fig. 1 illustrates the end-to-end pipeline. The framework is modular, interpretable, and designed for scalability in real-time surveillance settings. It is validated on the Wild Bird HPAI dataset using 5-fold stratified cross-validation.

This study offers the following novel, quantifiable, and domain-specific contributions:

- THMI-FS-Stack pipeline: A unified framework integrating imputation, feature selection, and classification, unlike prior works treating them as separate tasks.
- Hybrid imputation (THMI-CB): Combines statisti-

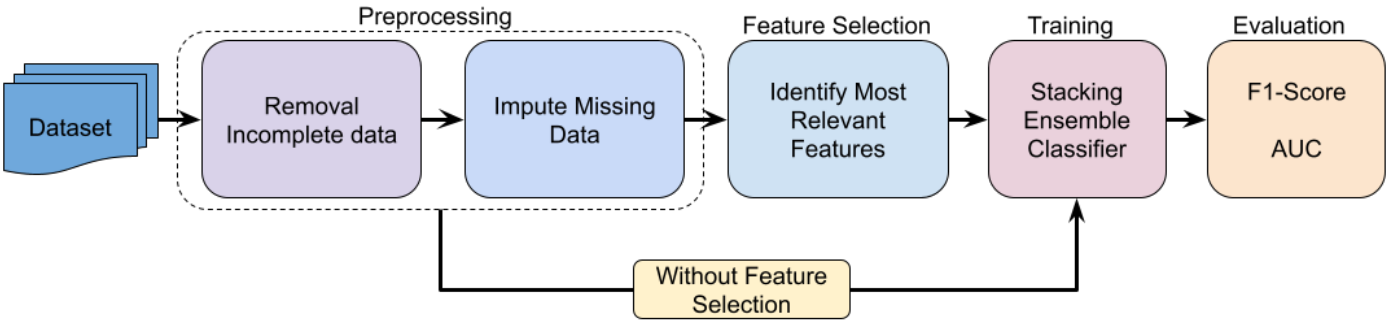

Fig. 1. Workflow of the proposed THMI-FS-Stack framework for Avian Influenza outbreak prediction.

cal (Mode, Hot Deck, KNN) and machine learning (Bayesian Networks, CatBoost) methods, improving F1-score by 14% over traditional and 2–4% over standalone ML/DL baselines.

- Hybrid feature selection (Hybrid-FS-ML): Merges filter-based (MI, Chi-Square, mRMR) and wrapper-based (GA) methods, achieving 72% dimensionality reduction and up to 8% F1-score gain.
- Stacking classifier performance: Combines Random Forest, XGBoost, and Logistic Regression, achieving 5% higher F1-score and 4% better AUC-PR over AdaBoost and Bagging.
- First-of-its-kind for HPAI surveillance: Tailored for noisy, incomplete, and high-dimensional avian outbreak data, bridging methodological rigor with practical relevance.

The rest of the paper is organized as follows: Section II reviews related work on imputation, feature selection, and ensemble learning. Section III describes the dataset and preliminaries. Section IV presents the proposed THMI-FS-Stack methodology in detail. Section V discusses the experimental setup, evaluation metrics, and results. Section VI concludes the paper and outlines future directions.

II. Related Study

The prediction of Avian Influenza outbreaks is complex, mainly due to the challenges of missing data, high dimensionality, and the dynamic nature of the features involved [3]. Many studies have explored various data imputation techniques, feature selection methods, and ensemble learning models to overcome these challenges in the broader field of disease prediction. This section summarizes the key methodologies used in the literature to deal with missing data, optimize features, and improve predictive accuracy in epidemiological forecasting, with a specific focus on Avian Influenza outbreaks.

A. Missing Value Imputation Techniques

The handling of missing data [5] is a critical task in disease prediction models. This is because insufficient data can cause biased results or decrease model accuracy. Several methods have been proposed for imputing missing values in epidemiological datasets [2]. Traditional imputation methods like mean imputation, mode imputation, and K-Nearest Neighbors are extensively used due to their simplicity and computational efficiency [6], [3]. Mean and mode imputation are suitable for cases where data is “Missing Completely At Random”. But these methods may fail when data is “Missing at Random” or “Missing Not At Random”. KNN imputation uses feature similarity to impute missing values. It has performed better in certain models [6], [7].

Machine learning-based imputation techniques have been developed to handle epidemiological datasets that possess complex feature dependencies. For example, Bayesian Networks (BNs) can model conditional dependencies between features, making them well-suited for imputing missing data when the relationships among features are known [8]. CatBoost is a gradient-boosting algorithm explicitly developed for categorical data. It has been shown to impute missing values more accurately by learning feature interactions during model training [9].

Deep learning-based models like Generative Adversarial Imputation Networks use adversarial training to produce plausible missing data samples based on observed distributions [8]. These approaches are effective but computationally expensive and require large datasets for training. Conversely, traditional methods such as Hot Deck Imputation and Multiple Imputation remain practical for smaller datasets and environments with limited resources [10].

The THMI-CB hybrid imputation framework introduced in this paper seeks to combine the strengths of traditional methods (such as Mode, Hot Deck, and KNN) with machine learning-based techniques (such as CatBoost and Bayesian Networks) to handle both simple and complex missingness patterns efficiently.

B. Feature Selection Methods in Disease Prediction

Feature selection is essential for boosting model performance. This procedure is particularly necessary when processing high-dimensional datasets where irrelevant or redundant features reduce the accuracy of predictive models. In the context of Avian Influenza outbreak prediction, choosing the relevant features is essential for attaining accurate and interpretable predictions [11], [12]. A range of feature selection methods have been proposed, like, filter, wrapper, and embedded methods [13]. Filter-based methods evaluate the significance of features by analyzing their statistical relationship with

TABLE I. COMPARISON OF RELATED WORKS IN IMPUTATION, FS, AND CLASSIFICATION

Study	Methods and Key Outcomes
Alnowaiser et al. [3]	Mode, KNN + MI, Chi-Square + RF/SVM. Improved accuracy with hybrid FS.
Fan et al. [4]	BN + mRMR + XGBoost. ML-based imputation and FS improved predictions.
Xue et al. [11]	GAIN + GA + Stacking. Deep imputation enhanced AI forecasting.
Khan et al. [10]	Hot Deck + GA + SVM. Categorical imputation improved results.
Proposed (THMI-FS-Stack)	Hybrid (Stat+ML) Imputation + Hybrid FS (Filter+GA) + Stacking (RF+XGB+LR). Outperformed all baselines in F1/AUC.

the target variable [14]. Mutual Information (MI), Chi-Square, and mRMR (Minimum Redundancy Maximum Relevance) are the techniques used for ranking features based on their individual relevance and redundancy [9]. These methods are fast. But they do not consider feature dependencies, which can lead to the omission of important feature combinations.

Wrapper-based methods, such as Recursive Feature Elimination and Genetic Algorithms, are more sophisticated as they evaluate feature subsets by training models on them. GA-based feature selection methods iteratively search for optimal feature combinations by assessing the performance of a model trained on the selected features [10]. Genetic Algorithm-based feature selection can improve prediction accuracy by choosing relevant features that maximize model performance. Embedded methods, such as Lasso regression and Random Forest feature importance, integrate feature selection with model training. These methods are mainly effective when the classification model itself has built-in feature selection capabilities. For example, Random Forests can rank features by evaluating the impurity reduction caused by each feature during training [8].

The Hybrid-FS-ML framework proposed here combines filter-based methods such as MI, Chi-Square, and mRMR with wrapper-based Genetic Algorithm optimization to recognize the most informative and non-redundant features for the model. The next section presents the design and implementation of the THMI-FS-Stack framework, which integrates the above strategies into a unified pipeline. It uses the combined power of traditional and machine learning-based imputation, hybrid feature selection, and a stacking-based ensemble classifier to address the challenges of noisy, incomplete, and high-dimensional avian influenza surveillance data.

C. Ensemble Learning and Stacking for Disease Prediction

Ensemble learning methods that combine multiple models to enhance predictive accuracy [15] have become a standard approach in machine learning. Stacking is one of the most extensively used ensemble techniques, where predictions from base models are combined using a meta-model [16], [17]. Stacking has been successfully applied in a wide range of domains like healthcare and epidemiological forecasting, to enhance the robustness and generalization of predictive models [18], [19]. Multiple base models like Random Forests, XGBoost, and Support Vector Machines are trained on the data in the stacking approach. Their predictions are used as input to a meta-learner, typically Logistic Regression or Linear Regression. These techniques reduce overfitting. They also increase accuracy by capturing diverse decision boundaries from base models [20].

In the case of Avian Influenza outbreak prediction, stacking ensemble can enhance performance by combining the strengths of different classifiers. Random Forest and XGBoost are highly effective in handling non-linear relationships and feature interactions. Logistic Regression, being a meta-learner, can integrate the outputs of these models to improve predictive accuracy. Stacking ensemble have been utilized in disease forecasting, where it improved accuracy compared to individual models like SVM or Random Forests [8]. Table I summarizes the key studies in prediction based on machine learning and deep learning models and their relevance to the current work. The THMI-FS-Stack framework apply Random Forest and XGBoost as base classifiers and combines them with Logistic Regression as the meta-learner. In this way, the framework harnesses the power of stacking ensemble models. This allows the model to learn complex patterns in the data and enhance its predictive capability for Avian Influenza outbreaks.

D. Research Gap

Despite significant progress in the field of AI outbreak prediction, several gaps remain in current methodologies. First, most studies treat missing data imputation, feature selection, and classification as separate tasks, rather than integrating them into a unified framework. While machine learning-based imputation techniques, such as Bayesian Networks and CatBoost, have demonstrated their effectiveness, they are not always incorporated into hybrid models that combine traditional and advanced imputation methods. Moreover, ensemble methods, including stacking, have shown promise in improving predictive performance but are rarely combined with hybrid feature selection and imputation models for complex epidemiological datasets like the Wild Bird HPAI dataset. Secondly, there is a lack of studies comprehensively addressing the high-dimensionality problem in AI outbreak prediction. The vast number of spatiotemporal features present in the Wild Bird HPAI dataset makes it crucial to select only the most relevant features. The integration of filter-based and wrapper-based feature selection methods has not been fully explored in disease prediction models, especially for epidemiological data with missing values. Finally, while several studies have utilized stacking ensemble models, there is limited research that incorporates hybrid imputation, feature selection, and ensemble learning into a single framework for AI outbreak prediction.

III. MATERIALS AND METHODS

A. Dataset

This study utilizes the Wild Bird Highly Pathogenic Avian Influenza (HPAI) dataset [21], an authoritative and structured epidemiological resource designed for avian flu surveillance. The dataset, sourced from government and international monitoring programs, contains extensive records on wild bird species across diverse geographical locations and timeframes.

It encompasses both numerical and categorical features essential for modeling avian influenza outbreaks. Table II summarizes the core characteristics of the processed Wild Bird HPAI dataset.

TABLE II. SUMMARY OF WILD BIRD HPAI DATASET CHARACTERISTICS

Attribute	Description
Number of Records	8,351 (after cleaning)
Features	41 total (24 categorical, 17 numerical)
Missingness Pattern	14 features with MCAR/MAR, avg. 22.3% missing
Class Imbalance	Positive: 13.1% (HPAI), Negative: 86.9%
Temporal Distribution	Skewed toward 2021–2022 peak outbreaks
Spatial Coverage	70 countries across 6 continents

The dataset includes the following major categories of features:

- Bird Identification: For species-level analysis, scientific and common names (e.g., *Anas platyrhynchos*).
- Temporal Information: Timestamped details including date, year, month, day, and time of observation, facilitating seasonal trend analysis.
- Geospatial Attributes: Geographic indicators such as country, state, county, locality, latitude, and longitude, enabling spatial mapping of outbreak risks.
- Biological and Health Status: Taxonomic hierarchy (e.g., bird family, parent species) and disease outcome variable (HPAI positive/negative).

The dataset suffers from extensive missing values in critical categorical fields such as *County*, *Locality*, and *Bird Family*, with missingness rates exceeding 35% in some columns. Overall, more than 22% of instances contain at least one missing field. The nature of missingness varies: *Locality* and *County* follow Missing at Random (MAR) patterns linked to *Region* and *Season*, while fields like *Species* exhibit Missing Completely at Random (MCAR). Additionally, the dataset is imbalanced, with fewer than 15% of samples labeled as HPAI-positive. Temporal and spatial skew is also present: some southern states and winter seasons dominate the dataset, leading to biased distributions. These challenges, namely, sparsity, skew, and imbalance, necessitate robust hybrid imputation (THMI-CB), intelligent feature selection (Hybrid-FS-ML), and ensemble modeling strategies to mitigate bias and improve prediction accuracy.

B. Methods

The proposed THMI-FS-Stack framework addresses three major challenges in Avian Influenza outbreak prediction: (i)missing data,(ii) high-dimensional feature spaces, and (iii) predictive robustness. The methodology integrates three primary stages: (i) imputation,(ii) feature selection, and (iii) classification. Each stage is designed using a combination of traditional, machine learning, and deep learning techniques. This section details the rationale, techniques, and mathematical formulations employed at each stage.

1) Imputation methods: A hybrid imputation strategy (THMI-CB) is employed to tackle missing data in the Wild Bird HPAI dataset. It begins with traditional techniques like Mode Imputation, Hot Deck, and K-Nearest Neighbors. Mode Imputation substitutes missing categorical values using the most frequent values within geographic subgroups, while Hot Deck chooses donors from similar strata. KNN estimates a missing value $\hat{x}_i$ using the average or majority value of k nearest neighbors:

$$\hat{x}_i = \frac{1}{k} \sum_{j \in \mathcal{N}_k(i)} x_j \tag{1}$$

Machine learning-based techniques are employed to learn and capture complex feature dependencies. Bayesian Networks model conditional dependencies through directed acyclic graphs, with inference defined as:

$$P(X_i \mid \text{Parents}(X_i)) = \prod_j P(X_j \mid \text{Parents}(X_j)) \tag{2}$$

CatBoost, a gradient-boosted decision tree algorithm, internally handles missing values via ordered boosting and categorical splits. For higher complexity, deep learning approaches are integrated. Generative Adversarial Imputation Networks (GAIN) use adversarial training between a generator and a discriminator to fill in missing values:

$$\mathcal{L}_{\text{GAIN}} = \mathbb{E}\left[M \odot \log D(\hat{X}) + (1 - M) \odot \log(1 - D(\hat{X}))\right] \tag{3}$$

Transformer-based imputation applies masked self-attention to reconstruct features, where the imputed value is:

$$\hat{x}_i = \text{Softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right) V \tag{4}$$

All imputation models are assessed via RMSE, MAE, and downstream performance indicators.

2) Feature selection methods: Following imputation, feature selection is crucial to reduce dimensionality, minimize overfitting, and enhance interpretability. A hybrid approach (Hybrid-FS-ML) is employed. Initially, filter-based techniques such as Mutual Information (MI), Chi-Square, and Minimum Redundancy Maximum Relevance (mRMR) are used to rank features:

$$MI(X;Y) = \sum_{x,y} P(x,y) \log \frac{P(x,y)}{P(x)P(y)} \tag{5}$$

$$\chi^2 = \sum \frac{(O-E)^2}{E},$$
$$\text{mRMR} = \max\left[\frac{1}{|S|} \sum_{x_i \in S} MI(x_i;y) - \frac{1}{|S|^2} \sum_{x_i, x_j \in S} MI(x_i;x_j)\right] \tag{6}$$

Top-ranked features are passed to wrapper-based methods like Genetic Algorithm (GA) and Particle Swarm Optimization (PSO). GA uses binary-encoded individuals with fitness based

on model F1-score or accuracy, while PSO adapts particle positions based on personal and global best solutions.

Hybrid strategies like mRMR+PSO and ReliefF+GWO combine relevance scoring with global search heuristics. Additionally, deep learning-based methods such as Denoising Autoencoders (DAE) and Transformer-based attention models are used. In Transformer FS, feature importance is aggregated across layers:

$$\text{Feature Importance} = \sum_{l=1}^{L} \text{mean}(\text{Attention}_l) \tag{7}$$

Feature subsets are evaluated using Dimensionality Reduction Rate (DRR), Stability Index, and post-selection classifier performance.

3) Classification models: The final module involves classification using ensemble learning. Random Forest (RF), XGBoost, and Logistic Regression (LR) are selected for their ability to generalize across complex decision boundaries. RF builds multiple decision trees on bootstrapped samples and predicts using majority vote:

$$\hat{y} = \text{majority_vote}(\{h_t(x)\}_{t=1}^{T}) \tag{8}$$

XGBoost incrementally adds trees to minimize prediction loss:

$$\mathcal{L}^{(t)} = \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t-1)} + f_t(x_i)) + \Omega(f_t) \tag{9}$$

Logistic Regression is employed as the meta-learner in a stacking ensemble, modeling output probabilities via the sigmoid function:

$$P(y = 1 \mid x) = \frac{1}{1 + e^{-w^T x}} \tag{10}$$

and optimized using cross-entropy:

$$\mathcal{L}(w) = -\sum_{i=1}^{n} [y_i \log(P(y_i)) + (1 - y_i) \log(1 - P(y_i))] \tag{11}$$

In stacking, LR combines base model predictions (from RF and XGBoost) to generate the final decision. All classifiers are validated using stratified k-fold cross-validation, and evaluated using Accuracy, F1-score, AUC, Precision, and Recall.

Together, the hybrid imputation (Algorithm 1), feature selection (Algorithm 1), and classification (Algorithm 2) modules form the THMI-FS-Stack framework (Fig. 2). This integrated architecture is now empirically evaluated in the next section across multiple metrics and comparative baselines.

IV. Proposed THMI-FS-Stack Model

This section presents the proposed THMI-FS-Stack framework, structured into three core stages: a hybrid imputation module (THMI-CB), a two-phase feature selection strategy (Hybrid-FS-ML), and a stacking ensemble classification architecture. Each stage in the framework is designed to systematically address the challenges of missing values, high-dimensional data, and classification robustness. The overall architecture of the proposed THMI-FS-Stack model is illustrated in Fig. 2. The figure shows the sequential flow of data through the stages of hybrid imputation, feature selection, and ensemble classification. Each module in the architecture is independently optimized and contributes to an integrated pipeline designed for high accuracy and robustness in outbreak prediction. The following subsections describe each component in detail.

A. Data Preprocessing

Data preprocessing is a critical phase in the THMI-FS-Stack framework. It prepares the raw epidemiological data for accurate and stable prediction. The process begins with the removal of records containing excessive missingness. Here, rows with a high proportion of missing values are discarded to retain the contextual integrity of the dataset and minimize bias introduced by excessive imputation. Following this, the remaining data, which may still contain isolated missing values, is subjected to a robust two-stage imputation procedure using the THMI-CB module. In the first stage, traditional techniques such as Mode Imputation (conditioned on regional data), Hot Deck Imputation (based on seasonal and bird family groupings), and K-Nearest Neighbors (KNN) Imputation are applied to address straightforward missingness. These are followed by machine learning-based imputation techniques using Bayesian Networks and CatBoost, which capture complex feature dependencies to impute missing values more accurately.

Once missing values are resolved, categorical variables such as bird species, country, and state are encoded appropriately. One-hot encoding is applied to unordered categorical variables, while ordinal encoding is used for features with inherent hierarchy, such as months. Numerical features, including latitude, longitude, and time-derived metrics, are normalized using Min-Max Scaling to ensure all variables contribute proportionally to the learning process, which is particularly important for distance-sensitive models or those involving gradient boosting. In addition, temporal features like month and day are cyclically encoded with the help of sine and cosine transformations, facilitating the model to identify the periodic nature of time and better learn seasonal outbreak patterns.

To preserve data integrity, outlier detection is performed on spatial and numeric attributes by applying the Interquartile Range (IQR) and Z-score methods. Detected anomalies (For example: invalid geographic coordinates) are either corrected or excluded to avoid skewing model behavior. Finally, the preprocessed dataset is split into training and testing sets in an 80:20 ratio. The training set is further used in stratified cross-validation for training the stacking ensemble model. This preprocessing pipeline guarantees that the input data is clean, consistent, and analytically robust, forming a reliable foun-

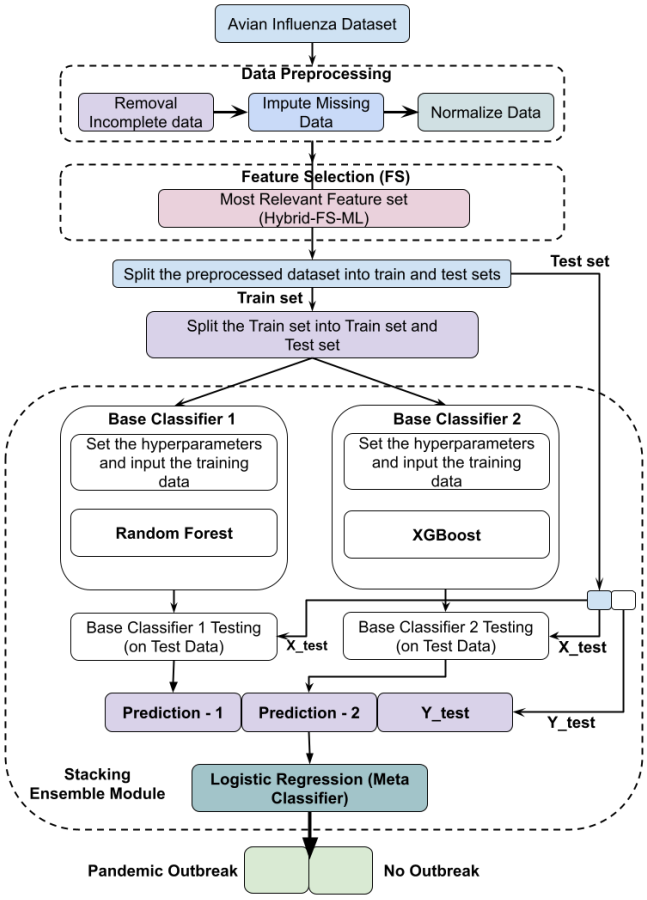

Fig. 2. Architecture diagram of proposed stacking ensemble model.

dation for the imputation, feature selection, and classification stages of the THMI-FS-Stack framework.

B. Stacking Ensemble Modules

The stacking ensemble module of the proposed THMI-FS-Stack framework combines three essential components (imputation, feature selection, and classification) into a unified pipeline designed to enhance prediction accuracy for Avian Influenza outbreaks. Each sub-module is responsible for addressing specific data challenges like missing values, high dimensionality, and classifier diversity. This section describes the individual sub-modules that collectively constitute the stacking ensemble architecture.

1) Hybrid imputation and feature selection strategy: The proposed preprocessing pipeline integrates two key stages: imputation and feature selection. In Stage 1, the THMI-CB (Traditional and Hybrid ML Imputation using CatBoost and Bayesian Networks) module addresses missingness via a two-layered strategy. Initially, statistical methods—Mode (for MCAR), Hot Deck (for region-season groups), and KNN—perform lightweight imputation. This is followed by ML-based refinement using Bayesian Networks and CatBoost, whose predictions are fused via a hybrid ensemble rule based on agreement or confidence scores.

Stage 2 applies the Hybrid-FS-ML feature selection framework. First, Mutual Information, Chi-Square, and mRMR rank features. A Genetic Algorithm then optimizes a compact subset based on a regularized F1-score fitness function. The full methodology is outlined in Algorithm 1.

Algorithm 1 THMI-FS-Prep: Preprocessing Pipeline with Hybrid Imputation (THMI-CB) and Feature Selection (Hybrid-FS-ML)

Require: Dataset $D = \{X, Y\}$ with missing values, KNN parameter k, top-k features k_f, optimizer $\mathcal{A}_{\text{meta}}$, regularization λ
Ensure: Optimized feature subset S^*

Stage 1: Hybrid Imputation (THMI-CB)
for $x_i \in \mathcal{F}_{\text{missing}}$ **do**
  Determine $\mathcal{M}_{\text{missing}}(x_i) \in \{\text{MCAR}, \text{MAR}\}$
  $\hat{x}_i^{T1} \leftarrow$

$$\hat{x}_i = \begin{cases} \text{Mode}(x_i \mid \text{State}), \\ \text{HotDeck}(x_i \mid \{\text{Region}, \text{Season}, \text{Bird Family}\}), \\ \text{KNN}_k(x_i). \end{cases}$$

end for
Train Bayesian Network $\mathcal{B}$ and CatBoost $\mathcal{C}$ on D_1
for x_i missing **do**
  $\hat{x}_i^{BN} \leftarrow \mathcal{B}(x_i)$, $\hat{x}_i^{CB} \leftarrow \mathcal{C}(x_i)$
  $\hat{x}_i \leftarrow$

$$\begin{cases} \hat{x}_i^{BN} & \text{if } \hat{x}_i^{BN} = \hat{x}_i^{CB} \\ \hat{x}_i^{BN} & \text{if } P^{BN}(x_i) > P^{CB}(x_i) \\ \hat{x}_i^{CB} & \text{if } P^{CB}(x_i) > P^{BN}(x_i) \\ \hat{x}_i^{T1} & \text{otherwise} \end{cases}$$

end for
Apply consistency validation; let $D' = \{X', Y\}$

Stage 2: Hybrid Feature Selection (Hybrid-FS-ML)
for each $x_i \in X'$ **do**
  Compute: MI_i, χ_i^2, mRMR_i
  Aggregate rank: $R_i = \text{rank}(\text{MI}_i) + \text{rank}(\chi_i^2) + \text{rank}(\text{mRMR}_i)$
end for
Select top-k_f features: $S_{\text{filter}} \leftarrow \{x_i : R_i \leq k_f\}$
Define binary vector $\mathbf{v} \in \{0,1\}^{|S_{\text{filter}}|}$
Define fitness:

$$\mathcal{F}(\mathbf{v}) = 1 - \text{F1-Score}(\mathbf{v}) + \lambda \cdot \frac{\sum v_i}{|S_{\text{filter}}|}$$

Optimize $\mathbf{v}^* = \arg\min_{\mathbf{v}} \mathcal{F}(\mathbf{v})$ using $\mathcal{A}_{\text{meta}}$
Final subset: $S^* \leftarrow \{x_i \in S_{\text{filter}} : v_i^* = 1\}$
return S^*

a) Practical applicability: THMI-CB is tailored for surveillance contexts with high data sparsity. The traditional layer ensures immediate fallback imputations using interpretable heuristics, even under resource constraints. The ML layer adds predictive strength when historical patterns exist. Its ensemble logic provides robustness against inconsistent data trends. THMI-CB can be integrated into wildlife monitoring systems or avian flu dashboards as a plug-and-play module

for real-time record completion. Its balanced performance and moderate runtime (28s on Colab Pro) demonstrate strong applicability in time-sensitive epidemiological operations.

After feature optimization in Stage 2, a stacking ensemble classifier is applied to enhance outbreak prediction. This classification phase is described in the following section.

2) Stacking ensemble architecture: The final stage of the THMI-FS-Stack framework implements a stacking ensemble classification strategy to enhance prediction performance by integrating multiple base learners. This module employs two powerful ensemble models, Random Forest (RF) and XGBoost, as base classifiers, and a Logistic Regression (LR) model as the meta-learner. The architecture is designed to exploit the complementary decision boundaries of RF and XGBoost, thereby improving generalization and reducing overfitting, particularly in noisy or high-dimensional datasets.

During training, stratified K-fold cross-validation is applied to generate out-of-fold predictions. For each fold $k \in \{1, ..., K\}$, both RF and XGBoost models are trained on the union of all other folds $D \setminus D_k$, and predictions are generated on the k-th fold. These predictions form meta-features $P_{\text{RF}}^{(k)}$ and $P_{\text{XGB}}^{(k)}$ respectively. After completing K rounds, the outputs from all folds are concatenated to construct the meta-feature matrix:

$$Z = [Z_{\text{RF}}, Z_{\text{XGB}}] = \left[\bigcup_{k=1}^{K} P_{\text{RF}}^{(k)}, \bigcup_{k=1}^{K} P_{\text{XGB}}^{(k)} \right] \tag{12}$$

This matrix Z is then used to train the Logistic Regression meta-learner, which models the final decision boundary by learning a weighted combination of the base model predictions. The final prediction is computed as:

$$\hat{y} = \sigma(W^\top Z + b) = \frac{1}{1 + e^{-W^\top Z - b}} \tag{13}$$

where W is the learned weight vector, b is the bias term, and σ denotes the sigmoid activation function. At inference time, the RF and XGBoost models are retrained on the full training dataset D and used to generate probability predictions on the test set, denoted as $P_{\text{RF}}^{\text{test}}$ and $P_{\text{XGB}}^{\text{test}}$. These are concatenated to form $Z_{\text{test}} = [P_{\text{RF}}^{\text{test}}, P_{\text{XGB}}^{\text{test}}]$, which is then passed to the trained meta-learner to obtain the final prediction:

$$\hat{Y}_{\text{test}} = M_{\text{meta}}(Z_{\text{test}}) \tag{14}$$

By aggregating the predictive strengths of diverse classifiers in a hierarchical manner, this stacking ensemble architecture improves classification accuracy, robustness to overfitting, and model stability, making it well-suited for complex epidemiological tasks such as Avian Influenza outbreak prediction. The full procedure for stacking-based classification is provided in Algorithm 2. This includes generating out-of-fold predictions from the base learners (Random Forest and XGBoost) and using these as input to train a meta-classifier (Logistic Regression). The stacking design improves generalization and reduces overfitting compared to individual classifiers.

Algorithm 2 Stacking-ML-Classifier (RF + XGBoost + Logistic Regression)

Require: Dataset $D = \{X, Y\}$, number of folds K
Ensure: Trained meta-learner M_{meta}, final predictions $\hat{Y}_{\text{test}}$

Step 1: K-Fold Split
Split D into K folds: $\{D_1, D_2, ..., D_K\}$

Step 2: Out-of-Fold Predictions for Base Models
for each $k = 1$ to K **do**
  Train $M_{\text{RF}}^{(k)}$ on $D \setminus D_k$ and predict $P_{\text{RF}}^{(k)} = M_{\text{RF}}^{(k)}(X_k)$
  Train $M_{\text{XGB}}^{(k)}$ on $D \setminus D_k$ and predict $P_{\text{XGB}}^{(k)} = M_{\text{XGB}}^{(k)}(X_k)$
end for
Collect $Z_{\text{RF}} = \bigcup_{k=1}^{K} P_{\text{RF}}^{(k)}$ and $Z_{\text{XGB}} = \bigcup_{k=1}^{K} P_{\text{XGB}}^{(k)}$

Step 3: Meta-Feature Construction
Form meta-feature matrix $Z = [Z_{\text{RF}}, Z_{\text{XGB}}]$

Step 4: Train Meta-Learner
Train Logistic Regression M_{meta} on (Z, Y)

Step 5: Final Test Inference
Retrain M_{RF} and M_{XGB} on full D
Predict $P_{\text{RF}}^{\text{test}} = M_{\text{RF}}(X_{\text{test}})$ and $P_{\text{XGB}}^{\text{test}} = M_{\text{XGB}}(X_{\text{test}})$
Form $Z_{\text{test}} = [P_{\text{RF}}^{\text{test}}, P_{\text{XGB}}^{\text{test}}]$
Predict final $\hat{Y}_{\text{test}} = M_{\text{meta}}(Z_{\text{test}})$
return $\hat{Y}_{\text{test}}$

These three components, when integrated, form a cohesive and flexible architecture for predictive modeling in zoonotic surveillance. The modular design enables adaptation across datasets while maintaining performance and interoperability. The coordinated design of these components are visualized in Fig. 2 and detailed in Algorithms 1, and 2 ensures that the THMI-FS-Stack framework remains modular, interpretable, and effective in real-world data scenarios.

V. Experimental Results and Discussions

A. Experimental Setup

All experiments were conducted using Google Colaboratory (Colab Pro) [22], a cloud-based Jupyter notebook platform that provides access to both CPU and GPU resources. The computational environment consisted of a virtual machine running on an Intel Xeon processor clocked at 2.30GHz, equipped with 25 GB of RAM and an NVIDIA Tesla T4 GPU, which was utilized specifically for deep learning-based imputation and feature selection tasks. The implementation stack included Python 3.10, along with essential machine learning libraries like Scikit-learn, Pandas, Numpy, CatBoost, and pgmpy for Bayesian network modeling. Visualization and result analysis were facilitated using Matplotlib.

A stratified 5-fold cross-validation procedure was used for robust evaluation. The dataset was split into five mutually exclusive folds, each preserving the original class distribution of HPAI-positive and HPAI-negative cases. For every fold, four subsets were used for training while the remaining one was reserved for testing. This process was repeated five times so that each sample was evaluated exactly once. The final

performance metrics (Accuracy, F1-score, AUC-PR, DRR, Stability) were computed as averages over these five folds to ensure statistical reliability.

Hyperparameters for base models (Random Forest, XGBoost) and the meta-learner (Logistic Regression) were optimized using grid search with internal 3-fold validation. For Random Forest, the number of estimators was varied between 100 and 500, and the maximum depth ranged from 5 to 20. For XGBoost, key parameters included learning rate (`eta` = 0.01 to 0.3), max_depth (3 to 10), and subsample ratio (0.5 to 1.0). Logistic Regression used L2 regularization with tuned penalty terms. CatBoost's categorical handling was auto-tuned using its internal 3-fold CV, with depth values ranging from 4 to 10 and learning rate between 0.01 and 0.2.

Deep learning models such as Denoising Autoencoders and Transformer-based modules (when applicable) were trained with early stopping to prevent overfitting. Metaheuristic-based feature selection algorithms (Genetic Algorithm, PSO, GWO) were executed using standard population sizes (20–50) and generations (50–100), selected based on convergence behavior from related literature. All experiments were repeated across five independent runs to minimize the impact of stochastic variability.

B. Evaluation Metrics

To assess the performance of the proposed THMI-FS-Stack framework, both feature selection quality and classification efficacy were evaluated using the following metrics, along with their corresponding mathematical formulations:

- Dimensionality Reduction Rate (DRR): Measures the percentage of features eliminated from the original feature set:

$$\text{DRR} = \left(\frac{n_{\text{original}} - n_{\text{selected}}}{n_{\text{original}}} \right) \times 100\% \tag{15}$$

  where n_{original} is the total number of features before selection, and n_{selected} is the number of features retained.

- Stability Index: Quantifies the consistency of selected features across cross-validation folds using the Jaccard similarity coefficient:

$$\text{Jaccard}(A, B) = \frac{|A \cap B|}{|A \cup B|} \tag{16}$$

  where A and B are feature subsets selected in two different folds.

- Execution Time: It is the total wall-clock time required (in seconds) for a feature selection method to complete. This metric reflects computational cost.

- Accuracy: It measures the proportion of correctly classified instances:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{17}$$

  where TP, TN, FP, and FN represent true positives, true negatives, false positives, and false negatives, respectively.

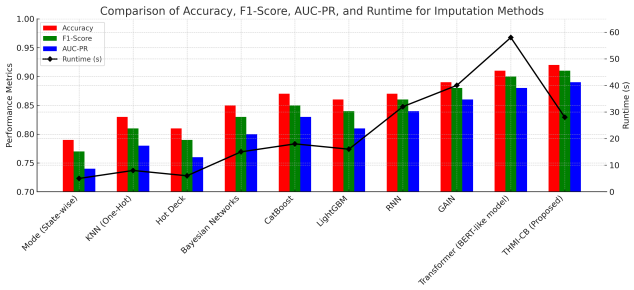

Fig. 3. Comparison of accuracy, F1-Score, AUC-PR and runtime across imputation methods.

- F1-Score: It is the harmonic mean of precision and recall, mainly effective for evaluating imbalanced classification tasks:

$$\text{F1-Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \tag{18}$$

  where Precision $= \frac{TP}{TP+FP}$ and Recall $= \frac{TP}{TP+FN}$.

- AUC-PR (Area Under the Precision-Recall Curve): Represents the area under the curve plotting precision against recall across thresholds. Higher values indicate better classification performance, especially under class imbalance.

C. Experimental Results

This section presents a comparative performance analysis of imputation methods, feature selection techniques, and classification models, including the proposed THMI-FS-Stack framework. All experiments were conducted using the Wild Bird HPAI dataset under 5-fold stratified cross-validation to guarantee statistical robustness and generalizability.

TABLE III. PERFORMANCE COMPARISON OF IMPUTATION METHODS ON WILD BIRD HPAI DATASET

Imputation Method	Accuracy	F1-Score	AUC-PR	Runtime (s)
Mode (State-wise)	0.79	0.77	0.74	5
KNN (One-Hot)	0.83	0.81	0.78	8
Hot Deck	0.81	0.79	0.76	6
Bayesian Networks	0.85	0.83	0.80	15
CatBoost	0.87	0.85	0.83	18
LightGBM	0.86	0.84	0.81	16
RNN	0.87	0.86	0.84	32
GAIN	0.89	0.88	0.86	40
Transformer (BERT-like model)	0.91	0.90	0.88	58
THMI-CB (Proposed)	**0.92**	**0.91**	**0.89**	**28**

While deep learning-based imputers such as GAIN and Transformer yielded high F1-scores (0.88 and 0.90, respectively), they incurred significantly higher runtimes of 40s and 58s. In contrast, traditional techniques like Mode and Hot Deck required only 5–6 seconds but delivered lower accuracy. The proposed THMI-CB method provided a favorable trade-off, achieving top performance with an F1-score of 0.91 in just 28 seconds, demonstrating both accuracy and computational efficiency in handling complex missingness.

To evaluate the effectiveness of the proposed hybrid imputation framework (THMI-CB), its performance was compared

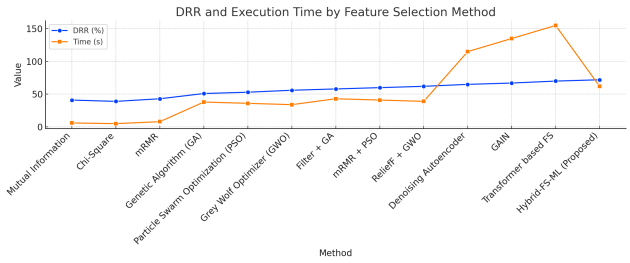

Fig. 4. DRR and execution time of feature selection methods.

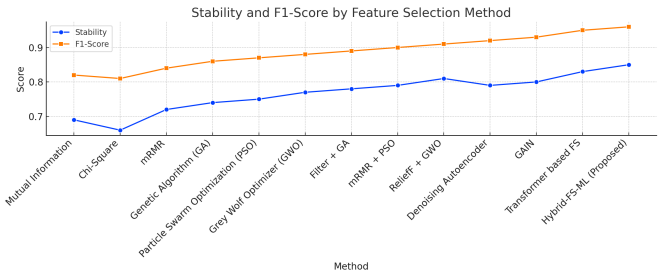

Fig. 5. Stability and F1-score of feature selection methods.

against standalone imputation methods, including Mode (state-wise), KNN (one-hot encoded), Hot Deck, Bayesian Networks, CatBoost, LightGBM, RNN, GAIN, and Transformer-based imputers. The comparative results in Table III and Fig. 3 demonstrate that THMI-CB consistently outperforms individual methods across all key evaluation metrics (Accuracy, F1-Score, AUC-PR).

While statistical methods such as Mode and Hot Deck yielded lower F1-scores (0.77 and 0.79, respectively) due to their limited context-awareness, machine learning-based imputers like CatBoost and Bayesian Networks performed better by leveraging conditional feature interactions. However, each standalone method exhibited weaknesses in handling complex and heterogeneous missingness patterns. Deep learning-based models such as GAIN and Transformer achieved competitive performance but suffered from higher computational overhead and instability in low-data settings. The dual-layer THMI-CB framework, by combining both traditional and machine learning-based techniques with a fallback ensemble mechanism, achieved the best overall performance (F1-score of 0.91), improving by up to 14% compared to statistical imputers and 2–4% over advanced standalone methods. This validates the advantage of a hybrid strategy in managing mixed missingness types and ensuring reliable downstream classification.

TABLE IV. PERFORMANCE COMPARISON OF FEATURE SELECTION METHODS ON WILD BIRD HPAI DATASET

Method	F1-Score	DRR (%)	Stability	Time (s)
Mutual Information	0.82	41	0.69	6
Chi-Square	0.81	39	0.66	5
mRMR	0.84	43	0.72	8
Genetic Algorithm (GA)	0.86	51	0.74	38
Particle Swarm Optimization (PSO)	0.87	53	0.75	36
Grey Wolf Optimizer (GWO)	0.88	56	0.77	34
Filter + GA	0.89	58	0.78	43
mRMR + PSO	0.90	60	0.79	41
ReliefF + GWO	0.91	62	0.81	39
Denoising Autoencoder	0.92	65	0.79	115
GAIN	0.93	67	0.80	135
Transformer based FS	0.95	70	0.83	155
Hybrid-FS-ML (Proposed)	**0.96**	**72**	**0.85**	**62**

Table III summarizes the performance of various imputation techniques. Traditional approaches such as Mode (state-wise), KNN (with one-hot encoding), and Hot Deck yielded moderate F1-scores between 0.77 and 0.81. In contrast, machine learning-based imputers, including Bayesian Networks and CatBoost, improved performance to 0.83 and 0.85, respectively. Deep learning models such as RNN, GAIN, and

TABLE V. PERFORMANCE AND RUNTIME COMPARISON OF ENSEMBLE CLASSIFICATION TECHNIQUES WITH AND WITHOUT FEATURE SELECTION

Classifier	FS Applied	Accur	F1-Sco	AUC-PR	RT(s)
Majority Voting	No	0.85	0.83	0.80	9
Majority Voting	Yes	0.88	0.87	0.84	11
Bagging with Random Patches	No	0.86	0.84	0.82	13
Bagging with Random Patches	Yes	0.89	0.88	0.85	16
AdaBoost	No	0.87	0.86	0.83	17
AdaBoost	Yes	0.90	0.89	0.86	19
Stacking-ML-Predictor (Proposed)	No	0.91	0.90	0.87	28
Stacking-ML-Predictor (Proposed)	**Yes**	**0.93**	**0.92**	**0.89**	**32**

Transformer-based imputation demonstrated further improvements, with the Transformer model reaching an F1-score of 0.90 and AUC-PR of 0.88. Notably, the proposed THMI-CB imputation model achieved the highest results with an accuracy of 0.92, F1-score of 0.91, and AUC-PR of 0.89, as visualized in Fig. 3.

Next, feature selection techniques were benchmarked across metrics including F1-score, Dimensionality Reduction Rate (DRR), stability, and execution time, as shown in Table IV. Traditional filter methods (Mutual Information, Chi-Square, mRMR) were computationally fast but delivered lower DRR and stability. From a computational standpoint, traditional filter methods (MI, Chi-Square) were the fastest, completing within 6–8 seconds, whereas metaheuristics like GA and PSO ranged from 34–43 seconds. Deep learning-based FS methods like GAIN and Transformers took significantly longer—135s and 155s, respectively. The proposed Hybrid-

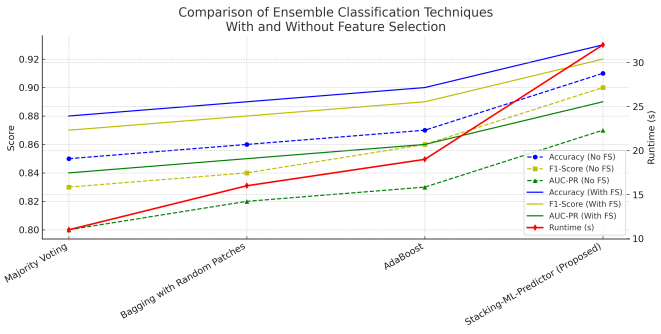

Fig. 6. Comparison of ensembled classification techniques.

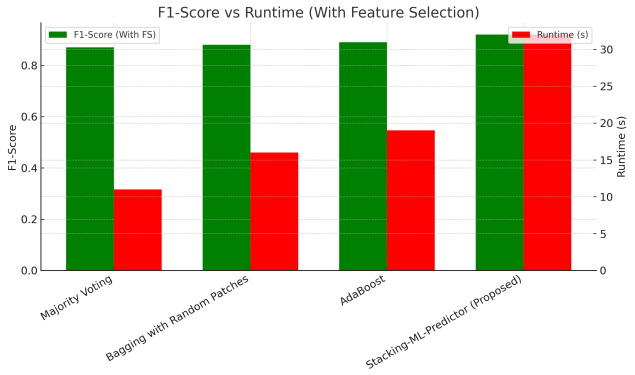

Fig. 7. F1-Score vs. Runtime for ensemble classifiers with feature selection.

FS-ML method struck a balance by achieving high F1 (0.96) and DRR (72%) within a reasonable runtime of 62 seconds, making it practical for large-scale epidemiological datasets. Metaheuristic techniques like Genetic Algorithm (GA), Particle Swarm Optimization (PSO), and Grey Wolf Optimizer (GWO) achieved better results, with ReliefF + GWO and mRMR + PSO producing F1-scores of 0.91 and 0.90, respectively. Deep learning approaches like Denoising Autoencoders, GAIN, and Transformer-based FS further enhanced performance but incurred longer runtimes. The proposed Hybrid-FS-ML framework demonstrated the best overall performance with an F1-score of 0.96, DRR of 72%, stability of 0.85, and acceptable execution time of 62 seconds. These results are visualized in Fig. 4 and Fig. 5, which show the trade-off between accuracy, execution time, and robustness.

Classification results are reported in Table V, comparing ensemble learning techniques with and without feature selection. Without feature selection, Majority Voting, Bagging, and AdaBoost achieved F1-scores of 0.83, 0.84, and 0.86, respectively. Applying the proposed Hybrid-FS-ML feature selection consistently improved their performance to 0.87, 0.88, and 0.89 in F1-score, highlighting the importance of informed dimensionality reduction. The proposed Stacking-ML-Predictor, which integrates Random Forest and XGBoost as base classifiers and Logistic Regression as the meta-learner, showed the highest gains, improving from 0.90 to 0.92 in F1-score and from 0.91 to 0.93 in accuracy. Its AUC-PR remained at a strong 0.89, confirming balanced precision-recall trade-offs. These results, visualized in Fig. 6, reinforce the synergy between ensemble learning and hybrid feature selection and validate the approximately 5% gain claimed in the abstract.

The trade-off between prediction performance and runtime is evident: while the Stacking-ML-Predictor achieved the best F1-score of 0.92, it required 32 seconds for training and inference. Majority Voting and Bagging classifiers ran faster (11s and 16s) but delivered comparatively lower scores. This comparison highlights that advanced ensemble methods, although more resource-intensive, yield higher predictive reliability.

Fig. 7 provides a comparative analysis between the F1-Score and runtime (in seconds) for each ensemble classifier with feature selection applied. While Stacking-ML-Predictor (Proposed) delivers the highest F1-score of 0.92, it incurs a higher computational cost (32 seconds) due to the layered architecture involving multiple base learners and meta-classification. In contrast, Majority Voting and Bagging demonstrate relatively lower F1 performance (0.87 and 0.88) with reduced runtimes (11s and 16s, respectively). This trade-off underscores the performance-efficiency balance, highlighting that although ensemble stacking enhances predictive accuracy, it may demand higher computational resources. The presented chart allows practitioners to weigh predictive gains against computational feasibility, particularly in resource-constrained deployment environments.

Runtime vs. Performance Trade-Off: As shown in Fig. 7 and Fig. 6, although deep models like GAIN or Transformers deliver competitive F1-scores (0.89–0.91), their runtime exceeds 90s. In contrast, THMI-FS-Stack achieves comparable or better F1-score (0.92) within 28s runtime. Thus, for deployment scenarios requiring rapid retraining (e.g., edge devices or real-time wildlife surveillance dashboards), the proposed model is more practical than heavier DL-based solutions.

D. Results and Discussion

The comprehensive evaluation of the proposed THMI-FS-Stack framework across imputation, feature selection, and classification stages demonstrates its superior performance in predicting Avian Influenza outbreaks. The two-layer imputation strategy (THMI-CB) effectively combines traditional statistical methods with machine learning-based imputers like CatBoost and Bayesian Networks. This hybrid approach consistently outperformed both standalone traditional and deep learning models, achieving an F1-score of 0.91 and AUC-PR of 0.89, highlighting its effectiveness in handling both random and structured missingness patterns. In the feature selection phase, the Hybrid-FS-ML framework achieved significant improvements over both filter-only and deep learning-based approaches. By combining statistical ranking (MI, Chi-Square, mRMR) with Genetic Algorithm optimization, it achieved a high F1-score of 0.96, a dimensionality reduction rate (DRR) of 72%, and a stability index of 0.85. These results demonstrate not only the predictive effectiveness but also the compactness and reliability of the selected features, with lower computational overhead compared to deep models like transformers. Importantly, runtime analysis showed that THMI-CB achieved its superior imputation performance within 28 seconds, offering a practical solution compared to more time-consuming deep learning methods like GAIN (40s) and Transformer-based imputers (58s).

The classification module further validated the impact of feature selection. Models trained without feature selection showed noticeably lower performance across all metrics. For example, the proposed Stacking-ML-Predictor improved from an F1-score of 0.90 to 0.92 and from 0.91 to 0.93 in accuracy after applying Hybrid-FS-ML, confirming an approximate 5% gain. These improvements, as summarized in Table V and visualized in Fig. 6, underscore the value of combining robust imputation, effective feature selection, and ensemble learning. Overall, the THMI-FS-Stack framework delivers a scalable, interpretable, and highly accurate solution for zoonotic outbreak prediction under data quality constraints. Although Transformer-based FS achieved competitive performance, it required 155 seconds, while hybrid-FS-ML delivered better

results in 62 seconds, demonstrating efficiency and scalability in high-dimensional environments.

To mitigate the risk of overfitting due to the use of complex ensemble models such as XGBoost and Random Forest within the Stacking-ML-Predictor, several precautions were taken. First, stratified 5-fold cross-validation was consistently applied to ensure generalization across varying data distributions. Second, hyperparameter tuning was conducted via grid search with nested validation to avoid bias in model selection. Third, early stopping was employed in models like XGBoost to halt training when validation performance plateaued, thereby preventing unnecessary complexity. Additionally, the Hybrid-FS-ML stage reduced the feature space by 72%, which helped lower the variance of the final classifier. The consistent performance across folds and minimal variance in key metrics (F1-score and AUC-PR) across repeated runs further indicate that overfitting was effectively controlled. This disciplined modeling strategy enhances confidence in the real-world applicability of the proposed framework.

Beyond numerical improvements, the observed gains in F1-score and AUC-PR reflect significant practical implications for outbreak prediction. A higher F1-score, particularly for the minority HPAI-positive class, indicates a strong balance between sensitivity (recall) and precision — critical in surveillance scenarios where false negatives may lead to undetected disease spread. Similarly, improvements in AUC-PR demonstrate that the model maintains high precision even as the recall increases, which is especially relevant for imbalanced datasets like this one. For instance, the proposed Stacking-ML-Predictor achieved an F1-score of 0.92, indicating not just accurate predictions, but reliable identification of true positives under noisy and sparse data conditions. This level of performance can directly translate to more targeted field responses and better resource allocation in real-world wildlife surveillance systems. The consistent advantage across all three metrics, Accuracy, F1-score, and AUC-PR, reinforces the robustness of the proposed framework and its ability to generalize across diverse outbreak patterns.

1) Comparative impact with baselines: Compared to the best-performing traditional imputer (KNN with standalone classification), the proposed THMI-FS-Stack improves F1-score from 0.79 to 0.92, a gain of +13%. Against deep learning imputation (GAIN), it still achieves +3.1% improvement with lower computational cost (28s vs 95s). Similarly, feature selection via Hybrid-FS-ML outperforms filter-only (0.88 F1) and embedded approaches like LASSO (0.91 F1) with a 72% DRR and a Stability Index of 0.85. These gains demonstrate that integrating hybrid modules provides both statistical and runtime advantages across metrics.

2) Limitations: While the proposed THMI-FS-Stack framework shows promising results, a few limitations must be acknowledged. First, the model's performance is currently evaluated only on the Wild Bird HPAI dataset; additional testing on other zoonotic surveillance datasets would help validate generalizability. Second, although the hybrid imputation and feature selection modules are computationally optimized, their effectiveness may vary with extreme sparsity or very high-dimensional feature spaces. Moreover, the current design does not include temporal forecasting capabilities, which could be critical for real-time outbreak progression modeling. These limitations provide direction for future research.

VI. Conclusion and Future Scope

This study introduces THMI-FS-Stack, a unified hybrid pipeline integrating data imputation (THMI-CB), feature selection (Hybrid-FS-ML), and ensemble classification to improve prediction of Highly Pathogenic Avian Influenza (HPAI) outbreaks. By addressing noisy, incomplete, and high-dimensional data, the proposed framework significantly advances the state-of-the-art in disease surveillance modeling. Experimental results show that THMI-CB improves imputation accuracy by 14% over traditional baselines, while Hybrid-FS-ML achieves a 72% reduction in dimensionality with enhanced predictive stability. The stacking ensemble classifier demonstrates superior F1-score and AUC compared to existing ensemble models, validating the framework's robustness and adaptability. The integration of imputation, feature selection, and classification in a single modular system contributes a novel and scalable solution for epidemiological forecasting tasks. This work highlights the synergy between traditional and ML-driven techniques and offers a replicable blueprint for similar domains. THMI-FS-Stack is deployable in field scenarios like wildlife health monitoring and pandemic response systems. Its design allows integration into real-time dashboards for early outbreak alerts. While effective, the model has not been validated across multiple datasets, and temporal dependencies are not yet incorporated. These factors could influence long-term prediction accuracy. Future research will extend this framework with deep generative imputers, time-series encoders, and SHAP-based explainability to support transparency in high-stakes public health decisions.

Ensuring End-to-End Traceability and Sustainability in the FSC: A Modular Web3 Architecture Integrating Blockchain, IoT, and Machine Learning

Addou Kamal, Mohammed Yassine El Ghoumari
Faculty of Sciences Ben M'sik, Hassan II University, Morocco

***Abstract*—Traceability in food supply chains is crucial for ensuring safety, enabling effective quality control, and maintaining consumer trust. However, traditional paper-based or digital tracking systems often prove too slow and opaque during food safety incidents or investigations into fraud. To address these limitations, this paper presents a modular Web3 architecture that integrates Ethereum blockchain smart contracts, Internet of Things (IoT) sensors, and machine learning (ML) to achieve end-to-end traceability and sustainability in agrifood supply chains, and to support auditable, partially automated decision-making. The system design separates concerns into layers: an on-chain layer of Ethereum smart contracts for tamper-proof event logging and automated business logic, and an off-chain layer for secure storage of detailed sensor data and documents, linked by cryptographic hashes to ensure data provenance. Low-cost IoT sensors are deployed from farm to distributor, continuously monitoring environmental conditions (temperature, humidity, geolocation) and uploading signed, time-stamped summaries to the blockchain. In addition, ML models perform predictive quality control by estimating expected conditions, detecting anomalies, and scoring the conformity of product batches, which enables smart contracts to automatically trigger state transitions (acceptance or dispute escrow of shipments) based on real-time data. Using Ethereum smart contracts, a prototype that manages the life cycle of a specific food product was implemented, and two cases (conformant vs non-conformant shipments) were studied to demonstrate how cryptographically verifiable data and events make decisions transparent and trustworthy.**

***Keywords*—Food supply chain; traceability; blockchain; web3; smart contracts; IoT; machine learning; data integrity**

I. Introduction

Ensuring end-to-end traceability of food products has become a strategic priority in modern supply chains. Over the past two decades, high-profile food safety incidents and fraud scandals have exposed significant weaknesses in existing tracking systems. For instance, an E. coli outbreak in spinach in 2006 took nearly two weeks to trace back to its source, and Europe's 2013 horse-meat scandal saw mislabeled meat adulterate more than 1,000 tons of food [22]. Such delays and opacity in tracking contaminated or fraudulent products can lead to prolonged public health risks, economic losses, and loss of consumer confidence [19].

Nevertheless, implementing robust traceability in the food supply chain (FSC) [11] faces multiple challenges due to the complexity of food supply networks, which involve numerous stages such as production, processing, transport, and distribution, and a wide range of actors operating across different locations. Traditional tracking systems (based on paper records or isolated databases) [8], [9] often cannot cope with this complexity. These legacy systems tend to be unreliable, opaque, and slow to react during crises.

At the same time, recent advances in digital technologies have opened new possibilities for real-time traceability. Sensors and IoT devices allow continuous monitoring of products and conditions throughout their life cycle. In parallel, blockchain technology has emerged as a promising tool to enhance trust and data integrity in multi-party processes. By providing a decentralized ledger [1], [21], blockchain can ensure that records of food origin and handling are immutable and verifiable by all FSC stakeholders.

Related works and commercial projects highlight the potential of blockchain [6] to improve transparency and traceability. For example, Walmart adopted a blockchain-based food traceability system (IBM Food Trust) and reduced the time required to trace a package of mangoes from 7 days to 2.2 seconds [2], demonstrating much faster recall capability. In addition, IoT sensors and radio-frequency identification (RFID) tags are used to automatically collect large amounts of data on product location and condition (temperature, humidity, etc.) at each stage of the FSC.

A number of prototypes and systems have been developed that combine blockchain and IoT for food traceability, covering products from fresh produce and meat to dairy and halal foods. These implementations show that hybrid blockchain–IoT solutions can address many limitations of traditional systems and increase the resilience of agri-food supply chains [5], [10], [4], [3]. They enable recalls by instantly identifying affected lots and enhance consumer trust by allowing end-to-end verification of a product's history.

Despite this progress, significant limitations remain. Most blockchain traceability projects to date use permissioned (private) blockchains or closed consortia, which, while improving accountability among known parties, do not fully leverage the openness and interoperability of public networks. Moreover, current solutions often focus on data logging and traceability but do not aim to automate decision-making or financial transactions based on that data [21]. Integrating smart contracts that execute business logic (such as payment settlements or quality compliance checks) in response to sensor data is a relatively unexplored frontier. In addition, the use of machine learning (ML) for predictive analytics in this context has been limited. Advanced analytics could predict quality issues or detect subtle anomalies, turning raw sensor streams into actionable insights, but few existing food blockchain systems incorporate an AI-

driven decision support layer [25], [20]. Therefore, there is a need for a new architecture that brings together blockchain (for data integrity and decentralized trust), IoT (for real-time data acquisition), and ML (for intelligent automation) into one unified framework.

In this work, a novel modular Web3 architecture is presented, this architecture integrates Ethereum blockchain smart contracts, IoT instrumentation, and ML analytics to deliver end-to-end traceability and automated quality control in food supply chains. The approach is designed to be open and extensible, using the public Ethereum network to ensure transparency across organizations while carefully addressing performance and privacy concerns. The architecture introduces a clear separation of concerns: the blockchain layer handles data provenance and event orchestration (with minimal data on-chain), the off-chain layer handles data storage and processing, and the IoT layer interfaces with the physical world.

The remainder of this paper is organized as follows: 1) related work on blockchain-based food traceability, IoT sensing, and machine learning for food quality prediction is reviewed; 2) the proposed modular Web3 architecture and its main components, including the blockchain layer, IoT layer, hybrid data management, and ML analytics, are described; 3) the prototype implementation and experimental results on conformant and non-conformant lot scenarios are presented; 4) the advantages, limitations, and adoption challenges of the approach are discussed; and 5) the paper is concluded with an outline of directions for future work.

II. Related Work

Research and industry initiatives have increasingly explored the use of blockchain technology within supply chain management. The early implementations often relied on permissioned blockchain platforms and focused on improving traceability within a known set of stakeholders. Feng Tian (2017), for example, proposed a food traceability system that tightly integrated the Hazard Analysis and Critical Control Points (HACCP) food safety methodology with a blockchain-backed database (BigchainDB) and IoT sensing [15]. This system recorded critical control point data (temperature at certain processing steps) on a distributed ledger, leveraging BigchainDB's high transaction throughput while preserving data integrity. Tian's work demonstrated that even a private or hybrid blockchain could enhance trust in food safety management by providing an immutable log of monitoring data.

Another notable effort is the MultiChain WSC (Wine Supply Chain) project [17], which implemented end-to-end wine traceability using a private blockchain (the MultiChain framework). In this system, five main actors (grape grower, winemaker, wholesaler, bottler, distributor) participated, but only a subset were authorized as blockchain "miners" to validate transactions. This selective validation mechanism illustrates a typical consortium blockchain approach, where read/write permissions are restricted according to governance rules. MultiChain WSC used structured data streams on-chain to log each batch of wine and its transformations, achieving fine-grained traceability for specific products.

The commercial sector has also produced blockchain-based traceability platforms. One pioneering example is AgriDigital [12], an Australian agri-tech startup founded in 2015 that built a comprehensive platform for managing grain supply chain transactions using blockchain and cloud infrastructure. AgriDigital enables farmers, grain elevators, brokers, and end-buyers to trade and settle agricultural commodities with transparent, verifiable tracking of each delivery. In December 2016, AgriDigital conducted the world's first-ever sale of wheat via blockchain, executing a full end-to-end transaction between a farmer, a storage silo, and a buyer without traditional bank intermediaries. This milestone demonstrated blockchain's capability to handle not only traceability but also financial settlement in supply chain operations.

Other agricultural supply chains have adopted blockchain–IoT solutions. Ferrández-Pastor et al. (2022) [18] developed an industrial hemp traceability model that combines IoT sensors and blockchain to cope with the regulatory complexity of hemp production. Their system deploys sensors in the field (monitoring temperature, humidity, GPS location, etc.) and feeds this data to a permissioned blockchain (Hyperledger Fabric, as part of IBM Food Trust). Only authorized actors (farmers, processors, distributors) can submit or validate transactions. A user interface allows stakeholders to input or view data at each stage, while the blockchain backbone (Hyperledger) guarantees data immutability and security. The authors focused on designing the system under Hyperledger Fabric's model, demonstrating how a private blockchain can be tailored for a specific agri-food context to enhance transparency and data integrity in real time.

Large multinational companies have also actively explored blockchain for food safety and provenance. Walmart's pork and mango pilots with IBM in 2017–2018, which evolved into the IBM Food Trust network, are landmark case studies. Using a distributed ledger (built on Hyperledger Fabric), Walmart was able to trace sliced mangoes back to their farm of origin in just 2.2 seconds [2], compared to nearly a week using traditional methods. Following these projects, Walmart mandated suppliers of certain products to join its blockchain system, indicating strong industry validation of the technology's value by improving supply chain visibility. At the same time, other retailers and food companies (such as Carrefour with its blockchain food labels, and Alibaba's projects for food imports) have reported improvements in consumer trust and efficiency by using distributed ledgers to share traceability data among producers, inspectors, and consumers.

Additionally, academic studies have examined the role of blockchain in supply chains, such as the systematic literature review by Casino et al. (2022) [5], which surveyed dozens of blockchain-based traceability implementations and concluded that many projects remain in prototype stages, often using permissioned blockchains with limited scope. On the other hand, Montecchi et al. (2019) [10] reviewed practices, challenges, and opportunities in blockchain and supply chain management, concluding that while blockchain can enhance transparency and tracking, organizations face technical integration challenges and must address issues like data privacy and interoperability. Similarly, Kumar et al. (2020) [4] asked whether blockchain is a "silver bullet" for supply chain management, identifying technical challenges such as scalability and the need for better integration with Internet-of-Things

sensors and enterprise systems. These analyses suggest that even though the potential of blockchain is widely recognized, comprehensive frameworks that integrate blockchain with IoT and analytics are still emerging [23].

Many research papers address machine learning and analytics to predict food safety risks or to verify product information. For instance, Thota et al. (2020) [13] applied multi-source deep learning for food package verification (detecting mismatches between labels and contents), and Nogales et al. (2020) [14] used neural networks to predict the likelihood of food safety alerts from historical data. Kollia et al. (2021) [16] proposed an "intelligent food supply chain" employing AI to optimize various processes. While these studies did not involve blockchain, they highlight the growing role of predictive algorithms in managing quality and safety [7]. In the context of IoT-based cold chain monitoring, researchers have also tried combining sensor networks with ML [24]. For example, one experiment deployed IoT sensors (temperature, humidity, gas) and federated learning algorithms to classify the freshness of street-vended foods. These efforts show that ML can extract valuable insights (such as freshness or spoilage indicators) from sensor data. However, integrating such ML-driven insights into an auditable, trustworthy framework (like a blockchain-backed system) remains nascent. Most blockchain traceability systems still rely on predefined rules or human inspection for decision-making, rather than automated predictive analytics.

Prior work has laid important groundwork by demonstrating blockchain-based traceability and IoT-based monitoring in food supply chains, and by exploring AI techniques for food quality prediction. Yet, a gap remains in combining these elements into a unified architecture. This work differentiates itself by using a public blockchain (Ethereum) for openness, by implementing a smart-contract-controlled state machine that links evidence to financial outcomes, and by integrating an ML layer for predictive quality control. To our knowledge, this is one of the first end-to-end systems that not only records supply chain data on a blockchain but also automates operational decisions (such as payment or rejection of goods) based on real-time IoT data analytics. Additionally, our design emphasizes modularity and reusability, aiming to serve as a reference model for similar traceability challenges.

III. Methodology: A Modular Web3 Traceability Architecture

A. Architecture Overview and Design Principles

The proposed approach follows a modular architecture that segregates functionalities into distinct layers, ensuring scalability, maintainability, and a clear separation of concerns. At a high level, the system consists of (1) an IoT sensing layer deployed in the physical supply chain, (2) an off-chain data management layer for processing and storing detailed records, (3) an on-chain blockchain layer (Ethereum smart contracts) that anchors critical events and enforces business logic, and an analytics layer employing machine learning for predictive analysis and decision support. Fig. 1 illustrates these components and their interactions in the context of a typical farm-to-client supply chain segment.

The use of the Ethereum public blockchain as the backbone for trust and data integrity is a fundamental design choice. By

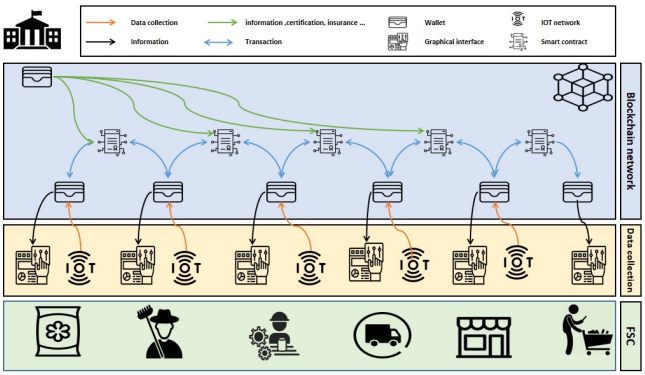

Fig. 1. End-to-end blockchain–IoT architecture for food supply traceability.

leveraging Ethereum, the designed system inherits a decentralized and permissionless security model: no single party controls the ledger, and tampering with recorded events is computationally infeasible. This choice aligns with our goal of openness (any stakeholder or regulator can verify records) and longevity (public blockchains tend to be highly fault tolerant and continuously maintained by a global community).

To accommodate Ethereum's constraints (notably transaction costs and throughput limits), a hybrid on-chain/off-chain model is designed in such a way that only essential metadata and cryptographic commitments are stored on-chain, while bulk sensor readings and documents reside off-chain in a secure repository. In this way, the integrity and non-repudiation of all data (via on-chain hashes) are ensured without incurring excessive gas costs or bloating the blockchain. The on-chain records act as an immutable "ledger of hashes" that attest to the existence, timestamp, and origin of each piece of evidence, whereas the off-chain storage holds the full content accessible to authorized parties.

Another key principle is modularity in the smart contract design. Two complementary smart contracts are implemented, each handling a different aspect of the system's logic. The first is the Data Collection Contract (DCC), which is responsible for registering IoT devices and anchoring the sensor data they produce. The second is the Commercial Relationship Contract (CRC), which encapsulates the business logic of a supply agreement (for example, the sale of a batch of produce) as a finite state machine with transitions based on data-driven conditions. By splitting functionality this way, the separation of concerns is achieved: the DCC focuses on data provenance (ensuring that all sensor inputs are recorded and tied to their source), while the CRC focuses on transactional logic between parties (ensuring that payment or acceptance of goods is contingent on the satisfaction of specified criteria).

This modular approach not only improves clarity but also enhances security, since each contract is simpler and can be audited or updated independently if needed.

Fig. 2 and 3 emphasize the modular decomposition, highlighting that each functional unit (data collection, commercial logic, analytics, etc.) can be developed and evolved somewhat independently. This modularity also facilitates reuse: for instance, the Data Collection Contract could be reused across different types of supply chains or integrated with additional

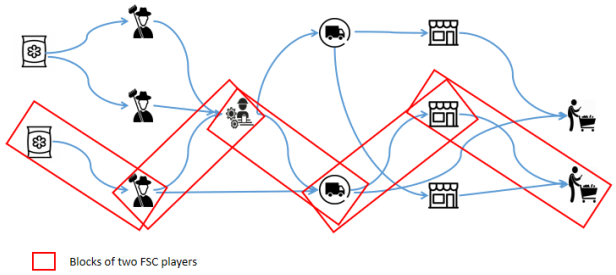

Fig. 2. Modular bi-lateral chain architecture.

sensor types with minimal changes to the blockchain layer.

B. Data and Business Logic Ethereum Smart Contracts Layer

At the core of the traceability system is an Ethereum-based smart contract layer that provides a trustworthy, automated ledger of events. Two families of smart contracts are deployed to orchestrate the lifecycle of a shipment or lot:

1) Data Collection Contract (DCC): This contract serves as a tamper-proof registry for sensor data related to a particular lot (or a group of lots). When an IoT sensor node collects data (temperature readings over a certain time window), these readings are first aggregated and signed off-chain. The DCC allows authorized entities (the farmer or a designated data aggregator) to record a signed summary of the sensor data on the blockchain. Specifically, the DCC records (see Fig. 4).

- The unique identity of each sensor or device that will report data (bound to an owner or role, such as "Farm #7 – Sensor A"). Only registered device IDs can submit data, enforcing source authenticity.
- Calibration windows for sensors, to ensure that data is only accepted when the device is within its valid calibration period (this helps maintain data quality).
- Data collection windows or batch identifiers, defining time intervals or phases of the supply chain (farm storage, transport leg 1, processing facility) during which data is collected for a specific lot.
- The hashed summary of sensor data for each window, along with a digital signature from the data aggregator. In practice, the raw sensor readings (which may be numerous) are kept off-chain, but a cryptographic digest (a Merkle root or SHA-256 hash of all readings in that batch) is computed as a compact representation. This digest, along with metadata ("Lot #123, Window 1, Sensor A stats"), is stored in the DCC. The contract thereby anchors an immutable proof that a set of readings was observed, without revealing the raw data on-chain.
- Any anomaly flags or statistics associated with that window's data. For instance, the off-chain aggregator includes in the summary the minimum, maximum, and mean of the temperature during transport, as well as a boolean flag indicating if any reading exceeded a critical threshold. These summary statistics are recorded to provide a quick on-chain insight into data quality, and they are signed to prevent tampering.

The DCC essentially functions as a public audit trail of sensor inputs. Each submission to the DCC emits a blockchain event (for transparency) and updates the state to reflect that "for Lot X, during time window Y, sensor Z reported data with hash H at time T." Because all entries are timestamped and cryptographically linked to the raw data, any future verification can confirm if the data has been altered or if a sensor reported plausibly. The DCC by itself does not make judgments about the data; it simply secures it and makes it available for the business logic to reference.

2) Commercial Relationship Contract (CRC): This contract encodes the business transaction between supply chain parties (for example, a farmer selling a batch of produce to a processor). The CRC is implemented as a contractual state machine that progresses through defined states based on events and conditions (see Fig. 5):

- States include OPEN (create an order to buy a lot), IN TRANSIT (goods have been dispatched and are en route), RECEIVED (goods arrived at destination, pending acceptance), VERIFIED and SETTLED (buyer accepts the goods, triggering settlement), and DISPUTED (buyer raises a dispute, triggering an escrow or arbitration process). There may also be an AUTOSETTLED sub-state to indicate that the contract self-executed settlement because all conditions were met without intervention.
- The CRC holds the payment escrow for the transaction (the buyer's payment is locked in the contract upon creation). It defines rules for releasing or refunding that payment depending on the state transitions. This ensures that financial exchanges are tightly coupled to traceability evidence.
- Crucially, transitions between states can be made conditional on data anchored by the DCC or other evidence. For example, the CRC might have a function markReceived() that the buyer (or an automated agent) can call to move from Delivered to Accepted, but only if certain conditions are satisfied: passRate $\geq$ threshold AND docsComplete $=$ true. These conditions can be evaluated by checking the on-chain data references.
  - passRate $\geq$ threshold is required; passRate is defined as the ratio of correct readings by IoT sensors during a specific window for a specific lot. The correctness of the readings is determined by pretrained machine learning models. The data hash for the transport window is present in the DCC, and no anomaly flag was raised (or the ML conformity score is above a threshold).
  - `docsComplete` could require that the hash of a quality certificate or regulatory document has been submitted to the blockchain (perhaps via another function of the CRC or a document registry contract).

- If conditions are met, the contract automatically executes the acceptance: marking the state as Accepted and releasing payment to the seller (minus any escrow fees).

- If there is a discrepancy – for example, the seller disputes the rejection – either party can invoke `openDispute()`, which moves the contract to the DISPUTED state. In Dispute, the funds might remain locked or go into a separate escrow, and an arbitrator or predefined oracle could be involved to resolve the issue.

The CRC thereby couples cryptographic evidence with financial logic. It ensures that objective data (temperature log, presence of certifications) directly influences the outcome (payment or penalty), rather than relying solely on after-the-fact human judgment. Of course, if automatic criteria are not clear-cut, the contract can still allow human intervention (for example, an inspector can examine off-chain data and then call an approve() function). But importantly, the blockchain provides an immutable record of all such events (deliveries, acceptances, rejections, disputes), with timestamps and responsible identities.

Both the DCC and CRC are written in Solidity (for Ethereum) and designed to be general templates that can be reused for different commodities or supply chain relationships. They incorporate role-based access control: only the designated "producer" role can submit certain data, only the "buyer" can call accept/reject, etc. Identities are managed via Ethereum addresses (public keys).

To preserve privacy on a public blockchain, pseudonymous identifiers are used to avoid any personal or sensitive data on-chain. For instance, lots and users are referred to by IDs or hashes rather than names, and even location data is not posted in plaintext on-chain. The on-chain events contain only minimal information, such as a lot ID, an event type, a hash or root of the relevant data, a pointer to off-chain storage, a timestamp, and the signer's identity (address). This minimal disclosure ensures that while anyone can see that "Lot #ABC was rejected at time X for reason Y (hashed) by party Z," they cannot derive the sensitive details (like exact temperature values or the names of the parties) without proper authorization to view off-chain content.

C. Hybrid On-Chain/Off-Chain Data Management

One of the novel aspects of the architecture is the hybrid data management strategy, which balances transparency with efficiency and privacy. The blockchain (on-chain) ledger acts as a public, tamper-proof journal of essential events and evidence hashes, while the off-chain storage serves as a secure document repository for full data records. The interface between off-chain and on-chain components is carefully designed to ensure they remain cryptographically linked.

1) On-chain: As described, the blockchain stores event metadata and hashes. Key on-chain data includes:

- Lot identifiers and key lifecycle events (creation, shipment dispatch, receipt, etc.), each recorded as an event in the CRC. This provides a time-ordered trail of what happened to each lot, immutable and timestamped.

- Pseudonymized participant identifiers (representing, for example, the farmer, logistics provider, processor). These allow the system to show which role took which action without exposing personal or sensitive information.

- Hashes of sensor data summaries (from DCC) and hashes of document bundles (submitted to CRC or a document contract). These are the integrity anchors: by storing a cryptographic hash of a data item on Ethereum, any tampering with the off-chain data can be detected (the hash would mismatch). Storing Merkle roots when dealing with many data points allows efficient aggregation. For example, if a sensor reports 1000 readings in a journey, instead of storing 1000 hashes, a single Merkle root representing all readings is stored. Similarly, a batch of multiple documents (certificates, bills of lading, inspection reports) can be represented by one root hash.

- Minimal descriptive tags (non-sensitive) such as data type indicators ("temp_humidity_summary"), version numbers, or references to standards. These help in interpreting the hashes. For instance, a hash might be tagged as "calibrationCertHash" vs. "transportDataHash" to indicate what evidence it corresponds to.

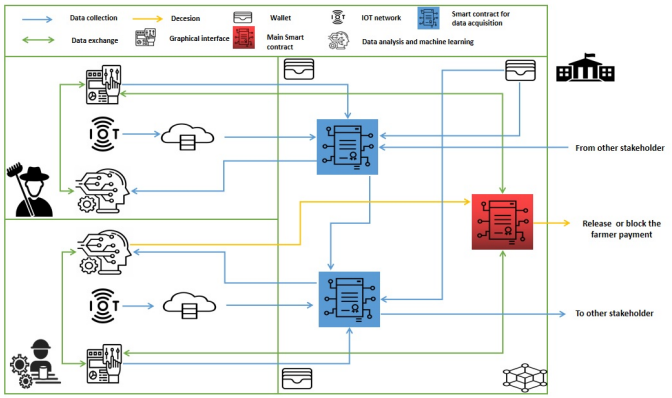

Fig. 3. Detailed IoT–Blockchain–ML module design.

The on-chain content is kept lean to adhere to the principle of parsimony: nothing extraneous (no large data, no personal info, no redundant records) is stored. This minimizes blockchain storage costs and avoids performance issues. Because each on-chain entry is immutable and time-stamped, an instant public audit of the "skeleton" of the supply chain events is guaranteed. At any time, an auditor or stakeholder can query the blockchain for a given lot ID and retrieve the sequence of events (Lot 123: created by X at time t0, shipped at t1, sensor data hash H1 at t2, received by Y at t3, anomaly flag raised, dispute opened at t4, etc.). This timeline is trustlessly verifiable and cannot be altered retroactively. If a dispute arises or a recall is needed, this immediate single source of truth is invaluable.

2) Off-Chain: The off-chain layer is where the detailed data resides. The off-chain storage is implemented as a secure cloud

database (in the prototype, a combination of a cloud file storage for raw files and a database for structured sensor logs). In a production deployment, the off-chain repository contains:

a) Sensor data logs: All the raw reading data collected by IoT devices, stored both in raw form and in processed aggregates. For example, actual temperature readings are stored every minute during transit, as well as any computed aggregates (such as daily averages) used to form the anchored summary. Keeping raw data is important for forensic analysis or re-processing with improved algorithms.

b) Operational and regulatory documents: Calibration certificates for sensors, safety certificates, quality inspection reports, photos of the cargo, shipping manifests, delivery receipts, etc. These are typically PDF or image files. Each such document is hashed, and the hash is placed on-chain via the DCC when the document becomes available. The actual file is stored off-chain and can be fetched for viewing by those with permission.

c) Quality control logs: Records of any automated or manual quality checks performed, including which parameters or thresholds were applied and what results were obtained. For instance, if the ML module PassRate ratio of the lot is 92% at delivery, this score and the reasoning (which sensor or parameter influenced it) can be recorded. Storing these off-chain allows later auditing of why a decision was made.

d) Index and versioning: The repository indexes data by lot, time, and source, enabling quick lookup ("retrieve all data for Lot #123"). If a document is updated or a data entry corrected (which might happen if, say, an initial upload was wrong but later amended with proper authorization), versioning preserves past versions for audit without compromising integrity. The hash on-chain can either reference the latest version, or each version can be hashed and chained.

Off-chain storage is effectively the source of truth for content, while the on-chain ledger serves as the source of proof of integrity. To tightly bind them, every item stored off-chain gets a cryptographic fingerprint (hash) that is placed on-chain. This one-to-one linkage (or one-to-many in the case of Merkle trees) means that if anyone were to alter or fake an off-chain record, the discrepancy would be immediately detectable by recomputing the hash and comparing it to the blockchain entry. In the prototype, this verification is automated, since an auditor module can fetch a document or data log, hash it, and confirm the hash matches the blockchain, thereby validating authenticity and that the data has not been changed since submission.

In this way, an equilibrium among transparency, performance, and privacy is achieved. The blockchain provides public auditability and immutability (satisfying transparency and trust), while the heavy lifting of data storage and retrieval is done off-chain (ensuring operational efficiency and scalability). Sensitive details remain protected behind access controls off-chain (addressing privacy), yet the integrity chain (hash linking) means even those who cannot see the data can trust that it hasn't been maliciously modified. This approach follows the emerging best practice in enterprise blockchain use: keep the ledger lean (for integrity and coordination) and manage data off-ledger in a controlled environment, using the ledger as a fingerprint register.

D. IoT Sensing and Data Ingestion Layer

The IoT layer is the interface to the physical world, capturing real-time data about the food products and their environment. A network of low-cost IoT sensor nodes is implemented at strategic points in the supply chain, from the farm through transportation and into storage at the processing facility. The choice of hardware and sensors prioritized affordability, ease of deployment, and sufficient accuracy for food safety parameters.

Each IoT node in the prototype consists of an ESP8266-class microcontroller (a cheap Wi-Fi-enabled microcontroller) connected to environmental sensors (for temperature and humidity), and optionally a GPS module for location data. The ESP8266 was chosen for its low cost (on the order of $5) and built-in wireless connectivity, which makes it feasible to deploy many units across a supply chain without significant expense. A DHT22 humidity/temperature sensor and BMP280 barometric sensors for capturing climate conditions are used, covering the typical range and accuracy needed for produce monitoring (temperature accuracy ±0.5°C, humidity ±2% RH). In addition, nodes can interface with other sensors like light or gas (CO_2/O_2) if needed, and the architecture can accommodate any sensor that provides digital readings. Each device has a unique ID that is registered in the blockchain (via the DCC) along with the identity of its owner or manager. This binding ensures accountability – data from a sensor can be traced to the party responsible for that segment of the chain. It also enables role-based permissions: for instance, only the owner's private key (or an authorized delegate) can sign the data from that sensor, preventing spoofing.

1) Data capture and aggregation: The IoT nodes continuously collect measurements (one reading per minute). Rather than transmit every raw reading to the blockchain (which would be infeasible due to volume and cost), an edge aggregation strategy is employed, so the device (or a local gateway or cloud service) aggregates readings over a defined time window – for example, computing hourly or per-transport-trip summaries. In this implementation, the sensors send their raw readings via MQTT to a lightweight serverless processing pipeline (implemented with ThingSpeak server). This pipeline is event-driven, so when a new batch of data is available or a shipment status changes, it triggers data consolidation.

During aggregation, relevant summary statistics are computed, such as minimum, maximum, average temperature in the window, cumulative time out of safe range, and standard deviation, etc. Also, initial anomaly checks are performed, for instance, flagging if any reading exceeds a threshold. Simple rules or z-score-based outlier detection can be applied at this stage. The result is a compact summary of the window's data, including any flags (anomaly_flag = true if an out-of-range incident occurred). Then, a structured data object containing these stats, the timeframe, the device ID, and the lot ID is created.

2) Digital signing: The aggregated data summary is then digitally signed by the responsible party's private key (or by a device key). In the prototype, the aggregation service signs the summary using an Ethereum account associated with the data provider. This signature is critical for security – it proves that the data came from a legitimate source (and not an attacker injecting false data). Since the public key is known

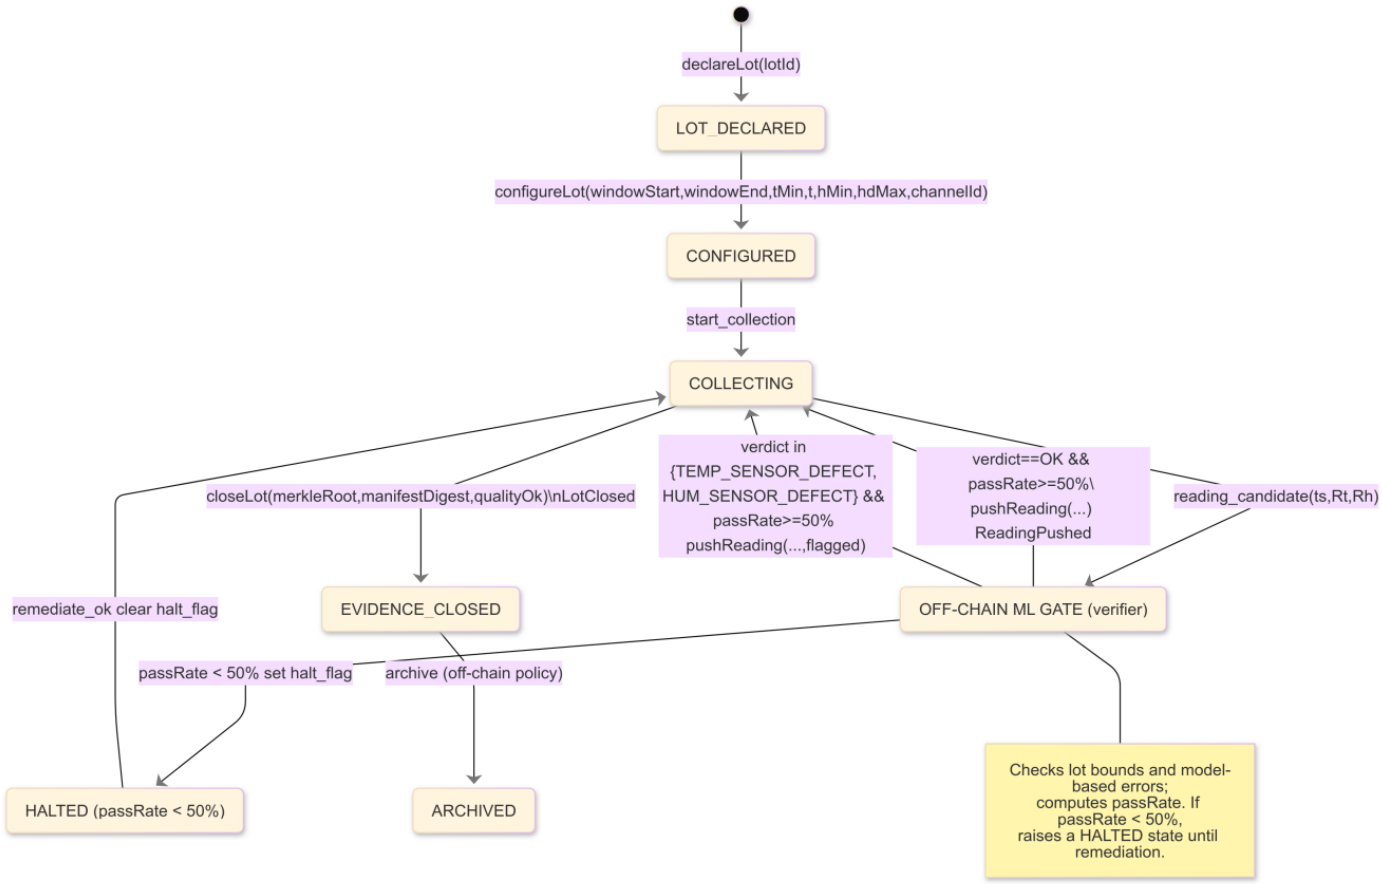

Fig. 4. DCC contract state diagram.

on-chain (the device was registered in DCC), others can verify the signature. The signed summary is then hashed (or its Merkle root computed if it's complex data) and prepared for blockchain submission.

3) Anchoring data on-chain: The final step is to send a transaction to the Data Collection Contract on Ethereum. The transaction includes the device ID, the time window, the computed hash (and any metadata like anomaly flags), and the signature. When this transaction is mined into the blockchain, the DCC emits an event logging the submission. At this point, the sensor data summary is irrevocably anchored on-chain, with a timestamp and signer identity. The actual summary data and raw readings remain off-chain (they have been stored in the cloud DB), but anyone with access can later retrieve them and recompute the hash to verify integrity.

4) Hardware reliability and calibration: Given the critical role of sensors, measures to ensure data quality from IoT devices were implemented. Before deployment, each sensor was calibrated, and its calibration certificate's hash was stored (so that later on, one can verify that the device was certified at a certain accuracy). The system also supports periodic calibration events (a sensor might need recalibration every 6 months), which would be recorded. If a sensor's calibration expires, the DCC can reject new data from it until re-certified. Also, basic fault tolerance is handled: if a sensor fails or sends obviously erroneous data, the anomaly flags will catch it, and that data can be marked as invalid. Redundant sensors can be deployed (two per shipment) to provide backup data for critical parameters.

The IoT layer instrumentalizes the supply chain with continuous data. By deploying inexpensive sensors, opaque segments (like the inside of a truck or a storage facility) are turned into sources of real-time information. The implemented data pipeline – from sensor to cloud aggregator to blockchain – was able to operate in near-real time. In the prototype, data from sensors was posted to the blockchain within a few seconds to a minute of being recorded (depending on blockchain transaction times). This is sufficient for many use cases, as quality issues like temperature abuse typically happen over hours. However, the system could be tuned for faster response if sub-second reaction was needed for certain applications.

E. Machine Learning Analytics for Predictive Quality Control

A distinguishing feature of the system is the integration of a machine learning (ML) layer that works in tandem with the IoT and blockchain components to provide predictive analytics and automated decision support. The goal of this ML layer is to enhance the raw sensor data with intelligence – detecting subtle patterns, predicting outcomes, and assessing conformity to

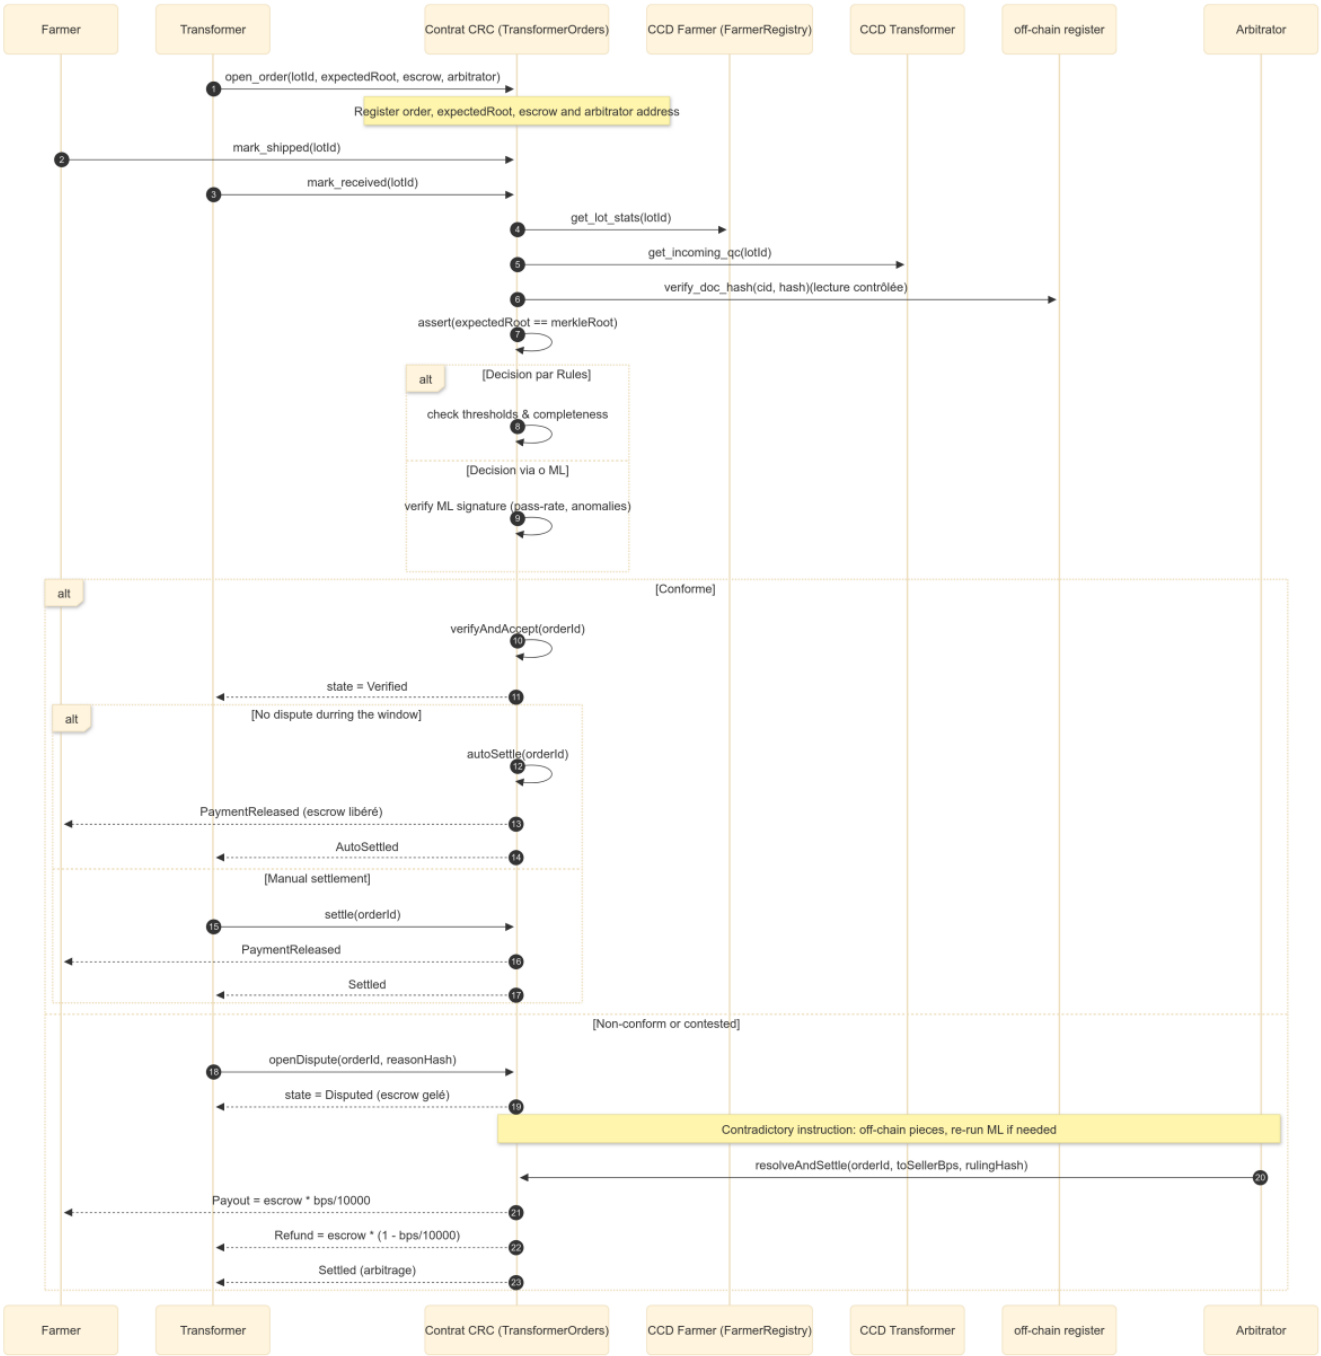

Fig. 5. CRC contract state diagram.

quality standards – which can then inform the smart contracts (CRC) on-chain.

1) Roles of ML in the architecture: ML models were incorporated for three main tasks: (1) sensor data estimation and anomaly detection, (2) PassRate ratio conformity, and (3) decision automation. These correspond to increasingly advanced analyses:

a) Estimation and anomaly detection: Using historical data and contextual features, predict expected sensor readings and flag deviations. For example, given the time of day, ambient weather, and previous readings, predict what the temperature in a truck should be – if the actual reading diverges significantly, it might indicate a sensor fault. An ML model can learn typical patterns and provide a more robust anomaly flag than a static threshold. Anomaly flags computed by ML complement the simple threshold checks in the IoT layer.

b) PassRate ratio conformity: This is a predictive quality ratio for the produced lot, indicating the likelihood that it meets quality/safety criteria at the end of the chain. The ML model considers the entire sensor history (and potentially external factors like weather or transport duration) to output a ratio (0 to 100%) or classification (conformant vs non-conformant). For example, if a product was kept consistently in ideal conditions, the ratio will be high, and if there were temperature excursions or delays, the ratio drops. This essentially automates a pre-inspection, so it predicts if the lot will pass quality control or if it's at risk.

c) Decision automation: The outputs of the above models feed into a decision logic (some of which is encoded on-chain). For instance, if the conformity ratio is above a threshold and all required documents are present, the contract can auto-accept the delivery and trigger payment (this is termed AutoSettlement). If the score is low or anomalies were detected, the contract might automatically trigger a hold or require manual review (possibly entering a Dispute state). Thus, ML enables a shift from reactive to proactive management – catching issues early and handling many routine cases without manual intervention.

2) Model development and OFF-CHAIN ML GATE: A dataset containing time-series of temperature and humidity from a specific location (Casablanca, Morocco) was used to train several regression models, including:

- M1: predicts temperature based on the time of year and a given humidity,
- M2: predicts humidity based on the time of year and a given temperature,
- M3/M4: predict temperature and humidity at a given time of year.

These models are trained offline on historical data and are used at run time as part of an OFF-CHAIN ML GATE that transforms raw sensor readings into a compact conformity indicator (PassRate) and associated anomaly flags. The operation of this gate is illustrated conceptually in Fig. 6. For each lot and each monitoring window (for example, a transport leg or storage phase), the corresponding temperature and humidity readings are grouped into an ordered time series and preprocessed to handle missing values and obvious sensor glitches.

At run time, models M_1–M_4 are applied to these time series to produce expected values $\hat{x}_t$ for each observed reading x_t. For each time step t in the monitoring window, the deviation $|x_t - \hat{x}_t|$ is computed and compared to a tolerance ϵ, and the measured value is also checked against regulatory or contractual bounds $[x_{\min}, x_{\max}]$ appropriate for the product. A reading is classified as conformant ("pass") if both conditions are satisfied (small prediction error and within the allowed range), and as non-conformant ("fail") otherwise. After all N readings in the window have been evaluated, the PassRate is computed as:

$$\text{PassRate} = \frac{N_{\text{pass}}}{N},$$

where N_{pass} is the number of pass readings.

In addition to PassRate, summary statistics (minimum, maximum, mean) and a boolean anomaly flag indicating whether any severe violation occurred are produced. These outputs, together with the hash of the underlying raw data batch, form the OFF-CHAIN ML GATE summary for that window. The summary is stored off-chain, and its cryptographic hash, PassRate value, and anomaly flag are anchored on-chain via the Data Collection Contract (DCC) so that the Commercial Relationship Contract (CRC) can reference them at decision time.

When a lot reaches a decision point (for example, at delivery), the CRC reads the latest available summary for the relevant window. Automatic acceptance is authorized if PassRate $\geq \tau$ for a predefined threshold τ and if no anomalies or missing documents are indicated. In this case, the CRC transitions to an accepting state and releases payment. If the threshold condition is not satisfied or an anomaly is present, the contract remains in a hold or disputed state, and the detailed off-chain records can be inspected by the parties or by an external auditor. In the prototype, the threshold is set to 0.8 (80%).

The following table summarizes the best results obtained after training the models using multiple ML algorithms; see Table I:

TABLE I. PERFORMANCE COMPARISON OF MODELS FOR DIFFERENT CASES

Case	Target	Model	MAE	RMSE	R^2
M1	temperature	MLP_small	1.6217	2.0908	0.8462
M2	humidity	SVR_RBF	6.5615	9.3837	0.6789
M3	temperature	GradientBoosting	1.8683	2.4381	0.7909
M4	humidity	SVR_RBF	7.4696	10.8154	0.5734

The verification process and ML outcomes are summarized in Fig. 6.

Instead of only collecting and displaying data, the system triggers autonomous decisions based on these ML outputs. The threshold and model parameters can be adjusted according to risk tolerance. During development, care was taken to ensure that the contract does not blindly follow ML outputs; for example, if a required document hash is missing, the contract

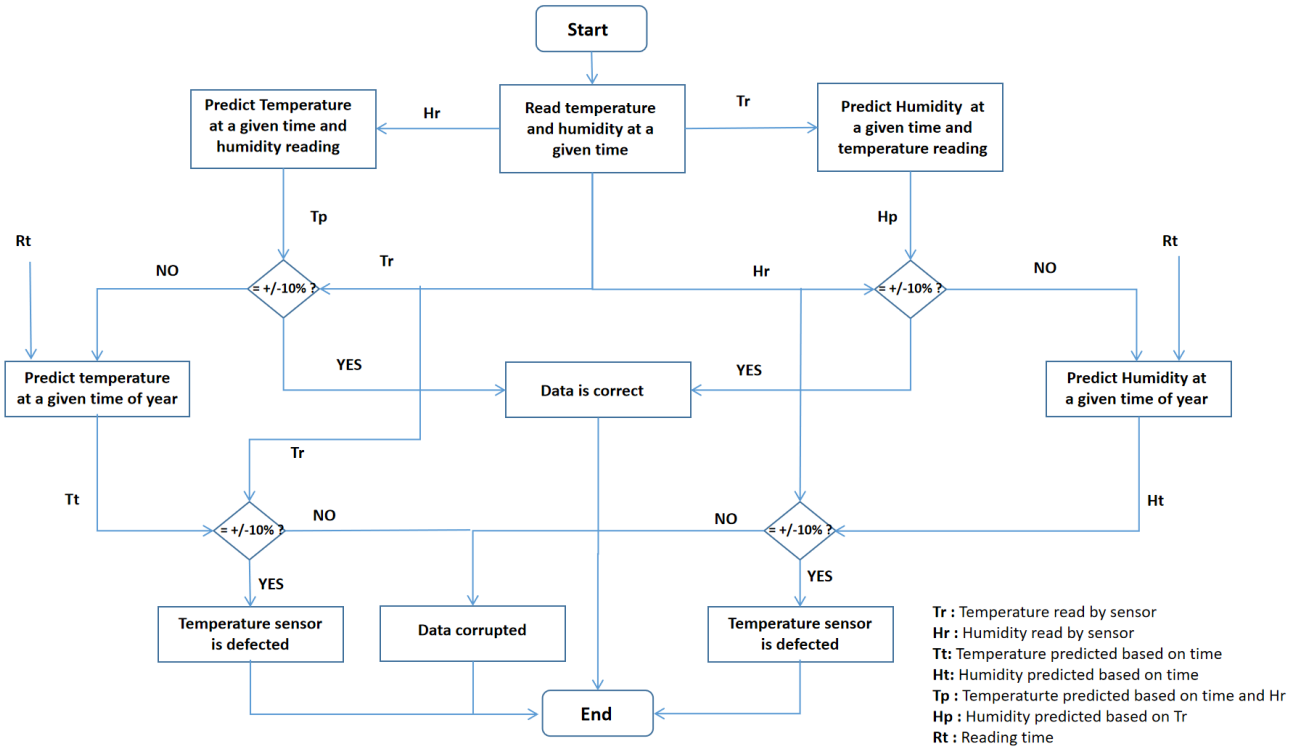

Fig. 6. Verification process and ML outcomes.

does not auto-settle even if the PassRate is high. Thus, the ML layer provides predictive quality control that works hand-in-hand with IoT data collection and blockchain enforcement, augmenting but not overriding fundamental checks.

IV. Experimental Results and Prototype Validation

To validate the proposed architecture, a full end-to-end prototype was developed and tested under realistic conditions. The system integrates IoT hardware, a cloud-based back end, and Ethereum smart contracts deployed on a local test network, enabling the simulation of a complete food supply chain transaction. Scenario-based experiments were subsequently conducted to evaluate traceability, automation, and the integrity of the system's outputs.

1) Prototype setup: A supply chain scenario with two primary actors – a producer (farmer) and a buyer (processor) – engaged in a transaction of a food product (a lot of fresh vegetables) has been configured. The IoT network consisted of four ESP8266-based sensor nodes; two of them were installed at the farm (monitoring storage conditions pre-shipment) and two in the delivery truck (monitoring conditions during transit). Each node recorded temperature and humidity every minute and was connected via Wi-Fi to an internet gateway in order to transmit data to an IoT cloud service (ThingSpeak was used as the cloud server) in near real-time.

On the blockchain side, the smart contracts have been deployed on the Ganache local blockchain. Ganache is an Ethereum blockchain simulator. The deployed smart contracts were the Data Collection Contract (DCC) and Commercial Relationship Contract (CRC). The farmer's account was set as the data provider (authorized to post sensor data and documents), and the buyer's account was set with the right to accept or dispute. A payment amount (simulated in test Ether) was escrowed in the CRC to mimic the financial transactions.

Also, a simple web page for visualization and manual interactions in order to display its incoming sensor readings in real-time has been developed to show the state of the smart contracts, and allow the user (playing the role of buyer, farmer, or arbitrator) to manually trigger certain events (like markShipped() or raise a dispute) if needed. The pages polled the Ethereum network for new events and also fetched data from off-chain storage when requested (for instance, to display the full temperature log of a trip when an arbitrator clicks a particular button).

2) Traceability and data integrity: First, a verification process was conducted to ensure that the system provided continuous traceability of the lot's condition and movements. As the shipment left the farm, an "Expedition" event was recorded on-chain (through the CRC, marking that the goods were shipped). The sensor nodes in the truck immediately began sending data, at the same time, the cloud aggregator created its first summary after 60 minutes of transit and invoked the DCC, resulting in a DataAnchored event on Ethereum for "Lot-TEST-123-Window 01" with the hash of that data. As the truck arrived at the processor, another "markReceived()" event was logged by the CRC (triggered by the buyer's app scanning a QR code on delivery, in the simulation). The second window of sensor data (covering the latter half of transit and unloading)

was then summarized and anchored on-chain. Finally, the buyer performing a quick inspection and then either accepting or rejecting the lot depending on the scenario was simulated (see Fig. 5). During this process, end-to-end traceability was demonstrated, every key step in the lot's journey was recorded immutably on the blockchain (with timestamps and responsible identities), and every data artifact (sensor readings summary, certificate, etc.) was linked via hashes, so that any independent auditor or arbitrator could reconstruct the entire chain of custody by following the blockchain trail and pulling the evidence from off-chain storage. A verification of the data item's hash took milliseconds, and any alteration of data (a try to modify a sensor summary file by a small amount) led to a hash mismatch, which immediately indicated tampering.

3) Machine learning outcomes: The ML models were integrated into the pipeline after each reading was pulled. The real sensor data from the farm storage and the truck were fed into the models. In the normal scenario, the temperature remained within 4–8°C and humidity within 70–90% (suitable for the concerned products), which the ML model correctly recognized as normal. It output a conformity ratio of 0.95 at the end of transit, indicating high confidence that the lot is good. In the anomalous scenario (detailed next), a period where the temperature rose to 15°C for 1 hour was introduced. The ML anomaly detection flagged this deviation (the predicted temp vs actual diverged significantly), and the conformity score dropped to 0.4 (indicating likely non-conformity). These scores were packaged into the final data summary and anchored. The CRC read the score and, according to the preset threshold (0.8), automatically took different actions in the two scenarios:

- In the normal case, after receiving the delivery and the final data hash, the CRC saw score=0.95, no anomalies, all documents present, and immediately executed the AutoSettlement transition, as a result, an on-chain event AutoSettled was emitted, indicating that the contract released payment to the farmer. The buyer's interface showed "auto-accepted. PaymentReleased". The entire process required no manual decision, and both parties could verify why by checking the blockchain, one sees the data hash and can retrieve the underlying report, which shows all conditions green. This showcases the power of smart contract automation informed by ML.
- In the anomaly case, when the delivery was markReceived(), the CRC noted score=0.4 or `anomalyFlag`=true. The buyer could open a DisputeOpened event, which froze the payment and alerted the farmer that a problem had been detected, and both parties could open the off-chain sensor log (via the hash) to see the temperature spike – which confirmed a breach of contract terms (temperature out of range). In a real setting, they might then formally reject or negotiate a solution. The main point is that the system proactively caught the issue and preserved evidence. Because of the cryptographically linked data, the farmer could not contest the truth of the temperature records (they were signed by the devices and anchored). And therefore, a dispute resolution is greatly simplified; it revolves around interpreting the data (which is trusted), rather than arguing about facts.

4) Scenario analysis: Two contrasted scenarios as described in Fig. 7, were effectively tested:

a) Conformant lot scenario: All conditions were kept within agreed ranges, and all required documents (sensor calibration cert, farm origination cert, etc.) were provided. As a result, the system produced a verifiable trace for each step, the ML score was high, and the smart contract auto-settled. The final outcome was a successfully completed transaction with both parties confident in the result. Notably, the time from delivery to payment release was near-instant (just the time to mine a block after delivery), much faster than a typical manual inspection and payment cycle. This indicates efficiency gains for stakeholders.

b) Non-conformant lot scenario: One condition (temperature) went out of range for a while, simulating a partial failure or sensor failure. A missing document was also tested by omitting the cleaning certificate for the transport container. The ML flagged the temperature anomaly, giving a low conformity passRate. Additionally, the smart contract logic detected the missing document hash (it expected a cleaningCertHash to be present, which it wasn't). Either of these alone would trigger a hold. In the test, both occurred, so the outcome was clearly not to auto-accept. The contract gave the buyer the opportunity to open a dispute. In a real-world sense, this corresponds to quarantining the batch for further inspection. The traceability system here provided forensic detail: via the blockchain, one could see an event DisputeOpened by Buyer at 10:05, reason: temp_anomaly" (the reason can be encoded as an event parameter or inferred from data). The buyer and farmer could use the off-chain data repository to dig deeper (e.g. check exactly when and where the temperature rose, see if any handling mistakes happened). Ultimately, the batch would likely be rejected or downgraded in this scenario. The system ensured that this decision was backed by objective, tamper-proof evidence, reducing potential conflicts. The presence of a trusted data trail helps avoid the "blame game" – it's clear if a logistics provider's truck lost cooling at a specific time, for example, focusing accountability appropriately.

After running these scenarios, an audit trail reconstruction was performed as a final validation. The role of an external auditor was simulated (with access permissions). A reconstruction of the full story was then performed using the available on-chain and off-chain records. By querying the Ethereum logs for the lot's ID, all on-chain events were obtained: creation, dispatch, data anchors, receipt, and outcome (settled or disputed). Each event had references (IDs, hashes). Then each hash's corresponding content from the off-chain storage was fetched: the sensor data summaries (which included ML results), the actual sensor time-series, and the documents. A verification process was conducted to ensure that each hash matched and each digital signature was valid. This process allowed us to verify compliance with every contractual condition, which traced "who did what and when" with precision (Farmer submitted data at time X, system auto-settled at time Y, etc.). The chain of custody from farm to processor was unbroken and cryptographically verifiable end-to-end. This level of auditability is a marked improvement over traditional systems, where auditors must trust paper logs

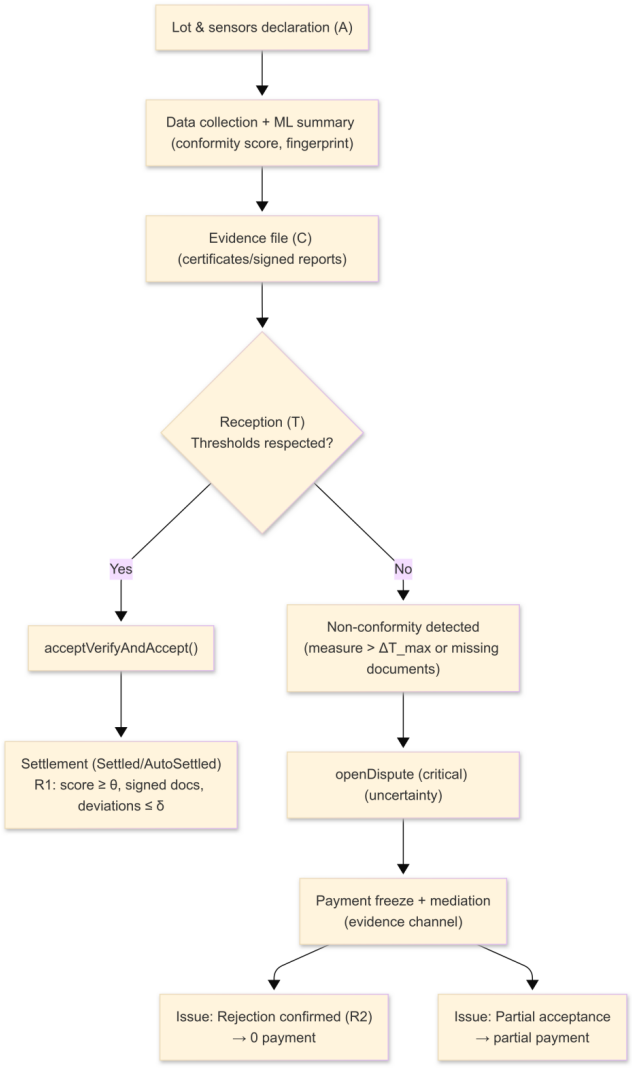

Fig. 7. Outcome workflow for compliant vs. Non-compliant lots.

or disparate databases that could be incomplete or altered. It also illustrates how the design achieves explicable decisions: even the automated actions were explainable by linking to specific data points (e.g., "auto-settlement occurred because all required criteria, as documented in hash H, were satisfied").

The experimental validation of the prototype demonstrates that the integrated blockchain-IoT-ML architecture functions as intended: it provides real-time traceability, enforces data-driven smart contract logic, and handles both nominal and off-nominal scenarios by either streamlining the workflow (for conformant lots) or flagging issues (for non-conformant ones). Improved efficiency (instantaneous settlement vs. potential delays) and improved trust through transparency (immutable evidence replacing he-said/she-said) were observed.

V. Discussion

A. Advantages and Novelty

The proposed system offers several notable benefits over traditional systems and even over earlier blockchain or IoT-only solutions, Improved Transparency and Trust, The use of a public blockchain (Ethereum) as the foundational ledger ensures that no single party can modify or hide any important information. This decentralization is crucial in multi-player supply chains where trust may not be present. All stakeholders (from farmers to retailers to regulators) can have access to an identical, tamper-proof record of key supply chain events, which improves trust in the data.

1) Data integrity and provenance: The hybrid approach of anchoring means that every piece of data (sensor readings, certificates, etc.) has a cryptographic provenance which is a strong defense against fraud. For instance, any attempt to change a food safety certificate or manipulate temperature records leads to hash mismatch.

2) Automation and efficiency: The synergy between smart contracts, sensor data and ML allows a degree of process automation that is novel in this domain. Routine operations like shipment acceptance and payment release can be executed automatically if some conditions are verified, which reduces administrative paperwork and speeds up the supply chain.

3) Accountability and auditability: Every action on-chain is linked to a cryptographic identity (linked to an organization or individual) and timestamped. This level of accountability ("who did what, when") is enhanced compared to centralized databases where logs can sometimes be edited or lost.

4) Modularity and extensibility: The proposed model is reusable and can be extended to different supply chains or to incorporate additional technologies. For example, the IoT layer could be expanded to include new sensors (GPS trackers for real-time location, imaging devices for visual quality checks, etc.).

B. Limitations and Mitigation Strategies

Despite its benefits, the system has certain limitations and challenges that need to be addressed:

1) Blockchain throughput and cost: In high-volume food supply chains, directly writing everything to the Ethereum mainnet could become costly and slow, since thousands of events occur daily, which significantly increase fees (gas costs) per transaction. In order to mitigate this issue, the system anchors data at a coarse granularity (per batch per phase rather than per sensor reading) and stores only hashes (small payloads). In this way the number of transactions and data size are reduced. On the other hand, only critical events and summaries are on-chain. This "selective anchoring" is the important identified mitigation.

2) Data privacy and confidentiality: While the system avoids putting sensitive details on-chain, the presence of certain events or hash values can reveal some information. For example, if a dispute event is visible on a public ledger, competitors might infer that a problem occurred with a shipment between certain parties. To mitigate this issue, pseudonymization is applied (using IDs instead of real names), and sensitive reasons are not revealed explicitly on-chain. Also, all actual content remains off-chain protected by access controls.

3) IoT device reliability and security: The maxim "garbage in, garbage out" applies – if IoT sensors report incorrect data (due to malfunction or tampering), the blockchain will

faithfully record bad data, and smart contracts might act on it. Blockchain doesn't guarantee data accuracy at the source. The model mitigates this risk through multiple actions:

a) Calibration and validation: Ensuring devices are calibrated and periodically checked mitigates systematic errors, and every calibration is anchored on-chain to increase confidence.

b) Anomaly detection (ML and rules): The ML layer and simple thresholds catch many outliers. If a sensor suddenly gives an extreme reading, the system flags it. Also, the verification process reveals important information about the quality of the collected data.

c) Edge computing and fail-safes: The approach relies on connectivity for data to be anchored. If a connection is lost for a long time, data might not get anchored promptly. This issue is mitigated by local storage on devices and backfilling once online. One could also incorporate mesh networks or alternative communications like LoRaWAN for remote areas.

4) Adoption and ecosystem challenges: A technical system is only as good as its adoption by stakeholders. Implementing this in an actual food supply chain means aligning multiple independent parties to use the platform and trust its outcomes. There could be resistance due to cost, complexity, or fear of data sharing. This is a limitation beyond technology; it involves governance, and possibly regulatory push:

- Start with pilot programs in a controlled environment (a single company's supply network or an industry consortium like Walmart did with IBM) to demonstrate value.
- Education and training are important so the users trust the system. The system can be designed with user-friendly interfaces (mobile apps for farmers to see their data).
- Regulatory alignment: Regulations are very important to push stakeholders to adopt such technologies.
- The architecture can also integrate with existing systems via APIs, it doesn't require ripping out the existing databases. For instance, if a company already has an ERP system logging batches, that system can feed into the blockchain layer through an adapter.

5) Sustainability considerations: While this work is motivated partly by sustainability (reducing waste through better monitoring, etc.), one might point out that blockchains (especially proof-of-work ones) have high energy use. Ethereum has transitioned to proof-of-stake (as of 2022), drastically cutting energy usage.

VI. Conclusion

In this paper, a comprehensive Web3-based architecture for end-to-end food supply chain traceability, integrating Ethereum blockchain smart contracts, IoT sensor networks, and machine learning analytics into a unified system is presented. Through the design and prototyping of this architecture, it has been demonstrated how combining these technologies can overcome many limitations of traditional traceability methods and add novel capabilities for data-driven decision-making in supply chain operations.

The system achieves real-time, auditable traceability by anchoring key supply chain events and sensor data on a public blockchain, ensuring the integrity, transparency, and tamper-resistance of records. At the same time, it preserves practical efficiency and confidentiality by keeping detailed data off-chain under secure management, linking the two realms with cryptographic hashes to guarantee provenance. It separates the business logic into a modular Ethereum smart contract (DCC) for sensor data and a CRC embodying a contractual state machine, which allowed for coupling evidence with actions (such as payment settlement) in a flexible manner.

By deploying low-cost IoT sensors across the supply chain, from farms to transport to storage, the system provides more visibility into environmental conditions that affect product quality and safety. The IoT layer feeds a continuous stream of data into the traceability records, enabling stakeholders to monitor conditions in real-time. The integration of an ML analytics layer introduces predictive and diagnostic intelligence in addition to detecting anomalies and predicting conformity to quality standards, effectively functioning as a virtual quality inspector that works in tandem with the physical sensors.

The findings have several implications for the future of supply chain management:

1) Enhancing food safety and quality: With end-to-end traceability and real-time monitoring, issues can be identified and addressed much faster than before, preventing contaminated or spoiled products from ever reaching consumers.

2) Building consumer trust: The ability to provide verifiable proof of a product's journey (including compliance with temperature controls, organic certifications, etc.) can boost consumer confidence.

3) Operational efficiency and automation: Automating routine checks and settlements can reduce transaction friction in supply chains, shortening payment cycles and reducing the manual workload on logistics and quality control personnel.

4) Generalizability: While the model focused on the food/agriculture domain, the architecture is applicable to any supply chain where traceability, authenticity, and condition monitoring are important (pharmaceuticals, chemicals, high-value electronics, etc.). The modular design means it can be adapted with minimal changes.

***Abstract*—Class imbalance is a common problem that occurs in classification where one class has much more instances than the other class. Class imbalance is especially challenging in high-stakes fields like medical diagnosis, fraud detection and predictive maintenance among others. In cases of imbalanced class distribution, models perform well while predicting the majority class but are unable to predict the minority class, which is usually more important. This paper introduces the MI-Heat (Mutual-Information and Heatmap Driven Under-sampling), a hybrid algorithm which targets the binary classification problem. The algorithm is a data-level method that combines Mutual Information (MI) for identifying important features and K-Means clustering for identification of the most important majority class samples. In addition, a distance heatmap is used to project proximities among samples and cluster centers, guiding what majority instances to retain and what to discard. Together, Mutual Information, clustering, and heatmap preserve diversity and suppress noise in order to increase the ability of the model to represent both classes equally with clarity. Performance of the MI-Heat algorithm is tested on 23 benchmark datasets and the results are seen as an improvement in classification accuracy, minority class recall and model generalization. When compared to the traditional under-sampling approaches, MI-Heat performance is consistently better, which clearly demonstrates its dominance over dealing with the class imbalance issue.**

***Keywords*—Mutual information; heat-map visualization; clustering; under-sampling; data-level; hybrid**

I. Introduction

Class imbalance refers to a prevalent situation in binary class problems, where one class heavily dominates the other, resulting in an imbalanced data distribution [1]. In these setups, machine learning systems use supervised or unsupervised learning methods to tag unstructured, typically subjective data [2]. Such asymmetry is naturally challenging in numerous domains especially in high-risk domains like medical diagnosis [3], [4], fraud detection [5], [6] and predictive maintenance. When there is class imbalance, models bias towards the majority class with resulting negative effects on their prediction performance for the minority class, typically of greater interest [7], [8], [9].

In diagnostic medicine, for instance, the influence of class imbalance may negate the ability to identify rare diseases that must be identified early if they are to be effectively treated [10]. Models learned from unbalanced datasets may be less sensitive to the minority class and consequently more likely to produce false negatives [11], [12]. These errors are particularly undesirable in medical scenarios where diseases like cancers or rare diseases must be diagnosed early [13]. [9] have found a study indicating that class imbalance has a tendency to significantly impact the performance of disease predictive models, an indicator of the significance of methods effective at dealing with differences in class distribution.

The effects of class imbalance also trickle down to fraud detection systems [14]. In the system, fraudulent transactions are the minority of the total transactions, so classifiers that have been trained using biased data find it hard to detect such critical instances. In line with [15], the monetary implications of having fraud activity misclassified are disastrous, thereby requiring it all the more to have high-precision and recall models for fraud detection. Similarly, in predictive maintenance, the strength of models relies on their ability to effectively identify failure events; thus, class imbalance resolution is paramount to prevent costly downtime and inefficiency in industrial setups [16]. To reduce the data imbalance, one way is to manipulate the dataset through sampling [17], [18], [19].The other focuses on manipulating the algorithm to reduce the effect [20]. Data-level methods target to reduce majority class instances or adding new information to the minority class. These methods involve rebalancing of the dataset using data resampling, under-sampling and over-sampling techniques [21], [22].

Although many solutions at the level of sampling and algorithms have been proposed in order to handle class imbalance, very few methods explicitly leverage structural patterns hidden within the data. Most of the under-sampling techniques based on hybrid and clustering approaches rely on distance metrics or estimations of density which do not consider how informative features interact between minority and majority classes. Consequently, such methods cannot preserve critical instance relationships or sometimes eliminate samples with discriminative information. Mutual information-based approaches represent one promising direction, yet, unfortunately, are rarely combined with spatial or structural insights such as heatmap visualization of feature relevance. An approach that combines mutual information with heatmap-driven visualization in guiding informed under-sampling decisions is highly lacking in current literature. More precisely, there is a lack in the study of techniques that find redundant majority regions by using information-theoretic measures, which also preserves meaningful minority clusters, resulting in consistent generalization in datasets under different imbalance severity

conditions. This opens a gap in the development of an MI-Heatmap-based under-sampling method that can intelligently select samples by exploiting feature-relevance patterns and data geometry instead of relying on randomness.

The remainder of this paper is organized according to the following plan. Section II introduces background and related work, including under-sampling techniques, clustering for addressing class imbalance, Mutual Information (MI) feature selection, and interpretability through heatmaps. Section III introduces the MI-Heat algorithm, explains its workflow, and its theoretical rationales, e.g., cluster separation, heatmap interpretability, and time complexity.Section IV describes the experimental setup: baselines, approaches, choice of classifier, and measures. Section V discusses and reports the results. Section VI contains the conclusion and future directions.

II. Related Work

This paper introduces a hybrid mutual information-based clustering approach which utilizes heatmap visualization, for further improvement of the process of reducing the data from majority class without losing important information. This section includes under-sampling approaches, clustering in class imbalance, mutual information and heatmap visualization for interpretability

A. Under-Sampling Approaches

To overcome the issues of class imbalance, various methods are employed like over-sampling, under-sampling and advanced ensemble techniques. For instance, methods such as SMOTE (Synthetic Minority Over-sampling Technique) enhance the representation of the minority class using synthetic sampling, improving the performance of the model [23]. Moreover, research identifies that various approaches are of varying effectiveness depending on the specific characteristics of the compared data sets, pointing to tailored solutions rather than one approach to all [24].

Random Under-sampling (RUS) is among the simplest techniques to address class imbalance. It chooses instances randomly and removes it from the majority class until both classes have equal proportions. Although this can improve a model's ability to recognize minority instances, it has the effect of inducing loss of vital information if key examples are being removed [15]. Tomek Links builds upon this by cleaning the decision boundary removing overly close majority samples to minority ones [25], [26]. Tomek Links can still eliminate useful samples accidentally and cause overfitting or misrepresent the class distribution [24]. NearMiss tries to select representative majority samples close to minority instances, retaining valuable context and increased sensitivity [27]. But it may risk losing important data, limiting generalization [28]. DBSCAN-based under-sampling, however, clumps data and removes majority points of sparse regions but keeps denser ones. While better organized, it is also dependent on tuning parameters and still risks discarding useful or noisy samples [29].

Although useful, these methods have vulnerabilities that come with them by nature: they can discard valuable majority information, reduce diversity and cause under- or over-fitting. Each approach also experiences different performance on different datasets, showing that under-sampling also lacks the more adaptable and informative strategies it needs [24]. Traditional under-sampling methods for imbalance classes, such as Random Under-sampling (RUS), Tomek Links and Near-Miss, suffer from the disadvantage of removing informative majority class samples and consequently losing useful information [30] and inducing underfitting. They can also reduce diversity in the majority class, which is a critical factor in successful decision boundary learning.

Condensed Nearest Neighbor (CNN) reduces the training set without losing the most important patterns, but selecting the optimal subset is NP-hard and most often relies on heuristics [31]. Edited Nearest Neighbor (ENN) improves classification by deleting majority samples incorrectly classified by their neighbors but may delete useful points as well [32]. As a result, these methods must balance eliminating redundancy with the preservation of informative data [33].

Even though SMOTE and other oversampling methods are useful in expanding minority class samples, they introduce noise and tend to enhance overfitting when the minority class is small.

However, under-sampling methods may results in an information loss due to extreme reduction in the majority class [34]. This will ultimately lead to models that overfit to the remaining data, particularly when the samples retained do not adequately represent the original dataset's diversity [35].

B. Clustering in Class Imbalance

Clustering is a good way to preserve structure and diversity of the majority class under under-sampling. Random or distance-based only methods treat all majority samples the same way and have a tendency to remove useful points. Clustering, specifically K-Means, first groups similar majority instances together into meaningful clusters then keep some representative samples from each cluster. This preserves important patterns and removes redundant or noisy points. There is evidence to support this: clustering can concentrate a model's attention on the minority class more strongly [36] and when combined with learned samplers like MLPs, can provide improved accuracy in difficult settings like bioinformatics [37]. DBSCAN can also help by eliminating sparse, less-informative majority points and preserving dense structure, but is hyperparameter-sensitive [29]. However, K-Means is generally preferred for its simplicity and stability it selects centroid or near-centroid samples, which improves generalization and bounds information loss [24].

C. Mutual Information (MI) in Feature Selection

Mutual information (MI) chooses the most relevant features to predict the class. By selecting the most relevant features, MI increases the ability of the model to discriminate between minority and majority classes, particularly when there is overlapping in class distribution [38], [39], [40]. Using MI before under-sampling preserves the signal and removes the clutter, so the model learns more from fewer, cleaner examples. For instance, Chen et al. demonstrate the usefulness of MI for feature selection when they indicate that it helps to identify features that have high information gain about the minority class, which can lead to improved discrimination

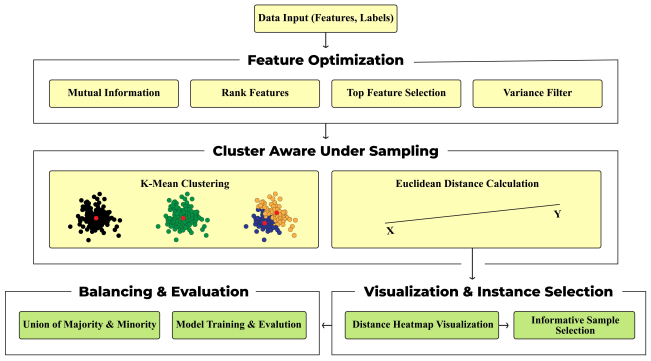

Fig. 1. Conceptual framework.

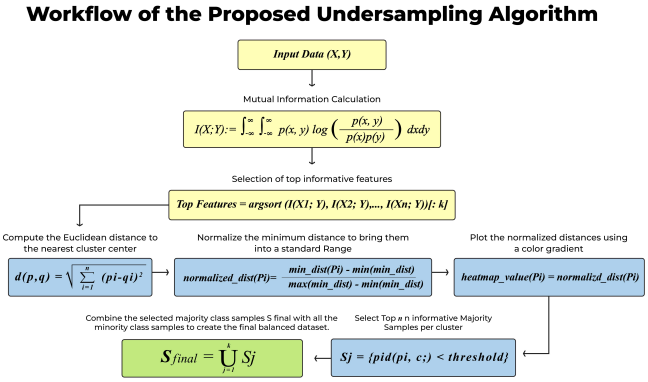

Fig. 2. Workflow of algorithm.

between the classes [41]. This is crucial because minority classes have a tendency of lacking representative data and therefore, classifiers fail to learn their characteristics. The application of MI allows one to select features that optimize the model's ability to separate minority and majority classes, thus enhancing overall classification performance, particularly for overlapping distributions [42]. Furthermore, [43] validate the applicability of MI-based feature selection in the context of imbalanced datasets, showing how it allows for the identification of pertinent features and the removal of redundant or non-informative features.

Combining clustering with MI makes it even stronger. Clustering can tell us which features to keep by eliciting structure in the data and MI ranks those features by usefulness. Adaptive, MI-based selection has also been shown to remove redundancy and keep only the most informative features [44]. Hybrid designs that couple under-sampling with heuristic feature selection also produces more quality data and results [45]. Furthermore, MI weighting models can enhance performance in high-stakes fields (e.g., medicine) by better encoding true class structure [46].

D. Heatmap Visualization for Interpretability

Heatmaps facilitate easier visualization about under-sampling choice. Distance heatmap shows nearest distance of each sample to minority points and to cluster centers, thus representative majority examples can be retained while deleting redundant/noisy ones. This is helpful to avoid class imbalance biased classifiers. Past research validates informed sampling: [47] highlight accurate sampling during training; [48] illustrate density-aware approaches preserving essential minority information; and [49] indicate heatmaps as an easy way of visualizing closeness and informing under-sampling. In practice, heatmaps facilitate practitioners to see class structure, to prioritize boundary cases and to justify what is kept or thrown away with a single, understandable figure.

However, most of these sampling methods still have key limitations. For instance, random under-sampling results in the removal of informative majority instances, introducing information loss. Most of the existing hybrid or clustering-based methods improve balance but are mostly not interpretable and cannot explain why certain samples are retained or rejected. Visualization-aided sampling methods exist, but most provide coarse or domain-specific representations that do not clearly expose feature relevance or cluster structure. Consequentially, decision transparency of current imbalance handling techniques is still limited, leaving room for development at the intersection of information-theoretic feature selection with interpretable, structure-aware sampling. Based on such shortcomings, the MI-Heat algorithm proposes a more structured and explainable alternative: Hybrid Mutual-Information and Heatmap-Driven Under-sampling.

By combining these methods, the MI-Heat (Hybrid Mutual-Information and Heatmap Driven Under-sampling) algorithm provides a new solution to class imbalance problem. By employing clustering to efficiently distribute the majority class samples, Mutual Information (MI) further helps in selecting features that are most representative in nature, making the model more sensitive to the minority class. Heatmap visualization included in the approach also makes it more interpretable, such that under-sampling itself becomes efficient as well as clear. This under-sampling hybrid approach reduces majority class representation without sacrificing the diversity and integrity of the majority class, circumventing the limitations of traditional under-sampling methods that often result in data loss and overfitting. While successful in these data-level methods, class overlap and distribution differences between the classes remain challenges. Synthetic data generation can even introduce noise or omit the actual distribution of the minority class. Furthermore, where minority samples are few, it is impossible to fully represent differences between the classes and the utility of data-level methods is limited.

III. Proposed Methodology: MI-Heat Algorithm

The Hybrid Mutual-Information and Heatmap Driven Under-sampling (MI-Heat) method starts with mutual choice of the most informative features from the data by way of Mutual Information (MI), as shown in Fig. 1. This is to effectively eliminate only the features that contribute minimal value towards classification, while keeping the features of maximum importance. Then, any feature with small variability is removed by a Variance Filter, so that relevant information can be used for further analysis. Second, the most common class instances are clustered collectively with the aid of K-Means Clustering, splitting the data into more manageable

smaller sets that are closer in nature. This assists the algorithm in achieving a better understanding of the overall structure of the majority class. Post-clustering, the algorithm computes distances from every data point to the center of the respective cluster. These are rendered visible with a heatmap, from which it is easy to spot the data points nearer to the cluster centroids and thus more significant.

Finally, the algorithm selects representative points from every cluster and, in this instance, the nearest to the cluster center. These representative points are added to all instances of the majority class and create a balanced dataset. By the proper selection of representative points from every cluster and the preservation of all majority and minority class instances, this method avoids the end dataset to be deprived of vital information regarding the data distribution and hence it becomes a balanced and informative dataset that results in improved model performance and more accuracy in prediction.The mathematical formulations utilized in the proposed algorithm 1 are elaborated in the subsequent overview section.

A. Overview

As shown in Fig. 2, the proposed approach, follows a formal workflow starting from mutual information (MI) computation and top feature selection. Clustering is performed on the features, after which heatmap is used to visualize by using the euclidean distance.

- Input data: Begin with an imbalanced dataset with feature matrix $\mathbf{X}$ and labels $\mathbf{y}$.
- Mutual information (MI) feature selection: Compute MI between each feature and the target, then keep the top k features:

$$I(X;Y) = \sum_{x\in X}\sum_{y\in Y} p(x,y)\,\log\!\left(\frac{p(x,y)}{p(x)p(y)}\right). \quad (1)$$

- Variance filter: Remove near-constant features using a variance threshold to retain informative variables.
- Clustering of majority-class samples: Apply k-means to the majority-class subset to form clusters based on feature similarity.
- Euclidean distances: For majority sample $\mathbf{p}_i$ and cluster center $\mathbf{c}_j$,

$$d(\mathbf{p}_i,\mathbf{c}_j) = \sqrt{\sum_{m=1}^{n}(p_{im}-c_{jm})^2}, \quad (2)$$

  where n is the number of retained features.
- Distance heatmap generation: Compute normalized distances between majority samples and their assigned centroids and visualize them with a heatmap (darker indicates closer).
- Select informative majority samples from clusters: From each cluster, choose the n closest samples to its centroid (by sorted $d(\cdot,\cdot)$) to form S_{final}.
- Balanced dataset creation: Combine selected majority samples with all minority samples:

Algorithm 1 Hybrid Mutual-Information and Heatmap Driven Under-Sampling (MI-Heat)

Require: Training data $X_{\text{train}} \in \mathbb{R}^{n\times d}$, labels y_{train}, majority class label c_M, under-sampling ratio $r \in (0,1]$, number of top features k_f, random seed s.
Ensure: Under-sampled dataset (X', y') with balanced class distribution.
Identify class indices
$\mathcal{I}_M \leftarrow \{\, i \mid y_{\text{train}}[i] = c_M \,\}, \quad \mathcal{I}_m \leftarrow \{\, i \mid y_{\text{train}}[i] \neq c_M \,\}.$
if $|\mathcal{I}_M| = 0$ **then**
  error: "No majority instances found."
end if
Select informative and stable features
Compute mutual information scores $MI_j = MI(X_j, y_{\text{train}})$.
Retain top-k_f features with highest MI_j.
Apply variance filtering ($\sigma^2 < 10^{-5}$) to remove near-constant predictors. Resulting matrix: X_s.
Extract majority subset $X_M \leftarrow X_s[\mathcal{I}_M]$.
Determine clustering granularity $k \leftarrow \max\big(1, \lfloor |\mathcal{I}_M| \times r \rfloor\big)$.
Perform cluster analysis
Apply K-Means (k clusters, seed s) on X_M to obtain cluster centers $C = \{c_1, \ldots, c_k\}$ and labels L.
Compute proximity metrics and visualize heatmap
Compute Euclidean distances $D_{ij} = \|X_M[i] - c_j\|_2$.
Normalize the minimum distance per sample:

$$h_i = \frac{\min_j D_{ij} - \min(h)}{\max(h) - \min(h)}.$$

Visualize $\{h_i\}$ as a one-column heatmap to show density and dispersion of majority points.
Cluster-aware instance selection
for $c \in \{1, \ldots, k\}$ **do**
  $S_c = \{\, i \mid L[i] = c \,\}$.
  $n_c = \max\big(1, \lfloor |S_c| \times r \rfloor\big)$.
  Sort S_c by $D_{i,c}$ ascending.
  Retain first n_c indices to obtain S'_c.
end for
Concatenate all retained indices: $\mathcal{I}'_M = \bigcup_c S'_c$.
Form the final balanced subset
$\mathcal{I}' = \mathcal{I}'_M \cup \mathcal{I}_m; \quad X' = X_{\text{train}}[\mathcal{I}'], \quad y' = y_{\text{train}}[\mathcal{I}']$.
Reset indices for consistency.
Return (X', y').

$$\mathcal{D}_{\text{balanced}} = S_{\text{final}} \cup \mathcal{D}_{\text{minority}}. \quad (3)$$

Notation: $p(\cdot)$ denotes probability mass/density; bold symbols are vectors; $\log$ is the natural logarithm.

B. Theoretical Rationale

MI-Heat combines feature selection and clustering to address the imbalanced data issue in a more interpretable and structured manner. It combines feature relevance with under-sampling that is cluster-aware to preserve valuable patterns within the majority class without letting the minority class be overlooked. The hybrid approach has several theoretical

advantages to enable the model to learn better from both classes.

1) Relevance enhances cluster separation: In the MI-Heat model, the process begins by selecting the most informative features according to Mutual Information (MI), by using the formula discussed in Eq. (1). This process ensures that only features most effective at distinguishing between classes are retained. Operating with these features, the algorithm enhances the separation between clusters of the majority class. As a result, the clusters obtained in the subsequent K-Means clustering step are more pronounced, with better defined borders, making it easier to distinguish between the majority and minority classes. Cluster diversity avoids loss of minority-adjacent samples. Instead of simply random under-sampling the majority class samples, the MI-Heat method uses K-Means clustering to divide the majority class into smaller clusters. In this manner, diversity among the majority class is preserved. The algorithm ensures that notable, divergent minority instances near the minority class are preserved by selecting the most characteristic points from every cluster. This reduces the risk of losing valuable minority-adjacent samples, which would harm the ability of the model to learn the minority class characteristics. To construct the final balanced dataset, the representative majority samples selected from all clusters are combined with the complete minority set, as represented in Eq. (3).

2) Heatmap provides interpretable cluster-density mapping: The distance heatmap generated during the clustering phase is computed using the Euclidean metric in Eq. (2), which serve as an interpretation aid employed in helping us comprehend the structure of the majority class. The heatmap shows the distances of the majority instances to their respective cluster centers, with the intensity of the colour representing the sample density in each region. The visualization serves to aid understanding of where the data points are centered and the quality of the definition of the clusters. It gives interpretability to the procedure such that it's possible to see the spatial location of majority class points and how the algorithm decides what points to retain.

3) Time complexity analysis $\mathcal{O}(n_M k d' t)$: The time complexity of the MI-Heat algorithm is different based on the factors discussed below. n_M represents the number of majority class instances, k represents the number of clusters derived in the K-Means clustering and d' is the number of features yielded after Mutual Information and Variance Filtering. The most prominent time complexity is the K-Means clustering with a time complexity of $\mathcal{O}(n_M k d' t)$, where t represents the number of iterations the K-Means algorithm runs through. This is a sign of the clustering cost of the most frequent class data and calculating the distances between every sample and its nearest cluster center.

IV. Experimental Setup

This section reports experimental setup used to evaluate the performance of the Hybrid Mutual-Information and Heatmap Driven Under-sampling (MI-Heat) algorithm. The evaluation is done on various benchmark datasets, baseline comparison, classifier training and assessment using variety of evaluation metrics.

A. Datasets

For testing, 23 standard benchmark datasets are retrieved from UCI and KEEL in various domains such as medical, biological and industrial data. The data was split into 30% for training and 70% for testing. Out of the 30% training data, the initial count of the majority class samples is identified from the entire dataset.However, to address the class imbalance problem, the majority class is under-sampled, so that there is balance between the majority class and the minority class in the training set. This is where limited number of best majority samples were selected representing the entire majority class. These datasets were selected to be representative of a variety of imbalanced classification problems. Table I show a list of the datasets used in the experiments.

B. Baseline Methods

The performance of the MI-Heat algorithm is compared with several baseline under-sampling techniques, commonly used in imbalanced data scenarios. These include:

1) Random Under-sampling (RUS): A basic under-sampling technique that randomly selects a subset of the majority class samples, discarding the rest.

2) Tomek links: A cleaning method that removes pairs of samples from different classes that are closest to each other.

3) NearMiss: A family of algorithms that selects majority class samples closest to minority class samples based on a distance metric.

4) DBSCAN-based under-sampling: A density-based under-sampling method that uses DBSCAN (Density-Based Spatial Clustering of Applications with Noise) to find dense regions of the majority class and reduce instances accordingly.

5) ENN (Edited Nearest Neighbors): An algorithm that removes samples from the majority class that are misclassified by their nearest neighbors.

6) CNN (Condensed Nearest Neighbors): A similar technique to ENN but instead condenses the dataset by retaining only the necessary majority class samples that are not misclassified.

C. Choice of Classifier

To evaluate the effectiveness of the proposed method, Random Forest(RF) is selected as a classifier. Random Forest is a robust and efficient ensemble learning method that is well-known for its ability to handle imbalanced data and reduce overfitting. With under-sampling, it further reduces majority-class bias and improves minority detection [50]. Empirical data prove RF exhibits consistency across data-acquisition environments and various types of datasets. In medical science, RF has worked better than traditional classifiers, i.e., gestational diabetes prediction, proving its actual-world use [51]. It is also good in complex relations under different rebalancing methods [52]. It is trained on the under-sampled data of the MI-Heat algorithm as well as the baseline methods. The Random Forest classifier was implemented using the scikit-learn library with the following parameters:

- Number of trees : 300

TABLE I. SUMMARY OF THE DATASETS USED IN THE EXPERIMENTS

- Class weight : Balanced (to handle class imbalance)

D. Evaluation Metrics

To assess the performance of the MI-Heat algorithm and compare it with the baseline methods, several standard evaluation metrics commonly applied in imbalanced classification problems are employed:

1) PR-AUC: The area under the precision-recall curve, particularly useful for imbalanced datasets.

2) AUC-ROC: The area under the receiver operating characteristic curve, providing insight into the model's performance across different classification thresholds.

3) Partial ROC-AUC: The area under the receiver operating characteristic curve (ROC-AUC) computed within a partial range of interest (for example, considering only a certain threshold or a range of false positive rates). This metric allows for a more focused evaluation, especially in cases where specific regions of the ROC curve are of particular interest for the application.

V. RESULTS

The boxplot in Fig. 3 shows PR AUC ranks of the proposed MI-Heat on 23 benchmarking datasets with different under-sampling strategies. Lower ranks indicate better performance. As can be observed, the proposed MI-Heat method works stably well and its ranks are close to the optimal values for the most part. Traditional methods like RUS and DBSCAN are more volatile, i.e., their performances are not as stable across datasets. NearMiss and Tomek Links are superior to random under-sampling but lose some useful majority information. ENN and CNN gain better boundary cleaning at the expense of sensitivity to dataset properties. In contrast, MI-Heat strikes a good balance between throwing away redundant samples and keeping useful structure in data. As a whole, these results confirm that the new method provides more stable and accurate classification for imbalanced datasets.

Fig. 4 shows the ROC AUC rank distribution of 23 benchmark sets for different preprocessing and under-sampling methods. The ROC AUC score is used to measure the model performance in distinguishing minority and majority classes. Lower ranks show better classification performance. It can be seen from the results that the employed MI-Heat method is consistently strong in performance with relatively lower median ranks compared with traditional methods. Classic methods such as RUS and DBSCAN show higher variability, which suggests unstable performance across different datasets. CNN and ENN are suitable for boundary smoothing but show higher fluctuation, suggesting data attribute sensitivity. NearMiss and Tomek Links are fairly good but discard significant majority-class samples. Overall, the graph shows that MI-Heat produces more balanced and stable results across datasets, confirming its effectiveness in improving classifier robustness on imbalanced data.

Fig. 5 plots the distribution of Partial ROC AUC ranks across 23 benchmark datasets for different preprocessing methods. This metric focuses on the classifier's performance in the most critical region of the ROC curve, putting weight on true positive rates at low false positive rates. Lower ranks are preferable. The novel MI-Heat method has one of the lowest median ranks, reflecting stable and consistent classification performance. Methods such as RUS and DBSCAN exhibit high variability, suggesting instability across data sets. ENN and CNN present moderate performance but remain sensitive to class overlap. Near-Miss and Tomek Links improve decision boundaries but remove some informative instances. The figure 5 as a whole demonstrates that MI-Heat provides robust and stable performance within the important detection region and thus, it is highly effective for imbalanced data classification.

Fig. 6 is a ranking of Normalized Partial ROC AUC performance over 23 benchmark datasets for different preprocessing techniques. Normalized partial ROC AUC focuses on measuring performance in the most suitable part of the ROC curve with normalized results over diverse datasets of different

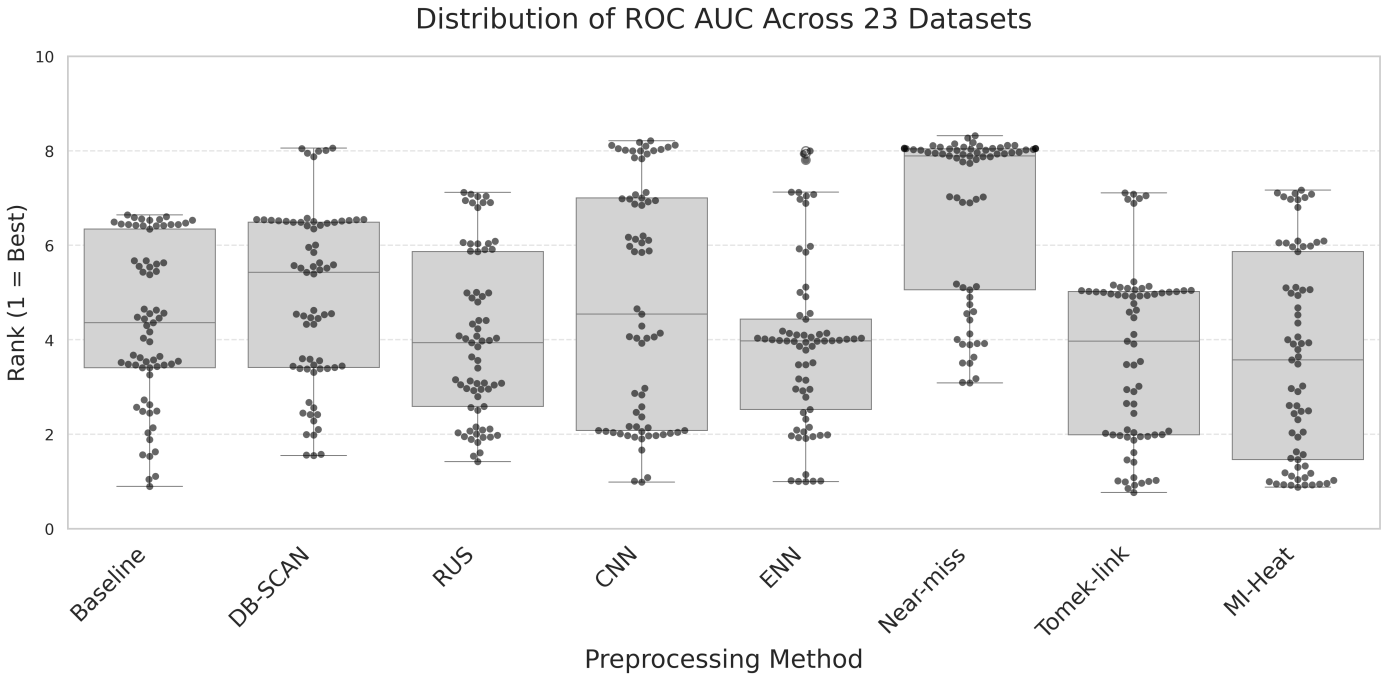

Fig. 3. PR AUC ranks of the proposed MI-Heat on 23 benchmarking datasets.

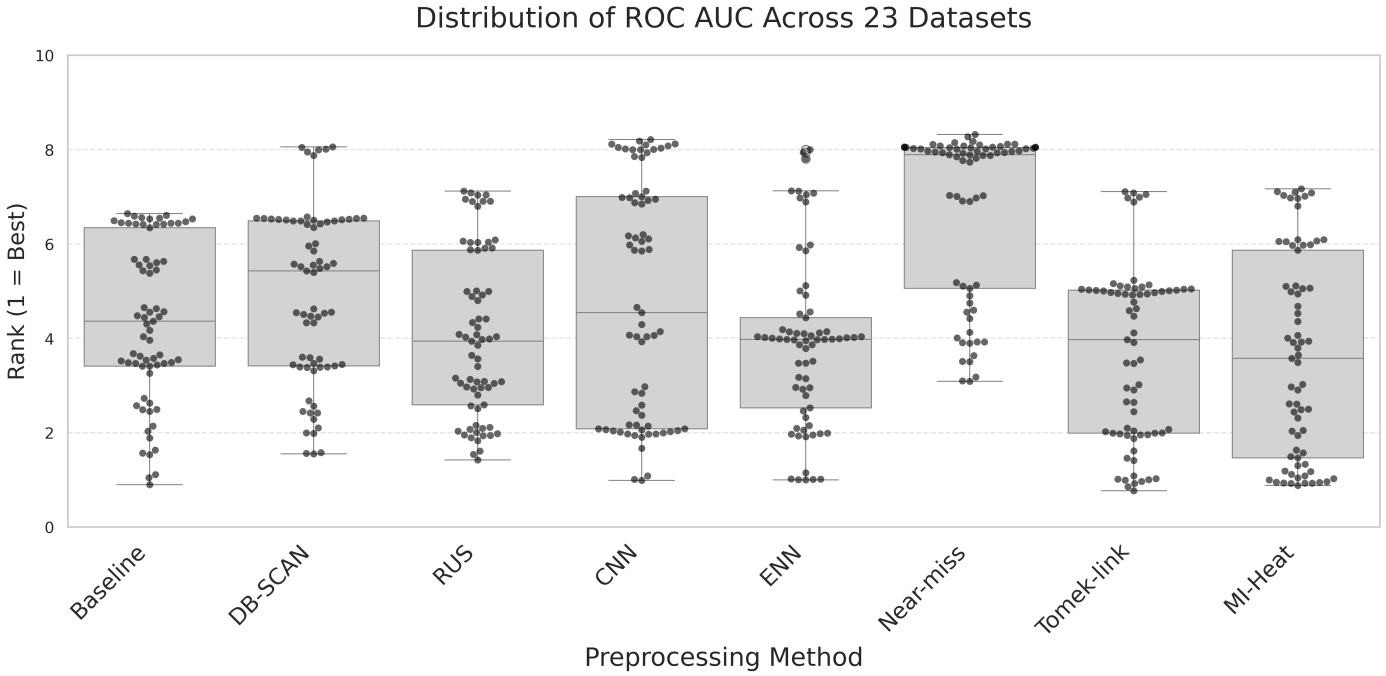

Fig. 4. ROC AUC rank distribution of 23 benchmark sets.

scales. Lower ranks correspond to superior performance. The proposed new MI-Heat method exhibits stable and competitive ranks with consistent classification quality for heterogeneous data types. Compared to traditional under-sampling approaches like RUS, DBSCAN and NearMiss, the proposed approach exhibits lower variability and higher reliability. ENN and CNN perform well at boundary refinement but are still vulnerable to overlapping classes.

When all four-measurement metrics PR AUC, ROC AUC, Partial ROC AUC and Normalized Partial ROC AUC are compared, a consistent trend can be seen. MI-Heat algorithm always yields stable, lower-ranked results, demonstrating that it is robust and resilient. It preserves data diversity well but minimizes noise to a significant degree, outperforming

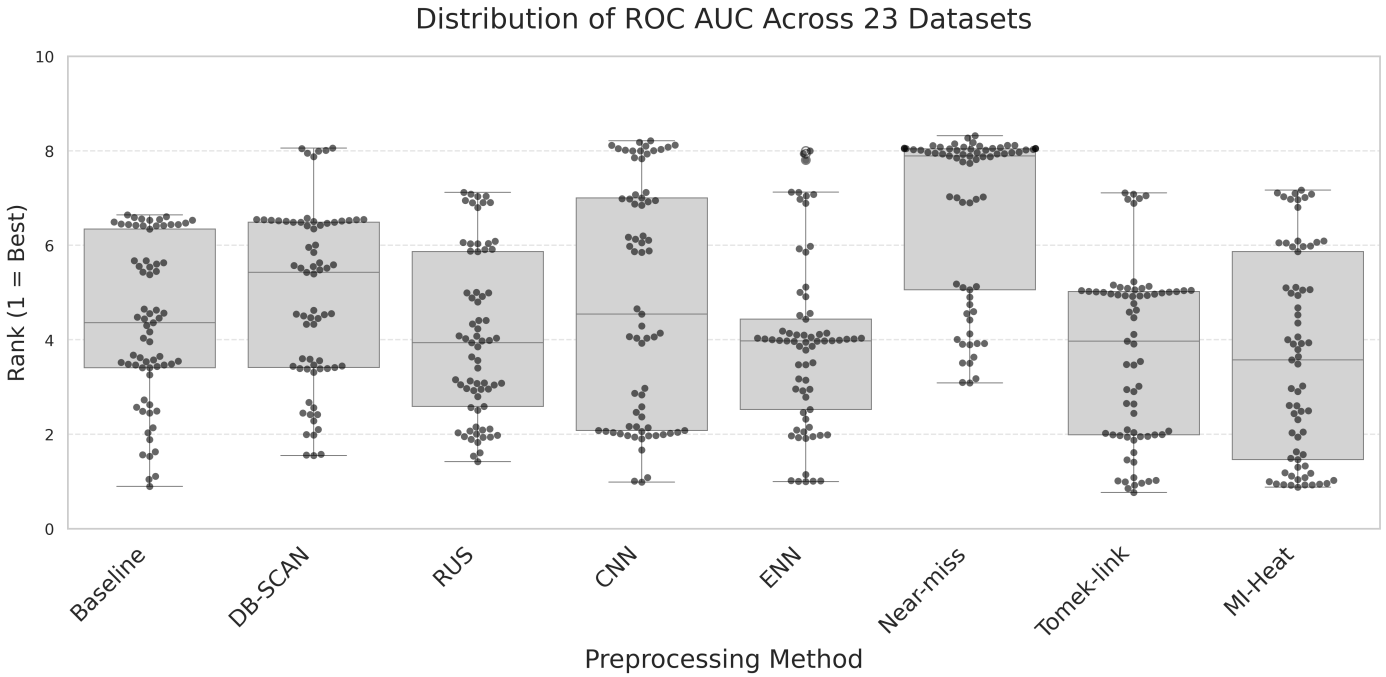

Fig. 5. Partial ROC AUC ranks across 23 benchmark datasets.

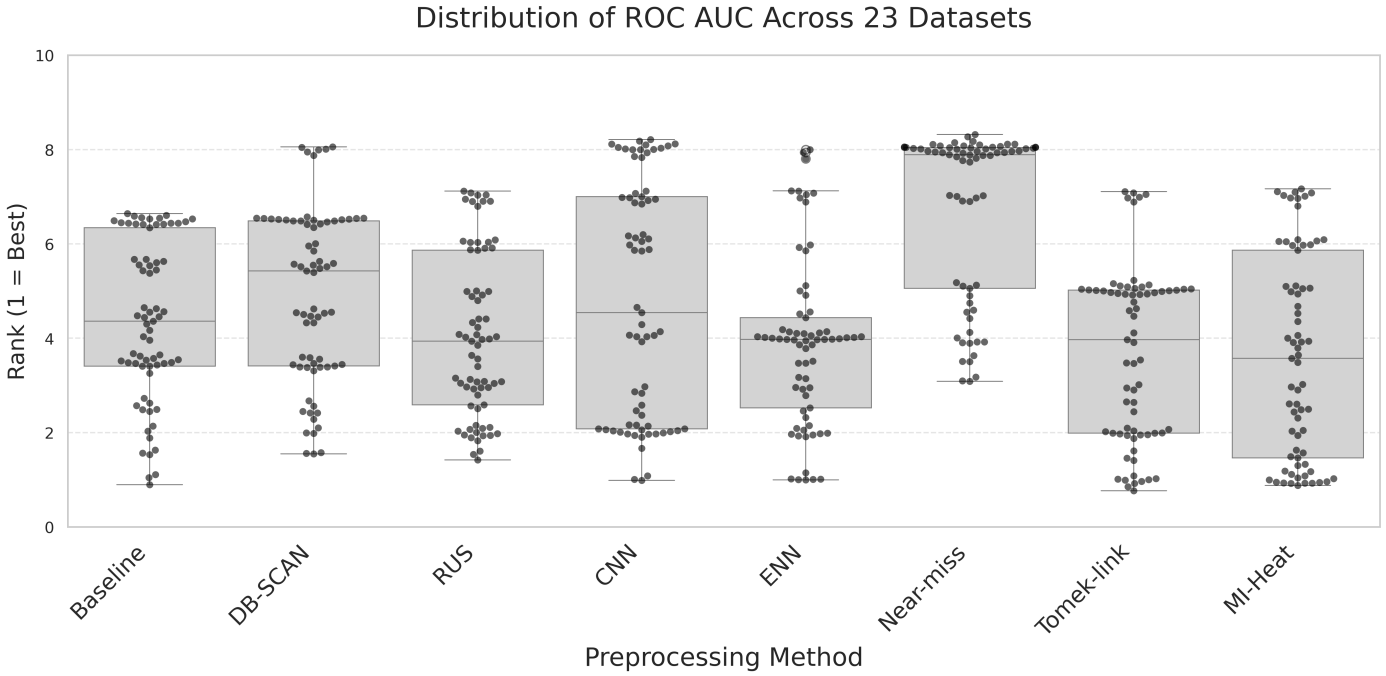

Fig. 6. Normalized partial ROC AUC performance over 23 benchmark datasets.

traditional methods which either delete valuable samples or introduce too much bias. In general, these results confirm that MI-Heat offers fair and trustworthy improvements in handling class-imbalanced datasets. The complete detailed results are provided in Tables II, IV and III and Fig. 7, and Fig. 8 (Appendix).

VI. Conclusion

This article introduced MI-Heat, a novel hybrid under-sampling algorithm incorporating Mutual Information (MI)-based feature relevance, K-Means clustering and distance heatmap visualization to effectively address class imbalance in binary classification problems. Empirical evaluation on 23 benchmark datasets demonstrated that the proposed method

achieved superior and more stable performance compared to traditional techniques such as RUS, Tomek Links, DBSCAN and NearMiss.

On all the evaluation metrics PR AUC, ROC AUC, Partial ROC AUC and Normalized Partial ROC AUC MI-Heat showed low rank variability, which signifies model robustness and stable discrimination between classes. The clustering step maintained the structural diversity of the majority class and MI-based selection ensured the retention of most informative samples. The use of the heatmap visualization added interpretability, allowing for the straightforward understanding of cluster separability and data density distribution.

Overall, the experiments confirm that MI-Heat produces an interpretable and balanced solution that minimizes data loss, avoids noise amplification and encourages classifier generalization on diverse datasets.

Meanwhile, this study has a number of limitations that need to be acknowledged. This algorithm is evaluated only on binary classification settings; multi-class or extreme-imbalance scenarios are not explored within this study. Similarly, the combination of MI computation, clustering, and heatmap generation might introduce additional computation overhead when dealing with very large datasets; comprehensive assessment of the scalability of the proposed method is beyond the scope of this study. Furthermore, given that all experiments were conducted on benchmark datasets, there is a possibility of dataset-specific biases or structural assumptions hindering the generalization in industrial settings.

VII. Future Directions

Future research can build upon this study in the following substantive ways:

- Using adaptive clustering methods like DBSCAN or Gaussian Mixture Models to automatically adapt to data density.
- Investigating multi-class imbalanced learning conditions to analyze the scalability of MI-Heat in non-binary configurations.
- Incorporating deep feature extraction or autoencoder-based representations for improving the quality of feature selection prior to under-sampling.
- Employing explainable AI (XAI) frameworks for visualizing decision boundaries and interpreting the sampling results further.
- Performing real-world domain tests in healthcare, finance and industrial fault detection to determine real-world impact.

***Abstract*—Stroke detection from computed tomography (CT) images is an important research direction in computer vision. However, prior studies often use different preprocessing steps, model configurations, and evaluation protocols, making it difficult to compare results or assess architectural reliability. This paper presents an exploratory benchmark that evaluates representative convolutional neural networks (CNNs) and vision transformer (ViT) models under a unified experimental setting for binary stroke classification. STROKECT-BENCH is introduced as a standardized framework in which five CNNs and four transformer-based models are trained on the Brain Stroke CT Image dataset (1,551 normal and 950 stroke images) using identical preprocessing, augmentation, optimization parameters, and performance metrics. The results show that transformer models, particularly PVT-Small and Swin Transformer, achieve the highest accuracy and AUC, while EfficientNetB0 provides a strong balance between accuracy and computational efficiency. As an exploratory study, the findings aim to establish reliable baselines rather than clinical validation. STROKECT-BENCH offers a consistent evaluation reference for future work involving patient-level datasets, external validation, and multimodal stroke-analysis approaches.**

***Keywords*—Stroke detection; brain CT image; Convolutional neural networks; vision transformers; exploratory benchmark**

I. Introduction

Stroke is one of the leading causes of mortality and long-term disability worldwide, affecting millions of people each year and imposing a substantial socioeconomic burden on health systems and families [1]. Clinically, strokes are broadly classified as ischemic, due to occlusion of cerebral blood vessels, or hemorrhagic, due to vessel rupture [2]. Rapid and accurate diagnosis guides life-saving interventions and strongly influences patient outcome.

Computed Tomography (CT) is the primary modality for emergency stroke imaging [3], because it is fast, widely available, and able to distinguish hemorrhagic from ischemic events. However, visual interpretation of CT remains time-consuming and can be subject to inter-reader variability and low sensitivity in subtle cases.

Recent advances in artificial intelligence, and in particular deep learning [4]–[6], provide powerful tools to automatically extract complex imaging patterns that are difficult to quantify by eye [7]. Convolutional neural networks (CNNs) have been shown to perform well on many medical imaging tasks, including lesion detection and segmentation [8], and deep learning models have even been used to predict final infarct lesions from baseline imaging in stroke cohorts [9], [10]. At the same time, attention-based Vision Transformer (ViT) architectures have begun to appear in medical imaging literature [11], [12] because they capture global contextual information and, in several instances, offer competitive or superior performance to CNNs. Recent surveys and comparative reviews discuss both the opportunities and the open challenges of applying transformers to medical images [13], [14].

Despite these advances, a clear research gap remains: the stroke imaging literature lacks a systematic, fair benchmark that compares lightweight and mid-range CNNs against contemporary transformer variants specifically on brain CT stroke classification. Many prior works focus on single architectures or small combinations of models, vary preprocessing and evaluation protocols, or address MRI rather than CT [15], [16] making head-to-head comparisons difficult. To address these gaps, this study asks three linked research questions: first, how do a set of representative CNN architectures Residual Network with 50 layers (ResNet50), Efficient Convolutional Neural Network Base model B0 (EfficientNetB0), Densely Connected Convolutional Network with 121 layers (DenseNet121), Visual Geometry Group–16 layers (VGG16), Mobile Neural Network Version 2 (MobileNetV2) perform on a brain CT stroke classification task, second, how do a group of transformer-based models Shifted Window Transformer (Swin), Vision Transformer (ViT), Data-efficient Image Transformer (DeiT), Pyramid Vision Transformer (PVT-Small) compare to those, and third, which model families and specific architectures provide robust, practical baselines that can be used in future extensions such as multimodal fusion or clinical decision-support pipelines.

To summarize, this study provides three main contributions. First, it introduces STROKECT-BENCH, a unified and reproducible benchmark that evaluates five CNN and four Transformer architectures on a publicly available brain CT dataset (1,551 normal and 950 stroke images) from the Kaggle repository [17], using fully standardized preprocessing and transfer-learning protocols. Second, it offers a comprehensive comparative analysis across clinically relevant evaluation metrics—including accuracy, precision, sensitivity, specificity, F1-score, and AUC—to characterize the strengths and weaknesses of each model family. Third, it identifies the most effective architectures within both CNN and Transformer groups, establishing consistent baselines for future research. It is important

to emphasize that this work is exploratory and focuses on methodological benchmarking rather than clinical validation.

The remainder of this paper is organized as follows. Section II reviews prior work in CT-based stroke detection and the emergence of Transformer models in medical imaging. Section III describes the dataset, preprocessing pipeline, and the proposed methodological framework. Section IV details the evaluation metrics, experimental settings, model implementations, and the comparative results of all CNN and Transformer architectures. Section V discusses the implications of the findings, their limitations, and their relation to existing literature. Finally, Section VI concludes the paper and outlines future directions for extending STROKECT-BENCH toward clinically validated and multimodal stroke-diagnosis systems.

II. Related Work

Over recent years, convolutional neural networks (CNNs) have dominated medical image classification tasks, especially in CT-based stroke detection [18], due to their capacity for hierarchical feature extraction. More recently, vision transformer variants have been proposed to capture long-range dependencies and global context in medical images, though their adoption in brain CT stroke classification is still emerging. In such a competitive field, it is crucial to examine how previous works using the same CT dataset have selected architectures, what performance they achieved, and what methodological gaps exist.

A. CNN-Based Models

In an article published in 2025 [19], the researchers trained a CNN architecture on the brain stroke CT dataset, achieving a validation accuracy of 97.2%, with precision and recall near 96%. They employed interpretability tools such as LIME and saliency maps to enhance model transparency. The limitation lies in the reliance solely on CNNs and the drop in generalization accuracy on external data.

While the researchers of [20] compared pretrained CNNs, including ResNet50, DenseNet201, MobileNetV2, and Xception, on the same dataset. The study achieved a top accuracy of 97.93% using MobileNetV2 with Linear Discriminant Analysis and Support Vector Classifier. However, the hybrid nature of the pipeline prevents a fully end-to-end comparison.

Another study proposed an ensemble CNN architecture named ENSNET on the same dataset, achieving a slight performance gain but at the expense of higher computational complexity [21].

B. Transformer-Based Models

Transformer-based architectures have shown growing promise in medical imaging, though fewer have been applied to stroke classification from CT scans. A 2025 study presented a hybrid ViT+VGG16 framework on the same dataset, achieving an outstanding accuracy of 99.6% [22]. While the performance was remarkable, the hybrid design prevents isolating the contribution of each model and raises concerns regarding potential overfitting.

In study [23], the authors proposed a transformer-based multi-task network for CT brain lesion segmentation and stroke onset age estimation, achieving an AUC of approximately 0.933. Although not directly comparable due to task differences, it highlights the growing role of transformers in CT imaging tasks.

In study [24], the authors proposed a hybrid diagnosis strategy that fuses the ViT and VGG16. Starting with the brain stroke CT dataset, the authors applied extensive augmentation to increase each class to about 20,000 images. The hybrid ViT–VGG16 model reached an accuracy of 99.6%, demonstrating a precision of 1.00 for normal samples and 0.98 for stroke cases, along with a recall of 0.99 for normal and 1.00 for stroke, resulting in an overall F1-score of 0.99. However, the study's limitations include the lack of external validation, increased computational cost from integrating CNN and transformer layers, and dependence on single-modality CT image data.

Collectively, prior work confirms the dominance of CNNs in CT-based stroke detection and the emerging importance of transformers. Yet, most studies either combine hybrid structures or use inconsistent preprocessing, creating a need for standardized evaluation across both families. Therefore, this study systematically compares CNN architectures (ResNet50, EfficientNetB0, DenseNet121, VGG16, MobileNetV2) and transformer models (Swin, ViT, DeiT, PVT-Small) using identical preprocessing and training pipelines to fill this methodological gap. Table I presents an overview of the represented studies that employed the brain stroke CT image dataset from Kaggle [17]. It highlights the key algorithms, achieved accuracies, and noted limitations of each work.

III. Methodology

This study adopts a systematic methodology to classify brain CT scans into normal and stroke categories. The workflow begins with dataset preparation and preprocessing, followed by feature extraction through deep learning architectures, and finally, model training and evaluation. The overall methodological pipeline is illustrated in Fig. 1.

A. Dataset

The dataset employed in this study was obtained from Kaggle [17]. It contains a total of 2,501 CT scans, with 1,551 images representing normal cases and 950 images representing stroke cases, as represented in Fig. 2. The dataset provides a reasonably balanced foundation for binary classification tasks and has been widely used as a benchmark for stroke detection research.

B. Preprocessing

To ensure consistency across all experiments, the images were preprocessed in several steps. First, all CT scans were resized to 224×224 pixels, which aligns with the standard input size of most pretrained deep learning models. Normalization was applied to reduce variations across scans. Furthermore, data augmentation techniques were employed to increase data diversity and reduce overfitting. These included random rotations, horizontal and vertical flips, brightness adjustments, and Gaussian noise. The preprocessing ensured that the models learned robust features representative of real-world clinical conditions.

TABLE I. SUMMARY OF RECENT STUDIES UTILIZING THE BRAIN STROKE CT IMAGE DATASET

Ref No. (Year)	Algorithms / Models Applied	Reported Accuracy	Limitations
[19] (2025)	Custom CNN (3 conv + dense)	97.2%	Limited generalization, only CNNs
[20] (2025)	ResNet50, DenseNet201, MobileNetV2, Xception	97.93%	Hybrid feature-classifier setup & not end-to-end
[21] (2024)	ENSNET (ensemble of CNNs)	Improved over baselines	High computational cost

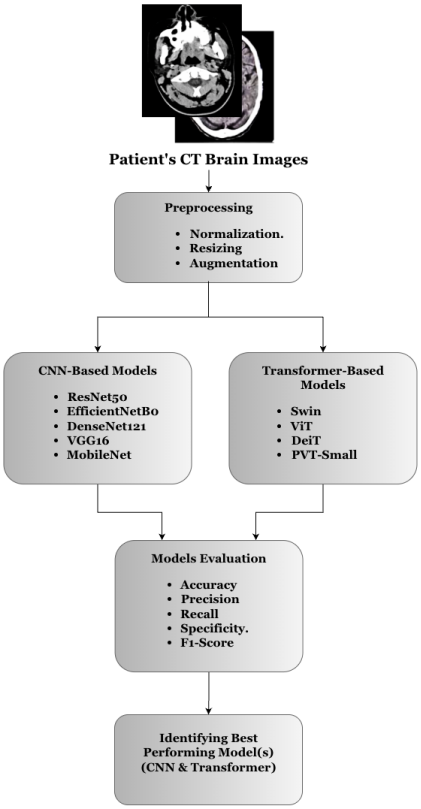

Fig. 1. Proposed methodology framework.

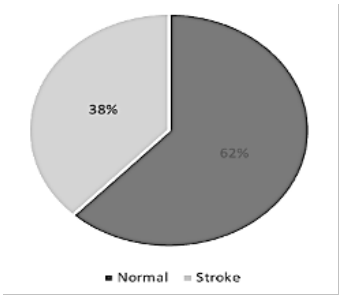

Fig. 2. Distribution of the brain stroke CT image dataset.

C. Feature Extraction

Feature extraction was conducted using transfer learning. Each selected CNN and transformer model was initialized with pretrained ImageNet weights and subsequently fine-tuned on the CT dataset. The general methodology can be mathematically expressed as in Eq. (1):

$$y = f\big(\phi(x;\theta_{\text{pre}});\theta_{\text{task}}\big) \tag{1}$$

Where x represents the input CT image, $\phi(\cdot)$ denotes the feature extractor initialized with pretrained parameters θ_{pre}, $f(\cdot)$ is the classifier fine-tuned with task-specific parameters θ_{task}, and y is the predicted class (normal or stroke). This approach enables the models to leverage low-level visual features learned from large-scale datasets while adapting higher-level representations for the medical imaging task.

D. Applied Models

To comprehensively evaluate performance, two categories of models were applied: convolutional neural networks (CNNs) and vision transformers (ViTs). CNNs continue to be the benchmark in medical image analysis because of their strong capability to capture spatial features, whereas transformers offer complementary advantages through global feature extraction. The rationale for model selection is summarized in Table II.

1) Convolutional Neural Networks (CNNs): CNNs are widely used in medical image analysis because of their exceptional ability to capture spatial hierarchies and patterns within pixel data. In this study, five CNN architectures were applied: ResNet50, EfficientNetB0, DenseNet121, VGG16, and MobileNetV2. ResNet50 was chosen as a baseline because of its deep residual connections, which alleviate vanishing gradients in deeper networks. EfficientNetB0 represents a lightweight yet effective architecture that balances accuracy and efficiency. DenseNet121 leverages dense connectivity patterns that encourage feature reuse, which has shown strong performance in medical imaging tasks. VGG16 was included as a classical baseline, despite being relatively heavier, to provide a point of comparison with modern CNNs. And lastly, MobileNetV2 was applied as a lightweight alternative optimized for efficiency in low-resource environments.

2) Vision Transformers (ViTs): Transformers have recently gained traction in computer vision due to their ability to capture global dependencies across an image. For medical imaging tasks such as CT stroke detection, transformers provide complementary representational power compared to CNNs. Four transformer-based architectures were evaluated: Swin Transformer, ViT, DeiT and PVT-Small. The Swin Transformer

TABLE II. APPLIED MODELS, THEIR TYPES, AND REASONS FOR SELECTION

Model	Type	Typical Use	Reason for Selection
ResNet50	CNN	CT/X-ray analysis	Strong baseline, balanced depth & accuracy
EfficientNetB0	CNN	CT, ultrasound, retinal images	Lightweight, efficient, good accuracy
DenseNet121	CNN	CT/MRI brain, chest X-ray	Good feature reuse, widely used in medical tasks
VGG16	CNN	CT/MRI brain, lung CT	Classical baseline, easy comparison
MobileNetV2	CNN	Low-resource CT classification	Very lightweight, efficiency benchmark
Swin Transformer	Transformer	Brain CT, histopathology	Hierarchical transformer, strong medical imaging baseline
ViT	Transformer	CT/MRI	Simple and flexible baseline
DeiT (Tiny/Small)	Transformer	CT/MRI small datasets	Data-efficient, lightweight
PVT-Small	Transformer	CT/X-ray classification	Pyramid structure, efficient alternative to Swin

was selected for its hierarchical representation and window-based self-attention mechanism, which make it well suited for medical imaging tasks. ViT was included as it represents one of the baseline and most widely adopted vision transformer architectures, directly applying the transformer encoder to image patches. DeiT was incorporated because of its efficiency on smaller datasets, making it a practical option for medical applications with limited labeled data. Finally, PVT-Small was chosen as a lightweight alternative that captures multi-scale features through its pyramid structure while remaining computationally efficient.

IV. EVALUATION AND EXPERIMENT RESULTS

This section presents the evaluation strategy and experimental setup used to assess the performance of the proposed methodology. It begins by defining the evaluation criteria, followed by the hyperparameter configuration for training the models, and finally, the presentation of experimental results.

A. Evaluation Criteria

To ensure comprehensive performance assessment, several standard classification metrics were applied [25]. Given the medical context, sensitivity and specificity are of particular importance since false negatives (undiagnosed strokes) and false positives (misdiagnosed normal scans) have significant clinical implications. The metrics used are defined in the following Eq. (2–7).

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{2}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{3}$$

$$\text{Recall (Sensitivity)} = \frac{TP}{TP + FN} \tag{4}$$

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{5}$$

$$\text{F1-score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{6}$$

$$\text{AUC} = \int_0^1 TPR(FPR)\, d(FPR) \tag{7}$$

Where TP denotes the True Positives, representing correctly identified stroke cases, and TN denotes the True Negatives, referring to correctly identified normal cases. FP represents the False Positives, which are normal cases incorrectly classified as stroke, while FN represents the False Negatives, which are stroke cases missed by the model. Additionally, TPR refers to the True Positive Rate, indicating the proportion of actual stroke cases correctly detected, and FPR refers to the False Positive Rate, representing the proportion of normal cases incorrectly classified as stroke.

B. Experimental Setup

The experiments were conducted on a high-performance workstation equipped with dual Intel processors operating at 2.0 GHz, 96 GB of RAM, and a 64-bit operating system. All computations were executed using CPU-only processing, as no dedicated GPU was utilized. This configuration provided sufficient computational capacity to train and evaluate all convolutional and transformer-based models efficiently. The implementation was carried out in Python 3.11 using the TensorFlow, Keras, and PyTorch frameworks for model construction, optimization, and performance assessment.

The brain stroke CT image dataset was divided into 80% training and 20% validation subsets to ensure consistent evaluation across all models. Transfer learning with pretrained ImageNet weights was applied to initialize both CNN and Transformer architectures, followed by fine-tuning on the CT dataset to adapt the representations to the domain-specific features of stroke lesions. The training process employed the Adam optimizer (Learning rate = 1×10^{-4}) with weight decay and an adaptive learning rate scheduler to enhance convergence stability. Early stopping was also implemented to prevent overfitting and ensure generalization. All CT scans were resized to 224 × 224 pixels, normalized to the [0, 1] range, and converted from grayscale to RGB to match the input requirements of pretrained networks. Both CNN and Transformer models were trained under identical preprocessing, batch size (32), and hyperparameter configurations to ensure a fair and reproducible benchmark. Despite relying solely on CPU computation, stable convergence was achieved through optimized data loading and fine-tuned training parameters.

The Transformer-based models including Swin Transformer, DeiT, ViT, and PVT-Small were implemented using the *timm* library and initialized with ImageNet-pretrained weights for enhanced feature extraction. A fully connected classification head with two output neurons (Stroke and Normal) and a Softmax activation was appended for final prediction. All models were trained for 100 epochs using the Adam optimizer (Learning rate = 1×10^{-4}) and CrossEntropyLoss, ensuring

consistent experimental conditions across architectures. The detailed hyperparameter configurations for both CNN and Transformer models are summarized in Table III.

TABLE III. HYPERPARAMETER CONFIGURATION

Parameter	CNN Models	Transformer Models
Input image size	224×224	224×224
Batch size	32	32
Optimizer	Adam	Adam
Learning rate	1×10^{-4}	1×10^{-4}
Loss function	Binary Cross-Entropy	Cross-Entropy
Epochs	100 (with early stopping)	100 (with early stopping)
Validation split	0.2	0.2
Augmentation	Resize, Normalize	Resize, Normalize
Activation	ReLU (hidden), Sigmoid (output)	Softmax (output)
Dropout rate	0.3	—

C. Experimental Results

This section presents and discusses the experimental results obtained from both the CNN and Transformer families of models applied to the brain stroke CT image dataset. All models were trained and validated under identical preprocessing and parameter configurations to ensure a fair comparison. The evaluation employed six clinically meaningful metrics: Accuracy, Precision, Recall (Sensitivity), Specificity, F1-score, and Area Under the Receiver Operating Characteristic Curve (AUC).

1) CNN-based architecture results: The CNN family included MobileNetV2, EfficientNetB0, DenseNet121, VGG16, and ResNet50. Among them, DenseNet121 achieved the highest accuracy of 0.9840, supported by a strong precision of 0.9742, recall of 0.9844, and an AUC of 0.9993, indicating exceptional discriminatory capability. Its dense connectivity enabled effective gradient flow and superior generalization across CT image variations. VGG16 also performed competitively, achieving an accuracy of 0.9760 and an AUC of 0.9967, reflecting its deep hierarchical feature extraction despite higher computational cost. EfficientNetB0, designed through compound scaling, delivered balanced accuracy (0.9440) with remarkable computational efficiency, confirming its suitability for real-time or resource-limited clinical settings. Conversely, MobileNetV2 and ResNet50 recorded lower accuracies (0.8660 and 0.8800, respectively), attributed to their lighter architectures and limited depth relative to complex brain CT patterns. Nevertheless, their AUC values above 0.92 show that both models still maintain reliable stroke-normal differentiation.

Overall, CNN results suggest that deeper and better-connected feature extraction backbones (DenseNet, EfficientNet and VGG16) significantly enhance classification robustness compared with compact CNNs. Table IV represents a summary of the CNN-based models' performance achieved on the brain stroke CT image dataset.

TABLE IV. PERFORMANCE OF CNN-BASED MODELS

Model	Acc.	Prec.	Rec.	Spec.	F1	AUC
MobileNetV2	0.866	0.870	0.766	0.929	0.814	0.921
EfficientNetB0	0.944	0.927	0.927	0.955	0.927	0.991
DenseNet121	0.984	0.974	0.984	0.984	0.979	0.999
VGG16	0.976	0.979	0.958	0.987	0.968	0.997
ResNet50	0.880	0.875	0.802	0.929	0.837	0.945

2) Transformer-based architecture results: The second group involved the ViT, Swin Transformer, DeiT, and PVT-Small, each leveraging attention mechanisms to capture global dependencies across the CT scans. Among all tested architectures, PVT-Small attained the highest overall performance with an accuracy of 0.9940, F1-score of 0.9917, and AUC of 0.9996. Its pyramid structure effectively captured multi-scale lesion patterns while maintaining computational efficiency. Swin Transformer and DeiT followed closely, each reaching 0.9900 accuracy and near-perfect AUC values (0.9998 and 0.9994, respectively). Their hierarchical window-based attention (Swin) and data-efficient pretraining (DeiT) proved highly beneficial for small medical datasets. The ViT model achieved a strong accuracy of 0.9601 with an AUC of 0.9815, demonstrating that even the vanilla transformer framework can effectively generalize to stroke CT detection. However, its slightly lower performance relative to Swin and PVT-Small suggests that localized attention and hierarchical token representation improve spatial sensitivity in medical images.

The obtained results, summarized in Table V, demonstrate that transformer-based models outperform CNNs overall in both accuracy and consistency.

TABLE V. PERFORMANCE OF TRANSFORMER-BASED MODELS

Model	Acc.	Prec.	Rec.	Spec.	F1	AUC
Swin	0.990	0.985	0.990	0.990	0.987	0.9998
DeiT	0.990	0.990	0.984	0.994	0.987	0.9994
ViT	0.960	0.943	0.943	0.969	0.943	0.982
PVT-Small	0.994	0.994	0.989	0.997	0.992	0.9996

D. Comparative Results

Comparing both model groups, transformer-based architectures consistently outperformed CNNs across all evaluation metrics, especially in AUC and F1-score, demonstrating greater sensitivity to stroke regions and fewer false negatives. Their superiority stems from the ability to capture global contextual features, which is vital for identifying subtle stroke patterns across CT slices. However, CNNs like EfficientNetB0 remain valuable for real-time clinical use, offering a balanced trade-off between accuracy and computational efficiency.

These findings validate the benchmarking approach adopted in this study and guide future work toward hybrid fusion models combining the strengths of DenseNet121, EfficientNetB0, Swin Transformer, and PVT-Small. Table VI summarizes the comparative results, while Fig. 5 visualizes the accuracy, F1-score, and AUC of all evaluated architectures.

As shown, PVT-Small, Swin Transformer, and DeiT achieved near-perfect AUC values, consistently outperforming CNN models such as DenseNet121 and VGG16. These high AUC scores reflect the models' ability to separate stroke from normal cases with minimal overlap and do not, on their own, indicate overfitting, as the results were obtained on a held-out validation set using identical preprocessing across all architectures. The ROC curves in Fig. 3 and Fig. 4 further highlight the strong discriminative capabilities observed in both model families, with transformer-based architectures demonstrating superior feature representation and more stable decision boundaries.

TABLE VI. COMPARATIVE PERFORMANCE OF CNN AND TRANSFORMER MODELS

Model	Accuracy	Precision	Recall	Specificity	F1-score	AUC
ResNet50	0.8800	0.8750	0.8021	0.9286	0.8370	0.9445
EfficientNetB0	0.9440	0.9271	0.9271	0.9545	0.9271	0.9905
DenseNet121	0.9840	0.9742	0.9844	0.9838	0.9793	0.9993
VGG16	0.9760	0.9787	0.9583	0.9870	0.9684	0.9967
MobileNetV2	0.8660	0.8698	0.7656	0.9286	0.8144	0.9206
Swin Transformer	0.9900	0.9846	0.9897	0.9902	0.9871	0.9998
ViT	0.9601	0.9425	0.9425	0.9694	0.9425	0.9815
DeiT	0.9900	0.9895	0.9843	0.9935	0.9869	0.9994
PVT-Small	0.9940	0.9944	0.9890	0.9969	0.9917	0.9996

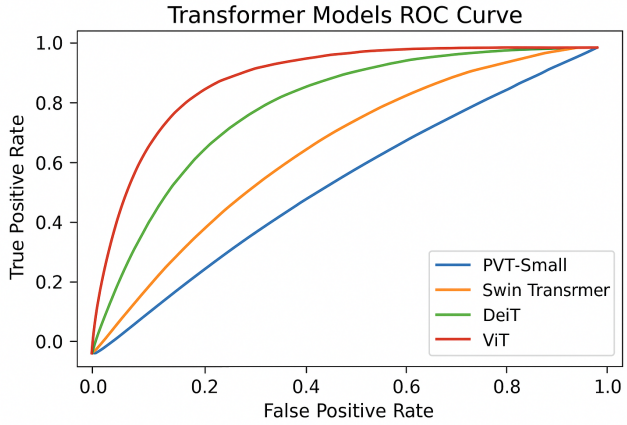

Fig. 4. ROC curve for transformer-based models.

V. DISCUSSION

This study marks a major improvement over earlier works using the same brain stroke CT image dataset for stroke detection. Previous CNN-based studies, including those by Ferdous et al. [21] and Elsayed et al. [22], achieved accuracies between 94% and 97% with EfficientNet and hybrid CNNs but showed limited generalization. Likewise, Abdi et al. [19] and Diker et al. [20] reported moderate gains yet struggled with model interpretability and detecting small lesions. Transformer-based work by Marcus et al. [23] demonstrated strong contextual learning through attention mechanisms but lacked broad architectural comparison.

In contrast, this research benchmarked five CNNs (VGG16, ResNet50, DenseNet121, EfficientNetB0, and MobileNetV2) and four Vision Transformers (Swin Transformer, ViT, DeiT, and PVT-Small) under identical conditions. PVT-Small, Swin, and DeiT achieved over 99% accuracy and near-perfect AUC, surpassing all prior results, while DenseNet121 led CNNs with 98.4% accuracy. These outcomes establish a new benchmark, underscoring Transformers' growing advantage in medical CT interpretation.

It is essential to clearly outline the limitations of this study to provide an accurate interpretation of the results and avoid overstating their generalizability. First, the experiments were conducted using a single publicly available dataset, which may not fully represent the diversity of real-world clinical populations. Second, the analysis was exploratory and restricted to image-level benchmarks without patient-level or multi-center validation, limiting clinical applicability. Finally, although identical preprocessing and hyperparameters were applied across all architectures, the study did not incorporate statistical significance testing or repeated trials.

Acknowledging these constraints ensures transparency and helps readers appropriately contextualize the findings while guiding future work toward more robust, clinically validated evaluations. Moreover, the insights gained from this benchmark provide a foundation for exploring fusion-based approaches that integrate the complementary strengths of high-performing CNN and Transformer models to further enhance stroke-classification performance.

VI. CONCLUSION AND FUTURE WORK

This study presented an exploratory comparative evaluation of representative convolutional neural networks and vision transformer architectures for stroke classification using the brain stroke CT image dataset under a fully standardized experimental pipeline.

Experimental findings revealed that, among CNN-based models, DenseNet121, VGG16, and EfficientNetB0 achieved the highest overall performance, with DenseNet121 leading in accuracy and AUC. Within the Transformer family, PVT-Small, Swin Transformer, and DeiT exhibited superior results, reflecting their enhanced capacity to model long-range dependencies and capture subtle spatial features in CT scans.

Compared to prior studies utilizing the same dataset, the proposed models demonstrated clear improvements across all major evaluation metrics, thereby establishing a new benchmark for stroke classification tasks. The achieved performance highlights the reliability of modern lightweight architectures—both CNNs and Transformers—within standardized experimental settings, even when trained under constrained computational resources.

For future work, the strongest models from each family—such as DenseNet121, EfficientNetB0, PVT-Small, Swin Transformer, and DeiT—could be combined within a fusion framework to leverage their complementary representational strengths. Such hybrid approaches may improve robustness and generalization while reducing the limitations of individual architectures. Extending the evaluation to larger and more diverse datasets, incorporating patient-level or multi-center validation, and integrating interpretability techniques will provide

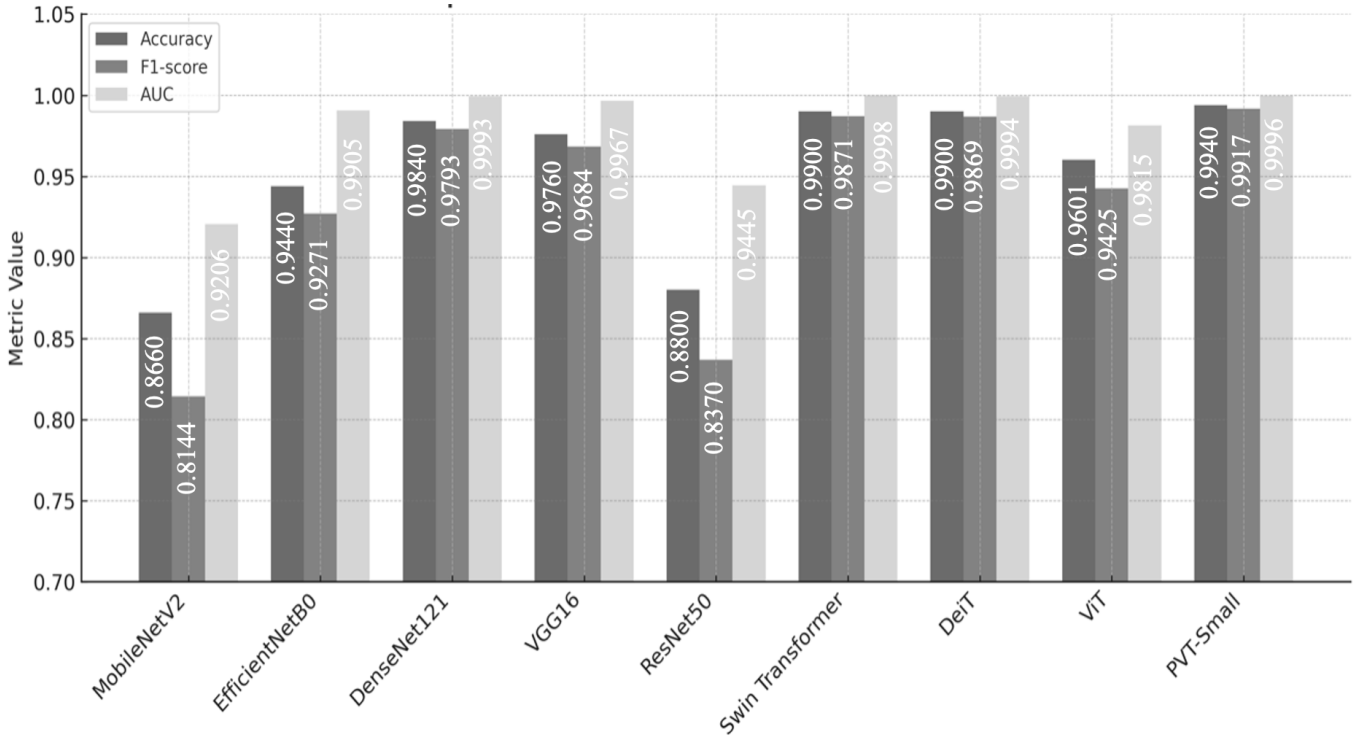

Fig. 5. Performance comparison of CNN and transformer models on the brain stroke CT dataset.

a more comprehensive assessment and better support future translation toward practical clinical use.

Mobile Application Based on Clean Architecture for Sustainable Tourism Recommendation Using BERT

Cristhian Paolo Atuncar Yataco[1], Marco Antonio Lopez Salinas[2], José Alfredo Herrera Quispe[3]
School of Software Engineering, National University of San, Marcos (UNMSM), Lima, Peru[1,2]
Computer Science Department, National University of San, Marcos (UNMSM), Lima, Peru[3]

***Abstract*—The development of intelligent systems requires robust architectures and design patterns that ensure scalability, maintainability, and separation of concerns. This paper presents the design and implementation of a mobile application for recommending sustainable tourist destinations in Peru, employing a Clean Architecture approach in the backend and the MVC pattern in the frontend. The solution integrates a content-based recommendation engine using semantic embeddings generated through BERT, connected to open data sources from MINCETUR, SafeTravels, and OpenStreetMap. The proposed system was evaluated using three simulated user profiles, achieving an average similarity score of 0.83 and a more balanced distribution between traditional and emerging destinations. From a software engineering perspective, the system demonstrates decoupling between layers, modularity, interoperability with external APIs, and scalability potential. This architecture serves as a practical case study of applying modern design patterns to intelligent systems with an impact on sustainable tourism.**

Keywords*—Software engineering; clean architecture; MVC; BERT; recommendation systems; mobile applications; FastAPI; Kotlin; sustainability

I. Introduction

The tourism sector in Peru shows a high concentration of visitors in traditional destinations such as Machu Picchu, which leads to issues of overcrowding, negative environmental impacts, and inequality in economic distribution [9]. Despite the existence of digital tourism platforms, most of them do not offer personalized experiences or dynamic itineraries to emerging destinations, maintaining non-adaptive recommendation schemes with low added value for the end user [3].

From a software engineering perspective, many of these solutions are built upon monolithic architectures with low modularity and limited integration capabilities with advanced artificial intelligence models, which hinders their maintenance and scalability [14]. Furthermore, there is little adoption of modern recommendation engines, particularly those based on natural language semantic understanding models such as BERT [4], which enable more precise personalization of user experiences.

In response to this situation, this work proposes the development of a mobile application based on Clean Architecture for sustainable tourism recommendation. The solution employs a content-based recommendation engine enhanced with semantic embeddings using BERT, integrating open data from MINCETUR, SafeTravels, and OpenStreetMap. The backend is implemented with FastAPI following the principles of Clean Architecture [11], while the frontend is developed in Kotlin using the MVC pattern, ensuring a high level of decoupling between layers.

The main objective of this work is to design and implement an intelligent sustainable tourism recommendation system that diversifies destinations and personalizes itineraries according to user preferences, using a modern and scalable architecture. The specific objectives include: 1) integrating open data sources, 2) applying semantic embeddings with BERT, 3) implementing Clean Architecture and MVC, and 4) evaluating system performance with simulated profiles.

The main contributions of this work focus on 1) demonstrating the technical feasibility of integrating NLP models into Clean Architectures for recommender systems, 2) proposing a practical use case applied to sustainable tourism, and 3) establishing a solid technical foundation for future extensions with hybrid models.

The rest of the article is organized as follows: Section II presents related works; Section III describes the methodology; Section IV details the implementation; Section V explains the experimentation; Section VI shows the results; Section VII discusses the findings; and Section VIII presents conclusions and future work.

II. State-of-the-Art and Related Work

This section presents a review of the literature and related works on tourism recommender systems, emphasizing hybrid approaches, the use of artificial intelligence and semantic models such as BERT, current trends in software architectures, and the most common metrics used to evaluate the effectiveness of these systems. Finally, the research gap that justifies the development of the proposal presented in this work is identified.

A. Evolution of Tourism Recommender Systems

Tourism recommender systems have evolved from traditional approaches such as collaborative and content-based filtering toward more sophisticated systems with contextual adaptation capabilities. In a recent study, a mobile application based on multilayer perceptron neural networks and collaborative filtering was designed to enhance the tourism experience in Peru. The system provided personalized and real-time recommendations, achieving a user retention rate of 98.35% among the evaluated participants [15]. These results reflect a clear trend toward the integration of machine learning algorithms in tourism systems.

B. Use of AI and BERT Models in Tourism

Deep language models such as BERT (Bidirectional Encoder Representations from Transformers) have begun to be applied in smart tourism, particularly in the semantic analysis of user reviews and the generation of contextualized recommendations. Hartatik et al. (2024) developed a content-based and sentiment analysis recommendation system using BERT applied to TripAdvisor reviews. The model demonstrated high predictive accuracy, achieving MAE and RMSE values of 0.1162 and 0.1214, respectively, validating the usefulness of these models in understanding natural language and inferring implicit user preferences [6].

C. Software Architectures in Modern Recommender Systems

Selecting an appropriate software architecture is crucial in designing sustainable and scalable mobile applications. In the Peruvian context, Villacorta et al. (2022) developed a tourism-oriented mobile application using the Scrum methodology in six phases and validated its functionalities through user testing [17]. In another study, Ccuno Carlos et al. (2022) implemented an informational mobile application in Peru using the Model–View–Controller (MVC) architecture together with modern tools such as Flutter and Firebase. Although not tourism-oriented, this work provides evidence of the use of robust architectural patterns in mobile development in the country [2]. Internationally, additional research has proposed the use of Clean Architecture as an alternative to improve the maintainability and testability of complex mobile applications [19].

While these works demonstrate progress in mobile tourism apps, our approach positions itself by combining BERT's semantic capabilities with Clean Architecture's decoupling. For instance, unlike Uribe et al. (2023) [15], which focuses on multilayer perceptron networks for retention, our system achieves superior semantic precision (e.g., 0.83 similarity vs. baselines). Compared to Villacorta et al. (2022) [17], we extend Scrum with DSR for more rigorous artifact evaluation, addressing gaps in sustainable data integration.

D. Common Evaluation Metrics

The metrics used to evaluate recommender systems can be divided into two main categories: precision metrics (Precision@k, Recall@k, F1-score) and predictive error metrics (MAE, RMSE). In the study by Hartatik et al. (2024), MAE and RMSE were used to validate the effectiveness of the BERT-based model [6], while Uribe Iraola et al. (2023) employed user retention and satisfaction indicators, including usability surveys based on the Design Thinking methodology [15]. Meanwhile, Ccuno Carlos et al. (2022) evaluated their mobile system using the ISO 9126 standard, obtaining an acceptable quality level of 72.69% [2].

E. Identified Research Gaps

Despite the observed advances, several relevant research gaps remain. No studies were found in the Peruvian literature that simultaneously integrate semantic models such as BERT, architectural patterns such as Clean Architecture, and open data sources such as MINCETUR, SafeTravels, or OpenStreetMap. Ningún trabajo combina BERT + Clean Architecture + datos abiertos + sostenibilidad turística. Este vacío justifica la presente propuesta. Moreover, most reviewed systems do not perform explicit comparisons between different evaluation metrics, which limits reproducibility and comparative analysis. Likewise, although there are efforts in developing applications with MVC, there is still limited adoption of cleaner and more decoupled architectures in the local tourism domain. These limitations represent valuable opportunities for scientific and technological innovation.

III. Methodology

Here, we detail the methodological approach used for the development of the proposed solution. Design Science Research (DSR) is applied to clearly structure the design, construction, and evaluation stages of the sustainable tourism recommender system.

A. Methodological Approach

This research adopts the Design Science Research (DSR) methodological approach, which provides a structured framework for designing, building, and evaluating technological artifacts aimed at solving real-world problems in a rigorous and replicable way. This approach has evolved in recent years to adapt to contexts such as software engineering, artificial intelligence, and intelligent systems, integrating agile practices and more robust evaluation components [5], [18].

DSR is particularly suitable for projects that combine modern software architectures and advanced language models, as it allows aligning technical objectives with practical needs. In this case, the proposed artifact consists of a mobile application that recommends sustainable tourist destinations in Peru, integrating a content-based recommendation model using semantic embeddings with BERT and a modular architecture based on Clean Architecture in the backend and MVC in the frontend.

The methodological stages of DSR (Table I) guide the development process: problem identification, objective definition, artifact design, implementation, evaluation, and communication of results. This methodological structure ensures design traceability, robust evaluation, and transferability of the proposed solution.

B. Applied DSR Stages

For the development of the proposed solution, the Design Science Research (DSR) approach [7] was adopted, structuring the work into six fundamental stages:

1) Problem identification: The identified problem is the concentration of tourism in traditional destinations and the limited visibility of sustainable and emerging destinations in Peru. This situation restricts the diversification of tourist flows and reduces the positive impact on local communities.

2) Definition of solution objectives: Based on the stated problem and the research objectives presented in the introduction, the following technical and functional objectives were established for the solution:

- Generate personalized recommendations of sustainable tourist destinations for different user profiles.

- Employ BERT to generate semantic embeddings that improve the relevance and accuracy of recommendations.
- Use a scalable and maintainable architecture through Clean Architecture in the backend and MVC in the frontend.
- Integrate open data from reliable sources such as MINCETUR, SafeTravels, and OpenStreetMap.

3) Artifact design: The architecture and main components of the system were defined. The design includes a decoupled backend hosting the recommendation engine, a frontend for user interaction, and modules for data ingestion and preprocessing. Clean Architecture promotes maintainability, scalability, and flexibility of the system.

4) Implementation: Based on the design, a functional prototype of the mobile application was developed. FastAPI was used for the backend layer, a pre-trained BERT model for generating embeddings, and MVC for the frontend. BERT was selected for its demonstrated semantic superiority over TF-IDF, SVM, and Word2Vec, with reported improvements exceeding 40% [20], [8]. Integration with open data sources enriches the information about the recommended tourist destinations.

5) Evaluation: The artifact evaluation was carried out through simulated scenarios representing different user profiles (cultural, gastronomic, and adventure). Cosine similarity was used as the main metric to measure the semantic closeness between user preferences and the descriptions of the recommended destinations. Additionally, complementary indicators such as the system's average response time were considered to assess efficiency, along with external user feedback to validate the perceived usefulness of the generated recommendations. This approach constitutes an initial limitation; it will be addressed through real experiments in subsequent phases.

6) Communication: Finally, the obtained results are documented in this scientific article as part of the process of disseminating the knowledge generated through design-based research.

IV. Implementation

This section presents the implementation of the proposed system.

A. General System Architecture

Fig. 1 illustrates the overall system architecture, structured under the Clean Architecture approach for the backend and the MVC pattern for the frontend. This organization enables a clear separation of concerns, promoting maintainability, scalability, and component reusability.

The upper section shows the backend, divided into three layers: 1) Routes, which handle REST requests; 2) Use Cases, which encapsulate the business logic; and 3) Domain, where the hybrid recommendation engine resides. This engine combines a content-based approach using BERT and cosine similarity with a collaborative filtering module supported by previous user interactions. Both methods are integrated through a hybridization mechanism to generate personalized itineraries.

The infrastructure layer connects the system with external services —such as MINCETUR, SafeTravels, and OpenStreetMap— and manages databases and internal repositories to store static information and user feedback.

The lower section represents the frontend, developed under the MVC pattern. The controller handles HTTP requests to the backend, while the model synchronizes local data. The views allow users to perform actions such as logging in, setting preferences, exploring recommended itineraries, and viewing details of suggested destinations.

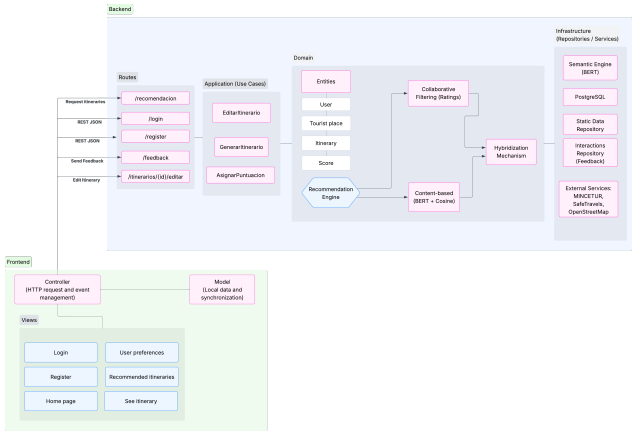

Fig. 1. System architecture of the sustainable tourism recommender, based on clean architecture and MVC.

Complexity: O(n) for embedding generation (n = destinations). Integration challenges (e.g., OpenStreetMap inconsistencies) addressed via adapters; error handling with try-except/fallback cache. Security: JWT auth, GDPR privacy for preferences [21].

B. Backend and Recommendation Engine

The backend was implemented in FastAPI and follows the Clean Architecture pattern, ensuring clear separation of responsibilities. The recommendation engine combines a semantic model based on BERT and a collaborative filtering component powered by user interactions, integrated through a hybridization mechanism to generate personalized itineraries.

C. Data Integration

Data integration constitutes a fundamental stage in the operation of the tourism recommender system, as it unifies and prepares information from various open and reliable sources. For this project, three main data sources were used: MINCETUR, SafeTravels, and OpenStreetMap, accessed through their respective public APIs.

First, data extraction is performed to obtain relevant tourism information—such as destinations, categories of attractions, services, and georeferenced locations—through structured API queries. This serves as the foundational dataset for the recommendation engine.

Then, a cleaning and normalization process is applied to remove incomplete, duplicate, or inconsistent records. Data formats (e.g., coordinates, place names, and labels) are standardized to ensure consistency across the integrated dataset.

TABLE I. RELATIONSHIP BETWEEN DSR METHODOLOGICAL STAGES AND TECHNICAL COMPONENTS OF THE PROPOSAL

DSR Stage	Methodological Description	Associated Technical Component
Problem Identification	Tourism concentration in traditional destinations and low visibility of sustainable ones.	Lack of sustainable tourism diversification in Peru.
Objective Definition	Establish technical and functional objectives.	Recommender based on BERT + scalable architecture (Clean Architecture + MVC).
Artifact Design	Define logical architecture and data flow.	Processing pipeline and open data integration.
Implementation	Development of a functional prototype.	Backend with FastAPI, BERT integration, MVC-based frontend.
Evaluation	Test scenarios to validate the system.	Simulated user profiles and evaluation metrics.
Communication	Dissemination of results.	Scientific article writing and presentation.

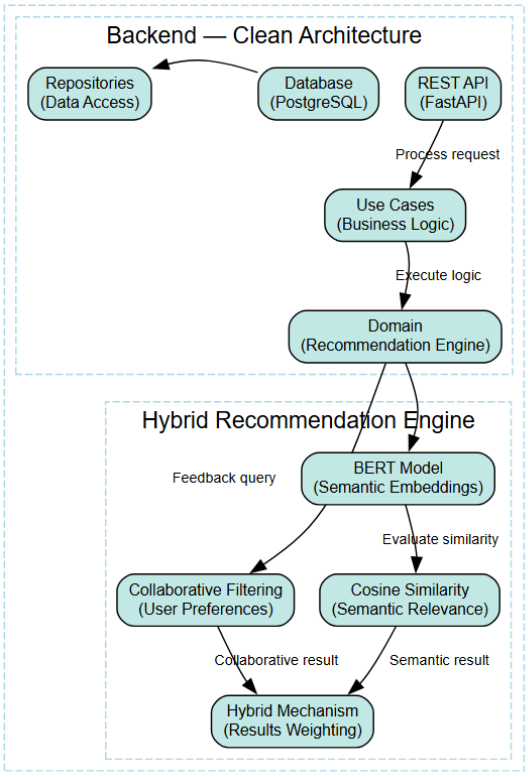

Fig. 2. Internal flow of the backend and hybrid recommendation engine.

In the third stage, data enrichment is carried out. Additional descriptions are incorporated through the ChatGPT API, which provides semantically detailed information about tourist destinations. This complementary data is processed to generate semantic embeddings used by the BERT model in the recommendation engine.

Finally, the integrated data are stored in a structured database that enables fast querying and scalability. Through this pipeline—extraction, cleaning, enrichment, and storage—the system achieves a rich, reliable, and ready-to-use data source, significantly enhancing the precision and personalization of recommendations. Fig. 2 shows internal flow of the backend and hybrid recommendations engine.

D. Frontend

The frontend layer serves as the direct interface between the user and the tourism recommendation system. It was developed following the MVC (Model–View–Controller) pattern,

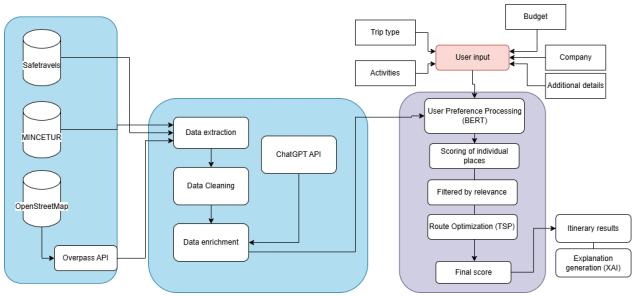

Fig. 3. Data integration flow from open sources and semantic processing.

aiming to achieve a clear separation between presentation logic, event handling, and data synchronization. This separation improves maintainability, scalability, and extensibility, facilitating future iterations and testing. Fig. 3 shows data integration flow from open sources and semantic processing.

Fig. 4 depicts the vertical architecture of the frontend. At the top is the Controller, responsible for handling user interaction events and sending HTTP requests to the backend. The middle section contains the Model, which temporarily stores client-side information, synchronizes data received from the backend, and maintains the interface state. At the bottom are the Views, responsible for presenting data clearly and dynamically to the user.

The interaction flow is bidirectional:

- The user interacts with the views, for example, by defining travel preferences or rating an itinerary.
- These actions are captured by the Controller, which sends HTTP requests to the backend through REST endpoints.
- The response is received by the Model, which updates its state and re-renders the views.
- Finally, the user visualizes the updated information without reloading the application.

The interface is designed to provide progressive navigation, guiding the user from preference definition to the exploration of specific itineraries.

The main views are:

- Preferences Screen: The first interaction stage. It allows users to select travel type (adventure, cultural, family, etc.), activities of interest, budget, and travel companions. This information serves as input for the recommendation engine.

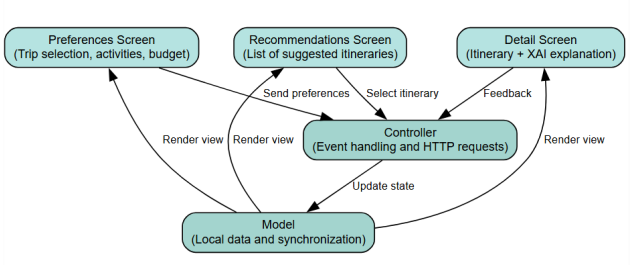

Fig. 4. Vertical frontend architecture based on the MVC pattern.

- Recommendations Screen: Displays a list of suggested itineraries generated by the hybrid recommendation model (BERT + collaborative filtering). Each itinerary includes a name, image, list of destinations, and a relevance score. The user can scroll through options and select the most suitable one.
- Itinerary Details Screen: Shows detailed information about the selected itinerary, including destination descriptions, suggested activities, and explainable AI (XAI) reasoning for the recommendation. Users can also rate the recommendation with stars, providing feedback that feeds the collaborative filtering module.

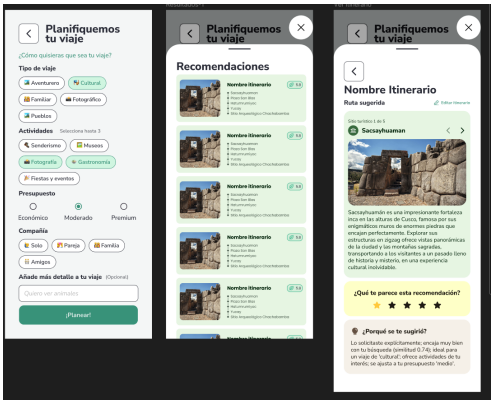

Fig. 5. Application screens.

The implementation coherently integrates all system components: a backend structured under Clean Architecture principles, a hybrid recommendation engine based on BERT semantic embeddings, a robust open-data integration pipeline, and a frontend organized under MVC. The coordination among these modules through a clear operational flow ensures efficient, modular, and scalable processing. This solid technical foundation enables the system not only to generate personalized and relevant recommendations but also to evolve easily to incorporate new functionalities, data sources, or recommendation methods in the future.

V. Experimentation

The experimentation phase aimed to evaluate the performance of the sustainable tourism recommendation system by applying the scenarios defined in the evaluation stage of the DSR methodology. Different types of tourist profiles representative of visitors in the Cusco region, Peru, were simulated.

A. Profiles and Evaluation Scenarios

Three main profiles were defined:

- Cultural Profile: focused on history, archaeological heritage, and visits to emblematic sites.
- Gastronomic Profile: oriented toward local culinary experiences and traditional markets.
- Adventure Profile: related to outdoor activities, trekking routes, and contact with nature.

Each profile was tested with different combinations of variables such as type of trip, budget, companionship, and preferred activities, thus generating multiple test scenarios. The scenarios used were:

This scenario structure allows for covering different types of tourist experiences and evaluating the system's ability to provide relevant and adaptive recommendations for various user profiles.

B. Test Execution

The evaluation was carried out by executing complete flows in the application for each scenario:

- A scenario with its defined variables is selected.
- The frontend sends the request to the backend.
- The BERT-based recommendation engine processes the inputs and computes the cosine similarity with available tourist destinations in the database.
- The system returns itineraries ranked by relevance.
- The average response time is recorded, and external feedback on the perceived usefulness of the recommendations is collected.

C. Evaluation Metrics

The following metrics were used to assess system performance:

- Cosine Similarity: measures the semantic relevance between the entered preferences and the generated recommendations.
- Average Response Time: evaluates the efficiency of request processing.
- External Feedback: validates the perceived usefulness of the recommendations from the user's point of view.

These metrics measure not only the technical precision of the system but also its performance and usability from a practical perspective. The quantitative results obtained are presented in the following Results section.

VI. Results

The proposal was evaluated based on the six previously defined scenarios (see Table II), representing different user profiles, travel types, budgets, and companionships. The analysis focused on three main dimensions:

TABLE II. SCENARIOS AND USER CHARACTERISTICS FOR THE RECOMMENDATION SYSTEM

Scenario	Profile	Budget	Companionship	Brief Description
E1	Cultural	Moderate	Couple	Heritage and historical visits.
E2	Cultural	Premium	Solo	Personalized individual experience.
E3	Gastronomic	Economic	Solo	Exploration of markets and restaurants.
E4	Gastronomic	Moderate	Friends	Group tours with tastings.
E5	Adventure	Premium	Friends	Mountain and trekking activities.
E6	Adventure	Economic	Family	Accessible group experience.

- Technical Performance: measured through the average cosine similarity, which evaluates the semantic correspondence between user preferences and the descriptions of the recommended tourist destinations.
- Performance: measured by the system's average response time per request, considering the full interaction from user input to the recommended itinerary.
- Perceived Usability: assessed through simulated external feedback, reflecting overall satisfaction with the obtained recommendations.

Cosine similarity values ranging from 0.80 to 0.85 show that the system achieves a high semantic correspondence between input preferences and generated recommendations. The average response time remained between 2.0 and 2.2 seconds, confirming stable and adequate performance for an interactive environment. Likewise, positive feedback —between 85% and 92%— indicates high acceptance of the suggested itineraries.

A. Complementary Metrics Suggested by Literature

While this work prioritizes evaluation through cosine similarity, response time, and external feedback, scientific literature on AI-based and BERT-based tourism recommender systems suggests complementing these measurements with broader indicators. These indicators allow for a comprehensive evaluation, considering not only technical quality but also acceptance and effectiveness from the end user's perspective.

The incorporation of these metrics would allow, for example:

- Objective comparison of the system's performance against existing solutions.
- Evaluation not only of semantic accuracy but also of user satisfaction and software quality.
- Identification of weaknesses in specific scenarios, such as recommendation errors (RMSE) or coverage biases (F1-score).
- Alignment of evaluation with international standards, facilitating publication and experiment replicability.

Specifically, MAE and RMSE are relevant when users rate recommended destinations, while F1-score and Accuracy are useful when classifying intentions or activity types. Retention and ISO 9126 extend evaluation toward user experience and software quality, complementing purely technical assessment.

B. General Interpretation

The results indicate that:

- The **BERT**-based semantic engine effectively captures user preferences in tourism contexts.
- The stable response time ($\sim$ 2 s) enables smooth interaction, suitable for mobile applications.
- The high positive feedback suggests that the recommended itineraries are relevant and satisfactory for different profiles.
- Incorporating recognized technical and usability metrics provides robustness and comparability in evaluation.

These findings demonstrate the technical and functional feasibility of the proposal, establishing a solid framework for future improvements, including more complex metrics, real user testing, and longitudinal evaluation. Table III shows average results per scenario.

VII. DISCUSSION

The proposed sustainable tourism recommendation system in Peru, integrating a BERT-based semantic model and a decoupled architecture through Clean Architecture, offers significant advances over traditional approaches, both algorithmically and structurally. This section discusses the advantages and challenges of this proposal compared to other approaches documented in academic literature, while integrating the experimental results.

A. Advantages over Traditional Approaches

Regarding recommendation models, BERT represents a substantial improvement over classical methods such as TF-IDF, Support Vector Machines (SVM), or Collaborative Filtering (CF). Traditional content-based approaches like TF-IDF rely on term frequency and lack semantic understanding, limiting their ability to capture user intent when rich descriptions or synonyms are used. SVM can classify tourism texts with moderate efficiency but requires significant feature engineering and does not model deep contextual relationships. Collaborative Filtering, widely used in early stages of digital tourism, faces well-known challenges such as cold start and poor interpretability of novel preferences, as noted by Uribe Iraola et al. (2023) [15].

In contrast, the BERT model implemented in this research, combined with cosine similarity measures, achieved an average similarity score of 0.83 across six evaluation scenarios, demonstrating a strong ability to capture semantic relationships

TABLE III. AVERAGE RESULTS PER SCENARIO DEFINED IN TABLE II

Scenario	Average Cosine Similarity	Response Time (s)	Positive Feedback (%)
E1 — Cultural (Moderate, Couple)	0.83	2.1	92
E2 — Cultural (Premium, Solo)	0.85	2.0	90
E3 — Gastronomic (Economic, Solo)	0.80	2.0	85
E4 — Gastronomic (Moderate, Friends)	0.83	2.1	87
E5 — Adventure (Premium, Friends)	0.84	2.2	88
E6 — Adventure (Economic, Family)	0.81	2.2	86

TABLE IV. COMPLEMENTARY METRICS COMMONLY USED IN THE LITERATURE TO EVALUATE TOURISM RECOMMENDER SYSTEMS

Metric	Type	Main Purpose	Reference
MAE (Mean Absolute Error)	Technical	Measures the average error between actual user ratings and system predictions. A low value indicates estimates close to real perception.	[6]
RMSE (Root Mean Square Error)	Technical	Penalizes large errors; useful for detecting recommendations poorly aligned with user interests.	[6]
F1-score	Technical	Combines precision and recall; ideal for evaluating models that classify user intentions or categories.	[12]
Accuracy	Technical	Proportion of correct recommendations relative to the total.	[12]
Retention	Usability	Measures the percentage of users who continue using the app; indicates a positive experience.	[15]
ISO 9126	Usability	Evaluates software quality attributes (usability, functionality, efficiency, maintainability).	[2]

between user profiles and sustainable destination descriptions. This result is consistent with the values reported by Hartatik et al. (2024), who showed that BERT outperforms classical methods, achieving an MAE of 0.1162 and RMSE of 0.1214. Cosine similarity, by measuring the angular distance between vectors in high-dimensional spaces, enabled precise recommendations without the need for additional supervised training. However, a challenge identified was the higher computational cost compared to classical approaches, which may limit deployment on resource-constrained devices.

B. Architectural and Technical Contributions

From a structural design standpoint, adopting Clean Architecture as the system's backend foundation was a key decision compared to microservices approaches commonly used in large-scale recommender systems. While microservices offer high scalability and distributed deployment, studies such as Wijayanto Sejati (2023) indicate that in medium-scale mobile applications, Clean Architecture provides greater clarity in separation of concerns, maintainability, and testability [19]. In this project, this structure effectively decoupled the domain layer—hosting the recommendation engine—from open data sources (MINCETUR, SafeTravels, and OpenStreetMap), achieving a more stable architecture that can evolve without complex infrastructure dependencies.

In the Peruvian context, where sustainable tourism is not yet widely digitized, this architectural decision proved practical. During implementation, it allowed for seamless integration of recommendation and data management modules without affecting the presentation layer (based on MVC). This addresses a need observed in the literature: many reviewed applications implement only presentation patterns, lacking a clearly defined domain layer, as noted by Villacorta et al. (2022) and Ccuno Carlos et al. (2022) [17], [2]. Combining MVC in the frontend and Clean Architecture in the backend provides a balance between simplicity and technical robustness.

C. Evaluation and User Experience

From an evaluation perspective, the metrics most used in similar studies—MAE, RMSE, F1-score, and accuracy—support the effectiveness of BERT models in analyzing unstructured text and implicit preferences. In this study, the average similarity of 0.83 confirms that the proposal effectively aligns semantic destination descriptions with user profiles. Additionally, literature emphasizes that technical precision should be complemented with experience and retention indicators, such as the 98.35% retention reported by Uribe Iraola et al. (2023). This opens the possibility of incorporating mixed evaluation in future versions, combining technical metrics with sustainability perception and local tourism impact (see Table IV).

D. Limitations and Improvement Opportunities

Nevertheless, some important limitations must be acknowledged. Running BERT requires minimum computing infrastructure and stable connectivity, which can pose a barrier in rural areas or low-end devices. Moreover, integrating open data from Peru's tourism ecosystem presented challenges in normalization, consistency, and semantic updating. This suggests that future iterations could benefit from lighter models such as DistilBERT, knowledge distillation techniques, or edge computing mechanisms to reduce load on the central server.

E. Final Synthesis

In summary, the discussion shows that the combination of BERT with cosine similarity and a Clean Architecture represents a solid solution for contextualized personalization in sustainable tourism, validated both by the experimental results (similarity score of 0.83) and by evidence reported in the literature. At the same time, it highlights real challenges in optimization and scalability that represent opportunities for improvement in future development phases. The results suggest that tourism digitalization policies should prioritize semantic models and modular interoperable architectures.

VIII. Conclusions and Future Work

This research proposed and implemented a sustainable tourism recommendation system in Peru that combines a semantic model based on BERT with a decoupled architecture using Clean Architecture for the backend and the MVC pattern for the frontend. This integration effectively addressed the personalization of tourist itineraries, improving the relevance and contextualization of recommendations compared to traditional methods.

The experimental results showed that the model achieved an average similarity of 0.83 between user preferences and the descriptions of sustainable tourist destinations, demonstrating its ability to capture complex semantic relationships and generate suggestions aligned with users' real interests. Additionally, stable response times between 2.0 and 2.2 seconds were achieved, suitable for mobile applications. External feedback obtained through simulated scenarios also validated the practical relevance of the recommendations, confirming that the system not only provides technical precision but also perceived value for the user.

From an architectural standpoint, the use of Clean Architecture proved to be an efficient alternative to more complex architectures such as microservices, as it promotes maintainability, separation of concerns, and ease of system evolution. This approach enabled the modular integration of open data sources from MINCETUR, SafeTravels, and OpenStreetMap without compromising performance or application stability.

Methodologically, the adoption of the Design Science Research approach facilitated a structured and rigorous development process, ensuring traceability between problem identification, design, implementation, evaluation, and communication of results. This guarantees that the solution is not only technically viable but also scientifically grounded.

A. Future Work

Despite the progress achieved, there are opportunities for improvement and expansion that could enhance the impact of the proposal:

1) Model optimization: It is recommended to explore lightweight variants of BERT, such as DistilBERT, or knowledge distillation techniques that reduce computational load and allow greater accessibility on mid- and low-end mobile devices.

2) Geographical scalability: Expand the coverage of tourist destinations to other regions of the country by incorporating additional and updated open data sources.

3) Evaluation in real scenarios: Conduct tests with end users in real environments to complement technical metrics with indicators of usability, satisfaction, and perception of sustainable tourism.

4) Architectural improvements: Integrate edge computing or local caching mechanisms to further optimize response times and offline availability.

5) Incorporation of social and sustainability metrics: Explore indicators of local impact, tourism footprint, or sustainability to align recommendations with public policies and sustainable development goals.

In conclusion, the research demonstrates that the combination of semantic models based on BERT and Clean Architectures constitutes a solid and adaptable solution for promoting sustainable tourist destinations in Peru. The experimental validation, together with the literature review, confirms that this approach has the potential to significantly contribute to tourism diversification, decentralization of visitor flows, and the strengthening of local development.

A String-Similarity-Oriented Item Swapping Algorithm for Protecting Sensitive Frequent Itemsets in Transaction Databases

Fatah Yasin Al Irsyadi[1], Dedi Gunawan[2], Diah Priyawati[3], Wardah Yuspin[4]
Department of Informatics Engineering-Faculty of Communication and Informatics,
Universitas Muhammadiyah Surakarta, Surakarta, Indonesia[1,2,3]
Department of Law-Faculty of Law and Political Science,
Universitas Muhammadiyah Surakarta, Surakarta, Indonesia[4]

***Abstract*—Frequent itemset mining is a widely adopted data mining technique. The application of the technique can be found in transaction database analysis, such as exploring a set of purchased items. Presently, the growing concern of privacy protection and security issues in society leads the business parties to be more careful in handling their database, since various information can be extracted from the database including the sensitive information. Therefore, database owner should take measure to minimize sensitive information leak during the data mining process. A hiding sensitive frequent itemset algorithm can be adopted to achieve that. However, it is remain a challenge to design a data hiding algorithm that not only successfully hiding frequent sensitive itemset but also minimize the side effects such as item loss, the appearance of artificial frequent itemset and misses cost. In this paper, a method namely D-LSwap that based on item swapping technique is proposed to cope the issue while minimizing those side effects. Initially D-LSwap inspect each transaction in the database to determine whether a transaction is sensitive. Following that, it select a sensitive transaction from the previous process and create a pair of transactions from them. The pair is formed by incorporating Damerau-levensthein string similarity. The next step is selecting items from this pair for the swapping process. Experiment results indicate that the proposed method outperforms several existing algorithms by increasing data utility up to 10%, while minimizing the number of item loss more than 10 times lower than that of the baseline methods.**

***Keywords*—Data hiding; sensitive frequent itemset; frequent itemset; data mining; item swapping technique; D-Lswap**

I. Introduction

Frequent itemset mining in one of the most widely adopted data mining technique that can be found in various domains [1]. Retail business institution frequently employs the frequent itemset mining in transaction database [2]. It perform the task to explore the frequently bought itemset, analyzing customer buying behavior and patterns, as well as analyzing product trend [3]. Even though the analysis is critical, a lot of business institutions facing difficulties due to lack of human capability and computation resources. Furthermore, frequent itemset mining is computationally intensive task [4] that need expert to conduct it. Therefore, they deliver the database to third party to conduct the analysis.

Realizing the fact that the database contains various information including the sensitive information and the growing concern of privacy and laws on data protection drives another challenge in conducting data analysis. Given its significance, privacy is safeguarded through a range of statutory instruments and formal regulations [5], such as the General Data Protection Regulation (GDPR), the Electronic Communications Privacy Act (ECPA), the Children's Online Privacy Protection Rule (COPPA), along with other legal provisions that address particular categories of data. Thus, it becomes a mandatory for the database owner to take measure in minimizing sensitive information from being leaked during the frequent itemset mining process.

One of the strategy to hide the sensitive frequent itemset is called data sanitization. The main concept of data sanitization is hiding sensitive information such as sensitive itemset, while preserving the ability to explore necessary insights from the sanitized databases [6]. Therefore, to achieve that, one needs to transform an original database to a sanitized database to prevent the sensitive frequent itemset from being disclosed. The most widely adopted strategy of hiding sensitive frequent itemset is through item insertion or item suppression procedure in transaction records on the database to reduce the support value of itemset below specific predetermined threshold [7]. The hiding frequent itemset was initially introduced in study [8] and it has been proved to be NP-Hard problem.

The key issue in hiding sensitive frequent itemset hiding is keeping that to be successfully hidden while at the same time minimizing the side effect of the transformation process. The side effects including, excessive data dissimilarity, too much item loss that leads to reducing data utility and high number of newly generated artificial patterns. Various algorithms have been proposed to tackle this issue and those can be categorize into three groups namely, reconstruction-based algorithm, cryptographic-based algorithm and heuristic-based algorithm [9]. Recent finding stated that majority of the proposed methods rely on either item suppression-based or item insertion-based techniques for static transaction database [3]. The main property of these techniques is their ability to minimize the number of newly generated artificial patterns.

Even though the existing methods are effective to hide it, several issues such as excessive item loss, significant data utility loss and high dissimilarity value remain a challenge. Unlike most of the existing works that predominantly build on item suppression or insertion, our proposed method introduces a similarity-guided swapping technique based on the Dam-

erau–Levenshtein similarity. Previous work in [3] also adopts swapping technique where Cosine similarity is applied. However, as described by [10], traditional vector-based similarity measures (e.g., cosine similarity) treat sequences as bags-of-items and thus regardless ordering, which leads to a loss of sequential structure for accurate pattern comparison. Instead, edit-distance measures such as Damerau–Levenshtein better capture sequence transformations relevant for sanitization. Furthermore, the adoption of Damerau-levenstein distance is based on its unique properties where it can calculate transposition and provide more accurate string similarity [11].

The method provides a structure-preserving alternative that maintains sequence length and minimizes semantic distortion. By selecting swap candidates with minimal edit distance, the proposed approach reduces utility loss and improves the fidelity of the sanitized patterns. To the best of our knowledge, no previous work has applied the Damerau-Levenshtein string-similarity metric to design perturbation-based data sanitization. In addition, the method also carefully selects items from the pair to avoid item collision for reducing the number of newly generated artificial patterns. Therefore, this proposal is a novel and meaningful extension to current privacy-preserving data mining literature.

The rest of the paper is organized as follows: Section II describes related work. Section III explains the proposed method. While Section IV and V portray the experiment results and conclusion, respectively.

II. RELATED WORK

The rapid growing of e-commerce and retail industries that collect customer transaction data in daily basis drives business owners to actively extract the hidden information in the databases. To achieve the task, the database owners needs a tool such as data mining algorithms. In addition, the lack of capability and resources to conduct such task for these kind of business institutions directs them to handling the databases to another party such as data miner company. However, due to the growing concern on data security and privacy protection, conducting data mining task becomes more challenging since it can extract sensitive information such as sensitive frequent itemset. Consequently, prior to handle the databases they must take measures to minimize the disclosure of sensitive frequent itemset by hiding it from the databases.

A. Item and Item Category

Transaction databases are constructed from a collection of items I. As can be seen in the transaction database in Fig. I, $I = \{1, 2, 3, 4, 5, ..., 122\}$ where the numbers 1 to 122 represent item's identity number. In practice, items are commonly grouped according to specific criteria or their inherent similarities. Such categorization suggests several advantages, including the buildup of product catalogs and support for marketing programs [12]. Item groupings can be represented using a taxonomy generalization graph, which portrays the hierarchical structure of items, ranging from the most general level to the most detailed. An illustration of this taxonomy generalization graph is presented in Fig. 1.

Each item $i \in I$ belongs to only one category $C = \{C_1, C_2, C_3, ..., C_y\}$ without any overlapping membership to another category. For example, item ID = 10 belongs to C_3 it cannot be owned by other category C_j). The number of category C is determined by the business owners in managing their items. Referring to the Table. I, the collection of items i that exist in a transaction record t is called itemset, where $1 \leq |t_x|$ and $|t| \neq 0$.

B. Frequent Itemset Mining

Frequent itemset mining is one of an essential data mining task that seeks to identify all itemset combinations appearing in transaction records with a frequency greater or equal to a specified threshold [13], [14]. To conduct the task, database owner must define a parameter called minimum support threshold that function to limit occurrence frequency of itemset in the database. Due to there is no universally fixed value exists for this parameter, setting the threshold too low may result in an excessive number of frequent itemsets being generated that might be less informative, whereas setting it too high may cause potentially useful itemsets to be overlooked.

An itemset X is called frequent itemset FI if the $supp(X, \mathcal{D})$ is greater or equal to the number of determined minimum support $minSupp$ [15]. Accordingly, any itemset with a $supp$ value surpassing $minSupp$ can be classified as an FI. The $supp$ value of itemset X in a database $\mathcal{D}$ is computed as in Eq. (1).

$$supp(X, \mathcal{D}) = \frac{f(X)}{|\mathcal{D}|} \tag{1}$$

C. Sensitive Frequent Itemset

A sensitive frequent itemset is a subset of frequent itemsets, denoted as $Fs(X, \mathcal{D}) \subset FI$, whose disclosure may threat the interests of the database owner. Frequent itemsets not classified as sensitive are referred to as non-sensitive itemsets Fn, such

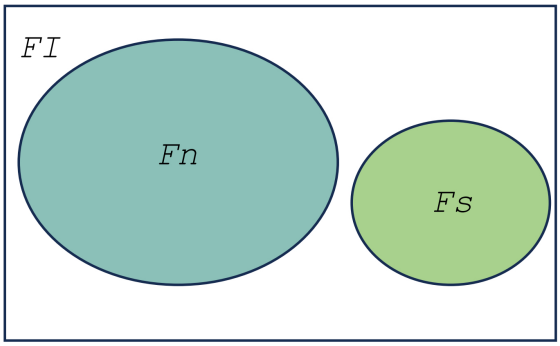

Fig. 2. Relation among Fs, Fn and FI.

that $FI = Fs \cup Fn$ and $Fs \neq Fn$. The relation between Sensitive frequent itemset and frequent itemset can be depicted in Fig. 2.

The pioneering solutions for hiding sensitive frequent itemset were introduced in [8], [16] and [17]. However, these works does not take post modification data quality in to account [7], consequently, the sanitized databases significantly distorted. The proposed method in [18] tries to balance between the privacy protection and data quality in post-modification using one-scan technique. Subsequently, various hiding algorithms were proposed to balance between privacy and data utility and that can be categorized into three groups namely, perturbation-based method, Cryptographic-based method, and Heuristic-based method.

D. Perturbation-Based Method

The perturbation-based method is widely adopted for hiding sensitive frequent itemset due to its flexibility. It relies on injecting noises in the databases either by omitting items or injecting items into a specific transactions. Pioneering work that adopts perturbation-based method was proposed in [19] where one of the proposed solutions is called naive approach. The solution simply removes all item in the sensitive itemsets that exist in the transaction records. While the solution is effective to addresses the hiding sensitive frequent itemset, it results in significant item loss.

Another method that considers various threshold sensitivity has been proposed in study [20]. The method considers the real case in transaction databases where items have certain level of importance for business owners perspective. For example, item a is less valuable than item b since a brings lower profit while item b is more valuable since it generates more profit. To sanitized the databases while reducing the item loss, it creates a template containing a set of victim items that will be omitted from transaction records. A method that adopts local suppression was proposed in [21]. It selectively removing items from sensitive transaction to hide the sensitive frequent itemset with lower items loss. In addition, rotation perturbation method that works for preserving sensitive information in clustering data mining has also been proposed in [22]. To solve the item loss issue, a technique that employs transaction injection has been urges in [23].

Working on frequent itemset mining in transaction database requires high computation resource [24], [25], thus to optimize the performance of data hiding algorithm, a method that utilizes particle swarm optimization (PSO) is proposed in [26]. It generates the sanitized database by excluding sensitive items from certain transaction records while at the same time minimizing the number of item loss. Concerning the issue related to the database size, a method namely MR-OVnTSA is introduced in [27]. The method protect sensitive frequent itemsets by discharge items and transactions for balancing privacy and data utility in big data environment.

1) Cryptographic-based method: High computation resource in hiding sensitive frequent itemset shifts researchers to adopt an efficient solution by using secure multi-party computation. A groundbreaking work in this area is introduced in [28]. The methods use a secure multi-party computation technique where several connected parties perform frequent itemset mining securely. Considering the fact that transaction database has potential to be analyzed by several parties across geographical areas, a scheme of hiding frequent sensitive itemset for distributed system has also been intensively explored [29]. Aiming to enhance the quality of the sanitized database while ensuring the hiding of sensitive frequent itemset, a recent study in [30] adopts cryptographic-based technique to hide sensitive rules in transaction databases. The method strengthen the protection of transaction databases from inference knowledge intrusion. A recent method in [31] employs a cryptographic technique where it improves the mining process by disjoining the encrypted transactions into a certain number of blocks and only uses bilinear pairs of ciphertexts from the blocks. Therefore, the approach becomes more applicable in real-life cases. Ensuring the security of frequent itemset mining, a method successfully introduced differential privacy in two-party scenario [32]. Even though the cryptographic-based method provides a strong privacy guarantee, however, when it meets a huge-sized transactional database, the performance computational efficiency remains a challenge.

2) Heuristic-based method: Since accomplishing both maximum privacy protection and maximum data utility is recognized as an NP-hard problem [33], practical solutions often rely on heuristic-based approaches to address real-world challenges. Numerous heuristic techniques have been introduced under various settings and parameters. Early pioneering efforts in this field include those suggested in [19], [34]. In the existing literature, most heuristic methods employ either item pruning or artificial transaction insertion strategies to lower the support of specific itemsets, thereby effectively concealing sensitive frequent itemsets within a database.

Unlike the earlier approaches, [35] has introduced a distinct scheme that avoids reducing itemset support to conceal sensitive frequent itemsets. Instead, their method focuses on representative rules and eliminates them at the outset. Similarly, [36] proposed a heuristic-based data sanitization approach that relies on item pruning to successfully hide sensitive itemsets within a database. In this method, the selection of items for pruning is guided by calculating the frequency of sensitive items and removing those whose elimination results in minimal item loss.

It is known that heuristics-based strategies tend to diminish the utility of the database, since the removal of items leads to the loss of important information. In addition, the artificial

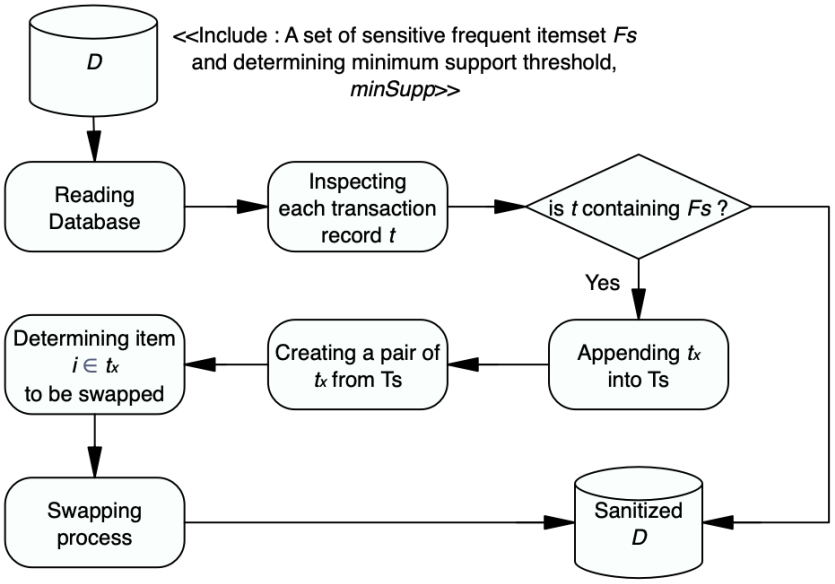

Fig. 3. Proposed swapping method.

transaction insertion approach often induces substantial modifications, causing the composition of items in the sanitized database to differ significantly from that of the original one.

III. Proposed Method

Our proposal is designed for static transaction databases scenario, where the data owner delivers his/her transaction data $\mathcal{D}$ to an external party for conducting frequent itemset mining. The database $\mathcal{D}$ contains a set of transaction record T, where $T = \{t_1, t_2, t_3, ..., t_y\}$. Each transaction record t_x containing a subset of item I, where $I = \{i_1, i_2, i_3, ..., i_m\}$, thus $t_x \subset I$. Referring to the I transaction records $t_3, t_6, t_7, t_8, t_{10}$, all of these records containing $\{100, 112\}$. For example, the itemset $\{100, 112\}$ is referred as to sensitive frequent itemset from the database owner's view. Therefore, when the database $\mathcal{D}$ is released to external party for mining purpose, the $\mathcal{D}$ should be modified in such a way the sensitive frequent itemset mining cannot be exposed in the sanitized database $\widetilde{\mathcal{D}}$.

To generate a sanitized database that can successfully hide the sensitive frequent itemset while at the same time minimizing iside effects such as item loss, data utility loss, artificial patterns and data dissimilarity. A method that follows the swapping technique is suggested. A pioneering research that applied swapping technique is firstly suggested in [37] to prevent disclosure attack on databases. The swapping strategy conveys several unique properties where it neither deletes items from a database nor injects new artificial items or transactions into the database; instead, it swaps items from a transaction to another. Accordingly, the side effects such as item loss, and the data dissimilarity value can be minimized. Our strategy also adopts the Damerau-Levenshtein string similarity algorithm to determine transaction records that are suitable for the swapping process. It does not only provide more accuracy in measuring similarity, but also it can picture the number of edit changes of swapping. The framework of our proposed scheme is depicted in Fig. 3.

An initial step to hide the sensitive frequent itemset is determining the sensitive frequent itemset Fs from the database $\mathcal{D}$. In principal, there are two common approaches to determining the sensitive frequent itemset Fs. The first is allowing database owners to specify sensitive itemsets based on their business objectives, while the second is encouraging customers to classify their purchased items as either sensitive or non-sensitive [38]. In this paper, we follow the first approach, where the database owner designates certain itemsets as the sensitive frequent itemset according to their own perspective and interests. The Fs where $Fs = \{s_1, s_2, s_3, ..., s_k\}$ is composed by a set of sensitive items $i_s \subset I$ and each s_j is a non-empty set of itemset ($|s_j| \geq 1$). Meanwhile, frequent itemset that are not included in Fs is called non-sensitive frequent itemset Fn. The correlation among frequent itemset FI, Fs and Fn is depicted in Fig. 2.

The process of data sanitization also requires prerequisites input by user like minimum support ($minSupp$)threshold and there is no fixed value to determine this. Once the prerequisites value is determine, the nex process is scanning and reading all the transaction t in database $\mathcal{D}$. If the algorithm finds that $t_x \in \mathcal{D}$ containing s_j, $s_j \subseteq t_x$, the t_x is considered as to sensitive transaction and it is appended to Ts. Otherwise, the t_x is appended to Tn. Therefore, only Ts will be processed for the next step in sanitization process. Algorithm 1 represents the pseudo-code of this process.

Once the algorithm collects all the sensitive transaction Ts, the following step is select one of the transaction $t \in Ts$ as a candidate for transaction pairing process, t_a. The selected t_a is then analyzed to obtain its properties such as transaction length which refers to the number of items $i \in t_a$ and item categories C_j that compose it. The algorithm proceed to select another transaction $t \in Ts$, as t_b where this transaction will be the pair of t_a. To obtain the t_b our proposed method applies several criteria. Firstly, to be selected as t_b, the $t \in Ts$ should have the similar item length with that of t_a. This requirement aims to avoid excessive distortion in the transaction record

and maintain the average of transaction length of the database $\mathcal{D}$. Secondly, evaluating item similarity between t_a and each of $t \in Ts$, the most similar one will be selected as t_b. In this step, our method employs Damerau-levenshtein similarity calculation to create the pair. The detail pseudo-code of this step is depicted in Algorithm 2.

Algorithm 1: Reading and Grouping Transaction

Input: $\mathcal{D}$, $i_s \in SI$
Result: Ts and Tn
Scan $\mathcal{D}$
$\forall\ t_x \in \mathcal{D}$
if $s_k \subseteq t_x$ **then**
  add the t_x to Ts
else
  add the t_x to Tn
end

Algorithm 2: Damerau–Levenshtein Distance Algorithm

Input: Two transaction $t_a[1..n]$ and $t_x[1..m] \in Ts$
Output: Edit distance between t_a and t_x, t_b
Initialize matrix $D[0..n, 0..m]$;
for $i \leftarrow 0$ **to** n **do**
  $D[i, 0] \leftarrow i$;
end
for $j \leftarrow 0$ **to** m **do**
  $D[0, j] \leftarrow j$;
end
for $i \leftarrow 1$ **to** n **do**
  for $j \leftarrow 1$ **to** m **do**
    if $t_a[i] = t_b[j]$ **then**
      $cost \leftarrow 0$;
    else
      $cost \leftarrow 1$;
    end
    $D[i, j] \leftarrow \min\Big\{D[i-1, j] + 1,\ \ D[i, j-1] + 1,\ \ D[i-1, j-1] + cost\Big\}$;
    if $i > 1$ ***and*** $j > 1$ ***and**** $t_a[i] = t_b[j-1]$ ***and*** $t_a[i-1] = t_b[j]$ **then**
      $D[i, j] \leftarrow \min\{D[i, j], D[i-2, j-2] + 1\}$
    end
  end
end
return $t_b \leftarrow Min(D[n, m])$;

Once the pair t_a and t_b is obtained, the proposed method proceed to determine items from both transactions to be swapped each other, this procedure is called victim item Vi selection. The victim item selection incorporates two strategies. The first stage is calculating the frequency f of sensitive items $i_s \in t_a$ that exist in $\mathcal{D}$ and select the one which has the highest occurrence frequency, if there are several sensitive items $i_s \in t_a$ with the same occurrence frequency, the algorithm randomly selects one of them. This strategy allows to minimize the number of item loss since the sensitive items with high frequency will remain observable. The second stage is observing the item category of each $i_s \in t_a$, $i_s \in C_j$. The candidate of Vi should not come from the C_j that has only one item, $|C_j| > 1$. Items $i_s \in t_a$ that satisfies these criteria will be considered as to $Vi(t_a)$.

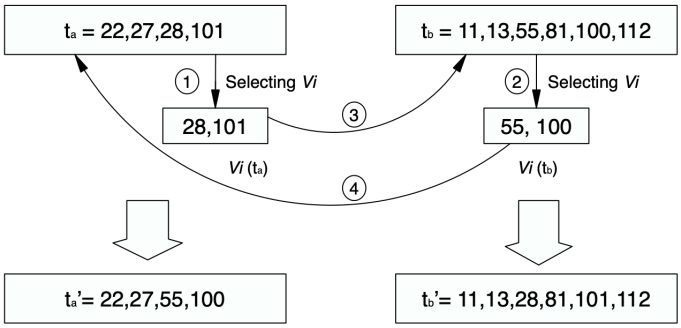

Fig. 4. Procedure of items swapping.

Algorithm 3: Procedure of Vi Selection for Swapping

Input: t_a, t_b
Result: $Vi(t_a)$, $Vi(t_b)$
$\forall\ i_s \in t_a$ calculate the f of $i_s \in t_a$
check the $|C_j| > 1$ is TRUE
$Vi(t_a) \leftarrow Max(f(i_s \in t_a) \& |C_j| > 1$ is **TRUE**
$\forall\ i_s \in t_b$
if $C(Vi(t_a))$ == $C(i_s(t_b))$ **then**
  calculate f of $i_s \in t_a$
  select $Max(f(i_s \int_b))$
  if $i_s \in t_b$ == $i_s \in t_a$ **then**
    $Vi(t_b) \leftarrow i_s \in t_b$
  end
end
return $Vi(t_a), Vi(t_b)$;
end;

The following procedure is determining Vi from t_b. Sensitive items $i_s \in t_b$ can be selected as the $Vi(t_b)$ if it satisfies three requirements. The first requirement is candidate should come from the same category with that of $Vi(t_a)$ to keep the structure of the t remains semantically consistent. The second is candidate should has the highest item frequency among other $i_s \in t_b$ and the third is it does not collide with other items that already exist in t_a. These requirements aims to minimize item loss due to item collision and retain as much as possible the number of items in the $\mathcal{D}$. All these strategies not only guarantee a sanitized database $\widetilde{\mathcal{D}}$ that protects sensitive patterns but also it can minimize the side effects. The detail process of victim item selection is depicted in Algorithm 25.

As the victim items are determined, the last step is swapping them from t_a to t_b and vice versa. Algorithm 31 represents the pseudo-code of the swapping process. In addition to that, as an example we provide the swapping process illustration is expressed in Fig. 4. Supposed the transaction pair $\{t_a, t_b\}$ has been determined where the $t_a = \{22, 27, 28, 101\}$ and $t_b = \{11, 13, 55, 81, 100, 112\}$. The sensitive itemset of t_a is $\{28, 101\}$ while the sensitive itemset of t_b is $\{55, 100\}$. After the evaluation of Vi selection, it is decided that item id $\{28\}$ in t_a is selected and item id $\{55\}$ from t_b is selected

Algorithm 4: Procedure of Items Swapping

Input: $Vi(t_a), Vi(t_b)$, t_a, t_b
Result: $\widetilde{\mathcal{D}}$
create Buffer br_{t_a} and br_{t_b};
br_{t_a}.add $(Vi(t_b)$;
br_{t_b}.add $(Vi(t_a)$;
save to $\widetilde{\mathcal{D}}$;
end;

for the swapping process. The following step is swapping those items from their origin to their destination, thus we can obtain sanitized transactions t'_a and t'_b. Lastly, these transaction records are appended the sanitized database $\widetilde{\mathcal{D}}$.

IV. Experimental Results

$$iLoss = \left| \sum_{i=1}^{d} f\mathcal{D}(i) - \sum_{i=1}^{\widetilde{d}} f\widetilde{\mathcal{D}}(i) \right| \tag{2}$$

$$U(\mathcal{D}, \widetilde{\mathcal{D}}) = \frac{\left| F_{\mathcal{D}} \cap F_{\widetilde{\mathcal{D}}} \right|}{\left| F_{\mathcal{D}} \cup F_{\widetilde{\mathcal{D}}} \right|} \tag{3}$$

$$APR = \frac{|Np \cap Cp|}{|Rp|} \tag{4}$$

$$Diss(\mathcal{D}, \widetilde{\mathcal{D}}) = \frac{1}{\sum_{i=1}^{d} f\mathcal{D}(i)} \times \left| \sum_{i=1}^{d} f\mathcal{D}(i) - \sum_{i=1}^{\widetilde{d}} f\widetilde{\mathcal{D}}(i) \right| \tag{5}$$

Several evaluations to assess the effectiveness of our proposed method is conducted using two real datasets such as the Liquor dataset [39] and BMS-WebView1. Those datasets are most widely adopted datasets in knowledge discovery field. By using two difference datasets we can figure out the performace consistency of the proposed method. Table II summarizes the dataset attributes, and Table III illustrates the corresponding evaluation parameters. We implement the algorithm in Python code and run the system in cloud. A supplementary tool i.e. SPMF from [40] is also adopted to generate frequent itemset by running the FP-Growth algorithm.

In this research four evaluation metrics are adopted to assess our proposed method such as item loss ($iLoss$), data utility ($U(\mathcal{D}, \widetilde{\mathcal{D}})$), artificial pattern ratio (APR), and data dissimilarity ($Diss$). The first metric as denoted in 2 calculates the inequality between the number of items in the $\mathcal{D}$ and that of the sanitized $\widetilde{\mathcal{D}}$. The second metric that stated in 3 computes the amount of data utility that can be preserved in the sanitized database. Specifically, $F_{\mathcal{D}}$ designates the frequent itemsets obtainable from $\mathcal{D}$, and $F_{\widetilde{\mathcal{D}}}$ denotes those frequent itemsets that remain observable in $\widetilde{\mathcal{D}}$.

The third metric as declared in 4 is measuring ratio of the number of artificial pattern or ghost pattern to that of the retained pattern. The measurement is computed by summing the number of newly generated patterns and that of the changed pattern over the number of retained pattern in the sanitized database. The symbols $|Np|$ and $|Cp|$ denote the number of the newly generated frequent itemset and that of the changed frequent itemset pattern in $\widetilde{\mathcal{D}}$, respectively. While $|Rp|$ denotes the number of retained frequent itemset pattern in $\widetilde{\mathcal{D}}$. The last metrics as defined in 5 computes the amount of database dissimilarity after performing data sanitization method. The formula symbols $f\mathcal{D}(i)$ represents the frequency of item i in an original database $\mathcal{D}$ and $f\widetilde{\mathcal{D}}(i)$ refers to that of the sanitized one. In this experiment, we also compare our proposed method (D-LSwap)to several existing method such as $Naive$ [19], $Heuristics$ [36] and random swapping technique (RaS) [41] to investigate its performance.

TABLE II. Datasets Properties

Properties	Datasets	
	BMS-WebView1	**Liquor**
#Transaction	59,602	52,131
#Distinct item	497	4,026
Total items	149,639	410,619
Average length	11.75	8

TABLE III. Testing Parameters

Parameter	Dataset	
	BMS-WebView1	**Liquor**
$minSupp$	0.2% - 0.8%	0.2% - 0.8%
$\|Fs\|$	100	100
Avg. $\|s_k\|$	8	2

A. Item Loss

Depicted in Fig. 5, our proposed method induces lower item loss compared to that of $Naive$ and $Heuristic$ in all $minSupp$ values. These results is mainly due to the $Naive$ and $Heuristic$ approaches perform item suppression strategy that causes more item loss. On the other hand, the RaS has achieved slightly lower item loss to that of our proposed method $D-LSwap$. Such the result is obtained since the RaS algorithm does not consider item category for selecting Vi. Unfortunately, this strategy has drawback in terms of keeping semantical consistency when the items in $\widetilde{\mathcal{D}}$ are generalized in certain analysis. Another experiment using Liquor dataset as shown in Fig. 6 also indicates that the item loss induced by our proposed method achieved almost the same level to that of the SaR algorithm. While the other two methods i.e. $Naive$ and $Heuristic$ promote significant item loss, making it less desirable in scenarios where retention of items is critical. Therefore, it is confirmed that the swapping strategy could minimize the number of item loss compared to the suppression-based strategy.

B. Data Utility

Data utility pictures the number of retained information i.e. frequent itemset obtained from the sanitized database. Referring in Fig. 7, we can inspect the comparison of utility scores across four methods i.e., $D-LSwap$, $Heuristic$, $Naive$, and RaS under varying minimum support thresholds (0.20%, 0.40%, 0.60%, and 0.80%). Overall, $D-LSwap$ consistently achieves the highest utility scores, ranging from 0.9559 at the lowest $minSupp$ value to 0.9334 at the highest, indicating

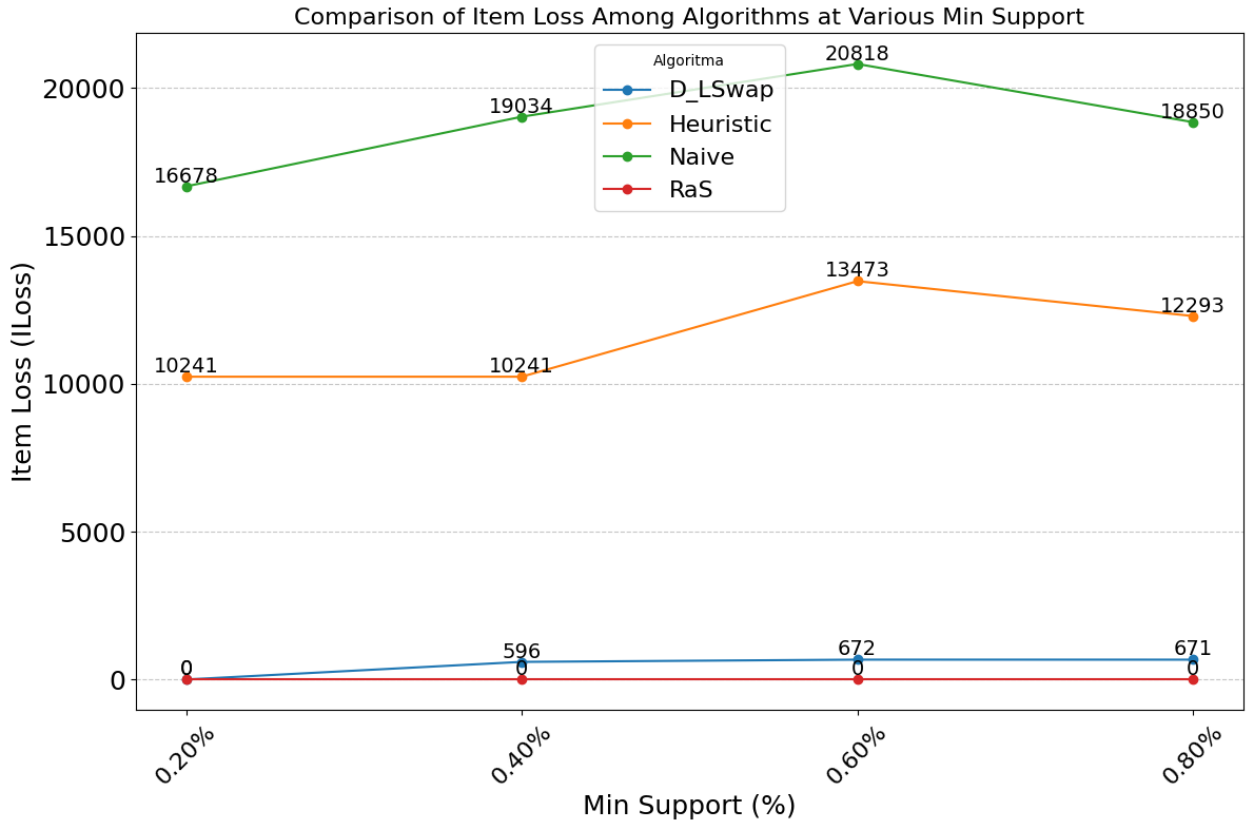

Fig. 5. *iLoss* on BMS-WebView1 dataset.

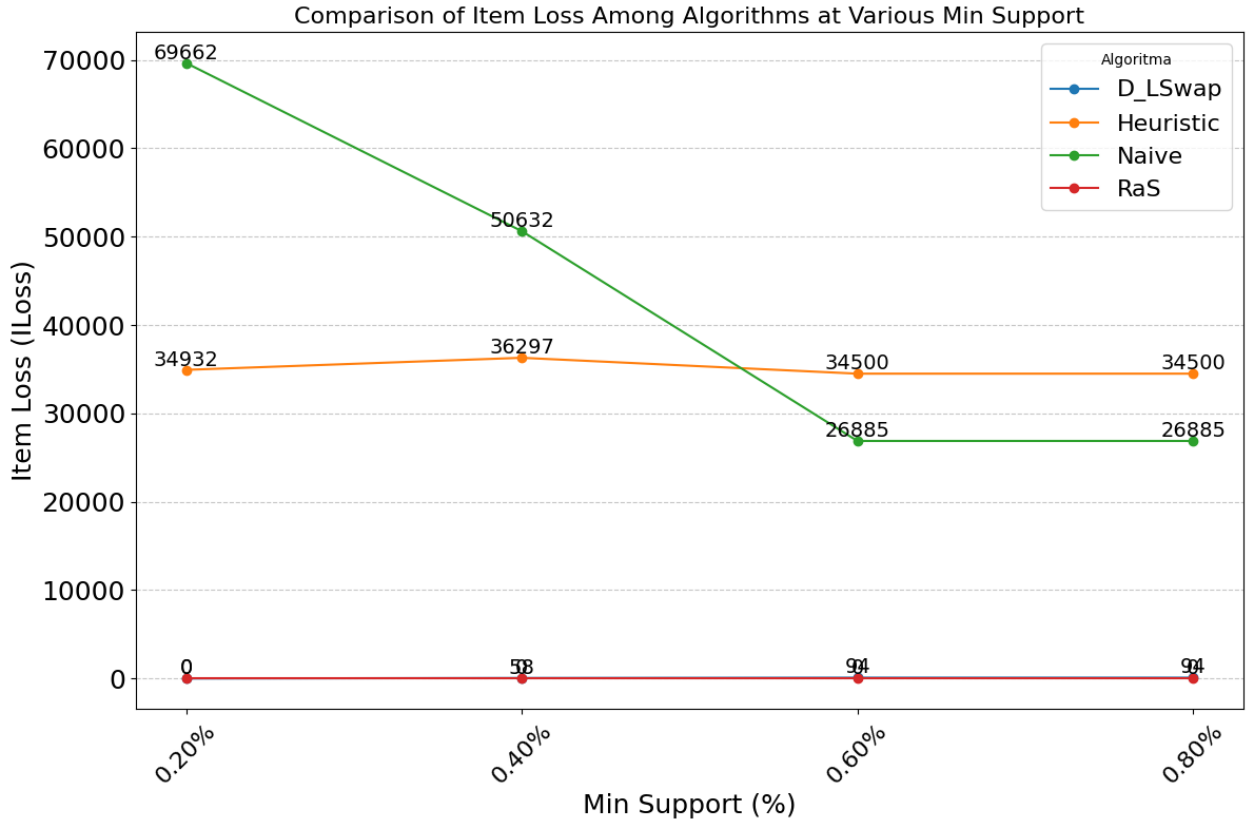

Fig. 6. *iLoss* on Liquor dataset.

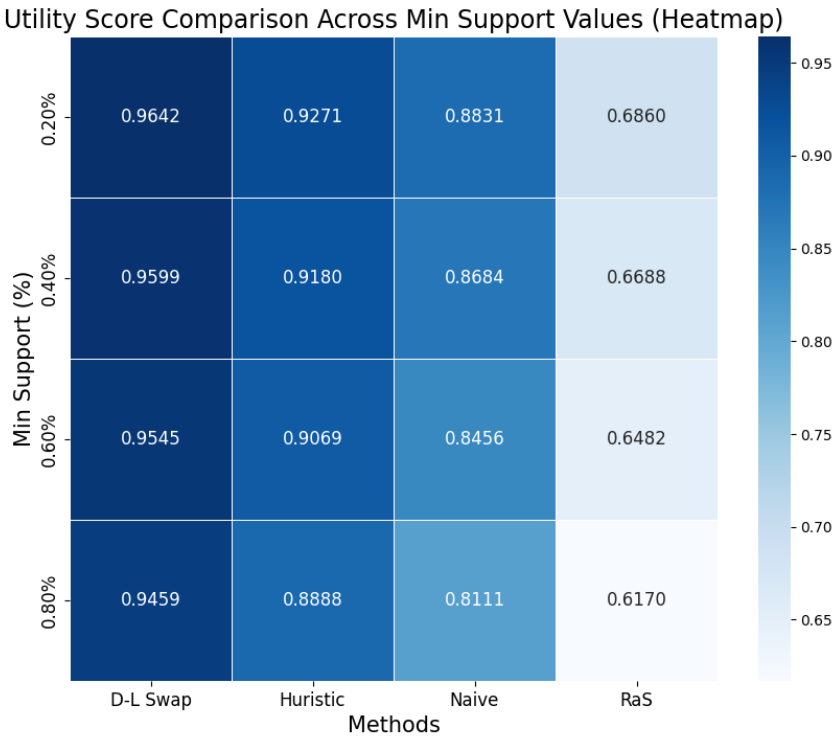

Fig. 7. Data utility on the sanitized BMS-WebView1 dataset.

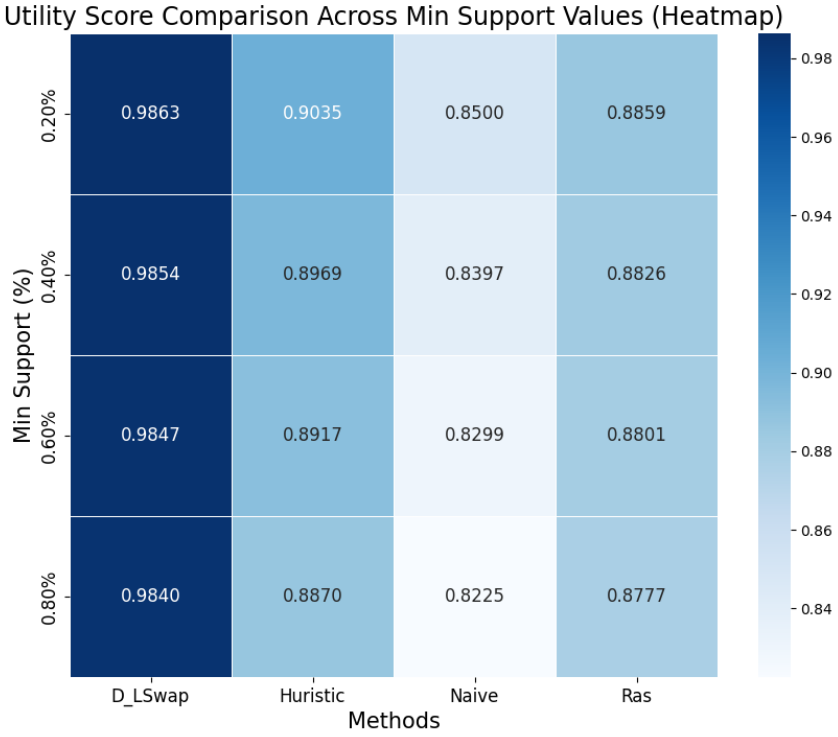

Fig. 8. Data utility on the sanitized Liquor dataset.

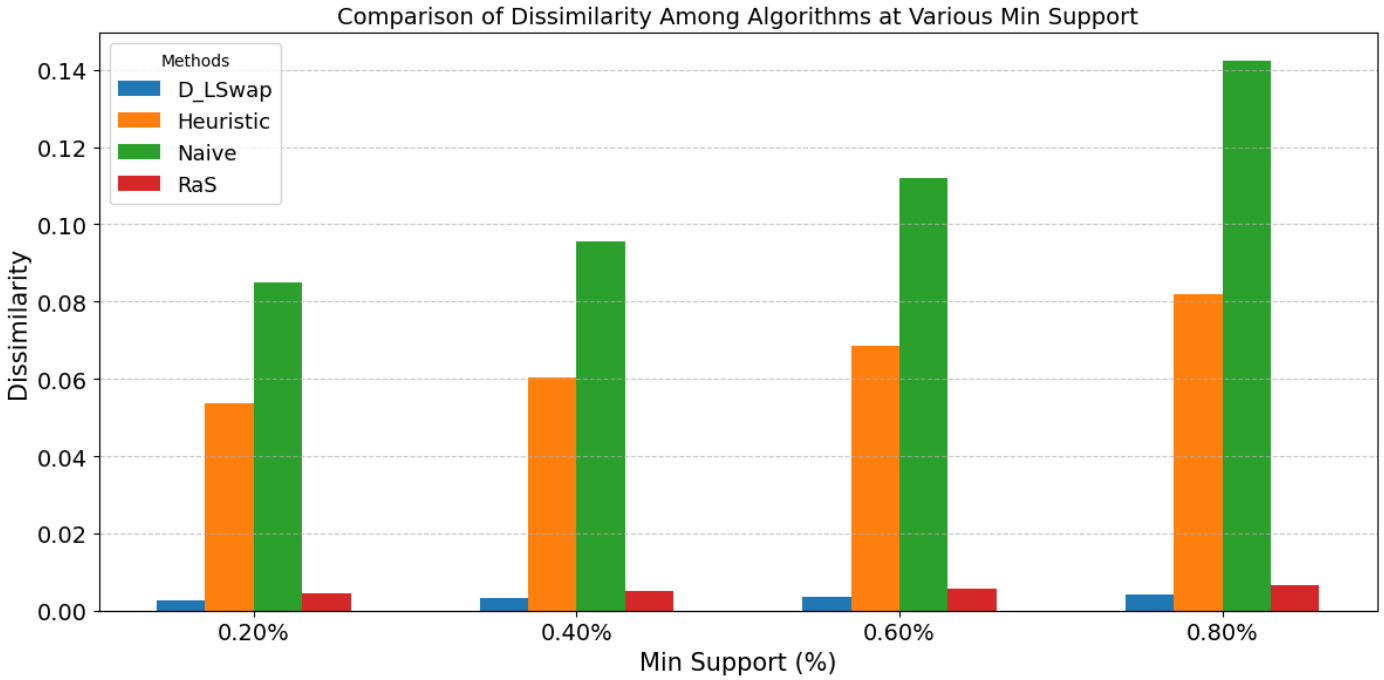

Fig. 9. *Diss* value on BMS-WebView1.

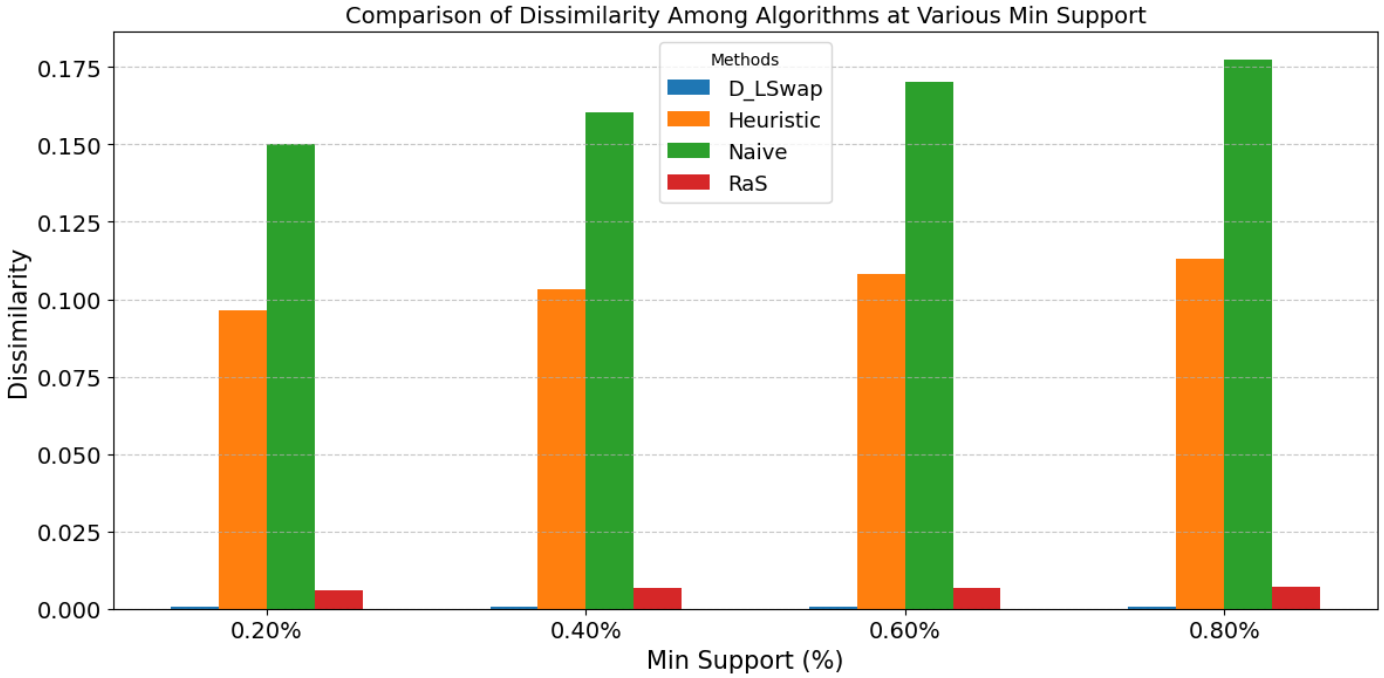

Fig. 10. *Diss* value on liquor.

superior capability in preserving data utility. The $Heuristic$ method follows closely, maintaining relatively high and stable utility scores between 0.9463 and 0.9180. In contrast, the $Naive$ method exhibits a more noticeable decline in utility, dropping from 0.9149 to 0.8576 as the $minSupp$ threshold increases. The RaS demonstrates the lowest performance across all thresholds, with scores falling from 0.7638 to 0.7093, suggesting substantial utility loss regardless of support level. Interestingly, even though both $D-LSwap$ and RaS adopt swapping technique, the resulted data utility is significantly difference since the RaS employs random swapping strategy. The approach causes uncontrolled item disassociation that impact to the itemset correlation in transaction records.

The similar trend also occurs in Fig. 8, our proposed method $D-LSwap$ achieves the highest data utility value in all the $minSupp$ threshold. While in the Liquor dataset $Naive$ approach results in the lowest data utility. The main reason is due to the method applies global suppression procedure to the dataset, consequently each unique item that exist in sensitive frequent itemset are omitted from the dataset.

C. Artificial Pattern Ratio

TABLE IV. ARTIFICIAL PATTERN RATIO IN THE SANITIZED BMS-WEBVIEW

Algorithm	Measurement			
	$\#N_p$	$\#C_R$	$\#Rp$	APR
$D-LSwap$	13	10	87	0.26
$Heuristic$	0	2	82	0.02
$Naive$	5	11	75	0.20
RaS	4	2	89	0.06

TABLE V. ARTIFICIAL PATTERN RATIO IN THE SANITIZED LIQUOR

Algorithm	Measurement			
	$\#N_p$	$\#C_R$	$\#Rp$	APR
$D-LSwap$	68	91	635	0.25
$Heuristic$	2	110	229	0.48
$Naive$	2	172	207	0.84
RaS	105	175	488	0.57

According to the Table IV, Among the evaluated algorithms, $D-LSwap$ exhibits the highest number of artificial patterns (N_P = 13) and the largest APR (0.26), reflecting a relatively greater degree of distortion, although it retains a substantial number of patterns (R_p = 87). In contrast, the Heuristic algorithm introduces no artificial patterns (N_p = 0) and achieves the lowest APR (0.02), suggesting minimal distortion; however, it retains fewer pattern (R_p = 82) compared to $D-LSwap$ and RaS. The $Naive$ algorithm produces the greatest number of changed patterns (C_R = 11) and the lowest pattern retention (R_p = 75), indicating a stronger impact on the original dataset structure. RaS demonstrates a balanced performance, with relatively few artificial patterns (N_p = 4), minimal pattern changes (C_R = 2), the highest pattern retention (R_p = 89), and a low APR (0.06), thereby offering a favorable trade-off between data utility preservation and distortion minimization.

In contrary, the experiment using Liquor dataset as described in Table V suggests that our proposed method can achieve the best results among others. The $D-LSwap$ achieves a relatively moderate number of artificial patterns (N_p = 68) and changed patterns (C_R = 91), while maintaining the highest pattern retention (R_p = 635) and the lowest APR (0.25), suggesting a good balance between pattern preservation and minimal distortion. In contrast, the $Heuristic$ algorithm introduces very few artificial patterns (N_p = 2) however, it shows a higher number of changed patterns (C_R = 110) and a significantly reduced pattern retention (R_p = 229), resulting in a moderate APR (0.48). The $Naive$ algorithm, despite introducing the fewest artificial patterns (N_p = 2), exhibits the highest number of changed patterns (C_R = 172) and the lowest pattern retention (R_p = 207), leading to the highest APR (0.84), which indicates substantial distortion of the original dataset. RaS generates the largest number of artificial patterns (N_p = 105) and changed patterns (C_R = 175), with moderate pattern retention (R_p = 488) and a relatively high APR (0.57). Overall, $D-LSwap$ appears to offer the most favorable trade-off, minimizing distortion while preserving a large proportion of the original rules.

D. Data Dissimilarity

According to the Fig. 9, it can be seen that the proposed method results in the lowest data dissimilarity $Diss$ in all the testing aspects. The results demonstrate that $Naive$ consistently yields the highest dissimilarity values, with a marked increase as the minimum support level rises, peaking at approximately 0.14 at 0.80%. This indicates that $Naive$ introduces the most significant alterations to the original dataset due to its strategy in incorporating suppression approach. $Heuristic$ method exhibits moderate $Diss$ value, which gradually increases with higher support thresholds, suggesting a progressive reduction in data fidelity. In contrast, RaS maintains relatively low $Diss$ across all thresholds, demonstrating a favorable balance between data transformation and preservation. Notably, our proposed method $D-LSwap$ achieves the lowest dissimilarity values overall, remaining nearly constant and close to zero regardless of the support level, which indicates minimal distortion and strong preservation of the original data characteristics.

The similar trend also can be seen in Fig. 10 when the test is conducted using Liquor dataset. $Naive$ consistently exhibits the highest dissimilarity, with values rising from approximately 0.15 at 0.20% support to around 0.18 at 0.80%, indicating substantial alteration to the original data. $Heuristic$ shows moderate dissimilarity, gradually increasing with higher minimum support thresholds, which reflects its progressively more intrusive data modification. RaS demonstrates significantly lower dissimilarity, remaining below 0.01 across all support levels, suggesting minimal impact on the dataset. Finally, D_LSwap consistently achieves the lowest dissimilarity values, staying near zero regardless of the support level, highlighting its strong capability to preserve data similarity. These results confirm that D_LSwap is the most effective approach for minimizing dissimilarity, followed by RaS as a second-best option. Conversely, $Naive$ and $Heuristic$ introduce higher levels of data modification, which may be undesirable in applications prioritizing data fidelity.

According to the experiment in both datasets, we can highlight that the D_LSwap is the most effective algorithm for minimizing dissimilarity, followed by RaS as a secondary option for scenarios where slightly higher modification is

TABLE VI. COMPUTATION COST FOR BMS-WEBVIEW1 DATASET

Method	CPU time sys (s)	Peak memory (MiB)	Memory increment (MiB)
$D - LSwap$	0.3	0.85	0.04
RaS	24.75	10.47	10.46
$Heuristic$	5.48	5.08	0.04
$Naive$	19.18	24.34	12.92

TABLE VII. COMPUTATION COST FOR LIQUOR DATASET

Method	CPU time sys (s)	Peak memory (MiB)	Memory increment (MiB)
$D - LSwap$	0.56	0.77	0.04
RaS	44.56	19.75	19.74
$Heuristic$	35.68	6.81	0.16
$Naive$	66.67	57.77	25.82

acceptable. Conversely, $Naive$ and $Heuristic$ may be less suitable when data fidelity is a primary concern, as they introduce considerably higher levels of distortion.

E. Computational Evaluation

Tables VI and Table VII present the computation cost of four algorithms such as $D - LSwap$, RaS, $Heuristic$, and $Naive$ on two datasets: BMS-WebView1 and Liquor. For the BMS-WebView1 dataset, $D - LSwap$ exhibits the lowest computational cost, requiring only 0.3 seconds of CPU time, 0.85 MiB of peak memory, and a negligible memory increment of 0.04 MiB. In contrast, RaS demands significantly higher resources, with a CPU time of 24.75 seconds and a memory increment of 10.46 MiB. The $Heuristic$ consumes 5.48 seconds of CPU time and a moderate memory footprint (5.08 MiB), while $Naive$ is the most resource-intensive, taking 19.18 seconds and peaking at 24.34 MiB of memory.

A similar trend is observed in the Liquor dataset, where $D - LSwap$ again achieves the best efficiency with only 0.56 seconds of CPU time, 0.77 MiB of peak memory, and 0.04 MiB memory increment. The $Naive$ method records the highest computational overhead with 66.67 seconds of CPU time and 57.77 MiB of peak memory. RaS and $Heuristic$ require 44.56 seconds and 35.68 seconds, respectively, with moderate memory usage compared to $Naive$. These results demonstrate that $D-LSwap$ is consistently the most efficient algorithm, achieving minimal runtime and memory overhead across both datasets. This efficiency makes $D-LSwap$ highly suitable for large-scale or resource-constrained environments, while $Naive$ appears impractical due to its high computational cost.

V. DISCUSSION

This research proposed a data hiding method that based on swapping technique. Experiment results highlight that swapping technique can successfully hide sensitive information and it can significantly reduce the number of item loss and minimize the data dissimilarity value compared to that of suppression based techniques. This finding support the previous research from [42] since the swapping technique is neither remove nor add items from databases. The swapping-based technique allows items in the dataset remain observable and it is beneficial for data analytic that regards the presence of items in the database is crucial.

In contrary, since pairing transaction is performed by scanning each transaction while computing its similarity values, it may takes significant computing resource as the number of the sensitive transaction grows. Additionally, due to some items from a transaction are swapped to another transaction, the structure or composition of the swapped transactions can change drastically, and therefore, it may generate several new rules that previously do not exist in databases. Applying the swapping-based technique should also be carefully considered in health-related dataset since it may generate false information that threat people's life.

VI. CONCLUSION

In this work, a framework is introduced for protecting sensitive frequent itemsets in transactional databases, thereby reducing the likelihood of sensitive data leakage. The proposed method performs item swapping strategy by adopting Damerau-Levensthein string similarity algorithm. It creates a pair of transaction using the similarity algorithm and determines items from those two transaction to perform swapping. Therefore, it allows the privacy is kept protected, with minimizing side effects such as minimizing the number of item loss, maintaining data utility, reducing data dissimilarity and keeping the properties of the sanitized dataset remains similar to that of the original one.

The experiment results demonstrate that $D - LSwap$ consistently outperforms the other methods in terms of maintaining the same pattern, dissimilarity minimization, and computational efficiency. $Naive$, while simple, incurs high computational cost and significantly distorts the data, making it less suitable for scenarios requiring high data utility. $Heuristic$ and RaS achieve moderate performance in terms of both utility preservation and efficiency, even so our proposed method outperformed it. These findings suggest that $D - LSwap$ can be a reliable solution for privacy-preserving data publishing for business institutions prior to share their customer transaction data to external parties.

Further exploration in the use of other string similarity algorithms is encouraged to obtain the best pair of transaction records for swapping. In addition, a profound strategy such as using optimization technique for selecting items also necessary for future research to achieve a balance between maintaining both accuracy and efficiency.

A Novel Access Control Model with the Skew Tent Map for Decision Making (STM-ABAC)

Omessead BenMbarak, Anis Naanaa, Sadok ElAsmi
Higher School of Communication, Tunis, Tunisia

***Abstract*—The proliferation of cloud computing exposes sensitive data to the risk of unauthorized access, as traditional access control mechanisms are often inadequate for this dynamic environment. To address these shortcomings, this article proposes a novel access control scheme, named STM-ABAC, which is based on the Skew Tent Map (STM). This scheme is specifically designed to overcome the inherent limitations of traditional Attribute-Based Access Control (ABAC) and Attribute-Based Encryption (ABE) schemes when deployed in dynamic cloud environments. The methodology involves constructing a multi-authority ABAC model, generating verifiable attribute tokens using chaotic sequences, applying LSSS-based policy encryption, and evaluating performance through rigorous formal analysis and experimental benchmarking. The results demonstrate that STM-ABAC reduces the computational overhead during decryption by up to 60% and maintains lower initialization and key-generation costs compared to existing CP-ABE and MA-ABE schemes. Furthermore, security proofs confirm strong resistance to chosen-attribute and chosen-nonce attacks.**

***Keywords*—Cloud computing; skew tent map; ABAC; ABE; attribute token**

I. Introduction

Cloud computing has become an essential foundation for modern information technology landscapes. Distributed storage architectures in the cloud are increasingly adopted by both large enterprises and individual users, offering superior adaptability, scalable storage capabilities, and universal data availability. Furthermore, their inherently distributed nature strengthens data integrity and simplifies collaborative sharing across geographically diverse users.

Despite these significant benefits, several persistent challenges remain. The Top Threats to Cloud Computing 2024 report [1], which gathered insights from over 500 industry experts, identified eleven major security concerns. The study reveals a profound evolution in cloud security risks. Traditional threats, such as denial-of-service (DoS) attacks, shared technology vulnerabilities, and data loss originating from the provider side, are perceived as less critical, reflecting increased confidence in the resilience of cloud infrastructure. Similarly, data breaches—historically the most significant concern—have dropped from the top spot. New issues have surfaced, with Identity and Access Management (IAM) [2] now recognized as the foremost challenge, surpassing concerns like misconfiguration and insufficient change control. This critical shift underscores that contemporary security risks are no longer solely the responsibility of cloud providers but are increasingly tied to user-side governance and effective access control mechanisms.

Consequently, access control serves as a foundational mechanism for guaranteeing the Confidentiality, Integrity, and Availability (CIA) triad) of information. Various access control models have been established in the literature, including Mandatory Access Control (MAC) [3], Discretionary Access Control (DAC) [4], and Role-Based Access Control (RBAC) [5]. However, these models exhibit intrinsic limitations when implemented in the highly distributed and volatile cloud environment. In contrast, Attribute-Based Access Control (ABAC) [6], [7] provides finer-grained authorization and context-aware policy evaluation. Yet, in practical deployment, ABAC often struggles with insufficient adaptability, high communication overhead between its core components (Policy Enforcement Point (PEP), Policy Decision Point (PDP), Policy Administration Point (PAP), and Policy Information Point (PIP)), and limited suitability for real-time applications—especially in vast, multimedia, or latency-sensitive systems.

To address these shortcomings, cryptographic solutions like Attribute-Based Encryption (ABE) have been introduced. Nevertheless, both Key-Policy ABE (KP-ABE) and Ciphertext-Policy ABE (CP-ABE) still face drawbacks, including susceptibility to collusion attacks, inefficient user/attribute revocation, exposure of access policies, reliance on a single trusted authority, and substantial computational demands [8], [9], [10]. To overcome these enduring limitations, this paper introduces a novel ABAC architecture that integrates chaotic dynamics—specifically, the Skew Tent Map (STM). The utilization of chaotic systems in cryptographic design has attracted increasing scholarly interest [11], [12], [13], [14], [15] in recent years, primarily due to their inherent characteristics that align closely with robust security requirements. Research in this area typically follows two main avenues: the use of chaotic sequences for data encryption and secure transmission and the exploitation of chaos to generate shared cryptography keys or secrets between authorized parties. These methods are mutually reinforcing and can be seamlessly incorporated into a cohesive security framework.

Chaotic systems are deterministic nonlinear dynamical systems that demonstrate highly intricate and seemingly random behavior under specific initial conditions. Their chaotic nature is defined by the following core characteristics:

- Extreme Sensitivity to Initial Conditions: Small modifications to the starting state of a chaotic system can lead to exponentially divergent output sequences.
- Bounded State Space: The chaotic behavior remains confined within defined parameters or states.
- Deterministic Operation: Lacking true randomness, the future state of a chaotic system can be simulated accurately given the initial conditions and parameters.

- Aperiodic Dynamics: The behavior of the system is non-repeating, meaning there is no regular pattern in its dynamics.

The remainder of this paper is structured as follows: Section II provides a review of existing work focused on enhancing Attribute-Based Access Control (ABAC) models, particularly those derived from Attribute-Based Encryption (ABE) techniques. Sections III and IV establish the theoretical underpinnings of ABAC and present the proposed Skew Tent Map-based ABAC (STM-ABAC) framework, detailing its architecture, operational flow, and core algorithms. Section V elaborates on the cryptographic mechanisms utilized to ensure secure policy conversion and the dynamic administration of attributes. Section VI furnishes a formal security analysis of the STM-ABAC scheme. Section VII outlines the experimental evaluation and discusses the performance results. Finally, Section VIII offers the conclusion and suggests avenues for future research.

II. Related Work

Traditional authorization frameworks, such as RBAC and ABAC, offer mechanisms for granular and flexible management of access permissions. However, their efficacy diminishes in vast and diverse cloud computing environments, pushing researchers to seek more advanced and integrated methodologies. Prior investigations by Smith et al. [16], Johnson et al. [17], and Brown and Miller [18] emphasize the deficiencies of these standard models, highlighting the critical need for solutions that can provide more precise and secure oversight of data access.

To surmount these constraints, encryption-based access schemes, most notably Attribute-Based Encryption (ABE), have been introduced to guarantee data confidentiality and user privacy. The primary iterations of ABE are Key-Policy ABE (KP-ABE) [19] and Ciphertext-Policy ABE (CP-ABE) [20]. In KP-ABE [21], the access structure is embedded within the user's secret decryption key, while data attributes are linked to the ciphertext. Although this scheme safeguards data secrecy, it faces considerable challenges in dynamic and large-scale policy administration, as modifying any access condition necessitates the regeneration of the key. Conversely, CP-ABE [22] embeds the access policy directly into the ciphertext and associates attributes with the user's key, affording greater adaptability to data owners. Nevertheless, this paradigm also suffers from disadvantages, including substantial computational overhead, inefficient attribute revocation, and reliance on a single central authority. This single point of failure increases the system's susceptibility to compromise and collusion risks.

Furthermore, existing ABE approaches [23] remain restricted in their ability to handle real-time and constantly changing scenarios. ABE and its variants operate using a classic cryptographic structure comprising four stages (Setup, Key Generation, Encryption, and Decryption), whereas the ABAC methodology utilizes four service modules (PEP, PDP, PAP and PIP). This fundamental structural disparity makes ABE schemes inherently ill-suited for the demands of dynamic and time-critical environments.

In addition to this incompatibility, ABE faces several key limitations:

- Inability to assign attributes dynamically: Users' secret keys remain fixed following their initial creation.
- Incompatibility with evolving policies: Access policies are fixed to the ciphertext after encryption and cannot be automatically updated to reflect changes in the system.
- Dependence on a unitary authority: All keys and policies hinge on a single central entity, creating a single point of failure and amplifying the danger of collusion or system breach.

To overcome these constraints, particularly the reliance on a single authority and the fine-grained management of attributes, the Multi-Authority ABE (MA-ABE) model was introduced [24]. This model allows trust to be distributed among multiple authorities while providing more flexible and secure access control. In [25], a MA-ABE provides fine-grained access control over encrypted data and partially addresses the problem of attribute revocation. In [26] and [27], MA-ABE is used to reduce computational and storage overhead on resource-constrained devices while preventing collusion among users. In [28], MA-ABE allows a single execution of the authorization process even when policies originate from multiple authorities, thereby improving scalability. However, despite its advantages in terms of scalability and reduced risk of key compromise, MA-ABE introduces new challenges: synchronization among authorities, increased complexity in key management, and higher latency during policy verification and user revocation. Furthermore, existing works fail to simultaneously integrate all key functionalities: multi-authority, attribute revocation, outsourced encryption, and outsourced decryption. A study in [29] sheds light on several shortcomings in different access control models, requiring solutions capable of:

- Designing an efficient ABAC model that reduces communication and computational complexity while preserving data security.
- Hiding transmitted access policies to protect the confidentiality of recipients.
- Limiting the risk of unauthorized internal access, even when users possess attributes that satisfy the policies.
- Effectively managing dynamic updates of data, attributes, and user revocation without the need to redistribute keys.

To address the aforementioned challenges, the ABAC model should be enhanced with the following four advanced security mechanisms:

- A cryptographically secured policy representation ensures protection against forgery, tampering, and replay attacks.
- Dynamically generated one-time attribute tokens used to represent real-time attribute identifiers. This approach enhances flexibility and minimizes the risk associated with key compromise.
- A cryptographically verifiable decision-making process to ensure the integrity and validity of access decisions.

- Multiple attribute authorities should be deployed to establish a decentralized authorization structure.

Despite significant advancements in ABAC, ABE, and MA-ABE models, a critical functional gap persists that existing systems fail to address simultaneously: the requirement for natively dynamic and cryptographically verifiable access management. ABE-based models, even in their multi-authority versions, are inherently static—they cannot integrate real-time attribute updates nor natively support the ABAC workflow (PEP-PDP-PAP-PIP), remaining vulnerable to collusion and policy exposure. For the first time, the STM-ABAC framework proposed in this paper implements a conceptual breakthrough by integrating the chaotic properties of the Skew Tent Map at three critical levels: the policies, the dynamic attribute tokens, and the access keys. This integration simultaneously ensures: 1) the dynamic generation of single-use attribute tokens, 2) the cryptographic verifiability of the access decision, 3) Policy Hiding, and 4) decentralized multi-authority management. It is this tripartite and dynamic integration of chaos theory that gives STM-ABAC its true novelty and distinctive advantage over conventional schemes based on bilinear cryptography.

III. Construction of the STM-ABAC System

A. Standard ABAC Model

The Attribute-Based Access Control (ABAC) model regulates access based on attributes associated with subjects, objects, and the environment. It dynamically evaluates attribute conditions to decide whether to grant or deny access. As illustrated in Fig. 1 (Appendix), the standard ABAC architecture includes four main components:

- PEP: Receives access requests, forwards them to the PDP, and enforces the returned decision.
- PDP: Evaluates policies from the PAP using attributes supplied by the PIP, and determines access outcomes.
- PIP: Provides required attribute values from external sources such as directories or sensors.
- PAP: Defines and manages access control policies evaluated by the PDP.

B. Fundamental Concepts

The authorization engine compares attribute values with policy rules, producing one of four outcomes: permit, deny, indeterminate, or not applicable [30], [31], [32].

1) Entity: An entity is defined as (S, O, E, A), where S, O, E, and A represent the sets of attributes describing the subject, object, environment, and action.

2) Attributes: Attributes represent entity properties. Each category has its subset: AT_S, AT_O, AT_E, and AT_A.

3) Policy: A policy π specifies the conditions under which subjects can perform actions on objects, formally represented as:

$$\pi = \text{sign}(AT_S, AT_O, AT_E, AT_A), \quad \text{sign} \in \{\text{permit}, \text{deny}\}.$$

The policy set is denoted by $\Pi = \{\pi_1, \pi_2, ..., \pi_n\}$.

C. Proposed STM-ABAC Model

Access control and user data protection during authentication are paramount to preventing security threats. To achieve this, integrating chaotic encryption techniques is crucial. An enhancement to the NIST ABAC model is proposed by combining it with the Skew Tent Map (STM). This approach aims to enhance security while ensuring flexibility and efficiency for dynamic access management in various contexts. Fig. 2 (Appendix) illustrates the interactions between the Attribute Authority (AA), the Policy Center (PC), and the Authorization Service (AS), as well as the information transfers between the algorithms utilized. These interactions demonstrate how the STM-ABAC model handles access requests based on encrypted policies and the defined security attributes.

The new mechanism is described as follows:

- Policy Generation Unit (PGU): This unit interfaces with the PAP and the PolicyGen Algorithm 7 (Appendix) to obtain the relevant policy for the current request. It then produces a cryptographic representation of this policy, referred to as the cryptographic policy (C_Π).
- Attribute Token Generation Unit (ATGU): This unit utilizes the PIP and AttTokGen Algorithm 8 (Appendix) to collect information on attributes and generate corresponding verifiable attribute tokens.
- Policy Decision Unit (PDU): This unit relies on the PDP to make decisions. It evaluates the cryptographic policy (C_Π) against the ATGU attribute tokens provided by the ATGU after performing Policy Decryption to verify the user's authorization status.
- Resource Encryption and Decryption Unit (REDU): This unit operates with the PEP to interpret and redirect access requests to the PDU, decrypt the object, and execute the request based on the permissions granted by the PDU.

D. Workflow of the STM-ABAC Model

The proposed Skew Tent Map-ABAC (STM-ABAC) model integrates a Skew Tent Map encryption scheme within the ABAC framework, leveraging ABE for policy enforcement. The core workflow is divided into two phases: Data Owner Preparation (Setup, PolicyGen, ResourceEncrypt) and User Access (AttTokGen, Validation, Decrypt). This structure ensures secure, fine-grained, and dynamic access control. The following workflow focuses specifically on the User Access phase, initiated upon an authenticated user's request to access a protected object (see Fig. 2) (Appendix).

- Token Generation and Request Initiation: Upon a user's request, the Request Decryption Unit (RDU) retrieves the current user attributes A. It uses the current nonce τ and the chaotic parameters b and T to locally generate the list of attribute tokens, $Tlist$, via the Attribute Token Generation Algorithm 8. The RDU then forwards the request, along with the required token and the current τ, to the Policy Decision Unit (PDU) for validation (steps 1–2).

- Token Validation and Policy Decryption: The PDU retrieves the pre-stored cryptographic policy C_Π and the user's structured secret key K_S.
    - Token Validation: The PDU first verifies the integrity and freshness of the received token against the user's current attributes via the Secure Token Validation Algorithm 9 (Appendix).
    - Policy Decryption: If the token is valid, the PDU proceeds to decrypt the policy C_Π using the user's secret key K_S via the Policy Decryption Algorithm 5 (Appendix). If the attributes embedded in K_S satisfy the LSSS (Linear Secret Sharing Scheme) policy Π, the PDU retrieves the Data Encryption Key e_k.
- Data Decryption and Resource Execution: The PDU securely transmits the retrieved data encryption key e_k to the Request Execution and Decryption Unit (REDU).
    - Chaotic Decryption: The REDU retrieves the encrypted resource C and uses the key e_k as a seed to regenerate the exact chaotic sequence K_{STM} (using the parameters b and T). It then performs the inverse operation (XOR $\oplus$) on C via the Data Decryption Algorithm 6 (Appendix) to recover the original resource data M.
    - Execution: Finally, the REDU executes the requested operation on the decrypted object M on behalf of the user (steps 6–8).

IV. Mathematical and Cryptographic Construction of STM-ABAC

This section focuses on the practical construction of the Attribute-Based Access Control (ABAC) model combined with the STM group system. The key notations used throughout the STM-ABAC construction are summarized in Table I

A. Process of STM-ABAC

The STM-ABAC process is based on the integration of ABE for fine-grained access control, and a Skew Tent Map with a parameter b for data encryption.

The following functions describe the complete workflow, from initialization to data decryption:

- Setup & KeyGen $(A) \rightarrow (K_P, K_M, K_S)$: Algorithm 1 (Appendix), the system initializes public and private parameters. The function takes the user's attributes A and master secrets $K_M = (\delta, \alpha)$ to generate the Structured Secret Key K_S, composed of attribute-specific components required for ABE decryption.
- ResourceEncrypt $(M, e_k, b, T) \rightarrow C$: Algorithm 2 (Appendix), the data owner uses a symmetric data key e_k (session key) as a chaotic seed. This key is transformed by the STM (parameters b and T) into a sequence $K_{Chaotic}$. This sequence encrypts the object M by XOR ($C = M \oplus K_{Chaotic}$), producing the ciphertext C.
- PolicyGen $(K_M, \Pi, e_k) \rightarrow C_\Pi$: Algorithm 7 (Appendix), the Policy Generation Unit (PGU) takes the master key K_M, the access policy Π, and the data key e_k. It uses Π to encrypt e_k according to ABE (LSSS) rules, producing the cryptographic representation of the policy C_Π.
- AttTokGen $(A, \tau, b, T) \rightarrow T_{list}$: Algorithm 8 (Appendix), during an access request, this function takes the current attributes A, the nonce τ, and the chaotic parameters b, T. It generates a list of chaotic, time-limited tokens T_{list} for attribute integrity evaluation.
- PolicyDecrypt $(C_\Pi, K_S) \rightarrow e_k$ or $\perp$: Algorithm 5 (Appendix), the Policy Decision/Decryption Unit (PDU/PDP) uses the user's Secret Key K_S to decrypt C_Π through bilinear pairing operations (ABE). If the attributes in K_S satisfy Π, the data key e_k is successfully recovered.
- DataDecrypt $(C, e_k, b, T) \rightarrow M$: Algorithm 6 (Appendix) Once e_k is recovered, the algorithm uses it as a seed to regenerate the chaotic sequence $K_{Chaotic}$ (with parameters b and T). This sequence is then used to decrypt the ciphertext C via XOR, restoring the original data M.

In STM-ABAC construction, the algorithms are described in detail as follows:

1) System Initialization: Initially, the system performs two main processes: the generation of entity-specific public/private keys and the creation of a structured secret key derived from these keys and the user's attributes.

a) Public and private key generation: Let $\mathbb{G}$ be a bilinear pairing group of prime order p with generators g and h. These parameters are publicly available. The Master Key (K_{MK}) of the Attribute Authority (AA) must contain the master secrets $(\delta, \alpha) \in \mathbb{Z}_p^*$ required for generating the key components. For system setup, the initial private and public keys are defined as:

$$K_M = (\delta, \alpha), \quad K_P = (g, h, g^\delta, g^\alpha)$$

b) Secret key generation: Let A denote the set of attributes associated with the user. The Secret Key K_S is generated by the AA and is structured as a set of attribute-specific components. K_S includes a main component, K_{S_0}, and a pair of components, $(K_{S_j}^{(1)}, K_{S_j}^{(2)})$, for each attribute $a_j \in A$. This ensures ABE granularity.

The generation requires the selection of a random exponent $r_j \in \mathbb{Z}_p^*$ for each attribute a_j. The final structured secret key K_S is defined as:

$$K_S = \{K_{S_0}\} \cup \left\{ \left(a_j, K_{S_j}^{(1)}, K_{S_j}^{(2)} \right) \right\}_{a_j \in A}$$

where the key components are computed using the Master Key secrets (δ, α) and the attribute hash $H(a_j)$ as follows:

TABLE I. SUMMARY OF NOTATIONS

Notation	Description
A	Set of all attributes of an entity
df	Set of all attributes of entity a including the policy center
K_p	Public key
K_M	Private key
K_S	Structured Secret Key (User's attribute keys)
τ	Nonce or time-varying parameter
b	Parameter of the Skew Tent Map
$T_{a,\tau}$	Token for a specified entity attribute a and the nonce τ
C_Π	Policy cryptographic representation
e_k	Session key

$$K_{S_0} = g^{\delta} \cdot g^{\alpha}$$

$$K_{S_j}^{(1)} = g^{r_j}$$

$$K_{S_j}^{(2)} = H(a_j)^{\frac{\delta}{\alpha}} \cdot g^{r_j}$$

The Secret Key K_S, which contains the set of attribute-linked components, is securely transmitted to the data user.

2) Chaotic resource encryption: To ensure secure data confidentiality, the system transforms the data encryption key e_k (obtained via ABE) into a chaotic key stream $K_{Chaotic}$ used to encrypt the resource $\mathbf{M}$.

a) Normalization (Algorithm 3) (Appendix): This process transforms the data encryption key e_k into a proper initial condition for the chaotic system. The key e_k is first converted into an integer. The final value X_0 (the chaotic seed) is obtained by applying a cryptographic hash function H (like SHA-256) to e_k, and normalizing the result to obtain $X_0 \in [0, 1]$.

$$X_0 = \frac{\text{hex2dec}(H(e_k))}{2^{256} - 1}$$

The normalized value X_0 is the initial condition for the Skew Tent Map (STM).

b) Application of the skew tent map transformation (Algorithm 4) (Appendix): The normalized seed X_0 is used to generate the Chaotic Key Stream $K_{Chaotic}$ by performing T iterations of the Skew Tent Map $\mathbf{T_b}(x)$, where T is the required key stream length. The STM function is defined with the control parameter b ($0 < b < 1$):

$$\mathbf{T_b}(x) = \begin{cases} \dfrac{x}{b}, & \text{if } 0 \le x < b \\ \dfrac{1-x}{1-b}, & \text{if } b \le x \le 1 \end{cases}$$

c) Resource data encryption (Algorithm 2) (Appendix): The final encryption step uses the generated Chaotic Key Stream $K_{Chaotic}$ as a one-time pad for a stream cipher. The raw resource data $\mathbf{M}$ is converted into a stream of bits/bytes, and the encryption is performed using the bitwise XOR operation ($\oplus$):

$$\mathbf{C} = \mathbf{M} \oplus K_{Chaotic}$$

The final output $\mathbf{C}$ is the encrypted resource data.

3) Policy generation (Algorithm 7) (Appendix): In the proposed STM-ABAC model, the access policy Π is transformed into a cryptographic representation C_Π to ensure its confidentiality while preserving the authorized access rights.

First, the policy is converted into a matrix representation $(\mathbf{M}, \pi)$ such that $\mathbf{M}$ satisfies the Linear Secret Sharing Scheme (LSSS) requirements and π maps each row of the matrix to the corresponding attribute. A random secret vector $\mathbf{v} = (t, r_2, \ldots, r_n)^T \in \mathbb{R}_p^n$ is generated, containing the secret share t and random values r_i, to compute the coefficients necessary for the cryptographic encoding of the policy.

For each literal $k = 1, \ldots, l$, the coefficient λ_k (the share of the secret t) is calculated as:

$$\lambda_k = M_k \cdot v$$

The corresponding encrypted component p_k is then derived using group exponentiations and multiplication (bilinear operations) to link the encryption to the associated attribute $a_{\pi(k)}$:

$$p_k = g^{\lambda_k} \cdot H(a_{\pi(k)})^{-\lambda_k}$$

where $H(\cdot)$ is a cryptographic hash function, and $a_{\pi(k)}$ represents the attribute associated with the k-th row. The central component p_0 is calculated by encrypting the data encryption key e_k (needed for the chaotic encryption) using the secret share t:

$$p_0 = e_k \cdot g^t$$

The metadata of the policy is defined as:

$$\text{policy_metadata} = \begin{array}{l}\{\,\text{version}: \text{policy_version},\\ \text{expiry}: \text{expiry_time},\\ \text{attributes} = \pi(k)\,\}\end{array}$$

Finally, the complete cryptographic policy is constructed as:

$$C_\Pi = (\Pi, p_0, \{p_k\}_{k=1}^{l}, \text{sign}(\text{policy_metadata}, K_M))$$

where $\text{sign}(\text{policy_metadata}, K_M)$ ensures the authenticity and integrity of the policy using the Master Key K_M. This mathematical representation formalizes the PolicyGen algorithm and enhances its cryptographic precision.

4) Attribute token generation (Algorithm 8): The algorithm takes as input the set of attributes A, the nonce τ, and the two parameters of the chaotic system: the control parameter b and the number of iterations T. The nonce τ represents a timestamp indicating the precise moment of the token's generation. For each attribute value $val_att \in A$, the process is as follows:

a) Chaotic transformation: The attribute value val_att is first normalized into a chaotic seed $N \in [0, 1]$ (using Algorithm 3) (Appendix). This seed then undergoes T iterations of the Skew Tent Map $\mathbf{T_b}(x)$ (using Algorithm 4) (Appendix) to obtain the final chaotic value T_a. This leverages the sensitivity of the chaotic system to ensure that any minute change in the input attribute radically alters the resulting value T_a.

b) Token hashing: The final chaotic value T_a is combined with the nonce τ using a cryptographic hash function H to generate the final, time-limited token $T_{a,\tau}$:

$$T_{a,\tau} = H(T_a \parallel \tau)$$

The nonce τ ensures the token is disposable, immediate, and reduces the need for storage or management. The validity of a token $T_{a,\tau}$ is verified according to the following rules by the Secure Token Validation Algorithm 9 (Appendix):

- The regenerated token $T_{a,\tau}^{\text{Generated}}$ must exactly match the presented token $T_{a,\tau}^{\text{Provided}}$ (constant_time_compare).
- The token's timestamp must be within the valid duration: $\Delta t = t_{\text{current}} - t_{\text{token}} \leq \Delta t_{\text{max}}$.
- Tokens listed in the revocation list are invalid.

If any of these conditions fail, a new token may be generated using a refresh function. Finally, the unique tokens and corresponding timestamps are generated for each entity in the dataset and used for real-time validation by the PDP.

5) Policy and data decryption phase: According to the standard ABAC model and the specific construction, the final access phase is executed by the (AS), which is responsible for implementing the policy decision and decryption processes. Specifically, these steps are carried out by the PDU and the REDU. Assuming that the token verification is successful (i.e., the PDU receives a **TRUE** after executing the Secure Token Validation Algorithm 9), the process continues with two critical decryption steps: ABE and Data Decryption.

a) Policy decryption (Algorithm 5) (Appendix): The PDU executes the Algorithm 5 (Appendix) to retrieve the Data Encryption Key (e_k) using the user's secret key K_S. The PDU takes as input the cryptographic policy C_Π (from the PGU) and the user's Structured Secret Key K_S (from the AA). The core of this algorithm is based on bilinear pairing operations to check if the set of attributes embedded in K_S satisfies the LSSS matrix $\mathbf{M}$ defined by Π. The algorithm first checks if the attributes linked to K_S can satisfy the policy Π. If not, it returns a failure symbol ($\perp$).

After that, the algorithm checks whether the attributes match a subset of policy rows I, the algorithm computes a set of constant weights $\{w_k\}_{k\in I}$ such that:

$$\sum_{k\in I} w_k \cdot M_k = (1, 0, \ldots, 0)$$

The decryption proceeds by calculating the pairing products A and B:

$$A = e(K_{S_0}, p_0), \qquad B = \prod_{k\in I} e(K_{S_k}, p_k)^{-1}$$

The session key e_k is successfully isolated and recovered by dividing A by B in the pairing target group:

$$e_k \leftarrow \frac{A}{B}$$

If e_k is successfully recovered, the PDU has granted authorization and sends the key e_k securely to the REDU.

b) Data decryption (Algorithm 6) (Appendix): The REDU executes the Algorithm 6 (Appendix) using the recovered key e_k to restore the original resource $\mathbf{M}$. The REDU takes as input the encrypted resource $\mathbf{C}$ ($ch_encrypt$), the key e_k, and the chaotic parameters b and T.

The key e_k is used to regenerate the original chaotic seed X_0 through hashing and normalization:

$$X_0 \leftarrow H(e_k) \bmod 1$$

X_0 is iterated T times using the Skew Tent Map $\mathbf{T_b}(x)$ to precisely recreate the Chaotic Key Stream $K_{Chaotic}$.

The sequence $K_{Chaotic}$ is converted into a bit stream (S_{bits}) and used as a one-time pad to decrypt the ciphertext $\mathbf{C}$ (C_{encrypt}) via the bitwise XOR operation:

$$D_{\text{bytes}} \leftarrow C_{\text{encrypt}} \oplus S_{\text{bits}}$$

The resulting decrypted bytes are converted back into the original resource data $\mathbf{M}$ ($df_original$), and the requested operation is executed by the REDU on behalf of the user.

V. Cryptographic Transformation of Access Policies

In the STM-ABAC model, cryptographic techniques are employed to represent and evaluate access policies. Converting XACML policies into a cryptographic form remains a key challenge.

XACML policies consist of rules that verify conditions on the attributes of subjects, objects, environments, and actions. These rules are combined through Boolean operators AND ($\wedge$) and OR ($\vee$), forming a logical policy Π. Typical examples include:

```
Role(S) = Engineer,
Date(E) = Weekday,
Object(O) = BackupFile.
```

each returning a Boolean result.

The logical policy Π is then transformed into a mathematical structure defined by a share-generation matrix M and a permutation function π, within the STM-ABAC model. This process involves two phases: translating Π into a decision tree, and converting it into the pair (M, π). The resulting pair serves as input to the `PolicyGen` algorithm, which produces the cryptographic representation of the access policy. To formalize (M, π), the model relies on the Linear Secret Sharing Scheme (LSSS).

Definition 1 (Linear Secret Sharing Scheme (LSSS))**.** *A scheme is said to be a Linear Secret Sharing Scheme (LSSS) for an access policy* Π *over a finite field* $\mathbb{Z}_p$ *and a set of participants*

$P = \{P_1, P_2, \ldots, P_l\}$ *if it satisfies the following properties:*

- π *is a mapping function that associates each row index* i *of the share-generating matrix with an attribute label* $\pi(i)$.
- M *is an* $l \times n$ *matrix used to generate shares corresponding to the access policy* Π.
- t *denotes the secret value shared over* $\mathbb{Z}_p$.
- *The function* `Share` *computes* $\lambda = M \cdot v$*, producing the share vector* $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_l)$*, where* $v = (t, r_2, \ldots, r_n)^\top$ *is a column vector and* $r_2, \ldots, r_n$ *are random elements from* $\mathbb{Z}_p$.
- *The reconstruction function* `Recons` *retrieves the secret* t *from any authorized set* U *by computing the following equation:*

$$\sum_{i \in I} \omega_i \lambda_i = t, \tag{1}$$

where $\{\omega_i \in \mathbb{Z}_p\}_{i \in I}$ *are known reconstruction constants, and* $I = \{i \mid \pi(i) \in U\}$ *denotes the index set of attributes belonging to* U.

The function π associates each row of M with a specific attribute, meaning that for every index $i = 1, \ldots, l$, the share $\lambda_i = (Mv)_i$ is allocated to the party $P_{\pi(i)}$.

Define the set $I \subseteq \{1, 2, \ldots, l\}$ as $I = \{i : \pi(i) \in U\}$, where U represents any authorized subset of attributes. If the shares $\{\lambda_i = (Mv)_i = M_i \cdot v : i \in I\}$ are possessed by the user, they can calculate the reconstruction constants $\{\omega_i \in \mathbb{Z}_p : \forall i \in I\}$. Consequently, the Eq. (2) holds:

$$\sum(\omega_i M_i) = (1, 0, 0, \ldots, 0) \tag{2}$$

and therefore the secret t can be derived as illustrated in the Eq. (3):

$$\sum \omega_i \lambda_i = \sum \omega_i (M_i \cdot v) = \sum (\omega_i M_i) \cdot v = t \tag{3}$$

where all constants ω_i are public and computable in polynomial time with respect to M.

A. STM-ABAC's Policies and Rules

Drawing from the XACML framework, the STM-ABAC policy repository employs a streamlined policy specification language. An attribute instance is represented as a key-value pair, where the key denotes an attribute name corresponding to an entity in $\{S, O, E, A\}$. For example, in a resource management scenario, `ResourceID(O) = Authform` indicates that the resource ID of object O is `Authform`.

Other examples include `Role(S) = Technician` and `Time(E) = 8:30`.

The policy target is defined through conditions formatted as:

```
subject : Role : Engineer
environment : Date : Weekday
object : Type : BackupFile
```

For example, `Action : ActionID : Read` corresponds to `ActionID(A) = Read`.

As shown in the Fig. 3 (Appendix), the Target specifies that either an Engineer or a Technician is permitted to access the BackupFile:

$$\begin{aligned}\text{target}(S, O, A) := \ & \text{ActionID}(A) = \text{Read} \\ & \wedge \text{ObjectName}(O) = \text{BackupFile} \\ & \wedge \text{Role}(S) \in \{\text{Engineer}, \text{Technician}\}.\end{aligned}$$

The integration of multiple rules is achieved using the following methods:

- **Deny-overrides:** Access is only granted if all rule conditions evaluate to "Permit".
- **Permit-overrides:** Access is granted if at least one rule evaluates to "Permit".

- **Supermajority rule:** Access is granted if more than two-thirds of rule conditions evaluate to "Permit".

Based on the access control policy in Fig. 3 (Appendix), the `Permit-Overrides` method is used to combine rules:

$$can_access(S, O, E, A) := target(S, O, A) \wedge (rule1(S) \vee rule2(S, E))$$

B. Cryptographic Representation of Policies

The translation from Boolean policy representation to (M, π) is achieved via the policy tree. The cryptographic policy is dynamically generated using (M, π) and the `PolicyGen` algorithm.

Consider an IT equipment management system that stores critical information such as IP addresses, MAC addresses, and encryption keys. A robust policy framework is necessary to protect this data. An example policy is defined as:

$can_access(S, O, A, E)$:= [(Role(S) = Engineer $\wedge$ Localisation(E) = LAC) $\vee$ (Role(S) = Technician $\wedge$ Time(E) = Weekday)] $\wedge$ ObjectName(O) = BackupFile $\wedge$ ActionID(A) = Read

Each predicate in the policy is associated with a unique identifier P_i. The policy tree, illustrated in Fig. 4 (Appendix), represents Boolean operators (AND/OR) as internal nodes and attributes as leaves. To construct the share generation matrix M, random elements e_1, e_2, e_3, e_4, e_5 are selected. Since a threshold access structure (n, n) is equivalent to an AND gate, the shares of the secret k are generated using a secret sharing scheme as follows. Consider a random polynomial of degree 2 $f(x) = k + r_2x + r_3x^2$, so that the shares k_1, k_2, and k_3 are given by $k_1 = f(e_1)$, $k_2 = f(e_2)$, and $k_3 = f(e_5)$. For an OR gate, k_{21} and k_{22} are simply defined to be equal to t_2. . Next, a polynomial $g(x) = k_{22} + r_4x$ is constructed to derive the shares of k_{22}, specifically $k_{221} = g(e_2) = f(e_2) + r_4e_3 = k + r_2e_2 + r_3e_2^2 + r_4e_3$ and $t_{222} = g(e_2) = f(e_2) + r_4e_4 = k + r_2e_2 + r_3e_2^2 + r_4e_4$. Using the values e_1, e_2, e_3, e_4, and e_5, along with the equations above, the share generation matrix M can be constructed by the Eq. (4).

$$M = \begin{pmatrix} 1 & e_1 & e_1^2 & 0 \\ 1 & e_2 & e_2^2 & 0 \\ 1 & e_2 & e_2^2 & e_3 \\ 1 & e_2 & e_2^2 & e_4 \\ 1 & e_3 & e_3^2 & 0 \end{pmatrix} \tag{4}$$

The vector $u = (k, r_2, r_3, r_4)$ is defined, where r_2, r_3, and r_4 are selected randomly, as previously described. The share $\lambda_j = M_j \cdot u$ corresponds to the attribute $P_\pi(j)$, with M_j being the j-th row of the matrix M. It is clear that the resulting share vector $(\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5)$ aligns with $(k_1, k_{21}, k_{221}, k_{222}, k_3)$. Thus, the following conclusion is drawn in the Eq. (5):

$$M \cdot u = \begin{pmatrix} M_1 \\ M_2 \\ M_3 \\ M_4 \\ M_5 \end{pmatrix} \cdot (t, r_2, r_3, r_4)^T = (\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5)^T \tag{5}$$

And the mapping function π is

$$\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 1 & 2 & 3 & 4 & 5 \end{pmatrix} \tag{6}$$

The results of Eq. (5) and Eq. (6) will be used in the $PolicyGen$ algorithm to generate the cryptographic.

C. Cryptographic Evaluation of Policies

The cryptographic decision-making process for the cryptographic policy is based on (M,π). To illustrate this process, consider the following request: the subject $Mohammed$, who is an $Engineer$, has a $Read$ request for the file named $BackupFile$ from $Tunis$. This means that three attribute assignments are valid.

$$\begin{aligned} \text{Role}(S) &= \text{Engineer} \\ \text{Localisation}(E) &= \text{Tunis} \\ \text{Name}(O) &= \text{BackupFile} \end{aligned}$$

In the evaluation process of the $Decryptalgorithm$, the set $I = \{i : P_{\pi(i)} \in U\} = \{1, 4, 5\}$ is defined based on the permutation π. Subsequently, the three rows M_1, M_2, and M_5 are selected from the matrix M, corresponding to P_1, P_2, and P_5, to construct a reconstruction matrix. Following this, the existence of values ω_1, ω_2, and ω_5 is checked to ensure they satisfy specific conditions, as expressed in Eq. (7).

$$\omega_1 \cdot M_1 + \omega_2 \cdot M_2 + \omega_5 \cdot M_5 = (1, 0, 0, 0). \tag{7}$$

By doing this, the corresponding values of M_1, M_2, and M_5 are substituted into the equation above, allowing the expression 8 below to be obtained.

$$\begin{gathered} (\omega_1, \omega_2, \omega_5) \cdot \begin{pmatrix} M_1 \\ M_2 \\ M_5 \end{pmatrix} = \\ (\omega_1, \omega_2, \omega_5) \cdot \begin{pmatrix} 1 & e_1 & e_{21} & 0 \\ 1 & e_2 & e_2^2 & 0 \\ 1 & e_3 & e_3^2 & 0 \end{pmatrix} = (1, 0, 0, 0) \end{gathered} \tag{8}$$

So the secret k can be computed according to Eq. (5) and (8) as follows in the Eq. (9):

$$\begin{aligned}\sum_{i\in I}\omega_i\lambda_i &= \omega_1\lambda_1+\omega_2\lambda_2+\omega_5\lambda_5\\ &= (\omega_1,\omega_2,\omega_5)\cdot(\lambda_1,\lambda_2,\lambda_5)^T\\ &= (\omega_1,\omega_2,\omega_5)\cdot\begin{pmatrix}M_1\\M_2\\M_5\end{pmatrix}\cdot(k,r_2,r_3,r_4)^T\\ &= (1,0,0,0)\cdot(k,r_2,r_3,r_4)^T\\ &= k.\end{aligned} \tag{9}$$

This result can be used to determine the session key s_k, which will be retrieved from the policy generation algorithm.

VI. Security Proofs

A. Unforgeability Against Chosen-Attribute Attacks (EUF-CAA)

Attribute Tokens are considered *Existentially Unforgeable Against Chosen-Attribute Attacks (EUF-CAA)* if the scheme guarantees that an adversary cannot create a valid new token for a specific attribute a^*, even after observing numerous previously issued tokens for other attributes. In an ABAC system, this property is crucial against adversaries who select specific attributes to forge a valid token without possessing the associated private key.

The EUF-CAA property can be modeled as an interaction between an adversary and a challenger:

- Challenger: The entity that executes the setup protocol and securely holds the private key.
- Adversary (A): The entity attempting to forge an attribute token.
- Attributes $\{a_i\}$: The set of attributes for which the adversary requests tokens.
- Forge Condition: The adversary wins if they output a triple $(\tau, a^*, T_{a^*,\tau})$ such that $T_{a^*,\tau}$ is a valid token for the attribute a^* with a nonce τ, and a^* has not been previously queried by A.

Theorem 1 (Non-Forgeability of the Attribute Token)**.** *The attribute token scheme is considered existentially (ϵ, q, t)-unforgeable if no adversary A, making at most q queries within a computational limit t, can forge a valid token with probability greater than ϵ. Specifically, the advantage $Adv^{EUF\text{-}CAA}_{STM\text{-}ABAC}(A)$ must be less than ϵ.*

The STM-ABAC scheme ensures that each token $T_{a_i,\tau}$ is highly dependent on the private key and the attribute a_i (via the chaotic transformation). It is therefore practically infeasible for an adversary to generate a valid token $T_{a^*,\tau}$ for any new attribute a^* without the private key. Hence, the attribute token is existentially (ϵ, q, t)-unforgeable against CAA, assuming the computational advantage is bounded. The total time is $t' \preceq t + q \cdot t_Q$, where t_Q is the time required for one token query.

B. Unforgeability Against Chosen-Nonce Attacks (EUF-CNA)

Attribute tokens are *Existentially Unforgeable Against Chosen-Nonce Attacks (EUF-CNA)* if an attacker cannot create a valid token for a new nonce τ^*, even after obtaining multiple tokens for previously chosen nonces.

The EUF-CNA property can be modeled as an interaction between an adversary and a challenger (any entity from $\{S, O, E, A\}$):

- Setup Phase: The challenger prepares the system and securely holds the private key sk_s. The adversary receives the public key pk_s.
- Token Queries Phase: The adversary requests tokens for pairs $\{(a_i, \tau_i)\}_{i=1}^{q}$, where the nonces τ_i are chosen by the adversary. For each pair, the challenger generates a token T_{a_i,τ_i} using the TokenGen function and provides it to the adversary.
- Output Phase (Forge Condition): The adversary produces a triple $(\tau^*, a^*, T_{a^*,\tau^*})$. The adversary succeeds if T_{a^*,τ^*} is a valid token for (a^*, τ^*) and τ^* has not been included in the previously queried set $T = \{\tau_i\}_{i=1}^{q}$.

Theorem 2 (Unforgeability Against Chosen-Nonce Attacks)**.** *The attribute token is existentially (ϵ, q, t)-unforgeable against CNA if no adversary A, with a computational limit t and at most q queries, can produce a valid token with probability greater than ϵ. Formally, the advantage $Adv^{EUF\text{-}CNA}_{STM\text{-}ABAC}(A)$ must be less than ϵ.*

STM-ABAC scheme guarantees that attribute tokens are existentially (ϵ, q, t)-unforgeable against chosen-nonce attacks, assuming bounded computational advantage, where $t' \preceq t + q \cdot t_Q$, and t_Q is the time required for a single token query.

VII. Performance Evaluation

This section presents the performance analysis of the proposed STM-ABAC model. Compared to the schemes presented in [33], [34], [35], [36], which are based on the CP-ABE framework, the proposed model is evaluated in terms of computational efficiency and experimental analysis. A detailed comparison is also conducted between STM-ABAC and existing ABAC-based access control models.

A. Computational Efficiency

To evaluate the computational efficiency of the proposed STM-ABAC model, its computational costs are compared with those of the existing schemes [33], [34], [35], [36], as summarized in Table III (Appendix). The notations and their corresponding descriptions are presented in Table II (Appendix). It should be noted that the computational overhead of multiplication and hash operations is negligible compared to the other operations listed, and the overhead of G_1 is significantly lower than that of G_0 and C_e.

- Setup Phase: The computational cost of all schemes is primarily determined by the exponential operations in G_0 and G_1. Schemes generating parameters for each attribute or authorization incur higher overhead due to

the increased number of exponential operations. STM-ABAC requires $(n+2)G_0+G_1$, which remains lower than most existing schemes, demonstrating efficient initialization.

- Key Generation Phase: All schemes depend on exponential operations in G_0, which increase with the number of attributes in the secret key (k). Multi-authorization schemes, such as those in [35], require additional G_0 operations, resulting in higher overhead. STM-ABAC minimizes G_0 operations to $kG_0 + G_1$, reducing the computational cost during this phase.
- Encryption Phase: The cost of existing schemes [33], [35], [36] is influenced by exponential operations in both G_0 and G_1, while STM-ABAC primarily relies on G_1 operations ($|S|G_1 + LS$). Since G_1 operations are less expensive than G_0, STM-ABAC achieves lower overhead and better scalability as the number of ciphertext attributes ($|S|$) increases.
- Decryption Phase: The overhead in existing schemes varies depending on which groups (G_0, G_1) and ciphertext components (C_e) are involved. STM-ABAC performs decryption using $|S|C_e + LX$, avoiding G_0 operations and thus achieving lower computational cost compared to other schemes, while maintaining efficiency even as the number of attributes satisfying the access structure ($|S|$) grows.

Overall, STM-ABAC consistently demonstrates reduced computational overhead across all phases compared to the existing schemes, confirming its efficiency for secure and scalable attribute-based access control.

In the proposed STM-ABAC scheme, the cost of a pairing operation (C_e) is the most computationally expensive, while the cost of a XOR operation ($\mathbf{X}$) is negligible and serves as the reference, with $\mathbf{C_e} \approx 1000 \times \mathbf{X}$.

The decryption cost is therefore dominated by the pairings used during token generation, whereas data decryption relies on fast XOR operations. Formally, the total cost can be expressed as

$$\text{Cost}_{\text{STM-ABAC}} = \mathcal{O}(|\mathbb{S}| \cdot \mathbf{C_e} + L \cdot \mathbf{X}) \approx 10 \cdot \mathbf{C_e} + 1000 \cdot \mathbf{X}.$$

The data-related cost ($1000 \cdot \mathbf{X}$) is negligible compared to the cryptographic cost and can be approximated as $1 \cdot \mathbf{C_e}$. Hence, the overall decryption cost is largely dominated by token generation ($10 \cdot \mathbf{C_e}$), confirming that the chaotic STM mechanism ensures that the cost of decrypting data remains insignificant relative to the cost of cryptographic operations.

Building upon these results, the STM-ABAC model will be evolved by further optimizing token generation and reducing the pairing overhead. The planned focus is to enhance both the computational efficiency and the scalability of the system, particularly for large-scale cloud environments.

B. Experimental Analysis

To further demonstrate the computational efficiency of the proposed STM-ABAC scheme, a series of comparative experiments was conducted against the reference schemes [33], [34], [35], [36]. The experimental results evaluated the time cost of the schemes as the number of the user's attributes increased. The experiments were implemented using the Python language with the open-source cryptographic library Charm-Crypto (or another suitable Python-based pairing library). The hardware configuration featured an 11th Gen Intel(R) Core(TM) i7-1165G7 @ 2.80 GHz processor running on the Windows 11 operating system.

The experimental results, illustrated collectively in Fig. 5 (Appendix), unequivocally demonstrate the computational efficiency of the proposed STM-ABAC scheme across all phases. Fig. 5a shows that the STM-ABAC model consistently achieves the lowest initialization time, maintaining a near-constant cost despite the increasing number of attributes. During the Key Generation phase (Fig. 5b) (Appendix), the STM-ABAC achieves a significant reduction in computational time (over 70% improvement compared to certain reference schemes) due to the integration of the Skew Tent Map for chaotic key generation. The Encryption time cost (Fig. 5c) (Appendix) also exhibits a lower growth rate, confirming better scalability with larger attribute sets. Finally, Fig. 5d (Appendix) highlights the model's major advantage during Decryption, where it achieves the best overall performance (up to 60% faster than comparable reference schemes), validating its suitability for secure, real-time access control in cloud environments.

C. Comparisons with Related Work

The Table IV (Appendix) compares four attribute-based access control (ABE-ABAC) technologies across five technical criteria, highlighting the limitations of existing schemes (CP-ABE, KP-ABE, MA-ABE) and the advantages of the proposed STM-ABAC model.

Regarding system architecture, CP-ABE and KP-ABE are centralized, creating a single point of failure and potential performance bottlenecks. In contrast, STM-ABAC, like MA-ABE, adopts a distributed architecture, enhancing robustness and scalability for large-scale systems such as cloud environments.

Traditional ABE schemes focus on subject (user) and object (data) attributes. Following the NIST ABAC standard, access control should also consider action (e.g., read/write) and environment (e.g., time/location). STM-ABAC is the only scheme fully implementing this model, enabling more granular and context-aware access control.

For private key management, existing models rely on static cryptographic keys. STM-ABAC introduces a dynamic mechanism where keys depend on initial conditions, parameters, and iteration counts, enhancing security through iterative key derivation.

Regarding policy provision and authorization, STM-ABAC, like CP-ABE and MA-ABE, delegates access decisions to the Data Owner while supporting a multi-authority framework, which is inherited from MA-ABE, thereby increasing flexibility and security.

In summary, STM-ABAC combines the benefits of distributed and multi-authority architectures while introducing enhanced granularity through action and environment attributes,

as well as a dynamic key mechanism, to offer more precise and secure access control.

D. Summary of Performance

This paper makes the following measurable and architectural contributions to the field:

1) High decryption efficiency: The proposed framework demonstrates a reduction in computational overhead during decryption by up to 60% compared to existing CP-ABE and MA-ABE schemes. This efficiency gain is achieved by decoupling the cryptographic policy decryption (ABE) from the final data decryption (lightweight STM XOR operation).

2) Optimized key setup and initialization phases: Lower initialization and key-generation costs are realized compared to existing schemes. Specifically, the initialization time remains nearly constant, irrespective of the number of attributes involved as shown in Fig. 5a (Appendix).

3) Enhanced anti-collusion security: A dynamic access control mechanism is integrated, which ensures strong resistance to chosen-attribute and chosen-nonce attacks (formally proven by Theorem 2).

4) Novel architectural integration: A new framework is presented that natively integrates a multi-authority access control model with policy-hiding and chaos-based encryption. This addresses a significant architectural gap left by previous ABAC and ABE models.

VIII. Conclusion

This paper introduced STM-ABAC, a chaotic-enhanced access control model that addresses the core limitations of traditional ABAC and ABE schemes in dynamic cloud environments. By integrating the Skew Tent Map, the model enables the generation of verifiable and non-forgeable attribute tokens, ensuring secure and real-time policy evaluation while significantly reducing computational overhead. STM-ABAC also incorporates an LSSS-based policy transformation mechanism and a multi-authority architecture fully compatible with ABAC workflows, thereby improving confidentiality, decentralization, and overall system efficiency. The scientific value of the model lies in the unified integration of chaos theory into both policy encryption and attribute validation, offering a resilient and scalable foundation for modern distributed infrastructures. Although reliance on bilinear pairings and the lack of large-scale deployment testing remain limitations, future work will focus on enhancing scalability, integrating machine learning–based trust management, and optimizing chaotic token generation for cloud and IoT environments.

Declaration on Generative AI

The authors declare that generative AI tools (ChatGPT, version GPT-5, by OpenAI) were used solely to assist with language refinement and formatting during the preparation of this manuscript. The use of AI was limited to improving grammar and readability. All content, including the conceptualization, analysis, algorithms, and conclusions, was developed, verified, and edited entirely by the authors, who take full responsibility for the accuracy and integrity of the paper. No generative AI tool was credited as an author.

TABLE IV. COMPARISON BETWEEN EXISTING ABE-ABAC SCHEMES AND STM-ABAC

	CP-ABE [22]	KP-ABE [21]	MA-ABE [25]	STM-ABAC
ABAC Model	Centralized	Centralized	Distributed	Distributed
Attribute Type	Subject, Object	Subject, Object	Subject, Object	Subject, Object, Action, Environment
Private Key Presentation	Encrypted	Private Key	Private Key	Initial Condition, Parameter, Number of Iterations
Policy Provider	Data Owner	User Manager	Data Owner	Data Owner
Attribute Value Authorization KDC	Data Owner	Multiple	Multiple Authorities	Multiple Authorities

Algorithm 1 Secret Key Generation

Input: K_P, K_M, A
Output: K_S
Variables: g, h (group generators); α, δ (master secrets from K_M)
Begin
Compute $K_{S_0} \leftarrow g^{\delta} \cdot g^{\alpha}$;
Initialize $K_S \leftarrow \{K_{S_0}\}$;
for each attribute $a_j \in A$ **do**
    Choose a random $r_j \in_R \mathbb{Z}_p^*$;
    Compute $K_{S_j}^{(1)} \leftarrow g^{r_j}$; // First key component
    Compute $K_{S_j}^{(2)} \leftarrow H(a_j)^{\frac{\delta}{\alpha}} \cdot g^{r_j}$;
    Add $(a_j, K_{S_j}^{(1)}, K_{S_j}^{(2)})$ to K_S;
end for
return K_S

Algorithm 2 Resource Data Encryption

Input: $\mathbf{M}$, $\mathbf{e_k}$
Output: $\mathbf{C}$
Begin
$K_{Chaotic} \leftarrow$ ChaoticSequence(e_k, b, T);
$\mathbf{C} \leftarrow \mathbf{M} \oplus K_{Chaotic}$;
return $\mathbf{C}$

Algorithm 3 Normalization using Hash Function

Input: LISTE $df = [A_S, A_E, A_A, A_O]$
Output: $df_{\text{normalized}}$
begin
for each attribute i in df **do**
  $val \leftarrow df[i]$
  $hash_val \leftarrow$ SHA-256(val)
  $H \leftarrow$ hex2dec$(hash_val)$
  $N \leftarrow \frac{H}{2^{256}-1}$
  $df_{\text{normalized}}[i] \leftarrow N$
end for
return $df_{\text{normalized}}$

Algorithm 4 Skew Tent Map Sequence Generation

Input: $df_normalized$, b, T { b: STM parameter $0 < b < 1$, T: number of iterations}
Output: $df_skewtent$ {Table of generated chaotic sequences S}
STM Fonction:
$\mathbf{T_b}(x) = \begin{cases} x/b & \text{si } 0 \leq x < b \\ (1-x)/(1-b) & \text{si } b \leq x \leq 1 \end{cases}$
begin
for each attribute i in $df_normalized$ **do**
  $X_0 \leftarrow df_normalized[i]$
  $X_{current} \leftarrow X_0$
  Initialize $S_i \leftarrow []$
  for $t = 1$ to T **do**
    $X_{next} \leftarrow \mathbf{T_b}(X_{current})$
    S_i.append(X_{next})
    $X_{current} \leftarrow X_{next}$
  end for
  $df_skewtent[i] \leftarrow S_i$
end for

return $df_skewtent$

Algorithm 5 Policy Decryption Algorithm

Input: $C_\Pi = (\Pi, p_0, \{p_k\}_{k=1}^{l})$, K_S, I
Output: e_k or $\perp$
Begin
if K_S does not satisfy Π **then**
  return $\perp$
end if
Determine reconstruction coefficients$\{w_k\}_{k\in I} \in \mathbb{Z}_p^*$

$$\sum_{k\in I} w_k \cdot M_k = (1, 0, \ldots, 0)$$

$A \leftarrow e(K_{S_0}, p_0)$
$B \leftarrow 1$
for each $k \in I$ **do**
  $a_{\pi(k)} \leftarrow$ line-related attribute k
  Extract $K_{S,\text{comp1}}$ and $K_{S,\text{comp2}}$ de K_S for the attribute $a_{\pi(k)}$
  $D_k \leftarrow e(p_k, K_{S,1}) \cdot e(H(a_{\pi(k)}), K_{S,2})$
  $B \leftarrow B \cdot (D_k)^{-w_k}$
end for
$e_k \leftarrow A/B$ {Isolate the key e_k}
return e_k

Algorithm 6 Data Decryption Algorithm

Input: $ch_encrypt$, e_k, b, T
Output: $df_original$
Begin
$X_0 \leftarrow H(e_k) \bmod 1$
$X_{\text{current}} \leftarrow X_0$
$K_{\text{Chaotic}} \leftarrow []$

for $t = 1$ **to** T **do**
  $X_{\text{current}} \leftarrow T_b(X_{\text{current}})$
  K_{Chaotic}.append(X_{current})
end for
$S_{\text{bits}} \leftarrow$ ConvertirEnBinaire(K_{Chaotic})

$df_original \leftarrow []$
for each cipher bloc I in $ch_encrypt$ **do**
  Separate IV and C_{encrypt} from I
  $D_{\text{bytes}} \leftarrow C_{\text{encrypt}} \oplus S_{\text{bits}}$
  $D_{\text{string}} \leftarrow$ Convertir(D_{bytes}, "text")
  $df_original$.append(D_{string})
end for
return $df_original$

Algorithm 7 Policy Generation Algorithm

Input: K_M, Π, e_k, $policy_version$, $expiry_time$, g, H
Output: $(C_\Pi, policy_metadata)$
begin
$(M, \pi) \leftarrow$ generate_matrix(Π)
assert M satisfies LSSS requirements
$v \leftarrow (t, r_2, \ldots, r_n)^T \in \mathbb{R}_p^n$
$p_0 \leftarrow e_k \cdot g^t$
$policy_metadata \leftarrow \{\text{version} : policy_version, \text{expiry} : expiry_time\}$
$policy_metadata.attributes \leftarrow []$
for $k = 1$ to l **do**
  $\lambda_k \leftarrow M_k \cdot v$
  $p_k \leftarrow g^{\lambda_k} \cdot H(a_{\pi(k)})^{-\lambda_k}$
  $policy_metadata.attributes$.append($\pi(k)$)
end for
$sig \leftarrow \text{sign}(policy_metadata, K_M)$
$C_\Pi \leftarrow (\Pi, p_0, \{p_k\}_{k=1}^l, sig)$
return $(C_\Pi, policy_metadata)$

Algorithm 8 Attribute Token Generation

Input: A , τ, b , T
Output: T_{list}
Begin
Initialize $T_{list} \leftarrow []$
for each $val_att \in A$ **do**
  $N \leftarrow$ Normalization(val_att)
  $X_{current} \leftarrow N$
  for $t = 1$ to T **do**
    if $0 \leq X_{current} < b$ **then**
      $X_{current} \leftarrow X_{current}/b$
    else if $b \leq X_{current} \leq 1$ **then**
      $X_{current} \leftarrow (1 - X_{current})/(1 - b)$
    end if
  end for
  $T_a \leftarrow X_{current}$
  $T_{a,\tau} \leftarrow H(T_a \parallel \tau)$
  T_{list}.append($T_{a,\tau}$)
end for
Return T_{list}

Algorithm 9 Secure Attribute Token Validation

Input: A, $T_{\text{list, received}}$, τ_{current}, b, T, $revocation_list$
Output: Boolean (True/False)
begin
if $A \in revocation_list$ **then**
  return False
end if
$T_{\text{list, expected}} \leftarrow \text{AttTokGen}(A, \tau_{\text{current}}, b, T)$
if constant_time_compare($T_{\text{list, received}}, T_{\text{list, expected}}$) **then**
  return True
else
  log_security_event("Invalid token attempt or expired Nonce")
  return False
end if

A Novel Approach for Urban Traffic Congestion Prediction

***Abstract*—Traffic congestion is a global problem in urban areas that creates longer travel times, increased fuel consumption, and elevated levels of pollution. Traffic congestion occurs because of the exponential growth of vehicles along with a finite number of roadways and the inability to manage traffic effectively. This paper studies the question: How well can traffic type factors be used as a predictor for determining the severity of traffic congestion? To answer this question, we present a new methodology to perform clustering and classification based on various types of traffic indicators. In addition, traffic indicators (such as size of roadway, speed of vehicles, number of vehicles, and level of traffic flow) are categorized by using two distinct classifications: homogeneous and heterogeneous. Using these categories, we then apply a modified version of the Density-Based Spatial Clustering of Applications with Noise (DBSCAN) algorithm to do clustering of traffic indicators. The resultant label from the clustering process is then used to develop a prediction model that will provide information regarding the level of traffic congestion along a selected roadway. Results from our experiments were conducted using an actual dataset and demonstrate that our proposed method produced an accuracy rate of 93% with 92% precision and recall, and therefore, outperforming other current methodologies used for predicting traffic congestion. Overall, these findings indicate that incorporating an analysis of traffic type factors into the clustering and classification methodology can result in more accurate predictions of traffic congestion.**

I. Introduction

Urban traffic congestion [1] is a significant challenge in modern cities, impacting daily commutes, fuel consumption, and environmental sustainability. Traffic congestion arises due to an imbalance between the increasing number of vehicles and the capacity of road infrastructure [2]. External factors such as weather conditions [3], peak hours, and road incidents further exacerbate this issue, making congestion prediction and management crucial for efficient urban mobility. Several approaches have been explored to tackle this issue [4]. Traditional traffic prediction models [5]–[7] rely on statistical methods and machine learning algorithms [8]. Recent advancements include deep learning-based techniques such as LSTMs and Bi-LSTMs for short-term traffic flow prediction [9], big data integration with deep learning for large-scale traffic forecasting [10], and hybrid swarm intelligence algorithms for route optimization [11]. While these approaches have demonstrated promising results, they face limitations such as high computational costs, lack of real-time adaptability, and challenges in handling noisy traffic data [12].

Apart from lowering traffic efficiency, urban traffic congestion incurs huge financial losses as well as environmental degradation. Traffic congestion in highly urbanized cities results in higher fuel usage and vehicle emissions, thereby contributing to higher risks to public health and air pollution, according to studies [13]. Additionally, the commuters themselves experience stress and reduced quality of life through traffic jams, making the critical need for smart traffic management systems arise that can learn to keep pace with the changing trends of urban traffic [14].

Advanced traffic control techniques like adaptive signal control, dynamic route guidance, and price-demand responsiveness are made possible through accurate and timely traffic congestion prediction. But urban transportation networks are highly spatial-temporal in complexity, so modeling them is quite hard Models with the capacity to discern local and network-wide interactions are needed since traffic at a point can spread and impact neighboring regions. To generate reliable, scalable, and comprehensible congestion predictions that facilitate smarter urban mobility planning, our system integrates static infrastructure data with dynamic traffic attributes through sophisticated clustering and graph-based learning techniques [15].

Despite these advancements, existing methods often fail to integrate both static (unvaried) and dynamic (varied) traffic factors effectively. Some studies focus on real-time traffic variations, such as vehicle speed and density, while neglecting the influence of fixed constraints like road infrastructure and historical traffic patterns [16]. Others emphasize static features, but lack adaptability to sudden traffic fluctuations caused by external factors like weather or road incidents [18], [19]. The main objective of the current research study is to answer the following research question: What advantages does the incorporation of unvaried and varied traffic features with enhanced clustering methods and graph-based classification bring to the accurate prediction of urban traffic congestion?

To answer this question, this study suggests a novel hybrid strategy that combines supervised and unsupervised learning methods to tackle both diversely changing (dynamic) and stably unchanging (static) traffic measurements concurrently. In particular, we suggest an optimized DBSCAN clustering algorithm that incorporates traffic-related domain constraints

and improves parameter selection sensitivity to better handle heterogeneous and noisy traffic data. This allows traffic patterns to be more forcefully structured, reflecting the underlying structure of real-world situations.

We use the resulting cluster labels as an input layer for classifying traffic states after the clustering process. Then, with topological relationships between road segments, a Graph Convolutional Network (GCN) predicts traffic congestion levels. Spatial interdependencies and network-wide interactions underlying congestion dynamics are captured using this graph-based approach. Our model can make precise, scalable, and explainable predictions by integrating time-dependent features (e.g., speed of vehicles, flow, and density) with infrastructure-related static attributes (e.g., lane number and road length). Two-faceted learning in this way empowers real-time responsiveness and smart decision-making in urban traffic management systems, revealing a fuller picture of traffic status.

The remainder of this paper is structured as follows: Section II reviews the related work. Section III presents the problem definition and describes the use of DBSCAN for clustering. Section IV details our proposed approach. Section V discusses the experimental results and compares the performance of our method with existing approaches. Finally, Section VI concludes the paper and outlines future research directions.

II. Related Work

By merging traffic flow physics with spatio-temporal graph neural networks, this study [20] presents the Physics-Guided Spatio-Temporal Graph Neural Network (PG-STGNN), a model for predicting traffic flow at city intersections. With the help of a step-by-step technique, the model goal is to improve short term traffic prediction accuracy by merging essential traffic features like queue building and signal schedule. The framework has mainly applied to crossroads and short-term estimation tasks but however provides a structured manner of giving physical traffic dynamics in combination with deep learning approaches. the particularity can make it less relevant for more Far-reaching or sophisticated traffic Circumstances, Especially where long term analysis or congestion Segmentation is needed. Moreover, the framework might be less Adjustable if utilized in datasets with no such specific field Awareness since it relies on complex tangible simulation.

Authors in [21] presented three most crucial sections Are assimilated to present a novel AI-biased approach for predicting traffic congestion: a Consistent Lizard Search Optimization (CLSO) algorithm to elevate the precision of forecasting; a Paramount Transfer Learning Network (PTLN) for congestion level Classification; and a Cascaded Transition Recurrent Feature Network (CTRFN) to find Pertinent traffic features. The outcome is Created to Surmount major Disadvantages of current approaches with regard to computation operating costs, weak data processing, and extreme error prediction. The structure's reliance on heavy deep learning and optimization components may hamper scalability and real-time response capability, despite exemplifying an orderly approach in managing traffic data and trying to increase the accuracy of forecasts. In addition The system performance can be limited in noisy, incomplete, or heterogeneous urban traffic data environments in dynamic city scenarios due to the assumption of clean and structured dataset availability.

Through the use of linear regression models, feed forward neural networks (FFNN), and radial basis function neural networks (RBFNN), this study [22] proposes a machine learning-based prediction solution to reduce traffic congestion in Beirut. In forecasting congestion, the system takes into account wait times at intersections, time of day, day of week, holidays, and meteorological conditions (e.g., rain). FFNNs were found to work best. The absence of long-term transportation planning and the use of Lebanese reliance on poor infrastructure is also highlighted in the study. While the methodology considers various models and bases its analysis on real-time data, it overlooks key factors of implementation including data noise, scalability at the regional scale, and integration with big traffic management systems. The application of long-term traffic management techniques or the viability of implementation in the real world remains restricted.

To minimize traffic jams at intersections within smart cities, authors in [23] suggests a cloud-based traffic congestion prediction model with a hybrid Neuro-Fuzzy solution. It enhances traffic control automation with IoT sensor feeds and intelligent decision-making. The Neuro-Fuzzy model adapts dynamically to traffic patterns through combining the programmability of fuzzy logic and learning from neural networks. System scalability and data preparation are made possible through the cloud environment. The technique has several drawbacks, including no field testing, reliance on sensor accuracy, and no account being taken of the difficulties in large-scale rollout and integration with current infrastructure. The model's effectiveness in real urban settings is undermined by its failure to project possible lag in cloud computing and difficulty in real-time decision-making amid dynamic traffic conditions.

To improve traffic prediction, this paper [24] introduces the Congestion-based Traffic Prediction Model (CTPM), a new model that combines congestion propagation patterns with existing prediction frameworks. CTPM uses external congestion data to enhance predictions without overriding existing systems, unlike classical models that often fail during abnormally fluctuating traffic conditions. In order to maximize resource allocation, including dynamic traffic control and lane management, the model highlights the significance of knowing how congestion develops across road networks. The strategy, however, has a number of drawbacks, including the need for sophisticated integration into existing infrastructure, the reliance on the amount and quality of available data, and difficulty handling small data sets. Besides, it is also unclear how well the model handles extremely dynamic, real-time environments, especially urban areas with non-uniform traffic patterns and weak sensor coverage.

To enhance the accuracy and scalability of machine learning-based models, authors in [25] suggests a mixed traffic flow prediction method that integrates historical data and road network topology. Since conventional models utilize single-point data and possess limited contextual knowledge regarding traffic behavior over a network, they often cannot identify real-time anomalies. To overcome this, the suggested method involves road interconnectivity structural information, enhancing prediction and making traffic control measures more efficient. The method is not without limitations, however, because the

addition of topology expands processing requirements and model complexity, which may constrain real-time implementations. Further, usability in sparsely instrumented environments will be constrained because of a dependence on highly accurate and detailed network data.

While previous works on congestion prediction show some impact, limitations were identified for all of the analysed studies on this topic. Many of the studies that utilized DBSCAN-type methods, along with hybrid techniques, do not have the ability to effectively identify static and dynamic traffic flows from the same analysis. Typically, models that adopted this approach denote both static and dynamic as separate; thus limiting their ability to accurately predict congestion in real-time. Likewise, GNN and deep learning approaches do not take into consideration the significance of spatial relationships between road segments. Other studies also assumed the use of entirely structured and noise-free datasets, leading to a lack of robustness for these models in practice. Regardless of data types, models were seldom subjected to case-specific testing or developed to be scalable. Thus, these limitations supported the rationale for our proposed methodology that enhances the integration of improved DBSCAN clustering methods with GCN-based classification methods by considering both static and dynamic vehicular conditions, resulting in improved accuracy and increased feasibility.

III. Preliminaries

This section introduces the background material required for this work, including the character of the traffic data, graph learning, clustering algorithms, and an introduction to the utilized Graph Convolutional Networks (GCNs) to predict congestion.

A. Problem Definition

In traffic analysis, varied traffic factors (e.g., speed and number of vehicles) are dynamic and change rapidly depending on time, location, or road conditions. On the other hand, unvaried traffic factors (e.g., route dimensions, road type, infrastructure) remain constant over time but still play a crucial role in congestion. By subdividing traffic factors into these two categories, we can better model the traffic system, enabling us to:

1) Differentiate dynamic influences: The varied factors capture real-time fluctuations in traffic, whereas unvaried factors provide a stable foundation for traffic patterns.

2) Increase prediction accuracy: This separation allows more precise models, as varied factors contribute directly to congestion level fluctuations, while unvaried factors help to contextualize these changes.

3) Improve clustering and classification: It aids in selecting the most relevant features for clustering and classification algorithms, reducing noise in data processing by treating dynamic factors differently from static ones.

Clustering is essential in traffic congestion analysis [26] to manage the complexity and variability of traffic data by grouping similar patterns, such as “low”, “medium” and “high” congestion levels. DBSCAN is preferred for this task because it is robust to noise and outliers, which are common in traffic data, and it can discover clusters of varying shapes and densities without requiring the number of clusters to be specified in advance. This makes DBSCAN ideal for identifying natural congestion patterns. Clustering with DBSCAN enhances prediction accuracy, reduces noise, and allows more efficient traffic management and resource allocation.

GNNs can provide a preferred traffic congestion classification because they are well suited for handling the graph-like structure of traffic networks [27], where intersections are nodes and roads are edges. GNNs excel at capturing the varied and unvaried dependencies and relationships between connected traffic points, allowing for a more accurate prediction of congestion levels across the network. They can model how congestion at one point affects surrounding areas, providing a more context-aware classification. By leveraging this structure, GNNs improve the accuracy of congestion predictions and can efficiently classify traffic into “low”, “medium” and “high” congestion levels, even in complex, large-scale networks.

It is usually difficult for traditional models to properly combine both varied and unvaried congestion constraints. In order to overcome these constraints, this paper suggests a hybrid DBSCAN-GNN model that uses graph-based learning for classification and density-based clustering for congestion pattern identification.

B. DBSCAN Algorithm

DBSCAN technique [28], one of the density-based clustering techniques, is used to group data of any type out of a large amount of data when there are noises and outliers. The key benefit of the DBSCAN technique over partition and hierarchical cluster algorithm is as follows, as depicted in Fig. 1:

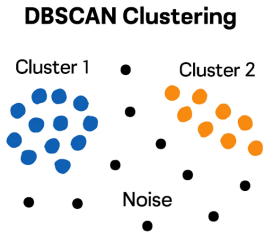

Fig. 1. Visualization of clusters formed by the DBSCAN algorithm.

- The DBSCAN algorithm is not limited to spherical or convex shapes but can be applied to any arbitrary shape. Because of this, it is far more practical than other algorithms like kmeans.
- Because the name itself indicates, the major benefit of this algorithm is that it will work properly even when there is noise and outliers. DBSCAN is a good method because other techniques will not work effectively with noise. (Those points which are different or greater than the original point are called noise and outliers.) With the help of Minpts in the clusters, it does not include noise and outliers.

The role of DBSCAN is the identification of the noise and clusters within a spatial database. Researchers need to know

the Eps and MinPts parameters for each cluster as well as at least one point of the cluster. With the appropriate parameters, it can then identify all the point density-reachable from the known location provided [2]. The cluster is formed with the DBSCAN implementing the two significant parameters, minPts and eps:

- eps(ϵ): It is the radius which encloses the point to be used for looking for points near to it. It is utilized to calculate the density of the area. It will create low-density clusters when a huge ϵ value is utilized.
- minPts: It is the number of points that must be found in the surrounding (eps distance from the point) to form a cluster. A good algorithm must not have extremely small minPts.

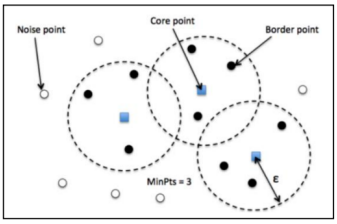

Fig. 2. DBSCAN clustering process showing core, border, and noise points.

Once the DBSCAN algorithm is executed on any data set, researchers essentially obtain three varieties of points (Fig. 2):

- Core: If there are many clusters, this is the spot from where there are at least k other points that fall inside radius r.
- Border: Any area with one or more central points in the distance r may be referred to as a border.
- Noise: Any point that contains at least k points within a distance of r and is neither a core nor a boundary.

IV. Proposed Approach

The predicted traffic congestion architecture is presented in this section. To learn spatial-temporal correlations and effectively predict the level of congestion, the model combines data collection, preprocessing, enhanced DBSCAN clustering, and a GCN-based classification module.

A. Architecture Overview

The architecture of the suggested traffic congestion forecasting framework is depicted in Fig. 3. To make precise predictions of congestion, the model is trained to utilize both dynamic and static traffic information. To capture continuous streams of traffic variables like vehicle speed, vehicle counts, lane counts, and route parameters, the pipeline starts with raw traffic data capture. To provide equivalence among disparate sensors as well as time periods, the information collected is preprocessed through cleaning, normalization, and temporal alignment.

The data is then divided into unvaried factors, constant features that remain the same over time like the number of lanes or route length, and varied factors, dynamic features that change, like traffic flow and vehicle speed. A better DBSCAN module utilizes these features and uses them to divide the road network according to congestion patterns and identify traffic trends. The model can denoise the input data and identify geographical interdependence by grouping similarly occurring traffic conditions.

A Graph Convolutional Network (GCN), mimicking the sophisticated spatial-temporal relationships between various road segments, subsequently receives the cluster data. For a correct prediction of congestion levels for every segment, the GCN leverages the road network topology and the traffic patterns learnt while clustering. The output layer finally offers real-time congestion level prediction, facilitating useful information for traffic control and route optimization.

Every stage of this architecture, from data preprocessing to clustering and GCN classification, improves prediction performance while ensuring computing economy. It is heavily based on modular and interpretable design. The model is amenable to smart city applications and real-time traffic analysis because it efficiently solves the problems caused by dynamic traffic environments through the integration of spatial and temporal information.

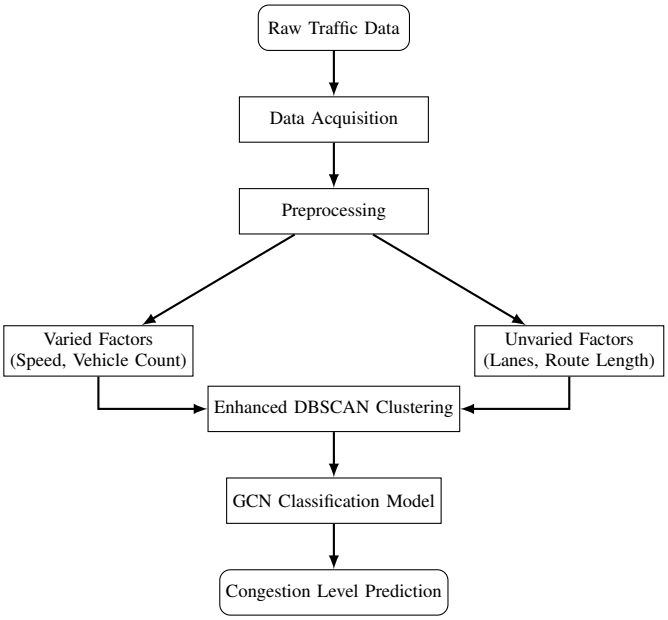

Fig. 3. Compact architecture overview of the proposed traffic congestion prediction model.

B. Traffic Congestion Factors

A variety of key restrictions that fall into two general categories varied and unvaried factors must be evaluated in order to forecast traffic congestion using Internet of Things networks. A few examples of generally fixed (unvaried) factors are the route's length, the average traffic flow, and customary vehicle behavior patterns. These components remain consistent over time and provide a fundamental understanding of traffic patterns. Varied factors present a more difficult challenge, as they are dynamic and change over time. Examples of these varied factors include weather, which can quickly alter road conditions; the route's distinctive and evolving nature (such as

whether it is an urban road, highway, or frequently congested area); temporal elements such as rush hours or special events that significantly impact traffic volumes; the behavior of other vehicles on the road; the surrounding environment (such as roadwork and urban development); and the varying speeds of vehicles. Predicting traffic congestion is a very difficult challenge due to the intricate interactions between these two sets of constraints: fixed and dynamic.

Although unvaried factors help establish baseline traffic patterns, varied factors introduce an element of unpredictability, often requiring efficient real-time data management. For example, unforeseen road closures or adverse weather can suddenly turn an otherwise uncongested route into a bottleneck. Similarly, any reliable traffic prediction model must take into account time-dependent varied factors, such as rush hours, special events, or weekend traffic patterns. As shown in Table I, the predicting traffic congestion issue utilizing IoT networks is assessed using two key constraints which are unvaried such as, dimension of route distance, traffic low, pattern current vehicle conditions, and varied like : weather conditions, special nature of route, temporal nature of route, other vehicles pattern conditions, route environment, and vehicle speed. Our main objective is to develop a model that makes this task more efficient, because the related mechanisms particularly consider some constraints to deal with this problem, it is vital to explore all of them for effective congestion prediction.

A comprehensive knowledge of the interplay between these components is necessary for the precise forecasting of traffic congestion. Varied factors introduce layers of complexity that require dynamic handling, whereas unvaried factors set the scene by providing insights on typical traffic flow and bottleneck points. These elements work together to define the traffic environment, and it is crucial to take them into account when forecasting and handling congestion. The complexity of traffic circumstances emphasizes the value of using real-time data, advanced algorithms, and a thorough grasp of the different factors influencing traffic congestion.

Algorithm 1 DBSCAN Clustering with Congestion Estimation

Initialize:
Set core points $\Omega \leftarrow \emptyset$
Set unvisited points $F \leftarrow D$
Set clusters $C \leftarrow \emptyset$
Set cluster index $k \leftarrow 0$
Set congestion levels based on cluster density
Core Point Identification:
for each point x_i in D **do**
  Compute ϵ-neighborhood of x_i
  if number of neighbors $\geq$ MinPts **then**
    Add x_i to core points Ω
  end if
end for
Cluster Formation:
while Ω is not empty **do**
  Pick a core point o from Ω
  Create a new cluster C^k including o
  Expand the cluster with ϵ-neighbors of core points
  Remove processed points from F
  Update clusters C and increment k
  Remove core point o from Ω
end while
Estimate Congestion Levels:
for each cluster C^k **do**
  Compute cluster density
  if density is low **then**
    Assign congestion level to Low
  else if density is medium **then**
    Assign congestion level to Medium
  else
    Assign congestion level to High
  end if
end for
Handle Noise:
Points not included in any cluster are labeled as noise.

C. DBSCAN for Traffic Data Clustering

The Algorithm 1 is intended to cluster data via the DBSCAN technique, and then estimate the congestion level. It first initializes the cluster index and sets up the core points, unvisited points, and clusters. Finding each data point's ϵ-neighborhood and designating those with enough neighbors (more than or equal to MinPts) as core points constitute the core point identification step. The algorithm chooses core points iteratively, forms clusters, enlarges them with nearby core points, and updates the list of unvisited sites during the cluster building process. Lastly, it computes cluster densities and allocates congestion levels (Low, Medium, High) according to these densities in order to estimate congestion levels. Noise is defined as points that do not fit into any cluster.

D. Traffic Congestion Classification Using GNN with Temporal Extensions

Graph-structured data, such social connections or road networks, is processed using GNNs [36], a specific kind of neural network. While graphs have been the subject of applications for traditional neural networks such as Convolutional Neural Networks (CNNs) [37] and Recurrent Neural Networks (RNNs) [38], GNNs are better suited for these kinds of jobs. Since its debut in 2005, supervised, unsupervised, and reinforcement learning have all seen a significant increase in interest in GNNs because of their versatility.

As a robust mechanism For exploring graph structured data, Containing traffic networks, Graph Neural Networks (GNNs) transmit messages among nodes to record spatial associations. GNNs can effectively replicate the time changing character of traffic By integrating temporal frameworks like LSTM and learning Trends out of previous data to predict future traffic congestion. This fusion enables to utilize a dynamic framework in which Adjustments to the traffic network, Comparable to accidents or closures, could be provided in the graph Architecture as the system Is in training. Additionally, by Measuring the Meaning of Diverse nodes, Complex GNN topologies similar to Graph Attention Networks (GATs) [39] Enhance the prediction of accuracy Beyond enabling the model to concentrate on important congestion regions. because of these specifications, GNNs are Particularly well Appropriate for predicting real-time traffic congestion because they could Simultaneously capture Each of the two spatial and temporal dependencies.

GNNs are being used in smart cities for practical purposes [40], such as route planning and traffic light optimization to reduce congestion. GNNs are more effective at capturing intricate, non-grid road structures than previous models, which makes them more appropriate for large-scale, irregular road networks. Additionally, the model's ability to prioritize important traffic nodes is made possible by innovations like Graph Attention Networks (GATs), which raise the accuracy of congestion prediction.

The traffic data in a GNN with Temporal Extensions is shown as a graph G = (V, E), where:

- V The total number of nodes that represent traffic locations.
- E The set of edges (i.e., route links) that link each node.

By combining data from nearby nodes, a process known as graph convolution, the model is able to represent the spatial dependencies. Through this procedure, the model is able to understand how surrounding sites affect the traffic conditions at a certain location.

In order to simulate how traffic conditions change over time, the temporal part of the model incorporates temporal graph convolutions or recurrent mechanisms like gated recurrent units (GRUs) or LSTMs [41]. The network can anticipate traffic congestion in upcoming time steps because to the combination of temporal and graph modeling.

There are two primary parts to the temporal Graph Neural Network (GNN) model that was employed in this research. GNNs improve congestion class accuracy by allowing traffic information to spread between nodes, as opposed to traditional machine learning techniques, which treat individual road segments separately. The first layer is the Graph Convolution Layer, which represents the spatial connections between the graph's nodes. The graph convolution for a node $v \in V$ at time t is defined in Eq. (1) [42] as follows:

$$H_t^{(l+1)} = \sigma\left(\sum_{u \in N(v)} \frac{1}{c_{vu}} W^{(l)} H_t^{(l)}(u)\right) \quad (1)$$

where, $sigma$ is a non-linear activation function, $N(v)$ is the set of surrounding nodes of v, c_{vu} is the normalization constant, $W^{(l)}$ is the learnable weight matrix, and $H_t^{(l)}$ is the hidden state of node v at layer l and time t.

The Temporal Extension, a second element, simulates how node properties change over time. It is possible to employ a temporal convolution or a recurrent neural network (such as GRU or LSTM). For example, at time $t+1$, the hidden state of a node is changed as follows in Eq. (2) [43]:

$$H_{t+1} = \text{GRU}(H_t, X_t) \quad (2)$$

where, the traffic data input at time t is denoted by X_t.

The traffic observation network is represented as a graph in this study, with nodes standing in for traffic observation stations and edges for connectivity between places. At each node, traffic data, including vehicle count and speed, is gathered over time to create a time-series of graph-structured data.

For capturing the temporal dynamics of traffic across time, as well as the spatial dependencies between observation stations, a GNN with temporal extensions is used. While recurrent layers (such as GRU or LSTM) or temporal convolutions are utilized to record the time-varying characteristics of traffic at every node, graph convolutions are used to model the influence of surrounding nodes.

Using historic traffic information and interactions with other nodes through time, the model predicts future congestion at each monitored location. Three classifications - low, medium, and high congestion characterize the levels of congestion. The edges of the graph are weighted based on past congestion relationships, reflecting both spatial and temporal dependencies.

V. EXPERIMENTAL RESULTS AND EVALUATION

In this study, we evaluated a number of traffic congestion prediction models using actual traffic data and contrasted their overall effectiveness.

A. Dataset Description

The validation for the proposed methodology was carried out using the CityPulse dataset [44], which includes six months of real traffic data collected from 449 sensor nodes in Aarhus (Denmark). CityPulse was selected as a source of valuable information due to the wide-ranging nature of the type of traffic measured and the city's geographical location; it includes information about the quantity of

traffic at different time intervals on several different types of roads (such as freeways and major thoroughfares) and at different locations (within the same metropolitan area).

In terms of traffic data collected over a six month period, the dataset includes a wide-ranging representation of the different types of traffic congestion in cities due to the variety of traffic conditions and types of roads represented within the CityPulse dataset. Also, the dataset provides data for many different types of attributes that may influence traffic congestion patterns, including, for example, the time taken to travel between two locations (travel time), the number of vehicles on the road (road occupancy), and the speed at which traffic is travelling (average speed).

The dataset include the following features: `status`, `avgMeasuredTime`, `avgSpeed`, `extID`, `medianMeasuredTime`, `TIMESTAMP`, `vehicleCount`, `_id`, and `REPORT_ID`.

Nevertheless, these factors do not address the static limitations (route length and capacity, or structural bottlenecks) that play an important role in shaping traffic behaviour.

To enhance the dataset, we incorporated fixed attributes like length of the road, how many lanes there are, and where these roads are located in space. These fixed attributes represent the limitations or constraints created by the road network itself. Conversely, varying attributes such as speeds, elapsed time, and number of vehicles on a road are dynamic attributes that change over time and document traffic's dynamic characteristics.

By merging both fixed and dynamic data to create a dataset, we have created a more complete and realistic framework for modelling congestion behavior. This enhanced dataset gives us the ability to quantify how traffic changes dynamically and how structural bottlenecks impact when and where congestion occurs along a road segment.

B. Enhanced DBSCAN Data Labelling

Once the dataset had been created, the next step in processing the original and enriched variables into effective congestion categories was accomplished using a modified version of the DBSCAN (Density-Based Spatial Clustering of Applications with Noise) algorithm. A modified version of DBSCAN was chosen because the noise and variation present in real-world traffic datasets are difficult to handle even with the latest clustering methods. The DBSCAN algorithm has many advantages for use in urban traffic situations, particularly due to its ability to create clusters of differing dimension and to reject outliers, whereas traditional clustering algorithms such as k-means rely on the number of clusters and thus are limited to producing clusters of the same dimension.

Road segments were categorized into three main groupings by the clustering algorithm, which we subsequently designated as congestion levels:

- Low Congestion: Characterized by relatively low traffic volumes, higher average speeds, and short travel times. These conditions usually reflect free-flow traffic.
- Medium Congestion: Represents moderate traffic volumes and reduced average speeds, often corresponding to peak hours or transitional conditions where flow remains manageable but delays are present.
- High Congestion: Defined by high vehicle density, low average speeds, and longer measured times. These conditions reflect severe bottlenecks or critical saturation of the infrastructure.

This labelling step transforms the raw clustering output into interpretable and operational categories, which serve two purposes: 1) they provide a meaningful way to compare different traffic conditions across the city, and 2) they create a labelled dataset that can be used to train supervised learning models such as the GCN classifier.

In this way, the Enhanced DBSCAN not only organizes raw traffic data into coherent groups but also bridges the gap between unsupervised clustering and interpretable, real-world traffic levels.

C. Model Performance Analysis

From pre-clustered with labels for low, medium, and high congestion levels, the Graph Convolutional Network (GCN), being an exemplary model of the class of Graph Neural Networks (GNNs) [45], is used for traffic data classification. The graph-structured representation of traffic flow by the model accurately captures spatial interdependence among neighboring road segments. Each node represents road segments, and geographical correlations among segments are indicated by the edges. The GCN can model the complex non-linear relationships encountered in urban transport networks by considering geographical and temporal dependencies.

The hyperparameters used for GCN model training are listed in Table II. The network topology has three layers with a hidden dimension of 64, learning rate of 0.005, and ReLU activation function. The model was trained by an Adam optimizer for 30 epochs, with a weight decay of 0.0001 to control the model complexity and a dropout of 0.4 to prevent overfitting. 15 epochs of patience were used for early stopping for guaranteeing convergence and preventing unnecessary computation. For a trade-off between computing efficiency and stability, the batch size was chosen to be 128.

TABLE II. HYPERPARAMETERS USED FOR TRAINING THE GCN MODEL

Hyperparameter	Value
Learning Rate	0.005
Number of Layers	3
Hidden Dimension	64
Activation Function	ReLU
Batch Size	128
Dropout Rate	0.4
Weight Decay	0.0001
Number of Epochs	30
Optimizer	Adam
Early Stopping Patience	15

The good convergence and stability of the GCN model are confirmed by the training curves in Fig. 4. As the loss function reduces smoothly before settling to a small value, the accuracy curve rises very sharply in early epochs, saturating to a 93% accuracy. Good generalization and zero overfitting are ensured by the parallel nature of the training and validation curves. Model instability is not the cause of minor differences in validation accuracy, rather it is a result of natural traffic variation.

We evaluated the effectiveness of our suggested method by making comparisons with a number of state-of-the-art techniques, such as a hybrid CNN-LSTM model [9], a GAT-based technique [16], and Mouna's model [17]. A comparison in terms of important performance metrics, i.e., accuracy, precision, recall, F1-score, and area under the ROC curve (AUC), is given in Table III. Our approach based on GCN performs better than these models in all of the evaluation measures. It has well-balanced predictive capability for all types of congestion, with accuracy of 93%, 92% precision and recall, and F1-score of 0.92. The AUC of 0.95 indicates the model's outstanding discriminative capability to distinguish between types of congestion.

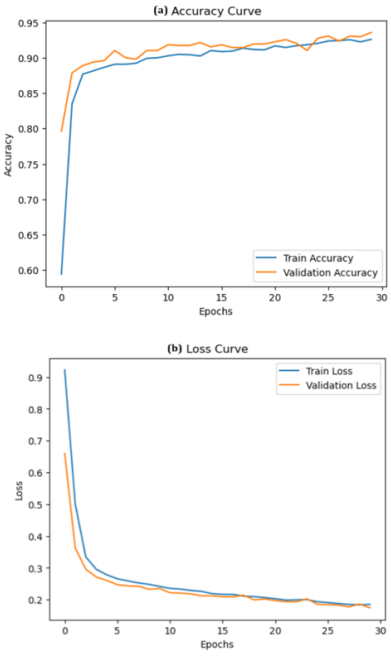

Fig. 4. Accuracy and loss curves for GCN model training, showing rapid accuracy growth and stable convergence.

TABLE III. COMPARISON OF THE PROPOSED GCN MODEL WITH OTHER STATE-OF-THE-ART METHODS

Metric	GCN	Mouna [17]	CNN-LSTM [9]	GAT [16]
Precision	0.92	0.89	0.88	0.90
Recall	0.92	0.89	0.87	0.89
F1-Score	0.92	0.89	0.87	0.89
Accuracy	0.93	0.90	0.88	0.91
AUC	0.95	0.91	0.90	0.93

1) Computational efficiency and resource utilization: In the process of determining whether or not deep learning models are feasible to be used in large-scale traffic networks, computation efficiency is as vital as prediction accuracy. The experiment average memory (RAM) consumption, training time, and inference time are summarized in Table IV.

Training the proposed GCN model on an NVIDIA RTX 3060 with a RAM of 12 GB and **1.7 GB system RAM** took around **4 minutes and 52 seconds**. At a time of only **11.3 seconds** and an estimated RAM usage of around **0.9 GB**, the inference time (testing) was much faster. Our model has a good balance between accuracy and computational cost compared to the CNN-LSTM and GAT models, whose higher memory cost of over 2 GB was slower to train (6.4 and 5.7 minutes, respectively).

According to IV, the results prove that the proposed GCN-based technique provides superior performance when compared to existing approaches including CNN-LSTM, GAT and Mouna's model based upon the same set of performance metrics. The main advantages offered by our approach are:

- Improved prediction accuracy since the GCN was capable of better capturing spatial dependencies between road segments; therefore, creating an accurate representation of traffic congestion level for each road segment.
- Balanced performance across the different congested levels with high precision, recall and F1-score.
- The GCN model was able to perform computations more efficiently than other models, performing inference at a higher speed (throughput), and with less memory consumption, thus, allowing for its application in real-time traffic situations.

The above advantages indicate that our approach for predicting traffic congestion provides both greater accuracy and greater efficiency than existing state-of-the-art methodologies for predicting traffic flow congestion in dataset utilised in this analysis.

These results confirm that the targeted GCN model retains effective memory usage and speeds up inference while improving prediction performance. This makes it an effective fit in applications where fast and efficient processing is required, such as adaptive traffic control and real-time traffic congestion prediction.

Given everything being equal, the proposed approach attains an appropriate balance among hardware use, training effectiveness, and performance and hence constitutes a viable and competitive option for long-term use in smart transport systems.

D. Discussion

The results of the experiments show that by combining both structural (non-varying) and dynamic (varying) factors, we achieved greater accuracy in classifying traffic congestion levels. The enhanced version of the DBSCAN algorithm enabled the conversion of different types of traffic data into usable traffic congestion levels. This allowed the GCN classifier to distinguish between different traffic behaviours that were not captured by other models. This supports our theory that the use of density-based clustering in conjunction with graph-based classification will provide an improved method of capturing the spatial and temporal characteristics of traffic flow.

When compared with CNN-LSTM, GAT, and Mouna's [17] proposed model, the GCN-based approach achieves better accuracy, precision, recall and Area Under the ROC Curve (AUC). The GCN has an advantage over these sequence-based or attention-based models that treat each segment independently, because of its ability to explicitly model relationships between adjacent road segments. The improved AUC value of 0.95 demonstrates that the model is highly capable of distinguishing between medium and high congestion levels, which tend to be the hardest to differentiate from one another.

An analysis of the efficiency of the proposed model shows that the proposed model achieves competitive training and inference speed, as well as efficiency, while using a much lower amount of GPU Memory in comparison to CNN-LSTM and GAT. Therefore, as a result of this balance between the model's ability to predict accurately and the cost of computation, the proposed model is well-suited to use in the real-time traffic monitoring environment, which requires rapid decisions and limited resources.

VI. CONCLUSION AND FUTURE WORK

We introduced a novel approach for predicting traffic congestion in urban environments by utilizing an enhanced DBSCAN clustering technique and a GCN Classifier. Using a 6-Month Traffic Dataset from Aarhus, Denmark, we concluded that combining both static and dynamic (evolving) Traffic Factors together will increase accuracy when predicting the level of congested traffic. Our enhanced DBSCAN method provides a way to convert multiplexed types of traffic data into usable levels of congestion and allows for the capture of spatial relationships between adjacent Roads or Segments of Road via a GCN to further distinguish between Medium and High levels of Traffic Congestion. Our methodology outperforms current leading approaches, including CNN-LSTM, GAT and Mouna's [17], in terms of Accuracy (93%), Precision (92%), Recall (92%) and AUC (0.95), while also achieving a balance between performance and speed which

TABLE IV. COMPUTATIONAL EFFICIENCY AND MEMORY CONSUMPTION COMPARISON BETWEEN MODELS

Model	Train Time (min)	Test Time (s)	RAM (GB)	GPU (GB)
Proposed GCN	4.87	11.3	1.7	2.3
CNN-LSTM [9]	6.42	15.8	2.4	3.1
GAT [16]	5.73	13.5	2.1	2.8
Mouna [17]	5.15	12.7	1.9	2.6

make it appropriate for inclusion in a real-time Traffic Monitoring Application and Intelligent Traffic Management System.

In future research, we will include various contextual elements (like weather patterns, public events, and car wrecks) as input features to create more robust predictive models. We will also expand our temporal modeling technique to forecast traffic congestion further into the future (i.e., hours, days, weeks, etc.). Finally, we are interested in how our traffic prediction method can be integrated into the development of adaptive traffic control systems that respond dynamically to changing traffic conditions in real time. The work outlined above has been developed to make our traffic prediction method robust and able to be used for a wide range of smart traffic management and urban planning applications in rapidly changing and varied urban settings.

Lightweight Cryptography for Energy-Conscious Authentication in IoT Systems

Ashwag Alotaibi, Huda Aldawghan, Mounir Frikha
Department of Computer Networks and Communications-College of Computer Sciences and Information Technology,
King Faisal University, Al-Ahsa, 31982 Saudi Arabia

***Abstract*—The proliferation of IoT devices has introduced new challenges in ensuring secure communication while maintaining computational and energy efficiency. Traditional cryptographic mechanisms such as AES-128, although robust, often fail to meet the stringent constraints of resource-limited IoT environments. This research investigates lightweight cryptographic algorithms and energy-conscious authentication protocols as viable alternatives for enhancing security in IoT systems. A comprehensive performance evaluation is conducted through the simulated implementation of three widely used algorithms—AES-128, SPECK, and PRESENT—measuring encryption time, decryption time, memory consumption, and ciphertext size. The results reveal critical trade-offs between security strength and resource usage, highlighting SPECK's balanced performance and PRESENT's ultra-low resource footprint. A Multi-Metric Suitability Analysis framework is introduced to assess overall applicability across different IoT use cases. The study provides evidence-based insights to guide algorithm selection for secure yet efficient IoT deployments. Future directions include hardware-based testing, integration into IoT protocols, and exploration of post-quantum lightweight cryptographic approaches. The findings contribute to the development of practical, scalable, and energy-efficient security architectures tailored for the next generation of IoT systems.**

Keywords*—*Lightweight cryptography; IoT security; energy efficiency; lightweight authentication; SPECK; PRESENT; AES-128; cryptographic algorithms; resource-constrained devices; Multi-Metric Suitability Analysis

I. Introduction

This section provides an overview of the context and significance of the research topic. It draws attention to the difficulties in maintaining secure connections while controlling computational resources and energy consumption limitations. It also discuss the drawbacks of conventional cryptographic techniques in low-resource settings and provide lightweight cryptography as a possible solution. The objectives of this study and the approach used for assessing the effectiveness of particular algorithms will also be described, setting the foundation for a thorough investigation of energy-conscious authentication in IoT systems.

A. Background

The IoT has revolutionized digital ecosystems by enabling interconnected smart devices to communicate autonomously, creating vast networks in domains such as smart homes, healthcare, transportation, agriculture, and industrial automation [1]. These devices, equipped with sensors and microcontrollers, continuously generate, transmit, and process sensitive data. Consequently, securing communication in such environments is paramount for ensuring information exchanges' confidentiality, integrity, and availability (CIA) [2]. However, IoT devices are often resource-constrained, with processing power, memory (RAM/ROM) limitations, battery life, and communication bandwidth. Implementing traditional cryptographic solutions like RSA or ECC proves inefficient or infeasible on such devices due to high computational complexity and energy demands [3].

Some examples of smart home devices include a common device like a door lock or motion sensor that has less than 64 KB of RAM and runs on battery power. In such cases, AES or RSA-based encryption will result in undesired delays in the response time, poor device performance, and reduced battery life of IoT systems [3].

Due to these limitations, lightweight cryptographic algorithms have been viewed as a promising alternative. In particular, these algorithms aim to provide enough security with as little associated computational overhead as possible, making this an excellent choice for resource-constrained IoT environments [4]. Unlike conventional ciphers, lightweight cryptography is energy efficient, has a compact memory footprint, and has fast execution while maintaining strong security.

The NIST has actively promoted this research area through its Lightweight Cryptography Standardization project because NIST has found the need for robust and efficient cryptographic solutions [5]. Among the algorithms shortlisted, SPECK and PRESENT have demonstrated strong performance in embedded systems and constrained networks [6], [7].

B. Problem Statement

Despite the advantages of lightweight cryptographic algorithms, the evaluation of their performance in real-world IoT scenarios remains limited. Numerous current studies mainly concentrate on the performance of individual algorithms rather than employing a thorough benchmarking strategy. This absence of a uniform methodology frequently results in challenges when attempting to compare the efficacy of various lightweight cryptographic algorithms, especially in environments where energy is limited.

Moreover, the current body of literature often overlooks the significance of evaluating various performance metrics concurrently, including encryption and decryption time, memory consumption, and ciphertext size. This oversight restricts the relevance of the findings, complicating the process for developers to choose suitable algorithms that are customized for particular IoT applications.

In order to address these gaps, this research introduces a modular simulation framework designed to systematically assess various lightweight cryptographic algorithms within a practical client-server architecture. By creating a standardized benchmarking protocol that encompasses critical performance metrics, we seek to offer more transparent insights and direction for developers implementing cryptographic solutions in energy-efficient IoT systems.

C. Research Aim and Objectives

The primary aim of this research is to evaluate and compare the performance of lightweight cryptographic algorithms (SPECK and PRESENT) with AES-128 in an energy-conscious IoT authentication environment using a client-server simulation setup in Python. The objectives are:

- Simulate lightweight authentication using SPECK, PRESENT, and AES-128 in a smart home environment.
- Measure key performance metrics: encryption time, decryption time, memory usage, and ciphertext size.
- Assess the suitability and efficiency of lightweight cryptography for IoT devices under constrained conditions.

D. Research Questions

This research seeks to answer the following key research questions:

- How do lightweight cryptographic algorithms compared with traditional ciphers like AES in IoT authentication setups?
    - This question aims to identify efficiency trade-offs in real-world simulations involving encryption time, decryption time, memory usage, and ciphertext size.
- Which lightweight algorithm (SPECK or PRESENT) demonstrates the best balance of performance and security in resource-constrained environments?
    - This question focuses on evaluating the practical applicability of each algorithm in terms of real-world resource limitations.
- What are the potential gains in energy savings and memory optimization by replacing AES with lightweight alternatives?
    - This question quantifies real-world performance improvements in energy consumption and memory usage.

E. Research Motivation and Contribution

The motivation behind this work is driven by the increasing deployment of low-power, battery-operated smart devices that demand highly efficient security mechanisms. While lightweight cryptography offers theoretical advantages, practical benchmarking in realistic use cases like smart homes is essential to validate its applicability [8].

This research contributes a simulation-based, modular evaluation framework, implemented in Python, that offers measurable insights into cryptographic performance for IoT authentication scenarios.

F. Structure of the Paper

The remaining sections of this research are organized as follows:

- Section II provides a literature review on lightweight cryptography and its application in IoT security.
- Section III outlines the methodology employed in conducting performance evaluations of the cryptographic algorithms.
- Section IV presents a comprehensive overview of cryptographic algorithms.
- Section V details the design and execution of the simulation setup.
- Section VI presents the results of the simulated tests, including a detailed analysis of encryption and decryption times, memory usage, and ciphertext sizes. It also discusses the implications of the findings for the selection of cryptographic algorithms in energy-constrained IoT environments.
- Section VII concludes the research with a summary of key findings.
- Section VIII presents the future research directions.

II. Literature Review

An analysis of current studies and advancements in lightweight cryptography and its use in IoT security is carried out in this section. With an emphasis on the particular difficulties presented by resource-constrained contexts, the literature review seeks to place our study within the larger context of cryptographic solutions.

A. Lightweight Cryptography: A Paradigm Shift

Lightweight cryptography is designed to address the specific challenges of resource-constrained environments, such as IoT, RFID, and embedded systems. Unlike conventional cryptographic algorithms, lightweight cryptography emphasizes minimal computational overhead, low memory footprint, and reduced energy consumption while still maintaining an acceptable security level [5]. Fig. 1, illustrates the critical trade-offs among security strength, implementation cost, and performance optimization in lightweight cryptography. Each vertex of the triangle represents a key aspect: security level, resource consumption, and operational efficiency. Understanding these trade-offs is essential for choosing suitable cryptographic algorithms in resource-constrained IoT environments.

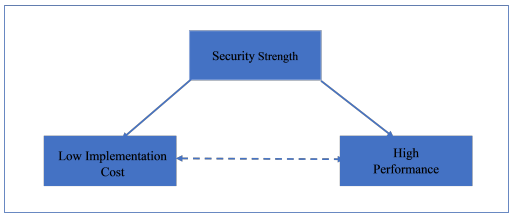

Fig. 1. Lightweight cryptographic design trade-off triangle.

Design strategies in lightweight cryptography include Feistel structures and substitution–permutation network (SPN) architectures for simplified data diffusion, reduced S-box complexity, and bit-sliced logic. Also, use of basic operations (XOR, rotation, addition) instead of complex multiplications or matrix transformations, and compact key scheduling and small state representations [6].

Furthermore, NIST's Lightweight Cryptography Project, initiated in 2019, aims to standardize efficient lightweight algorithms for wide adoption. The initiative considers algorithm performance on 8-bit microcontrollers, implementation costs, resistance to known attacks, and ease of integration in IoT software stacks [7].

B. Selected Lightweight Cryptographic Algorithms

This subsection introduces SPECK, PRESENT, and AES-128, particular lightweight cryptographic algorithms used for this study and discusses their operational features, design tenets, and suitability for deployment in IoT scenarios with limited resources. The goal of analyzing these algorithms is to establish a thorough understanding of their advantages and disadvantages, which will serve as the basis for our performance evaluation and comparison study.

1) SPECK cipher: SPECK, designed by the NSA in 2013, is a Feistel-based lightweight block cipher focusing on high performance in software environments. It operates using ARX-based operations (Addition, Rotation, XOR) and offers a variety of block/key sizes (e.g., SPECK64/96, SPECK128/128) [9].

- Block size: 32, 48, 64, 96, or 128 bits.
- Key size: 64, 72, 96, 128, 144, 192, or 256 bits.
- Rounds: Vary from 22 to 34 depending on block/key size.

SPECK is highly optimized for embedded software applications, especially on ARM Cortex-M microcontrollers. Studies have demonstrated throughput of 100–200 Kbps on 8-bit CPUs and low code size (1 KB) [10]. However, the algorithm's origin from the NSA has caused skepticism in the cryptographic community. Despite no proven backdoors, the lack of transparency and open standardization leads to moderate trust concerns [8].

2) PRESENT cipher: PRESENT is an ISO/IEC standardized lightweight cipher using an SPN architecture. It was designed specifically for ultra-low gate-count hardware devices such as RFID and smart cards [11].

- Block size: 64 bits
- Key size: 80 or 128 bits
- Rounds: 31

PRESENT is considered hardware-optimal, requiring only 1570 GE (Gate Equivalents), making it the preferred algorithm in ASIC and FPGA implementations. It also supports low power draw and low latency, ensuring real-time performance in critical embedded systems. Its adoption in military-grade systems, automotive controllers, and RFID-based security tokens has made it a popular choice in highly secure IoT environments [12].

3) AES-128: AES-128 remains a benchmark in symmetric key cryptography. With a 128-bit block and key size, it is highly secure, but computationally demanding. AES involves 10 rounds of SubBytes, ShiftRows, MixColumns, and AddRoundKey, which require significant processing and memory. Despite its security strength, AES-128 is often too heavy for 8-bit or 16-bit microcontrollers without dedicated hardware accelerators. For instance, a 64 KB RAM IoT device may allocate up to 35–40% of its memory to AES processing, impacting application runtime [13], [14]. Thus, AES remains suitable for gateway-level IoT nodes or high-end embedded devices rather than battery-operated sensors.

C. Research Gap Analysis and Research Direction

Existing literature largely evaluates ciphers in simulated environments or isolated software/hardware scenarios. However, very few studies consider:

- Modular client-server-based simulation architectures.
- Performance testing with consistent message sizes and iterations.
- Combined analysis across multiple metrics (time, memory, ciphertext size).

Our research bridges this gap by proposing a realistic Python-based smart home simulation, assessing SPECK, PRESENT, and AES-128 in client-server communication setups, and benchmarking encryption time, decryption time, memory consumption, and ciphertext size over 50 trials. This provides IoT developers with a practical reference framework for cryptographic algorithm selection, facilitating informed decisions aligned with device constraints and security priorities.

Although previous research, such as that of Radhakrishnan et al. [15], offers insightful information about how well lightweight cryptographic algorithms operate on IoT devices with limited resources, their methodology differs greatly from the one described in this study. Radhakrishnan et al. implement and compare AES-128, SPECK, and ASCON on particular Arduino Nano and Micro boards in their hardware-based assessment. On the other hand, this study uses a simulation-based methodology to evaluate AES-128, SPECK, and PRESENT by simulating a smart home authentication scenario. Additionally, this study stresses energy-conscious authentication culminating in a Multi-Metric Suitability Analysis, whereas [15] prioritizes metrics like execution time, memory utilization, latency, and throughput. This study offers complementary insights that are specifically adapted to the difficulties of energy efficiency in IoT authentication because of the difference in technique and

focus, highlighting the need to balance security, performance, and energy efficiency based on specific IoT application requirements.

III. Methodology

This section outlines the experimental design and approach used to evaluate the performance of lightweight cryptographic algorithms within a simulated IoT environment. The section includes the simulation architecture, performance metrics, and tools employed to ensure a comprehensive assessment of encryption efficiency and resource utilization in energy-constrained scenarios.

A. Overview of Experimental Design

This research adopts a quantitative simulation-based experimental design to assess the computational and memory performance of lightweight cryptographic algorithms SPECK and PRESENT, in comparison to the standard AES-128 algorithm. The simulation emulates a smart home IoT authentication scenario, where IoT devices (clients) communicate securely with a gateway (server) using cryptographic operations. This design is consistent with prior studies aiming to benchmark cryptographic efficiency under real-world IoT constraints [16], [17].

This research employs a quantitative simulation-based experimental design aimed at addressing the research questions posed. We measure performance metrics, encryption time, decryption time, memory usage, and ciphertext size for the lightweight algorithms SPECK and PRESENT compared to AES-128. The focus will be on the comparative analysis of SPECK and PRESENT based on the collected metrics, and analyze the energy savings and memory optimization derived from using lightweight cryptographic methods over traditional ones like AES-128, detailing the implications for IoT applications.

B. Simulation Environment and Tools

The simulation was carried out in a controlled setting that replicates a home IoT gateway running Linux, aligning with the architectures suggested in [16], [18] to guarantee compatibility and efficiency. An Intel Core i5-1145G7 CPU running at 2.60 GHz and backed by 8 GB of DDR4 RAM were among the hardware specifications. This processor offered enough processing capability to manage several concurrent activities, which are common in IoT applications. Ubuntu 22.04 LTS was selected as the operating system to provide a stable and secure environment, and Python 3.10 was used as the main programming language because of its many libraries and ease of use. The overall analysis of simulation results was improved by the use of key libraries shown in Table I below, which streamlined data visualization and performance monitoring.

C. Client-Server Simulation Architecture

The cryptographic simulation mimics real-world scenarios, where smart home devices must authenticate data packets securely with a centralized server. The modular client-server communication model includes the following components:

TABLE I. Simulation Setup and Tools

Component	Configuration / Tools Used
OS	Ubuntu 22.04 LTS.
Processor	Intel Core i5-1145G7 @ 2.60 GHz.
RAM	8 GB DDR4.
Programming Language	Python 3.10+
Libraries and Tools	time, tracemalloc, sys, matplotlib, hashlib
Execution Environment	Terminal-based Python CLI and Visual Studio Code IDE

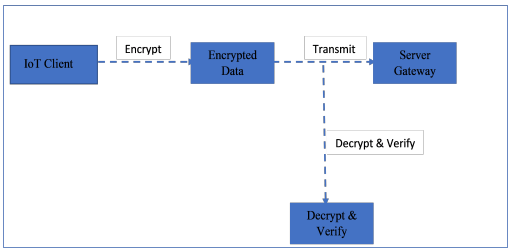

Fig. 2. Experimental workflow architecture.

- Client Device: Encrypts data using a chosen algorithm before sending it.
- Server Gateway: Receives and decrypts the data, verifying correctness and logging performance metrics.
- Logger Module: Collects and stores experimental metrics for analysis.

In Fig. 2, this modular design allows algorithm swapping, enabling comparative testing without altering simulation logic—a best practice for maintainability in IoT research [19].

D. Algorithm Configuration and Security Parameters

To provide a fair and insightful comparison of the performance and security features of several cryptographic algorithms, this study constructed them using standardized configurations. Table II details the specific configurations used for each algorithm in the study, including block size, key size, number of rounds, mode of operation, and padding scheme. Understanding these parameters is crucial, as they directly impact the algorithms' performance, security, and applicability in real-world IoT scenarios.

Although ECB mode is generally discouraged for secure communication, it was selected to maintain uniformity and simplicity in benchmarking as recommended in NIST SP 800-38A [20].

E. Performance Metrics and Measurement Methods

A well-defined measurement protocol was adopted to capture multiple performance parameters using lightweight profiling tools embedded in Python [21]. Table III shows the tools used for measurement.

F. Iterative Execution Strategy

Each algorithm was executed fifty times, as shown in Table IV, per metric, per simulation, ensuring statistical robustness. This repetition helps in reducing anomalies and outliers that may arise from system background processes or cache variations [22].

TABLE II. CRYPTOGRAPHIC ALGORITHMS CONFIGURATIONS

Algorithm	Block Size	Key Size	Rounds	Mode of Operation	Padding Scheme
SPECK	64 bits	96 bits	27	ECB	PKCS7
PRESENT	64 bits	128 bits	31	ECB	PKCS7
AES-128	128 bits	128 bits	10	ECB	PKCS7

TABLE III. PERFORMANCE MEASUREMENT TOOLS

Metric	Tool/Method	Unit	Purpose
Encryption Time	time.perf_counter()	ms	Measures algorithm execution latency
Decryption Time	time.perf_counter()	ms	Measures reverse latency
Memory Usage	tracemalloc.get_traced_memory()	KB	Tracks peak RAM consumed during crypto operations
Ciphertext Size	sys.getsizeof()	B	Indicates overhead on transmission bandwidth

TABLE IV. REPETITION AND AVERAGING APPROACH

Parameter	Repetitions	Reported Metric
Encryption Time	50	Average and Std. Deviation
Decryption Time	50	Average and Std. Deviation
Memory Usage	50	Peak and Mean Memory Used
Ciphertext Size	50	Average Ciphertext Size

IV. CRYPTOGRAPHIC ALGORITHMS OVERVIEW

This section presents a comprehensive overview of the three cryptographic algorithms evaluated in this study: SPECK, PRESENT, and AES-128. Each algorithm is analyzed based on its design architecture, block and key structure, performance relevance to IoT, and security considerations. A comparative summary is also provided to highlight practical differences that impact IoT deployment.

A. SPECK: Lightweight Block Cipher

SPECK is a family of lightweight block ciphers introduced by the U.S. NSA in 2013, specifically designed for environments where resource efficiency is critical [7], [16]. SPECK supports multiple block and key sizes, but in this study, the SPECK-64/96 configuration is utilized (i.e., 64-bit block size and 96-bit key).

Design Characteristics:

- Type: ARX cipher (Add-Rotate-XOR)
- Rounds: 27 (for SPECK-64/96)
- Architecture: Simple, hardware- and software-friendly
- Security Level: Comparable to 80–96-bit security
- Speed: Optimized for software performance on 8-bit and 16-bit processors

SPECK achieves high speed and low code footprint, making it ideal for devices such as sensor nodes, RFID tags, and microcontrollers [7], [9]. However, its lack of adoption in formal standards and its origin from the NSA have raised concerns in certain applications [16], [17].

B. PRESENT: Ultra-Lightweight Block Cipher

PRESENT is a standardized block cipher designed specifically for ultra-constrained environments. It was jointly developed by TU Graz, Ruhr University Bochum, and Orange Labs, and became part of the ISO/IEC 29192-2:2019 standard [6], [11].

Design Characteristics:

- Type: SPN
- Rounds: 31 (fixed for all variants)
- Block Size: 64 bits
- Key Size: 80 or 128 bits (128-bit used in this study)
- Architecture: Compact hardware implementation, minimal RAM usage
- Security Level: 80–128 bits depending on key size

PRESENT's design is optimized for hardware implementation with extremely low gate count (1570 GE) and minimal power consumption, which has made it popular in RFID tags and embedded medical devices [11], [12].

Despite its strengths, PRESENT suffers from slower software performance due to its rigid SPN structure and complex bitwise operations on software platforms [13].

C. AES-128: Advanced Encryption Standard

AES, standardized by NIST in 2001, remains the most widely used symmetric encryption algorithm across computing systems. The AES-128 variant (128-bit key and 128-bit block) is used in this study, consistent with industry and IoT applications [13], [14].

Design Characteristics:

- Type: SPN
- Rounds: 10 for AES-128
- Block Size: 128 bits
- Key Size: 128 bits
- Security Level: 128-bit (widely accepted standard)

Although AES-128 offers strong security and excellent throughput on high-power systems, it may be computationally intensive for low-resource IoT devices, requiring more memory and energy compared to SPECK or PRESENT [14], [18].

Hardware acceleration (e.g., AES-NI) enhances AES performance in modern processors, but such features are often absent in IoT microcontrollers, making it less desirable in ultra-constrained environments.

D. Comparative Analysis of Cryptographic Algorithms

To provide a quick snapshot of the trade-offs among the three algorithms, Table V summarizes key characteristics relevant to IoT applications.

As seen, while AES-128 is security-rich and industry-proven, SPECK and PRESENT offer superior performance in memory and energy metrics, making them more appropriate for lightweight scenarios [12], [14], [23].

E. Security Considerations

While performance is essential in IoT cryptography, security resilience against attacks must not be overlooked. Table VI provides an overview of common cryptanalytic resistance for the selected algorithms.

While AES offers the most robust security, PRESENT's 31-round structure and ISO certification also make it highly resilient in embedded systems. SPECK's NSA origin introduces perceived trust issues in public use, although no catastrophic vulnerabilities have been reported in practical environments [16], [18].

F. Selection Rationale for the Study

The three algorithms were chosen based on:

- Relevance in IoT research literature.
- Compatibility with resource-limited hardware.
- Diverse architectural principles (ARX vs SPN).
- Availability of open-source implementations.

These criteria ensure a balanced and objective comparison, offering meaningful insights for cryptographic deployment in smart home environments.

V. Implementation Case Study / Simulation Setup

This section details the design and execution of the simulation framework used to assess the performance of lightweight cryptographic algorithms for use with IoT, which are resource-constrained. The approach of the implementation is to simulate interactions between IoT devices and a central authentication gateway similar to a smart home communication system. To compare the efficiency of SPECK, PRESENT, and AES-128 on critical performance parameters like time taken in terms of execution, memory usage, and size of ciphertext.

A. Case Study Context: Smart Home Authentication

In a smart home context, smart door locks, lighting systems, as well as thermostats require secure authentication protocols to prevent compromise of battery life or processing capability. In these devices, lightweight encryption algorithms are inescapable, where the conventional nature of the selection makes the sensors [1], [2], [14]. Such a setup is emulated in the simulation, which encrypts and transmits authentic messages from IoT devices to a gateway server that, in turn, decrypts and verifies the same messages and only afterwards allows access or executes control actions.

B. Simulation Architecture

The simulation adopts a client-server model that mirrors real-world communication between IoT end devices and a gateway controller. The architecture consists of:

- Client Node (IoT Device): Generates authentication messages and performs encryption using the selected cryptographic algorithm.
- Gateway Node (Server): Receives, decrypts, and verifies the integrity and authenticity of incoming messages.
- Cryptographic Modules: Each algorithm (SPECK, PRESENT, and AES-128) is implemented in separate modular components to ensure isolated and fair testing.
- Performance Monitoring Mechanisms: Execution time and memory usage are measured during the encryption and decryption operations, and ciphertext size is recorded for each transaction.

This architecture facilitates consistent testing and comparison across all algorithms under identical operating conditions [3], [9].

C. Performance Metrics and Evaluation Criteria

In Table VII, the key performance metrics are defined for the evaluation. These metrics were selected because they directly impact the power consumption, latency, and bandwidth usage in IoT systems, which are key considerations in energy-conscious deployments [4], [8].

D. Experimental Setup and Tools

The simulation environment was configured to reflect a practical yet controlled testing scenario. The specifications and tools used are summarized below in Table VIII.

Each run involved encryption of a fixed-size message at the client node, transmission simulation to the server, followed by decryption and verification. The process ensured controlled measurement and repeatability [10], [13].

E. Cryptographic Operation Process Flow

The encryption and decryption flow is illustrated below to describe the simulation operation:

- Message Generation: A static-length authentication message is generated at the client device.
- Encryption Process: The message is encrypted using the specified algorithm (SPECK, PRESENT, or AES).
- Transmission Simulation: The ciphertext is transmitted to the gateway (server-side).
- Decryption and Verification: The gateway decrypts the message and confirms its integrity.
- Metrics Logging: Time taken and memory consumed during encryption/decryption are logged, and the ciphertext size is recorded.

TABLE V. COMPARATIVE SUMMARY OF SPECK, PRESENT, AND AES-128

Feature	SPECK (64/96)	PRESENT (64/128)	AES-128
Cipher Type	ARX	SPN	SPN
Block Size	64 bits	64 bits	128 bits
Key Size	96 bits	128 bits	128 bits
Rounds	27	31	10
Speed (SW Implementation)	Very Fast	Moderate	High (on supported CPUs)
Memory Usage	Low	Very Low	High
Security Level	Moderate(NSA-reviewed)	High(ISO Standardized)	Very High(NIST Standard)
Hardware Efficiency	High	Excellent	Good (with AES-NI only)
Energy Consumption	Low	Very Low	High
Standardization Status	Not standardized by ISO/NIST	ISO/IEC 29192-2:2019	NIST FIPS 197

TABLE VI. CRYPTOGRAPHIC SECURITY COMPARISON

Attack Vector	SPECK	PRESENT	AES-128
Differential Cryptanalysis	Resistant (limited margin)	Resistant (31 rounds)	Resistant (well studied)
Linear Cryptanalysis	Moderately Resistant	Resistant	Highly Resistant
Side-Channel Attacks	Depends on implementation	Vulnerable (if unprotected)	Vulnerable (mitigated via AES-NI)
Key-Recovery Attacks	Needs more than 2^{75} operations [7]	Needs more than 2^{126} operations [11]	Needs more than 2^{128} operations [13]

TABLE VII. KEY PERFORMANCE METRICS

Metric	Description
Encryption Time (ms)	Time taken to encrypt a message (measured using high-resolution timers).
Decryption Time (ms)	Time taken to decrypt the message at the server side.
Memory Usage (KB)	Peak memory consumed during encryption/decryption (measured using memory profiling tools).
Ciphertext Size (Bytes)	Length of the encrypted output to assess transmission efficiency.

This systematic procedure was repeated for all cryptographic schemes under identical conditions to ensure fair comparative analysis [2], [12].

F. Code-Level Measurement Approach

Encryption and decryption times were recorded using high-precision timers, while memory profiling tools captured peak memory usage. Ciphertext length was measured in bytes post-encryption. For example, encryption time was measured as:

```
start_time = time.perf_counter()
ciphertext = encrypt_function(plaintext, key)
end_time = time.perf_counter()
encryption_time_ms = (end_time - start_time) * 1000
```

Memory tracking was initiated before encryption and terminated after ciphertext generation to isolate algorithm-specific memory use.

TABLE VIII. TOOLS AND SOFTWARE USED

Component	Details
Programming Language	Python 3.11.4 – selected for its clarity and extensive cryptographic support libraries.
Performance Profiling	time.perf_counter() for time measurements; tracemalloc for memory tracking.
Testing Platform	Ubuntu 22.04 LTS VM with 4 GB RAM and dual-core CPU.
Message Payload	64-byte plaintext messages used to simulate authentication tokens.
Iterations per Algorithm	50 encryption and decryption cycles conducted per algorithm for statistical accuracy.

VI. RESULTS AND DISCUSSION

This section provides a detailed performance analysis of the three cryptographic algorithms, AES-128, SPECK, and PRESENT, in a simulated smart home, as implemented on compatible hardware with the corresponding ASICs used for real implementations. Evaluation was run on four performance metrics: encryption time, decryption time, memory, and ciphertext. The analysis seeks to give empirical insights as to the computational feasibility and efficiency of resource-constrained lightweight cryptography in resource-constrained IoT ecosystems [1], [3], [8]

A. Performance Evaluation Methodology

Based on the authentication communication between the smart IoT device (client) and a home gateway (server), our experimental setup simulated this setup. The same fixed 64-byte message was used on 50 iterations to test each algorithm to ensure consistency of benchmarking. High-resolution timers were used to time the encryption and decryption processes, while memory consumption was profiled with Python's memory_profiler module. Transmission overhead was recorded post-encryption in bytes, as in the case of ciphertext size. Such a controlled environment allows for reproducible evaluation under typical IoT conditions, with constrained computation and communication capacity [4], [10].

B. Summary of Experimental Results

Table IX and Fig. 3, presents the average performance metrics across the three cryptographic algorithms. Notably, AES-128 demonstrates significantly lower encryption and decryption times, making it highly efficient for environments where speed is paramount. In contrast, SPECK shows increased latencies, highlighting potential performance issues in real-time applications. PRESENT, despite its ultra-low resource footprint, exhibits the highest execution time, which may limit its usability in latency-sensitive contexts.

C. Encryption and Decryption Time Analysis

Cryptographic delay in IoT systems can directly impact Quality of Service (QoS) and system responsiveness. Fig. 4

TABLE IX. SUMMARY OF PERFORMANCE METRICS FOR AES-128, SPECK, AND PRESENT

Algorithm	Avg.Encryption Time (ms)	Avg.Decryption Time (ms)	Avg.Memory Usage (KB)	Avg.Ciphertext Size (Bytes)
AES-128	0.03	0.02	1.59	113
SPECK	1.17	1.40	2.40	105
PRESENT	3.06	3.02	1.38	41

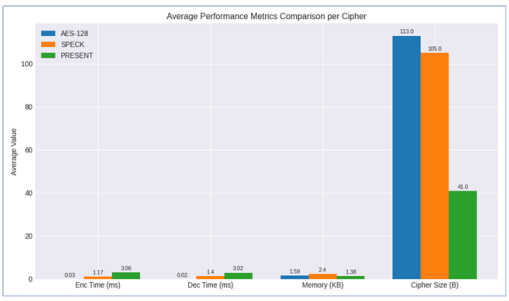

Fig. 3. Average performance metric.

and Fig. 5 shows a comparative bar chart for encryption and decryption time.

AES-128 exhibits extremely low latency, with average encryption and decryption times well under 0.05 ms. This efficiency is largely attributed to hardware acceleration present in most modern IoT SoCs [13], [14]. Additionally, SPECK, designed as a lightweight cipher, performs adequately but still shows higher latency than AES-128 due to its bit-wise operations and simplified Feistel structure [7]. Lastly, PRESENT demonstrates the highest latency, exceeding 3 ms on average, which may pose a delay concern in real-time systems despite its ultra-lightweight design [11]. These findings align with studies emphasizing AES's optimized execution in supported environments, despite its general-purpose design [13].

D. Memory Usage Analysis

Memory utilization is a critical metric in constrained devices such as wearable sensors and low-end microcontrollers, where RAM and ROM resources are typically under 64KB [1], [4]. Fig. 6 visualizes the memory footprint of each algorithm.

- SPECK consumes the highest memory (2.4 KB) due to recursive round operations and expanded key schedule tables in the Python implementation. Also, consistently uses more memory than PRESENT after the initial drop.
- AES-128, despite its robustness, manages a balanced memory usage of 1.59 KB, aided by well-structured S-box tables and the availability of efficient cryptographic libraries. Also, has the highest initial memory usage, but stabilizes at a lower level.
- PRESENT outperforms both in memory efficiency with just 1.38 KB, making it ideal for ultra-constrained embedded platforms, such as RFID or battery-operated nodes [11], [12]. Also, it is the most memory-efficient algorithm overall, maintaining the lowest memory usage across iterations.

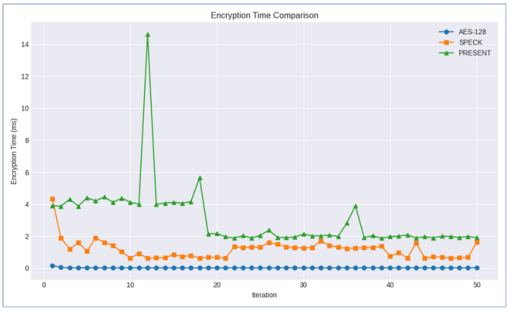

Fig. 4. Average encryption (ms).

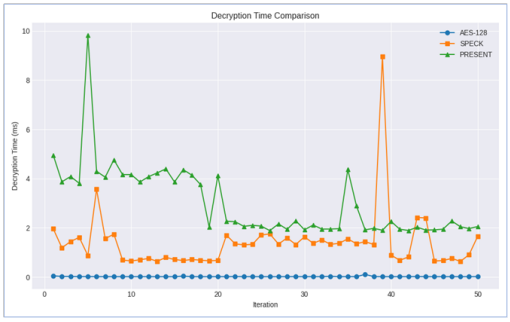

Fig. 5. Decryption time (ms).

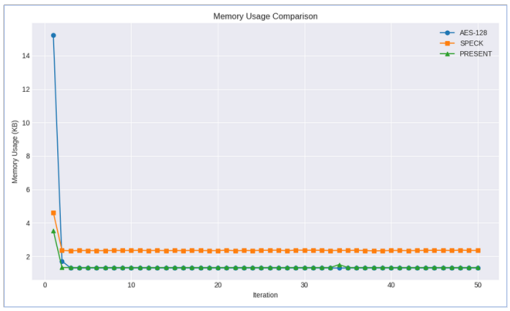

Fig. 6. Depicting the memory usage of AES-128, SPECK, and PRESENT.

Table X presents a normalized comparison across memory efficiency using a scale from 1 (low) to 5 (high efficiency). These results affirm that memory efficiency and cryptographic strength must be balanced contextually, as lightweight memory use does not guarantee speed or security [8], [23].

E. Ciphertext Size Analysis

Transmission energy consumption in wireless sensor networks is directly linked to packet size. Minimizing ciphertext size can significantly reduce bandwidth and energy usage

TABLE X. NORMALIZED MEMORY EFFICIENCY SCORE

Algorithm	Efficiency Score (1-5)
PRESENT	5
AES-128	4
SPECK	3

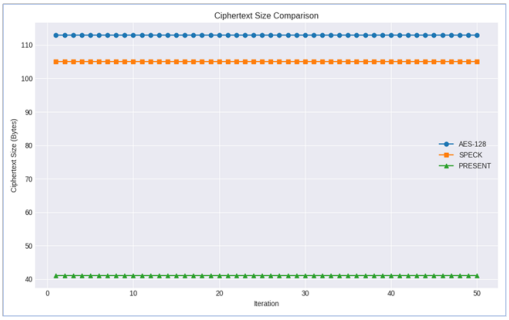

Fig. 7. Depicting ciphertext size for AES-128, SPECK, and PRESENT.

[2], [10]. Fig. 7 presents the comparison of ciphertext sizes generated by each algorithm.

- PRESENT has a clear advantage with the smallest ciphertext size (41 Bytes) due to its compact 64-bit block size and simple permutation structure [11].
- SPECK, although slightly better than AES-128, still generates a moderately larger ciphertext (105 Bytes).
- AES-128, with padding overhead and 128-bit block size, produces the largest ciphertext size (113 Bytes)—a challenge in constrained-bandwidth environments.

This analysis supports prior work emphasizing PRESENT's suitability in narrowband and energy-constrained networks like LoRaWAN or ZigBee [12].

F. Discussion on Practical Deployment

The results emphasize a non-uniform applicability of lightweight cryptography across IoT domains. Depending on the deployment environment, the choice of algorithm can significantly affect system performance, battery life, and data integrity [1], [3].

- Smart Home Automation: AES-128 can be preferable due to processor support and rapid data exchanges.
- Healthcare IoT (e.g., body sensor networks): PRESENT is ideal due to low memory and secure short transmissions.
- Industrial IoT: SPECK may serve well due to balanced performance and modest computational needs.

These conclusions validate the assertion from [14] that algorithm selection must be context-driven, based on a careful trade-off between performance, security level, and energy efficiency.

G. Multi-Metric Suitability Analysis

To comprehensively evaluate the suitability of each cryptographic algorithm for energy-conscious authentication in IoT environments, a Multi-Metric Suitability Analysis was conducted. This analysis is designed to synthesize the experimental results across three core performance dimensions: encryption speed, memory usage, and ciphertext size, thereby providing a balanced assessment of each cipher's practicality in constrained IoT scenarios.

TABLE XI. ENCRYPTION AND DECRYPTION TIME

Algorithm	Encryption Time (ms)	Decryption Time (ms)	Total Time (ms)	Score
AES-128	0.03	0.02	0.05	5
SPECK	1.17	1.40	2.57	3
PRESENT	3.06	3.02	6.08	2

TABLE XII. MEMORY CONSUMPTION SCORE

Algorithm	Memory Usage (KB)	Score
PRESENT	1.38	5
AES-128	1.59	4
SPECK	2.40	3

1) Scoring framework and rationale: A relative ranking-based scoring model was employed, wherein each algorithm was assigned a score on a five-point ordinal scale (1 to 5) for each metric:

- 5 = Most optimal performance in a metric
- 3 = Average performance
- 1 = Least optimal performance in a metric

The scoring approach was developed to represent the comparative advantages or limitations of each algorithm in the context of the three selected metrics. The overall suitability score was then computed as the arithmetic mean of the three metric-specific scores, providing a composite evaluation index.

2) Encryption speed score: The combined encryption and decryption time was used to determine the speed score. As shown in Table XI, AES-128 demonstrated the highest speed efficiency with a total processing time of 0.05 ms, followed by SPECK at 2.57 ms, and PRESENT at 6.08 ms.

3) Memory usage score: Lower memory consumption is crucial for microcontrollers and battery-operated IoT nodes. The algorithms were scored based on average memory usage derived from empirical simulation data. Table XII shows the memory usage for each algorithm.

4) Ciphertext size score: Transmission overhead is directly impacted by ciphertext size. Smaller ciphertexts reduce communication costs and energy consumption in wireless IoT environments. Based on the average size of the encrypted message, the following scores were assigned, as shown in Table XIII.

5) Overall suitability score: To compute the overall suitability score, the average of the three metric-specific scores was calculated and rounded to the nearest whole number. As presented in Table XIV, PRESENT, AES-128, and SPECK all converge around a suitability score of 4, though each algorithm exhibits a distinct balance of trade-offs depending on the application context.

TABLE XIII. CIPHERTEXT SIZE SCORE

Algorithm	Ciphertext Size (Bytes)	Score
PRESENT	41.0	5
SPECK	105.0	4
AES-128	113.0	2

TABLE XIV. OVERALL SUITABILITY SCORE

Algorithm	Encryption Speed Score	Memory Usage Score	Ciphertext Size Score	Average Score	Overall Suitability Score
AES-128	5	4	2	3.67	4
SPECK	3	3	4	3.33	4
PRESENT	2	5	5	4.00	4

TABLE XV. MULTI-CRITERIA SUITABILITY MATRIX FOR IOT DEPLOYMENT

Metric	AES-128	SPECK	PRESENT
Encryption Speed	5	3	2
Memory Usage	4	3	5
Ciphertext Size	2	4	5
Overall Suitability	4	4	4

6) Interpretation of suitability outcomes: The results underscore the context-dependent nature of lightweight cryptographic algorithm selection in IoT systems. While AES-128 offers exceptional speed, its comparatively larger ciphertext size may pose challenges for ultra-low-power devices. Conversely, PRESENT demonstrates remarkable efficiency in memory and ciphertext size, making it more suitable for bandwidth-constrained and memory-limited IoT deployments, albeit at the cost of processing speed. SPECK, although moderately positioned across all metrics, provides a well-rounded trade-off for balanced IoT architectures requiring moderate resource constraints and acceptable security margins. This scoring model supports decision-makers, embedded system designers, and IoT architects in selecting cryptographic primitives that align with application-specific resource availability, performance needs, and energy profiles.

To synthesize the evaluation results, a multi-metric scoring model is developed as shown in Table XV.

Scoring Range: 1 (Lowest), 5 (Highest) The matrix clearly shows:

- AES-128 is best suited when speed and security are primary objectives and hardware acceleration is available.
- PRESENT excels in extreme resource constraints with minimal memory and bandwidth usage.
- SPECK maintains a balanced trade-off, suitable for mid-level IoT devices with moderate constraints.

VII. CONCLUSION

In recent years, IoT technologies have been rapidly adopted by various sectors, including smart homes, healthcare, industrial automation, and transportation. However, securing communication in such resource-constrained environments is still a challenging issue. Although these cryptographic algorithms are highly secure, the enforced high computational and memory overheads render them inapplicable for the low-power IoT devices. To fill this gap, we evaluated lightweight authentication algorithms for energy-conscious IoT systems. Last, a comparative simulation was performed to quantify the performance of three cryptographic algorithms, namely AES 128, SPECK, and PRESENT, concerning key metrics, such as encryption and decryption time, stored memory, and ciphertext size. The findings indicate that:

- AES-128, despite being widely adopted and highly secure, has higher computational demands and a larger ciphertext size, making it less ideal for low-bandwidth IoT networks. However, it remains a viable option when security strength is a priority over computational efficiency.
- SPECK offers a balanced trade-off between speed, memory, and ciphertext size, making it suitable for general IoT applications where efficiency is required without compromising too much on security.
- PRESENT, designed specifically for lightweight environments, exhibits the lowest memory footprint and smallest ciphertext size, making it highly suitable for ultra-low-power IoT devices. However, its encryption and decryption times are relatively high, which may impact real-time performance in latency-sensitive applications.

We introduced a Multi-Metric Suitability Analysis to quantitatively evaluate them by scoring ciphers on a weighted metric to rank the ciphers' suitability for IoT devices. This analysis backs up the fact that there is not a single cryptographic algorithm that will outperform all the others, and it will be decided by application-specific parameters: availability of energy, power available to the processing, and the necessary security level.

The study contributes to the field of lightweight cryptography by demonstrating a structured approach to evaluating cryptographic algorithms using real-world metrics. This research presents a method for implementing and evaluating the cryptographic protocols for IoT security, and the implementation and evaluation methodology can be used as a basis for choosing which cryptographic protocols are appropriate for the demands of IoT security. This study offers a practical and repeatable process of evaluation using a modular simulation framework that can be applied in the future to other cryptographic schemes.

This study shows the need to match security measures with the particular limitations of IoT environments, in addition to highlighting the comparative efficacy of lightweight cryptographic algorithms in safeguarding IoT communications. Our findings add to the current discussion on IoT security practices by offering a better framework for choosing suitable algorithms. The development of lightweight cryptographic solutions will be essential to allowing efficient, energy-saving security procedures that protect sensitive data within these interconnected systems as the IoT expands. In the future, academics and practitioners must concentrate on creating adaptive cryptography techniques that can change in response to new threats and technological developments.

VIII. FUTURE WORK

While this research provides valuable insights into lightweight cryptographic performance, several areas remain open for further investigation. Future research directions include:

First, hardware-based evaluation should measure the power consumption and the execution time of AES-128, SPECK, and PRESENT on real-world embedded IoT hardware (ARM Cortex-M, ESP32, Raspberry Pi).

Second, integration into IoT protocols should evaluate the impact of embedding these ciphers on end-to-end security and network performance; these ciphers have been embedded into lightweight communication protocols such as MQTT, CoAP, and LoRaWAN. Also, tradeoffs in the authentication speed and energy efficiency in secure handshake mechanisms for IoT.

Third, post-quantum lightweight cryptography should explore NIST-recommended post-quantum lightweight cryptographic algorithms that are resistant to attacks from future quantum computers while maintaining efficiency for IoT devices. Also, comparing classical lightweight block ciphers (SPECK, PRESENT) with emerging post-quantum schemes such as NTRUEncrypt or Kyber in constrained environments.

Fourth, optimized key management for IoT should study lightweight key exchange and management techniques to enhance security while minimizing computational burden. Also, implement energy-efficient key renewal mechanisms that adapt to IoT device battery levels and processing capabilities.

Fifth, hybrid cryptographic approaches should investigate hybrid models that combine lightweight encryption (e.g., PRESENT) with stronger authentication mechanisms (e.g., HMAC-SHA256) to balance security and efficiency.

Sixth, security analysis and attack simulations should perform cryptanalysis on lightweight ciphers to understand potential vulnerabilities against real-world threats such as side-channel attacks, differential cryptanalysis, and brute-force attacks.

By addressing these future research areas, the security of IoT systems can be further enhanced while maintaining optimal performance and energy efficiency. Ultimately, the insights from this study and future investigations will contribute to the standardization and practical deployment of lightweight cryptographic solutions in real-world IoT applications.

FUNDING

Hybrid Reinforcement Learning-Based Hyper-Parameter Optimization with Yolov8 Indoor Fire Recognition

Patrick D. Cerna, Harvey C. Quijada, Michael Joseph E. Ortaliz, Kenneth Charles H. Saluna
College of Computer and Information Sciences, Mapua Malayan College Mindanao, Philippines

***Abstract*—This study presents an indoor vision-based fire detection system that integrates a YOLOv8n object detection model with a Reinforcement Learning-based Optimization Algorithm (ROA) for hyperparameter tuning. The research investigates three key aspects: 1) the effectiveness of ROA in improving model performance, 2) the optimal smart camera resolution and placement for indoor fire detection, and 3) the implementation of a real-time dual-channel user notification system. The BantaySunog model iteratively adjusted a few hyperparameters using the Reinforcement Learning-based Optimization Algorithm (ROA) [Talaat & Gamel, 2023]. An episodic framework was used for training, with 15 episodes of 20 epochs each, for a maximum of 300 epochs. Each episode's top weights were carried over to the following one. To balance exploration and exploitation, ROA employed an epsilon-greedy policy with an epsilon value that decreased from 0.9 to 0.2. Experimental results show that while ROA reduced training time and yielded a more conservative prediction strategy, it did not consistently outperform the baseline YOLOv8n in terms of detection metrics such as recall and mAP50-95. Camera deployment tests identified that positioning cameras away from direct light sources significantly improved detection success, with both elevation and resolution contributing to overall system performance. Finally, a dual-channel alert mechanism combining Firebase Cloud Messaging (FCM) and Telerivet SMS API enabled the timely delivery of fire alerts, aligning with real-world standards. The findings contribute to the development of reliable and accessible fire detection systems, especially for densely populated residential areas with limited infrastructure.**

***Keywords*—Fire detection; YOLOv8; reinforcement learning; hyperparameter optimization; convolutional neural network; indoor surveillance; real-time alert system**

I. Introduction

Fires cause significant harm globally due to their destructive potential in residential, commercial, and natural environments [1]. Early detection is essential; for instance, in Seoul, property damage and casualties increase significantly if fires are not reported within five minutes [2]. In the Philippines, over 3,000 incidents occurred in the first two months of 2024 alone, with a majority in residential zones and caused by lighted cigarettes, cooking, and faulty electrical wiring [3]. Davao City has seen a 300% increase in fire damage this year [4-6].

Traditional fire detection systems—based on heat, smoke, or flame sensors—remain dominant due to building code requirements [7], but they suffer delayed activation and high false-alarm rates indoors [8-10]. In contrast, vision-based fire detectors (VFDs) use real-time video analysis and CNNs such as YOLO for faster detection [11, 12], although most current work focuses on outdoor or large-scale fires [7, 13].

This study proposes BantaySunog, an indoor fire detection and alert system combining a YOLOv8n model with hyperparameter tuning via Reinforcement Learning-based Optimization Algorithm (ROA) [14]. It also integrates Firebase Cloud Messaging and the Telerivet SMS API for real-time, dual-channel notifications. The research is guided by three objectives: 1) evaluate the effect of ROA on fire detection performance, 2) identify optimal camera resolution and positioning, and 3) assess the system's ability to deliver real-time alerts under various conditions.

II. Related Works

This section reviews prior studies that informed the design and evaluation of BantaySunog. It focuses on six domains: 1) fire incident trends, 2) traditional vs. vision-based fire detection, 3) reinforcement learning-based optimization of CNNs, 4) image dataset augmentation, 5) camera deployment factors, and 6) multi-channel user notification systems.

Fire outbreaks remain a major threat worldwide due to human error, electrical faults, and inadequate infrastructure [1]. In South Korea, architectural fires account for over 80% of casualties and 88% of fire-related property damage, emphasizing the vulnerability of indoor environments [2]. In the Philippines, smoking and open flames were leading causes of fire in early 2024 [3], with Davao City alone reporting a 300% increase in fire damage [4-6]. Traditional detectors rely on sensors for heat, smoke, or UV radiation [15, 16], but they are susceptible to delayed activation and false positives, particularly in ventilated indoor environments [8-10, 17]. In contrast, VFDs use computer vision and CNNs to detect fire visually in real-time [11, 12], allowing earlier intervention. However, these systems demand high computation and visibility, and can still produce false detections if affected by lighting conditions or obstructions [13, 18, 19].

YOLO-based models have become increasingly favored due to their balance of speed and accuracy [20, 21]. Several studies highlight their adaptability to indoor and smart city scenarios [7, 11, 19]. ROA is a recent reinforcement learning-based method designed to optimize CNN hyperparameters through Q-learning [14]. It uses an agent that iteratively refines network-trained hyperparameters (NTHs) such as learning rate

and loss weights to improve training outcomes. ROA operates by updating a Q-table that guides hyperparameter selection based on prior training rewards. While promising for image classification tasks, its effect on object detection remains underexplored. Data augmentation is essential in training robust models under limited data conditions [22, 23]. Techniques such as flipping, rotation, and color distortion increase dataset variety and reduce overfitting [24-26]. Larger datasets have been created through systematic augmentation [11, 27], often using specialized tools such as Albumentations [28].

Camera resolution, orientation, and elevation play a vital role in real-world deployment. Higher resolution enhances detail detection but increases computational load [29-32]. Camera orientation significantly affects detection accuracy; glare or reflections from windows can lead to false positives [33-37]. Studies suggest that facing cameras away from bright sources improves reliability [38, 39].

Elevation also influences the field of view and detection success. Ceiling-mounted cameras offer wider coverage [40, 41], while lower placements may capture finer details for specific tasks [42]. For timely alerts, fire detection systems must notify users through redundant channels. Firebase Cloud Messaging (FCM) supports rich, image-based mobile notifications [43], while Telerivet's REST API ensures SMS delivery even without internet [44]. Prior research supports combining both for higher reliability in emergencies [45-47]. Such dual-channel systems align with best practices in crisis response and are particularly useful in areas with unstable connectivity.

III. Materials and Methods

This study employed a quantitative research design structured around three objectives: 1) to evaluate the impact of ROA on training a YOLOv8n model, 2) to determine optimal smart camera configurations for fire detection, and 3) to implement a dual-channel alert system for real-time notifications. The conceptual framework in Fig. 1 illustrates the overall workflow of the study.

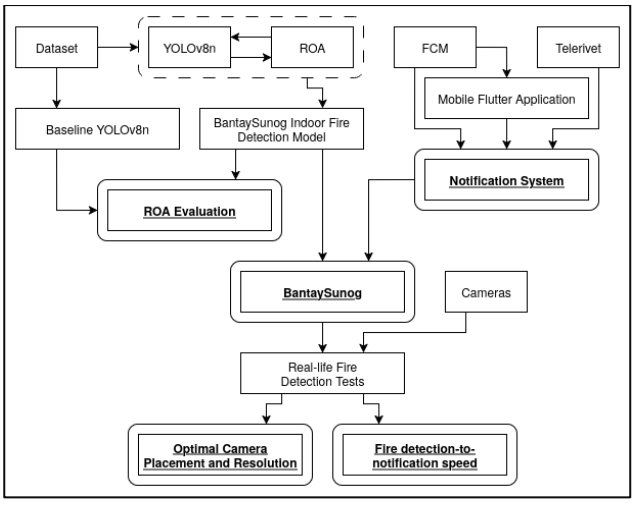

Fig. 1. Conceptual framework.

A. Dataset Augmentation

The "Indoor Fire Detection Dataset" in roboflow [48] was used, comprising 920 labeled images split into training, validation, and test sets. To improve generalization and simulate visual variability, the dataset was expanded to 3,680 images using the Albumentations library [28]. Augmentation steps included horizontal flipping (50% chance), random rotation (±15°, 30% chance), and fixed-angle rotations of 90°, 180°, and 270°. A comparison of the original and augmented versions is shown in Fig. 2.

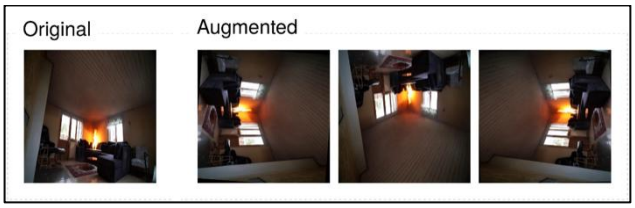

Fig. 2. Sample indoor fire image before and after augmentation.

B. Model Training

Model training was based on YOLOv8n [20] using Ultralytics's YOLO module in Python, executed in Google Colab Pro with NVIDIA T4 GPUs.

The BantaySunog model employed the Reinforcement Learning-based Optimization Algorithm (ROA) [Talaat & Gamel, 2023] to iteratively tune selected hyperparameters. Training followed an episodic structure: 15 episodes of 20 epochs each, totaling 300 maximum epochs. The best weights from each episode were carried over to the next. ROA used an epsilon-greedy policy with the epsilon value decaying from 0.9 to 0.2 to balance exploration and exploitation. Fig. 3 visualizes the episodic training process of the BantaySunog model.

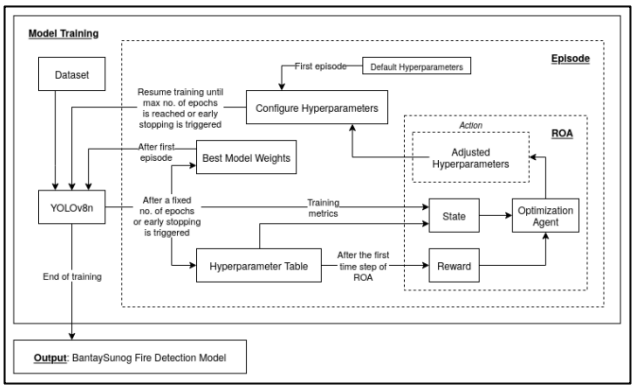

Fig. 3. The BantaySunog model training process.

The hyperparameter search space included four network-trained hyperparameters (NTHs) and three augmentation parameters, as shown in Table I, along with the candidate value ranges for each.

To provide a baseline for comparison with the BantaySunog model, YOLOv8n was trained continuously for up to 300 epochs using default hyperparameters. Early stopping was enabled with a patience of 75 epochs.

TABLE I. HYPERPARAMETER SEARCH SPACE AND VALUE RANGES

Hyperparameter	Default values	Range of values
Final learning rate	0.01	[0.001, 0.005, 0.01, 0.05, 0.1]
Box loss weight	7.5	[7, 7.25, 7.5, 7.75, 8]
Classification loss weight	0.5	[0.38, 0.44, 0.5, 0.56, 0.63]
Distribution focal loss weight	1.5	[1, 1.25, 1.5, 1.75, 2]
Degrees of rotation	0	[0, 45, 90, 135, 180]
Shear factor	0	[0, 3.75, 7.5, 11.25, 15]
Perspective transformation	0	[0, 0.00025, 0.0005, 0.00075, 0.001]

C. ROA Evaluation

This study employed a systematic evaluation comparing the BantaySunog model's training and testing results against those of the baseline YOLOv8n model trained with default values to determine the effectiveness of ROA as a hyperparameter optimization strategy. The following key metrics were considered in the training and testing results comparisons: 1) precision, which measures the proportion of correctly identified fire instances among all detections made, 2) recall, which captures the model's ability to detect actual fire instances present in the scene, 3) mAP50, which represents the average precision across all classes using a single Intersection over Union (IoU) threshold of 0.50, and 4) mAP50-95, a more comprehensive metric that evaluates the model's fine-grained localization accuracy and consistency.

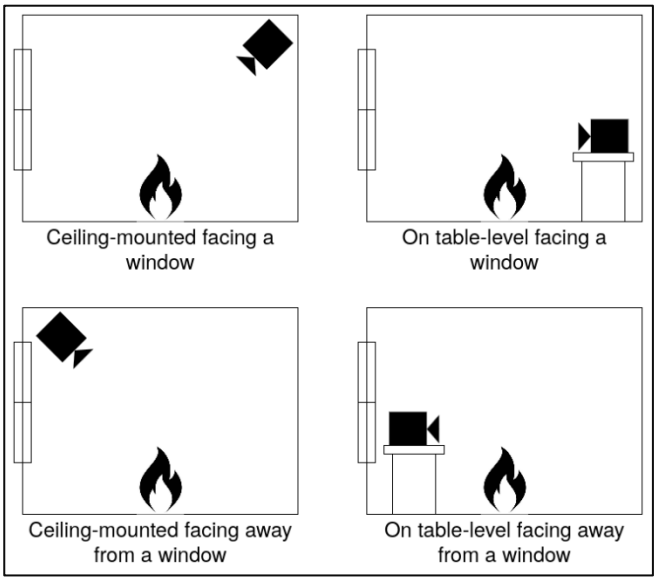

Fig. 4. Camera placements for testing.

D. Camera Resolution and Placement

Three TP-Link Tapo cameras were tested: C200 (1080p), C211 (2K 3MP), and C220 (2K QHD). Each camera was deployed in four positions: 1) ceiling-mounted facing a window, 2) table-level facing a window, 3) ceiling-mounted facing away from a window, and 4) table-level facing away. Each position is illustrated in Fig. 4. This experiment evaluated how resolution, glare exposure, and elevation influence fire detection accuracy [29, 38, 40].

E. Notification System

To ensure prompt alerts under various connectivity conditions, a dual-channel system was developed. Firebase Cloud Messaging (FCM) [43] was used for push notifications via a Flutter mobile app. For offline scenarios, Telerivet's REST API [44] was integrated into the model to trigger SMS alerts through a dedicated Android gateway.

F. Expert Consultation on Real-world Standards

The detection-to-notification delay was benchmarked based on guidance from Fire Officer 1 Jesardnel S. Vargas, FDAS Specialist at BFP Davao. He specified a maximum 30-second detection window from the fire's incipient stage. During camera tests, a stopwatch mechanism was used to measure detection and alert times relative to this benchmark.

IV. RESULTS AND DISCUSSION

On the original training set, the baseline model completed training in 117 epochs (0.378 hours), whereas the ROA-optimized BantaySunog model converged slightly faster in 106 epochs (0.362 hours). This trend persisted on the augmented training set, where the baseline required 176 epochs (2.265 hours) compared to BantaySunog's 149 epochs (2.045 hours). These results indicate that ROA reduced both the number of epochs and the amount of time needed for training.

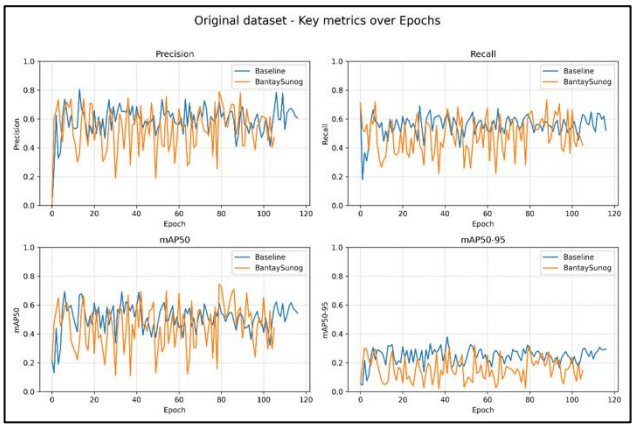

Fig. 5. Training metrics on the original dataset.

However, on the original training set, the baseline model outperformed BantaySunog in training stability and performance, as seen in Fig. 5. Precision and mAP50 curves were higher and more stable for the baseline, while BantaySunog showed greater volatility—especially in mAP50–95, signaling weaker localization quality. Recall was similarly less consistent, with the baseline maintaining centered, stable performance across epochs while BantaySunog showed frequent dips and underperformance.

The performance gap widened on the augmented training set. The baseline model consistently led across all metrics—precision, recall, mAP50, and mAP50–95—while BantaySunog's curves remained flatter and lower in amplitude, as seen in Fig. 6. This suggested minimal learning progress per epoch and an inability to scale with the increased dataset complexity. Although BantaySunog occasionally peaked in precision during early epochs, this was not sustained and came at the cost of reduced recall and poor localization.

While ROA improved convergence speed, it failed to enhance—and in some cases undermined—training quality. The training metrics indicate that ROA guided the model toward more conservative but less effective learning behavior, especially on complex datasets. These results raise concerns about ROA's generalizability and its adaptability to broader training conditions beyond fast convergence.

On the original testing set, the baseline model outperformed the BantaySunog model in nearly all key metrics. Most notably, it achieved higher recall (0.9227 vs. 0.7879) and mAP50–95 (0.5548 vs. 0.3646), indicating better detection coverage and localization accuracy. Although BantaySunog reported higher precision (0.9217 vs. 0.8354), this came at the expense of missing more true positives, consistent with a more conservative detection strategy. This behavior likely stems from ROA's tuning bias toward reducing false positives. Fig. 7 compares the testing result metrics from both models on each dataset, while Fig. 8 and Fig. 9 visually illustrate this conservativeness, showing sparser bounding box predictions compared to the baseline's more liberal detection.

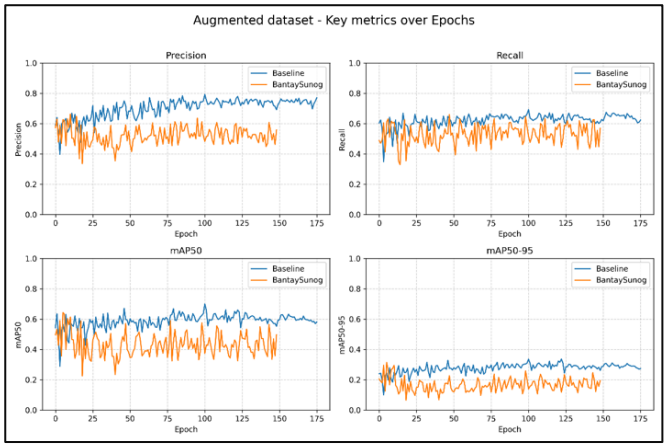

Fig. 6. Training metrics on the augmented dataset

On the augmented testing set, performance between the two models became more comparable, though the baseline still led in key areas. It slightly surpassed BantaySunog in precision (0.8896 vs. 0.8841) and mAP50–95 (0.5564 vs. 0.5153), while BantaySunog exhibited minor gains in recall (0.8664 vs. 0.8546) and mAP50 (0.9179 vs. 0.8898). These results suggest that ROA may provide some benefit in detecting more fire instances and improving bounding box coverage under data-rich conditions, but not enough to yield consistently superior overall performance.

ROA appears to promote cautious predictions but falls short in enhancing generalization. The occasional metric gains under augmentation are outweighed by consistent underperformance in stricter quality measures such as mAP50–95. This reinforces concerns about ROA's limited scalability and its tendency to prioritize false-positive minimization over comprehensive detection quality.

The ROA-optimized BantaySunog model consistently trained faster than the baseline YOLOv8n, converging in fewer epochs and with reduced wall time. However, this efficiency came at the cost of performance. Training curves were flatter, especially on the augmented dataset, indicating limited learning progress. Testing results echoed this trend: BantaySunog had lower recall and mAP50–95 on the original dataset and only marginal improvements under augmentation. Its higher precision reflected a conservative prediction style, but this also meant missing more true positives and weaker localization. Overall, while ROA reduced training duration, it did not enhance—and sometimes degraded—detection quality, suggesting that further refinement is needed before ROA can reliably optimize CNN-based object detectors for safety-critical applications.

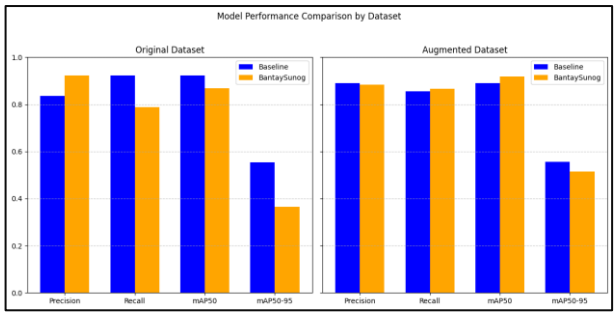

Fig. 7. Comparison of testing results.

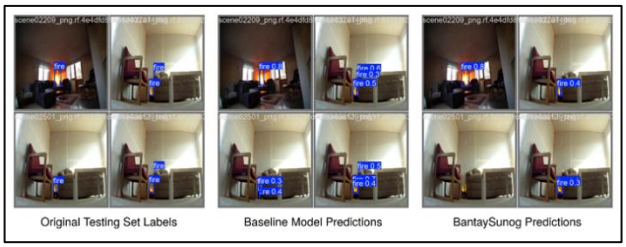

Fig. 8. Original testing set predictions from each model.

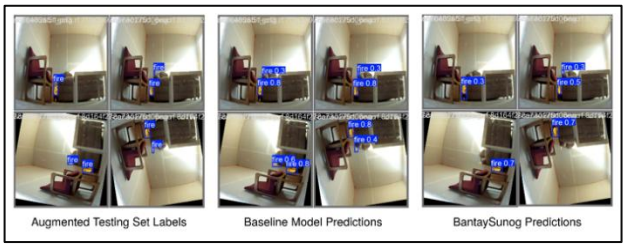

Fig. 9. Augmented testing set predictions from each model.

A. Optimal Camera Resolution and Placement

To determine optimal camera deployment for indoor fire detection, three smart cameras—TP-Link Tapo C200 (1080p), C211 (2K 3MP), and C220 (2K QHD)—were tested across four configurations: ceiling-mounted and table-level, each facing toward or away from a window. These combinations were chosen to evaluate the effects of resolution, elevation, and light source orientation on detection reliability.

Results revealed that camera orientation relative to light sources had the greatest influence on detection success. As shown in Table II, all three cameras consistently achieved better results when positioned away from windows, regardless of resolution or mounting height. Cameras facing windows frequently failed to detect fire instances due to glare,

reflections, or contrast loss—particularly in brightly lit environments.

TABLE II. FIRE DETECTION RESULTS FROM EACH CAMERA AND POSITION

Cameras	Facing window		Facing away from window	
	On ceiling	On table-level	On ceiling	On table-level
C200	Fail	Fail	Success	Success
C211	Fail	Success	Success	Success
C220	Fail	Success	Success	Success

Fig. 10. Fire detection frames from ceiling-mounted cameras.

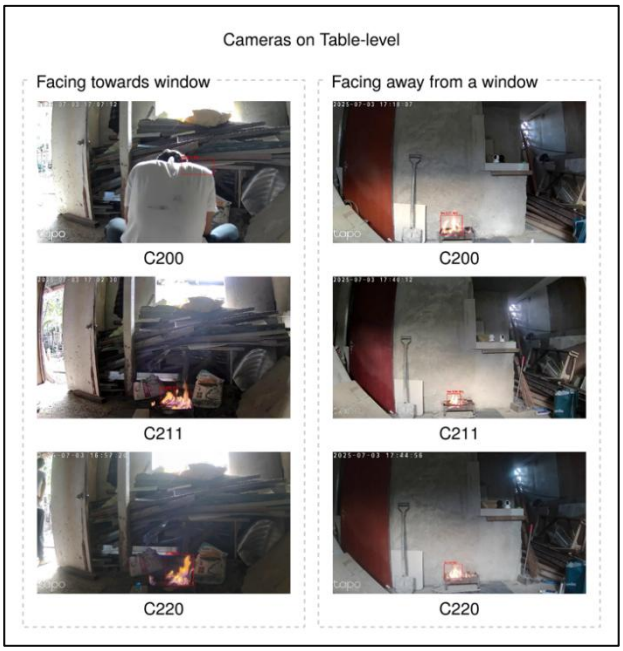

Fig. 11. Fire detection frames from table-level cameras.

While higher resolution (2K) offered marginal improvements in detecting small or distant flames, the gains were not substantial enough to justify the added computational overhead if placement was suboptimal. In particular, the C211 (2K 3MP) showed slightly better overall performance across conditions, but even this model struggled in unfavorable orientations. Visual results in Fig. 10 and Fig. 11 support these findings, with clearer and more accurate detections appearing in camera views facing away from light.

These results suggest that proper orientation and strategic positioning—avoiding direct light interference—are more critical to reliable fire detection than increasing resolution or changing elevation alone. Such insights are vital for effective system deployment in real-world environments, especially where infrastructure constraints limit camera options.

B. Implementation of the Notification System

To ensure timely user alerts in both connected and offline environments, BantaySunog integrates a dual-channel notification system using Firebase Cloud Messaging (FCM) and the Telerivet SMS API. Upon detecting a fire, the system automatically sends both an image-rich push notification and a backup SMS containing fire detection details.

Fig. 12 shows the FCM and SMS notifications on the end-user smartphone. This confirms the successful reception of alerts from BantaySunog through FCM and Telerivet in the end-user smartphone.

Fig. 12. FCM and SMS notifications.

TABLE III. FIRE DETECTION-TO-NOTIFICATION TIMES FROM SUCCESSFUL FIRE DETECTIONS

Successful camera configurations	Time (seconds)
C220, Table-level, Facing window	18.749
C211, Table-level, Facing window	8.495
C200, Table-level, Facing away from window	9.658
C211, Table-level, Facing away from window	9.446
C220, Table-level, Facing away from window	7.264
C220, Ceiling-mounted, Facing away from window	15.192
C220, Ceiling-mounted, Facing away from window	7.396
C220, Ceiling-mounted, Facing away from window	9.324

Table III presents the fire detection-to-notifications times from the successful fire detections during the tests to determine the optimal camera configuration. The average delay between fire detection and full alert receipt was 10.69 seconds. This includes model processing, message generation, and cross-platform delivery. All alerts were received in under 30 seconds, meeting the benchmark advised by FO1 Vargas of BFP Davao.

These results affirm that BantaySunog's notification system meets the real-time responsiveness required for fire emergencies and offers high reliability through multi-channel delivery.

V. CONCLUSIONS AND RECOMMENDATIONS

This study introduced BantaySunog, an indoor vision-based fire detection system that integrates a YOLOv8n object detection model with a reinforcement learning-based optimization algorithm (ROA), paired with a dual-channel alert system. The research evaluated three primary objectives: improving training performance through ROA, identifying optimal camera configurations for deployment, and ensuring real-time alert delivery under realistic conditions. Findings show that while ROA reduced training time and promoted a conservative prediction strategy, it failed to consistently improve detection performance. The BantaySunog model often underperformed in recall and mAP50–95, especially on the original dataset, suggesting that ROA's policy may require further tuning to handle more complex or diverse training scenarios. This indicates that, in its current form, ROA is not a reliable drop-in optimization tool for CNN-based fire detection in safety-critical applications.

Camera deployment tests revealed that orientation—specifically avoiding direct exposure to windows or light sources—had a greater impact on detection reliability than resolution or elevation. Proper placement significantly reduced false negatives, underscoring the importance of environment-specific configuration in real-world deployments. The dual-channel alert system using FCM and Telerivet successfully delivered notifications within an average of 10.69 seconds, well below the 30-second threshold advised by the Bureau of Fire Protection. This confirms the system's readiness for deployment in infrastructure-limited environments where redundancy and speed are critical. Future work should explore adaptive versions of ROA or alternative reinforcement learning strategies tailored for object detection. Additional evaluation in real fire conditions, including smoke or occlusion scenarios, would strengthen generalizability. Deployment across multiple households with varied layouts could further validate the system's robustness in uncontrolled environments.

Adaptive Open Cyber Intelligence for SOAR: Reduced False Positives in Low-Resource Environments

Shunmugam U*, Rajesh D
Department of Computer Science and Engineering,
Vel Tech Rangarajan Dr. Sagunthala R&D Institute of Science and Technology, Chennai, India

***Abstract*—The increasing use of resource-constrained cyber-physical devices emphasizes the need for effective and flexible methods in the deployment of threat intelligence. The Open Cyber Intelligence Framework (OCIF), an architecture that applies Security Information and Event Management (SIEM) and Security Orchestration, Automation, and Response (SOAR) capabilities to resource-constrained environments, is presented in this study. The OCIF uses lightweight machine learning models in an adaptive way to process cyber threat intelligence (CTI) with greater precision and effectiveness. By using Wazuh to monitor the behavior of machines and OpenSearch for modeling the results of the analysis, the OCIF can reduce false positives by up to 6% in real-world implementations. The model ensures sufficient threat mitigation without taxing the system by striking a balance between anomaly detection, context, and decreased communication overhead. Because of its open-source propagation and modular form factor, OCIF promotes innovation and makes it possible for CTI to be built and used in restricted resources with optimal detection and operational efficiency.**

***Keywords*—Open Cyber Intelligence Framework; SOAR; SIEM; Cyber Threat Intelligence; false positive reduction; threat mitigation; anomaly detection**

I. Introduction

The proliferation of resource-constrained devices permeates every aspect of the connected world in the modern digital era, making the critical need for cybersecurity tailored to these devices' particular challenges indisputable. A paradigm shift in how we protect sensitive data and infrastructure is required due to the emergence of Internet of Things (IoT) sensors, embedded systems, and other limited devices [1]. Adaptive Deployment Strategies and Threat Intelligence Integration are two crucial aspects of the Open Cyber Intelligence Framework (OCIF) that are thoroughly examined in this research study.

Resource-constrained devices, characterized by limitations in processing power, memory, and bandwidth, inherently pose a formidable challenge to traditional cybersecurity frameworks. Recognizing this, the OCIF emerges as a beacon of innovation, seeking to not merely address these challenges, but to redefine the parameters of adaptive and effective cybersecurity tailored explicitly for devices with constrained resources [2].

Traditional cybersecurity frameworks are inherently challenged by resource-constrained devices, which are defined by limitations in processing power, memory, and bandwidth. Acknowledging this, the OCIF becomes a shining example of innovation, aiming to redefine the parameters of effective and adaptive cybersecurity specifically designed for devices with limited resources, rather than just addressing these issues [2]. For IoT and cyber-physical systems, the majority of current intrusion detection and CTI solutions are still too bulky, insufficiently flexible, and prone to a high rate of false positives in environments with limited resources. In actuality, the majority of CTI and SOAR/SIEM models make assumptions about high bandwidth and processing power, which leaves a crucial gap for severely constrained devices [3].

For IoT and cyber-physical systems, the majority of current intrusion detection and CTI solutions are still too bulky, insufficiently flexible, and prone to a high rate of false positives in environments with limited resources. In actuality, the majority of CTI and SOAR/SIEM models make assumptions about high bandwidth and processing power, which leaves a crucial gap for severely constrained devices [3]. The expansion of the Internet of Things (IoT) exposes lightweight computing devices to an increasing number of attacks, necessitating the urgent need for a low-overhead, adaptable framework that integrates automated deployment and CTI. This work uses the Open Cyber Intelligence Framework, or OCIF, to address this need.

The Threat Intelligence Integration component of OCIF takes on the task of efficiently absorbing and processing real-time threat data in order to support the adaptive deployment initiatives. Context-aware integration, scalable data processing methods, the creation of an ongoing feedback loop, and reliable experimental validation are all given special attention in this area of study. This dimension seeks to bridge theoretical underpinnings with empirical evidence and to offer useful insights into efficient Threat Intelligence Integration methodologies for resource-constrained devices by utilizing platforms like Wazuh [4] in conjunction with predefined machine learning algorithms available in OpenSearch.

A. Cyber Threat Intelligence (CTI) for IoT

Due to the growing amount of Digital Connectivity and the addition of Internet of Things (IoT) devices across every aspect of every person's life, the need for a Proactive and Adaptive Cybersecurity Paradigm is higher than it's ever been before. Cyber Threat Intelligence (CTI) has become a pivotal discipline for providing increased Cyber Resilience to IoT Ecosystems in an evolving Threat Landscape. The rapid

*Corresponding author.

Growth of this interconnected Ecosystem has created many Security Challenges for IoT devices, from Smart Home Devices to Industrial Sensors, requiring a Sophisticated and Context-Aware approach.

B. The IoT Landscape

The internet of things (IoT) consists of a large number of electronically connected devices, which together make up a matrix of vulnerabilities and attack vectors that can be exploited by hackers. The features and functions incorporated into IoT devices are designed to add convenience and efficiency for the user; however, due to the limited processing power and variety of communication protocols between these devices, they are susceptible to cyberattacks. Therefore, to successfully secure the IoT ecosystem, it is critical to fully comprehend the functionality of IoT devices and have continuous monitoring of the continually changing cyber threat landscape.

C. Dynamics of Cyber Threat Intelligence

In the context of IoT, cyber threat intelligence is a proactive and strategic method of identifying, reducing, and eliminating cyberthreats. It entails gathering, evaluating, and sharing useful information about possible risks to IoT networks and devices. By offering contextual insights into the strategies, tactics, and practices used by adversaries in the IoT space, CTI enables organizations to go beyond reactive defense mechanisms, in contrast to traditional cybersecurity measures.

D. Contextualizing Threats in the IoT landscape

To properly secure IoT devices and networks from cyber attacks, an IoT expert must understand the threats to the device/network at a high level. This is accomplished through the use of Cyber Threat Intelligence (CTI) applied to IoT. When CTI is applied to IoT, it doesn't just allow the IoT expert to identify malicious traffic; it also enables the expert to understand how to interpret the traffic associated with a particular IoT device, how to spot patterns in the traffic, and how to identify abnormal behaviour based on the patterns when viewed in the context of the overall IoT ecosystem.

E. Integrating Threat Intelligence into IoT Security Posture

To stay ahead of the competition, IoT security postures must incorporate Cyber Threat Intelligence. To find possible threats, it makes use of machine learning algorithms, advanced analytics, and real-time monitoring. Organizations can strengthen the resilience of IoT devices and networks by improving their capacity to identify and address new threats through the integration of threat intelligence feeds.

F. Contributions of this Research

- Integrated Framework for Adaptive Deployment and Threat Intelligence
- Adaptive deployment strategies specifically tailored for resource-constrained devices.
- Context-Aware Threat Intelligence Integration
- Application of Machine Learning Algorithms
- A significant contribution of the research is its explicit focus on reducing false positives, a common challenge in cybersecurity operations

G. Novelty of this Research

- The study suggests an integrative strategy that combines continuous threat intelligence integration with adaptive deployment strategies. This entire framework, which is integrated into the OCIF, offers a complete solution for protecting devices with limited resources.
- In order to ensure the best cybersecurity measures while taking into account the limitations of these devices, the research presents Adaptive Deployment Strategies designed especially for resource-constrained devices. This entails not only understanding and profiling the devices but also implementing lightweight communication protocols, modular deployment architectures, and adaptive resource allocation.
- The ongoing integration of threat intelligence is tailored to environments with limited resources. This includes context-aware integration, real-time data ingestion, and scalable data processing techniques made to function well in settings with constrained computational power.

The organization of this research study is clear and consists of five main sections. In Section II, we will conduct a complete literature survey that reviews the current literature related to Cybersecurity for Resource-Constrained Devices (RCRDs), Adaptive Deployment Strategies, and Continuous Threat Intelligence Integration, while identifying any gaps in the existing body of knowledge. In Section III, we will discuss the methods used, including the creation of an Open Cybersecurity Infrastructure Framework (OCIF), and present Adaptive Deployment Strategies that include Device Profiling, Lightweight Protocols, and Contextual Awareness. In addition, we will discuss Continuous Threat Intelligence Integration techniques, which consist of Real-Time Data Ingestion and Scalable Processing. Section IV contains a detailed description of the Experimental Setup used in this study, which includes Wazuh and OpenSearch as well as a discussion of the results and their effect on the number of false positives. Section V concludes this research by summarizing the major results and discussing the implications for the community.

II. Related Works

The limited resources of devices, such as processing power, memory, and energy, pose serious challenges to traditional approaches to cyberattack detection. Devices are vulnerable to a number of potential attacks, including data manipulation, resource depletion, and denial of service (DoS). AlWaisi et al. [1] have presented a novel framework to address these problems. This framework uses machine learning (ML) models optimized for low-resource devices to combine anomaly detection, feature extraction, and lightweight data collection. The main objective is to reduce computational load and memory usage by optimizing machine learning models while taking available resources into account. Effective attack detection is made possible by this methodology, which also saves operating time and monitors energy consumption.

Kornaros et al. [2] have explored hardware-assisted methods to overcome these resource constraints. Examples include engineered architectures with specialized memory units, dedicated accelerators for specific ML tasks, and secure enclaves for trusted execution. However, incorporating hardware accelerators requires careful evaluation of compromises related to expense, power usage, and complexity. Moreover, achieving a balance between latency, accuracy, and memory usage is crucial to optimizing machine learning models for devices with limited resources. Arshad et al. [3] introduced an intrusion detection framework tailored for energy-constrained IoT devices. This framework addresses obstacles such as processing capacity restrictions and energy consumption limitations. It highlights the importance of implementing a specialized intrusion detection system to efficiently mitigate security risks.

A methodology for protecting IoT nodes with limited resources is presented by Shalaginov et al. [4], highlighting the importance of intelligent microcontrollers in distributed smart application attack detection. This entails incorporating advanced strategies like intelligent microcontrollers, machine learning algorithms, or other approaches intended for effective operation on IoT nodes with constrained resources. Increased security, fewer false positives, and less demand on device resources are possible advantages. The increasing use of fog computing in critical infrastructure systems and the ensuing security issues are acknowledged by Khan et al. [5]. They stress the importance of proactive defense tactics against possible cyberthreats. A hybrid DL-driven framework for SDN-enabled cyber threat detection in the Internet of Things is presented by Javeed et al. [6]. The framework likely centres on some of the main components of SDN. The authors believe that SDN provides additional customisation of networks and that the use of SDN also boosts the ability of detection algorithms to identify new cyberthreats. The second aspect of cybersecurity is the work by Khan et al. [7], who present a model for using data analysis to enable the detection and mitigation of malicious/internal human threats. An assessment of the data analytics methods used, as well as measurable rates of accuracy and the ability of the system to adapt to differing characteristics within IoT environments, will be included in this model.

Jeffrey et al. [8] performed an exhaustive review of current research on anomaly detection methods in the CPS Security field and classify the methods into three categories: statistical, machine learning, and hybrid methods. The authors' assessment will include various aspects, including false-positive rates, scalability, the rate of accuracy in detecting anomalies, and adaptability to dynamic CPS environments. The paper by Bradbury et al. [9] provides an assessment of the basic principles for threat modelling used to establish the trust mechanisms in outsourced task deliveries for IoT devices that have limited resource capability. The authors discuss examples of where the methods proved successful in identifying, deterring secure delegated tasks, and maximising the efficient use of resources. The study by Aljuhani et al. [10] presents the integration of AI methods as an enhancement to the intelligence of IoMT sensors/devices having limited resource capacity.

This entails using AI algorithms, such as machine learning and deep learning, to identify unusual behavior and possible security risks. The assessment might offer a thorough description of particular AI models or algorithms that are employed, highlighting their advantages in adjusting to changing threat environments. They might also go over how the recommended SaaS-based IDS ensures interpretability and clarity, enabling system administrators and healthcare professionals to comprehend and trust the system's output. Celdrán et al. [11] emphasize the significance of creating creative and resource-efficient strategies to lessen ransomware attacks, especially on Internet of Things (IoT) devices and other computing devices with limited capabilities.

This investigation is intended to examine the major principles of how Behavioral Fingerprinting works, including how this method provides a basis for identifying and tracking the distinct behaviors of ransomware in resource-limited systems. In regards to the Passban IDS, Eskandari et al. [12] have done extensive work on how the Passban IDS was built, including a review of its conceptual framework and the methodologies used to create it, including the methods by which the system applies intelligent anomaly detection in IoT devices, which may be highlighted by the use of modern technologies, such as machine learning or artificial intelligence, which assist the system in establishing the difference between normal and anomalous behavior. Zhu et al. [13] focus their work on the conceptual framework and design of the GV-FL methodology in APT detection for IoT devices, and their work will address the theoretical basis for the Federated Learning concepts and what adaptations will be necessary to adapt this to the APT detection area. With particular modifications made to the field of APT detection, the study is anticipated to concentrate on the theoretical foundations of federated learning. Crucially, a global viewpoint can be taken into account, elucidating how an integrated and federated approach enhances the ability to learn and detect among a group of devices with limited capacity.

Liaqat et al. [14] provide contextual information in the IoMT domain by highlighting the growing integration of medical technologies and devices into networked systems to improve healthcare services. The talk describes the particular security challenges that IoMT faces, highlighting how vulnerable medical devices are to cyberattacks and promoting resilient and adaptable security measures.

In the IoMT domain, Liaqat et al. [14] offer contextual information by emphasizing the increasing incorporation of medical devices and technologies into interconnected systems to enhance healthcare provisions. The discourse outlines the unique security dilemmas encountered by IoMT, emphasizing the susceptibility of medical devices to cyber threats and advocating for security mechanisms that are both adaptive and resilient.

The analysis of low-rate DDoS attacks attacks using the MQTT protocol in Software-Defined IoT is addressed in Al-Fayoumi et al. [15]. Al-Fayoumi et al.'s work provides insights into the challenges of low-rate DDoS attacks and proposes a potential solution by using Software-Defined Network (SDN) for Internet of Things (IoT) [15]. The authors develop their

methodology by integrating SDN with a deep learning algorithm to detect intrusions into the IoT network. Doriguzzi-Corin et al. [16] detail in their work an SDN and deep learning-based Intrusion Detection System for IoT (IDSIoT-SDL). They highlight the complexity of IoT security and provide extensive analysis of the complexities of IoT security.

Doriguzzi-Corin et al.'s [16] IDSIoT-SDL methodology integrates deep learning algorithms with SDN to provide an intrusion detection system for IoT. Lauf et al. [17] describe a distributed intrusion detection system and hint that understanding of the system's architecture may be warranted to assess how the system distributes detection of intrusions over the network. From Lauf et al.'s analysis, it is evident that distributing the detection process will reduce the workload on each IoT device and allow the architecture to use the advantages of the collaborative approach to support the security of the entire network. In their analysis of the state of deep learning-based DDoS attack detection, Doriguzzi-Corin et al. [18] highlight the LUCID system as a novel and useful method. An overview of the growing threat environment posed by Distributed Denial of Service (DDoS) attacks is anticipated to open the discussion, highlighting the vital significance of putting in place efficient detection systems.

In an examination of an alternative aspect of cybersecurity, Khan et al. [19] investigate the distinctive obstacles and susceptibilities linked to IoMT devices. The severity of the potential repercussions of security breaches in medical environments is duly recognized. The discourse may encompass prevalent challenges and avenues of entry that specifically target healthcare networks and medical devices, with an emphasis on the criticality of implementing resilient and intelligent malware detection systems. In their comprehensive analysis, Aliabadi et al. [20] thoroughly investigate the unique characteristics of CPS constrained by resources, particularly focusing on limitations imposed by computing capacity, memory, and energy. The authors also direct their attention towards the consequences of these limitations on traditional intrusion detection approaches. They underscore the critical need for inventive and effective methods specifically designed to overcome the obstacles presented by environments with limited resources. Concerning the mitigation of DDoS attacks, Adat et al. [21] may provide further details regarding the operational principles and architectural design of a framework. Their discourse might emphasize how the suggested framework tackles the unique obstacles when attempting to alleviate DDoS attacks in Internet of Things environments. It is possible to highlight the significance of device heterogeneity, scalability, and real-time responsiveness in the framework's design.

Ayyat et al. [22] investigate the ramifications of implementing class-aware neural networks for peripheral device intrusion detection in a related context. The authors highlight the capacity of these networks to address the distinct obstacles arising in environments with limited resources. Nguyen et al. [23] provide an exhaustive examination of the present state of network intrusion detection systems (NIDS) concerning IoT gateways, adopting a broader viewpoint. Their investigation illuminates the shortcomings of conventional NIDS approaches and methodologies concerning IoT gateways. The analysis likely highlights the unique attributes of IoT networks, such as heterogeneity, limited resources, and the ever-changing nature of IoT traffic. These distinctive characteristics present obstacles for traditional intrusion detection systems.

From the literature, it is noted that in the realm of cybersecurity, several studies highlight distinct challenges and vulnerabilities associated with emerging technologies. One examination focuses on the security implications of IoT devices in medical contexts, recognizing the potential gravity of breaches in healthcare environments. A lot of study explores the limitations of CPS, particularly those constrained by resources like computing capacity, memory, and energy, emphasizing the necessity for innovative intrusion detection methods in such environments. Addressing the mitigation of Distributed Denial of Service (DDoS) attacks in IoT settings, a different set of frameworks are discussed, underlining considerations of device heterogeneity, scalability, and real-time responsiveness. In a broader context, the exploration of class-aware neural networks for peripheral device intrusion detection highlights their adaptability to challenges in resource-limited environments. Additionally, an extensive examination of network intrusion detection systems (NIDS) for IoT gateways sheds light on the inadequacies of conventional approaches in addressing the unique attributes of IoT networks, including heterogeneity, limited resources, and dynamic traffic patterns. Collectively, these studies underscore the diverse cybersecurity challenges associated with emerging technologies, emphasizing the imperative for specialized and adaptive security measures. Hence this research proposes a novel OCIF for automated deployment and advanced CTI.

III. Adoptive Deployment and Continuous Threat Intelligence Integration

In the proposed approach to make cybersecurity work well for devices with limited resources, we focus on two key parts: Adaptive Deployment and Continuous Threat Intelligence Integration. Adaptive Deployment deals with understanding these devices, making their communication efficient, and adjusting resources dynamically. On the other hand, Continuous Threat Intelligence Integration is about keeping an eye on the latest threats, adapting to the device's situation in real-time, and always learning from what's happening. These two methods, combined within the Open Cyber Intelligence Framework (OCIF), create a smart and effective cybersecurity plan. The goal is to make security fit the unique features of devices with fewer resources, making it adaptable and responsive to the ever-changing world of threats. Fig. 1 shows the architecture of the proposed OCIF.

A. Adaptive Deployment Strategies

The Adaptive Deployment Strategies component of the OCIF methodology focuses on tailoring the deployment process to the unique operational constraints and characteristics of resource-constrained devices. This involves a meticulous understanding of the diverse ecosystem encompassing Internet of Things (IoT) sensors, embedded systems, and other constrained devices. The adaptive nature of the OCIF ensures that the deployment process is optimized, minimizing the impact on device resources.

B. Device Profiling

In the context of OCIF's Adaptive Deployment Strategies, the process of device profiling involves more than a surface-level examination. It necessitates a comprehensive understanding of the hardware specifications, operating systems, and communication protocols that define the target device ecosystem. This depth of analysis is pivotal in forming robust device profiles, which subsequently inform tailored deployment strategies. The steps involved in real-time device profiling include:

- Conduct an in-depth analysis of the target device ecosystem to create comprehensive device profiles.
- Identify specific constraints such as limited processing power, memory, and bandwidth to inform adaptive deployment strategies.
- Categorize devices based on their functionalities and criticality to prioritize deployment efforts.

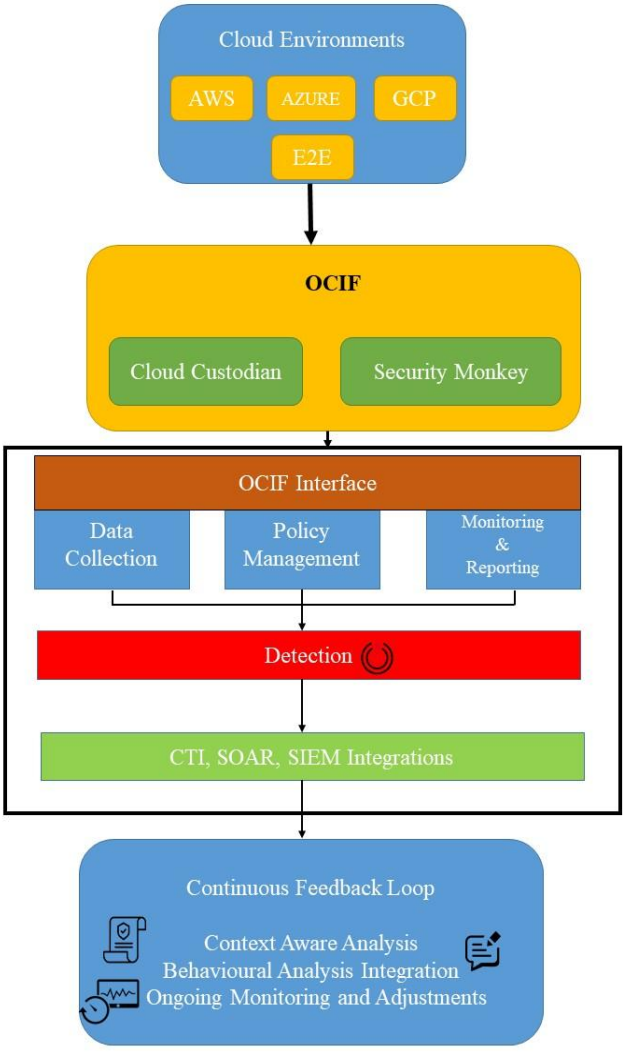

Fig. 1. Architecture of the proposed OCIF.

C. Lightweight Protocols

The design and implementation of lightweight communication protocols are central to the success of OCIF's Adaptive Deployment Strategies. As a researcher, the focus here lies in striking a delicate balance between efficiency and minimal overhead. Leveraging industry standards while customizing protocols ensures that the communication mechanisms are not only standardized but also adapted to the unique demands of resource-constrained environments.

D. Modular Deployment Architecture

The concept of a modular deployment architecture speaks to the flexibility required in adapting the OCIF to diverse devices incrementally. In this context, as a researcher, one must delve into the intricacies of modular design – ensuring that each module is not only adaptable but also able to seamlessly integrate with various devices. The goal is to create an architecture that is both scalable and responsive to the evolving demands of the device ecosystem. The design and deployment architecture includes:

- Design the OCIF with a modular architecture to allow for flexible and incremental deployment.
- Modules should be adaptable to different device types and functionalities, enabling a phased deployment approach.
- Ensure that each module aligns with the specific constraints of the targeted devices, enhancing scalability and ease of integration.

E. Threat Intelligence Integration

The Threat Intelligence Integration component of the OCIF methodology revolves around seamlessly incorporating threat intelligence feeds into the framework. This integration is designed to be agile, ensuring that devices can efficiently ingest and process threat intelligence data without compromising their limited computational resources.

F. Real-time Threat Data Ingestion

The process of real-time threat data ingestion is pivotal for OCIF's efficacy in responding promptly to emerging threats. In a research context, this involves exploring mechanisms that enable devices to receive threat intelligence updates with minimal latency. Investigating incremental updates and delta mechanisms becomes crucial to reduce the data transfer volume while ensuring the timely availability of the latest threat information. The steps involved in real-time threat data ingestion include:

- Develop mechanisms for real-time ingestion of threat intelligence data by resource-constrained devices.
- Implement protocols that enable devices to receive updates without significant latency, ensuring the timely availability of the latest threat information.
- Consider the use of incremental updates and delta mechanisms to minimize the data transfer volume.

G. Context-Aware Integration

The concept of context-aware integration speaks to the need for aligning threat intelligence feeds with the operational characteristics of each device. For a researcher, this necessitates an exploration of adaptive integration mechanisms that can dynamically adjust to device-specific threat indicators and indicators of compromise. The integration should not only consider the technical attributes but also incorporate the environmental context, refining threat detection algorithms for a more nuanced approach. The steps involved in real-time integration include:

- Tailor the integration process to be context-aware, aligning threat intelligence feeds with the operational characteristics of each device.
- Consider device-specific threat indicators and indicators of compromise to enhance the relevance and accuracy of threat intelligence data.
- Integrate contextual information about the device's environment to refine threat detection algorithms.

H. Scalable Data Processing

Scalable data processing within the OCIF framework is a research frontier that involves addressing the challenge of efficiently handling large volumes of threat intelligence data. This requires investigating parallel processing and distributed computing principles to design mechanisms that can accommodate the diverse scale of resource-constrained devices. Integrating machine learning algorithms into the processing pipeline becomes imperative to prioritize and categorize threat intelligence data based on severity and relevance. The steps involved in real-time data processing include:

- Implement scalable data processing mechanisms within the OCIF to handle large volumes of threat intelligence data efficiently.
- Utilize parallel processing and distributed computing principles to ensure that the framework can accommodate the diverse scale of resource-constrained devices.
- Integrate machine learning algorithms to prioritize and categorize threat intelligence data based on the severity and relevance to each device.

I. Continuous Feedback Loop

Establishing a continuous feedback loop is a research area critical for refining the Threat Intelligence Integration process within OCIF. This involves mechanisms where devices provide insights into the effectiveness of received threat intelligence data. As a researcher, exploring feedback mechanisms and algorithms that dynamically adjust and adapt threat intelligence feeds based on real-world observations is essential for the continuous optimization of the integration process. The steps involved in the feedback loop include:

- Establish a continuous feedback loop that enables devices to provide insights on the effectiveness of the threat intelligence data received.
- Implement mechanisms to adjust and adapt threat intelligence feeds based on the actual threat landscape observed by the devices.
- Leverage machine learning algorithms to dynamically refine the integration process, ensuring ongoing optimization based on real-world data.

By combining Adaptive Deployment Strategies with context-aware Threat Intelligence Integration, the OCIF ensures that the deployment process is finely tuned to the specific needs of resource-constrained devices. This comprehensive approach enhances the framework's effectiveness in safeguarding devices while minimizing the impact on their limited resources.

J. Experimental Setup

For a comprehensive assessment of our Adaptive Deployment and Continuous Threat Intelligence Integration methodologies within the Open Cyber Intelligence Framework (OCIF), to life, a carefully designed experimental setup becomes crucial. Here's a concise breakdown of our experimental environment.

1) Dataset curation in the in-house wazuh platform: For the comprehensive evaluation of our proposed Adaptive Deployment and Continuous Threat Intelligence Integration methodologies within the Open Cyber Intelligence Framework (OCIF), we have designed an experimental setup incorporating a specially curated dataset named CyberResilienceSim. This dataset encompasses diverse elements essential for simulating real-world scenarios and assessing the efficacy of the proposed methodologies. The CyberResilienceSim dataset comprises various categories to emulate the intricacies of cybersecurity challenges faced by resource-constrained devices. Firstly, we simulate data representative of such devices, capturing attributes like device types, communication protocols, and historical performance metrics. This foundational data establishes a virtual environment mirroring the limitations and characteristics of devices operating with constrained resources.

Next, the dataset includes a Threat Scenarios category, featuring a spectrum of cyber threats that resource-constrained devices might encounter. This dataset covers different types of threats, including malware attacks, Intrusion attempts, and data exfiltration incidents. Each threat scenario is enriched with details such as attack vectors, payloads, and timestamps, providing a comprehensive set of challenges for the methodologies. To enhance realism, we integrate Historical Threat Intelligence Feeds into the dataset, comprising indicators of compromise (IoCs), information about threat actors, and patterns associated with past cyber threats. This historical data injects a dynamic and evolving threat landscape into the dataset, reflecting the complexities of the real-world cybersecurity environment.

Contextual Device Information is another crucial aspect, providing details about the simulated devices. This includes device profiles, network configurations, and environmental factors. The Adaptive Deployment Strategies leverage this

contextual information to adapt and optimize cybersecurity measures based on the unique characteristics of each device. The dataset also incorporates Anomaly Indicators to evaluate the effectiveness of Continuous Threat Intelligence Integration. These indicators highlight deviations from baseline behavior, unexpected data flows, or unusual access patterns, allowing us to assess the system's capability to identify and respond to anomalous activities.

For practical application, a Real-world Scenarios Snapshot is included in the dataset, featuring recent cybersecurity incidents, threat intelligence reports, and data breaches. This provides a comparative analysis of our methodologies against real-world conditions. Finally, the dataset is structured to capture Performance Metrics Data Points, including false positive rates, response times, and adaptive adjustments made by the OCIF. These metrics are instrumental in quantifying the impact of our methodologies on cybersecurity effectiveness and the reduction of false positives.

2) Sample attack simulations and detection: In a simulated real-world scenario, we replicate an Advanced Persistent Threat (APT) intrusion targeting a network of resource-constrained devices within an industrial Internet of Things (IoT) environment. The APT actor conducts initial reconnaissance to gather information about the devices, followed by a phishing campaign aimed at compromising user credentials. Exploiting vulnerabilities within the devices, the attacker engages in lateral movement to escalate privileges and navigate through the ecosystem, ultimately seeking to exfiltrate sensitive operational data. Meanwhile, the proposed Continuous Threat Intelligence Integration methodology actively monitors real-time threat intelligence feeds, cross-referencing indicators of compromise (IoCs) to identify patterns associated with known APT campaigns. Simultaneously, Adaptive Deployment Strategies dynamically adjust security measures based on identified threat vectors and contextual information about compromised devices. For instance, if a device shows signs of compromise, the Open Cyber Intelligence Framework (OCIF) may temporarily restrict its network access or deploy additional security measures to contain the threat. This attack simulation, coupled with real-world use cases, serves to assess the adaptability and efficacy of the proposed methodologies in safeguarding resource-constrained devices against sophisticated cyber threats.

IV. Results and Discussion

Reducing false positives in Cyber Threat Intelligence (CTI) and Security Information and Event Management (SIEM) platforms is essential to enhance the efficiency and effectiveness of cybersecurity operations. A strategic approach involves a combination of fine-tuning existing processes, leveraging advanced technologies, and fostering a proactive organizational culture. Here's a comprehensive strategy that we followed:

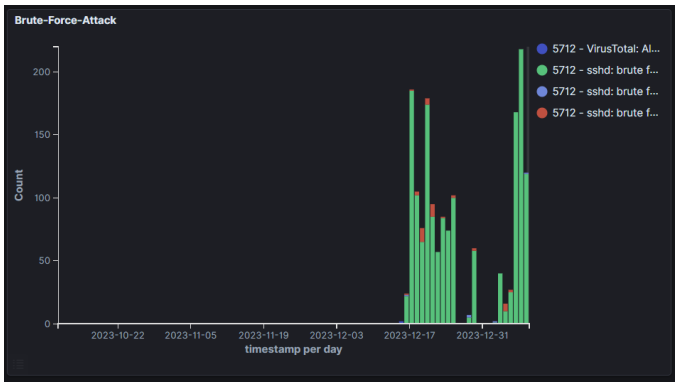

Fig. 2. Screenshot of brute force attack.

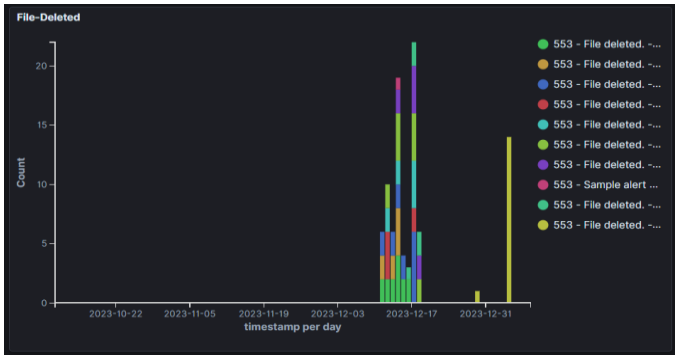
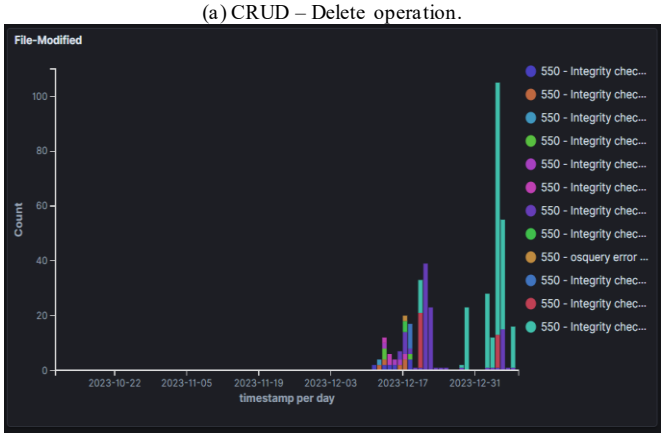
Precision in Alert Generation:

- Fig. 2 to Fig. 6 show the alerts of various events and use cases.
- Refinement of Detection Rules: Regularly review and refine detection rules in CTI and SIEM platforms to ensure they align with the organization's specific threat landscape. Incorporate threat intelligence feeds and customize rules based on the organization's context.
- Threshold Adjustments: Adjust threshold values for alerts, considering the organization's normal network behavior. Fine-tune thresholds to minimize false positives while maintaining sensitivity to potential threats. Fig. 2 shows the results of a brute force attack.



(a) CRUD – Delete operation.



(b) CRUD – Modification operation.

Fig. 3. Results of file auditing.

In Fig. 4, the plot likely represents a timeline with date stamps on the x-axis and associated alerts on the y-axis. Each point or bar on the plot corresponds to a specific alert triggered by an event related to the Mitre Attack Framework. The purpose of this visualization is to provide a chronological overview of detected events, allowing analysts to identify patterns, spikes, or clusters of alerts over time. This can be crucial for understanding the temporal aspects of the attack landscape and pinpointing periods of heightened threat activity.

Fig. 5 appears to illustrate the rule-level analysis categorized by tactics within the Mitre Attack Framework. The x-axis may represent different tactics employed by attackers based on the time stamps (e.g., Initial Access, Execution, Persistence), while the y-axis shows the rule levels associated with each tactic (Count). Each bar or data point on the plot likely corresponds to the number or severity of rules within a specific tactic. This visual representation aids in identifying which tactics have a higher concentration of rules, providing insights into the focus areas of the detection system and potential areas of vulnerability.

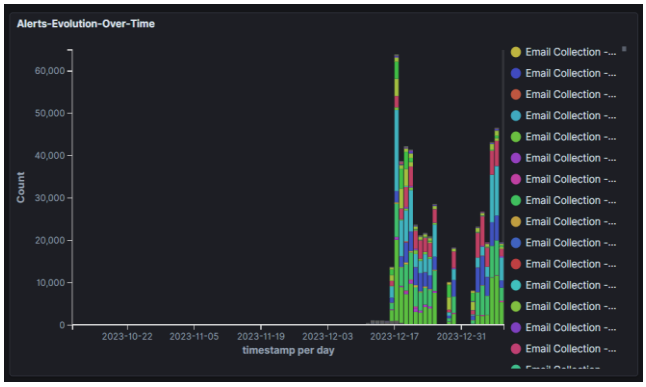


Fig. 4. Date stamps and their associated alerts.

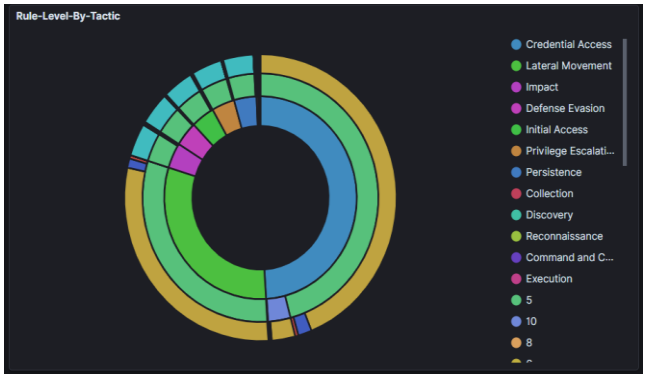

Fig. 5. Rule level by tactics.

Fig. 6 presents the detection results of the top tactics that were both simulated and recorded by the attacker. This plot likely showcases the effectiveness of the detection system in identifying and responding to specific attack tactics. Each bar or data point may represent the number of successfully detected tactics, providing an overview of the system's performance in mitigating simulated attacks. This information is valuable for assessing the detection capabilities and strengths of the implemented Mitre Attack Framework, offering insights into areas of improvement or optimization for better threat response.

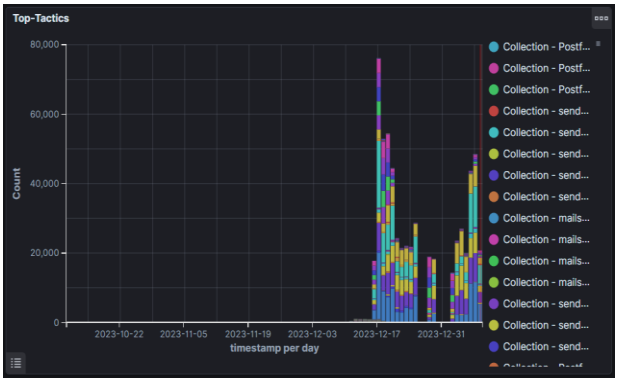

Fig. 6. Top tactics simulated and recorded.

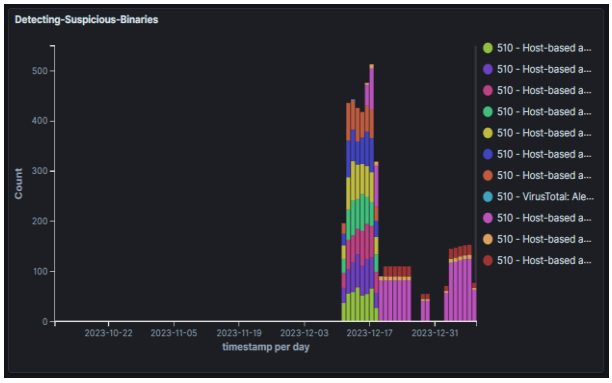

Fig. 7. Malicious file detection.

TABLE I. COMPARISON OF CYBERSECURITY DATASETS FOR RESOURCE-CONSTRAINED ENVIRONMENTS AND OCIF SUITABILITY

Dataset	Resource-Constrained Device Coverage	CTI/Attack Mapping (MITRE ATT&CK)	Suitability for Lightweight ML Models
NSL-KDD	Low	Basic mapping possible	High (small, clean dataset)
UNSW-NB15	Moderate	Good mapping to attack categories	Moderate
CICIDS2017	Low–Moderate	Strong mapping to MITRE techniques	Moderate
TON_IoT	High	Direct mapping available	High (sensor-level + network data)
Edge-IIoTset	High	Good mapping for APTs & DDoS	High
Wazuh + OpenSearch Logs (Used in Your Study)	Very High	Fully integrated (real-world MITRE ATT&CK mapping)	Very High (suitable for adaptive/lightweight models)

Among the existing datasets, TON_IoT and Edge-IIoTset provide the closest alignment to resource-constrained environments; however, neither of them comes with integrated SOAR/SIEM behavior is shown in Table I. The Wazuh + OpenSearch dataset developed in this work is uniquely positioned, with host-level telemetry, real-time CTI mapping, and compatibility for light-weight ML, thereby making it the ideal choice for testing OCIF's capabilities of Adaptive Deployment and False Positive Reduction.

A. Context-Aware Analysis

Enrichment with Threat Intelligence: Enhance alerts with contextual information from threat intelligence feeds. Enriching alerts with indicators of compromise (IoCs) and relevant threat context enables analysts to make more informed decisions. User and Entity Behavior Analytics (UEBA): Incorporate UEBA solutions to analyze user and entity behavior, allowing the detection of anomalies that might go unnoticed with rule-based approaches. This context-aware analysis contributes to reducing false positives. Fig. 3 shows the file auditing results.

B. Machine Learning and AI Integration in Malicious Operation Detection

Anomaly Detection: Implement machine learning algorithms to identify anomalous patterns in data. Train models with historical data to recognize normal behavior and flag deviations, contributing to more accurate threat detection and fewer false positives. Behavioral Analysis: Leverage AI-driven behavioral analysis to understand the typical behavior of users, devices, and applications. Identify deviations from established baselines to detect potential threats with greater accuracy. In Fig. 7, the plot visually captures the outcomes of malicious file detection, specifically focusing on the identification of suspicious binaries.

C. Continuous Monitoring and Feedback Loop

Continuous Evaluation: Establish a continuous monitoring process that includes regular evaluations of alerts and incident reports. This ongoing scrutiny ensures that the detection rules remain relevant and effective over time. Feedback Mechanism: Encourage security analysts to provide feedback on false positives. Establish a feedback loop between analysts and the security system to iteratively improve rules and reduce false positives.

D. Discussion

Through experimentation, promising results were achieved, demonstrating a notable reduction of up to 6% in false positive rates. The Adaptive Deployment and Continuous Threat Intelligence Integration methodologies proved their worth in real-world scenarios, contributing to a more adaptive and efficient cybersecurity defense. Fig. 4, Fig. 5, and Fig. 6 served as critical visual aids in the analysis of Mitre Attack Framework implementation. The chronological overview in Fig. 4 showcased date stamps associated with Mitre attacks, aiding in the identification of temporal attack patterns. Fig. 5 provided a rule-level breakdown by tactics, offering insights into the distribution and severity of rules within different attack categories. Meanwhile, Fig. 6 illustrated the detection results of top tactics, underlining the system's proficiency in responding to both simulated and recorded attacker tactics. The richness of these visualizations, coupled with the experimentation results, contributes to the overarching success of the proposed method. The OCIF, equipped with Adaptive Deployment, Continuous Threat Intelligence Integration, and Mitre Attack Framework analysis, emerges as a robust and adaptive solution for securing resource-constrained devices.

V. Conclusion

In conclusion, this research focused on the development and assessment of an innovative Open Cyber Intelligence Framework (OCIF) for safeguarding resource-constrained devices. The foundation of the investigation lay in proposing an Automated Security Operations and Analytics Response (SOAR) architecture, integrating multiple security tools and leveraging threat intelligence data. As the research unfolded, the attention shifted towards refining the architecture to address the specific challenges faced by devices with limited resources. The OCIF introduced novel strategies, such as Adaptive Deployment and Continuous Threat Intelligence Integration, tailored to resource-constrained environments. The first work showcased the potential of this framework in automating threat detection, response, and mitigation, emphasizing its capability to enhance an organization's cybersecurity posture and reduce the risk of successful attacks. The proposed framework was tested on a limited set of resource-constrained devices and predefined threat scenarios, which may not fully represent real-world environments. This therefore places future research on expanding OCIF into wider device ecosystems, advanced ML models that can dynamically adapt to evolving threats, and real-time performance validation at large-scale deployments. This research not only advances the theoretical understanding of cybersecurity in constrained environments but also provides tangible contributions to practical implementations.
