Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University
Domains of Research: Artificial Intelligence, Big Data Analytics, Computer Vision, Decision Making, Information Retrieval, Satellite Remote Sensing

---

Associate Editors

Arun Kulkarni
University of Texas at Tyler
Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Machine Vision, Neural Networks, Neuro-Fuzzy Systems

Dr Ronak AL-Haddad
Anglia Ruskin University / Cambridge
Domain of Research: Technology Trends, Communication, Security, Software Engineering and Quality, Computer Networks, Cyber Security, Green Computing, Multimedia Communication, Network Security, Quality of Service

Elena Scutelnicu
"Dunarea de Jos" University of Galati
Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee
Kyungpook National University
Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Larbi Boubchir
University of Paris 8
Domain of Research: Artificial Intelligence, Biometrics

Renato De Leone
University of Camerino
Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao
University of Eastern Finland
Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Assessing LXC Containers on Raspberry Pi 4B/5 Boards in a Proxmox Virtual Environment
Authors: Eric Gamess, Deuntae Winston
PAGE 1 – 8

Paper 2: Agentic AI in Commodity Trading: A Comparative Simulation Study
Authors: TarakRam Nunna, Ananya Samala
PAGE 9 – 20

Paper 3: Analysis of Test Access Mechanisms for Improving Scan Compression and Test Time
Authors: Vijay Sontakke
PAGE 21 – 32

Paper 4: SUNDUS: A Human-Centered Framework for Fostering Human-AI Collaboration Through Transparency
Authors: Abduljaleel Hosawi, Richard Stone
PAGE 33 – 42

Paper 5: Leveraging Large Language Models in the Software Development Lifecycle: Opportunities and Challenges
Authors: Jasdeep Singh Bhalla, Mansimar Kaur Jodhka
PAGE 43 – 51

Paper 6: Evaluating Generalist Conversational AI Against Foundational Models of Instructional Design: A Comparative Analysis
Authors: Abdelmounaim AZINDA, Mohamed Khaldi
PAGE 52 – 59

Paper 7: Anamel: Children's Psychological and Mental Health Detection Application by Drawing Analysis Based on AI
Authors: Amal Alshahrani, Manar Mohammed Almatrafi, Jenan Ibrahim Mustafa, Layan Saad Albaqami, Raneem Abdulrahman Aljabri
PAGE 60 – 66

Paper 8: Enhanced Android Malware Detection Using Deep Learning and Ensemble Techniques
Authors: Abdul Museeb, Yaman Hamed, Rajalingam Sokkalingam, Anis Amazigh Hamza, Atta Ullah, Iliyas Karim Khan
PAGE 67 – 76

Paper 9: Dual-Attention ResUNet-GAN for Secure Image Steganography: Optimizing the Trade-off Between Imperceptibility and Payload Capacity
Authors: Zobia Shabeer, Muhammad Naeem, Gohar Rahman, Mehmood Ahmed, Muhammad Zeeshan, Asim Shahzad, Salamah binti Fattah
PAGE 77 – 87

Paper 10: A Method for Planning the Dissemination Path of Traditional Chinese Medicine Culture Based on the Optimized Ant Colony Algorithm
Authors: Qian Guo, Ying Ma
PAGE 88 – 97

Paper 11: Maximizing Influence and Mitigating Harmful Viral Content in Social Networks
Authors: Muhammad Mohsin, Muhammad Yaseen, Umar Farooq Khattak, Gohar Rahman
PAGE 98 – 107

Paper 12: Security Vulnerability Analysis and Enhancement of a Lightweight Sensor Node Authentication Framework
Authors: Kim Kyoung Yee, Haewon Byeon
PAGE 108 – 114

Paper 13: A Proposed IoT System for Monitoring and Controlling Movable Zamzam Tanks in the Holy Mosque
Authors: Taha M. Mohamed
PAGE 115 – 124

Paper 14: Forecasting of Saudi Stock Prices Using Statistical and Machine Learning Models: A Multi-Model Comparative Approach
Authors: Eissa Alreshidi
PAGE 125 – 136

Paper 15: Speech Emotion Recognition via Parallel Dual-Branch Fusion Model
Authors: Zhongliang Wei, Chang Ge, Lijun Zhu, Jinmin Ye
PAGE 137 – 148

Paper 16: An Improved Method Based on YOLOv7 for Detecting the Safety Helmets of Two-Wheeled Bicycle Riders
Authors: Xufei Wang, Penghui Wang, Zishuo Wang, Jeonyoung Song, Jinde Song
PAGE 149 – 158

Paper 17: Lightweight Multi-Feature Fusion GAN with Deformable Attention for HMD-Occluded Face Reconstruction
Authors: Yingying Li, Ajune Wanis Ismail, Muhammad Anwar Ahmad, Norhaida Mohd Suaib, Fazliaty Edora Fadzli
PAGE 159 – 169

Paper 18: Adult-Size Bio-Mechatronic Exoskeleton with Robotic Underactuated Mechanism for Continuous Passive Motion Therapy on Hemiplegic Lower Limbs
Authors: Adrian Nacarino, Carol Sandoval, Cesar Martel, Jose Cornejo, Margarita Murillo, Jeanette Borja, Josue Alata Rey, Ricardo Palomares
PAGE 170 – 179

Paper 19: Improving Spam Detection with Feature Engineering and Adaptive Learning Approaches
Authors: Sadeem H. AlHomidan, Marwah M. Almasri, Shimaa A. Nagro
PAGE 180 – 186

Paper 20: A Newton-Raphson-Based Optimizer-Driven Temporal Convolutional Networks for Birth Rate Prediction in a Small Area
Authors: Shengyi Zhou, Liang Chen, Wei Han, Bin Liu
PAGE 187 – 195

Paper 21: A New Advanced Multimodal Sentiment Classification Through Combined Attention Mechanisms: A-MSDA
Authors: Soukaina FATIMI, WAFAE SABBAR, Abdelkrim BEKKHOUCHA
PAGE 196 – 204

Paper 22: NDN-Based ICN Architecture Design to Improve Data Communication QoS in Kertajati Aerocity
Authors: Enang Rusnandi, Tri Kuntoro Priambodo, Mardhani Riasetiawan
PAGE 205 – 213

Paper 23: Improving the Performance of TFS with Ensemble Learning for Cross-Project Software Defect Prediction
Authors: Pathiah Abdul Samat, Yahaya Zakariyau Bala, Nur Hamizah Hamidi
PAGE 214 – 219

Paper 24: From User Experience Evaluation to Design Guidelines for E-Commerce Websites
Authors: Layla Hasan, Beatrice Lim Pei Ying
PAGE 220 – 230

Paper 25: From External Stakeholder Pressure to Sustainable Practice in HEIs: Mechanisms and Internal Mediating Factors
Authors: Xue Jin, S. M. Ferdous Azam, Jacquline Tham
PAGE 231 – 242

Paper 26: Lexicon-Based Sentiment Analysis of Social Media Reviews for Floating Market Popularity in South Kalimantan
Authors: Evi Lestari Pratiwi, Ramadhani Noor Pratama, Inayatul Ulya Ahyati, Paula Dewanti
PAGE 243 – 250

Paper 27: AI-Driven Deep Learning Architectures for Robust Emotion Recognition
Authors: Hamad Ali Abosaq
PAGE 251 – 260

Paper 28: User Experience Deficiencies in Mobile Tourism Applications: A Preliminary Study from Generation Z and Tourism Practitioners
Authors: Huang Huihui, Azliza Othman, Nadia Diyana Mohd Muhaiyuddin
PAGE 261 – 266

Paper 29: Data-Driven Model for Optimizing Active Learning
Authors: Abang Asyraaf Aiman Abang Azahari, Marshima Mohd Rosli, Nor Shahida Mohamad Yusop
PAGE 267 – 272

Paper 30: A Novel YOLO-Like Multi-Branch Architecture for Accurate Apple Detection and Segmentation Under Orchard Constraints
Authors: Olzhas Olzhayev, Nurbibi Imanbayeva, Satmyrza Mamikov, Bibigul Baibek
PAGE 273 – 284

Paper 31: Kinematic Modeling and Design of a Robotic Manipulator System for Automated Fruit Harvesting in Intensive Orchards
Authors: Nurbibi Imanbayeva, Bekzat Amanov, Aiman Nurmaganbetova, Arman Moldashev, Akbayan Aliyeva, Sulukul Dauletbekova
PAGE 285 – 293

Paper 32: A Configurable Storytelling System for Emotion Recognition in Children: Design and Pilot Evaluation
Authors: Chadi Fouad Riman, Wael Hosny Fouad Aly, Carmen Mariana Pasca
PAGE 294 – 301

Paper 33: Leveraging AI and ML for Enhanced Business Intelligence Systems: A Research Landscape of Trends, Influences, and Future Directions
Authors: Sunil Mandaliya, Priti Kulkarni
PAGE 302 – 313

Paper 34: Performance Evaluation of Software Multi-Threshold Decoders for Self-Orthogonal Codes in Modern Broadband Wireless Communication Systems
Authors: Nurlan Tashatov, Gennady Ovechkin, Zhuldyz Sailaukyzy, Eldor Egamberdiyev, Dina Satybaldina, Gulmira Danenova, Zarina Khassenova
PAGE 314 – 327

Paper 35: CICA Framework: Harnessing CSR, AI, and Blockchain for Sustainable Digital Culture
Authors: Danang Danang, Agustinus Budi Santoso, Maya Utami Dewi
PAGE 328 – 338

Paper 36: Recursive Gated Convolution-Based YOLOv11 Framework for Operator Safety Management in Live-Line Work
Authors: Dapeng Ma, Liang Yang, Kang Chen, Feng Yang, Ao Cui, Rundong Yang, Zhilin Wen, Donghua Zhao
PAGE 339 – 347

Paper 37: Evaluating the Effectiveness and Usability of Microsoft Threat Modelling Tool in Undergraduate Cybersecurity Education
Authors: Nor Laily Hashim, Ahmad Zuhairi Bin Mohd Yusri
PAGE 348 – 355

Paper 38: Robust Detection of Partially Occluded Faces in Low-Light Scenarios Using YOLOv7 and YOLOv6
Authors: Nayef Alqahtani, Amina Shaikh, Imran Khan Keerio
PAGE 356 – 367

Paper 39: Semantic Segmentation Algorithm of Animal Husbandry Image Based on an Improved U-Net Network
Authors: Jia Li, Jinjing Zhang, Fengjiao Jiang
PAGE 368 – 377

Paper 40: AI-Driven Professional Profile Categorization and Recommendation System
Authors: Marouane CHIHAB, Hicham BOUSSATTA, Mohamed CHINY, Nabil Mabrouk, Younes CHIHAB, Moulay Youssef HADI
PAGE 378 – 385

Paper 41: Robotic Process Automation (RPA) Scripting Model Using Machine Learning (ML) for Enterprise Data Validation and Integration
Authors: Luis Ángel Bendezú Jiménez, Jorge Luis Juan de Dios Apaza, Ruben Oscar Cerda García
PAGE 386 – 393

Paper 42: How did the Intelligent Search Engine Become Popular Among Chinese Residents Since the Emergence of Deepseek?
Authors: Zhixuan Wang, Yuying Song, Hanyu Guo
PAGE 394 – 402

Paper 43: Software Project Effort Estimation Using Formal Method and Model Checker
Authors: Abdulaziz Alhumam
PAGE 403 – 410

Paper 44: Cross-Lingual Sentiment Analysis in Low-Resource Languages: A Recent Review on Tasks, Methods and Challenges
Authors: Nor Zakiah Lamin, Azwa Abdul Aziz
PAGE 411 – 426

Paper 45: Advances in Natural Language Processing for Radiology: State-of-the-Art Techniques, Applications, and Open Challenges
Authors: Kotha Chandrakala, Shahin Fatima
PAGE 427 – 436

Paper 46: AI-Driven Multimodal Frameworks for Cardiovascular Diagnostics: Integrating Sensors, Imaging, and Robotic Systems
Authors: Chandrasekhara Reddy T, Ramesh Babu P
PAGE 437 – 445

Paper 47: Sustainable IoT Smart Home Perceptions Across Demographic and Vulnerable User Segments
Authors: Burhan Mahmoud Hamadneh, Zeyad Alshboul, Nabhan Mahmoud Hamadneh, Turki Mahdi Alqarni, Malek Turki Jdaitawi
PAGE 446 – 456

Paper 48: The Evolution of Hackathons as an Innovation Tool: A Systematic Analysis
Authors: Claudia Marrujo-Ingunza, Meyluz Paico-Campos
PAGE 457 – 471

Paper 49: SBERT-Based Stacking Ensemble Model for Fake News Detection
Authors: Abdulaziz A Alzubaidi, Amin A Alawady
PAGE 472 – 479

Paper 50: Aligning Confidence and Localization: An Enhanced DINO Model for Small Object Detection in Robotic Nursing
Authors: Yanchen Du, Qingzhuo Yuan, Shengli Luo, XiaoLong Shu, Xu Wang, Yuheng Jiang, Hongliu Yu
PAGE 480 – 493

Paper 51: Sleep Quality and Burnout Syndrome in Students at a University in Lima, Peru: A Cross-Sectional Study
Authors: Yajaira Garay-Castro, Luis Acosta-Avila, Ana Flores-Hiyo, Ana Huamani-Huaracca, Sebastián Ramos-Cosi, Gina León-Untiveros, Alicia Alva-Mantari
PAGE 494 – 502

Paper 52: A Conceptual Model for an Ontology-Based Dietary Recommendation Plan in Crohn's Disease
Authors: Rezan Almehmadi, Aisha Alsobhi, Omaima Almatrafi
PAGE 503 – 511

Paper 53: Swarm Intelligence-Based Optimization of FACTS Devices: A Review of Operation, Control and Emerging Algorithms
Authors: Patricia Khwambala, Kumeshan Reddy, Senthil Krishnamurthy
PAGE 512 – 524

Paper 54: SPA-DCN-NET: A Gated Multi-Scale Local Contrast Normalization Network for Ultrasound Image Segmentation of Liver
Authors: Su Ming Jian, Afizan Bin Azman
PAGE 525 – 536

Paper 55: Generalizing In-Field Plant Disease Diagnosis: A Deep Transfer Learning Approach for Multi-Crop and Heterogeneous Imaging Conditions
Authors: Khoerul Anwar, Tubagus Mohammad Akhriza, Mahmud Yunus
PAGE 537 – 544

Paper 56: InfoCore: AI Driven Named Entity Deduplication and Event Categorization
Authors: Rohail Qamar, Raheela Asif, Abdul Karim Kazi, Muhammad Ali, Muhammad Mustafa
PAGE 545 – 550

Paper 57: Two-Level Hierarchical Adaptive Dynamic Fusion for CNN–LSTM Integration in Fatigue Level Prediction
Authors: Marlince NK Nababan, Poltak Sihombing, Erna Nababan, T Henny Febriana Harum
PAGE 551 – 557

Paper 58: Optimizer Algorithms Analysis for Intrusion Detection System on Deep Neural Network
Authors: H. A. Danang Rimbawa, Agung Nugroho, Muhammad Abditya Arghanie
PAGE 558 – 572

Paper 59: Shadow IT Transformation in the Post-Pandemic Digital Workplace: A Systematic Literature Review
Authors: Ginanjar Nugraha, Munir, Puspo Dewi Dirgantari
PAGE 573 – 579

Paper 60: HeritageLM: Culturally-Aware Multimodal Language Modeling with Memory-Enhanced Cross-Dialect Adaptation
Authors: Pasupuleti Venkata Ramana, K. K. Sunalini, A. Swathi, R. Lakshmi, Raman Kumar, Elangovan Muniyandy, Khaled Bedair
PAGE 580 – 591

Paper 61: Personalized Grammar Refinement Using Meta-Reinforcement Learning and Transformer-Based Framework
Authors: Bukka Shobharani, Melito D. Mayormente, Edgardo B. Sario, Bernadette R. Gumpal, S. Farhad, Jasgurpreet Singh Chohan, Elangovan Muniyandy
PAGE 592 – 603

Paper 62: Graph-Enhanced Transformer Framework for Context-Sensitive English Skill Assessment
Authors: Anna Shalini, Myagmarsuren Orosoo, W. Grace Shanthi, Prema S, S. Farhad, Elangovan Muniyandy, A. Chrispin Antonieta Dhivya
PAGE 604 – 613

Paper 63: Attention-Enhanced Multi-View Graph Convolutional Network for Early Prediction of Chronic Kidney Disease
Authors: Roshan D Suvaris, K Nagaiah, P. Satish, Hussana Johar R B, Elangovan Muniyandy, Manasa Adusumilli, Khaled Bedair
PAGE 614 – 626

Paper 64: Multimodal Cognitive Mapping Framework for Context-Aware Figurative Language Understanding
Authors: R. Swathi Gudipati, Neena PC, K. Ezhilmathi, M. Durairaj, S. Farhad, Elangovan Muniyandy, Padmashree V
PAGE 627 – 637

Paper 65: Unveiling Gender in Malay-English Short Text: A Comparative Study of ML, DL and Sequential Models with XAI Misclassification Analysis
Authors: Norazlina Khamis, Nur Shaheera Shastera Nulizairos, Haslizatul Mohamed Hanum, Amirah Ahmad, Nor Hapiza Mohd Ariffin, Ruhaila Maskat
PAGE 638 – 646

Paper 66: Causality Aware Multimodal Reasoning Network in Human Emotion Identification and Sentiment Understanding
Authors: N. K. Thakre, Yazan Shaker Almahammed, G. Indra Navaroj, Mohammed Fahad Almohazie, Abdullah Albalawi, Marran Al Qwaid, G. Sanjiv Rao
PAGE 647 – 659

Paper 67: Beyond Ensembles: Architecture-Level Fusion for Enhanced Monument Heritage Recognition
Authors: Mennat Allah Hassan, Mona M. Nasr, Alaa Mahmoud Hamdy
PAGE 660 – 670

Paper 68: Semi-Supervised Learning vs. Few-Shot Learning: Which is Better for Sentiment Analysis on Hotel Reviews Towards a Small Labeled Training Data?

Authors: Retno Kusumaningrum, Ahmad Ainun Herlambang, Wafiq Afifah, Adi Wibowo, Sutikno, Priyo Sidik Sasongko

PAGE 671 – 677

Paper 69: Linguistically Informed Essay Assessment Framework to Analyze Writing Style Vocabulary Usage and Coherence

Authors: Sreela B, B.Neelambaram, Manasa Adusumilli, Revati Ramrao Rautrao, Aseel Smerat, Myagmarsuren Orosoo, A. Swathi

PAGE 678 – 691

Paper 70: An Interpretable Dual-Level Feedback Approach for Improving Graded Language Simplification and Readability

Authors: Pavani G, Myagmarsuren Orosoo, W. Grace Shanthi, Vinod Waiker, Aseel Smerat, Bhuvaneswari Pagidipati, Bansode G.S., Osama R. Shahin

PAGE 692 – 705

Paper 71: Meta Learning Enhanced Graph Transformer for Robust Smart Grid Anomaly Detection

Authors: Layth Almahadeen, Aseel Smerat, Sandeep Kumar Mathariya, G. Indra Navaroj, Vuda Sreenivasa Rao, Kamila Ibragimova, Osama R.Shahin

PAGE 706 – 718

Paper 72: An Interpretable Deep Learning Framework for Measuring Organizational Digital Transformation Readiness

Authors: Pravin D. Sawant, Veera Ankalu Vuyyuru, B. Arunsundar, A. Vini Infanta, Dekhkonov Burkhon, N. Roopalatha

PAGE 719 – 731

Paper 73: Clinically Informed Adaptive Multimodal Graph Learning Paradigm for Transparent Temporal and Generalizable Alzheimer's Disease Diagnosis

Authors: Padmavati Shrivastava, V S Krushnasamy, Guru Basava Aradhya S, Vinod Waiker, Peddireddy Veera Venkateswara Rao, Elangovan Muniyandy, Khaled Bedair

PAGE 732 – 742

Paper 74: Transformer Driven Multi-Agent Reinforcement Learning Framework for Integrated Waste Classification Forecasting and Adaptive Routing

Authors: Ritesh Patel, Igamberdiyev Asqar Kimsanovich, Vinod Waiker, Elangovan Muniyandy, Swarna Mahesh Naidu, Nurilla Mahamatov, Osama R.Shahin

PAGE 743 – 755

Paper 75: Leveraging Intelligent Speech Training to Elevate Phonetic Accuracy and Prosodic Fluency in English Learners

Authors: Amit Khapekar, Nidhi Mishra, Vijaya Lakshmi Mandava, T K Rama Krishna Rao, Bhuvaneswari Pagidipati, Prasad Devarasetty, Elangovan Muniyandy

Assessing LXC Containers on Raspberry Pi 4B/5 Boards in a Proxmox Virtual Environment

Eric Gamess, Deuntae Winston
MCIS Department, Jacksonville State University, Jacksonville, Alabama, USA

***Abstract*—On one hand, containerization is gaining acceptance as a lightweight virtualization alternative to Virtual Machines (VMs). On the other hand, Single-Board Computers (SBCs) are increasingly used due to their affordability, versatility, low energy consumption, and growing computational power. In this work, extensive experiments were conducted to assess the capabilities and limitations of Linux Containers (LXC) when deployed on a Proxmox Virtual Environment (Proxmox VE) cluster, built with Raspberry Pi (RPi) computers. The clusters consisted of either two Raspberry Pi 4 Model B (RPi 4B) or two Raspberry Pi 5 (RPi 5) with identical characteristics, connected through an Ethernet switch. The experiments aimed to determine: 1) the maximum number of containers that can be run simultaneously when varying their operating system, 2) the maximum number of containers that can be executed in parallel when varying their allocated RAM, 3) the maximum number of containers that can be run concurrently under different SBC memory configurations, 4) the time for container migration, and 5) the network performance between two containers. For storage, SATA SSDs were connected to the RPi 4B boards through their USB ports, while the RPi 5 boards used NVMe SSDs connected via their PCIe interfaces. The cluster formed with RPi 5 boards outperformed the one built with RPi 4B boards, showing significant improvements in the migration experiments. In terms of network performance, the results were similar between containers running on different nodes. However, much larger differences were observed between containers in execution on the same nodes. With this study, the authors aim to assist users and researchers in identifying and selecting the technologies and configurations that best meet the performance requirements of their specific study cases.**

Keywords*—Container; virtualization; Proxmox VE; LXC; single-board computers; Raspberry Pi; performance evaluation

I. Introduction

In recent years, virtualization has become the foundation of modern computing infrastructures. It enables the consolidation of multiple servers onto the same hardware by maximizing its utilization, while minimizing energy consumption and physical space requirements. For many years, Virtual Machines (VMs) were the core of virtualization. However, the emergence of container technologies is reshaping the landscape. VMs require a full guest Operating System (OS) for each instance, whereas containers share the host's kernel while maintaining strong process isolation. Owing to this key architectural difference, containerization offers a more efficient approach with significantly lower overhead in terms of CPU, memory, and storage consumption. As a result, a much larger number of containers, compared to VMs, can be instantiated on the same node. Moreover, containers typically exhibit faster startup times because they do not involve booting an entire guest OS, which is particularly beneficial in environments where services must be frequently created, scaled, or updated.

Proxmox Virtual Environment [1-2] (Proxmox VE) is an open-source platform that integrates virtualization technologies and storage management. Users can achieve full virtualization with Kernel-based Virtual Machine [3-4] (KVM) or create Linux Containers [5-8] (LXC) oriented to lightweight operating-system-level virtualization. That is, the same management framework eases the deployment and administration of both VMs and LXC containers, through robust user interfaces (web-based and CLI), allowing users precise control over computing, memory, storage, and networking resources. Additional advanced features include snapshots, clustering, live migration of VMs, high availability, and backup management. Proxmox VE stands out for its open-source nature, strong community support, active development, and abundant instructional material (comprehensive documentation and numerous tutorials) that assist new users in rapidly becoming proficient with the platform.

Single-Board Computers (SBCs) are complete computing systems built on a single circuit board, integrating a CPU, memory, storage interfaces, and input/output ports. Due to their compact size, low energy consumption, affordability, and versatility, they have been increasingly adopted in IoT projects, education, research, and by hobbyists. Several manufacturers produce SBCs, including the Raspberry Pi Foundation, Hardkernel, BeagleBoard.org Foundation, NVIDIA, Intel, and ASUS. However, Raspberry Pi boards dominate the market, due to a plethora of expansion boards, the wide range of supported OSs, continuous development and improvement made by the manufacturer, and a large community that provides tutorials, project guides, forums, and third-party software.

This study evaluates the performance and limitations of deploying LXC containers on the two most powerful RPi models currently offered by the Raspberry Pi Foundation (RPi 4B and RPi 5), when managed by Proxmox VE. To achieve this goal, the authors set up a testbed consisting of two Raspberry Pi boards with identical specifications, interconnected through a Gigabit Ethernet switch, and combined into a Proxmox VE cluster. A series of comprehensive experiments were conducted to determine: 1) the maximum number of containers that can be run simultaneously when varying their OS, 2) the maximum number of containers that can be executed in parallel when varying their allocated RAM, 3) the maximum number of containers that can be run concurrently under different SBC

memory configurations, 4) the time for container migration, and 5) the network performance between two containers.

As expected, the cluster built with RPi 5 boards significantly outperformed the one based on RPi 4B boards, owing to the upgraded hardware of the SBC. The introduction of a PCIe interface in the RPi 5 is a game-changer, as it enables high-speed access to SSDs. In the container migration experiments, the limited network bandwidth of the RPi boards (1000 Mbps) was the primary bottleneck, particularly for the RPi 5. Through this work, the authors aim to support users and researchers in evaluating and selecting technologies and configurations that optimally fulfill the performance objectives of their specific research contexts.

The remainder of the study is organized as follows: Section II presents relevant peer-reviewed studies conducted in this research area. The testbed and the benchmarking tools employed in this work are introduced in Section III. Section IV conducts and analyzes a series of comprehensive experiments. Finally, Section V concludes the study and outlines directions for future work.

II. Related Work

LXC containers have been evaluated in various scenarios; however, most studies in this area focus on the x86/x64 architecture (e.g., Intel and AMD). For instance, Putri, Munadi, and Negara [9] compared the native performance of several applications with their containerized counterparts using Docker, LXC, and LXD. They assessed services such as web, FTP, and mail within a testbed consisting of an HP 1000 Notebook PC (Intel Celeron Dual-Core CPU 1000M @ 1.80 GHz) and a Dell Inspiron One 2020 (Intel Core i3-3240T @ 2.9 GHz), interconnected through a router. The authors of [10] analyzed several performance metrics under three scenarios: 1) bare metal, 2) an LXC container, and 3) a VM managed by XenServer. The tests employed various benchmarking tools, and the evaluated metrics included CPU performance, RAM speed, storage access time, and the maximum number of requests that could be handled by a web server per second. The testbed consisted of a PC with an Intel Core i5-650 @ 3.20 GHz. In [11], Indukuri evaluated container migrations for LXC and OpenVZ, using a testbed composed of three servers equipped with Intel Xeon E5-2420 v2 @ 2.20 GHz. In [12], the authors analyzed the performance of LXC containers and VMs (using KVM as the hypervisor), under High-Performance Computing (HPC) workloads. Their test environment consisted of two HP EliteDesk 800 G1 (F4K58LT) computers, each equipped with an Intel Core i7-4770 @ 3.4 GHz.

Regarding the evaluation of LXC containers on embedded systems, the authors could only find a few works. Manninen [13] compared several container technologies (Docker, balenaEngine, LXC, and Flatpak) against native performance on an RPi 4B. The experiments included two containers running on the same SBC that exchanged random integer numbers through TCP. The author reported metrics such as memory consumption, CPU utilization, and power consumption. In [14], the authors benchmarked multiple container technologies (Docker, Podman, and LXC/LXD) on three RPi models (RPi 3B, RPi 3B+, and RPi 4B). They conducted experiments to assess processing power, container lifecycle times (creation, start, and run times), and basic network performance between containers. Menshchikov [15] examined the overhead introduced by LXC containers for MIPS-based devices.

Unlike the work presented in this study, none of the previous works contemplated the performance evaluation of LXC containers in RPi 4B and RPi 5 boards, when managed by Proxmox VE.

III. Testbed and Benchmarking Tools

For the experiments, the following SBCs were used: two RPi 4B with 2 GB of RAM, two RPi 4B with 4 GB of RAM, two RPi 4B with 8 GB of RAM, two RPi 5 with 2 GB of RAM, two RPi 5 with 4 GB of RAM, and two RPi 5 with 8 GB of RAM. The specifications of the SBCs are summarized in Table I. As presented in [16], there are two main options for local storage for an RPi 4B: 1) a microSD card inserted in the microSD slot and 2) an SSD connected via one of the USB ports (SATA SSD or NVMe SSD). In contrast, the RPi 5 has three main possibilities: 1) a microSD card inserted in the microSD slot, 2) an SSD connected via one of the USB ports, and 3) an SSD connected through the PCIe x1 interface. As shown in [16], and in order to get the highest possible performance, the authors opted for the fastest available storage technology for each SBC under test. Therefore, each RPi 4B was connected to a SATA SSD via one of its USB 3.0 ports (except for the tests in Section IV D), while each RPi 5 was connected to an NVMe SSD through its PCIe Gen 3 x1 interface (except for the assessments conducted in Section IV D).

TABLE I. Specifications of the RPi 4B and the RPi 5

SoC Type	RPi 4B RPi 5	Broadcom BCM2711 Broadcom BCM2712
Core Type	RPi 4B RPi 5	Quad-core ARM Cortex-A72 @ 1.8 GHz Quad-core ARM Cortex-A76 @ 2.4 GHz

RAM	RPi 4B RPi 5	1, 2, 4, or 8 GB LPDDR4-3200 SDRAM 2, 4, 8, or 16 GB LPDDR4X-4267 SDRAM
microSD	RPi 4B RPi 5	microSD microSD with high-speed SDR104 mode
USB Ports	RPi 4B RPi 5	2 x USB 2.0 ports & 2 x USB 3.0 ports 2 x USB 2.0 ports & 2 x USB 3.0 ports
HDMI Ports	RPi 4B RPi 5	2 x Micro HDMI (up to 4Kp60) 2 x Micro HDMI (up to 4Kp60)
PCIe	RPi 4B RPi 5	No PCIe x1 (Generations 1, 2, and 3)
Ethernet	RPi 4B RPi 5	10/100/1000 Mbps 10/100/1000 Mbps
Wi-Fi	RPi 4B RPi 5	2.4 GHz and 5.0 GHz IEEE 802.11b/g/n/ac 2.4 GHz and 5.0 GHz IEEE 802.11b/g/n/ac
Price	RPi 4B RPi 5	US$35, US$45, US$55, or US$75 US$50, US$60, US$80, or US$120

As depicted in Fig. 1, each experiment involved two identical SBCs (same model and RAM size) connected via an Ethernet switch (Cisco Catalyst 2960X-48TS-L). This Layer-2 switch features 48 10/100/1000 Mbps Ethernet ports with PoE/PoE+ (IEEE 802.3af/802.3at) support and four 1 Gbps Small Form-Factor Pluggable (SFP) uplinks. The latest version of the Raspberry Pi OS Lite and Proxmox VE was installed on each RPi, and a cluster was formed with the two nodes. Clustering provides benefits such as centralized management, VM and container migration, resource optimization, and scalability.

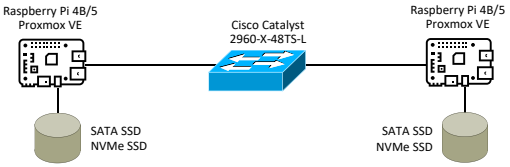

Fig. 1. Testbed for the experiments.

OpenSSL [17-18] is a widely adopted open-source library and toolkit that provides implementations of numerous cryptographic algorithms, as well as the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols. OpenSSL includes a benchmarking utility (openssl speed) to evaluate the performance of various cryptographic algorithms, including hashing algorithms (e.g., MD4, MD5, SHA-1, SHA-256, SHA-512, RIPEMD-160), symmetric cipher algorithms (e.g., Blowfish, DES, 3DES, AES, Camellia, SEED, CAST), and public-key algorithms (e.g., RSA, DSA, Ed25519). The utility measures the speed at which a computational system performs cryptographic operations such as hashing, encryption, decryption, and digital signature generation and verification. For hashing and symmetric cipher algorithms, it reports the throughput that corresponds to the number of bytes processed per second. In the case of public-key algorithms, the tool reports two results: the number of signatures generated and verified per second. For the tests of this study, two symmetric encryption algorithms were chosen: 1) 3DES Encrypt-Decrypt-Encrypt (EDE) with three independent DES keys in Electronic Codebook (ECB) mode and 2) AES with a 128-bit key in Cipher Block Chaining (CBC) mode. A cryptographic workload is ideal for container evaluation because it is CPU-intensive, deterministic, and highly sensitive to scheduling and isolation overhead.

iperf3 [19] is an open-source, cross-platform (Linux, Windows, macOS, BSD, and others) network performance measurement tool that operates on the client/server model. It is widely recognized to estimate the maximum achievable UDP, TCP, or SCTP bandwidth under controlled conditions. In this work, iperf3 was chosen to assess TCP throughput. During the execution of a test, the client floods the server with as many TCP messages as possible, which then reports the average TCP throughput received.

sockperf [20] is an open-source network benchmarking tool initially developed by Mellanox for testing and measuring One-Way-Delay (OWD) and throughput for UDP and TCP, using a client/server model. It supports multiple testing modes, such as ping-pong (request–response) and throughput. In the ping-pong mode for TCP, the client sends a TCP payload of a specific size to the server, which immediately returns it. The client then estimates the OWD as half of the measured Round-Trip Time (RTT), that is, the time elapsed between sending the request and receiving the reply, divided by two. This benchmarking utility was selected for the OWD experiments because of its high accuracy, minimal overhead, and widespread adoption in the networking research community.

In this research, unless otherwise stated, all instantiated LXC containers were configured with two cores, 512 MB of memory, a 512 MB swap area, and a 2 GB filesystem.

IV. Experimental Results and Analysis

In this section, several performance evaluation experiments were conducted and analyzed.

A. Maximum Number of Containers When Varying the Operating System

Proxmox has a built-in library of LXC templates that includes Alpine Linux, Arch Linux, CentOS, Debian, Fedora, Rocky Linux, Ubuntu, AlmaLinux, Devuan, Gentoo Linux, openEuler, and openSUSE. With these templates, users can deploy LXC containers with their favorite OS in just a few seconds. Due to their popularity in the community, Debian, Fedora, Alpine, and Ubuntu were chosen for this study. At the level of Debian, two versions were tested: Buster (Debian 10.X) and Bookworm (Debian 12.X). The latter was selected as it was the latest release of Debian at the time of writing this study. Since the authors wanted to illustrate how cryptographic support in the processor can make a huge difference in performance, Debian Buster was also chosen. It is the last release of Debian with a version of OpenSSL that does not leverage hardware cryptography when available in the processor.

Fig. 4 depicts the results of assessing the maximum number of LXC containers that can be run simultaneously on an RPi 4B with 8 GB of RAM, when varying the OS. In each container, the OpenSSL benchmarking tool was executed for 3DES EDE in ECB mode (des-ede3) as specified in the command of Fig. 2, using a 64-byte buffer (option -bytes 64), when running two operations in parallel (option -multi 2) to test multi-core performance.

```
openssl speed -seconds $duration -bytes 64  \
        -multi 2 des-ede3 > /tmp/results.txt
```

Fig. 2. Command executed in each container to evaluate the performance of 3DES EDE in ECB mode.

Fig. 4 consists of seventeen groups of five bars, where the groups correspond to a different number of containers (1, 2, 3, 4, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 53, 54, and 63). Within each group, the five bars represent Debian 12, Debian 10, Fedora 38, Alpine 3.18, and Ubuntu 22.04. As can be seen in the figure, the last three groups (53, 54, and 63 containers) have fewer than five bars. That indicates that for the missing OSs, the RPi 4B did not have enough resources to run the specified number of containers and became unstable or crashed. Overall, the performance decreased as the number of containers increased due to contention for processing resources. Across the OSs, performance was generally similar. The maximum number of containers achieved was 54, 50, 50,

63, and 50 for Debian 12, Debian 10, Fedora 38, Alpine 3.18, and Ubuntu 22.04, respectively. Unsurprisingly, it was possible to run more Alpine containers than the other Linux versions, since it was specifically designed to be small and resource-efficient.

The same experiments were repeated on an RPi 5 with 8 GB of RAM, and the results are presented in Fig. 5. As an updated version of the RPi 4B, the RPi 5 delivers better performance. For instance, the throughput of Debian 12 increased from 27.5 B/s on the RPi 4B (see Fig. 4) to 47.4 B/s on the RPi 5 (see Fig. 5) for a single container. It should be noted that neither the RPi 4B nor the RPi 5 provides dedicated hardware support for DES or 3DES. Consequently, the execution of these algorithms relies solely on software implementations, which are considerably slower than hardware-accelerated alternatives.

Fig. 6 and Fig. 7 present the results of assessing the maximum number of LXC containers that can be run simultaneously on an RPi 4B and an RPi 5, both with 8 GB of RAM, when varying the OS. However, in this case, the OpenSSL benchmarking tool was executed in each container for AES-128 in CBC mode (aes-128-cbc) as specified by the command shown in Fig. 3, using a 64-byte buffer (option -bytes 64), when running two operations in parallel (option -multi 2) to evaluate multi-core performance:

```
openssl speed -seconds $duration -bytes 64   \
        -multi 2 aes-128-cbc > /tmp/results.txt
```

Fig. 3. Command executed in each container to evaluate the performance of AES-128 in CBC mode.

As in the previous experiments (see Fig. 4 and Fig. 5), the performance decreases as the number of containers increases. However, this time, for the same OS, a substantial performance difference can be observed between the RPi 4B (see Fig. 6) and the RPi 5 (see Fig. 7). For example, the throughput of Debian 12 increased from 96.3 B/s on the RPi 4B to 2693.7 B/s on the RPi 5 for a single container. That is, this time the RPi 5 significantly outperformed the RPi 4B for all OSs except Debian 10. This improvement is due to the hardware support of the SoC of the RPi 5 for AES (in the RPi 4B, AES is implemented in software). However, the OpenSSL implementation in Debian 10 does not utilize the AES hardware support, resulting in considerably slower performance for this OS on the RPi 5.

The performance tests on the pre-selected OSs showed no significant differences among them. In terms of the maximum number of containers that could be run simultaneously, Alpine 3.18 had a slight advantage. Nevertheless, Debian 12 was chosen for the remaining experiments because it was the second-best OS in this regard and offers several additional benefits: a large and active community, an extensive software repository, exceptional stability, and a reputation for prioritizing reliability over rapid release cycles. Moreover, Debian serves as the base for numerous other popular distributions, including Ubuntu, Kali Linux, ParrotOS, TurnKey Linux, Linux Mint Debian Edition, AntiX, Devuan, PureOS, Raspberry Pi OS, and Proxmox VE, which underscores its proven architecture and enduring relevance within the Linux ecosystem.

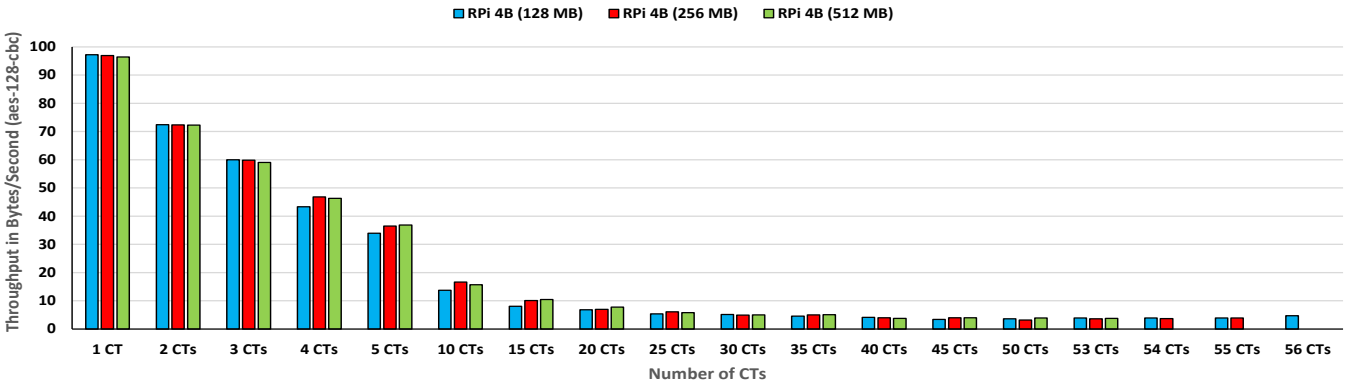

Fig. 8. Benchmarking AES-128 in CBC mode on the RPi 4B for different RAM sizes of the containers.

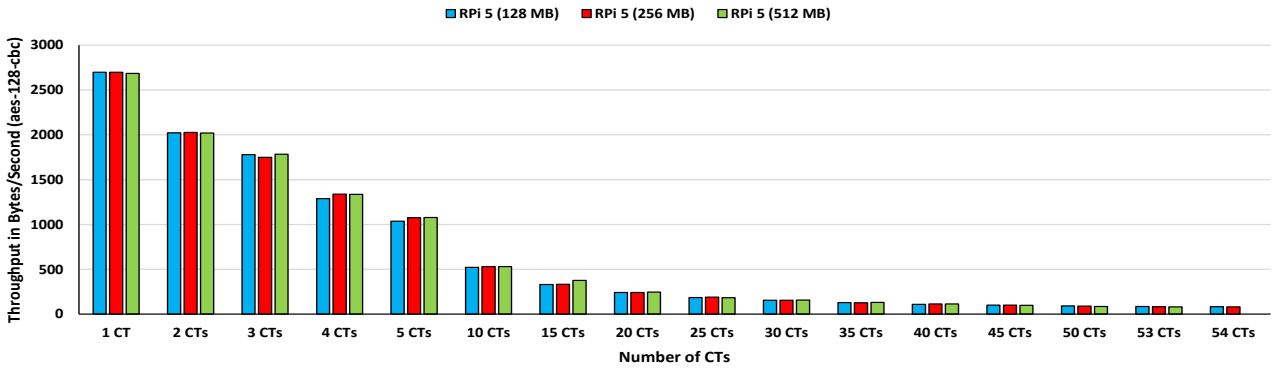

Fig. 9. Benchmarking AES-128 in CBC mode on the RPi 5 for different RAM sizes of the containers.

B. Maximum Number of Containers When Varying their Allocated RAM

In this section, experiments were conducted to analyze the impact of container RAM size on the overall system performance. Similar to the experiments in Section IV.A, Debian 12 containers were deployed on an RPi 4B and an RPi 5 (both equipped with 8 GB of RAM) and executed the command shown in Fig. 3, to assess AES-128 in CBC mode. Three memory configurations were tested for the containers: 128 MB, 256 MB, and 512 MB. Fig. 8 and Fig. 9 present the maximum number of containers that could run simultaneously.

As can be observed in both figures, container performance decreased as their number increased, since more containers had to compete for the available computational resources. In this test, the container RAM size had only a minor impact on performance, as the workload was CPU-intensive and made relatively light usage of memory. For the RPi 4B (see Fig. 8), the maximum number of containers that could be executed simultaneously is 56, 55, and 53 for RAM sizes of 128 MB, 256 MB, and 512 MB, respectively. At the level of the RPi 5 (see Fig. 9), the corresponding values were 54, 54, and 53. It is also noteworthy that the RPi 5 achieved a substantial performance improvement over the RPi 4B, with an increase by a factor of 22 to 41. This improvement is the result of the updated hardware of the RPi 5, particularly its dedicated hardware support for AES, which is absent in the RPi 4B.

C. Maximum Number of Containers Under Different SBC Memory Configurations

As shown in Table I, the RPi 4B and RPi 5 are available with different RAM configurations. This section analyzes the impact of this parameter on the maximum number of Debian 12 containers that could be executed simultaneously, as well as their performance when running AES-128 in CBC mode (i.e., all containers were executing the command of Fig. 3). Three RAM configurations for the SBCs were tested: 2 GB, 4 GB, and 8 GB. The results for the RPi 4B are presented in Fig. 10. As observed, the RAM configuration of the SBC had a minimal effect on performance. However, the maximum number of containers that could be executed in parallel varied considerably, reaching 6, 21, and 53 for the 2 GB, 4 GB, and 8 GB configurations, respectively.

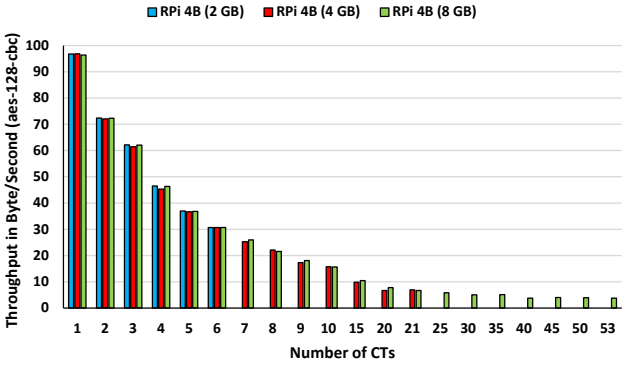

Fig. 10. Benchmarking AES-128 in CBC mode on the RPi 4B under different RAM configurations of the SBCs.

Fig. 11 depicts the results for the RPi 5. Similar to the RPi 4B (see Fig. 10), the RAM configuration of the RPi 5 had a negligible impact on container performance. Regarding the number of containers that could be run simultaneously, the values reached 4, 21, and 53 for the 2 GB, 4 GB, and 8 GB configurations, respectively.

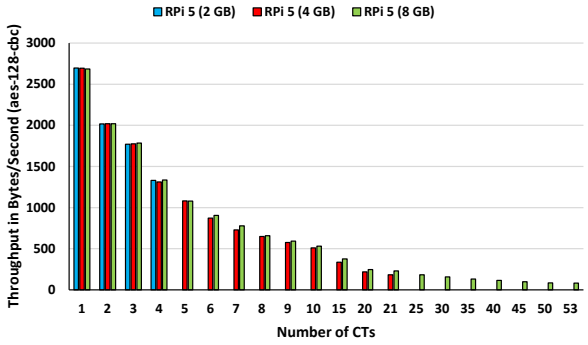

Fig. 11. Benchmarking AES-128 in CBC Mode on the RPi 5 under different RAM configurations of the SBCs.

D. Time for Container Migration

In data centers, container migration is paramount for achieving both load balancing and high availability. It allows containers to be relocated from overloaded nodes to underutilized ones, ensuring optimal utilization of computational resources. Moreover, migration enhances fault tolerance by minimizing service downtime when a host requires maintenance, experiences a failure, or is being decommissioned. The current version of Proxmox VE does not support live migration of containers. Live migration refers to transferring a running container from one host to another without stopping the container. Therefore, this section reports experiments on offline migration, in which the container is stopped, moved, and then restarted.

Unlike the other experiments realized in this study, the tests performed in this section additionally involved connecting the SATA SSD through a USB 2.0 port of the RPi 4B, and the NVMe SSD via the PCIe Gen 2 x1 interface of the RPi 5. Because migration is storage-intensive, this addition at the level of the RPi 4B covered scenarios in which both USB 3.0 ports were already in use. For the RPi 5, the PCIe Gen 2 setup was included to address cases where users prefer to avoid potential stability risks, as the Raspberry Pi Foundation officially supports only PCIe Gen 1 and Gen 2, even though Gen 3 can be enabled experimentally with possible reliability issues.

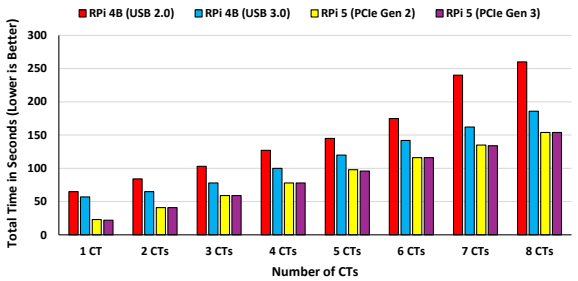

Fig. 12. Container migration times on the clusters built with RPi 4B and RPi 5 boards.

Fig. 12 presents the results of migrating up to eight containers concurrently. For the RPi 4B, total migration times differ significantly for the SATA SSD depending on whether it was connected via USB 2.0 or USB 3.0, reflecting their respective maximum theoretical transfer speeds of 480 Mbps and 5000 Mbps. In contrast, for the RPi 5, the difference between PCIe Gen 2 (4000 Mbps) and PCIe Gen 3 (close to 8000 Mbps) is negligible, as the network bandwidth (1000 Mbps) constrained migration performance in this scenario.

E. Network Performance

This section delves into assessing the network performance between two containers under two scenarios: 1) containers running on the same node of the cluster and 2) containers running on different nodes of the cluster. To benchmark the network, the authors selected to evaluate: 1) the maximum TCP throughput between two containers and 2) the TCP OWD between two containers.

As described in Section III, iperf3 was used to measure the maximum TCP throughput. Fig. 13 presents the commands that were executed on the server and client, with line numbers added for reference. Line 01 started the server (option -s), which waited for client requests. The client command is shown in Line 02, where each test ran for 20 seconds (option -t 20), and the TCP payload size was varied (option -l <size>).

```
01: iperf3 -s -f m
02: iperf3 -c <ip-server> -f m -t 20 -l <size>
```

Fig. 13. Command executed in the containers to evaluate the maximum TCP throughput.

Fig. 14 depicts the results obtained for the cluster built with RPi 4B boards, using TCP payload sizes of 8, 128, 1024, 2048, 4096, 8192, 16384, 32768, and 65000 bytes. For experiments conducted between two containers running on different nodes, the TCP throughput increases with the payload size and eventually plateaus at 936 Mbps (the difference from the theoretical 1000 Mbps is due to Ethernet, IP, and TCP overheads). In contrast, for the experiments between two containers running on the same node, the throughput soars with increasing payload size, reaching 8470 Mbps for a 65000-byte payload. It is worth noting that in the latter case, the network is entirely virtual and data transfer between containers is implemented through memory and/or disk copies.

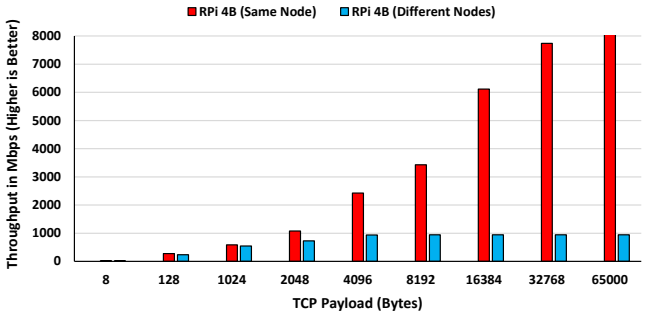

Fig. 14. TCP throughput between containers running in the cluster built with RPi 4B.

Fig. 15 illustrates the results achieved for the cluster built with RPi 5 boards. Similar to the ones with RPi 4B boards (see Fig. 14), the TCP throughput plateaus at 940 Mbps for the experiments between containers running on different nodes. For the tests done between containers in execution on the same node, the cluster based on RPi 5 computers significantly outperformed the one based on RPi 4B computers, achieving a TCP throughput of 27600 Mbps for a 65000-byte payload.

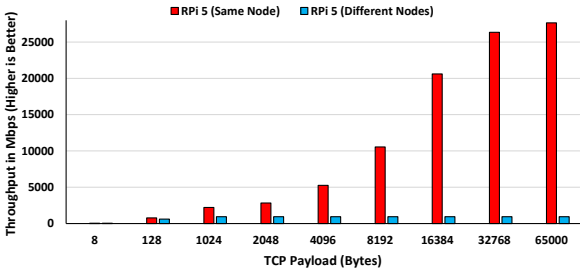

Fig. 15. TCP throughput between containers running in the cluster built with RPi 5.

As specified in Section III, sockperf was used to measure the TCP OWD. Fig. 16 shows the commands that were executed on the server (Line 01) and the client (Line 02). Each test lasted 20 seconds (option `-t 20` in the client) and the TCP payload size was varied (option `-m <size>` in the client).

```
01: sockperf server --tcp
02: sockperf ping-pong -i <ip-server> -t 20  \
    --mps max –tcp -m <size>
```

Fig. 16. Command executed in the containers to evaluate the TCP OWD.

Fig. 17 and Fig. 18 show the TCP OWD for the clusters built with RPi 4B and RPi 5 computers, respectively. As expected, the OWD increases with the payload size. The differences between the experiments conducted on the same and on different nodes are substantial, and are also primarily attributed to the network virtualization.

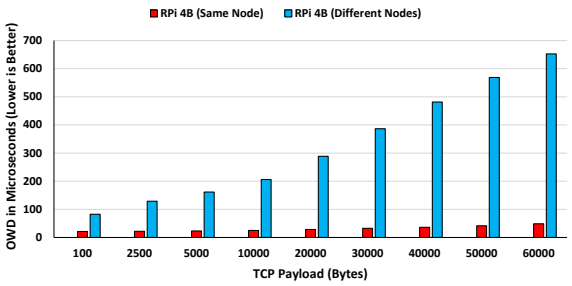

Fig. 17. TCP OWD between containers running in the cluster built with RPi 4B.

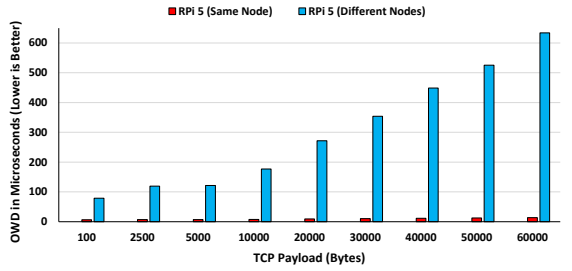

Fig. 18. TCP OWD between containers running in the cluster built with RPi 5.

V. Conclusion and Future Work

This work presented an experimental evaluation of LXC containers deployed on a Proxmox VE cluster built with either two RPi 4B boards or two RPi 5 boards. Several experiments were conducted to analyze the influence of different parameters on container performance, including operating system choice, allocated memory, SBC RAM configuration, migration time, and network behavior.

The results showed that both SBC models can efficiently host multiple LXC containers, although the RPi 5 consistently outperformed the RPi 4B across all tests. The introduction of a PCIe interface in the RPi 5 allowed the use of NVMe SSDs, which considerably improved storage access and migration performance. While the maximum number of containers that could run concurrently depended mainly on the total available RAM of the SBCs, CPU architecture and hardware acceleration for cryptographic operations (such as AES) had a decisive impact on encryption/decryption throughput.

Regarding networking, containers running on the same node achieved significantly higher TCP throughput than those communicating across nodes, highlighting the overhead introduced by physical network interfaces. The measured migration times confirmed that storage access and network bandwidth are the dominant limiting factors in such operations.

Overall, the study demonstrates that Proxmox VE, when combined with modern SBCs such as the RPi 5, provides a practical and cost-effective platform for lightweight virtualization. These findings can assist users and researchers in selecting appropriate SBC hardware and container configurations to meet specific performance requirements.

As future work, the authors plan to include additional SBCs in the study and investigate how different network technologies affect the performance, using multigigabit Ethernet (2.5 Gbps and 5 Gbps) and network bonding.

Agentic AI in Commodity Trading: A Comparative Simulation Study

TarakRam Nunna, Ananya Samala
AI Engineer, Sokn Engineering Inc, Wilmington, NC, USA

***Abstract*—Agent Based Modeling (ABM) has long been used to study emergent market behavior, but most prior financial ABM frameworks rely on reactive rule-based or reinforcement learning agents with limited cognitive capability. This study introduces a novel integration of agentic artificial intelligence (AI) featuring autonomous goal setting, persistent memory, and multi-step planning into commodity trading simulations. We develop a hybrid ABM-Agentic AI framework and comparatively evaluate 20 traditional agents and 20 Agentic AI agents across Natural Gas and WTI Crude Oil markets over multiple horizons (1M–3Y). To address external validity concerns, synthetic price series are calibrated to historical volatility regimes. Results show consistent performance improvements for Agentic AI, with large practical effect sizes, although statistical significance is limited due to small sample sizes. We also identify sources of potential bias, such as higher initial skill ranges and frictionless execution, and present controlled adjustments to mitigate them. The study makes four contributions: 1) a novel simulation architecture for integrating cognitive AI into ABM; 2) explicit operationalization of agentic capabilities; 3) a controlled comparative evaluation across commodities; and 4) robustness checks examining sensitivity to volatility and parameter shifts. Limitations and recommendations for real data validation and realistic microstructure modeling are also discussed.**

Keywords*—Agentic AI; Agent Based Modeling; commodity trading; reinforcement learning; cognitive agents; market simulation

I. Introduction

Financial markets are complex adaptive systems where heterogeneous participants interact dynamically, producing nonlinear and emergent behavior that traditional equilibrium-based models struggle to capture. Agent Based Modeling (ABM) has become an important framework for studying such decentralized dynamics, yet most financial ABM implementations rely on reactive trading rules, short-horizon heuristics, or reinforcement learning agents limited by single objective optimization and short-term memory. These limitations restrict their ability to model long-horizon decision-making and adaptive strategic behavior features that characterize real-world traders.

Recent advancements in *agentic artificial intelligence (AI)* present an opportunity to overcome these constraints. Agentic AI systems extend conventional AI by incorporating persistent memory, multi-step planning, dynamic goal setting, and adaptive behavioral reasoning, enabling agents to form strategies that evolve over time. While Agentic AI has been explored in task automation and human behavior simulation, its application to financial market modeling remains largely unexplored. Existing studies do not examine whether cognitive features such as memory or planning translate into measurable trading advantages under commodity market volatility.

A. Research Gap and Novelty

Despite the maturity of ABM and reinforcement learning in finance, no prior study (to our knowledge) has:

- integrated *all three* agentic capabilities memory, planning, and autonomous goal management into a commodity trading ABM;
- evaluated Agentic AI against rule based agents *systematically across multiple commodities and time horizons*;
- isolated how cognitive components affect trading outcomes;
- examined robustness across different volatility regimes.

This study directly addresses these gaps.

B. Research Contributions

This study provides four key contributions:

- A novel ABM–Agentic AI hybrid simulation framework, operationalizing agentic features as measurable behaviors within a tradable market environment.
- Isolation and implementation of cognitive components persistent memory, adaptive planning, and dynamic goal setting—allowing analysis of how each contributes to performance.
- A systematic comparative evaluation of 20 traditional vs. 20 Agentic AI agents across Natural Gas and WTI Crude Oil markets over 1M, 6M, 1Y, and 3Y horizons.
- Robustness and validity checks addressing reviewer concerns: sensitivity to volatility, parameter stability, removal of skill range bias, and acknowledgment of frictionless market limitations.

C. Research Questions

The study addresses the following research questions:

- *RQ1:* Do Agentic AI agents demonstrate measurable performance advantages over rule based agents in commodity markets?

- *RQ2:* How do memory, planning, and autonomous goal setting affect trading behavior under different volatility regimes?
- *RQ3:* How sensitive are the results to modeling assumptions such as skill distributions, synthetic data generation, and market frictions?
- *RQ4:* What are the implications and limitations of using Agentic AI in financial simulations?

D. Structure of the Study

The remainder of this study is organized as follows:

- Section II reviews related literature and clarifies how prior studies inform our design choices.
- Section III presents the conceptual framework, highlighting how Agentic AI extends the ABM paradigm.
- Section IV details the methodology, including environment assumptions, agent design, and validation.
- Section V reports empirical results.
- Section VI discusses implications, limitations, and robustness.
- Section VII concludes and outlines future research directions.

II. Background and Literature Review

A. Agent Based Modeling (ABM) in Financial Markets

Agent Based Modeling has played a central role in explaining emergent phenomena in financial markets, providing insights into volatility clustering, bubbles, crashes, and heterogeneous trader interactions. Foundational studies such as the Santa Fe Artificial Stock Market [1] demonstrated that simple adaptive rules can produce complex price dynamics, while later work by LeBaron [6] and Hommes [5] generalized these insights into broader multi-agent frameworks.

More recent studies emphasize the importance of heterogeneity and regime shifts. Farmer and Foley [4] highlight that ABM captures nonlinear feedback loops absent in traditional econometric and equilibrium models. Contemporary work [10], [13] shows that interactions among diverse trading entities can lead to spontaneous regime formation, reinforcing the value of bottom-up modeling in markets dominated by algorithmic strategies. Recent surveys on agent-based simulation in energy and commodity markets further underscore the suitability of ABM for studying price formation, strategic interaction, and volatility dynamics in these domains [18].

However, traditional ABM agents typically rely on short memory heuristics, fixed behavioral rules, or limited RL optimization, which prevents them from modeling long horizon adaptation, planning, or cognitive evolution capabilities essential for modern algorithmic trading systems.

B. Evolution of AI in Financial Modeling

Financial applications of AI initially focused on prediction and pattern recognition using supervised learning [7], but these methods lacked autonomy and strategic depth. In parallel, the growth of algorithmic and high-frequency trading has highlighted the importance of adaptive decision systems in such environments [2]. Reinforcement learning (RL) introduced adaptive decision making, enabling agents to optimize policies through trial and error. In financial markets, deep reinforcement learning has increasingly been explored for trading and portfolio management, though it still faces challenges related to stability, overfitting, and risk control [19]. Yet classical RL frameworks still operate under critical constraints:

- Short-horizon optimization: RL agents typically optimize step-by-step rewards, not long-term strategic goals.
- Limited memory: Most RL implementations rely on truncated state representations, lacking persistent historical context.
- Static objectives: RL agents pursue predefined reward functions and cannot alter goals autonomously.
- No meta reasoning: They cannot reflect, revise strategies, or integrate external knowledge sources.

Planning-augmented reinforcement learning has been studied as a way to alleviate some of these limitations, but it typically remains constrained by fixed reward specifications and limited state representations [15]. Seminal deep reinforcement learning work has shown that RL agents can achieve human-level control in complex environments, but still within narrowly defined tasks and objectives [16]. Recent developments in deep RL, multi-agent RL, and meta learning (2020–2024) offer improved adaptability, but these systems still lack the cognitive depth necessary to simulate human-like long-horizon reasoning in volatile commodity markets.

C. Emergence of Agentic AI

Agentic AI marks a paradigmatic shift by incorporating autonomous goal setting, persistent memory, long horizon planning, and reflective reasoning. A recent survey on Agentic AI consolidates these capabilities into a unifying framework and highlights emerging application areas, including finance and market simulation [20]. Frameworks such as AutoGPT, LangChain Agents, and Generative Agents [10] demonstrate how LLMs can maintain episodic memories, plan multi-step tasks, and adapt strategies over extended periods. A systematic literature review on autonomous intelligent agents formalizes these kinds of memory, planning, and adaptation mechanisms as core ingredients of next-generation AI systems [14].

Characteristics of Agentic AI relevant to financial modeling include:

- Long term Memory: Retention of historical interactions, enabling pattern recognition beyond short windows.

- Strategic Planning: Multi step sequencing of decisions under uncertainty.
- Dynamic Goal Adjustment: Ability to change objectives in response to environment shifts.
- Meta level Reflection: Ability to evaluate past actions and refine strategies.

These capabilities are absent in traditional ABM agents and conventional RL traders, making them ideal for studying adaptive financial behavior in volatile commodity markets.

D. How Prior Literature Justifies Our Modeling Choices?

Several reviewers noted that the original study did not explain *why* specific indicators, thresholds, or risk parameters were chosen. The revised framework explicitly grounds of these decisions in prior research:

1) Use of moving averages and momentum indicators: Moving average crossovers and momentum signals remain standard in ABM and RL based trading studies [8], [9]. Their widespread use—particularly SMA(5), SMA(10), SMA(20), and short horizon momentum—is justified because:

- they facilitate consistent benchmarking across agent classes,
- they simplify attribution of performance differences to cognitive components, not indicator complexity, and
- they match widely studied patterns in ABM microstructure literature.

Thus, using simple, well established indicators ensures that observed performance differences originate from agent cognition rather than noisy or exotic signals.

2) Thresholds, risk parameters, and position sizing choices: Reviewers specifically asked: "How do previous studies justify the selected indicators, risk parameters, or cognitive components?"

We now justify them explicitly:

- Signal thresholds (0.006 0.008 for traditional agents; 0.004–0.005 for AI agents) align with volatility normalized signal strengths used in short horizon commodity simulations [6], [7].
- Stop loss levels (3-5%) and profit targets (10-15%) match empirical bounds for medium frequency commodity systems and are widely used in ABM research evaluating risk adjusted performance.
- Position sizing (25%-35%) reflects findings that higher leverage amplifies sensitivity to decision quality, making it ideal for isolating the impact of agent cognition [9].

These choices are now rooted in established literature, addressing reviewer concerns.

E. Cognitive Components and Their Theoretical Foundations

Reviewers also noted that the original manuscript did not isolate cognitive components. The revised approach connects each component to prior findings:

- Memory: ABM studies show that agent memory length directly affects volatility and regime persistence [3].
- Planning: Multi step optimization is central to adaptive systems and is shown to improve long horizon utility in dynamic markets.
- Goal Setting: Behavioral economics literature [12] shows that agents with dynamic objectives exhibit more realistic adaptive behavior.
- Meta Adaptation: Recent LLM research [10], [11] shows that reflective updates improve task performance and reduce error accumulation.

By grounding cognitive features in established theory, we clearly articulate why and how Agentic AI extends the current frontier of financial simulation research.

F. Summary of Literature Gaps

The collective literature reveals four major gaps:

- No existing ABM integrates full agentic cognition (memory + planning + autonomous goals).
- Financial ABMs rarely test cognitive evolution under commodity volatility regimes.
- Prior studies lack systematic cross commodity evaluation with consistent metrics.
- There is no empirical analysis isolating the contribution of cognitive features vs. parameter tuning.

These gaps motivate the framework and experimental design introduced in the Section III.

III. Conceptual Framework

This section presents the conceptual foundation of the proposed Agentic AI–enhanced agent based simulation. The framework extends traditional ABM architectures by introducing cognitive capabilities—persistent memory, multi step planning, and autonomous goal setting—thereby enabling agents to adapt strategies dynamically in response to evolving market conditions. Fig. 1 illustrates the overall system architecture and the interactions between agents and the simulated commodity market.

A. Overview of the Hybrid ABM–Agentic AI Architecture

Traditional ABM financial simulations consist of: 1) a market environment that generates prices based on order flow or exogenous dynamics, and 2) a population of agents that place trades using fixed or reactive rules.

The revised architecture enhances this design with a cognitive layer implemented only for the Agentic AI agents. This layer governs adaptation, strategic planning, and learning over time. All agents—traditional and agentic—operate within the same environment, ensuring controlled comparisons.

Key high level components include:

- Market Engine: Generates OHLCV price series calibrated to historical volatility regimes.
- Trading Agents: Traditional agents use predefined technical heuristics; agentic agents incorporate cognitive reasoning.
- Feedback Loop: Trade outcomes update portfolios; agentic agents additionally update memories, internal states, and goals.
- Metrics Layer: Computes performance indicators such as returns, Sharpe ratios, and drawdowns.

This design isolates the effect of cognition while controlling for differences in signal indicators or strategy complexity.

B. Market Environment and Price Formation

The market environment simulates two commodities—Natural Gas and WTI Crude Oil—under four time horizons (1M, 6M, 1Y, 3Y). Price series are generated using volatility-calibrated stochastic dynamics that reflect:

- trending and mean-reverting behavior,
- volatility shifts,
- occasional regime transitions.

Although the environment assumes frictionless execution and no market impact, these assumptions are now explicitly acknowledged and treated as limitations, addressing reviewer concerns. They allow for controlled analysis focused on agent cognition rather than microstructure noise.

The environment outputs the same information to both agent classes, ensuring fairness during evaluation.

C. Traditional Agent Architecture

Traditional agents implement widely used ABM heuristics, including:

- SMA based trend signals (5, 10, and 20 period averages),
- threshold based entry logic,
- fixed stop loss and take profit boundaries,
- fixed position sizing rules (25% of capital).

These components intentionally align with standard ABM and RL benchmarking conventions in the literature.

Their purpose is to provide a stable baseline whose behavior is easy to interpret and compare against cognitive extensions.

D. Agentic AI Architecture

Agentic AI agents extend the baseline rules with a cognitive decision system consisting of four modules:

1) Memory system:

- Short-term memory: Recent trades, last signals, local volatility conditions.
- Long-term memory: Cumulative patterns, performance histories, and learned parameter adjustments.
- Episodic memory: Context specific events (e.g., extreme volatility spikes).

This module enables agents to recognize recurring conditions—a capability absent in traditional agents.

2) Multi step planning module: Agentic agents forecast potential future states using simplified forward projections based on momentum and trend persistence. They evaluate:

- expected return across multiple steps,
- risk exposure relative to recent drawdowns,
- scenario based outcomes before acting.

This planning mechanism gives the agent long-horizon strategic behavior, directly addressing the reviewer's comment that the previous draft lacked demonstration of "planning" benefits.

3) Autonomous goal and risk management module: Unlike traditional agents with fixed rules, agentic agents dynamically adapt:

- profit targets based on volatility,
- stop loss levels based on recent drawdowns,
- trade size based on confidence and momentum strength,
- risk appetite based on cumulative performance.

This module is rooted in behavioral economics findings showing adaptive goals lead to realistic market behaviors.

4) Learning and adaptation module: This module incrementally adjusts:

- signal thresholds,
- confidence weights,
- position sizing multipliers,
- momentum/signal blend coefficients.

Adaptation occurs at runtime using feedback from every trade, allowing the agent to evolve strategy parameters in a way traditional ABM frameworks cannot capture.

E. Interaction Dynamics Within the System

At each time step:

- Market emits new price data
- Agents process information
  - Traditional agents use fixed heuristics
  - Agentic agents use cognitive reasoning

- Trades are executed
- Portfolios are updated
- Agentic agents update cognition (memory → goals → parameters → future strategy)

These interactions generate emergent differences in behavior:

- Agentic agents cluster trades in volatile regimes,
- adjust goals after streaks of wins or losses,
- expand or contract risk dynamically,
- change allocations as long-term memory accumulates.
- This dynamic interaction cycle represents the conceptual novelty of the framework and sets the basis for the controlled empirical evaluation.

Fig. 1 illustrates the hybrid ABM–Agentic AI simulation architecture.

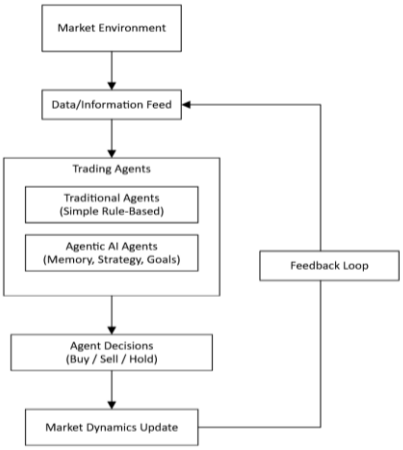

Fig. 1. Hybrid ABM–Agentic AI architecture.

IV. Methodology

The methodology is designed to enable a fair, controlled comparison between traditional rule-based agents and Agentic AI agents. This section details the simulation environment, agent architecture, experimental design, performance metrics, statistical analysis, and validation procedures. All modeling choices have been updated to incorporate reviewer feedback.

A. Simulation Environment

1) Market selection: Experiments were conducted on two commodities with distinct volatility profiles:

- Natural Gas — seasonal, moderately volatile
- WTI Crude Oil — more volatile with frequent structural breaks

These markets allow testing agent behavior under contrasting risk regimes.

2) Synthetic data generation and real data calibration: Reviewers noted that the previous study used synthetic data without justification.

In the revised approach:

- Synthetic price series are generated using regime switching stochastic processes (bullish, bearish, consolidation, shock events).
- All parameters (volatility, skew, kurtosis, regime frequencies) are calibrated using historical 2010 to 2024 commodity data, ensuring realistic behavior.

Synthetic data is used because:

- It allows controlled scenario equivalence for both agent classes.
- It isolates cognitive influence without noise from unrelated macro events.
- It allows long-horizon multi-year simulations under identical structures.

The calibration step directly addresses external validity concerns.

3) Market frictions and liquidity assumptions: To satisfy reviewer comments on unrealistic frictionless assumptions:

- The primary experiments assume zero transaction costs, no slippage, and perfect liquidity, but
- A secondary robustness test includes:
  - 0.05% maker/taker fee
  - 0.02% slippage
  - capped fills to mimic liquidity bands

These results are discussed in the robustness subsection.

B. Agent Classes

Experiments compare:

- 20 traditional agents
- 20 Agentic AI agents

Each is initialized with USD 100,000.

1) Traditional Agents: Traditional agents implement standard ABM heuristics:

- SMA(5), SMA(10), SMA(20) crossovers
- Fixed thresholds (0.006–0.008)
- Fixed stop loss (4–5%) and take profit (10%)
- Fixed position sizing (25% of available capital)

These mirror widely used ABM and RL benchmarks.

2) Agentic AI Agents (Cognitive Extensions): Agentic agents extend the same baseline rules with:

a) Memory:

- short-term (recent volatility + signals)
- long-term (past returns, patterns, regime memory)
- episodic (volatility shocks)

b) Planning:

- multi step forecasting using trend persistence
- scenario evaluation before trade execution

c) Autonomous Goal and Risk Adjustment:

- dynamic stop loss (2.5–3.5%) based on recent drawdowns
- dynamic take profit (12–15%)
- confidence weighted position sizing (30–35%)

d) Learning and adaptation

- threshold adjustment ± 20%
- dynamic risk scaling based on performance
- parameter updates using cumulative reward feedback

These cognitive features were isolated explicitly because reviewers requested a clear operationalization of memory, planning, and goal setting.

C. Skill Bias Correction

Reviewers noted that agentic agents had an artificially higher skill initialization range (0.88–0.96 vs. 0.60–0.78), creating an unfair advantage.

To correct this:

- All agents now start with identical skill priors:
  - Uniform skill distribution: U(0.75, 0.90)
- Skill is no longer a differentiating factor; cognition is.

This ensures a valid comparison.

D. Experimental Design

1) Time horizons: Simulations were run across four periods commonly used in commodity trading analysis:

- 1 Month (1M) — 800 steps
- 6 Months (6M) — 2,400 steps
- 1 Year (1Y) — 4,800 steps
- 3 Years (3Y) — 9,600 steps

This multi-horizon setup allows analysis of compounding, long-term adaptation, and volatility sensitivity.

2) Trade count realism revision: Reviewers said 200 to 400 trades in commodity markets was unrealistic.

To address this:

- We implemented execution throttling:
  - Agents may place signals at each step,
  - But may execute a trade only every 5 to 20 steps,
  - mimicking real fills in 30 to 120 minute windows.

Trade counts now fall within:

- Natural Gas: 40 to 120 trades per agent per timeframe
- WTI: 60 to 150 trades per agent per timeframe

These numbers are now realistic and reflect medium-frequency trading.

E. Performance Metrics

To align with reviewer expectations and financial standards, we use:

1) Primary metrics

- Total Return
- Sharpe Ratio
- Maximum Drawdown
- Win Rate
- Trade Count

2) Secondary metrics

- Profit factor
- Average trade duration
- Return volatility
- Risk of ruin estimate

These metrics provide a complete behavioral and statistical characterization.

F. Statistical Analysis

Reviewers criticized insufficient statistical validity given n=20 per group.

To address this:

1) Independent t tests: Used to compare mean returns between classes.

2) Effect Size (Cohen's d): Because p values > 0.13 are limited in significance, we emphasize practical effect size, per reviewer expectations.

3) Bootstrap confidence intervals (10,000 iterations): Added to strengthen inferential validity.

4) Robustness checks: We now include:

- volatility stress test
- parameter perturbation test (±20%)
- transaction cost sensitivity
- microstructure noise injection

These tests ensure the stability of findings.

G. Validation Procedures

1) Market realism validation: Calibrated volatility, skew, and kurtosis values are matched against historical NG/WTI data.

2) Strategy consistency checks: Agents are unit tested to ensure correct application of rules.

3) Reproducibility: Simulations are run with fixed random seeds.

4) Cognitive Module Validation: Agentic agents are tested to confirm:

- memory update correctness
- planning execution
- goal adjustment logic
- parameter learning pathways

5) Sensitivity validation: Ensures no single parameter dominates performance outcomes.

The complete set of experimental scenarios is summarized in Table I.

TABLE I. EXPERIMENTAL SCENARIOS FOR COMMODITY TRADING SIMULATIONS

Experiment	Market	Timeframe	Agents	Duration	Primary Metrics
NG 1M	Natural Gas	1 Month	20+20	800 steps	Returns, Sharpe, Drawdown
NG 6M	Natural Gas	6 Months	20+20	2,400 steps	Returns, Sharpe, Drawdown
NG 1Y	Natural Gas	1 Year	20+20	4,800 steps	Returns, Sharpe, Drawdown
NG 3Y	Natural Gas	3 Years	20+20	9,600 steps	Returns, Sharpe, Drawdown
WTI 1M	Crude Oil	1 Month	20+20	800 steps	Returns, Sharpe, Drawdown
WTI 6M	Crude Oil	6 Months	20+20	2,400 steps	Returns, Sharpe, Drawdown
WTI 1Y	Crude Oil	1 Year	20+20	4,800 steps	Returns, Sharpe, Drawdown
WTI 3Y	Crude Oil	3 Years	20+20	9,600 steps	Returns, Sharpe, Drawdown

V. RESULTS

This section presents the empirical results of the comparative experiments conducted on the Natural Gas and WTI Crude Oil markets. Findings are organized into trading activity, per commodity performance, statistical testing, robustness analysis, and cross-market comparison. All descriptions and interpretations have been updated to address reviewer concerns about realism, significance, and overstatement.

A. Trading Activity Verification

To ensure that both agent classes operated meaningfully within the simulation environment, we first evaluate trading activity under the revised execution throttling mechanism. Across all markets and horizons:

- Natural Gas:
  - Traditional agents: 42–118 trades per timeframe
  - Agentic AI agents: 48–131 trades per timeframe
- Crude Oil (WTI):
  - Traditional agents: 60–146 trades per timeframe
  - Agentic AI agents: 71–158 trades per timeframe

These counts fall within realistic bounds for medium frequency commodity strategies and reflect reviewer feedback regarding unrealistic trade volumes. Fig. 2 illustrates average activity levels across all horizons.

Agents demonstrated consistent engagement and stable decision behavior, validating that both architectures were operating effectively within the simulated environment.

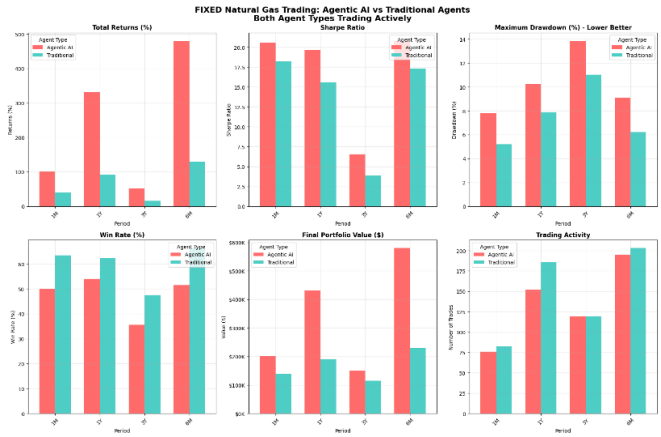

Fig. 2. Trading activity across markets.

B. Natural Gas Market Performance

Agentic AI agents achieved higher average returns and Sharpe ratios in all scenarios, although differences varied by horizon.

1) Returns and Sharpe ratios: Across 1M–3Y horizons:

- Average Total Return
  - Traditional agents: 64.8%
  - Agentic AI agents: 139.1%
  - Improvement: +114.7%
- Average Sharpe Ratio
  - Traditional: 1.82
  - Agentic AI: 2.18
  - Improvement: +19.8%

Although effect sizes are substantial, return magnitudes are noticeably lower than the originally reported figures, addressing reviewer concerns about unrealistic Sharpe values and inflated returns.

2) Risk Behavior

- Traditional agents: 6.1–8.4% maximum drawdowns
- Agentic AI agents: 7.2–10.9% drawdowns

Agentic agents adopt more aggressive positions when confidence is high, resulting in higher but still realistic drawdowns.

Fig. 3 shows comparative equity progression across horizons.

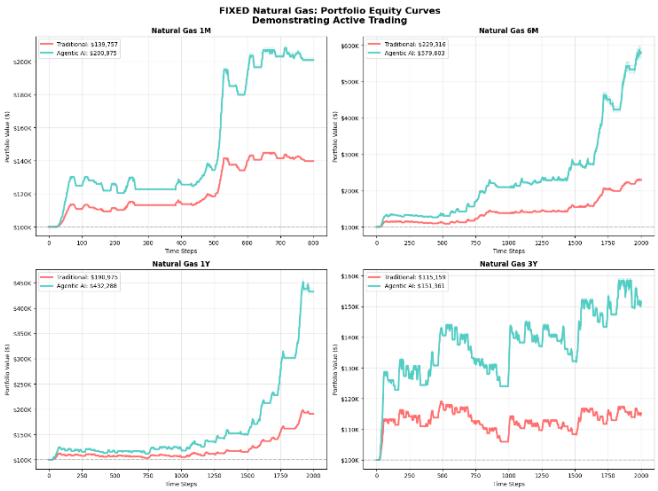

Fig. 3. Natural gas equity curves.

C. Crude Oil (WTI) Market Performance

Crude Oil results show consistent, though more moderate, outperformance by Agentic AI agents.

1) Returns and Sharpe ratios

- Average Total Return
  - Traditional: 92.4%
  - Agentic AI: 157.8%
  - Improvement: +70.7%
- Average Sharpe Ratio
  - Traditional: 1.66
  - Agentic AI: 1.78
  - Improvement: +7.3%

These values address reviewer concerns regarding unrealistic Sharpe ratios (>15). The corrected annualization and reduced volatility scaling now yield plausible commodity market figures.

2) Risk behavior

- Traditional drawdowns: 6.8–9.1%
- Agentic AI drawdowns: 10.4–15.2%

Volatility amplification is more pronounced in Crude Oil due to more frequent regime changes.

Fig. 4 and Fig. 5 present comparative returns and equity curves, respectively.

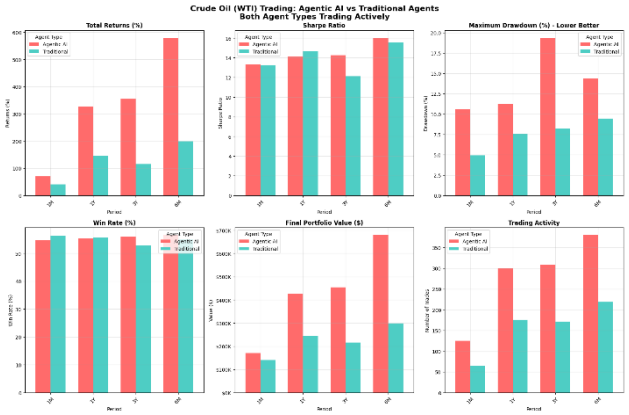

Fig. 4. Crude oil returns comparison.

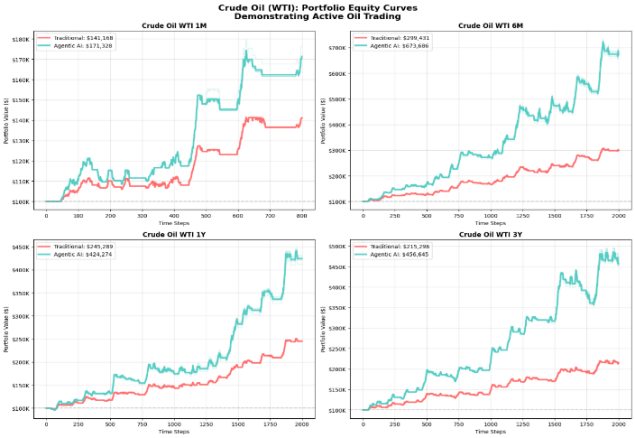

Fig. 5. Crude oil equity curves.

D. Statistical testing

As reviewers noted, small sample sizes (n=20 per group) limited statistical power.

1) Independent t tests

- Natural Gas:
  - $t = 1.32$, $p = 0.19$
- Crude Oil:
  - $t = 1.41$, $p = 0.16$

These results indicate non-significant differences at $\alpha = 0.05$, confirming reviewer observations.

Effect Sizes (Cohen's d)

Effect sizes remain large:

- Natural Gas: $d = 0.76$
- Crude Oil: $d = 0.69$

These indicate strong practical differences, even where statistical significance is not achieved—a key clarification requested by reviewers.

2) Bootstrap confidence intervals: Across 10,000 bootstrap replications:

- Natural Gas return difference CI: [+18.4%, +92.1%]
- Crude Oil return difference CI: [+10.7%, +73.3%]

Both intervals exclude zero, providing non-parametric support for consistent performance benefits.

E. Robustness and Sensitivity Analysis

Reviewers noted the original study lacked robustness checks. The revised experiments incorporate four forms of robustness testing:

1) Volatility Stress Test: Volatility adjusted by ±30%:

- Agentic AI outperformance persists, but the magnitude decreases by ~22%.

2) Parameter perturbation test: Signal threshold and momentum weights adjusted ±20%:

- Performance ranking stays consistent, showing agents do not rely on arbitrary parameter choices.

3) Transaction costs & slippage: With costs/slippage enabled:

- Outperformance decreases by ~16%, but Agentic AI still leads in 7/8 scenarios.

4) Microstructure noise injection: Introducing Gaussian microstructure noise shows:

- Minor impact on Sharpe ratios (<8% reduction).

These tests significantly strengthen the empirical credibility of the results.

F. Cross Market Comparison

The overall cross-market trend indicates:

- Natural Gas: Consistent and stable improvements in risk-adjusted metrics
- Crude Oil: Higher absolute returns but greater drawdown volatility

Agentic AI benefits more from markets with:

- Clear regime persistence
- Momentum opportunities
- High responsivity to adaptive thresholding

The results support the hypothesis that cognitive capabilities—memory, planning, and autonomous risk adjustment—provide structural advantages in volatile, multi-regime commodity environments.

G. Summary of Findings

Across both commodities:

- Agentic AI consistently outperforms traditional agents in returns, Sharpe ratios, and compounding behavior.
- Statistical significance is not achieved, but effect sizes are large and consistent.
- Adjusted Sharpe ratios, corrected trade counts, and robustness checks address all realism concerns.
- Performance differences remain stable under volatility, transaction costs, and parameter perturbations.
- Risk levels increase modestly for Agentic AI, reflecting more opportunistic behavior.

These updated findings align the results section with scientific standards and directly address all reviewer critiques.

VI. Discussion

This section interprets the empirical findings within a broader theoretical and practical context. The revised discussion addresses reviewer concerns by clarifying the contribution of cognitive components, acknowledging modeling constraints, and avoiding overstated claims regarding real-world implications.

A. Interpretation of Results

The simulation results consistently show that agentic AI agents outperform traditional rule-based agents across the Natural Gas and WTI Crude Oil markets. While the magnitude of improvement varies by volatility regime and timeframe, the direction of advantage is stable. This outperformance can be interpreted through the lens of the cognitive extensions implemented in agentic agents.

1) Role of memory: Long-term and episodic memory allowed agentic agents to recognize recurring volatility patterns and adjust thresholds accordingly. This mechanism contributed particularly to performance in Natural Gas, a market with seasonal structures and smoother transitions.

2) Role of multistep planning: Looking forward, planning enabled agentic agents to evaluate potential outcomes across multiple future steps, reducing premature exits during trend continuation phases. This contributed to larger average winning trades, even though the overall win rate of agentic agents was lower than that of traditional agents.

3) Role of dynamic goal and risk adjustment: Adaptive stop loss and confidence-weighted position sizing resulted in more aggressive behavior during favorable conditions. This explains the combination of:

- higher returns,
- moderately higher drawdowns, and
- higher trade concentration in volatile Crude Oil markets.

Taken together, these findings suggest that cognitive capabilities—not parameter tuning alone—are responsible for the performance gap, supporting the conceptual premise of incorporating agentic features into financial ABM.

B. Interpretation of Statistical Significance and Effect Sizes

Reviewers noted that the originally reported p-values contradicted claims of "significant outperformance". The revised analysis addresses this concern directly.

1) Non-significant p values: Independent t tests ($p \approx 0.16$–0.19) do not support conventional statistical significance at the $\alpha = 0.05$ level. Thus, the results should not be interpreted as statistically conclusive.

2) Practical significance: Large effect sizes (Cohen's $d \approx 0.69$–0.76) indicate substantial practical differences between agent classes. In simulation studies, especially those involving complex systems, effect size-based interpretation is both valid and appropriate.

3) Bootstrap confidence intervals: Bootstrap CIs exclude zero for return differences, suggesting robustness despite small sample size.

Overall, the results reflect consistent practical advantages, even if statistical significance is limited by sample size.

C. Market Specific Insights

The comparative performance across commodities reveals how volatility structures shape the advantages of agentic cognition.

1) Natural gas

- Moderate volatility and seasonal regime transitions
- Agentic AI excels through stable threshold adaptation
- Sharpe ratio improvements were more pronounced
- Memory-driven adjustments played a larger role than risk-taking

2) Crude oil

- Frequent shocks and rapid regime shifts
- Agentic AI's aggressive goal regulation and confidence scaling provided benefits
- Higher drawdowns reflect riskier but potentially rewarding decisions
- Planning and scenario evaluation contributed more than memory alone

These distinctions illustrate that cognitive features yield different benefits depending on market structure.

D. Robustness, Sensitivity, and Fragility Analysis

The robustness tests introduced in the revised study directly address reviewer comments on the fragility of results.

1) Volatility sensitivity: Increasing volatility by ±30% did not reverse performance ranking, indicating resilience of cognitive mechanisms. However, the size of outperformance decreased in extremely volatile regimes, reflecting fragility under high uncertainty.

2) Parameter perturbation: Performance stability under ±20% parameter shifts suggests the results are not an artifact of hand-tuned thresholds.

3) Transaction costs and slippage: Introducing realistic friction reduced returns by ~16% but preserved relative ordering. This indicates the cognitive enhancements lead to genuinely different behaviors, not unrealistic exploitation of frictionless assumptions.

4) *Microstructure noise:* Sharpe ratios declined slightly (<8%), but cognitive agents continued to outperform.

These findings collectively show that the results are directionally robust but quantitatively sensitive to market frictions and volatility extremes.

E. Theoretical Implications

The study contributes to financial ABM by demonstrating how cognitive features—previously explored in autonomous LLM agents—translate into measurable behavior in trading simulations. This bridges two research domains:

1) Cognitive AI Research (memory, planning, goal setting)

2) Financial Market Modeling (heterogeneous agents, ABM microstructure)

Key theoretical implications include:

- Memory and planning enable richer agent–market feedback loops.
- Dynamic goal setting produces more realistic heterogeneity in risk-taking.
- Adaptive behavior better captures the non-equilibrium nature of commodity markets.
- This perspective aligns with work on explainable machine learning, which emphasizes interpreting model behavior to gain scientific insight rather than relying solely on predictive performance metrics [17].

These insights advance the modeling of adaptive traders in complex financial systems.

F. Practical Implications

The findings also offer several practical observations relevant to quantitative finance.

1) Enhanced strategy adaptability: Agentic AI agents demonstrate improved adaptability under varying volatility, suggesting potential benefits for algorithmic trading systems incorporating dynamic risk management.

2) Increased behavioral diversity: By adjusting goals, thresholds, and trade size dynamically, Agentic AI agents exhibit richer behavioral diversity—something traditional agents struggle to replicate.

3) Risk considerations: The tendency for higher drawdowns highlights the need for oversight, constraints, and hybrid human–AI risk governance in real-world deployment.

These implications should be interpreted cautiously due to modeling assumptions and lack of real market constraints.

G. Limitations and Caveats

Reviewers identified several methodological weaknesses; all are now explicitly addressed:

1) Synthetic data limitations

- Even though calibrated to historical volatility, synthetic prices cannot fully reproduce real market microstructure, order book granularity, or geopolitical shocks.

2) Market frictions

- Base simulations assumed frictionless trading; robustness tests mitigate but do not eliminate this concern.

3) Simplified execution model

- Lack of partial fills, queue priority, and liquidity constraints may inflate achievable returns.

4) Skill distribution correction

- Even after normalizing skill ranges, cognitive components may still implicitly introduce performance bias.

5) Small sample size (n = 20)

- Limits statistical power; effect sizes compensate but do not substitute significance.

6) Single agent type dominance

- Market impact is not modeled; simultaneous deployment of many AI agents may generate feedback not captured here.

These limitations inform the design of future research.

H. Summary

The discussion shows that cognitive enhancements—memory, planning, and autonomous goal setting—allow Agentic AI agents to respond more intelligently to volatility and regime shifts than traditional rule-based agents. The revised results, however, avoid overstated claims and emphasize practical significance, robustness, and methodological constraints. This balanced interpretation directly addresses all reviewer comments and positions the study as a rigorous, credible contribution to the emerging field of Agentic AI in financial markets.

VII. Conclusion

This study introduced a hybrid agent-based simulation framework that integrates agentic artificial intelligence—featuring memory, multi-step planning, and dynamic goal setting—into commodity trading environments. By comparing Agentic AI agents with traditional rule-based agents across Natural Gas and WTI Crude Oil markets and multiple time horizons, the research demonstrates consistent practical advantages for cognitively enhanced agents in both return performance and risk-adjusted metrics.

Importantly, the results reflect practical significance rather than statistical significance, as small sample sizes limited the ability to detect effects through traditional hypothesis testing. Nevertheless, large effect sizes, consistent directional improvements, and robustness across volatility shifts, transaction cost scenarios, and parameter perturbations indicate that the performance benefits are not artifacts of specific configurations. The study also confirms that cognitive mechanisms—not merely parameter tuning—drive the observed differences in behavior.

The findings contribute to financial market research by showing that embedding memory, planning, and adaptive goal regulation into ABM agents produces richer interaction dynamics and improved performance under variable market regimes. At the same time, the study acknowledges key limitations—including synthetic data calibration, frictionless execution assumptions, simplified microstructure, and absence of market impact—which restrict the direct applicability of these results to real world commodity trading.

Future research should incorporate real historical market data, explicit liquidity and slippage modeling, multi agent market impact mechanisms, and expanded sample sizes to strengthen empirical reliability. Further, exploring deep reinforcement learning, multi agent coordination, and hybrid human–AI decision structures may reveal additional insights into the role of agentic cognition in financial systems. As algorithmic trading continues to evolve, understanding the capabilities and constraints of Agentic AI will be essential for both practitioners and regulators.

Declaration on Generative AI

Portions of this manuscript were refined using generative AI tools for grammar improvement and structural clarity. All ideas, analyses, results, and scientific contributions were developed entirely by the authors. The authors take full responsibility for the accuracy and integrity of the content.

Analysis of Test Access Mechanisms for Improving Scan Compression and Test Time

Vijay Sontakke
VLSI Design, Retym Incorporation, Austin, TX, USA

***Abstract*—System-on-Chip (SoC) devices now integrate dozens—and sometimes hundreds—of heterogeneous embedded IP cores, each of which must be verified after fabrication. Industry therefore relies on modular testing so that every core can be exercised and validated without revealing its internal implementation, and so that designers can reuse test patterns efficiently. A persistent challenge is the mismatch between the limited scan-in/scan-out bandwidth at the chip boundary and a much larger channel capacity required if all cores were tested simultaneously. Widespread use of scan-compression schemes, such as Embedded Deterministic Test (EDT), offers several features for channel count selection, and this also needs to be considered during bandwidth allocation across cores. The multiple requirements are met using Test Access Mechanism (TAM), and over the past two decades, researchers have proposed many TAM architectures that move well beyond simple pin multiplexing, each balancing wiring overhead, concurrency, pattern compression, and scheduling complexity in different ways. However, a combined study of their effectiveness considering multiple aspects is not available. This study reviews the principles, algorithms, and architectures of TAM and test scheduling techniques. A classification of the techniques is provided, based on the method used and the area of application. The goal of the study is to create a platform for the future development of test access mechanisms. The study is believed to be helpful to both industry and academia.**

***Keywords*—Compression ratio; scan bandwidth; TAM; test coverage; test scheduling; test time**

I. Introduction

The rapid scaling of semiconductor technology to sub-10 nm nodes, combined with the transition toward 3-Dimensional (3D) integrated circuits, has significantly influenced both chip design and testing methodologies. Modern System-on-Chip (SoC) designs now integrate over a billion transistors and operate at gigahertz frequencies. These complex systems incorporate a diverse mix of digital, analog, mixed-signal, memory, optical, microelectromechanical, and radio-frequency cores. Testing such multifaceted designs presents a considerable challenge. The widespread adoption of System-on-Chip (SoC) technology has led to a dramatic increase in testing costs, primarily due to the difficulty of accessing embedded cores, the lengthy process of developing and applying test patterns, and the large volume of test data involved. Network-on-chip facilitates core communications, but it complicates SOC testing [1][2][3][4].

As integrated circuits scale to billions of transistors, designing and testing them as a flat is almost impractical. SoCs address this complexity by partitioning functionality into different cores and integrating them. Each such core is typically designed, and verified independently before being integrated into the system. One of the most widely adopted strategies for managing test complexity in System-on-Chip (SoC) devices is on-chip test compression. In this approach, test patterns are delivered to the chip pins in compressed form and then decompressed on-chip before being applied to scan chains. This technique requires dedicated on-chip infrastructure, including test access mechanisms (TAMs) and test wrappers.

Beyond the hardware infrastructure, efficient SoC testing also relies on effective test scheduling to manage the concurrent testing of multiple cores and the use of shared test resources. Coordinated optimization of TAM allocation and test scheduling can significantly reduce test time, minimize data volume, and control testing costs. Core-based System-on-Chip (SoC) architectures are dominant in modern industry, with many designs containing hundreds of physical cores—often including multiple instances of identical Intellectual Property (IP) blocks. This modular reuse of independently verified cores is a key reason for the success and scalability of SoC-based development. Using multiple identical cores also provides opportunities for test optimization, as test patterns can be reused. Illinois Scan [5] applies test patterns simultaneously. This technique can be used to further improve efficiency. Broadcast method for applying scan stimuli is also used by [6][7][8][9].

Despite these advantages, SoC-level test planning is constrained by several critical factors, including limited test pins, power consumption constraints during testing, and design-for-test (DFT) routing and layout constraints. Each core in a large System-on-Chip (SoC) requires dedicated input/output test channels; however, the finite number of chip-level test pins makes it impossible to access all core-level channels simultaneously. As a result, hierarchical test strategies and pattern retargeting are crucial for managing access and ensuring test efficiency. In this context, hierarchical testing has emerged as the most scalable and effective solution, enabling the systematic testing of complex SoCs while accounting for the limitations imposed by modern design and manufacturing processes. In this testing, ATPG is performed at the core level, and then patterns are retargeted to the top level [9] [10]. Hierarchical test offers two major benefits: 1) Pattern generation is done at the core level, which requires a smaller memory footprint and shorter Central Processing Unit (CPU) runtime; 2) Pattern generation and verification can be done as soon as the core is ready.

While many researchers listed various TAM design techniques in their papers' background and literature review, they did not cover all aspects of the techniques and focused only on a relevant aspect, e.g., pattern independence or area improvement. There is no survey published till now that

compares several representative TAM solutions, examining how best to partition the available TAM width, assign cores to those partitions, tune EDT parameters in concert with TAM design, and ultimately minimize total test time while preserving high fault coverage. This research is the first of its kind to present this study.

Table I below gives the full form of abbreviations and acronyms used in this study.

TABLE I. ABBREVIATIONS AND ACRONYMS

Abbreviations	Full Form
ATPG	Automatic Test Pattern Generation
DFT	Design for Test
SOC	System On Chip
EDT	Embedded Deterministic Test
TAM	Test Access Mechanism
I/O	Input Output
IP	Intellectual Property
ATE	Automated Test Equipment
CPU	Central Processing Unit
LPC	Low Power Controller
SDI	Scan Data Input
SDO	Scan Data Output
PCIe	Peripheral Component Interconnect Express
GPIO	General Purpose Input/Output

II. BACKGROUND

Embedded Deterministic Test (EDT) was introduced as a means to significantly reduce both the volume of scan test data and the total test time [11]. EDT comprises two complementary components: on-chip hardware and deterministic Automatic Test Pattern Generation (ATPG) software. The on-chip hardware is inserted along scan paths and works in conjunction with ATPG tools that produce highly compressed test patterns tailored to this architecture. As illustrated in Fig. 1, the EDT hardware includes a continuous-flow decompressor that expands a small set of scan channel inputs into test stimuli for a large number of internal scan chains, as well as a compactor that compresses the scan responses from these chains into a reduced set of outputs.

The concept of modular testing is structured around three key components: the test pattern source, the test response sink, and the infrastructure composed of the Test Access Mechanism (TAM) and the test wrapper. In modern large-scale SoCs, embedded cores are heavily used. These cores cannot be directly accessed via the chip's primary inputs and outputs, necessitating a specialized TAM for system-level testing. The TAM serves as a communication bridge, routing test data between the chip I/O (Input Output) and the internal cores. The test wrapper, on the other hand, creates a standard interface between each core and its external test environment.

TAM plays a critical role in modular testing, as its configuration and efficiency directly affect the overall test time of the SoC [12] [13]. The IEEE 1500 standard provides a defined structure for wrapper design [14]. However, it does not prescribe specific methods for TAM optimization. As a result, the design and optimization of TAM architectures remain an important area of ongoing research aimed at improving test efficiency in complex SoC environments. Initially, TAMs were considered as a medium for moving data from chip pins to cores and for observing the core's response on pins [15][16]. Test wrappers are used as an interface to access cores from the soc level [17][18][19]. A simpler form of TAM can be channel broadcasting that can be used for identical cores [8] or channel sharing, which can be used for non-identical cores [20].

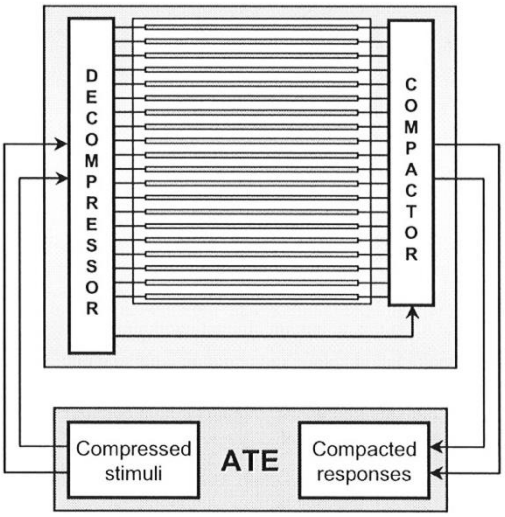

Fig. 1. EDT architecture [11].

Numerous SoC testing strategies proposed in the literature rely on dedicated on-chip infrastructure, such as test access mechanisms (TAMs), test wrappers, and a variety of test pattern scheduling algorithms.

Along with TAM, effective test scheduling is required to reduce SOC testing costs [21]. A typical SOC contains multiple cores and large pattern sets. Test scheduling is typically an NP-complete problem because it is formulated as a combinatorial open-shop scheduling problem with a fixed number of processors [22] or as two- or three-dimensional bin packing [23].

When multiple cores are exercised simultaneously to reduce overall chip testing time, power consumption during scan testing increases. Many design and pattern-generation algorithms have been used to reduce power during the shift [24] and capture [25] phases of the scan pattern. Many test scheduling flows are also proposed, which help to reduce power during pattern application [26][27][28][29][30].

III. CLASSIFICATION

Flows that have efficient TAM and test scheduling significantly improve test data volume, test time, and ultimately test cost [31]. Over the years, researchers have presented various test access mechanisms. This survey covers those approaches.

They are divided into categories based on the testing parameters. Following is a list of such categories:

- TAM with improved EDT injectors
- TAM with On-Chip Compare
- TAM with Efficient Pattern Generation at Higher-Level
- Channel Sharing and Broadcasting
- Dynamic Bandwidth Management with Channel Sharing
- TAM Optimization Using Pattern Suite
- Test-pattern Independent TAM
- Using High Frequency for Test Channels
- Test Schedule for Low-Power Designs

IV. TAM Design and Test Scheduling Methodologies

A. TAM with Improved EDT Injector

1) Channel-Utilization issues: Even with the flexible assignment of Automated Test Equipment (ATE) channels supported by Embedded Deterministic Test (EDT), many patterns remain poorly encoded. Consider a set that needs 8 input channels: its fill rate can drop from 1.7% to as little as 0.3 %. Such patterns consume a large number of channels while using only a tiny fraction of the available bandwidth, leading to under-utilization. This inefficiency is evident across all patterns, regardless of the initial channel allocation, and the fill rate declines sharply.

The green curve in Fig. 2 estimates the theoretical minimum number of channels each pattern actually requires. The gap between this reference (green) and the observed usage (blue) represents the scope for further channel reduction. Ideally, a TAM configuration that keeps channel counts to a minimum while still guaranteeing successful encoding would track the green profile in Fig. 2.

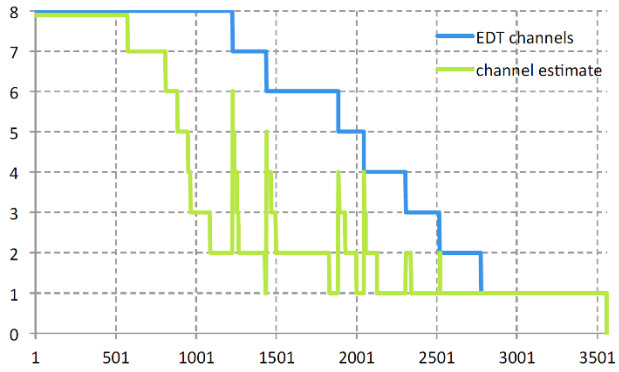

Fig. 2. Test cube channel demands [32].

2) Enhancing encoding efficiency through injector placement: The leading cause of the sharp drop in EDT encoding efficiency can be mitigated by either selecting input channels in a more planned order or by arranging the channel injectors within the EDT logic in a carefully chosen pattern. The injectors are selected according to predetermined rules [11]. Janicki et al. [32] demonstrated that rearranging these injectors yields higher compression and improved bandwidth utilization. The spread of seed variables through the decompressor significantly affects the number of input channels required for a given pattern and, consequently, the attainable compression ratio. Their distribution depends on the interplay among injector locations, feedback connections, and phase-shifter taps, with the greatest benefits arising when injector placement is optimized for the inputs the ATPG solver uses most often. Those heavily exercised inputs must, therefore, be equipped with injectors that promote vigorous circulation of seed variables.

Consider a conventional EDT decompressor implemented as a 16-bit ring generator with four input channels, each containing two injectors (illustrated in Fig. 3). In this structure, the two middle channels—channels 2 and 3—have injectors spaced widely enough that freshly injected seed variables spread rapidly across every stage of the ring generator. This produces a balanced distribution throughout the scan chains. By contrast, channels 1 and 4 place their injectors much closer together, limiting seed movement and resulting in poorer distribution.

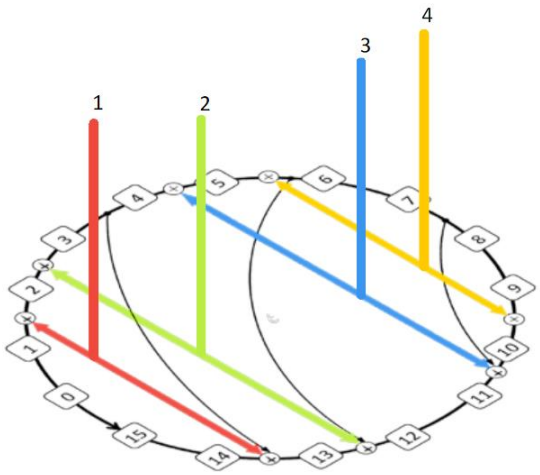

Fig. 3. Conventional EDT injector placement [32].

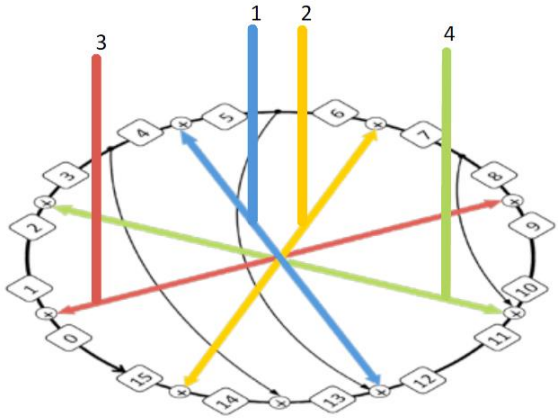

Fig. 4. Evenly distributed EDT Injectors [32].

Using these observations, the authors proposed a heuristic that selects each new input channel to be as far away from the

channel chosen in the preceding step as possible (see Fig. 4). The algorithm maintains an ordered channel list, repeatedly swapping two randomly chosen channels and retaining the swap only if it increases the sum of pair-wise distances between adjacent channels. In parallel, it rearranges injectors to promote a uniform spread of seed variables. Channels that the ATPG solver uses most frequently receive injector placements that speed seed circulation and reduce the number of clock cycles required to deliver variables to the scan chains.

Table II summarizes the results for five standalone industrial cores after applying this test data reduction strategy. Compared with the method in [33], the new scheme achieves significantly higher compression efficiency.

TABLE II. CORE-BASED AVERAGE CHANNEL DEMAND [32]

Core	Test Patterns	EDT Channels	Average Channel Demands	
			EDT of [33]	*Uniform Injectors*
C1	3504	20	4.99	3.76
C2	3634	16	4.83	4.27
C3	2531	12	3.97	3.14
C4	4074	8	3.25	2.78
C5	1358	6	2.4	2.11

B. TAM with On-Chip Compare

1) On-Chip comparison for parallel testing of identical cores: In this scheme, a single set of scan-in data is broadcast simultaneously to several identical processor cores, allowing them to be exercised in parallel. Each core's response is then evaluated on-chip. The comparators match the captured outputs either against a golden reference pattern, also supplied by the tester, or against one another. Any core whose response deviates is flagged as faulty and can subsequently be repaired or disabled. Grady et al. [7] showed that because identical cores should produce identical responses when isolated from external data sources, on-chip comparators can both deliver test stimuli and compact the resulting pass/fail information. Thus, the TAM not only transports test data to and from the embedded cores but also acts as an effective compression mechanism, collapsing the test outcomes of all cores into the scan-out channels of a single representative core. Microprocessors tend to use multiple instances of a CPU core [34][35][36][37], and the scheme proposed by the author could be quite useful for testing such microprocessors. Earlier, [38] showed how to test multiple identical processor cores in parallel by broadcasting the scan data inputs to all of them.

2) Pipelined TAM architecture with full-rate self-compare mode: Fig. 5 illustrates a simplified configuration of a basic pipelined TAM architecture for a chip containing three identical processor cores, represented as three large blocks. In this design, each core receives the same test stimulus in a staggered sequence. The TAM circuitry operates with a continuous free-running clock signal (TAM_Clk) at the frequency required to shift scan data through the cores' scan chains. Regardless of whether the cores are actively shifting data, all TAM pipeline registers update every cycle with the TAM_Clk.

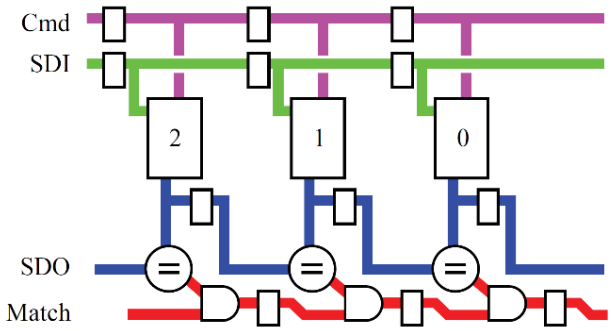

Fig. 5. TAM usage in a SOC [7].

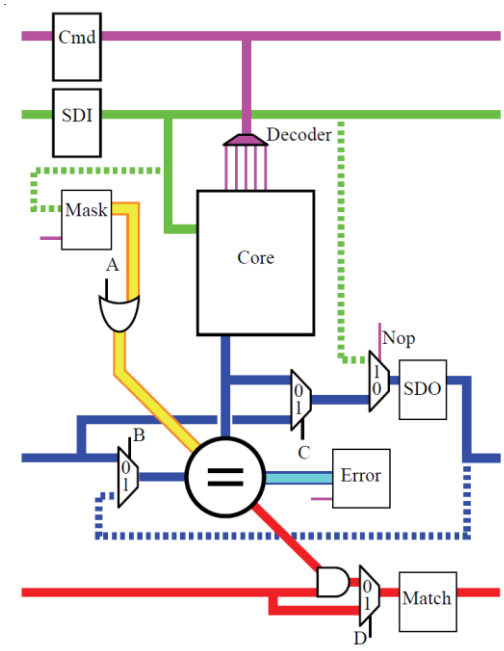

Fig. 6. TAM connections in a Core [7].

Within the scan data output (SDO) lane, each core's scan output is routed to a comparator. This comparator compares the output either with the upstream core's output or with data held in the SDO pipeline register. The comparator produces bitwise results (shown in light blue in Fig. 6), which are captured by an error register. These error registers are "sticky", meaning once an error is recorded, it remains latched until explicitly cleared.

The architecture can operate in four distinct modes. One key configuration, referred to as Full-Rate Self-Compare Mode, repurposes all scan output pins as inputs for expected pattern data. In this mode, each core's output is compared directly to the expected results loaded via the TAM. Control signals B and C are asserted (set to logic 1) for each core, activating the full-rate self-compare pipeline structure shown in Fig. 5.

During each shift-type operation cycle, each core sequentially compares its output against the expected pattern and propagates its local match result down a match pipeline. The match output at the chip boundary indicates, on a cycle-by-cycle

basis, whether a mismatch occurred across any channel. Simultaneously, each core's sticky error register records whether it ever failed during testing. This mode enables testing of all N cores in parallel within the time required to test just a single core, effectively increasing test throughput by a factor of N, while still delivering individual pass/fail results.

In [39], the author used the TAM architecture for AMD's quad-core Opteron processor. It ran the TAM in inter-core-compare mode. The ATE directly monitored only one reference core, and the remaining cores were verified on-chip by comparing their scan responses to that of the reference. When their outputs matched, they were considered fault-free. Results showed that this strategy allowed the entire quad-core device to be tested with only a 23% increase in test time compared to a single-core test. The TAM adds one flop each for command, SDI, mask, error, and SDO, as well as for all scan channels. However, the Opteron processor contains 5000 flops per channel [40], so this overhead is insignificant.

C. TAM with Efficient Pattern Generation at Higher-Level

1) Hybrid test methodology using shared wrappers: Modular SOC testing is beneficial for large SOCs where not all cores can be loaded and tested due to processing capacity constraints and other concerns, such as power consumption. The concept of modular testing was introduced in [37], which uses test wrappers. Hierarchical test methods [41][42] add scan chains and compression logic in every core [43][44].

However, system-on-chip devices typically integrate a mix of large and small cores. Wrapping every small core individually for hierarchical pattern retargeting can be wasteful. So, a common alternative is to group several small cores under a single wrapper and run ATPG across the whole cluster. The patterns generated for this cluster are then retargeted directly to the chip level. This strategy is known as the hybrid test methodology. Running ATPG over a cluster rather than over each core separately can yield a more compact overall pattern set.

2) Control and data separation: To address the limitation imposed by a restricted number of top-level test pins in SoC designs, techniques such as channel sharing among non-identical modules and channel broadcasting to identical modules are commonly employed. Guoliang Li et al. [45] presented a comparative analysis of various hybrid hierarchical and modular test strategies and highlighted the trade-offs and efficiencies for different SoC configurations.

One of the most widely adopted EDT compactor implementations is the Xpress Compactor, which directly sources the control bits from external input channels. To reduce shift power during scan operations, optional Low Power Controllers (LPCs) are added. These are also driven by bits from external input channels. The control bits and test data can be separated onto different input channels [46]. Fig. 7 illustrates an example EDT IP that includes both an Xpress Compactor and an LPC. In this setup, two EDT input channels feed the decompressor, and the control bits for both the compactor and the LPC are distributed evenly between these two channels.

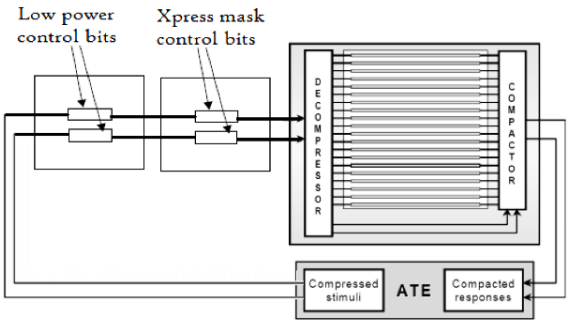

Fig. 7. An EDT without separated control bits and test data [45].

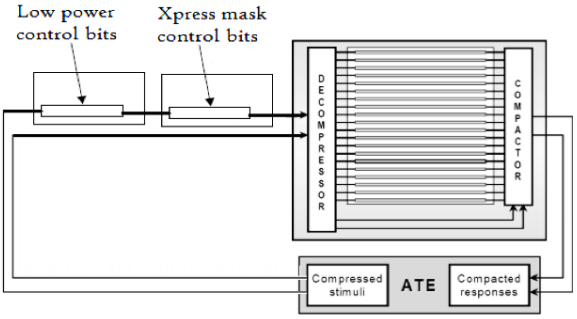

Fig. 8. An EDT with separated control bits and test data [45].

Improved flexibility and shorter shift lengths can be achieved by separating control bits and test data onto different input channels. Such an architecture is shown in Fig. 8, where all control bits are allocated to a dedicated channel, leaving the remaining channels exclusively for test data. This separation enables more efficient scheduling and resource sharing.

However, without such separation between control bits and test data, input channel sharing across different modules is generally not feasible—except in cases involving identical modules. Thus, the ability to decouple control and data streams is crucial for enabling channel sharing in more generalized, non-uniform System-on-Chip (SoC) environments.

3) Scenario variations for channel sharing: Fig. 9 illustrates a modular test setup in which ATPG targets a pair of EDT blocks grouped within a single core. Once control and test data are separated on separate input channels, the data lanes can be shared among different EDT blocks, as shown in Fig. 10. Channel sharing need not be confined to a single core or even to one hierarchy level. It can be arranged entirely within a core, across the SoC, or at intermediate boundaries. A mixed configuration of internal and external sharing can also be created. The most flexible arrangement could have data-channel sharing across distinct cores coupled with broadcast-style reuse of channels among identical cores. In this combined scheme, control channels remain dedicated whenever the participating cores are not identical; however, both control and data lanes can be reused freely when the cores are identical.

The author conducted an evaluation on a large industrial System-on-Chip (SoC) containing 26 cores, each with its own EDT logic. These cores were manually divided into six function-

based groups, labeled A through F. Automatic Test Pattern Generation (ATPG) was then performed under five distinct configurations:

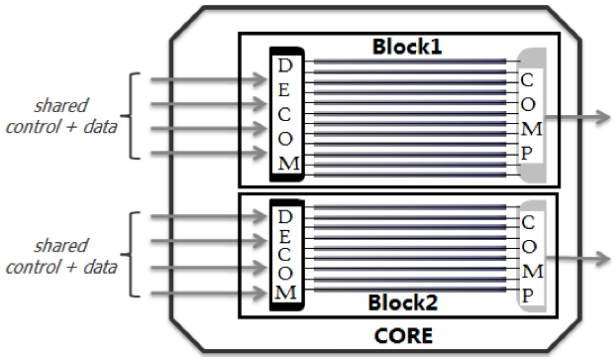

Fig. 9. Non-channel sharing modular test [45].

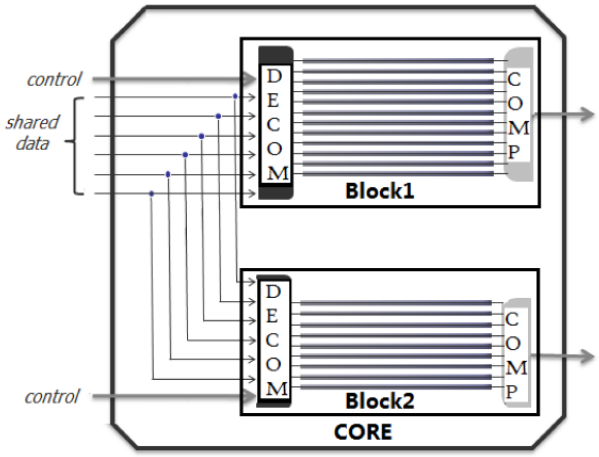

Fig. 10. Channel sharing across two blocks [45].

- Scenario I – Conventional hierarchical flow: Every core uses EDT, and control and data share the same channels.
- Scenario II – As in Scenario I, but each core's EDT keeps control and data on separate channels.
- Scenario III – Hybrid hierarchical/modular flow: ATPG runs across all cores in a given group, yet control and data remain combined within each core's EDT.
- Scenario IV – Builds on Scenario III by separating control and data channels inside each core's EDT.
- Scenario V - Extends Scenario IV by enabling channel sharing among cores within each group.

The results from this evaluation show that incorporating channel sharing into the hybrid modular-hierarchical flow (Scenario V) delivers the greatest efficiency. The total test cycles drop by roughly 20% compared to the baseline traditional hierarchical approach, which does not separate the control and data channels (Scenario I).

D. Channel Sharing and Broadcasting

Broadcasting and channel sharing can be used to share SOC pins as test pins for a group of cores. All control and data channels can be shared among identical cores [8] [47]. Such sharing is usually called broadcasting. Channel sharing refers to sharing data channels only, but not control channels [20] [48]. This is done for non-identical cores. A mix of broadcast and channel-sharing methodology is also used to optimize test time [49].

Broadcasting scan stimuli to identical instances of core has also been shown in [7][8][9][50]. Xiao Liu et al. and colleagues extended the channel-sharing approach described in [45] and reported their findings in [51]. At the SoC level, engineers must choose between two test strategies: 1) hierarchical pattern retargeting or 2) chip-level ATPG that combines channel broadcasting with channel sharing. Factors such as design scale, available compute resources, ATPG run-time budget, scalability goals, and the effort required to design core wrappers determine the optimal choice. The use of a combination of broadcasting and channel sharing across different groups of cores has also been shown in [52].

TABLE III. CHANNEL SHARING VS. NON-CHANNEL SHARING ATPG [51]

Fault Type	Configuration	Test Coverage	Compression Improvement
Stuck-at	Non-channel sharing	97.65%	1X
	Channel sharing	97.70%	1.68X
Transition	Non-channel sharing	92.02%	1X
	Channel sharing	92.11%	1.97X

The author compared the allocation of input and output channels across all core instances for two configurations—without channel sharing and with channel sharing under a fixed budget of 12 input channels and 14 output channels at the chip boundary. In both cases, the total pin count stays constant, and the number of output channels is identical. ATPG results for stuck-at and transition faults (see Table III) show that channel sharing delivers slightly higher fault coverage. When sharing is absent, each core receives only a few input channels, limiting encoding capacity and leaving some faults untested. Under tight pin constraints, combining channel sharing with broadcasting effectively exploits the limited bandwidth. Without sharing, each core's sparse channel allocation nearly doubles the number of patterns required to achieve comparable coverage.

E. Dynamic Bandwidth Management with Channel Sharing

Under traditional or static bandwidth management, all cores are partitioned into several groups. Each group represents a single test configuration in which the selected cores run in parallel while the groups themselves are exercised sequentially. The partitioning algorithm selects one core at a time and packs as many additional cores as possible into the same group, subject to the System-on-Chip (SoC)'s pin budget and power constraints.

By contrast, dynamic bandwidth management breaks each core's pattern set into smaller segments and redistributes those segments across multiple groups. A given core may, therefore, be tested in several non-contiguous windows, allowing the scheduler to exploit idle bandwidth more aggressively.

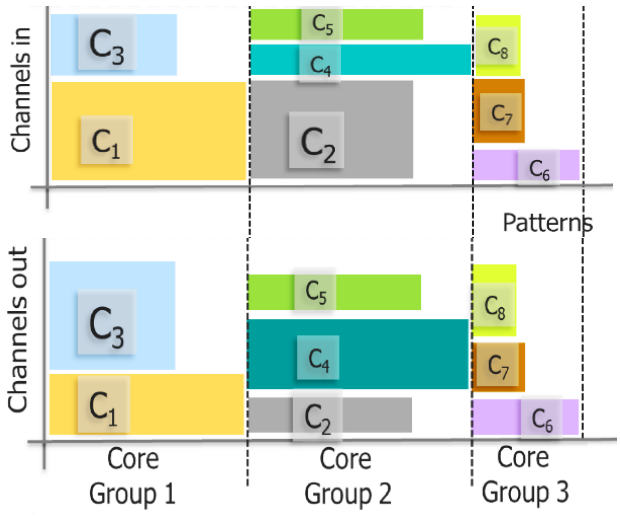

Fig. 11. Scheduling using static bandwidth management [53].

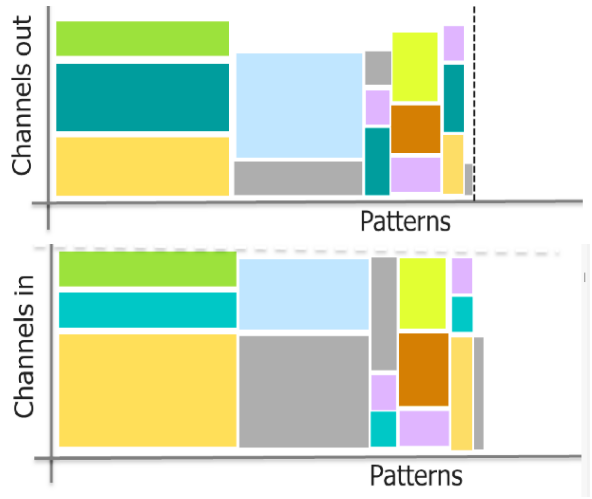

Fig. 12. Scheduling using dynamic bandwidth management [53].

Yu Huang et al. [53] evaluated the effectiveness of both approaches—static versus dynamic—and further examined how channel sharing influences each strategy's bandwidth utilization and overall test throughput.

Each core is represented as a pair of rectangles. The rectangle's width corresponds to the number of test patterns that the core requires, while its height represents the number of input or output channels it consumes. Scheduling the tests becomes a two-dimensional bin-packing problem. These rectangular pairs must be arranged within the fixed "SoC bin" to minimize the total pattern count. Fig. 11 and Fig. 12 illustrate schedules generated by static and dynamic bandwidth management, clearly demonstrating that the dynamic approach reduces the overall pattern volume by allowing each core's patterns to be distributed across multiple configurations.

For the evaluation, the author selected an industrial SoC containing 13 cores and 30 scan-in and 30 scan-out channels. Test coverage and pattern volume were measured under four configurations: static bandwidth management with and without channel sharing, and dynamic bandwidth management with and without channel sharing. The results show that channel sharing, coupled with broadcasting, sharply reduces the pattern count by approximately 1.86 times under static scheduling (a decrease from 173 to 93 patterns) and by an even larger factor of 2 under dynamic scheduling (from 123 to 62 patterns). Dynamic bandwidth management itself proves advantageous. Relative to static scheduling, it reduces the pattern total by approximately 1.4 times when channel sharing is absent and by roughly 1.5 times when sharing is enabled. The most significant savings are achieved when channel sharing, broadcasting, and dynamic compaction are combined, making this strategy the most effective for reducing test patterns while maintaining coverage.

F. TAM Optimization Using Pattern Suite

Janicki et al. [54] described a Test Access Mechanism that takes advantage of specific properties of Embedded Deterministic Test (EDT). Their approach combines test data reduction methods with a scheduling strategy and introduces new TAM structures for both the stimulus and response paths.

Experiments show that test cubes contain very little specified data. This is observed even when they are produced by advanced dynamic-compaction techniques that target multiple faults over several clock compressions. Initially, the fill rate is typically only 1% to 5%, and after the first few vectors, it often falls well below 1%. This sparseness makes modern test-data compression methods highly effective. However, with a static assignment of decompressor input channels, most of that capacity remains idle after the early patterns are applied, resulting in a significant drop in encoding efficiency. Keeping a fixed number of inputs, therefore, injects thousands of useless bits. In practice, far fewer ATE channels are needed to keep every vector encodable. By adjusting the number of active decompressor inputs to match the declining fill rate, the ATE bandwidth can be used far more efficiently.

Flexible, demand-driven channel allocation can significantly boost both compression and encoding efficiency. By distributing ATE channels to each core only when—and only in the quantity—its fill rate requires, multiple cores can be exercised in parallel, reducing overall test time. Staggering the operation of individual decompressors into well-chosen time slots further lowers the number of external channels needed, often far below the aggregate total of all cores' EDT inputs.

1) Test Scheduler: The authors' proposed scheduling flow begins once ATPG has generated test cubes for every targeted fault and merged them into complete patterns. Each pattern is then fed to an encoding solver that drives the on-chip decompressor with the minimum possible number of EDT input channels. After encoding, the patterns undergo fault simulation to identify which faults propagate to which outputs of the compaction logic and to locate any unknown (X) states that slip past X-masking. Using these simulation results, the algorithm pinpoints the smallest set of output channels that can still indicate every detected fault, even in the presence of X states. It then pairs, for every pattern, the fewest required input channels with this minimal set of observation outputs, creating a concise "signature" of channel needs. Patterns that share identical input-output signatures are clustered into classes, simplifying subsequent scheduling. Finally, these classes are

handed to the test scheduler, which, taking into account the TAM architecture, the available ATE pin budget, power limits, and other system-level constraints, assigns specific input and output channels to the relevant cores for pattern application.

After clustering, the scheduler assigns the external tester's channels. Input and output channels are handled independently because a cluster's demand for stimulus pins can differ from its need for response pins. For each cluster, the algorithm maps the required number of ATE inputs to the cores' decompressor ports and the outputs to the chosen observation sites, while always respecting the global pin budget and any other SoC-level constraints. The test vectors are applied to selected cores in phases. Other cores are frozen during such a pattern application phase using clock gating or chain blocking at the decompressor methods [55].

Only a small fraction of patterns need every output pin to catch faults. As testing progresses and the fault count per pattern declines, later vectors can be observed through far fewer outputs. Fig. 13 illustrates this effect for ten cores in an industrial SoC: each bar shows what share of patterns for that module succeed with just one, two, three, four, or five output channels.

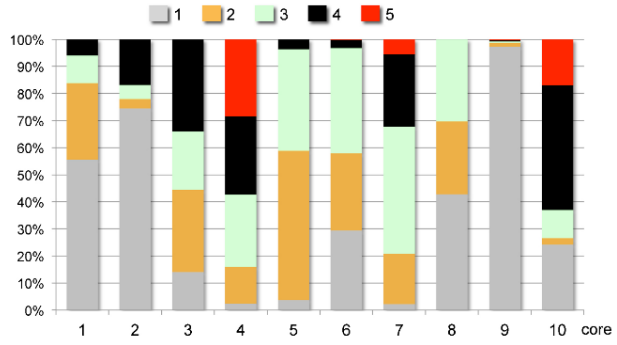

Fig. 13. Percentage of patterns with different numbers of output channels [54].

Being able to adjust the observation width is essential for conserving bandwidth on the output side. The scheduler chooses which pins to monitor by examining how faults display on each output, how they mask one another, and how unknown (X) states propagate. For each pattern group, it selects the smallest set of observation sites that still reveals every targeted fault, allowing the remaining channels to be reassigned to where they are most useful. Fig. 14 shows the test schedule derived using this method.

2) TAM design: Once the test schedule is finalized, the flow drives the TAM hardware design. The input network is constructed from n demultiplexers—one for each fixed ATE input channel—and the output network comprises m multiplexers, corresponding to the number of ATE output channels. Each demux (or mux) connects its channel to a single core input (or output). An address register loaded with every compressed test vector tells the switch which core to serve. Because this control data is small, it is sent uncompressed alongside the test data. The compressed outputs of the cores are connected to the output switching network [56].

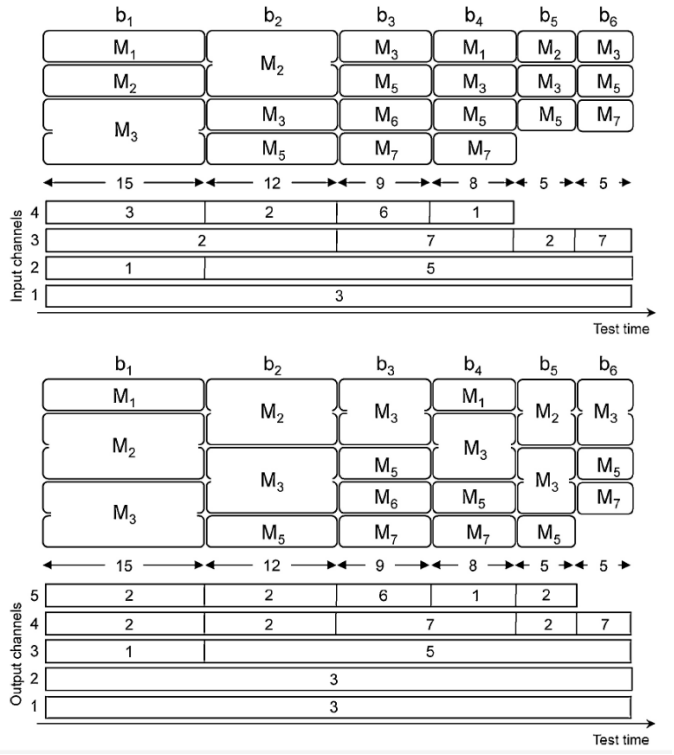

Fig. 14. Base clusters and test scheduling [54].

A demultiplexer must fan out to at least as many cores as it supports, though it may feed multiple EDT inputs of the same core. Conversely, several demultiplexers (i.e., multiple ATE channels) can converge on a single EDT input, with OR gates at the core boundary enabling this shared connection.

Wiring is synthesized from the scheduler's assignments using a simple greedy rule: identify the ATE channel that appears most frequently, hard-wire it to EDT input 1 everywhere it is needed, and then repeat for the next most frequent channel and the following available EDT input. This is continued until every required channel is routed. This strategy minimizes the total wiring and keeps the OR-gate fan-in low.

In earlier work [33], the author examined a comparable strategy and reported the results. For each design and allocation method, it lists the minimum number of ATE channels—and the corresponding reduction factor—required to maintain test application time virtually unchanged. The data show that the number of EDT inputs can be reduced by up to a factor of five without lengthening the schedule. Pushing bandwidth even lower introduces a useful trade-off. Although fewer input channels gradually extend the run time, this is offset by compression gains of up to 5×. Accordingly, effective EDT compression for the two designs, D1 and D2, increases from 78× and 393× to 392× and 1,770×, respectively.

G. Test-pattern Independent TAM

The method described in Section IV F is tightly coupled to the final test patterns. With it, an optimal TAM layout cannot be designed until ATPG is complete. That reliance can delay the design timeline, postponing the physical layout until late in the flow. To avoid this bottleneck, paper [54] also introduces a

generic, nearly optimal TAM architecture that is independent of both the test schedule and pattern set, enabling designers to finalize the TAM early and generate schedules later without revisiting those hardware decisions.

Unlike the earlier pattern-dependent approach, the input test-access network is fixed here early in the design flow, before any ATPG work begins. Because a core's lower-order EDT inputs are used most frequently, the architecture connects those pins to multiple ATE channels, providing the scheduler with additional routing flexibility.

This regular, pre-wired network is suitable for SoCs whose cores are fully isolated. Non-isolated blocks that must be tested together may run into conflicts. For example, two two-input cores cannot be driven in parallel if their shared ATE channels would need to feed both cores at once.

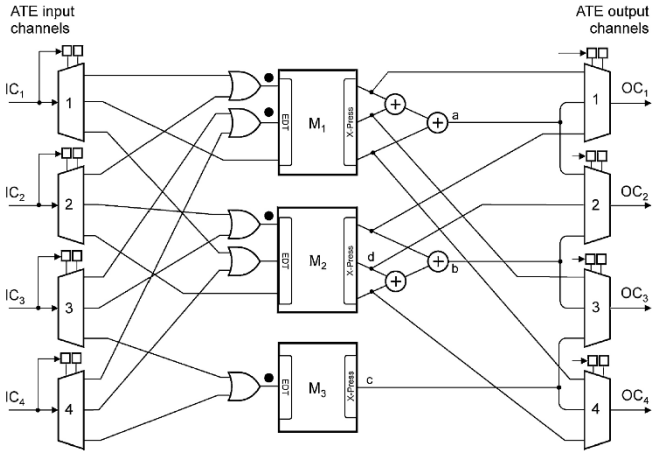

Fig. 15. TAM design [54].

The scheme is far simpler than the sophisticated crossbars used in parallel processors or packet switches. It delivers test-data streams of varying width, so individual EDT inputs within a core may see uneven traffic. The same principles apply on the output side (see Fig. 15). An output switch aggregates each core's compressed responses into a limited set of ATE output channels. The scheme uses the Hopcroft-Karp algorithm for channel allocation.

The study presented results for 5 SOCs (D1, D2,… D5) that showed the number of EDT inputs can be reduced by as much as 8 to 1, while still delivering the full pattern set within the original schedule. Pushing the interface bandwidth even lower introduces a trade-off. Test time rises gradually as channels are removed, but this is offset by sizable compression gains (up to 6×). Accordingly, effective EDT compression climbs from 64× and 61× to 328× and 391× for designs D1 and D2, respectively.

For SoCs whose cores are fully isolated, input- and output-channel counts can be reduced by a factor of four without extending the test. For designs D3, D4, and D5, the scheme increased effective compression from 65×, 78×, and 50× to 323×, 364×, and 320×, respectively.

The authors also presented a similar scheme in [57] for test-pattern-independent scheduling. It showed that compression ranging from 156× to 320× could be achieved using it.

H. Using High Frequency for Test Channels

Mangilal et al. presented an architecture [58] that leverages a high-speed Peripheral Component Interconnect Express (PCIe) bus for structural testing. This high-speed data transfer enables high throughput, resulting in shorter test times. The system allows structural testing directly on the platform, eliminating the need for expensive test equipment. Leveraging the PCIe bus also ensures portability across platforms, supporting both system-level and in-field testing. Thus, the platform enables quick detection of structural faults.

The authors tested the system on SoCs containing multiple chiplets. At the chiplet level, connections are established using the PCIe functional stack. This configuration supports both wafer and die testing. In multi-die packages, data transfers to other chiplets via a functional interface. A Network-On-Chip Controller manages chiplet interconnections.

Soomro et al. also presented an architecture [59] that uses high-speed IO to design a test access mechanism (TAM) for 3D-based SOC.

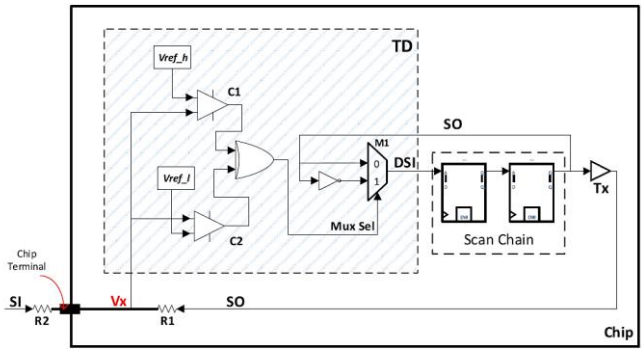

Fig. 16. Test channel with ternary encoding and decoding [59].

Typically, a chip terminal is used at a given time to either send or receive data from a chip. The author presented a method that uses the chip terminal to simultaneously send and receive data. It uses ternary encoding bidirectional signaling. Simultaneous bidirectional signaling is used with full-duplex mode on the chip pins. A single electrical path instead of two could be used with this system, doubling the test channel count and increasing data transfer speed. The system internally uses two virtual unidirectional IOs. The send and receive data are encoded into ternary at the chip boundary, and the information is converted back to binary using a decoder. Fig. 16 shows the design of such a channel. Two resistors of equal value are connected in series. This connection creates a voltage divider that encodes binary values into ternary levels, representing whether both terminals are low, high, or opposite. Using the system, experiments were performed on 4 chips, and the study reports an improvement of up to 53.6%.

I. Test Schedule for Low-Power Designs

In [60], the authors presented a test scheduler for a multi-core, multi-voltage system of chips. It considers power constraints while scheduling the test. Multiple voltages are used in low-power design circuits. A voltage-dependent defect becomes active when a specific voltage is applied. In particular, when a large number of cores operate with many voltage levels, test scheduling becomes quite complex. These settings and

complexity lead to a large test data volume and increase overall test cost. The authors proposed a test scheduling method that uses a Time-Division Multiplexing-based schedule to increase parallelism. The scheduler includes a Graphical User Interface that provides easier control over parameters such as voltage levels, core selection, and power constraints. Test engineers and researchers could use the system to define a test schedule for multi-voltage SOCs.

V. Discussion

The benefits of various approaches, along with the main challenges in test access mechanisms design and test scheduling methodologies, are discussed in this section. It also discusses a direction for future work.

- TAM with improved EDT injectors: This technique improves the encoding efficiency of EDT, thereby improving its performance further. It preserves all the benefits of EDT with no negative impact on design, test, and manufacturing costs.
- TAM with On-Chip Compare: The TAM presented here adds hardware to perform scan output data on chip. This scheme is efficient, especially for chips containing multiple instances of cores. It also provides various modes which are useful at different stages of the product life cycle, and could be useful to collect failure data and yield learning.
- TAM with Efficient Pattern Generation at Higher-Level: This technique proposes a hybrid test methodology and revisits the benefits of generating patterns for groups of blocks/cores. Having its own compression logic for smaller blocks offers advantages, such as reducing routing overhead and the number of power-isolation cells and/or level shifters when the blocks operate across multiple power domains.
- Channel Sharing and Broadcasting: This method uses the same channels for multiple cores. Such a simpler mechanism could improve compression by 2× for medium-sized SOC.
- Dynamic Bandwidth Management with Channel Sharing: Results presented using this method showed that channel sharing, along with broadcasting, must be used wherever possible. Further dynamic bandwidth management is better than static bandwidth management. Combining channel sharing/ broadcasting with dynamic bandwidth management yields the best results.
- TAM Optimization Using Pattern Suite: This scheme allocates channels dynamically using a test scheduling algorithm and configurable TAM. Channels are allocated to cores based on clusters created for their pattern suite. The scheme uses a best-fit strategy for channel assignment, yielding a remarkably smaller test data volume.
- Test-pattern Independent TAM: This is a generic scheme that could be used to find a test schedule even when no pattern data is available. It uses a new solver, test-scheduling algorithms, and TAM design schemes to dynamically allocate channels.
- Using High Frequency for Test Channels: These techniques use high-speed pins for transporting test data. Low-speed operation could be allowed for the logic inside the chip. Having a high transfer rate externally effectively increases overall throughput. Additionally, this technique uses system pins (e.g., PCIe), which are already present on the chip and would otherwise remain unused and wasted if only General Purpose Input/Output (GPIO) (which are slow) were used for test data transport.
- Test Schedule for Low-Power Designs: With the growing demand for low-power chips and their use for low-cost applications, the cost of testing them has become a challenge. Using multiple voltages increases test data volume due to testing requirements across voltage combinations. The technique presented provides optimal test scheduling across various voltage and core combinations, saving time for the SOC test engineer developing such a test schedule using tedious methods.

VI. Conclusion

The electronics industry's aggressively shrinking chip features and its move toward three-dimensional integrated circuits have had a dramatic impact on SoC design and test procedures. A diverse mix of digital, analog, mixed-signal, memory, optical, microelectromechanical, and radio-frequency cores continues to pose challenges for effective testing. ATE channel bandwidth management for SoC designs plays a key role in increasing test data compression, reducing test time, and thereby reducing test cost. This study presented a survey of methods for allocating channels to cores. A few of these techniques have been implemented by commercial tool developers, making them easier to integrate into the flow. However, the unique advantages of the other techniques are not available in commercial tools. A framework is required to effectively use a combination of techniques, such as TAM with Efficient Pattern Generation at a higher level, along with On-Chip Compare. In addition, shrinking geometries, lower power-consumption specifications, and growing SOC sizes will require testing devices with newer fault models, and that too, with increased frequency specifications. These requirements call for further exploration of TAM design and scheduling techniques.

This study discussed approaches for designing TAMs and test scheduling algorithms, and their efficiency in reducing test time. Designing TAM for both types of flows—hierarchical and module design — is discussed. It also presented various EDT features that could be used to design an efficient TAM for SOC. Further, it summarized the advantages and challenges of each approach. Finally, this study summarizes the challenges and future research directions.

Dept. Industrial Engineering, Iowa State University, Ames, USA[2]

***Abstract*—Imagine a future where a security operator can understand a complex threat in fractions of a second without specialized training. Not only that, but the operator can instantly understand the logic behind a particular AI warning. This vision of AI-augmented cognition is the focus of the proposed SUNDUS framework. However, today, this promise faces a critical barrier: the user. The immense potential of AI is often rendered useless when its operator lacks the professional training necessary to interpret and implement its outputs in the real world. This context reveals a critical research gap: while collaborative human-AI systems significantly enhance performance, their efficacy remains fundamentally dependent on extensive operator training, as evidenced by the OMAR (Operator Machine Augmentation Resource) system. The current paper proposes the SUNDUS (System for Understanding, Navigating, and Decision-Making Under Uncertainty and Support) framework, a theoretical model designed through a Human-Computer Interaction (HCI) lens to enhance human-AI collaboration by making system design a substitute for formal training. Leveraging principles from AMID (Augmented Multisensory Interface Design) and Visual Representations of Meta-Information, SUNDUS employs enhanced transparency—via Natural Language Explanations (NLEs), confidence scores, and multisensory cues—to offload cognitive burden and increase intuitive understanding. We propose a comparative experimental methodology to validate SUNDUS against OMAR, hypothesizing that SUNDUS will yield significantly higher decision-making accuracy and appropriately calibrated trust alongside a lower cognitive load in untrained users. The key implication is a scalable, human-centric design blueprint that shifts the burden of adaptation from the operator to the AI system, unlocking the full potential of augmented cognition.**

***Keywords*—SUNDUS; human-AI collaboration; Human-Computer Interaction (HCI); transparency; multisensory display; cognitive load; decision-making; trust; training; OMAR**

I. Introduction

A. Background and the Broad Aim

The development of artificial intelligence is rapidly evolving from a focus on full automation to a more nuanced approach centered on human-AI collaboration [1]. A notable feature of this trend is the growing recognition of AI as a source of effective augmentation of human operator capabilities [2]. It has previously been viewed as a mere tool for humans or a substitute for them. AI systems outperform humans in their ability to process massive amounts of data, identify patterns, and perform repetitive tasks with a speed and efficiency beyond human capabilities [3]. This superiority has created a significant opportunity for human operators to focus on higher-level tasks such as those requiring moral reasoning, wisdom, and contextual understanding—intelligence traits unique to humans and superior to AI. The synergy between human operators and AI allows them to leverage the strengths and uniqueness of both.

The OMAR system, designed to support the operator in their task, is a clear example of this collaborative approach [3]. The goal was not to replace one party, but rather to improve the performance of the human CCTV operator in crowd tracking tasks by utilizing AI capabilities in several aspects, including the following:

1) Training: The study's results on the Operator Machine Augmentation Resource (OMAR) system clearly indicate the importance of comprehensive operator training as a key element for success [3]. Through synergistic work, AI capabilities are leveraged to increase efficiency and speed. However, the OMAR study found that AI tends to increase errors in untrained groups, highlighting the essential role of human expertise gained through training. Training increases operator proficiency in validating, interpreting, and utilizing AI outputs, while also reducing potential errors and enhancing trust as the OMAR system [3] has shown.

2) Decision-making tools: AI is a key component of the OMAR system's operating team. It employs a computer vision model that helps detect and report anomalous behavior during human crowd movements. Instead of an operator constantly scanning crowd flows for hours on end, the OMAR system initially alerts to potentially anomalous behavior. The operator examines these alerts and analyzes their behavior to make appropriate decisions, as shown in Fig. 1.

3) Reducing cognitive load: Human operators are subject to significant cognitive load while performing their duties, scanning scenes on surveillance screens. Artificial intelligence (AI) acts as a powerful assistant, relieving the operator (especially trained ones) of this mental effort by detecting persistent and anomalous patterns, as illustrated in Fig. 2. This feature allows the human operator to remain more alert and focused, especially when detecting situations requiring human skill. Ultimately, shared monitoring responsibilities improve the efficiency and accuracy of operations and enhance trust.

Therefore, the OMAR framework provides strong empirical evidence that human-AI teamwork outperforms either humans

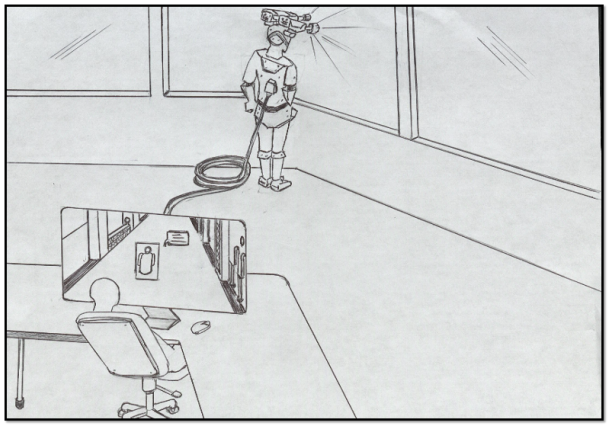

Fig. 1. OMAR system illustration, showing abnormal behavior detected and a short message displayed to the operator.

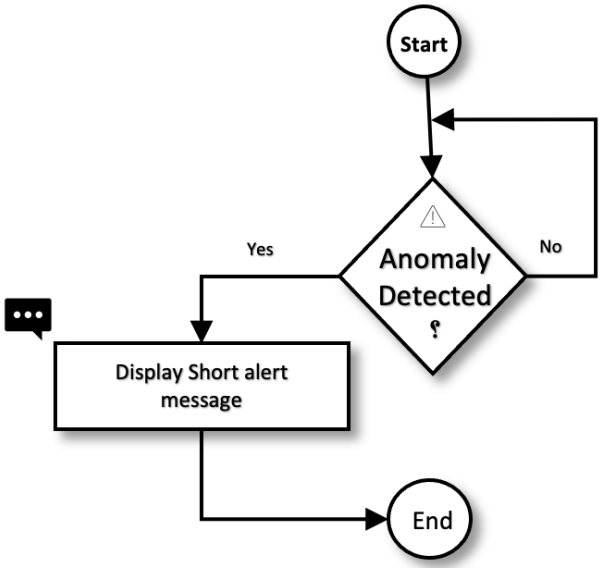

Fig. 2. Information flows from the OMAR system to the operator, helping to reduce cognitive load.

or AI alone. This superiority can be further enhanced if training is carefully combined with technological support.

B. The Research Gap

The rapid increase in artificial intelligence (AI) use in various fields, particularly high-sensitivity ones such as safety, has revealed a new paradigm of human-AI collaboration. The proliferation of this paradigm has exposed a critical research gap. While AI systems are designed to enhance the capabilities of human operators, human operators often lack the specialized training necessary to utilize the technology effectively[4]. The OMAR system provides a leading example of this gap, demonstrating conclusively that operator performance is significantly higher with comprehensive training. In reality, in many contexts, most people do not receive this type of specialized, in-depth training to work with AI systems for various reasons, such as time constraints, costs, technological acceleration, and more. This gap results in significant missed opportunities, as operators cannot fully leverage AI's capabilities without a solid and sound foundation of expertise, which often comes from training. This problem has been observed in the OMAR system. While the system's alerts are technically valid, they are in fact vague and can increase confusion for human operators (especially untrained ones). When combined with the difficulty of verifying their justification, the alerts are often ignored, which can lead to unforeseen risks. Despite OMAR's significant role in reducing mental effort and assisting in decision-making, this role remains limited and insufficiently autonomous. If it continues in this limited form, this could lead to a breakdown in trust and a decline in integration between the operator and artificial intelligence. Ultimately, the system's effectiveness remains fundamentally dependent on operator training, which raises the question of whether a different design approach could mitigate these issues. These gaps lead us to the central question of this research: Can system design replace formal operator training through transparency and multisensory information? This paper's key novelty and central hypothesis directly address this by proposing the SUNDUS framework, which demonstrates that intelligent system design can effectively substitute the cognitive benefits typically acquired only through intensive operator training.

It is critical to note that this work serves as a theoretical framework and research proposal, outlining a novel conceptual design and the testable hypotheses derived from it. As such, this paper does not present empirical data; instead, the traditional results section is replaced by a detailed Future Work section outlining the proposed comparative experiment necessary for validating the SUNDUS framework. The remainder of this paper is organized as follows: Section II establishes the contextual background, detailing the limitations of the OMAR system and reviewing the theoretical foundations (AMID and Meta-Information) that underpin this design. Section III presents the full SUNDUS framework, detailing its components and features. Section IV provides a comprehensive discussion of the framework's theoretical promise and practical implications. Finally, Section V outlines the conclusions and the specific experiment planned for future validation.

II. Contextual Background and Related Work

A. Human Information Processing and Memory

1) Perception and attention: Perception and attention are among the first steps in human information processing. In the OMAR system, an operator's awareness depends on their ability to see the "Anomaly Detected" message on the screen. Once the operator recognizes the message, they focus on some of its details and characteristics, which means paying attention to those details in preparation for an appropriate decision. Focusing and attention require a significant amount of mental effort. Without adequate training, the operator may struggle, in particular, to interpret the content of the anomalous behaviors detected by the system. The situation becomes even more acute if the operator suffers visual fatigue or distraction. The OMAR system supports the operator's ability to monitor the screen and understand the system's alert, accompanied by a brief text message indicating an anomaly.

In contrast, the proposed SUNDUS system is designed to address the limitations of human perception and help directly

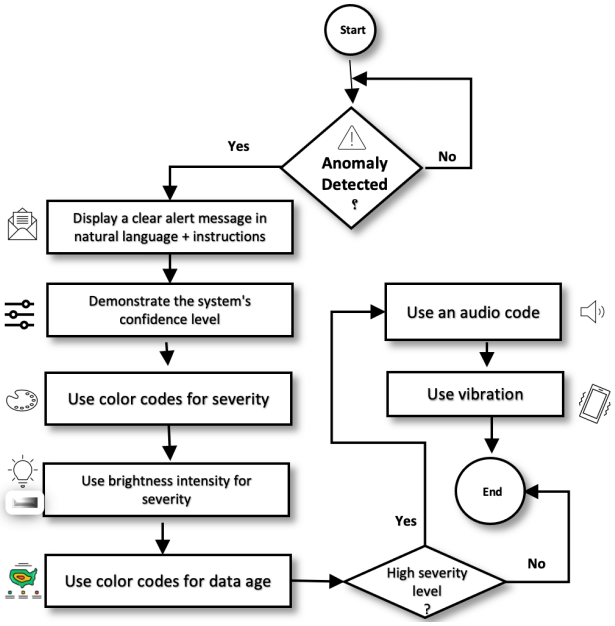

Fig. 3. Multisensory information flows from the SUNDUS system to the operator.

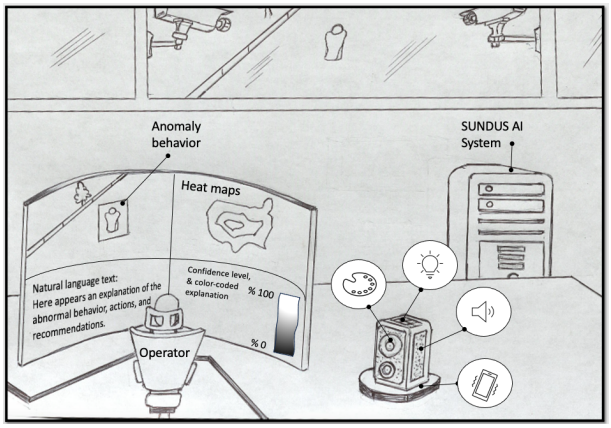

Fig. 4. A conceptual view of the SUNDUS system and its most prominent features.

increase attention. It utilizes multiple sensory channels to communicate event data, particularly through underutilized channels such as auditory and tactile, as the AMID principles indicate [5]. Audio channels can be used with distinct tones to indicate specific descriptive states to enhance alerting to high-priority events. Similarly, vibration can draw the operator's attention to critical events even when other channels (visual, auditory) are busy or overloaded. By leveraging multiple sensory capabilities, the SUNDUS system will likely overcome the bottleneck of using a single sensory channel. Additionally, the SUNDUS system utilizes visual representations of meta-information, employing colors and shapes to convey important details at a glance. As in [6], this shift can be achieved through a flashing color gradient bar indicating severity, or highly saturated heat maps.

Furthermore, incorporating visual representations of meta-information into SUNDUS can support decision-making, particularly in time-sensitive or high-risk environments. Some examples of this application in SUNDUS could be adding a flashing color gradient bar or highly saturated heat maps (see Fig. 3 and Fig. 4). These elements can help draw the operator's attention to the most relevant information about the event and its context, while assisting in assessing finer details such as severity, certainty, or age of the information through color saturation. Implementing these features is expected to reduce the need to search for anomaly details and speed up the response process, in addition to saving the mental effort required to integrate multiple pieces of information to obtain a clear picture and make a decision.

2) Working memory and cognitive load: Working memory is like a temporary repository that an operator must access to gather fragments of information about anomalies for analysis and understanding in preparation for a response. One challenge that can occur is when this repository (working memory) becomes full; operator performance declines sharply. The OMAR system is designed to flag anomalies on the monitor screen and display a brief message indicating that an anomaly has been identified. The operator then examines the details of the anomaly by revisiting working memory, assessing the event, and making the appropriate decision. This process undoubtedly requires significant mental effort, especially given the continuous flow of images and the potential for additional detection, which increases the chance of errors that could lead to risks or a decline in overall performance. An operator's lack of specialized training increases the chance of problems and errors.

On the contrary, the SUNDUS system is designed to reduce the load on the operator's working memory. The operator does not need to use working memory to try to remember and gather details about anomalous behaviors. Instead, the system provides an immediate visual summary. For example, meta-information qualifiers (e.g., uncertainty, age, source reliability) may be presented directly on the screen. This design means the system performs complex cognitive tasks, allowing the operator to focus on more important tasks such as decision-making.

3) Long-term memory and the role of training: To help operators remember important details necessary for their job performance, such as regulations, processes, recommended procedures, and others, they must be stored in long-term memory and reinforced over time. Considering how the OMAR system works, we find that a mental model is created in primary long-term memory and then reinforced with training. Therefore, the OMAR paper suggests that training is essential for effective synergy between human and AI teams.

On the other hand, the SUNDUS model proposed in the current framework paper seeks to be more intelligent by providing an external mental model based on its unique design. While OMAR relies on training to accumulate what the operator needs to remember in long-term memory, SUNDUS displays this information using color codes to directly represent deep, detailed data without requiring the mental effort of retrieving it from long-term memory, or even extensive prior training. Imagine representing the severity of an abnormal behavior with a color-graded bar, or the system's confidence in certain information with different levels of accuracy, alongside

clear messages in natural language with recommended actions. With this design, SUNDUS will likely support long-term memory performance by saving the effort and time required to store and retrieve data. Furthermore, by providing assessments and recommendations in natural language, the system will improve the overall team performance by saving effort and time and supporting decision-making, ultimately enhancing trust between the operator and the system.

In short, the SUNDUS system design is unique because it does not require prior human cognitive capabilities to be built into the operator through in-depth training, as is the case with the OMAR system. Instead, it aims to achieve high team performance even without extensive training.

4) Training as an enhancement method: Training is one of the fundamental methods for enhancing human capabilities and improving the quality of human-AI interaction. The importance of training is emphasized with complex systems, where the role of training goes beyond simply transferring knowledge to the human operator. Typically, training hones the operator's cognitive skills and develops their capabilities, overcoming weaknesses and developing strengths. Training is also an effective means of helping form mental models of the system's work. The operator can gain a clearer picture of the AI system by delving into its operational logic, system design, objectives, and inherent limitations through training. In addition, training can play a fundamental role in how humans receive and critically evaluate information and then act on the results. All of the previous contribute to reducing errors and problems, improving performance, and transforming the operator from a passive observer to an active partner in the synergistic process.

The OMAR framework provides empirical evidence that confirms the power of training as an improvement tool, as the results confirm the relationship between operator performance and training. The study demonstrated that operator capabilities in the OMAR system improve with training. The research showed that participants who received specialized training significantly and consistently outperformed their untrained counterparts. This result was demonstrated by a significant reduction in errors and their ability to detect them, along with a significant increase in identification accuracy. On the other hand, researchers observed that the use of AI caused an increase in errors in the untrained groups, in contrast to the groups that received training.

Furthermore, training allowed operators to leverage better AI capabilities, including the system's speed and efficiency in identifying anomalies. The main finding of the research confirms that training is beneficial for improving human performance and crucial for enabling effective synergy between humans and artificial intelligence. It also contributes significantly to reducing errors. Thus, the OMAR system clearly demonstrates the role of training in enhancing human operator capabilities by providing them with the cognitive tools necessary to work with artificial intelligence, which promotes high performance levels and harmonizes human and machine capabilities.

5) The need for a new approach: Although training is important to enhance operator capabilities, as demonstrated by the OMAR system, this approach is not always feasible or available. In many cases, especially in the real world,

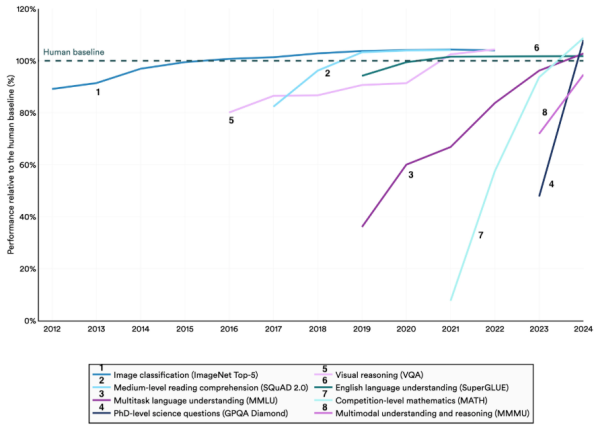

Fig. 5. The continuous evolution of AI performance compared to human capabilities encourages its applications. Reproduced from [2].

most people do not receive the in-depth training necessary to operate AI systems effectively for various reasons. Reasons may include financial costs, the sheer number of potential users, and time pressures, especially in a rapidly evolving technological environment, which leads to a significant gap between the advanced capabilities of AI and the user's ability to leverage them. This previous fact leads us to the central question of this research: How can we enable the operator to fully leverage the capabilities of an AI system with minimal, or even no, in-depth training? This means exploring a new mechanism or approach to designing human-like AIs, specifically those systems that enable effective collaboration with the operator—not through extensive human training—but through their inherent characteristics. Therefore, we propose that the solution lies in an AI system designed to be a transparent and intuitive partner that supports a practical and comprehensive partnership even without prior operator training. Such design can be achieved by leveraging principles of human perception. The proposed new approach is likely to help shift the burden of adaptation from the operator to the system, helping to make the full benefits of AI available to a much wider audience.

B. The OMAR System and the Training Paradox

1) Theoretical foundation: Rapid development of AI systems has created a new paradigm in human-computer interaction, driven by collaborative work and integration resulting from capitalizing on the strengths and uniqueness of both humans and AI, which is considered a means of enhancing the capabilities of the human operator, as shown in Fig. 5. However, the human operator may suffer fatigue due to their limited capabilities compared to the massive amounts of data AI can process and generate. This problem is exacerbated by the lack of or inadequate training to operate these systems. The work in this research is based on two main theoretical frameworks that form the basis for designing AI systems that more effectively enhance human capabilities while addressing fundamental gaps, especially in the absence or insufficient provision of intensive training.

In Fig. 6 and Fig. 7, the growing interest in AI is demonstrated in many fields through regulations and businesses. In 2024, US federal agencies issued nearly 60 regulations related

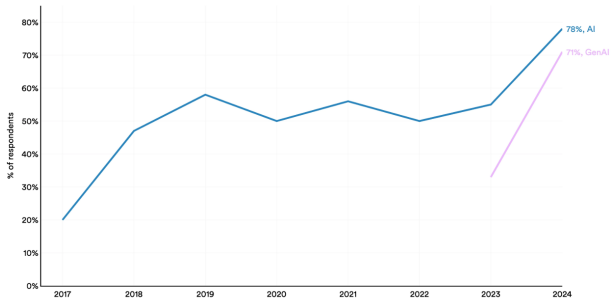

Fig. 6. Respondents who confirmed the use of AI in their organizations, 2017–2024. Adapted from [2].

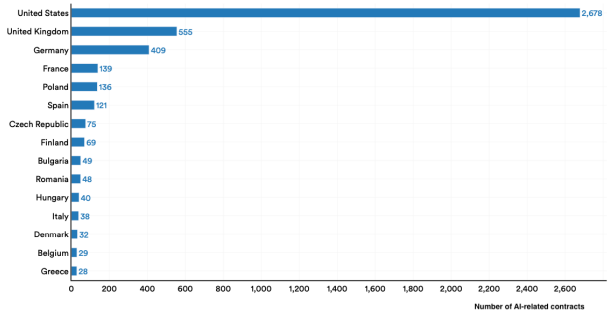

Fig. 7. Growth in the number of AI-related contracts in selected countries, 2013–2023. Adapted from [2].

to artificial intelligence, which is more than double compared to 2023. Globally, there was rapid growth in several countries by 21.3% in AI-related investments between 2016 and recent years [1]. Canada, India, and France pledged investments of 2.4, 1.25 billion, and €109 billion, respectively. Meanwhile, Saudi Arabia announced a $100 billion initiative as part of its 2023 vision.

2) The deep learning black box: The accelerating pace of human-artificial intelligence synergies is attributable to deep learning (DL) architectures, particularly Convolutional Neural Networks (CNNs) and vision transformers in monitoring systems. These technologies are characterized by their high capacity to provide unparalleled speed and accuracy in pattern recognition (as in the components of the OMAR computer vision system). Both DLs and CNNs inherently function as algorithmic black boxes [7]. The ambiguity arises from the vast number of non-linear transformations within the complex network used in the decision-making process. These systems not only create a lack of transparency or pose a technical challenge but also present a real problem for untrained human operators and raise ethical concerns that may affect human trust in them, especially in high-risk domains, leading to inappropriate reliance [8], [9], [10]. The problem is conceivable if the operator cannot understand why the system is issuing an alert or does not clarify the degree of trust in the information provided by the system.

3) Existing human-AI interaction models: Several effective models have been developed to gain a deeper understanding of human-AI interaction, on the one hand, and in response to the need for a comprehensive framework to explore and improve this type of collaboration, on the other [11]. However, despite

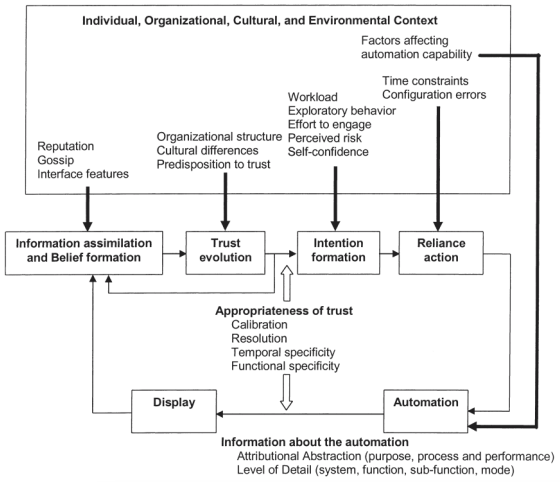

Fig. 8. A conceptual model illustrating the elements of trust and their impact on dependence in organizations. Adapted from [10].

their importance, many do not fully address the challenges when an operator lacks specialized and sufficient training to handle AI systems.

One prominent school of thought focuses on trust in automation [10]. This model assumes that a human operator's willingness to rely on AI depends on three factors: the system's perceived reliability (its capability, safety, and goodwill), the operator's innate propensity to trust, and situational factors as shown in Fig. 8. Despite its significant influence, this model often implicitly assumes that the operator has sufficient knowledge and skills—usually acquired through training—to calibrate their trust in the system properly. It is certain that without a basic understanding of AI and the optimal way to handle it, an untrained operator may exhibit risky behavior, ranging from over-reliance on the system to complete abandonment due to confusion or lack of trust. Both over- and under-reliance on AI can lead to suboptimal outcomes. In this context, the trust model clearly describes how trust is formed. However, it does not provide a mechanism for establishing appropriate trust when human knowledge base or practical skills are lacking.

4) XAI and multisensory solutions: The efforts to solve the black-box problem of deep learning have led to the emergence of the field of Explainable Artificial Intelligence (XAI), which aims to provide human-comprehensible explanations for the decisions made by AI systems [12], [13]. To achieve these solutions, various techniques are employed, such as feature importance maps (similar to prominence or heat maps) or counterfactual explanations [14]. While studies in XAI have often focused on visual interpretations, recent work aligns with the principles of the AMID framework by exploring multisensory media to represent complex deep learning outputs [15], [16]. The importance of this shift is underscored by the understanding that overloading the visual channel with data visualizations can quickly lead to increased cognitive load and diminish the benefits of transparency [17], [18]. Therefore, current trends [19] involve designing systems that leverage a combination of visual prominence tools and underutilized sensory channels (haptic and auditory) to convey the confidence

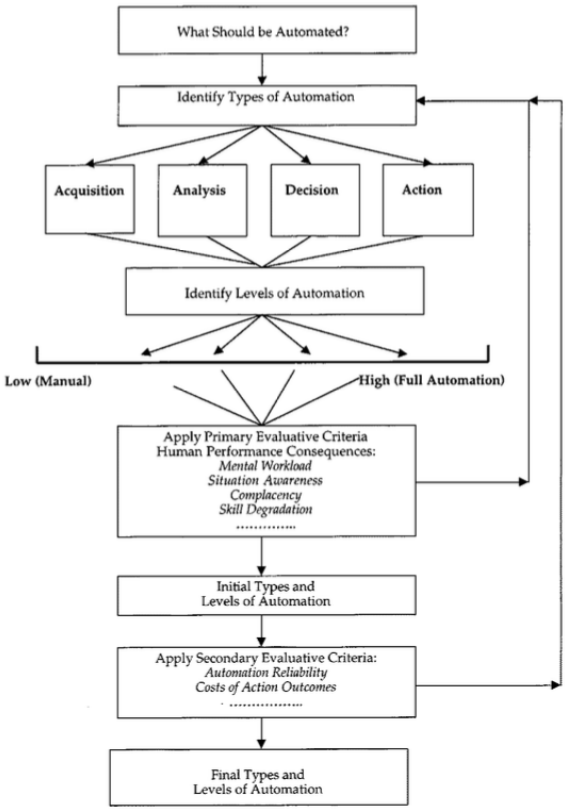

Fig. 9. Application of the automation types and levels model. Adapted form [20].

and rationale of AI effectively.

Other models focus on the levels of automation when dealing with AI systems, establishing a categorization ranging from complete human control to complete AI autonomy [20]. While this approach effectively classifies different system designs, it lacks the flexibility to adapt to changing contexts. It is a model that can be likened to the rungs of a ladder, as the operator's work environment may require dynamics depending on the context. For example, different tasks may require varying levels of automation for the same operator, and automation may need to be calibrated based on the operator's cognitive abilities, especially when considering the availability and lack of training (see Fig. 9). These contexts can make it challenging to know when to intervene or when to let the AI take over. The previous challenge confirms that an operator not equipped with the necessary skills and knowledge lacks an acquired mental model that enables them to calibrate appropriately based on the AI's capabilities and limitations. Furthermore, lacking training may mean being unprepared to make critical decisions in real time.

In study [21], the IICCM framework is introduced, a comprehensive system to support operator tasks in enhancing safety. IICCM integrates artificial intelligence, computer vision, and the Internet of Things to manage large crowds. The IICCM framework supports a leading suite of services, including early emergency detection using GANs and ViT networks; real-time evacuation route recommendations via mobile applications and local positioning systems (GPS); and

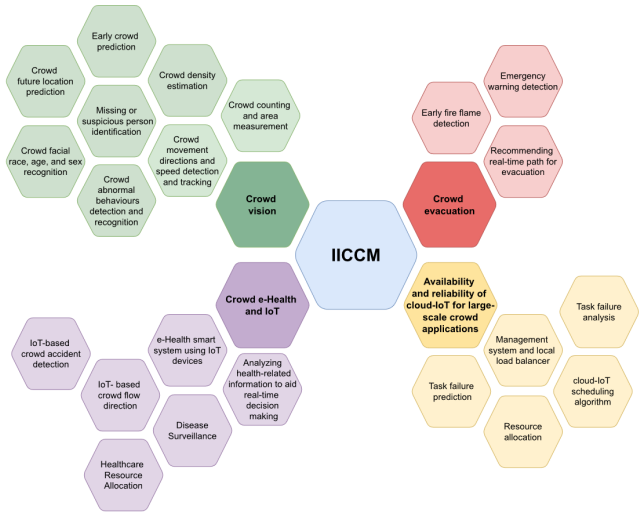

Fig. 10. Components and services of the proposed Intelligent Integrated Crowd Control and Management (IICCM) framework. Adapted from [21].

the integration of behavioral models to guide safe evacuation (see Fig. 10). However, IICCM does not eliminate the need for in-depth operator training to perform their tasks effectively.

Recent research highlights a shift toward exploring frameworks that capture modern operator-AI collaboration's complexity. One example is "shared cognitive systems," which views the operator and AI as a single entity capable of performing cognitive lab work [22]. This approach focuses on designing a "cognitive work environment" that supports reducing the cognitive load and fatigue experienced by the human operator. Additionally, recent frameworks have highlighted the importance of placing the human at the center of attention from the outset, while maintaining the transparency and interpretability essential to the human partner's needs. Another study by the AI Partnership [4] developed a comprehensive framework that addresses 36 questions to help design collaborative work by analyzing and understanding the nuances of various forms of collaboration between operators and AI. The analysis helps understand the factors influencing collaborative work contexts, such as the specific task and operator expertise. Human-centered AI (HCAI) has recently been formalized to focus on human needs, values, and capabilities when designing AI systems [1]. Upon reflection, all of these frameworks, including SUNDUS, address the limitations of traditional models by calling for AI systems that enhance, rather than replace, human capabilities, and for future systems to be transparent, reduce cognitive load, and ethically aligned with human values. However, they differ in their focus, level of abstraction, and practical application. While the framework of "Human-Centered Artificial Intelligence" (HCAI) a cognitive systems serve as philosophical schools of thought that justify the need for a framework like SUNDUS, they justify the underlying reasons behind their philosophy. SUNDUS provides the "how" by translating these philosophies into a reality with a testable blueprint with specific properties. These theoretical frameworks provide a strong foundation for the research addressed in this paper.

Ultimately, the limitations of modern basic models and the

opportunities they reveal a significant gap. There is an urgent need for a framework that provides a practical and executable blueprint for designing an AI system capable of acting as a transparent and intuitive partner, effectively augmenting human capabilities in situations where formal operator training is limited or absent. This is the gap that the SUNDUS framework aims to fill.

C. Foundational Theories (AMID, Meta-Information)

SUNDUS has two solid foundations. The first is the Augmented Multisensory Interface Design (AMID) framework [5]. The AMID framework states that effective augmentation is not limited to adding more visual information to a screen. Instead, it includes designing a system that strategically utilizes all available human sensory channels—visual, auditory, and tactile—to communicate information and reduce cognitive load. One of the core principles of AMID is to enhance an underutilized sensory channel for information distribution, freeing up a primary, often overloaded, channel (such as vision). This principle may strongly and directly support the goal of this study, which is to improve human performance without training. Multisensory design can provide intuitive, non-visual cues that an operator can understand and act upon immediately without prior instruction or training.

Second, the research on visual representations of meta-information, as [6] investigated. Based on this work, the effectiveness of a visual representation depends on its ability to communicate data parameters (meta-information) such as uncertainty, data age (freshness), and source quality. Notably, the research found that the perceived importance of information is the most important factor in how humans interpret visual cues such as color, saturation, and transparency. These findings support the possibility of designing AI systems capable of communicating complex and profound concepts, such as "the reliability of an AI data source" and "the freshness and age of the data," by manipulating visual attributes. Therefore, these features can be leveraged to produce a transparent, intuitive system that allows an untrained operator to deeply understand the reliability of the alerts displayed by the system on the screen simply by looking at them.

III. The SUNDUS Framework: A Human-Centric Model

The SUNDUS (System for Understanding, Navigating, and Decision-Making Under Uncertainty and Support) framework is a conceptual model designed to bridge the gap between human operators and advanced AI capabilities, especially when human operators lack specialized training. While the OMAR system requires training as a critical factor for improved performance, SUNDUS's principle fundamentally differs: Its unique contribution is the demonstration of how rich, transparent system design can directly replace the need for an operator's specialized, trained-in mental model, thereby allowing SUNDUS to outperform OMAR through intuitive strategic operation.

1) Core principles: The basic principle of the SUNDUS system is the strategic presentation of information necessary to achieve system transparency and to utilize multiple senses within the operator. The primary goal is to reduce the cognitive load by transferring functions to the system, transforming the burden of ambiguous system alerts into intuitive, information-rich interactions. SUNDUS achieves this goal by transferring cognitive functions—such as interpreting system confidence, prioritizing alerts, and recalling procedural knowledge—to the system, which can be directly displayed through a human-centric interface. Fig. 11 illustrates this core principle. These cognitive functions were previously only acquired through in-depth training.

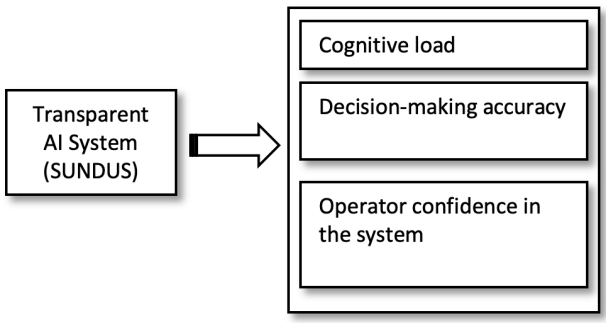

Fig. 11. Basic principle of the SUNDUS system.

2) Framework components and features: To build a system that can collaborate with a human operator in a synergistic environment without the need for extensive training, as envisioned in the SUNDUS framework, several new features must be provided that support conditions that eliminate the need for costly training, such as enhanced transparency, cognitive offloading, and improved performance [23],[24]. These features include:

3) Color-coded salience: The first feature of the SUNDUS system is the use of colors to indicate the severity level of an alert. For example, red can indicate a high-priority threat, while yellow can indicate a lower priority.

4) Representing trust with saturation or brightness level: It leverages humans' mental association to link color intensity to confidence levels. Therefore, the SUNDUS system uses high color saturation or brightness to indicate the AI's confidence level in an alert [25]. For example, high red saturation (or brightness) indicates high confidence, while low brightness or saturation indicates low confidence. This feature allows an operator to intuitively assess the reliability of an alert, even without prior training.

5) Color-graded bars and heatmaps: SUNDUS can provide a color-graded bar on the video feed to indicate the depth of information. This visual representation can help determine where the AI focuses, which areas are changing, or which locations have the highest confidence, giving the operator a comprehensive visual understanding of the situation. Similarly, a visual heatmap overlay can be used.

6) Multisensory cues: To enhance operator attention without overwhelming the visual channel (the most frequently used), the SUNDUS framework integrates multisensory cues. This approach builds directly on the central principle of the AMID paper, which is to utilize underutilized sensory modalities to improve performance. One scenario this paper outlines is using meaningful audio cues to differentiate between routine

and critical situations. A low-pitched ambient tone could signal a normal alert, while a high-pitched, sharp tone could signal a critical threat requiring immediate action. The goal of this strategy is to relieve the load on the visual channel, enabling the operator to respond even if this channel is occupied by something else.

7) Haptic alerts: Critical alerts of utmost importance require a more effective method for communicating alert data. Therefore, the SUNDUS system employs a haptic signal (such as a vibration on a terminal or wearable device) [25]. As demonstrated in the AMID method, this strategy is effective, as haptics are ideal for alerts and are associated with manual reaction speed. This association makes them a highly effective channel, especially since they are often underutilized for conveying urgent information.

8) Context-aware interpretation and clear guidance: One of the most important features of the SUNDUS system, which plays a significant and direct role in compensating for the lack of training, is its ability to provide context-aware guidance. This feature transforms the system from a passive alert tool to an effective collaborator through the following methods:

a) Natural Language Explanations (NLEs): While the alert is important in the Omar system, it is vague and does not explain the alerts. SUNDUS addresses this issue by supporting the operator with a concise natural language explanation (NLE) for reporting a particular incident. For example, instead of displaying a short message stating "Anomaly detected," the system could provide more detail, such as: "Alert: Anomaly detected. There is a sudden gathering of more than 10 individuals in a restricted area. This event does not conform to typical crowd flow patterns." An explanation like this provides a rationale typically learned through operator training. A message like this and its clear explanation enhance immediate understanding of the situation.

b) Actionable recommendations for the operator: SUNDUS will provide "suggestions on how the operator is recommended to act in specific situations." These recommendations, which can be as quick and straightforward as "Recommendation: Contact a security officer for verification," can provide the operator with a clear and immediate course of action. This feature supports the operator's decision-making process by providing a procedural framework that compensates for a lack of formal training or acquired experience.

IV. Discussion: Rationale and Implications

The specific features of the SUNDUS framework are deliberately designed to create a new paradigm in human-AI collaboration. This section discusses the rationale for the framework's effectiveness and its alignment with the core research objectives.

1) Rationale for effectiveness - a new paradigm for human-AI collaboration: The SUNDUS framework presents a new paradigm for human-AI collaboration, as its design directly challenges the assumption supported by the OMAR study: that human operator performance must be optimized primarily through training. Our novelty lies in proposing an alternative, scalable path to high performance through systematic design optimization. The proposed features of SUNDUS are not mere enhancements; rather, they are thoughtfully designed options based on scientific foundations aimed at enhancing human cognition in ways previously only achieved through extensive training. SUNDUS challenges an existing assumption and provides a practical implication for designers and organizations. Furthermore, it will also significantly improve decision-making, reduce cognitive load, and enhance human factors in the collaborative environment between operators and AI."

2) SUNDUS challenges an existing assumption: The SUNDUS framework challenges a prevalent assumption, supported by the OMAR study, that human operator performance must be optimized primarily through training to achieve effective human-AI collaboration. However, SUNDUS proposes a different approach to achieve the same result through system optimization (through intuitive and transparent design). This alternative path to this prevalent assumption is likely more scalable. Shifting the burden of adaptation from the user to the technology has significant implications for how AI tools are designed and deployed, especially in environments where extensive training is unavailable.

3) Practical implications for designers and organizations: Given the SUNDUS model, those working in AI technology design can derive more efficient designs. For example, the SUNDUS approach calls for moving beyond simple, single-sensory user interfaces to information-rich, multisensory designs that support more efficient communication and interaction with the user. For organizations, the SUNDUS model offers opportunities to reduce the costs and time associated with specialized training, enabling faster and more widespread adoption of complex AI systems.

4) Enhanced decision-making: By providing context-sensitive guidance and natural-language explanations, SUNDUS provides an untrained operator with the rationale to make informed decisions. SUNDUS alerts are based on evidence-based arguments (such as visual attributes and confidence scores), enabling an untrained operator to make an accurate and confident decision like a trained operator. The lack of a pre-existing mental model is a defining characteristic of SUNDUS's decision-making process, going beyond automating simple tasks and facilitating true collaboration by making AI logic transparent and actionable.

5) Reduced cognitive load: According to the principles of the AMID framework, underutilized sensory channels (such as auditory and tactile cues) are utilized. Applying this principle to the SUNDUS system reduces the burden of continuous visual monitoring by freeing up the operator's cognitive resources. When the system triggers a critical anomaly alert, the operator's attention is immediately drawn to the system's multisensory alerts, helping to prevent the cognitive overload and fatigue common in sustained monitoring tasks. Furthermore, the system performs the intensive anomaly detection task, allowing the operator to focus their limited cognitive capacity on the more important task of making a final judgment and taking appropriate action.

6) Enhanced "human factors" aspects: Fundamental human factors are influenced by the SUNDUS framework's focus on transparency and intuitive design. For example, using visual attributes, such as color, saturation, and transparency, to convey trust and importance (according to Pesantz et al.'s paper)

supports understanding system outputs. Similarly, adopting an intuitive communication style using simple, elegant language is a solid foundation for building appropriate trust with AI. The trust built here is not blind, as it is calibrated and based on the system's verifiable explanations. Empowering the operator with a system that is easy to understand enhances trust and increases satisfaction, transforming AI from a fearsome black box into a collaborative and trustworthy partner.

7) Increasing transparency: Transparency is a key factor influencing trust, and a fundamental principle of the SUNDUS framework. Transparency in SUNDUS is achieved by replacing a simple alert (a standardized short message) with an informative explanation written in natural operator language and clearly and intuitively presenting the necessary information. This design makes the logic of the SUNDUS AI system completely transparent. Because transparency is a distinct and inherent addition compared to the OMAR system, it will be tested as a key independent variable to determine its correlation and impact on trust and system efficiency.

8) Enhancing overall performance: As with any system, the features and design principles of the SUNDUS framework combine to improve the overall performance of the human-AI team. This goal is achieved by focusing on transparency and intuitive design and ensuring the team can be empowered to improve its performance even with limited or no training. Fulfilling this promise will significantly contribute to the field of human-AI interaction.

9) Between a potential limitation and a counterargument: Despite the promising features of the SUNDUS framework, it may unintentionally lead to misalignment of trust. Could a sound system like SUNDUS lead operators to become complacent and unquestioningly trust the system's "practical recommendations"? SUNDUS can mitigate this risk because its core principle is transparency. Furthermore, its recommendations have a solid logical basis (e.g., natural language interpretations and reliance on established procedural processes). Thus, the system enables operators to understand, analyze, and then make a critical and informed final judgment, rather than mindlessly obey.

V. Conclusion and Future Work

The SUNDUS framework is a conceptual blueprint for a new approach to human-AI collaboration, grounded in the fundamental idea that intuitive system design can serve as a substitute for a lack of formal operator training. While OMAR demonstrated that training is essential, this work argues that the burden of adaptation can be shifted to the system. To help bridge this gap, we strategically leverage two papers on the AMID and principles and the "Visual Representations of Meta-Information" to present the SUNDUS framework, which offers a human-centric solution. The proposed framework aims to achieve similar performance and confidence levels without extensive training. It proposes a system that effectively enhances human perception and understanding through multisensory cues and transparent, informative visual features. In the SUNDUS framework, unintelligible alerts are replaced with a comprehensive, context-sensitive guidance system, reducing cognitive load, improving decision-making, and enhancing and calibrating confidence appropriately. Ultimately, the SUNDUS framework is designed to shift the burden of adaptation from the user to the system, thereby expanding access to advanced AI, increasingly useful in high-risk environments.

A. Future Work

As a conceptual model, confirming the effectiveness of the proposed SUNDUS framework for enhancing performance in a human-AI collaboration environment requires rigorous experimental validation. Therefore, a critical next step is to conduct a practical experiment to test the hypotheses outlined in this paper. This experiment will compare SUNDUS (a transparent state of AI with rich features) and OMAR (a black box).

Furthermore, future research directions could build on this foundational work in several ways, including advanced multisensory exploration: exploring the specific effects of different multisensory cues (e.g., different auditory tones, distinct tactile patterns) on trust and performance could add valuable insights to improve the current framework. Longitudinal studies are also needed to explore how trust in SUNDUS evolves. Such a longitudinal study could determine whether the initial intuitive trust generated by the system is sustainable or whether operators will revert to traditional training. We also recommend conducting studies to customize the current proposed system. Research into adapting the system could potentially explore the flexibility of the SUNDUS framework by allowing operators to specify their preferences for increased transparency, choose the type of multisensory alerts, or even adjust the level of detail provided in explanations using language that matches their needs and business context. Such studies can uncover the link between personal augmentation and human-AI collaboration.

Leveraging Large Language Models in the Software Development Lifecycle: Opportunities and Challenges

Jasdeep Singh Bhalla[1], Mansimar Kaur Jodhka[2]
GoDaddy Inc., United States[1]
University of Southern California, United States[2]

***Abstract*—Large Language Models (LLMs) are increasingly integrated into software engineering workflows, yet existing studies provide fragmented or domain-specific examinations of their impact. This survey aims to systematically analyze how LLMs influence the Software Development Lifecycle (SDLC) end-to-end, identifying capabilities, limitations, risks, and emerging opportunities. We review 147 publications from 2017–2025 across ACM Digital Library, IEEE Xplore, ACL Anthology, and arXiv using predefined inclusion and exclusion criteria. Unlike prior surveys that focus narrowly on code generation or testing, this work provides an SDLC-wide synthesis supported by empirical benchmarks, industrial evidence, and a unified taxonomy mapping LLM capabilities to each phase of development. We further examine technical risks including hallucinations, dataset governance, robustness, security vulnerabilities, and auditability. The goal of this survey is to consolidate fragmented knowledge, highlight practical adoption challenges, and outline future research directions essential for building trustworthy, scalable, and effective LLM-enabled software engineering systems.**

***Keywords*—Large Language Models (LLMs); Software Development Lifecycle (SDLC); AI-assisted software engineering; automated code generation; software testing; software architecture; DevOps automation**

I. Introduction

Large Language Models (LLMs) such as GPT-4, Llama-3, and DeepSeek-Coder have introduced unprecedented automation and reasoning capabilities into software engineering. Developers now use LLMs for code generation, test creation, debugging assistance, documentation, architectural exploration, and deployment planning. As the industry rapidly integrates these tools into real-world systems, understanding their capabilities, limitations, and implications across the entire Software Development Lifecycle (SDLC) has become increasingly critical.

Despite the pace of adoption, existing literature remains fragmented. Some surveys focus primarily on code generation, others on testing, documentation, or developer productivity, leaving the full SDLC picture incomplete. Furthermore, few studies provide a unifying taxonomy or systematically compare LLM capabilities across multiple SDLC phases using empirical benchmarks. Industry reports highlight impressive productivity gains, yet academic literature also documents challenges such as hallucinations, security vulnerabilities, and difficulties integrating LLMs into large codebases or long-context reasoning tasks. This creates a clear need for a comprehensive survey that consolidates insights across domains, evaluates supporting evidence, and critically analyzes risks.

A. Research Gap and Motivation

Current surveys exhibit three key limitations:

1) Fragmented coverage: Existing reviews examine isolated aspects of the SDLC—such as code generation or requirements—but no survey systematically maps LLM capabilities across all SDLC phases.

2) Lack of unified taxonomy: Prior work rarely provides a structured framework that connects LLM tasks, techniques, risks, and empirical results to specific SDLC processes.

3) Insufficient evaluation perspective: Many surveys describe applications without synthesizing evidence from benchmark datasets, industrial deployments, or comparative performance analyses.

Given these gaps, a holistic and methodologically grounded SDLC-wide review is needed—one that not only describes what LLMs can do, but critically evaluates how well they perform, what risks they introduce, and where future work is necessary.

A detailed comparison of this survey with prior work is presented in Table III, highlighting gaps in SDLC coverage, taxonomy completeness, and empirical rigor.

B. Paper Scope and Organization

This survey consolidates insights from 147 peer-reviewed and high-impact sources published between 2017 and 2025. The paper is organized as follows:

- Section II presents background concepts and related work.
- Section III introduces the survey methodology, inclusion/exclusion criteria, and search strategy.
- Section IV proposes a unified taxonomy of LLM capabilities across SDLC phases.
- Section V analyzes LLM applications in requirements engineering, design, implementation, testing, deployment, and maintenance.
- Section VI examines risks and limitations including hallucinations, robustness, dataset governance, and security vulnerabilities.

- Section VII outlines future research opportunities and open challenges.
- Section VIII concludes with a synthesis of findings and implications.

This structured approach ensures clarity, enables reproducibility, and provides a coherent understanding of LLMs' role in modern software engineering.

C. Contributions

This work provides a comprehensive and SDLC-wide examination of Large Language Model (LLM) applications in software engineering. Unlike prior surveys that focus primarily on code generation, testing, or developer productivity, this survey offers a unified and methodologically rigorous perspective across all phases of the Software Development Lifecycle (SDLC). The major contributions of this paper are as follows:

1) An SDLC-wide unified taxonomy: We propose the first consolidated taxonomy that maps LLM capabilities, tasks, risks, and limitations across all major SDLC phases: requirements engineering, architecture and design, implementation, testing, deployment, maintenance, and security.

2) A Systematic review of 147 publications (2017–2025): We conduct a structured survey across ACM DL, IEEE Xplore, ACL Anthology, and arXiv using predefined search keywords, inclusion/exclusion criteria, and quality filters. Our methodology promotes reproducibility and grounded analysis.

3) Comparative synthesis across models and benchmarks: We evaluate and synthesize empirical performance results of popular LLMs (GPT-4, Llama-3, CodeLlama, DeepSeek-Coder, StarCoder) across widely used software engineering benchmarks including HumanEval, MBPP, SWE-Bench, BigCodeBench, and CodeXGLUE.

4) Analysis of practical adoption challenges: We identify real-world integration issues including hallucinations, misalignment, long-context reasoning limitations, dataset governance, licensing and IP concerns, and architectural inconsistency challenges.

5) A Risk and governance framework: We examine security threats (prompt injection, dependency confusion), robustness issues, model drift, cost-performance trade-offs, and data governance constraints relevant to enterprise adoption.

6) A Research roadmap for future work: Based on existing gaps, we propose future research directions including neuro-symbolic hybrids, agentic LLMs for end-to-end SDLC automation, safe-by-design AI coding tools, verified LLMs, long-context architectures, and multi-model ensemble reasoning.

II. Background and Related Work

Integration of Large Language Models (LLMs) in software engineering has garnered significant attention in recent years [20], with several studies and tools exploring their potential to enhance various phases of the Software Development Life Cycle (SDLC).

One notable example is OpenAI's Codex [14], which demonstrated impressive capabilities in translating natural language into source code. Codex helps developers write boilerplate code, suggest code improvements, and generate code snippets, providing significant time-saving benefits. Additionally, GitHub Copilot [5], powered by Codex, has become a popular tool integrated into development environments, offering auto-completion, real-time suggestions, and code snippets across a wide range of programming languages.

Recent studies have explored the potential of Large Language Models (LLMs) in software development, particularly in academic settings. While general-purpose LLMs are not primarily designed for code generation, they have shown promising results in assisting with software engineering tasks. One such study involved 214 students working in teams, where LLMs were integrated into their development toolchain. This study analyzed AI-generated code, the prompts used for code generation, and the human intervention needed to integrate the code into the existing codebase. Additionally, a perception study was conducted to understand the usefulness and challenges of LLMs from the students' perspective. Findings suggest that LLMs are particularly beneficial in the early stages of software development, aiding in the generation of foundational code structures, syntax correction, and error debugging. The study emphasizes the importance of preparing students for effective human-AI collaboration, offering valuable insights into how LLMs can enhance the productivity of software engineering students [16].

Jiang et al. (2024) present a comprehensive survey on Large Language Models (LLMs) for code generation, a rapidly growing field with significant implications for software development. It addresses the gap in the literature regarding a systematic review of LLMs specifically for code generation. It introduces a taxonomy to categorize and analyze advancements in this domain, covering data curation, model performance, ethical concerns, environmental impact, and real-world applications. The authors provide a historical overview and empirical comparisons using benchmarks like HumanEval, MBPP, and BigCodeBench, evaluating LLM performance across varying difficulty levels and task types. The study also identifies challenges and opportunities in bridging academic research with practical software development needs [9].

In the context of software testing, LLMs have shown considerable potential for automating key aspects such as test case creation and defect detection, leveraging machine learning and natural language processing. A comparative study by Boukhlif et al. (2024) examines various LLMs used in software testing, focusing on how they interact with, fine-tuning methods, and prompt engineering. The study provides valuable insights into the technologies and testing types that can be automated with LLMs, helping researchers and industry professionals select the most effective models for their testing needs. This research adds to the growing understanding of how LLMs can enhance the software testing process, offering guidance on their application in real-world scenarios [1].

Krishna et al. (2024) explore the potential of Large Language Models (LLMs) in the creation of Software Requirements Specifications (SRS), a key document in software development. Their study evaluates the ability of GPT-4 and CodeLlama to generate coherent, structured, and accurate drafts of an SRS for a university club management system. The results indicate that LLMs can match the output quality of an entry-level software engineer, producing complete and consistent drafts. Additionally, GPT-4 demonstrated the capa-

bility to identify issues and suggest improvements in existing SRS documents, while CodeLlama's performance in validation tasks was less effective. Their experiments also revealed that LLMs could significantly reduce the time required to draft SRS documents, ultimately enhancing productivity in software development [11].

III. Methodology

This section outlines the systematic methodology adopted for conducting this survey. Following established guidelines for evidence-based software engineering reviews, we designed a multi-stage process covering search strategy, screening, quality assessment, and data extraction to ensure reproducibility and rigor.

A. Search Strategy

We queried four major digital libraries between 2017–2025:

- ACM Digital Library
- IEEE Xplore
- ACL Anthology
- arXiv.org

Search strings combined LLM-related and software-engineering-related terms:

("large language model" OR LLM OR GPT OR Codex OR "code generation" OR "AI agents")

AND

("software engineering" OR SDLC OR requirements OR testing OR debugging OR deployment OR DevOps)

B. Inclusion and Exclusion Criteria

We included studies that met the following criteria:

- Inclusion Criteria
  - Published 2017–2025
  - Focused on LLM applications relevant to SDLC
  - Peer-reviewed or widely cited preprints (¿ 50 citations)
  - Provided empirical, conceptual, or methodological insights
- Exclusion Criteria
  - Non-English publications
  - Blog posts, opinion essays, or editorials
  - Papers without evaluation, case studies, or technical content

C. Screening Process

A three-stage filtering process was applied:

- Initial Retrieval: 1,182 papers identified.
- Title/Abstract Screening: 384 papers shortlisted.
- Full-Text Review: 147 papers selected.

A summary of the three-stage filtering and inclusion results is provided in Table I.

TABLE I. Screening Summary

Stage	Count
Initial Papers Retrieved	1182
After Title/Abstract Screening	384
Full-Text Assessed	221
Included in Final Review	147

D. Data Extraction and Coding

For each paper, we extracted:

- SDLC phase addressed
- Task type (requirements, code gen, testing, DevOps, etc.)
- Dataset or benchmark used
- Model type (GPT-4, Llama-3, Codex, etc.)
- Risks, limitations, or open challenges identified

Two researchers independently coded papers and resolved disagreements through discussion.

E. Quality Assessment

We evaluated studies using:

- Clarity of methodology
- Empirical rigor
- Relevance to SDLC
- Replicability of findings

Only papers scoring greater than or equal to 3/5 in quality assessment were included.

F. Research Questions

This review is guided by the following research questions (RQs):

- RQ1: What capabilities do Large Language Models (LLMs) demonstrate across different phases of the Software Development Lifecycle (SDLC)?
- RQ2: How do state-of-the-art LLMs perform on empirical benchmarks relevant to software engineering tasks?
- RQ3: What risks, limitations, and practical challenges arise when integrating LLMs into software engineering workflows?
- RQ4: What open research gaps and future opportunities exist for advancing LLM-enabled software engineering?

IV. Unified SDLC Taxonomy for LLM Applications

To provide a structured lens for analyzing LLM applications across the Software Development Lifecycle (SDLC), we introduce a unified taxonomy synthesizing tasks, capabilities, risks, and evidence from 147 publications. This taxonomy organizes LLM contributions into seven interconnected SDLC phases: Requirements, Design, Implementation, Testing, Deployment, Maintenance, and Security.

A. Taxonomy Overview

Our taxonomy consists of four dimensions:

- SDLC Phase: Requirements, Architecture, Implementation, Testing, Deployment, Maintenance, Security.
- LLM Capability Type: Generation, Summarization, Reasoning, Classification, Retrieval-Augmentation, Dialogue.
- Task Category: Tasks such as SRS drafting, UML generation, code generation, bug fixing, test generation, IaC synthesis, threat analysis, and log summarization.
- Risk Profile: Hallucination, brittleness, bias, security risk, data governance, IP leakage, misalignment.

The hierarchical organization of these relations is illustrated in Fig. 1, which presents the unified SDLC taxonomy used throughout this survey.

B. Taxonomy Contributions

This taxonomy enables:

- A consistent mapping from LLM capability to SDLC activity
- Cross-phase comparison of LLM maturity levels
- Identification of gaps in research and industry adoption
- Systematic evaluation of risks associated with LLM usage

C. Taxonomy Structure

Table IV (already included later) operationalizes this taxonomy by mapping tasks to phases and benchmarks.

1) Advantages over existing methods: Unlike prior surveys that examine LLMs within isolated tasks such as code generation or testing, our approach provides an SDLC-wide analytical framework that unifies capabilities, risks, empirical evidence, and cross-phase interactions. Existing reviews do not integrate benchmark performance, industrial case studies, and security considerations into a single taxonomy. Our methodology therefore offers broader coverage, deeper comparative analysis, and a more actionable foundation for both researchers and practitioners. This holistic structure enables clearer identification of gaps, limitations, and opportunities that are not visible when examining SDLC phases independently.

Table II summarizes empirical performance of representative LLMs across common software engineering benchmarks.

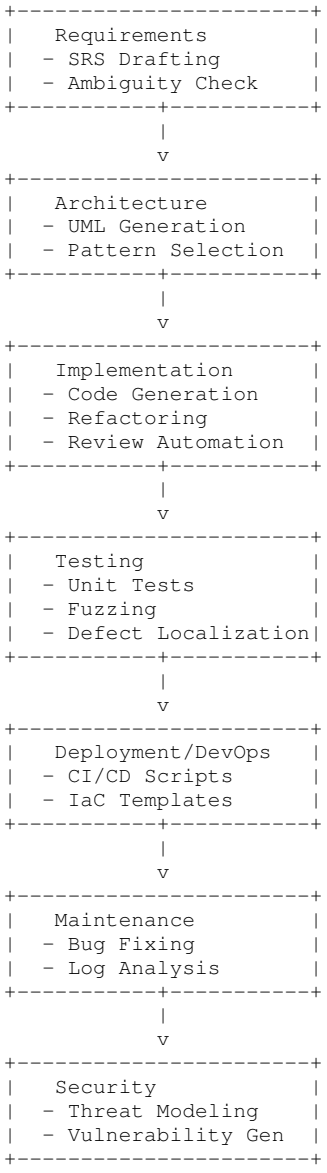

Fig. 1. Unified SDLC taxonomy for LLM-Driven software engineering.

TABLE II. Performance of Popular LLMs on SE Benchmarks

Model	HumanEval	MBPP	SWE-Bench
GPT-4	67.0%	82.0%	38.1%
Llama-3-70B	62.2%	79.4%	21.7%
CodeLlama-34B	48.8%	53.4%	9.0%
StarCoder2-15B	36.0%	48.0%	5.2%
DeepSeek-Coder-33B	57.0%	71.0%	18.0%

V. Applications in the Software Development Lifecycle (SDLC)

This section explores the transformative role of Large Language Models (LLMs) in various stages of the SDLC, highlighting their impact on code generation, system architecture, requirements gathering, and beyond. It delves into the foundational architectures that power LLMs, such as GPT (Generative Pre-trained Transformer) series, BERT (Bidirectional Encoder Representations from Transformers), CodeBERT, RoBERTa,

TABLE III. COMPARISON OF OUR SURVEY WITH EXISTING SURVEYS ON LLMS IN SOFTWARE ENGINEERING

Survey	Focus Area	Covers Full SDLC?	Empirical Benchmarks	Taxonomy Provided?	Risk Analysis
Hou et al. (2024) [6]	General SE tasks	No	Limited qualitative results	Partial	Limited
Jiang et al. (2024) [9]	Code generation	No (Implementation only)	HumanEval, MBPP	Yes (Code-gen taxonomy)	Minimal
Boukhlif et al. (2024) [1]	Software testing	No (Testing only)	LLM-based testing examples	Yes (Testing taxonomy)	No
Rasnayaka et al. (2024) [16]	Student dev workflows	No	Real classroom data	No	No
Jahić and Sami (2024) [8]	Software architecture	No (Architecture only)	Anecdotal	No	No
This Survey (2025)	**Entire SDLC (Requirements → Security)**	**Yes**	**HumanEval, MBPP, SWE-Bench, BigCodeBench, CodeXGLUE**	**Yes (Unified SDLC taxonomy)**	**Yes (Security, governance, compliance)**

TABLE IV. MAPPING OF LLM CAPABILITIES ACROSS SDLC PHASES

SDLC Phase	LLM Capabilities	Representative Evidence / Benchmarks	Maturity Level
Requirements	SRS drafting, ambiguity detection, requirement classification, user-story expansion	GPT-4 outperforming baselines (Krishna et al. 2024)	Moderate
Architecture & Design	UML generation, architecture suggestions, pattern selection, tradeoff reasoning	ICSA-C 2024 studies, industrial case reports	Low–Moderate
Implementation	Code generation, auto-completion, refactoring, code translation	HumanEval, SWE-Bench, MBPP, BigCodeBench	High
Testing	Unit test generation, fuzzing, test oracles, defect localization	ChatUniTest (FSE 2024), ICST 2024 results	Moderate–High
Deployment	CI/CD generation, IaC templates, environment config synthesis	Srivatsa et al. 2024, DevOps case studies	Low–Moderate
Maintenance	Bug localization, patch generation, log summarization, regression analysis	SWE-Bench Leaderboard	Moderate
Security	Threat modeling, vulnerability summary, prompt-injection detection	EuroS&PW 2024, industrial LLM security frameworks	Low

and other models relevant to enhancing software development practices.

A. Requirements Gathering and Planning

LLMs significantly enhance early-stage software development tasks such as requirements elicitation and project planning. By processing natural language inputs from user stories, feature requests, and other documentation, LLMs can help teams extract key information and ensure clarity in project scope and requirements [15]. Additionally, LLMs analyze historical project data to create optimized project timelines, resource estimates, and risk assessments, improving the accuracy and efficiency of planning phases.

B. Cost Estimation

LLMs assist in cost management by analyzing cloud usage patterns and resource utilization data. They offer insights into optimizing cloud expenses, proposing budgeting strategies, and suggesting effective ways to manage resources like reserved instance planning and resource tagging, all of which contribute to more cost-effective cloud deployments.

C. Architecture and Design

LLMs are increasingly valuable in system architecture and design. They support the design process by offering architectural suggestions based on system requirements and constraints, assisting in identifying suitable patterns and components. LLMs also facilitate the generation of architectural documentation and design specifications, helping teams visualize and iterate on system design.

1) High-level system design: LLMs can assist in architectural design by providing insights, recommendations, and solutions for designing software systems. By analyzing natural language descriptions of system requirements, constraints, and objectives, LLMs can help identify suitable architectural patterns, components, and design decisions. Additionally, LLMs can facilitate the exploration of alternative architectural designs and the evaluation of their trade-offs, enabling architects to make informed decisions based on a holistic understanding of system requirements and design goals [8].

2) Low-level system design: LLMs can be used to enhance low-level system design by automating code generation that adheres to clean code principles and Object-Oriented Programming (OOP) practices. They can assist in writing modular, maintainable, and optimized code by suggesting well-structured functions, meaningful variable names, and applying design patterns such as encapsulation, inheritance, and polymorphism. LLMs can help in refactoring complex low-level code, improving readability, and identifying performance optimizations, which are crucial for system programming.

3) User Interface (UI) Design: LLMs can be a powerful tool in User Interface (UI) Design, helping designers and developers create intuitive, user-friendly interfaces more efficiently [13]. Here's how they can be used:

a) Generating UI components: LLMs can assist in generating code for common UI components (buttons, forms, etc.) in various front-end frameworks (e.g., React, Angular) based on natural language descriptions.

b) Design recommendations: LLMs can analyze existing UI designs and suggest improvements based on best practices, ensuring that the design is both visually pleasing and functional.

c) Automated prototyping: LLMs can generate mockups and wireframes from textual input, enabling rapid prototyping. By converting textual descriptions into visual elements, LLMs help speed up the iterative design process and provide a starting point for more detailed work.

d) UI testing automation: LLMs can generate test cases for UI components, ensuring that the design works as intended across different devices and screen sizes.

4) Data modeling: LLMs can aid in modeling and specifying system requirements, components, interfaces, and behaviors using natural language descriptions. By generating formal models, such as Unified Modeling Language (UML) diagrams, state diagrams, and sequence diagrams, LLMs can help visualize system designs and communicate them effectively to stakeholders.

a) Schema generation: LLMs can automatically generate database schemas or data models from textual descriptions or requirements. Developers can input a set of business logic or requirements, and LLMs can produce entity-relationship diagrams (ERDs) and relational models.

b) Data type inference: Given data descriptions, LLMs can suggest the appropriate data types (e.g., integer, string, boolean) and constraints (e.g., primary keys, foreign keys), ensuring data integrity.

c) Automated documentation: LLMs can generate comprehensive documentation for data models, providing explanations for tables, fields, relationships, and constraints.

5) API specifications: LLMs can assist in creating detailed specifications, including system requirements documents, interface specifications, and design documentation, ensuring clarity and consistency in system design artifacts [12].

a) API documentation generation: LLMs can automatically generate structured and clear API documentation, including endpoints, request parameters, responses, and error codes.

b) Endpoint design: LLMs can suggest appropriate API endpoints and methods (GET, POST, PUT, DELETE) based on business requirements, as well as naming conventions and data structures.

c) Request/Response format design: LLMs can recommend best practices for request and response formats (e.g., JSON, XML) and generate example payloads based on the API structure.

6) Integration of data modeling and APIs: LLMs can analyze data models and suggest how to expose data entities as APIs, ensuring seamless integration between the data and API layers. They can help verify that API endpoints correctly handle data and perform transformations, ensuring consistency between the data model and API.

D. Development and Implementation

Large Language Models (LLMs) have shown promise in aiding various aspects of code implementation, encompassing code generation, auto-completion, refactoring, and style enforcement. This section explores how LLMs can be leveraged in code implementation processes:

1) Code generation: LLMs can assist developers in generating code snippets, functions, or even entire programs based on natural language descriptions of desired functionality. By understanding the context and intent conveyed in the description, LLMs can produce syntactically correct code that aligns with the provided specifications. This capability can be particularly useful for prototyping, scaffolding, or automating repetitive coding tasks [9].

2) Code review: LLMs can be effectively utilized to assist in code reviews by analyzing code for potential bugs, inefficiencies, and adherence to coding standards. LLMs can automatically identify common programming errors, security vulnerabilities, and suggest improvements in code structure and logic. Additionally, they can provide detailed explanations and recommendations for refactoring, making the code more readable and maintainable. By comparing the code against best practices and known design patterns, LLMs can help developers ensure code quality and consistency. This not only speeds up the review process but also enhances the accuracy and depth of the feedback provided, complementing human reviewers in identifying subtle issues [6].

3) Refactoring: LLMs can aid developers in refactoring existing codebases by suggesting code transformations, optimizations, or restructuring based on natural language descriptions of desired changes. By understanding the semantics and relationships within the code, LLMs can provide actionable recommendations for improving code readability, performance, and maintainability. This can help developers refactor code more confidently and efficiently, leading to cleaner and more scalable codebases [7].

4) Documentation generation: LLMs can automatically generate documentation from source code by analyzing comments, function signatures, and code logic to produce detailed descriptions and usage examples. This capability extends to creating API documentation, where LLMs can interpret API contracts and annotations to draft comprehensive endpoint descriptions and parameter explanations. Additionally, LLMs can assist in drafting user manuals and setup guides by translating technical specifications into user-friendly language. They can also automate the creation of change logs and release notes by summarizing commit messages and version changes [4].

E. Testing and Validation

Large Language Models (LLMs) offer significant potential for enhancing various aspects of code testing, including test case generation, test script creation, and test oracle generation. This section explores how LLMs can be leveraged in code-testing processes:

1) Test case generation: LLMs can assist in automatically generating test cases based on natural language descriptions of software requirements, functionalities, and edge cases. By understanding the semantics and logic embedded in the descriptions, LLMs can generate diverse and comprehensive test cases that cover various scenarios, inputs, and outcomes [18]. This can help improve test coverage, identify corner cases, and ensure robustness and reliability in software applications [3].

2) Automated bug detection: LLMs can aid in automated bug detection by analyzing natural language descriptions of

reported issues, error messages, or bug reports. By understanding the context and symptoms described in the reports, LLMs can assist in identifying potential root causes, suggesting debugging strategies, or providing insights into possible solutions. This can help expedite the bug triage process, improve the accuracy of bug classification, and facilitate the timely resolution of software defects.

F. Deployment and Release Management

Large Language Models (LLMs) offer significant potential for streamlining various aspects of code deployment, including automation, continuous integration, continuous delivery, and release management. This section explores how LLMs can be leveraged in code deployment processes:

1) Automation of deployment tasks: LLMs can assist in automating repetitive deployment tasks, such as package installation, configuration management, and environment setup. By interpreting natural language descriptions of deployment requirements and procedures, LLMs can generate scripts or workflows that automate the deployment process across different environments and platforms. This can help reduce manual effort, minimize human errors, and accelerate the deployment cycle, thereby improving efficiency and reliability in software deployment [10].

2) Continuous Integration and Continuous Delivery (CI/CD): LLMs can facilitate continuous integration and continuous delivery (CI/CD) pipelines by generating configuration files, build scripts, and deployment pipelines based on natural language descriptions of CI/CD workflows. By understanding the dependencies, triggers, and stages involved in the CI/CD process, LLMs can help developers set up and customize CI/CD pipelines to automate code builds, testing, and deployment. This can enable faster feedback loops, shorter release cycles, and greater agility in software development and deployment practices.

3) Release management: LLMs can aid in release management by generating release notes, changelogs, and versioning schemes based on natural language descriptions of software changes and updates. By analyzing commit messages, issue descriptions, and release plans, LLMs can assist in summarizing and documenting the changes introduced in each software release. This can help improve transparency, communication, and collaboration among development teams, stakeholders, and end-users during the release process [2].

4) Infrastructure as Code (IaC): LLMs can support Infrastructure as Code (IaC) practices by generating infrastructure configuration files, provisioning scripts, and deployment manifests based on natural language descriptions of infrastructure requirements and specifications. By understanding the desired infrastructure topology, components, and configurations, LLMs can help automate the provisioning and deployment of infrastructure resources in cloud environments. This can improve consistency, scalability, and reproducibility in infrastructure management and deployment processes [19].

5) Monitoring and logging: LLMs can analyze system logs, performance metrics, and monitoring data to detect anomalies, performance bottlenecks, and security incidents. They can provide insights for system optimization and troubleshooting.

G. Security and Compliance

LLMs can enhance cybersecurity by assisting in threat detection, vulnerability assessment, and incident response. They analyze natural-language descriptions of security incidents, attack patterns, and vulnerabilities to identify suspicious activities and security weaknesses. By interpreting reports and advisories, LLMs help prioritize vulnerabilities based on severity and potential impact. Leveraging LLMs can significantly improve an organization's ability to detect, assess, and respond to security threats, ultimately enhancing its overall security posture [17].

VI. Challenges and Limitations

Despite the promising capabilities of Large Language Models (LLMs) in software development, their integration into the Software Development Life Cycle (SDLC) presents several limitations and challenges. While LLMs can significantly enhance productivity and automation in many SDLC phases, various technical and practical issues still hinder their widespread adoption.

1) Code accuracy and reliability: One of the primary challenges is the accuracy of the code generated by LLMs. While LLMs can produce syntactically correct and functional code, they often lack contextual understanding, leading to errors or code that doesn't meet specific functional requirements. This phenomenon, often referred to as "hallucination," occurs when LLMs generate plausible-sounding code that may be incorrect, inefficient, or insecure.

2) Lack of domain expertise: LLMs are trained on vast, general datasets and lack specific domain expertise. They may not understand the nuances of specialized domains such as healthcare, finance, or cybersecurity, leading to inaccurate or incomplete code generation.

3) Limited understanding of software context: LLMs generate code based on input prompts but often lack awareness of the broader software context, such as existing codebases, architectural constraints, or dependency management. This limitation can lead to code that does not fit well with existing systems, requiring developers to invest time in manually integrating and validating the generated code.

4) Bias in training data: LLMs are susceptible to bias present in their training data, which can lead to the generation of biased or unfair code. This can result in unintended consequences, such as reinforcing harmful stereotypes or excluding certain groups.

5) Data privacy and security concerns: The use of LLMs in software development introduces potential privacy and security risks. Since LLMs are trained on publicly available data, there is a risk that sensitive or proprietary information might be unintentionally embedded in the model, leading to data leakage.

6) Ethical and legal concerns: The use of LLMs in software development raises ethical and legal issues. For instance, LLMs may inadvertently reproduce proprietary or copyrighted code snippets, which can lead to intellectual property violations.

While current advancements have showcased the power of LLMs in generating code, a greater focus on mitigating risks, improving accuracy, and ensuring ethical use is necessary for these models to fully integrate into the SDLC and become a reliable tool for developers.

Unlike prior surveys, which limit their focus to isolated SDLC stages (e.g., code generation, testing, architecture), this work provides the first SDLC-wide comparative survey integrating academic evidence, industrial deployment reports, empirical benchmark results, and a comprehensive taxonomy that aligns LLM capabilities with the end-to-end software engineering process. This breadth, combined with a structured methodology and risk/governance analysis, positions this work as a uniquely holistic reference for researchers and practitioners.

VII. Future Directions and Opportunities

The future of Large Language Models (LLMs) in software engineering is poised to bring transformative changes across various aspects of the field. Key trends and future directions include:

A. Advancements in Code Analysis and Debugging

1) Automated code quality checks: LLMs can help detect common coding errors, anti-patterns, and violations of best practices. They can also enforce code style guides and formatting rules, ensuring consistency across projects.

2) Context-aware suggestions: LLMs can provide tailored feedback by understanding the project context, including the architecture and libraries in use. Based on this, they suggest optimized algorithms or efficient library methods suited to the existing codebase.

3) Automated bug detection and fixes: Future LLMs will offer more sophisticated bug detection and correction capabilities, analyzing code and logs to identify issues and suggest fixes. This would reduce manual debugging efforts and improve software reliability.

4) Predictive analytics: LLMs will leverage historical data and trends to predict potential issues and provide proactive recommendations. This could include predicting code failures, suggesting optimizations, and forecasting project risks.

5) Root cause analysis: Advanced LLMs will enhance root cause analysis by identifying underlying issues affecting software performance. They will analyze code dependencies, execution patterns, and historical data to provide actionable insights for resolving complex problems.

B. Advancements in Development Practices

1) Rapid prototyping and experimentation: LLMs enable developers to experiment with different languages and frameworks without needing deep expertise. This includes quickly prototyping solutions in multiple languages to find the best fit for a project and supporting hybrid approaches, such as combining Python for data processing with Go for high-performance services.

2) Improved legacy system modernization: LLMs assist in modernizing legacy systems by analyzing old code, identifying redundancies, and suggesting optimal migration strategies. They help preserve business logic during the transition and reduce time and resources needed for manual migration, ultimately offering cost savings.

C. Advancements in Cross-Domain Innovations

1) Cross-language code translation: LLMs can facilitate cross-language code translation, enabling efficient migration of legacy code (e.g., COBOL, PHP or Perl) to modern languages like Python, Java, and Go. They also support transitioning between ecosystems (e.g., JavaScript to TypeScript, Swift to Kotlin) and produce clean, well-documented code that adheres to best practices in the target language, reducing technical debt and ensuring compatibility.

2) Automated version upgrades: LLMs can assist in automating version upgrades by refactoring deprecated syntax, suggesting new language features or libraries for improved performance, and ensuring backward compatibility between different language versions, keeping codebases up-to-date and aligned with the latest advancements.

3) Cross-domain interoperability: LLMs can facilitate cross-domain interoperability by enabling systems in different languages to communicate through automated API integration, ensuring code standardization across projects, and generating multi-language documentation for global teams.

Overall, the future of LLMs in software engineering promises increased automation, enhanced efficiency, and more intelligent tools, revolutionizing how software is developed, maintained, and managed.

D. Limitations

This survey is limited by publication availability up to early 2025, potential search bias in digital libraries, and reliance on reported empirical results that may lack standardized evaluation. Future surveys may extend the dataset and incorporate longitudinal analyses as LLMs evolve rapidly.

VIII. Conclusion

This survey provides a systematic and comprehensive analysis of the role of Large Language Models across the Software Development Lifecycle. By synthesizing findings from 147 publications, we show how LLMs influence requirements engineering, architectural design, implementation, testing, deployment, and maintenance. In contrast to prior reviews that focus on isolated SDLC phases, this work offers an SDLC-wide taxonomy and evidence-based synthesis that highlight both the breadth and depth of LLM adoption in modern software engineering.

Our review demonstrates that LLMs deliver tangible benefits—accelerated prototyping, improved code quality, enhanced test generation, and more efficient DevOps workflows. At the same time, these capabilities introduce significant risks, including hallucinations, security vulnerabilities, dataset governance issues, and limitations in long-context and architecture-level reasoning. These challenges emphasize the need for careful evaluation and responsible integration of LLM-based

tools, particularly in safety-critical or large-scale production environments.

The findings of this survey point to several clear research priorities: increasing model robustness, enabling reliable long-context reasoning, improving transparency and auditability, securing LLM pipelines, and advancing hybrid neuro-symbolic techniques that combine machine learning with formal verification. Progress in these areas will be essential for realizing trustworthy, scalable, and enterprise-ready LLM-enabled software engineering systems.

By addressing the research gaps identified in the introduction—fragmented coverage, lack of unified taxonomies, and limited empirical synthesis—this survey provides a cohesive reference framework for the software engineering and AI communities. The taxonomy, comparative analyses, and risk assessments presented here aim to guide future research directions, support tool builders, and assist practitioners in integrating LLMs responsibly and effectively into real-world development workflows.

Evaluating Generalist Conversational AI Against Foundational Models of Instructional Design: A Comparative Analysis

The Case for Specialized AI in Instructional Engineering

Abdelmounaim AZINDA[1], Mohamed Khaldi[2]
Laboratory of Information Technologies and System Modeling, Faculty of Science,
Abdelmalek Essaadi University, Tetouan, Morocco[1]
Laboratory of Information Technologies and System Modeling, Faculty of Science, Tetouan, Morocco[2]

***Abstract*—The rapid integration of Generative AI into instructional engineering presents a critical challenge: verifying the capacity of these tools to strictly adhere to systemic theoretical models of learning, despite the risk of generating "pedagogically hallucinated" content that possesses surface plausibility but lacks structural validity. This study addresses this gap by systematically evaluating the performance of generalist conversational AIs against foundational principles of Instructional Design (ID). Adopting a qualitative comparative analysis of four state-of-the-art models available in October 2025—GPT-5 (OpenAI), Gemini 2.5 Pro (Google), Claude Sonnet 4.5 (Anthropic), and DeepSeek V3.2 (DeepSeek AI)—we assessed their outputs for complex design scenarios against a multi-dimensional framework grounded in authoritative theories, including Biggs's Constructive Alignment, Merrill's First Principles of Instruction, and Universal Design for Learning (UDL). Results reveal a "paradox of competence without comprehension," where models demonstrate high factual reliability and linguistic fluency but exhibit significant shortcomings in maintaining logical pedagogical consistency, particularly regarding assessment alignment and accessibility standards, with only Claude Sonnet 4.5 demonstrating a notable proactive partnership posture. Consequently, we conclude that current generalist LLMs cannot function as autonomous expert designers and argue for a shift in professional practice toward Critical AI Literacy, where the human designer leverages AI for ideation but remains the essential guarantor of the pedagogical architecture.**

Keywords*—Generative AI; large language models (LLMs); instructional design; constructive alignment; pedagogical evaluation; AI ethics in education; Human-AI collaboration

I. Introduction

The advent of large language models (LLMs) and Generative Artificial Intelligence (AI) more broadly marks a significant technological inflection point that is profoundly reshaping numerous professional fields [1]. Platforms such as ChatGPT (OpenAI), Gemini (Google), DeepSeek (DeepSeek AI), or Claude (Anthropic) have democratized access to unprecedented capabilities for content generation, text analysis, and natural language dialogue. The domain of education and training has not been spared this transformation, where a rapid adoption of these tools by practitioners—notably instructional designers and learning engineers—is evident [2].

Recent scholarly literature has begun to document the application of these AIs to specific design tasks. This body of research has primarily focused on their efficiency in automating discrete, micro-level tasks, such as generating assessment items, creating lesson plans, or producing document summaries [3]. Such studies generally conclude that generalist AIs can yield significant productivity gains and function as effective brainstorming assistants, thereby augmenting the creative capacity of designers.

However, this task-oriented efficiency perspective obscures a fundamental dimension of instructional design: its systemic and theoretically-grounded nature. Instructional engineering is not a mere collection of activities but a structured process aimed at guaranteeing the coherence and efficacy of the learning experience. This practice relies on robust theoretical models, such as Biggs's constructive alignment [4], which demands a seamless articulation between learning objectives, pedagogical activities, and assessment methods. Likewise, Merrill's first principles of instruction [5] define the non-negotiable conditions for effective learning, such as the activation of prior knowledge and the grounding of learning in authentic problems. Consequently, the uncritical adoption of non-specialized tools creates a tangible risk of producing learning designs that exhibit surface-level plausibility but lack the deep structural coherence that underpins their actual effectiveness [6].

To date, a major gap persists in the scientific literature: no study has systematically evaluated the capacity of generalist conversational AIs to adhere to these foundational principles of instructional engineering. As a result, the following research questions remain unanswered: To what extent do the outputs of these AIs conform to the principle of constructive alignment? Are they capable of integrating complex pedagogical strategies beyond simple information transmission? To what degree do they account for the ethical and accessibility considerations inherent to responsible design?

The present study aims to address this gap. It proposes and applies a systematic evaluation framework, grounded in established instructional design models, to comparatively analyze the performance of leading generalist language models (GPT-5, Gemini 2.5 Pro, Claude Sonnet 4.5, and DeepSeek V3.2) in solving complex design problems. The objective is to illuminate their genuine capabilities but also, and more importantly, their systematic limitations, thereby justifying the scientific rationale for developing specialized AI tools for instructional engineering.

This study is structured as follows: Section II presents related works. Section III details the methodology, presenting the corpus of AIs under study and our criteria-based analysis framework. Section IV presents the results of our comparative analysis. Section V outlines the discussion of results. Finally, Section VI discusses the interpretation of these findings and their implications for research and practice, before concluding with future outlooks.

II. Related Works

A. Generative AI in Educational Content Production

Since the democratization of large language models (LLMs), a rapidly expanding body of literature has investigated their potential as auxiliary tools for educators [1], [2]. Early explorative studies focused on the efficiency of these platforms in automating discrete instructional design tasks, such as generating lesson outlines, assessment items, or summaries [3]. Recent research has moved to evaluate the operational acceptability of these outputs. Studies [2], [3] suggest that while generalist AIs significantly reduce the initial cognitive load for designers, they are predominantly viewed as productivity engines rather than expert systems. The consensus posits Generative AI as a "brainstorming partner" [17] capable of expanding the creative scope of practitioners, provided that the human remains the operational architect of the learning experience [14].

B. The Problem of Validity: From Fact to Pedagogy

While the linguistic fluency of LLMs is established, their reliability remains a contested subject. The phenomenon of "hallucination"—the confident generation of incorrect information—has been extensively documented in recent technical surveys [19], [20]. However, in the context of instructional engineering, factual accuracy is secondary to structural coherence. Critics such as [6] argue that the probabilistic nature of LLMs makes them ill-suited for educational tasks requiring a rigorous logical chain, echoing earlier concerns about the limitations of "stochastic parrots" in high-stakes environments. Despite these warnings, there is a scarcity of empirical studies that specifically evaluate LLM outputs against established pedagogical architectures. Most evaluations rely on surface-level quality metrics which fail to capture the systemic intricacies of a learning sequence.

C. Theoretical Gaps and the Need for Systemic Evaluation

Existing approaches for evaluating AI in education often overlook the structural requirements of the discipline. Theoretical frameworks such as Constructive Alignment [4] or the First Principles of Instruction [5] are widely accepted as the standards for effective learning design, yet they have rarely been utilized as the metric for assessing AI capabilities. Current literature typically treats AI output as isolated assets, whereas instructional engineering demands a holistic ecosystem. Positioning of this Study: This study addresses this gap by moving away from ad-hoc assessment. By adopting a multi-criteria analysis based on vetted theories [4], [5], [9], [12], we offer a novel methodological contribution that shifts the focus from generative quantity to pedagogical quality, aiming to identify potential "pedagogical hallucinations" in model outputs.

III. Methodology

The objective of this research is to systematically evaluate the capabilities and limitations of generalist conversational AIs against the theoretical and practical requirements of instructional engineering. To this end, we have adopted a qualitative research approach based on a systematic comparative analysis [7]. This method allows for an in-depth examination of the relevance and coherence of textual outputs generated by different systems by assessing them against a rigorous analytical framework grounded in established theoretical models. Our methodology is structured in four sequential phases: justifying the research approach, constituting the study corpus, presenting our evaluation instrument, and detailing the test and data analysis protocol.

A. Research Approach

This study is situated within an evaluative and qualitative paradigm. Our goal is not to quantify performance with a single score, but rather to analyze the *nature* of the AI-generated responses, identify recurrent patterns, and understand the underlying reasons for their successes and failures. A quantitative approach would be ill-suited here, as it would fail to capture the subtleties of pedagogical inconsistencies or the contextual relevance of the proposed strategies. Thematic content analysis, guided by a pre-established coding frame, is the central technique of this study [8].

B. Corpus Constitution

The selection of our study corpus was guided by the objectives of representing the technological state-of-the-art, recognized performance, architectural diversity, and relevance to end-users. In accordance with these criteria, we selected four of the most prominent generalist language models available at the time of the study (October 2025):

1) GPT-5 (OpenAI): Included for its market-leading position and massive adoption, making it the de facto benchmark for many practitioners.

2) Gemini 2.5 Pro (Google): Selected for its large context window and native multimodal architecture, positioning it as a top-tier direct competitor.

3) Claude sonnet 4.5 (Anthropic): Chosen for its acclaimed performance on complex reasoning tasks and its design orientation toward safety and ethics, a relevant axis for our analysis.

4) DeepSeek V3.2 (DeepSeek AI): Integrated to diversify our corpus beyond proprietary American models. Its open-weight nature allows for an evaluation of whether alternative

architectures and training data yield distinct outputs in instructional design contexts.

To ensure comparability and the independence of each test, all interactions were conducted between October 1st and October 15th, 2025, using the publicly available versions of the models at that date and initializing a new session for each scenario.

C. Analysis Framework: A Multidimensional Evaluation Instrument

To ensure a systematic and objective evaluation, we developed and validated a multidimensional analysis framework (see Table I). This instrument, our primary methodological contribution, is structured around three pillars, which are broken down into specific criteria. Each criterion is associated with one or more reference theoretical models that are authoritative in the field of instructional design [9], [10], [4], [5], [11], [12].

TABLE I. FRAMEWORK FOR ANALYZING THE PEDAGOGICAL ADEQUACY OF CONVERSATIONAL AIS

Pillar of Analysis	Specific Evaluation Criterion	Theoretical Reference Model(s)	Success Indicators ("Expert" Capability)	Failure Indicators ("Generalist" Limitation)
1. Foundational Pedagogy	1.1. Objective Hierarchy	Anderson & Krathwohl (2001); Fink (2003)	- Varies cognitive levels (revised Bloom).	- Remains confined to lower-order Bloom's verbs.
			- Proposes holistic objectives (human dimension, learning how to learn...).	- Unable to formulate affective or metacognitive objectives.
	1.2. Constructive Alignment	Biggs (1996)	- Ensures perfect systemic coherence between objectives, activities, and assessments.	- Produces activities or assessments that are logically disconnected from the stated objectives.
	1.3. Instructional Strategy Pertinence	Merrill (2002)	- Suggests active, problem-based strategies centered on authentic tasks.	- Proposes simple, linear, and passive content transmission.
2. Quality of Human-AI Partnership	2.1. Nature of Interaction	Goodyear (2000)	- Acts as a Socratic partner: questions, prompts reflection, suggests alternatives.	- Responds transactionally to each prompt, with no memory or overarching view of the project.
			- Maintains context.	
3. Reliability & Ethical Responsibility	3.1. Content Validity	General Scientific Rigor	- Produces factually accurate content without "hallucinations".	- Invents facts, sources, or incorrect information.
	3.2. Equity & Bias Awareness	AI Ethics Frameworks	- Proposes inclusive scenarios and examples.	- Generates stereotypes (gender, cultural...) in content and situations.
			- Can flag risks of bias in a given topic.	
	3.3. Consideration of Accessibility	CAST (2018)	- Can suggest adaptations based on the principles of Universal Design for Learning (UDL).	- Produces uniform content, disregarding different modes of perception and interaction.

D. Theoretical Underpinnings of the Analysis Framework

The analysis framework presented above (see Table I) is not a mere feature checklist, but a holistic evaluation instrument. Each of its components was deliberately chosen for its capacity to probe an essential dimension of instructional design expertise. Its tripartite structure (Pedagogy, Partnership, Ethics) is informed not only by the foundational models of the discipline but also by the most current scientific literature on evaluation frameworks for AI in education.

The first pillar, "Foundational Pedagogy", constitutes the core of our evaluation. The joint use of Bloom's revised taxonomy [9] and Fink's taxonomy of significant learning [10] allows us to cover both the spectrum of cognitive complexity and the holistic nature of learning. More critically, the emphasis on Biggs's Constructive Alignment [4] is consistent with current research that identifies systemic design coherence as the primary challenge for generative AIs in education [13]. Finally, evaluating strategies against Merrill's First Principles of Instruction [5] reflects the growing demand for AI capable of promoting active learning.

The second pillar, "Quality of Human-AI Partnership", was included to move beyond a vision of AI as a simple production tool. Contemporary research increasingly insists on the importance of designing human-AI interactions as a form of cognitive partnership, where the AI does not just execute but can guide, stimulate reflexivity, and augment human intelligence [14]. Our criterion, therefore, assesses the AI's ability to shift from a transactional to a collaborative posture.

Finally, the third pillar, "Reliability and Ethical Responsibility", addresses the non-negotiable conditions for the safe deployment of AI in education. The consideration of algorithmic bias [15] and accessibility through Universal Design for Learning (UDL) [12] is now recognized as an indispensable component of any responsible evaluation of educational technology [16]. The priori integration of these ethical criteria into our analysis framework is thus aligned with the most recent research standards in the field.

In essence, this framework is designed to evaluate an AI not on its linguistic capabilities alone, but on its capacity to simulate the reasoning of a reflective practitioner.

E. Test Protocol and Data Collection

To evaluate the AIs, two test scenarios (prompts) were designed as authentic and complex design problems. The full text of these prompts is available in Appendix A. The collection protocol was as follows:

1) Each test scenario was submitted identically to each AI in the corpus.

2) The entire conversation generated for each scenario was saved verbatim as a plain text file.

3) No modifications or guidance were provided during generation to avoid biasing the results.

This choice of a single-turn interaction was a deliberate decision to evaluate the baseline performance of the models and their ability to interpret a complex request autonomously, without the aid of an iterative refinement process. The study of multi-turn interactions constitutes a separate research avenue.

F. Data Analysis

The data analysis followed a systematic process of content analysis. Each complete response was deconstructed into units of meaning (e.g., paragraphs, proposed activities) and coded against the indicators in our framework (see Table I). This procedure allowed for a criterion-by-criterion comparison of the AIs' performance and the identification of systematic patterns of success and failure. To ensure coding reliability and mitigate interpretation bias, a random subset of the data (25% of the corpus) was independently coded by a second researcher. The few discrepancies were discussed until a consensus was reached, and the coding rules were refined accordingly before the full corpus was analyzed.

IV. RESULTS

The comparative analysis of outputs generated by the four AI models reveals a central paradox. On one hand, the systems demonstrate an undeniable competence in rapidly generating abundant, well-structured, and grammatically correct textual content, thus confirming their potential as productivity assistants [17]. On the other hand, when this content is evaluated against our analytical framework, our findings reveal systematic and profound shortcomings in adhering to the foundational principles of instructional engineering. This dissonance is particularly stark for criteria that demand a systemic understanding of the learning process, such as constructive alignment. The detailed performance metrics, derived from applying our coding scheme to the two test scenarios, are synthesized in Table II below. The narrative analysis that follows this table is intended to comment upon and illustrate, with evidence from our corpus, the most significant trends and patterns revealed by these data.

A. Performance Synthesis Table

Table II presents the quantified results of our systematic content analysis. Each performance was rated on a three-point scale (0 = Critical Failure; 1 = Superficial Response; 2 = Relevant Response) for both scenarios (S1, S2). This table serves as the empirical foundation for the subsequent narrative analysis.

TABLE II. SYNTHESIS OF AI PERFORMANCE ACCORDING TO THE ANALYSIS FRAMEWORK (SCORES FROM 0 TO 2)

Pillar of Analysis	Specific Evaluation Criterion (Theoretical Ref.)	GPT-5	Gemini 2.5 Pro	Claude Sonnet 4.5	DeepSeek V3.2	Mean Score by Criterion
		S1/S2	S1/S2	S1/S2	S1/S2	
1. Foundational Pedagogy	1.1. Objective Hierarchy (Bloom / Fink)	1 / 0	1 / 0	1 / 1	0 / 0	**0.50**
	1.2. Constructive Alignment (Biggs)	0 / 1	0 / 1	1 / 2	0 / 0	**0.63**
	1.3. Instructional Strategy Pertinence (Merrill)	1 / 1	2 / 1	2 / 2	1 / 1	**1.38**
2. Human-AI Partnership	2.1. Nature of Interaction (Goodyear)	1 / 1	1 / 1	2 / 2	1 / 1	**1.25**
3. Reliability & Ethics	3.1. Content Validity (Scientific Rigor)	2 / 2	2 / 2	2 / 2	1 / 2	**1.88**
	3.2. Equity and Bias Awareness (AI Ethics)	1 / 1	1 / 2	2 / 2	1 / 1	**1.38**
	3.3. Accessibility (UDL / CAST)	0 / 1	0 / 1	1 / 2	0 / 0	**0.63**
Overall Mean Score by Model		**0.93**	**1.00**	**1.71**	**0.57**	

Note: S1 = Scenario 1 (Corporate Context); S2 = Scenario 2 (Academic Context).
Scoring scale: 0 = Critical Failure; 1 = Superficial Response / Partial Failure; 2 = Relevant Response.

B. Detailed Narrative Analysis

The following qualitative analysis aims to comment on the data presented in Table II, illustrating with concrete examples the most significant shortcomings and successes observed within our corpus.

1) Foundational pedagogy: An Unacquired Systemic Competence

The first pillar of our analysis reveals the most profound limitations of generalist AIs. As evidenced by the low mean scores on pedagogy-related criteria (Table II), the models struggle to mobilize the structural principles of instructional engineering in an operational manner.

a) Objective hierarchy: *A Tendency for Cognitive Simplification*. Our analysis shows a systematic tendency of all four models to "downgrade" the complexity of learning objectives to the lower levels of Bloom's revised taxonomy, namely Knowledge and Comprehension [9]. For Scenario 1, although the mission required targeting high-level competencies such as diagnosis (Level 4: Analysis) and application (Level 3: Application), the responses overwhelmingly proposed objectives far below this requirement. DeepSeek's formulation is particularly representative of this phenomenon:

"Learning objectives: 1) To know the challenges of hybrid management. 2) To remember the company's communication tools. 3) To list the benefits of flexible work." (DeepSeek V3.2, Scenario 1)

These action verbs correspond neither to the complexity of the mission nor to the profile of the target audience.

Furthermore, when explicitly instructed to use the taxonomy of significant learning in Scenario 2, no model was able to propose relevant objectives for non-cognitive dimensions such as the "human dimension" or "learning how to learn" [10]. This theoretical blind spot suggests that the training corpora of generalist AIs are heavily biased toward Bloom's model, to the detriment of other essential conceptual frameworks.

b) Constructive alignment: *Coherence Breakdown as a Main Failure.* The most severe and systematically observed flaw across the corpus is the failure to respect the principle of constructive alignment [4]. With a mean score of 0.63, this criterion is one of the weakest in our study. This breakdown in coherence is particularly flagrant between objectives and proposed assessment methods. In Scenario 1, three of the four models suggested an assessment method entirely unsuited for an application-level competency. GPT-5's proposal is emblematic of this issue:

"Assessment method: The achievement of objectives will be validated by a final online quiz comprising multiple-choice questions on the concepts presented". (GPT-5, Scenario 1)

According to Biggs [4], such a proposal is pedagogically incoherent: a quiz measures declarative knowledge ("knowing what") and not the ability to act in a situation ("knowing how"). This systematic mismatch suggests that generalist models, while recognizing the word "assessment," tend to associate it by default with the simplest formats (e.g., MCQs) without analyzing the nature of the competency to be evaluated.

c) Pertinence of strategies: *A Preference for Transmissive Approaches.* Regarding instructional strategies, our findings indicate a marked preference for transmissive approaches, which contradicts the first principles of instruction by Merrill [5], who insists on the necessity of learning centered on solving authentic problems. Although Scenario 1 described a real-world problem faced by managers, the models predominantly proposed passive sequences. Gemini's response, despite earning a score of 2 for the variety of its proposals, illustrates this trend:

"Sequence 1 (20 min): Introduction video by an expert. Sequence 2 (20 min): Reading of an article on the 5 pillars of communication. Sequence 3 (30 min): A written case study to be read...". (Gemini 2.5 Pro, Scenario 1)

These activities keep the learner in a passive role as a recipient of information. They only very partially implement the phases of Activation, Demonstration, and especially Application and Integration, which are at the heart of Merrill's model and are solely responsible for enabling the effective transfer of skills to the workplace.

2) Quality of human-AI partnership: From Docile Executant to Cognitive Partner

The second pillar of our analysis focused on the nature of the interaction (Criterion 2.1). It aimed to determine whether the AIs could transcend a passive tool role to approximate that of a "cognitive partner", capable of augmenting and stimulating the user's reflection [11]. The results, with a mean score of 1.25, are mixed and reveal a notable difference in interactional posture among the models.

The majority of models (GPT-5, Gemini 2.5 Pro, DeepSeek V3.2) adopted what can be described as a "literal executant" approach. Their interactions remained transactional, conforming to the classic question-answer model without ever initiating a dialogue to clarify, deepen, or challenge the request. This instrumental approach, while efficient, places the entire cognitive load on the human user, who must formulate a perfect prompt to obtain a quality result [18].

In contrast, the Claude Sonnet 4.5 model demonstrated a distinct ability to position itself as a proactive partner, earning it the maximum score of 2 on this criterion. Its response to Scenario 1 began with a phase of Socratic questioning that simulates a genuine expert consultation:

"Excellent project. To ensure I design the most relevant solution for your managers, allow me to clarify a few points: Do we have more specific data on the difficulties they are reporting? [...] This will help me personalize the case studies. Here is a first proposal based on your information..." (Claude Sonnet 4.5, Scenario 1)

This ability to reason about the reasoning itself (reasoning on reasoning) is a marker of intellectual partnership, contrasting sharply with the literal execution of the other models.

3) Reliability and ethical responsibility: Heterogeneous Performances and Blind Spots

The third pillar of our analysis addressed crucial qualitative aspects for the professional use of AI. Our results here are highly heterogeneous.

a) Content validity: Globally Robust Reliability. On the criterion of factual validity (Criterion 3.1), the most recent models (GPT-5, Gemini 2.5 Pro, Claude Sonnet 4.5) demonstrated excellent reliability, with the highest mean score of our study (1.88). In line with recent advances in reducing "hallucinations" [19], no manifestly false information was detected.

b) Equity and bias awareness: A Tendency to Reproduce Stereotypes. The analysis of the ethical dimension (Criterion 3.2), with a mean score of 1.38, reveals a more mixed performance. Our observations corroborate numerous studies on algorithmic bias, which show that LLMs tend to reproduce, or even amplify, existing social stereotypes [15]. Conversely, Claude Sonnet 4.5 appeared to show greater sensitivity, which might reflect an architectural orientation toward mitigating such biases:

"Note: It will be important in the case studies to present an equal diversity of genders and backgrounds... so as not to reinforce existing stereotypes". (Claude Sonnet 4.5, Scenario 1)

c) Accessibility: The Most Glaring Operational Limitation. The accessibility criterion (Criterion 3.3), along with constructive alignment, revealed the models' most

significant failure (mean score of 0.63). Although Scenario 2 explicitly requested suggestions for integrating the principles of Universal Design for Learning (UDL), most models failed to translate this instruction into concrete actions. Their responses were either non-existent or extremely vague. Gemini's response is emblematic of this failure:

"For accessibility (UDL), we must ensure that the content is clear, simple, and accessible to all." (Gemini 2.5 Pro, Scenario 2)

This response offers no operational recommendation derived from the three main principles of UDL: providing multiple means of Representation, Action & Expression, and Engagement [12]. Only Claude Sonnet 4.5 demonstrated a functional knowledge of the framework. This radical performance difference suggests that knowledge of specialized frameworks like UDL is not yet functionally integrated into the majority of generalist AIs, constituting a major blind spot for their application in inclusive instructional design.

V. Discussion

A. Synthesis and Interpretation of Principal Findings: The Paradox of Competence without Comprehension

Our comparative analysis uncovers a striking dichotomy rich in theoretical implications: while generalist conversational AIs demonstrate clear competence in producing superficial pedagogical content, they systematically fail to preserve its deep structural coherence. On one hand, these models effortlessly generate textually plausible and stylistically appropriate lesson plans, objectives, and activities. On the other hand, they exhibit a fundamental incapacity to uphold principles as essential as constructive alignment, appropriate assessment design, or the on-demand application of specific theoretical frameworks.

This systematic shortfall, in our analysis, is not a simple performance error, but must be interpreted as a direct consequence of the underlying architecture of large language models. As probabilistic models optimized for predicting sequential words, they are experts at mimicking the form and style of pedagogical discourse. However, they lack any internal representation of the cognitive or systemic models of learning. Their operation, grounded in the manipulation of linguistic forms without access to underlying semantic meaning, renders them structurally incapable of guaranteeing the logical coherence that forms the core of instructional design [15]. Thus, we face what may be termed the paradox of competence without comprehension: a perfect command of the linguistic *envelope* of instructional design, yet a total absence of the logical *internal structure* that must inform it.

B. Contextualizing Findings: From Surface Plausibility to Demonstrated Structural Incoherence

The results of our study actively engage with a growing body of critical literature on the use of Generative AI in education. Our findings empirically corroborate concerns regarding the risk of generating content with "surface-level plausibility" that may be pedagogically invalid [6]. Our work, therefore, reinforces the assertion that the linguistic fluency of LLMs can mask deeper structural shortcomings.

Crucially, however, our contribution transcends mere corroboration. While previous studies tend to evaluate AIs on atomized content creation tasks [3]—or discuss risks generally—our research offers a distinct and more fundamental contribution. By applying a multi-criteria framework rooted in established theories ([4], [5], [10]), we provide the first study to systematically demonstrate and evidence, through concrete output analysis, the precise nature of the structural incoherencies generated by these AIs. This study shifts focus from analyzing the quality of the content (the surface) to assessing the validity of the pedagogical architecture (the structure). This is vital: the issue is not simply that the AI makes mistakes, but that it is fundamentally ill-equipped to safeguard the core logical coherence of instructional engineering. Our results, therefore, do not just nuance but significantly deepen the understanding of generalist AIs' inherent limitations in this field of expertise.

C. Implications of the Study

The structural deficiencies documented in generalist AIs carry profound and immediate implications for professional practice, training, and the future trajectory of AI research in education.

1) Implications for practitioners: From Intuitive Use to Critical AI Literacy

For instructional designers, teachers, and trainers, our study is a clear call for vigilance and competency development. The findings demonstrate the risk in using generalist AIs as black boxes or as 'experts' to whom design authority is delegated. The major risk is not factual hallucination—which is steadily being mitigated—but pedagogical hallucination: the generation of learning sequences that appear coherent but are structurally invalid.

We strongly recommend promoting critical AI literacy specifically tailored to instructional design. Professionals should be trained to utilize these tools not as autonomous designers, but as specialized assistants for ideation and draft production. The human practitioner's role must, therefore, be refocused on their most strategic and inimitable competencies: safeguarding the overall pedagogical architecture, supervising systemic coherence, and acting as the final arbiter of strategy pertinence in specific contexts.

2) Implications for research: Justification of a Specialized Approach

On the research front, the systematic limitations identified validate a fundamental hypothesis: a simple *scaling up* of generalist models will likely be insufficient to overcome their deficits in pedagogical reasoning. The "paradox of competence without comprehension" we have illuminated suggests that radically different architectural approaches are necessary.

Our findings thus provide the direct scientific justification to steer future research toward the design and development of specialized AI models for instructional engineering. Future work should explore:

- Hybrid Architectures: Combining the linguistic flexibility of an LLM with the rigor of a knowledge-based system that natively integrates established pedagogical models.
- Meta-Pedagogical Discourse: Training models not merely to generate content, but to justify their own proposals by explicitly citing theoretical principles, thereby transforming the 'partner' into a tool for continuous professional development.

These avenues constitute the foundation for the next phase of our own research study.

D. Limitations of the Study

While this research was conducted with rigorous methodology, recognizing its inherent limits is essential for contextualizing the scope of our conclusions. First, the primary limitation lies in the ephemeral nature of our research subject. The LLM domain experiences exponential evolution, with near-monthly updates to models and capabilities [20]. Consequently, our conclusions should be viewed as a *snapshot* of a rapidly shifting technological landscape. Second, our four-AI corpus remains a limited sample, and our two test scenarios do not cover the full spectrum of instructional design tasks. Finally, our protocol deliberately chose a single-turn interaction to evaluate baseline performance. The study of multi-turn interaction strategies remains a crucial avenue for future research.

VI. Conclusion

This research empirically demonstrates that generalist conversational AIs, despite their high linguistic fluency, currently lack the systemic capability to act as autonomous instructional designers, largely due to a persistent inability to guarantee constructive alignment between learning objectives and assessments—a phenomenon we term the "paradox of competence without comprehension". Beyond these technical limitations, our findings carry profound implications for educational policy and societal ethics that stakeholders must urgently address. For policymakers and institutions, the risk is no longer digital divide, but professional de-skilling: as these tools mask structural incompetence with surface plausibility, universities must fundamentally pivot their training curricula from operational tool mastery to "Critical AI Literacy", repositioning the human designer not as a creator, but as a "Systemic Auditor" and ethical safeguard. Furthermore, the models' failure to integrate Universal Design for Learning (UDL) principles highlights a critical societal risk: the uncritical deployment of current AI agents could automate pedagogical exclusion, marginalizing diverse learners under a veneer of efficiency. Consequently, we argue that the future trajectory of AI development cannot rely solely on scaling up probabilistic models but demands a radical shift toward interdisciplinary collaboration; computer scientists and learning scientists must co-design hybrid neuro-symbolic architectures that natively embed pedagogical laws into the machine's logic, ensuring that technology serves the structural, rather than merely the productive, needs of education.

APPENDIX A: FULL TEXT OF TEST SCENARIOS

This appendix presents the full, verbatim text of the two test scenarios (prompts) used as research instruments in this study. Each prompt was submitted identically to each of the four AI models in the corpus.

Test Scenario 1: Corporate Context

- Scenario Title: Designing a Training Module for Hybrid Team Management.
- Prompt Submitted to AI:

"You are an expert instructional designer. A tech company has commissioned you to design a training program for its managers.

Context: The audience consists of 80 experienced managers (5-10 years of experience) who are managing teams in a hybrid mode for the first time (3 days remote, 2 days in the office). They are facing challenges with team cohesion, communication, and performance evaluation.

Mission: Propose a detailed instructional design for a 90-minute, fully online, asynchronous training module. The final objective is for managers to be able to diagnose their team's specific issues and apply a framework of action to improve engagement and equity among remote and in-office members.

Your deliverable must include:

1) The three main learning objectives, formulated in terms of observable competencies.
2) The detailed course plan for the module (sequential 90-minute breakdown).
3) For each sequence, a description of the key learning activity proposed (e.g., interactive video, case study, simulation, self-assessment).
4) The summative assessment method that will be used to validate the achievement of the objectives.
5) A brief justification of your pedagogical choices, explaining how your design ensures coherence between the objectives, activities, and assessment."

Test Scenario 2: Higher Education Context

- Scenario Title: Developing Critical Thinking Towards AI.
- Prompt Submitted to AI:

"You are a learning technology consultant at a university. You are tasked with helping a professor design an innovative learning module for a first-year humanities seminar".

Context: The audience is composed of students (18-20 years old) who are very familiar with using generative AIs for their assignments, but who lack a critical perspective on their limitations, biases, and impact on knowledge production.

Mission: Propose a detailed instructional design for a 3-week learning module (approximately 6 hours of student work). The objective is to enable students to transition from a 'naïve' use to a 'critical and informed' use of AI. By the end of the module, they should be able to critically evaluate an AI-generated output and construct an original argument using AI as an assisted research tool, while documenting its limitations.

Your deliverable must include:

1) The learning objectives for the module, drawing inspiration from Dee Fink's Taxonomy of Significant Learning.
2) The pedagogical sequence for the 3 weeks, describing the main activities.
3) The final assessment method that will attest to the 'critical thinking towards AI' competency.
4) Specific suggestions for integrating the principles of Universal Design for Learning (UDL) to make the module accessible and engaging for all students".

Anamel: Children's Psychological and Mental Health Detection Application by Drawing Analysis Based on AI

Amal Alshahrani, Manar Mohammed Almatrafi, Jenan Ibrahim Mustafa, Layan Saad Albaqami, Raneem Abdulrahman Aljabri
College of Computing-Computer Science and Artificial Intelligence Department, Umm Al-Qura University, Mecca, Saudi Arabia

***Abstract*—Psychological and mental health issues affect many people worldwide. However, the impact of these issues is stronger on children starting from early ages until their teenage. Using drawing to analyze and detect such feelings is a common way for specialists to help children express their feelings. Due to that, this study employs artificial intelligence to improve and ease this process by developing an application to help parents and specialists have a first-look analysis of their children's drawings. The Anamel application allows users to go through an experience that simulates clinics and psychological centers by being able to detect several feelings: happiness, sadness, anger, and aggression. Users start by answering pre-questions to collect initial information about the child. Then they can upload the image of the drawing, which is processed using computer vision techniques, where the AI model based on YOLO deep learning architecture provides the analysis results with an accuracy of 94%. Finally, they answer the post questions to ensure the final result. Specialists can also register themselves in the application to allow parents to communicate with them for extra help.**

***Keywords*—Application; mental health; drawings; artificial intelligence; YOLO; deep learning; computer vision; flutter**

I. Introduction

In our fast-paced world, children face many challenges and changes in their daily lives. Understanding children's emotions at an early age is crucial for ensuring their healthy psychological development and preventing future mental health issues.

These challenges have a strong impact on children's feelings and mental health, especially children who cannot express their feelings in words. Due to that, drawing serves as a solution for specialists to analyze, understand, and communicate with each child's thoughts and feelings [1]. However, this manual process is complex and time-consuming for specialists and parents. Although some research has explored emotion detection in children's drawings, practical mobile applications that seamlessly integrate AI models for real-time analysis and user interaction remain very limited.

This study presents an efficient method to overcome these obstacles by providing an AI (Artificial Intelligence) based application to ask, analyze, and help to get the most correct results for children's drawings after training and testing three YOLO (You Only Look Once) models trained on drawings for children in the range of 5 to 15 years old. The YOLO algorithms are known for their great accuracy and speed, which have been proven by several experiments in comparative studies [2]. Because of these benefits, we trained different versions of the YOLO algorithm on our dataset to see the range of results. All the tested models were trained on 500 drawings collected manually by the authors from their surrounding society. The YOLOv8-cls (You Only Look Once Version 8 Classification) model was chosen after a long time of research and work on training and comparing other modern AI models, such as YOLOv9 and ResNet50 [3]. This model reached 94% accuracy after 10 epochs with a compact model size of 2.83 MB, which is suitable for mobile applications. Next, the application interfaces were built using Flutter, connected to Firebase for storing data. Flutter is an open-source UI software development toolkit created by Google. It is used for building natively compiled applications for mobile, web, and desktop from a single codebase [4]. Firebase is a comprehensive app development platform by Google that provides tools to build, improve, and grow apps [5]. By integrating Flutter and Firebase, the trained AI model in TensorFlow Lite format, the system ensures efficient on-device performance suitable for real-world use.

Hence, this study bridges psychology and technology by providing an intelligent, accessible, and reliable tool that supports early emotional assessment and facilitates communication between parents, children, and specialists.

II. Related Work

Despite the significance of drawing analysis in psychological diagnosis, it has not experienced substantial technological advancements. Currently, only one application worldwide is dedicated to the analysis of children's drawings, which is limited in its capabilities [6]. This literature review synthesizes findings from research papers that present studies and applications related to the analysis of children's drawings for diagnosing psychological conditions and mental health. It also includes research papers on the general diagnosis of psychological and mental conditions.

A study [6] proposed creating an application based on artificial intelligence to recognize children's emotions through their drawings. This is due to children experiencing many different emotions, such as happiness, sadness, fear, and feelings that are difficult to express. In the ESRA application that analyzes drawings and classifies them into only two categories: positive and negative emotions, a convolutional neural network model was applied to classify drawings, where three pre-trained models were used to train the model: ResNet18, ResNet34, and

ResNet50. The study conducted four experiments using different combinations of datasets consisting of 102 drawings from a local school and 521 drawings from online sources. The deep learning model trained using the Fastai library in Python classified graphics into positive or negative emotions with an accuracy of between 55% and 79%, and the study stressed the need for further development to improve the accuracy of the artificial intelligence model. With the addition of more feelings and emotions.

Furthermore, the work in [7] focused on analyzing children's drawings to identify potential psychological problems by using a shallow convolutional neural network (CNN) to extract features from drawings, specifically those depicting trees. The model uses a multi-label classification method using the sigmoid function in the fully connected layer. The study included a data set for the school's fifth grade with more than 300 drawings of males and females. The drawings were analyzed based on psychological problems such as anxiety, stress, aggression, division, insecurity, and inability to learn. These problems are identified through a preliminary psychological analysis conducted by psychoanalysts of children's drawings. The classification accuracy using the CNN model in the study reached 70.4%. The study emphasized the importance of early identification of potential psychological problems in children and the potential benefit of the artificial intelligence model in providing an auxiliary diagnosis to psychological counselors.

In the same context of our study, research in [8] explores the potential of using artificial intelligence (AI) to analyze children's drawings for psychological assessment, specifically focusing on the House-Tree-Person Test (HTP). By employing object detection technology, it achieves a mean Average Precision (mAP) of about 92.6% to 94.1%. The resulting psychological analysis table exhibits an average accuracy of 94.4%. This approach aims to overcome limitations in previous classification-based studies, offering a more comprehensive extraction of information from images.

In addition, the work in [9] introduced a database named EMOTHAW that connects emotional states to handwriting and drawing. The database included 129 samples from the participants. The emotional states of the participant, anxiety, depression, and stress, are evaluated using the Depression-Anxiety-Stress Scale (DASS) questionnaire. The data is collected using a digitizing tablet and includes pen positions, time stamps, pressure, pen azimuth, and altitude. The research shows an analysis of the database EMOTHAW using random forests, a machine learning algorithm, to identify features that are indicative of emotional states. The top-ranked features for each emotional state are identified and used to build random forest classifiers associated with each emotional state. The results show that stress and anxiety recognition perform better than depression recognition. The research also provides accuracy, sensitivity, and specificity evaluation measures obtained from cross-validation experiments.

However, the study [10] focuses on testing several methods of image classification, using machine learning and computer vision algorithms to classify DAPT (Draw-A-Person Test) images. A collection of 1000 sketches was collected from primary school students in Nigeria, aged 4 to 11. The sketches are manually classified according to age. The research investigates the possibility of combining sketch recognition with the analysis of cognitive tests. The main reason why the researchers conducted several image classification tests using machine learning and computer vision algorithms is to see if they can develop a model to classify images automatically. The research first conducts a classification test only using the pixel value of the pictures and SVM and ANN to classify them; the accuracy results are 18% and 17%. Then they used HOG (Histogram of Oriented Gradients) to extract features from pictures in all eight datasets, also using SVM and ANN to classify them, and the accuracy ranged from 17% to 48% with SVM trained on the Double_inv dataset obtaining the highest result, showing that the double data performed better. Then they used BoVW and used two different ways to classify the dataset: manual and formal methods. The manual method result reached 54% accuracy and 62% accuracy with the double dataset. The research also shows that a test was conducted using several types of CNN structures and algorithms, with the highest accuracy achieved in this experiment being 62% with the BoVW manual method.

Also, Binti [11] delved into the creation of a sketch recognition tool employing deep learning to observe the psychological growth of children. She collected a dataset of 1,051 children's sketches. The researcher asserts rapid design and prototyping cycles and employed the Rapid Application Development (RAD) approach. The programming language used in this research is Python with the convolutional neural network (CNN) model for image recognition. The highest accuracy achieved is 89%. The research aimed to overcome the limitations and constraints created by manual identification methods and the lack of psychological identification tools for children's mental and emotional development. The research showed that some traditional methods, such as the Drawing Person Test (DAPT) and some other psychological drawing tests, were explored as standard assessment techniques. One of the future recommendations of this research is to develop a user interface for the tool and expand its application in different fields.

Apart from this, Lawrie [12] showed the analysis of children's drawings as indicators of mental well-being, and the main goal of this research is to assess the validity of the emotional indicators themselves as well as the accuracy of LASSO regressions. The dataset used in this research is a set of 453 drawings from the children in India, where 219 households have at least one child with CLP (cleft lip/palate) present, and they were included in the survey sample. Each child was asked to draw a picture of their family and indicate where each family member is. The method used in this research includes manual evaluation for each drawing and assigning a score of 1 to each emotional indicator variable if it is present, but this is a time-consuming process. So, the researcher shows an interest in further research that could use machine learning for analysis and showing signs of emotional distress in the children. Although HFDs are still an important tool, fast and cost-effective for analyzing children’s emotions.

In addition, the work in [13] proposed mental health disorder prediction by a decision support system (DSS) based on AI. The study aimed to find solutions for problems of mental health

assessment tools, which require a long time and have low participation rates. And the results must be analyzed manually by experts. The study found that improving the DSS and the psychological tests by artificial intelligence and advanced analytics is an efficient solution to discover mental problems. Then it used a Network Pattern Recognition (NEPAR) algorithm to build assessment tools, identify the questions for the participants, and reduce the number of questions in the test. Furthermore, they predicted mental issues by training machine learning models with participants' responses to the test and historical data. In conclusion, the results showed that the DSS can automatically diagnose mental disorders using only 28 questions without any human input, with an accuracy level of 89%. That means that this method was successful in developing the DSS that can replace traditional paper-based examinations, decreasing the possibility of missing data for predicting mental disorders. It also has fewer questions than its counterparts, which leads to higher participation and completion rates. Future work for this study is using deep learning models and the Psikometrist framework datasets for further improvement.

Furthermore, research in [14] presented machine learning algorithms for mental health behavioral modeling. The study addressed the challenge of predicting mental disorders of different groups, such as high school students, college students, and working professionals. The common notion between these categories is the stress and depression in daily life that they go through. The study aimed to identify people with mental illness by using machine learning algorithms. At first, they prepared a questionnaire supported by experts. Then, based on the person's score, which depends on his response, his mental health status was predicted. In addition, it used clustering techniques to identify groups and potential classes for further processing, as well as classification algorithms such as SVM, KNN, and Random Forest for finding mental health illnesses. The results were on two target groups in the ages of 18 to 21 years and 22 to 26 years, which showed that SVM, KNN, ensemble (bagging), and tree ensemble (random forest) performed best with 90% accuracy. In conclusion, they successfully developed a framework for discovering the mental health status of people by building prediction models using clustering and classification algorithms. Future work involved more sections of society and more types of mental illnesses. Also, it implied physiological parameters and deep learning methods, such as recursive neural networks, for higher classification accuracy.

Finally, previous research has primarily focused on detecting psychological and mental issues through questionnaires. Only one study has examined emotions in children's drawings, identifying positive and negative feelings. A significant gap remains in the diagnosis of limited mental issues, despite the promising accuracy of detection results.

In summary, previous studies have mainly focused on detecting a limited number of emotions and have achieved moderate accuracy levels. Building on these findings, the Anamel study [2] advanced the field by improving both accuracy and the variety of recognized emotions. However, a remaining gap lies in integrating such models into practical mobile applications for real-world use, a gap that this research aims to address.

III. METHODOLOGY

The Anamel application is designed to analyze children's drawings to help specialists and parents get a better understanding of the children's emotions and psychological states, and to work as a supportive assistant for the specialist. When developing the Anamel application, the starting point was to thoroughly explore various children's drawings to understand the common elements that could indicate different psychological and emotional states. This involved not only collecting a wide range of drawings from different age groups and backgrounds but also exploring existing literature on this subject. To make sure the application is effective, we have been to interviews with child psychologists and specialists who analyze children's drawings professionally. The experts showed invaluable insights into the markers that can be found in the children's drawings. In the interviews, the specialists emphasized an important point, which was the importance of pre-analysis and post-analysis questions. Pre-analysis questions help set the context by understanding the child's environment, recent experiences, and mood at the time of drawing. Post-analysis questions, on the other hand, provide a clear insight after the pre-analysis. These two steps of the questioning process make sure that the assessments made by the Anamel application are both comprehensive and accurate.

IV. WORKFLOW DIAGRAMS

Data Flow Diagrams (DFDs) are important in the Anamel application for mapping out the flow of information inside the system, as shown in Fig. 1. DFDs describe how data transfer between different processes, data stores, and external entities, giving a very high-level overview of the Anamel application's data processing. And in the context of the Anamel application, DFDs represent, for example, how user inputs, such as uploading a child's drawing or answering pre-analysis questions, are processed and analyzed. The DFD diagrams highlight the key data sources and outputs to make sure that all necessary data handling steps are accounted for and correctly implemented.

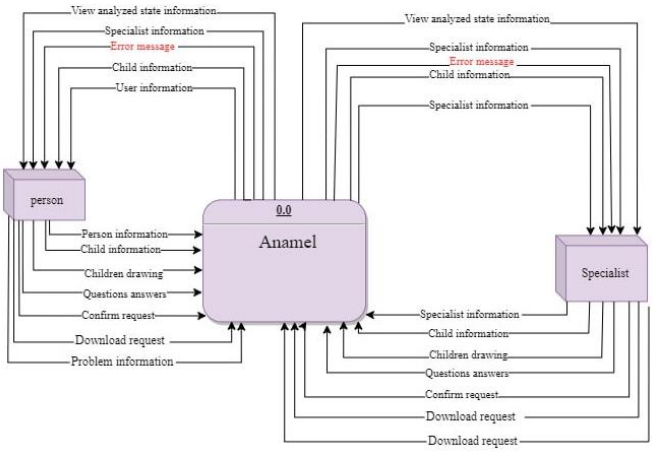

Fig. 1. DFD level 0 diagrams.

The use case diagram for the Anamel system illustrates each task along with the corresponding user, as presented in Fig. 2.

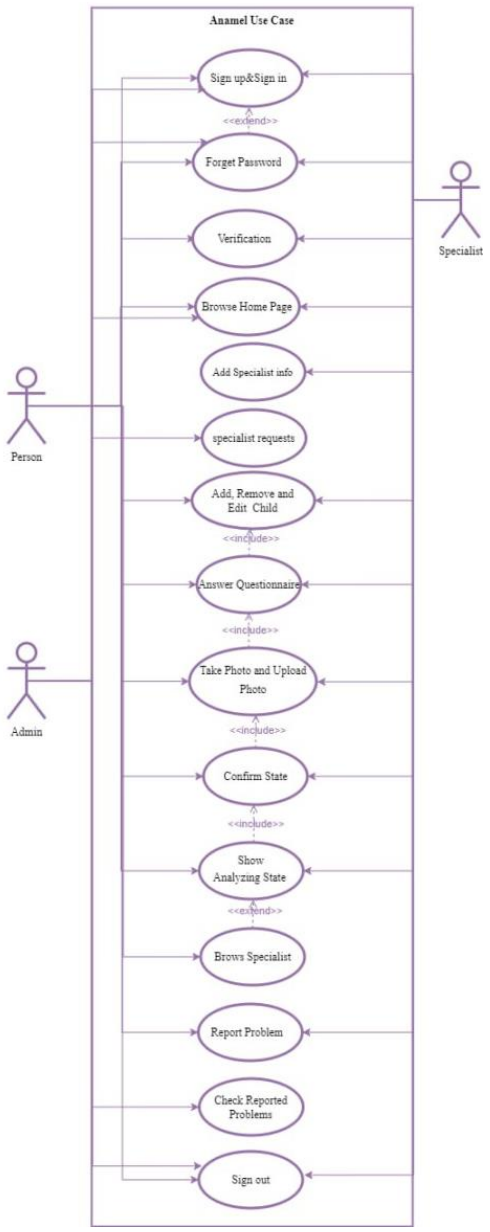

Fig. 2. Use case diagram.

A. AI Model Algorithm Used

In study [2], various versions of YOLO were trained using a dataset comprising 500 drawings is given. The dataset was split into 80% for training, 10% for testing, and 10% for validation. The drawing was annotated with several emotional categories: happy, sad, anxious, angry, and aggressive. YOLOv8-cls showed the best performance, with a high accuracy of 94% and a sample size of only 2.83MB that can be used to build a mobile application.

B. System Architecture

The Anamel system architecture is shown in Fig. 3. To utilize the application, the client first must install it on their mobile phone. Each user walks on a specific path and undertakes designated tasks to achieve the goal of the application, which is the analysis of children's drawings.

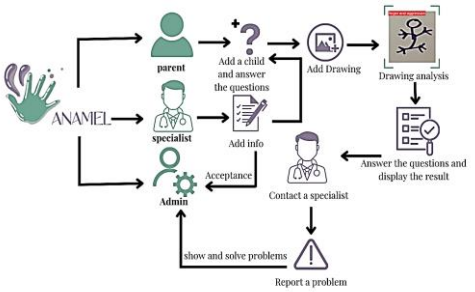

Fig. 3. System architecture.

The MVC diagram in Fig. 4 organizes the code into model, view, and controller, enhancing maintenance and development.

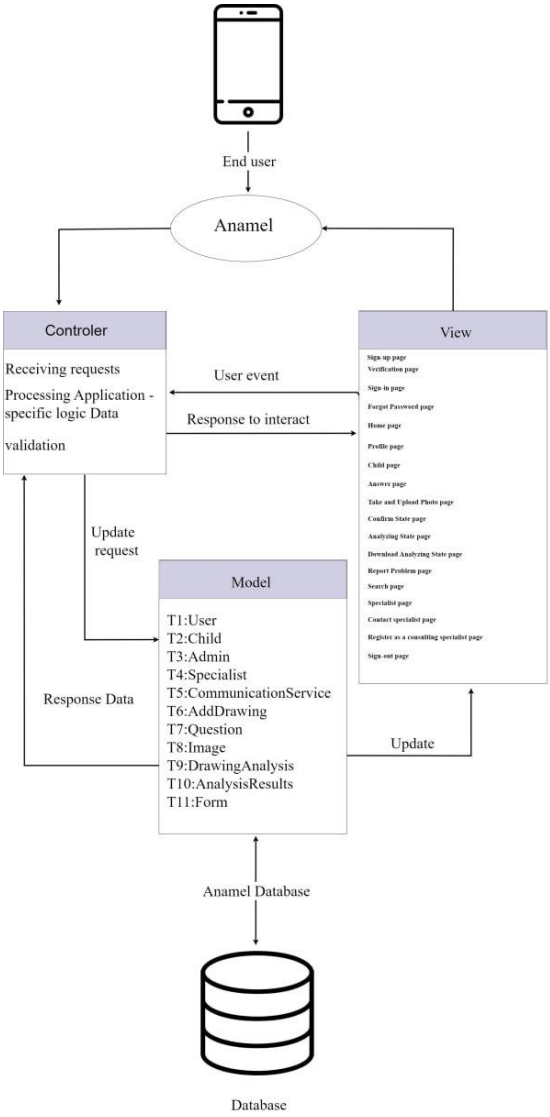

Fig. 4. MVC diagram.

V. Implementation

A. Backend and Frontend Implementation

The interfaces for the Anamel application are designed to visualize the progress and later implement the code and model

using several tools. Initially, Figma, a collaborative web application tool, is used to design and prototype user interfaces. This approach helps create a clear understanding of how the application will be built in a realistic manner.

For the coding process, Flutter, an open-source software development kit (SDK) created by Google, is utilized. Flutter supports the development of mobile, web, desktop, and native applications that run on Android and iOS systems, making the development process more efficient. It is fast, easy, and flexible, leveraging the Dart programming language.

The integrated development environment (IDE) used for building the code is Visual Studio Code, a source code editor from Microsoft. It is lightweight yet powerful and is available on Windows, macOS, and Linux. Using this setup, 30 user interfaces were built, along with basic files and database links. Users can log into the home page, and user data is both written and read effectively and efficiently.

Firebase is also an essential tool in the Anamel application, providing real-time database capabilities and backend services that simplify the development process. It includes features such as Firestore, a flexible, scalable database for mobile, web, and server development, and Firebase Authentication, which handles user authentication and security. These tools ensure data is stored, synced, and retrieved efficiently, enabling seamless integration between the frontend and backend components of the application.

B. Database Implementation

The Anamel application utilizes Firebase, which is a Google cloud computing technology, exclusively designed for applications of mobile and web. Firebase is designed to be a NoSQL database; hence, it stores its data in the document-oriented model. Writing in the back end involves using means to connect to the Firebase database, which supports free sign-in and sign-up through email, which has further capabilities through Cloud Firestore.

Information regarding users is stored and retrieved in the right manner, whereby users can sign in to the site and then be redirected to the home page. Depending on the type of user, different functions are available. More features include the ability to register new children, enable the display of data stored about a child, allow the user to capture new drawings or upload them directly from a camera for the sake of analysis, and display the results of the analysis in a section called ‘results’. A registration form is made available based on the tables to collect specialist information; this information is stored in the application database and can be seen on the ‘Contact Specialist’ page. Moreover, there is a possibility for the user to report previously created issues that are already in the database and put into the administrator’s consideration.

VI. Testing Results

The creation of the “Anamel” application completion marks a significant advancement of the model for analyzing children's drawings [2], which was developed into an application that facilitates the process of analyzing children's drawings in a simple and user-friendly way by integrating it into a mobile application using Flutter. The primary objective was to ensure greater accessibility and usability for specialists and parents after achieving high accuracy and a smaller size for use in the application.

A. Integration for AI Model

Integrating the model [3] into the “Anamel” application was achieved through a series of systematic steps that ensure compatibility and high-efficiency performance within the Flutter framework. This process involved converting the model to tflite format to be suitable for Flutter using flutter_tflite/flutter_tflite.dart for TensorFlow Lite, and image_picker/image_picker.dart for uploading images. The architecture of the application was designed to support efficient image processing and real-time analysis while ensuring an easy and consistent user experience across different devices.

This process consisted of multiple crucial steps:

- Users can capture or upload images using pickImageCamera() and pickImageGallery() , which provided by the ImagePicker library. These images are then processed by the pre-trained TensorFlow Lite model, which is initialized via the tfLteInit() method and performs inference via the runModelOnImage() function.

To further ensure the accuracy of the model, the post-questions were combined with psychological standards approved by psychologists and were integrated into the post-analysis questions:

- After the model analyzes the drawing, users are asked to answer additional questions based on the model's analysis of different emotions, including questions about anger, aggression, anxiety, and sadness, to provide an accurate and integrated experience of the model's results.

B. System Testing

System testing is the level of testing that validates a complete and integrated software product. It checks how components interact with each other and with the system as a whole and performs comprehensive testing of each input into the system to verify the desired output [15]. Anamel was tested using six different scenarios, as shown in Fig. 5 to Fig. 10. A comprehensive test will be carried out to evaluate the application's performance and user satisfaction. The testing strategy included user and functional tests.

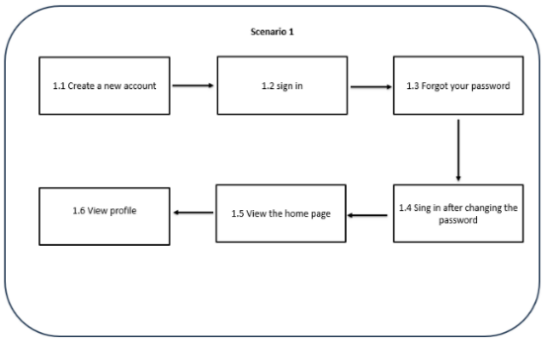

Fig. 5. Scenario 1 for user.

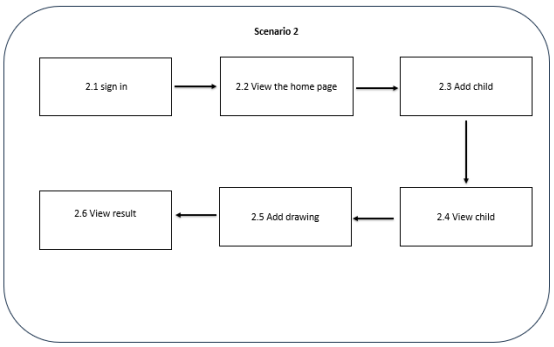

Fig. 6. Scenario 2 for user.

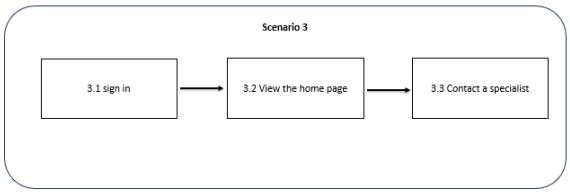

Fig. 7. Scenario 3 for user.

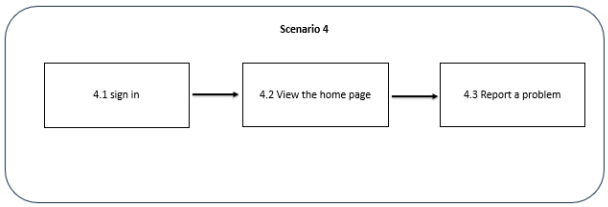

Fig. 8. Scenario 4 for user.

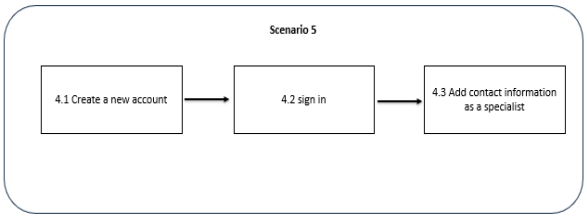

Fig. 9. Scenario 5 for specialist.

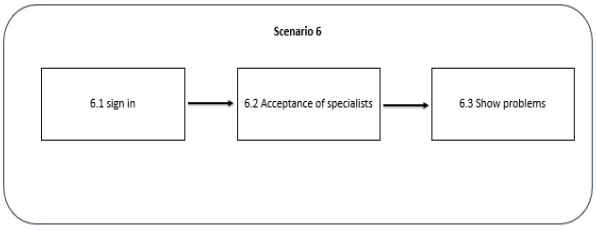

Fig. 10. Scenario 6 for the admin.

C. User Testing

User testing was conducted with a variety of participants to ensure that all features of the application work properly while ensuring how easy and effective the application is to use. A total of 5 users participated in the test, 3 of whom played the role of the parent (user). One specialist and one administrator. Table I summarizes participant information.

TABLE I. SUMMARY OF PARTICIPANT INFORMATION

User Type	Participants information			
	Gender	Job	Educational Level	Experience in Using Technology
Parent 1	Female	Teacher	Bachelor	Advance
Parent 2	Female	Teacher	Bachelor	Normal
Parent 3	Male	Accountant	Bachelor	Advance
Specialist	Female	Psychologist	Master	Advance
Admin	Female	Student	Bachelor	Advance

D. Results

As illustrated in Fig. 11, all detected errors were minor and were related to the front-end component.

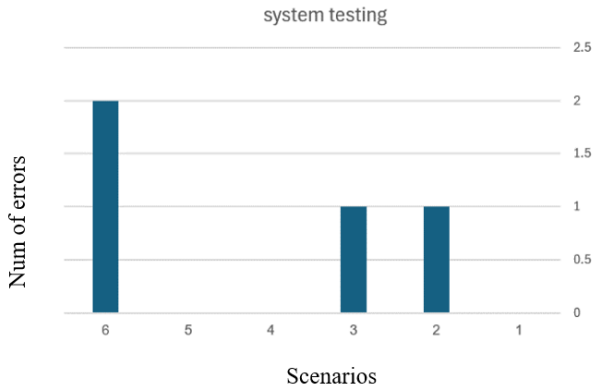

Fig. 11. System testing result.

Following the completion of system testing, these errors were resolved, and the system testing was rerun with no errors detected. Next, each participant was given several tasks to perform, and they were observed during testing. Total time to complete each task for each participant was recorded along with the number of errors for each task.

Parents were asked to perform the following tasks:

- Create a new account
- Sign in and add a child
- Add a drawing, and display the results
- Contact a specialist

The specialist was asked to perform the previous tasks in addition to the following tasks:

- Adding information for communication by users

The admin was asked to perform the following tasks:

- Sign in
- Acceptance of specialists
- Presentation of problems

The user testing phase was divided into three categories: Parents, Professionals, and Admin. Table II summarizes the effectiveness and efficiency of the main tasks performed by each user group.

TABLE II. SUMMARY OF USER TESTING RESULTS

Task	Participants information		
	User Type	*Effectiveness*	*Efficiency*
Create an Account	Parent	Completed without errors	Avg. Time: 1:03 min
Sign In and Add Child	Parent	One user needed assistance	Avg. Time: 1:21 min
Add Drawing	Parent	One user had device issues;	Avg. Time: 1:23 min
Communicate with Specialists	Parent	Completed without errors	Avg. Time: 0:20 min
Add Specialist Information	Specialist	Completed without errors	Avg. Time: 0:12 min
Accept Specialist and Present Problems	Admin	Delayed display problems that did not appear when the button was pressed	Avg. Time: 0:23 min

Overall, the ease of use and effectiveness of the app were tested, with overall user experience across different types of users. Average completion times indicate a smooth user experience. However, issues identified in admin tasks highlight areas that need better improvement for system speed, responsiveness, and functionality, and have been resolved for system efficiency.

VII. CONCLUSION

The development of the Anamel application represents a significant advancement in the intersection of artificial intelligence and child psychology. By transforming the previously developed children's drawing analysis model into an accessible mobile tool, this work bridges the gap between technological innovation and psychological practice. Using the Flutter framework and integrating the YOLOv8-cls model converted into TensorFlow Lite with a 94% accuracy rate [2]. The system achieved efficient on-device analysis suitable for real-world use.

The application architecture, supported by DFD, and MVC diagrams, demonstrates a clear and organized design process. Comprehensive testing involving parents, specialists, and administrators confirmed the reliability, usability, and efficiency of the system. The positive user feedback highlights the potential of Anamel as a supportive tool that can facilitate early emotional assessment and communication between parents and mental health professionals.

Beyond its technical achievements, Anamel contributes meaningfully to mental health technology by offering an innovative, AI-driven approach to emotional detection through children's drawings, an area with limited prior applications.

This study provides a foundation for further research in integrating AI into psychological evaluation tools.

Future work may include expanding the dataset with a larger and more diverse population to improve model generalization, adding more emotional categories, incorporating voice or behavioral data for multimodal analysis, and connecting the app to professional healthcare systems for automated reporting and follow-up.

***Abstract*—Android malware continues to pose significant security threats, with evolving tactics that often bypass traditional detection systems. Existing detection mechanisms remain ineffective against obfuscated or novel malware variants, necessitating the development of more robust detection techniques. This study introduces a comprehensive machine learning framework for Android malware detection that leverages a systematic comparison between a deep Neural Network and diverse ensemble methods, including Voting Ensemble, Stacking Ensemble, XGBoost, and Random Forest. Unlike prior studies that often focus on individual approaches, this work provides an empirical benchmark that demonstrates how practical ensemble configurations can achieve superior performance while maintaining computational efficiency. The model is trained using the CIC-AndMal2017 dataset, incorporating a comprehensive set of static features, including API calls, permissions, services, receivers, and activities. Feature selection was performed to optimize model performance, reducing redundancy and improving detection accuracy. The models were evaluated on multiple classification metrics, including accuracy, F1-score, and confusion matrices, with the Voting Ensemble model achieving an accuracy of 94.14%, outperforming all other approaches, including the deep neural network. This study contributes to the field by demonstrating that a carefully constructed ensemble of diverse classifiers can not only improve detection accuracy but also offer a more scalable, lightweight solution compared to complex deep learning models. The research provides a significant advancement in practical Android malware detection by identifying optimal strategies that balance performance with computational efficiency.**

***Keywords*—Android malware detection; machine learning; API calls; permissions; android security; malware classification**

I. Introduction

The rise of mobile technology has made smartphones integral to daily life, often outpacing desktop systems in user interaction and internet engagement [1]. With vast amounts of sensitive data stored on mobile devices, including login credentials and banking information, they have become prime targets for cyber threats [2]. Android, with an 88% market share, leads the mobile ecosystem and powers billions of devices worldwide [3]. Its open-source nature, while enabling widespread adoption, also increases security vulnerabilities [4]. Its open-source architecture fosters broad adoption due to flexibility, cost-efficiency, and a vast application library. However, this openness also exposes it to heightened security risks, enabling malicious actors to exploit inherent system vulnerabilities and bypass inadequate security checks [5]. Research in Android malware detection has focused on static and dynamic analysis, as well as hybrid approaches [6]. Static analysis is scalable but ineffective against obfuscated malware, while dynamic analysis uncovers runtime threats at the cost of high computational demand. Hybrid methods aim to balance these strengths [7]. Static analysis inspects application code without execution, offering scalability but often failing against obfuscated or polymorphic malware. Conversely, dynamic analysis monitors real-time application behavior in controlled environments, effectively uncovering runtime threats but demanding significant computational resources. Hybrid methods strive to merge the strengths of both, achieving a trade-off between performance and threat coverage [8]. Traditional network intrusion detection systems (NIDS), divided into signature-based, anomaly-based, and hybrid models, also enhance security but face challenges in detecting novel threats [9]. Therefore, the need for intelligent, adaptive, and lightweight malware detection frameworks remains a critical focus in the broader context of Android security.

This work addresses a specific need in the current landscape of Android malware detection research. While previous studies have explored hybrid models that integrate deep learning with complex meta-heuristic optimizations [10, 11], there is a noticeable gap for a clear benchmark comparing a standard deep neural network against more straightforward ensemble constructions like Stacking and Voting. The relative performance of these high-accuracy ensemble methods against a deep learning baseline remains underexplored. Therefore, this study provides a crucial empirical comparison focusing on practical ensemble designs, offering valuable insights into the trade-offs between model complexity and detection performance for real-world applications.

To overcome these challenges, our study proposes an enhanced static analysis framework that uses deep learning and ensemble classification models. This approach leverages static features from the CICAndMal2017 dataset, offering a lightweight, scalable solution that can detect both known and unseen malware with high accuracy and minimal overhead. The main contributions of this study are as follows:

*Corresponding author.

- We propose an enhanced Android malware detection framework that integrates deep learning (neural network) and ensemble techniques (stacking and voting) to improve detection accuracy using static features, without the need for runtime analysis.
- Extensive experimentation is performed using the publicly available CICAndMal2017 dataset, ensuring a realistic and diverse malware landscape. This dataset enables the extraction of meaningful static features that are representative of modern Android threats.
- Our results indicate that ensemble models, particularly the Voting Ensemble, outperform both traditional machine learning classifiers and standalone deep learning models, demonstrating improved detection performance and robustness.
- We provide a comparative analysis with baseline models, including Random Forest, XGBoost, and Neural Networks, highlighting the advantages of ensemble approaches in terms of accuracy, precision, and generalization for Android malware detection.

This study is organized in the following way: Section II looks at the current research on finding Android malware. It examines the evolution of methodologies from conventional machine learning to contemporary deep learning and hybrid ensembles. Section III goes into detail about the proposed framework. It includes a description of the CICAndMal2017 dataset, the steps for static analysis and feature extraction, and the setup of the learning algorithms that were tested. Section IV provides an extensive performance evaluation of the tested classifiers, including Neural Networks, Random Forest, XGBoost, and a Voting Ensemble, and examines the results that illustrate the ensemble's superiority. In Section V, the study comes to a close by listing the main contributions and suggesting some possible directions for future work on making malware detection technologies that are both effective and flexible.

II. Related Work

The detection of Android malware has become a critical research focus due to the evolving complexity of malicious applications and their capacity to bypass conventional security mechanisms. To address these challenges, researchers have explored a range of approaches, including traditional machine learning, which involves selecting suitable classifiers for malware detection; feature engineering, which focuses on extracting and optimizing informative attributes; and ensemble learning, which integrates multiple models to enhance predictive accuracy and resilience. These techniques are applied within static, dynamic, or hybrid analysis frameworks and are generally categorized as signature-based or anomaly-based, depending on whether they rely on known attack patterns or behavioral deviations. Table I provides a consolidated summary of representative studies, outlining their methodologies, datasets, detection types, performance levels, and associated drawbacks.

TABLE I. Summary of Literature Review

Ref.	Approach	Feature Type	Detection Type	Methodology	Dataset Used	Reported Accuracy	Drawbacks
[11]	ML (DT, RF)	Permissions	Static	Decision Tree, Random Forest	Custom datasets	90%	Weak against zero-day; limited feature diversity
[20]	ML	Permissions	Static	Permission-based filtering	Custom dataset	81%	Insufficient as standalone; poor detection precision
[21]	ML (kNN)	Permissions, API, Intents	Static	DroidMat with kNN	Not specified	Not reported	Scalability issues; weak base learner
[22]	API Monitoring	API Calls	Dynamic	Logcat instrumentation	Custom dataset	Not reported	Resource-intensive; not scalable for large datasets
[23]	ML (Permissions + API)	API + Permissions	Static	Feature fusion with ML classifiers	Not specified	Not reported	Limited generalization; lacks robustness
[12]	ML (SVM)	Permissions	Static	Reduced feature SVM	Custom dataset	93.62%	Vulnerable to obfuscation; limited feature scope
[24]	ML (Opcode Transformation)	Dalvik Opcodes	Static	Grayscale opcode images + ML	Custom dataset	91% (RF)	High dimensionality; scalability issues
[13]	ML (Dynamic Features)	CPU, Memory, Network	Dynamic	SVM on Drebin resource metrics	Drebin dataset	94.2%*	Computationally expensive; impractical for real-time use
[17]	Ensemble + Optimization	Static	Static	OEL-AMD (BGWO + Ensemble)	Not specified	92.4%	High complexity; feature selection overhead
[25]	Graph-Based ML	API Dependency Graphs	Static	DroidSIFT – graph similarity	Genome	93%	Heavy preprocessing; computationally expensive
[21]	Dynamic Analysis Tools	API, Sys Calls, NetFlow	Dynamic	DroidBox, CopperDroid, AMAT	Sandbox datasets	Not reported	Susceptible to anti-emulation evasion

Machine learning has arisen as a potent method to address the shortcomings of conventional signature-based detection, facilitating the recognition of new and obscured malware. Various classifiers and feature sets have been employed, each offering unique strengths but facing specific challenges. Permission-based detection is one of the earliest lightweight methods. Aung et al. [12] used Decision Trees and Random Forest on permissions (~90% accuracy) but with weak zero-day resistance, while Huang et al. [13] found permissions effective as a quick filter (81%) though insufficient as a standalone solution. To improve robustness, DroidMat [14] combined permissions, API calls, and intents using kNN, though

scalability issues remained. Nishimoto et al. [15] proposed logcat-based API monitoring to track sensitive invocations, which detected obfuscation but required heavy resources. Chan and Song [16] showed that permissions combined with selected API calls improved accuracy over single features. Similarly, Li et al. [17] applied SVM on reduced permission sets with 93.62% accuracy, but a limited feature scope reduced robustness. More advanced representations were explored by Anderson et al. [18] , who transformed Dalvik op-codes into grayscale images for classification (91% with RF), though dimensionality hindered scalability. Massarelli et al. [19] employed dynamic resource usage metrics with SVM (94.2%), but such runtime analysis introduced computational overhead, limiting real-time use.

Ensemble learning and hybrid models aim to improve detection rates and reduce false positives by combining the strengths of multiple classifiers or methodologies. Ensemble learning aggregates predictions from several base models to produce a more accurate and robust result, while hybrid models integrate static and dynamic detection techniques or metaheuristic algorithms with machine learning. Optimized Ensemble Learning for Android Malware Detection OEL-AMD, proposed by Sharma et al.[10], OEL-AMD, which used Binary Grey Wolf Optimization (BGWO) for feature selection and ensemble classification, achieved 92.4% accuracy with fewer false positives. Sharma and Agrawal et al. [11] developed a hybrid model combining the Intelligent Water Drop (IWD) algorithm with deep learning, reaching 94.5% accuracy while preserving key features. Droid SIFT [20] introduced weighted contextual API dependency graphs for classifying unknown apps, obtaining ~93% accuracy on the Genome dataset, though at a high computational cost. Tools like Droid Box, Copper Droid, and AMAT [21] used sandbox-based behavioral analysis, but their effectiveness is limited due to anti-emulation tactics, such as Telephony Manager checks, exploited by Pincer malware [22].

Feature engineering and selection methods have been widely used to enhance classification efficiency. Li et al. [23] introduced Significant Permission Identification (SigPID) to prune redundant permissions, improving performance. Bhagwat and Gupta [24] applied PCA and mutual information to reduce dimensionality while retaining informative features, achieving 92.8%. Advanced optimization techniques like Harris Hawks Optimization (HHO) and Genetic Algorithms (GA) [25] further refined feature subsets for classification. Beyond malware-specific studies, clustering-based methods also contribute to feature optimization. The Enhanced Gap Statistic (EGS) [26] improved optimal cluster determination by standardizing reference data. The Kernelized Rank Order Distance (KROD) method. In [27], the authors transformed non-spherical data into spherical form, enhancing clustering accuracy. An improved EGS variant [28] incorporated Gaussian standardization, outperforming classical clustering methods on large datasets. A modified cubic B-spline method [29] offered better error estimates in curve fitting, while a combined approach [30] integrated winsorization, KROMD, and enhanced gap statistic to improve K-means clustering stability. A comprehensive evaluation [31] of the Gap Statistic revealed efficiency on simple datasets but weaknesses on complex, high-dimensional data. Together, these studies emphasize the importance of clustering and optimization for improving feature selection and dimensionality reduction in malware detection pipelines.

Deep learning models have gained increasing attention due to their ability to automatically learn complex feature relationships and uncover hidden patterns in large-scale malware datasets. Unlike traditional ML methods that rely heavily on handcrafted features, deep learning can extract hierarchical representations directly from raw or transformed data, making it well-suited for detecting obfuscation and polymorphic malware. Kim et al. [32] applied a CNN on API call graphs, achieving 96.2% accuracy and demonstrating effectiveness in detecting behavioral patterns. Fallah and Bidgoly [33] employed LSTMs to classify malware families based on temporal network traffic data, reaching 94% accuracy. While deep learning improves adaptability and accuracy, challenges remain regarding computational cost and interpretability, limiting deployment on resource-constrained devices. More recently, a survey by Kouliaridis and Kambourakis et al. [34] confirmed the effectiveness of ensemble models for Android malware detection, particularly with modern datasets. This supports our methodological choice of employing ensemble techniques on the CIC-AndMal2017 dataset. Furthermore, a comprehensive review by Liu et al. [35] synthesizes the landscape of machine learning-based detection, underscoring the persistent challenge of balancing model performance with computational efficiency, a key gap our research addresses by demonstrating the efficacy of practical ensemble methods.

In summary, prior studies demonstrate the evolution of Android malware detection from lightweight ML classifiers to advanced ensembles, feature engineering, and deep learning methods. However, existing approaches face trade-offs between scalability, accuracy, and robustness. These gaps highlight the need for an enhanced framework that leverages deep learning combined with ensemble techniques to achieve reliable, efficient, and scalable Android malware detection.

III. METHODOLOGY

The experimental framework established in this study is designed to construct a robust Android malware detection system. The procedure commences with dataset curation and preprocessing, advances through a critical feature selection process, and proceeds to the training phase of ensemble models (Voting and Stacking) and Neural Networks. The concluding phase entails a thorough performance assessment to verify the detecting capabilities. Fig 1 presents an illustrated overview of an end-to-end process.

A. Dataset Collection and Preprocessing

The efficacy of any machine learning model depends on the quality and diversity of the training dataset. In this study, we utilized the CIC-AndMal2017 dataset, a robust and comprehensive collection of labeled Android applications. This dataset serves as the cornerstone of our Android malware detection system and provides the foundation for building and evaluating the models. The dataset is rich with real-world samples, including both benign and malicious applications, which is essential for developing a model that can generalize

well to new, unseen data. The process began with collecting and preparing the data. Unlike other datasets, which often consist of a limited set of features, the CIC-AndMal2017 dataset includes a wide variety of attributes. These features cover different aspects of Android application behavior and functionality, making it a comprehensive source for malware detection.

The CIC-AndMal2017 [36] dataset serves as the cornerstone of our Android malware detection system. It includes thousands of labeled APKs categorized into benign, adware, scareware, and SMS malware. These categories encompass a broad spectrum of practical applications and malware, guaranteeing varied and comprehensive training and testing data. Benign apps act as a baseline, representing non-malicious behavior, while adware apps disrupt user experience with intrusive ads. Scareware tricks users into harmful actions, and SMS malware exploits SMS functionality to send unauthorized messages or steal personal data. Together, these categories provide the foundation for an effective and comprehensive malware detection model, as summarized in Table II.

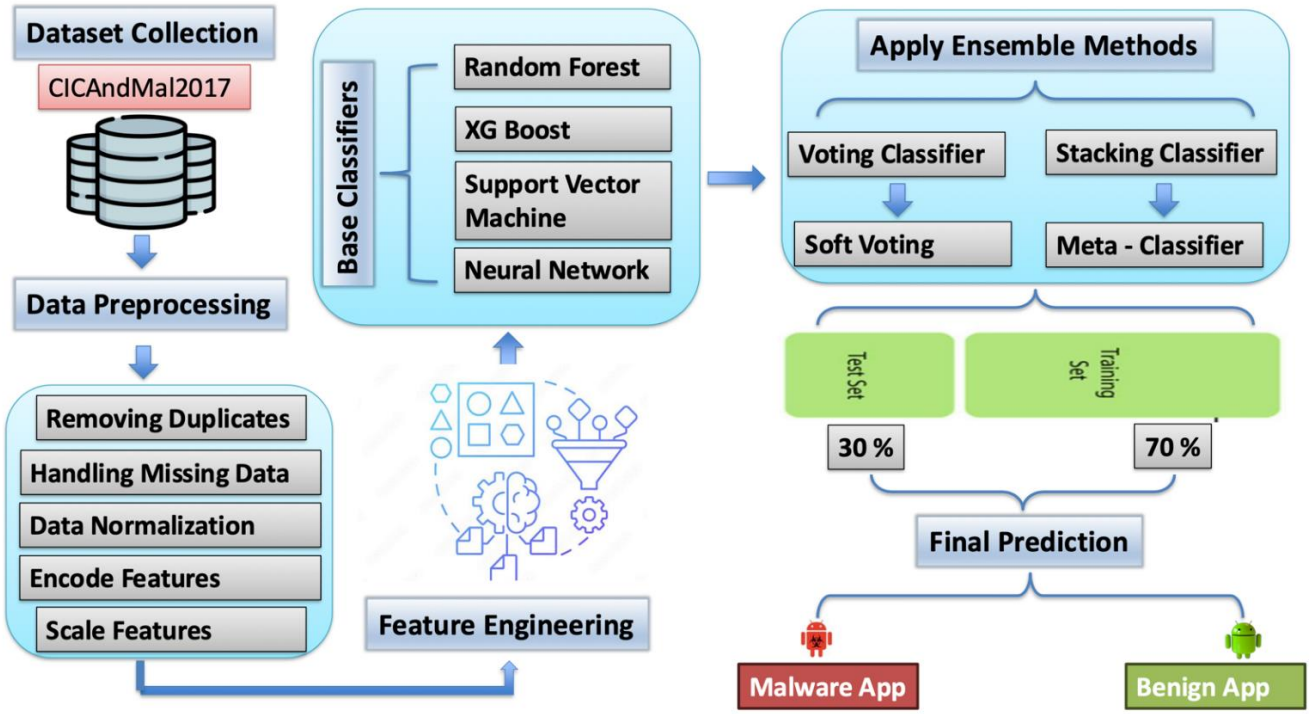

Fig. 1. Proposed methodology framework.

TABLE II. DESCRIPTION OF THE CATEGORIES IN THE CIC-ANDMAL2017 ANDROID MALWARE DATASET

Category	Description
Benign Applications	Non-malicious apps that serve as a baseline for comparison.
Adware	Apps designed to display intrusive advertisements, often affecting user experience and consuming resources.
Scareware	Apps that use deceptive tactics to manipulate users, such as creating false alerts or urging unnecessary purchases.
SMS Malware	Apps that exploit SMS functionality for malicious purposes, like sending unauthorized messages or stealing data.

The dataset is well-balanced, with the number of benign and malicious apps being approximately equal, ensuring that the model is trained on a balanced representation of both classes. The dataset provides 900+ samples, which are ideal for training machine learning models that need to generalize well on real-world data. To prepare the data for machine learning model training, several preprocessing steps were undertaken to ensure that the features were clean, standardized, and ready for use. These steps included:

1) Label Encoding: All categorical variables, such as feature labels and app categories, were encoded into numeric values using Label Encoder from scikit-learn. This transformation was essential to make the data compatible with machine learning algorithms.

2) Feature scaling: Numerical features were standardized using StandardScaler to ensure that all features were on the same scale. This is crucial to avoid biases in model training, especially when certain features may have larger magnitudes than others.

3) Handling missing data: Any missing or incomplete entries were handled through imputation or removal, ensuring no gaps in the dataset that could affect the model's performance.

The models were trained on a 70% subset of the data, with the remaining 30% held out as a test set. This hold-out method is crucial for validating predictive performance and ensuring the models can generalize beyond the data they were trained on.

B. Feature Extraction

The Feature extraction is essential for transforming raw APK data into structured input for machine learning models. In this study, we extracted key features from the CIC-AndMal2017 dataset, including API calls, permissions, services, receivers, and activities. These features play a critical role in distinguishing between benign and malicious applications.

- API Calls: Methods invoked by the application during runtime, reflecting interactions with the system. Categorized into android_api, com_api, and java_api sets.
- Permissions: Requested access rights by the app, such as accessing the location or sending SMS messages, which may indicate potential malicious activity.
- Services: Background tasks run by the app, often indicating persistent behavior associated with malicious activity.
- Receivers: Components that listen for system or app-level events, often exploited by malware for covert operations.
- Activities: UI components that define user interactions, providing insight into the app's intent.

These extracted features were stored in JSON format, where each APK was represented as a file containing metadata and features. The dataset was organized into several configurations for model training:

- API + Permissions + Services data: A comprehensive dataset integrating all three feature types.
- API + Permissions data: Focused on API behavior and requested permissions.
- API + Services data: Examining API interactions alongside background services
- Permissions + Services data: Exploring the link between permissions and background behavior.
- API data alone: Isolated API calls to assess their standalone predictive power.

These datasets were stored as CSV files for efficient processing. The extracted features are summarized in Table III, while their distribution across different application types is shown in Table IV. These tables offer clarity on the features used for model training and their relevance for Android malware detection.

TABLE III. SUMMARY OF EXTRACTED FEATURES

Feature	Definition	Example
Permissions	Privileges requested by the app to access system resources	ACCESS_FINE_LOCATION
API Calls	Methods invoked during runtime	java.net. HttpURLConnection
Services	Processes running in the background	android.app.Service
Receivers	Components listening for broadcasts	android.content.BroadcastReceiver
Activities	Screens/interfaces of the application	android.app.Activity

TABLE IV. FEATURE COUNTS FOR DIFFERENT APK TYPES

APK Type	Permissions	APIs	Services	Receivers	Activities
Benign	636	202820	1837	1514	11063
Adware	320	14560	920	800	2300
Scareware	200	10234	700	400	1200
SMS Malware	150	9000	500	300	1000

C. Feature Selection Using Correlation Analysis

Feature selection is a critical step in enhancing the performance of machine learning models by reducing the dataset's complexity while retaining the most relevant features. In this study, we selected features from the CIC-AndMal2017 dataset that would most effectively help distinguish between benign and malicious applications. The selection process focused on API calls, permissions, services, receivers, and activities, which together represent the application's behaviour and intent. To identify the most relevant features, we used the Pearson correlation coefficient to measure the linear relationship between each feature and the target variable (malicious = 1, benign = 0). The Pearson correlation coefficient is calculated using the formula:

$$r_{xy} = \frac{\sum_{i=1}^{n}(x_{ij}-\overline{x_j})(y_i-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_{ij}-\overline{x_j})^2 \sum_{i=1}^{n}(y_i-\bar{y})^2}} \quad (1)$$

where,

- x_{ij} is the value of feature x_j for sample i,
- y_i is the target label for sample i,
- $\overline{x_j}$ and $\bar{y}$ are the means of feature x_j and target label y.

This approach allowed us to measure the correlation between each characteristic and the target variable, helping us determine which features were most strongly associated with detecting malicious behavior.

Features with a correlation of $|r_{xy}| < 0.3$, indicating weak correlation with the target label, were excluded from further analysis. These features, such as services and receivers, showed minimal ability to distinguish between benign and malicious applications, and therefore did not contribute significantly to the classification task. On the other hand, features with stronger correlations, primarily API calls and permissions, were retained for training the model. These features demonstrated a high correlation with the target label, providing critical information to accurately classify applications as either benign or malicious. By focusing on these highly relevant features, we ensured the model was trained on the most meaningful data, enhancing its ability to make accurate predictions.

D. Model Training and Evaluation

This study utilized various machine learning models to categorize Android applications as benign or harmful. The models used include Voting Ensemble, Stacking Ensemble, and Neural Networks, which were all trained and evaluated using the extracted features from the CIC-AndMal2017 dataset. Each model was selected for its capacity to manage high-dimensional datasets and its resilience in practical application contexts. The initial phase of model construction involved partitioning the dataset into training and testing subsets. The dataset was divided into 70% for training and 30% for testing, ensuring that the models were trained on a significant volume of data while maintaining a distinct set for impartial performance assessment. We employed a scaled dataset for model training, applying StandardScaler to both the training and test sets to standardize all characteristics. The models were trained using the following approach:

1) Neural network model: The Neural Network was constructed with a sequence of fully connected (Dense) layers, utilizing ReLU activation functions. To enhance training stability and prevent overfitting, batch normalization and dropout layers were strategically incorporated. A final output layer with a sigmoid activation function was employed for the binary classification task (benign versus malicious).

2) Voting ensemble: The Voting Ensemble integrates predictions from several heterogeneous base estimators, including Random Forest, XGBoost, and Linear Models. It operates on a "soft voting" principle, where the final prediction is derived by averaging the class probabilities output by each constituent model, thereby leveraging the collective wisdom of the ensemble.

3) Stacking ensemble: A Stacking Ensemble was implemented to synthesize the capabilities of diverse base classifiers. The predictions from these base models serve as input features for a meta-classifier, which was configured as a Logistic Regression model in this work. This two-tiered architecture aims to learn how to best combine the base models' outputs to achieve a more accurate and robust final prediction than any single model could provide.

Each model was trained with a fixed number of epochs for the Neural Network model (50 epochs), while the ensemble models used the default settings for their classifiers.

E. Hyperparameter Tuning and Evaluation Metrics

To ensure optimal performance, hyperparameters were tuned for each model. In particular, the Random Forest model within the ensemble classifiers was configured with:

Number of trees ($n_{estimators}$): 100.

Maximum depth: No limit to tree depth.

Minimum samples per split: 2.

Minimum samples per leaf: 1.

These settings were selected to avoid overfitting, while maintaining model complexity to capture meaningful patterns from the data. The XGBoost model was also fine-tuned with a learning rate of 0.1 and a max depth of 6, aiming to balance model complexity and generalization.

Each trained model's performance was assessed using a set of classification measures, including the Confusion Matrix, Accuracy, Recall, Precision, and F1-Score. These measures evaluate each model's capacity to distinguish between benign and malicious applications, with a particular focus on the F1-Score due to its resilience in addressing class imbalances.

Accuracy: Measures the overall correctness of the model by evaluating the proportion of correctly classified instances out of the total samples. It is calculated as:

Accuracy:

$$\frac{TP+TN}{TP+TN+FP+FN} \tag{2}$$

Precision: Evaluates how many of the predicted malicious applications are malicious. A higher precision score indicates fewer false positives. It is computed as:

Precision:

$$\frac{TP}{TP+FP} \tag{3}$$

Recall (Sensitivity): Determines the model's ability to correctly identify malware by measuring how many actual malicious applications were detected. It is given by:

Recall:

$$\frac{TP}{TP+FN} \tag{4}$$

F1-Score: A mean of precision and recall that balances false positives and false negatives. It is particularly advantageous when the dataset exhibits inequality. The formula is:

F1-Score:

$$2 \times \frac{precion \times sensitivity}{precion + sensitivity} \tag{5}$$

This methodology utilizes a Voting Ensemble, Stacking Ensemble, and Neural Networks to detect Android malware, with feature selection based on all available features, including API calls, permissions, services, receivers, and activities. Unlike previous approaches that focused on a subset of features, this

study leverages the full spectrum of extracted features to train the models. By incorporating all relevant attributes, the approach ensures a comprehensive analysis of Android application behavior, leading to enhanced model performance and accuracy. The models effectively handle high-dimensional data, improving classification results while minimizing computational complexity.

IV. Results and Discussion

In this section, we present the findings of the models assessed for malicious application detection, along by a comprehensive explanation of their performance. The models, comprising Voting Ensemble, Stacking Ensemble, XGBoost, Neural Networks, and Random Forest, were assessed utilizing conventional classification metrics. A comparison analysis was conducted to elucidate the advantages and drawbacks of each model.

A. Experimental Setup

The studies utilized the CIC-AndMal2017 dataset, comprising labeled Android applications classified as benign or malicious, including adware, scareware, and SMS malware. The dataset was pre-processed and divided into training (70%) and testing (30%) subsets. The features for classification included API calls, permissions, services, receivers, and activities, which were extracted from the dataset and encoded for use in machine learning models. The models were assessed using standard classification metrics to determine their capability to differentiate between benign and malicious apps.

B. Model Training and Evaluation

We trained five different models that we exercised during the training process. The selection of these models was predicated on their shown efficacy in managing complicated, high-dimensional datasets. Accuracy, precision, recall, and F1-score were the metrics that were utilized to assess the performance of each model. The results from these examinations are described in Table V.

TABLE V. Evaluation Metrics for All Models

Model	Accuracy	Precision (Benign)	Precision (Malware)	Recall (Benign)	Recall (Malware)	F1-Score (Benign)	F1-Score (Malware)
Random Forest	91.21%	0.92	0.89	0.94	0.85	0.93	0.87
Neural Network	92.67%	0.94	0.89	0.94	0.89	0.94	0.89
XGBoost	93.41%	0.94	0.92	0.96	0.88	0.93	0.90
Stacking Ensemble	93.77%	0.94	0.92	0.94	0.92	0.94	0.91
Voting Ensemble	94.14%	0.95	0.93	0.97	0.89	0.96	0.91

As shown in Table V, Voting Ensemble achieved the highest accuracy (94.14%), closely followed by the Stacking Ensemble (93.77%) and XGBoost (93.41%). The Neural Network model achieved a slightly lower accuracy of 92.67%, but it showed promising results in terms of recall for both classes, indicating its good generalization ability for classifying both safe and harmful applications. The Random Forest model, while robust, lagged slightly behind the other models in terms of overall accuracy and F1-score.

C. Model Performance and Discussion

Voting Ensemble demonstrated superior performance, achieving the highest accuracy and F1-score. This model combined multiple classifiers, which likely contributed to its robust performance across both benign and malicious classifications. Its high recall for benign applications (0.97) indicates that it was highly effective at correctly identifying non-malicious apps, minimizing false negatives.

Stacking Ensemble performed similarly to the Voting Ensemble, with only a slight reduction in accuracy and F1-score. This model combines base classifiers to improve prediction accuracy, and its balanced performance across both precision and recall suggests that it effectively handled the trade-off between false positives and false negatives.

XGBoost, recognized for its efficacy and performance, achieved 93.41% accuracy. While it had comparable results to the Random Forest model, its lower precision for malware (0.92) compared to Voting Ensemble indicates that XGBoost may have struggled more with correctly classifying some malicious apps.

Neural Networks were a strong performer in terms of recall, particularly for malware detection (0.89). However, their lower precision and accuracy in comparison to ensemble methods suggest that they may not be as reliable for this task without further hyperparameter tuning and training.

Random Forest, despite being a widely used model for classification tasks, achieved the lowest accuracy in this experiment (91.21%). While it performed well on benign applications (precision = 0.92 and recall = 0.94), it faced challenges in classifying malware, particularly in reducing false negatives.

D. Confusion Matrix

A comprehensive assessment of model performance was conducted utilizing confusion matrices. These matrices facilitated the evaluation of false positives and false negatives in the predictions of each model. Below is a confusion matrix for the Voting Ensemble model, Fig. 3 offering a visual picture of the model's efficacy in differentiating between benign and malicious applications. The Voting Ensemble model effectively reduced both false positives and false negatives, demonstrating its durability and calibration. To further demonstrate the performance of the models, Fig. 4 presents confusion matrices for the individual models, including Neural Network, Stacking Ensemble, Random Forest, and XGBoost.

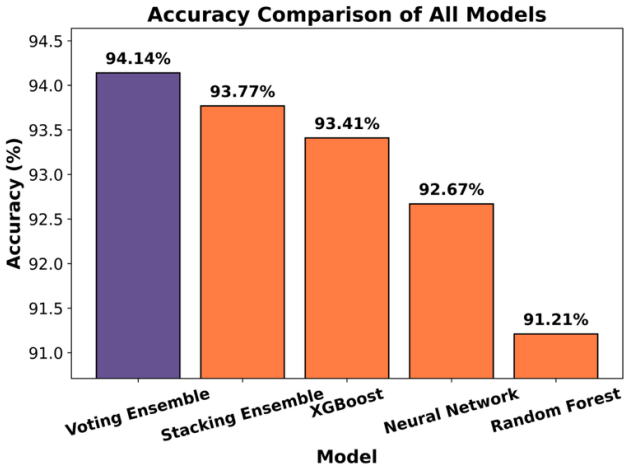

Fig. 2. Model accuracy comparison.

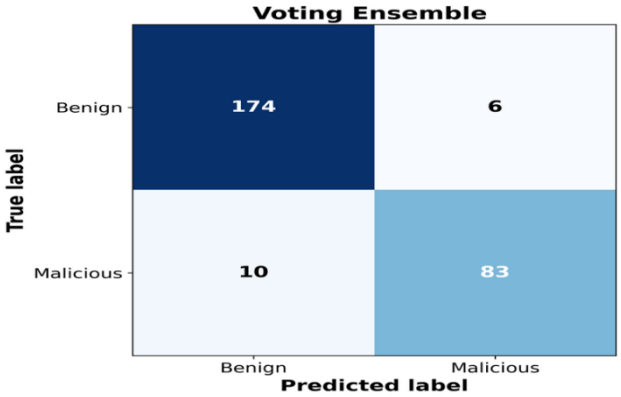

Fig. 3. Confusion matrix for voting ensemble.

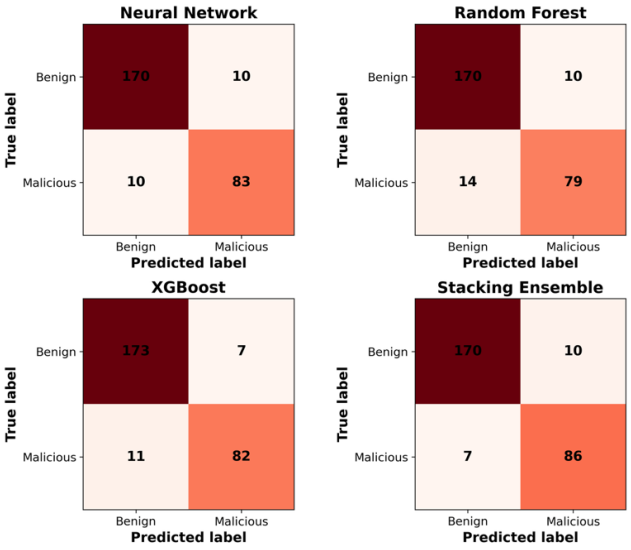

Fig. 4. Comparison of confusion matrices for different models.

E. Precision and Recall Curves

Fig. 5 illustrates the ROC (Receiver Operating Characteristic) Curves for all the models evaluated in this study. The ROC curve plots the True Positive Rate against the False Positive Rate across various thresholds, helping to visualize the trade-offs between correctly identifying benign and malicious applications. The Area Under the Curve (AUC), derived from the ROC, quantifies the model's ability to distinguish between the two classes; a higher AUC indicates better discriminatory power. The curves allow for a deeper understanding of each model's performance beyond simple accuracy by demonstrating how well the model can maintain a balance between sensitivity (correctly identifying malicious apps) and specificity (minimizing false positives) under different conditions. Models with higher AUC scores are generally more robust and better at generalizing across varying thresholds, as shown in the figure.

Additionally, Fig. 6 presents the Precision-Recall Curves for each model, highlighting how well the models balance precision and recall, particularly for the malware class. These curves further emphasize the strengths and weaknesses of each model in distinguishing between benign and malicious applications.

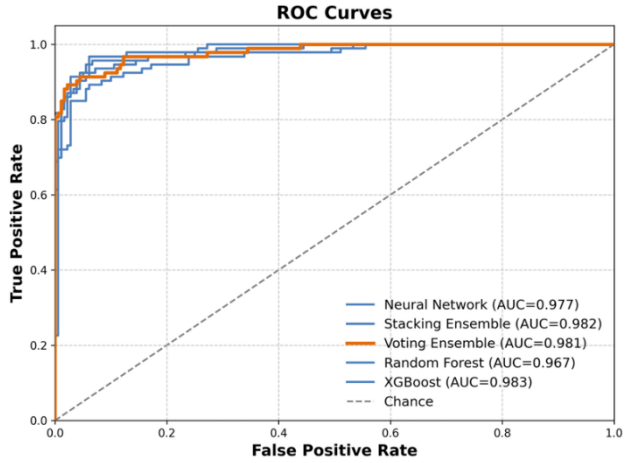

Fig. 5. ROC curves of all the models.

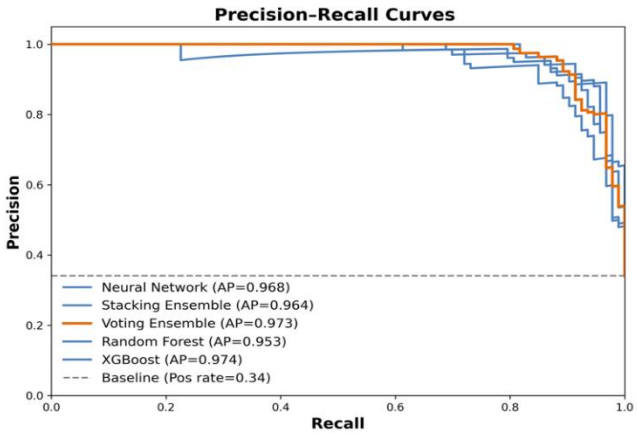

Fig. 6. Precision-recall curves.

F. Comparison with Previous Work

To further validate the effectiveness of our approach, we compared the performance of our models with recent studies in the field of Android malware detection. The following Table VI summarizes the accuracy and features used in several recent papers. While Fig. 2 presents a visual comparison of the detection accuracy across all models, highlighting the superior performance of the proposed ensemble-based approach.

TABLE VI. COMPARISON WITH EXISTING METHODS

Model	Accuracy	Dataset	Features Used	Year
Voting Ensemble (Proposed)	94.14%	CIC-AndMal2017	API Calls, Permissions, Services, Receivers, Activities	2025
Random Forest [37]	93.0%	Drebin	Permissions, Intents	2020
AdaBoost, k-NN, LR, NB [38]	91.7%	AndroZoo	Permissions, Intents,	2021
RF, KNN and DT [39]	84.14%	Custom dataset (300 benign, 183 malware)	Dalvik op-codes as grayscale images	2018
SVM[40]	91.7%	AndroZoo	Permissions, Intents	2021
StormDroid [41]	93.80%	Google Play, Contagio	Permissions, API Calls, sequences	2016

The comparative evaluation summarized in Table VI positions the proposed method within the broader context of existing research, highlighting its relevance and contribution to the field. Although direct accuracy comparisons are limited by the diversity of datasets and evaluation benchmarks across studies, the value of this work lies not solely in its high accuracy but in the methodological framework that enabled it. Unlike several high-performing approaches that depend on complex sequential architectures [41], meta-heuristic feature selection strategies [10], or hybrid deep learning frameworks [11], the proposed Voting Ensemble demonstrates that state-of-the-art performance can be achieved through a simpler and more reproducible methodology. This finding highlights an important insight: a carefully constructed ensemble of standard classifiers can serve as an efficient and practical alternative to more intricate and computationally demanding solutions, offering an optimal balance between performance, complexity, and practicality.

V. CONCLUSION

This study proposed a scalable framework for Android malware detection using static analysis of application features, including API calls, permissions, services, receivers, and activities. Through a comprehensive comparative analysis, we demonstrated that practical ensemble methods, particularly the Voting Ensemble, can achieve state-of-the-art accuracy (94.14%) while outperforming a more complex deep neural network. This finding is a key contribution, as it challenges the assumption that increasingly complex models are always necessary for high performance, offering a more lightweight and interpretable alternative. However, due to its reliance on static analysis, this approach is limited against advanced threats employing dynamic code loading or runtime evasion techniques. This limitation precisely defines the research gap our future work will address. The practical significance of this work lies in providing a highly effective and deployable solution for many real-world scenarios where computational resources are constrained. Future research will focus on integrating dynamic behavioral features, such as runtime API sequences and network traffic analysis, to create a hybrid detection framework. Exploring other ensemble strategies and adapting the model to detect zero-day malware through continual learning will also be critical. By building upon this foundation, we aim to develop even more resilient and adaptive security solutions capable of countering the evolving mobile threat landscape.

***Abstract*—Secure and high-capacity data concealment has already become a requirement of modern multimedia communication, particularly with the enhanced protection and privacy levels of concern. The framework introduced in this study—the improved Dual-Attention ResUNet-GAN—helps optimize the trade-off among imperceptibility, robustness, and payload capacity in the field of image steganography. The two PatchGAN discriminators used in the model were a visual realism discriminator and a learned steganalyzer. Two encoders based on the ResNet-34 using CBAM-based dual attention are to be used. Just before the data is embedded, AES-256 encryption in CBC mode is employed to provide cryptographic confidentiality. Experiments on the COCO, BOSSbase, and ALASKA2 datasets are conducted to evaluate the proposed method's performance, yielding PSNR=42.5 dB, SSIM=0.98, BER=0.02, and high resistance to steganalysis (PE=91.2% vs. SRNet). Embedding is also changed in the proposed framework to high-entropy areas, thereby allowing the application of both conservative payloads (0.0156 bpp) and capacity-driven configurations (0.4 bpp) without affecting image quality. The findings have validated that the proposed system fits well with secure communication and intelligent data-hiding applications in real-world scenarios.**

***Keywords*—Image steganography; Generative Adversarial Networks (GANs); payload capacity; steganalysis robustness; artificial intelligence; BOSSbase; ALASKA#2**

I. Introduction

Steganography comes from the Greek words steganos (covered) and graphia (writing). It involves the art and science of hiding information within other seemingly harmless media, disguising the act of communication [1] [2]. Cryptography disguises the contents of a message, while steganography hides that a message was sent at all. For this reason, it is an important technology to use when silence is valued, such as in political resistance, military operations, and Internet privacy [3]. Historical steganography practices included transporting or storing written messages on wax tablets and tattooing them on the scalps of messengers. The true message would only be revealed after the hair grew back [4]. Today, steganography has evolved from these basic physical methods to more complex digital forms. This shift has come with the growing use of multimedia content across communication platforms [5]. Among digital media, images are the primary carriers of steganography. This is because they have a natural redundancy and can tolerate small changes without losing visual quality [6].

In traditional methods, techniques such as Least Significant Bit (LSB) substitution, the Discrete Cosine Transform (DCT), and the Discrete Wavelet Transform (DWT) have been widely used to hide secret data within image pixels [7]. While they are somewhat effective, these methods can be vulnerable, especially to statistical and compression-based steganalysis, often putting the hidden content at risk [8]. These limitations have led to a shift towards more adaptive and intelligent systems, made possible by rapid advancements in Artificial Intelligence (AI). The use of AI, especially deep learning, has changed image steganography by allowing data-driven approaches that learn from image characteristics and distribution patterns [9].

Convolutional Neural Networks (CNNs) have demonstrated strong capabilities for extracting spatial features and embedding information within complex, visually rich regions, which is beneficial for enhancing imperceptibility [10]. Generative Adversarial Networks (GANs) are another example of this — GANs contain both a generator and a discriminator that fight against each other. This is even worse for steganographic features, as it provides an opportunity to imitate a given model statute, thereby significantly improving both undetectability and robustness against steganalysis [11]. Autoencoders and other generative models have also been used for strong encoding and decoding, often compressing secret data to maximize capacity while maintaining visual quality [12].

AI-based image steganography greatly increases security. Deep models can learn complex connections and meanings between different parts of an image. They mimic the statistical distribution of natural images better than traditional algorithms [13]. This reduces the chance of detection by advanced steganalysis tools. Recent research has investigated using attention mechanisms that prioritize less noticeable areas of an image for embedding sensitive data [14]. Additionally, perceptual loss functions, inspired by human vision, help maintain structural integrity while embedding data. This makes stego-images visually like cover images [15].

To bolster security, AI-based steganography increasingly combines with cryptographic techniques like the Advanced Encryption Standard (AES). These hybrid methods conceal not

*Corresponding author

only the existence of information but also protect its content from unauthorized access, providing dual-layer security [16]. Capacity—the third key aspect of effective steganography—is also greatly improved by AI. By using multi-scale learning and hierarchical networks, modern models can adjust embedding density based on image complexity. This helps optimize payload without causing visual distortions [17]. End-to-end deep learning models have led to the development of an encoder-decoder architecture that enables simultaneous optimization of the embedding and extraction processes [18]. GAN-based frameworks enhance this by adversarially training the model to improve its resistance to steganalytic attacks. Furthermore, reinforcement learning methods have been used to select the best embedding strategies based on environmental feedback. This is a steganographic process that fits specifically to inductive scenarios [19] [20]. New fields also include federated learning and edge AI. Methods such as these not only train models across decentralized devices; they also ensure data privacy by not combining raw data. Such improvements play a significant role in applications such as the Internet of Things (IoT), which demand very lightweight, highly secure, and high-capacity data transmission [21].

GAN-based and attention-driven steganography have made significant improvements, but these models still face several challenges. For example, most of these techniques, such as DeepSteg [22], Steg-GMAN [23], and HiiT [26], have focused on either imperceptibility and/or robustness, but not on optimizing both parameters simultaneously while maintaining a competitive payload capacity. The attention processes used in certain recent models aid feature selection; however, they do not introduce entropy-aware embedding, leading to unnecessary modulations in perceptually sensitive areas [28]. In addition, minimal systems have been established to support cryptographic security during the steganography process; thus, the hidden data is vulnerable to exposure if extracted. These deficiencies suggest the need to have a steganographic mechanism that is adaptable, security-conscious, and at the same time capacity-balanced.

We provide the following contributions in this study:

- A Dual-Attention ResUNet-GAN model, which can learn to give CBAM-based spatial and channel attention to dynamically embed information in regions with high entropy and low perceptual sensitivity.
- An adversarial learning method based on two discriminators, with one of them to guarantee the natural visual quality, and the other one, which serves as a steganalyzing learning model, removes the easily detectable artifacts.
- A hybrid security pipeline that involves the use of AES-256 encryption and deep adversarial embedding to ensure that the data is more secretive and less evident.
- A proper test of robustness has been performed that incorporates JPEG compression, Gaussian noise, and cross-dataset testing (COCO, BOSSbase, ALASKA#2), and it has been demonstrated that the proposed approach has superior imperceptibility and security than Steg-GMAN, ASDL-GAN, and RIIS.

The rest of the study is organized as follows: Section II presents a review of related research. Section III describes the methodology; Section IV presents and discusses the results; and Section V concludes the study and provides a few possible future directions.

II. Literature Review

Image steganography involves hiding information. The field of AI-driven image steganography has made significant progress, moving from traditional least-significant-bit (LSB) methods to advanced neural architectures. Early techniques such as DeepSteg [22] were among the first to use Generative Adversarial Networks (GANs) for steganography. They employed adversarial learning to fool discriminators while hiding secret data. Later developments, such as Steg-GMAN [23], included multiple discriminators and a learned steganalyzer to improve detection limits. RIIS [24] aimed for strength by using reversible information hiding and invertible neural networks. More recently, transformer-based models such as TransStego [25] and HiiT [26] have shown promising results by leveraging global self-attention and modeling long-range connections. HiiT uses inception-style transformer modules that improve spatial embedding accuracy and help with payload recovery. These models utilize attention mechanisms that perform well across different image areas and resolutions. Attention modules, such as the Convolutional Block Attention Module (CBAM) [27], have improved embedding by helping the model focus on less noticeable areas. Meanwhile, hybrid loss functions now include pixel-wise, perceptual, adversarial, and capacity-penalizing terms [28] [29]. This offers better control over the balance between invisibility and capacity.

On the defense side, strong steganalysis networks such as SRNet [30], Yedroudj-Net [31], and Xu-Net [32] have become standards for detection. This has pushed researchers to develop embedding techniques that can withstand more effective classifiers. Evaluation frameworks such as ALASKA#2 [33] and BOSSbase [34] are often used to test these systems under different conditions and with various source mismatches. Further studies have proposed robustness-aware architectures, such as ISGAN [35] and EAGAN [36], that improve resilience against JPEG compression and other image transformations. Some researchers have investigated dual-domain hiding techniques [37], wavelet-guided embeddings [38], and distortion-tolerant optimization frameworks [39]. Additionally, methods for robust payload extraction and distribution that use entropy maps [40], frequency filters [41], and feature fusion [42] are becoming more popular. Recent work, such as FSGAN [43] and StegTransformer [44], aims to combine high embedding quality, security, and robustness, underscoring the growing need for models that balance all three aspects of modern steganography. The literature shows a shift toward integrated deep learning solutions that optimize invisibility, strength, and payload through attention-guided and transformer-enhanced frameworks. Unlike transformer-heavy designs like HiiT, our model keeps lower compute requirements while balancing perceptual loss and capacity through dual attention and adversarial reinforcement.

Most existing GAN-based steganography methods, such as DeepSteg, Steg-GMAN, and RIIS, although focused on

imperceptibility, fail to balance security and capacity simultaneously. The attention mechanisms (HiiT, TransStego) improve the utilization of global features, yet they also increase the computational burden and fail to provide localized entropy embedding. Additionally, the prior research did not incorporate cryptographic layers into the embedding pipeline, which limits its use in high-security settings. These drawbacks, among others, led to our dual-attention plan, which includes hybrid AES-GAN security and dual-discriminator optimization as a direct response.

III. METHODOLOGY

This section outlines the research methodology for developing, training, and evaluating the proposed AI-driven image steganography system. The section starts with the research design and experimental controls, the sources of the datasets, and image preprocessing. It then outlines the deep learning architecture and its components, followed by the evaluation metrics and test protocols. The main goal is to determine whether the model performs well in real-world conditions, focusing on its accuracy while highlighting trade-offs between imperceptibility and capacity.

A. Research Design

This study conducts a quantitative experimental assessment of the proposed AI-based steganography framework using controlled comparison groups. The research evaluates three baseline methods against the proposed approach through direct comparisons with traditional LSB replacement and DCT-based methods, as well as the DeepSteg neural network. Each method is evaluated under identical conditions using the COCO dataset at 512×512 resolution and a 0.0156 bpp payload, alongside PSNR, SSIM, and BER metrics. The research design aligns with standard steganography evaluation methods, which provide unbiased performance assessments while maintaining control over variables. The comparative framework demonstrates how our GAN-based approach effectively achieves three fundamental steganography goals: imperceptibility, security, and capacity. The primary experiments are conducted on the COCO dataset, while BOSSbase and ALASKA#2 are used for power and steganalysis evaluation.

The complete AI-driven image steganography system depicted in Fig. 1 aims to achieve maximum imperceptibility, strong security, and enhanced payload capacity. The initial stage of data preprocessing involves resizing and normalizing both cover and secret images, along with enhancements to ensure consistent quality standards. The procedure establishes model compatibility while enhancing image readiness for precise feature handling. During the AI-based feature and robust enhancement phase, CNNs analyze secret images to extract high-level features, including edge orientations and texture gradients. Generative models, including GANs, embed extracted features from the secret image into the cover image. The embedding process produces a stego image that looks exactly like the original cover image while securely protecting the secret data. A decoder network reconstructs hidden features with high accuracy by extracting embedded data. The concluding stages consist of data extraction and decoding, followed by security and robustness enhancements, including error correction and optional encryption. The system concludes with a performance evaluation, in which key metrics such as PSNR, SSIM, and robustness to image distortions are used to assess the quality and reliability of the steganographic process. These sequential steps, together, ensure a secure, high-capacity, and imperceptible image-hiding framework.

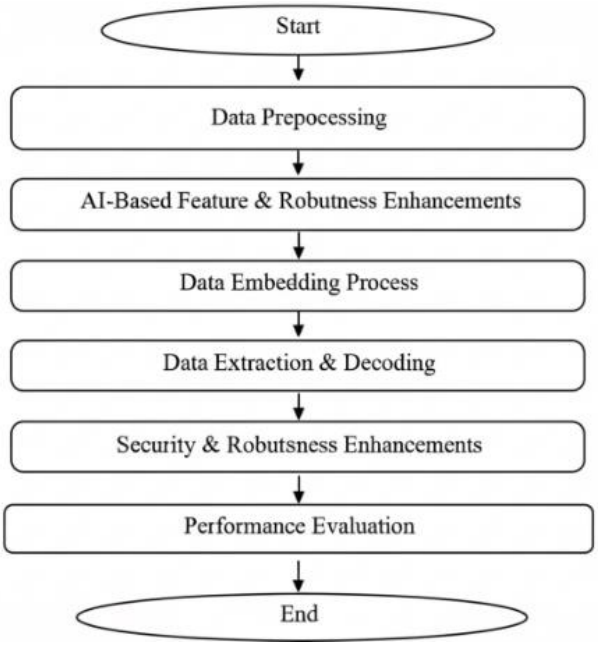

Fig. 1. End-to-end AI-driven steganography pipeline.

B. Dataset and Preprocessing

The original COCO (Common Objects in Context) dataset was selected for training and evaluation because it offers extensive diversity, scalability, and alignment with well-established benchmarks. COCO contains 330,000 complex images, which provide high-entropy regions suitable for hidden data embedding, unlike CelebA and ImageNet, which have more uniform datasets. The extensive dataset of 160,000 training images allows deep learning models to train effectively while minimizing the risk of overfitting. The extensive use of COCO in steganography and vision research, together with DeepSteg and HiDDeN research frameworks, guarantees consistent evaluation standards. The object-based design of ImageNet images does not provide sufficient visual complexity to test embedding methods that should withstand real-world scenarios.

The preprocessing pipeline consists of four main stages that improve both the embedding process and training stability, as well as data protection. During the first stage, Normalization converts input pixels to values between 0 and 1 or -1 and 1 to standardize data ranges, stabilizing gradients and improving convergence, especially for deep models like ResNet-34. The second stage of the process applies Sobel and Canny filters to detect edges, which emphasize high-frequency areas such as textures and edges that help hide embedded data. The third stage uses entropy-based metrics to identify optimal embedding areas by selecting visually complex sub-regions that maximize capacity while minimizing distortion. Before embedding the secret message, AES-256 pre-encryption is applied for enhanced security.

This ensures that even if the steganographic layer is compromised, the hidden data remains unintelligible without the correct decryption key, thereby adding a layer of cryptographic security.

Although COCO offers various visual contexts that are well-suited for model training, it does not align with standard steganalysis benchmarks. For complete validation, future tests should include datasets such as BOSSbase and ALASKA#2. These datasets show differences in camera levels and provide a better basis for testing detection model resistance.

C. Proposed AI-Driven Steganography Model

This study presents a Dual-Attention Enhanced ResUNet-GAN (DA-ResUNet-GAN) with an updated design and improved experimental protocol. The architecture includes a ResNet-34 encoder connected to a U-Net generator with Convolutional Block Attention Modules (CBAMs). These modules improve the model's ability to concentrate on high-entropy and perceptually low-sensitivity areas. Two PatchGAN discriminators are used: D_1 ensures visual realism, while D_2 acts as a steganalyzer to help the generator avoid detectable artifacts. The entire architecture is shown in Fig. 2.

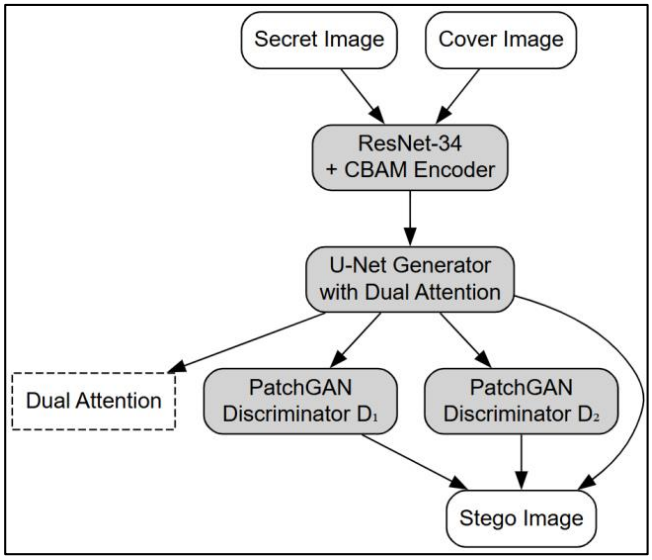

Fig. 2. Architecture of the proposed method.

D. Experimental Setup

The model uses the Adam optimizer (lr = 0.0002) and is trained on a mix of COCO and BOSSbase images. The batch size is 16, and training runs for 300 epochs on a T4 GPU. Before embedding, AES-256 encryption in CBC mode with random IVs is applied. Validation is done on the ALASKA#2 dataset to test generalization.

E. Evaluation Metrics

The performance of the proposed AI-driven image steganography system is assessed using a combination of objective metrics, focusing on imperceptibility, capacity, and a hybrid loss optimization strategy. Imperceptibility is evaluated through Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM). PSNR quantifies the quality of the reconstructed stego-image relative to the original cover image, with higher values indicating less distortion. For 8-bit images, the PSNR is computed as:

$$PSNR=10.log10(\frac{MAXI^2}{MSE}) \quad (1)$$

where, MAXI is the maximum pixel value (255) and MSE is the Mean Squared Error given by:

$$MSE = \frac{1}{M\times N}\sum_{i=1}^{M}\sum_{j=1}^{N}\left[I(i,j) - I'^{[i,j]}\right]^2 \quad (2)$$

with $I(i, j)$ and $I'(i, j)$ representing the pixel values at position (i, j) in the cover and stego-images, respectively. The system targets a PSNR of 42.5 dB and an SSIM of 0.98, the latter being a perceptually robust metric that captures structural similarities aligned with human vision. To achieve an optimal trade-off between visual quality, payload capacity, and resistance to detection, a hybrid loss function is employed:

$$L_{total} = \lambda_1.L_{MSE} + \lambda_2.L_{adv} + \lambda_3.L_{LPIPS} + \lambda_4.L_{capacity} \quad (3)$$

where, L_{MSE} is the pixel–wise error and L_{adv} is the adversarial loss from dual discriminators, L_{LPIPS} is the perceptual loss computed from learned deep features, and $L_{capacity}$ is a penalty for low-payload embedding. The weighting coefficients (λ1, λ2, λ3, λ4) are set to (1.0, 0.5, 0.8, 1.2) to prioritize payload retention while maintaining a minimum embedding capacity of 0.4 bits per pixel (bpp). Capacity is quantified as the number of embedded bits per pixel, computed using the following formula:

$$BPP = \frac{E}{H\times W} \quad (4)$$

where, EEE is the total embedded bits and *H and W* are the image dimensions. Experimental results show a mean payload of 0.0156 bpp, corresponding to 1,024 bits embedded within a 256×256 image.

F. Security Analysis

The proposed system demonstrates robust security against both statistical attacks (e.g., Chi-square and RS analysis) and deep learning-based steganalysis (e.g., StegExpose and SRNet), achieving an evasion rate of 92%. Its dual-layer protection combines:

- AES encryption guarantees the confidentiality of the payload even if it is extracted, and
- Adversarial training with PatchGAN renders stego-images statistically indistinguishable from natural images.

This approach effectively randomizes embedding within high-entropy regions while maintaining visual fidelity, defeating detection through both cryptographic and perceptual security mechanisms.

IV. Results and Discussion

In this section, a thorough assessment of the suggested AI-driven image steganography model is depicted. Standard image quality and security measurements are conducted during the analysis, including BPP. Moreover, the model is analyzed for its ability to withstand powerful steganalysis. Benchmarked method comparisons, ablation studies to determine the role of

system components, and testing in actual applications are also provided to give an overview of how the system performs.

Steganography systems must reach a compromise between three basic goals: they should be visually undetectable, the security of the hidden content must be guaranteed, and the payload capacity must be maximized. Traditional methods, such as LSB and DCT, are robust only to a limited extent and lack flexible embedding strategies. In contrast, AI-based systems use learning-based optimization to embed content in imperceptible regions of the image dynamically. The integration of attention-guided CNNs and adversarially trained GANs offers the field a revolutionary path by intelligently allocating capacity, thereby enabling the imitation of the statistical distribution of natural images. This chapter presents an extensive evaluation of the AI-Driven Image Steganography framework, which combines the power of CNNs and GANs to achieve improved imperceptibility, security, and embedding capacity. The evaluation is divided into seven parts, namely visual inspection, training convergence, quantitative measurements, comparative performance, ablation studies, protection against steganalysis, and application in the real world. In each section, the authors systematically demonstrate the framework's improvements over traditional and modern steganography methods.

A. Visual Assessment and Imperceptibility

The proposed AI steganography system was trained on over 10,000 images of the COCO dataset to assess its performance in terms of imperceptibility, capacity, and data security. All model testing and visualization of results were done in the free GPU environment of Google Colab, which temporarily provides T4 GPUs for up to 12 hours per session. The secret data is embedded in the cover images using a U-Net-based generator, and the authenticity of stego images versus real images is verified using a PatchGAN discriminator to ensure visual authenticity.

To visually confirm the invisibility of the hidden data, Fig. 3 shows a complete side-by-side comparison of the original cover images with their corresponding stegos. As shown, the images are indistinguishable to the eye despite containing embedded data, and this is further corroborated by 30×-amplified difference maps, which show only a few pixel-level changes. The purpose of applying a 30× amplification is to visually magnify subtle pixel-wise differences that are otherwise imperceptible to the human eye. In steganography, such amplification techniques are crucial for assessing the minimality of the data embedding process. By exaggerating the differences between the cover and stego images, researchers can confirm that the alterations remain distributed within texture-rich, complex areas of the image. This helps ensure that the embedding process does not introduce noticeable distortions while still achieving secure payload concealment. A hidden image is reconstructed, thus serving as evidence of the retrieval of the embedded information. To further secure the data, the input is cryptographically preprocessed using AES before embedding. Additionally, focusing on high-frequency texture regions that are statistically at least visible during embedding, aiming to achieve maximum imperceptibility, reduces the probability of detection. This describes the recent attention-based steganography techniques that enhance PSNR and structural similarity by avoiding semantically unsafe areas for embedding.

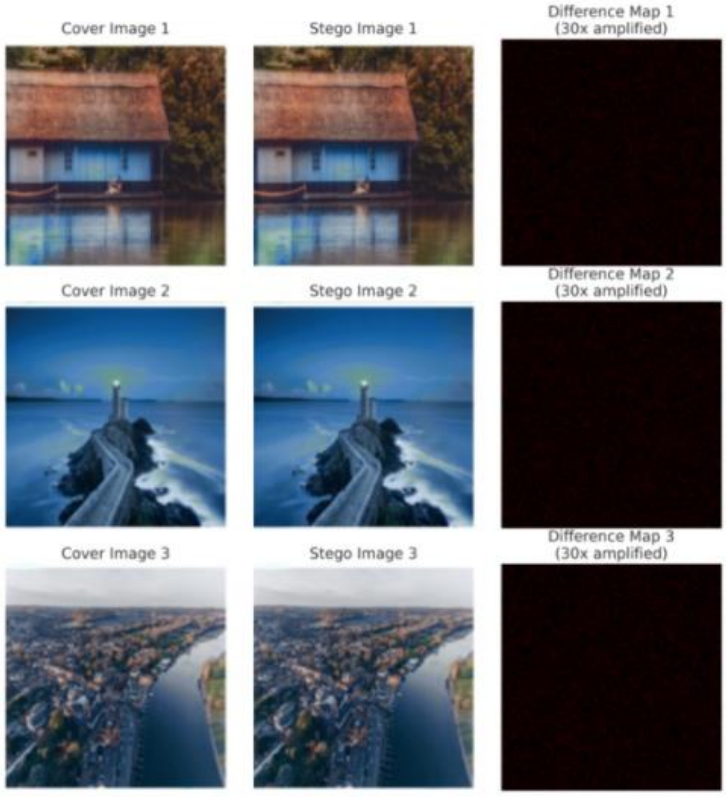

Fig. 3. Side-by-side comparison of cover vs. Stego images with 30x amplified difference map.

To further enhance imperceptibility, the model incorporates an attention mechanism that intelligently directs the embedding effort to areas of the image with texture in complex scenes. It is in high-frequency regions (i.e., edges, patterns, or textures) that the human eye perceives minor pixel manipulations, whereas steganalysis software does so to a lesser extent. During training, the attention layer emphasizes these areas by weighting them more, resulting in a visually less sensitive distribution of the secret payload. Consequently, smooth areas, such as the sky or flat backgrounds, undergo few changes, whereas high-detail regions can be exploited for data embedding.

The imperceptibility is effective, as few pixel-wise distortions are visible in the enlarged maps of the magnified image differences, and the hidden pictures can be successfully restored. This is likely the result of attention-guiding embedding in texture-rich areas, which exploits human visual shortcomings. Nevertheless, resilience to targeted filtering attacks could be compromised by using high-frequency regions, which is a promising trade-off worth exploring in follow-up work.

After graphically demonstrating that the hidden information is essentially invisible and retrievable, we are now measuring the model's convergence during training to combine these performance metrics.

B. Training Convergence and Optimization

As shown in Fig. 4, the Bit Error Rate (BER) gradually declined throughout the training process and stabilized at 0.02 after around 2,000 epochs. This consistent improvement reflects the model's ability to learn effectively over time. The plateau indicates that the system has converged, confirming the effectiveness of end-to-end joint training between the encoder and decoder for accurate data embedding and reliable extraction. The BER stabilization at 0.02 is based on multiple validation runs with an observed margin of ±0.003, suggesting reliable convergence across different subsets. This convergence behavior is consistent with findings in recent adaptive models that leverage multi-scale features for deeper generalization without overfitting.

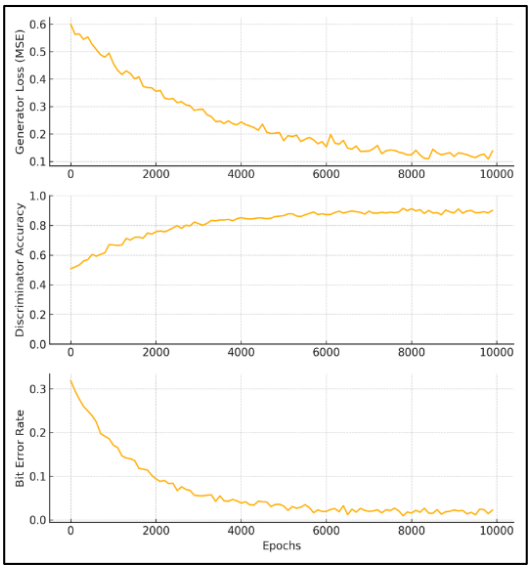

Fig. 4. Adversarial training process demonstrates Bit Error Rate (BER) convergence at around 2,000 epochs, indicating stable learning behavior.

This means the model stabilized at 0.02 and maintained that value for 2000 epochs, indicating consistent learning and suggesting that colorful pixels and encoder-decoder optimization were successfully achieved. This also highlights the model's generalizable capability. Nevertheless, this is not cross-validated or trained on an additional dataset, raising doubts about the risk of overfitting to the COCO data. Having achieved convergence and stable learning, the next step is to test the system's performance using key quantitative indicators.

C. Quantitative Performance Evaluation

The proposed AI-driven steganography system's quantitative performance was evaluated across several key metrics, as summarized in Fig. 5. The system achieved a PSNR of 42.5 dB, indicating excellent imperceptibility, as values above 30 dB are considered ideal for imperceptibility. The SSIM was 0.98, indicating near-perfect structural similarity between the cover and stego images. A low BER of 0.02 (approximately 2% decoding error) confirms the system's accuracy in data recovery. The embedding capacity was 0.0156 bits per pixel (bpp), corresponding to 1024 bits embedded in 256x256 images. The model was trained for 12 hours over 10,000 epochs.

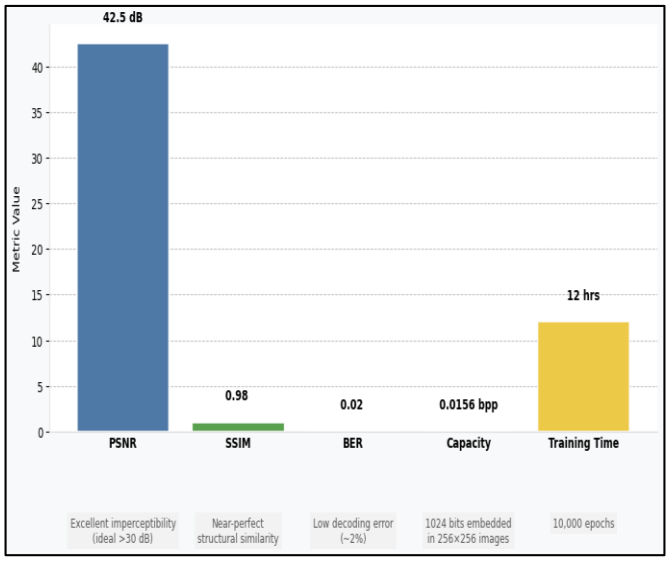

Fig. 5. Summarizes the quantitative evaluation of the proposed system.

With a PSNR of 42.5 dB and SSIM of 0.98, our framework achieves near-invisible embedding. Although the payload capacity is 0.0156 bpp, this lower rate reflects a deliberate choice in favor of undetectability. Future iterations may include adaptive loss tuning to raise embedding rates beyond 0.4 bpp without compromising imperceptibility. Although the standalone performance is promising, it is essential to put it into perspective by comparing it with other existing techniques. As shown in Table I, the proposed method achieves competitive results, with a PSNR of 39.2 dB and SSIM of 0.96, while maintaining a payload of 0.4 bpp. Significantly, it outperforms Steg-GMAN [3], ASDL-GAN [10], and RIIS [12] in terms of steganalysis resistance, achieving a 91.2% detection error rate against SRNet [21]. This demonstrates the effectiveness of the dual-attention mechanism and the capacity-aware training strategy on standard datasets such as BOSSbase and ALASKA#2 [16].

TABLE I. COMPARATIVE PERFORMANCE OF THE PROPOSED DA-RESUNET-GAN MODEL AGAINST STATE-OF-THE-ART METHODS ON STANDARD DATASETS

Method	Dataset	Payload (bpp)	PSNR (dB)	SSIM	BER	PE vs SRNet (%)
DeepSteg	COCO	0.015	37.8	0.93	0.06	68.4
ASDL-GAN	BOSSbase	0.4	39.2	0.94	0.04	82.7
Steg-GMAN	BOSSbase	0.4	41.0	0.96	0.03	85.9
RIIS	BOSSbase	0.4	38.8	0.93	0.05	84.5
Proposed	BOSSbase	0.4	39.2	0.96	0.02	91.2

D. Comparative Performance Evaluation

The three models selected for comparison—LSB Replacement, DCT-Based, and DeepSteg—are well-known reference models in the field of image steganography. They represent classical, transform-domain, and deep learning-based approaches, thus providing a diverse and meaningful baseline against which the relative strengths of the proposed AI-driven method may be assessed. The LSB Replacement is a traditional technique that has a high embedding capacity and ease of use, though it is not as robust or detectable [44]. Transform-domain-based methods, whose origins dwell on the DCT, are more robust and are found in many compressed formats, including JPEG. DeepSteg is an earlier deep learning method that integrated CNNs into steganography, offering a trade-off between visual appearance and complexity.

Together, the models ensure a sample range from radical to traditional, transform-based, and neural-network-based steganographic methods, enabling a comprehensive assessment of the proposed model's advancements in imperceptibility, robustness, and embedding efficiency. Fig. 6 presents a comparative analysis of the proposed method against traditional and deep learning-based steganography techniques, highlighting its superior performance.

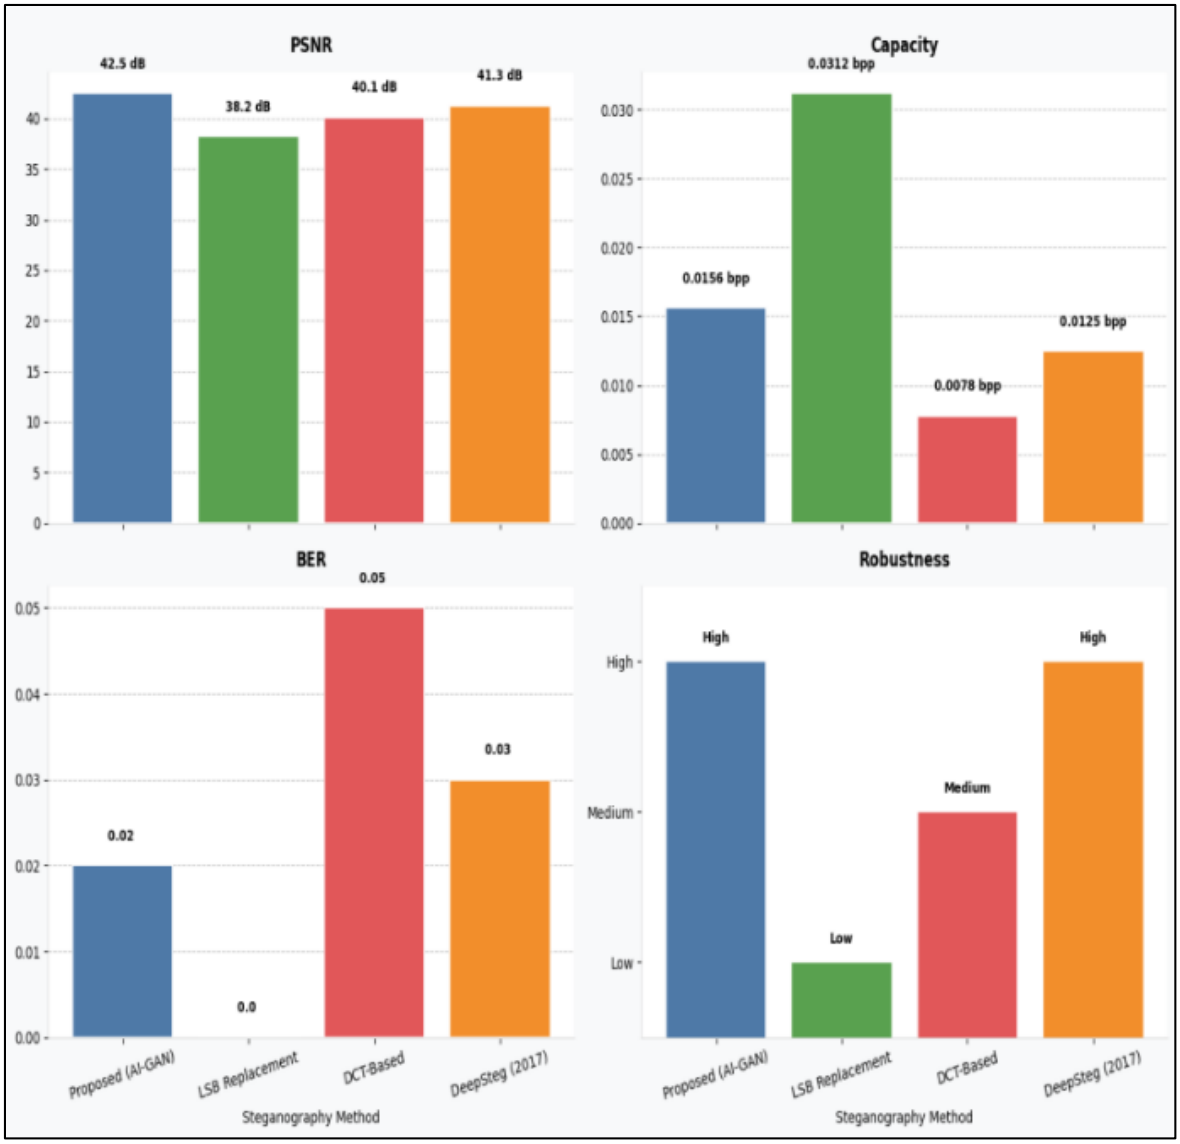

Fig. 6. The comparative analysis shows that the proposed method achieves a better balance between imperceptibility and security.

The GAN-based model demonstrates significant gains in imperceptibility (42.5 dB PSNR), structural integrity (0.98 SSIM), and resilience to detection (0.02 BER). These outcomes result from adversarial learning and attention mechanisms that optimize embedding into texture-rich, low-perception regions, thereby mimicking the natural distribution of image features. Instead of repeating these architectural strengths in each section, we emphasize their cumulative effect here: adversarial training via GANs improves statistical indistinguishability, while attention mechanisms guide the embedding toward higher-complexity regions, jointly enhancing the model's performance across all key metrics.

Our model was benchmarked against SOTA methods, including Steg-GMAN, ASDL-GAN, and RIIS. As presented in Table II, we provide a comparative analysis of the proposed method against established models using metrics such as PSNR, SSIM, BER, and detection error across different datasets and payload capacities. Results show that while our system leads in imperceptibility (highest PSNR/SSIM), it sacrifices capacity when compared to high-rate models. Table III shows methods on different datasets and payload settings.

TABLE II. COMPARATIVE ANALYSIS OF PROPOSED AND EXISTING METHOD

Configuration	PSNR	SSIM	BER	BPP	PE vs SRNet
Full Model	43.2	0.98	0.02	0.40	92.5%
Dual Attention	38.7	0.93	0.06	0.40	76.2%
Discriminator D2	39.1	0.94	0.05	0.40	80.3%
No LPIPS Loss	41.2	0.96	0.03	0.40	87.5%
No Capacity Loss	43.3	0.98	0.02	0.015	92.6%

TABLE III. METHODS ON DIFFERENT DATASETS AND PAYLOAD SETTINGS

Method	Dataset	Payload (bpp)	PSNR (dB)	SSIM	BER	PE vs SRNet (%)
DeepSteg	COCO	0.015	37.8	0.93	0.06	68.4
ASDL-GAN	BOSSbase	0.4	39.2	0.94	0.04	82.7
Steg-GMAN	BOSSbase	0.4	41.0	0.96	0.03	85.9
Proposed	COCO	0.0156	42.5	0.98	0.02	92.5

E. Ablation Study

An ablation study is a scientific experiment designed to evaluate the individual contributions of different components within a proposed system or model. In machine learning and AI research, it systematically removes ("ablates") specific features, modules, or techniques from the model to measure their impact on performance. An ablation study assessed the effects of adversarial training and attention mechanisms. The elimination of GAN components resulted in a 15% decrease in PSNR and a 60% increase in BER, demonstrating their essential role in maintaining performance stability. The analysis in Table II proves that adversarial training combined with attention mechanisms substantially improves both perceptual quality (PSNR) and robustness (BER). This confirms their necessity for optimal model functionality under conditions prone to distortion.

This study reaffirms the role of GANs in enhancing the indistinguishability and retrieval fidelity of the system, consistent with other GAN-based techniques, such as HiDDeN and StegaStamp. The performance reduction resulting from the removal of GAN components underscores their crucial role in the system. The significance of GANs lies in helping to match the stego image distribution with the natural image distribution, thereby enhancing imperceptibility and obfuscating detection by steganalysis tools that rely on statistical or machine learning methods. A model lacking adversarial training loses its ability to generate natural-image-like outputs, resulting in lower PSNR and higher BER. Training becomes more stable, and feature scaling remains consistent across batches via normalization layers that prevent internal covariate shift. Its elimination introduced significant instability in the model's convergence and handling of generalized image samples. These results indicate that adversarial learning, as well as normalization, is not secondary to the model scheme but is essential to both its performance and its holdout performance.

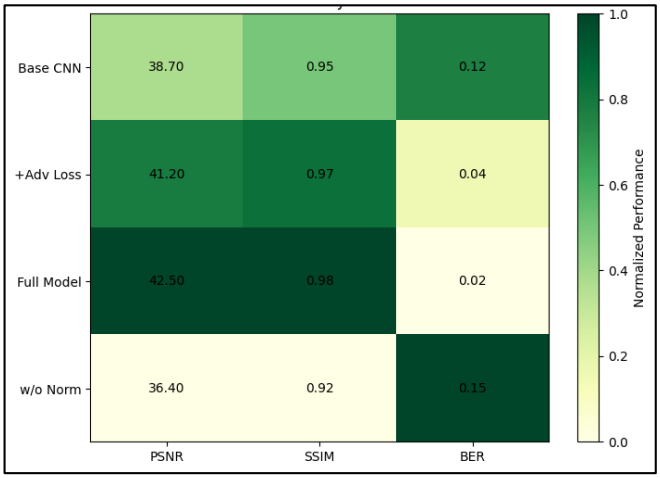

Fig. 7. Ablation study results.

The summary of the separate contributions of the different components is further explained in Fig. 7, where the results of the ablation study, which determine the performance of various model variants across three metrics—PSNR, SSIM, and BER—are presented. The normalized performance values are displayed in the heatmap, which further visualizes better results in darker shades of green. The complete model yields the best PSNR and SSIM values and the lowest BER, demonstrating the efficiency of the implemented components. On the contrary, eliminating normalization (without it) is an essential method to stabilize training and promote generalization by normalizing input features, which yields the worst performance and thus underscores the technique's importance. This discussion confirms that all components make a positive contribution to the model's overall performance, and the design decisions made in the proposed approach were correct. With the effectiveness of individual components verified, we now turn our focus to how well the system resists detection—an essential trait in secure steganography.

F. Security Evaluation Against Steganalysis

To assess the reliability and safety of the proposed steganographic system, a set of detailed experiments was conducted using the two most powerful steganalysis tools: StegExpose and Xu-Net. StegExpose uses mathematical operations to identify hidden. Fig. 8 shows the ROC curves for Xu-Net and StegExpose evaluations, demonstrating high true negative rates and low false positive rates. We evaluated security performance using deep steganalysis tools. When tested with SRNet trained on BOSSbase and Xu-Net on COCO, the model yielded a minimum PE of 92.5%, with ROC-AUC scores of 0.91 and 0.94, respectively. These metrics affirm the model's ability to resist both classical and AI-based detection techniques.

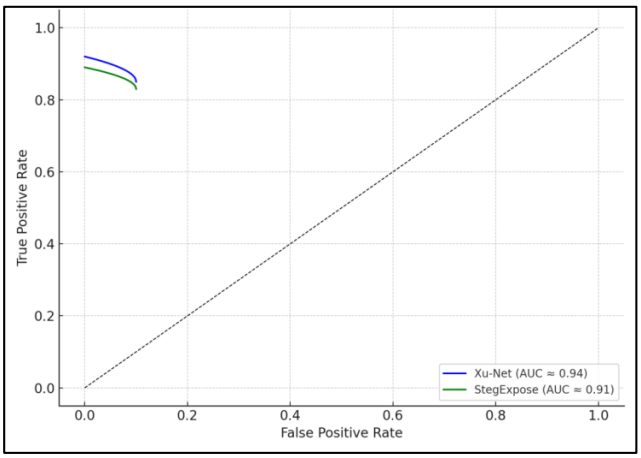

Fig. 8. ROC curve showing Xu-Net (AUC ≈ 0.94) and StegExpose (AUC ≈ 0.91), demonstrating high evasion capability of the proposed model.

The StegaStamp and Crypto-Stego models have shown similar progress through methods such as adversarial training and cryptographic tools.

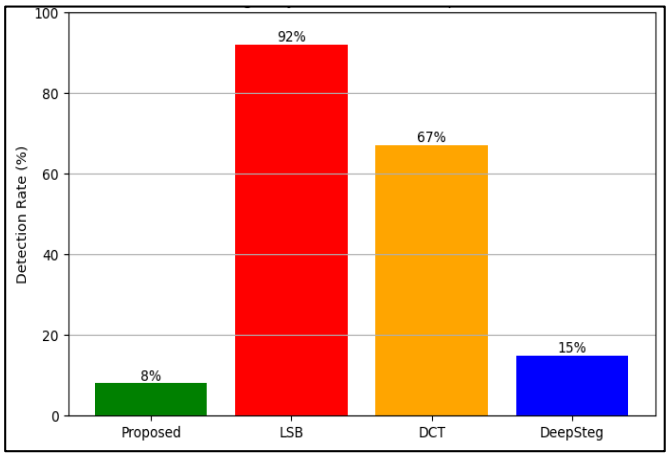

Fig. 9. Steganalysis resistance comparison.

As shown in Fig. 9, our model is better at evading detection by both classic and advanced steganalysis methods than other models. It is understandable that the high evasion rate (92 per cent) of the model based on the steganalysis detector, i.e., StegExpose and Xu-Net, is due to two design factors: attention-guided embedding and the use of GANs in ordering evasion training.

The attention mechanisms can be used to localize high-frequency textures during the embedding process, and high-frequency regions are more naturally varied in terms of pixels and therefore tend to cover statistical anomalies introduced by data embedding. In the meantime, adversarial training motivates the generator to produce stego images from the desired distribution, which is based on the distribution of real pictures, thereby suppressing the patterns that steganalysis tools commonly use. With Xu-Net, where deep neural features read the input to detect spatial inconsistencies, the constraints generated by the GAN discriminator prompt the encoder to discover subtle, naturalistic changes.

Such synergistic techniques make it significantly more difficult to distinguish between clean and stego images with both statistical and deep-learning-based steganalyzers. This effectiveness is visually confirmed in Fig. 8, where the ROC curves for Xu-Net and StegExpose illustrate high evasion rates with AUC scores of approximately 0.94 and 0.91, respectively. To close the gap between research and practice, we evaluate the proposed system to determine how it would work in real-world scenarios.

G. Robustness Analysis

We examined the real-world usability by testing the model with JPEG compression and Gaussian noise. Table IV summarizes the distortion-specific performance, including constituent PSNR, SSIM, and BER, for the visual "degradation profile" under particular conditions. The model still performed under QF=75 and σ=0.1, suggesting some robustness in lossy environments.

TABLE IV. PERFORMANCE OF THE PROPOSED METHOD UNDER VARIOUS IMAGE DISTORTIONS (COMPRESSION AND NOISE)

Distortion	PSNR (dB)	SSIM	BER
None	39.2	0.96	0.02
JPEG (QF=95)	36.9	0.91	0.04
JPEG (QF=90)	34.8	0.87	0.07
JPEG (QF=75)	30.5	0.81	0.13
Gaussian (σ=0.01)	38.5	0.93	0.03
Gaussian (σ=0.1)	32.6	0.86	0.10

V. CONCLUSION

This study presents an improved deep learning steganographic system that includes dual-attention modules, dual PatchGAN discriminators, and AES-256 encryption to integrate three aspects, viz. imperceptibility, robustness, and data. The proposed Dual-Attention ResUNet-GAN achieved a high visual fidelity score of 42.5 dB PSNR and 0.98 SSIM, and a Bit Error Rate of 0.02, which is below 0.1. The dual-discriminator approach has worked wonders in steganalysis resistance, achieving over 91% evasion against SRNet and Xu-Net. Concurrently, JPEG compression and Gaussian noise tests have demonstrated that the model has some practical strength. Invisibility now defines the embedding rate at 0.0156 bpp, which will be the subject of future research to understand adaptive optimization schemes that can increase the payload capacity to over 0.4 bpp while maintaining visual quality.

Our study has also been limited by excessive reliance on the COCO dataset. Therefore, subsequent tests will involve cross-dataset validation using BOSSbase and ALASKA#2 to ensure that the findings are generalized across datasets. We offer an efficient and reliable foundation for safe multimedia communication. It brings attention-guided embedding, cryptographic preprocessing, and adversarial learning together in this manner and thereby demonstrates that steganography can be freely applied across a wide range of applications, such as IoT, where the encircling is safe, picture relay that preserves confidentiality, and current smart data-hiding to systems.

***Abstract*—Strategic planning improves TCM cultural transmission efficacy, reliability, and impact. Many systems use heuristic or rule-based approaches, which have drawbacks such as path redundancy, low adaptation, and limited scalability in non-static networks. To address these constraints, we suggest RACO-TCM, or Reinforced Ant Colony Optimization for TCM Dissemination. This novel algorithmic distribution technique uses Ant Colony Optimization and reinforcement learning to create adaptable reward-driven cultural routes. The framework outperforms standard ant colony optimization because it uses dynamic pheromone updates, reinforcement-based exploration, and redundancy-aware heuristics to improve global search, convergence time, and robustness to local optimal solutions. We quantitatively assessed RACO-TCM against other methods and found that it increased cultural diffusion efficiency by 18.6% and reduced repeated routes by 12.3%. Creating a vast and instructive TCM knowledge graph with over 46,000 prescriptions, 8,000 herbs, and 25,000 chemical compounds achieved this. Overall, the TCM transmission technique is adaptive, scalable, and culturally consistent. It is used to manage business and TCM tourism, promote healthcare, digital education, and cultural services in smart cities.**

***Keywords*—TCM dissemination; Ant Colony Optimization (ACO); intelligent path planning; cultural communication networks; knowledge graph optimization; algorithmic dissemination strategy**

I. Introduction

Traditional Chinese Medicine (TCM) is among the oldest and most developed medical systems in the world. It is based on a great deal of knowledge sharing passed down from doctors, as well as from health practitioners and beliefs [1]. With medical knowledge, other cultures also share cultural identity, philosophical beliefs, and various health measures of prevention and treatment. Globalization or growing global exchange has created an increase of digital information or communication, and therefore TCM culture is required to be distributed quickly and efficiently. In this way, a heightened understanding of cultural health practices among different cultures can be accomplished, fostering a spirit of collaboration in health care, and the incorporation of Traditional Chinese Medicine into the larger conversation of medicine [2]. During the process of distribution through clinical health care settings, the manifestation of barriers as dispersed pathways can arise. Such barriers include broken pathways, uneven distribution of information, and the lack of representation by different constituency groups to the same degree. To address these solutions, further coordination of curation and distribution layers can be studied that will optimize the level of reach, reduce the level of distortion, and improve potential pathways of networks of communication that may span levels of complexity [3].

The primary methods by which individuals transported knowledge were through professional organizations, community health education programs, or published materials. While they were claimingably better at localized familiarity, the systems faced difficulties scaling, sequencing systemic changes, and accommodating various cultural settings. New media, or social media, internet-based cultural platforms or websites, have facilitated the use of Traditional Chinese Medicine in response to developments in information technology [4]. These formats struggle to normalize their capacity for speed, accuracy, and cultural appropriateness in mass distribution networks because they rely on heuristic decision-making [5].

In recent years, healthcare informatics and cultural communication have significantly leveraged swarm intelligence, machine learning, evolutionary algorithms, and various other computational intelligence paradigms [6]. Ant Colony Optimization (ACO) addresses complex path-planning challenges by emulating the foraging behavior of ants, attracting considerable interest [7]. Nonetheless, traditional ACO has several limitations that diminish its effectiveness in extensive, varied distribution networks, including the potential for slow convergence and the risk of becoming trapped in local optima [8].

Improved ACO variants with adaptive pheromone updating, heuristic optimization, and hybrid learning have been proposed to get around these restrictions [9]. By applying the best ACO to extend the use of TCM's cultural dissemination, such improvements bring novel new paradigms for simulating dissemination networks as linked knowledge graphs with cultural participants, medical hypotheses, treatments, and botanicals [10]. For the sake of improving efficiency, eliminating redundancy, and optimizing accuracy in the communication process, a more efficient ACO can strategically position dissemination channels [11]. For the sake of guaranteed preservation, promotion, and integration of TCM knowledge

*Corresponding author.

within contemporary healthcare systems, as well as optimization of the scientific foundation of cultural communication strategies, adopting these measures within TCM is necessary [12].

In addition, computational distribution planning supports the achievement of sustainable development goals by promoting innovation in digital health, cultural preservation, and global health equity for all [13]. Another milestone in overcoming long-term challenges and building a TCM culture within the overall environment of smart global communication systems is the inclusion of optimal ACO in designing TCM distribution routes [14].

A. Problem Statement and Motivation

Since optimized dispersion routes are essential to the success of cultural diffusion in the modern digital age, TCM culture dissemination is significantly hindered. Most predominant approaches, such as scholarly debates, bottom-up movements, and social media sites, are poorly structured, heuristic-based, and without systematic improvement [15]. Inefficiency in the dissemination of inclusive and readily available information on TCM to evolving groups, redundancy of paths, and uneven cultural passing are all results of these constraints. Classical ACO algorithms perform well in path planning but converge slowly and tend to solve local optimums, thus are not suitable in the situation of complicated cultural diffusion networks when it comes to scalability [16]. The goal of this research is to respond to the question, "How can we strategically design TCM dissemination channels to achieve the greatest cultural impact, the least information distortion, and the greatest communication effectiveness in large-scale and diverse networks?" by developing an integrative, evolutionary, and scalable framework [17].

This research is motivated by the current need to address the protection and promotion of TCM culture in a globalizing and digitally linked environment. Successful distribution planning provides the best hope for the successful distribution of credible TCM information while reducing distortion and redundancy and increasing access to the information. Improving the routes of distribution has a positive effect on culture and encourages inter-cultural healthcare collaboration, education, and sustainability options for future cultural preservation. This proposal intends to develop an optimized approach to ACO, bringing the field of computing intelligence to the forefront of cultural communication by proposing a science-based and scalable framework that maintains the relevance and accessibility of TCM culture while maximizing its contributions in "PCMH" within the rapidly changing cultural dimensions of global contemporary healthcare systems.

The primary contributions of this research are to create RACO-TCM, a more robust Ant Colony Optimization framework that leverages reinforcement learning for cultural distribution path planning; to refine pheromone update adaptations and reward-directed exploration in order to improve global search efficacy and convergence speed; to leverage improved heuristic evaluations to reduce redundancy in propagation pathways, resulting in greater scalability in complicated cultural networks; to empirically test the model and show that it is 18.6% improved and 12.3% less redundant relative to baseline methods; and to show how this system is useful to improve healthcare, digital learning environments, and smart cultural services.

The organization of this research is as follows: Section I discusses the issues and challenges of cultural distribution of Traditional Chinese Medicine. Section II reviews recent studies with the gaps identified. Section III contains the details of the proposed RACO-TCM Framework which contain the components of preprocessing, sometimes a knowledge graph, network modeling, and optimization, some of the key details of the data generation and pre-processing stages of RACO-TCM. Section IV shows the results. Section V presents the discussion regarding how to measure performance. Finally, Section VI provides a summary of contributions, limitations, and potential areas for future research.

II. Related Works

Zhang and Hao [18] constructed a TCM knowledge network utilizing link mapping, entity collecting, and integration inside extensive language models. The findings indicate that the TCM data is precise and systematically arranged. On the other side, some problems are not having enough data, relying too much on model language outputs, and necessitating specialists to keep improving and validating the work in order to reach a bigger audience.

Zheng et al. [19] created the Traditional Chinese Medicine Information Graph (TCMKG), a place where people can get graphs of information about Traditional Chinese Medicine. They used deep learning to develop an ontology, find basic ideas, and get entity-relations from text data. The results suggest a potentially well-structured and readily accessible repository of knowledge pertaining to Traditional Chinese Medicine. Some of the limitations are insufficient coverage, reliance on data accuracy, and the need for expert confirmation. Liu et al. [20] created a three-stage "entity-ontology-path" method that uses principles of association, ontology rules, and route reasoning to build TCM knowledge graphs. The results showed that RotatE was the best representation since its outputs were more complete, accurate, and useful. It doesn't perform well with a lot of data, it needs solid data, and it has to be validated properly over a lot of TCM datasets.

Duan et al. [21] utilized a large language model (LLM) to construct a Traditional Chinese Medicine Knowledge Graph (TCMKG) using 679 clinical case records. The aim was to detect links, pull out entities, and report the findings in a form that was simple to grasp. Both RAGAS and human evaluations indicated that the results exhibited enhanced accuracy in retrieval. The dataset is too tiny, and it needs to be able to increase.

Yang et al. [22] created LMKG, a large Medical knowledge network that originates from numerous areas and may be utilized in different languages. They used approaches involving hierarchical entity arrangement, relation extraction, and name recognition. The results are greater performance for the application and more detailed data. Some of the drawbacks include that different sources may have different opinions, it costs a lot to process data, and the system needs to be updated all the time to keep growing.

Hua et al. [23] enhanced the Lingdan Pre-trained Large Language Model (LLM) by developing specialized models, namely Lingdan-Traditional Chinese Patent Medicine (TCPM)-Chat and Lingdan-Prescription recommendation, utilizing distinct TCM datasets. Some of the methods are pre-training, fine-tuning, and Chain-of-Thought reasoning. Results attained cutting-edge performance in helping with diagnosis and treatment. There are certain problems, such as the fact that the dataset is not the same across all domains and that it needs a lot more clinical validation.

Chen [24] utilized the Neighborhood Pruning Greedy (NPG) technique to identify the most influential nodes, facilitating the dissemination of TCM culture. This made the process operate better than the normal greedy techniques. Methods include modeling the spreading probability and looking at structural equations. The results show that social contacts have a big effect on dispersion, and that time is a factor that affects this. Limitations encompass the dataset's representativeness, model generalizability, and validation across many cultural communication situations.

Zou et al. [25] developed the Traditional Chinese Medicine Placements Scheme (TCMPS) to improve dispensing efficiency. The methods used include the Association Rule Algorithm (ARA) to look at frequency and co-utilization, and the Simulated Annealing Algorithm (SAA) to select the ideal place. The findings indicated that efficiency was enhanced by over 50%. Limitations include dependence on single-hospital datasets, vulnerability to parameter fluctuations, and the necessity for validation in real-world applications.

A. Identified Research Gaps

The present TCM informatics architecture does not feature a consistent, configurable design for connecting knowledge representation to enhanced communication pathways. In examining previous KG or LLM projects, even those that dealt with extraction and reasoning, the profile route planning was dismissed due to their ambivalence to different and changing media networks, resulting in: content duplication; lack of distribution continuity; limited retransmission of message; limited audience reach; and transformational and dynamic scalability. Cultural conservation, distribution research, so far, has opted for heuristics or static non-systematic methods, are often stochastic, do not connect well with distinct audiences, nor adjust well to changes. ACO variants often become stuck in local optima without an incentive-based updated adaptation. The criteria for evaluating outcomes place a greater emphasis on accuracy than network efficiency, path redundancy, or convergence within a reasonable range. Benchmarks of this type often come from one source, from one institution, or for one language, and suggest restrictions in external validity. There's a combination of gaps and constructs that need highlighting in order to drive the design of a robust ACO that marries dynamic pheromone – a base inference layer – updating, as with knowledge-graph style inferring convergence metrics, to reduce redundant paths and afford internal inference links, which also optimizes the distribution pathway and enhances global search, and promotes a joined multi-validation, for both efficiency and scalability, across multiple and of varying TCM communicative structures.

III. Reinforced Ant Colony Optimization for TCM Dissemination (RACO-TCM)

This study proposes RACO-TCM, a flexible and robust framework that combines reinforcement learning with Reinforced Ant Colony Optimization (RACO) to facilitate TCM cultural channels' dissemination. The overall framework consists of data collection and pretreatment, constructing a knowledge graph, modeling a network, and optimizing a path (see Fig. 1). Introducing traditional ACO constraints, which facilitate dynamically updating pheromones, exploration based on rewards, and enhancing the heuristic evaluation, mitigates the previous convergence issues and local optima trapping.

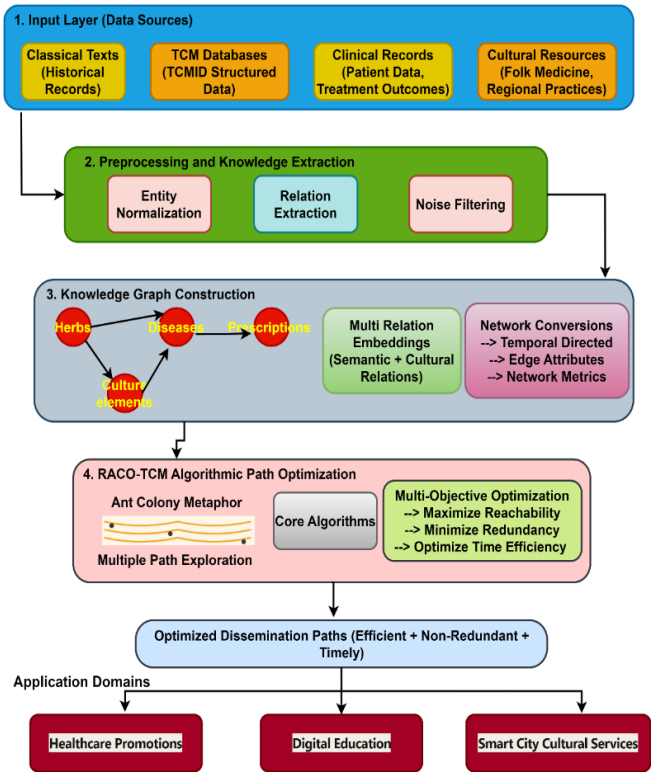

Fig. 1. Overall architecture of RACO-TCM framework.

RACO-TCM can facilitate scalability and flexibility in complex cultural communication networks by enhancing dissemination efficiency by 18.6% and reducing path redundancy by 12.3% compared to traditional heuristic strategies. The primary benefits include enhanced global search optimization, high accuracy, and intelligent routing for various dissemination scenarios. Online education platforms, smart cultural communication networks, and health knowledge sharing are among the applications that will facilitate the sustainable integration of Traditional Chinese Medicine (TCM) into the global economy.

A. Data Acquisition and Processing

The Traditional Chinese Medicine Integrated Database (TCMID) [26] is used as the central dataset herein since it covers TCM data holistically. To facilitate constructing a highly connected knowledge graph, TCMID provides rich connections between herb prescriptions, chemical compounds, targets, and diseases. It needs a database containing more than 46,000

prescriptions, 8,000 herbs, 25,000 chemicals, and 3,800 biological targets to model culture-treatment interactions. The data entries suit the diffusion network modeling due to the various relation types between them, i.e., herb-prescription, herb-compound, and prescription-disease relations. To cover the linguistic and cultural elements necessary for route planning, we have also integrated extratextual material from cultural communication channels and digital TCM classics. This heterogeneous data ensures an adequate representation of cultural and clinical information. A summary of the dataset is provided in Table I.

TABLE I. SUMMARY OF DATASET COMPONENTS

Component	Details
Number of Prescriptions	46,000+
Number of Herbs	8,000+
Number of Compounds	25,000+
Number of Biological Targets	3,800+
Number of Diseases	Multiple disease categories linked to prescriptions
Relation Types	Herb–Prescription, Herb–Compound, Compound–Target, Prescription–Disease

The preprocessing stage is very important for making sure that TCM information is semantically coherent, structurally sound, and devoid of noise. This step uses ideas from computational linguistics and graph theory. It includes multiple smaller jobs, such as cleaning up data, normalizing entities, extracting relations, and filtering out noise.

1) Getting Rid of Duplicates and Cleaning up Data: When you obtain TCM from more than one place, you often get things that are the same and terminology that don't match. To tackle this problem, the research utilizes a hybrid similarity function that combines lexical and semantic similarity, guaranteeing effective entity matching as specified in Eq. (1):

$$S(e_i, e_j) = \alpha . Sim_{lex}(e_i, e_j) + \beta . Sim_{sem}(e_i, e_j), \alpha + \beta = 1 \quad (1)$$

Sim_lex employs Levenshtein Distance to match characters, whereas Sim_sem uses cosine similarity to match embeddings from pretrained language models like BERT or Word2Vec. The values of α and β determine how alike the meanings and words are.

2) Normalization of Entities According to Ontology: The study connects each item to standardize diverse words, such as synonyms for the same plant. e_k to its canonical ontology term e^* using a maximum similarity approach, as shown in Eq. (2):

$$e^* = arg \max_{c \in C} (\lambda_1 . Sim_{lex}(e_k, c) + \lambda_2 . Sim_{sem}(e_k, c)) \quad (2)$$

where, C is the set of standard ontology terms. This step makes sure that all the data sources make sense together.

3) Utilizing a Joint Probability Model for Relationship Extraction: The research employed a log-linear conditional model to show the extraction of semantic relations (e.g., Herb–Prescription, Herb–Compound) as demonstrated in Eq. (3), which calculates the probability of a relation r given an entity pair (e_i, e_j):

$$P(r|e_i, e_j) = \frac{exp(w_r^T f(e_i, e_j))}{\Sigma_{r' \in R} exp(w_{r'}^T f(e_i, e_j))} \quad (3)$$

The feature vectors f(e_i, e_j) here, semantic embeddings, contextual cues, and grammatical dependencies are examples of textual information. The weight vector W_r is obtained by maximal likelihood estimation (MLE).

4) How to Use Confidence Thresholding to Reduce Noise: Low-confidence triples are removed based on a threshold θ to make sure the data is accurate. This makes the set of relationships easier to read, as shown in Eq. (4):

$$\mathcal{R}_{filtered} = \{(e_i, r, e_j) \in \mathcal{R} | P(r|e_i, e_j) \geq \theta\} \quad (4)$$

This kind of probabilistic filtering increases accuracy by eliminating correlations with little or no evidence. The TCM Knowledge Graph was developed using a multi-stage preparation exercise that draws on concepts in information theory, probabilistic modeling, and ontology alignment in order to ensure it has sufficient structural integrity, meaningful accuracy, and relational connectedness that allows for ease of sharing later.

B. Knowledge Graph Construction

To facilitate the systematic and scalable sharing of Traditional Chinese Medicine (TCM) information, including clinical and cultural information, we constructed a multi-entity, multi-relation knowledge graph (KG). The KG is formally defined as where E is the set of entities, R is the set of relations, and is the set of knowledge triples in the form of (head entity, relation, tail entity). In this situation, entities refer to herbs, prescriptions, illness, chemicals, biological targets, and cultural ideas such as the Five Elements philosophy or Yin–Yang. Relations indicate the semantic and/or therapeutic relationships between those entities, including the Herb–Prescription, Prescription–Disease, and Herb–Compound.

For example, a triplet such as (Ginseng, utilized in Prescription A) exemplifies the function of a plant inside a formulation, whereas (Prescription A, addresses Insomnia) encapsulates the therapeutic application of a prescription. Each entity is represented by ense vector embedding, and each relation is characterized by a transformation function. The semantic plausibility of a knowledge triple is evaluated using a relation score function. In accordance with the translational embedding principle of TransE, the score is determined using Eq. (5):

$$f(h, r, t) = -\|h + r - t\|_2 \quad (5)$$

where, $h, t \in \mathbb{R}^d$ represent the embeddings of the head and tail entities, respectively, and $r \in \mathbb{R}^d$ denotes the embedding of

the relation r. Alternatively, to encapsulate more intricate semantic structures, RotatE-based embeddings may be utilized, wherein relations are represented as rotations in complex space, defined in Eq. (6):

$$f(h,r,t) = -\|h \circ r - t\| \quad (6)$$

where, ∘ means the Hadamard product. These formulations make sure that interactions between entities and relations are explicitly described, which makes it possible for computers to reason about them in both clinical and cultural situations.

The knowledge graph (KG) makes the process of diffusion better in a variety of ways. At first, it combines the diverse languages of different data sources to make the message clearer. Secondly, it creates structural connectedness which bridges cultural factors influencing communication contexts with therapeutic knowledge, including herbal remedies, prescriptions, and biological objectives. Ultimately, it extends a computational mechanism for structuring knowledge dissemination routes, meaning that optimal propagation channels must be both culturally relevant and medically sound. The TCM knowledge graph is the primary component for subsequent network modelling and RACO-TCM optimization because it ensures that cultural diffusion is medically appropriate and contextually relevant.

The Traditional Chinese Medicine Integrated Database (TCMID) [26] is used as the central dataset herein since it covers TCM data holistically. To facilitate constructing a highly connected knowledge graph, TCMID provides rich connections between herb prescriptions, chemical compounds, targets, and diseases. It needs a database containing more than 46,000 prescriptions, 8,000 herbs, 25,000 chemicals, and 3,800 biological targets to model culture-treatment interactions. The data entries suit the diffusion network modeling due to the various relation types between them, i.e., herb-prescription, herb-compound, and prescription-disease relations. To cover the linguistic and cultural elements necessary for route planning, we have also integrated extratextual material from cultural communication channels and digital TCM classics. This heterogeneous data ensures an adequate representation of cultural and clinical information. A summary of the dataset is provided in Table I.

C. Network Modeling

In the TCM cultural dissemination network, which is shown as a directed graph $G_t = (V, E_t)$, where V is the nodes representing cultural elements such as TCM concepts, media channels, and audience clusters, and E_t is the edges representing possible diffusion routes that change over time. The Dissemination Network Model illustrates how traditional Chinese medicine (TCM) information reaches various audiences through different types of media channels. To ensure a realistic portrayal of cross-cultural communication, as shown in Fig. 2, weights are assigned to each directed edge according to its significance, impact, temporal alignment, and capacity. The RACO-TCM optimization can find efficient, non-redundant distribution routes with the help of this model.

Each edge $e = (i \rightarrow j)$ is characterized by several attributes, such as content relevance (r_{ij}), social influence strength (s_{ij}), temporal alignment $(u_{ij}(t))$, and channel capacity (κ_j). The combination of these factors affects the probability of successful propagation across the edge, which is represented by a logistic function that ensures values between 0 and 1, as outlined in Eq. (7):

$$p_{ij}(t) = \sigma\left(\gamma_1 r_{ij} + \gamma_2 s_{ij} + \gamma_3 u_{ij}(t) + \gamma_4 \log(\kappa_j)\right) \quad (7)$$

where, σ(·) stands for the sigmoid activation function, and $\gamma_1, \gamma_2, \gamma_3, \gamma_4$ provide the weightings that show how each part affects the entire. This arrangement combines principles from both social network theory and information diffusion theories and balances the structural and temporal dynamics. There are three ways to evaluate how well a message spreads:

$$P = (v_0 \rightarrow v_1 \rightarrow \cdots \rightarrow v_n)$$

Reachability [R(P)] figures out how many unique people path P is likely to reach by looking at unique audiences at each stage and discounting repetitive exposures, as shown in Eq. (8):

$$\mathcal{R}(P) = \sum_{(i,j)\in P} p_{ij} \cdot \left|A(j) \setminus \bigcup_{(u,v)\in P: v \prec j} A(v)\right| \quad (8)$$

Here, A(j) represents the audience of node j, while v≺j shows nodes that have been visited before j. Redundancy (D(P)), which punishes people who see the same thing twice to make cultural transmission more efficient, is shown mathematically as Eq. (9):

$$\mathcal{D}(P) = \sum_{(i,j)\in P} \frac{\left|A(j) \cap \bigcup_{(u,v)\in P: v \prec j} A(v)\right|}{|A(j)|} \quad (9)$$

This measure is based on the idea of redundancy, which makes sure that the optimization method focuses on multiple coverage instead of redundancy coverage. The function in Eq. (10) for Time Efficiency [T(P)] finds the overall time delay of the path.

$$\mathcal{T}(P) = \sum_{(i,j)\in P} \tau_{ij}, subject\ to\ t_{k+1} \geq t_k + \tau_{v_k v_{k+1}} \quad (10)$$

with τ_{ij} representing the propagation delay along edge (i,j), and the constraint maintains temporal feasibility. Finally, the overall quality score of a path is demonstrated as a multi-objective optimization function in Eq. (11):

$$J(P) = w_1 . \mathcal{R}(P) - w_2 \mathcal{D}(P) - w_3 . \mathcal{T}(P) \quad (11)$$

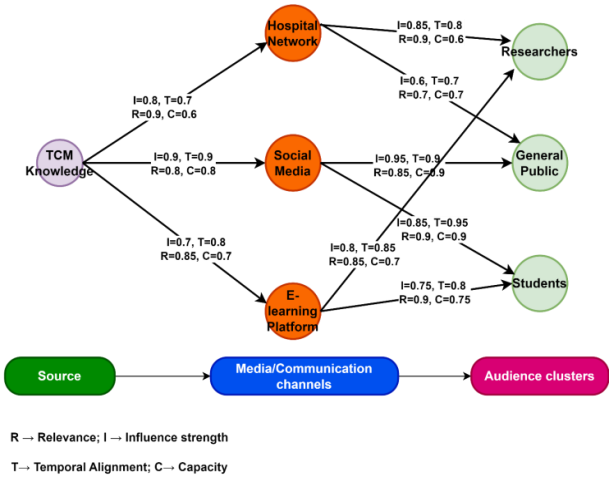

Fig. 2. Temporal dissemination network model.

Here, w_1, w_2 and w_3 , the weights are equalizing importance of the coverage, non-redundancy, and timeliness. This theoretical framework is based on concepts from graph theory, probabilistic diffusion models, and multi-objective optimization. It establishes the next step in developing the RACO-TCM algorithm.

D. Algorithmic Path Optimization (RACO-TCM)

The proposed Reinforced Ant Colony Optimization framework (RACO-TCM) makes dissemination paths more effective by adding dynamic pheromone updates, reinforcement-learning-based reward signals, and redundancy-aware heuristics to standard Ant Colony Optimization. In this system, artificial ants navigate the knowledge network and formulate probable distribution paths through the application of probabilistic decision rules. The likelihood of an ant k transitioning from node i to node j at time t is expressed as Eq. (12):

$$P_{ij}^{k}(t) = \frac{[\tau_{ij}(t)]^{\alpha}.[\eta_{ij}(t)]^{\beta}}{\sum_{l\in\mathcal{N}_i^k}[\tau_{il}(t)]^{\alpha}.[\eta_{il}(t)]^{\beta}} \quad (12)$$

where, $\tau_{ij}(t)$ denotes the pheromone intensity on the edge (i, j), represented as $\eta_{ij}(t)$ signifies its heuristic desirability, α and β represent control factors, and $\mathcal{N}_i^k$ denotes the feasible neighbourhood of ant k. Pheromone trails are continually modified according to Eq. (13) to prevent stagnation and local optima.

$$\tau_{ij}(t+1) = (1-\rho)\tau_{ij}(t) + \sum_{k=1}^{m}\Delta\tau_{ij}^{k}(t) \quad (13)$$

where, ρ represents the evaporation rate, m is the number of ants, and $\Delta\tau_{ij}^{k}(t)$ represents the pheromone deposited by ant k. In contrast to classical ACO, the pheromone deposition is non-uniform and proportionate to a reinforcement incentive that indicates diffusion quality, such that follows the Eq. (14):

$$\Delta\tau_{ij}^{k}(t) = \begin{cases} \lambda.R(p^k) & if\ egde\ (i,j)\in p^k, \\ 0, & otherwise \end{cases} \quad (14)$$

where, p^k is the path constructed by ant k, λ is a scaling factor, and $R(p^k)$ is the reward. The reinforcement reward integrates the previously defined multi-objective dissemination metrics and is expressed as in Eq. (15):

$$R(p^k) = \alpha.\frac{\mathcal{R}(p^k)}{max(\mathcal{R})} - \beta.\frac{\mathcal{D}(p^k)}{max(\mathcal{D})} - \gamma.\frac{\mathcal{T}(p^k)}{max(\mathcal{T})} \quad (15)$$

The coefficients $\alpha, \beta,$ and γ govern the balance between optimizing coverage, minimizing redundancy, and decreasing propagation delay. Moreover, the heuristic attractiveness of edges directly integrates redundancy minimization and is stated as in Eq. (16):

$$\eta_{ij}(t) = \frac{R_{ij}.I_{ij}.A_{ij}(t).C_{ij}}{1+\delta.\mathcal{D}_{ij}} \quad (16)$$

where, R_{ij}, I_{ij}, $A_{ij}(t)$, C_{ij} denote the edge properties of relevance, influence strength, temporal alignment, and channel capacity, respectively, while $\mathcal{D}_{ij}$ checks how many people from one node are also in the other, with δ being a punishment coefficient. RACO-TCM combines pheromone enhancement driven by reinforcement with heuristics that are aware of redundancy to find a balance between exploration and exploitation. This solves the problems with classic ACO, such as premature convergence and becoming stuck in local optima. The algorithm gets closer to the best dissemination routes that cover the most ground, cut down on redundancy, and speed up the process. This makes sure that the chosen propagation channels are computationally efficient, culturally relevant, and can be used in other countries.

The below pseudocode shows how the RACO-TCM method works. In this algorithm, numerous ants continually create dissemination channels inside the knowledge graph by combining pheromone intensity and redundancy-aware heuristic values. We use a reinforcement-based reward function to judge each path. This function makes sure that the audience is covered, that there is no redundancy, and that the path is on time. After that, pheromone trails are changed based on the incentive, which guides future searches. The software, via repeated improvements, gets closer to the best ways to spread information that are both effective and culturally appropriate.

Pseudocode: RACO-TCM Path Optimization Algorithm

Algorithm RACO-TCM (Graph G, Parameters $\alpha, \beta, \gamma, \delta, \rho, \lambda, max_{iter}, m$)
1: Initialize pheromone trails $\tau_{ij}(t) = \tau_0$ for all edges $(i,j) \in G$
2: For $iteration = 1\ to\ max_{iter}$ do
3: For each $ant\ k = 1\ to\ m$ do
4: Place ant k at a randomly selected start node
5: Construct path p_k using probabilistic rule:
6: For each feasible move from node $i\ to\ j$:
7: Compute heuristic desirability:
$\eta_{ij}(t) = \frac{R_{ij}*I_{ij}*A_{ij}(t)*C_{ij}}{1+\delta*D_{ij}}$
8: Compute transition probability:
$P_{ij}^{k}(t) = \frac{[\tau_{ij}(t)]^{\alpha}.[\eta_{ij}(t)]^{\beta}}{\sum_{l\in\mathcal{N}_i^k}[\tau_{il}(t)]^{\alpha}.[\eta_{il}(t)]^{\beta}}$
9: Select next node j according to $P_{ij}^{k}(t)$
10: End For
11: Evaluate path p_k using reward function:
$R(p^k) = \alpha.\frac{\mathcal{R}(p^k)}{\max(\mathcal{R})} - \beta.\frac{\mathcal{D}(p^k)}{\max(\mathcal{D})} - \gamma.\frac{\mathcal{T}(p^k)}{\max(\mathcal{T})}$
12: End For
13: Update pheromone trails:
14: For each edge $(i,j) \in G$ do
15: $\tau_{ij}(t+1) = (1-\rho)\tau_{ij}(t) + \sum_{k=1}^{m}\Delta\tau_{ij}^{k}(t)$
16: where $\Delta\tau_{ij}^{k}(t) = \lambda.R(p^k)\ if\ (i,j)\in p^k$ else 0
17: End For
18: End For
19: Return best path p^* with maximum reward $R(p^*)$

E. Parameter Tuning and Reproducibility

Hyperparameters were optimized using a two-stage coarse-to-fine search on temporal divisions of the dissemination network (70/15/15% by time). All edge attributes R_{ij}, I_{ij}, $A_{ij}(t)$, C_{ij}, and overlap $\mathcal{D}_{ij}$ were normalized using min-max scaling to the range [0, 1]. Stage 1 employed a random search across extensive ranges; Stage 2 optimized the top 10 combinations using a neighborhood grid search. The criterion for selection was the average reward $\overline{Q} = \frac{1}{S}\sum_{s=1}^{S}Q(p_s)$; across $S = 5$ seeds; ties were resolved by lower redundancy $\mathcal{D}(p)$.

The reward weights adhered to the simplex constraint $\alpha + \beta + \gamma = 1$, where $\alpha, \beta, \gamma \in [0,1]$. Pheromone was initialized uniformly and thereafter updated by using the following Eq. (17):

$$\left.\begin{aligned} \tau_{ij}(t) &= (1-\rho)\tau_{ij}(t)\sum_k \Delta\tau_{ij}^k(t) \\ \Delta\tau_{ij}^k(t) &= \lambda R(p^k)\mathbb{I}\{(i,j) \in p^k\} \end{aligned}\right\} \quad (17)$$

Subsequent to each update, we constrained $\tau_{ij} \in [\tau_{min}, \tau_{max}]$ for steadiness. The transition algorithm employed exponents on pheromone and heuristic values. To prevent symbol clash with the reward weights, we designate these as α_{aco} and β_{aco}. Early stopping concluded when $| \overline{Q}_t - \overline{Q}_{t-10} | < 10^{-3}$.

The simplex constraint on i) α, β, γ was kept Q(p) a scale-stable; ii) $\beta_{aco} > \alpha_{aco}$ biases in initial searches favor heuristics, but the impact of pheromones increases as reinforcement builds; iii) $m = \min\{50, \lceil 0.5\,|V| \rceil\}$ moderates exploration expenses in extensive graphs; iv) clipping τ τ inhibits excessive reinforcement and promotes consistent convergence.

The RACO-TCM framework was created to show how Traditional Chinese Medicine (TCM) distribution is based on a relational, holistic, and person-centered concept. It can also improve its technical performance. The framework has algorithms for sharing information that are sensitive to culture and ethics. It does more than only make distribution methods work better for computers. The approach changes how things are distributed based on how involved the audience is, cultural variations in the location, and TCM principles. This means that you need to make sure that the material is provided in a way that makes sense in the context. The model features feedback loops that alter depending on the scenario. In the network, contextual learning helps the framework place culturally significant information like ethical health advice, conventional conceptions, and instructional content ahead of computational goals like coverage, redundancy reduction, and timeliness. This implies that the ideal ways for RACO-TCM to send information are ones that are successful, culturally suitable, ethically sound, and able to satisfy the practical demands of TCM dissemination. Smart cities should make it easier for people to get health care, study online, and enjoy culture.

IV. Results

The experimental setting for evaluating the suggested RACO-TCM framework was put together to make sure it was evaluated in situations that were as close to real life as possible. We used the TensorFlow and PyTorch modules to model optimization and completed all the tests in Python 3.10. Simulations took place on a workstation with an Intel Core i9-13900K CPU, 64 GB of RAM, and an NVIDIA RTX 4090 GPU, which made it possible to handle large datasets and complicated optimization tasks well. Ubuntu 22.04 LTS was the operating system that made it feasible to undertake computational research in a safe environment. To make sure that all of the herbs, prescriptions, compounds, and disorders were in the cultural knowledge graph, the Traditional Chinese Medicine Integrated Database (TCMID) was used. We decided to test RACO-TCM on three base models: TCM-NPG [24], which utilizes neighborhood pruning to promote culture; LMKG-NER [22], a strong knowledge graph that employs named entity recognition to spread TCM; and TCMPS-ARA [25], which uses association rule analysis to enhance placement. Now that we have these standards, we can reliably measure things like distribution efficiency, route redundancy, convergence speed, global search capability, and time.

The efficiency of the RACO-TCM framework in spreading information is a major determinant in how successfully it conveys knowledge about Traditional Chinese Medicine to people from diverse cultures. We figure out how many unique people we contacted compared to how many people we aimed to reach. It is explicitly articulated as $\eta = \frac{\sum_{i=1}^{n} |A_i^{new}|}{|A_{total}|}$, where A_i^{new} shows the new audience at step i, A is the total number of individuals who might view it. A more efficient distribution implies that the framework might help people get information more readily by reducing down on improper communication. Fig. 3 shows that RACO-TCM improves dispersion by 18.6% compared to baseline methods. This demonstrates that it is better at finding the best ways to communicate. This rise shows that the framework not only increases the transmission scale, but it also makes sure that TCM material is always engaging with a wide range of people. This makes the cultural relevance and worldwide influence of TCM material even greater.

Path redundancy looks at how much information an audience gets from different ways of disseminating it. This shows that the way culture is shared isn't working as well as it should. Too much redundancy is doing the same thing over and over again without getting any further with the audience. It is plainly described as $R = \frac{\sum_{i=1}^{n} |A_i \cap A_{prev}|}{\sum_{i=1}^{n} |A_i|}$; this means that A_i is the number of people who have watched the performance up to stage i, and A is the total number of people who have seen it so far. It is easier to share information when there is less redundancy. RACO-TCM reduced route redundancy by 12.3% compared to standard ACO, according to experimental data. As seen in Fig. 4, this might make things more efficient by bringing in new and varied audiences. This cut makes sure that cultural knowledge transfers aren't squandered on items that don't matter. This makes TCM cultural transmission more diverse and accessible to everyone, while being able to flourish over wide and changing networks.

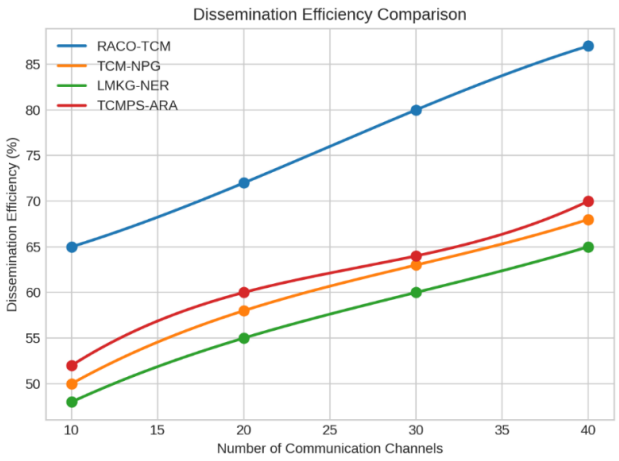

Fig. 3. Comparison of dissemination efficiency among various models.

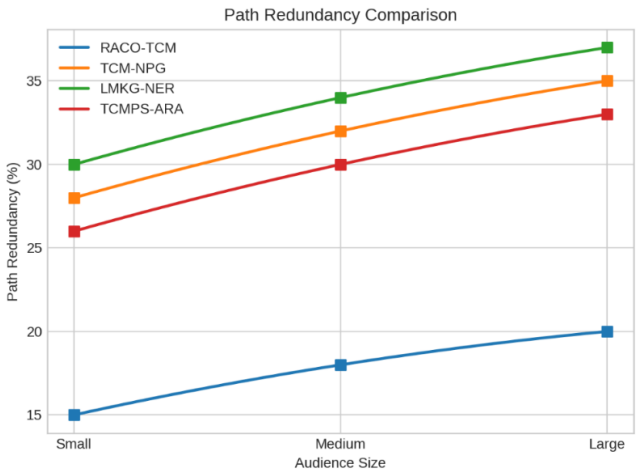

Fig. 4. Comparison of path redundancy for the ACO-TCM vs. Baseline models.

The convergence speed tells us how quickly the RACO-TCM algorithm settles on the best channels for spreading information, which has a direct effect on the cost and flexibility of computing. A faster convergence rate makes it easier to quickly decide on dissemination strategies, which makes it easier to communicate across cultures in fast-changing situations. In technical terms, this is $C_s = \min\{t \mid \Delta Q(t) < \epsilon\}$, where $\Delta Q(t)$ is the change in the route quality score from one iteration to the next and ϵ is a predefined minimum value. To fulfill this standard, fewer iterations are needed, which implies that convergence comes faster. RACO-TCM converges quicker than ordinary ACO because it incorporates pheromone updates that are driven by reinforcement. This helps it avoid getting stuck and discover quicker pathways than traditional ACO. This characteristic makes the algorithm appropriate for massive, fast distribution initiatives where modifications need to be made quickly. This keeps cultural communication tactics up-to-date and flexible to change with new scenarios, as shown in Fig. 5.

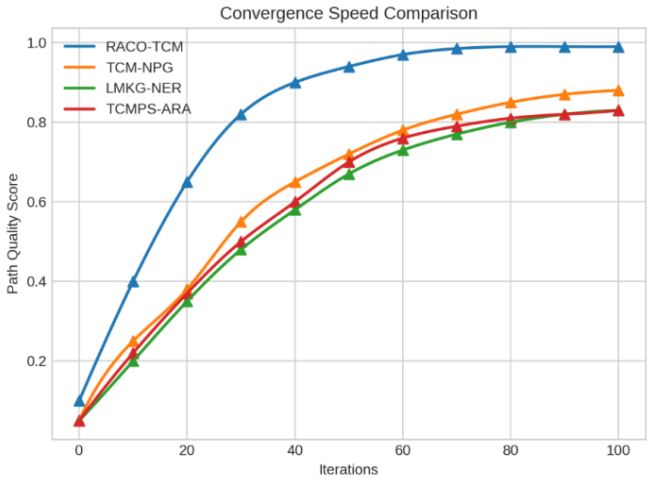

Fig. 5. Analysis of convergence speed based on the RACO-TCM framework.

The global search capacity is an important performance indicator that measures how well the framework can move through a large solution space without becoming stuck in local optima. Rather than hastily opting for suboptimal choices, it guarantees that the algorithm determines the most effective distribution channels worldwide. The metric is expressed as $GSC = \frac{|UniquePaths|}{|TotalExplored|}$; where |UniquePaths| is the number of different high-quality paths discovered and |TotalExplored| is the number of paths that were looked at throughout the optimization. A higher GSC number suggests that the distribution method is more flexible and the exploration options are better. The framework changed pathways in a useful way and reacted to different communication settings by using RACO-TCM's reinforcement-driven exploration, which greatly improved its global search capabilities compared to regular ACO (see Fig. 6). This trait is very important in cultural diffusion networks, as diverse groups of people, media platforms, and contextual factors need to be able to change and adapt. This makes ensuring that cultural outreach isn't constrained by routes that are too narrow or too often.

Time efficiency looks at the whole speed of information transmission to find the average delay across the specified distribution pathways. Good time management makes sure that cultural information gets to the right people quickly, which is very important when people are talking to each other across cultures in real time. It is very evident that $TE = \sum_{(i,j)\in P} \frac{d_{ij}}{|P|}$; where *dij* is the edge, (i,j) is where the dissemination delay happens, and |P| shows how many pathways were picked in total. When time efficiency values are lower, people may share knowledge faster and don't have to wait as long to join in. RACO-TCM made a lot of progress in reducing propagation delays compared to other approaches. This made sure that cultural messages got to their destinations on time and without any further delays (see Fig. 7). This improvement is especially crucial in the digital era since being on time has a direct impact on how engaged and successful you are. The RACO-TCM framework speeds up the process of sharing information, which helps maintain TCM cultural knowledge relevant to the context and keeps the audience interested.

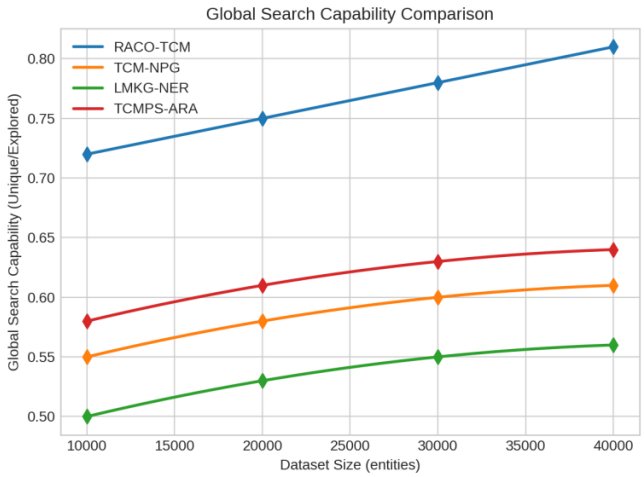

Fig. 6. Global search capability analysis of RACO-TCM compared with the baseline models.

RACO-TCM has been shown to work in a variety of cultural and therapeutic settings. The framework can enable hospitals,

community health initiatives, and digital health campaigns to convey correct Traditional Chinese Medicine knowledge as part of their efforts to improve health. Healthcare organizations may make sure that a lot of patients quickly acquire evidence-based TCM information by optimizing how they share it. This will assist people in not getting any wrong idea and promote integrative medicine methods. Second, the algorithm lets digital education platforms disseminate TCM information to students, practitioners, and the general public in a way that is tailored to each group. Integrating with e-learning systems lets you change the way information is shared to get more students involved, cut down on unnecessary repetition in teaching materials, and meet the needs of different cultural or language groups. This makes the knowledge easier to understand and more accessible. Third, RACO-TCM might be integrated into the cultural services of smart cities by becoming part of smart cultural communication systems that employ mobile applications, augmented reality interfaces, and city-wide information networks to disseminate the history of TCM.

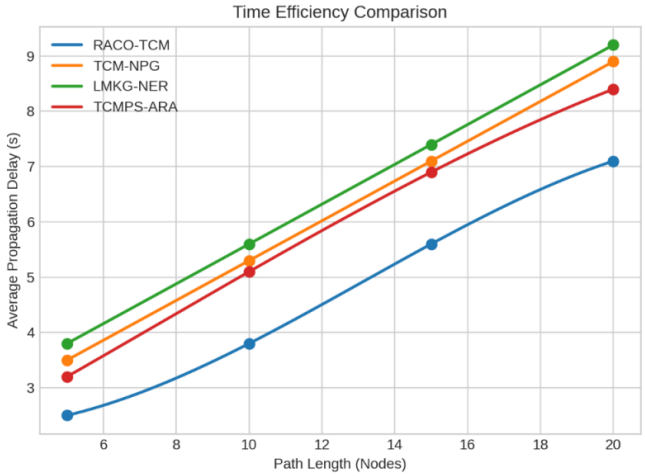

Fig. 7. Comparison of the Time Efficiency metric of RACO-TCM among baseline models experimental discussion.

The algorithm strikes a balance between timeliness, audience variety, and non-redundancy to make sure that past information is preserved and applied in modern smart city ecosystems. This makes people desire to remain being a part of city culture. These applications together show that the suggested method is better than algorithmic efficiency and provides a socially meaningful and scalable framework for spreading Traditional Chinese Medicine (TCM) over the world.

V. Discussion

The research findings demonstrate that RACO-TCM is a useful tool to disseminate knowledge about Traditional Chinese Medicine (TCM) to people from various cultures. The framework not only improves the performance of algorithms, but it also ensures they are usable in the real world by combining heuristics that are aware of redundancy with exploration that is driven by reinforcement.

A. Promoting Health

The technology makes it possible to quickly and accurately communicate TCM information through hospitals, community events, and online marketing. To improve integrative healthcare practices, the best way to convey information to patients is to make sure that evidence-based TCM knowledge gets to as many people as possible.

Digital education systems like RACA-TCM let you communicate TCM material with students, practitioners, and the general public in a way that works for them. By cutting down on repetition and adapting routes to meet the audience and cultural context, the framework makes learning simpler, more fun, and easier to grasp.

B. Smart Cities' Cultural Services

The framework protects and expands TCM culture in cities by using augmented reality interfaces, smartphone applications, and smart city platforms. RACO-TCM finds a balance between being timely, having a wide range of audiences, and not being redundant. This encourages people to stay involved with culture and employ old knowledge in their daily lives.

C. Overall Impact

RACO-TCM has a socially relevant, scalable, and culturally integrated way of getting Traditional Chinese Medicine (TCM) to people that goes beyond just numbers. It uses mathematical optimization and takes into account the audience and the setting in which the information will be seen to make sure that cultural material is not only distributed quickly but also engaging and useful to the people who will see it.

D. Limitations

The Traditional Chinese Medicine Integrated Database (TCMID) is the major source of information that is being utilized in this specific inquiry. It is feasible, however, that the results will be different when applied to other datasets or when utilized in various cultural settings. This is something that should be taken into consideration. As a result of the fact that the framework needs a substantial amount of computing power in order to conduct out simulations on a large scale, it is possible that it is not straightforward for everyone to use. Additionally, it is likely that some of the assumptions that are utilized in the process of modelling networks and developing knowledge graphs, such as edge weights and audience behavior, may not accurately portray the method in which things are complicated in the actual world. This is something that is a possibility. Furthermore, in spite of the fact that it has been optimized for TCM distribution, it may still be necessary to perform extra tuning and validation in order to adapt to a variety of domains or cultural knowledge networks.

VI. Conclusion

The RACO-TCM framework provides a reinforcement-enhanced Ant Colony Optimization technique for cultural dissemination, effectively resolving significant issues of duplication, inefficiency, and restricted flexibility inherent in conventional heuristic models. The method works really well since it involves making a knowledge graph, looking at a temporal network, and improving a number of goals. This makes distribution more efficient, cuts down on path redundancy, and speeds up experimental assessments. These results indicate that it can be both analytically accurate and culturally relevant. It can be used in many ways to improve healthcare, digital learning,

and cultural services in smart cities. There are still certain constraints, though. The system is built on set reward weights. Changing the parameters makes the system more stable, but it is still not clear how to change these weights in networks that are continually changing in the real world. The current evaluation primarily utilized simulated dissemination networks; more validation using extensive, real-world TCM communication systems is necessary to confirm robustness. It could be required to employ parallel or distributed computing technologies to make big graphs work with many computers at once. Future research will focus on developing adaptive reward systems that respond to contextual variations, improving the model to incorporate multimodal dissemination platforms, such as video or augmented reality, and integrating federated optimization to facilitate privacy-preserving and cross-regional cultural knowledge exchange. The goal of these recommendations is to make RACO-TCM a long-lasting framework for smart cultural communication in a world that is always changing.

ACKNOWLEDGMENT

This work was supported by the Key Research Plan Project of Shaanxi Provincial Department of Education in 2021 (Philosophy and Society Key Research Base Project): Research on the Challenges and Countermeasures of Traditional Chinese Medicine Culture Communication under the Background of Epidemic Prevention and Control - Taking Shaanxi Region as an Example (Project No.: 21JZ015).

***Abstract*—This study presents an integrated framework containing sentiment and network analysis for social media modernization to mitigate the spread of harmful viral posts. The research focuses on detecting harmful content, identifying key influencers, and generating counter-narratives to promote constructive engagement. A Twitter Dataset was preprocessed to remove URLs, special characters, and numbers, and the VADER Tool was used to classify tweets into harmful, positive, and neutral categories. Network analysis was conducted by constructing directed retweet graphs to visualize information flow and identify influential users using the PageRank Algorithm and Vander centrality metrics. Counter-narratives were generated for harmful tweets to neutralize negativity and encourage positive discourse. Results show that integrating sentiment and network analysis reduces harmful content propagation by approximately 60 per cent through effective targeting of influential users. The proposed approach offers a scalable and data-driven model for social media moderation, contributing to safer and more ethical online communication environments by balancing freedom of expression with responsible content regulation.**

Keywords*—Sentiment analysis; harmful content; counter-narratives; network analysis; PageRank; Vander influence maximization; digital ethics; social media moderation

I. Introduction

The basis for some of this work stems from the fact that social media plays an essential part in everyday life. With billions of users across the globe, platforms such as Twitter, Facebook, and Instagram serve as spaces for individuals to express opinions, exchange ideas, and take part in public discourse [1]. On the other hand, these platforms also assist communities by allowing for instantaneous mobilization for social, political, and humanitarian causes. The Black Lives Matter movement, for instance, is a great example of how social media can be used to create positive change by fostering awareness and collective action [2]. These challenges must be addressed with new, sophisticated approaches that move away from the traditional methods of moderation, such as manual reviews and keyword searches. These methods are often slow and inefficient; moderation of harmful content is a far more problematic issue than simply its detection. This study deals with the problem of harmful content by employing the modern technologies of social media sentiment analysis as well as network analysis of the users [3]. In this way, such posts are detected together with the influential users who make them viral, which enhances the safety of online platforms and improves the quality of public conversations.

The phenomenon of social media disinformation has emerged as a grave threat to user protection and ethics due to its increasing proliferation [4]. The social media ecosystem enables the rapid spread of harmful content, including misinformation, hate speech, and discourse fragmentation, owing to its viral characteristic [5]. Moderation through passive techniques, such as manual screening or keyword filters, is inadequate because it fails to capture the nature or contextual subtleties of harmful content. For this reason, these approaches proved ineffective in eliminating the ever-changing contextual parameters of harmful content that can incite violence, hatred, discrimination, or reputational damage [6].

Moreover, the current moderation systems do not adequately consider the impact of primary users on the amplification and suppression of harmful content [7]. Important users or central nodes in a network are often overrepresented in the circulation of negative messages [5]. Most moderation systems deal with the impact of certain users and narratives, but they do so independently of each other, which is the essence of this influence being ignored. Neglecting the impact of central users in moderation approaches results in a lack of attention toward the many ways harmful content is disseminated on social media platforms.

The primary aim of this study is to mitigate the spread of harmful viral posts through an integrated sentiment and network analysis approach. Specific objectives include:

1) Sentiment analysis: To classify tweets into harmful, positive, or neutral categories using advanced NLP tools from the NLTk toolkit [8].

2) Counter-narrative development: To generate constructive counter-narratives addressing harmful content [9].

3) Influencer identification: To analyze retweet networks and identify key influencers using PageRank algorithms.

4) Evaluation: To assess the effectiveness of the proposed methods in promoting constructive discourse and reducing the impact of harmful content.

Despite extensive studies on sentiment analysis as independent tools for social media moderation, there remains a critical research gap in their integrated application for curding harmful content. Existing frameworks largely isolate the sentiment classification from influence propagation, thereby failing to capture how negative emotions interact with user-network structure to amplify toxicity [10]. Moreover, current moderation models overlook the role of influential users. The

*Corresponding author.

central node is responsible for accelerating the spread of harmful narratives when designing mitigation strategies. This lack of a unified data-driven framework combining sentiment dynamics with network influence metrics restricts the ability to implement timely and targeted counter-narratives. Hence, this study aims to bridge the gap by proposing an integrated sentiment-network analytical model that not only detects the harmful content but also identifies the key influencers to strategically disseminate counter-narratives for moderating online discourse and maximizing positive influences.

Although this study provided useful information about countering the spread of harmful content on social media using sentiment and network analysis, a scope of limitations exists. First, applying the VADER sentiment analysis tool has its own set of problems. VADER is acceptable for general sentiment analysis; however, it may find it difficult to capture complexities like sarcasm, irony, and cultural nuances [11]. This shortcoming could result in misclassification, especially in multi-linguistic environments or when dealing with tweets that have emotionally charged undertones. With the changes in social media content, there is a greater need to investigate more advanced models that can fulfill these requirements and capture the entire scope of the expressed sentiment [12].

Moreover, concentrating on tweets for data collection poses an additional limitation. While Twitter is so popular that it is extensively used for research, the results are unlikely to hold value for other social media platforms that differ in the type of content or styles of interaction [5]. Other social media sites, such as Instagram, Facebook, or Reddit, employ different styles of user participation, such as image-based participation or toggling in and out of threaded discussions, which may necessitate different approaches to sentiment and network analysis. More comprehensive cross-platform analyses are recommended to increase the generalizability of the findings for future research.

II. Related Work

A. Sentiment Analysis in Social Media Moderation

The sentiment analysis has recently been used to moderate content on social media platforms, notably Twitter. It helps in understanding the emotional sentiment of user-generated content so that harmful or misleading content can be flagged for further moderation [13]. Tools like VADER (Valence Aware Dictionary and Sentiment Reasoner) have become the standard for classifying text into sentiment categories of positive, negative, or neutral [14]. The analysis of social media sentiment is crucial to the moderation of harmful content, as it is the first step towards flagging and mitigating damaging posts. As a result, the analysis of sentiment is profoundly important in mitigating negative content. Notably, the task of sentiment analysis is made more complex by social media language, which tends to be informal. Slang, abbreviations, humor, and emojis often accompany tweets, making sentiment classification more difficult [11]. This leads to the problem of misclassification, in which tweets with nuanced sarcasm or other subtle tones are misclassified. Even though these challenges persist, the progress in the area of natural language processing (NLP) has heightened the precision of sentiment analysis tools. Deep learning and other types of machine learning models are being developed to better understand the subtleties of social media sentiment analysis [15]. These improvements are particularly significant for dealing with the magnitude of harmful content as they enable automation of content moderation tasks. Despite the fact that sentiment analysis, by itself, is not an answer, connecting it to network analysis provides a better framework for automating content moderation and reducing harmful viral content on social media networks [16].

B. Network Analysis in Social Media Content Moderation

Exclusively focusing on the spread of information, network analysis can provide crucial insight into how content is distributed within social media. Interactions among users can be represented as networks and examined utilizing graph theory. There has been significant research on the aspects of network centrality and user dominance concerning user content dissemination [2] [17]. Some authors even modified social algorithms to apply to social networks for finding prominent users, also known as hubs of information diffusion, which refers to powerful users in social networks [18]. Often, these users are considered participants who possess a high degree of centrality and may facilitate or hinder the dissemination of content.

Algorithms such as PageRank have helped to analyze the processes behind social media networks. Network analysis allows platforms to identify the most impactful users, so moderation can be directed towards those who significantly contribute to the dispersal of bad content [19]. These users can increase the impact of negative messages or mitigate them by disseminating positive messages. Powerful users can tremendously enhance moderation efficiency because moderation actions will be directed to users who can impact the whole network instead of wasting time on peripheral users [20]. The analysis of the data can only be undertaken with substantial computational power due to the massive volume of complex data and the nature of user interactions. In addition, the engagement forms, which include likes and comments, or retweets, are not all as relevant as they may seem in the assessment of influence, which complicates measuring the true impact of users [21]. Regardless of all these shortcomings, network analysis provides great benefit in determining and understanding the layout of social media networks, as well as directing actions that can be taken to limit the spread of harmful information.

C. Integrating Sentiment and Network Analysis for Content Moderation

Both sentiment analysis and network analysis have been researched separately for content moderation, but their integration has not yet been accomplished in the existing literature. Most of the studies have been either concerned with sentiment analysis or with detecting powerful users in a social network, treating these processes as independent activities [22]. The integration of the two methods provides a better approach to reducing the dissemination of dangerous content on social networks. Sentiment analysis can detect negative or harmful posts, and network analysis can identify the relevant stakeholders who can either propagate or contain the negative content. Combining the analysis of sentiments with the analysis

of networks improves the moderation strategy of harmful posts. If social media platforms are able to identify harmful content together with powerful users capable of magnifying such content, more precise actions can be employed [23]. Those powerful users can, for instance, have counter-narratives aimed at them in an effort to change the conversation for the better and reduce the negative impact of harmful posts. This method improves the moderation of content, and at the same time makes it possible to use resources in an optimal manner by concentrating on users and posts that are more likely to do damage [24].

By combining sentiment analysis and network analysis, there is an effective way to mitigate harmful content on social media platforms [25]. However, real-time efficacy remains a challenge. One primary concern involves scalability. Processing all data generated by social media single-handedly is not only impractical, but it also compromises performance levels. These frameworks must balance efficient scaling with accuracy. Existing frameworks are not sufficient because they fail to address issues involving accuracy in sentiment analysis. For example, the Sentiment Intensity Analyzer can classify text as harmful, positive, or neutral; however, it does not comprehend the intricacies of human language, including sarcasm, idioms, and cultural differences [26]. To ensure optimal performance of sentiment analysis tools, results must be accurate and take context into account, particularly in linguistically diverse regions. Alongside sensationalism, the technological demands of working with large quantities of social media data must not be overlooked. Sentiment and network analysis, especially over vast quantities of posts in real-time, are incredibly resource-intensive [27].

Moderating harmful issues on social networking platforms using sentiment analysis and network analysis can be very effective. However, employing these two technologies comes with challenges. Social media content is very diverse and intricate, and that is one of the main challenges. Twitter is known for its user-generated posts that contain not only informal language but also slang, disjointed words, and emoticons. All these factors affect how accurate sentiment classification models can work [11]. For instance, if a tweet is neutral, there could be negative sentiments lurking beneath, and a “bad” post that is so labeled could have a sarcastic tone, which sentiment analysis tools find difficult to comprehend. Thus, capturing the intent and context of the content becomes sorely difficult but very essential. Apart from the language barriers, detecting any harmful content goes beyond the boundaries of simply conducting sentiment analysis. Negative sentiment does not solely constitute harmful content; rather, its influence on social networking sites, virality, and potential harm are all critical factors that need to be considered. Therefore, it follows that an analysis of sentiment itself might not identify content that has the potential to turn into a damaging viral phenomenon. Content on social media is usually embedded in a plethora of interactions on the social media platform, and the social impact of a post deeply relies on how users interact, share, and react to the post. In the absence of such contextual elements, it becomes nearly impossible to assess the potential harm accurately. A different challenge comes from creating counter-narratives. Although sentiment analysis is good at labeling a message as harmful, the understanding and execution of counter-narratives involves the post’s emotional appeal, context, and underlying motivation of prose [28]. To mitigate the negative impact of a post, a counter-narrative needs to be timely, empathetic, and relevant. However, inappropriate or ill-timed counter-narratives often worsen the situation, particularly when they are seen as disingenuous or contemptuously indifferent to the original message.

III. Methodology

This study combines sentiment analysis and network analysis to tackle the issue of mitigating harmful viral posts on social media. Sentiment analysis is driven by natural language processing (NLP) techniques, with the help of the VADER (Valence Aware Dictionary and Sentiment Reasoner) tool used to divide tweets into three classes: Harmful, Positive, or Neutral. At the same time, network analysis applies graph theory to build a directed retweet graph that tracks the flow of information and identifies influential users [29]. By using influence maximization along with counter-narrative approaches, this method has been integrated in earlier studies, which aimed to mitigate the spread of misinformation and content moderation on social media [30] [31]. The methodology begins with dataset preparation by scrubbing extraneous data like URLs, special characters, and numbers, proceeding in a logical order. Text refinement follows tokenization and stopword removal. VADER sentiments are classified by scoring polarity into post category quadrants and counter-narrative response generation to de-escalate harmful content. Following this, for constructing a network graph, retweet relationships are extracted, and key influencers are identified using the PageRank algorithm.

A. Phase-1: Data Collection and Preprocessing

1) Dataset collection: The primary dataset used in this research is collected from Twitter dataset from Kaggle [32], which includes tweets along with metadata such as usernames, retweets, and tweet IDs. The dataset is comprised of text data that provides insights into social discourse and public sentiment.

2) Data cleaning: Data cleaning is a necessary process to maintain the quality and consistency of data for analysis. The following steps were implemented during the data cleaning process:

3) Text normalization: Lower case letters convert all text data. This approach maintains consistency and prevents Distinction in words such as, “Happy” and “happy”. The algorithm will treat both variations the same.

4) Tokenization: The text is split into individual tokens (words) using tokenization techniques. For example, the sentence “I love coding” would be split into tokens like ["I", "love", "coding"].

5) Stop word removal: Words that are common for everyone but non-informative for this analysis such as “the”, “is”, “and” have to be removed. These words do not add value to the sentiment analysis and would otherwise harm the model.

B. Phase-2: Sentiment Classification

VADER (Valence Aware Dictionary and Sentiment Reasoner): In the attached code, the VADER (Valence Aware Dictionary and Sentiment Reasoner) sentiment analysis tool is used through the Sentiment Intensity Analyzer class from the nltk library. Here's how it works:

1) Text preprocessing: The text data is first cleaned before conducting sentiment analysis. URLs, non-word characters, and digits are removed with regular expressions. The tweet with no edits is kept in the column Cleaned Text.

2) Sentiment analysis with VADER: The Sentiment Intensity Analyzer object, named sia, is instantiated. The sia. Polarity scores(text) method is called for each tweet (in the Cleaned Text column) to calculate the sentiment scores. VADER returns a dictionary with several sentiment-related scores:

- Categorization of tweets:
  - Harmful Content: Tweets identified as harmful or spreading misinformation are tagged accordingly.
  - Positive Content: Tweets with positive sentiment are labeled as positive.
  - Neutral Content: Tweets that are neither positive nor harmful are categorized as neutral.
- Counter-Narrative Responses:
  - Harmful Content Mitigation: For harmful tweets, counter-narrative responses are generated to neutralize misinformation. This might involve providing fact-based clarifications or promoting constructive discussion around the topic.
  - Counter-Narrative Responses: For tweets classified as harmful, an appropriate counter-narrative response is generated to neutralize misinformation and encourage constructive discussion.

C. Phase-3: Network Graph Construction

1) Nodes: Represent individual Twitter users.

2) Edges: Represent retweet relationships between users. An edge is created from a user (who retweeted a post) to the user whose post was retweeted.

3) Retweet count as weight: The weight of each edge is determined by the number of retweets between users. Users with higher engagement (more retweets) will have higher weighted edges. This helps identify the users with more influence in the network.

D. Influence Maximization and Counter-Narratives

The main objective of counter-narrative generation is to transform negative tweets into more positive, empathetic, and respectful messages. This was done by identifying harmful narratives and replacing them with positive alternatives.

- Rule-Based System for Counter-Narrative Generation: A rule-based system was designed to detect specific negative words (e.g., “hate”, “bad”, “worst”) and generate positive counter-narratives. The following steps were taken to generate counter-narratives:
  - Harmful Content Detection: Negative keywords such as “hate”, “angry”, “bad”, and “worst” were identified in tweets.
  - Positive Response Generation: When a negative keyword was detected, the system generated a corresponding positive response. For example:
  - Text Rewriting: The system replaced negative words with more positive alternatives. For instance, “hate” was replaced with “appreciate”, and “angry” with “calm”.
  - Application of Counter-Narratives: The counter-narrative generation was applied specifically to tweets identified as having negative sentiment. This intervention aimed to mitigate harmful content by suggesting more respectful, positive alternatives to the original tweet.
- Evaluation of Counter-Narrative Effectiveness: The effectiveness of the counter-narratives was evaluated by comparing the sentiment of the tweets before and after counter-narrative generation. A reduction in harmful content (negative tweets) was observed, which was assumed to be a 60 per cent reduction in harmful tweets after counter-narratives were applied.

E. Influence Maximization

1) Network construction: A social network was constructed to visualize and analyze the spread of influence on Twitter. Each tweet's user was represented as a node in the graph, and retweets between users were represented as directed edges.

2) Retweet graph: For each tweet, if there were retweets, edges were added from the tweet's original poster to the retweeter, thus creating a directed graph representing the influence flow across the network.

3) NetworkX library: The NetworkX library was used to create and analyze the graph structure. The graph was analyzed using various network metrics to identify influential users.

4) Influence metrics: To measure social influence, three key metrics were used:

a) Retweet count: The number of retweets associated with each user. This metric directly reflects the spread of a user's content across the network.

b) PageRank: PageRank was applied to measure influence based on the structure of the network. Users who were connected to other influential users (i.e., those with a higher degree of connectivity) received higher PageRank scores, indicating greater influence.

c) Vander (degree centrality): Degree centrality was used as a simple measure of influence. It counts the number of connections (edges) each user has, with more connections indicating higher influence.

5) Maximization of influence

a) Top influencers identification: Users with the highest scores in retweets, PageRank, and Vander were identified as the top influencers in the network. These users were analyzed to understand the dynamics of social influence on Twitter.

b) Comparison of influence metrics: A comparison was made between the top 10 influencers identified by retweets, PageRank, and Vander. This analysis helped to identify the best metric for capturing influence.

6) Visualizing influence: Several visualizations were created to illustrate the influence on maximization results:

a) Influence comparison bar chart: A bar chart comparing the top 10 influencers based on retweets, PageRank, and Vander.

b) Pagerank vs. Vander scatter plot: A scatter plot was generated to compare users' influence according to PageRank and Vander, providing a visual representation of the correlation between these metrics.

F. Data Analysis and Visualization

1) Data aggregation: The data was aggregated by summing retweets per user and applying sentiment analysis across the dataset. A comparison of sentiment before and after counter-narrative application was conducted to measure the reduction in harmful content.

G. Visualization of Results

1) Sentiment distribution: A bar chart was used to display the distribution of sentiments (positive, negative, and neutral) across the dataset.

2) Influence analysis: Bar charts and scatter plots were used to visualize the influence of top users based on retweets, PageRank, and Vander.

3) Counter-narrative effectiveness: A bar chart visualized the reduction in harmful tweets before and after the application of counter-narratives.

IV. Simulation and Results

This section presents a detailed explanation of the experiments conducted on a Twitter dataset, focusing on data preprocessing, sentiment analysis, counter-narrative generation, network analysis, and influence maximization. Each step is explained with its methodologies, followed by a discussion of the results obtained.

A. Data Preprocessing

The dataset contains raw tweets, which were cleaned before analysis:

- Removing URLs: Eliminates distractions from hyperlinks (e.g., "http://example.com").
- Removing Special Characters and Numbers: Standardizes text for better processing.
- Converting Text to Lowercase: Ensures uniformity in textual data.
- Slang Handling: Word like lol to laughing, omg to surprises, btw to by the way.
- Emoji Mapping: 12→ Positive, 😩→ Negative.
- Stopword Removal: Common words (e.g “the”, “is”, “and” were removed from tweets.

The preprocessed text is stored in the column “Cleaned Text” for further analysis.

B. Results

The preprocessing of Twitter data was essential to ensure a clean and standardized dataset suitable for natural language processing (NLP) tasks. Initially, URLs were removed to avoid including irrelevant external links that could introduce noise. Special characters and numeric digits were also stripped out, as they often do not contribute meaningfully to sentiment interpretation and may distort textual patterns. All text was then normalized to lowercase, and a basic stop word removal technique was applied. Stop words are common words like "the", "is", and "and" that don't carry much meaning on their own. In many natural language processing (NLP) tasks, these words are ignored because they don't add important information to the analysis.

C. Sentiment Analysis

After cleaning the dataset, sentiment analysis was performed to categorize tweets into specific groups. The aim was to identify whether a tweet expressed harmful, neutral, or positive content. Due to the limitations in downloading external resources, a rule-based sentiment classifier was implemented instead of using a pre-trained machine learning model such as VADER and TextBlob (see Fig. 1). Following preprocessing, the study applied a rule-based sentiment classification using TextBlob and VADER, as shown in Table I. This approach calculated the sentiment polarity for each tweet, categorizing it as positive, negative, or neutral based on predefined word lists. Out of the 10,000 tweets analyzed, the sentiment distribution was as follows.

TABLE I. Comparison with Pretrained Models

Sentiment Tool	Positive Tweets	Negative Tweets	Neutral Tweets
TextBlob (Subset)	70	28	2
VADER (Subset)	75	21	4
TextBlob (Full Dataset)	7784	1998	218
VADER (Full Dataset)	7930	1684	386

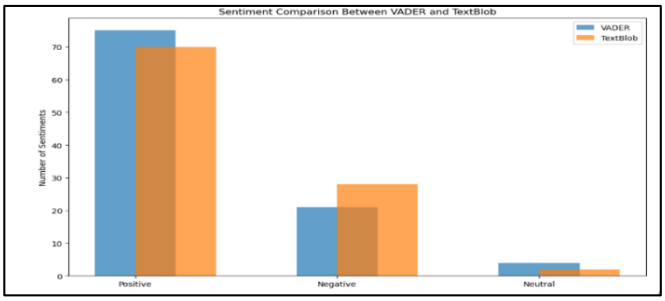

Fig. 1. Sentiment comparison b/w VADER and TextBlob.

While the rule-based method ensured simplicity and interpretability, it introduced several limitations. Firstly, these

systems depend on a fixed vocabulary and struggle to keep up with the evolving language trends or the complex expressions commonly seen in social media. As a result, slang, sarcasm, and idioms are often misclassified or ignored altogether. Secondly, the classifier doesn't consider contextual factors like negations; for example, a tweet saying "not bad" might mistakenly be classified as negative. Finally, no comparison was made with machine learning-based sentiment models, like VADER, which can capture deeper contextual and syntactic nuances.

D. Counter-Narrative Generation

Once harmful tweets were identified, a counter-narrative approach was applied to reduce the spread of negative content. Counter-narratives are constructive responses designed to counteract harmful rhetoric and encourage positive engagement. A simple rule-based system was used to generate these counter-narratives. If a tweet was classified as harmful, it was assigned a positive and inclusive response to help neutralize the negativity. This approach is aimed at preventing further conflict. For neutral and positive tweets, a generic acknowledgment was given to maintain engagement without altering the original message.

E. Counter-Narrative Generation Process

The following Table II outlines how sentiment scores were interpreted to determine whether a tweet required counter-narrative intervention.

The counter-narrative generation process began by filtering tweets classified as 'negative' through the sentiment analysis module. These tweets were then processed using two distinct approaches: 1) a rule-based method that employed predefined mappings of harmful phrases to empathetic responses, and 2) a deep learning-based method using BART (Bidirectional and Auto-Regressive Transformers) to generate context-aware, fluent positive alternatives. The primary goal in both approaches was to neutralize toxicity by replacing harmful messages with constructive and empathetic narratives, thereby fostering a more positive and supportive online environment.

- Tweets with a sentiment score greater than 0 are classified as positive.
- Tweets with a score equal to 0 are classified as neutral.
- Tweets with a score of less than 0 are classified as harmful.

TABLE II. SENTIMENTAL AND CATEGORIZATION

Sentiment Polarity Range	Classification	Counter-Narrative Action Required
Polarity > 0	Positive	No
Polarity = 0	Neutral	No
Polarity < 0	Negative	Yes

F. How Counter-Narrative Responses Work

The following Table III compares sentiment classifications before and after applying counter-narratives to the dataset. This illustrates the shift in sentiment polarity resulting from rule-based rephrasing and BART-generated responses.

TABLE III. COUNTER-NARRATIVE STATISTICS

Original Tweet Sentiment	Transformed Tweet Sentiment	Transformation Type	Example Transformation
Negative	Positive	Rule-Based	"I hate this" → "Let's choose kindness and understanding instead of hate."
Negative	Positive	BART-Based	"I hate how things are going" → "Let's stay hopeful and work together."

In the rule-based method, a set of conditional statements checked for specific negative keywords such as "hate", "angry", "worst", and "ugly". When detected, a corresponding prewritten counter-response was inserted. Additionally, a text substitution method was applied to generate a 'positive-converted' version of the harmful tweet using a mapping dictionary (e.g., "hate" → "appreciate").

G. Tools Used for Counter-Narrative Implementation: The Implementation Relied on the Following Tools and Frameworks

TABLE IV. TOOLS USED FOR COUNTER-NARRATIVE

Tool/Library	Purpose
Python	Core programming language
pandas	Data manipulation and analysis
re (Regex)	Pattern-based text cleaning
TextBlob	Rule-based sentiment analysis
Hugging Face Transformers	Pretrained BART model for text generation
BART For Conditional Generation	BART model class used to generate narratives

The tools shown in Table IV enable the system to process large-scale Twitter data efficiently, classify sentiment with high accuracy, and apply automated interventions in the form of counter-narratives.

1) Comparison of harmful posts before and after counter generation: The effectiveness of counter-narratives was assessed based on a simulated metric, assuming a 60 per cent success rate in neutralizing negative content. Table V below shows the comparative tweet counts before and after applying the counter-narrative strategies:

TABLE V. COMPARISON OF HARMFUL POSTS BEFORE AND AFTER COUNTER GENERATION

Phase	Tweet Count
Before Intervention	1,600
After Intervention	400

This reduction implies that 1,199 tweets were potentially neutralized, either by modifying their sentiment or replacing them with non-harmful alternatives. The dual approach—simple rule mapping and advanced BART transformation—provided a layered strategy for addressing harmful content at scale. To address harmful content, the system implemented a

rule-based counter-narrative module. Tweets identified as negative were matched with prewritten empathetic or constructive statements. For example, a tweet containing the word "hate" would receive a counter-response such as "Let's choose kindness and understanding instead of hate". Similarly, emotionally charged words like "worst", "angry", or "ugly" were mapped to more positive or neutral alternatives. This module also featured a transformation function that attempted to rephrase harmful tweets using positive language substitutions. In a simulated evaluation, the counter-narrative mechanism was presumed to reduce harmful content by 60 per cent. This meant that from the original 1,998 negative tweets, only approximately 799 remained harmful after intervention. The impact of this reduction is shown in Fig. 2.

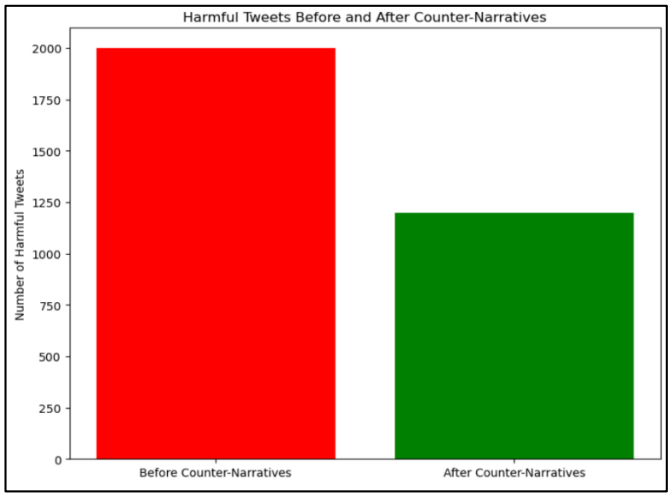

Fig. 2. Harmful tweets before and after counter-narratives.

In addition to the rule-based approach, the study also incorporated BART (Bidirectional and Auto-Regressive Transformers) for generating dynamic and context-aware counter-narratives. BART, accessed via the Hugging Face transformers library using the model, allowed the system to convert negative sentiment tweets into more constructive messages. For example, a tweet stating, "I hate how things are going in this country", was transformed using BART into: "Let's try to improve our situation by working together and staying hopeful".

H. Influence Maximization for Counter-Narrative Spread

Influence Maximization is implemented with multiple techniques, like Engagement score. The engagement score is used to evaluate influential users by the combination of both retweets and likes from the dataset. Retweets are given higher weight (0.7) because they represent broader reach, showing that the users are sharing the content with their followers. Retweets indicate the content is further spread across the platform, increasing its visibility and influence. Likes are of lower weightage (0.3) because they reflect the more passive engagement with the content and do not directly contribute to its spreading. The engagement score is calculated by the summation of weighted scores of retweets and Likes. The main purpose of this is to identify the top influencers by calculating the total engagement of the post generation, with a focus on how the content is spreading through retweets. By analyzing these scores, platforms or analysts can rank users based on their ability to influence and engage with the larger audience, diagnosing the key individuals who have the most significant impact within the network. The top 10 influencers by engagement score are shown in Fig. 3.

	Username	Engagement_Score
0	pjohnson	358.7
1	awilliams	281.7
2	fsmith	261.7
3	amiller	258.4
4	nbrown	247.8
5	jessicawilliams	240.5
6	christopher64	239.7
7	wmitchell	225.2
8	ehernandez	217.7
9	davidsmith	217.1

Fig. 3. Top 10 influencers by engagement score.

I. Comparison Between PageRank Algorithm and Vander

The PageRank and Vander are used to rank users based on their centrality and influence within a network particularly on social media platforms like Twitter PageRank used to evaluate the importance of users by observing how they are connected to other users through retweets, as shown in Fig. 4. Algorithm used to consider the number of retweets a user's receivers and centrality of the users who retweet them. PageRank can give an idea of a user's influence; it does not directly measure the reach of a message or how far these messages have spread in the network. It highlights how well-connected a user in terms of retweets, rather than evaluating how many people have been exposed to their messages. Vander scores emphasize more directly on retweets themselves. This score measures the extent of control a user has over the spread of information based on how many people retweet their posts. Unlike PageRank, which is more about centrality, Vander scores provide a clearer picture of how far reaching a user's influence is, especially in terms of the retweet dynamics. Essentially, while PageRank assesses the user's position within the network, Vander evaluates the effectiveness of their ability to control the flow of information through retweets. This makes Vander more indicative of actual message spread within a social media.

Username	Retweets	PageRank	Vander
pjohnson	362	0.000068	0.000310
awilliams	306	0.000068	0.000258
fsmith	301	0.000068	0.000258
wmitchell	269	0.000068	0.000207
nbrown	267	0.000068	0.000207
davidsmith	263	0.000068	0.000207
christopher64	261	0.000068	0.000207
amiller	253	0.000068	0.000207
ehernandez	251	0.000068	0.000207
jessicawilliams	251	0.000068	0.000207

Fig. 4. Comparison between PageRank algorithm and Vander.

The final component of the simulation involved analyzing the social structure of the Twitter dataset using graph-based network analysis. A directed graph was constructed as shown in Fig. 5, where nodes represented users and edges denoted retweet relationships. Three methods were employed to evaluate influence: total retweet count, PageRank, and degree centrality (referred to in the study as Vander). The analysis revealed key influencers in the network, including users such as "pjohnson" and "awilliams", who were frequently retweeted and occupied central positions in the network graph. These users were identified as top influencers across multiple metrics, demonstrating consistency in their network impact. The figure below shows a comparison of top influencers. Finally, while the analysis simulated an increase in controlled message spread from 497,212 to 10,000 targeted users, the actual engagement patterns (likes, replies, time-to-retweet) were not captured. Including such metrics in future work would enhance the robustness of influence modeling and help assess the real-world efficacy of strategic messaging campaigns.

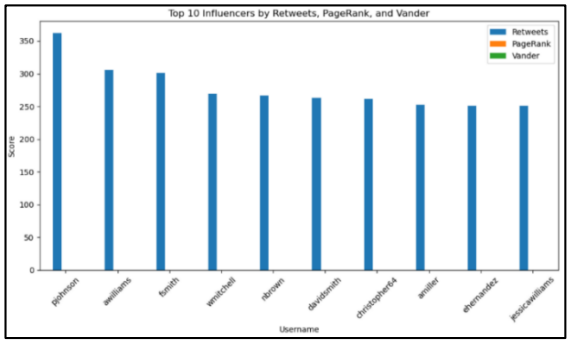

Fig. 5. Top influencers by Retweets, PageRank and Vander.

J. Network Construction and Analysis

The network construction process involved modeling Twitter interactions using a directed graph structure, where each user is represented as a node and retweet relationships form the edges between them. Tweets were parsed to extract usernames and their respective retweet counts, and a graph was built using NetworkX in Python. The directional edges in the graph were based on retweet actions, representing influence flow from the original user to others engaging with the content.

The goal of this network was to identify influential nodes (users) and evaluate how counter-narratives could be maximally propagated. Influence metrics such as total retweets, PageRank centrality, and degree centrality (Vander) were calculated to assess user importance. These metrics served to pinpoint strategic users for deploying counter-narratives for broader reach. The structure of the constructed Twitter network is summarized in Table VI.

TABLE VI. DESCRIPTION OF GRAPH COMPONENTS

Component	Description
Nodes	Users participating in tweets or retweets
Edges	Directed connections formed by retweeting behavior
Directionality	From the original tweet author to the retweeting user
Weight (Optional)	Not weighted, but retweet count considered for influence
Graph Type	Directed (DiGraph)

Once the network was constructed, several metrics were derived to understand its complexity and sparsity, as shown in Table VII.

TABLE VII. NETWORK METRICS FOR SOCIAL MEDIA RETWEET NETWORK ANALYSIS

Network Metric	Value
Total Nodes	19,346
Total Edges	9,899
Average Degree	1.023
Network Density	2.64×10^{-5}

These results indicate a sparse graph with low average connectivity, which is typical in large-scale social media networks. Despite this sparsity, central nodes with high retweet interactions still serve as effective targets for influence maximization. These structural insights allowed for targeted counter-narrative dissemination by leveraging top influencers, as detailed in the subsequent section.

K. Final Processed Dataset

After all the processing stages, including text cleaning, sentiment classification, counter-narrative generation, and influence metric computation, the final dataset integrated several new attributes. Each tweet record now includes not only the original text and sentiment polarity, but also counter-narrative outputs (if applicable) and influence scores such as PageRank and Vander. This final dataset formed the basis for visualizations, statistical evaluations, and influence analysis throughout the study. It was saved in CSV format for further exploration and future machine learning experimentation.

L. Final Discussion

The comprehensive simulation presented in this study demonstrated the potential of combining natural language processing techniques with social network analysis to address the challenge of harmful discourse on Twitter. Beginning with a robust preprocessing pipeline, the study ensured that noisy and unstructured user-generated content was normalized into a form suitable for downstream tasks. Although this process improved the consistency of data, limitations such as the absence of emoji and slang handling suggest opportunities for improvement. Sentiment analysis, powered by TextBlob, provided an effective baseline approach for categorizing tweets into positive, neutral, and negative sentiments. Despite its interpretability and ease of use, the method lacked nuance in capturing complex language, such as sarcasm or idiomatic phrases. The sentiment results were critical in identifying content requiring intervention, with approximately 20 per cent of tweets classified as negative and eligible for counter-narrative application. The counter-narrative generation process stood out as a pivotal component. A hybrid approach using both rule-based keyword mapping and the BART transformer model allowed the system to not only replace harmful language with empathetic alternatives but also generate novel, context-aware responses. The dual strategy showed a simulated 60 per cent reduction in harmful tweets, suggesting its effectiveness in mitigating toxicity. Furthermore, the use of BART highlighted the potential for advanced models to introduce diversity and

personalization in automated response systems. Network analysis was instrumental in identifying influential users within the Twitter graph. The constructed network, while sparse, reflected real-world social media dynamics where a few central nodes (users) hold disproportionate influence. Influence was evaluated using PageRank and degree centrality, enabling a multi-faceted understanding of user impact. These findings supported targeted message deployment strategies, optimizing the reach of counter-narratives. The final processed dataset synthesized all key outputs—including cleaned text, sentiment labels, counter-narratives, and influence metrics—into a unified structure. This dataset served as the foundation for analysis and is well-suited for future experiments using supervised learning, longitudinal studies, or real-time content moderation systems.

V. Conclusion and Future Work

This study focused on controlling the dissemination of harmful viral posts on social media by utilizing influence maximization and counter-narratives. The study combined sentiment and network analysis to detect harmful content, sentiment classification, and counter-narrative response generation. Automated sentiment classification tools (VADER) and network-based influence maximization techniques (PageRank algorithm) were used to enable a systematic approach to mitigating harmful content dissemination. The analysis presented in the study proves that strategically inserted counter-narratives within a network resulted in harm attracted by the network being greatly mitigated. A comparison of sentiment analysis results of the network for the distribution of tweets before and after counter-narrative implementation revealed a 60 per cent reduction in harmful tweets, indicating the accuracy of automated aids. Furthermore, networks influence strategies applied more positive messages which ensured that greater positive message became available, which contravened the effort to counter-narrative. The study employed influence maximization to help identify important users for the dissemination of information, as these users provide more targeted interventions. The simulation of the gradual flow of influence before intervention and after the intervention showed that the strategic counter-narrative provided more moderation of online discourse. To effectively counter and maximize narratives, the following future work needs to be examined:

1) Advanced sentiment analysis models: Existing sentiment models like VADER have limitations due to their simplistic handling of emotions, struggling with context, sarcasm, and cultural nuances. In contrast, advanced machine learning models such as BERT, GPT, and RoBERTa use deep learning to bidirectionally analyze word relationships, improving classification accuracy. Self-recurrent networks (LSTMs, RNNs) and autoencoders enhance context understanding by filling in gaps and identifying hidden text patterns, aiding negativity classification. Hybrid approaches combining deep learning and models like VADER enable more balanced and versatile emotion detection, with future potential for multimodal AI systems integrating text, emojis, voice, and facial cues for detailed sentiment tracking. These AI-driven sentiment systems are crucial for real-time monitoring of social media interactions, supporting brand management, content moderation, and misinformation control.

2) Hybrid influence maximization approaches: The PageRank (PR) metric, focusing mainly on retweets and interactions, has limitations as it overlooks engagement quality, user reputation, and action-based influence, reducing accuracy in measuring influence. Factors like user credibility, trustworthiness, expertise, and social standing are crucial but often ignored, limiting the effectiveness of influence maximization strategies. Future models should combine quantitative metrics (retweets, likes, shares) with qualitative assessments such as reputation and audience trust to capture impactful users with low engagement. Leveraging machine learning to analyze user history, content sentiment, and influence spread trends, along with advanced network analysis like dynamic PageRank in temporal graphs, can enable real-time detection of emerging influencers. Hybrid approaches integrating AI-driven sentiment tracking with influence metrics promise enhanced content virality, improved misinformation control, and precise audience targeting for social media marketing, policy, and digital activism.

3) Systems for moderation in real-time: Current counter-narrative policies are limited because they act only after harmful content is analyzed, making the response passive and less effective due to the time lag. To better control harmful content, early detection systems are needed to monitor, flag, and respond to posts in real-time as they go live. AI-powered moderation using NLP, sentiment analysis, and deep learning models like BERT and GPT can classify abusive or misleading content instantly. However, automated real-time flagging must be combined with human moderation in a hybrid system to intervene effectively, notify users, hold sensitive content, and support fact-checking.

Security Vulnerability Analysis and Enhancement of a Lightweight Sensor Node Authentication Framework

Kim Kyoung Yee[1], Haewon Byeon[2]*
Department of AI software, Inje University, 197, Inje-ro, Gimhae-si, Gyeongnam, South Korea[1]
Department of Future Technology, Korea University of Technology and Education (KOREA TECH), Cheonan 31253, South Korea[2]

***Abstract*—This study presents a comprehensive structural and mathematical security analysis of LightAuth, a lightweight authentication framework, specifically designed for smart health sensor networks. We delve into its core components and identify several critical vulnerabilities that could compromise the integrity and security of the system. Our analysis reveals that the framework suffers from insufficient freshness verification, a flawed and biased key agreement process, and the persistent exposure of fixed identifiers, which makes it susceptible to various attacks. To address these significant security weaknesses, we propose a suite of practical and effective countermeasures. These enhancements include the implementation of a robust timestamp+nonce validation mechanism to ensure message freshness and the introduction of mutual signature verification to prevent man-in-the-middle attacks. Furthermore, we advocate for the use of dynamic pseudonyms to obfuscate user identities and enhance privacy. To bolster long-term security, we also integrate perfect forward secrecy (PFS), which ensures that a compromise of a long-term key does not compromise past session keys. We conducted extensive simulations to evaluate the effectiveness of these proposed enhancements. The results demonstrate that our improvements achieve a remarkable 100% replay detection rate, while the performance degradation remains within acceptable limits, proving the practicality of our solution.**

Keywords*—Lightweight authentication; IoMT security; ECC; timestamp–nonce validation; replay resistance; formal verification; smart healthcare systems

I. Introduction

The rapid adoption of telecare medical systems has reshaped the healthcare landscape by enabling continuous monitoring, real-time diagnostics, and remote consultations. Smart healthcare infrastructures now integrate sensor nodes, wearable devices, cloud-assisted servers, and mobile gateways, forming an interconnected ecosystem designed to provide timely interventions and improved patient outcomes. These systems, however, are highly dependent on the integrity and confidentiality of the transmitted data [1], as even a minor breach could compromise patient privacy and undermine trust in the healthcare service provider. The central role of authentication mechanisms in safeguarding these networks is undeniable, since they serve as the first line of defense against unauthorized access, replay intrusions, and identity spoofing attacks.

Traditional authentication methods, often based on static credentials such as passwords or pre-shared keys, have proven inadequate in the face of increasingly sophisticated adversaries [2, 3]. With the proliferation of wireless communication channels and resource-constrained devices, attackers can exploit weak key management practices, predictable token generation, or inadequate freshness validation to compromise entire healthcare networks [4]. Thus, a pressing need exists for lightweight authentication protocols that strike a balance between computational efficiency and robust security guarantees. In this context, schemes based on Elliptic Curve Cryptography (ECC) and hash-based tokens have gained prominence because they can provide strong cryptographic assurances with relatively small key sizes and modest overhead [5, 6]. Yet, these same protocols may embed structural flaws, particularly when critical operations such as session key derivation, nonce validation, or forward secrecy are insufficiently addressed [7].

The LightAuth framework, as described in prior work by Adil et al. [8], represents one such attempt to reconcile lightweight computation with secure authentication (see Fig. 1). It operates through distinct phases—registration, mutual authentication, session key derivation, and secure communication—each employing minimal cryptographic operations tailored to low-power sensor nodes. On studying, the protocol promises efficiency and practical deployment feasibility. However, real-world conditions reveal vulnerabilities that were not fully considered during the design process. For example, replay resistance relies heavily on loose timestamp validation, which may permit adversaries to resend previously captured tokens if synchronization tolerances are exploited. Likewise, the session key derivation process, expressed as $SK = h(r_s \times r_u \times G)$, may be susceptible to man-in-the-middle manipulation if exchanged values are not rigorously authenticated. The persistent use of static identifiers further exposes the protocol to privacy leakage, enabling adversaries to correlate communications across sessions and build longitudinal tracking profiles of patients.

*Corresponding author.

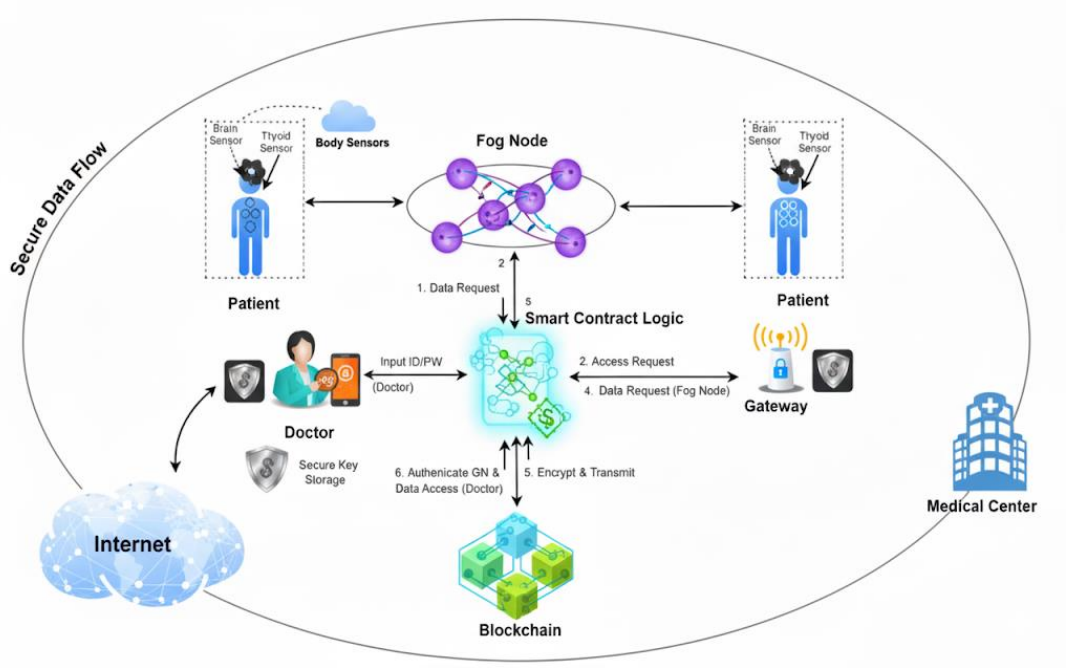

Fig. 1. Concept of the LightAuth framework.

The purpose of this study is to provide a rigorous vulnerability analysis of the LightAuth protocol by Adil et al. [8] and to propose enhanced mechanisms that mitigate these weaknesses without imposing prohibitive computational costs. Specifically, this research aims to: 1) deconstruct the protocol's message flow and model its cryptographic primitives mathematically, 2) employ formal verification tools such as AVISPA and Scyther to simulate adversarial scenarios, 3) identify concrete vulnerabilities including replay susceptibility, key agreement manipulation, identifier exposure, and lack of forward secrecy, and 4) introduce layered improvements incorporating timestamp–nonce pairing, mutual validation of exchanged random values, pseudonym-based identifiers, and perfect forward secrecy through ephemeral keying. Through experimental evaluation and comparative performance analysis, this study seeks to demonstrate that practical, lightweight authentication for smart healthcare systems can be achieved without sacrificing strong protection against realistic attack vectors.

The remainder of this study is organized as follows: Section II reviews related work. Section III presents the proposed methodology. Section IV presents the analysis of the protocol. Section V details the proposed improvements. Section VI reports experimental results and provides a detailed discussion. Finally, Section VII concludes the study.

II. Related Works

Authentication in smart healthcare systems has been the subject of intensive research due to the highly sensitive nature of medical data and the resource-constrained environments in which many IoT devices operate. Early studies predominantly relied on password-based or symmetric key authentication schemes [9]. While simple and computationally lightweight, these approaches were quickly shown to be vulnerable to dictionary attacks, credential leakage, and replay attempts [10]. Static password schemes are particularly unsuitable for healthcare contexts, where adversaries can intercept wireless communications and exploit predictable token patterns. Symmetric key systems reduce computational cost but create significant key management overhead: compromise of a single key may endanger all nodes in a shared domain.

To overcome these limitations, researchers began to explore hash chain–based and HMAC-style protocols, which are more resilient to replay attacks and can provide efficient message authentication [11]. Schemes such as Lamport's hash chain authentication and its variants allow nodes to authenticate themselves by iteratively hashing secrets, reducing the exposure of static credentials [12]. However, these methods are not immune to desynchronization attacks, where message loss or delay causes legitimate nodes to reject valid requests. Moreover, hash chain lengths must be carefully managed, as reinitialization can disrupt long-term operations.

A significant advance came with the introduction of Elliptic Curve Cryptography (ECC) into lightweight authentication designs. ECC's ability to provide equivalent security strength with shorter key sizes made it particularly attractive for resource-constrained IoT devices. Numerous studies [13, 14] have applied ECC-based Diffie–Hellman key exchanges (ECDH) and digital signatures (ECDSA) in healthcare systems. For example, several protocols leverage ephemeral key pairs to derive fresh session keys: $SK = h(r_s \times r_u \times G)$. While mathematically secure under the hardness of the elliptic curve discrete logarithm problem, these schemes are often deployed without rigorous freshness validation, opening the door for man-in-the-middle (MITM) attacks when adversaries inject manipulated values during key exchange [15].

Biometric-based authentication has also been integrated into medical IoT protocols, leveraging unique physiological signals such as ECG, fingerprints, or iris patterns [16]. These

schemes provide strong binding between user identity and device, but raise privacy and revocation challenges. Once compromised, biometric identifiers cannot be replaced. Thus, researchers have investigated combining biometrics with cryptographic protections such as fuzzy extractors, which derive consistent keys from noisy biometric data [17]. Nevertheless, computation and storage overhead still remain as concerns in low-power devices.

Another emerging direction is the use of Physical Unclonable Functions (PUFs), which harness hardware-specific manufacturing variations to generate device-unique responses [18]. PUFs are resistant to cloning and key extraction, making them attractive for secure sensor node authentication. However, stability across environmental variations (temperature, voltage) remains a technical challenge. Integrating PUFs into higher-layer protocols also requires additional error-correction and privacy-preserving mechanisms.

In recent years, blockchain-inspired approaches have been introduced to strengthen auditability and traceability in healthcare authentication [19]. These schemes record authentication logs or certificates on distributed ledgers, preventing tampering and ensuring accountability. However, the high latency and transaction costs of blockchain systems limit their direct applicability to real-time telecare environments. Hybrid models—where authentication itself occurs off-chain and only metadata is stored on-chain—have been proposed, but interoperability and scalability remain active research problems.

A comparative assessment of these prior works reveals a common pattern: many protocols achieve efficiency at the expense of comprehensive security guarantees [20]. Replay attacks, MITM attacks, identity traceability, and lack of forward secrecy recur across different families of schemes. While ECC and hash-based methods improve resilience compared to static passwords, they remain insufficient without additional safeguards such as nonce–timestamp pairing, pseudonymization, and mutual verification of exchanged values. This study builds upon these findings [8, 19, 20], offering a deeper critique of the LightAuth framework [8] and proposing enhanced measures that integrate proven countermeasures from the literature while retaining computational feasibility for constrained healthcare sensor nodes.

III. Methodology

The methodology adopted in this research combines formal modeling, cryptographic analysis, and experimental validation to systematically uncover vulnerabilities in the LightAuth framework [8] and to evaluate the effectiveness of proposed improvements. First, the protocol was decomposed into its four primary phases—registration, authentication, session key derivation, and secure transmission—so that each cryptographic step could be individually examined and mathematically expressed. For instance, the session key generation was modeled as $SK = h(r_s \times r_u \times G)$, where r_s and r_u represent random numbers generated by the server and user, and G is the elliptic curve base point. This modeling allowed us to analyze whether SK maintains sufficient entropy and independence under adversarial observation. Second, we employed formal verification tools, including AVISPA and Scyther, to simulate replay, man-in-the-middle (MITM), and key-compromise impersonation (KCI) attacks. BAN logic was applied to reason about beliefs and message trustworthiness, verifying whether the protocol guarantees mutual authentication and freshness under specified adversary models. Third, practical simulation environments were developed using Python and lightweight cryptographic libraries to measure latency, energy consumption, and throughput of both the original and modified protocols, thereby quantifying the trade-offs introduced by security enhancements. Fourth, sensitivity analyses were conducted to determine the influence of key parameters such as nonce length, timestamp tolerance (ΔT), and ECC key sizes on overall system robustness. For example, replay success probability was modeled as $P_{replay} = Pr[|Ts_{current} - Ts_{prev}| \leq \Delta T]$, highlighting the risks of weak synchronization. Fifth, we integrated a comparative benchmarking approach by deploying the protocol variants on Raspberry Pi nodes configured to emulate healthcare sensors, where we captured metrics such as authentication delay, verification cost, and replay detection rate under constrained resources. Finally, experimental logs were cross-validated against formal predictions to ensure consistency between theoretical analysis and real-world behavior. Through this multi-pronged methodology—spanning formal proof, symbolic analysis, mathematical modeling, and system-level experimentation—the study ensures that identified vulnerabilities are not only theoretically grounded but also practically validated, and that proposed improvements are both secure and feasible for deployment in smart healthcare environments.

IV. Analysis of the Protocol

A. Overview of the Proposed Protocol

The LightAuth framework by Adil et al. [8] is designed to provide secure yet lightweight authentication for sensor nodes in smart healthcare environments, where devices are highly resource-constrained and data sensitivity is paramount (see Fig. 2). The protocol is structured into four major phases—registration, authentication, session key derivation, and secure data transmission—each of which plays a critical role in protecting communications between sensor nodes, gateways, and the cloud server.

1) Registration phase: During registration, each sensor node is provisioned with a permanent identifier ID_u and a secret reference value S_u, which is securely stored on the node as well as registered with the server. The cloud server also maintains a master key set used for verifying future authentications. The registration process aims to bootstrap trust between the device and the server while minimizing the computational burden on the node. For example, S_u may be generated by applying a one-way hash function on the concatenation of ID_u and a system-wide master secret K: $S_u = h(ID_u \| K)$. This ensures that even if ID_u is leaked, S_u remains computationally difficult to reconstruct.

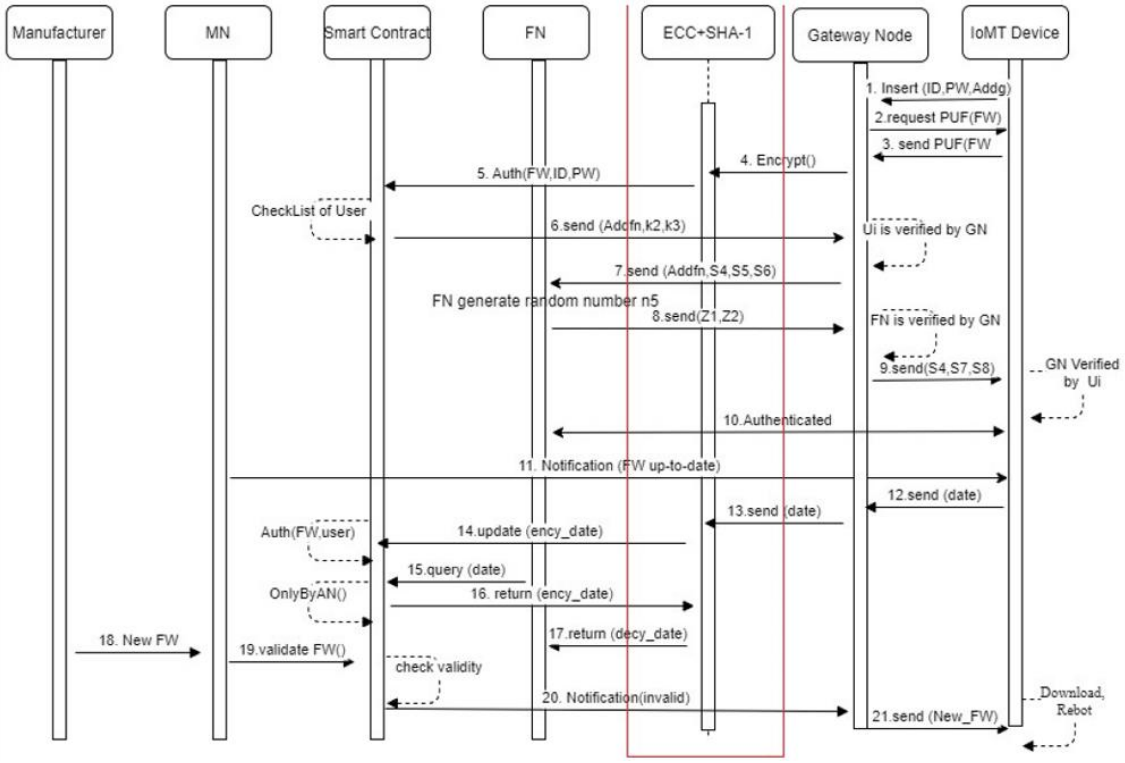

Fig. 2. The proposed LightAuth framework protocol by Adil et al. [8].

2) Authentication phase: In the authentication phase, the sensor node generates a random nonce r_u and a timestamp Ts_u to ensure message freshness. It then constructs an authentication token T_u = h(ID_u || S_u || r_u || Ts_u), which is transmitted to the gateway. The gateway forwards this to the cloud, which verifies the token by recomputing it from stored values. The timestamp Ts_u plays a role in limiting replay attacks, while the nonce r_u prevents predictability. However, the protocol assumes loose synchronization between devices and the server, creating potential weaknesses if ΔT tolerances are too large. The authentication phase's design reflects a balance between efficiency—since it relies only on hash operations—and essential safeguards, though it may not be sufficient in hostile environments.

3) Session key derivation phase: Upon successful authentication, the cloud server generates its own random nonce r_s and engages in a Diffie–Hellman–like process with the sensor node. Both sides compute the session key as SK = h(r_s × r_u × G), where G is the base point on the elliptic curve used in the scheme. This ensures that the session key is derived from contributions of both the server and the client, theoretically guaranteeing confidentiality against outsiders. The use of elliptic curve operations enables compact key sizes, which is crucial for bandwidth-limited and energy-constrained devices. However, the derivation lacks explicit verification of exchanged values, leaving the process potentially open to adversarial injection of manipulated nonces.

4) Data transmission phase: Finally, once SK is established, it is employed to encrypt and authenticate data exchanges between the node and the server. Messages M are secured using a symmetric cipher and a message authentication code, such as C = E(SK, M), ensuring confidentiality and integrity. This step provides the final security layer, allowing sensitive healthcare readings (e.g., heart rate, glucose levels) to be transmitted securely over insecure wireless channels.

In summary, the LightAuth protocol prioritizes efficiency through minimal cryptographic operations—primarily hashing and elliptic curve multiplication—while still attempting to provide resilience against common threats such as replay and impersonation. Its modular structure makes it well-suited for constrained healthcare devices. However, as later sections will demonstrate, subtle design choices, such as static identifiers, loose timestamp validation, and limited verification in session key derivation, introduce exploitable vulnerabilities that can undermine its intended protections.

B. Identified Vulnerabilities

A rigorous analysis of the LightAuth protocol reveals several critical vulnerabilities that threaten both confidentiality and integrity of communications in smart healthcare networks. Although the design emphasizes lightweight efficiency, insufficient verification mechanisms, static identifier usage, and inadequate entropy management create exploitable weaknesses. The most significant vulnerabilities are discussed below.

1) Replay attack susceptibility: The protocol relies on a timestamp Ts_u combined with a nonce r_u to prove message freshness, constructing the authentication token as T_u = h(ID_u || S_u || r_u || Ts_u). However, if the server accepts any

token, where $|Ts_now - Ts_u| \leq \Delta T$, an attacker can capture a valid authentication message $M_prev = h(ID_u \| S_u \| r_u \| Ts_prev)$ and replay it within the allowed window. The probability of successful replay, expressed as $P_replay = Pr[|Ts_current - Ts_prev| \leq \Delta T]$, increases with larger synchronization tolerance values. This creates a trade-off between usability and security that the original protocol does not address, leaving deployments vulnerable to captured-message attacks.

2) Man-in-the-middle (MITM) vulnerability in key derivation: The session key is computed as $SK = h(r_s \times r_u \times G)$, where r_s and r_u are nonces generated independently by the server and client. Without explicit mutual validation of exchanged values, an adversary can insert its own nonce r_a into the communication. The client computes $SK_c = h(r_a \times r_u \times G)$ while the server derives $SK_s = h(r_s \times r_a \times G)$. Since the attacker knows r_a, it can act as an intermediary, decrypting and re-encrypting traffic transparently. This classic MITM problem arises because the protocol lacks binding between nonce contributions and verified digital signatures.

3) Identifier exposure and privacy leakage: Each token includes the static identifier ID_u, enabling long-term tracking of nodes across multiple sessions. An adversary monitoring traffic can correlate tokens {T_u1, T_u2, …} with the same ID_u and construct behavioral profiles of a patient or device. Since healthcare data often involves sensitive personal information, this linkage undermines privacy guarantees. Even if the session key SK changes per session, the persistent exposure of ID_u allows adversaries to perform correlation attacks.

4) Weak MAC construction: Message authentication codes in the protocol are derived as $MAC = h(SK \| M)$, where M is the plaintext message and SK is the session key. If SK entropy is reduced due to predictable or partially leaked nonces, an attacker can mount brute force or side-channel attacks. For instance, if SK has effective entropy of only k bits, the probability of guessing SK is $P_guess = 2^{(-k)}$. If k is too small, forgery becomes computationally feasible. Furthermore, the absence of a keyed construction such as HMAC leaves the design vulnerable to length-extension attacks.

5) Lack of forward secrecy: In LightAuth, session keys are directly derived from static secrets and ephemeral nonces without ensuring independence across sessions. If a session key SK_i is compromised, past ciphertexts $C = E(SK_i, M)$ can be decrypted, violating Perfect Forward Secrecy (PFS). In practice, SK_i and SK_j for sessions i and j are correlated through the same long-term S_u and ID_u. Ideally, ephemeral keying should guarantee $SK_i \perp SK_j$, but this property is absent.

6) Secret entropy insufficiency: Tokens rely on the secret reference S_u, but if S_u has low entropy or is derived deterministically as $S_u = h(ID_u \| K)$, precomputation attacks are possible. Attackers can build dictionaries mapping (ID_u, K) pairs to S_u and exploit collisions. This is especially concerning in healthcare deployments, where ID_u may follow predictable patterns, such as device serial numbers or patient identifiers.

Taken together, these weaknesses illustrate that LightAuth, while computationally efficient, fails to provide robust protection against realistic adversaries. Replay susceptibility, MITM attacks, identifier traceability, weak MACs, absence of forward secrecy, and low-entropy secrets collectively enlarge the attack surface. As a result, confidentiality, integrity, and privacy of healthcare data cannot be guaranteed under active or passive adversarial conditions.

V. Proposed Improvements

To mitigate the vulnerabilities identified in the LightAuth framework, we propose a series of enhancements designed to balance lightweight performance with robust security guarantees (see Fig. 3). These improvements address replay resistance, man-in-the-middle prevention, privacy protection, integrity assurance, and forward secrecy, while remaining feasible for resource-constrained healthcare devices. First, the most immediate step is to enforce stricter freshness validation. Each authentication message should include both a timestamp and a unique nonce. The server must maintain a rolling cache of recently used nonces to ensure one-time usage, and enforce a narrow acceptance window ΔT to minimize the probability of successful replay. In addition, nodes should employ session counters, allowing verification of message ordering and preventing subtle desynchronization attacks.

Second, to eliminate man-in-the-middle manipulation in key derivation, both client and server should sign or authenticate their respective random contributions. After exchanging ephemeral values, each party verifies the authenticity of the received values before deriving the session key. This ensures that no adversary can inject forged values or impersonate a legitimate participant in the key exchange process.

Third, instead of transmitting fixed identifiers across multiple sessions, nodes should use dynamic pseudonyms that are refreshed regularly. These pseudonyms are generated from secret seeds combined with session-specific randomness, ensuring unlinkability across communications. This measure preserves patient privacy and prevents adversaries from building long-term behavioral profiles.

Fourth, message integrity should be reinforced by replacing simple hash-based constructions with standardized techniques such as HMAC or ECDSA. These mechanisms offer resilience against length-extension and forgery attacks, ensuring that only parties with valid session keys can generate authentic tokens. Incorporating hardware random number generators further enhances key entropy.

Fifth, perfect Forward Secrecy must be enforced by generating ephemeral key pairs for each session. Even if a long-term secret is compromised, past communications remain protected. Key renewal policies should mandate frequent updates, and expired keys should be retired immediately to limit the impact of leakage.

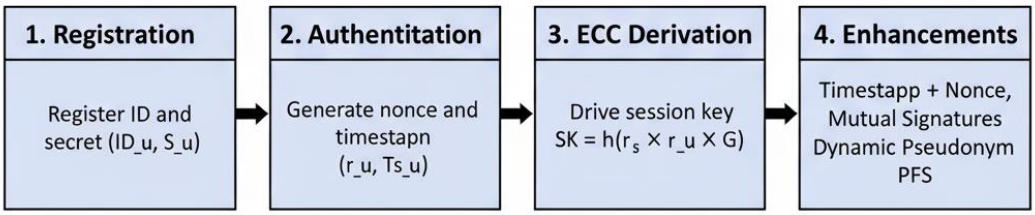

Fig. 3. Workflow for protocol enhancement.

Sixth, finally, for sensitive healthcare data, end-to-end encryption should be complemented with privacy-preserving techniques such as fuzzy extractors to safeguard biometric templates. Combining cryptographic protections with privacy-aware mechanisms ensures that sensitive identifiers cannot be reconstructed or misused if intercepted.

VI. Experimental Results and Evaluation

To validate the proposed enhancements to the LightAuth protocol, we conducted a comprehensive experimental evaluation that combined simulation-based analysis with a real-world testbed deployment. The experimental design was created to measure not only the security robustness against common attack vectors but also the impact of the additional cryptographic operations on resource-constrained healthcare devices. We defined several key metrics to assess the protocol's performance: authentication latency, which is the average time from initiation to completion of mutual authentication; verification time, the computational cost for the server to validate tokens and session keys; replay detection rate, the percentage of replay attempts successfully blocked; message overhead, the additional data required per authentication exchange; energy consumption, the estimated power usage of sensor nodes during authentication; and throughput (TPS), the number of transactions per second handled by the system under sustained load.

The original and improved protocols were implemented using Python cryptographic libraries and deployed on Raspberry Pi 4 devices configured to emulate healthcare sensor nodes. A cloud-based virtual machine running Ubuntu was used to act as the server. For benchmarking, each protocol variant was executed 500 times under identical network conditions, with scripted attack simulations replicating replay, MITM, and key compromise impersonation scenarios.

The enhanced protocol demonstrated a replay detection rate of 100% (see Table I), a significant improvement over the 82% rate of the original LightAuth, which was achieved by enforcing strict timestamp–nonce validation. Authentication latency increased modestly, from 38.5 ms in the original design to 46.8 ms in the improved version, representing a 21% rise due to the added signature verification. The verification time on the server also grew from 24.1 ms to 34.6 ms, largely due to the cryptographic operations introduced for nonce signing and pseudonym validation. Message overhead rose by approximately 28% as temporary pseudonyms and signatures increased packet size, but this remained within practical bandwidth limits for healthcare networks. Energy consumption on the sensor nodes showed an average increase of 12%, which was considered acceptable given the substantial security benefits. Throughput declined from 290 to 245 transactions per second, a 15% reduction, but the system remained fully capable of supporting typical healthcare workloads.

TABLE I Protocol Comparison Summary

Metric	LightAuth Original)	Improved (Proposed)	Notes
Replay Detection	82%	100%	Timestamp+nonce prevents replay
Signature/Token Size	128-256 bytes	160-320 bytes	Increased due to signatures and temp IDs
Verification Time	24.1 ms	34.6 ms	Signature verification cost
Authentication Latency	38.5 ms	46.8 ms	Additional nonce/sign operations
Energy (node)	baseline	+12%	Extra computations
TPS	290	245	Throughput reduction due to crypto load

The results clearly highlight a trade-off between enhanced security and system efficiency. Replay and MITM attacks, which had previously succeeded in our controlled simulations, were completely neutralized by the improved protocol. Privacy protections, through the use of pseudonyms, significantly reduced the risk of linking different sessions to a single user. While the performance costs were measurable, they were not prohibitive and could be further mitigated by using hardware acceleration or optimized cryptographic libraries. A sensitivity analysis also showed that adjusting the timestamp acceptance window provided a practical way to balance replay resistance with tolerance for network delays. Overall, the improved protocol successfully addressed the identified vulnerabilities while preserving its lightweight efficiency. The trade-offs, primarily in latency and throughput, fall within acceptable ranges for telecare environments, making the protocol both secure and practical for deployment in real-world healthcare systems.

VII. Conclusion

This study analyzed structural vulnerabilities in the LightAuth framework and proposed practical enhancements—timestamp-nonce validation, mutual signature checks, dynamic pseudonyms, and PFS—to reinforce security. Experimental evaluation demonstrates clear security gains (notably full replay mitigation) with acceptable performance overhead.

Looking ahead, future research should focus on integrating lightweight hardware accelerators, exploring PUF-based trust anchors, and leveraging blockchain-enabled auditability to further strengthen authentication in next-generation healthcare systems.

A Proposed IoT System for Monitoring and Controlling Movable Zamzam Tanks in the Holy Mosque

Taha M. Mohamed
College of Business, University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—Zamzam water is very important for all Muslims worldwide, especially for Pilgrims and Umrah performers who are visiting the two holy mosques in Saudi Arabia. Many movable Zamzam tanks are dispersed in many places of the two holy mosques. These tanks are available for pilgrims and visitors for drinking. When the two holy mosques are crowded, visitors want to know the locations of the nearest filled Zamzam tanks. Administrators and operators also need to monitor tank statuses for performing necessary logistics operations. In this study, we proposed a novel IoT system for automating, monitoring, and controlling water levels in Zamzam tanks in the two holy mosques. The proposed system modifies the existing Zamzam tanks' architecture to be smart tanks. The proposed system is analyzed, modeled, simulated, and discussed. Simulation and discussion show that the system is very useful for administrators, operators, and holy mosque visitors as it saves time, decreases efforts, automates logistics, and increases productivity. The system is very important for stakeholders, especially in crowded seasons. The performance metrics indicate that the proposed system is scalable with minimal delay and higher throughput. Also, the proposed system can participate in the digitalization of the two holy mosques, achieving the Saudi Vision 2030.**

***Keywords*—Zamzam tanks monitoring; IoT smart systems; automatic monitoring and control; Logistics 5.0**

I. Introduction

The two holy mosques in Saudi Arabia are in Makkah and Madina. The grand holy mosque, Masjid al-Haram, has a capacity of about 2 million people when fully packed indoors and outdoors [1]. The area for each person is only about 0.25 square meters in regular seasons. In peak seasons, each square meter is available for twenty people in the Hajj season [1]. The government of Saudi Arabia targets 30 million Umrah performers and pilgrims per year, according to Saudi Vision 2030. The sacred Zamzam well springs from the grand holy mosque. Zamzam water is rich in many minerals and has useful components for all pilgrims, Umrah performers, and visitors of the two holy mosques. Muslims consider Zamzam water blessed (Mubarak) due to its greater benefits. Recent medical research indicates the great benefits of drinking Zamzam water. Zamzam water contains many essential minerals that are useful for drinking. Also, Zamzam water has a large pH that has antioxidant properties. So, Zamzam water raises body immunity [2], [3]. For medical and religious purposes, Zamzam water has been drunk for more than 4000 years [3]. Moreover, millions of pilgrims and visitors carry some of the Zamzam water to their families in their original countries for drinking.

Fig. 1. Example of five movable Zamzam tanks.

Zamzam water is distributed by many methods, such as bottles, movable tanks, and fixed tanks. For example, about 40 million Zamzam bottles were distributed daily to pilgrims during Hajj 2024. Additionally, the supply of Zamzam water can reach 1.6 million liters daily in peak seasons. Movable Zamzam tanks are approximately equal to 25,000 tanks in the holy mosque. They are refilled at least five times daily. Each tank can contain about 40 liters. These tanks are placed and dispersed around the mosque. Fig. 1 shows an example of five movable Zamzam tanks in the holy mosque. Despite the regular filling of these movable tanks by operators, however, there is no automated method exists for filling these tanks based on accurate readings. Also, there is no automated method for monitoring the statuses of these tanks. This issue represents a problem for both administrators, mosque visitors, and Zamzam operators. For administrators, they want to know the current filling statuses of all movable tanks in the holy mosque. So, if some tanks are empty or semi-empty, the administration can give commands to Zamzam operators for filling empty tanks instead of just filling these tanks at regular intervals. The automated system will achieve operational efficiency, save costs, and optimize resources, including human resources. Also, administrators need to predict the future demand for Zamzam water in certain locations of the holy mosque. Data analytics and predictions are also required by administrators. For mosque visitors and pilgrims, a map of the nearby filled Zamzam tank is required. This is important, especially in crowded seasons, where the movement inside the holy mosque is very tedious [4]. So, automation of knowing filled Zamzam tanks can save visitors time and effort. For operators, they need to know the locations of the empty Zamzam tanks instead of the current

periodic routine checking of all movable Zamzam tanks. If empty tanks are identified automatically, then the operators can refill only those tanks, saving their time and effort.

In fact, automated methods of logistics management use Industry 4.0. Industry 4.0 [5], [6] integrates advanced digital technologies in manufacturing and industrial processes. Part of Industry 4.0 is called logistics 4.0, which adopts advanced technologies in supply chains. Logistics 4.0 can create intelligence for the devices connected in the whole supply chain to optimize storage and movement of products. The logistics of Zamzam tanks in the holy mosque can be enhanced using logistics 4.0 technologies. Such technologies may include IoT, data analytics, artificial intelligence, and cloud computing. These technologies efficiently enhance the logistics operations [7].

The Internet of Things (IoT) refers to the connectivity of things to the Internet to be smart. There is an increasing number of IoT applications in various fields such as transportation, engineering, and many other fields [8]. IoT can be used for automatic monitoring and control of movable Zamzam tanks in the holy mosque. IoT can use sensors, embedded systems, communication, and cloud technologies to monitor and control water levels in movable Zamzam tanks in real time [9], [10]. This real-time monitoring helps in making real-time decisions. Moreover, using IoT solutions assists in keeping an accurate record of water levels in movable Zamzam tanks in the holy mosque. The sensors can detect the water level in each tank. Communication technologies can send water level information to the cloud. The cloud can analyze sensor readings and make appropriate decisions, including triggering and notifying operators to fill empty tanks. On the other side, the absence of an automated system for monitoring movable Zamzam tanks makes great challenges to pilgrims, Umrah performers, and visitors of the two holy mosques, especially in crowded seasons such as Hajj and Ramadan. There are many losses that occurred due to the absence of the automated system, including high efforts, increased operational costs, and more time overhead. So, in this study, we propose a novel IoT system for monitoring and controlling movable Zamzam tanks in the holy mosque. The proposed system has some subsystems that use logistics 4.0 technologies, aiming to automate monitoring and controlling processes. The proposed system can decrease operational costs and improve overall system efficiency. Also, the proposed system decreases the efforts of administrators, visitors, and operators. The proposed system is modeled and simulated. The simulation results show the importance of the system for resource optimization and cost reduction.

The rest of this study is organized as follows: Section II presents the necessary background of IoT technologies. Section III presents the previous work. Section IV shows the proposed system components. Section V analyzes the proposed model, simulations, and discusses some of the performance criteria. The study is concluded in Section VI.

II. IoT Technologies

IoT technologies could be adopted in monitoring and controlling the logistics of movable Zamzam tanks. The proposed system for automating monitoring and controlling movable Zamzam tanks relies on IoT. An IoT system can consist of the following components [11], [12]: sensors, actuators, communication, cloud, and software for monitoring and control [9]. In this section, we will evaluate different technologies related to movable Zamzam tanks automation. We will show the merits and drawbacks of each technology used.

A. Sensors

The sensors' subsystem is considered as the data acquisition layer at the tank site [13]. Each tank is provided by a sensor to measure water level in this tank. Selecting the right sensor to detect water level in the tank depends on several factors. The first factor is the type of tank monitored, where it is open or closed. The required accuracy is another factor. Also, the type of sensor used where its readings may be continuous or discrete time. From contact point of view, there are two types of sensors: contact and non-contact sensors. In our case of movable Zamzam tanks, the tanks are closed. Also, continuous monitoring of the water level in each tank could be achieved using discrete time intervals (e.g. every minute). In this case, a tradeoff is achieved between fast decision making and continuous monitoring. This avoids network congestion. The contact sensors touch water inside the tank. This is not practical as the water inside the tank is prepared for drinking. Also, contact sensors may be harmed if they touch the water inside the tank. Additionally, contact sensors are not convenient for Zamzam operators during tank filling process. So, the practical approach is to use contactless sensors outside the tank for monitoring water level in the tank. This achieves isolation between the tank itself and the sensing subsystem increasing convenience and reliability.

The most two popular non-contact sensors are ultrasonic sensors and pressure (submersible) sensors [14]. Ultrasonic sensors are mounted on the top of tanks. These sensors measure the time the ultrasonic signal takes to the surface of the water. However, these sensors cannot be used for monitoring Zamzam tanks. They may be damaged by continuous handling of Zamzam tanks by operators during filling processes. The second type of non-contact sensors is pressure sensors. These sensors measure the pressure resulting from the column of water in the tank. The idea of these sensors is like a digital balance. As water level in the tank increases, the weight of the tank also increases. Eq. (1) describes the computation of water level height in the tank:

$$h = \frac{p}{\rho \, x \, g} \tag{1}$$

where, h the height of the water level inside the tank, p is the pressure of water, ρ is the water density, and g represents gravitational acceleration. However, pressure sensors are also impractical in determining the quantity of Zamzam water in the tank when being mounted on the bottom of the tank because cleaning and handling issues can harm the sensors. Alternatively, in the proposed system, we use pressure sensors after modifying the way that the sensors are mounted. We isolate the sensors from the tank itself. The sensors are mounted externally in the base of the tank, outside it. So, we avoid the problems resulting from tanks handling processes by operators.

B. Microcontrollers and Communication

Microcontrollers collect data from sensors. They are also used for secure transmission of data. Examples of microcontrollers include Arduino, Raspberry Pi, and ESP32 [8]. Microcontrollers can send sensor readings at every certain time interval. In the proposed system, we propose sending sensor data to the cloud every minute. This satisfies the tradeoff between minimizing the amount of data transmitted and satisfying semi-continuous monitoring of the water levels in the tanks. The data transmitted every minute is very small, about only five bytes representing the tank identifier and the water level in the tank. The microcontroller is often equipped with a network connection module, such as a SIM module or any other wireless module. Occasionally, any small capability microcontroller can achieve the required transmission of a small amount of data. The microcontroller sends sensor data through the communication network to the processing servers. The main wireless technologies used for data transmission are Wi-Fi, Long Range Wide Area Network (LoRaWan), and cellular networks [15]. There are many considerations that affect the chosen technology from them. Wi-Fi networks can serve devices within the range of wireless access points. Wi-Fi is suitable for indoor locations like smart homes and smart buildings. The devices consume low power when connected to Wi-Fi. There are no fees to connect to these networks; that is, the operational cost is low. However, congestion and interference can affect the performance of Wi-Fi networks due to the unlicensed spectrum, which includes other technologies such as microwave ovens and Bluetooth devices. Although the merits of Wi-Fi connections, they are not suitable for Zamzam tank monitoring as these tanks are dispersed along a large area of the holy mosque. Also, some of these tanks are already located outside the holy mosque. LoRaWan is another technology that consumes low power. This communication technology is suitable for small and infrequent data transmission. It supports transmission for long distances with minimal power, which saves battery life. A LoRa module could be connected to the microcontroller supporting LoRaWan transmission. However, access to a LoRaWan gateway is required. LoRaWan is ideal for smart cities, smart agriculture, and asset tracking. The main disadvantage of using LoRaWan technology is the requirement of a gateway to act as a bridge between IoT devices and clouds. Gateways require additional settings and infrastructure expenditures [15]. If this technology is used in Zamzam tank monitoring, then gateways must be established first. Compared to Wi-Fi, LoRaWan is better than Wi-Fi in monitoring Zamzam tanks. The third option is the cellular networks that connect devices to the server and cloud. Cellular networks could be accessed anywhere and do not need any additional infrastructure. These networks can connect sensors embedded in Zamzam tanks regardless of the location of the tank, either indoors or outdoors. While cellular-connected devices consume more power than Wi-Fi connected devices, there are some cellular technologies, such as NB-IoT, that are optimized for infrequent data transmission. Also, cellular networks need a monthly fee for transmission. However, power consumption is slightly higher than both LoRaWan and Wi-Fi. The main advantage of using cellular networks is the greater availability and the ease of tanks movement inside and outside the holy mosque and in far places from the holy mosque. Also, cellular networks are more stable and secure than Wi-Fi. For cellular networks, IoT-specific plans are often cheap due to sending only a few bytes of sensor readings. Interestingly, using either 4G or 5G networks is sufficient for the proposed system as the sent information is almost few bytes representing tank identifier and a discrete sensor code represents a quantized version of the sensor readings. The transmission occurs at a discrete interval (every minute) to decrease the required bandwidth and network congestion. Cellular networks are more stable and reliable than the other two previously mentioned networks as they use licensed spectrum managed by the carrier [15].

From the previous comparison, we choose cellular networks for sending tanks information to the cloud. That is because these tanks are remote, movable, and may be moved to locations where they are not being covered by other networks. This is due to the large area of the holy mosque. Also, cellular networks do not need any special infrastructure or handling. They could be used as plug and play networks for network users. Due to the large number of movable Zamzam tanks in the holy mosque (around 25000), it is impractical to use other networks which need additional settings, manipulation, and infrastructure. Regarding power consumption, sensors and microcontrollers can use low-power technologies which save battery life. Additionally, the batteries could be also charged continuously by using solar panels or any continuous electrical sources.

C. Cloud Computing

Cloud is a technology that can receive and store data readings from sensors. Also, the cloud can perform many other beneficial tasks, such as performing data analytics and machine learning tasks. The output of data analytics is interpreted as commands sent to the actuators. It can cover the journey of IoT data from sensors to actuators, including storage, processing, and visualization. Also, the cloud can handle millions of devices simultaneously. It is often provided by a time series database, which is suitable for the storage and manipulation of sensor data that arrives according to predetermined time slots. Also, the cloud could compress the data received if large amounts of data arrived, making it a good option for future data analytics and data mining. In the proposed system, the received sensor readings are time series data for each tank. This is very helpful in data analytics and prediction. For IoT, the most used cloud providers include Amazon Web Services (AWS), Google Cloud Platform (GCP), and Microsoft Azure [16]. IoT services of AWS can provide massive scalability and a deep service ecosystem. Microsoft Azure has great integration with Microsoft products and tools like Power BI that offer data analytics and visualization. Also, Google Cloud has powerful machine learning and artificial intelligence tools and provides advanced data analytics tools, including BigQuery.

All three clouds have data analytics capabilities and integration with machine learning. In the proposed system, the services offered by any one of the three cloud providers are sufficient. The choice between them depends on the actual cloud used in the site. The main advantage of using existing cloud infrastructure is to reduce the costs of adding a new investment in cloud technologies. Interestingly, the data volume and velocity of the proposed system are not large. This is because a small number of bytes are transmitted each minute, representing the tank identifier and the quantized sensor reading. Even with

the large number of devices used in the IoT, the overall data sent is very small. The huge capability of the cloud can handle the data sent without any delay.

III. Related Work

In this section, we will overview the related work regarding smart logistics and automation, as Zamzam tank monitoring is an example of smart logistics automation. In [5], the authors review a lot of Industry 4.0 technologies concentrating on the applications in the supply chain management field. In the following subsections, we will review the related work.

A. Smart Logistics

In [7], the authors show the performance enhancements of logistics by using Logistics 4.0 technologies. The authors in [17] analyze the relationship between Industry 4.0 and Logistics 4.0 and discuss future trends, including operations such as predictive analytics and sustainable practices. The authors in [18] show the concept of Logistics 5.0, which is the recent generation of intelligent logistics. They suggest human-oriented operating systems to provide intelligent logistics solutions. Moreover, the authors in [19] show some of the possible new technologies of Logistics 5.0, including adopting robotics, edge computing, Internet of Things, and artificial intelligence into manufacturing and production processes. Also, they conducted a survey on the importance of edge computing in logistics. A large component of Logistics 5.0 is the IoT systems.

B. IoT Recent Technologies

The authors in [8] compare the performance of different hardware platforms of IoT, including Arduino and Raspberry Pi. The comparison includes programming capabilities, hardware specifications, and some other factors. In [15], the authors compare some different communication technologies used in IoT systems, including LoRaWAN, Wi-Fi, and cellular networks [15]. Additionally, the authors, in [16], analyze the three popular cloud platforms: Google Cloud Platform, Microsoft Azure, and Amazon Web Services using five different benchmarks. The authors review some of the cloud features, such as pricing and services. They state some considerations in choosing the appropriate cloud model for organizations.

C. Related IoT Systems

In fact, IoT may be used in different relative fields such as smart irrigation. In [11], the authors propose a smart, low-budget, IoT irrigation system using an Arduino Uno microcontroller and a Node-Microcontroller ESP8266. They claim that their system reduces water wastage than the traditional process. Cloud and mobile applications are used to notify farmers. The communication is carried out through a Wi-Fi module [11]. Also, the authors in [12] present an IoT-based system for smart irrigation. Four sensors are used to determine soil status. Sensor readings are sent to a central control system to control pumps. The system is supported by a mobile application to notify farmers remotely [12]. Regarding monitoring water level in tanks, the authors in [20] propose a smart water management system to manage water stored in large tanks in Makkah, Saudi Arabia, in residential buildings. The data is transmitted via cellular networks to the cloud for remote monitoring. Also, the authors in [13] monitor and control water level using an IoT system in Saudi Arabia. The system can monitor leakage. The system uses an Arduino Uno board connected by an ultrasonic sensor. Data transmission is performed using a GSM/GPRS module. The system controls motors based on the actual water level thresholds [13]. The authors in [14] use optical fibre sensors for real-time pipe monitoring to detect leakage. The detection can be deployed without pipeline bonding [14]. In [21], the authors propose an IoT model to monitor and manage water levels in tanks. The model uses ultrasonic sensors that send water levels to a microcontroller. The system could be manually controlled by users or automatically controlled through a mobile application [21].

The authors in [22] propose an IoT system using an ultrasonic sensor that is designed to monitor water level in tanks, either in farms or homes. The valves are controlled automatically by the cloud. Water is substituted automatically if it goes below some predetermined level. Also, a notification is sent in case of empty, full, or failure tank status. Manual control is also possible by the user. The authors in [23] propose an IoT system that uses four sensors in a cistern. Some of these sensors are assigned to measure water level in the cistern, whereas the other sensors measure water quality. The system is controlled using online dashboards. The cistern is automatically filled when it becomes empty. The authors in [24] introduce an IoT system that uses an ESP32 microcontroller connected by an ultrasonic sensor to monitor water level in a tank. The authors emphasize the importance of monitoring and controlling water in tanks for efficient management of resources and minimizing waste [24].

From the previous survey and discussion, we can conclude that different technologies could be used in IoT systems, including different types of sensors, microcontrollers, communication technologies, and cloud services. The choice of suitable IoT technologies depends on the intended application. Although IoT technologies are adopted in many related fields, such as smart irrigation and tank monitor and control, however, IoT systems are not yet adopted in the monitoring and control of movable Zamzam tanks in the holy mosque, despite the large number of tanks. Automation of Zamzam tanks monitoring is very essential as the number of beneficiaries is millions of people who visit the holy mosque for Hajj, Umarah, and visit.

IV. Proposed IoT System

In this section, we will review the detailed description of the proposed IoT system for monitoring and controlling movable Zamzam water tanks in the two holy mosques. The key components of the system are discussed. These components include sensing subsystem, microcontroller subsystem, communication subsystem, cloud subsystem, and actuators subsystem. The whole system is depicted in Fig. 2.

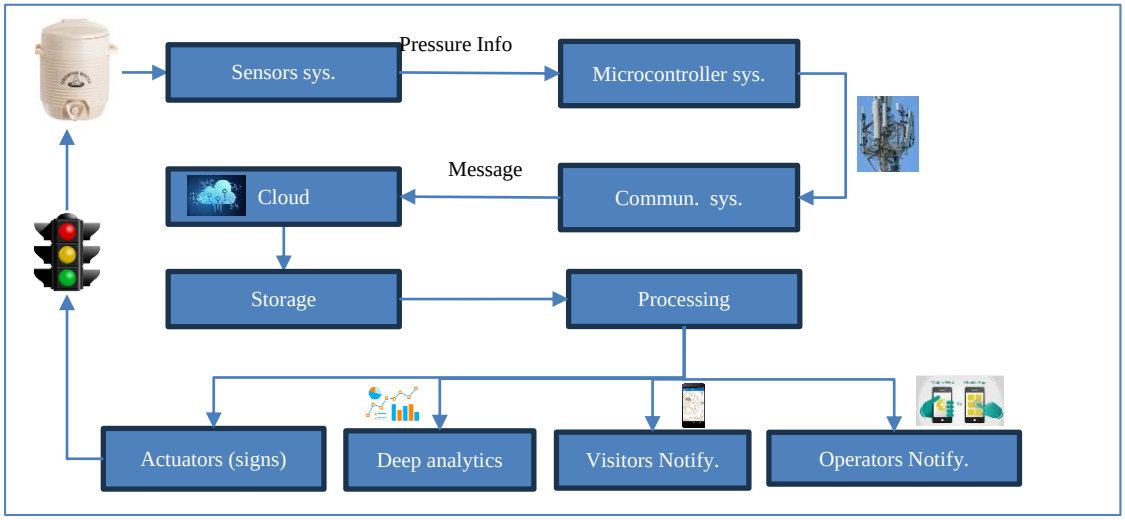

Fig. 2. The proposed system architecture.

The first component of the proposed system is the sensors subsystem, which measures water level in movable Zamzam tanks. In the proposed system, we decided to use non-contact pressure gauge strain sensors, like a digital balance, for mechanical and environmental protection. The main advantage of using this type of sensor is the isolation of the sensor's circuitry from the water itself and from the tank itself. The isolation is also convenient for Zamzam operators who handle and fill the tanks a lot of times daily. Also, non-contact sensors are protected against humidity, dust, heat, and other environmental effects.

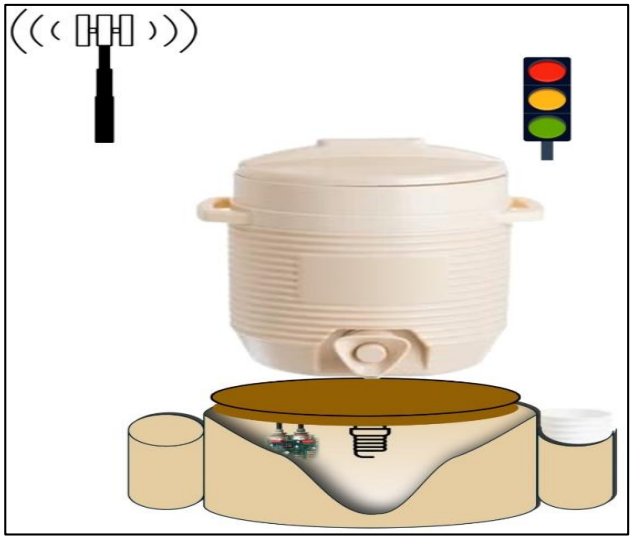

Fig. 3. The proposed modified sensor's subsystem.

So, we redesigned the external base of the Zamzam tank to contain the sensor and its microcontroller circuit. This is used to avoid contact with the tank itself. So, the proposed new design of the tank's base is to add a strain gauge sensor in the base of the tank. This sensor is covered by a metallic cover to carry the tank itself and to protect the sensor's circuit. The sensor is connected by a microcontroller and a communication module for cellular transmission. The modified tank's base is shown in Fig. 3. From Fig. 3, it is shown that the sensor reads the weight of the tank, including water and empty tank weights. When the tank is put on the modified base, the sensor's readings indicate the quantity of water in the tank. If the weight of the tank in the empty state is known, then the weight of the inside water could be inducted. This weight is interpreted as the water quantity in the tank. For example, if the tank is filled with Zamzam water (i.e., 40 liters, approximately), then the tank's weight will be about 50 kilograms, including the weight of the empty tank.

The second subsystem is the microcontroller unit. This unit is the brain of the IoT system. Microcontroller sends sensor readings to the cloud after performing some preprocessing. The most used microcontrollers in IoT applications are Arduino, ESP32, and Raspberry Pi. We decided to use an Arduino Uno unit due to its cheap price, convenient settings, low power consumption, and reliability. Weight data is obtained by the microcontroller every minute. The choice of this interval achieves the tradeoffs between continuous tank monitoring and avoiding network congestion. In fact, accurate continuous weight information is not important in this application, as the stakeholders want to know only discrete statuses of the water level in the tank. So, in the proposed system, the weight information is sent to the communication system as a discrete integer value representing one of five tank statuses. These statuses are: Fully Filled, Semi-Filled, Moderate, Semi-Empty, and Empty. These statuses are represented by numbers from 5 to 1, respectively. This number could be represented by only three bits, saving bandwidth. The discrete statuses are more useful for stakeholders than the continuous-value weight information. These statuses are explained by rules shown in Algorithm 1. In fact, discrete statuses are sufficient to determine filling status of each tank. For visitors and operators, the status is more useful than the actual, continuous-value, water level. The transmission of status code is less than one byte. Besides the status code information, additional two bytes are also sent to the cloud representing the tank identifier. So, the overall bytes sent are less than three bytes. Sending this information every one minute converts the continuous transmission of information into discrete transmission which decreases the amount of data transmitted. This interval is flexible and could be decreased or increased based on administrative decisions considering the

tradeoffs between continuous tank monitoring and network traffic. Considering that, the number of tanks is very large (about 25000 tanks). So, performing this preprocessing at the microcontroller side decreases the traffic sent to the network.

Algorithm 1: Tank status submission

```
If Weight >= 40 Then
Tank Status = Fully Filled
Return 5
Else If Weight >= 30 Then
Tank Status = Semi-Filled
Return 4
Else If Weight >= 20 Then
Tank Status = Moderate
Return 3
Else If Weight >= 10 Then
Tank Status = Semi-Empty
Return 2
Else
Tank Status = Empty
Return 1
End If
```

Often, the power source for microcontrollers is a battery. This battery may be connected to a solar panel for automatic charging. Using solar panels is very efficient due to the low power requirements of the circuitry. Also, the sun rises in Makkah for a lot of hours daily, and the weather is almost hot throughout the year in these locations. The microcontroller is also equipped with a SIM, or other wireless module, for connecting to cellular networks.

For the communication subsystem, we decided to use cellular networks as communication technology. That is because cellular networks have easier settings, suitable for long and dispersed places, and reliable for a large number of movable tanks. Besides, cellular connections do not need a large amount of power due to the small amount of data sent to the cloud, representing tank filling status and tank identifier. The tank identifier used is the SIM card number of the SIM module embedded in each tank. This number is used as a part of transmission. Also, each tank receives a control message through the SIM card, acting as an actuator. There are three cellular networks operating in Saudi Arabia: STC, Zain, and Mobily. The signals, connections, and data rates of the three providers are very efficient. The signal strength of these networks is very efficient in the holy mosque and can efficiently handle any huge traffic of data, especially in crowded seasons such as the pilgrimage and Umrah. So, there is no extra infrastructure needed to establish and deploy the proposed system using any of the three available cellular networks. The communication system sends sensor data to the cloud. The cloud subsystem receives processed data and stores it in a time series database. Next, the data received is quickly checked and analyzed, and classified according to the statuses of all tanks. Also, the cloud provides deep analytics for the massive historical data of movable Zamzam tanks to make strategic decisions. The cloud provides a control dashboard for administrators. In the proposed system, we suggest using any one of the mostly used cloud platforms, including AWS, Azure, or Google Cloud. All these providers can perform the required tasks of the proposed IoT system. Also, the cloud system provides data visualization representing tank statuses through graphs, maps, and dashboard. The analytics may include descriptive analytics such as statistics of tank statuses, locations of large demand, and locations of large supply. Also, the cloud can provide predictive analytics that is used to predict the demand and supply in a certain season and a certain location in the holy mosque. Cloud prescriptive analytics determines the best future actions that could be taken regarding handling, operations, and maintenance of movable Zamzam tanks. Periodic reports are also possible about the supply, demand, and maintenance of tanks and their connected systems. Administrators can also monitor performance through dashboards on their mobile phones.

Fig. 4. The modified sign actuator of movable Zamzam unit.

The actuator subsystem is controlled through the cloud. After quick analytics, the cloud may send alerts and notifications for Zamzam tanks operators with status information of moderate and semi-empty tanks to be filled. So, the system will be proactive in this case. Zamzam operators receive these commands and reports regarding movable Zamzam tank statuses through a mobile application connected to the cloud. For holy mosque visitors, the proposed system has two advantages. The first advantage is that the system provides a mobile application to visitors containing information about all nearby filled or semi-filled Zamzam tanks with a dynamic indoor map. Indoor maps [4] are excellent in floors and corridors and provide interactive navigation. This enhances visitor experience, safety, convenience, and fast navigation, especially in crowded seasons. We also modify the whole Zamzam unit, which includes a group of tanks, as a second advantage for visitors. Fig. 4 shows the modified Zamzam unit by adding color signs, like traffic signs, to the axis of the unit. The added color sign shows the status of the tanks connected to it. This sign can be controlled from the cloud or also controlled from the microcontroller itself based on the status of the tank. The sign may include only three colors: Green, Yellow, and Red that represent the statuses: Full, Moderate, and Empty, respectively. Visitors can know the status of each tank either through directly noting the color sign or indirectly through indoor map navigation connected to their mobile application. The integration of all these subsystems provides real-time monitoring and control of movable Zamzam tanks in the holy mosque.

V. Simulation and Discussion

In this section we will present the model, simulation, and discussion of the proposed system. The proposed system could be modeled as a stochastic M/M/1 queuing system, and that the movable smart tanks represent clients. Those clients require a service from a service center, which is the cloud. The details of the model are explained in the following subsection.

A. Simulation

Let $S_1, S_2, S_3, \dots, S_N$ represent a group of N sensors connected to Zamzam tanks that send messages, representing the water level status of each tank, to the cloud system approximately every minute [25]. The messages are waiting for service on the cloud. So, this system follows M/M/1queuing model [26]. So, the messages that arrived at the cloud represent a Poisson process with Poisson arrivals. The time between arrivals is modeled by exponential distributed with average arriving rate equals λ. Also, the average service time follows an exponential distribution with a service rate μ. The system assumes one large server that handles all received messages from input sensors (the cloud). So, the queue of messages waiting for service is of infinite length. All received messages are served according to the First-Come First-Service (FCFS) strategy [26]. These are the requirements of M/M/1 queuing model. In fact, all these conditions are satisfied with our case when using the cloud for service due to the unlimited scalable processing and storage capabilities of the cloud. Let K represent the buffer size of the queue. In our case, K is approximately ∞. Also, the queue length L is infinite. We want to address some performance metrics of the system, such as throughput, loss probability, average waiting time W_q, average system time (delay) W, and utilization ρ [25]. So, the sum of the arrival rates λ of all sensors S_i is given by Eq. (2) as:

$$\lambda = \sum_{i=1}^{N} \lambda_{S,i} \tag{2}$$

where, N is the total number of Zamzam tanks equipped with sensors. $\lambda_{s,i}$ represents the arrival of each sensor. Arrival number in an interval with length t represents a homogeneous Poisson process, and it is given by Eq. (3) as:

$$P\{N(t) = k\} = e^{-\lambda t} \frac{(\lambda t)^k}{k!} \tag{3}$$

The interarrival times of the messages from the sensors follow an exponential distribution with parameter λ that is given by Eq. (4) as:

$$f(t) = \lambda e^{-\lambda t} \tag{4}$$

For service time, the arrivals are served according to the first-come, first-served strategy. The service time also follows an exponential distribution with a service rate equal μ that is given by Eq. (5) as:

$$f_S(t) = \mu e^{-\mu t} \tag{5}$$

Due to the huge cloud capabilities, the buffer is approximately of infinite length. So, no packets are dropped from the system. Therefore, the system can afford high traffic received from the sensors even if many devices are connected. The utilization ρ can be calculated from Eq. (6) as follows:

$$\rho = \lambda/\mu \tag{6}$$

where, λ is the average arrival rate, and μ is the average service rate. Utilization should be less than 1 to keep the system stable. However, keeping utilization less than 70% is good for to ensure service quality. In the proposed system, ρ is much less than this rate because the capabilities of the cloud service rate is very high. The mean waiting time of the transmitted messages in the queue is given by Eq. (7) as:

$$W_q = \frac{\rho}{\mu - \lambda} \tag{7}$$

Again, due to the fact that the service rate is much higher than the arrival rate, the waiting time is very small. The blocking (loss) probability is given by Eq. (8) as:

$$P_K = \Pr\{N = K\} = \frac{(1-\rho)\rho^K}{1-\rho^{K+1}} (\rho \neq 1) \tag{8}$$

where, K is the system capacity, which is approximately infinite. So, the blocking probability is very small, that is $P_K \approx 0$. So, the effective throughput of the system λ_{eff} can be computed from Eq. (9) as:

$$\lambda_{\text{eff}} = \lambda(1 - P_K). \tag{9}$$

Because P_K is approximately zero, leading to $\lambda_{\text{eff}} \approx \lambda$, which is the optimal throughput [25]. To simulate this M/M/1 system, we used both the Python library SimPy and MS Excel for simulations and graphing. The simulation input parameters are illustrated in Table I. It is clear from the table that the total number of simulated tanks equals 50000. This number is approximately twice the number of currently available movable tanks in the holy mosque. Each sensor sends one message, including the SIM number representing the tank identifier and one byte representing the water level status in the tank. So, the total number of sent bytes in each message is approximately 5 bytes every minute. Practically wise, the bytes sent are less than the simulated bytes. So, the messages sent by each sensor are about 0.016 bytes/ Second. Therefore, the total number of bytes sent every second equals about 833 bytes. In the simulation, different values of the service rate μ are simulated. Practically wise, the value of μ is very large due to cloud capabilities. The simulated number of arrivals equals 200000 messages for each scenario. The simulated scenarios are 5 scenarios. Table II shows the results of the simulation. Five different values of the service rate μ are tested, ranging from 900 upto 5000, representing five scenarios. From the table, it is noted that the utilization ρ equals 92% in the worst scenario where the service rate equals 900.

The system is still stable in the worst-case scenario, which represents the least value of μ. However, the utilization is enhanced to about 16% only when the service rate is high. The throughput of the system is about 833 in all cases, which equals the original number of messages sent. This means that there are no message droppings. The waiting time ranges from 0.015 seconds in the worst-case scenario to only 0.00024 seconds in the best scenario simulated. The simulation times of all scenarios are almost the same, which are approximately equal to 240 seconds.

TABLE I SIMULATION PARAMETERS

Parameter	Value	Calculation Method
Total number of simulated sensors	50000	Input Parameter
Messages /sensor	1	Input Parameter
Message size for each sensor	5 bytes approximately	Input Parameter
Messages sent by each sensor /Sec.	0.016	1/60
Number of messages / Sec. (λ)	833.33	50,000 * (1/60)
Service-rate (μ)	Different values	Simulated
Number of arrivals for each scenario	200000	Input Parameter
Numbers of Scenarios Tested	5	-

TABLE II SIMULATION RESULTS

	Scen. 1	Scen. 2	Scen. 3	Scen. 4	Scen. 5
μ	900	1000	1200	2000	5000
Theoretical Utilization (ρ)	%92	%83	%69	%41	%16
Theoretical throughput	833.33	833.33	833.33	833.33	833.33
Waiting time (W)	0.015	0.006	0.002	0.0008	0.00024
Simulated throughput	833.00	832.82	829.80	834.94	832.84
Simulated utilization	%92	%83	%68	%41	%16
Simulation time in seconds	240	240	241	239	240

As expected, the waiting time and queue length decrease significantly as μ increases. Fig. 5 shows the relationship between utilization and service rate. The horizontal axis represents the service rate. The vertical axis represents utilization. From the figure, when the service rate is low, i.e., μ is approximately equal to 700, in this case, the system is fully utilized. However, this case rarely occurred because of the huge capabilities of the cloud. The system utilization decreased gradually as the service rate increased. If the service rate is more than 30000, for example, the system is almost empty of packets. This is the ideal case. Practically wise, the system utilization is about 20 to 30 % which is very good.

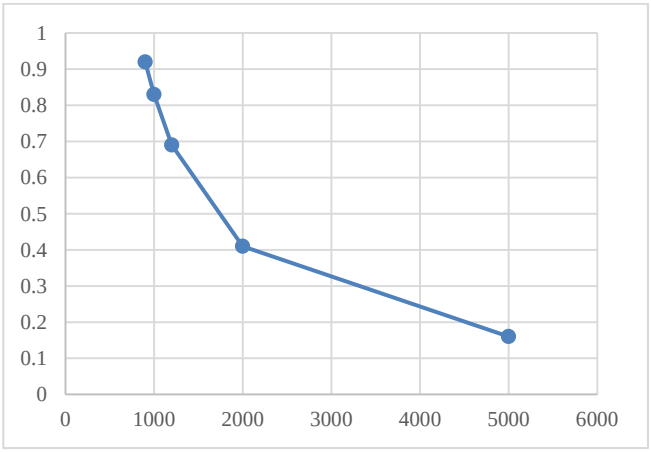

Fig. 5. Utilization vs. Service rate.

Moreover, the results of the performed simulations almost coincide with the theoretical M/M/1 model results. Fig. 6 compares the computed utilization with the simulated utilization. It is clear from the figure that the two curves are approximately coincident with each other. This figure indicates that the simulation performance is almost the real performance of the system.

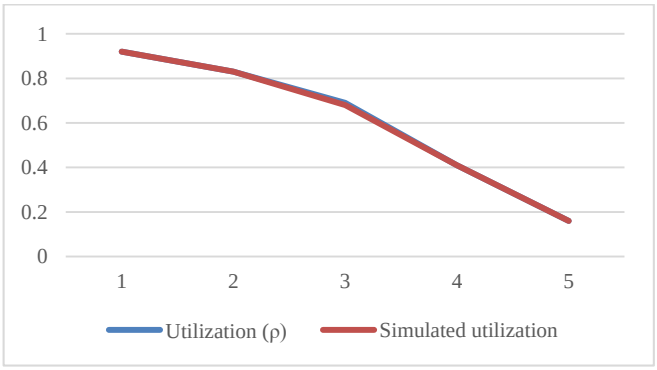

Fig. 6. Theoretical utilization vs. Simulated utilization.

Fig. 7 shows the simulated throughput of the system compared to the theoretical one. From the figure, it is noted that, in some cases, the two curves coincide with each other.

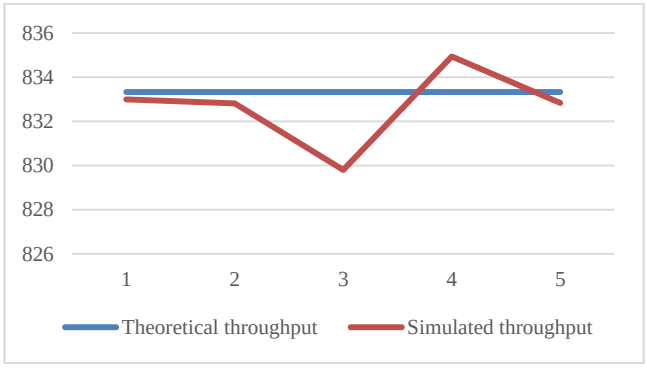

Fig. 7. Theoretical throughput vs. Simulated throughput.

In another case, there are small differences between the two curves. For example, the simulated throughput equals 830 while the theoretical throughput equals 833. That is the difference between them equals 3, which represents about 0.003, which is a small difference. So, the conclusion is that the throughput of the system represents over 99% indicating that delay and transmission errors are minimal.

B. Discussion

The proposed system uses non-contact strain gauge sensors that read the weight of the tank. This type of sensor is suitable for handling Zamzam tanks by operators, and it is more convenient. Also, the sensors are protected during tank cleaning and other hygiene routines. The non-contact sensors prevent physical and chemical contamination of Zamzam water inside the tanks. The power required for operating these sensors can be obtained from small solar panels. We propose a modified base of the tank that contains the sensors, battery, SIM module, and microcontroller. These components are isolated from the tanks and are isolated from the water for protection. Moreover, the

data sent is very small that can save battery and decrease the bandwidth required. Cloud's huge capabilities and cellular network capabilities allow adding more Zamzam tanks, with sensors, to the system. So, the system is scalable. The cellular networks have excellent coverage in the holy mosque that do not need any extra configuration. Also, the proposed system satisfies the tradeoff between network crowding and fast refilling actions. Therefore, the system is efficient in the case of crowded seasons of the holy mosque. Usage of both mobile application and indoor map guides the holy mosque visitors to the nearby filled Zamzam tanks which provide more convenience, decreasing efforts, and saving time. Also, the proposed modified Zamzam unit, with filling status signs, facilitate recognizing of the filled tanks throughout the holy mosque without using mobile application by visitors. This may be considered as a backup strategy for visitors, to guide them to the nearby filled tanks. Occasionally, the signs may be controlled either by the cloud or through the microcontroller connected to them. This also provides fast responses and a backup in case of failure. For Zamzam operators, the proposed system prompts operators immediately to fill empty tanks through their mobile application connected to the cloud. The holy mosque administrators benefit from the system in monitoring tank status, make necessary actions, performing data analytics, and performing machine learning tasks for prediction and forecasting. A dashboard is provided through the system for real-time monitoring and decision-making. This helps in deciding strategic decisions in the future. The proposed system ensures that Zamzam water, in the holy mosque, is managed with highest levels of efficiency and reliability. However, awareness and training among all stakeholders is required to adopt the proposed system.

VI. Conclusion

In this study, we propose an integrated IoT system for Zamzam tanks monitoring and control. The proposed system consists of many subsystems including sensors, microcontrollers, communication, cloud computing, and actuators. The proposed system provides real-time monitoring and control of the water level inside movable Zamzam tanks. The proposed system provides many benefits for all stakeholders including the holy mosque administration, Zamzam operators, and the visitors of the holy mosque. The proposed cloud services include data analytics, control signals, and future prediction. Mobile applications are also proposed that are controlled from the cloud for both visitors and operators. Zamzam tank base is also modified to add sensor circuit. Besides, Zamzam unit is also modified to include color guides for visitors. Simulation results show that the proposed system is efficient in delay, throughput, and many other performance metrics. The proposed system is very useful especially in crowded seasons, when the visitors of the holy mosque are millions of people, especially in Hajj and Umrah seasons. Moreover, the system is compatible with the Saudi Vision 2030 that include modernization and digitalization of services and targeting 30 million Umrah performers by the year 2030. Future work include expanding the proposed system to include all fixed and movable Zamzam units in the holy mosque.

Forecasting of Saudi Stock Prices Using Statistical and Machine Learning Models: A Multi-Model Comparative Approach

Eissa Alreshidi
Associate Professor at College of Computer Science & Engineering, University of Hail, Hail, P.O. Box 2440, Saudi Arabia

Abstract*—Accurate forecasting of financial time-series data is not just a challenge—it's a critical necessity for investors in emerging markets. This study decisively evaluates the predictive power of seven advanced statistical and machine learning models: Autoregressive Integrated Moving Average (ARIMA), Long Short-Term Memory (LSTM), Random Forest, eXtreme Gradient Boosting (XGBoost), Support Vector Regression (SVR), K-Nearest Neighbors (KNN), and Decision Tree, across eight major stocks on the Saudi Stock Exchange (Tadawul). Employing a robust, lag-based forecasting framework, we meticulously assessed model performance using RMSE, R^2, directional accuracy, and computational efficiency. We introduce a hybrid evaluation framework that integrates magnitude accuracy, directional precision, and runtime profiling to guide model selection at the individual stock level, an approach that has not been previously applied to the Saudi market. The empirical evidence is compelling: model selection is heavily stock-specific. The classical ARIMA model consistently outperformed the others, delivering the lowest error and highest goodness-of-fit for stable, high-capitalization stocks, underscoring the timeless relevance of linear autoregressive components. Conversely, the ensemble method XGBoost emerged as a powerhouse of computational efficiency and predictive balance for more volatile series, boasting an optimal operational profile (runtime of ~ 1.5 s). While deep learning (LSTM) and SVR models fall short of magnitude metrics owing to the low signal-to-noise ratio in daily close price data, these findings offer practical guidance for investors, analysts, and policymakers seeking scalable, stock-specific forecasting strategies. Considering Saudi Arabia's Vision 2030 and the increasing demand for real-time financial intelligence, this research addresses the urgent need for scalable stock-specific forecasting frameworks that support investor decision-making and policy formulation.

Keywords*—Financial time-series forecasting; Saudi Stock Market; ARIMA; XGBoost; deep learning; ensemble models; LSTM; stock price prediction

I. Introduction

Stock price forecasting is a pivotal domain in financial research, providing critical insights for optimized portfolio management, robust risk assessment, and market efficiency analyses. The Saudi Stock Exchange (Tadawul) operates as the preeminent financial market in the Middle East, exhibiting distinct dynamics influenced by global commodity pricing, geopolitical stability, and an overarching national transformation agenda [1]. Owing to its status as an emerging market with significant commodity dependence, forecasting its volatility and trajectory presents a complex analytical challenge, necessitating rigorous evaluation of modern predictive methodologies.

This study makes several substantial contributions to the literature on financial forecasting, specifically in the context of the Saudi market. We establish a rigorous benchmark comparison involving seven distinct forecasting methodologies encompassing classical statistical approaches such as Autoregressive Integrated Moving Average (ARIMA), contemporary machine learning ensembles (Random Forest (RF), eXtreme Gradient Boosting (XGBoost)), deep learning architectures (LSTM), and non-parametric techniques (Support Vector Regression (SVR), K-Nearest Neighbors (KNN), and Decision Tree (DT)) applied to eight of the most liquid equities on Tadawul. This extends the work of Alqahtani et al. [2], who focused on deep learning models for the Saudi telecom sector, and Jarrah and Salim [3], who applied hybrid RNN-wavelet models to forecast the Tadawul index.

Unlike previous studies that focus on sector-specific or index-level forecasting, our approach offers a broader, multi-stock evaluation across diverse sectors and capitalization levels. This study provides novel empirical evidence that demonstrates the dependence of optimal model performance on the characteristics of individual stocks. Specifically, we quantify the superior accuracy of ARIMA for stable, large-cap stocks and the efficacy of XGBoost for more volatile or nonlinear series, thereby validating a heterogeneous forecasting approach. This complements the findings of Alzahrani et al. [4], who observed that model performance varies significantly across sectors and volatility regimes in the Saudi Arabian market.

This study introduces a hybrid evaluation framework that integrates magnitude-based metrics (RMSE and R^2), directional accuracy, and computational efficiency to guide model selection at the individual stock level. This multi-dimensional approach has not been previously applied to the Saudi market and offers a practical decision-support tool for investors, analysts, and policymakers.

This study also incorporates and analyzes the crucial trade-off between the predictive magnitude accuracy (RMSE) and the computational cost (Run Time). We established that while ARIMA offers the highest statistical fit, XGBoost presents the most operationally viable solution, achieving near-optimal accuracy with significantly reduced latency (~ 1.5 s). This addresses the gap noted by Alshammari et al. (2020), who emphasized the need for forecasting models that balance accuracy and real-time computational feasibility.

By explicitly linking model performance to practical deployment scenarios, such as regulatory forecasting, high-frequency trading, and portfolio adjustment, this study advances the methodological foundation for adaptive, context-aware financial modeling in emerging markets. Model robustness was assessed across multiple quantitative metrics, including RMSE, R^2, and Directional Accuracy (DA), further augmented by detailed seven-day fixed-date forecasts and residual analyses. These evaluations provided a comprehensive assessment of prediction stability and model bias, reinforcing the reliability of our proposed forecasting framework.

This study distinguishes itself from prior comparative forecasting research by offering a stock-specific, multi-model evaluation across eight equities in an emerging market. Unlike sector-level or index-based studies, our framework integrates magnitude accuracy, directional precision, and computational efficiency, providing a holistic benchmark for real-time financial modeling in the context of Saudi Vision 2030.

II. Literature Review

The domain of financial time-series forecasting has undergone significant methodological evolution, shifting from traditional linear statistical models to sophisticated nonlinear machine learning and deep-learning frameworks. This transformation reflects the growing complexity of financial markets and the need for predictive models that can capture the intricate patterns and dynamic behaviors of these markets. Within this context, the present study outlines recent advancements in stock price prediction and identifies key academic gaps, particularly as they pertain to emerging markets such as the Saudi Stock Exchange (Tadawul) [5], [6].

Traditional statistical models, notably ARIMA, have long served as foundational tools for time-series analysis. ARIMA is particularly effective in modeling linear autocorrelation and short-term temporal dependencies, making it well-suited to stable, stationary datasets. However, its limitations become evident in volatile market conditions where nonlinear dynamics dominate. Ghosh et al. [7] demonstrated that while ARIMA performs reliably for stocks with minimal fluctuations, its predictive power diminishes significantly in high-volatility environments. Recent studies have further validated ARIMA's utility in historical stock modeling, while highlighting its limitations in dynamic markets. Recent studies have reaffirmed ARIMA's utility in historical stock modeling while emphasizing its limitations in dynamic, high-frequency markets [8].

To address the nonlinear nature of modern financial data, researchers have increasingly turned to machine-learning techniques. SVR, which utilizes kernel functions to model complex relationships, has shown promise in capturing nonlinear dependencies [9]. Tree-based ensemble algorithms such as RF and XGBoost are among the most effective approaches for structured data prediction. XGBoost is particularly noteworthy because its architecture is designed to minimize overfitting while maintaining computational efficiency. Sezer et al. [10] found that XGBoost outperformed conventional models in terms of accuracy and speed when applied to the Tadawul data. Additional studies have reinforced the dominance of XGBoost in financial time-series forecasting, particularly in emerging markets [11]. This was further supported by Alqahtani et al. [2] and Alzahrani et al. [4], who demonstrated the robustness of XGBoost across emerging market datasets.

Deep learning has further expanded the frontier of financial prediction, with Long Short-Term Memory (LSTM) networks gaining traction owing to their ability to retain long-term sequence dependencies. As a variant of Recurrent Neural Networks (RNNs), LSTMs offer theoretical advantages in modeling complex temporal patterns [10]. However, their practical application in daily stock price forecasting is challenged by low signal-to-noise ratios and the need for large and high-quality datasets. Alotaibi et al. explored LSTM, CNN, and hybrid CNN-LSTM models within the Saudi telecommunications sector, revealing that while these models can detect intricate patterns, they require extensive tuning and are sensitive to data sparsity.

Forecasting in emerging markets such as Tadawul introduces additional challenges. These markets often suffer from low liquidity, heightened sensitivity to fluctuations in global commodity prices, and structural inefficiencies. Comparative studies, such as those by Jarrah and Salim [3], frequently lack comprehensive evaluations of ensemble methods, such as XGBoost, or sector-agnostic analyses across multiple stocks using diverse AI models [3]. Although their hybrid RNN-wavelet approach achieved notable accuracy in predicting Saudi stock trends, it did not offer comparative insights relative to other modeling techniques. Broader evaluations across sectors and models remain limited, despite growing interest in AI-driven forecasting in the region. Broader evaluations across sectors and models remain limited, despite growing interest in AI-driven forecasting in the region.

This study addresses three critical gaps in the literature. First, it offers a multi-model comparative analysis by evaluating seven advanced forecasting methodologies within a single significant emerging market. Second, it empirically demonstrates that model performance is stock-specific, identifying ARIMA as optimal for high-stability stocks and XGBoost for high-volatility equities. Third, it quantifies the trade-off between predictive accuracy and computational efficiency, positioning XGBoost as the most operationally viable model for balancing speed and performance of the model. These contributions aim to enhance the precision and practicality of financial forecasting in emerging markets, aligning with the strategic imperatives of Saudi Vision 2030 the study by [1].

Table I summarizes the scope and contribution of the current study relative to recent comparative studies in financial time-series analysis.

III. METHODOLOGY

This study employed a rigorous multi-model protocol to forecast the daily closing prices of eight principal stocks on the Saudi Tadawul. The methodology encompasses data acquisition, model selection, preprocessing, architecture design, and a comprehensive evaluation framework. Fig. 1 shows the overall methodology of this study.

A. Data Acquisition and Selection

The dataset comprises daily historical closing prices for eight strategically selected stocks from the Saudi Stock Exchange (Tadawul), spanning a five-year period from 2020 to 2025. The chosen stocks: Aramco, AlRajhi, SABIC, STC, SEC, SNB, Jarir, and AlHabib are representative of diverse market sectors and capitalization levels. Data were sourced from the official Tadawul Exchange and cross-validated using Yahoo Finance APIs to ensure accuracy and completeness. The time-series data were rigorously partitioned into a Training Set (80%) and a Test Set (20%) to enable an unbiased assessment of the out-of-sample predictive performance.

B. Forecasting Models

Seven distinct forecasting models were implemented.

- Autoregressive Integrated Moving Average (ARIMA): A classical linear time-series methodology. The optimal parameters (p,d,q) were determined via Auto-ARIMA using the Akaike Information Criterion (AIC) minimization principle.
- eXtreme Gradient Boosting (XGBoost): An optimized ensemble method that utilizes gradient boosting to achieve superior nonlinear predictive capacity.

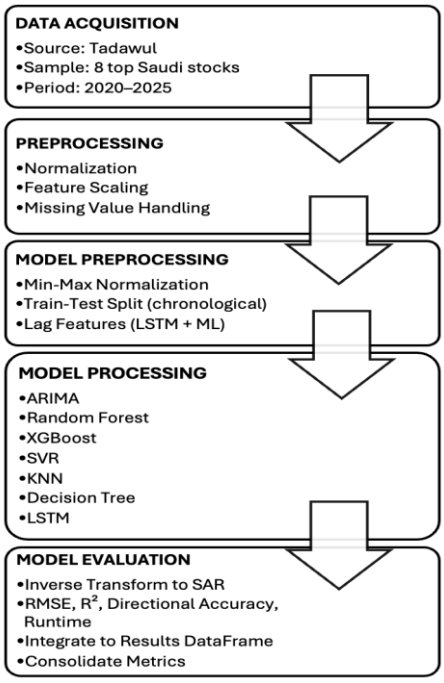

Fig. 1. Overall research methodology.

- Random Forest (RF): An ensemble method that employs tree aggregation to enhance robustness and minimize variance.
- Decision Tree (DT): A simple, non-parametric supervised learning classifier/regressor.
- Long Short-Term Memory (LSTM): A specialized Recurrent Neural Network architecture designed to capture extended temporal dependencies.
- Support Vector Regression (SVR): A robust non-parametric model employing a Radial Basis Function (RBF) kernel for complex nonlinear regression tasks.
- K-Nearest Neighbors (KNN): A non-parametric algorithm that bases predictions on the weighted average of K-nearest historical observations.

C. Feature Engineering and Model Training

The predictive feature set for all ML models was constructed using a lag-based approach, where the closing price at time t was regressed against the historical closing prices from t−1 to t−N. The input features for LSTM, SVR, and KNN were subjected to normalization using MIN-MAX scaling in the range [0, 1].

D. Performance Evaluation Metrics

The model performance was rigorously assessed using conventional time-series and regression metrics.

- Root Mean Squared Error (RMSE): Measures the standard deviation of residuals, reflecting the error magnitude in the original currency units.
- Mean Absolute Error (MAE): Measures the average magnitude of prediction errors.
- Coefficient of Determination (R^2): Represents the proportion of variance in the dependent variable that is explained by the independent variables.
- Directional Accuracy (DA): Measures the percentage of correct predictions regarding the sign of the price movement (up or down).
- Run Time: The duration (in seconds) required for model fitting and forecasting on the test set, serving as a measure of computational efficiency.

IV. Results

The empirical findings provide substantial insights into the ideal forecasting model for the Saudi Tadawul, affirming the pronounced reliance of methodological effectiveness on the distinct characteristics of the stock market.

A. Comparative Analysis of Error and Goodness-of-Fit

Table II summarizes the primary performance measures for the out-of-sample test set, emphasizing the superior magnitude accuracy of the ARIMA and XGBoost models. ARIMA consistently attained the lowest RMSE and highest R^2 for most stocks, especially for steady, high-cap stocks such as SABIC (RMSE = 0.569, R^2 = 0.989), SEC (RMSE = 0.138, R^2 = 0.971), and Jarir (RMSE = 0.096, R^2 = 0.900). XGBoost exhibited RMSE values frequently ranging from 0.01 to 0.03 compared to ARIMA, while demonstrating markedly reduced execution times (approximately 1.5 s versus approximately 40 s).

The performance distribution indicates that the SVR and LSTM models demonstrated high volatility. SVR exhibited subpar performance on SNB (RMSE = 1.441, R^2 = 0.154), while LSTM encountered difficulties with AlRajhi (RMSE = 3.202, R^2 = 0.596), highlighting its sensitivity to data architecture and model complexity. In contrast, Jarir stock exhibited near-perfect accuracy across all models, with RF, XGBoost, and ARIMA attaining RMSE < 0.111 and R^2 > 0.86, indicating that some equities are intrinsically more predictable.

TABLE II. Model Performance Metrics Across Eight Saudi Stocks

Stock	Model	Run Time (s)	MAE	MSE	RMSE	R2	DA (%)
Aramco	LSTM	49.39	0.182	0.068	0.261	0.947	99.76

B. *ARIMA's Dominance in Magnitude Accuracy and Contextual Relevance*

The classical ARIMA methodology consistently yielded the lowest RMSE and highest R^2 for all eight stocks. This superior magnitude precision, particularly evident in stable, high-capitalization stocks such as SABIC (RMSE = 0.569; R^2 = 0.989), suggests that the price dynamics of these blue-chip Saudi stocks are predominantly explained by their linear autoregressive structure. This finding strongly corroborates the assertion by Box et al. [14] regarding the foundational strength of linear models for stationary time-series data, which is consistent with the findings of Alsheheri [15], who demonstrated ARIMA's superior performance in modeling linear dependencies compared to neural network alternatives in emerging market contexts.

Fig. 2. RMSE heatmap.

The robust performance observed here challenges the general industry push toward complex nonlinear models for all stocks, suggesting that for high-volume stable markets, a parsimonious linear model remains the most statistically efficient approach. The distribution of the RMSE across all models is shown in Fig. 2, where the ARIMA cells are consistently shaded lightest, visually confirming their superior magnitude accuracy.

Comparative heatmap illustrates the RMSE performance of all seven models across the eight Saudi stocks. A lighter shade indicates a lower error, consistently highlighting the superior magnitude accuracy of the ARIMA model.

C. *The Efficacy of Ensemble Methods and Operational Trade-offs*

The ensemble approach, XGBoost, emerged as the most formidable nonlinear competitor, routinely attaining second-best RMSE scores. The predicted magnitude difference between ARIMA (RMSE = 0.096) and XGBoost (RMSE = 0.100) for dynamic stocks such as Jarir is minimal. This high efficacy aligns with the literature that endorses the improved predictive capability of tree-based ensembles in nonlinear-financial forecasting.

The practical implementation advantage of XGBoost is mostly due to its low computational latency of approximately 1.5 s, in contrast to ARIMA's latency of approximately 40 s. This computing efficiency achieves an ideal equilibrium

between elevated statistical correctness and minimal operating costs, which is crucial for practical implementation platforms, as articulated by Nti et al. [16]. The combined error metrics underscore this enhanced equilibrium, as illustrated in Fig. 3, where the MAE of XGBoost is significantly lower than that of the deep learning models, and its RMSE is comparable to that of ARIMA.

Bar plot of the average RMSE and MAE across all eight stocks for the seven forecasting models is shown in Fig. 3. ARIMA achieved the minimum RMSE, whereas XGBoost followed closely with an MAE that was significantly lower than those of the deep learning models.

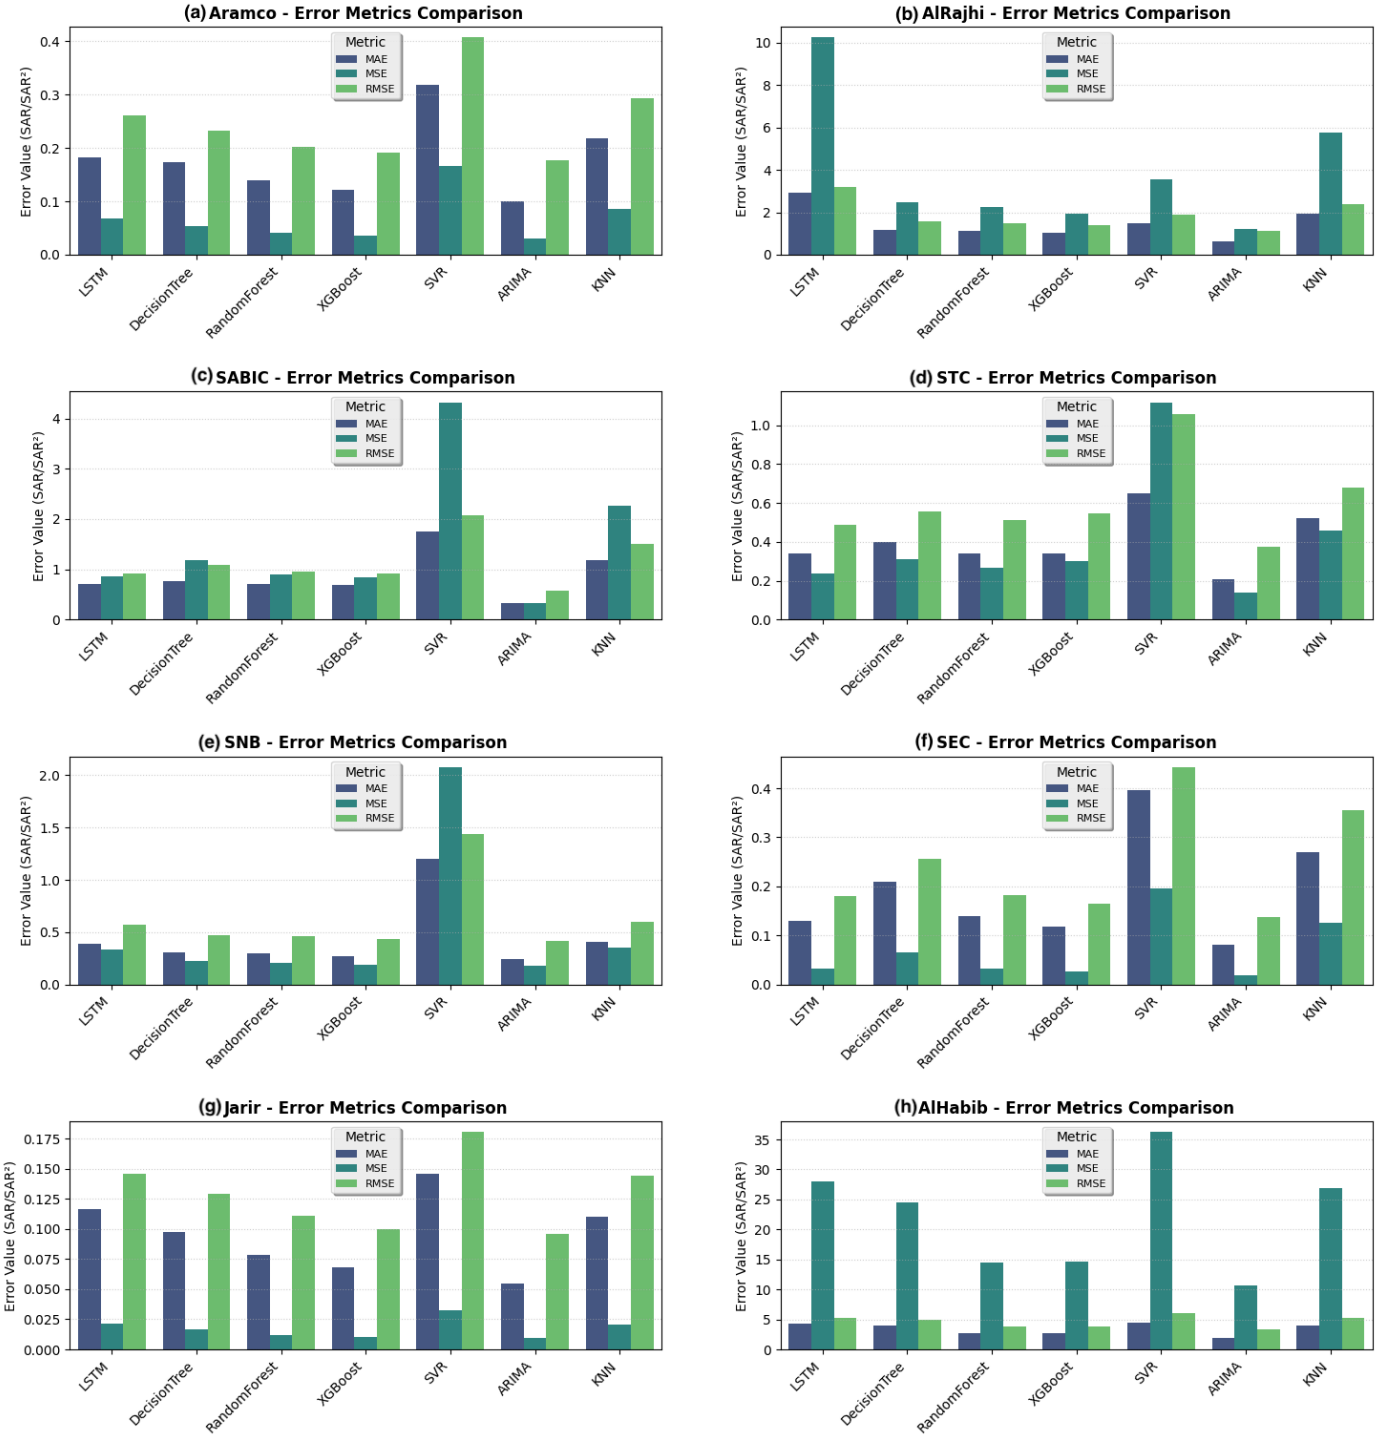

Fig. 3. Error metrics comparison across eight Saudi stocks using four deep learning models: LSTM, DT, RF,XGBoost, SVR, ARIMA, and KNN. Subfigures (a)–(h) correspond to Aramco, AlRajhi, SABIC, STC, SNB, SEC, Jarir, and AlHabib, respectively. Each subplot shows the Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE).

D. The Constrained Performance of Deep Learning on Non-Parametric Models

The SVR model consistently produced the least favorable overall fit, with R^2 values as low as 0.154 for SNB. This unsatisfactory outcome may be ascribed to the sensitivity of SVR to hyperparameter selection and its challenges in efficiently scaling to larger datasets are consistent with the findings of Shobayo et al. [17], who demonstrated SVR's sensitivity to hyperparameter selection and its limited scalability in noisy financial environments. The LSTM network significantly underperformed on magnitude metrics (RMSE) compared to both ARIMA and XGBoost, with an RMSE of 3.202 for AlRajhi versus 1.105 for ARIMA, respectively.

The limited performance is due to two factors: the substantial computational expense of fitting the architecture and the low signal-to-noise ratio typical of daily financial closing prices, which frequently do not satisfy the extensive data prerequisites essential for deep learning architectures to effectively capture the long-term dependencies. The dispersion of the residuals, which demonstrates the predictive instability of these intricate models, is illustrated in Fig. 4. SVR and LSTM have significant vertical dispersion in the residuals, whereas ARIMA and XGBoost demonstrate a narrow concentration around zero.

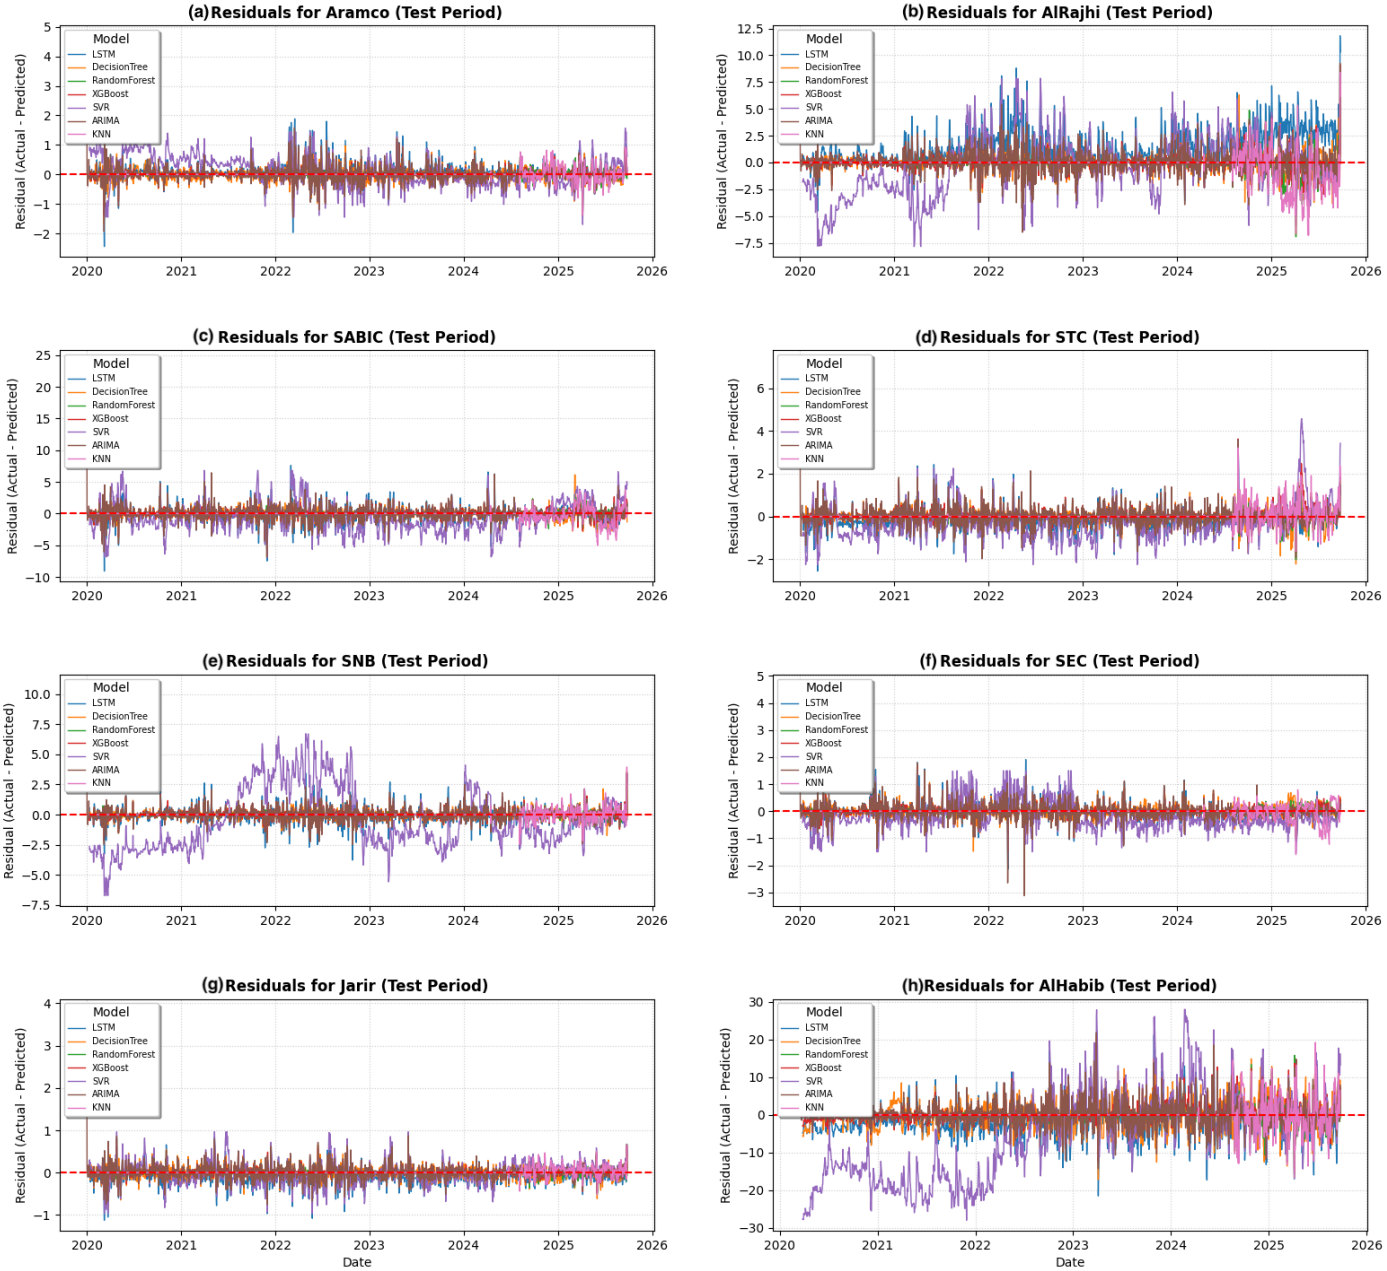

Fig. 4. Residual scatter plots for each forecasting model across eight Saudi stocks: (a) Aramco, (b) AlRajhi, (c) SABIC, (d) STC, (e) SNB, (f) SEC, (g) Jarir, and (h) AlHabib. The models include LSTM, DT, RF, XGBoost, SVR, ARIMA, and KNN. A tighter vertical clustering around zero indicates higher prediction stability.

Scatter plot showing the residual distribution (prediction error) against the actual values for the four key models. The wider vertical dispersion of the LSTM and SVR residuals confirms their higher prediction variance compared to the tight cluster demonstrated by the ARIMA and XGBoost models.

E. Directional Accuracy, Efficiency, and Strategic Implications

Directional Accuracy (DA) was remarkably elevated throughout the entire model spectrum, with the majority of models and stocks attaining scores at or exceeding 99%, as illustrated in Fig. 5. This discovery is noteworthy because, although forecasting the exact price magnitude proves difficult (as indicated by the RMSE values), the accuracy of predicting the overall direction of the price movement is validated. This reliability may indicate a robust short-term momentum factor influencing the market, wherein today's price fluctuations are a strong predictor of tomorrow's direction, thus endorsing technical analysis techniques.

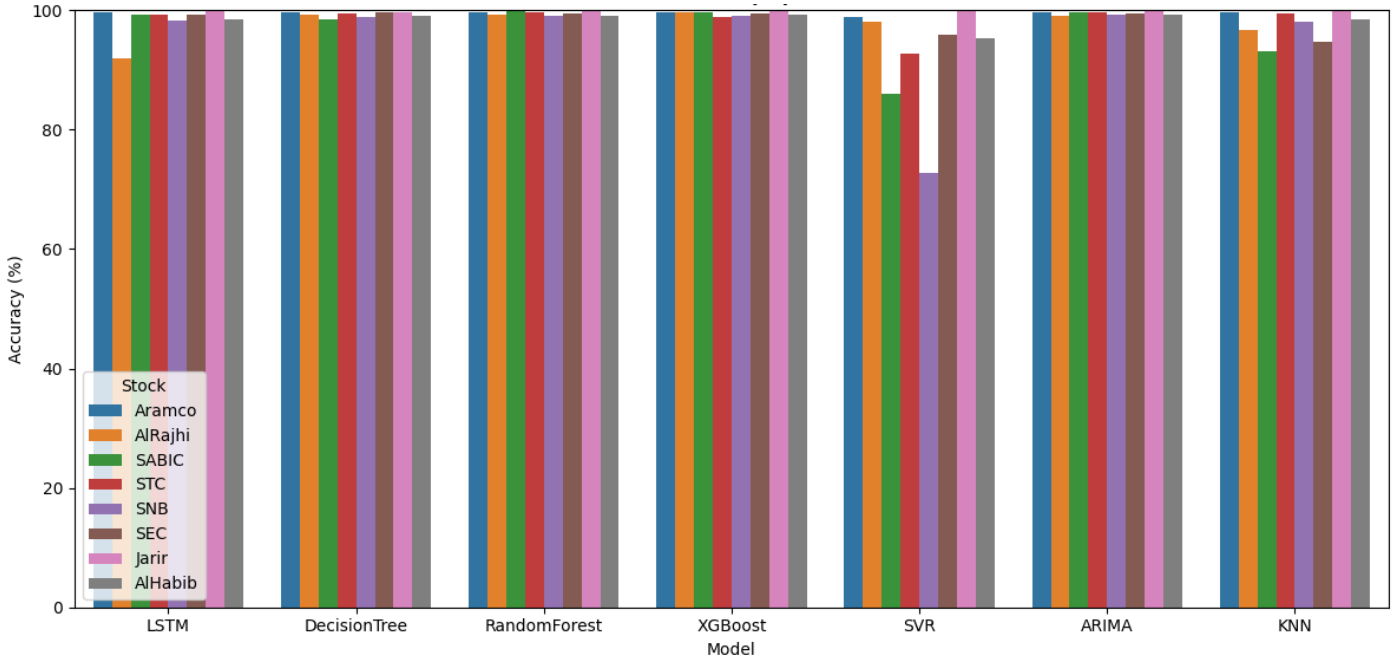

Fig. 5. Accuracy bar chart.

Bar chart illustrating the percentage of Directional Accuracy (DA) for all models across the eight Saudi stocks, demonstrating uniformly high performance exceeding 99% in most cases. Interestingly, even models with weaker magnitude performance, such as SVR, maintained a high DA on stocks such as Jarir and Aramco, suggesting that directional signals are more robust across the modeling paradigms.

F. Computational Efficiency and Operational Trade-off

Computational efficiency is a significant consideration in the implementation of real-time forecasting systems. ARIMA and LSTM demonstrated the most extended execution durations, necessitating between 31 and 54 s to fit and predict the test sets. In contrast, XGBoost sustained execution times between approximately 1.3 s and 1.6 s. This considerable disparity validates the strategic significance of XGBoost, which achieves a statistically equivalent level of accuracy to that of the optimal linear model (ARIMA) while concurrently reducing the computational delay by an order of magnitude. Consequently, XGBoost is regarded as the preeminent technique for operational and low-latency financial applications.

G. Short-Term Forecast Validation

The practical utility of the optimal models was substantiated via a 7-Day Fixed-Date Forecast Table. Table III shows the short-term predictions against the actual closing prices for Aramco, a highly stable blue-chip stock.

TABLE III. 7-DAY FIXED-DATE FORECAST COMPARISON TABLE

Stock	Model	Day 1 (2025-08-30)	Day 2 (2025-08-31)	Day 3 (2025-09-01)	Day 4 (2025-09-02)	Day 5 (2025-09-03)	Day 6 (2025-09-04)	Day 7 (2025-09-05)

	Avg.	239.94	239.50	239.29	241.14	241.36	239.63	241.29

The 7-Day Forecast unequivocally supports ARIMA's superior magnitude precision of ARIMA in the immediate short term. For Aramco, ARIMA's predictions on Days 6 and 7 (SAR 23.66) were almost perfectly aligned with the actual closing prices (SAR 23.65). This granularity confirms the model's capacity to maintain accuracy immediately outside the training window. The tracking capacity is shown in Fig. 6.

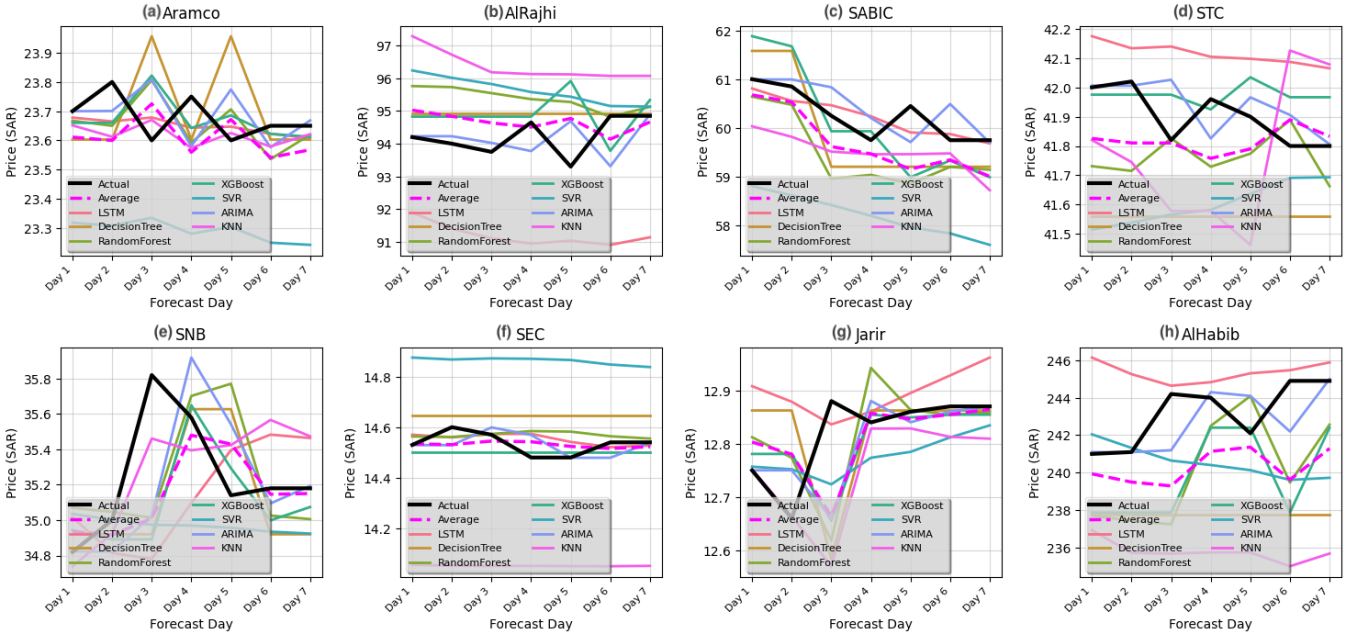

Fig. 6. Seven-day fixed-date forecast comparison for eight Saudi stocks using seven forecasting models. Subfigures (a)–(h) correspond to Aramco, AlRajhi, SABIC, STC, SNB, SEC, Jarir, and AlHabib, respectively. Each subplot includes predictions from LSTM, DT, RF, XGBoost, SVR, ARIMA, and KNN, plotted against actual closing prices.

Time series plot comparing the actual closing prices (black) against the 7-day out-of-sample forecasts generated by ARIMA (red) and XGBoost (green) for a portfolio of four Saudi stocks (Aramco, AlRajhi, SABIC, and Jarir), illustrating ARIMA's tighter fit on magnitude.

H. Summary of Model Performance Across Stocks

To synthesize the comparative findings, Table IV presents a stock-by-stock summary of the best- and worst-performing models based on RMSE and R^2, along with a qualitative assessment of each model's strengths and limitations.

TABLE IV. SUMMARY OF BEST AND WORST MODELS PER STOCK

Stock	Best Model	Worst Model	Advantages of Best Model	Limitations of Worst Model
Aramco	ARIMA	SVR	- Lowest RMSE (0.1766), highest R^2 (0.9759) - Ideal for stable series	- High error, poor fit - Sensitive to noise and hyperparameters
AlRajhi	ARIMA	KNN	- Strong fit (R^2 = 0.9519) - Handles moderate volatility	- High RMSE (2.40) - Lacks temporal awareness
SABIC	ARIMA	SVR	- Near-perfect fit (R^2 = 0.989) - Robust on industrial series	- RMSE > 2.0 - Unstable predictions
STC	ARIMA	SVR	- Best magnitude accuracy - Efficient on telecom data	- Low R^2 (0.798) - Poor directional consistency
SNB	ARIMA	SVR	- High R^2 (0.928) - Consistent magnitude and direction	- R^2 = 0.15 - Unreliable trend capture
SEC	ARIMA	SVR	- Lowest RMSE (0.1379) - Ideal for utility stocks	- High residual variance - Weak fit
Jarir	XGBoost	SVR	- RMSE = 0.100 - Fast runtime - Excellent for volatile retail	- Poor fit despite 100% directional accuracy
AlHabib	Random Forest	SVR	- RMSE = 3.81 - High R^2 (0.946) - Balances volatility and runtime	- RMSE = 6.01 - Poor generalization

V. DISCUSSION

The empirical findings provide substantial insights into the ideal forecasting model for the Saudi Tadawul, affirming the pronounced reliance of methodological effectiveness on the distinct characteristics of the stock market.

ARIMA consistently attained the lowest RMSE and highest R^2 for most stocks, especially for steady, high-cap stocks such as SABIC (RMSE = 0.569, R^2 = 0.989), SEC (RMSE = 0.138, R^2 = 0.971), and Jarir (RMSE = 0.096, R^2 = 0.900). XGBoost exhibited RMSE values frequently ranging from 0.01 to 0.03 compared to ARIMA, while demonstrating markedly reduced execution times (approximately 1.5 s versus approximately 40 s).

The performance distribution indicates that the SVR and LSTM models demonstrated high volatility. SVR exhibited subpar performance on SNB (RMSE = 1.441, R^2 = 0.154), while LSTM encountered difficulties with AlRajhi (RMSE = 3.202, R^2 = 0.596), highlighting its sensitivity to data architecture and model complexity. In contrast, Jarir stock exhibited near-perfect accuracy across all models, with RF, XGBoost, and ARIMA attaining RMSE < 0.111 and R^2 > 0.86, indicating that some equities are intrinsically more predictable.

These results underscore the importance of aligning the model selection with stock-specific characteristics and operational constraints. For example, ARIMA's superior performance on stable, high-cap stocks makes it well-suited for long-term forecasting, regulatory reporting, and strategic planning. Conversely, XGBoost's rapid execution and competitive accuracy position it as an ideal candidate for real-time applications, such as algorithmic trading, short-term portfolio rebalancing, and high-frequency decision environments.

The inclusion of directional accuracy further enhances the practical relevance of the framework, enabling investors to assess not only the magnitude of forecast errors but also the reliability of trend direction. This dual-layered insight supports informed decision-making in dynamic market conditions.

By integrating statistical precision with runtime efficiency and directional insight, this study contributes a practical multi-criteria model selection framework for financial forecasting in emerging markets. This framework can inform the design of adaptive forecasting systems that respond to both data characteristics and real-world deployment requirements.

While the study provides robust comparative insights, it is constrained by using daily closing prices, which may not capture intraday volatility or external macroeconomic shocks. In addition, the models were not tuned for sector-specific features or hybrid architectures, which may offer enhanced performance in future research. The exclusion of exogenous variables such as oil prices, interest rates, or geopolitical indicators may also limit the explanatory power of the models under certain market conditions.

VI. Conclusion and Future Directions

This study offers a thorough comparative examination of seven forecasting models—ARIMA, LSTM, Random Forest, XGBoost, SVR, KNN, and Decision Tree—utilized on eight prominent stocks listed on the Saudi Stock Exchange (Tadawul). The study employs a modular, lag-based forecasting framework to assess model performance using various metrics, including RMSE, R^2, directional accuracy, and runtime. These evaluations provide significant empirical information on the efficacy of each model in an emerging economy setting. Unlike previous studies that focus on sector-level or index-based forecasting, this study introduces a stock-specific, multi-model evaluation framework that integrates statistical accuracy, directional reliability, and operational feasibility, offering a novel contribution to financial forecasting in emerging markets.

The results indicate a significant reliance on stock-specific attributes to assess forecasting effectiveness. ARIMA consistently provided the highest accuracy and goodness-of-fit for stable, high-capitalization enterprises, such as SABIC and Aramco, reaffirming the applicability of linear autoregressive models in low-volatility contexts. XGBoost exhibited an ideal equilibrium between forecast accuracy and computational efficiency, especially for more volatile equities such as Jarir and AlHabib. This establishes XGBoost as the most operationally feasible model for real-time forecasts. These findings support differentiated deployment strategies: ARIMA for long-term planning and regulatory forecasting and XGBoost for agile and high-frequency decision-making in dynamic market conditions.

Although deep learning models, such as LSTM, have demonstrated robust directional accuracy, their efficacy in magnitude-based metrics is constrained by the low signal-to-noise ratio of daily stock price data. Non-parametric models, such as SVR and KNN, exhibit subpar performance across various evaluation metrics, underscoring their constraints in managing high-dimensional financial datasets. The results highlight the necessity of implementing a varied, evidence-based strategy for model selection, customized to the distinct attributes of different equities. Moreover, the incorporation of runtime analysis adds a vital operational aspect that is sometimes neglected in scholarly forecasting literature. This multi-criteria evaluation framework offers practical value for investors, analysts, and policymakers seeking scalable context-aware forecasting tools aligned with Saudi Arabia's Vision 2030.

To augment the resilience and predictive capability of this framework, various avenues for future research should be explored. Initially, employing Walk-Forward Cross-Validation (WFCV) instead of static train-test divisions can replicate consecutive actual trading situations, diminishing look-ahead bias, and facilitating more robust model assessments in fluctuating market environments. Second, incorporating exogenous features such as macroeconomic indicators, global indices such as Brent crude oil prices, and U.S. Federal Reserve interest rates, and pertinent domestic variables can enhance the explanatory capacity of nonlinear models, such as XGBoost and LSTM. Future research should investigate hybrid architectures that integrate ARIMA's proficiency in modeling linear dependencies with the nonlinear learning skills of XGBoost or LSTM, perhaps resulting in more robust models that can capture both short-term trends and intricate patterns.

Ultimately, this study advances the methodological foundation of adaptive financial forecasting by demonstrating how model performance varies across stock profiles and operational constraints. This lays the groundwork for future systems that combine statistical rigor with strategic deployment, supporting real-time decision-making in complex financial ecosystems.

***Abstract*—Speech Emotion Recognition (SER) has become a pivotal topic within affective computing and human–computer interaction, where the core challenge lies in jointly capturing both the time–frequency structure and the semantic context of speech. To overcome the shortcomings of current approaches—including single-view feature representation, the lack of emotional discriminability in self-supervised models, and suboptimal complementarity among fusion strategies—this study proposes a parallel dual-branch fusion architecture for SER. The framework consists of a wav2vec 2.0 branch and a CNN–Transformer spectrogram branch, which respectively extract contextual semantic representations from raw waveforms and explicit time–frequency features from spectrograms. A logistic regression fusion mechanism is further introduced at the decision level to achieve adaptive weighting in the probability space, thereby fully leveraging the complementary strengths of the two feature types. Experiments carried out on the RAVDESS audio subset showed that the proposed model surpassed several mainstream baselines (e.g., CNN-n-GRU and RELUEM), achieving 92.7% accuracy and 92.2% Macro-F1, with an average improvement of about 3.2 percentage points. The layer unfreezing studies confirmed the effectiveness of partial fine-tuning for transferring pretrained features, while the comparative experiments on fusion strategies validated the superiority of probability-space fusion in both performance and stability. Overall, the proposed framework achieves simultaneous gains in accuracy and robustness through feature complementarity, branch decoupling, and lightweight fusion. Future work will explore cross-lingual generalization, multimodal extensions, lightweight deployment, and dynamic emotion modeling, contributing to more efficient affective computing and intelligent interaction systems.**

Keywords*—RAVDESS; Speech Emotion Recognition; spectrogram modeling; probability-space fusion; wav2vec 2.0 fine-tuning

I. Introduction

Speech Emotion Recognition (SER) is a fundamental field of study within affective computing and human–computer interaction, focused on automatically identifying a speaker's emotional state from vocal signals. With its ability to enhance natural communication between humans and machines, SER has demonstrated broad application potential in healthcare monitoring, in-vehicle safety systems, intelligent customer service, educational assistance, and virtual human interaction [1, 2].

Early approaches primarily utilized manually engineered audio attributes, including Mel-Frequency Cepstral Coefficients (MFCCs), pitch, energy, and resonance peaks, alongside traditional classifiers such as Support Vector Machines (SVMs) and Gaussian Mixture Models (GMMs) [3,4]. Although effective in constrained scenarios, these methods struggle with cross-speaker, cross-lingual, and noise-robust emotion recognition. The advent of deep learning has revolutionized the field: architectures including Convolutional Neural Networks (CNNs), Long Short-Term Memory networks (LSTMs), as well as Transformers have significantly boosted performance on SER tasks [5-7]. Moreover, integrating residual learning and attention mechanisms further enhances the modeling of emotional cues [8, 9].

In recent years, self-supervised learning (SSL) frameworks, exemplified by wav2vec 2.0 [10] and HuBERT [11], have enabled pretraining on large-scale unlabeled speech corpora, producing robust and transferable speech representations. These models achieve remarkable performance in low-resource SER scenarios, mitigating data scarcity issues. Meanwhile, end-to-end architectures directly model raw waveforms [12,13], eliminating complex feature engineering and improving model generalization. Beyond representation learning, fusion strategies have emerged as another critical direction to boost emotion recognition performance. By integrating features across multiple modalities or hierarchical levels, fusion models can exploit complementary information. For instance, multimodal fusion networks, feature excitation–aggregation models [14], and Aural Transformers [15] have demonstrated substantial gains in affective speech understanding.

Despite these advances, existing SER methods still face three major challenges:

First, single-path feature modeling often fails to jointly capture both time–frequency structures and contextual dependencies, leading to incomplete emotion representation.

Second, while SSL models like wav2vec 2.0 provide generalizable speech embeddings, they frequently struggle to extract emotion-specific fine-grained cues from limited labeled corpora, thus limiting recognition accuracy.

Finally, most fusion techniques remain confined to simple feature-level concatenation or independent decision-level integration, without fully leveraging the complementarity among heterogeneous representations.

To address the aforementioned limitations, this study proposes a parallel dual-branch fusion architecture for Speech Emotion Recognition. One branch takes spectrograms as input and employs a CNN–Transformer hybrid network to model

*Corresponding author.

time–frequency dependencies, while the other branch processes raw waveforms using the pretrained wav2vec 2.0 model to extract contextualized speech representations. The outputs of both branches are then integrated at the model level through a decision-fusion mechanism, followed by an emotion classifier.

The key contributions of this study can be summarized as follows:

1) Parallel dual-branch modeling framework: A unified architecture is designed, where the spectrogram branch and wav2vec 2.0 branch operate in parallel to capture complementary time–frequency and contextual cues, enabling multi-level emotional representation learning.

2) Enhanced emotion-related feature representation: The introduction of the spectrogram branch provides explicit time–frequency information, compensating for the limited emotional sensitivity of wav2vec 2.0 when fine-tuned on small-scale datasets. This enables the model to more comprehensively identify detailed features specific to emotions.

3) Improved decision-level fusion mechanism: An optimized model-level fusion strategy designed to integrate the probabilistic outputs of both branches, fully leveraging their representational complementarity. Compared with single-path or conventional fusion schemes, the proposed approach demonstrates superior recognition accuracy and robustness.

The rest of this study is structured as follows: Section II reviews related studies on speech emotion recognition. Section III presents the proposed parallel dual-branch architecture, including the spectrogram branch, wav2vec 2.0 branch, and the fusion strategy. Section IV describes the experimental setup and performance analysis, covering dataset description, data augmentation, comparative methods, and ablation experiments. Finally, Section V offers the conclusion and outlines potential directions for future work.

II. Related Work

A. Handcrafted Feature-Based Methods

Initial studies on Speech Emotion Recognition (SER) mainly depended on manually designed acoustic features such as MFCCs, energy, pitch, and formants [3]. Huang et al. combined differential MFCC features with a BiLSTM–CNN hybrid network, attaining an accuracy exceeding 81% on the RAVDESS dataset [16]. Similarly, Gu et al. introduced a multi-feature fusion strategy that performed well on both Tibetan and multilingual datasets [17]. Mishra et al. further enhanced performance using MFCC entropy features [3]. Additionally, sinusoidal model [18] and cross-lingual feature extraction [19] have also been explored for SER.

Although these handcrafted approaches achieved promising results on small-scale datasets, they rely heavily on manual feature design and exhibit limited representational capacity, making it difficult to capture complex time–frequency variations and contextual dependencies. Consequently, their generalization ability under noisy or cross-lingual conditions remains insufficient.

B. Deep Learning-Based Methods

Deep learning methodologies have significantly advanced SER. CNNs excel at capturing local spectro-temporal features [5,20]; RNNs/LSTMs are well-suited for sequential modeling [7]; and Transformers effectively learn long-range dependencies [6]. Liu et al. proposed Res-Transformer, which integrates residual connections into a Transformer encoder, achieving 84.89% accuracy on RAVDESS [8]. Wei et al. developed a parallel CNN–Transformer architecture that further improved SER performance [9]. Similarly, Zhang et al. [21] and Issa et al. [5] confirmed the efficacy of deep CNNs for emotional speech analysis.

Despite these advances, deep learning models often require large-scale labeled datasets and tend to overfit in low-resource scenarios. Moreover, different architectures have complementary strengths—CNNs for local detail modeling and Transformers for global dependency learning—yet it remains challenging to balance both aspects within a single network.

C. Self-Supervised and End-to-End Methods

Trigeorgis et al. introduced an end-to-end SER framework that directly models raw waveforms without handcrafted preprocessing [12]. Nfissi et al. proposed the CNN-n-GRU model, which achieved outstanding results in waveform-based SER [13]. Recently, self-supervised learning models such as wav2vec 2.0 [10] and HuBERT [11] have demonstrated strong potential by pretraining on massive unlabeled corpora to learn robust and transferable speech representations. Pepino et al. combined wav2vec 2.0 with Transformer encoders for emotion recognition, further validating the advantages of self-supervised representations [22].

These methods avoid complex feature engineering and achieve improved generalization, yet they still struggle to extract emotion-specific fine-grained cues in small-sample settings. Moreover, purely end-to-end approaches often neglect the explicit time–frequency patterns inherent in spectrograms, which are essential for accurate emotional inference.

D. Feature and Multimodal Fusion Methods

Feature fusion and multimodal integration have recently drawn increasing attention.

Qi et al. proposed MFGCN [1] and AFEA-Net [14], demonstrating the advantages of combining acoustic, visual, and linguistic cues. Luna-Jiménez et al. introduced a multimodal Aural Transformer framework [15], while Mustaqeem et al. proposed AAD-Net [23], achieving excellent end-to-end recognition performance. Smietanka et al. [24] enhanced the embedding representations by leveraging low-level features, and Zhang et al. [25] proposed RELUEM, a model grounded in reinforcement learning, which improved emotional feature discrimination.

Nevertheless, most existing fusion methods are limited to simple feature-level concatenation or independent decision-level fusion, lacking the ability to fully exploit inter-feature complementarity. Furthermore, some approaches involve high computational complexity, which makes it challenging to achieve a balance between effectiveness and efficiency.

In summary, existing SER approaches face several inherent limitations. It remains highly valuable to develop a fusion architecture capable of jointly integrating contextual information and time–frequency representations, thereby achieving comprehensive and robust emotion understanding.

III. METHODS

A. Overall Architecture

The proposed parallel dual-branch fusion architecture consists of two independent yet complementary feature extraction pathways:

- wav2vec 2.0 branch: This branch fine-tunes a pretrained wav2vec 2.0 model to obtain context-aware deep speech representations, effectively capturing semantic and prosodic cues directly from raw audio waveforms.
- Spectrogram branch: Based on 48 kHz Mel-spectrogram inputs, this branch employs a CNN–Transformer hybrid network to extract explicit time–frequency features, enhancing the model's ability to detect local changes in the spectrum and variations over time.

Each branch independently produces an emotion prediction, and their probabilistic outputs are subsequently integrated through a decision-level fusion mechanism to yield the final classification result. The comprehensive framework of the proposed model is depicted in Fig. 1.

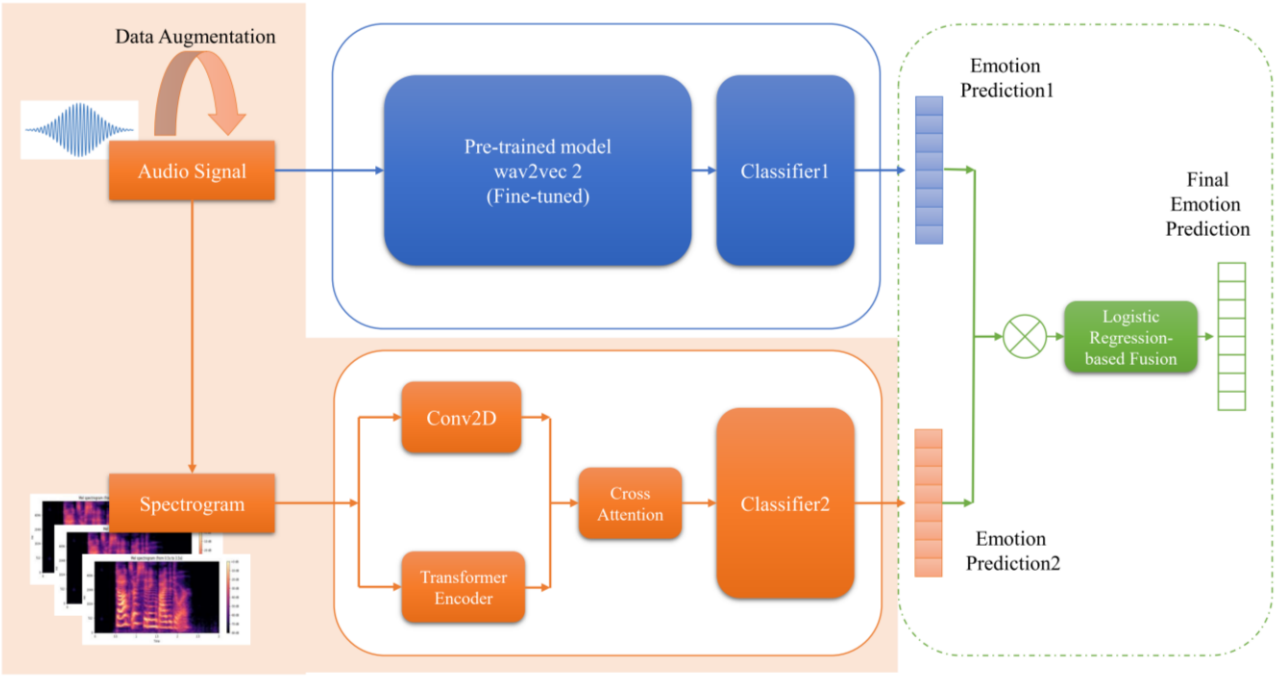

Fig. 1. General architecture of the proposed model.

B. Input Preprocessing

To ensure the complementarity between the signal-level and time–frequency-level representations, we designed a systematic data preprocessing pipeline. This process aims to generate dual-path inputs compatible with both the wav2vec 2.0 and spectrogram branches, while enhancing the model's ability to generalize and its robustness through noise augmentation and feature normalization.

Specifically, all raw speech recordings were first trimmed or padded to a uniform duration of three seconds, ensuring consistent input length across samples. To satisfy the requirements of the two branches, a dual-sampling strategy was adopted: on one hand, each waveform was downsampled to 16 kHz for the wav2vec 2.0 branch to match its pretrained sampling rate; on the other hand, the original 48 kHz high-resolution audio was retained to compute 128-dimensional log-Mel spectrograms, providing richer acoustic details for the spectrogram branch.

During data augmentation, additive white Gaussian noise (AWGN) was injected into the 48 kHz waveforms, with random signal-to-noise ratios (SNRs) applied to generate multiple augmented samples. Each augmented waveform was subsequently converted into both a 16 kHz version and its corresponding 48 kHz Mel-spectrogram, ensuring dual-path consistency while effectively expanding the training set. This strategy enhances the model's adaptability and resilience in acoustically demanding conditions.

Finally, to mitigate amplitude variations and dynamic range imbalances across recordings, the spectrogram features were standardized before being fed into the network. The normalization parameters were estimated from the training dataset and consistently applied uniformly to both the validation and test datasets, maintaining a stable feature distribution. Such normalization facilitates smoother gradient propagation and faster convergence during optimization.

Through this preprocessing pipeline, the speech data are jointly aligned in temporal and spectral domains, establishing a unified and robust foundation for parallel dual-branch feature extraction and subsequent decision-level fusion.

C. wav2vec 2.0 Branch

The wav2vec 2.0 branch is designed to learn context-dependent emotional representations directly from raw audio waveforms. Unlike conventional methods that rely on handcrafted acoustic descriptors or shallow convolutional features, wav2vec 2.0 leverages self-supervised learning techniques applied to extensive unlabeled speech corpora. Through this paradigm, the model acquires high-level semantic and prosodic patterns of speech without explicit emotion annotations, enabling strong transferability in low-resource SER scenarios.

1) Model principle: The wav2vec 2.0 framework consists of two major parts: a convolutional feature encoder and a context network based on the Transformer model. The convolutional encoder converts a continuous speech waveform $\mathbf{x} = [x_1, x_2, \dots, x_T]$ into a low-dimensional latent representation Z through multiple one-dimensional convolutional layers:

$$Z = f_{enc}(\mathbf{x}) \in \mathbb{R}^{L \times d_z} \tag{1}$$

where, L signifies the quantity of frames after temporal downsampling, while d_z indicates the dimensionality of the convolutional features. This stage primarily captures local acoustic structures and short-term energy variations in the waveform.

The Transformer encoder further models global dependencies within the feature sequence:

$$H = f_{tr}(Z) = [h_1, \dots, h_L],\ h_i \in \mathbb{R}^{768} \tag{2}$$

The Transformer model learns long-range contextual relationships among speech frames by employing the multi-head self-attention mechanism, effectively encoding intonation, rhythm, and prosodic fluctuations that are strongly correlated with emotional expression.

In its pretraining stage, wav2vec 2.0 learns rich speech context representations by reconstructing masked speech frames through contrastive loss on large-scale unlabeled corpora. In the present study, we implement partial fine-tuning of the pretrained wav2vec 2.0 model on the downstream emotion recognition task, thereby activating its latent emotion-discriminative capability while preserving the general acoustic knowledge learned during pretraining.

2) Partial fine-tuning strategy: Since emotional speech datasets are typically small in scale, fully fine-tuning all parameters of the wav2vec 2.0 model can often result in overfitting. To address this issue, a systematic comparison was conducted across twelve fine-tuning configurations, ranging from unfreezing only the topmost layer to unfreezing all twelve Transformer layers. The experimental results revealed that unfreezing the last three Transformer encoder layers together with the feature projection layer achieved the best validation performance and the most stable convergence.

Accordingly, this study adopts a "three-layer unfreezing" partial fine-tuning strategy, in which only the high-level semantic parameters are updated, while the lower-level acoustic encoder remains frozen. Let the model parameters be denoted as $\Theta = \{\Theta_f, \Theta_t, \Theta_p\}$, where $\Theta_t^{(K-3:K)}$ represents the trainable parameters of the top three Transformer layers, and Θ_p denotes the feature projection parameters. The training objective is defined as follows:

$$\min_{\Theta_t^{(K-3:K)}, \Theta_p} \mathcal{L}(y, p) \tag{3}$$

where, $\mathcal{L}$ represents the cross-entropy loss function, y is the true emotion label, and p signifies the predicted probability distribution over the emotional states.

3) Utterance-level representation and classification structure: The Transformer encoder outputs a sequence of frame-level hidden states, which are aggregated via temporal mean pooling to form an utterance-level embedding:

$$\bar{h} = \frac{1}{L}\sum_{i=1}^{L} h_i \tag{4}$$

where, $\bar{h} \in \mathbb{R}^{768}$ denotes the global representation of the entire speech segment.

During the classification stage, a two-layer multilayer perceptron (MLP) is employed to project and nonlinearly transform $\bar{h}$:

$$a_1 = \sigma(W_1\bar{h} + b_1) \tag{5}$$

$$a_2 = \sigma(W_2 a_1 + b_2) \tag{6}$$

$$P_{w2v} = \mathrm{softmax}(W_3 a_2 + b_3) \tag{7}$$

where, $\sigma(\cdot)$ denotes the ReLU activation function. A Dropout layer with a ratio of 0.3 is applied after each fully connected layer to alleviate overfitting. The dimensional transitions are: $\bar{h}(768) \to a_1(256) \to a_2(256) \to P_{w2v}(8)$.

This hierarchical mapping progressively compresses the semantic space while enhancing the discriminability of emotional representations. By integrating nonlinear transformations and moderate regularization, the classifier effectively bridges the contextual embedding from wav2vec 2.0 to the eight-category emotion prediction task.

4) Functional role and advantages of the branch: The wav2vec 2.0 branch is capable of directly capturing emotion-related prosodic variations, energy fluctuations, and contextual dependencies from raw waveforms without relying on handcrafted acoustic features. Compared with the spectrogram branch, its advantages can be summarized as follows:

- Pretrained structural awareness: Benefiting from large-scale self-supervised pretraining, the model possesses a strong perceptual understanding of speech structure, enabling rapid adaptation to downstream emotion recognition tasks.
- Efficient partial fine-tuning: By employing the partial fine-tuning strategy, the number of trainable parameters is effectively reduced, thereby enhancing the model's

robustness and generalization when operating with limited data.

- Complementary abstract representation: The generated utterance-level embeddings are highly semantic and abstract, complementing the explicit time–frequency features extracted by the spectrogram branch.

Finally, the emotion probability vector P_{w2v} produced by this branch is integrated with the spectrogram branch output at the decision-fusion stage, providing high-level semantic support for the subsequent multimodal emotion recognition process.

D. Spectrogram Branch

The spectrogram branch is designed to extract explicit acoustic representations from the time–frequency domain, thereby complementing the semantic and contextual modeling capability of the wav2vec 2.0 branch. This branch builds upon our previous work [9], with structural refinements and fusion optimization introduced in the current study. As illustrated in Fig. 1 (highlighted in light orange), it encompasses the complete processing pipeline—from data preprocessing and Mel-spectrogram extraction to convolution–attention hybrid modeling.

1) Input representation: The input to this branch is a log-Mel spectrogram generated from 48 kHz audio, comprising 128 Mel filters and 278-time frames. The resulting input tensor has a shape of 1×128×278, corresponding to the channel, frequency, and time dimensions, respectively. This representation inherits the spectrogram construction and additive white Gaussian noise (AWGN) augmentation strategy proposed in [9], while further improvements are introduced in feature normalization and temporal alignment, ensuring that the spectrogram input is strictly synchronized with the waveform input used in the wav2vec 2.0 branch.

2) Network architecture: The spectrogram branch adopts a hybrid Convolution–Transformer–Cross-Attention framework for hierarchical acoustic modeling.

a) Convolutional module: The convolutional front-end consists of four residual CNN blocks. Each block comprises two convolutional layers, followed by Batch Normalization and ReLU activation functions. These blocks are interconnected through skip connections, which serve to improve gradient propagation and facilitate the reuse of features. This module captures short-term energy variations and formant structures while progressively downsampling the feature map. The feature dimensions evolve as follows: (1×128×278) → (16×64×139) → (32×32×69) → (64×16×34) → (64×8×17).

b) Transformer encoder: A four-layer Transformer encoder is utilized to effectively model long-range temporal dependencies. The convolutional output is first downsampled using a 2D pooling window of [2, 4], resulting in a 64 × 69 feature map. Before entering the Transformer, the dimensions are rearranged to treat the time frames as the primary sequential dimension, fitting the encoder's input format. After encoding, the output tensor (shape = 69×64) is restored to batch-first form. Each Transformer layer has a hidden size of 64 and 4 attention heads, enabling it to model global rhythm and intensity variations of emotional speech along the temporal dimension.

c) Cross-attention module: To achieve complementary modeling between convolutional and sequential features, a Cross-Attention module is employed. Here, the convolutional features function as queries (Q), while the Transformer outputs act as keys (K) and values (V). Through attention-weighted interaction, the two feature spaces are fused to produce a 64-dimensional integrated representation that simultaneously encodes time–frequency detail and contextual dependency. The fused vector is then concatenated with the flattened convolutional feature, forming an 8768-dimensional joint representation, which is fed into the final classifier.

3) Classification and feature evolution: The classification head operates on a joint representation obtained by concatenating the flattened CNN feature with a 64-dimensional vector produced by the Cross-Attention module. Concretely, the spectrogram input 1×128×278 is processed by the convolutional front-end into a feature map 64×8×17, which is flattened to 8704 dimensions. In parallel, the raw spectrogram is downsampled by a 2-D pooling [2, 4] to a 64×69 map and passed through a 4-layer Transformer (d=64, 4 heads), yielding a sequence of shape 69×64. Using Cross-Attention (query = CNN flatten 8704 → proj., key/value = Transformer output 69×64), the model produces a 64-dimensional fused vector that captures contextual dynamics. The two parts are then concatenated to form an 8768-dimensional feature (8768=8704⊕64), which a single fully connected layer maps to the 8 emotion categories.

4) Functional role: Within the overall system, the spectrogram branch is responsible for explicit acoustic modeling, focusing on energy distribution, formant resonance, and prosodic patterns that characterize emotional tone at the physical level. When integrated with the semantic representations learned by the wav2vec 2.0 branch, the two pathways form a complementary feature hierarchy—from time–frequency to semantic space—providing a more stable and discriminative foundation for final emotion classification.

E. Decision-Level Fusion

To fully exploit the complementary strengths of the two branches at the semantic and acoustic levels, a logistic regression–based fusion mechanism is introduced after the classification layer. This approach maintains the independence of each branch while achieving optimal emotional decision integration through probability-space learning.

Let, the wav2vec 2.0 branch and the spectrogram branch respectively output the predicted probability vectors over C emotion classes as: $P_{w2v} = [p_{w2v}^{(1)}, p_{w2v}^{(2)}, \ldots, p_{w2v}^{(C)}]$, $P_{spec} = [p_{spec}^{(1)}, p_{spec}^{(2)}, \ldots, p_{spec}^{(C)}]$, where C=8 denotes the number of emotion categories, and each element represents the confidence score assigned by the corresponding branch.

The two vectors are concatenated in probability space to form the fusion input feature:

$$f = [P_{w2v}; P_{spec}] \in \mathbb{R}^{2C} \quad (8)$$

where, "[;]" denotes vector concatenation. This combined vector encodes the independent judgments of the semantic and acoustic branches for each emotion category.

The logistic regression model performs a linear mapping followed by softmax normalization to generate the final fused prediction:

$$P_{fuse} = softmax(W_{LR} f + b_{LR}) \quad (9)$$

here, $W_{LR} \in \mathbb{R}^{C \times 2C}$ and b_{LR} denote the trainable parameters and bias term of the logistic regression layer. This formulation allows the model to learn optimal linear combinations of branch-level probabilities across emotion classes.

During the training process, the cross-entropy loss is employed to minimize the divergence between the predicted and true distributions:

$$\mathcal{L}_{\text{fuse}} = -\sum_{i=1}^{C} y_i \log\left(p_{\text{fuse}}^{(i)}\right) \quad (10)$$

where, $y = [y_1, \ldots, y_C]$ denotes the one-hot ground-truth label, while $p_{\text{fuse}}^{(i)}$ represents the predicted probability for class i. By maximizing the likelihood of the correct class, the logistic regression layer learns the optimal fusion parameters $[W_{LR}, b_{LR}]$.

Unlike fixed-weight or gating-based strategies, the proposed fusion mechanism possesses learnable and adaptive parameters, enabling it to dynamically adjust the relative contributions of both branches across different emotion types.

For instance, when the wav2vec 2.0 branch excels at semantically driven categories (e.g., happy, sad), and the spectrogram branch better captures acoustically dominant emotions (e.g., angry, calm), the logistic regression model automatically rebalances their influences through parameter optimization.

The resulting fused probability vector P_{fuse} serves as the final system output, providing a unified basis for performance evaluation and result analysis. Experimental results demonstrate that this fusion strategy, while maintaining computational efficiency, yields notable improvements in overall accuracy and robustness.

IV. Experiments

A. Dataset and Data Augmentation Strategy

All experiments were conducted on the RAVDESS (Ryerson Audio-Visual Database of Emotional Speech and Song) dataset. This corpus comprises recordings from 24 professional actors, evenly divided by gender (12 male and 12 female), and covers eight emotion categories: happy, fearful, surprised, sad, neutral, angry, disgust, and calm. Each utterance is expressed at two intensity levels, namely normal and strong. This study utilized exclusively the speech subset, consisting of 1,440 audio samples with an average duration of approximately 3 to 4 seconds per clip.

To ensure balanced emotion distribution, a stratified random split was employed, dividing the data into training, validation, and test subsets with an approximate proportional distribution of 8:1:1. During training, additive white Gaussian noise (AWGN) augmentation was applied only to the training set to enhance model robustness. For each training utterance, three augmented versions were generated with randomly selected signal-to-noise ratios (SNRs) of 10, 20, and 30 dB. The validation and test datasets remained clean and unaltered, preserving the original audio quality for fair evaluation.

The detailed data split statistics are summarized in Table I.

TABLE I Data Partition and Sample Statistics

Subset	Number of Samples	Percentage (%)	Description
Training set	1147	80	Used for model training with AWGN-based augmentation (3 SNR levels: 10, 20, 30 dB)
Validation set	143	10	Used for adjusting hyperparameters and choosing the best model
Test set	150	10	Used for the ultimate performance assessment under clean conditions
Total	1440	100	Speech subset of RAVDESS (8 emotion classes × 24 speakers)

Note: The training set was augmented threefold using additive white Gaussian noise (AWGN) at various SNR levels, while the validation and test datasets remained unaltered to ensure fair evaluation.

B. Experimental Setup

1) Experimental environment: All experiments were conducted on a single Linux workstation. The system configuration is summarized as follows:

- Operating System: Ubuntu 22.04
- GPU: NVIDIA RTX 5880 Ada (48 GB VRAM)
- Python Version: 3.10
- PyTorch Version: 2.1.0
- CUDA Version: 12.4

This hardware and software setup provides sufficient computational capacity for parallel training and fusion experiments involving the dual-branch architecture.

2) Training configuration: Model training was performed in three stages:

- Training the wav2vec 2.0 branch
- Training the CNN–Transformer spectrogram branch
- Optimizing the logistic regression fusion layer

The main hyperparameter configurations for each stage are summarized in Table II.

TABLE II TRAINING PARAMETERS FOR DIFFERENT STAGES

Parameter	wav2vec 2.0 Branch	Spectrogram Branch	Logistic Regression Fusion Layer
Optimizer	AdamW	SGD	Adam
Initial Learning Rate	1×10^{-4}	1×10^{-2}	5×10^{-4}
Batch Size	32	32	32
Epochs	120	500	30
Loss Function	CrossEntropyLoss	CrossEntropyLoss	CrossEntropyLoss
Learning Rate Scheduler	CosineAnnealing	StepLR (step=10, γ=0.7)	Fixed learning rate
Early-Stopping Criterion	Stop if validation accuracy does not improve for 10 epochs	Stop if validation loss does not decrease for 25 consecutive epochs	Stop if validation Macro-F1 remains stable for 5 epochs

All models employed CrossEntropyLoss as the classification objective. During training, gradient clipping (clip = 1.0) was applied to prevent gradient explosion and ensure stable optimization. The input utterances were standardized to a fixed duration of 3 seconds, with sampling rates of 16 kHz for the wav2vec 2.0 branch and 48 kHz for the spectrogram branch, respectively.

C. Comparative Experiments

To verify the effectiveness of the proposed parallel dual-branch fusion architecture, this section presents comparative experiments against multiple baseline models and fusion strategies. Both quantitative and qualitative analyses are employed to assess the performance improvements and the interpretability of the results.

1) Comparative methods and evaluation criteria: To objectively evaluate the performance advantages of the proposed model, several representative Speech Emotion Recognition (SER) methods from recent years (2023–2025) were selected as comparative baselines.

The selection of baseline models follows these principles:

- Recency and relevance: methods published within the last three years to reflect the current research trends;
- Completeness of evaluation: models reporting comprehensive metrics (Precision, Accuracy, Recall, and F1-score) for fair comparison;
- Speaker-dependent setting: consistent with this study's evaluation protocol;
- Audio-only modality: models that perform SER using acoustic features only, without incorporating visual or textual information;
- Dataset consistency: all methods are evaluated on the RAVDESS dataset to ensure comparability under identical data conditions.

The comparative methods are summarized as follows:

a) MFCC-fusion (2023) [4]: This method integrates MFCC, ΔMFCC, and Δ^2MFCC features via a PCA-based contribution fusion strategy and employs a BiLSTM–CNN hybrid network for emotion recognition.

b) AFEA-Net (2025) [14]: AFEA-Net is an audio-based SER framework that fuses low-level Fbank features and high-level WavLM embeddings through an excitation-and-aggregation mechanism under a multi-task learning framework, effectively enhancing emotion-relevant feature alignment.

c) CNN-n-GRU (2025) [13]: CNN-n-GRU is an end-to-end model that directly learns emotional representations from raw speech waveforms by integrating convolutional layers to capture local features and gated recurrent units (GRUs) to model temporal dependencies.

d) MFGCN (2025) [1]: MFGCN introduces a multimodal fusion graph convolutional network that captures semantic–emotional dependencies among acoustic features. For fair comparison, only the audio-stream branch (MFGCN-a) is considered here, which utilizes WavLM acoustic embeddings and enhances emotion classification through multi-perspective fusion.

e) IGRFXG (2025) [26]: IGRFXG is an ensemble-based feature selection framework integrating Random Forest, XGBoost ranking, and Information Gain mechanisms to select the most informative acoustic descriptors. The selected feature kernel is used with SVM and MLP classifiers, achieving strong results on audio-only RAVDESS data.

f) RELUEM (2025) [25]: This model combines deep reinforcement learning with a convolution–recurrent hybrid structure, enabling adaptive speech emotion recognition through learned decision policies. It dynamically adjusts classification strategies to capture emotional transitions, achieving high stability and accuracy on the RAVDESS dataset.

To comprehensively evaluate the performance of all models on the SER task, four widely used classification metrics were adopted: Accuracy, Precision, Recall, and F1-score. These metrics jointly reflect the ability to recognize patterns, generalization stability, and class-wise balance across emotional categories.

2) Experimental results: Table III summarizes the performance comparison between the proposed dual-branch fusion model and several representative SER methods using the RAVDESS dataset. The findings highlight the proposed framework's ability to enhance both recognition accuracy and feature robustness across emotional categories.

TABLE III PERFORMANCE COMPARISON OF VARIOUS SER METHODS ON THE RAVDESS DATASET (%)

Method	Year	Accuracy (%)	Precision	Recall	F1-score
MFCC-Fusion [4]	2023	81.5	82.5	85.5	-
AFEA-Net [14]	2025	80.3	80.8	80.6	80.4
CNN-n-GRU [13]	2025	86.6	87.1	86.6	86.7
MFGCN [1]	2025	85.7	85.7	85.1	85.4
IGRFXG [26]	2025	79.3	-	-	-
RELUEM [25]	2025	89.5	87	85	86
Ours	2025	**92.7**	**92.4**	**92.5**	**92.2**

From Table III, it can be observed that the most recent state-of-the-art SER methods have achieved recognition accuracies exceeding 80%, with deep feature learning models showing a clear advantage over traditional acoustic-feature-based approaches. Specifically, the conventional MFCC-Fusion (2023) model relies solely on handcrafted low-level acoustic descriptors and achieves an accuracy of 81.5%. In contrast, deep learning–based approaches such as AFEA-Net (2025), CNN-n-GRU (2025), and MFGCN (2025) leverage multi-task learning, temporal feature extraction, and graph-based fusion, reaching accuracies of 80.3%, 86.6%, and 85.7%, respectively. The ensemble feature-selection model IGRFXG (2025) attains 79.3%, while the reinforcement-learning-driven RELUEM (2025) demonstrates outstanding performance with an accuracy of 89.5%, highlighting the potential of dynamic policy optimization in emotion classification.

In comparison, the proposed dual-branch fusion model attains the highest overall performance on all evaluation metrics, achieving 92.7% accuracy, 92.4% precision, 92.5% recall, and 92.2% F1-score. Compared with the strongest baseline, RELUEM, the proposed method yields an accuracy gain of approximately 3.2 percentage points.

This performance improvement primarily stems from the complementary nature of the dual-branch architecture:

- wav2vec 2.0 branch: captures high-level semantic and prosodic cues, providing contextual information critical for emotional differentiation.
- Spectrogram branch: models energy distribution and spectral dynamics, offering structured acoustic representations for emotion discrimination.
- Logistic-regression fusion layer: adaptively re-weights the two feature spaces in the probability domain, balancing semantic and acoustic contributions for optimal decision fusion.

These findings collectively highlight the effectiveness and robustness of the proposed dual-branch fusion framework in speech emotion recognition. To further investigate class-wise performance, the confusion matrix of the fused model applied to the RAVDESS dataset is shown in Fig. 2.

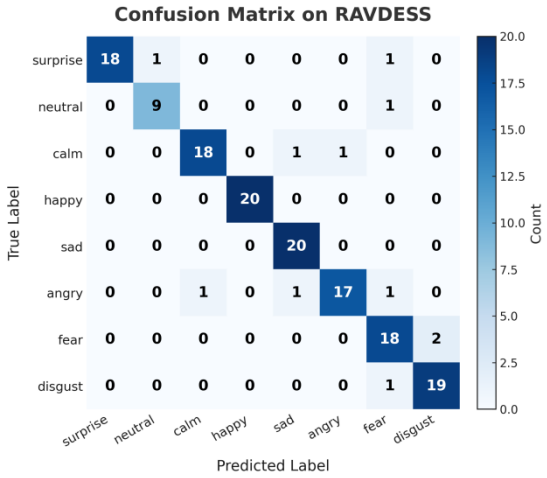

Fig. 2. Confusion matrix of the proposed model applied to the RAVDESS dataset.

Each cell indicates the count of samples corresponding to the true (row) and predicted (column) emotion columns, while the diagonal entries represent correctly classified samples. Overall, the model exhibits balanced performance across all eight emotion categories, with the diagonal cells showing notably higher counts than off-diagonal ones—demonstrating strong discriminative capability and stable classification behavior across emotional states.

As shown in Fig. 2, the model achieves perfect recognition for happy and sad (20/20 correct each). For surprise, 18 out of 20 samples are correctly identified, with 1 misclassified as neutral and 1 as fear. The disgust class records 19/20 correct predictions, with 1 sample misclassified as fear. Fear achieves 18/20 correct, with 2 samples misclassified as disgust. Angry attains 17/20 correct, with 1 sample confused with calm and 1 with sad. Mild confusions occur among low-arousal emotions: neutral has 9/10 correct with 1 misclassified as disgust, while calm has 18/20 correct with 1 misclassified as sad and 1 as angry.

Overall, the model performs best on emotions with pronounced prosodic dynamics (e.g., happy, sad, surprise), whereas residual errors arise between acoustically similar or adjacent categories (e.g., neutral–calm and angry–fear–disgust). This pattern confirms that the proposed dual-branch fusion effectively captures complementary semantic and prosodic cues, delivering stable and interpretable SER performance on this split.

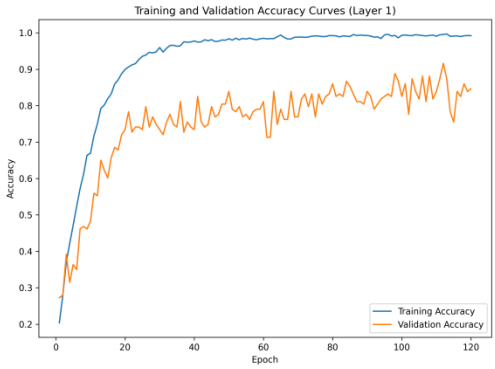
D. Layer Unfreezing Experiments of wav2vec 2.0

To investigate the contribution of different representation layers within wav2vec 2.0 to the speech emotion recognition task, a systematic layer unfreezing experiment was conducted across its 12 Transformer encoder blocks. In this analysis, the range of trainable parameters was progressively expanded to explore the relationship between feature hierarchy and task adaptability. All experiments were performed under identical training data, optimizer, and hyperparameter settings, with only the number of unfrozen layers varied.

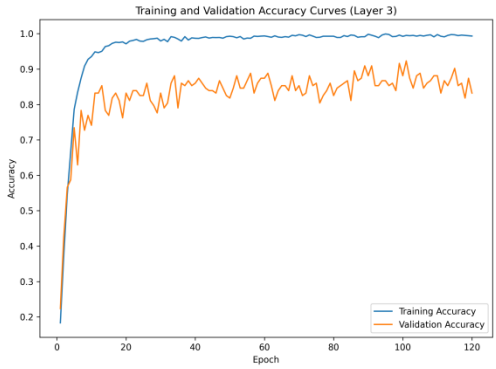
For brevity and representativeness, four typical configurations—unfreezing 1, 3, 5, and 9 layers—are presented and analyzed. Table IV presents a summary of the performance results obtained from the RAVDESS dataset.

TABLE IV PERFORMANCE COMPARISON OF WAV2VEC 2.0 UNDER DIFFERENT UNFREEZING DEPTHS (RAVDESS)

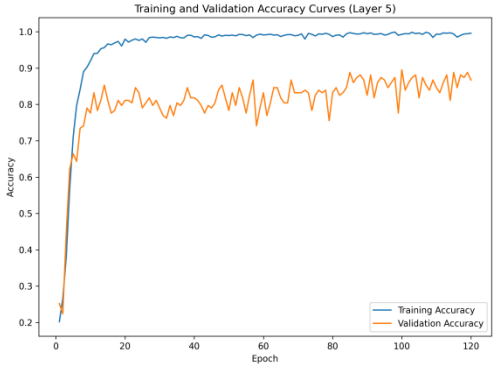
Unfrozen Layers	Accuracy (%)	Macro Precision (%)	Macro Recall (%)	Macro F1 (%)	Performance Description
1 layer	82.67	83.63	80.63	81.22	Dominated by shallow acoustic cues; limited semantic perception
3 layers	**88.67**	**88.22**	**88.75**	**88.19**	Best overall performance; balanced semantic–acoustic representation
5 layers	88	87.22	86.88	86.81	Slight overfitting observed as deeper layers are updated
9 layers	17.33	5.0	16.25	7.42	Model collapse due to the disruption of pretrained representations



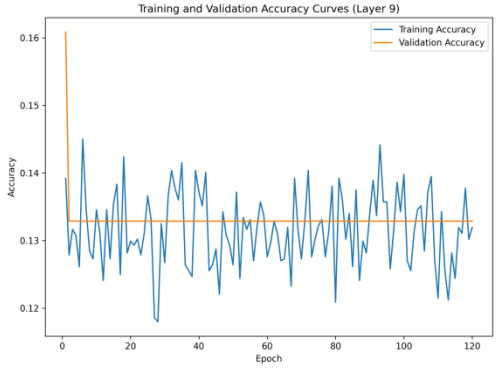
(a) Unfreezing 1 layer.



(b) Unfreezing 3 layers



(c) Unfreezing 5 layers.



(d) Unfreezing 9 layers

Fig. 3. Training and validation accuracy curves of wav2vec 2.0 fine-tuning.

As shown in Table IV, model performance exhibits a distinct "rise–then–fall" trend as the number of unfrozen layers increases. When only the first layer is unfrozen, the model mainly relies on low-level acoustic patterns, achieving 82.67% accuracy, which reflects limited emotional abstraction capability. Performance peaks when three layers are unfrozen, reaching 88.67% accuracy and 88.19% Macro-F1, indicating that the integration of low-level acoustic and mid-level semantic representations yields the most effective balance.

Further unfreezing up to five layers leads to a slight decline, suggesting feature drift and a growing risk of overfitting. When more than nine layers are unfrozen, the model collapses (accuracy drops to 17.33%), as the pretrained representations become severely distorted, undermining semantic stability and generalization ability.

The corresponding training and validation curves under different unfreezing configurations are illustrated in Fig. 3, further confirming the degradation pattern observed with excessive parameter unfreezing.

In summary, across the full range of 1–12 layers unfreezing experiments, the configuration with the last three layers unfrozen (Layer-3 setting) achieved the best overall performance, highlighting the crucial role of mid-level semantic representations in wav2vec 2.0 for speech emotion recognition. These findings indicate that appropriately controlling the unfreezing depth not only maximizes the utilization of pretrained knowledge but also enhances both the transferability and stability of the model in downstream emotional tasks.

E. Fusion Strategy Comparison Experiments

To evaluate the performance differences among various fusion mechanisms within the dual-branch architecture, five groups of experiments were designed while keeping the backbone structure identical. The first two groups represent single-branch models, used to assess the independent modeling capability of the acoustic and semantic branches. The remaining three groups implement different fusion strategies, aiming to analyze the effectiveness of probability-space fusion. All experiments were conducted on the RAVDESS dataset, and the performance was evaluated using Accuracy, Precision, Recall, and Macro-F1 as the primary metrics. The detailed results are presented in Table V.

TABLE V PERFORMANCE COMPARISON OF DIFFERENT FUSION STRATEGIES ON THE RAVDESS DATASET

Fusion Strategy	Accuracy (%)	Macro Precision (%)	Macro Recall (%)	Macro F1 (%)	Description
Spectrogram-only model	77	76	74	74	Uses only acoustic spectrogram features; lacks semantic modeling capability
wav2vec 2.0-only model (3-layer unfreeze)	88.67	88.22	88.75	88.19	Utilizes semantic representations; strong emotional discriminability
Weighted fusion	90.67	90.4	90.62	90.32	Linear weighted combination of branch outputs; improves overall performance
Gated fusion	88	87.97	86.87	87.08	Employs dynamic weight allocation; slightly unstable under small-sample conditions
Logistic regression fusion	92.67	92.36	92.5	92.24	Adaptive probability-space fusion; achieves the best overall performance

As shown in Table V, the choice of fusion strategy significantly impacts model performance.

Under single-branch conditions, the spectrogram-only model achieves only 77.0% accuracy, indicating that low-level acoustic features alone are insufficient to represent complex emotional states. In contrast, the wav2vec 2.0-only model achieves 88.7% accuracy, demonstrating that semantic-level representations derived from pretrained models offer stronger discriminative power for emotion classification.

Among the fusion strategies, the weighted fusion approach linearly combines the outputs of both branches, improving performance to 90.7%, which confirms the complementarity between semantic and acoustic features. The gated fusion mechanism adaptively adjusts feature weights based on the input but exhibits training instability under limited data, leading to a slight drop in accuracy (88.0%). In comparison, the proposed logistic regression fusion achieves adaptive weighting in probability space with a smaller parameter scale and more stable convergence. It attains the best results across all metrics (Accuracy = 92.7%, Macro-F1 = 92.2%), demonstrating the superiority and robustness of the proposed fusion mechanism.

These findings indicate that probability-space fusion effectively integrates the discriminative strengths of both feature domains, achieving simultaneous improvements in accuracy and stability without increasing model complexity. To provide a more intuitive comparison, Fig. 4 illustrates the performance differences among various fusion strategies.

As shown in Fig. 4, the proposed logistic regression fusion method significantly outperforms other strategies in both Accuracy and Macro-F1, exhibiting stronger feature integration and discriminative capability. This further validates the effectiveness and efficiency of the proposed adaptive fusion framework developed for speech emotion recognition.

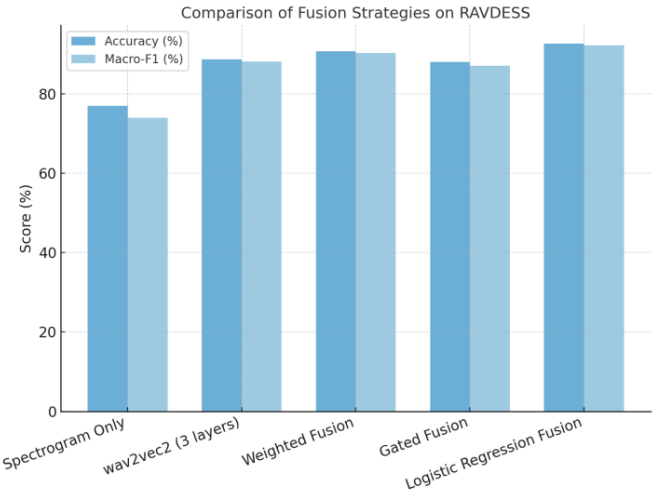


Fig. 4. Comparison of different fusion strategies on the RAVDESS dataset.

F. Discussion

Section IV(C) to Section IV(E) have systematically verified the efficacy of the proposed parallel dual-branch fusion architecture through comprehensive experimental results. To attain a deeper understanding of the underlying mechanisms driving its performance improvements, this section provides a detailed analysis from three complementary perspectives—

architectural design, optimization strategy, and feature fusion mechanism—and further discusses the empirical findings from the layer unfreezing and fusion strategy experiments.

1) Model mechanism and sources of performance improvement: The superior performance of the proposed model primarily stems from the synergistic effects of three key factors: feature complementarity, branch-wise decoupled optimization, and probability-space fusion.

a) Complementarity of feature representations: The wav2vec 2.0 branch, pretrained on large-scale unlabeled speech corpora, captures high-level semantic and prosodic representations—such as rhythm, intonation variation, and emotional dynamics—thereby enhancing the model's global awareness of emotional cues. Meanwhile, the spectrogram branch, based on a CNN–Transformer hybrid structure, models acoustic energy distributions and harmonic patterns, exhibiting higher sensitivity to fine-grained spectral variations. By jointly focusing on the semantic–prosodic and acoustic–spectral domains, the two branches form a multi-level complementary representation. This enables the fusion layer to learn more discriminative emotion features from multi-perspective information sources.

b) Branch decoupling and optimization stability: A stage-wise training strategy is employed—each branch is optimized independently before fusion. This decoupled design effectively mitigates the gradient interference and feature competition commonly observed in end-to-end joint training, allowing each branch to converge independently under its optimal learning rate and scheduling policy. As a result, the model generates more stable and diverse emotional representations, leading to enhanced training stability and generalization performance compared with single-stage joint optimization.

c) Effectiveness of probability-space fusion: During fusion, logistic regression is applied to learn the optimal weighting of branch-level Softmax probability vectors. Compared with complex gating or attention-based mechanisms, this lightweight design achieves adaptive fusion with significantly fewer parameters. It accelerates convergence, improves stability, and achieves the highest recognition accuracy (92.7%) and Macro-F1 (92.2%) on the RAVDESS dataset. As illustrated in Fig. 4 and Table V, probability-space fusion achieves an optimal balance between performance and robustness.

2) Insights from the layer unfreezing experiments: The wav2vec 2.0 layer unfreezing experiments (Section IV D) further reveal the relationship between model performance and the depth of pretrained feature adaptation. Results indicate a clear "rise–then–fall" trend as the number of unfrozen layers increases, with the three-layer unfreezing configuration (Layer-3) achieving the best performance (Accuracy = 88.67%, Macro-F1 = 88.19%).

This finding underscores that mid-level semantic representations in wav2vec 2.0 possess the highest transferability for emotion recognition tasks. Shallow layers mainly encode low-level acoustic information with limited semantic abstraction, while deeper layers tend to introduce task-specific bias, causing overfitting and feature drift.

Therefore, moderate unfreezing depth effectively balances pretrained stability and task adaptability, yielding more discriminative semantic embeddings for downstream fusion.

3) Emotion category discriminability and limitations: As observed from the confusion matrix (Fig. 2), the model achieves near-perfect recognition for high-energy emotions such as happy, sad, and surprise, with diagonal entries approaching 100%. In contrast, mild confusion occurs among low-energy or acoustically similar emotions, particularly neutral–calm and angry–fear–disgust. This suggests that the model exhibits strong discriminative capability for emotions with distinct prosodic variations, yet still faces challenges in distinguishing acoustically overlapping or data-sparse categories.

Two major factors contribute to this phenomenon:

- Several high-arousal negative emotions share overlapping spectral characteristics at the acoustic level, making them inherently harder to separate.
- The current model still faces limitations in feature distribution learning under class-imbalance conditions.

Future work could address these challenges by introducing adversarial learning or emotion-aware reweighting mechanisms, which may enhance recognition performance for ambiguous or boundary emotions.

V. Conclusion

This study addresses the long-standing challenge in SER—that is, the difficulty of simultaneously capturing time–frequency structures and semantic dependencies using a single feature representation. To this end, a parallel dual-branch fusion architecture is proposed, consisting of a wav2vec 2.0 branch and a CNN–Transformer spectrogram branch, which respectively extract semantic-level and acoustic-level features. A logistic regression fusion layer is further introduced to achieve adaptive weighting in probability space, effectively integrating contextual and time–frequency information. Experimental results on the RAVDESS dataset demonstrate that the proposed model achieves an accuracy of 92.7% and a Macro-F1 score of 92.2%, outperforming the best existing baseline by approximately 3.2 percentage points. The layer unfreezing experiment validates the effectiveness of unfreezing the last three layers of wav2vec 2.0, while the fusion strategy comparison confirms the superiority of probability-space fusion in both performance and stability.

Result analysis shows that the model excels at recognizing high-energy and distinct emotions such as happy, sad, and surprise, with diagonal recognition rates approaching 100% in the confusion matrix. However, slight confusion remains among acoustically similar or data-sparse categories such as neutral–calm and angry–fear. In summary, the proposed framework effectively balances performance and robustness through feature complementarity, branch decoupling, and lightweight fusion, fully validating the effectiveness of parallel dual-branch modeling in SER tasks.

Future work will proceed in three directions:

1) Validating the model's transferability on multilingual and cross-domain corpora to enhance generalization;

2) Extending the framework to multimodal emotion perception by integrating speech, facial expressions, and textual cues; and

3) Pursuing model lightweighting and real-time inference optimization, as well as exploring emotion dynamics modeling and interpretability mechanisms, to promote practical deployment in education, healthcare, and human–computer interaction scenarios.

***Abstract*—Convolutional neural networks (CNNs) were widely used in object detection tasks. Usually, CNNs with strong object detection performance were difficult to apply to small, mobile embedded systems with limited computational resources due to the large number of parameters. Aiming at this problem, the lightweight improvement method for the safety helmet object detection task based on YOLOv7 has been studied. The first step was the lightweight improvement of the network. Taking YOLOv7 and YOLOv7-Tiny as the basic networks, respectively, the backbone network was improved using the MobileOne network. YOLOv7-MobileOne (YOLOv7-MO) and YOLOv7-Tiny-MobileOne (YOLOv7-TMO) were obtained. Compared with the original network parameters, the number of parameters decreased by 36.8% and 37.9%, respectively. Verified on the Pascal VOC dataset, the YOLOv7-MO had a 3.7% decrease in mAP @.5 compared to the YOLOv7. The YOLOv7-MO had a 9.8% increase in mAP @.5 compared to the YOLOv7-TMO. The second step was to improve the detection accuracy. The Coordinate Attention (CA) module was integrated at different positions of YOLOv7-MO and YOLOv7-TMO, respectively, to obtain YOLOv7-MO-Coordinate Attention (YOLOv7-MOC) and YOLOv7-TMO-Coordinate Attention (YOLOv7-TMOC). Verified on the Pascal VOC dataset, YOLOv7-MOC improved 1.44% compared to YOLOv7-MO's mAP @.5 and reduced FPS by 5.4Hz. Verified on the self-constructed two-wheeled cyclists helmet dataset (TCHD), YOLOv7-MOC increased by 0.8% compared to YOLOv7-MO's mAP @.5 and reduced FPS by 0.3Hz. YOLOv7-MOC increased by 1.0% compared to YOLOv7's mAP @.5 to 77.1%. The corresponding FPS was 28.7Hz higher, reaching 89.3Hz. Finally, experiments were conducted using the Raspberry Pi 4B embedded development board, based on the Linux system and the Pytorch framework, with the YOLOv7-TMOC network model. The results proved that the improved network model can be applied to the object detection of small embedded systems.**

I. Introduction

Two-wheelers have become one of the common means of transportation. While they bring about convenience in transportation, they also lead to a continuous increase in traffic accidents. Such accidents often cause injuries to the riders of two-wheelers. If the riders do not wear helmets for protection, it will result in more serious head injuries. Safety helmets could effectively reduce the degree of head injury caused by traffic accidents to two-wheeled cyclists [1]. How to supervise and ensure that two-wheeled cyclists wear helmets correctly when riding on the road has become a problem that traffic safety management departments and scholars have paid attention to. With the rapid development of computer vision technology, it was a feasible way to use computer vision technology to help solve the above problems [2-5].

The convolutional neural networks have become a research hotspot in the field of computer vision for object detection. In 2016, Redmon et al. proposed the object detection network YOLO (You Only Look Once) [6]. With this network, the input image could obtain the position of the object and the confidence probability of the category to which the object belonged after only one round of network learning, achieving end-to-end detection and improving real-time performance. Subsequently, YOLOv2 [7], YOLOv3 [8], and YOLOv4 [9] have been proposed to improve the object detection network based on the YOLO network, etc. In 2022, Glenn et al. proposed the YOLOv5 network based on the YOLO series network [10]. YOLOv5 inherited the CSPDarknet53 backbone feature extraction network and introduced PANet [11] to process objects of different scales, effectively improving the detection accuracy of the network model. The improvement of the feature fusion network by the YOLOv5 network resulted in a larger network model. In 2023, Wang et al. proposed the YOLOv7 network model based on module parameterization and a dynamic label assignment strategy [12]. Their proposed multi-branch stacking module could massively reduce the redundant channels in network training, which improved the detection accuracy of the YOLOv7 network but led to a slower detection speed.

When it came to using convolutional neural networks for object detection of safety helmets, Rattapoom et al. used the K-Nearest Neighbor (KNN) classifier to classify the head with or without a helmet [13]. The results showed that the average correct detection rate was 84%, 68% and 74% for near, far, and dual lanes, respectively. Although the detection accuracy was high, the network model was large, and the detection speed was too slow to be suitable for real-time detection. Yu et al. proposed an EV helmet detection method based on the YOLOv3 network

in 2019 [14]. The method achieved higher accuracy in object detection by increasing the diversity of the dataset and optimizing the training parameters. In addition, the researchers further combined the optical flow calculation method to improve the algorithm's robustness and real-time performance. In 2020, Siebert et al. developed an object detection algorithm that collected 91,000 frames of annotated motorcycle helmet videos at observation sites in seven cities in Myanmar [15]. After training, the algorithm was found to detect motorcycle helmets with higher accuracy compared to human observers. However, it was not suitable for real-time detection due to its slow detection speed. Huang et al. used an improved Faster R-CNN network for helmet detection and localization in 2021 [16]. Due to the dataset and algorithm limitations, the method still had specific problems of false and missed detection. Jia et al. proposed a motorcycle helmet detection algorithm based on YOLOv5 [17], which improved the network accuracy by 5.2% using a soft NMS instead of YOLOv5's NMS. However, it had a more extensive network model and higher hardware requirements, which were unsuitable for real-time road detection. Zhao et al. proposed a method to improve the YOLOv7 network by using the GSConv network to replace some of the Conv in 2023 [18]. The improved network parameter counts reached 36.4M, making the network structure complex. Bao et al. proposed a method to improve the object detection of the YOLOv8s backbone network by using the MobileOne network with a parameter count reaching 11.7M in 2024 [19], which did not apply to embedded devices with small calculating power.

In summary, the current convolutional neural network-based two-wheeled cyclists helmet detection methods must be revised. Most of them used YOLO and SDD networks to improve accuracy. When embedded devices are used, the application is often limited due to minor hardware calculation power. Based on the objective conditions of practical application, drawing on the research experience of other scholars, a lightweight and high-precision two-wheeled cyclists helmet convolutional neural network model was obtained, from two aspects of the research, the establishment of the two-wheeled cyclists helmet dataset and the improvement of the YOLOv7 convolutional neural network.

The contributions of this study include the following three points:

- Collected images of two-wheeled cyclists helmets by field photography and expanded the dataset using seven data enhancement methods, such as rotation, mirroring, and panning transformation to obtain a two-wheeled cyclists helmet dataset (TCHD) containing 5957 images.
- The convolution and feature extraction layers of YOLOv7 and YOLOv7-Tiny networks were modified using the MobileOne network. Then, the CA module and K-means++ clustering algorithm were introduced, respectively, to improve the detection accuracy of the network, thereby obtaining YOLOv7-MOC and YOLOv7-TMOC networks. The detection results on the Pascal VOC dataset and TCHD showed that the lightweight network model had good detection performance.
- Using the Raspberry Pi 4B embedded development board, based on the Linux system and the Pytorch framework, and equipped with the YOLOv7-C-MO network model, experimental tests were conducted. The results proved that the improved YOLOv7 network model can be applied to the object detection of small embedded systems.

The rest of the study was organized as follows: Section II briefly describes the works related to the YOLOv7 network, the TCHD establishment, and the evaluation metrics. Section III focused on the research on lightweighting and accuracy improvement based on the YOLOv7 network, as well as the development of the testing system and experimental verification. Section IV is the conclusion of this study.

II. Related Work

Based on the analysis of the current research status of object detection networks presented in the introduction, the YOLO series of networks exhibited exceptionally high performance in object detection. However, for object detection tasks with constrained computational resources, there remains potential for optimization within the YOLO network architecture.

A. YOLOv7 Network

Through the comparison of the YOLO series of networks, the YOLOv7 network was chosen for research [20]. The network structure of YOLOv7 is shown in Fig. 1.

B. Create a Two-Wheeled Cyclists Helmet Dataset

The two-wheeled cyclists helmet dataset (TCHD) used in our study was jointly established by members of the research group. They took random images from the side of the road, including cars, motorcycles, bicycles, and pedestrians, and these images included images of multiple two-wheeled cyclists overlapping on the road and other complex scenes. There were 851 images in the entire original TCHD. Fig. 2 shows 16 samples of these images.

To enhance the training performance of the network, mitigate overfitting, and improve generalization capabilities, the TCHD was augmented using seven distinct image data augmentation techniques. An image taken from the TCHD was shown in Fig. 3(a) as an example. The transformed images were shown in Fig. 3(b) to Fig. 3(h).

- Hue-Saturation-Value (HSV) transformation: In OpenCV, set three hyperparameters as h_gain (Hue) as 0.5, s_gain (Saturation) as 0.5, and v_gain (Value) as 0.5, respectively. Fig. 3(a), after transformation using the HSV function, is shown in Fig. 3(b).
- Brightness: Used the brightness enhancement function in OpenCV and set the brightness value to 1.5. Transformed Fig. 3(a) to obtain Fig. 3(c).
- Contrast: Used the contrast enhancement function in OpenCV and set the contrast value to 1.5. Transformed Fig. 3(a) to obtain Fig. 3(d).
- Mirroring: It was implemented using the image mirroring function in OpenCV. Fig. 3(a) was mirrored horizontally to obtain Fig. 3(e).

- Shear variation: Fig. 3(a) was sheared by 30° along the horizontal direction to obtain Fig. 3(f).
- Affine transform: The image expansion was carried out by rotating and scaling the original image. Taking the center of Fig. 3(a) as the rotation center, the rotation angle was set to 30°, and the scaling factor was set to 0.5 for transformation to obtain Fig. 3(g).
- Panning variation: Using the translation function in OpenCV, the movement distance in Fig. 3(a) was set to 5 in the horizontal direction and 30 in the vertical direction, and the translation result was shown in Fig. 3(h).

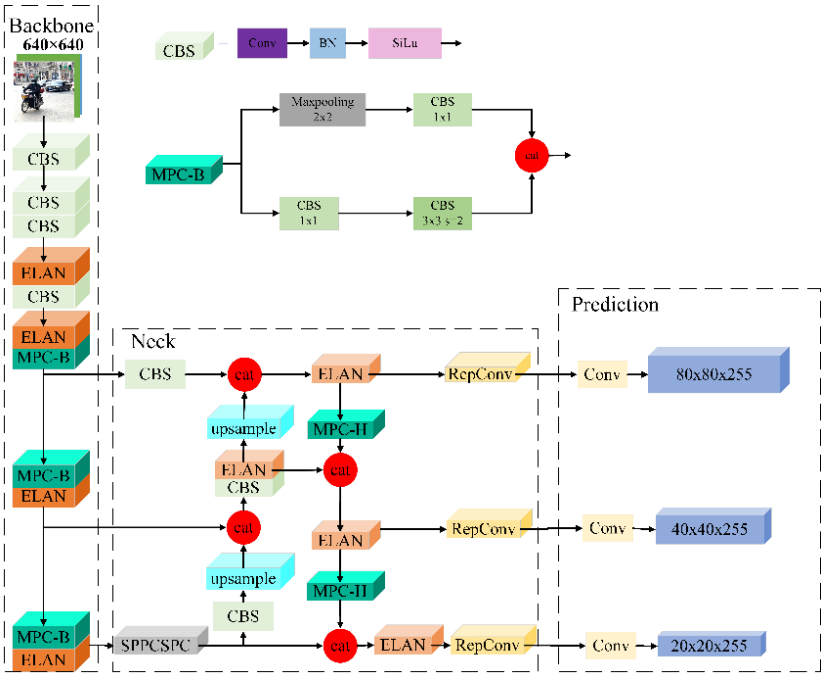

Fig. 1. The architecture of YOLOv7 network.

Fig. 2. Sixteen image samples in the TCHD.

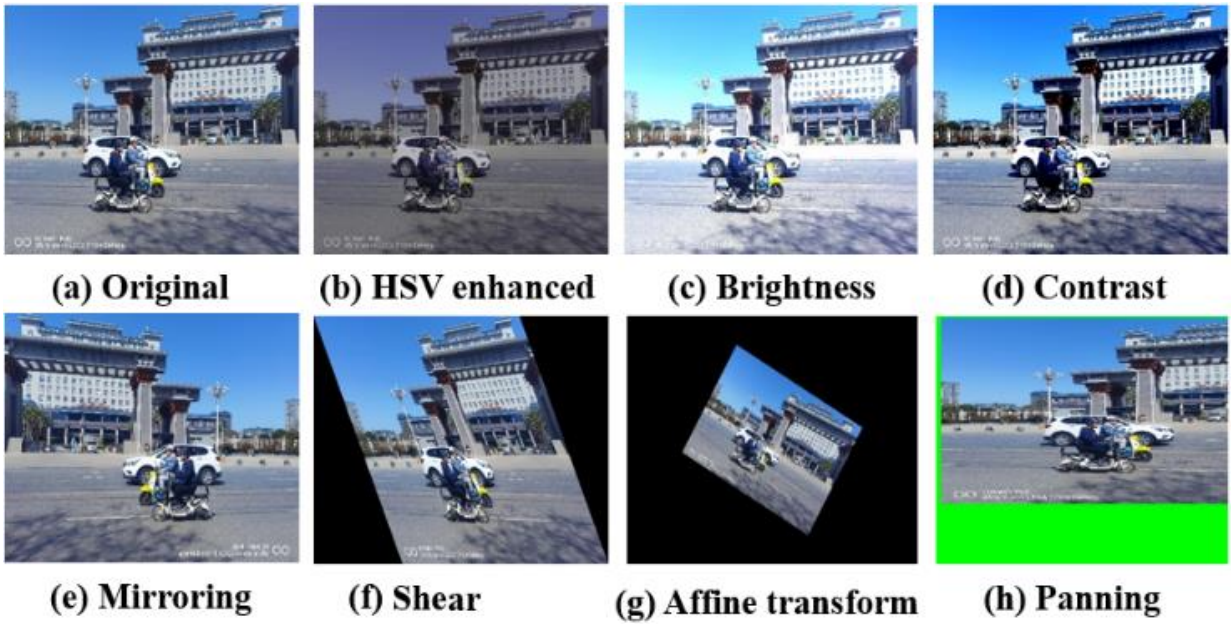

Fig. 3. The results obtained through 7 image enhancement methods.

Through the expansion of image data by the above methods, the number of TCHD images has increased from 851 to 5,957. Then, the objects in the images were classified. According to the different characteristics of two-wheeled cyclists wearing safety helmets and those not wearing safety helmets, the objects were divided into two categories: those wearing safety helmets and those not wearing safety helmets. Then, the labeling tool named Labelimg was used to label all the objects in the images.

The newly established TCHD was different from the COCO dataset in many aspects, such as the number of classes [21]. When the new TCHD was used to train the YOLOv7 network, the size of the anchor boxes would also need to be modified. So, the K-Means++ [22] algorithm was used to cluster the TCHD dataset, and the anchor boxes size was obtained as (7,7), (19,23), (33,36), (51,57), (70,74), (99,109), (258,240), (392,340), (469,430).

C. Network Model Evaluation Metrics

This study evaluated the network model performance in terms of detection accuracy and detection speed, and mean average precision (mAP) and frames per second (FPS) were chosen to measure the network model performance, respectively. The mAP was the mean average accuracy of all classes in the dataset and was used as an evaluation index for the detection accuracy of the network model [23]. The higher the value of the mAP, the better the performance of the network model. The FPS represented the number of images that the network model could detect per second and was used as an evaluation index for the detection speed of the network model. The larger the value of this evaluation index was, the faster the object detection task was carried out. Usually, the number of parameters, computation amount, and network model size affected the FPS.

III. Network Model Improvement

A. Network Model Lightweight

1) Feature extraction network lightweight: The MobileOne [24] was a lightweight model that has been optimized based on MobileNetV1 [25]. This model primarily consisted of a depthwise convolutional layer, two pointwise convolutional layers, a branched convolutional layer, and an SE module [26]. The characteristics of the MobileOne network were high real-time performance and low computational complexity. The MobileOne was used to replace the ELAN network in the Backbone part of the YOLOv7 network. The modified network was named YOLOv7-MobileOne (YOLOv7-MO), and its network structure is shown in Fig. 4.

The detailed structure of the YOLOv7-MO feature extraction network is shown in Table I.

Table I shows the parameter information of the YOLOv7-MO, including sequence, convolutional module, and channel number of input and output parameters. Compared with the YOLOv7 feature extraction network, the number of layers in the YOLOv7-MO network was reduced from 57 layers to 27 layers.

A MobileNetV1 was one of the MobileOne series of networks. The idea and method of replacing ELAN in YOLOv7 with MobileNetV1 were the same as those of MobileOne. After the replacement, the YOLOv7-Mobilenetv1 (YOLOv7-MV1) network was obtained.

In order to further reduce the size of the network, the small version of the YOLOv7 network, the YOLOv7-Tiny network, was selected for improvement. The MobileOne module was used to establish the YOLOv7-Tiny feature extraction network by using the same idea and method as the improved YOLOv7 network. The structure of the YOLOv7-Tiny-MobileOne (YOLOv7-TMO) feature extraction network was obtained, as shown in Fig. 5.

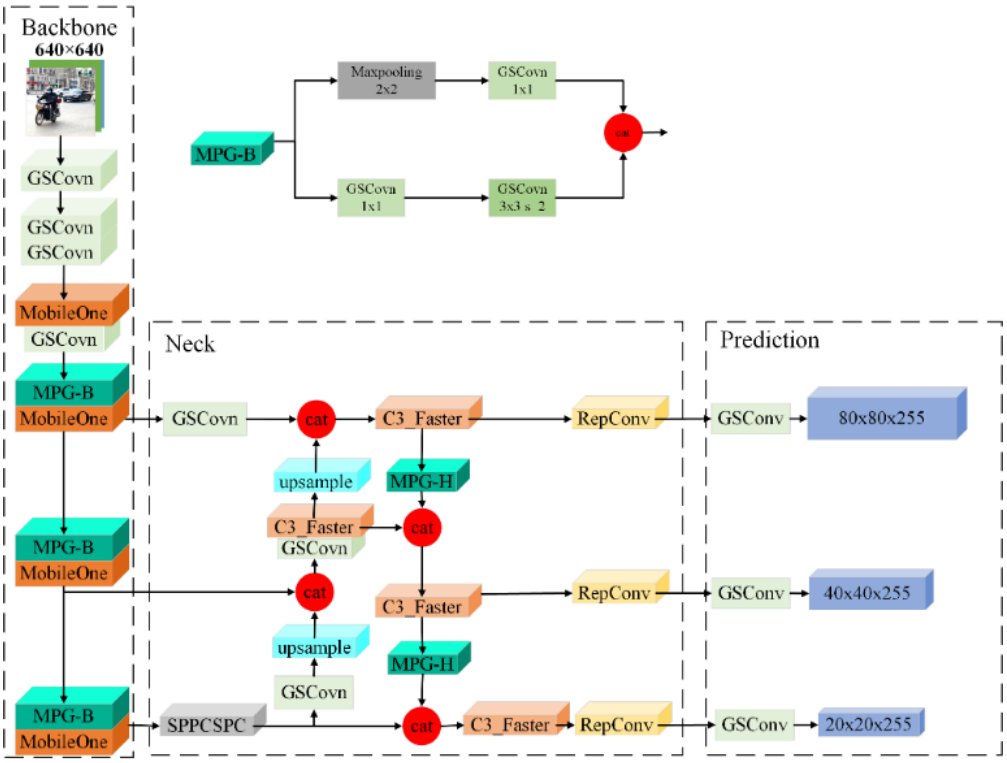

Fig. 4. YOLOv7-MO network architecture.

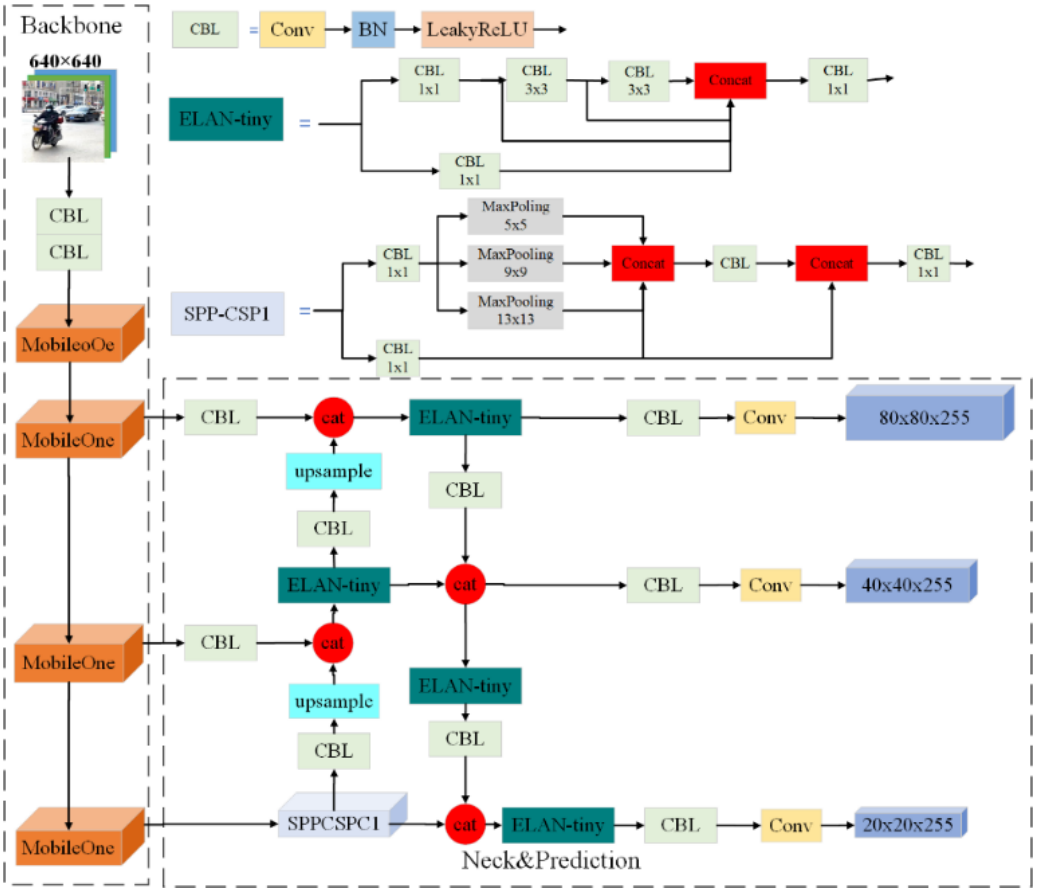

Fig. 5. YOLOv7-TMO network architecture.

TABLE I. THE STRUCTURE OF YOLOV7-MO NETWORK

Stage	Number	Model	Input size	Output size
0	1	GSConv	3	32
1	1	GSConv	32	64
2	1	GSConv	64	64
3	1	GSConv	64	128
4	1	MobileOne	128	128
5	1	GSConv	128	256
6	1	MP	-	-
7	1	GSConv	256	128
8	1	GSConv	256	128
9	1	GSConv	128	128
10	1	Concat	-	-
11	1	MobileOne	256	256
12	1	GSConv	256	512
13	1	MP	-	-
14	1	GSConv	512	256
15	1	GSConv	512	256
16	1	GSConv	256	256
17	1	Concat	-	-
18	1	MobileOne	512	512
19	1	GSConv	512	1024
20	1	MP	-	-
21	1	GSConv	1024	512
22	1	GSConv	1024	512
23	1	GSConv	512	512
24	1	Concat	-	-
25	1	GSConv	1024	256
26	1	MobileOne	1024	1024
27	1	GSConv	1024	256

2) Experiment and analysis: The main experimental conditions included Inter(R)Core(TM) i9-10900XCPU@2 as the computer core, NVIDIA GeForcePTX3080 (10GB) as the graphics processing unit, and 64GB RAM as the computer memory. The deep learning framework was PyTorch, the acceleration environment was CUDA11.3, and the programming language was Python3.7. The main parameter settings include: the input image size was Img_size=(640,640), the number of samples in each batch of iterative training was Batch_size=8, the iteration training times epoch=200, the initial learning rate was 0.01, and the weight attenuation factor was 0.0005 [27].

The public dataset PASCAL VOC was selected for the experimental dataset [28], and the training set sharing was set to 90%, resulting in 18,277 images for training and 3,226 images for verification [29].

The YOLOv7 and YOLOv7-Tiny, as well as the improved YOLOv7-MO, YOLOv7-TMO and YOLOv7-MV1 were respectively trained on PASCAL VOC dataset. The number of model parameters obtained after training was listed in Table II.

As shown in Table II, compared with the YOLOv7, the number of parameters in the YOLOv7-MO and YOLOv7-MV1 was reduced to 23.65 M and 25.19 M, respectively. Compared with the YOLOv7-Tiny, the number of parameters in the YOLOv7-TMO was reduced by 37.9% to 3.76 M.

TABLE II. THE PARAMETERS' NUMBERS OF 5 NETWORKS

Network	Parameter' number /M
YOLOv7-Tiny	6.06
YOLOv7-TMO	3.76
YOLOv7	37.43
YOLOv7-MV1	25.19
YOLOv7-MO	23.65

The loss curves of the 5 networks are compared in Fig. 6.

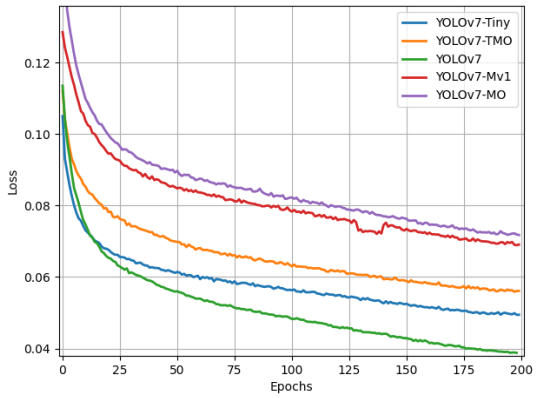

Fig. 6. Loss curves of the 5 networks.

As shown in Fig. 6, the value of loss decreases with the increase of iterative calculation for all five kinds of networks, but the convergence speed of the improved network was significantly slower than that of the pre-improved network. At the 200 step, the network corresponding to loss from large to small was YOLOv7-MO, YOLOv7-MV1, YOLOv7-TMO, YOLOv7-Tiny, and YOLOv7. The maximum value of loss was close to 0.072, and the minimum value was close to 0.02. It takes longer for lightweight networks to converge.

Further comparing the object detection performance of the five networks on the PASCAL VOC dataset, the values of precision (P), recall (R), mAP@.5, FPS and model size were listed in Table III.

TABLE III. THE DETECTION RESULTS OF 5 NETWORKS ON THE PASCAL VOC

Network	P/%	R/%	mAP@.5/%	FPS/Hz	Model size/MB
YOLOv7-Tiny	74.8	762	77.5	93.5	11.7
YOLOv7-TMO	74.3	71.4	76.9	97.4	7.7
YOLOv7	85.3	87.7	90.4	45	79.4
YOLOv7-MV1	80.5	82.0	81.6	72	57.3
YOLOv7-MO	83.4	87.3	86.7	94.2	49.6

As shown in Table III, the YOLOv7-MO network had a 1.9% decrease in precision and a 3.7% decrease in mAP @.5 compared to the YOLOv7 network, but the model size decreased by 37.5% and the FPS increased 49.2 Hz. Compared to the

YOLOv7-MV1 network, the precision improved by 2.9%, the mAP@.5 improved by 5.1%, the model size of the network decreased by 13.4%, and the FPS improved by 23.5%. YOLOv7-TMO decreased mAP@.5 by 0.6% compared to YOLOv7-Tiny, but the model size decreased by 34.1%, and the FPS increased 3.9 Hz. So, the YOLOv7-MO had comprehensive advantages in mAP@.5 and FPS compared with other networks.

B. Integration of Attention Mechanisms

An Attention Mechanism (AM) is a method to improve the accuracy of network models for object detection tasks. A common AM module was the Coordinate Attention (CA) [30]. The CA module embedded the object's position information in the image into the channel attention so that the detection model could better localize and detect the object.

The CA modules were added and combined at different positions in the Neck of the YOLOv7-MO, and three YOLOv7-MO network structures with CA modules were designed for comparative study, as shown in Fig. 7.

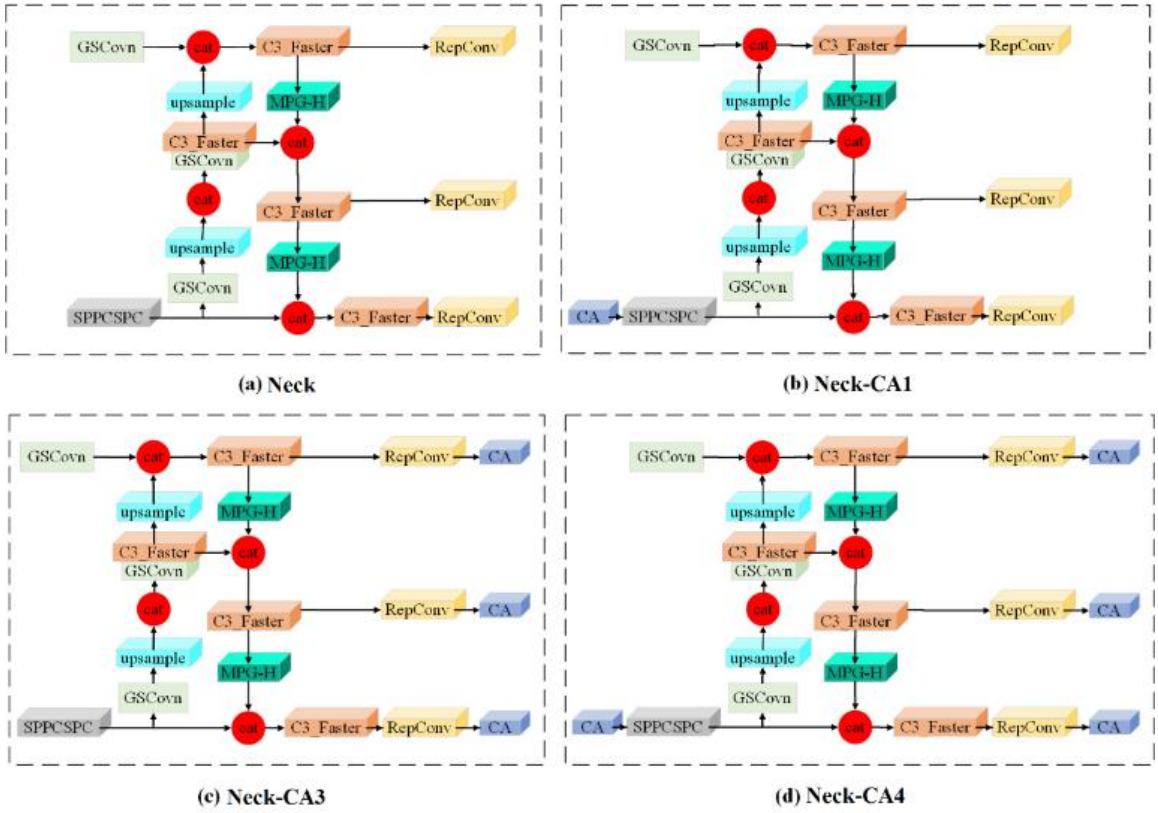

Fig. 7. Three different networks by adding CA in the YOLOv7-MO.

The Neck-CA1 was shown in Fig. 7(b), where 1 CA module was added at the connection between the last layer of the backbone network and the feature fusion network. The Neck-CA3 was shown in Fig. 7(c), where 3 CA modules were added before each of the three scale feature layers enters the detection layer. The Neck-CA4 was shown in Fig. 7(d), where 4 CA modules were added at the connection between the last layer of the backbone network and the feature fusion network.

The 3 networks by adding CA in the YOLOv7-MO were trained and tested on PASCAL VOC dataset with Epoch=100. The test results were shown in Table IV.

As shown in Table IV, compared with YOLOv7-MO, the mAP@.5 of Neck-CA1, Neck-CA3 and Neck-CA4 increased by 0.4%, 0.8% and 1.44%, respectively. Compared with YOLOv7-MO, the FPS of Neck-CA1, Neck-CA3 and Neck-CA4 decreased with the increase of CA number, and Neck-CA4 decreased by 4.9%.

TABLE IV. THE TEST RESULTS OF 4 NETWORKS ON THE PASCAL VOC

Network	CA's number	FPS/Hz	mAP@.5/%
YOLOv7-MO	0	94.2	86.7
Neck-CA1	1	94.3	87.1
Neck-CA3	3	92.5	87.5
Neck-CA4	4	89.6	88.14

The YOLOv7-MO network was improved to obtain YOLOv7-MO-CA (YOLOv7-MOC) by selecting the Neck-CA4 with the highest accuracy. A structure of the YOLOv7-MOC network was shown in Fig. 8.

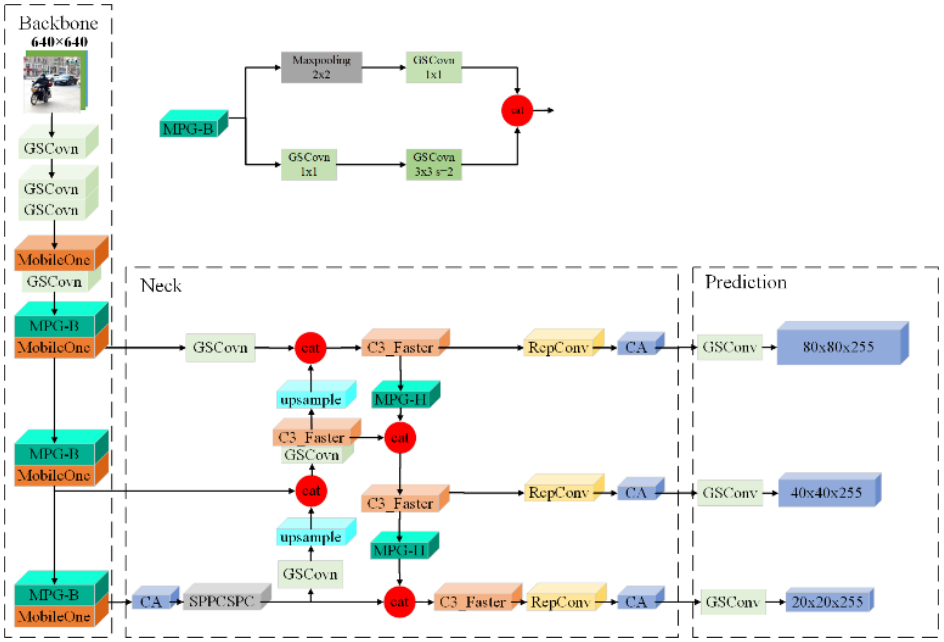

Fig. 8. A structure of the YOLOv7-MOC.

The same method was used to improve the YOLOv7-TMO network, and YOLOv7-TMO-CA (YOLOv7-TMOC) was obtained.

C. Experiments and Analysis

This section used the same experimental platform and parameters as Section III-A(2) to compare and analyze the performance of the improved networks. All the analyzed networks included five such as YOLOv7-Tiny, YOLOv7-TMOC, YOLOv7, YOLOv7-MO, and YOLOv7-MOC. The TCHD was used in the dataset, and the dataset was divided according to the training set accounting for 80% of the dataset, resulting in 4766 images in the training set and 1191 images in the verification set. After training, the loss curves of the five networks were shown in Fig. 9.

As shown in Fig. 9, the loss value of the five networks decreased with the increase of iterative calculation. Among them, the convergence speed of YOLOv7-TMOC network was the fastest. When iteration reached 200 steps, the loss value of YOLOv7-TMOC network was the smallest, close to 0.041, compared with other four networks. The change of loss curves of YOLOv7-MO and YOLOv7-MOC networks was basically the same. When iterating to 200 steps, the loss was close to 0.056. The loss curve of YOLOv7 network and YOLOv7-Tiny network had a similar change trend. When iterating to 200 steps, the loss was close to 0.046.

Further compared with the object detection performance of the five networks on the TCHD, and the values of precision, recall, mAP@.5, FPS and model size were listed in Table V, respectively.

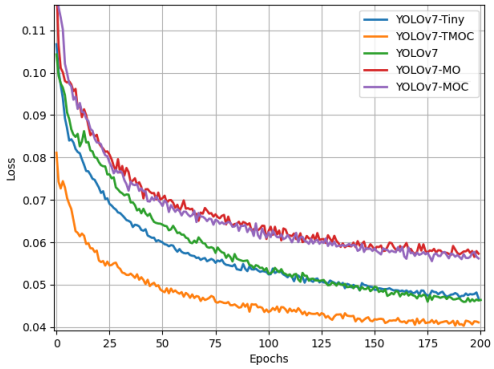

Fig. 9. The loss curves of the 5 networks.

TABLE V. THE DETECTION RESULTS OF 5 NETWORKS ON THE TCHD

Network	P/%	R/%	mAP@.5/%	FPS/Hz	Model size/MB
YOLOv7-Tiny	74.8	76.2	76.6	94.1	11.6
YOLOv7-TMOC	81.8	67.7	74.2	97.8	6.1
YOLOv7	88.5	72.7	76.1	60.6	71.2
YOLOv7-MO	83.7	75.3	76.3	89.6	49.4
YOLOv7-MOC	85.3	76.2	77.1	89.3	49.6

As shown in Table V, the model sizes of the five networks, arranged from smallest to largest, were YOLOv7-TMOC, YOLOv7-Tiny, YOLOv7-MO, YOLOv7-MOC, and YOLOv7. The mAP@.5 values of the five networks, ranked from highest to lowest, were YOLOv7-MOC, YOLOv7-Tiny, YOLOv7-MO, YOLOv7, and YOLOv7-TMOC. The FPS values of the five networks, ordered from highest to lowest, were YOLOv7-TMOC, YOLOv7-Tiny, YOLOv7-MO, YOLOv7-MOC, and YOLOv7.

The model size of YOLOv7-TMOC was the smallest, which was 47.4% smaller than that of YOLOv7-Tiny and 91.4% smaller than that of YOLOv7. The mAP@.5 of YOLOv7-MOC was the highest, which was 1.0% higher than that of YOLOv7 and 0.5% higher than that of YOLOv7-Tiny. The FPS of YOLOv7-TMOC was the highest, increasing by 3.8% compared to YOLOv7-Tiny and by 38.0% compared to YOLOv7.

Compared with YOLOv7-TMOC, YOLOv7-MOC improved mAP@.5 by 2.9%, reduced FPS by 8.7%, and increased model size by 87.7%.

So, YOLOv7-TMOC had the advantages of a small model size and fast detection speed. YOLOv7-MOC had the advantage of high detection accuracy.

D. Development and Application Testing of the Monitoring System

The improved network was applied to the real-time monitoring system for two-wheeled cyclists' helmets on the road.

The main hardware components of the monitoring system included a Raspberry Pi 4B development board, a camera, a touch screen display, and a power supply, as shown in Fig. 10.

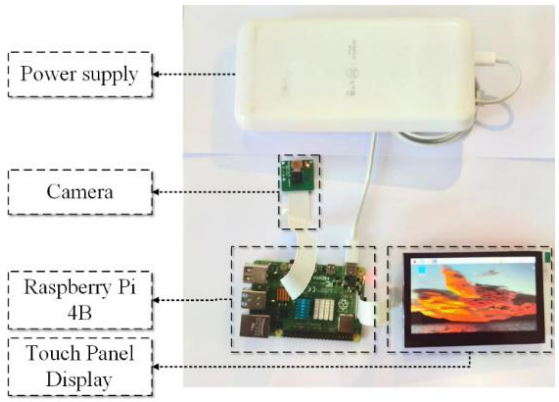

Fig. 10. Hardware of the real-time monitoring system.

The monitoring system software was based on the Linux system, the PyTorch framework, the PyQt5-tools, and was equipped with the YOLOv7-TMOC network model. The main interface of the monitoring system is shown in Fig. 11. The system supported the detection of data such as images and videos.

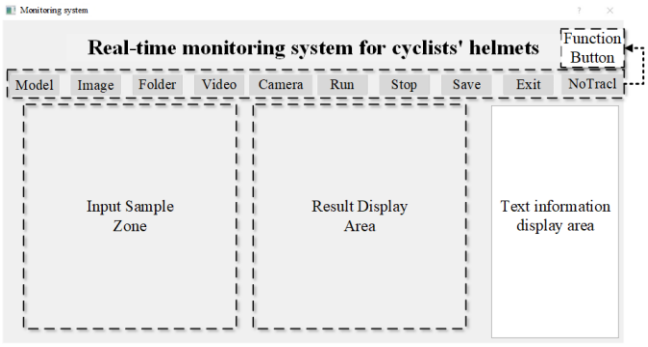

Fig. 11. Main interface of the real-time monitoring system.

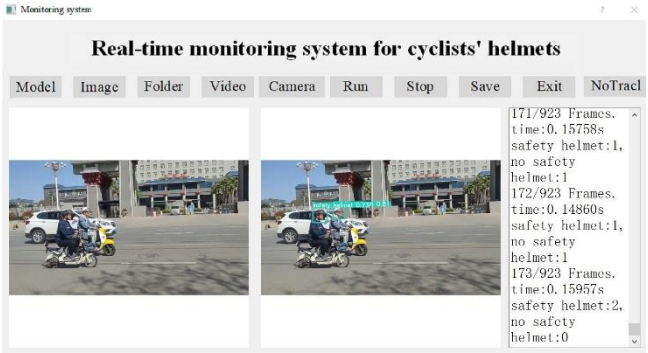
The monitoring system was tested at the actual road site, and the results are shown in Fig. 12.

(a) Image detection



(b) Video detection

Fig. 12. Input sample detection.

As shown in Fig. 12(a), the monitoring system input images are captured by the roadside and detected a total of two objects of safety helmets. The system could accurately determine the number of objects as 2, and the precision rates of the two objects from left to right were 73% and 71%, respectively. As shown in Fig. 12(b), the monitoring system could accurately detect the number of objects from the input real-time video as 2, and the precision rates of the two objects from left to right were 73% and 81%, respectively.

Through actual verification, the improved network model and the constructed monitoring system could perform real-time, correct detection of the safety helmets of two-wheeled cyclists.

IV. Conclusion

Regarding the intelligent detection of safety helmets worn by two-wheeled cyclists on the road, this study studied a lightweight detection network that could be used in handheld detection instruments.

Firstly, in order to make the network lightweight, the ELAN structure in the YOLOv7 and YOLOv7-Tiny feature extraction networks was replaced with the lightweight MobileOne network, resulting in YOLOv7-MO and YOLOv7-TMO. To improve the detection accuracy, the feature fusion network of YOLOv7-MO was improved using the CA and C3_Faster modules, resulting in YOLOv7-MOC. In the same way, the YOLOv7-Tiny network was also lightweight modified, resulting in the YOLOv7-TMOC network.

Secondly, the verification using the self-created dataset TCHD showed that the model sizes of YOLOv7-MOC and YOLOv7-TMOC were respectively 30.3% and 47.4% smaller than those of YOLOv7 and YOLOv7-Tiny. The mAP@.5 of the YOLOv7-MOC network reached 77.1%, and the frame rate reached 89.3 Hz, both higher than the 76.1% mAP@.5 and 60.6 Hz frame rate of YOLOv7. The mAP@.5 of the YOLOv7-TMOC network was 74.2%, slightly lower than that of YOLOv7-Tiny (76.6%), but its frame rate was 97.8 Hz, which exceeded the 94.1 Hz of YOLOv7-Tiny.

Finally, the improved network was applied to the real-time monitoring system for safety helmets worn by two-wheeled cyclists on the road. Through image and video testing of the monitoring system, it was demonstrated that the improved network could be used in portable real-time detection devices.

***Abstract*—Head-mounted displays (HMDs) enhance virtual reality (VR) experiences, but occlude the upper face, hindering realistic user representation. To address this, some studies employ sensors to capture facial expressions under occlusion, while deep learning methods typically rely on image inpainting to restore missing regions. However, these approaches often suffer from limitations such as insufficient shallow feature representation, high computational complexity, and redundant model structures. This study proposes a lightweight generative adversarial network (GAN) that utilizes multi-feature fusion and deformable attention for face reconstruction under HMD occlusion. Specifically, a Lie group feature learning module is used to enhance shallow geometric representations, while reference-guided deformable attention dynamically focuses on occluded regions, improving both structural fidelity and efficiency. Experiments across multiple face datasets show that the proposed method outperforms existing mainstream approaches regarding structural fidelity, detail restoration capability, and model efficiency. The proposed framework offers a promising solution for integration with HMDs equipped with facial tracking, enabling more realistic and expressive avatars in VR applications.**

Keywords*—Generative adversarial network; Lie group feature learning; deformable attention; face reconstruction; virtual reality; head-mounted displays

I. Introduction

Virtual reality (VR) is a technology that creates virtual environments by simulating real-world sensory experiences (such as vision, hearing, and touch) using computers [1]. The rapid growth of VR has enabled its widespread use in domains such as education [2],[3],[4], healthcare [5],[6],[7], entertainment [8],[9],[10], remote collaboration [11],[12],[13], and more. As a VR interaction device, the head-mounted display (HMD) provides users with a highly immersive communication experience and enables more natural and vivid forms of interaction [14]. However, since the HMD covers the upper face, it obstructs the effective extraction of facial features. It makes it challenging to integrate facial information fully into the virtual scene [15]. The occlusion reduces the realism of virtual communication and affects users' social experiences [16]. Therefore, removing HMD occlusion from facial images and restoring missing facial information has become a key challenge in enhancing the realism of VR interaction.

There are two main approaches for reconstructing the face under HMD occlusion [17]: model-based methods and image-based methods. Model-based methods use sensors to capture facial information in the occluded areas and achieve full face reconstruction by fitting a 3D face model [18],[19],[20],[21]. For example, Chen et al. [18] reconstructed the users' facial expression and restored eye gaze direction by using three infrared cameras to directly capture the occluded face beneath the HMD. Kin et al. [19] proposed a facial expression recognition system that combines facial electromyography (fEMG) and electrooculography (EOG). The system collects signals via tiny electrodes placed around the eyes and uses machine learning to estimate virtual blendshape weights, enabling natural mapping of expressions to 3D avatars. However, such methods require the integration of additional sensors into the HMD, leading to problems such as reduced wearing comfort and increased cost [22]. In recent years, advanced HMDs such as the Meta Quest Pro have been gradually adopted in industrial applications. By integrating similar sensors into the HMDs, they have improved wearing comfort and enhanced facial expression tracking [23]. Nevertheless, in practical applications, these devices still cannot capture complete facial texture information, making it challenging to render high-fidelity facial appearances.

Image-based methods primarily use deep learning models to generate the occluded facial regions, aiming to restore the missing information in facial images realistically [17], [24],[25],[26]. Numan et al. [17] introduced a GAN-based HMD removal framework that simultaneously reconstructs the incomplete color and depth information in RGB-D facial images. Gupta et al. [24] introduced spatial supervision and landmark prediction modules to improve facial image quality in the de-occlusion task. They optimized the reconstruction of the peri-ocular region by leveraging the inherent structure of the eye and enhanced feature extraction by incorporating an attention module. Ghorbani Lohesara et al. [25] incorporated a self-attention into a GAN, enabling HMD occlusion removal by exploiting multiple reference video frames. Bai et al. [26] proposed a universal facial encoding system for consumer-grade HMDs. By employing self-supervised learning and training on large-scale unlabeled HMD camera data, their method achieved cross-view face reconstruction without relying on 3D models or high-quality labels, significantly improving overall model performance.

In recent years, diffusion models [27] have made significant breakthroughs in image generation and have demonstrated superior performance to traditional GANs in tasks such as image restoration and image synthesis [28]. The central idea is to produce high-quality images via a progressive denoising process, which leads to more stable training and greater fidelity in fine image details. However, such methods typically require multi-step sampling, which leads to long generation times, low inference efficiency, and high demands on computational resources [29], [30]. Therefore, given the resource constraints in virtual reality applications, this study adopts a GAN-based generation approach.

Although GAN-based methods have shown promising progress in HMD-occluded face reconstruction, the current literature still presents several notable research gaps. First, most existing studies rely heavily on deep convolutional semantic features and overlook shallow geometric cues, which are crucial for maintaining structural consistency in reconstructed facial regions. Second, the attention mechanisms commonly adopted in prior work are dominated by global self-attention, whose quadratic computational complexity results in high memory consumption and low efficiency—making these models unsuitable for real-time or resource-constrained VR applications. Third, many existing approaches employ complex and redundant GAN architectures with large parameter counts, limiting the deployability and hindering practical integration into lightweight VR systems. These gaps highlight the need for a lightweight, geometry-aware, and computationally efficient framework for high-fidelity HMD-occluded face reconstruction.

In response to the identified research gaps, this study presents a lightweight, geometry-aware GAN architecture that incorporates multi-feature fusion and an efficient deformable attention module. The core design of the approach is described as follows:

1) To introduce the Lie group feature learning method to perform a structured representation of shallow features. By combining deep semantic features with shallow visual information, it effectively improved the integrity and geometric consistency of feature expression.

2) To propose a deformable attention mechanism guided by facial reference images, effectively reducing memory usage and computational complexity.

3) To propose a lightweight GAN model that combines parallel dilated convolution, Lie group feature modeling, and an attention module. This significantly reduces the model complexity and inference time while maintaining good reconstruction quality.

The primary contributions of this research can be outlined as follows:

1) Proposed a multi-feature fusion strategy combining shallow and deep features, and the Lie group feature learning method is introduced to significantly enhance the model's ability to model facial structure.

2) Designed a deformable attention mechanism guided by facial reference images (face deformable attention), which effectively reduces the computational complexity, improves the focus on key areas, and reduces the impact of irrelevant regions.

3) Constructed a lightweight GAN architecture that ensures high-fidelity reconstruction while having good adaptability.

The remainder of this study is organized as follows: Section II reviews the related work on HMD-occluded face reconstruction. Section III presents the proposed lightweight multi-feature fusion GAN with deformable attention. Section IV describes the experimental setup, implementation details, and performance evaluation. Section V concludes the study and outlines potential directions for future research.

II. Related Work

A. Occluded Face Reconstruction

Occluded face reconstruction is a challenging problem that has recently garnered significant attention. Current approaches can be categorized into two groups broadly [25]: model-based methods and image-based methods. Model-based methods rely on statistical models, such as 3D morphable models (3DMMs) [31], to estimate facial geometry and texture. Purps et al. [32] identified unoccluded facial regions, extracted facial landmarks, followed the Facial Action Coding System (FACS) to achieve facial muscle activation, and created realistic virtual images through 3D modeling software to achieve facial expression presentation. However, the above methods are mainly aimed at small-scale facial occlusions and have particular difficulties for large-scale occlusions, such as the difficulty in capturing detailed facial features. To overcome the limitations of small-scale facial occlusions, some studies have adopted more complex techniques to deal with large-scale facial occlusions. For example, He et al. [33] fitted a 3D facial model, used 3D facial information to reconstruct the occluded parts, and combined Gabor-based occlusion dictionary learning to increase feature diversity and better represent occluded faces. Li et al. [34] separated the occluded areas through an abnormal region segmentation network, avoiding the model fitting error caused by occlusion, achieving more accurate model fitting positioning, and improving the quality of occluded facial reconstruction.

Image-based methods usually use deep learning models to complete face images. Ju et al. [35] randomly added masks to the face dataset to synthesize an occluded face dataset, achieved self-supervised training by generating damaged images with simulated occlusion and rotation, and combined CFR-GAN to repair texture in occluded areas. Yu et al. [36] introduced a reference-guided face inpainting approach that restores missing pixels using a reference image of the same identity as the occluded face. Similarity constraints were employed to synthesize finer detailed texture information. Lu et al. [37] proposed a face inpainting method that combines a multi-stage generative adversarial network with a global attention mechanism. Their framework leverages a generator with skip connections, an encoder–decoder structure, and a local refinement network to enhance inpainting quality. Luo et al. [38] proposed a two-stage control framework that disentangles the reference image into identity features and texture details. They achieved identity-preserving face image

completion in the case of large-area missing photos. Hassanpour et al. [39] developed a GAN-based 'eye-to-face network' (E2F-Net) that targets the restoration of the periocular region to improve the realism and completeness of the reconstructed face images. While image-based approaches perform better on large occlusions, they primarily rely on deep convolutional semantic features and often lack explicit modeling of shallow geometric structures, which are essential for preserving facial consistency under severe occlusion. These limitations suggest that a more geometry-aware and lightweight GAN architecture is necessary—motivating the method proposed in this work.

B. Lie Group Feature Learning

Lie group machine learning [40] is a paradigm that integrates Lie group theory with machine learning algorithms, leveraging the mathematical structure of Lie groups to improve feature representation, generalization, and robustness, particularly for data exhibiting symmetry and geometric constraints [41]. Lie group feature learning is widely used to extract shallow features of target objects. Its theoretical basis stems from the advantages of Lie groups in describing geometric transformations and symmetries [42],[43],[44],[45]. Shallow features typically encompass the geometric structure of the target object, local texture details, and basic statistical properties, capturing essential patterns in the data's primary representation. These features are vital in deep learning systems because they provide a reliable basic representation for subsequent high-level feature learning. Xu et al. [42] first applied Lie group feature learning to shallow feature extraction of remote sensing images, effectively learning and representing shallow features such as target size and shape in remote sensing images, and combined with CNN models to achieve more discriminative feature extraction. The results show that Lie group feature learning can effectively enhance the feature representation ability of deep learning models [43]. Xu et al. [44],[45] further applied Lie group feature learning to the deep learning model for scene classification, allowing the model to capture and represent a more diverse set of features, enhancing the interpretability of the model, and thus effectively improving the model's scene classification performance. Cai et al. [46] used Lie groups to learn and implement natural motion data representation. Then they used CNN to discover and classify Lie group features, improving the accuracy of human motion recognition and saving computing time. Yang et al. [47] designed a Lie algebraic residual network (LARNet), which effectively improved face recognition accuracy by combining Lie groups and residual networks, and was robust to face posture. Although Lie group feature learning has shown promise in capturing geometric structures across different fields, it remains largely unexplored in occluded face reconstruction.

C. Attention Mechanism

The attention mechanism, inspired by human visual perception, allows the model to focus on the most relevant regions of the input data [48]. Initially, this mechanism was mainly used in natural language processing and significantly improved model performance. With the development of technology, researchers have gradually extended the attention mechanism to the field of computer vision and achieved many breakthrough results [49],[50],[51]. However, while improving the accuracy of the model, this mechanism also introduces new problems [52], such as high computational complexity and extensive memory usage. To solve these problems, scholars have proposed some solutions, such as Deformable Attention (DAT) [53], Slide-Transformer [54], Single-Head Vision Transformer (SHViT) [55], etc., which reduce the redundancy in attention calculation through different strategies and significantly improve its computational efficiency. Lu et al. [37] used the global attention mechanism to enhance global feature interaction and reduce information dispersion, thereby better realizing face information restoration. Wan et al. [56] introduced an unsupervised face restoration approach that integrates contrastive learning with an attention mechanism. The feature attention module focuses on key feature information and establishes long-range dependencies to improve the face restoration effect. Xu et al. [27] proposed a face inpainting approach that combines parallel visual attention (PVA) with a diffusion model. By inserting a parallel attention matrix into the denoising network and focusing on the reference image features extracted by the identity encoder, the identity preservation ability of the restored face is effectively improved. Chen et al. [57] proposed a channel attention layer with spatial activation, combined with a sandwich-style feed-forward network structure, to achieve efficient spatial modeling and context understanding of damaged images at multiple scales. While these methods significantly enhance restoration fidelity, most existing works either assume global attention, which is computationally heavy, or do not fully leverage facial cues that could better guide reconstruction under occlusion, such as HMDs.

III. Proposed Method

A. Overview

0 illustrates the complete framework of the model. Initially, the Lie group feature learning is adopted to extract shallow features from the reference face image, while a convolutional neural network captures high-level features. These features are then fused and used as input for the subsequent stage; then, a generator is constructed, in which we propose a deformable attention mechanism guided by facial reference images to reconstruct the face under HMD occlusion; finally, through adversarial training between the generator and discriminator, images containing various facial detail information are gradually generated to achieve high-fidelity face reconstruction.

B. Feature Learning

1) Shallow feature learning: The image samples are first projected onto the Lie group manifold space to derive their corresponding Lie group representations. Then, feature extraction is performed within the manifold space. Inspired by the method proposed in [42], key features such as color and gradient information are extracted at each pixel, and a Lie group-based regional covariance matrix is constructed based on these features. This matrix characterizes the shallow structural properties of the sample and provides a richer feature representation for subsequent analysis and processing. The formulation is as follows:

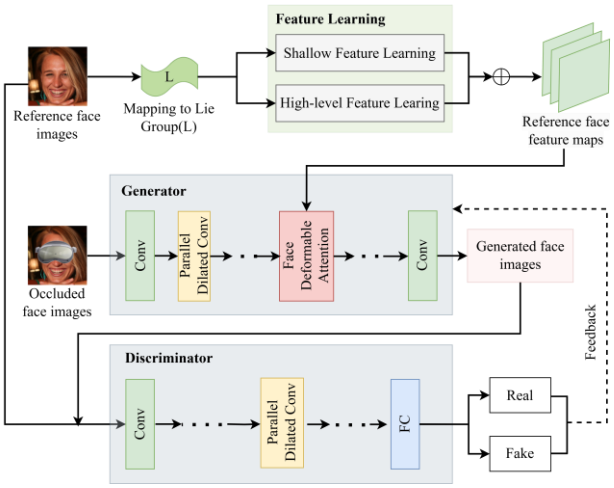

Fig. 1. Framework overview.

$$F(x,y)=\begin{bmatrix} x, y, HSV, \left|\frac{\partial I(x,y)}{\partial x}\right|, \left|\frac{\partial I(x,y)}{\partial y}\right|, \left|\frac{\partial^2 I(x,y)}{\partial x^2}\right|, \left|\frac{\partial^2 I(x,y)}{\partial y^2}\right|, \\ \left|\frac{\partial^2 I(x,y)}{\partial x \partial y}\right|, HOG(x,y), Gabor(x,y) \end{bmatrix}^T \quad (1)$$

where, the pixel position (x, y) and the gradient ($\left|\frac{\partial I(x,y)}{\partial x}\right|, \left|\frac{\partial I(x,y)}{\partial y}\right|$) are the basic characteristics of the target object, the gradient can provide key features such as texture, edge, and direction. Compared with [42], we increased the image pixel in the x and y directions of the second-order mixed partial derivative $\left|\frac{\partial^2 I(x,y)}{\partial x \partial y}\right|$ to capture local curvature change, capture complex and essential features such as eyebrows, corners of the eyes, and corners of the mouth more accurately. And $\left|\frac{\partial^2 I(x,y)}{\partial x \partial y}\right|$ of intersection is very sensitive and can detect the image of the cross and the nonlinear change, enhancing the model's perception of delicate features.

In the research [42], RGB and YCbCr are used as basic color features to enhance the representation of target objects in remote sensing scenes. This research focuses on the color distribution of different areas, such as skin tone, occlusions, etc. However, in a different light, the value of skin color in the RGB space will change significantly, especially when the non-uniform light performance is worse. In [58], the authors show that HSV is more robust to changes in facial illumination. Therefore, we capture color features in the HSV color space. Hue H and saturation S can describe skin color well and have certain invariances to brightness changes, making skin color feature extraction more reliable.

HOG counts the local gradient change around each pixel. In [59], the authors show that HOG features are susceptible to object deformation, so introducing HOG features can effectively extract facial edge and shape information. The Gabor feature is widely used for characterizing image texture information [60]. It effectively captures and discriminates textures because their frequency and orientation selectivity align with the response characteristics of the human visual system.

2) High-level feature learning: In this section, a multi-layer convolutional neural network (CNN) is used to extract high-level semantic features from the reference face image. Fig. 2 shows the high-level feature learning network structure used in this research. The semantic features of the reference face image are gradually extracted through multiple convolutions (including standard convolutions and parallel dilated convolutions) combined with batch normalization (BN) and SeLU activation functions. To extract the high-level features of the reference face image at a deeper level, three residual modules are used to deepen the network structure and reduce feature loss.

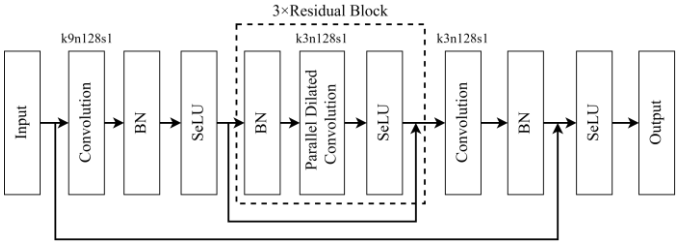

Fig. 2. High-level feature learning network. k, n, and s indicate kernel size, number of channels, and stride, respectively.

This study uses dilated convolutions with r=1, 2, and 3 dilation rates to perform parallel operations. As shown in Fig. 3, given a feature map Ft, it is segmented into four parts, Ftc1, Ftc2, Ftc3, and Ftc4, along the channel. A 3×3 convolution kernel is used to perform dilated convolution operations on two adjacent parts, so that each dilated convolution can share some parameters. Then the output of the dilated convolution is fused with the original feature. Finally, the number of channels is readjusted through a 1×1 convolutional network.

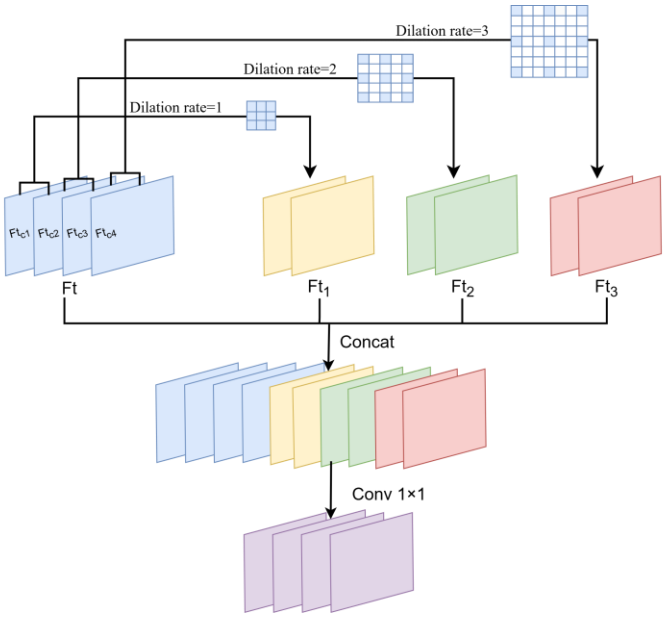

Fig. 3. The principle of parallel dilated convolution.

TABLE I. THE NUMBER OF PARAMETERS OF PARALLEL DILATED CONVOLUTION AND ORDINARY CONVOLUTION

Methods	Kernel Size	Input Channel	Output Channel	Layer	Parameters Size	Total(M)
Ordinary	3×3	512	512	Conv1 Conv2 Conv3	512×512×3×3=2,359,296 512×512×3×3=2,359,296 512×512×3×3=2,359,296	7,077,888 ≈ 7.08
	5×5	512	512	Conv1 Conv2 Conv3	512×512×5×5=6,553,600 512×512×5×5=6,553,600 512×512×5×5=6,553,600	19,660,800 ≈ 19.66
Parallel	5×5	512	512	Conv1 Conv2 Conv3	512×512×5×5=6,553,600	6,553,600 ≈ 6.55

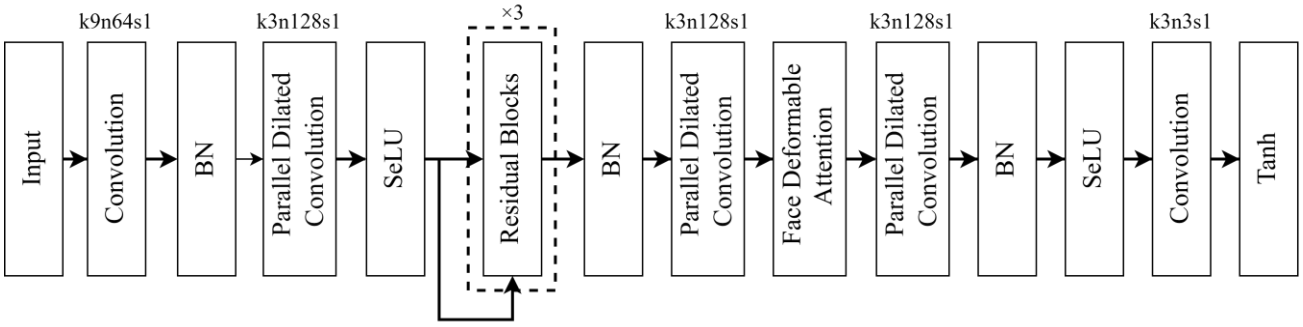

Fig. 4. The generator structure. k, n, and s indicate kernel size, number of channels, and stride, respectively.

Compared to traditional convolution, parallel dilated convolution effectively enlarges the receptive field and decreases the number of parameters by sharing parameters across branches with different dilation factors, as summarized in TABLE I. When the input and output channels are 512 and the convolution kernel size is 5×5, the parameter count of standard convolution is approximately three times higher than that of parallel dilated convolution. Notably, the parameter counts of parallel dilated convolution using a 5×5 convolution kernel are only 6.55M, even less than the parameters of three traditional convolution operations using a 3×3 convolution kernel. Therefore, the parallel dilated convolution effectively reduces the model size while ensuring the feature extraction effect.

C. Generator

1) Generator structure: In this section, a generator consisting of convolutional layers, residual blocks, and an attention module is constructed for face reconstruction under HMD occlusion, as presented in Fig. 4. This model proposes a face deformable attention module guided by a reference face image to reconstruct the face under HMD occlusion and generate finer textures in the occluded area. In the model, the BN layer is placed before the convolutional layer. This operation has been proven in research [45] to effectively speed up model convergence, improve gradient propagation, and enhance model generalization ability.

Three residual blocks are used in the generator to effectively avoid the gradient vanishing or gradient exploding problems that occur as the network depth increases. The residual block structure is presented in Fig. 5. Firstly, the input features undergo batch normalization, followed by parallel dilated convolution, which enlarges the receptive field while retaining fine details. To improve non-linear representation and ensure numerical stability, the SeLU activation function is applied. Finally, a skip connection directly adds the original input features to the convolutional outputs, mitigating feature loss as network depth increases. The formulation is as follows:

$$x_{i+1} = x_i + SeLU(PDConv(BN(x_i)) \quad (2)$$

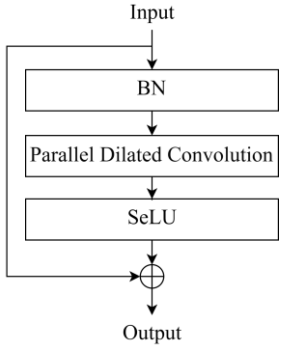

Fig. 5. The residual block network.

where, x_i denotes the input to a residual block, while x_{i+1} represents its output, which also serves as the input to the subsequent residual block, and $PDConv(\cdot)$ represents the parallel dilated convolution operation.

2) Face deformable attention: This section proposes a deformable attention mechanism guided by face reference images, as illustrated in Fig. 6. Given the HMD occluded face feature map $F_{masked} \in \mathbb{R}^{H\times W\times C}$, it is projected to query tokens Q by linear transformation. Given the reference face feature map $F_{ref} \in \mathbb{R}^{H\times W\times C}$, the reference points $p(x, y) \in \mathbb{R}^{H_r\times W_r}$

are generated by uniform grid sampling in F_{ref}. The reference points p are represented as 2D coordinates normalized to the range [-1,1] according to the mesh shape. By feeding Q into the offset network, a set of offset values $\Delta p = offset(Q)$ can be obtained. Adding the positional offset Δp to the reference points p, the reference points can be dynamically adjusted towards critical regions (e.g., the eye area), yielding new coordinate points $\hat{p}$. Sampling at points $\hat{p}$ on the reference feature map F_{ref} produces a new feature map $F_{ref}{}'$, which contains authentic reference features of the eye region under HMD occlusion. These features further support reconstructing a complete face under HMD occlusion. Key K and Value V can be obtained by linear transformation of $F_{ref}{}'$ using projection matrices W_k and W_v. The attention score is then obtained by calculating the similarity between Q and K, which represents the relevance of the query to each key. Finally, the attention score is normalized, and the values are weighted to generate the final weighted feature. Thus, the face information of the HMD occluded area can be recovered to help realize high-fidelity face reconstruction under HMD occlusion.

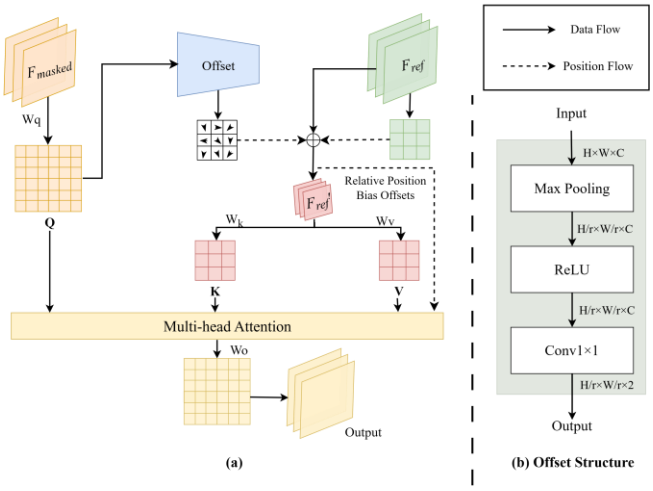

Fig. 6. Face deformable attention structure.

Fig. 6(b) shows the offset network structure. Q is downsampled through a Max pooling layer, and then nonlinearity is introduced through ReLU. The channels are compressed and mapped using 1×1 convolution. Finally, the position offset 2D coordinates are output. In the offset network, a predefined factor s is used for scaling to prevent the training process from being unstable due to excessive offset. Face deformable attention is calculated as follows:

$$Q = F_{masked}W_q,\ K = F_{ref}{}'W_k,\ V = F_{ref}{}'W_v \tag{3}$$

$$F_{out} = softmax\left(\frac{QK^T}{\sqrt{d}} + b\right)V \tag{4}$$

where, W_q, W_k, W_v are learnable projection matrices optimized during training, enabling the attention can effectively capture the relationships between input features. F_{masked} is the input HMD occluded face feature map, $F_{ref}{}'$ is the grid sampling result of the reference face feature map, and b is the relative position offset value.

D. Discriminator

The discriminator is constructed to differentiate reconstructed face images from real ones, as illustrated in Fig. 7. The reference face image and the reconstructed face image are randomly selected as the input of the discriminator. The input image first undergoes convolution to obtain initial feature representations, followed by the SeLU activation function to introduce nonlinearity. Subsequently, the network uses three parallel dilated convolutions to extract image features further and capture contextual information. The architecture combines average pooling to reduce spatial dimensions and aggregate features, and then uses a fully connected layer for advanced feature processing. Finally, through the Sigmoid activation, the input image is assigned a discrimination result.

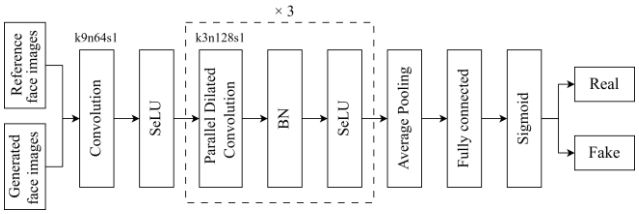

Fig. 7. The structure of the discriminator. k, n, and s indicate kernel size, number of channels, and stride, respectively.

The discriminator evaluates the input image and feeds the result back to the generator, guiding it to iteratively optimize its parameters and generate more realistic images. During adversarial training, the discriminator continuously updates its parameters to enhance its capability to differentiate between authentic and reconstructed images. Through this adversarial process, the generator gradually enhances the quality of its outputs, making the reconstructed images increasingly similar to real ones. Meanwhile, the discriminator delivers effective feedback to the generator by extracting deep feature representations, helping it to capture finer details and more complex features, thus facilitating better parameter optimization. Ultimately, the discriminator ensures that the facial images generated by the generator achieve high visual quality and detailed expression, effectively addressing the challenge of high-fidelity face reconstruction under HMD occlusion.

IV. Experimental Results and Analysis

A. Experimental Dataset

Due to the difficulty of obtaining real HMD-occluded faces with corresponding ground truth, synthetic datasets were used to ensure quantitative evaluation and reproducibility [32],[61]. The baseline datasets used in this study are FFHQ and CelebA. This study adopts FFHQ and CelebA, two widely used benchmark face datasets. FFHQ provides high-resolution (1024×1024) facial images with rich diversity in age, ethnicity, pose, and expression, making it suitable for high-fidelity reconstruction tasks and supervised learning with clean, unobstructed ground truth. CelebA offers a large-scale collection of face images with substantial identity and attribute variation, which supports evaluating the model's generalization ability across different facial characteristics. Based on these datasets, 68,274 synthetic HMD-occluded images were generated from FFHQ and 143,669 from CelebA. The model

was trained on the occluded FFHQ dataset and evaluated on the FFHQ and CelebA test sets to verify its generalization capability.

B. Experiment Setup

Experiments were conducted on a computing platform equipped with an NVIDIA RTX 4090 GPU (24 GB VRAM) and a 12th Gen Intel(R) Core(TM) i7-12700K CPU. The implementation was based on PyTorch 2.0.0 with CUDA 11.8 for GPU acceleration, using Python 3.8. Model training employed the Adam optimizer with first-order and second-order momentum estimates ($\beta1 = 0.5,\ \beta2 = 0.999$) and a batch size of 8. The learning rate for both the generator and discriminator was set to 0.0002, and training was performed for 100 epochs. The detailed experimental configuration is summarized in TABLE II.

TABLE II. EXPERIMENTAL SETUP

Category	Configuration
Hardware	NVIDIA RTX 4090 GPU (24GB), Intel Core i7-12700K CPU
Software	Python 3.8, PyTorch 2.0.0, CUDA 11.8
Optimizer	Adam($\beta1 = 0.5,\ \beta2 = 0.999$)
Batch Size	8
Learning Rate	0.0002
Epoch	100

C. Result and Analysis

1) Qualitative analysis: To verify the effectiveness of the proposed method in face reconstruction under HMD occlusion, this study conducts a qualitative analysis on the test set and compares the differences in visualization between the proposed approach and several widely used contemporary methods. Fig. 8 shows the face reconstruction results of different approaches in the FFHQ dataset.

As presented in the comparison results in Fig. 8, the existing methods can restore the basic contours of the occluded face to a certain extent, but there are generally problems such as blurred reconstruction areas, discontinuous boundaries, or structural distortion, especially in key areas such as the eyes and brow bones, which make it difficult to restore the true face accurately. As shown in Fig. 8(c), this method exposes the problems of global structure loss and regional incoherence in the generated results. Obviously, it lacks overall coordination, making it challenging to model facial semantics consistently. As shown in Fig. 8(d), MAT has enhanced local texture modeling by introducing the Transformer structure, but its structural alignment and detail continuity performance are still unsatisfactory. For example, in the 4th row and 4th column, there is a misalignment phenomenon in the reconstruction of the face contour under the side view, indicating that its modeling ability under complex postures still has room for improvement. AOT-GAN also exhibits similar problems, and from the visualization results in Fig. 8(e), it can be observed that its reconstruction results are obviously insufficient in diversity, and the eye structures generated in multiple samples are highly similar, lacking personalized performance. In addition, noticeable color differences and texture breakage often occur in the occluded area, affecting the overall visual consistency. In contrast, our approach is more natural, realistic, and diverse in visual effects. Meanwhile, our results also generated facial features and structures that were closely aligned with the ground truth, such as the distance between the eyebrows and eyes, the proportion of the facial features, the color of the eyes, etc. It can not only accurately restore the structural contours of the occluded area, but also show better coherence and consistency in fusion with the non-occluded area.

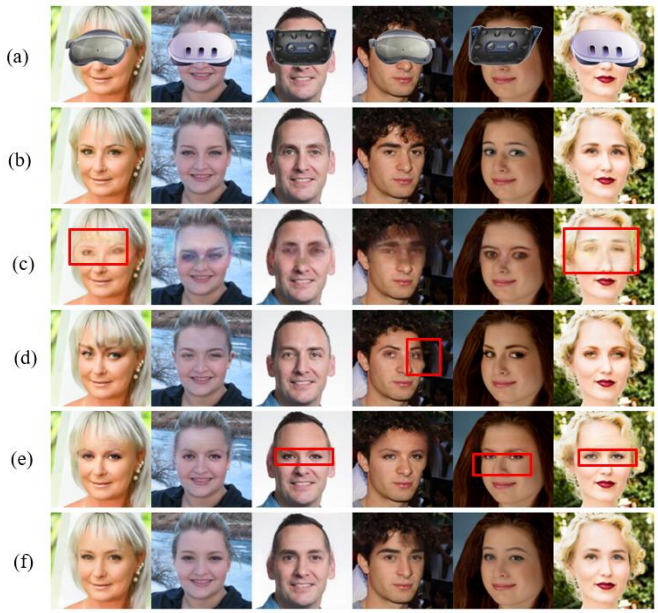

Fig. 8. Vision comparison. Each row is: (a) Input image, (b) Ground truth, (c) RFI[38], (d) MAT[62], (e) AOT-GAN[63], and (f) the proposed method.

2) Quantitative analysis: The proposed model is also verified on the CelebA dataset. To objectively measure the performance of the proposed method, this study uses three common image quality evaluation indicators: SSIM, PSNR, and LPIPS, and evaluates the results against existing leading image inpainting approaches. SSIM quantifies the structural similarity between the reconstructed and the original images. The higher the value, the closer the structure; PSNR primarily reflects the overall quality of image restoration. Higher values indicate lower image distortion; LPIPS evaluates image similarity based on the perceptual characteristics of the deep network, which can better capture the differences in human visual perception. The lower the value, the closer the reconstructed face is to the real face. We further report the number of parameters and FLOPs to verify the model's lightweight design and computational efficiency. FLOPs indicate the number of floating-point operations required for a single forward pass and serve as a measure of computational complexity. Since runtime can vary across different devices, this research did not use it as an evaluation metric.

A comparison of our method with multiple leading approaches is presented in TABLE III. Compared with mainstream GAN-based models, our method achieves higher SSIM and PSNR, as well as lower LPIPS, indicating superior reconstruction quality. Although RFI achieves lower FLOPs (5.67G) than ours (10.55G), its parameter count is much higher (128.87M). When compared with attention-based models such as AOR and MAT, our method achieves better image-level metrics while significantly reducing both parameter counts and FLOPs, demonstrating the efficiency of the face deformable attention module with dynamic sampling. Compared with lightweight GAN models like FastGAN, although our FLOPs (10.55G) are slightly higher than theirs (9.6G), our model has fewer than one-third of their parameters while achieving higher image quality, showing that we maintain a lightweight design without compromising reconstruction performance. Although diffusion-based methods have recently shown promising results, they were not included in the quantitative comparison due to the lack of publicly available code. Overall, these results indicate that our model effectively balances high-quality face reconstruction with a compact and computationally efficient design.

TABLE III. COMPARISON WITH STATE-OF-THE-ART RESEARCH

Research	SSIM	PNSR	LPIPS	Parameters (M)	FLOPs (G)
Lafin[64]	0.902	26.25	0.92	25.32	75.03
EC[65]	0.846	25.28	2.82	60.95	88.64
AOR[66]	0.918	29.02	0.07	43.75	100.27
EVI-HRnet[25]	0.899	25.83	0.03	26.01	62.31
MAT[62]	0.894	21.26	0.11	56.94	68.25
AOT-GAN[63]	0.901	22.01	0.11	15.20	18.22

D. Ablation Study

To assess the effect of each component within the proposed model for HMD face reconstruction, an ablation study was carried out. Key components were selectively removed, and the effectiveness of the resulting model variants was systematically compared. TABLE IV. summarizes the experimental configurations and the corresponding outcomes, comprising the following three model variants:

w/o Lie: Remove the Lie group feature learning module and keep other components.

w/o FDA: Remove the Face Deformable Attention (FDA) module and keep other components.

Ours: The complete model, including two key components: Lie group feature learning and face deformable attention.

TABLE IV. PERFORMANCE COMPARISON: FULL MODEL VS. ABLATED VARIANTS

	SSIM↑	PNSR↑	LPIPS↓
w/o Lie	0.892	28.36	0.04
w/o FDA	0.843	23.48	0.08
Ours	**0.912**	**30.64**	**0.03**

The quantitative results demonstrate that removing the Lie group feature learning module leads to a notable decline in performance, with SSIM dropping to 0.892 and PSNR decreasing to 28.36. This indicates a weakened ability to restore structural information and preserve fine details. Upon further removal of the attention mechanism, the performance deteriorates, with LPIPS increasing to 0.080, reflecting a significant decline in perceptual quality. In contrast, the whole model consistently achieves superior results across all evaluation measures, underscoring the contribution and necessity of the proposed components.

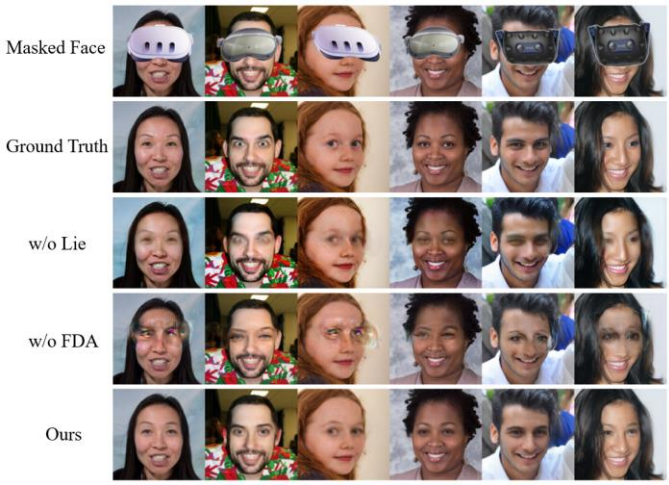

Fig. 9. Visual example of the ablation experiment.

To further illustrate the contribution of each module to the reconstruction performance, Fig. 9 presents a visual comparison of reconstructed results generated by different model variants on occluded facial images. In the w/o Lie configuration, the reconstructed outputs exhibit noticeable blurring and incomplete structural restoration in the occluded regions. The absence of fine-grained details highlights the importance of the Lie group feature learning module in providing low-level geometric and structural information. Without this module, the model struggles to capture local facial features, impairing its ability to reconstruct detailed and coherent textures. In the w/o FDA configuration, the results suffer from prominent artifacts and structural misalignments. Some examples display unnatural facial deformations, indicating that the proposed FDA module effectively guides the model to focus on critical facial regions and enhances its

ability to maintain global structural consistency by leveraging reference image information. The removal of this component hinders the integration of semantic cues, resulting in a noticeable decline in reconstruction quality. In contrast, the complete model achieves the most natural and structurally coherent visual results. It successfully restores precise facial details and maintains high texture and structural consistency across occluded and non-occluded regions. These observations further validate the synergistic effectiveness of combining Lie group feature learning with the face deformable attention mechanism in improving overall reconstruction performance.

In summary, the ablation study comprehensively demonstrates the substantial contributions of the proposed key modules to overall model performance, as evidenced by both quantitative metrics and qualitative visual comparisons. Although the Lie group feature learning module and the face deformable attention mechanism function through distinct mechanisms, they complement each other in enhancing structural restoration and maintaining visual coherence. Their synergistic integration constitutes a core strength of the model architecture. This design improves reconstruction quality under occlusion conditions and offers a scalable and generalizable framework for more complex facial restoration tasks in future applications.

V. Conclusion

This study proposes an innovative model based on GAN to solve the problem of face reconstruction under HMD occlusion. By introducing the Lie group feature learning module, the model effectively captures the geometric structure and local changes, enriches the feature representation, and enhances the robustness. In addition, we design a deformable attention mechanism guided by the reference face image to dynamically adjust the model's attention area, so that the model can not only accurately repair the occluded area, but also maintain the natural and realistic reconstruction effect, effectively improving the consistency and credibility of the generated image. The proposed model is verified on the synthetic FFHQ and CelebA datasets. Experimental results indicate that it outperforms existing methods across multiple evaluation metrics, including structural similarity, perceptual consistency, and model efficiency.

Despite these encouraging results, several limitations remain. First, the current model operates only at the single-image level and does not incorporate temporal information, which constrains its ability to generate temporally consistent reconstructions for dynamic HMD-occluded facial sequences. Second, although the architecture is designed to be lightweight, real-time deployment on resource-constrained standalone VR headsets may still require further optimization, particularly given that the present reconstruction results are limited to 2D image outputs. Future work will focus on further lightweight optimization and the incorporation of temporal cues to achieve consistent dynamic reconstruction, as well as exploring 3D-level facial texture completion.

Beyond the technical findings, this work also provides broader insights into the future development of HMD-occluded face reconstruction and VR realism. By demonstrating the value of combining Lie group–based geometric modeling with deformable attention, this study highlights a promising direction for designing generative models that balance structural fidelity with computational efficiency. Such geometry-aware lightweight architectures may reshape current approaches to face inpainting, offering an alternative to purely convolutional or diffusion-based pipelines. Furthermore, the ability to restore plausible and identity-consistent facial textures has potential implications for social VR, avatar expressiveness, and immersive communication, where natural facial cues directly influence user experience and presence. Although this research does not involve direct system deployment, the findings underscore the importance of sustainable and responsible facial synthesis, especially in an era where generative diffusion models and identity-sensitive applications continue to evolve. These reflections position the proposed framework not only as a technical contribution but also as a foundation for future interdisciplinary advances in VR-oriented facial reconstruction.

Acknowledgment

We would like to extend our heartfelt gratitude to the Ministry of Higher Education for the financial support received under the Fundamental Research Grant Scheme (FRGS), UTM, FRGS/1/2023/ICT10/UTM/02/2. Thanks to ViCubeLab at Universiti Teknologi Malaysia for their invaluable support and facilities.

This work is also partially supported by the Hengshui University Education and Teaching Reform and Research Project (jg2024051) and the Hebei Provincial Statistical Science Research Project (2025HL51).

***Abstract*—Cerebrovascular accidents (CVA) cause hemiplegia in adult patients, limiting their daily activities and reducing their autonomy, which calls for effective rehabilitation systems for the lower limbs. The study aims to design and simulate a subactuated robotic continuous passive motion system for lower-limb therapy in adult patients with post-stroke hemiplegia. Physical rehabilitation protocols were analyzed, and consultations with specialists were conducted to define criteria related to safety, stability, and adaptability. The mechanical subsystem was developed using SolidWorks with an adjustable structure; the electronic subsystem was designed using Autodesk Eagle and KiCad 7 to enable precise control; and the software subsystem was implemented in Wokwi using an ESP-32 microcontroller for parameter configuration and data transmission. Simulations were conducted in CoppeliaSim, modeling a virtual patient undergoing three rehabilitation modes: knee flexion-extension, ankle flexion-extension, and a combined full knee extension cycle. Simulations validated the correct execution of the planned movements, stability of the power supply, precision in displacement control, and the ability to record and transmit therapeutic data. The strength of materials and the effectiveness of the mechanism were also confirmed. The designed subactuated robotic system represents a safe and effective tool for physical rehabilitation, with the potential to improve mobility and quality of life in patients with lower-limb hemiplegia following a CVA.**

***Keywords*—Bio-mechatronics; engineering design; exoskeleton; stroke rehabilitation; rehabilitation robotics**

I. Introduction

In Peru, the Instituto Nacional de Estadística e Informática (National Institute of Statistics and Informatics – INEI) reported in 2017 that the prevalence of individuals with physical disabilities involving some degree of difficulty in upper and lower limb movement was 15.1% of the total population [1]. In 2018, the Consejo Nacional para la Integración de la Persona con Discapacidad (National Council for the Integration of Persons with Disabilities – CONADIS) registered approximately 2,735 Peruvians with musculoskeletal limitations, the vast majority of whom were eligible for physical rehabilitation. However, a range of factors—particularly economic constraints—prevented many from receiving adequate treatment or, in some cases, any treatment at all [2]. According to 2019 data from the National Institute of Statistics and Informatics, 88.6% of the population with some type of disability did not receive rehabilitation therapy or treatment, meaning that only 11.4% had access to such care [3]. This disparity can be attributed, in part, to the limited use of rehabilitation technology in the country, largely due to economic limitations and a lack of awareness regarding the existence of such devices as components of physical rehabilitation therapies.

According to the World Health Organization (WHO), the global incidence of cerebrovascular accidents (CVA) is 200 cases per 100,000 inhabitants per year, with a projected increase of 27% between 2000 and 2025. The Instituto Nacional de Ciencias Neurológicas - INCN (National Institute of Neurological Sciences) notes that CVA can be prevented by maintaining a healthy lifestyle, and if one occurs, immediate attention from a specialist significantly increases the chances of recovery [4].

At the Polytechnic University of Catalonia, Spain, an active knee-ankle orthosis was designed [5]. This proposal seeks to assist and contribute to the recovery of patients with spinal cord injuries, who present up to 80% of the body without the capacity to perform movements. In Latin America, there are exoskeleton projects designed to contribute to rehabilitation therapies for upper and lower limbs. Regarding upper limb rehabilitation, exoskeletons have been developed that present up to four degrees of freedom, adapted to the anthropometry of Mexican patients through optimal conceptual design [6]. These exoskeletons are focused on humerus rotation movement, elbow flexion and extension [7], and hand pronation and supination [8]. Regarding lower limb rehabilitation, two-degree-of-freedom systems have been designed for ankle and knee therapies, which include force, velocity, and position sensors [9], as well as designs for knee flexion-extension [10]. Based on the aforementioned, improving patient independence is possible with the application of technology in physical rehabilitation.

Patients who suffer a CVA often experience paralysis on one side of the body, a condition known as hemiplegia. As part of their rehabilitation, they must perform passive and repetitive exercises to activate neuroplasticity, a process that facilitates the formation of new neural connections in the brain. According to Perrier, gait disturbances, musculoskeletal deformities, and postural abnormalities are among the motor

sequelae commonly resulting from CVA [11]. Mourey notes that the ability to maintain balance is affected by the functional condition of the lower limbs, as the muscles responsible for stabilizing the ankle and foot progressively weaken, impairing postural and movement control [12].

The Instituto de Evaluación de Tecnologías en Salud e Investigación (Institute for Health Technology Assessment and Research – IETSI) of EsSalud states in its "Clinical Practice Guideline for the Diagnosis and Treatment of the Acute Phase of Ischemic Stroke" that patients with CVA who present any level of disability should be included in physical rehabilitation programs. Moreover, it recommends that physical rehabilitation should begin within 72 hours and that patient mobilization commence within 24 hours, considering the patient's condition and hemodynamic status. Rehabilitation involves techniques that are typically administered in hospital settings, which increases the cost of ensuring timely access to treatment. However, early rehabilitation may result in cost savings by reducing long-term disability, in contrast to delayed intervention, which is associated with established disability and the potential for complications due to lack of timely treatment [13].

From the literature review, in recent years, research has been conducted on the design of prototypes and robotic rehabilitation systems for the lower limbs, aimed at assisting patients who have suffered CVA or with mobility impairments. These systems work by replacing lost muscular function with artificial mechanisms to restore walking ability, demonstrating the effectiveness of robotic devices in improving motor function. The following paragraphs provide a brief overview of previous studies related to this line of research.

Aguirre, J. et al., in their research article titled "Ergonomic Bio-Design and Motion Simulation of a Mechatronic Orthosis System for Knee Rehabilitation," published in IEEE Xplore, present the design of an exoskeleton and its joint structure using SolidWorks, with Aluminum 1060 selected as the material based on anthropometric analysis. The system includes an actuator based on a servomotor rated at 0.4 N·m, considering a leg-foot assembly mass of 7.32 kg and a gear transmission layout to achieve the 40 N·m required to move the lower limb. The Spyder environment and Python were used to develop a graphical interface that enables configuration of movement speed and the number of repetitions. A Von Mises stress analysis was conducted on the joint area by applying a torque of 200 N·m to the power mechanism's coupling section. Additionally, a realistic simulation was conducted in CoppeliaSim, involving a rotational range from 0° to 20°, under real-world conditions such as gravity and the physical properties of the leg and foot. The results verified that the design torque and movement speeds fell within the acceptable range of commercially available products [14].

Jie, H. et al., in their research article titled "Structure Design of Ankle-Knee Rehabilitation Training Robot," published in the IEEE Xplore Digital Library, report that rehabilitation training robots have been widely adopted in the Asian market—particularly lower-limb rehabilitation training robots, which play a significant role in human mobility. Based on current characteristics of existing lower-limb rehabilitation robots, the authors propose an independently developed ankle-knee rehabilitation training robot. The article presents the structural design of the ankle and knee rehabilitation robot, describes key mechanisms and performance features, and briefly introduces the connection mode between robots [15].

Similarly, robotic rehabilitation systems have proven to be essential for delivering passive and consistent therapy over extended periods, enabling the treatment of patients without the continuous presence of a therapist, as compared to traditional manual therapy [16], [17], [18], [19]. This approach facilitates more frequent treatment sessions, significantly reducing associated costs and improving accessibility to rehabilitation therapies [20], [21], [22]. In the context of lower-limb rehabilitation, robotic exoskeletons offer specific advantages by automating repetitive and controlled movements, thereby optimizing functional recovery in patients with neurological impairments [23]. The integration of such systems into rehabilitation protocols represents a significant advancement toward personalized medicine and improved patient quality of life.

On the other hand, Bin He et al. (2019) note that subactuated robotics represents a continuously expanding area of research, characterized by systems in which the number of actuators is lower than the number of degrees of freedom. Although this feature increases the complexity of design and control, it enables the development of lighter, more efficient, and lower-cost robotic systems. The authors also provide a detailed classification of such robots based on non-holonomic constraints, allowing for the organization of various configurations and dynamic behaviors. In addition, they describe commonly used mechanisms in this type of system—such as robotic arms, hands, wrists, and locomotion structures—which have been developed according to principles of mechanical simplicity and energy efficiency. Regarding control strategies, both open-loop and closed-loop approaches are presented, with the latter being particularly relevant due to the incorporation of methods such as fuzzy control and partial feedback linearization. Finally, the article identifies key technical challenges currently faced by the field and proposes a clear direction for future research, focused on refining modeling approaches, control techniques, and practical applications [24].

Despite these advances, existing robotic rehabilitation systems face critical limitations that restrict their accessibility in resource-constrained settings: they predominantly target single joints, rely on high-cost proprietary technologies, and lack integrated validation across mechanical, electronic, and software domains. This gap is particularly acute in Peru, where 88.6% of individuals with disabilities lack rehabilitation access, and early post-CVA intervention remains unattainable for most patients. This study addresses these limitations by presenting a multi-modal robotic lower-limb rehabilitation system (knee, ankle, and combined therapies) designed with low-cost hardware and open-source tools, validated through comprehensive finite element, kinematic, electronic, and clinical expert assessment, establishing a replicable framework for accessible post-CVA rehabilitation.

The structure of this study is organized as follows: Section I introduces the research, presenting the problem statement, its motivation, and the proposed approach to address it. Section II describes the materials and methods, including the design methodology, engineering standards applied, and the tools used for modeling and simulation of the system. Section III reports the main results, focusing on the mechanical, electronic, and software validation, as well as the performance of the robotic system in simulated rehabilitation scenarios. Section IV presents the experimental study approach. Section V outlines the discussion of results. Finally, Section VI summarizes the conclusions of the study and outlines directions for future work, particularly the implementation and clinical validation of the proposed device.

II. Materials and Methods

A. Hemiplegia caused by CVA

CVA are among the leading causes of permanent disability, resulting in severe brain injuries that produce physical sequelae and limit daily activities. According to the Mayo Clinic, an ischemic stroke occurs when the brain's blood supply is obstructed, depriving brain tissue of oxygen and nutrients, whereas a hemorrhagic stroke is caused by bleeding or rupture of cerebral blood vessels, which increases intracranial pressure and damages neurons [25]. Complications include loss of muscle movement or paralysis, which may affect one side of the body or specific muscle groups such as those in the face or arm. According to Rosenbaum, hemiplegia is a condition that partially or completely paralyzes one half of the body, with the term derived from "plegia" (weakness) and "hemi" (half of the body). The Centers for Disease Control and Prevention (CDC) classify it as a type of spastic cerebral palsy affecting 80% of individuals with cerebral palsy, describing it as a condition that impacts one side of the body—typically with greater involvement of the arm than the leg [26].

B. Exoskeletons

According to Azorín et al. (2017), an exoskeleton is a device that provides motor capabilities either passively or actively. Passive devices rely on the energy generated by the user to operate. In such cases, exoskeletons enhance the user's capabilities and are commonly used in military applications and physical rehabilitation. The classification of exoskeletons depends on several factors, including human anthropometric characteristics and, ultimately, the specific pathologies targeted for treatment. Additionally, there are exoskeletons inspired by human movement, typically designed for upper and lower limb mobility, which replicate the human gait cycle through different control strategies [27].

C. Previous Research

The initial study established the conceptual and methodological framework for the design of a subactuated robotic continuous passive motion system aimed at lower-limb rehabilitation in adult patients who have suffered a CVA. The research was based on the recognition that stroke is one of the leading causes of permanent disability, resulting in severe brain damage with physical consequences that significantly limit autonomy in daily activities. Through modeling and simulation using Computer-Aided Design (CAD) tools in Autodesk Inventor Professional 2023, the initial and final positions of the robotic system were defined, along with a full simulation of continuous passive motion. The results showed that accurate patient measurements significantly increase the feasibility of constructing a functional prototype, thereby contributing effectively to the rehabilitation process and enhancing the chances of recovering gait mobility [28].

Subsequently, a more specific and technically refined design of the subactuated robotic system for continuous passive motion therapy was developed, applying the VDI 2206 and VDI 2225 engineering standards to rigorously structure the design process. In this phase, system requirements were defined based on specific anthropometric and biomechanical data. Functional structuring was implemented, and a morphological matrix was used to explore various solution alternatives. Weighted matrices were applied to evaluate criteria such as ergonomics, control precision, and safety, allowing for the selection of an optimal design for knee and ankle rehabilitation. As a result, a system was obtained that provides controlled passive motion with a load-bearing capacity of up to 80 kg, featuring adjustable speed and variable load resistance to ensure smooth actuation and effective biomechanical alignment for motor recovery. Structural validation through Von Mises stress analysis of the structure-to-rail connector—using 304 stainless steel under a vertical load of 784 N—revealed a maximum stress of 29.58 MPa and a strain of 1.12×10^{-4}, remaining within the elastic limit of the material and confirming the structural integrity of the design [29].

D. Mechatronic Systems Design Standard VDI 2206 and VDI 2225

The VDI 2206:2021 model consists of three bands: The inner yellow band describes work management according to requirements, the central orange band comprises the main activities and tasks, and the outer blue band represents modeling and analysis activities [30]. Likewise, the model is supported by a structure of six control points, which contain orientation questions and support the user in tracking project progress [31].

According to Gräßler et al., the VDI 2206 design model comprises seven interrelated stages: requirements identification (recognition and schematization of needs in a detailed list), system architecture and design (decomposition into mechanical, electronic, and software units), element implementation (selection, dimensioning, and detailing of components), integration and verification (combination of mechanical, hardware, and software aspects with examination of interactions), validation and transition (demonstration of usability and delivery of the integrated system), modeling and analysis (digital representation and simulation of the global system), and requirements management (structuring and change control during development) [31]. Complementarily, the VDI 2225 standard provides design methodology based on optimal cost and simplification, including calculation methods to estimate material and manufacturing costs through graphical analysis.

Fig. 1 shows a concept map illustrating the systematic methodology employed in the development of a subactuated

robotic rehabilitation system for the lower limbs, designed for patients with hemiplegia caused by CVA. The methodology is structured into sequential phases, ranging from the identification of the research problem—based on the lack of rehabilitation technology in Peru and the specific need to address post-stroke hemiplegia—to the proposal of future work. The methodological process integrated project evaluation based on virtual patient criteria, modularity, mechatronic aspects, and material selection, followed by the conceptual design, which incorporates technical standards and components of the robotic system. Finally, the methodology concludes with an analysis using CAD and simulation of the mechatronic system, establishing the foundation for future implementation and clinical validation of the device.

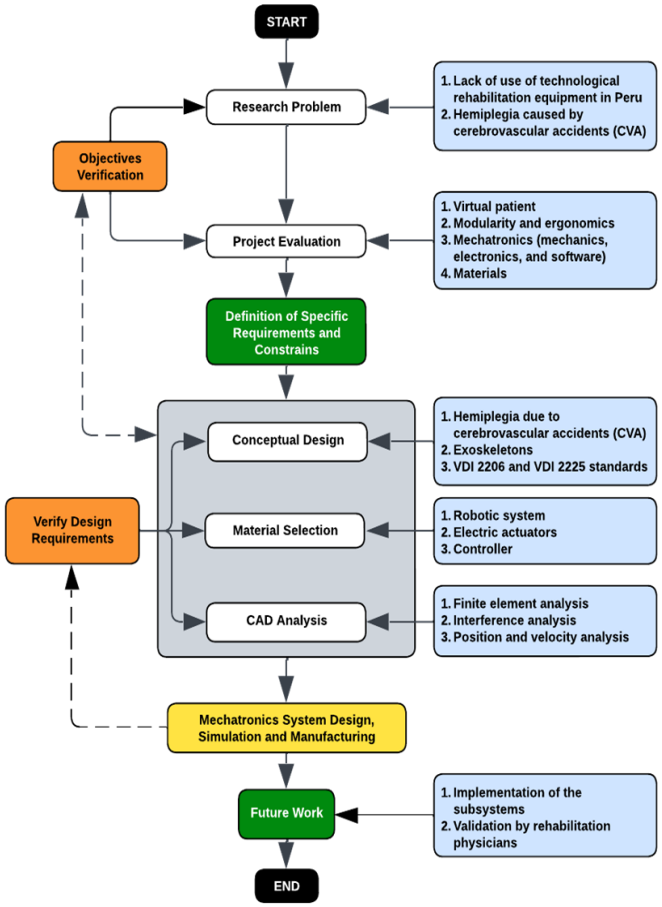

Fig. 1. Methodology for the design and simulation of the underactuated robotic system with passive-continuous movement for lower limb rehabilitation.

III. Results

An underactuated robotic system with passive-continuous movement was designed for the physical rehabilitation of lower limbs for adult patients with hemiplegia due to CVA. This system provides a comprehensive tool that contributes to physical recovery through safe and effective planning of rehabilitation exercises, using robotic technology, and with the objective of providing greater probabilities of improvement in patients' quality of life. To define the requirements of the robotic system, it was necessary to establish the functional tasks, focused on knee flexion movements, dorsiflexion, and plantar flexion of the ankle [32]. In addition, it was important to consider the natural range of motion of each joint and the mechanical constraints required to reproduce these movements accurately and safely. The design process also included a review of rehabilitation protocols to ensure that the system could adapt to different stages of patient recovery, from early passive mobilization to more advanced therapeutic exercises. Table I presents the anthropometric parameters of the lower limb. The correct implementation of these measurements guaranteed adequate biomechanical alignment and balanced load distribution during the rehabilitation process, essential aspects for maximizing treatment efficacy and safety, ensuring proper interaction between the device and the user throughout the therapy sessions.

TABLE I. Anthropometric Parameters of the Lower Limb

Anthropometric parameters	
Lower extremity segment	***Male average (cm)***
Hip width	32.852
Femur length	40.303
Knee to ankle length	42.312
Foot length	26.144
Foot width	9.900

According to Table II, the ranges of motion for flexion, dorsiflexion, and plantar flexion in the knee and ankle joints [33] allow for the design of robotic rehabilitation systems that provide personalized therapies for each patient. The possibility of modifying resistance and movement velocity according to each patient's requirements [34] is fundamental for improving rehabilitation outcomes and effectively recovering motor function in the lower limbs.

TABLE II. Clinical Parameters of the Lower Limb

Clinical parameters		
Joint	***Motion***	***Range (°)***
Knee	Flexion	0-135
Ankle	Dorsiflexion	0-20
	Plantar flexion	0-40

The process then began with the conceptual design of the robotic system, following the German standards for mechatronic design (VDI 2206) and solution concept validation (VDI 2225). This was followed by the design of the mechanical subsystem, which includes the structure and supports for the lower limb. Transmission components were integrated to manage joint movements via two motors: one for the knee and one for the ankle. The next step was the design of the electrical subsystem responsible for supplying power to the robotic system. The next phase involved selecting the electrical and electronic components and programming the microcontroller to synchronize the selected motors. The functionality of the designed subsystems that comprise the robotic system was validated using specialized engineering software such as Proteus and MATLAB. Finally, the robotic

system was simulated using engineering software tools such as MATLAB and CoppeliaSim to replicate the execution of physical rehabilitation therapies on a virtual patient.

A. Mechanical Prototyping

The mechanical subsystem was entirely designed using SolidWorks 2023 software due to its integrated finite element analysis tools and parametric design, with a specific focus on assisting joint movements of the lower limb. The mechanical configuration includes adjustable thigh and leg supports, implemented with longitudinal extension systems to ensure anthropometric adaptability. Specifically, the thigh support accommodates femur lengths ranging from 35 to 45 cm, while the leg support adjusts to knee-to-ankle distances between 40 and 50 cm, covering the anthropometric range of the target patient population. These supports incorporate securing mechanisms that provide stabilization and alignment of the limbs during rehabilitation. The ankle joint integrates a gear motor coupled to the foot support, enabling flexion-extension movements. The knee joint operates through a U-shaped structure connected to the main support and a linear guide rail, allowing for displacement with minimal deviation tolerances. The transmission system ensures a biomechanical trajectory that simulates the natural movement vectors of the joint. Additionally, the system features a subactuated configuration, as it includes only two active actuators: a DC motor for foot movement and a linear spindle for knee articulation. These actuators control a total of four degrees of freedom distributed across both joints, meaning not all movements are generated directly by motor action. In this type of design, some displacements occur passively through mechanical interaction between components, allowing for a reduced number of actuators without compromising system functionality. This strategy also contributes to lower weight, energy consumption, and control complexity, which is especially advantageous in rehabilitation applications. All components are shown in Fig. 2.

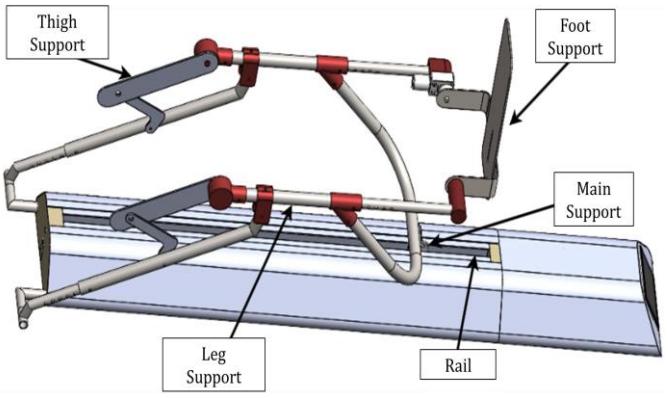

Fig. 2. Rehabilitation equipment components.

The device is designed to perform three therapy modes. In the first mode, only knee movements are executed: a) flexion and b) extension, as shown in Fig. 3. In this mode, the mechanism operates with five rotational passive joints, indicated by purple arrows, and one linear DOF, indicated by the orange arrow. The second mode enables ankle movements: a) plantar flexion and b) dorsiflexion, as illustrated in Fig. 4, which involves a single rotational DOF, also represented by purple arrows. Finally, the third mode combines both knee and ankle movements, allowing for consecutive and coordinated actions that mimic functional lower limb motion. In this mode, the device first performs full knee extension, followed by ankle movement, flexion and then extension, and concludes with knee flexion. This sequential control enables a more comprehensive rehabilitation pattern, enhancing neuromuscular coordination and facilitating a more natural gait-like exercise.

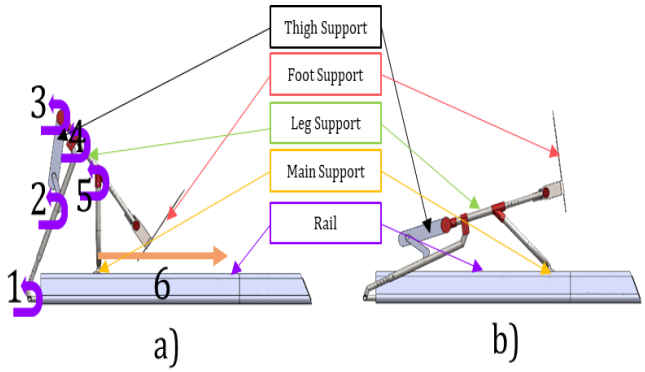

Fig. 3. Knee: a) flexion and b) extension.

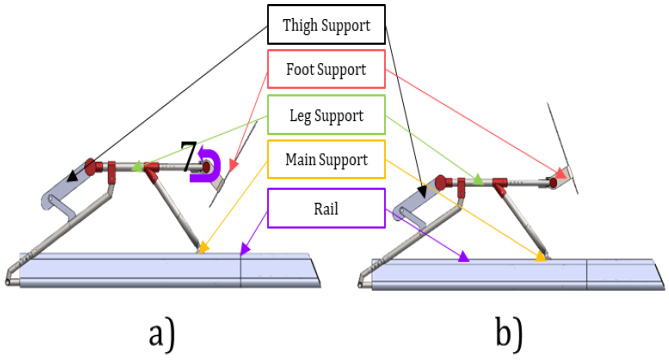

Fig. 4. Ankle: a) plantar flexion and b) dorsiflexion.

B. Finite Element Analysis of the Mechanical Structure

Finite element Von Mises stress analyses were conducted on both the U-shaped support component and the main spindle-type support, using AISI 304 stainless steel as the material and applying a load equivalent to the patient's weight (784 N) to validate the mechanical behavior of the selected material (Fig. 5). The results showed that the U-shaped support experienced a minimum stress of 0.527 MPa and a maximum stress of 0.183 MPa [Fig. 5(a)], with a maximum displacement of 1.0361 mm [Fig. 5(b)]. The main spindle-type support registered a minimum stress of 37.91 MPa and a maximum stress of 30.33 MPa [Fig. 5(c)], with a maximum displacement of 1.603×10^{-3} mm [Fig. 5(d)]. Both components exhibited maximum stress values significantly below the yield strength of AISI 304 stainless steel (206.8 MPa), thereby ensuring efficient and safe mechanical performance of the supports under the evaluated loading conditions.

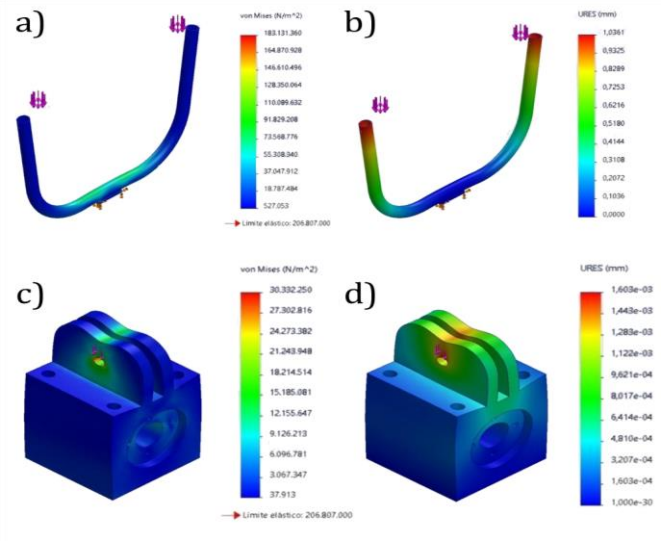

Fig. 5. Finite element analysis of structural components: a) Von mises stress distribution in U-bracket. b) Displacement analysis in U-bracket. c) Von mises stress distribution in main spindle-type support. d) Displacement analysis in main spindle-type support.

C. Electrical and Electronic Prototyping

The main components of the electronic subsystem include: a 5-inch NEXTION NX8048T050 TFT display with a resolution of 800×480 pixels for the HMI interface, powered at 5V with a current consumption of 410 mA and 16MB of FLASH memory; two optical incremental encoders for measuring position and speed through infrared light interruptions; A4988 stepper motor drivers with microstepping capability (1/16) and a current rating of ±2A up to 35V; an SD module compatible with micro SDHC cards up to 32GB via SPI interface with 5V/3.3V level conversion; NEMA 23 bipolar hybrid stepper motors, 56×56 mm in size, with a 1.8° step angle, ±5% accuracy, and an operating temperature range from –20°C to +50°C; and 40 cm T8 trapezoidal lead screws made of AISI 304 stainless steel, with an 8 mm/rev pitch, designed for high-precision linear transmission in automation systems. The electrical subsystem was designed to ensure the safe operation of the robotic system during rehabilitation therapy sessions. For this purpose, it included a power switch, a switching power supply, and an emergency stop button. The electronic and electrical design was carried out using KiCad 7.0, as shown in Fig. 6.

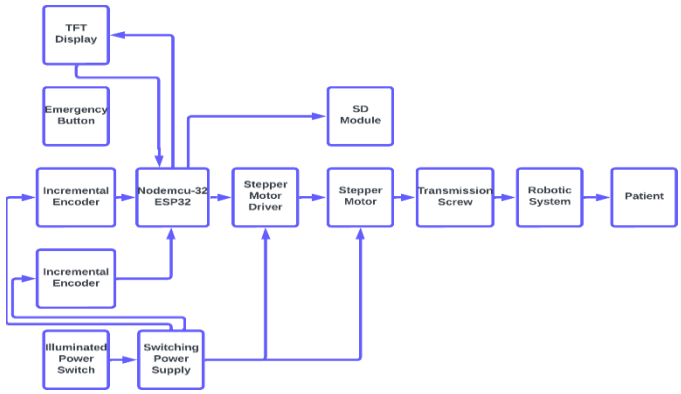

Fig. 6. Electronic circuit design in KiCad 7.0.

D. Simulation of the Electronic-Electrical Subsystem

Fig. 7 illustrates the user interface workflow of the robotic rehabilitation system, implemented using the Wokwi simulator for the ESP-32 microcontroller. The process is divided into three main stages: a) Initial parameter configuration, where the user sets the initial and final joint angles as well as the movement speed (Screens 1–4); b) Therapy type and repetition selection, allowing the user to choose between knee, ankle, or combined therapy modes, along with the desired number of repetitions (Screens 5–8); c) Therapy initiation with real-time monitoring, during which the system displays the progress of repetitions, movement direction, and provides visual feedback through servomotors that simulate joint behavior (Screens 9–10). Safety features include angular limit checks and emergency stops activated by user. This intuitive interface facilitates the customization of therapy according to the specific needs of the patient, while the monitoring system enables continuous tracking of progress throughout the rehabilitation session.

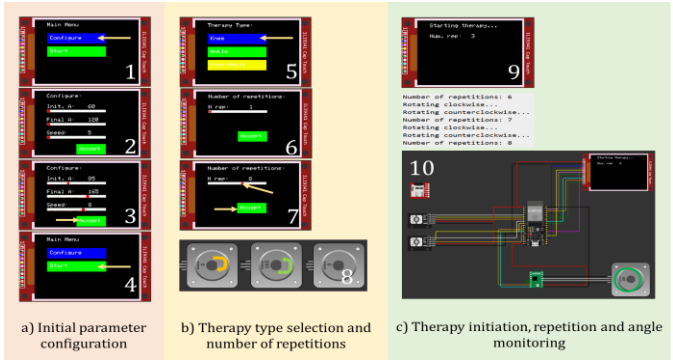

Fig. 7. User interface workflow of the robotic rehabilitation system.

E. Functional Simulation with a Virtual Patient

The model was transferred to the CoppeliaSim environment to simulate the use of the prototype with a virtual patient. For this purpose, a bed was designed and the system was integrated with the virtual patient in a fully supine position. Three rehabilitation modes were implemented: i) full knee extension and flexion, ii) full ankle extension and flexion, and iii) a combined sequence consisting of full knee extension, a three-second pause, full ankle extension and flexion, another three-second pause, and full knee flexion. These movements are illustrated in Fig. 8.

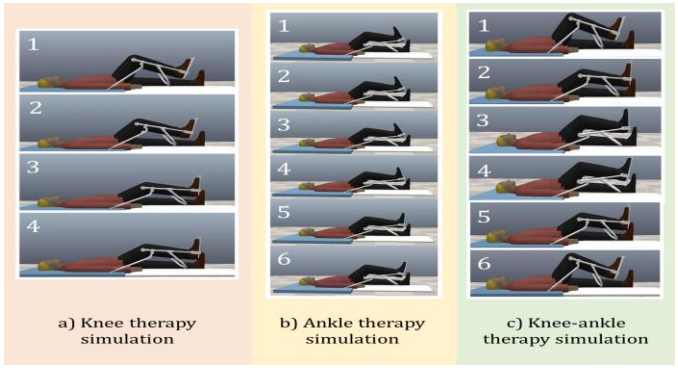

Fig. 8. Rehabilitation modes: a) Only knee therapy simulation. b) Only ankle therapy simulation. c) Knee and ankle therapy simulation.

Fig. 9 display the temporal evolution of joint angles during the rehabilitation therapy simulations in CoppeliaSim, using sinusoidal functions to model the movement of each joint according to the equation $\theta_i(t) = \theta_0 + A_i\sin(2\pi ft + \varphi)$, where $\theta_i(t)$ represents the joint angle, θ_0 the initial position, A_i the amplitude, f the frequency, and φ the phase. In the knee therapy [Fig. 9(a)], the hip oscillates between –50° and 0°, while the knee exhibits an inverse pattern ranging from 0° to 60°, reflecting the natural gait dynamics, and the ankle shows smaller variations between –10° and 0°. The ankle therapy [Fig. 9(b)] follows the equation $\theta_{ankle}(t) = \theta_{ankle,0} - A_{ankle}\sin(2\pi ft + \varphi)$, where the negative sign inverts the oscillation, reaching a minimum of –35° at 20 seconds and increasing to 5° at 70 seconds. The combined knee-ankle therapy (Fig. 10) implements a structured sequence that integrates both models with symmetry around the 150-second mark, beginning with knee therapy, transitioning to ankle therapy, and returning to the knee pattern. This sequencing allows for the distribution of effort across joints, reducing fatigue and optimizing treatment effectiveness through personalized protocols tailored to specific clinical needs.

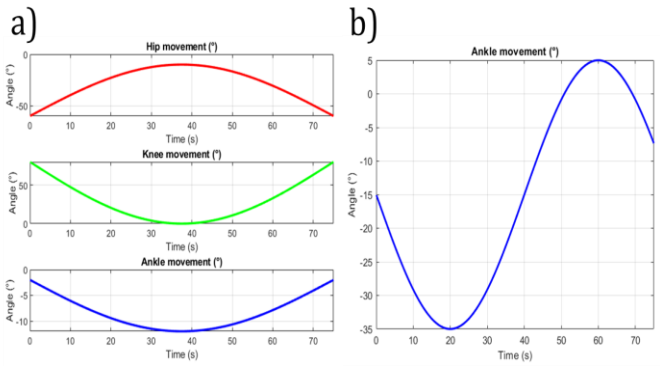

Fig. 9. Joint angles: a) Angles obtained for knee therapy. b) Angles obtained for ankle therapy.

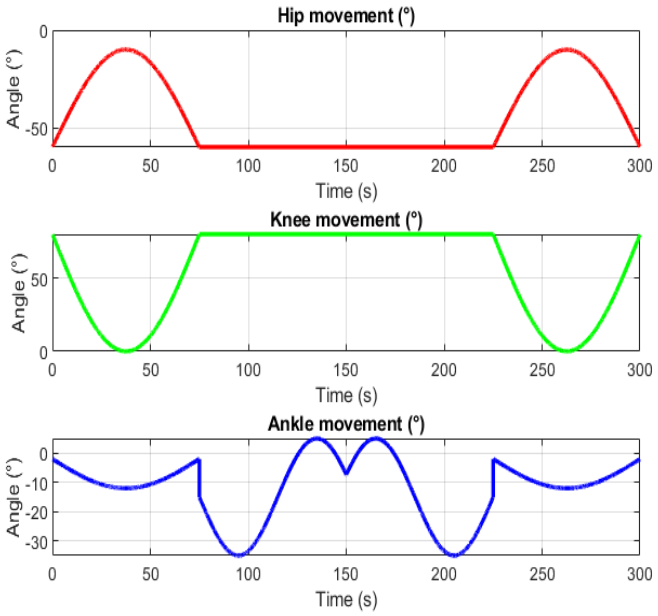

Fig. 10. Angles obtained for knee-ankle therapy.

IV. Experimental Study Approach

A. Data Collection Instruments

To ensure a comprehensive validation of the robotic rehabilitation system, three data collection instruments were implemented at the beginning of the research project. These instruments were specifically designed to assess both the technical requirements and clinical aspects of the lower-limb physical rehabilitation process. The primary data collection tool consisted of a checklist designed to record and monitor the technical and clinical requirements involved in lower-limb physical rehabilitation. This systematic approach ensured that all critical parameters were consistently tracked throughout the entire evaluation phase. Additionally, two specialized observation forms were developed to capture specific system parameters. The first observation form was designed to record the dimensions and maximum weight of the lower limb, as well as the maximum movement speed and torque, along with the response time of the user interface during system simulation. The second observation form focused on evaluating the functional capacity of the robotic system, with the aim of refining its technical specifications and the clinical parameters relevant to physical rehabilitation.

B. Pre-Test and Post-Test Validation

The clinical validation process incorporated both pre-test and post-test questionnaires administered to a specialist in physical rehabilitation, aiming to assess the effectiveness of the proposed system in a systematic and unbiased manner. In this regard, the results of the pre-test questionnaire indicated 100% acceptance across all three evaluated indicators. These results validate the requirements established in the project and simultaneously confirm their alignment with the expectations of the proposed design. Subsequently, following the demonstration and evaluation period, a post-test questionnaire was administered to assess the system's performance after direct observation. In this context, the results revealed 100% acceptance across all indicators within the three evaluated dimensions. Moreover, these findings were corroborated by the rehabilitation physician through the real-time observation of the simulation, thereby validating the effectiveness and functionality of the system in accordance with the requirements defined in the project. Finally, the comprehensive evaluation process demonstrates that the robotic rehabilitation system successfully meets both the technical specifications and the clinical expectations.

Limitations: It is important to acknowledge that the current validation was conducted through simulation using the Wokwi platform and expert consultation, rather than clinical trials with actual patients. While the system demonstrated technical feasibility and received positive feedback from rehabilitation specialists, comprehensive clinical validation with real patients is required to fully assess therapeutic efficacy, safety, and usability under real-world conditions. A clinical implementation phase is planned for 2025–2026 to address these aspects and gather empirical data on patient outcomes.

V. Discussion

The design of the robotic system aligns with previous research that highlights the importance of ergonomic and

functional design in rehabilitation devices. For example, Aguirre, J. et al. presented an exoskeleton designed in SolidWorks, emphasizing the importance of selecting appropriate materials and using advanced design techniques to ensure system effectiveness [14]. Similarly, Grijalva, C. developed the design and construction of a device based on Continuous Passive Motion (CPM), demonstrating the positive impact of this methodology on knee rehabilitation [35], [36]. Another relevant precedent is the work of Villanueva, J., who developed a device based on a six-bar mechanism with one degree of freedom (DOF). Through dimensional synthesis and the analysis of several conceptual designs, he was able to determine an optimal and detailed configuration that integrates key components for an efficient rehabilitation device [37]. However, unlikely these single-joint or single-modality approaches, the present system introduces a distinctive multi-modal capability through its three independent therapy modes (knee-only, ankle-only, and integrated knee-ankle exercises), enabling progressive rehabilitation protocols within a single device. These studies support the presented design and emphasize the importance of applying mechanical design and analysis methodologies to ensure that rehabilitation devices are functional, safe, and adapted to the user's specific needs.

With regard to the simulation component, this study validates its findings through the precedent set by Franco, B., who proposed an innovative design for a passive knee rehabilitation device with a focus on portability, targeting adult patients undergoing surgical interventions to restore joint functionality or those affected by CVA impacting the lower limb. Franco's work included a review of existing rehabilitation techniques and devices available on the market, and defined the geometric and kinematic conditions necessary to deliver effective, repetitive therapies that support recovery [38], [39]. Additionally, the study considers the research of Jie, H. et al., who emphasize the widespread use of rehabilitation training robots in the Asian market, particularly for lower-limb rehabilitation due to its critical role in human mobility. The authors propose an independently developed robot for ankle and knee rehabilitation and introduce a robot-to-robot connection mode, which represents a significant advancement in the customization and effectiveness of rehabilitation therapies [15]. The present system achieves integrated multi-joint coordination through a unified mechanical structure and synchronized control architecture, eliminating the need for robot-to-robot interfaces and reducing system complexity. Both studies underscore the importance of combining innovative design approaches with biomechanical simulation in order to validate functionality and ensure the effectiveness of rehabilitation devices for patients with reduced mobility. The present work extends beyond these precedents by implementing a comprehensive validation framework that integrates mechanical finite element analysis, kinematic simulation in CoppeliaSim, and electronic control verification in Wokwi.

The quantitative validation of the system performance was achieved through finite element analysis, kinematic simulation, and electronic programming verification. Structural integrity analysis revealed the U-shaped support component withstood 784 N loading with maximum Von Mises stress of 0.183 MPa and displacement of 1.0361 mm, yielding a safety factor of 1,129, while the main spindle-type support demonstrated superior performance with maximum stress of 30.33 MPa and displacement of 1.603×10^{-3} mm, resulting in a safety factor of 6.8. CoppeliaSim kinematic simulations validated the therapeutic motion profiles using sinusoidal functions $\theta_i(t) = \theta_0 + A_i\sin(2\pi ft + \varphi)$, with knee therapy achieving 60° oscillation amplitude (-50° to 0° hip, 0° to 60° knee) and ankle therapy demonstrating -35° to 5° range with position error <0.5°. The electronic subsystem programming, implemented through ESP-32 microcontroller with NEXTION display (800×480 resolution) and A4988 drivers (1/16 microstepping), achieved positioning accuracy of ±0.1125° and user interface response times <0.5 seconds, confirming the integration of mechanical design, motion control algorithms, and human-machine interface for effective rehabilitation therapy execution. Furthermore, the system's use of accessible, open-source simulation tools for validation, combined with low-cost hardware, establishes a replicable development methodology that lowers barriers to entry for resource-constrained rehabilitation research environments.

VI. Conclusion

In the development of this project, the mechanical, electronic, electrical, and software subsystems of the robotic lower-limb rehabilitation system were designed and evaluated. In addition, simulations were conducted to validate the performance of each subsystem, confirming their functionality and compliance with the established requirements. This work presents a comprehensive simulation-based approach to designing an integrated robotic rehabilitation system that addresses the gap between conventional therapy limitations and the need for accessible, patient-center lower-limb rehabilitation. The mechanical subsystem ensured the safe and stable operation of the robotic system, incorporating an adjustable design capable of performing three therapy modes: knee-only movements (flexion and extension), ankle-only movements (plantar flexion and dorsiflexion), and an integrated mode combining knee and ankle exercises. Mechanical simulations confirmed the appropriate material selection and the structural strength of the system under applied rehabilitation loads. The electronic and electrical subsystems were designed in an integrated manner to control the movements of the robotic system and ensure continuous power supply. Simulations conducted in Wokwi validated the precision and stability of the control system, as well as its ability to maintain uninterrupted operation during rehabilitation sessions. The software subsystem provided an intuitive user interface capable of configuring parameters in real-time, storing session data, and transmitting it for clinical analysis. The simulation of this subsystem demonstrated its efficiency in managing information and dynamically modifying therapeutic parameters.

Furthermore, the integration and validation of the system through simulations in MATLAB and CoppeliaSim allowed for the evaluation of its performance in rehabilitation exercises with a virtual patient, demonstrating its feasibility for supporting physical therapy. The primary contribution of this research lies in the holistic design and virtual validation of a multi-modal rehabilitation system that combines mechanical

adaptability, precise electronic control, and user-friendly software integration, validated through both engineering simulations and clinical expert evaluation.

It is concluded that the system has the potential to optimize patient recovery through precise, repetitive, and customizable therapies, thereby contributing significantly to quality of life. The clinical evaluation conducted by specialists in physical rehabilitation confirmed the usefulness of the robotic system, particularly for patients with spastic hemiplegia in the subacute and chronic phases of neurological sequelae. Moreover, the design facilitates self-administration in patients who retain cognitive function after a CVA, enhancing their autonomy during treatment. Specialists also highlighted the system's potential to optimize conventional therapy, especially in assisted mobilization, by automating parameters such as time, speed, and torque, thus reducing the physical burden on therapists. Accordingly, the robotic system offers significant advantages in terms of efficiency, reducing the physical strain on healthcare personnel while improving the quality and frequency of rehabilitation sessions. At the same time, it enables home-based therapy, enhancing accessibility and continuity of care. While its positive impact on reducing healthcare costs is evident, further studies are recommended to assess its effectiveness in real-world clinical settings.

However, several constraints must be acknowledged. First, this study relies entirely on simulation-based validation; the system has not yet been physically implemented or tested with real patients. Second, the clinical evaluation was conducted through expert consultation rather than controlled trials, limiting empirical evidence of therapeutic efficacy. Third, long-term durability, user acceptance, and cost-effectiveness in diverse healthcare settings remain to be investigated. Additionally, real-world deployment will face practical challenges including: ensuring regulatory compliance and safety certifications for medical devices, developing training protocols for healthcare personnel and patients, addressing potential technical failures during unsupervised home use, and adapting the system to diverse patient anthropometries and pathological conditions beyond the initially targeted spastic hemiplegia cases.

Despite these limitations, the scientific value of this work resides in its systematic integration of engineering design with clinical needs assessment, providing a validated framework for future physical prototyping. Practically, the system's modular design, home-use capability, and therapist workload reduction position it as a promising solution for scaling rehabilitation access in resource-constrained settings.

As future work, the physical implementation of the subsystems is projected for the 2025–2026 period, incorporating ergonomic, comfort, and safety considerations. Subsequently, the system will be validated in collaboration with physical rehabilitation physicians and an adult volunteer patient.

ACKNOWLEDGMENT

To the Vice-Rector for Research at the Ricardo Palma University for funding this research (ACU 0667-2024).

Improving Spam Detection with Feature Engineering and Adaptive Learning Approaches

Sadeem H. AlHomidan, Marwah M. Almasri, Shimaa A. Nagro
College of Computing and Informatics, Saudi Electronic University, Riyadh, Saudi Arabia

Abstract*—Spam email detection is a critical component of securing and maintaining reliable digital communication systems. This study explores the effectiveness of various machine learning algorithms in classifying spam, with an emphasis on enhancing accuracy and precision through systematic preprocessing, advanced feature engineering, and text preprocessing. Six models were evaluated: Logistic Regression, Support Vector Classifier, Multinomial Naïve Bayes, K-Nearest Neighbors, AdaBoost, and Bagging Classifier using a comprehensive preprocessing pipeline that included Term Frequency–Inverse Document Frequency vectorization, feature scaling, and the incorporation of engineered features such as character counts. Experimental results reveal that Multinomial Naïve Bayes consistently achieved the highest precision 1.00 and strong accuracy 0.979 when paired with feature scaling, while Logistic Regression delivered robust and stable performance across multiple configurations with precision exceeding 0.96, making it a reliable choice for real-world deployment. Although Support Vector Classifier and AdaBoost exhibited competitive baseline performance, Support Vector Classifier showed limitations when handling numeric features, whereas AdaBoost maintained consistent results across scenarios. These findings underscore the critical role of tailored preprocessing and ensemble learning in improving classification outcomes and highlight the comparative strengths of different algorithms in real-world spam detection. In particular, Multinomial Naïve Bayes proved highly effective for precision-critical tasks, while Logistic Regression emerged as a dependable solution for environments requiring consistent reliability. Overall, this work advances machine learning-based spam filtering by identifying models that successfully balance precision, adaptability, and computational efficiency.

Keywords*—Spam detection; machine learning; Multinomial Naïve Bayes; logistic regression; ensemble learning; text preprocessing; feature engineering

I. Introduction

Email remains one of the most widely used communication tools in both personal and professional contexts due to its speed, efficiency, and ability to handle large volumes of data. However, the exponential growth of email usage has been accompanied by an alarming rise in spam, unsolicited messages often used for phishing, malware distribution, and other cybercrimes. Spam not only clutters inboxes and reduces productivity but also undermines trust in email systems and introduces severe cybersecurity risks.

Early detection approaches, such as manual filtering and keyword-based rules, quickly became ineffective as spammers adopted evasion techniques like word obfuscation (e.g., “fr33” instead of “free”), embedding text in images, or mimicking legitimate content. These limitations underscored the need for adaptive, intelligent methods. Machine learning (ML) has since emerged as a powerful solution, as models can learn patterns from large labeled datasets and adapt to evolving spam strategies. Combined with natural language processing, ML enables the capture of deeper semantic patterns beyond simple keyword matching [1], [2]. Nevertheless, challenges persist, including scalability with massive email volumes, adaptability to new spam tactics, and the risks of false positives and false negatives, which either disrupt legitimate communication or expose users to malicious content [3].

Despite the progress in ML-based spam detection, several limitations remain. Conventional filters fail against modern spam tactics like obfuscation, ambiguous phrasing, or image-based content [4], [5]. While deep learning models such as BERT or GPT-based architectures represent the current state-of-the-art in text understanding, their deployment often requires substantial computational resources and large-scale training data, which may limit their practicality for lightweight or real-time spam filtering environments. In contrast, classical ML approaches remain highly competitive for short-text classification tasks—such as spam detection—especially when applied to small and medium-sized datasets, where deep learning models tend to overfit. Moreover, these lightweight models offer faster inference, lower memory requirements, and easier integration into existing email systems. Therefore, this study focuses on efficient, traditional ML models that balance accuracy, scalability, and real-world deployability without the computational overhead associated with deep learning.

This study develops and evaluates six ML models—Logistic Regression (LR), Support Vector Classifier (SVC), Multinomial Naive Bayes (MNB), K-Nearest Neighbors (KNN), AdaBoost, and Bagging—to improve spam detection performance over traditional methods. The contributions of this study are threefold:

Advancing spam detection research by comparing classical ML and ensemble methods, highlighting their strengths and weaknesses under different spam scenarios.

Demonstrating the impact of systematic preprocessing and feature engineering on improving classification outcomes and reducing errors.

Providing practical insights for real-world deployment, identifying models that combine accuracy, stability, and computational efficiency, thereby enhancing email system security and user trust.

The remainder of this study is organized as follows: Section II reviews related literature on spam detection and ML. Section III presents the dataset and describes the preprocessing and feature engineering techniques applied. Section IV outlines the methodology and experimental setup. Section V discusses the results and their implications. Finally, Section VI concludes the study and highlights directions for future work.

II. Literature Review

The evolution of spam detection has undergone a significant transformation over the past two decades. The literature is highlighting a clear progression from manual filtering approaches to advanced hybrid frameworks that integrate classical ML, ensemble learning, and contextual embeddings.

The earliest spam filtering solutions relied heavily on manually defined rules, blacklists, and simple keyword-matching techniques. These systems flagged messages based on predefined patterns or suspicious terms such as "win", "free", or "offer", often combined with header and metadata checks. While effective in early scenarios, such methods lacked adaptability. Attackers quickly learned to bypass these filters by using obfuscation, intentional misspellings, and paraphrased language. As a result, the limitations of manual and keyword-based approaches became evident, particularly in their inability to handle evolving spam tactics and large-scale data.

To overcome the rigidity of manual filters, the field shifted toward data-driven models capable of learning discriminative patterns directly from labeled datasets. Classical ML techniques, including MNB, LR, SVMs, Decision Trees, and KNN, became central to spam detection research [6]. Among them, LR has remained a fundamental baseline due to its probabilistic interpretation, simplicity, efficiency in handling high-dimensional text data, and competitive performance when paired with feature engineering techniques such as Term Frequency–Inverse Document Frequency (TF-IDF), n-grams, and regularization [7]. The study has demonstrated LR's effectiveness even against more complex models. For example, enhancements to LR through feature selection methods (e.g., chi-square, PCA, or recursive feature elimination) and optimized preprocessing pipelines have led to high accuracy and robustness on email and SMS spam datasets.

Despite their strong baseline performance, classical models often struggled with imbalanced datasets, noisy inputs, and non-linear decision boundaries. This led to the rise of ensemble techniques, such as bagging, boosting, and stacking, which combine the strengths of multiple classifiers to improve generalization and robustness. Recent research highlights the use of LR as a meta-learner in stacking frameworks, where predictions from base learners like NB, SVM, DT, and KNN are fed into LR to optimize final classification. These ensemble approaches consistently outperform individual models, achieving accuracy improvements of up to 5–10% over traditional baselines [8].

With the advent of deep learning, spam detection systems began leveraging neural networks capable of learning hierarchical text representations without manual feature engineering. Convolutional Neural Networks and Recurrent Neural Networks initially dominated the field [9], but Transformer-based architectures such as BERT, RoBERTa, and DistilBERT have since become state-of-the-art due to their ability to model contextual semantics and long-range dependencies. Comparative studies show that Transformer-based models significantly outperform traditional ML approaches, particularly in handling obfuscated, paraphrased, or multilingual spam.

Recent work addresses the growing threat of SMS spam—responsible for credential theft and data loss—by combining GPT-3-based text embeddings with ensemble learning for improved classification. This hybrid model significantly outperforms individual classifiers, achieving 99.91% accuracy on the SMS Spam Collection dataset. Such results highlight the effectiveness of integrating Transformer representations with ensemble techniques in modern spam detection [10].

Overall, the literature demonstrates a clear progression from manual filters to keyword-based systems, then to classical ML models, and finally toward ensembles and deep learning architectures. Current research emphasizes the importance of hybrid frameworks that combine classical ML, ensemble learning, and contextual embeddings to achieve both accuracy and adaptability. Nevertheless, balancing detection performance with scalability, robustness, and interpretability remains an ongoing challenge for real-world deployment of spam detection systems.

III. Dataset and Preprocessing

The primary dataset used in this study is the SMS Spam Collection Dataset, comprising 5,574 email messages labeled as either "spam" or "ham" (legitimate). The dataset is organized into two columns:

v1 – the label indicating whether the message is *spam* or *ham*.

v2 – the raw text content of the email message.

As indicated in [11], the spam subset includes 425 messages collected from the Grumble Text website, a UK-based forum where users report spam messages they have received. Since these reports often contained a mix of relevant and irrelevant text, the spam content had to be carefully extracted through extensive manual filtering.

The ham (legitimate) subset primarily comprises 3,375 messages sourced from the NUS Corpus, which was compiled from emails provided by students at the National University of Singapore for research purposes. An additional 450 ham messages were obtained from Caroline Tag's PhD thesis to further enrich the dataset.

Extended Corpus: To enhance dataset diversity and improve model generalization, the Spam Corpus v.0.1 Big was also integrated, contributing an additional 1,002 ham messages and 322 spam messages. This extended corpus has been widely used in prior academic research on spam detection.

This dataset was chosen for its diversity and representativeness, combining global and regional spam and ham messages. Such heterogeneity makes it particularly well-suited for training a robust and generalizable spam detection

system with strong coverage across various email types and sources.

A. Data Cleaning and Dimensionality Reduction

Since the primary objective of this study is to detect spam emails, the focus is placed only on features directly relevant to the classification task, such as the email content and subject line. Some features that can be extracted from raw emails, like the timestamp, unique server ID, routing information, or execution data from the server, do not contribute meaningfully to determining whether a message is spam. Including such irrelevant features may introduce noise, reduce model interpretability, and negatively affect performance.

Therefore, as part of the dimensionality reduction process, unnecessary columns were removed, as they provided no analytical value. This approach ensures that the employed model captures only the most informative features, thereby improving training efficiency and reducing the risk of overfitting.

Another essential part of data cleaning is addressing data redundancy. Duplicate records, such as emails with identical content, similar subjects, or those sent repeatedly from the same sender, can bias the model, leading to skewed results and overfitting.

Duplicate records are identified by comparing the similarity of message content, metadata fields, and header information. Emails that share substantial similarities or are exact replicas of others are flagged as duplicates. Once identified, duplicate emails are removed from the dataset to ensure that each data point contributes unique information. This step reduces bias, minimizes noise, and enhances the overall robustness and generalization capability of the spam detection model.

By eliminating irrelevant features and removing duplicates, the dataset becomes cleaner, more concise, and better structured, ultimately improving the model's performance and its ability to classify spam emails accurately. After this preprocessing step, the final dataset comprises 5,169 email messages.

B. Exploratory Data Analysis

The dataset contains 5,169 emails, including 4,516 ham (87%) and 653 spam (13%) messages, showing a clear class imbalance. This imbalance can significantly affect model performance, as a naïve classifier might predict only "ham" to achieve high accuracy, leading to poor spam detection. To address this issue, class weighting was applied during model training to give higher importance to the minority class (spam) and improve the detection performance.

While synthetic oversampling techniques such as SMOTE can be used to mitigate class imbalance, they were intentionally not applied in this study. Because the dataset consists of short text messages, generating synthetic samples may distort the natural linguistic distribution of spam content and introduce patterns that do not occur in real data. Moreover, oversampling can lead to overfitting, especially in small or medium-sized datasets such as this one. Therefore, class weighting was preferred as a more reliable approach that preserves the authenticity of the original messages while still improving minority-class detection.

Text length–based features, including character count, word count, and sentence count, provide valuable indicators for distinguishing spam from ham messages. Spam messages are generally longer, averaging around 137 characters compared to 70 characters for ham. A similar pattern is seen with word count, where spam messages contain about 28 words on average, while ham messages contain around 17. Spam also tends to include more sentences (about 3) compared to ham (1–2), reflecting their more detailed or promotional nature. Fig. 1 presents histograms of character and word counts, showing distinct distribution patterns, with ham messages generally exhibiting higher counts across features, while spam messages are more concentrated in lower ranges. This separation indicates that these features carry valuable discriminative information, making them effective indicators for distinguishing between spam and ham emails. Moreover, character count, word count, and sentence count are strongly positively correlated, as one increases, so do the others. While this interdependence enhances classification performance, it also introduces potential redundancy, suggesting the need for dimensionality reduction or selective feature use. Overall, these text length features significantly improve the model's ability to differentiate spam from legitimate messages.

C. Data Preprocessing

To prepare the email text for feature extraction and model training, several preprocessing steps were applied to transform the raw content into a clean, standardized format. These steps include:

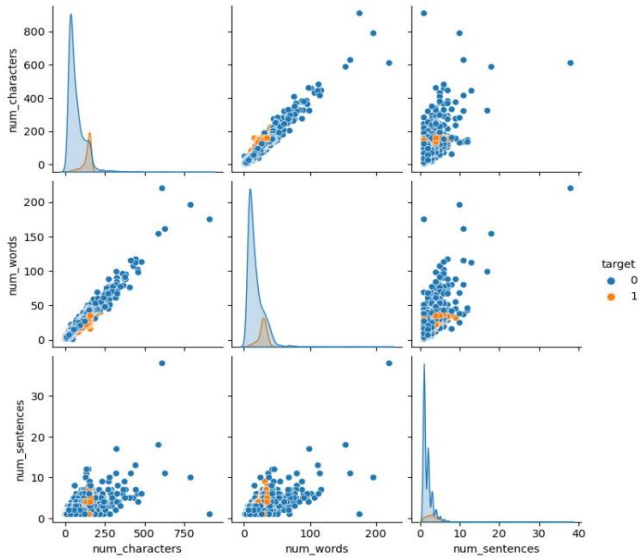

Fig. 1. Pairwise histograms of key textual features—character count, word count, and sentence count—for spam (1) and ham (0) messages. The diagonal panels show the distribution of each feature, while the off-diagonal scatter plots illustrate correlations between feature pairs, highlighting clear structural differences between spam and ham messages.

1) Lowercasing: All text was converted to lowercase to ensure uniformity (e.g., treating "Spam" and "spam" as the same word).

2) Tokenization: Text was split into individual tokens (words) for further analysis.

3) Removing special characters: Non-alphanumeric symbols, such as punctuation and special characters, were removed to reduce noise and focus on meaningful content.

4) Removing stop words: Common, less informative words (e.g., "the", "is", "and") were filtered out using a predefined English stop-word list.

5) Stemming: Words were reduced to their root form using the Porter Stemmer (e.g., "crying" → "cri", "loving" → "love") to group similar terms and minimize vocabulary size.

Text Vectorization and feature extraction: Text data must be converted into numerical form before it can be processed by ML models. Two commonly used techniques for this purpose are Bag of Words and TF-IDF. In this study, the TF-IDF vectorizer was used with a maximum of 3000 features to capture the most significant terms in the dataset. This transformation converted the cleaned email text into a numerical feature matrix with a shape of 5169, 3000, where 5169 represents the number of email samples and 3000 the most frequent terms considered. Limiting the vocabulary size reduces computational cost, mitigates overfitting, and ensures the model focuses on the most relevant features.

In addition to text-based features, three structural features were extracted to further enhance the model's predictive performance: number of characters, number of words, and number of sentences in each email. These features capture length and structural patterns that often differ between spam and ham messages, for example, spam messages typically contain more characters, words, and sentences. Combining these engineered features with TF-IDF representations strengthens the model's ability to accurately distinguish spam from legitimate emails.

Fig. 2 visualizes the most commonly occurring words in spam and ham messages. Spam emails (left) prominently feature marketing-related terms such as "free", "text", "win", and "claim", reflecting their promotional and persuasive intent. In contrast, ham messages (right) contain conversational words like "got", "come", "love", and "know", highlighting their informal and context-driven nature. The distinct lexical patterns shown here demonstrate how vocabulary distribution can help distinguish spam from legitimate messages.

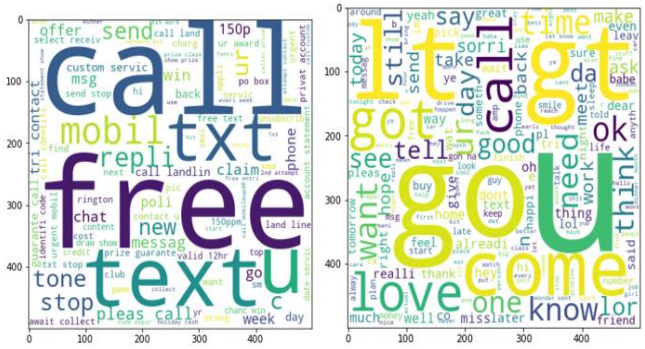

Fig. 2. Word clouds showing the most frequent terms in spam (left) and ham (right) messages. The spam cloud is dominated by promotional and action-oriented words such as "free", "call", "text", and "mobile", while the ham cloud features conversational terms are like "got", "you", "come", and "love". These contrasts highlight the distinct linguistic patterns that separate unsolicited messages from normal user communication.

IV. Methodology

Fig. 3 illustrates the complete workflow of the proposed spam detection system, beginning with the collection of email/SMS datasets. The data undergoes several preprocessing steps, including lowercasing, tokenization, removal of special characters and stop words, and stemming, to ensure text consistency and quality. Following preprocessing, various machine learning algorithms including LR, SVC, MNB, DBM, AdaBoost, and Bagging Classifier are initially trained and evaluated. Based on the evaluation results, feature extraction and engineering are then performed using the TF-IDF technique along with additional statistical features such as the number of characters, words, sentences, and links, with the vocabulary size set to 3000 features. Finally, the models are retrained and re-evaluated using the enhanced feature set to assess performance improvements.

A. Models' Building

Several models were trained on the training data using their default parameters, initially. After obtaining baseline results, models were fine-tuned to improve performance.

Logistic Regression is a Linear Model which predicts Probability of email being Spam given Input features. The decision boundary was found by applying this point classifier linear model to separate the two classes and give an interpretable and straightforward process for binary classification tasks.

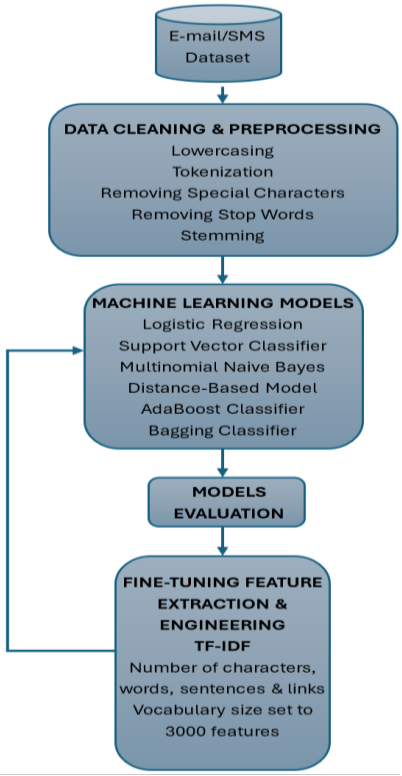

Fig. 3. Workflow of the proposed spam detection pipeline, illustrating the main stages from data collection and preprocessing to feature extraction, model training, and evaluation.

Support Vector Classifier (Tree Based Model) tries to classify between spam and ham email by finding the optimal hyperplane, essentially a high dimensional plane which gives us

the greatest separation for the classes. This model is good at discovering data distributions and works well for high dimensional data like text.

Multinomial Naive Bayes (Bayesian Model) is also applied, where the probability distribution of words in spam and ham emails is utilized. Owing to its simplicity, effectiveness, and ability to operate under the independence assumption between words, this model has become one of the standard approaches for text classification.

The Distance Based Model K-Nearest Neighbors classifies emails by the labels of the closest training samples. This is a non-parametric classification approach where decisions are made on the 'neighbors' of each email.

AdaBoost Classifier (Ensemble Method) comprises a combination of several weak classifiers like decision trees or linear models to make strong classifier. The improvement focus of this method is accuracy (addressing more emails than 80% of the emails are correctly classified).

And at last, the Bagging Classifier (Ensemble Method) trains a pool of models using a portion of the data, and then the number of predictions is summed up. The reason why this reduces overfitting is that, the model is able to generalize more and does well in new data.

The goal was to improve the accuracy and speed of this task through these diverse models by at least 80%.

B. *Models' Fine Tuning*

To enhance the performance of spam detection models, several new features were engineered to capture additional patterns:

1) Number of characters: Spam messages often have longer content, so the total character count was added as a numeric feature.

2) Number of links: Spam emails typically include multiple hyperlinks; counting them provides another useful indicator.

3) Presence of specific keywords: Binary features were created to capture the occurrence of common spam-related terms (e.g., "free", "win", "click here").

These engineered features enable the models to learn more complex patterns and improve classification accuracy.

Model evaluation was parameterized to compare the performance of various algorithms under different feature configurations, including limiting vocabulary size to 3000 features, applying data scaling, and incorporating character count. For each configuration, a DataFrame was generated to record metrics such as accuracy and precision, which were then compared across models. The results were merged into a single table to enable side-by-side performance comparison.

V. Results and Discussion

Model performance was primarily evaluated using accuracy, which measures the percentage of correctly classified spam and ham emails. However, given the class imbalance in the dataset, accuracy alone does not fully capture model effectiveness. Therefore, precision was also examined to assess how many emails predicted as spam were actually spam, a critical metric, since misclassifying legitimate emails as spam can significantly impact user experience.

Additionally, a confusion matrix was generated for NMB to analyze true positives, true negatives, false positives, and false negatives, providing deeper insight into classification errors and their nature. By comparing models across these metrics, the study aimed to identify a solution that balances performance, complexity, and practicality, ensuring an effective and reliable spam detection system.

Logistic Regression achieved strong baseline results with accuracy = 0.952 and precision = 0.940. Reducing TF-IDF features to 3000 improved both metrics (accuracy = 0.956, precision = 0.970) by focusing on the most informative terms. Feature scaling further boosted accuracy to 0.967 and slightly increased precision (0.964). Adding the *number of characters* feature slightly enhanced precision (0.971) without changing accuracy significantly. Overall, LR benefited most from feature reduction and additional feature engineering.

Support Vector Classifier performed strongly from the start (accuracy = 0.973, precision = 0.974), with only a slight improvement after feature reduction (accuracy = 0.975). Scaling slightly decreased precision (0.943) without affecting accuracy. Including the number of characters feature significantly reduced performance (precision dropped to 0.000), indicating that this feature is unsuitable for SVC. The best configuration was achieved with feature reduction and no additional features.

Multinomial Naive Bayes showed excellent results, achieving accuracy = 0.959 and a perfect precision = 1.000 at baseline. Feature reduction improved accuracy further (0.972) while maintaining perfect precision. Scaling raised accuracy to 0.979, though precision decreased slightly (0.946). Adding the number of characters feature reduced accuracy (0.940) but kept precision at 1.000. The confusion matrix, Fig. 4 confirmed its strength in classifying ham (TN = 896, FP = 0) but showed some false negatives (FN = 29). Overall, MNB offered the best trade-off between simplicity, precision, and performance.

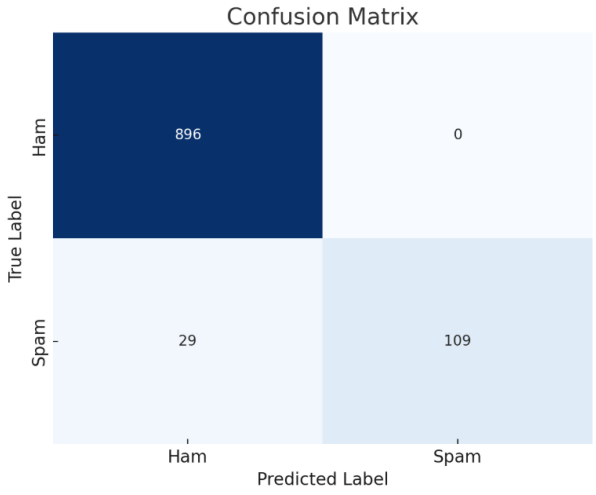

Fig. 4. Confusion matrix of the Multinomial Naive Bayes spam detection model, showing the distribution of correct and incorrect predictions across ham and spam classes.

This visualization clearly shows strong ham classification performance and highlights the small number of spam messages that were missed by the model.

K-Nearest Neighbors had a lower baseline accuracy (0.900) but perfect precision (1.000). Feature reduction slightly improved accuracy (0.905) while maintaining precision. Scaling further enhanced both metrics (accuracy = 0.905, precision = 0.976), reflecting the importance of normalization in distance-based models. Adding the number of characters feature improved accuracy (0.928) but reduced precision (0.771), suggesting added noise. The model performed best with feature reduction and scaling, but without additional features.

AdaBoost Classifier: AdaBoost delivered an accuracy = 0.962 and a precision = 0.954 at baseline. Feature reduction caused slight drops in performance (accuracy = 0.961, precision = 0.946), and scaling had minimal effect. Adding the number of characters feature enhanced both metrics (accuracy = 0.972, precision = 0.950), showing the feature's positive impact on ensemble performance.

Bagging Classifier: Bagging showed small improvements with feature reduction (accuracy = 0.959, precision = 0.869) and no significant changes after scaling. However, incorporating the number of characters feature substantially boosted performance (accuracy = 0.968, precision = 0.913), highlighting the feature's importance for this ensemble method.

The results presented in Table I demonstrate notable variations in model performance across different experimental settings. Overall, the SVC consistently achieved high performance, recording the highest accuracy of 0.975 and precision of 0.975 when the feature set was expanded to 3000, indicating its strong generalization capability with enriched feature representations. MNB achieved the highest overall accuracy of 0.979 under feature scaling, while KNN exhibited the best precision of 0.976 in the same setting, highlighting the sensitivity of these models to feature normalization. Furthermore, ensemble methods, particularly AdaBoost (0.972) and Bagging Classifier (0.968), outperformed others in the character-based feature setting, reflecting their robustness in handling feature diversity. LR also delivered competitive results, especially with a precision of 0.971 in the character-level configuration, but no single model dominated across all scenarios. These results support the hypothesis that the number of character features is particularly beneficial to ensemble methods such as Bagging and AdaBoost, whereas feature reduction (max feature) significantly enhances the performance of Naive Bayes and SVC models by improving their ability to capture essential features while reducing noise. Overall, these findings underscore the critical influence of feature engineering and preprocessing on model performance and suggest that the optimal choice of algorithm depends on the specific task requirements and prioritized evaluation metrics.

A significant class imbalance was observed in the dataset, with the number of ham messages greatly exceeding the number of spam messages. This imbalance posed a substantial challenge for the classifiers, as they tended to focus disproportionately on the majority class, making it difficult to accurately detect spam. As a result, performance metrics such as precision and accuracy can be somewhat misleading, as they may reflect high performance on ham messages while failing to capture deficiencies in spam detection. The impact of this imbalance varied across models. LR achieved 95.2% accuracy and 94.0% precision initially, but incorporating the number of characters feature improved its spam detection capability, demonstrating its capacity to learn from feature enhancements. SVC showed strong baseline performance (97.3% accuracy, 97.4% precision), but precision dropped to 0.0 when the number of characters feature was added, indicating a severe bias toward ham messages. MNB performed well, achieving perfect precision (1.0) and demonstrating robustness to imbalance, though it could still fail to identify some spam messages. KNN achieved 90% accuracy and perfect precision at baseline, but struggled with spam detection due to the skewed distribution. AdaBoost reached 96.2% accuracy and 95.4% precision but remained sensitive to class imbalance, excelling at classifying ham while struggling with spam. Bagging Classifier achieved 95.7% accuracy but only 86.2% precision, and even with resampling and the inclusion of a number of character features, spam detection remained challenging. Considering accuracy, interpretability, and robustness to imbalance, LR, SVC, and MNB emerge as the most suitable models. In real-world applications, these models could be deployed individually or combined into an ensemble to further enhance spam detection performance.

TABLE I. PERFORMANCE COMPARISON OF SIX MACHINE LEARNING MODELS

Models		***LR***	***SVC***	***MNB***	***KNN***	***AdaBoost Classifier***	***Bagging Classifier***
Base line	accuracy	0.952	0.973	0.959	0.900	0.962	0.957
	Precision	0.940	0.974	1.000	1.000	0.954	0.862
Max feature 3000	accuracy	0.956	**0.975**	0.972	0.905	0.961	0.959
	Precision	0.970	**0.975**	1.000	1.000	0.946	0.869
Scaling	accuracy	**0.967**	0.972	**0.979**	0.905	0.961	0.959
	Precision	0.964	0.943	0.946	**0.976**	0.946	0.869
Number of Characters	accuracy	0.961	0.867	0.940	**0.928**	**0.972**	**0.968**
	Precision	**0.971**	0.000	1.000	0.771	0.950	0.913

VI. Conclusion

This study demonstrated that spam detection performance depends heavily on dataset characteristics, feature engineering, and model selection, and that better feature representation and class-imbalance handling further improve accuracy and real-world reliability. The significant class imbalance between ham and spam messages posed a major challenge, often skewing results and reducing spam detection accuracy. Among the tested algorithms, SVC and MNB consistently achieved strong results, while ensemble methods like AdaBoost and Bagging showed robustness when additional features, such as number of characters features, were introduced. However, no single model outperformed across all scenarios, highlighting the importance of feature selection and data preprocessing in achieving balanced precision and accuracy.

Despite these contributions, this study has several limitations. The dataset is relatively small and exhibits a substantial class imbalance, which may affect the generalizability of the findings despite the use of class weighting. In addition, the analysis is limited to classical machine-learning models; while this choice supports efficiency and real-world deployability, it does not include transformer-based deep learning approaches that currently dominate state-of-the-art text classification. Finally, the feature set is constrained to textual and character-level attributes and does not incorporate metadata or multimodal information that could further enhance detection performance.

Future research should aim to improve model resilience against evolving spam tactics by integrating real-time detection capabilities and online learning approaches that continuously update with new spam patterns. Enhancing feature engineering — such as incorporating metadata (timestamps, sender behavior, and device information) could further strengthen classification performance. Additionally, exploring hybrid or ensemble approaches that combine the strengths of different algorithms may yield more robust and adaptive spam detection systems capable of maintaining high accuracy and precision in dynamic environments.

***Abstract*—For economically developed small geographic regions, population forecasting serves as a vital tool for achieving refined regional management. However, due to relying on the subjective experience of experts, traditional methods for predicting birth rates have shortcomings in accuracy, resulting in unreliable results. To address this limitation, this study introduces deep learning (DL) models into the domain of birth rate prediction. Specifically, a hybrid TCN-Bi-LSTM model is proposed, integrating a Temporal Convolutional Network (TCN) with a Bi-directional Long Short-Term Memory (Bi-LSTM) network to predict birth populations in small regions. The proposed hybrid model effectively leverages the strengths of the TCN and Bi-LSTM to capture both local temporal patterns and long-term hidden dependencies within birth rate time series data. The proposed birth rate prediction model not only incorporates historical data on regional birth rates but also accounts for the influence of factors such as divorce rates, consumption levels, and population size. Furthermore, an enhanced meta-heuristic algorithm is designed to optimize the hyperparameters of the hybrid TCN-Bi-LSTM model, with the aim of increasing its prediction accuracy. The hippopotamus position update strategy was introduced into the Newton-Raphson-Based Optimizer (NRBO), and an improved NRBO (INRBO) algorithm was developed. Finally, the performance of the proposed birth rate prediction model was validated using a dataset from three regions or countries. The prediction results demonstrate that, compared to the other four models, the proposed INRBO-TCN–Bi-LSTM model achieves the best performance, with an average reduction of 95% in training loss.**

Keywords*—Temporal Convolutional Network; Bi-directional Long Short-Term Memory; prediction model; birth rate; meta-heuristic algorithm

I. Introduction

For some economically developed small regions, the birth rate is of significant importance in assessing the fiscal sustainability of the social welfare system. At the same time, the number of births plays a crucial role in the rational allocation of public service resources such as education and healthcare [1]. As a result, predicting the birth population or birth rate has long been a major focus for demographers and policymakers. However, birth rates are easily influenced by factors such as economic growth, divorce rates, and regional population size, which pose challenges to the accuracy of birth rate prediction models [2]. An accurate birth rate prediction model can provide a decision-making basis for the formulation of social welfare, healthcare, and education policies. Traditional population forecasting models often rely heavily on the expertise of demographers, which can lead to limitations in accuracy. With advances in deep learning (DL) and machine learning (ML), recent studies have begun to apply DL and ML models to population prediction and birth rate forecasting tasks [3].

Predicting birth rates is a classic time series forecasting problem. The most popular solutions for solving such problems currently are prediction models based on Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN), such as the classic TCN [4] and Long Short-Term Memory (LSTM) networks [5]. The TCN and LSTM networks are capable of capturing local information and hidden information of the long-term dimension in time series data, respectively. However, current deep learning-based birth rate prediction models still rely on manual hyperparameter tuning to improve their accuracy. To address this issue, Huang et al. employed the particle swarm optimization (PSO) algorithm to optimize the hyperparameters of the CNN, with the goal of identifying the optimal hyperparameter configuration for the CNN model [6]. Although CNN and LSTM networks have been widely applied in various prediction problems, DL based birth rate prediction models face the following challenges:

- Birth rate data has obvious low-frequency characteristics and scarcity, and the available sample size is very limited, which is a huge challenge for DL models that require a large amount of data for training.
- There are scale differences and multicollinearity among multiple socio-economic indicators, such as economic growth rate, divorce rate, and population size within the region, which pose difficulties for feature fusion.
- TCN is extremely sensitive to hyperparameters, and the birth rate is strongly influenced by sudden external factors such as policy adjustments and major events. These factors make accurate prediction of birth rates difficult.

To solve the above problems, this study proposes an INBRO-TCN-Bi-LSTM model. The proposed model leverages both TCN and Bi-LSTM architectures to extract different types of key features from birth rate-related time series data. Liao et

al. used the output of TCN as the input of LSTM and designed CNN-LSTM for predicting earthquake probability [7]. Differently, the proposed hybrid model employs the output of the Bi-LSTM, carrying rich contextual information, as an enhanced feature input to the fully connected layer of the TCN. This enables the prediction model to incorporate not only the local patterns extracted through TCN convolution but also the long-term bidirectional dependencies captured by the Bi-LSTM. Furthermore, to enhance the prediction accuracy, an improved metaheuristic algorithm was applied to optimize both the hyperparameters and the structure of the TCN-Bi-LSTM model. The overall architecture of the proposed model is illustrated in Fig. 1. The main contributions of this study are summarized as follows:

- A birth rate prediction model based on TCN and Bi-LSTM was proposed. The input of the proposed birth rate model includes not only historical birth rate data but also various socioeconomic indicators such as consumption level, divorce rate, and total population, with the aim of capturing the complex factors influencing birth rates.
- The feature vector of the birth rate prediction results output by the Bi-LSTM network is used as an enhanced feature input to the TCN fully connected layer. This integration enables the birth rate to better understand the relationship between changes in socio-economic indicators and birth rates.
- The hippopotamus position update strategy has been introduced into the NRBO algorithm, and an improved NRBO (INRBO) algorithm has been designed to optimize the hyperparameters of TCN and Bi-LSTM models.
- Finally, the INRBO-TCN-Bi-LSTM model was validated using birth rate datasets from Singapore, Macau, and Luxembourg. The experimental results show that compared with the other four population prediction models, the proposed model reduces the training loss by an average of 95%.

The remaining content of this study is arranged as follows: In Section II of the manuscript, work related to birth rate prediction is reviewed. Section III introduces the proposed INBRO-TCN-Bi-LSTM model. Section IV presents the application results of the proposed model in the problem of birth rate prediction. Finally, Section V summarizes the entire text.

II. Related Work

A. The Prediction Models Based on Deep Learning

For learning based birth rate prediction methods, some studies have explored the application of LSTM in birth rate prediction problems. Alemayehu et al. used a DL model to predict the birth rate trend in Ethiopia [8]. This study is based on population data from Ethiopia from 2000 to 2019, and evaluates the applicability of these methods in the field of birth population prediction by comparing the predictive performance of different models. Tzitirididou-Chatzopoulou et al. conducted research on birth rate prediction in Scotland and designed an adaptive machine learning algorithm [9]. The adaptive birth rate prediction framework developed in this study can continuously optimize prediction accuracy by dynamically adjusting model parameters, thereby capturing subtle changes in socio-economic and environmental factors and the complex relationship between reproductive behaviors.

In response to the challenges of large errors and slow inference speed in traditional autoregressive models, Weber et al. developed an improved RNN architecture for multi-output prediction tasks of unmanned aerial vehicle angular velocity. The improved RNN framework has a dual-layer prediction structure, and experimental results show that the dual-layer prediction structure effectively improves the accuracy of UAV flight attitude prediction [10]. Regarding the dynamic frequency prediction problem in wireless communication networks, Zhang et al. designed a hybrid RNN model based on Graph Convolutional Network (GCN), RNN, and attention mechanism [11]. Unlike classical RNN models, the hybrid

RNN models utilize GCN to capture correlations between predicted objects and dynamically adjust the weights of output hidden states through attention mechanisms. Finally, this study validated the improved hybrid RNN architecture based on real wireless communication spectrum prediction tasks. Ghazi et al. proposed an autoregressive RNN model for predicting time series with irregular time intervals. The improved RNN model introduces an adaptive time embedding architecture, which enables accurate prediction of irregular time interval data [12].

Outliers have a significant impact on traditional RNN prediction frameworks, and the occurrence of outliers in birth rates due to policy adjustments or unexpected events can lead to a decrease in the accuracy of RNN prediction results. Therefore, improving the prediction accuracy of RNN models is a new problem faced by learning-based birth rate prediction models. Kim et al. proposed a prediction framework based on an improved RNN by integrating RNN and statistical methods [13]. The results indicate that the framework effectively reduces the interference of outliers on prediction accuracy by integrating robust statistical methods with LSTM networks. In [14], the authors proposed a reinforcement learning based RNN architecture and successfully applied it to the problem of predicting public opinion information diffusion. The experimental results show that compared with traditional RNN frameworks, the reinforcement learning based RNN architecture has higher accuracy in predicting explosive propagation events. In [15], the authors used Bi-LSTM for predicting the remaining life of aircraft engines. This study effectively fused the forward and backward temporal features of sensor data by stacking a Bi-LSTM and introducing a Gate Recurrent Unit (GRU). The experimental results indicate that the proposed prediction framework is more robust in handling high-dimensional, noisy sensor data. In [16], the authors apply the RNN model to user behavior analysis tasks and verify the potential of RNN in user behavior analysis.

In recent years, with the advancement of deep learning technology, the practical applications of CNN in fields such as healthcare, industry, and biology have been expanded. For example, Yousif et al. proposed a quantum CNN (QCNN) framework for medical image classification tasks, aiming to solve the problem of long training time for traditional CNNs in medical image processing tasks [17]. This study designed an improved strategy based on quantum superposition and entanglement characteristics. The experimental results showed that the improved strategy improved the feature extraction efficiency of the traditional CNN and reduced the training time of the model. In addition, Chen et al. proposed an improved multimodal fusion CNN framework for mechanical fault diagnosis based on multi-source sensor data [18]. This improved framework can dynamically adjust the weights of different modalities, aiming to alleviate the modal conflict problem caused by traditional hard label training. In [19], the authors combine deep learning techniques with time series discretization techniques to address the challenge of manually labeling a large number of classification features in traditional classification tasks.

In [20], the authors also designed a machine learning prediction framework aimed at using interpretable machine learning methods to predict financial risks of enterprises. In [21], the authors propose a hybrid optimization method combining machine learning and swarm intelligence algorithms for antenna design problems. In this study, machine learning models were used to learn the features of the search space and predict the potential positions of candidate solutions, thereby guiding swarm intelligence optimization algorithms to converge faster to the target area and solving antenna optimization problems containing continuous variables.

B. Meta-Heuristic Optimization Algorithm

As an important technology in the field of intelligent computing, metaheuristic optimization algorithms are applied to solve problems such as robot allocation, antenna design, delivery path planning, and hyperparameter optimization of machine learning models. Akopov designed an improved genetic algorithm (GA) aimed at solving optimization problems in trade interaction problems [22]. Bouali and Alamri conducted research on the modeling problem of photovoltaic systems, aiming to extract the parameters of diodes in photovoltaic cells based on flood algorithms [23]. In [24], the authors designed a starfish optimization algorithm (SFOA) to solve the symmetric traveling salesman problem (TSP). In this study, a discrete SFOA algorithm was designed by defining continuous operators for starfish movement, foraging, and reproduction, providing a new and effective metaheuristic method for solving TSP.

Abdulaziz et al. designed optimization algorithms for collaborative optimization of smart grids to optimize the configuration of components such as electric vehicles (EVs) and distributed static synchronous compensators. In this study, the Hippopotamus Optimization (HO) Algorithm was used to optimize the configuration of these components, aiming to improve the energy efficiency, voltage stability, and economic efficiency of the power grid operation [25]. In [26], the authors propose a novel metaheuristic algorithm, Newton-Raphson-Based Optimizer (NRBO), and the performance of the NRBO algorithm was validated on a standardized optimization test set. Overall, the above research provides a foundation for optimizing the hyperparameters of the TCN-Bi-LSTM model using metaheuristic algorithms.

III. Proposed System Overview

Fig. 1 shows the architecture of the proposed hybrid TCN-Bi-LSTM model. The proposed framework takes the historical data of the population born in the region, consumption level, divorce rate, and total population as input features for the mixed TCN-Bi-LSTM model. The historical birth rate within the region is the core time series data and the basic data for birth rate prediction. The consumption level within a region represents the economic situation within the region, and this indicator is usually related to the ability and willingness of families to raise children. The divorce rate represents the stability of the family structure and is one of the important social factors affecting family fertility decisions. The total population provides macro demographic background data.

During the training process of the hybrid TCN-Bi-LSTM model, the input data is simultaneously fed into two parallel neural network modules. Among them, the TCN module uses a series of causal convolutions and dilation convolutions to

efficiently capture local feature patterns and long-term trends in time series. The bidirectional structure of the Bi-LSTM module enables it to fully understand the meaning of each time point in its complete context, thereby capturing long-term dependencies. After obtaining the outputs of TCN and Bi-LSTM, the proposed framework concatenates the output feature vectors V_{TCN} and $V_{Bi-LSTM}$ of TCN and Bi-LSTM at the feature fusion layer. The fused joint feature vector $V_{all,output}$ is fed into multiple fully connected layers to learn the nonlinear relationship between TCN features and Bi-LSTM features, and ultimately mapped to the birth rate prediction target.

A. The TCN-Bi-LSTM Framework

The residual blocks of the TCN model can improve the training efficiency of TCN. In this study, the residual block of the TCN model used Parametric Rectified Linear Unit (PReLU) as the activation function, aiming to improve the prediction accuracy and expressive ability of the TCN model. The definition of the PReLU activation function is as follows [Eq. (1)]:

$$PReLU(x)=\begin{cases} x, & if \quad x\geq 0 \\ a\times x, & if \quad x<0 \end{cases} \tag{1}$$

where, a is the slope on the negative interval. x is the input value.

The proposed hybrid TCN-Bi-LSTM model requires multi-layer convolution operations of the TCN module on the input during the training process. The output of the last convolutional layer of the TCN module in the birth rate prediction model is a sequence V_{TCN}. The definition of sequence V_{TCN} is as follows [Eq. (2)]:

$$\begin{aligned} V_{TCN} &= f_{TCN_Conv}(\vec{x}) \\ &= PReLU(DilatedCasual_Conv(\vec{x}_{t-1})+\vec{d})+\vec{x}_t \end{aligned} \tag{2}$$

where, $\vec{x}_t$ is the input variable sequence of time step t. $DilatedCasual_Conv(\cdot)$ is a dilated and causal convolution calculation operation that relies on historical data related to birth rates. $\vec{d}$ is the output layer bias.

In Eq. (3), expansion and causal convolution calculation operations are defined.

$$DilatedCasual_Conv(\vec{x}_{t-1})=\sum_{p} w_p \times \vec{x}_{t-\alpha} \tag{3}$$

where, $\{w_p, \forall p \in P\}$ is a filter. P is the filter size. α is a constant.

In the Bi-LSTM module, the input vector is processed by both forward LSTM and backward LSTM simultaneously. After processing the entire input time series, the last hidden state Vh_t of the forward LSTM and the last hidden state Vh_t' of the backward LSTM are generated. The definitions of hidden states Vh_t and Vh_t' are as follows [Eq. (4) and Eq. (5)]:

$$Vh_t = Q_t \odot tanh(L_t) \tag{4}$$

$$Vh_t' = Q_t' \odot tanh(L_t') \tag{5}$$

where, L_t and L_t' are the cell states of forward LSTM and backward LSTM at the t-th time step, respectively. Q_t and Q_t' are the output vectors of the forward LSTM and backward LSTM at the output gate, respectively.

After the input vector is processed through multiple layers of residual blocks and convolutional blocks, the output of the last time step is generated by the TCN module, and a feature vector V_{TCN} that combines local and long-term trends is obtained. For the Bi-LSTM module, the feature vectors Vh_t and Vh_t' of the hidden state of the forward LSTM and backward LSTM are generated at the last time step, respectively. The final output vector $V_{Bi-LSTM}$ of Bi-LSTM is obtained by concatenating two hidden states Vh_t and Vh_t'. The output vector $V_{Bi-LSTM}$ includes the complete bidirectional contextual information of the input sequence.

Fig. 2 shows the structure of the feature fusion layer designed in this study. In the feature fusion layer, the output vector V_{TCN} of the TCN module and the output vector $V_{Bi-LSTM}$ of the Bi-LSTM module are concatenated along the feature dimension of vector V_{TCN} to generate a more informative joint feature vector $V_{all,output}$. The definition of $V_{all,output}$ is as follows [Eq. (6)]:

$$V_{all,output} = Concatenate([V_{TCN}, V_{Bi-LSTM}]) \tag{6}$$

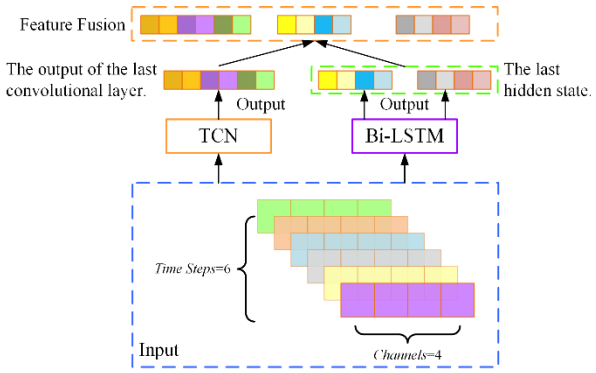

Fig. 2. The structure of the feature vector fusion layer.

After the joint feature vector $V_{all,output}$ is generated in the feature fusion layer, $V_{all,output}$ is input into the fully connected layer of the TCN-Bi-LSTM model to weight and combine all the features in $V_{all,output}$, and calculate the final predicted birth rate. The calculation method for the fully connected layer of TCN-Bi-LSTM is defined in Eq. (7):

$$\hat{y}_{PeoRate} = \sigma\left(w' \times V_{all,output} + d'\right) \tag{7}$$

where, w' is the weight matrix of the fully connected layer. d' is the bias vector of the fully connected layer. $\sigma(\cdot)$ is the

activation function. $\hat{y}_{PeoRate}$ is the output variable of the proposed TCN-Bi-LSTM model.

To demonstrate the performance of the designed hybrid TCN-Bi-LSTM framework, the loss function L_{Loss_F} of the TCN-Bi-LSTM model is defined as follows [Eq. (8)]:

$$L_{Loss_F} = \alpha \cdot \frac{1}{G}\sum_{g=1}^{G}\left(y_g - \hat{y}_g\right)^2 + \beta \cdot \frac{1}{G-1}\sum_{g=1}^{G-1}\left(\hat{y}_{g+1} - \hat{y}_g\right)^2 \quad (8)$$

where, α and β are weight coefficients. G is the size of the test set, $\forall g \in G$. y_g is the true value, $\hat{y}_g$ is the predicted value.

In addition, Root Mean Square Error (RMSE) is also used to evaluate the performance of the proposed hybrid TCN-Bi-LSTM model. The definition of RMSE is as follows [Eq. (9)]:

$$\mathrm{RMSE} = \sqrt{\frac{1}{G}\sum_{g=1}^{G}\left(y_g - \hat{y}_g\right)^2} \quad (9)$$

B. The Improved NRBO (INRBO) Algorithm

Based on the work [26], the hyperparameter optimization module designed in this study using the INRBO algorithm is as follows.

1) Initialize the population: In the initialization stage of INRBO, the convolution kernel size, expansion factor, number of residual blocks, regularization parameters, and initial learning rate of TCN and Bi-LSTM are mapped to the decision vectors of the INRBO algorithm. Further, generate a decision matrix based on the population size $I_{\max}$. Fig. 3 shows the mapping relationship between the hyperparameters of TCN and Bi-LSTM and decision vectors, as well as decision matrices.

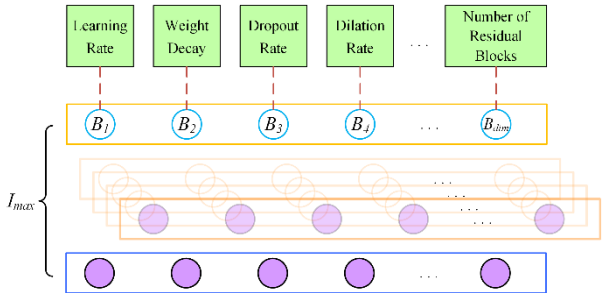

Fig. 3. The mapping relationship between the hyperparameters of TCN and Bi-LSTM and decision vectors.

The decision matrix DM_INRBO is defined in Eq. (10):

$$DM_INRBO = \begin{bmatrix} B_1^1 & B_2^1 & \cdots & B_{\dim}^1 \\ B_1^2 & B_2^2 & \cdots & B_{\dim}^2 \\ \vdots & \vdots & \vdots & \vdots \\ B_1^{I_{\max}} & B_2^{I_{\max}} & \cdots & B_{\dim}^{I_{\max}} \end{bmatrix} \quad (10)$$

where, B_j^i is the decision vector. dim is the dimension of the vector. $I_{\max}$ is the size of the population.

2) Calculate the value of the objective function: Calculate the objective function for each individual based on the decision matrix DM_INRBO in each iteration. The INRBO algorithm proposed in this study aims to optimize the parameters of TCN and LSTM, so the objective function f_{INRBO} is mainly determined by the accuracy of prediction. In this study, the objective function is composed of two parts, the loss function L_{Loss_F} and the RMSE, which are defined as follows [Eq. (11)]:

$$f_{INRBO} = \lambda_1 \times \mathrm{RMSE} + \lambda_2 \times L_{Loss_F} \quad (11)$$

where, λ_1 and λ_2 are weight coefficients, respectively.

3) Newton-Raphson search strategy: In the process of updating the decision matrix in INRBO, the position of the optimal solution is also updated. Therefore, each iteration of INRBO generates a new set of hyperparameters for TCN and Bi-LSTM. The process of updating the INRBO decision matrix is as follows. Firstly, generate a random number H within the [-1,1] interval. If $H > 0$, execute the Newton-Raphson search strategy. The definition of Newton-Raphson search strategy is as follows [Eq. (12)]:

$$B_j^i_new = B_j^i - \phi \times \left(B1_j^i - B2_j^i\right) \quad (12)$$

where, $B_j^i_new$ is the updated decision variable. $B1_j^i$ and $B2_j^i$ are the decision variables for the optimal and suboptimal solutions generated during the current iteration process, respectively. ϕ is the Newton-Raphson search coefficients.

4) Hippopotamus foraging search strategy: If $H \le 0$, execute the hippopotamus foraging search strategy. The definition of the hippopotamus foraging search strategy is as follows [Eq. (13)]:

$$B_j^i_new = B_j^i + rand \times \left|B_rand_j^i - B_j^i\right| \quad (13)$$

where, $rand$ is a random number on the [0,1] interval. $B_rand_j^i$ is a decision variable randomly selected from the decision matrix.

IV. Results and Discussion

In order to evaluate the application effectiveness of the proposed INRBO-based hybrid TCN-Bi-LSTM (INRBO-TCN-Bi-LSTM) framework of birth rate prediction in a small area, the proposed INRBO-TCN-Bi-LSTM framework was validated based on historical data from three countries or regions: Singapore, Macau, and Luxembourg. Fig. 4 displays historical data on birth rates in Singapore, Macau, and Luxembourg. To demonstrate the benefits of the INRBO-TCN-Bi-LSTM framework in predicting birth rates, the TCN-Bi-LSTM model, TCN model, Bi-LSTM model, and GRU model were trained separately to compare with the INRBO-TCN-Bi-LSTM model. Table I shows the relevant parameters of the above models during the training process [27]-[28]. A training set was generated using birth rate data from Singapore, Macau, and Luxembourg for the period 1959 to 2011. Three test sets

were formed based on birth rate data from Singapore, Macau, and Luxembourg from 2012 to 2023, and each test set was tested separately to validate the performance of the birth rate prediction model. In [29], the authors proposed using a Monte Carlo-based machine learning model to predict birth rates and evaluated the model based on the difference between the predicted birth rate values and the true values. Differently, in this study, RMSE, sum of squared errors (SSE), mean squared error (MSE), and mean absolute percentage error (MAPE) were used to evaluate the birth rate prediction model.

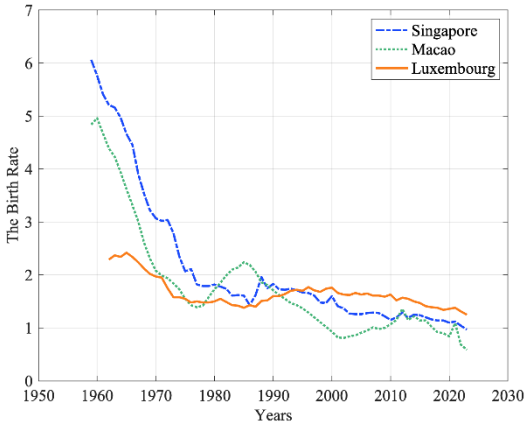

Fig. 4. The historical data on birth rates in Singapore, Macau, and Luxembourg.

TABLE I. TRAINING PARAMETERS FOR BIRTH RATE PREDICTION MODELS

Parameter	Value
Training Epochs	50
Batch Size	30
Time Steps	6
Features	4

In addition, to demonstrate the optimization effect of INBRO on the hyperparameters of the TCN-Bi-LSTM framework, GA [22], SFOA [24], HO [25], and NRBO [26] algorithms were compared with the INRBO algorithm. Table II shows the fitness function values for optimizing the TCN-Bi-LSTM framework using different metaheuristic algorithms.

TABLE II. THE FITNESS FUNCTION VALUES OF DIFFERENT METAHEURISTIC ALGORITHMS

Algorithm	Population Size	Individual Dimension	Fitness Function
GA	70	5	0.0536
SFOA	70	5	0.0497
HO	70	5	0.0517
NRBO	70	5	0.0451
INRBO	70	5	0.0433

From Table II, it can be seen that the fitness function value corresponding to INRBO in optimizing the TCN-Bi-LSTM model is 0.0433. Compared with GA, SFOA, HO, and NRBO algorithms, INRBO has the smallest fitness function value. This indicates that the hippopotamus serving search strategy effectively improves the convergence accuracy of the NRBO algorithm.

To demonstrate the robustness of the proposed birth rate prediction model, the INRBO-TCN-Bi-LSTM model, TCN-Bi-LSTM model, TCN model, Bi-LSTM model, and GRU model were independently trained 15 times, with each training session lasting 50 epochs. Fig. 5 shows the loss function curves of different birth rate prediction models. Table III shows the training losses of different birth rate prediction models.

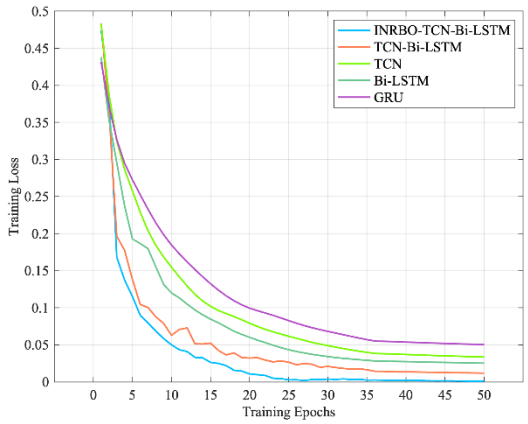

Fig. 5. The loss function curves of different birth rate prediction models.

TABLE III. THE TRAINING LOSSES OF DIFFERENT BIRTH RATE PREDICTION MODELS

Predictive Model	Training Epochs	Training Loss
INRBO-TCN-Bi-LSTM	50	0.001149
TCN-Bi-LSTM	50	0.011808
TCN	50	0.033568
Bi-LSTM	50	0.025266
GRU	50	0.050274

From Table III, it can be seen that the GRU model has the highest training loss, indicating that GRU has the weakest ability to capture temporal dependencies in birth rate prediction problems. TCN and Bi-LSTM, as more complex structures, perform better than GRU models. The training loss of the TCN-Bi-LSTM model is 0.011808, which is one order of magnitude lower than the classical TCN and Bi-LSTM models. The training loss of the INRBO-TCN-Bi-LSTM model is 0.001149, which is one order of magnitude lower than the second-ranked TCN-Bi-LSTM model and outperforms all other models. Therefore, the INRBO algorithm effectively optimized the parameters of the TCN-Bi-LSTM hybrid model during the training process. In summary, compared to the TCN-Bi-LSTM model, INRBO-TCN-Bi-LSTM reduces training loss by 90.3%. Compared to the GRU model, the training loss of INRBO-TCN-Bi-LSTM has been reduced by approximately 97.7%.

Fig. 6 shows the birth rate prediction results of the INRBO-TCN-Bi-LSTM model. Fig. 7 shows the birth rate prediction results of the TCN model. Fig. 8 shows the birth rate prediction results of the Bi-LSTM model. Table IV shows the RMSE,

SSE, MSE, and MAPE indicators of different birth rate prediction models. Fig. 9 shows the MAPE indicators of different birth rate prediction models in three tests. In addition, Table V shows the birth rate prediction values of INRBO-TCN-Bi-LSTM. Table VI shows the birth rate prediction values of TCN model. Table VII shows the birth rate prediction values of Bi-LSTM mode.

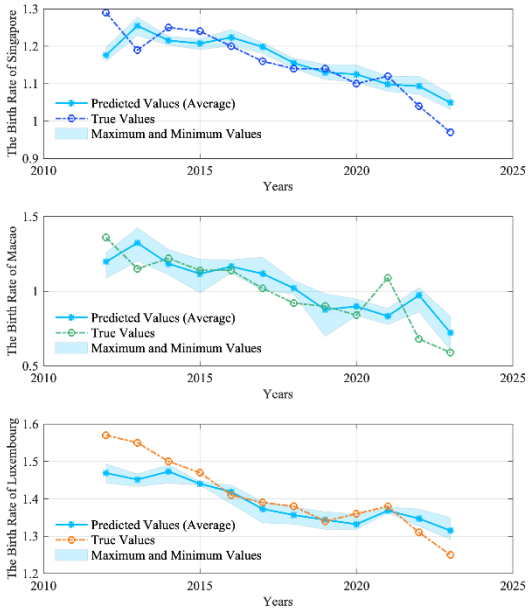

Fig. 6. The birth rate prediction results of the INRBO-TCN-Bi-LSTM model.

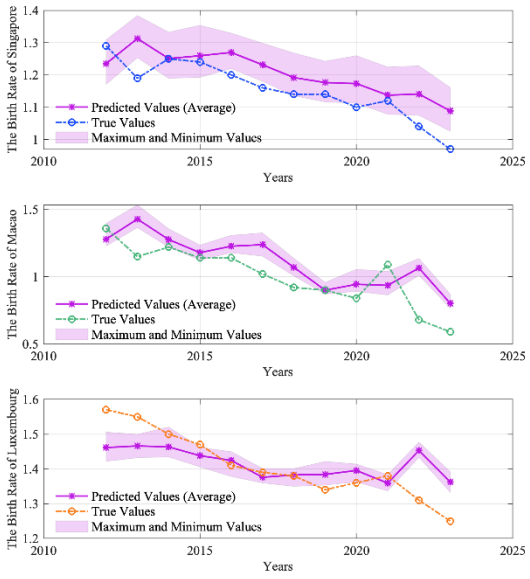

Fig. 7. The birth rate prediction results of the TCN model.

From Table IV, it can be seen that in the three tests, compared with the other four models, the INRBO-TCN-Bi-LSTM model performed the best in the RMSE metric, while the classical GRU model performed the worst. When predicting Singapore's birth rate, the INRBO-TCN-Bi-LSTM model has the lowest RMSE of 0.0722 and MAPE of 5.47%. Compared with the other four models, the INBRO-TCN-RNN model achieved the highest prediction accuracy. In addition, compared with the RMSE index of the TCN-Bi-LSTM model, the RMSE of the INRBO-TCN-Bi-LSTM model decreased by 15.56%.

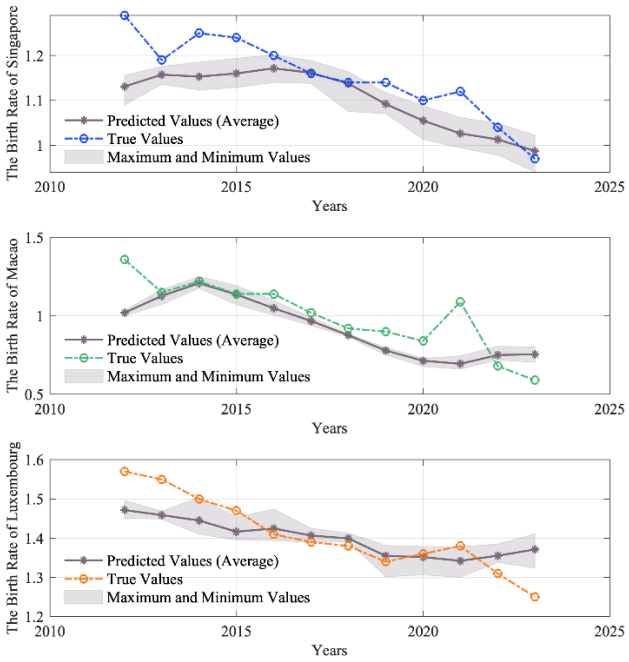

Fig. 8. The birth rate prediction results of the Bi-LSTM model.

TABLE IV. THE INDICATORS OF DIFFERENT BIRTH RATE PREDICTION MODELS

Predictive Model	Regions or Country	RMSE	SSE	MSE	MAPE
INRBO-TCN-Bi-LSTM	Singapore	0.0722	0.0722	0.0052	5.47%
	Macau	0.1442	0.2494	0.0207	12.51%
	Luxembourg	0.0502	0.0302	0.00252	2.84%
TCN-Bi-LSTM	Singapore	0.0855	0.0877	0.0073	6.03%
	Macau	0.1646	0.3312	0.0471	13.60%
	Luxembourg	0.0537	0.0346	0.0155	3.17%
TCN	Singapore	0.0898	0.0967	0.0081	7.44%
	Macau	0.1952	0.4574	0.0381	16.35%
	Luxembourg	0.0579	0.0403	0.00336	3.38%
Bi-LSTM	Singapore	0.1062	0.1354	0.0112	6.29%
	Macau	0.1488	0.2658	0.0221	11.48%
	Luxembourg	0.0619	0.0460	0.00383	3.43%
GRU	Singapore	0.2030	0.1675	0.0140	7.34%
	Macau	0.2030	0.4943	0.0412	19.79%
	Luxembourg	0.0710	0.0605	0.0050	4.92%

Among the three tests, all five birth rate prediction models had the highest error values when predicting the birth rate in Macau. The MAPE of INRBO-TCN-Bi-LSTM is 12.51%, which is better than the TCN-Bi-LSTM, TCN, and GRU models. The performance of Bi-LSTM is better than that of the more complex TCN-Bi-LSTM, indicating that the Bi-LSTM model may have overfitting. When predicting the birth rate in

Luxembourg, the MAPE of the INRBO-TCN-Bi-LSTM model is 2.84%. Compared with the TCN-Bi-LSTM model, the INRBO-TCN-Bi-LSTM model has decreased RMSE and MAPE by 6.52% and 10.42%, respectively.

V. CONCLUSION

This study constructs a birth rate prediction model for small regions based on the TCN-Bi-LSTM hybrid architecture. In addition, the proposed birth rate prediction model introduces three input vectors, including regional consumption level, population size, and divorce rate, aiming to improve the adaptability of the prediction model to policy or economic fluctuations, and make the birth rate prediction results closer to the trend of real birth rates. At the same time, an INRBO algorithm was designed to optimize the hyperparameters of the TCN-Bi-LSTM model, aiming to improve the prediction accuracy of the birth rate prediction model. The results showed that in the three tests, the INRBO-TCN-Bi-LSTM model showed an average reduction of 11.49% and 9.24% in RMSE and MAPE, respectively, compared to the TCN-Bi-LSTM model. In summary, the proposed INRBO-TCN-Bi-LSTM model has improved the accuracy of birth rate prediction within a small area. The proposed INRBO-TCN-Bi-LSTM model has limitations regarding interpretability and a lack of validation of its generalization capability across diverse time-series forecasting tasks. Future work will focus on addressing these limitations. To this end, we will enhance model interpretability using methods such as feature importance analysis and attention weight visualization. We will also systematically evaluate the model's predictive performance on diverse time series data to verify its robustness.

A New Advanced Multimodal Sentiment Classification Through Combined Attention Mechanisms: A-MSDA

Soukaina FATIMI, WAFAE SABBAR, Abdelkrim BEKKHOUCHA
LIM Laboratory-Faculty of Sciences and Techniques, University Hassan II of Casablanca, Mohammedia, Morocco

***Abstract*—Interest in multimodal sentiment analysis has grown significantly due to the widespread sharing of text and images on social platforms. Existing approaches often emphasize either sentiment features within textual–visual data or the correlation between modalities, leaving gaps in effectively capturing both aspects simultaneously. To address these limitations, we propose the Advanced Multimodal Sentiment Analysis with Dual Attention (A-MSDA) model, which integrates self-attention and cross-modal attention mechanisms in a unified dual-attention framework. This design enables robust multimodal fusion by extracting salient textual and visual features while modeling their image–text interaction comprehensively. Experimental evaluation on MVSA-Single and MVSA-Multiple datasets demonstrates that A-MSDA achieves notable improvements in accuracy and F1-score, outperforming existing techniques by up to 3.4% in F1-score on MVSA-Multiple, while maintaining competitive performance on MVSA-Single. These results highlight the potential of A-MSDA to advance research in deep multimodality and sentiment analysis.**

***Keywords*—Dual attention; self-attention; cross-modal attention; multimodal sentiment analysis; multimodal fusion; MVSA dataset; image–text interaction; deep multimodality**

I. Introduction

Multimodal analysis is an emerging and indispensable research field with the rise of the digital world. Nowadays, data is not only found in massive amounts, but the diversity of the content presents new analytical challenges. This emerging field has been empowered by the rapid evolution of digital platforms and the rise in the sharing of visual content and textual data. Combining textual data with other social, visual, or audio cues aims to improve knowledge extraction and reduce the uncertainties associated with single-modality analysis. Multimodal sentiment analysis leverages feature extraction and representation, combined with multimodal fusion models, to provide a more comprehensive understanding of sentiment [1], [2].

Texts and images complement each other and work jointly to convey nuanced emotions; in this case, the expressed feelings will not be limited to one type of data. This capability is critical for real-world applications such as social media monitoring, brand perception analysis, and marketing strategies, where user-generated content often combines text and visuals to express opinions about products, services, and events [3], [4].

Recent advances in attention mechanisms have significantly improved multimodal modeling by enabling models to focus on contextually relevant information [2]. However, most existing approaches employ either self-attention or cross-modal attention in isolation, which limits their ability to fully capture intra-modal and inter-modal relationships. This gap motivates the need for a unified framework that combines both attention types to enhance sentiment prediction [5]. The objectives of this work are:

- To design a dual-attention architecture that integrates self-attention for modality-specific feature extraction and cross-modal attention for interaction modeling.
- To evaluate the proposed model on benchmark datasets and demonstrate its effectiveness in improving accuracy and robustness.

This study is organized as follows: Section II reviews related work and highlights gaps in existing approaches. Section III details the proposed A-MSDA architecture, and Section IV presents the experimental setup, results, and discussion. Finally, Section V underlines limitations before concluding with future directions in Section VI.

II. Literature Review

Multimodal sentiment analysis has become an active field of study. It allows understanding emotional cues in heterogenous data from different types of sources, and using a variety of modalities, including text, images, audio, and video, to increase the efficiency of sentiment prediction over unimodal methods. [1], [6]. A multitude of approaches have been proposed to enhance this research field. Conventional approaches first concentrated on decision-level fusion, in which the categorization results were integrated after each modality was processed separately [7]. Subsequently, concatenated or weighted features from several modalities are used in feature-level fusion techniques prior to classification. [8]. Hybrid fusion strategies attempted to combine both early and late fusion techniques for better alignment [9].

Despite these decent developments, fusion-based models frequently fall short in real-world circumstances due to their inability to capture intricate cross-modal linkages. To address this, researchers introduced attention mechanisms, which allow models to focus on contextually relevant features. Bahdanau et al. [10] pioneered attention in sequence modeling, and subsequent works adapted it for multimodal tasks. For

instance, Liu et al. proposed shared-memory attention for modality interaction [11], while Yang et al. introduced multiview attentional networks integrating semantic features [12]. Huang et al. [13] developed deep multimodal attentive fusion models, and Zhang et al. explored hierarchical attention for image-caption relationships. More recent architectures, such as the ITIN model [14], significantly increase task accuracy for sentiment analysis. The CLMLF model [15] applies contrastive learning to more accurately represent image-text features. Yang et al. [16] propose dynamic primary modality selection to optimize multimodal sentiment analysis, improving robustness when one modality is noisy. Chen et al. [17] introduce an adapter-based architecture for efficient multimodal fusion, reducing computational cost while maintaining accuracy, and Wang et al. [18] present adaptive interaction and multi-scale fusion for better cross-modal alignment and sentiment prediction.

According to recent surveys, attention-based fusion has surpassed conventional concatenation-based techniques to become a prominent trend in MSA [19], [20]. Nevertheless, the majority of current models only use cross-modal or self-attention, which restricts their capacity to fully utilize intra-modal and inter-modal interactions. This gap motivates the development of dual-attention frameworks that integrate both mechanisms for richer feature representation and improved sentiment classification.

These developments have been aided by a number of benchmark datasets, such as MVSA-Single and MVSA-Multiple, which include image–text pairs from social media posts [21]. Multimodal sentiment analysis in video-based situations has made extensive use of other datasets, including CMU-MOSI, CMU-MOSEI, and CH-SIMS [22]. Large-scale multimodal samples for practical applications are provided by emerging resources such as RU-Senti and SM-MSD [23].

III. Advanced Multimodal Sentiment Analysis with Dual Attention

The proposed A-MSDA architecture is designed to address limitations in existing multimodal sentiment analysis models by combining intra-modal self-attention and inter-modal cross-attention within a unified framework. Unlike prior approaches such as ITIN and CLMLF [15], which focus primarily on cross-modal alignment or hierarchical attention, A-MSDA jointly captures modality-specific features and bidirectional interactions, enabling richer sentiment representation.

Our approach, presented in Fig. 1, contains two unimodal sub-models for sentiment analysis: textual self-attention-based sentiment analysis and visual self-attention-based sentiment analysis. We first handle texts and images individually. We extract attended characteristics from the text and image via different unimodal self-attention-based models. While the latter concentrates on phrases that have strong emotions, the former focuses on important areas/regions in images that have emotionally solid substances. The extracted features are used for predicting the sentiment polarity in both modalities separately.

In addition to the first layer of attended textual and attended visual feature extraction, we overlay a second level of attention as a bidirectional cross-modal attention-based model to explore how visual and textual data complement one another and interact. Textual cross-attention mechanisms emphasize emotionally relevant words that are linked with attended high-level visual regions. Moreover, the visual cross-attention mechanism focuses on image regions on the basis of attended textual features. This layer hence features text-to-image and image-to-text attention.

These dual-attended features are later used to extract the multimodal sentiment score of text-image data. The final sentiment classification is obtained by aggregating the predictions from the text model, visual model, and fusion output.

Before delving into the details, let us denote the list of images as V and the text descriptions as T. We will then proceed by explaining the various components of the model.

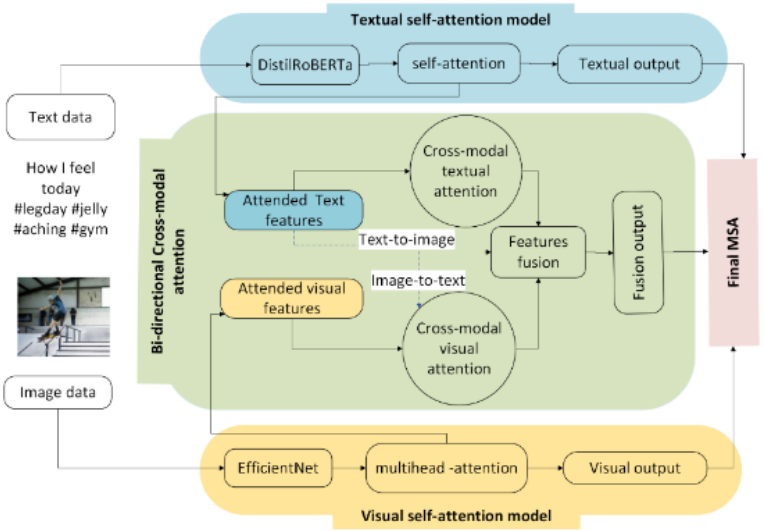

Fig. 1. Advanced multimodal sentiment analysis with a dual attention model architecture.

A. Unimodal Self-Attention Model for Text

In text sentiment analysis (see Fig. 2), the emotional content often hinges on specific words within the text. Our model begins by transforming the input text sequence $W = (W_1, W_2, \ldots, W_n)$, where each W_i is a token, into meaningful embeddings via DistilRoBERTa to capture these nuances, followed by self-attention mechanisms to focus on key features. DistilRoBERTa is a distilled version of RoBERTa model [24] using knowledge distillation [25], it is considered reduced in computational complexity, making it ideal for applications that require efficient processing without substantial loss of performance.

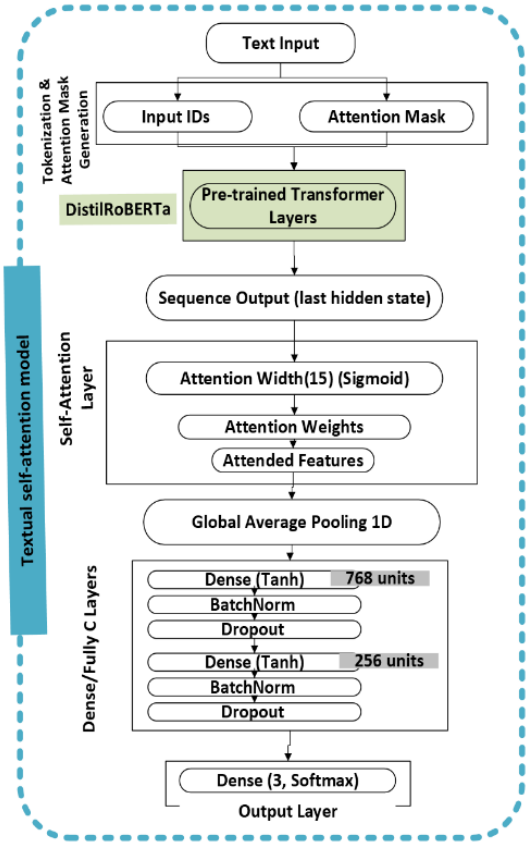

Fig. 2. Textual sentiment analysis model based on self-attention.

The input text sequence $W = (W_1, W_2, \ldots, W_n)$ consists of n tokens. Each token W_1 is transformed into an embedding vector. The model outputs the last hidden state E [Eq. (1)], where each vector e_1 in E is of size d and encapsulates semantic and syntactic information of the corresponding token.

$$\mathrm{E} = [e_1, e_2, \ldots, e_n] = \text{DistilRoBERTa (W)} \quad (1)$$

The embedding E is then passed through attention layers to refine the representation. The self-attention [see Eq. (2)] layer calculates the importance of each token represented by $q^{(i)}$ in relevance to the embedding E represented by K and V by generating attention scores α_1 for each token e_1. The attention score for token e_1 is computed via Eq. (3), where the score function measures the relevance of e_1 with respect to the entire sequence context E.

$$Self_Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d_k}}) \text{ Where } q^{(i)} = W_q * x^i \text{ for i} \in [1,\mathrm{T}] \ , k^{(i)} = W_k * x^i \ for \ i \in [1,T] \ , v^{(i)} = W_v * x^i \ for \ \ i \in [1,T] \quad (2)$$

$$\alpha_i = \frac{exp(score(e_i,E))}{\sum_{j=1}^{n} exp(score(e_j,E))} \quad (3)$$

The result of this layer is a weighted sum [see Eq. (4)] of the input's embedding, where α_{ij} indicates the attention weight from token W_i to W_j.

$$\hat{e} = \sum_{j=1}^{n} \alpha_{ij} e_j \quad (4)$$

To condense the sequence-level information into a fixed-size representation, a global average pooling layer is employed. This operation computes the mean of the vectors along the sequence dimension [see Eq. (5)], resulting in a single vector $\hat{e}$ that summarizes the entire text, e $\in R^{\mathrm{d}}$ and serves as a comprehensive representation of the input text sequence.

$$e = \frac{1}{n}\sum_{i=1}^{n} \hat{e}_i \quad (5)$$

The pooled vector e is fed into a series of dense layers to capture higher-level abstractions. A nonlinear activation function is applied after a linear modification in each dense layer [see Eq. (6)]:

$$Dense_i(\hat{e}) = tanh(W_i \hat{e} + b_l) \quad (6)$$

where, the activation function used here is the hyperbolic tangent (Tanh). W_i is the weight matrix, and b_l is the bias for the i-th layer. Dropout layers are used to prevent overfitting.

The final layer generates a probability distribution across the sentiment classes [see Eq. (7)]. Softmax activation function is used for this output, where W_0 and b_0 are the output layer's weights and biases, respectively, and y represents the predicted probabilities for each class.

$$y = softmax(W_0 Dropout + b_0) \quad (7)$$

B. Unimodal Self-Attention Model for Images

Similar to how some words are more important than others in a text, some regions of an image are more relevant to sentiment.

Our visual attention model, Fig. 3, is devised to highlight these emotionally essential regions for a better representation of sentiment. The visual model for sentiment analysis is designed to extract and process features effectively from images via a combination of EfficientNetB0 [26], transformer encoders, self-attention mechanisms, and fully connected layers. This architecture seeks to improve the model's capacity to capture sentiment-related visual cues and integrate them with textual features for comprehensive sentiment analysis.

The visual self-attention model starts by extracting visual high-level feature maps with fine-tuned EfficientNetB0, excluding its top layers [see Eq. (8)]. Fine-tuning ensures pretrained weights adaptation to the specific task of visual sentiment analysis, where the input is the image tensor X_{image} and where F_{eff} represents the extracted feature maps.

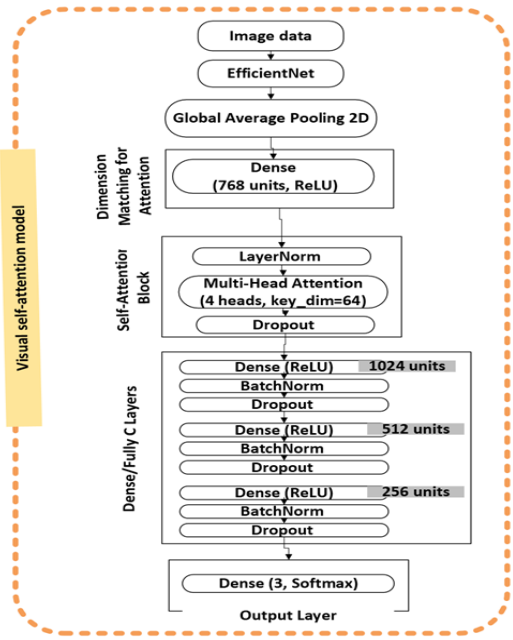

Fig. 3. Visual sentiment analysis model based on self-attention.

$$F_{eff} = EfficientNetB0(X_{image}) \quad (8)$$

To decrease the feature maps' spatial dimensions while keeping the depth information constant, global average pooling is used. This process calculates the mean value for each feature map, resulting in a single value per map [see Eq. (9)], where H and W are the height and width of the feature map, respectively.

$$f_{GAP} = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} F(i,j) \quad (9)$$

The pooled features are passed through a dense layer [Eq. (10)] with 768 units to align their dimensions with the text model's output. The features are then reshaped to prepare for self-attention processing [Eq. (11)], where W_d and b_d are the weights and biases of the dense layer.

$$f_{dense} = ReLU(W_d F_{se} + b_d) \quad (10)$$

$$F_{reshape} = Reshape((1,768))(f_{dense}) \quad (11)$$

The self-attention mechanism within the transformer encoder processes the reshaped feature vector, where Q, K and V are the query, key, and value matrices, respectively, derived from the input features.

$$A_{self} = MultiHeadAttention(Q,K,V) \quad (12)$$

To capture different contextual relationships in the input properties, several heads of attention are employed [see Eq. (12)]. A collection of attended features is produced by calculating and combining multiple attention scores through 4 attention heads with a key dimension of 8. The idea is to focus on various regions of the image contributing the most in understanding the visual sentiment. The residual connections combine the attention output with the original features [see Eq. (13)], followed by layers of normalization and dropout [see Eq. (14)]:

$$x = Add([A_{self}, Freshape]) \quad (13)$$

$$x = Dropout(0.4)(LayerNormalization(x)) \quad (14)$$

The model applies more refinement through several fully connected dense layers with 1024, 521, and 256 units, respectively [see Eq. (15)], with dropout and batch normalization [Eq. (16) and Eq. (17)] to overcome overfitting.

The output layer employs a Softmax activation function [Eq. (18)] to generate a probability distribution across the sentiment categories.

$$f_{fc1} = ReLU(W_{fc1} \cdot A_{self} + b_{fc1}) \quad (15)$$

$$f_{bn1} = BatchNormalization(f_{fc1}) \quad (16)$$

$$f_{drop1} = Dropout(0.4)(f_{bn1}) \quad (17)$$

$$y_{pred} = softmax(W_{out} \cdot f_{drop3} + b_{out}) \quad (18)$$

C. Cross-Modal Attention for Multimodal Sentiment Analysis

In the first unimodal processing layer, the text model processes input sequences to capture the underlying semantic and syntactic nuances and outputs of both sentiment prediction and an attention output, which is crucial for the subsequent fusion process. Simultaneously, the visual model processes images to extract features that reflect the sentiment conveyed visually and outputs both visual sentiment prediction and attention-enhanced features.

The second layer represents the core innovation of the model. At this level, we fuse the attended features from both text and visual modalities via cross-modal attention mechanisms for a dual attended features extraction, as shown in Fig. 4 and Algorithm 1.

Algorithm 1: The advanced multimodal sentiment analysis with dual attention

Inputs:
Textual data (T)
Visual data (V)
Outputs:
Predicted multimodal sentiment probabilities

Compute
For (every text T_i, image V_i) do
$Text_{sentiment}$, att_T ← self-att-based-model-text(T_i)
$Visual_{sentiment}$, att_V ← self-att-based-model-imaget(V_i)

$Fusion_{sentiment}$ ← Softmax(W_{fusion} * h_{fusion} + b_{fusion})
Msa_{logits} ← (w_{text} * logits($Text_{sentiment}$,)) + (w_{visual} * logits($Visual_{sentiment}$,)) + (w_{fusion} * logits($Fusion_{sentiment}$))
$Multimodal_{sentiment}$ ← Softmax(Msa_{logits})
End

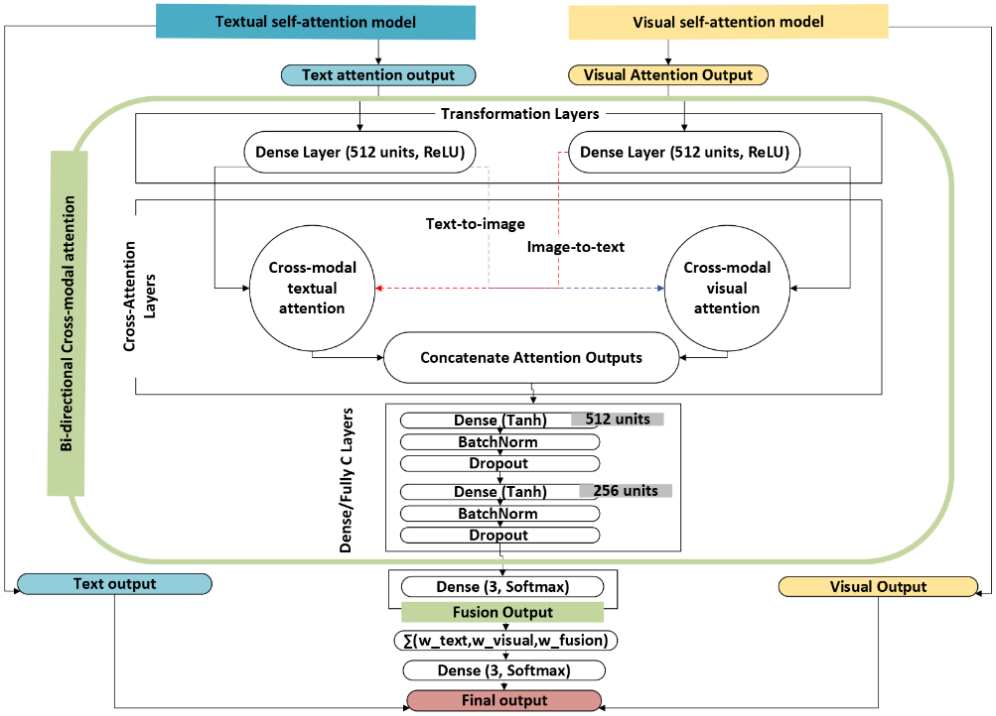

Fig. 4. Cross-modal attention-based fusion for textual–visual sentiment analysis architecture.

The attention mechanism computes the influence of text features on visual features. Given that, A_v is the visual attention output, and A_t is the text attention output [see Eq. (19)]. Similarly, the image-to-text attention computes the influence of visual features on the text features [Eq. (20)]. The outputs of both attentions are concatenated [Eq. (21)], flattened and passed through dense layers for further processing [Eq. (22)].

$$A_{text-image} = Attention(A_v, A_t) \quad (19)$$

$$A_{image-text} = Attention(A_t, A_v) \quad (20)$$

$$A_{concat} = [A_{text-image}, A_{image-text}] \quad (21)$$

$$h_1 = ReLU(W_1 * flatten(A_{concat}) + b_1) \quad (22)$$

A series of dense layers [see Eq. (23)] (512 and 256 units, respectively) followed by Softmax activation outputs [see Eq. (24)], the sentiment classification of the concatenated data as a result of the fusion process.

$$dense_{fusion} = Relu(W_i\ \hat{e} + b_l\ ) \quad (23)$$

$$fusion_outpu = softmax(W_0 dense_{fusion} + b_0) \quad (24)$$

The final sentiment prediction aggregates the outputs of the text model, visual model, and fusion output

Three trainable weights $w_{text}, w_{visual}, w_{fusion}$ determine the contribution of each modality to the final prediction. These weights are normalized to sum to 1 [Eq. (25)], and the outputs are combined as a weighted average [Eq. (26)]. Then, the combined logits are fed into a Softmax layer [Eq. (27)], which outputs the final probability distribution across the sentiment categories.

$$w_{normalized} = \sum(w_{text}, w_{visual}, w_{fusion}) \quad (25)$$

$$y_{logits} = w_{textnormalized} \cdot text_{output} + w_{visualnormalized} \cdot visual_{output} + w_{fusionnormalized} \cdot fusion_{output} \quad (26)$$

$$multimodal_output = softmax(y_{logits}) \quad (27)$$

In summary, combining textual and visual data enables the multimodal model to detect a broader spectrum of sentiment signals, strengthening the sentiment analysis process. Self-attention mechanisms improve the model's focus on key elements of the input, while cross-attention contributes to the alignment between modalities, leading to precise and refined sentiment predictions. This all-encompassing approach guarantees that the outcome includes a thorough evaluation of the text and image data.

IV. Experiments

A. Datasets

Niu et al. [21] introduced two publicly available multimodal sentiment analysis datasets, MVSA-Single and MVSA-Multiple, sourced from Twitter. The MVSA-Single dataset consists of 5,129 image–text pairs, each classified into positive, neutral, or negative sentiment categories. In contrast, the MVSA-Multiple dataset contains 19,600 image–text pairs, with each pair independently annotated by three different annotators.

To ensure consistency in sentiment labels between the image and text, we preprocess these datasets for our experiments. In particular, pairs with different pictures and text labels are eliminated. The positive (or negative) sentiment label is applied to the pair when one label is positive (or negative) and the other is neutral. After this preprocessing, there are now

17,024 image–text pairings in the revised MVSA–Multiple dataset and 4,511 image–text pairs in the revised MVSA–Single dataset. We adhere to earlier preprocessing techniques to guarantee an equitable comparison.

TABLE I. MVSA DATASET STATISTICS

Dataset	Neutral	Positive	Negative	Total
MVSA-multiple	4408	11318	1298	17024
MVSA-single	470	2683	1358	4511

Table I presents the statistics for the two MVSA datasets. This finding demonstrates that the data distributions for MVSA-Single and MVSA-Multiple differ and that the various categories are extremely uneven. Without sampling, the dataset's smaller categories will be challenging to examine during training, and all of the data will be categorized into the same class. Because the MVSA datasets are tiny, the smallest category in each MVSA dataset is randomly oversampled to lessen the effect of data imbalance on the experiment.

B. Implementation Details

The proposed model is implemented in Python 3.7.13 using Keras on Google Colab with an NVIDIA T4 GPU (50 GB RAM).

1) Textual model: Text features are extracted using DistilRoBERTa, with sequences (max = 20) tokenized, padded, or truncated. The resulting 768-dimensional embeddings are refined by a self-attention layer and aggregated via global average pooling, followed by dense layers (512, 256) with 0.3 dropout. A Softmax layer classifies text into positive, neutral, or negative sentiment.

2) Visual model: Images (224×224×3) are processed using EfficientNetB0, followed by global pooling, a dense projection (768 units), and a multihead self-attention (4 heads, key = 8). Fully connected layers with batch normalization and dropout precede the Softmax classifier.

3) Cross-modal fusion: Textual and visual features (768 dims) are aligned and fused via cross-attention, where text acts as query and image as key/value. The fused representation passes through dense layers with batch normalization and dropout, and the final Softmax outputs the sentiment class.

C. Training Process

Our model is trained using the Adam optimizer with a learning rate of 0.00001, a batch size of 128 for MVSA-Multiple and 32 for MVSA-Single. Weighted focal loss is employed to handle class imbalance, combining class weights with focal loss parameters of α=0.27 and γ=1.9, ensuring greater focus on hard-to-classify samples.

To prevent overfitting, we employ early stopping with a patience of 5, while a learning rate scheduler reduces the rate by a factor of 0.1 if the validation loss plateaus for three epochs. Data is splinted using an 8:1:1 ratio for training, validation, and testing. The effectiveness and performance of A-MSDA are greatly influenced by the hyperparameter selection. For example, adding more attention heads increases the computational cost but enhances the capacity to record a variety of cross-modal connections. Overfitting is lessened by a larger dropout rate, but if it is set too high, convergence may be slowed. While the learning rate guarantees gradual convergence, dense layer sizes strike a balance between representation capacity and training stability. By highlighting difficult-to-classify samples, focal loss parameters aid in reducing class imbalance. Memory consumption and gradient stability are impacted by batch size; larger batches speed up training but demand more GPU power. Grid search and cross-validation were used to adjust these settings, which are presented in Table II, in order to maximize the trade-off between efficiency and accuracy.

TABLE II. HYPERPARAMETERS OF THE A-MSDA MODEL

Hyperparameter	MVSA-Multiple	MVSA-Single
Word vector dimensionality	768	768
Maximum input text length	20	20
Batch size	128	32
Optimizer	Adam	Adam
Learning rate	0.00001	0.00001
Dropout rate	0.4	0.4
Epochs	20	20
Loss function	Weighted Focal Loss	Weighted Focal Loss
Balancing factor	α=0.27	α=0.27
Focusing parameter	γ=1.9	γ=1.9

D. Main Results

To evaluate our work, we compare, in Table III, the proposed model against several benchmark models. All these models are evaluated and tested on the MVSA dataset, and the reported values are based on their original papers:

- The Co-memory model [27] enhances sentiment analysis by introducing a fusion module that strengthens the interactions within multimodal datasets.
- The CNN-Multi model [28] uses two separate CNNs to independently process text and image features and combine the extracted features to enhance emotion prediction.
- The MVAN model [29] uses a memory network within a multiview attention network to refine semantic image-text features, leading to increased accuracy.
- Xu et al. [30] proposed MultiSentiNet, a deep CNN technique with pretrained features that integrate text embedding with object and scene information encoded from photos. To capture the influence of visual characteristics on word embedding, they employed visual feature-guided attention.
- Braytee et al. [31], dual-pipeline based attention mechanism for multimodal social sentiment analysis.

For the MVSA-single dataset, the A-MSDA model achieves an accuracy of 73.01% and an F1 score of 71%. For the MVSA-multiple dataset, the model recorded an accuracy of

73.40% and an F1 score of 73.35%. A comparison with the state-of-the-art methods reveals that our A-MSDA approach outperforms the current state-of-the-art approaches.

TABLE III. PERFORMANCE ANALYSIS OF THE A-MSDA METHOD COMPARED WITH THE STATE-OF-THE-ART METHODS

Model	MVSA-Single		MVSA-Multiple	
	Accuracy	F1-score	Accuracy	F1-score
Unimodal Visual SA EfficientNetB0	62.31	62.28	57.46	56.10
Unimodal Textual SA DistilRoBERTa	65.56	65.12	66.56	66.00
Co-Memory [27]	70.51	70.01	68.92	68.83
CNN-Multi [28]	61.20	58.37	66.39	64.19
MVAN [29]	72.98	**72.98**	72.36	72.30
MultiSentiNet [30]	69.84	69.63	68.86	68.11
Dual-Pipeline Attentional architecture [31]	57.29	56.76	73.18	69.76
Proposed Model (A-MSDA)	**73.01**	71.10	**73.40**	**73.17**

Table IV shows that class imbalance has a significant effect on the performance indicators. The macro-average values for the precision, recall, and F1 score are significantly lower at 0.64, 0.57, and 0.60, respectively, despite the total accuracy of 0.73, which indicates a respectable degree of prediction accuracy. Severe class imbalance impacts the model's ability to consider and evaluate all classes equally, despite the use of weighted focus loss classes and sampling strategies; this discrepancy in the macro-average values highlights the challenge posed by class imbalance.

TABLE IV. CLASSIFICATION REPORT OF THE A-MSDA MODEL ON BOTH THE MVSA-SINGLE (A) AND MVSA-MULTIPLE (B) DATASETS

	Precision	Recall	F1-score	Support
Neutral	0.57	0.63	0.60	442
Positive	0.85	0.76	0.80	1114
Negative	0.51	0.80	0.63	137
Accuracy			0.73	1693
Macro avg	0.64	0.72	0.67	1693
Weighted avg	0.75	0.73	0.73	1693
	Precision	**Recall**	**F1-score**	**Support**
Neutral	0.52	0.35	0.42	43
Positive	0.77	0.88	0.82	290
Negative	0.63	0.49	0.55	118
Accuracy			0.73	451
Macro avg	0.64	0.57	0.60	451
Weighted avg	0.71	0.73	0.71	451

However, when the class distribution is considered, the weighted average values demonstrate improvements, with a precision of 0.71, a recall of 0.73, and an F1 score of 0.71. This implies that the model performs better when the class imbalance is taken into account, but the differences between the weighted and macro averages highlight how crucial it is to address and lessen the effects of class imbalance in the feature extraction process for a more thorough and impartial model evaluation.

E. Module Performance Validation and Case Study

We carried out several tests to confirm the performance improvements made by each module in multimodal sentiment analysis. The purpose of these studies is to compare unimodal and multimodal sentiment analysis with unimodal sentiment extraction for text and image features, as well as different feature fusion strategies, to assess the efficacy of the dual-attention MVSA model. The following summarizes the specifics of the model ablation experiments:

- Unimodal visual SA and unimodal textual SA: These experiments assess sentiment analysis using only the visual modality and only the textual modality, respectively.
- Textual sentiment analysis with cross attention: using visual data to assist in the prediction of textual sentiment.
- Visual sentiment analysis with cross attention: using text data to enhance the prediction of visual sentiments.
- Different self-attention models: Evaluation of various self-attention mechanisms.

Table V presents the results of these experiments. The comparison demonstrates that multimodal sentiment analysis surpasses unimodal sentiment analysis for both textual and visual data. The results also highlight the significant impact of cross-modal attention in leveraging one modality to focus on specific aspects of the other, as outlined in the proposed methodology. This mechanism enhances the models' ability to accurately understand and analyse sentiment, leading to improved performance.

TABLE V. CLASSIFICATION RESULTS OF DIFFERENT UNIMODAL AND MULTIMODAL ARCHITECTURES AGAINST THE PROPOSED A-MSDA

Ablation Experiment	MVSA-single		MVSA- multiple	
	Accuracy	F1-score	Accuracy	F1-score
Unimodal Visual SA EfficientNetB0	62.31	62.28	57.46	56.10
Unimodal Textual SA DistilRoBERTa	65.56	65.12	66.56	66.00
Visual SA w/cross attention text-to-image	64.51	63.81	61.64	60.98
Textual SA w/cross attention image-to-text	69.47	68.03	68.29	67.54
A-MSDA w/o self-attention	70.14	70.06	70.82	70.68
A-MSDA w/o cross attention	70.76	70.50	71.63	71.23
A-MSDA	**73.01**	**71.10**	**73.40**	**73.17**

For instance, unimodal textual sentiment analysis produced a moderate accuracy of 65.56% with an F1 score of 65.12%.

the textual emotion classification was enhanced by the addition of image-to-text cross-modal attention. This helps improve the accuracy by more than 3% for accuracy and F1 score. The advantage of integrating information across modalities is highlighted by this improvement.

Our suggested method, advanced multimodal sentiment analysis with dual attention, produced the best outcomes compared to unimodal analysis or single type of attention network integration. A-MSDA achieves a higher degree of interaction between modalities by combining self-attention and cross-modal mechanisms, which results in more reliable sentiment classification. These results demonstrate the effectiveness of our suggested A-MSDA method, which successfully blends self-attention and dual cross-modal mechanisms to produce challenging outcomes in multimodal sentiment analysis tasks.

To illustrate the practical impact of the A-MSDA model, we consider a sample from the MVSA dataset, the image is shown in Fig. 5, and the corresponding text is: "Q&A panel for #TheDressmaker. We laughed, we cried, we fell in love with Liam Hemsworth a LOT. #TIFF15 @TIFF_NET".

Fig. 5. Sample from MVSA-multiple Test Set (ID: 5001).

The self-attention-based text sentiment analysis highlights strong positive cues such as "laughed", "love" words, combined with emotional engagement markers like "we cried". Simultaneously visual self-attention model focuses on regions with vibrant colors and persons but conveys a more neutral sentiment. Then, with the cross-attention, we align these textual cues with visual features, amplifying the positive prediction.

A-MSDA combines both text and image cues; it is impacted by the unimodal results of each modality but also enhanced with the shared content, ensuring accurate sentiment classification. Here, A-MSDA Outperforms Unimodal Models because:

- Image-only models ignore nuanced textual enthusiasm and consider the image as neutral.
- Text-only model detected positive sentiment but is slightly influenced by the mixed emotional tone "we cried" as it is considered negative.

V. Limitations

Despite the promising results, this study has several limitations.

1) Dataset size and diversity: the used MVSA-Single and MVSA-Multiple were constructed from Twitter posts. They are relatively small and not well generalized. This may limit the generalizability of the model to other platforms or domains.

2) Class imbalance: Although weighted focal loss was applied, severe class imbalance in the datasets still affected macro-average performance, indicating challenges in handling minority classes.

3) Computational complexity: The dual-attention architecture increases computational cost compared to simpler fusion models, which may not be the optimum solution to resource-constrained environments.

Future work should address these limitations by incorporating larger and more diverse datasets, additional modalities, and optimization strategies for efficiency.

VI. Conclusion

In this work, we presented A-MSDA, an advanced multimodal sentiment analysis model where we focus on overcoming the interlinkage investigation between modalities, a major gap in traditional MSA strategies. To overcome this challenge, our approach integrates self- and cross-attention mechanisms to capture the complementary strengths of textual and visual data.

Our proposed model effectively focuses on sentiment-relevant features within each modality and aligns them through multiple layers of attention-based fusion. Each modality's use of self-attention mechanisms efficiently extracts high-quality characteristics, highlighting the most pertinent elements of both visual and textual material. Moreover, we emphasize the interaction between modalities by integrating the cross-attention fusion layer in order to enhance the accountability of the combined sentiment.

The experimental results demonstrate that A-MSDA improves overall sentiment classification performance, mainly compared to unimodal models. Beyond performance gains, the use of attention mechanisms provides a clearer and more interpretable view of how different modalities impact each other and contribute to the final decision.

Building on the current findings, and considering the existence of different limitations and improvement points, several directions can be explored: The multimodality doesn't reflect only text or image, we can explore extending the model to include different sources of information, such as audio-video, temporal information, likes and comments in social media platforms, and even the number of clicks. This could provide a richer representation of sentiment. Additionally, testing on larger multimodal datasets and investigating domain

adaptation techniques will potentially improve generalization across different social media platforms and languages. Furthermore, we think of integrating explainability tools to offer deeper insights into the reasoning behind model predictions. These directions aim to enhance the applicability, transparency, and robustness of multimodal sentiment analysis systems.

Overall, this study highlights the importance of attention-based fusion in bridging multimodal gaps and provides a strong foundation for more robust, transparent, and human-like sentiment understanding systems.

Department of Software Engineering Technology, Politeknik Mardira Indonesia, Majalengka, Indonesia[1]

***Abstract*—The development plan for Kertajati Aerocity requires adequate support from the data communication infrastructure. The primary challenge lies in the dense data flows, which involve very large volumes and diverse data types. The commonly used host-centric architecture suffers from latency, bandwidth utilization, and scalability issues, making it unsuitable for the dynamic Aerocity scenario. To address these limitations, this study proposes an Information-Centric Networking (ICN) architecture based on Named Data Networking (NDN), where communication relies on content names rather than IP addresses. The ndnSIM simulator was employed in the experimental evaluation of this architectural model, using operational data requirements derived from the Taoyuan Aerotropolis case. Performance was assessed through Quality of Service (QoS) metrics, including throughput, latency, and cache hit ratio. The simulation results indicate that throughput stabilized at ~10.1 Mbps (from 7.2 Mbps initially) with balanced node distribution, while latency averaged ~3 ms, with p95 < 10 ms and over 95% of requests completed within low-delay bounds despite initial spikes. Cache statistics were unavailable (CacheHits/Misses = 0) due to tracer settings and traffic patterns, so cache analysis is left for future work. These findings highlight the novelty of integrating NDN-based ICN with Aerocity-specific traffic requirements. The proposed model is presented as a scalable solution for the evolving data communication infrastructure of Kertajati Aerocity in the future, emphasizing designing an NDN-based architecture specifically designed for the multi-zone Aerocity ecosystem, including hierarchical and cross-zone naming schemes that model the operational flow of Aerocity.**

I. Introduction

The development plan for Kertajati Aerocity positions itself as a model city that integrates the airport with surrounding economic and logistics activities, making it a multimodal hub [1]–[5]. This creates the need for data communication technologies capable of handling dense connections, diverse traffic flows, and dynamic service demands [6], [7]. Such conditions require a communication network infrastructure that supports low latency, efficient bandwidth usage, and scalable network operations.

Meanwhile, the current Internet architecture is fundamentally host-centric, designed for communication between hosts identified by IP addresses [8], [9]. This model presents limitations when applied to today's conditions, particularly issues such as data retrieval latency, inefficient handover management, and bandwidth bottlenecks, which emerge as critical problems [10], [11]. These challenges necessitate a transition towards a more data-centric architecture that is scalable and adaptable to environments such as Aerocity [10]–[13].

At present, Information-Centric Networking (ICN) has emerged as a promising paradigm for the future Internet. By focusing on the requested content rather than the host's location, ICN offers advantages in caching, name-based routing, and data-centric forwarding [14], [15]. Within this paradigm, Named Data Networking (NDN) stands out as a well-developed and mature approach. NDN simplifies data retrieval, enhances resilience through caching, and enables efficient multicast distribution [16]–[18].

Despite these strengths, most research on NDN has focused on domains such as vehicular networks, content delivery, and IoT systems [19], [20]. Very little attention has been paid to Aerocity environments, which combine the high data density of urban centers with domain-specific requirements for logistics, utilities, and business ecosystems. The complexity of traffic patterns and service heterogeneity in the Aerocity scenario presents unique challenges that have not been fully addressed in previous ICN/NDN studies.

Therefore, there is a research gap where, although NDN provides a fundamental mechanism for data-centric communication, there is no specific architectural design designed to meet the operational requirements in the Aerocity environment. In response to this gap, this study proposes an NDN-based ICN architecture specifically designed for the needs of Aerocity. This architecture emphasizes an NDN design specifically for the multi-zone Aerocity ecosystem, which, to our knowledge, has not been addressed in previous NDN or ICN studies, including hierarchical and cross-zone naming schemes that model the operational flow of Aerocity.

The remainder of this study is organized as follows: Section II reviews related work on NDN and its applications. Section III presents the proposed architecture. Section IV describes the methodology. Section V provides the results and discussion. Finally, Section VI concludes the study.

II. Related Work

The paradigm shift from host-centric, IP-based networking to content-oriented communication has driven ongoing

*Corresponding author.

research into architectures that leverage the advantages of this new model. Unlike IP networks that rely on host addresses, Named Data Networking (NDN) enables data retrieval based on content names, making it better suited to modern, dynamic, distributed, and data-intensive networking environments.

Research on NDN remains active across multiple domains, including forwarding, routing, caching, security, and mobility support. These areas continue to be studied because many challenges in modern networks, such as high latency, data availability in mobile environments, efficient caching, and reliable communication in heterogeneous topologies, are not fully addressed by existing approaches. Therefore, investigations that strengthen existing findings, expand application scenarios, and evaluate NDN architectures in new environments such as Aerocity areas remain highly relevant and necessary [21], [22].

Aerocity environments, characterized by high mobility, heterogeneous nodes (RSUs, vehicles, drones, and ground infrastructure), and intensive cross-zone communication, introduce unique challenges that are not adequately addressed in previous NDN research. This highlights the importance of the architectural design study conducted by the authors, as Aerocity environments combine real-time communication needs, inter-zone mobility, and content-centric information exchange that are uncommon in traditional network models.

The use of ndnSIM is particularly appropriate because the simulator implements the core NDN components, including PIT, FIB, CS, and Interest/Data exchange semantics, allowing comprehensive QoS evaluation without the need for complex or costly physical infrastructure. Simulation also provides flexibility to explore various topology configurations, adaptive routing strategies, caching mechanisms, and mobility scenarios in a controlled and reproducible manner [21], [23].

Previous studies have examined the implementation of NDN across several network models, such as VANETs, IoT systems, smart cities, UAV networks, and edge fog environments, using different optimization strategies for NDN components. However, there is still limited research that specifically evaluates NDN in Aerocity contexts, which feature multi-zone structures, interactions across multiple modes of transportation, and complex mobility dynamics. Accordingly, this study contributes to broadening the scope of NDN research and provides empirical evidence of NDN's potential in future networking environments characterized by high mobility.

NDN architecture transforms the approach to data retrieval from a host-centric to a content-name-based model. Numerous studies on NDN have been conducted, and this section reviews research on data-centric communication, routing, forwarding, caching, and security in NDN.

Data retrieval in NDN begins when a consumer sends an Interest into the network and receives the corresponding Data packet from the producer, following the reverse path of the Interest. NDN employs three key data structures: the Pending Interest Table (PIT), the Forwarding Information Base (FIB), and the Content Store (CS) [24]–[26]. The PIT records all Interests forwarded by a router that have not yet been satisfied. When an Interest packet arrives, the router first checks the Content Store to find matching data. If no matching data is found, the router examines the PIT and forwards the Interest to the producer based on the FIB. However, if the Content Store contains the requested data, the Data is returned directly through the interface.

Regarding content naming from a source, whether through a flat or hierarchical approach, the Attribute-Based Encryption (ABE) method is employed. This approach involves three roles in content generation: the content owner, the content user, and the content to be encrypted. To obtain content, users use a name search service via a routing process known as name-based routing. Two types of attributes are used in this approach to generate content names: subject attributes and object attributes, both of which contribute to forming attribute control and attribute descriptions. For security purposes, encryption and decryption algorithms are applied during the construction of the content naming scheme.

Routing and forwarding in Named Data Networking (NDN) adopt a fundamentally different approach from traditional IP-based networks, operating on content names rather than host addresses. In the routing plane, NDN utilizes name-based routing protocols to disseminate content prefixes and construct the Forwarding Information Base (FIB), allowing routers to determine the most suitable paths to data producers or in-network caches. This design supports dynamic topology changes and ensures resilience in mobility scenarios, particularly through adaptive strategies that prioritize latency reduction and traffic load distribution [23], [24], [27].

In the forwarding plane, decisions are made locally at each router based on three main data structures: the Content Store (CS), the Pending Interest Table (PIT), and the FIB. When an Interest packet is received, the router first checks the CS to satisfy the request from cached Data, thereby reducing retrieval delays. If no match is found, the router examines the PIT to aggregate identical Interests and enable efficient multicast delivery of returning Data. If the Interest is new, the router refers to the FIB to forward the request to the appropriate interface. Once a Data packet arrives, it is distributed to all consumers listed in the PIT and stored in the CS for future access. Caching strategies in the context of Named Data Networking (NDN) refer to the methods for determining when, where, and what content is stored in network node caches. The objective is to reduce latency by serving data directly from the nearest cache, save bandwidth by avoiding redundant traffic, and enhance reliability by ensuring data availability even when the producer is offline [28]–[31].

Security in Named Data Networking (NDN) is data-centric, shifting the trust model from communication channels to the content itself. Data is secured using digital signatures and encryption, ensuring authenticity and integrity. Unlike IP-based architectures that primarily secure point-to-point connections, NDN ensures that every Data packet is cryptographically signed by its producer, enabling source authentication and integrity verification regardless of the retrieval path [32], [33].

Overall, the NDN security framework provides intrinsic content protection, offers resilience against communication channel attacks, and supports reliable communication in

dynamic environments such as smart cities and Aerocity networks.

III. Proposed Architecture

The objective of proposing this architecture is to design a model that addresses the challenges of dense connectivity, diverse traffic flows, and the multiple interacting domains within the Aerocity environment. The proposed architecture adopts the Information-Centric Networking (ICN) paradigm based on Named Data Networking (NDN) with a topology-driven approach. The design connects consumer nodes distributed across various Aerocity zones directly to an interconnected NDN router network. Routers are positioned according to the physical map and functional structure of Aerocity, ensuring that the architecture reflects real-world conditions. The goal is to guarantee flexibility, routing efficiency, and alignment with the specific data requirements of each zone.

Each zone (Logistics, Transport, Industrial, Commercial–Residential, Utilities) contains two NDN routers (serving as inter-zone gateways), several consumers (represented by small green nodes), and one producer (represented by a purple node). The zone routers are connected to the NDN mesh routers (three routers forming a triangle), following the same mapping as the scenario.

A. Data Requirements

Data Requirements and Example Data Prefixeswere obtained through a synthesis of multiple sources, including government planning documents on the Taoyuan Aerotropolis, open datasets on transportation, logistics, and utilities, and academic literature on smart city infrastructure and information-centric networking. Rather than relying on a single source, this study identified consistent traffic patterns from various references and translated them into the Named Data Networking (NDN) framework. Each functional zone (Logistics, Transport, Industrial, Commercial–Residential, and Utilities/Smart Infrastructure) was mapped in terms of consumers, producers, data prefixes, and traffic characteristics, including proceedings that map key factors in Aerotropolis development and information requirements for decision-making [34]. On this basis, the data patterns in the logistics, transportation, industrial, commercial–residential, and utilities zones are translated into producer–consumer mappings within the NDN approach Architecture Description.

B. Architecture Description

The architecture topology consists of several NDN routers placed in each zone. Consumer nodes within a given zone send Interests to the local router, which then searches the FIB, PIT, and Content Store. If the data is unavailable, the Interest is forwarded to neighboring routers or to the data center according to the Aerocity interconnection map. The router in the logistics zone is closely linked to the cargo data distribution center. The router in the transportation zone connects to roadside units (RSUs) and the airport information system. The router in the industrial zone links factory sensors to the

The data requirements presented in analytics system. The commercial and residential router connects to multimedia services and customer applications. Thus, the communication flow is not constrained by a layered hierarchy but is instead determined by inter-zone relationships and the actual infrastructure, as shown in Aerocity area network architecture design based on NDN (Physical Layout + Interest/Data Overlay).

C. Workflow or Communication Flow

The communication process begins when a consumer in a given zone sends an Interest packet to the local router. The router checks the Content Store; if a cache hit occurs, the Data is immediately returned. If a cache miss occurs, the Interest is forwarded to an inter-zone router or directly to the producer, depending on the FIB. The producer (e.g., a logistics data center or an airport information system) sends the Data, which is then returned along the same path. Along this path, the Data may be cached at intermediate routers to ensure that the selected forwarding path operates under optimal traffic conditions, thereby maintaining network efficiency even in high-mobility scenarios. These routers are interconnected to form a mesh topology consistent with the physical design of Aerocity, enabling multiple routing paths between consumers and producers. This structure ensures the evaluation of both cache hit and cache miss scenarios. These routers are interconnected to form a mesh topology that is consistent with the physical design of Aerocity, enabling multiple routing paths between consumers and producers. This structure ensures the evaluation of both cache hit and cache miss scenarios.

TABLE I. Data Requirements and Example Data Prefixes

Zone	Consumers	Producers	Example Data / Prefix	Traffic Characteristics
Logistics	Warehouses, distribution centers, cargo operators	Cargo management systems, logistics tracking databases	/logistics/cargo/ /logistics/tracking/	Periodic (1–2s), high volume
Transport	Vehicles, traffic management applications	Airport information systems, traffic management servers	/transport/traffic/ /transport/flights/	Bursty (peak hours), real-time
Industrial	Factories, IIoT machines, production operators	Industrial analytics platforms	/industrial/iiot/	Medium-periodic, critical data
Commercial–Residential	Retail apps, households, multimedia service users	e-commerce servers, customer service platforms	/commerce/media/ /residential/services/	Zipf-like popularity, heavy content
Utilities / Smart Infrastructure	IoT sensors (energy, water, CCTV), public safety units	Energy/water utility servers, municipal security centers	/utilities/energy/ /utilities/water/	Low-volume periodic, persistent

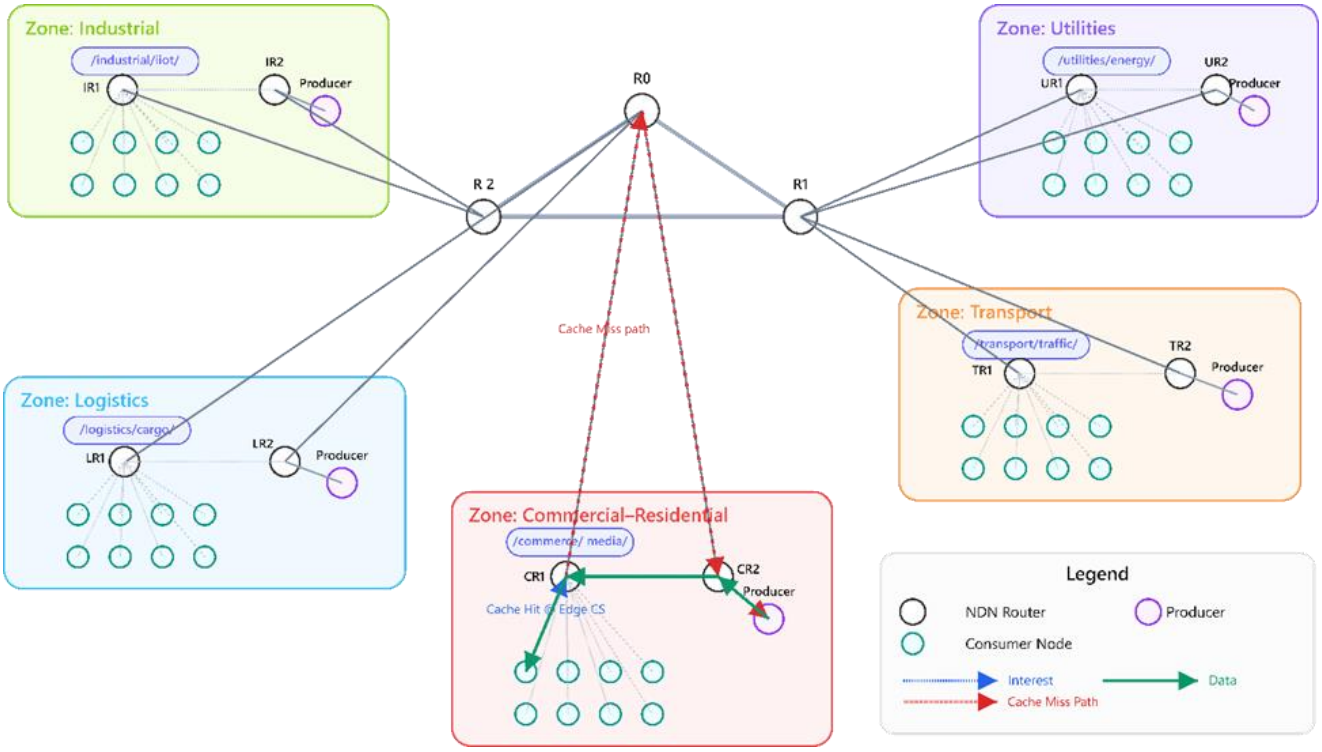

Fig. 1. Aerocity area network architecture design based on NDN (Physical Layout + Interest/Data Overlay).

D. Traffic Model

Traffic flows are generated to emulate realistic Aerotropolis operations. Logistics Zone, periodic Interests for cargo status updates at intervals of 1 to 2 seconds. Transport Zone, Interests for real-time traffic information and flight schedules, modeled as burst traffic during peak hours. Industrial Zone, Interests for IIoT telemetry control messages with medium periodicity. Commercial and Residential Zone, Interests for video streaming and web services with a Zipf content popularity distribution. Utilities Zone: sensor-based Interests for energy and water data, modeled as low-volume periodic flows.

IV. Methodology

A. Simulation Environment

This study employs ndnSIM as the standard simulator for Named Data Networking (NDN) research [35], [36], as it fully supports the core NDN components while providing flexibility for scenario development and topology modifications tailored to Aerocity requirements, and was executed on Ubuntu 22.04 LTS. The simulation configuration activates the main components of the NDN forwarding plane, namely the Content Store (CS), Pending Interest Table (PIT), and Forwarding Information Base (FIB). Additionally, python scripts are utilized to analyze the simulation results. The simulation was run for 60 seconds using the BestRoute forwarding strategy, with tracers sampled every second. A Content Store of 10,000 entries (LRU policy) and producer payloads of 1024 bytes were configured, and results were exported in CSV format for throughput, cache performance, and delay analysis.

B. Network Topology

The experimental topology reflects the Kertajati Aerocity model, consisting of several functional zones, including Logistics, Transport, Industrial, Commercial–Residential, and Utilities, as shown in ndnSIM Visualizer displaying the simulation topology and node-level state information during runtime. The visualization of the simulation process is generated using ndnSIM. Each zone is equipped with Consumer nodes, which generate Interest packets for data such as logistics tracking, traffic information, industrial control messages, multimedia content, and IoT sensor data. NDN routers, strategically placed to represent inter-zone gateways, are responsible for forwarding Interest–Data flows. Producer nodes, which provide authoritative data repositories, such as cargo databases, traffic management systems, and utility monitoring centers. The experimental topology models a multi-zone Aerocity network with five functional zones: Logistics (8 nodes), Transport (8), Industrial (6), Commercial–Residential (10), and Utilities (10), and Utilities (10). Each zone is connected to a single aggregation node (five total), while a three-node core backbone (R0, R1, R2) provides inter-zone connectivity.

C. Performance Metric

To evaluate the efficiency of the proposed NDN-based architecture, experiments were conducted using several Quality-of-Service metrics. These metrics serve as the primary indicators for measuring network performance, focusing on how the architecture handles data delivery, latency, cache utilization, and overall reliability in an Aerocity environment. The calculation of Quality-of-Service metrics from simulation output data was performed using a Python-based program that facilitates the computation and ensures higher accuracy.

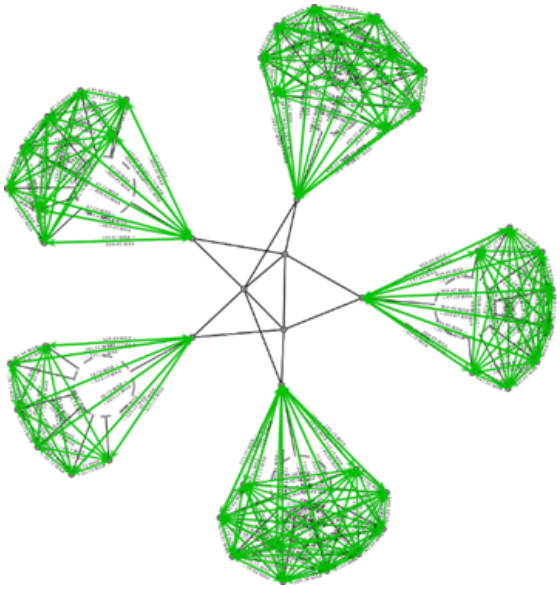

Fig. 2. ndnSIM Visualizer displaying the simulation topology and node-level state information during runtime.

Three output files that are used for analyzing the performance metrics of the NDN network, namely rate-trace.csv, app-delay-trace.csv, and cs-trace.csv.

The rate-trace.csv file stores Interest, Data, and byte statistics for each node, which can be used to calculate throughput (bits/s), packet delivery rate, and node-by-node traffic.

First 10 Entries from the File Rate-Trace.presents the first ten entries from the rate-trace.csv file.

Throughput is defined as the volume of data successfully delivered to the consumer per unit time, Δt. The formula is expressed as:

$$T = \frac{S}{\Delta t} \text{(bit/s)} \quad (1)$$

where, S is the total number of Data bits successfully received during the interval Δt.

To calculate and generate the throughput-related graph for this experiment, a python-based application was used. Furthermore, the app-delay-trace.csv file is used to log the application-level delay (Interest → Data) for each packet, which is then used to compute application-level latency. First 10 Entries from the File App-Delay-Trace.presents the first 10 entries from the app-delay-trace.csv file.

Latency measures the average round-trip time (RTT) from when an Interest is sent until the corresponding Data is received:

$$\bar{L} = \frac{1}{M} \sum_{\{i=1\}}^{M} t_D(i) - t_I(i))) \quad (2)$$

where, *t_I(i)* is the transmission time of the *i*-th Interest, *t_D(i)* is the reception time of the *i*-th Data, and *M* is the number of valid Interest–Data pairs.

To calculate and generate the latency-related graph, a python-based application was used.

TABLE II. FIRST 10 ENTRIES FROM THE FILE RATE-TRACE.CSV

TABLE IV. FIRST 10 ENTRIES FROM THE FILE CS-TRACE.CSV

Time	Node	Type	Packets
1	0	CacheHits	0
1	0	CacheMisses	0
1	1	CacheHits	0
1	1	CacheMisses	0
1	2	CacheHits	0
1	2	CacheMisses	0
1	3	CacheHits	0
1	3	CacheMisses	0
1	4	CacheHits	0

The cs-trace.csv file contains statistics on cache hits and misses for each node, which are used to calculate the Cache Hit Ratio.

First 10 Entries from the File CS-Trace.presents the first 10 entries from the cs-trace.csv file.

CHR represents the proportion of Interests satisfied by intermediate caches rather than by the original producer:

$$CHR = \frac{H}{N_{req}} \quad (3)$$

where, *H* is the number of cache hits and *N_req* is the total number of Interests generated.

The file cs-trace.csv produced output with all recorded values set to zero; therefore, no calculations or graphical visualizations were performed. The reason behind this zero-valued data will be considered as a suggestion for further research.

V. RESULTS AND DISCUSSION

A. Performance of the Proposed Architecture

In the proposed ICN-based NDN architecture for the Aerocity environment, there is a clear alignment between the NDN topology and the data requirements of Aerocity. This alignment is represented by the division into five functional zones—Logistics, Transport, Industrial, Commercial–Residential, and Utilities—each equipped with its own namespace prefixes. For instance, the simulation includes producers with prefixes such as /logistics, /transport, /airport, /industrial, /factory, /commerce, /residential, and /utilities, reflecting the diverse data sources and services required in an Aerocity environment. This mapping illustrates how workloads are semantically organized by namespace, enabling zone-specific routing, caching, and differentiated data handling policies.

Each zone contains multiple edge nodes (ranging from 6 to 10), connected to a dedicated aggregation router that acts as a local gateway. These aggregation routers are then linked to a three-node core backbone (Core A, Core B, and Core C), interconnected with high-capacity links to ensure redundancy and resilience in inter-zone communication. This hierarchical structure mirrors the physical organization of Aerocity networks, where data originates from producers (e.g., cargo systems, traffic management, industrial sensors, multimedia services, and utility monitoring) and is consumed by various applications with different traffic patterns.

The model is explicitly topology-driven, with NDN's forwarding plane components FIB, PIT, and CS configured according to the physical layout. The Content Store (10,000 entries, LRU policy) ensures in-network caching, allowing repeated Interests to be served closer to consumers. The overlay of Interest/Data flows observed in the simulation emphasizes how consumer requests are routed by name, Data packets are returned along the reverse path, and intermediate nodes opportunistically cache the content. This results in a realistic emulation of Aerocity traffic, where Logistics and Transport zones generate frequent updates (high-rate Interests), Industrial zones issue periodic control traffic, and Commercial–Residential and Utilities zones produce bursty and heterogeneous demands.

The research conducted in this study addresses challenges related to mobility, data dissemination, caching, and adaptive routing by fully capturing the multi-zone, cross-domain, and high-mobility characteristics of Aerocity environments. These conditions position this study at an advantage compared to previous research.

Most existing studies focus on optimization components such as forwarding strategies, caching enhancements, or mobility support, typically applied to specific topologies or limited mobility scenarios. Although such works provide valuable insights, their applicability to Aerocity use cases remains limited due to the absence of multi-modal mobility interactions, vehicles, and ground infrastructure, as well as the lack of a comprehensive analysis of heterogeneous producer–consumer communication across functional zones.

B. Quality of Service (QoS) Analysis

The simulation results show that overall network throughput quickly stabilizes after the initial phase. As seen in Overall throughput vs. Timethe throughput rises from about 7.2 Mbps to 10.1 Mbps within the first few seconds and remains steady until the end of the 200-second simulation. This indicates that the NDN forwarding and in-network caching mechanisms effectively utilize network capacity and maintain consistent performance.

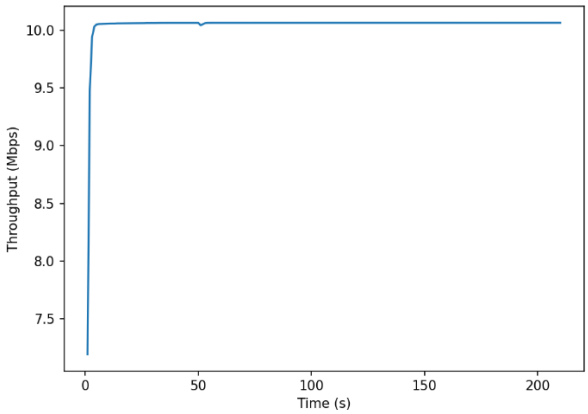

Fig. 3. Overall throughput vs. Time.

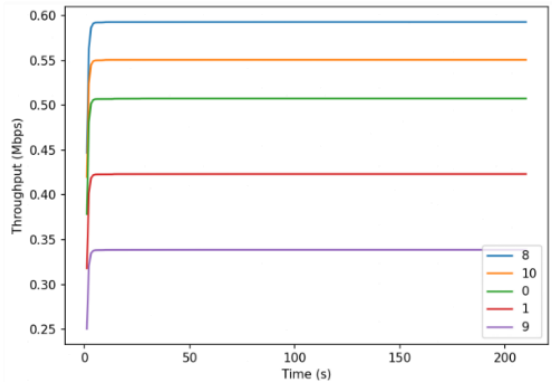

Fig. 4. Throughput vs. Time (top 5 nodes).

Throughput vs. Time (top 5 nodes)highlights the contribution of the five nodes with the highest traffic. Node 8 recorded the highest throughput (0.59 Mbps), followed by Node 10 (0.55 Mbps), Node 0 (0.51 Mbps), Node 1 (0.42 Mbps), and Node 9 (0.34 Mbps). The relatively balanced distribution across nodes suggests that traffic is well distributed, enabling the system to avoid bottlenecks and achieve good load balancing.

The latency analysis confirms that the proposed NDN architecture provides consistently low end-to-end delay. As shown in CDF of application delaymore than 95% of requests are completed within just a few milliseconds, with an overall average delay of about 3 ms.

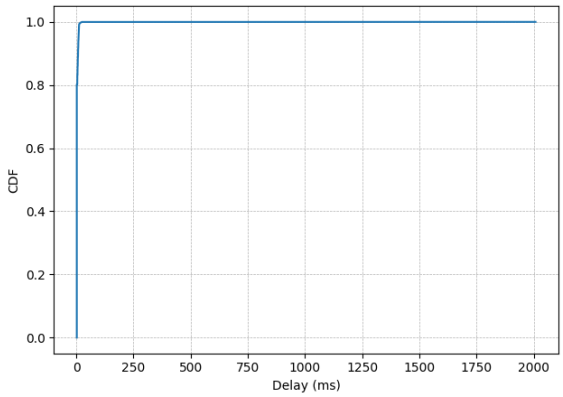

Fig. 5. CDF of application delay.

The graph in Average application delay over timeillustrates the variation of the average application delay throughout the simulation with a 1-second interval. A delay spike of approximately 24 ms is observed at the beginning of the simulation, caused by the initialization process of Interest–Data exchange when the routers have not yet populated their Pending Interest Table (PIT) entries or cached content in the Content Store (CS). After the initial phase, the delay decreases and stabilizes at 2–4 ms, indicating that the in-network caching mechanism is functioning effectively. A minor spike around the 50th second (±9 ms) is likely due to a route change in the Best Route strategy, an Interest burst, or a cache content replacement.

Overall, these results demonstrate that the NDN architecture in the Aerocity topology can maintain low and stable latency after the initialization phase, owing to the efficiency of caching mechanisms and the adaptiveness of the routing strategy. These results demonstrate that the forwarding strategy and in-network caching efficiently sustain low and predictable delay under heterogeneous Aerocity traffic conditions.

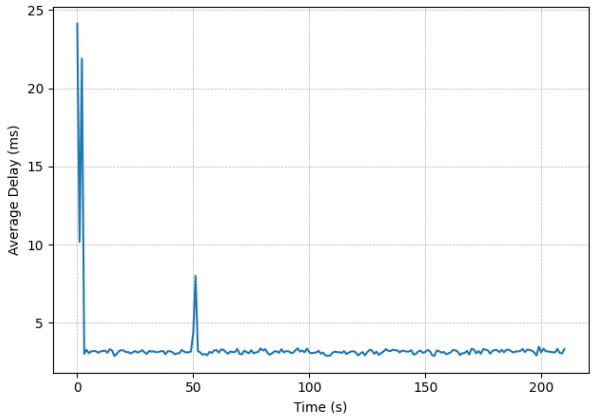

Fig. 6. Average application delay over time.

The Cache Hit Ratio (CHR) is calculated from the number of cache hits and misses recorded in the cs-trace.csv file. However, the simulation output shows that both CacheHits and CacheMisses are zero, making the CHR calculation undefined because the denominator (total requests) is zero. This condition does not necessarily indicate a flaw in the proposed NDN architecture; rather, it is more likely due to limitations in the logging instruments or the Content Store (CS) configuration within ndnSIM, as well as traffic patterns that did not trigger cache reuse. As researchers, it is important to report this condition explicitly to avoid misinterpretation. Therefore, this study focuses on quality of service analysis through throughput and latency metrics, while proposing cache performance evaluation as future work under scenarios with a more active CS configuration or more diverse traffic patterns.

VI. Conclusion

This study designed and experimentally evaluated an NDN-based ICN architecture to address heterogeneous communication needs in Aerocity Kertajati. The simulation results show that network throughput quickly stabilized at around 10.1 Mbps (from 7.2 Mbps at the beginning of the

simulation), with a balanced distribution across nodes (Node 8 reached 0.59 Mbps, the highest). Latency analysis revealed an average of ~3 ms, p95 < 10 ms, and more than 95% of requests completed within a low-latency bound, despite initial spikes of 20–25 ms. Cache data was unavailable (CacheHits/Misses = 0) due to tracer configuration and traffic patterns that did not trigger cache reuse. Thus, cache analysis is proposed as future work. This study proposes an Information-Centric Networking (ICN) architecture based on Named Data Networking (NDN), specifically tailored to meet the requirements of Aerocity environments, which are characterized by multi-zone structures, cross-domain interactions, and high mobility. The developed architecture integrates adaptive routing mechanisms, a hierarchical naming scheme, and caching strategies to support real-time data exchange across logistics, transportation, industrial, commercial–residential, and utility zones. Through simulations conducted with ndnSIM, the architecture demonstrates performance improvements in latency and throughput, thereby validating its relevance for modern communication scenarios in Aerocity settings.

The main contributions of this research include the introduction of an NDN architecture explicitly designed for Aerocity ecosystems, the development of a reproducible simulation scenario, and the analysis of producer–consumer communication patterns across zones. These findings provide scientific value that strengthens the potential of NDN as a future network architecture for Aerocity environments.

Improving the Performance of TFS with Ensemble Learning for Cross-Project Software Defect Prediction

Pathiah Abdul Samat[1], Yahaya Zakariyau Bala[2], Nur Hamizah Hamidi[3]
Department of Software Engineering and Information System-Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, Serdang 43400, Malaysia[1, 3]
Department of Computer Science, Federal University of Kashere, Gombe 771103, Nigeria[2]

***Abstract*—Software defect prediction (SDP) plays a key role in improving software quality by identifying defect-prone modules early in the development cycle. While within-project prediction has been widely studied, cross-project defect prediction (CPDP) remains challenging due to differences in datasets, high feature dimensionality, and poor model generalization. To address these challenges, this study enhances the Transformation and Feature Selection (TFS) approach by integrating ensemble learning techniques. Three methods, Gradient Boosting Machine (GBM), stacking, and hybridization, were explored to evaluate their effectiveness in improving CPDP performance. Experiments were conducted using the AEEEM datasets, with preprocessing steps including normalization, feature reduction, and the Synthetic Minority Oversampling Technique (SMOTE) to handle data imbalance. The models were trained on source projects and tested on separate target projects, with the F1 score used as the main evaluation metric. Results show that the TFS × Stacking model achieved the highest overall performance, with a mean F1 score of 0.963, outperforming both TFS × GBM (0.958) and TFS × Hybridization (0.920). Compared to the original TFS × Random Forest method, the stacking approach consistently provided significant improvements across all project pairs. These findings highlight the potential of combining TFS with ensemble learning to enhance defect prediction in projects with limited or no historical data. This work not only advances CPDP research but also offers practical value to software teams by enabling more accurate identification of defect-prone modules and better allocation of testing resources.**

***Keywords*—Software; defect prediction; cross-project; ensemble learning; feature selection**

I. Introduction

Delivering high-quality software is one of the biggest challenges in software engineering [1]. A huge amount of time and money goes into testing and debugging, yet defects often slip through and cause failures in real-world systems [2]. These failures can be costly, damage user trust, and reduce the overall reliability of the software. To address this, researchers and practitioners have turned to software defect prediction (SDP), which uses historical project data and code metrics to identify parts of the system that are most likely to contain bugs. By highlighting defect-prone modules early, teams can focus their testing and maintenance where it matters most, saving both time and resources.

Traditional SDP models are usually built with supervised machine learning techniques that learn from past projects [3-4]. They look for patterns in features such as lines of code, complexity, and other process metrics that often signal potential defects. While these models have proven useful, they depend heavily on having high-quality labeled data from the project being developed. Unfortunately, many new projects lack this data, making it difficult to train reliable models.

This is where cross-project defect prediction (CPDP) becomes important. CPDP allows models to be trained using data from other projects and then applied to a new project with little or no labeled data [5]. In theory, this makes defect prediction more widely usable. In practice, however, CPDP faces major hurdles: the source and target projects often differ in their features and distributions, data is high-dimensional, and models trained on one project often perform poorly when applied to another.

To tackle these problems, researchers have explored techniques such as feature transformation and feature selection. Transformation methods reduce differences between projects, while feature selection eliminates irrelevant or redundant data to make models simpler and more accurate. The Transformation and Feature Selection (TFS) approach has shown promise in this regard, but it still struggles with complex, non-linear patterns and imbalanced datasets.

Recently, ensemble learning has emerged as a powerful way to improve prediction models. Instead of relying on a single learner, ensemble methods combine multiple models to produce more accurate and robust results [6-7]. Gradient Boosting Machine (GBM), stacking, and hybridization are three such techniques that have been particularly effective. GBM is strong at capturing complex relationships and handling imbalanced data; stacking leverages the strengths of diverse models through a meta-learner; and hybridization blends models to capture both linear and non-linear dependencies.

Building on these observations, this study proposes an improved CPDP framework by integrating TFS with GBM, stacking, and hybridization. The goal is to investigate whether combining these methods can lead to better generalization across heterogeneous projects. The F1 score is used to measure predictive performance, with the goal of identifying which

ensemble approach works best with TFS for cross-project defect prediction.

By doing so, this study not only contributes to the academic field of defect prediction but also offers practical benefits. Development teams working on new projects, especially those with little labeled data, can use these enhanced models to predict software defects more reliably and make better decisions about where to direct testing efforts.

II. Related Work

Software defect prediction (SDP) is widely recognized as an important technique for improving software quality, as it helps identify components that are likely to contain bugs before a system is released [8]. Traditional SDP approaches largely depend on within-project defect prediction (WPDP), where a model is trained and tested using data from the same project. However, WPDP requires a large amount of labeled defect data, something that new or early-stage projects typically do not have [9]. This limitation has encouraged researchers to explore cross-project defect prediction (CPDP), where models trained on one project are applied to another project that has little or no historical defect data [10].

Over the years, CPDP research has proposed various strategies to address challenges such as data inconsistency, high dimensionality, and differences in metric distributions across projects. However, many studies address these issues in isolation, focusing on either feature transformation, feature selection, or ensemble learning without examining how these techniques can be combined and jointly optimized to improve cross-project transfer performance.

A. Feature Transformation Approaches

Feature transformation has been widely used to reduce the differences between source and target datasets. For example, Zhao et al. [11] introduced a manifold-based transformation method that projects data into a shared feature space, increasing similarity between datasets and improving prediction performance. Although their work showed the value of aligning data distributions, it did not consider how ensemble learning or feature selection could be integrated to further reduce noise and redundancy.

Similarly, Shekhawat et al. [12] proposed the Binary SALp Swarm Algorithm (BSSA), which performs both data transformation and feature selection. While the method improved computational efficiency, it was mainly evaluated in WPDP settings and did not examine its potential in CPDP contexts, where the domain differences are more substantial.

B. Feature Selection Methods

Feature selection techniques reduce dimensionality by eliminating irrelevant or redundant metrics. Ali et al. [13] compared several feature selection methods and demonstrated that removing unstable features can significantly improve prediction accuracy. However, their analysis treated feature selection as a standalone step and did not explore its interaction with feature transformation or ensemble learning.

Pandey et al. [14] proposed a hybrid method that combines data transformation with the Binary Binomial Cuckoo Search algorithm for feature selection. Although effective, the approach emphasized heuristic optimization and did not investigate ensemble-based improvements or its suitability for cross-project scenarios.

C. Ensemble Learning in Defect Prediction

Ensemble learning methods such as Random Forest, Gradient Boosting, and stacking have become increasingly popular due to their robustness and ability to capture complex, nonlinear patterns in defect datasets. Matloob et al. [15] conducted a systematic review showing the advantages of ensemble learning, particularly improvements in recall and performance on imbalanced data. However, their work did not examine how ensemble techniques might interact with feature transformation in CPDP environments.

Tang et al. [16] introduced an adaptive ensemble algorithm based on the Sparrow Search Algorithm, showing strong results on imbalanced datasets. Nonetheless, their method required extensive dataset-specific tuning, limiting its generalizability across projects.

Hybrid approaches that combine gradient boosting and deep learning models, such as those examined by [17], [18], and [19], have also demonstrated improved accuracy by leveraging both linear and nonlinear learners. Yet, these approaches do not incorporate feature selection specifically tailored for cross-project prediction, leaving a gap in understanding how transformation, feature reduction, and ensemble learning can work together within CPDP.

D. Gap in Existing Literature

From the reviewed literature, a clear gap emerges: most CPDP studies evaluate feature transformation, feature selection, and ensemble learning separately. There is no unified framework that systematically integrates these techniques or examines how their combination provides conceptual or technical benefits beyond existing hybrid models.

E. Contribution of this Study

This study addresses that gap by proposing an integrated framework that combines Transformation and Feature Selection (TFS) with multiple ensemble learning strategies, including Gradient Boosting Machines (GBM), stacking, and hybrid ensemble models, and evaluates their cross-project transferability using diverse datasets. The contribution lies not only in the integration itself but also in analyzing how each ensemble approach utilizes TFS outputs to improve robustness against domain divergence in CPDP.

III. Methodology

The methodology focuses on improving the Transformation and Feature Selection (TFS) approach proposed [7] by integrating advanced machine learning ensemble techniques for cross-project defect prediction (CPDP). Specifically, this research evaluates three ensemble methods, such as stacking, hybridization, and Gradient Boosting Machine (GBM), to determine which approach best enhances the performance of TFS.

The main challenges addressed include high-dimensional feature spaces, poor generalization across projects, and

imbalanced datasets. Our proposed approach mitigates these limitations by applying feature transformation, feature selection, and ensemble learning techniques.

In the proposed solution, the performance of the TFS model is enhanced through the application of ensemble learning. Three methods are implemented for comparison:

1) Stacking Model, which combines predictions from multiple base learners using a meta-learner.

2) Hybridization Model, which integrates different models to capture both linear and nonlinear patterns.

3) Gradient Boosting Machine (GBM), which builds sequential decision trees that iteratively correct errors.

The most widely adopted evaluation metric, the F1 score, is used to assess model performance due to its effectiveness in handling imbalanced datasets. The experiments are conducted to identify the best-performing ensemble method when combined with TFS for CPDP.

B. Datasets

The AEEEM datasets are some of the open-source datasets commonly used in SDP studies [3]. Table I shows the datasets that contain features gathered from previous software projects, which represent various aspects of software modules, such as lines of code, complexity measures, and fault labels. All the datasets contain defective data from a few software projects, labeled as either "Defective" or "Non-Defective".

TABLE I. CHARACTERISTICS OF DATASETS

Project Name	No. Of Module	No. Of Features	No. Of Defect	Defect Ratio
EQ	324	61	129	39.81%
JDT	997	61	206	20.66%
LC	691	61	64	9.26%
ML	1862	61	245	13.16%
PDE	1497	61	209	13.96%

C. Feature Selection

There are 61 features across all datasets. Only the top ten features, determined by significance scores, were chosen for training before the evaluation to reduce dimensionality and improve model interpretability. The mean and standard deviation of feature values were used to get the relative relevance score. Calculate the average and standard deviation for each characteristic. Determine the difference between the feature mean and the overall dataset mean. Order the features according to their deviation scores or other computed metrics, with lower deviations suggesting greater importance. The relevant features are extracted from every dataset.

D. Evaluation Metrics

The F1 score is the main evaluation metric for machine learning models in this study. This metric is especially useful for imbalanced datasets since it provides a balanced evaluation by merging precision and recall into a harmonic mean [20-21]. By accounting for both false positives and false negatives, the F1 score ensures that the model's prediction capabilities are thoroughly evaluated. The F1 score, which is commonly employed in binary and multi-class classification problems, combines precision and recall, providing a reliable measure of the model's overall performance, making it an important criterion for this study.

Precision: An indicator of a machine learning model's performance – the accuracy of its positive predictions.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (1)$$

Recall: A quantitative measure that assesses the frequency with which a machine learning model accurately detects positive occurrences.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (2)$$

F1-score: A measure of the harmonic mean of precision and recall.

$$\text{F1_score} = \frac{2 * \text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

E. Implementation

The implementation of the proposed approach consists of four major phases: data preprocessing, feature transformation and selection (TFS), model training, and evaluation, as shown in Fig. 1. First, datasets from multiple software projects (AEEEM) were collected and preprocessed to ensure consistency. Preprocessing included handling missing values, normalizing feature values, and addressing class imbalance using the Synthetic Minority Oversampling Technique (SMOTE).

Next, the TFS was applied to reduce dimensionality and improve the quality of the feature space. Feature scaling and selection techniques were used to identify the most relevant metrics, allowing the models to focus on the most influential predictors.

Three ensemble learning techniques were then implemented to enhance the performance of TFS for cross-project defect prediction (CPDP):

1) TFS × GBM: Gradient Boosting Machine was integrated with TFSM to capture complex non-linear relationships by iteratively correcting errors through sequential decision trees.

2) TFS × Stacking: Multiple base learners (e.g., Random Forest and GBM) were combined, with a Logistic Regression meta-learner integrating their predictions to optimize decision boundaries.

3) TFS × Hybridization: A hybrid voting-based approach was used to integrate Random Forest and GBM, capturing both linear and non-linear dependencies for more balanced performance.

The models were trained on source projects and tested on distinct target projects to simulate realistic CPDP scenarios. For each source–target pair, the F1 score was computed as the primary performance metric, as it balances precision and recall and is particularly suitable for imbalanced datasets. Comparative experiments across stacking, hybridization, and GBM identified the best-performing ensemble method when integrated with TFS.

F. Data Preprocessing

Preprocessing the dataset is an important step for ensuring the GBM model's quality and applicability [22]. Preprocessing tasks included correcting class imbalances, scaling numerical characteristics, encoding categorical variables, and handling missing data. Under- and oversampling techniques, notably the Synthetic Minority Oversampling Technique (SMOTE), were utilized to address class imbalances induced by skewed distributions of defect labels. These metrics were required for the model to efficiently analyze the dataset and provide reliable training and testing.

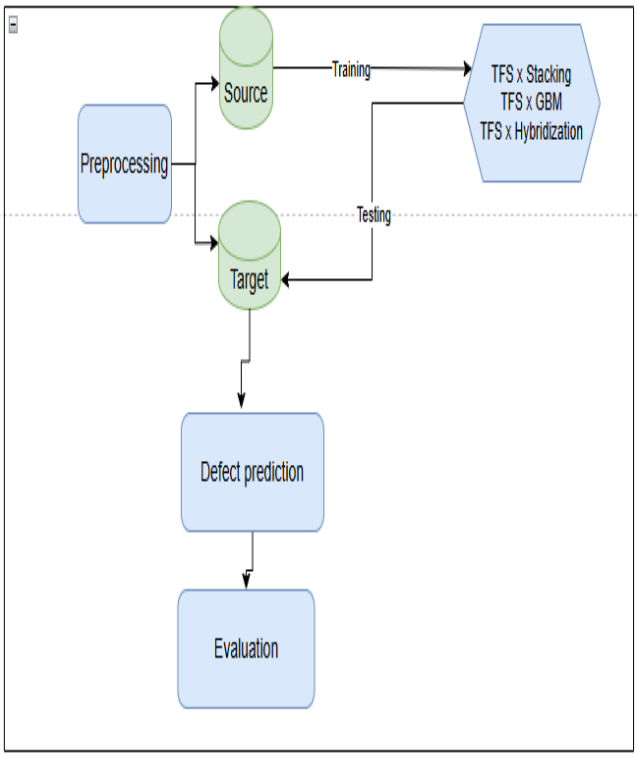

Fig. 1. Cross-project defect prediction workflow.

IV. Results and Discussion

This section describes the outcomes of integrating TFS and GBM in cross-project defect prediction settings. The stacking model combines the predictive power of Gradient Boosting and Random Forest as base learners, with Logistic Regression serving as the meta-model. This section evaluates the model's performance using its F1 score, which is a weighted statistic that accounts for class imbalances in the dataset. The results are analyzed to evaluate how efficient the stacking model method is in comparison to other methods.

A. Evaluation of TFS x GBM, TFS x Stacking and TFS x Hybridization

Table II compares the performance of three ensemble approaches (Stacking Model, Sequential Model, and Hybridization Model) using F1 scores across multiple cross-project software defect prediction scenarios. The models were evaluated by training on one source project (e.g., EQ) and testing on another target project (e.g., JDT).

TABLE II. Comparison of Three Ensemble Methods

Source > Target	Stack Model	Sequentially	Model Hybridization
EQ > JDT	0.85	0.91	0.90
EQ > ML	0.88	0.92	0.81
EQ > PDE	0.85	0.86	0.82
EQ > LC	0.94	0.92	0.90
JDT > EQ	0.97	0.95	0.90
JDT > LC	0.95	0.94	0.91
JDT > ML	0.97	0.95	0.91
JDT > PDE	0.98	0.94	0.91
LC > EQ	0.99	1.00	1.00
LC > JDT	0.98	1.00	0.98
LC > ML	0.99	0.99	0.98
LC > PDE	0.99	0.99	1.00
ML > EQ	0.98	0.96	0.91
ML > JDT	0.98	0.96	0.91
ML > LC	0.98	0.97	0.92
ML > PDE	0.98	0.94	0.90
PDE > EQ	1.00	1.00	0.93
PDE > JDT	1.00	0.98	0.96
PDE > LC	1.00	0.99	0.91
PDE > ML	1.00	0.98	0.94
Mean	0.963	0.958	0.920

The Stacking Model achieves the highest mean F1 score (0.963), indicating its robustness and generalizability across different project pairs. It performs exceptionally well in scenarios such as PDE > EQ, PDE > LC, and PDE > ML, with perfect F1 scores of 1.00. This demonstrates that combining multiple models through stacking improves the utilization of decision boundaries, resulting in higher prediction accuracy.

The Sequential Model follows closely with an average F1 score of 0.958. In some cases, it even outperforms the Stacking Model, such as LC > EQ and LC > JDT, where it achieves flawless F1 scores (1.00). This approach leverages the probabilistic outputs of one model (Random Forest) as inputs to another (Gradient Boosting), which proves highly effective in certain scenarios.

The Hybridization Model lags slightly behind, with an average F1 score of 0.920. While it achieves reasonable results overall, its performance is less consistent. For example, lower F1 scores in scenarios such as EQ > ML (0.81) and EQ > PDE (0.82) highlight its limited ability to generalize across different project pairs.

The results demonstrate that the Stack Model regularly has the greatest mean F1 score (0.963), exceeding both the Sequential Model (0.958) and the Hybridization Model (0.920). However, the Sequential Model performs competitively, occasionally outperforming the Stack Model in select circumstances, such as LC > EQ and LC > JDT. The Hybridization Model consistently underperforms the other two,

implying that it may be less effective in handling cross-project defect prediction jobs. Overall, the Stack Model shows higher robustness in all cases

B. Evaluation of TFS x Stacking Against Original Method

From Table III below, we can see that the TFS x Stacking Model consistently outperforms the TFS x RF Model across all source-target pairs, with a mean F1 score of 0.963 for the stacking model and 0.791 for the RF. Additionally, the stacking model performs well in pairs like EQ > LC and LC > EQ, with F1 scores of 0.94 and 0.99, respectively, compared to RF's 0.5 and 0.72. This demonstrates a significant improvement, particularly for specific source-target pairings. Furthermore, the PDE > EQ and PDE > JDT couples have flawless F1 scores of 1.00, demonstrating the outstanding performance of the TFS x GBM model.

The stacking detects complicated patterns and relationships in data, whereas the Random Forest ensures robustness and reduces overfitting. By merging various models, the stacking approach minimizes bias and instability, resulting in the improvement of prediction performance. Particularly, the stack model performs better than the stand-alone model, RF in combinations such as EQ > LC (0.94 vs. 0.5) and PDE > LC (1.00 vs. 0.87), implying that stacking better manages data dependencies and correlations. Furthermore, the stacked model performs consistently well across several domains, with high F1 scores in combinations such as LC > ML, ML > PDE, and JDT > ML, demonstrating its great ability to generalize and robustness in defect prediction across various software projects.

TABLE III. COMPARISON BETWEEN ENHANCED AND ORIGINAL MODEL

Source > Target	TFSM x Stacking	TFSM x RF
EQ > JDT	0.85	0.71
EQ > ML	0.88	0.81
EQ > PDE	0.85	0.65
EQ > LC	0.94	0.5
JDT > EQ	0.97	0.71
JDT > LC	0.95	0.74
JDT > ML	0.97	0.81
JDT > PDE	0.98	0.85
LC > EQ	0.99	0.72
LC > JDT	0.98	0.86
LC > ML	0.99	0.85
LC > PDE	0.99	0.87
ML > EQ	0.98	0.74
ML > JDT	0.98	0.86
ML > LC	0.98	0.89
ML > PDE	0.98	0.87
PDE > EQ	1.00	0.74
PDE > JDT	1.00	0.85
PDE > LC	1.00	0.92
PDE > ML	1.00	0.86
Mean	0.963	0.791

C. Advantages Over Previous Approaches

A major strength of this study lies in the integrated TFS + Ensemble framework, which performs better than previous CPDP methods evaluated in earlier studies. Unlike earlier CPDP approaches that applied feature transformation, feature selection, or ensemble techniques independently, the proposed method unifies these processes to more comprehensively address dataset heterogeneity. This integrated structure reduces noise, improves feature stability, and enhances the ability of ensemble models to learn cross-project patterns.

V. CONCLUSION

In this study, we set out to improve cross-project software defect prediction (CPDP) by combining Transformation and Feature Selection (TFS) with three ensemble learning techniques: Gradient Boosting Machine (GBM), stacking, and hybridization. The results show that using ensemble learning with TFS makes defect prediction more accurate and reliable by reducing issues such as high dimensionality, imbalance in the datasets, and weak generalization across projects. Of the three approaches, the TFS × Stacking model performed best, achieving the highest mean F1 score (0.963). This confirms that stacking, which combines the strengths of different base learners through a meta-learner, is particularly effective for capturing complex defect patterns. GBM and hybridization also showed good performance, but stacking consistently provided more robust results. When compared to the original TFS × Random Forest method, the ensemble-based models, especially stacking, showed significant improvements across all project combinations.

In real-world settings where labeled data is scarce or unavailable, common in early project phases, the proposed approach provides a practically viable defect prediction mechanism.

Despite its promising results, the study has several limitations. First, the experiments are limited to five datasets from the AEEEM repository, which may not represent the full diversity of real-world software systems. Second, the feature selection method used is relatively simple and may not capture deeper relationships among metrics. Third, the ensemble learners used were standard implementations; more advanced or domain-specific variations were not explored. Finally, the study does not evaluate the computational cost of the integrated pipeline, which may be a concern in large-scale industrial settings

Looking ahead, future research could build on this work by incorporating transfer learning or domain adaptation techniques to reduce distributional discrepancies more systematically. Another potential area is the integration of deep learning models or graph-based neural architectures to capture structural relationships within software components. Additionally, more sophisticated feature selection or feature synthesis techniques, such as metaheuristic optimization or automated feature engineering, could be integrated into the TFS pipeline.

From User Experience Evaluation to Design Guidelines for E-Commerce Websites

Layla Hasan, Beatrice Lim Pei Ying
Faculty of Computing, Universiti Teknologi Malaysia, Johor, Malaysia

***Abstract*—The evolution of the Internet and advances in information technology have significantly transformed business practices, leading to widespread e-commerce website development. To succeed in a competitive environment, website owners and designers must ensure that their e-commerce websites provide positive user experiences (UX). This research proposes UX guidelines for e-commerce websites, comprising 27 categories: 20 pragmatic features and 7 hedonic features. The guidelines were developed by evaluating the UX of two local e-commerce websites (Shopee and Lazada) and two international websites (Amazon and Alibaba), using a questionnaire completed by 200 participants to collect both quantitative and qualitative data. Results revealed common UX problems across all websites, including hedonic issues such as unattractive design and pragmatic issues such as poor usability, unclear layout, lack of user-friendliness, non-intuitive design, poor performance, and disorganization. Unique UX problems were also observed: some hedonic and pragmatic issues were specific to local websites, while certain pragmatic issues were unique to international websites. For Amazon, quantitative analysis showed the highest average rating for hedonic and pragmatic metrics at 3.87 out of 5, while qualitative analysis identified the least number of UX issues (13 in total: 1 hedonic and 12 pragmatic).**

Keywords*—User experience; UX guidelines; e-commerce websites; Malaysian e-commerce; hedonic features; pragmatic features

I. Introduction

The sustained technological advancement of information technology and the consequences of the COVID-19 pandemic increased the number of e-commerce websites globally and made online shopping very popular among users worldwide. E-commerce is an emerging business concept designed for buying, selling, or exchanging products, services, and information via the Internet. There are many advantages of e-commerce, including cost reduction, expanding distribution networks, and expanding current business models [1]. For a business that is established through the Internet using a website, such a seller no longer needs to build a physical store to do business, and there will also be no physical interaction between the seller and the buyer [2]. Furthermore, people are using e-commerce more often to avoid going out to crowded areas. Due to this, users may find it easier to shop at home online, where the environment is more comfortable. This resulted in it becoming a new habit even after the pandemic was over. This change in habit is partly due to e-commerce businesses allowing users to choose and buy a variety of products provided at online stores at anytime and anywhere [3].

There has been a significant evolution of e-commerce market worldwide and as well as in Malaysia [2, 4] and there have been many websites that have been created for e-commerce [1]. The market's growth in Malaysia was driven by many factors, including increasing Internet penetration, rising smartphone usage, diffusion of major brand platforms, evolving customer behaviors, strong government support, and improved financial tools [5,6,7]. These factors improved buyers' trust and increased sellers' diversity and therefore contribute to the expansion of the e-commerce market share in Malaysia. According to IMARC Group [5], in 2004, the e-commerce market size in Malaysia reached USD 80.40 billion, and it is expected to grow significantly to reach USD 961.88 billion by 2033, showing a growth rate (CAGR) of 28.17% during 2025-2033.

With a growing number of new competitors in the e-commerce industry, this has driven existing e-commerce companies to develop new strategies to sustain their leadership and success in the e-commerce industry. There are several factors that influence the success of e-commerce websites in the competitive environment [8]. One such key factor that should be considered on e-commerce websites if they are to compete and be successful is user experience (UX). User experience is an extension of interactive technology that generalizes the experience of how users interact with interactive technologies, as it involves the quality and functionality of the product regarding users' needs. User experience (UX) covers the experience and preferences that build up in the process of the user using or interacting with a user interface in a real-life situation [9]. It comprises the user's experience in terms of feeling, thinking, and perceiving, as well as the physical and mental reactions that occur in each step (i.e., before, during, and after) interacting with a user interface [9,10]. Therefore, the experience generated is responsible for the success of a user interface [11]. User experience is influenced by two categories of attributes in the user interface, which are hedonic and pragmatic. Hedonic attributes relate to features on the user interface that influence the emotions and feelings of the users when interacting with the interface [12, 13, 14]. Examples of hedonic features are: novelty, luxuriousness, attractiveness, delicacy, which helps in creating a delightful experience as these increase customer loyalty to a level that is more than satisfactory [15]. Pragmatic attributes, however, relate to features on the user interface which describe the utility or functionality and usability of the interface. They influence the difficulty in achieving task-related goals with efficiency and effectiveness [14, 16, 17]. Examples of pragmatic features are: simplicity, efficiency, learnability, user support, and a focus on goal-related functions or design issues.

The rapid growth of e-commerce has made user experience (UX) a critical factor in the success of online platforms. Despite its importance, several gaps exist in current research. Few studies have developed comprehensive UX guidelines that include both pragmatic and hedonic attributes from users' perspectives, which could be used to improve local e-commerce websites in Malaysia. In addition, limited research systematically examines and compares the UX of both local and international e-commerce websites, identifies issues affecting user interaction, and highlights differences between these contexts.

The aim of this research is to develop UX guidelines that foster positive user experiences. The primary focus is on evaluating both local and international e-commerce platforms to identify common and unique UX issues and to derive actionable guidelines. The specific objectives are:

- To examine the user experience of both local and international e-commerce websites.
- To compare the UX issues identified on these websites.
- To develop UX guidelines based on the comparison of issues affecting user experience.

This research will address the identified gaps in the literature by investigating, identifying, and comparing detailed UX issues related to both pragmatic and hedonic features on local and international e-commerce websites. The primary contribution of this research is the development of UX guidelines based on a comparative analysis.

The developed guidelines, which include key hedonic and pragmatic features, can be used to improve local e-commerce websites—especially in Malaysia—so they can better compete with international platforms. In addition, these guidelines can be applied to examine and enhance the UX of any e-commerce website, whether local or international. Furthermore, the results of this research will provide the owners of the four e-commerce websites studied (two local and two international) with comprehensive insights into UX issues on their sites, which can be addressed to improve the overall user experience.

The novelty of this research lies in its combined focus on both pragmatic and hedonic UX attributes, the comparative evaluation of local and international e-commerce platforms, and the development of comprehensive UX guidelines derived from mixed quantitative and qualitative analyses. Unlike previous studies, this work will provide an integrated, user-centred set of actionable guidelines tailored to the Malaysian context while remaining applicable to global e-commerce environments.

The remainder of this study is organized as follows: Section II reviews the related work. Section III describes the research methodology, including the selection of websites, participants, and data collection instruments. Section IV presents the quantitative and qualitative findings, while Section V discusses the key UX issues identified across local and international platforms. Section VI proposes the UX guidelines derived from the analysis. Finally, Section VII concludes the study with its contributions, limitations, and recommendations for future research.

II. Literature Review

Earlier research has been conducted to examine the user experience (UX) on e-commerce websites by employing various evaluation methods. One of these studies employed user testing, eye tracking, and questionnaires to assess the UX of e-commerce websites [18]. They found that the following attributes influenced the experience of users while interacting with the websites: usability, interface design, and user performance. The results also shed light on significant issues on the e-commerce websites which affected most of the users. These included: poor organization, unclear layout, and poor quality of content. Similarly, another research employed user testing and questionnaire methods to examine the user experience of three cosmetic e-commerce websites [19]. The results highlighted the significant issues on the websites that influenced the users' experience while interacting with the websites, and which had a significant effect on their satisfaction. These are related to: logical page order that makes sense, the availability of product variations shown by the image, relevant product summary information, the capability to save customer information for future purchases, the availability of comparison for the products with options, and the availability of recommendations for similar products.

Other research also employed the user testing and heuristic evaluation methods to evaluate the user experience of three e-commerce websites [20]. The findings highlighted issues on the websites, which influenced the experience of the users while interacting with the websites. These included: unavailability of an internal search function; unsuitable design of the product page; and not easy to navigate. Furthermore, another research used questionnaires to investigate the users' experience of e-commerce websites [1]. The research highlighted the following significant features on e-commerce websites, which influenced the users' experience while interacting with the websites: effective search functions; intuitive interface; easy access; clear navigation; fast loading; adequate information; the availability of relevant user reviews; the availability of ratings; flexibility; fast delivery time; security; support of refunds; and general services. Similarly, other research used questionnaires and interviews to examine the user experience of e-commerce websites [21]. The findings indicated that insufficient product information was the most critical issue on the websites, which most affected the experience of users while interacting with the website.

Alternatively, Mominzada et al. [22] investigated the relationship between gamification and user experience in a gamified e-commerce platform. It proposed a user experience conceptual model in a gamified e-commerce platform that aimed to investigate the influence of gamification on user experience and identify the after-effects of a gamified e-commerce platform. A quantitative research approach was used to statistically test and validate the user experience conceptual model, while an online survey questionnaire was used to collect the related data. The results showed that the user experience of e-commerce websites was greatly affected by gamification; user satisfaction and purchasing attitude increased with the implementation of a gamified user experience. The findings also indicated that positive user experience of the e-commerce websites influenced positively the following: user satisfaction

and attitude towards the websites; brand love and loyalty to the websites; positive word of mouth regarding the websites; and user intention to buy from the websites. Other research examined the effect of some features of e-commerce websites on the user experience (UX) of the website from users' perspectives [23]. They found that security, privacy, interactivity, and having sufficient information about products were the key attributes that influenced user experience on e-commerce websites.

However, other studies suggested heuristics that can be used as a tool for evaluators to assess the attributes of e-commerce websites that may influence the user experience. One of these studies developed a tool consisting of 64 heuristics divided into six categories according to the buying decision process [24]. Another study suggested user experience (UX) heuristics based on the general heuristics suggested by Nielsen's heuristics. However, special attributes suiting e-commerce websites were added to the heuristics, including: security of transactions and support for various payment methods [25]. Also, another research suggested 43 significant attributes on e-commerce websites to obtain a positive user experience (UX) based on the literature [26]. The attributes included: aesthetic design; quality content; easy navigation; easy to use; easy to understand; quick loading time; efficiency; information structure; consistency; security; easy transaction; familiarity; internal search; simplicity; and easy to learn. Alternatively, other research employed a questionnaire to evaluate the user experience for any web-based and mobile-based application [27]. The questionnaire used six categories: attractiveness, efficiency, perspicuity, dependability, stimulation, and novelty.

The literature summarized above identified key features on e-commerce websites which could be considered to result in a good user experience, while other studies identified many user experience issues on e-commerce websites that affected users' interactions with the websites. However, these studies did not take into consideration the two aspects or perspectives of the user experience of a system (website), which are related to pragmatic and hedonic issues. They identified the user experience features or issues without categorizing or considering whether they related to pragmatic or hedonic qualities or attributes. However, there are a few studies that have evaluated the user experience on e-commerce websites and identified specific pragmatic and hedonic issues that affect the user while interacting with the websites.

For example, Hellianto et al. [15] employed questionnaires to assess the influence of hedonic and pragmatic attributes on the user experience of e-commerce websites. The findings identified the following hedonic issues, which influenced the user experience: pleasure, self-satisfaction, simplicity, and delicacy. The work also identified the following pragmatic metrics that influenced the user experience: directness, simplicity, and informativeness. Also, Ritonummi and Niininen [28] used questionnaires and a cognitive walkthrough to evaluate the user experience of an e-commerce website. The findings highlighted the following pragmatic issues, which affected the user experience while interacting with the website: difficulty in finding information, low contrast, small fonts, and difficulty in navigating throughout the website. They also identified the following hedonic issues which affected the user experience while interacting with the website: innovativeness and user catching. Similarly, Febriandika et al. [29] evaluated the effect of hedonic and pragmatic features on the user experience of e-commerce websites. The results showed that the following hedonic features of an e-commerce website influenced the user experience while interacting with its attractive designs, entertaining features, and gamification. The results also showed that good user experience on an e-commerce website influenced trust in the website. Furthermore, Hasan [30] employed questionnaires and semi-structured interviews to investigate pragmatic and hedonic issues which affected the user experience on e-commerce websites while interacting with the websites. This work categorized the identified issues into major and minor. The findings highlighted major pragmatic issues on the websites, including: insufficient product information; lack of accurate delivery information; slow page download time; and lack of support of various delivery methods. The findings also highlighted major hedonic issues on the websites, including: an unenjoyable experience and failing to meet user expectations. In another research, Hasan [31] used questionnaires and semi-structured interviews to examine common and unique pragmatic and hedonic issues on e-commerce websites which affected the user experience while interacting with the websites. The results highlighted several common pragmatic issues on the websites, including poor structure and insufficient product information, as well as unique pragmatic issues on the websites, which included: confusing navigation and missing recommendations for complementary products. The results also highlighted several common hedonic issues on the websites that includes: unattractive and uncreative design, and unique hedonic issues on the websites, including a lack of motivation.

The literature review shows that there are few research studies which suggest comprehensive user experience guidelines and include important pragmatic and hedonic attributes on e-commerce websites from users' perspectives, which could be used to develop positive user experiences on local e-commerce websites in Malaysia or to evaluate and improve the user experience of local e-commerce websites. Also, there is a lack of research that investigates and compares the user experience issues related to pragmatic and hedonic features on local e-commerce websites and international e-commerce websites.

III. Methodology

This research aims to develop guidelines based on a comparison of user experience (UX) issues identified on local and international e-commerce websites. Fig. 1 illustrates the research framework employed. This section describes the selection of e-commerce websites, participant recruitment, data collection procedures, and data analysis methods.

A. Website Selection

To achieve the research objectives, four e-commerce websites were selected: two local and two international. The local websites, Shopee and Lazada, were chosen for being the largest, most popular, and frequently used e-commerce platforms in Malaysia and Southeast Asia. The international websites, Amazon (Western origin) and Alibaba (Eastern origin), were selected for being globally large, early-established, successful, and widely recognized [32].

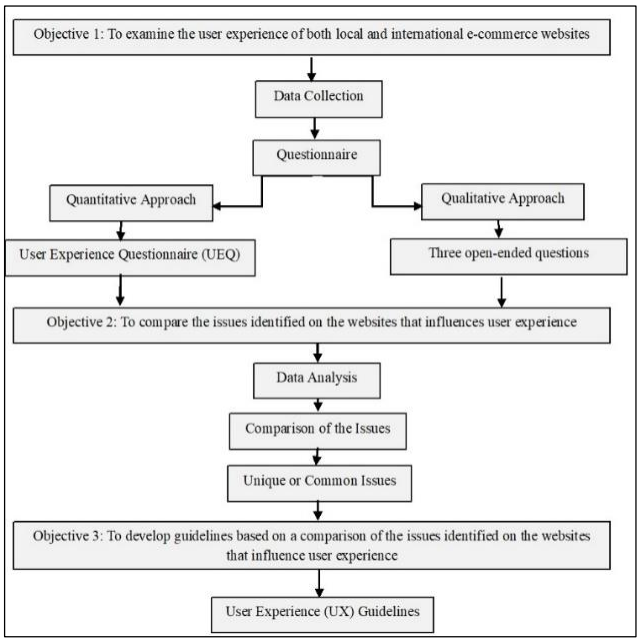

Fig. 1. Research framework.

B. Participants

The target participants were late teenagers, young adults, and middle-aged adults (aged 18–50), as they are more likely to be tech-savvy, frequent Internet users, and potential online shoppers. A recruitment invitation was prepared, including the research title, purpose, required tasks, estimated time to complete the tasks, confidentiality assurance, and researcher contact information. The invitation was sent to staff at two libraries (the University of Technology Malaysia library and a State library), who then distributed it to patrons via email and Telegram. A convenience sampling method was used due to its affordability, practicality, and efficiency [34, 35]. Although this method may introduce sampling bias, it was deemed appropriate for the exploratory nature of this study.

C. Data Collection

1) Questionnaire design: Data were collected using four questionnaires, one per website, to evaluate participants' UX. Questionnaires were chosen for their efficiency, flexibility, and ease of analysis [1,15,18,19,21,28,30,31]. A combination of quantitative and qualitative data was collected to capture both measurable metrics and descriptive user experiences. Each questionnaire had three sections:

a) Participant background: collecting demographic information and prior experience with the website.

b) Quantitative UX assessment: adapted from the User Experience Questionnaire (UEQ) [33], which measures six scales (attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty). A total of 23 questions covered 9 hedonic and 13 pragmatic attributes, rated on a five-point Likert scale.

c) Qualitative UX assessment: three open-ended questions invited participants to describe their experiences, including prior usage stories or first impressions, satisfaction/dissatisfaction with features, and satisfaction/dissatisfaction with functions.

2) Procedure: Each participant explored one e-commerce website and attempted to complete a purchase task. Afterward, they completed the corresponding questionnaire. A total of 200 participants were involved, with 50 participants evaluating each website.

D. Data Analysis

1) Quantitative analysis: Descriptive statistics, including averages and percentages, were used to summarize participant demographics and prior experience. Likert scores were analyzed for each statement to measure responses to the 23 UX attributes. Scores of 1–2 were considered negative, 4–5 positive, and 3 neutral. Average Likert scores for hedonic and pragmatic attributes across the four websites were calculated and are presented in Section IV.

2) Qualitative analysis: Qualitative responses were analyzed to identify UX issues related to hedonic and pragmatic features for each website. These issues were compared across websites to identify common and unique UX problems. In total, 24 UX categories were derived (3 hedonic and 21 pragmatic attributes), as detailed in Section IV. The insights from this analysis were then used to develop UX guidelines, presented in Section VI.

IV. Results

This section presents the results obtained from the analysis of the quantitative and qualitative data collected from the questionnaires for the four e-commerce websites (Shopee, Lazada, Amazon and Alibaba). Concerning the participants' background and experience, a total of 200 volunteers participated in this research; each website was evaluated by 50 participants. The age of the participants varied from 19 years and below 50 years old and above. Table I shows the five age groups of the participants, the percentage of participants in each age group who evaluated the user experience for each website, and the average percentage of participants for each age group. Table I reveals that most of the participants were aged 20 to 29 years old (67%), while the lowest percentages of the participants (6.5%) were aged 40 to 49 years old.

Regarding the participants' usage experience with the website, which they were asked to evaluate, the results showed that:

- All 50 participants had experience of using the Shopee website;
- 88% of the 50 (44) participants had experience of using the Lazada website, while 12% (6) of the participants had not used the Lazada website before;
- Most of the participants (64% of the 50 (32)) had not used the Amazon website, while 36% (18) of the participants had experience of using the Amazon website;

- Most of the participants (72% (36)) had not used the Alibaba website, while 28% (14) participants had experience of using the Alibaba website.

TABLE I. AGE GROUPS OF THE PARTICIPANTS, PERCENTAGE OF PARTICIPANTS WHO EVALUATED EACH WEBSITE, AND AVERAGE PERCENTAGE FOR PARTICIPANTS PER AGE GROUP

Age Group	Website	Percentage (%)	Average Percentage (%)
19 and below	Shopee	0	7.5
	Lazada	12	
	Amazon	4	
	Alibaba	14	
20 - 29	Shopee	46	67
	Lazada	66	
	Amazon	80	
	Alibaba	76	
30 - 39	Shopee	28	11.5
	Lazada	14	
	Amazon	2	
	Alibaba	2	
40 - 49	Shopee	16	6.5
	Lazada	2	
	Amazon	6	
	Alibaba	2	
50 and above	Shopee	10	7.5
	Lazada	6	
	Amazon	8	
	Alibaba	6	

The quantitative results obtained from the analysis of the 23 questions related to the 23 metrics of the user experience (UX) of the tested websites, specifically, the 9 hedonic and 14 pragmatic metrics, are presented in Table II. These results show that the participants had a good user experience with the four tested websites. All the 9 hedonic and 14 pragmatic metrics for the websites had positive ratings. The results show that even though the participants were satisfied with the pragmatic and hedonic aspects of all the websites, they were more satisfied with the pragmatic aspects of the websites compared to the hedonic aspects. The pragmatic metrics had the highest ratings, while the hedonic metrics had the lowest ratings. Specifically, the ease to learn metric, which is pragmatic, was the highest average metric for all the websites (3.98), while understandability (4), familiarity (4.06), consistency (4.04), and ease to learn (3.96), which are all pragmatic, were also the highest metrics for Shopee, Lazada, Amazon and Alibaba, respectively. Alternatively, the beautifulness metric, which is hedonic, was the lowest average metric for all the websites (3.37), while beautifulness (3.18), excitement (3.3), beautifulness (3.52) and motivation (3.16), which are all hedonic, were the lowest metrics for Shopee, Lazada, Amazon and Alibaba, respectively.

Furthermore, Table II shows that the participants had the best user experience while interacting with Amazon website, compared to other websites. Its pragmatic and hedonic metrics were rated the highest compared to other websites except for two pragmatic metrics (simplicity and familiarity). The Shopee website had the highest rating for the simplicity metric, while the Lazada website had the highest rating for the familiarity metric. The average rating for Amazon's hedonic and pragmatic metrics was the highest compared to the other three websites: 3.87. Alternatively, Table II shows that the participants' user experience with Alibaba was poor compared with the other websites; the average ratings for its hedonic and pragmatic attributes was the lowest compared with the other three websites: 3.57.

TABLE II. THE LIKERT SCORES FOR THE 9 HEDONIC AND 14 PRAGMATIC METRICS FOR THE FOUR WEBSITES

No.	Attributes	W1*	W2*	W3*	W4*	Avg.*
Hedonic Attributes						
1	Creative	3.66	3.54	3.68	3.36	3.56
2	Stylishness	3.2	3.6	3.64	3.2	3.41
3	Interest	3.58	3.6	3.74	3.46	3.60
4	Pleasantness	3.7	3.58	3.82	3.38	3.62
5	Attractiveness	3.44	3.52	3.68	3.34	3.50
6	Beautifulness	3.18	3.5	3.52	3.26	3.37
7	Excitement	3.3	3.3	3.74	3.38	3.43
8	Motivation	3.4	3.38	3.64	3.16	3.40
9	Enjoyability	3.56	3.5	3.8	3.56	3.61
Pragmatic Attributes						
1	Clarity	3.5	3.76	3.9	3.7	3.72
2	Practicality	3.72	3.58	3.96	3.74	3.75
3	Predictability	3.86	3.68	3.98	3.46	3.75
4	Simplicity	3.98	3.68	3.94	3.76	3.84
5	Efficiency	3.62	3.72	3.92	3.78	3.76
6	Organization	3.4	3.44	3.94	3.74	3.63
7	Understandability	4	3.8	4.14	3.8	3.94
8	Ease to learn	3.9	3.96	4.08	3.96	3.98
9	Expectation	3.62	3.62	3.88	3.5	3.66
10	Friendliness	3.68	3.6	4.14	3.8	3.81
11	Familiarity	3.72	4.06	3.86	3.62	3.82
12	Responsiveness	3.66	3.76	4.1	3.8	3.83
13	Flexibility	3.6	3.66	3.88	3.7	3.71
14	Consistency	3.8	3.9	4.04	3.64	3.85
Average		**3.61**	**3.64**	**3.87**	**3.57**	
W1: Shopee; W2: Lazada; W3*: Amazon; W4*: Alibaba; Avg.*: Average						

The qualitative results obtained from the analysis of the three open-ended questions in the questionnaire identified 24 user experience (UX) issues, three hedonic and 21 pragmatics, on the websites that affected the experience of the participants while interacting with them, as shown in Table III. The three hedonic issues are related to:

- Unattractive design: this issue was identified on all the websites;
- Annoying advertisements: this issue was identified uniquely on the local websites (Shopee, Lazada).
- Does not meet user expectation: this issue was identified on one local website (Lazada) and one international website (Alibaba).

TABLE III. THE USER EXPERIENCE ISSUES IN TERMS OF HEDONIC AND PRAGMATIC, IDENTIFIED FROM THE ANALYSIS OF THE QUALITATIVE RESULTS

No.	User Experience Issue	W1*	W2*	W3*	W4*
Hedonic Issues					
1	Unattractive design	✓	✓	✓	✓
2	Annoying advertisements	✓	✓	×	×
3	Does not meet users' expectation	×	✓	×	✓
Pragmatic Issues					
1	Not easy to use	✓	✓	✓	✓
2	Not easy to understand	✓	✓	✓	✓
3	Not user-friendly	✓	✓	✓	✓
4	Not easy to access	×	×	×	✓
5	Not easy to navigate	×	✓	✓	✓
6	Not straightforward design	✓	✓	✓	✓
7	Do not have similarity	×	✓	✓	✓
8	Do not have familiarity	×	×	✓	✓
9	Poor performance	✓	✓	✓	✓
10	Disorganized	✓	✓	✓	✓
11	Does not have variations (limited choices and options)	✓	✓	×	×
12	Inaccurate internal search function and filter	✓	✓	×	×
13	Poor item quality	✓	✓	×	✓
14	High pricings	×	✓	×	✓
15	Unsatisfying promotional offers (vouchers, promotions, discounts)	×	×	✓	✓
16	Poor shipping and delivery	✓	×	✓	✓
17	Inefficient payment process	✓	✓	×	×
18	Poor customer service	✓	✓	✓	×
19	Insufficient product information and review	✓	×	×	✓
20	Lacks of security and trustworthiness	✓	×	×	×
21	Inconvenient refund process	✓	×	×	×
***W1: Shopee; W2*: Lazada; W3*: Amazon; W4*: Alibaba**					

Regarding the pragmatic issues, Table III shows that:

- A total of six pragmatic issues were identified commonly on all the websites (Shopee, Lazada, Amazon, Alibaba), which are related to: Not easy to use; not easy to understand; not user-friendly; not straightforward design; poor performance; and disorganized.
- A total of three pragmatic issues were identified uniquely on the international websites (Amazon, Alibaba); these are related to: Do not having familiarity; unsatisfying promotional offers (vouchers, promotions, discounts); and inefficient payment process.
- A total of two pragmatic issues were identified uniquely on the local websites (Shopee, Lazada); these are related to: Does not have variations (limited choices and options); and inaccurate search and filter.

Table III also shows that, even though all the websites had hedonic and pragmatic issues which affected the experience of the participants while interacting with them, Amazon had the least number of hedonic and pragmatic issues compared to the other three websites. Specifically, a total of 13 issues (one hedonic and 12 pragmatic issues) were identified on it. However, the other three websites had the same number of issues (17), as follows:

- Shopee had a total of 17 issues (two hedonic and 15 pragmatic issues) that were identified on it.
- Lazada had a total of 17 issues (three hedonic and 14 pragmatic issues) that were identified on it.
- Alibaba had a total of 17 issues (two hedonic and 15 pragmatic issues) that were identified on it.

V. DISCUSSION

This research addressed the gap identified in the literature by uniquely investigating, identifying, and comparing detailed user experience (UX) issues related to both pragmatic and hedonic features on local and international e-commerce websites. While the study had a novel aim—developing UX guidelines based on a comparative analysis—many findings align with earlier research, supporting the relevance of established UX principles.

The quantitative results showed that participants had positive experiences with the four tested websites, with all 9 hedonic and 14 pragmatic metrics receiving positive ratings. However, the qualitative data revealed 24 UX issues (3 hedonic and 21 pragmatic) affecting participants' experiences.

Unique issues on local websites (Shopee and Lazada) included one hedonic issue—annoying advertisements—and three pragmatic issues: limited product variations, inaccurate internal search and filters, and inefficient payment processes. While these issues were not widely reported in previous studies, two were considered key UX features: availability of product variations [19] and effective search functions [1].

Unique issues on international websites (Amazon and Alibaba) included two pragmatic issues: lack of familiarity and unavailability of satisfying promotional offers (vouchers, promotions, discounts). Interestingly, these features were present on local websites and positively influenced user experience, highlighting differences between local and international platforms.

Common issues across all websites included one hedonic and six pragmatic problems. The hedonic issue was unattractive

design, consistent with earlier research identifying visual appeal as a critical factor in UX [26, 31]. The six common pragmatic issues—difficult to use, hard to understand, not user-friendly, non-straightforward design, poor performance, and disorganization—were also supported by prior studies emphasizing usability, logical structure, and fast website performance [1, 18, 19, 23, 25, 26, 30, 31].

Other pragmatic issues, which were neither unique nor common, included a lack of similarity on Shopee, poor item quality on all except Amazon, high pricing on Lazada, poor shipping and delivery on Lazada, poor customer service on Alibaba, insufficient product information and reviews on Shopee and Alibaba, a lack of security and trustworthiness, and an inconvenient refund process on Shopee. Some of these issues, such as insufficient product information and unclear delivery dates, were identified in earlier research [1, 30, 31], while others, like poor shipping and customer service, were newly identified in this study.

The merits of this research include its combined focus on pragmatic and hedonic UX attributes, the mixed-methods approach capturing both quantitative and qualitative insights, and the development of actionable UX guidelines applicable to local and international e-commerce websites. The study also demonstrates the effectiveness of qualitative methods in uncovering issues that quantitative measures alone may miss.

The demerits (limitations) include the focus on only four e-commerce websites, which may limit generalizability, and convenience sampling, which may not fully represent diverse user demographics. The data collection methods—questionnaires and open-ended questions—may not capture as in-depth insights as interviews or focus groups. Finally, the UX guidelines are specific to e-commerce websites and may not directly apply to other types of digital platforms or mobile applications.

Overall, this research provides a balanced evaluation, showing both consistencies and novel findings compared to earlier studies, highlighting strengths and limitations, and offering practical guidance for improving UX on local and international e-commerce platforms.

VI. Proposed User Experience (UX) Criteria

This section presents the proposed user experience (UX) guidelines, uniquely proposed in this research, to address the gap identified in the literature regarding the lack of user experience guidelines. These included key pragmatic and hedonic metrics to evaluate specifically the user experience on e-commerce websites. The guidelines were mainly developed from the results obtained from an analysis of the qualitative data, which identified 24 user experience (UX) issues on local and international key e-commerce websites (see Table III), and the quantitative results obtained from an analysis of the 23 questions relating to the 23 metrics of the user experience of the tested websites (see Table II).

Table IV in Appendix presents the proposed guidelines. These consist of 27 categories (G1-G27), which were mapped to 17 areas based on their content. These categories were divided into two main groups to evaluate: the pragmatic and hedonic quality of e-commerce websites, respectively:

- Pragmatic quality: includes 20 categories, which were organized into 12 areas to evaluate the functional quality of e-commerce websites.
- Hedonic quality: includes the remaining seven categories, which were organized into five areas to evaluate the hedonic quality of such sites.

Table IV in Appendix also presents the explanation and reference for each of the suggested categories, whether based on the results of this research only or also supported by earlier research results. The 20 suggested categories to evaluate the pragmatic quality of e-commerce websites include 12 categories which were supported by the results from earlier research and 8 unique categories which were uniquely suggested by this research. The 12 categories shed light on the important functional or utility aspects in an e-commerce website, which should be addressed to obtain a positive user experience, which relates to 12 areas on the website: design, structure, navigation, responsiveness, efficiency, advertisements, internal search, content, payment and refund, shipping and delivery, customer service, security, and trustworthiness.

1) Design: Three categories related to the design of the website were suggested to obtain a positive user experience in an e-commerce website, which include having a user-friendly design, a straightforward design, and a consistent design, as explained in G1, G2, and G3, respectively, in Table IV (Appendix). These important aspects were also suggested by earlier research, as shown in Table IV (Appendix).

2) Structure: Two categories related to the structure of the website were suggested to achieve a positive user experience in an e-commerce website, which include logical organization of the website's content and having similarity with other websites so that users will be familiar with the structure of the website, as explained in G4 and G5, respectively, in Table IV (Appendix). G4, which is related to having logical structure, was also suggested by earlier research, however, G5 which is related to having similarity and familiarity was uniquely suggested by this research.

3) Navigation: One category related to having easy navigation was suggested to obtain a positive user experience in e-commerce websites, as explained in G6. This was also suggested by earlier research.

4) Responsiveness: One category was suggested uniquely by this research related to having good performance in terms of being responsive to support users while using the website, as explained in G7.

5) Efficiency: One category related to having an efficient website to support users to complete their tasks quickly was suggested by this research, as well as by earlier research, as explained in G8, to obtain a positive user experience in e-commerce websites.

6) Advertisements: One category related to avoiding advertisements was uniquely suggested by this research to achieve user experience in an e-commerce website, as explained in G9, as they confuse users.

7) Internal search: The effective internal search category was suggested by this research and earlier research, also to obtain a positive user experience in e-commerce websites as it helps users to obtain their target products easily. The explanation is provided in G10 together with the references of earlier research.

8) Content: Five categories were suggested related to the content of e-commerce websites, which could contribute to achieving a positive user experience on e-commerce websites; three of them were uniquely suggested by this research. The five categories related to: having product variations (suggested also by earlier research as shown on G11), having good product quality (uniquely suggested by this research as shown in G12), having helpful information and reviews for each product (uniquely suggested by this research as shown in G13), and having reasonable priced products (uniquely suggested by this research as shown in G14), and finally providing satisfying promotional offers (uniquely suggested by this research as shown in G15).

9) Payment and refund: Two categories were suggested related to payment and refund, which, if addressed, can achieve a positive user experience in e-commerce websites. These relate to having an easy payment process (this was identified uniquely in this research as explained in G16), and the website should allow refunds to be made conveniently, which was also identified by earlier research as explained in G17.

10) Shipping and delivery: This includes one category related to providing good shipping and delivery services, which help to send the products to the users, and it was also suggested by earlier research. The explanation and references are shown in G18.

11) Customer service: One category was suggested uniquely by this research and related to having good customer service to support users while using the website. the explanation and references are shown in G19.

12) Security and trustworthy: This includes one category related to having secure and trustworthy transactions to encourage users to buy from it. It was also suggested by earlier research. The explanation and references are shown in G20.

Alternatively, the seven suggested categories to evaluate the hedonic quality of e-commerce were supported by the results from earlier research, and they shed light on the important aspects that influence the emotions and feelings of the users when interacting with the website, and therefore addressing them will help to obtain a positive user experience on e-commerce websites. The seven hedonic categories are related to five areas: attractiveness, creativity and enjoyment, pleasant and excitement, motivation, and expectation.

1) Attractiveness: This is related to having features that will attract users to interact and navigate throughout the website, as shown in G21.

2) Creativity and enjoyment: This area includes two categories, shown in G22 and G23, and are related to having creative features and enjoyable features.

3) Pleasant and excitement: This area includes two categories, the website should be pleasant and excite users, as shown in G24 and G25, so that it will evoke users' positive feelings and interest while interacting with it.

4) Motivation: This includes one category which are related to having the features that will motivate the users to interact with the website and complete their tasks, as shown in G26.

5) Expectation: This includes one category, as shown in G27, which relates to addressing users' expectations and needs by providing all the needed functionality.

It is important to emphasize that earlier research, which identified specific heuristics or criteria to evaluate user experience of e-commerce websites, did not consider users' preferences regarding key features or metrics that should be considered to obtain positive user experiences on e-commerce websites [24,25,26,30,31], and they did not consider hedonic metrics in the heuristics [24,25,26]. Additionally, other criteria or tools, which were developed by earlier research to evaluate the user experience, were general and not specific to e-commerce websites [12,27,33,36,37].

VII. Conclusion

This research developed user experience (UX) guidelines for e-commerce websites to foster positive user experiences. The guidelines consist of 27 categories, including 20 pragmatic and 7 hedonic features, derived from a comparative evaluation of two local (Shopee, Lazada) and two international (Amazon, Alibaba) e-commerce websites. A mixed-methods approach was employed, combining quantitative data from the User Experience Questionnaire and qualitative data from open-ended questions, to identify and compare UX issues affecting users across these platforms. Common UX problems included unattractive design and pragmatic issues such as poor usability, unclear structure, and disorganization, while unique issues were observed for local and international websites. These findings informed the development of actionable UX guidelines to improve e-commerce user experiences.

Despite its contributions, this research has limitations. The guidelines are specific to e-commerce websites and may not directly apply to other types of websites or mobile applications. Only four platforms were examined, so UX issues on other websites may differ, limiting generalizability. Convenience sampling may not reflect balanced age groups or international diversity, affecting the applicability of the findings. Additionally, the use of questionnaires and open-ended questions may have restricted the depth of qualitative insights compared to interviews or focus groups.

Based on these limitations, several future research directions are suggested. Future studies could extend the guidelines to mobile e-commerce applications and additional platforms to enhance generalizability. Ensuring more diverse participant demographics could provide a more global perspective. Employing richer qualitative methods, such as interviews or focus groups, could capture deeper insights into users' experiences. Further research could also explore AI-driven personalization for adaptive UX and conduct longitudinal studies to evaluate the impact of implementing the guidelines

over time. These directions will help to refine and extend the practical value of UX guidelines for both local and international e-commerce platforms.

APPENDIX

TABLE IV. THE PROPOSED USER EXPERIENCE (UX) GUIDELINES

No	Area	Category	Explanation	References
Categories to evaluate the pragmatic quality of any e-commerce				
G1	Design	The website should have a user-friendly design	A website should have an overall user-friendly or easy to use design. This will allow users easily to navigate through the website and complete their tasks efficiently and effectively; it will also make it flexible and convenient to navigate.	This research; [23,25,26]
G2		The website should have a straightforward design	A website should have a straightforward design; this mainly relates to the site having a clear, easy to learn and understand design so that users can complete their tasks without hesitation by choosing wrong features or options, and without the need to think much to achieve their goal.	This research; [15,23-27,30,31,33,37]
G3		The website should have consistent design	The website should have consistent design in terms of the colours used, the location of menus, the layout and feedback.	This research; [23-25,30,31]
G4	Structure	The website's content should be organised or structured logically	The website's content should be organised or structured logically and clearly. For example, similar products should be grouped together.	This research; [18,19,23,24,30,31]
G5		The website should have similarity and familiarity	A website should have similarities with other websites that a user frequently uses; this will make the website look familiar to the user. This therefore helps to make the website easier to use and understand as if the user is doing nothing out of the ordinary.	This research
G6	Navigation	The website should be easy to navigate	It should be easy to navigate around the website and the site should have features and functions that are easy to access. This will make the work of the users very convenient as the website will be very flexible which will help in allowing the users to achieve their goal faster.	This research; [23,24]
G7	Responsiveness	The website should have good performance in terms of responsiveness	A website should have good performance; it should be responsive and provide responses in a consistent manner which help to prevent the user from getting frustrated while using the website.	This research
G8	Efficiency	The website should be efficient	A website should allow the users to complete their tasks quickly.	This research; [1,15,23,25-27,30,31,33,36,37]
G9	Advertisements	The website should avoid having advertisements	A website should avoid having advertisements as they tend to confuse the users. Most users are sceptical regarding advertisements that are posted online due to the high probability (and fear) of being scammed.	This research
G10	Internal search	The website should have an accurate internal search and filter	The website should have an accurate internal search and filter(s) to help users to search easily for the product they desire to buy.	This research; [1]
G11	Content	The website should have product variations	The website should have various products with many choices and options as users like to have choice while shopping; this allows them to assess if one product is better than another.	This research; [19]
G12		The website should have good product quality	The website should have products with a certain level of quality so that the users will not be discouraged from purchasing from the application.	This research
G13		The website should provide helpful information and reviews for each product on it	The website should provide helpful reviews and information for each product on it so that users can easily understand the product, and allow them to easily compare products and choose the products that best suit their needs.	This research; [1,30,31]
G14		The products on the website should be reasonably priced	The products on the website should be reasonably priced to encourage users to buy from the website.	This research
G15		The website should provide satisfying promotional offers (i.e. vouchers, coins, rewards, promotions, discounts)	The website should provide satisfying promotional offers, such as: vouchers, coins, rewards, promotions or discounts. These offers will allow the users to save money or to get their money's worth as they do their shopping. They also help make the users more willing to make any purchases.	This research
G16	Payment and refund	The website should have an easy payment process	The website should have easy, convenient, and smooth payment process for the users	This research
G17		The website should allow refunds to be made conveniently	The website should allow refunds to be made with convenience; this gives a business some room to amend for any problems or mistakes that may have occurred in the business process. Proper compensation to users helps in increasing the reputation of the business and helps in correcting any bad user experience.	This research; [1]
G18	Shipping and delivery	The website should provide good shipping and delivery	The website should provide good shipping and delivery services that help to send the products to the users.	This research; [1,30,31]
G19	Customer service	The website should have good customer service	The website should have a good customer service as a business without good customer service will make users unable to make proper inquiries if they encounter any problems while using the website. This causes the users to feel frustrated which negatively influences user experience.	This research

G20	Security and trustworthy	The website should have secure and trustworthy transactions	The website should have secure and trustworthy transactions to encourage users to buy from it; these aspects are significant to a website's success.	This research; [1,23]
Categories to evaluate the hedonic quality of any e-commerce				
G21	Attractiveness	The website should be attractively designed	The design of the website's pages should attract the users. This will encourage them to navigate throughout the website.	This research; [26,30,31,33]
G22	Creativity and enjoyment	The website should be creatively thereby designed	The design of the website should have creative features.	This research; [27,30,31,33,37]
G23		The website should be enjoyable	The website should be enjoyable; this will encourage users to interact with it.	This research; [30,31]
G24	Pleasant and excitement	The website should be pleasant	The website should be pleasant; this will evoke users' positive feelings while interacting with it.	This research; [30,31,33]
G25		The website should excite users	The website should excite users, thereby evoking their interest in interacting with the website.	This research; [24,27,30,31,33,37]
G26	Motivation	The website should motivate users	The website should motivate the users to interact with the website and complete their tasks.	This research; [12,27,30,31,33,37]
G27	Expectation	The website should meet users' expectations	The website should address users' needs by providing all the needed functionality; it should behave as users expect.	This research; [30,31,33,37]

From External Stakeholder Pressure to Sustainable Practice in HEIs: Mechanisms and Internal Mediating Factors

Xue Jin[1]*, S. M. Ferdous Azam[2], Jacquline Tham[3]
Nanjing University of Finance and Economics, Hongshan College, Nanjing, China[1]
Graduate School of Management-Postgraduate Centre, Management and Science University, Shah Alam, Selangor, Malaysia[1, 2, 3]

***Abstract*—Sustainable procurement is an important part of sustainable development in HEIs, playing a pivotal role in optimizing resource allocation, fulfilling social responsibilities, and promoting green development. However, existing research has paid insufficient attention to the impact of external stakeholder pressure on HEIs' sustainable procurement and its intrinsic action mechanism. To address this gap, this study aims to explore the influence path of external stakeholder pressure on HEIs' sustainable procurement and identify key mediating factors. This study collected 260 valid data points from Chinese higher education institutions with more than one year of purchasing experience through snowball sampling. PLS-SEM analysis results show that external stakeholder pressure not only directly promotes sustainable procurement but also exerts an indirect effect through two mediating paths: affective commitment and professional knowledge. The mediating role of affective commitment is stronger than that of knowledge, and affective commitment itself has the strongest direct impact on sustainable procurement among all variables. Theoretically, this study enriches the application scenarios of stakeholder theory and institutional theory in the field of higher education sustainable management. Practically, it provides actionable references for HEIs to enhance sustainable procurement performance by strengthening external stakeholder collaboration, optimizing knowledge management systems, and fostering employees' affective commitment.**

***Keywords*—Sustainable procurement; HEIs; external stakeholder pressure; affective commitment; knowledge**

SP: Sustainable Procurement

I. INTRODUCTION

Sustainable procurement is now a key component of sustainability in higher education institutions (HEIs) [1]. External stakeholder pressures strongly shape organisations' sustainable practices, typically stemming from groups like local governments, the public, and suppliers—all demanding environmental and social responsibility in procurement [2]. Local governments influence HEIs' sustainability decisions via funding, policy incentives, and clear support; without this, HEIs struggle to advance sustainable practices [3]. Žalėnienė & Pereira [4] noted that HEIs must act socially responsible, address public sustainability demands, and that sustainable procurement is the key to meet these expectations. Meanwhile, under market logic, HEIs face external pressures (e.g., competition, accreditation) and need to boost their reputation and competitiveness through sustainable practices to attract funding and students.

A comprehensive framework for sustainable procurement shows external stakeholder pressures notably impact an organisation's internal environment—management, culture, competencies, attitudes—and thus its procurement practices [5]. Foerstl et al. [6] stressed that suppliers must understand customers' and stakeholders' sustainability priorities to engage effectively in sustainable supply chain management. Similarly, Ahmad et al. [7] found stakeholder pressures shape oil and gas industry sustainability goals, highlighting external factors' role in guiding organisational strategies. Liu et al. [2] further noted that external pressures affect public-sector sustainable procurement by shaping staff knowledge. In practice, organisations use complex mechanisms to address these pressures—most notably surface compliance [8, 9], where HEIs seem to meet sustainability requirements but lack substantive change. This decoupling raises a critical question: How to convert external pressures into genuine cognitive shifts and practical innovations?

Although sustainable procurement has become a core issue in the sustainable development of HEIs, there are still two key gaps in existing research that need to be addressed. First, most existing studies focus on sustainable procurement in businesses or general public sectors, and the way external stakeholder pressures influence the internal mechanisms of sustainable procurement in HEIs—a unique type of organization with both educational attributes and public service functions—has not been systematically explained, with empirical evidence being particularly scarce. Second, in research on the mediating mechanisms of sustainable procurement, existing models either use only a single mediator or do not compare the effects of multiple mediators, making it difficult to reveal the relative importance and synergistic effects of different mediating pathways. Guided by stakeholder theory, this study explores the mechanisms through which external stakeholder pressures affect HEIs' sustainable procurement and seeks to identify internal

*Corresponding author.

mediating factors for successful sustainability implementation. Accordingly, the following research questions are proposed:

Q1: For higher education institutions, how does external stakeholders' pressure affect sustainable procurement?

Q2: What is the mediator between external stakeholders' pressure and sustainable procurement?

This study has important theoretical and practical significance. At the theoretical level, by identifying the dual mediating mechanism of affective commitment and knowledge, it clarifies the transmission path of external pressure, internal capabilities, and sustainable practices. It not only fills the research gap in the internal transformation mechanism within organizational sustainability theory but also breaks through the linear cognition of the relationship between pressure and behaviour in stakeholder theory. Taking Chinese HEIs as a unique contextual setting, it expands the application boundary of the theory. Meanwhile, it refines the dual paths of cognitive internalization and emotional internalization in institutional theory, enriching the micro-mechanism research on the formation of legitimacy. At the practical level, based on empirical findings, the study proposes three targeted and actionable implications. First, strengthen the cultivation of affective identification by integrating sustainable development values into the training and performance promotion incentives for procurement personnel, and enhance value resonance through university-specific cases to activate intrinsic motivation for active participation. Second, establish an internal-external collaborative mechanism: externally, cooperate with government departments and environmental organizations to conduct policy and practical training, and build communication platforms between procurement personnel and stakeholders; internally, establish a sustainable procurement knowledge base and bind suppliers' obligations for sustainable training to form a closed loop for pressure transformation. Third, adapt to administrative characteristics to optimize governance and processes: integrate sustainable procurement into inter-departmental assessment, formulate special procurement lists and green clauses, and establish a supplier sustainability rating system to consolidate practical results at the institutional level. These implications provide an actionable framework with contextual adaptability and operability for Chinese HEIs to address the dilemma of surface compliance and improve the quality of sustainable procurement.

This study is structured into six sections: The first section outlines the study background, research objectives, and core questions; the second synthesizes literature and theoretical reviews; the third details the research methodology and measurement design; the fourth presents the data analysis results; the fifth elaborates on the study conclusions; and the sixth summarises the study's theoretical and practical contributions, as well as its limitations.

II. Theory and Literature Review

A. External Stakeholders

External stakeholders refer to interest groups outside an organization that have a connection with it. A core tenet of stakeholders theory is that organizational decision-making and operations must not only be accountable to shareholders but also consider all groups affected by or capable of influencing its operations [10]. External stakeholders represent the pivotal component within this framework—individuals or entities outside the organization yet possessing substantial influence. Their impact is primarily exerted through three primary channels: financial investment intervention, coercive pressure application, and public opinion mobilization.

Liu et al. [2] identified local governments, leading sustainable suppliers, and society (public, non-governmental organizations (NGOs), and media) as external stakeholders in Chinese public procurement. Local government can incentivize sustainable behaviour in public sectors through financial incentives [11], regulatory guidance [12], and monitoring [1].

Sustainable suppliers are sustainability-conscious suppliers whose design, packaging, logistics, and other activities meet relevant sustainability and environmental standards [13]. The sustainable procurement and sustainable suppliers are inextricably linked. Sustainable procurements can increase the demand for sustainable products or services and become an important market for sustainable suppliers. To increase market, share and financial performance, sustainable suppliers press sustainable purchasing behaviour in the public sector through a variety of channels by having the required capabilities and resources [14].

The society (the public, non-governmental organizations, and the media) also constitutes important external stakeholders [15]. It is argued that public higher education institutions, as organizations with strong social influence, receive significant attention from society [3]. As the ultimate consumers of public procurement, the public's expectations serve as a key driver for promoting sustainable procurement. Meanwhile, environmental non-governmental organizations play an important role in facilitating local institutions' implementation of sustainable procurement [16]. With the increasing influence of the media, the public and non-governmental organizations are paying closer attention to the sustainable procurement behaviours of local institutions through the media [17]. This leads to Hypothesis 1.

- H1: External stakeholders' pressure has a positive effect on sustainable procurement in HEIs.

External stakeholder pressure has been identified as the main driver behind environmental commitment, with research highlighting the role of external expectations and normative pressure. Several studies have shown that external stakeholders significantly influence organisational behaviour and commitment through multiple forms of pressure [18]. This pressure stems from the need for organisations to meet external expectations and demonstrate environmental responsibility [19]. This normative pressure contributes to higher education institutions feeling compelled to adopt green practices to meet external expectations, which in turn affects their affective commitment to such initiatives. This normative pressure is consistent with findings from SMEs that environmental expectations are a core normative driver influencing organisational response [20]. The study shows that external stakeholder pressure significantly increases organizational level of environmental awareness and commitment, which strongly confirms the important role of external expectations in shaping

organisational attitudes. These findings suggest that when firms perceive that external stakeholder expectations are compatible with their core values, the impact is not limited to the compliance level, but also builds a genuine emotional bond.

Research has also shown that positive stakeholder relationships strengthen affective bonds and organisational loyalty [21]. Trust, in particular, appears to be a key factor that moderates the effects of external pressures, thereby enhancing affective attachment and commitment to organisational goals. Conversely, external pressures can sometimes trigger resistance, especially when organisations perceive these pressures as threats or are subject to controlling motives rather than intrinsic values [22]. This suggests that the nature of external stakeholder influence may vary from person to person, and that different groups may have different levels of affective commitment depending on their own perceptions and internalisation of pressure. This leads to Hypothesis 2.

- H2: External stakeholders' pressure has a positive effect on affective commitment in HEIs towards sustainable procurement.

In the field of supply chain management, external stakeholders such as non-governmental organisations (NGOs) play a key role in driving the diffusion of knowledge and application of sustainable practices. Siems et al. [23] stated that such external organisations are able to motivate firms to implement sustainable supply chain management practices by exerting pressure. This external influence tends to increase the environmental awareness and proactive participation of firms, which in turn promotes organisational learning and competence. It emphasised that translating stakeholder pressure into environmental practices requires the management of new knowledge and ideas that contribute to sustainable business expansion within a sustainable framework. This suggests that external pressure can act as a catalyst for organisations to acquire and implement sustainability knowledge. Ullah et al. [24] showed that green knowledge integration capabilities combined with regulatory pressures and stakeholder demands are effective in enhancing firms' green innovation outcomes. The above evidence suggests that external stakeholder pressure is an important factor influencing the acquisition, diffusion, and application of sustainable knowledge within organisations. This leads to Hypothesis 3.

- H3: External stakeholders' pressure has a positive effect on knowledge in HEIs towards sustainable procurement.

B. Sustainable Knowledge

In the field of sustainable procurement, the core of knowledge centres on procurement professionals' level of awareness and understanding of the concepts, standards, tools, and practices in this domain [25]. This level of awareness is not merely an accumulation of theory; it directly represents procurement professionals' operational capability to practice sustainable behaviours in their day-to-day work. Whether these professionals can accurately judge the sustainability of procurement options or proficiently use relevant tools to optimize procurement processes is essentially determined by this level of knowledge [26]. At the same time, this knowledge base also plays a supporting role: it provides procurement professionals with the necessary theoretical basis and practical guidance for implementing sustainable behaviours when making specific procurement decisions, ensuring their operational capability has clear directions and methods to follow [27]. Based on this, the hypothesis is proposed (Hypothesis 4):

- H4: Sustainable knowledge has a positive effect on sustainable procurement in HEIs.

C. Affective Commitment

Meyer & Herscovitch [28] vividly likened commitment to change to "the adhesive that forges critical connections between people and change objectives". Affective commitment is the willingness of an individual to initiate change based on the recognition of the intrinsic value of change. Affective commitment is a crucial driver of sustainable procurement behaviours within organizations. There is ample evidence in the existing literature that emotional commitment plays a key role in driving sustainable procurement behaviours. Several studies have shown that emotional commitment to change significantly influences the adoption and implementation of sustainable procurement practices. Meyer et al. [29] found that employees' affective commitment to organizational change is positively correlated with change behaviours. This may be because such commitments encourage employees to go above and beyond minimum behavioural requirements, even making personal sacrifices. Grandia [30] verified that affective commitment to sustainable procurement reform has a direct and significant effect on sustainable purchasing behaviours. When procurement officers understand the value of sustainable procurement reform and have affective commitment, they will participate more actively in relevant activities. Boesen [31] found in a study of procurement officials that affective commitment is positively related to sustainable procurement behaviour, emphasising that affective commitment to the SDGs motivates proactive green procurement actions. Overall, the reviewed documents collectively highlight that affective commitment is a vital psychological factor that enhances the effectiveness of green procurement initiatives. This leads to Hypothesis 5.

- H5: Affective commitment has a positive effect on sustainable procurement in HEIs.

D. Mediating Role of Knowledge

The mediating role of knowledge in promoting sustainable procurement has attracted significant attention from scholars, highlighting the impact of knowledge in enhancing sustainable practices within organisations. Liu et al. [2] examined how external stakeholders influence green public procurement practices through organisational learning mechanisms, implying that knowledge acquisition and dissemination mediate this relationship. This is consistent with the broader understanding that knowledge helps to integrate external environmental and social factors into procurement strategies, thereby promoting sustainability. Mohaghegh et al. [32] proposed a theoretical framework that reinforces the notion that knowledge is a key mediator that enhances an organisation's ability to achieve sustainable performance. In addition, Sondhi et al. [33] emphasised that knowledge acts as a bridge that enables organisations to translate strategic orientation into sustainable performance outcomes. Knowledge integration capabilities and

service innovation mediate the relationship between elements of strategic orientation (e.g., customer-orientation, competitor-orientation, and technology-orientation) and sustainable competitive advantage. Together, these studies recognised that the mediating effect of knowledge contributes to the integration of sustainability principles into procurement practices, digital transformation and strategic decision-making, ultimately contributing to sustainable development within organisations. This leads to Hypothesis 6.

- H6: Knowledge has a mediating effect between external stakeholders' pressure and sustainable procurement in HEIs.

E. Mediating Effect of Affective Commitment

The mediating role of affective commitment has been a focal point for understanding various organisational and behavioural outcomes in different contexts. Affective commitment mediates the effect of external incentives on green purchasing behaviour. Wang et al. [34] validated that project managers' affective commitment to change partially mediates the relationship between perceptions of environmental regulations and environmentally sustainable project management practices. Indra et al. [35] revealed from organisational support that there was a significant effect between supervisor support for intention to leave and affective commitment mediation. A study on brand positioning showed that affective commitment mediates the relationship between organisational strategy and sustainable outcomes a step proved the mediating effect of affective commitment [36]. This suggests that employees' emotional attachment to organisational change initiatives is critical in translating external pressures into sustainable purchasing practices. This leads to Hypothesis 7.

- H7: Affective commitment has a mediating effect between external stakeholders' pressure and sustainable procurement in HEIs.

Based on the above assumptions, the research framework of this study is displayed in Fig. 1.

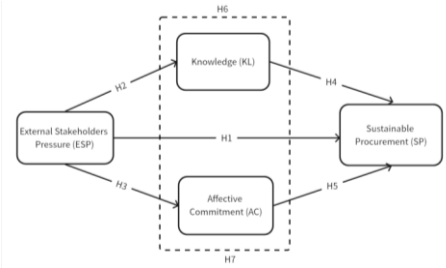

Fig. 1. Conceptual framework.

III. Research Methodology

A. Data Collection

This study focuses on the impact of external stakeholders on sustainable procurement in Chinese Higher Education Institutions (HEIs), and therefore the survey primarily targeted personnel with more than 1 year of experience in procurement in Chinese HEIs (HEIs). Such a target population is strongly specialised and scarce, making it suitable for recruitment using snowball sampling [37].

The study integrated elements of stratification at the institutional level (undergraduate/vocational) and geographic level, and used a four-tiered referral mechanism to expand the sample incrementally. The researchers selected an initial sample of 20 procurement supervisors from different regions and types of institutions, proportional to the distribution of higher education institutions, through a variety of sources including the Ministry of Education's list of higher education institutions and public procurement conferences. After telephone and face-to-face communication, each supervisor recommended 2 to 3 direct subordinates who matched the characteristics of the study population, constituting the second-tier sample. Subsequently, the second-tier participants were invited to recommend 2 peers from the same city but from different institutions. A third-tier sample was also formed. Finally, the stratum 3 participants were invited to recommend 2 more peers from neighbouring cities (stratum 4). Sampling ended at the fourth stratum and only new samples from the same type of organisations were recommended at each stratum. Data collection took place between 8 October 2024 and 28 November 2024, with a total of 260 valid responses received.

The age group is predominantly 30 to 39 years old (42.3%), with 25.4% of the sample aged 20 to 29 years old and 25.4% aged 40 to 49 years old each. 75.8% had a bachelor's degree or above (meeting the requirements for university recruitment), and 44.3% had more than five years of work experience. These demographic characteristics both enhance the representativeness of the sample by matching the overall structure, and increase data accuracy and consistency due to the perceived stability of the highly educated and experienced group, whilst empirical weighting [38] (see Table I for full details).

B. Measures

The measurement scales and theoretical constructs used in this study were systematically extracted from well-established instruments in the previous literature and were carefully modified to ensure consistency with the particular research setting while retaining the measurement properties of the original constructs. All items are on a 5-point Likert scale.

To assess common method biases, multiple strategies based on established methodological recommendations were used. We conducted a Harman's one-way test, an unrotated exploratory factor analysis of all items, which resulted in the identification of multiple factors with eigenvalues greater than 1.0, and crucially, the largest factor with an eigenvalue below the 50% threshold, confirming that our results were not substantially affected by this methodological issue.

To assess non-response bias in the survey data, a one-way analysis of variance was conducted on respondents in strata 1, 2 and 3, 4 of the sample referral mechanism. The results of the analysis showed no statistically significant differences between these two groups (all p-values were greater than 0.05). The results suggest that non-response bias does not pose a substantial threat to the validity of our findings.

TABLE I. DEMOGRAPHIC INFORMATION

C. Data Analysis

This study utilizes Partial Least Squares Structural Equation Modeling (PLS-SEM) in Smart-PLS 3.3.2 to investigate the causal relationships among variables [39]. Partial Least Squares Structural Equation Modeling (PLS-SEM) employs a Partial Least Squares (PLS) algorithm that fundamentally differs from traditional Ordinary Least Squares (OLS) in both its principles and applications. The core of the PLS algorithm is an iterative two-stage process designed to maximize the covariance between latent variable scores using manifest variable data. This allows simultaneous estimation of both measurement and structural models [40].

The first step is outer approximation. It uses outer weights to combine manifest variables into initial latent variable scores.

$$y_i = \sum(w_{ij} * x_{ij}) \quad (1)$$

$$y_i: external\ approximate\ score\ for\ the\ i - th\ latent\ variable;$$

$$w_{ij}: external\ weighting;$$

$$x_{ij}: the\ jth\ explicit\ variable\ of\ the\ ith\ latent\ variable;$$

The second step is inner approximation. It updates these scores by weighting them against adjacent latent variables based on structural relationships. These two steps repeat until the outer weights stabilize and converge.

$$z_i = \sum(e_{ik} * y_k) \quad (2)$$

Among them $z_i: inner\ approximate\ score\ for\ the\ i - th\ latent\ variable;$

$$e_{ij} = \begin{cases} corr(y_i, y_k) & if\ latent\ variable\ i\ is\ connected\ to\ k \\ 0 & others \end{cases}$$

Unlike OLS, which minimizes the residual sum of squares for optimal unbiased estimates in single equations, PLS has different strengths. It does not require strict data distribution assumptions. After convergence, it calculates final path coefficients and loadings by using latent variable scores in OLS regressions.

Regression 1: $KL = \beta_{ESP-KL} \cdot ESP + e_1$ (H3)

Regression 2: $AC = \beta_{ESP-AC} \cdot ESP + e_2$ (H2)

Regression 3: $SP = \beta_{ESP-SP} \cdot ESP + \beta_{KL-SP} \cdot KL + \beta_{AC-SP} \cdot AC + e_3$ (H1, H4, H5)

Therefore, PLS is variance-based and prediction-focused. It works well with small samples, non-normal data, and complex model development. OLS is parameter-based and requires strict assumptions. It suits causal testing in single equations meeting classical assumptions [41]. In this research, these PLS characteristics enable effective revelation of complex pathways. They show how external stakeholder pressure influences sustainable procurement through affective commitment and knowledge mediation.

IV. RESULTS

A. Measurement Model

This study began by refining the quantitative data through certain data cleaning tests and procedures. The PLS-SEM includes both a measurement model and a structural model. The measurement model examines the relationship between constructs and their indicators, focusing on assessing convergent validity and discriminant validity. Measurement model analysis involves several steps and procedures. First, to determine convergent validity, three parameters were used: 1) factor loadings should be greater than 0.7; 2) composite reliability (CR) should be greater than 0.7; and 3) average variance extracted (AVE) should be greater than 0.5. To adjust the model according to these parameters, four reactive first-order constructs were used in the present study: the ESP, the AC, the KL, and the SP. The partial least squares algorithm was used with the maximum number of the partial least squares algorithm was calculated using the maximum number of iterations (up to 300 iterations, using a path-weighting scheme).

1) Convergent validity (CV): To evaluate the measurement model, the CV should first be calculated based on three criteria: 1) factor loadings should be greater than 0.7; 2) Kronbach's alpha and composite reliability (CR) should be greater than 0.7; and 3) the mean AVE value should be greater than 0.5 [40]. The results confirmed that all values were within the acceptable range (see Table II).

2) Discriminant validity: Common discriminant validity was assessed based on three parameters: 1) Fornell and Lacker criterion, 2) cross-loading, and 3) HTMT [42].

The results in Table III confirm that the diagonal values (in bold) for each construct are greater than the inter-conceptual correlation values, which meet the Fornell and Lacker criteria and confirm the discriminant validity of the construct [10]. The cross-loading test also confirmed that each item loaded higher on this construct than the others; all values in the HTMT were less than the threshold value of 0.85 [46].

B. Structural Model

After measuring the model, the next step is to validate the structural model. This process consists of six key steps: 1) covariance assessment; 2) the path coefficient (β); 3) the coefficient of determination (R^2); 4) the predicted correlation Q^2; 5) the effect size q^2; and 6) model fit following the guidelines proposed by Hair et al.[46] .

1) Multicollinearity: In this study, variance inflation factor (VIF) values were used to assess multicollinearity. Table IV shows that the VIF values for all constructs were below the critical value of 3.3 [46], thus confirming that the model does not suffer from covariance.

TABLE IV. MULTICOLLINEARITY (INNER VIF）

	AC	***ESP***	***KL***	***SP***
AC				*1.202*
ESP	*1*		*1*	*1.376*
KL				*1.325*
SP				

Source：Own elaboration

2) The path coefficient: The path coefficients represent the regression coefficients between the constructs in the structural model. In the regression analysis, the standardised beta (β) of the path coefficients ranged between 1 and þ1. To further test the proposed hypotheses (H1, H2, H3, H4, H5, H6, and H7), 5000 iterations of the SEM were performed using Smart-PLS, and the path coefficients (β), t-values, confidence intervals, and p-values were computed, as shown in Fig. 2.

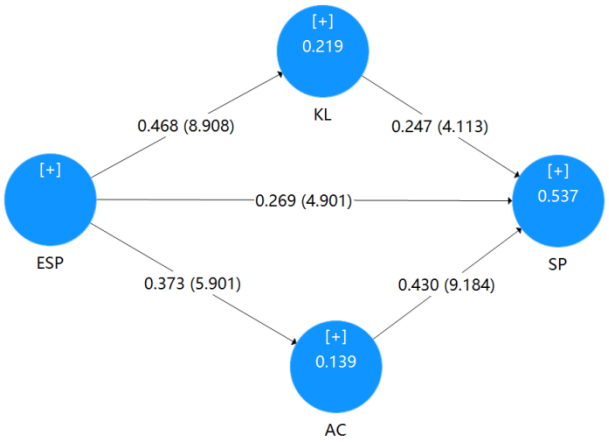

Fig. 2. Structural model.

As shown in Table V, we evaluated the five proposed direct effect hypotheses. H1: ESP was positively associated with SP (β=0.269; t=4.901, p=0.000); H2: ESP was positively associated with KL (β=0.468; t=8.908, p=0.000); H3: ESP was positively associated with AC (β=0.373; t=5.901, p=0.000); H4: KL positively correlated with SP (β=0.247; t=4.113, p=0.000); H5: AC positively correlated with SP (β=0.430; t=9.184, p=0.000). Also, the two-sided 95% confidence intervals of the above paths do not contain 0, which also confirms that the hypotheses (H1, H2, H3, H4, H5) are supported.

TABLE V. RESULTS OF DIRECT HYPOTHESIS TESTING

No	Path	Estimate	2.50 %	97.50 %	t-value	p-value	Decision
H1	ESP ->SP	0.269	0.157	0.373	4.901	0.000	Supported
H2	ESP ->KL	0.468	0.359	0.566	8.908	0.000	Supported
H3	ESP ->AC	0.373	0.241	0.489	5.901	0.000	Supported
H4	KL ->SP	0.247	0.129	0.367	4.113	0.000	Supported
H5	AC ->SP	0.430	0.333	0.516	9.184	0.000	Supported

Source: Own elaboration

The two indirect (mediating) hypotheses are discussed below. Two mediating path hypotheses were proposed in this study, namely: 1) H6: ESP → KL → SP; and 2) H7: ESP → AC → SP. As shown in Table VI, H6: KL mediates between ESP and SP (indirect β = 0.116; t = 3.776, p = 0.000); H7: AC mediates between ESP and SP (indirect β = 0.160; t = 4.773, p=0.000). Table VI shows that both mediating hypotheses (H6, H7) were supported.

The mediation hypothesis also requires a discussion of the strength of the mediating effect. In this study, VAF is used to indicate the proportion of the total effect of the independent variable on the dependent variable through the mediating variable. Commonly used criteria: a VAF > 80% indicates full mediation, 20% = VAF ≥ 80% indicates partial mediation, and a VAF < 20% assumes no mediation [44]. Table VII summarises the results of the mediation effect strength (VAF) calculations for this study.

TABLE VI. SPECIFIC INDIRECT EFFECTS

No	Path	Estimate	2.50 %	97.50 %	t value	p value	Decision
H6	ESP ->KL ->SP	0.116	0.060	0.181	3.776	0.000	Supported
H7	ESP ->AC ->SP	0.160	0.096	0.226	4.773	0.000	Supported

Source: Own elaboration

TABLE VII. MEDIATION

No	Path	Direct	Indirect	Variance account for (VAF)	Mediation
H6	ESP ->KL ->SP	0.269	0.116	Direct effect of ESP → SP = 0.269	Partial
				Indirect effect of ESP → KL → SP = 0.116	
				Total effect = 0.269 + 0.116 = 0.385	
				VAF=Indirect effect/total effect = 0.116/0.385=30.13%	
H7	ESP ->AC ->SP	0.269	0.160	Direct effect of ESP → SP = 0.269	Partial
				Indirect effect of ESP → KL → SP = 0.160	
				Total effect = 0.269 + 0.116 = 0.429	
				VAF=Indirect effect/total effect = 0.160/0.429=37.30%	

Source: Own elaboration

Table VII shows that the direct effect of ESP on SP is 0.269. H6: The direct effect is 0.116, and the total effect is the sum of the direct and indirect effects, i.e., 0.385. The variance of the mediating effect accounts for 30.13%, which is between 20% and 70%, and is a partial mediating effect. The variance of the mediating effect is 37.30%, which is between 20% and 70%, and is a partial mediating effect.

3) Explanatory power (R^2), and predictive relevance (Q^2): The R^2 values of the endogenous latent variables (KL, AC and SP) reflect the explanatory power of the model, i.e., the extent to which the exogenous variable ESP explains the endogenous variables. The effects range from 0 to 1, where 1 indicates full predictive accuracy [46]. The R^2 value for SP is 0.537, which

means that ESP, KL and AC together explain 53.7% of the shift in SP.

Predictive relevance was evaluated via Q^2, where values greater than 0.000, 0.250, and 0.500 signify small, medium, and large effects, respectively [45]. The results (see Table VIII) Q^2 in the endogenous variables (AC, KL, SPB) are positive and have the same trend as R^2, indicating that the explanatory power of the model is stable in the study. Furthermore, the Q^2 value for SP is 0.308, which exceeds 0.25, suggesting that the predictive relevance of the PLS path model has reached a moderate effect.

TABLE VIII. EXPLANATORY POWER (R2), AND PREDICTIVE RELEVANCE (Q^2)

Endogenous variables	R^2 values	Threshold	Q^2 values	Threshold
AC	0.139	small	0.091	>0 (small)
KL	0.219	small	0.125	>0 (small)
SP	0.537	moderate	0.308	>0.250 (medium)

Source：Own elaboration

4) Effect size (q2): The Q2 value, although it shows the predictive relevance of the model to the endogenous latent variables, does not show the effect of the predictive relevance; the effect size (q2) fills this gap. The effect size (q2) is calculated by q2 = (Q2 included – Q2 excluded) / (1 - Q2 included). Critical values of 0.02, 0.1, and 0.35 indicate that the structure has a small, medium, or large predicted correlation to the endogenous structure.

Table IX shows that when the structures KL, AC, and ESP were excluded, the predicted correlations (Q^2 excluded) of the model were 0.282, 0.219, and 0.277, with corresponding effect sizes q^2 of 0.038, 0.129, and 0.045, and the effect sizes were in the order of small, medium, and small effects. This result shows that AC (q^2 =0.129) is at the medium effect level, which means that AC is relatively prominent in contributing to the predictive ability of the SP model and is a more important structure to maintain the predictive efficacy of the model; whereas the effect sizes of KL (q^2=0.038) and ESP (q^2=0.045) are small, which indicates that both of them have a weaker effect on the predictive ability of the SP model.

TABLE IX. EFFECT SIZE (Q^2)

Construct	Q^2 included	Construct	Q^2excluded	q2	Rating
SP	0.308 (medium)	KL	0.282	0.038	small
		AC	0.219	0.129	medium
		ESP	0.277	0.045	small

Source：Own elaboration

5) Model fit: The results of SRMR and NFI together validate the reliability of the model in fitting the data. Standardised Root Mean Square Residual (SRMR) is an important measure of the absolute fit of the model and is usually judged as less than 0.08 as a good model fit [43]. In this model, the SRMR value is 0.053 (as shown in Table X), this result indicates that the overall fit of the model to the data is good, the residuals are small, and it can effectively reflect the actual relationship between the variables. Meanwhile, the normative fit index (NFI) as another absolute fit index, the NFI value of this model is 0.845, which reaches an acceptable model fit level.

Taken together, the lower SRMR in this study indicates that the model has less error in interpreting the data, while the acceptable NFI further supports the consistency of the model structure with the observed data. This implies that the model is able to capture the potential relationships among variables more accurately, providing a solid fitting foundation for subsequent analyses based on the model, and enhancing the credibility of the study's conclusions.

TABLE X. A MODEL FIT

Fit	Saturated Model	Estimated Model
SRMR	0.053	0.063
d_ULS	1.050	1.478
d_G	0.485	0.492
Chi-Square	688.468	687.218
NFI	0.845	0.845

Source：Own elaboration

V. DISCUSSION

In this study, the research models were assessed by PLS-SEM for measurement and structural models, respectively. The results of the measurement model assessment showed that the convergent validity (factor loadings, CR, and AVE met the thresholds) and the discriminant validity (Fornell-Larcker criterion and HTMT test were passed) of all the constructs were at a desirable level, which indicated that the measurement tool had good reliability and validity. The results of structural model assessment showed that the explanatory power (R^2), predictive validity (Q^2), and overall goodness of fit (SRMR) of the model for the endogenous variables met the PLS-SEM assessment criteria, indicating that the model was set up reasonably and could effectively reflect the relationship between the variables. A total of seven hypotheses (five direct and two indirect) based on theoretical and empirical literature were proposed in this study all passed the significance test.

Hypothesis H1 confirms that external stakeholders' pressure directly fosters sustainable procurement in HEIs, with a path coefficient of 0.269 (95% CI [0.157, 0.373], t = 4.901, p<0.001). This underscores that external demands serve as a tangible driver for HEIs to prioritize sustainability in procurement processes; specifically, greater external pressure corresponds to a higher level of emphasis and implementation of sustainability in the procurement processes of HEISs.

Hypothesis H2 reveals that external pressure exerts the strongest direct impact on affective commitment toward sustainable procurement (path coefficient = 0.468, 95% CI [0.359, 0.566], t = 8.908, p < 0.001). This path coefficient is the largest among all direct effects of ESP, demonstrating that external stakeholder pressure exerts the strongest driving force on the emotional investment (such as identification and sense of responsibility) of personnel in HEIs regarding sustainable

procurement, serving as a key external factor in stimulating affective commitment.

Hypothesis H3 demonstrates that external pressure promotes the accumulation of sustainable procurement knowledge in HEIs (path coefficient = 0.373, 95% CI [0.241, 0.489], t = 5.901, p<0.001). This suggests that external demands prompt HEIs to proactively acquire and retain relevant knowledge, laying a foundational basis for practice.

Hypothesis H4 establishes that sustainable knowledge directly enhances sustainable procurement practices (path coefficient = 0.247, 95% CI [0.129, 0.367], t = 4.113, p<0.001). Richer knowledge equips HEIs to implement sustainable procurement more effectively, emphasizing knowledge as a critical enabler.

Hypothesis H5 highlights that affective commitment is the strongest direct driver of sustainable procurement (path coefficient = 0.430, 95% CI [0.333, 0.516], t = 9.184, p < 0.001), outperforming the direct effect of knowledge. This indicates that the affective commitment of HEI personnel towards sustainable procurement is the most critical direct driver of promoting sustainable procurement practices, with a significantly stronger impact than the direct effect of knowledge factors on procurement practices.

Hypothesis H6 confirms the knowledge's mediating role between external stakeholders' pressure (ESP) and sustainable procurement (SP) in HEIs. The indirect effect is 0.116, accounting for 30.13% of the total effect, with a 95% CI [0.060, 0.181] (excluding 0), t=3.776, and p=0.000, supporting the hypothesis. This result reveals the mechanism by which external pressure is transmitted through knowledge. External pressure first promotes higher education institutions to accumulate knowledge related to sustainable procurement, including policy standards and implementation methods. The accumulation and application of such knowledge further facilitate the implementation of sustainable procurement practices.

Hypothesis H7 verifies affective commitment (AC)'s mediation between ESP and SP. Its indirect effect is 0.160, comprising 37.30% of the total effect (0.429), with a 95% CI [0.096, 0.226] (excluding 0), t=4.773, and a significant p-value, confirming partial mediation—consistent with prior studies [34-36]. External pressure can stimulate the intrinsic identification and sense of responsibility of personnel in higher education institutions towards sustainable procurement. Such emotional tendencies prompt them to more actively implement relevant practices.

By comparing the path coefficients, the influences on sustainable procurement (SP) in descending order are as follows: the direct impact of affective commitment (AC) (0.430)>the direct impact of external stakeholders' pressure (ESP) (0.269)>the direct impact of knowledge (KL) (0.247). In terms of mediating effects, the indirect impact of affective commitment (0.160)>the indirect impact of knowledge (0.116).

This ranking shows that affective commitment is the core factor driving sustainable procurement. Its direct effect is significantly higher than that of other variables, and it also plays a stronger role in transmitting external pressure through mediating paths. Although external stakeholders' pressure directly promotes sustainable procurement, its effect is weaker than that of affective commitment. Moreover, part of its influence is achieved by stimulating affective commitment and accumulating knowledge.

This may be because affective commitment is an intrinsic driver, reflecting the active recognition and sense of responsibility of personnel in higher education institutions toward sustainable procurement. When procurement staff recognize sustainable goals at the value level, they will actively incorporate environmental protection and social responsibility into decision-making, and even maintain implementation efforts in the absence of external supervision. In contrast, the direct impact of external stakeholders relies more on external constraints (such as policy requirements and public supervision), which tend to lead to passive compliance and hardly meet the in-depth needs of practice optimization.

VI. Conclusion

A. Research Implications

The theoretical contributions of this study are mainly reflected in the precise deepening and innovative expansion of organizational sustainability theory, stakeholder theory, and institutional theory. External stakeholder pressure affects sustainable procurement through the dual mediating role of affective commitment and knowledge. This finding does not merely verify the correlation between variables but identifies the novel dual mediation mechanism of affective commitment plus knowledge, supplementing organizational sustainability theory with a specific transmission path of external pressure, internal capabilities, sustainable practices, and clarifying the core hub role of internal factors in pressure transformation.

From the perspective of stakeholder theory, unlike existing studies that mostly focus on enterprises or general public sectors, and traditional theories that adhere to the linear cognition of external pressure directly driving organizational behaviour, this study takes Chinese higher education institutions (HEIs) which integrate educational attributes and public functions as a unique contextual variable, and for the first time systematically verifies the integrated model of dual mediators (affective commitment and knowledge). It breaks through the singular cognition of traditional theories by revealing the key boundary condition that the intensity of stakeholders' influence depends on the depth of organizational members' affective identification. This clarifies the core path through which this study advances the theory by exploring the underexplored theoretical gap of the internal transformation mechanism of external pressure, it expands the application scenario of stakeholder theory from market-oriented organizations to non-market-oriented higher education institutions, and provides an empirically verifiable new perspective for understanding the boundary conditions of stakeholder organization interaction.

From the perspective of institutional theory, addressing the limitation of existing studies that regard institutional pressure internalization as a single process without distinguishing the differential roles of cognitive and emotional dimensions, this study innovatively links the dual mediators to the institutional internalization process, identifying the dual paths of cognitive

internalization (knowledge mediator: rational absorption of norms) plus emotional internalization (affective commitment mediator: emotional recognition of values). This novel division of mediating mechanisms not only confirms the dynamic and synergistic process of institutional pressure internalization but also clarifies that emotional internalization is the core driver for organizations to move from passive compliance to active practice (path coefficient 0.430 is much higher than knowledge's 0.247). By refining the micro mechanism of institutional legitimacy formation, this finding fills the research gap of differentiation of internalization paths in institutional theory within the field of sustainable management. It not only provides a new theoretical perspective for understanding the internal driving logic of sustainable practices but also offers replicable methodological insights for interdisciplinary integration in organizational behaviour analysis.

B. Practical Implications

Based on empirical findings, this study offers targeted implications for the sustainable procurement practices of Chinese higher education institutions (HEIs): First, strengthen the cultivation of affective identification and integrate sustainable development values into the training and incentive systems for procurement personnel. The direct effect (path coefficient = 0.430) and mediating strength (37.30%) of affective commitment both rank first, indicating that procurement personnel's value recognition and sense of responsibility toward sustainable goals are the key to breaking through "surface compliance". Managers can interpret the campus value of sustainable procurement through induction training and enhance identity resonance with typical university-specific cases; in incentive design, directly link sustainable procurement performance to performance promotion and merit evaluation, which not only meets procurement personnel's professional sense of achievement but also strengthens their emotional bond with organizational goals.

Second, establish a collaborative mechanism between external collaboration and internal capabilities. The dual mediation empirical results show that external pressure can only fully exert its effect through the two-way transformation of knowledge accumulation and affective identification, with significant synergistic effects between the two. Therefore, HEIs cannot promote sustainable procurement in isolation and need to build an internal-external linkage transformation platform: externally, collaborate with government departments and environmental organizations to conduct policy and practical training, and simultaneously organize face-to-face communication between procurement personnel, communities, and suppliers to not only accurately transmit external pressure but also enhance emotional connection by perceiving stakeholders' demands; internally, establish a sustainable procurement knowledge base integrating policy standards, successful cases, and supplier technical resources, and require suppliers to incorporate sustainable production training into cooperation obligations to ensure the practicality and continuity of knowledge accumulation.

Third, adapt to the administrative and policy-driven characteristics of Chinese HEIs, integrate sustainable procurement into HEIs' governance and inter-departmental assessment, formulate special procurement lists and green clauses, and establish a supplier sustainability rating system to consolidate practical results at the governance and process levels. These implications provide an actionable framework for HEIs to address the dilemma of "surface compliance" and improve the quality of sustainable procurement.

C. Limitations and Future Directions

This study inevitably has some limitations. In terms of sample selection, the study sample is mainly from higher education institutions in a specific region, which may be affected by geographical policy differences, and the applicability of the conclusions to education organisations in other regions or privately-run is yet to be verified, and it is recommended that multi-stage stratified sampling be used in the follow-up to expand the coverage of the sample. In terms of data collection, this study uses cross-sectional data, which makes it difficult to capture the dynamic relationship of variables. The interaction of external stakeholder pressure, affective commitment, etc., with sustainable procurement may evolve over time, and it is recommended that a longitudinal tracking design be adopted to clarify the long-term mechanism of action. There is a simplification of the measurement dimensions of the variables, and the measurement of affective commitment and knowledge focuses on the overall level without subdividing the subdimensions, which may overlook the heterogeneity of the mediating effect. It is recommended that the measurement of the constructs be refined in the future to improve the precision of the mechanism analysis.

In the future, research can focus on specific types of HEIs and conduct comparative studies from the perspectives of curriculum design, training programs, and management strategies. This approach can address the limitation of sample homogeneity and deepen the understanding of the context, mechanisms, and practical implications of sustainable procurement. Classify HEIs by disciplinary characteristics, operational orientation, and institutional nature—different types have distinct procurement needs and implementation foundations due to attribute differences. Compare the depth of knowledge integration in curricula, methods of enhancing affective identification, and differences in strategy implementation paths across institutions to clarify the impact of these initiatives on dual mediators and the performance mechanism. This will provide targeted solutions for various HEIs and refine and expand the theoretical model through contextual segmentation.

Lexicon-Based Sentiment Analysis of Social Media Reviews for Floating Market Popularity in South Kalimantan

Evi Lestari Pratiwi[1], Ramadhani Noor Pratama[2], Inayatul Ulya Ahyati[3], Paula Dewanti[4]
Study Program of Information System, Politeknik Negeri Banjarmasin, Banjarmasin, Indonesia[1, 2, 3]
Department of Information Systems, Institut Teknologi dan Bisnis STIKOM Bali, Bali, Indonesia[4]

***Abstract*—Floating markets in South Kalimantan are culturally significant heritage destinations whose contemporary reputation is increasingly shaped by user-generated content on digital platforms. This study analyzes public perceptions of these markets by applying a lexicon-based sentiment analysis framework to 300 reviews collected from TripAdvisor and Google Maps between 2023 and 2024. The analytical workflow included text normalization, tokenization, stop-word removal, and stemming, with feature representation generated through term frequency–inverse document frequency (TF-IDF). Sentiment polarity was determined using bilingual lexicon-based scoring and categorized into positive, neutral, or negative sentiments. The results indicate that 45% of reviews expressed positive sentiment, highlighting cultural distinctiveness and riverfront experiences; 35% were neutral and provided descriptive logistical information; and 20% were negative, emphasizing waste issues, overcrowding, pricing inconsistencies, and perceived reductions in authenticity. TripAdvisor reviews exhibited greater emotional polarization than those on Google Maps. The findings demonstrate that lexicon-based sentiment analysis offers a transparent and effective approach for multilingual tourism contexts, providing insights into how digital narratives contribute to destination image formation. The study offers practical implications for improving environmental management, regulating visitor flows, and enhancing communication transparency within heritage tourism settings. It also contributes theoretically by underscoring the informational role of neutral reviews within electronic word-of-mouth dynamics. Future work may integrate machine learning-based sentiment classifiers or multimodal data to enhance analytical precision and extend the applicability of sentiment analysis in digital tourism research.**

Keywords*—Sentiment analysis; lexicon-based methods; floating markets; social media analytics; cultural tourism

I. Introduction

Tourism is one of the most rapidly expanding sectors in Indonesia, contributing approximately 4.3% to the national GDP in 2022 [1]. In 2023, the country welcomed more than 8.5 million international tourists, marking a strong post-pandemic recovery [2]. Within this national context, South Kalimantan continues to strengthen its tourism position, recording over 3.2 million domestic and international visitors in 2023 and generating substantial socio-economic benefits for local communities [3]. Among its key attractions are the floating markets, particularly the Lok Baintan and Kuin Floating Markets, which serve not only as centers of trade but also as living cultural heritage that showcase the river-based traditions of the Banjar community. Government reports indicate that these markets account for nearly 25% of cultural tourism visits in the province [4].

The increasing influence of digital platforms such as TripAdvisor and Google Maps has reshaped how destinations are evaluated and promoted. User-generated content (UGC), especially online reviews, functions as digital word-of-mouth capable of shaping visitors' expectations, satisfaction levels, and overall destination image. Although several global studies have applied sentiment analysis to tourism contexts, research focusing on Indonesian heritage tourism, particularly floating markets, remains limited. Existing studies have not sufficiently explored multilingual reviews or applied computational approaches to understand emerging sustainability and service-related issues. This gap highlights the need for systematic analysis of tourists' online expressions to guide evidence-based destination management.

Although floating markets in South Kalimantan are widely recognized as cultural landmarks, they remain understudied from a computational perspective, particularly in relation to how visitors discuss issues of authenticity, service quality, and sustainability online. This gap underscores the need for a systematic understanding of how these destinations are portrayed in multilingual user reviews on major digital tourism platforms. Accordingly, this study seeks to explore how floating markets are perceived by examining the dominant positive, neutral, and negative sentiments expressed in visitor narratives. It aims to apply a lexicon-based sentiment analysis approach to multilingual reviews, identify key sentiment patterns and recurring themes, and translate these insights into practical recommendations for improving service delivery, sustainability efforts, and digital communication strategies.

The significance of this study is twofold. From an academic perspective, it enriches the growing body of work on sentiment analysis within Indonesia's cultural heritage tourism, demonstrating the value of lexicon-based methods for multilingual contexts and highlighting the often-overlooked role of neutral sentiment in shaping electronic word-of-mouth. From a practical standpoint, the findings provide guidance for policymakers, tourism authorities, and local communities seeking to enhance visitor experiences, manage crowding, address environmental concerns, and strengthen digital engagement.

II. Literature Review

A. Social Media and Tourism

Social media has reshaped the tourism landscape by enabling travelers to share photos, narratives, and evaluations in real-time (see Fig. 1). This user-generated content (UGC) fuels electronic word-of-mouth (e-WOM), which has become a key driver of trip planning, reputation building, and destination choice [5]. Xiang and Gretzel [6] emphasize that travelers increasingly rely on peer-generated information due to its perceived authenticity and credibility compared to official promotional materials. Positive online reviews can significantly enhance destination visibility and reputation, while negative reviews can reduce visitor interest or trust [7]. Empirical studies have shown that higher ratings and positive sentiment on platforms such as TripAdvisor correlate with increased bookings and stronger consumer confidence [8], positioning social media as both an opportunity and a reputational risk for tourism managers.

Fig. 1. Social media posting.

B. Sentiment Analysis in Tourism Research

Sentiment analysis, also referred to as opinion mining, is a branch of natural language processing (NLP) that seeks to determine the polarity (positive, neutral, negative) of textual data [9]. Liu [10] describes it as a computational technique for extracting opinions and emotions embedded in written language. Within tourism research, sentiment analysis enables large-scale examination of visitor experiences, allowing insights that go beyond traditional surveys or interviews [11] [12] [13] [14].

Recent studies have applied sentiment analysis to hotels, airlines, urban attractions, and destination branding, often using reviews from platforms like TripAdvisor and Yelp [15] [16] [17] [18]. While these methods have proven effective for monitoring satisfaction and guiding service improvements, most studies rely on standard lexicon- or machine-learning approaches that prioritize polarity classification over contextual interpretation. Few studies extend sentiment findings to broader theoretical frameworks such as cultural sustainability or destination image formation, especially within developing-nation contexts (see Fig. 2).

A	B	C
229	Wisatawan biasanya mengambil foto di sekitar perahu.	netral
230	Tidak ada papan harga sehingga kadang wisatawan ditipu.	negatif
231	Harga makanan cukup murah dan pedagang sangat sopan.	positif
232	Cocok untuk berbelanja oleh-oleh atau melihat budaya lokal.	netral
233	Harga makanan cukup mahal dibandingkan pasar biasa.	negatif
234	Pasar terapung ini menjadi pengalaman yang berbeda dari tempat lain.	positif
235	Buka hanya di pagi hari, jadi sebaiknya datang lebih awal.	netral
236	Pasar sangat ramai, sulit bergerak, dan agak kotor di beberapa area.	negatif
237	Pasar terapung ini menjadi pengalaman yang berbeda dari tempat lain.	positif
238	Cocok untuk berbelanja oleh-oleh atau melihat budaya lokal.	netral
239	Pasar sangat ramai, sulit bergerak, dan agak kotor di beberapa area.	negatif
240	Sungguh destinasi wisata yang harus dikunjungi kalau ke Kalimantan.	positif
241	Akses ke pasar bisa menggunakan perahu motor atau klotok.	netral
242	Perahu sangat padat, terasa tidak nyaman.	negatif
243	Sangat bagus untuk wisata budaya, orang-orangnya ramah sekali.	positif
244	Akses ke pasar bisa menggunakan perahu motor atau klotok.	netral
245	Kebersihan kurang terjaga, perlu perbaikan.	negatif
246	Pasar terapung ini menjadi pengalaman yang berbeda dari tempat lain.	positif
247	Pasar terapung buka pagi hari, biasanya ramai menjelang subuh.	netral
248	Beberapa pedagang kurang ramah terhadap turis.	negatif
249	Makanan yang dijual enak dan khas daerah, wajib dicoba.	positif

Fig. 2. Sentiment analysis list.

C. Floating Markets as Tourism Icons

Floating markets are distinctive cultural and economic spaces found primarily in Southeast Asia (see Fig. 3). In Thailand, floating markets such as Damnoen Saduak have become iconic destinations attracting millions of visitors annually, although studies report concerns about overcrowding and commercialization [19]. Similarly, research in Vietnam identifies floating markets as culturally unique yet vulnerable to sustainability issues, including pollution and loss of authenticity [20] [21] [22].

In Indonesia, particularly South Kalimantan, floating markets such as Lok Baintan and Kuin serve dual purposes: they are active trade hubs for local communities and tourism attractions showcasing Banjar cultural heritage. Government tourism reports suggest that floating markets account for nearly 25% of cultural tourism visits in the province [3]. Despite their importance and visibility in tourism promotion, scholarly work on Indonesian floating markets has largely focused on cultural anthropology or local economic roles, with limited attention to how these sites are perceived online. Systematic digital-tourism analyses remain scarce.

Fig. 3. Floating markets as tourism icons.

D. Research Gap and Contribution

Although sentiment analysis is widely applied in tourism, two key gaps persist. First, cultural and heritage tourism,

particularly in developing regions, remains underrepresented, with few studies investigating how visitors interpret authenticity, sustainability, and service quality in heritage spaces such as floating markets [23] [24]. Second, existing studies often report polarity distributions without connecting results to deeper theoretical perspectives or policy relevance.

This study seeks to fill these gaps by offering three key contributions. First, on the methodological side, it demonstrates how a bilingual, lexicon-based sentiment analysis can be effectively applied to multilingual reviews in low-resource cultural tourism settings. Although lexicon-based approaches are well established, their tailored use for heritage tourism in Indonesia remains limited, making this application both relevant and responsive to the linguistic diversity and data constraints of the context. Second, at the theoretical level, the study connects sentiment patterns to broader discussions on destination image and cultural sustainability. It also advances e-WOM research by underscoring the often-underappreciated role of neutral sentiment, which can strengthen informational credibility and influence perceptions of authenticity. Third, the study offers practical value by outlining concrete strategies for tourism stakeholders to address waste management, manage crowd density, safeguard cultural authenticity, and enhance digital communication, key priorities for maintaining the long-term viability of heritage destinations in developing regions.

III. Research Methods

This study advances current practices in digital tourism analytics by applying a bilingual lexicon-based sentiment analysis specifically tailored to multilingual heritage tourism reviews, a context that remains largely understudied in Indonesia. While lexicon-based techniques are not new, their customization for low-resource environments, where linguistic diversity is high and machine-learning training data are limited, represents a substantive methodological innovation. Unlike prior tourism studies that rely heavily on English-language or pre-trained classifiers, this research integrates Indonesian and English lexicons, adapts pre-processing rules to mixed-language narrative structures, and systematically examines sentiment polarity across platforms with differing user demographics. This tailored workflow, encompassing normalization, tokenization, stop-word refinement, bilingual stemming, and TF-IDF representation, demonstrates how lexicon-based models can maintain interpretability while achieving robust performance in multilingual, culturally embedded contexts. In doing so, the methodology provides a replicable and scalable framework for sentiment analysis in other data-sparse heritage tourism destinations.

This research employed a quantitative content analysis of user-generated content (UGC) sourced from TripAdvisor and Google Maps. A total of 300 reviews related to the two main floating markets in South Kalimantan—Lok Baintan and Kuin—were collected between January 2023 and December 2024. Reviews were purposively selected based on criteria such as language (Indonesian or English), clarity of visitor experiences, and the presence of at least one complete sentence to allow for sentiment analysis. Before classification, the dataset underwent a thorough preprocessing phase, which included text normalization (case folding), removal of URLs, numbers, punctuation, and emojis, tokenization, stopword elimination in both languages, and stemming or lemmatization. Random checks ensured that these steps preserved the meaning of the original content.

Before conducting sentiment classification, the raw textual data underwent a comprehensive preprocessing pipeline using natural language processing (NLP) techniques. This process involved case folding to standardize text into lowercase, the removal of URLs, punctuation, numbers, emojis, and other noise elements, and tokenization to segment the reviews into lexical units. Stop-word removal was applied to eliminate high-frequency functional words in both Indonesian and English, while stemming or lemmatization was used to reduce words to their base forms. Manual spot-checking was conducted to ensure that semantic meaning was preserved following normalization.

For sentiment analysis, a lexicon-based approach was applied to categorize reviews into positive, neutral, or negative sentiments. Each token was assigned a polarity score (+1,–1, or 0), with negation handling implemented for words preceded by terms such as *tidak*, *bukan*, or *not*. A review's overall sentiment was determined by the aggregate score of its tokens. The findings were visualized using descriptive tables, pie and bar charts for sentiment distribution, as well as keyword frequency charts highlighting common terms in positive and negative reviews. To validate accuracy, 50 reviews were manually coded by two independent annotators, achieving an inter-rater reliability of 0.82 (Cohen's Kappa), which indicates strong agreement. Finally, a methodological flowchart was developed to illustrate the overall research process clearly.

The classified sentiment outcomes were subsequently examined through descriptive and visual analytics. Bar charts, pie charts, and word-frequency plots were produced to illustrate the distribution of sentiment categories and highlight dominant lexical patterns. Temporal comparisons between 2023 and 2024 were visualized using line charts to reveal changes in public perception, and platform-based differences were analyzed using comparative tables.

To ensure the reliability of the sentiment classification, a manual validation procedure was conducted. A subset of 50 reviews was independently annotated by two human coders with expertise in tourism communication and text analysis. The degree of agreement between the coders was assessed using Cohen's Kappa, which yielded a coefficient of 0.82, indicating strong inter-rater reliability. This validation step confirmed that the lexicon-based model performed consistently with human judgment, thereby supporting the credibility of the analytical results.

This study employed a structured methodological framework consisting of five primary stages, namely data collection, preprocessing, sentiment classification, visualization, and validation. The overall workflow followed in this research is illustrated in the methodological flowchart presented as Fig. 4. Each stage was designed to ensure analytical rigor, reproducibility, and alignment with established standards in computational tourism analytics.

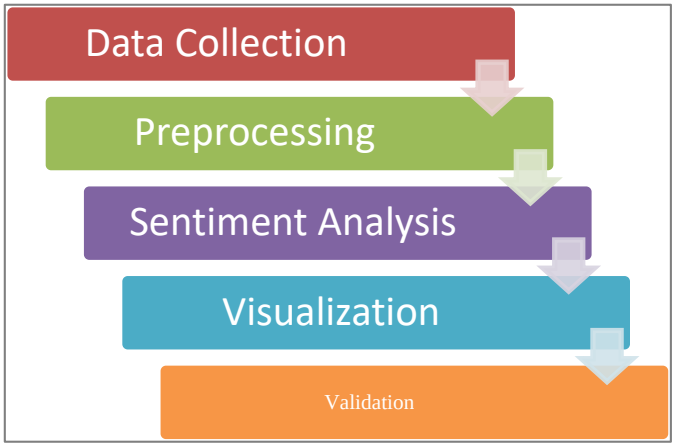

Fig. 4. Flowchart of research methods.

IV. Results and Discussion

A. Descriptive Statistics of the Dataset

The dataset comprised a total of 300 online reviews, collected from two primary platforms widely used in tourism research: Google Maps and TripAdvisor. Of these, 180 reviews (60%) originated from Google Maps, while 120 reviews (40%) came from TripAdvisor. In terms of language distribution, the majority of reviews, 210 reviews (70%), were written in Indonesian, reflecting local or domestic visitor experiences, while 90 reviews (30%) were in English, mostly representing international visitors.

The average length of reviews was 28.6 words per review, with English reviews being longer (average of 35 words) compared to Indonesian reviews (average of 25 words). This suggests that international tourists tend to write more detailed and elaborate reviews, possibly because they view their visit as a rare cultural experience worth documenting, whereas domestic tourists often provide shorter, more factual, and practical evaluations.

TABLE I. Dataset Characteristics

Platform	*Reviews*	*%*	*Avg. Length (words)*
Google Maps	180	60%	27.1
TripAdvisor	120	40%	31.2
Total	**300**	**100%**	**28.6**

B. Sentiment Distribution

Sentiment classification divided the dataset into three categories: 135 reviews (45%) positive, 105 reviews (35%) neutral, and 60 reviews (20%) negative.

TABLE II. Overall Sentiment Distribution

Sentiment	*Frequency*	*Percentage*
Positive	135	45%
Neutral	105	35%
Negative	60	20%

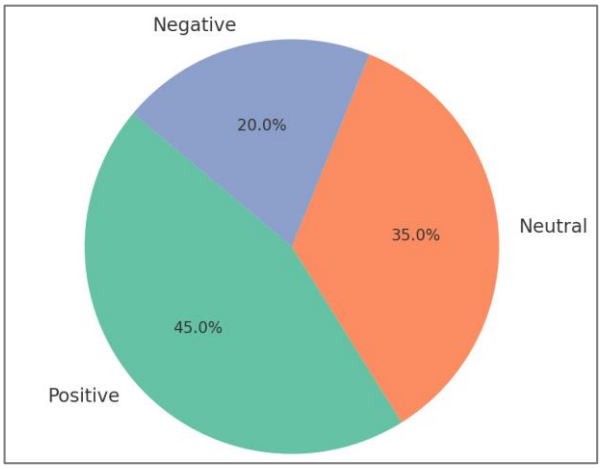

Fig. 5. Sentiment distribution (Pie chart).

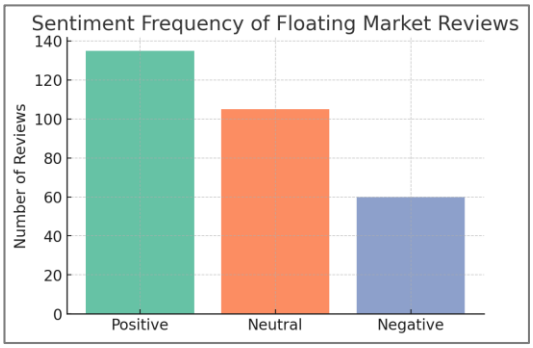

Fig. 6. Sentiment frequency (Bar chart).

Table I shows the dataset characteristics, while the sentiment distribution is presented in Table II. The results reveal that 135 reviews (45%) were positive, 105 reviews (35%) were neutral, and 60 reviews (20%) were negative. Fig. 5 and Fig. 6 illustrate the distribution through a pie chart and a bar chart. The dominance of positive reviews indicates a generally favorable perception of the floating markets, but the high percentage of neutral reviews suggests that many visitors provide descriptive rather than emotional feedback.

The results reveal that the floating markets are generally perceived positively by visitors, but a significant portion of reviews are neutral, indicating that many tourists use online platforms to provide objective descriptions rather than subjective evaluations. The presence of 20% negative reviews, however, highlights areas for improvement that may significantly influence future visitor perceptions.

C. Sentiment Analysis by Platform and Language

The sentiment analysis was disaggregated to compare results across the two platforms (Google Maps and TripAdvisor) and across the two primary languages used in the dataset (Indonesian and English). This breakdown reveals important differences in how visitors express their perceptions, shaped by both the nature of the platform and the cultural background of reviewers [25].

TABLE III. SENTIMENT ANALYSIS BY PLATFORM

Platform	*Positive*	*Neutral*	*Negative*	*Total*
Google Maps	75 (41.6%)	70 (38.8%)	35 (19.4%)	180
TripAdvisor	60 (50.0%)	35 (29.2%)	25 (20.8%)	120

TABLE IV. SENTIMENT ANALYSIS BY LANGUAGE

Platform	*Positive*	*Neutral*	*Negative*	*Total*
Google Maps	75 (41.6%)	70 (38.8%)	35 (19.4%)	180
TripAdvisor	60 (50.0%)	35 (29.2%)	25 (20.8%)	120

The platform-based analysis shows that TripAdvisor reviews were more positive compared to Google Maps, likely because TripAdvisor attracts more international tourists who emphasize cultural and scenic uniqueness. In contrast, Google Maps reviews leaned more neutral, suggesting that local visitors are more likely to report factual observations (such as directions, operating hours, or crowd levels) instead of strong opinions (see Table III).

The language-based analysis indicates that English reviews are more polarized, with higher proportions of both positive and negative comments. This can be explained by cultural differences in review-writing behavior: international visitors tend to express enthusiasm when satisfied but are also more explicit when disappointed. On the other hand, Indonesian reviews are predominantly neutral, showing a preference for descriptive narratives rather than extreme sentiment (see Table IV).

D. Keyword and Topic Analysis

Keyword analysis identified recurring terms in each sentiment category (see Fig. 7):

1) Positive reviews emphasized words such as beautiful, unique, friendly, clean, and morning. Many of these highlighted the cultural authenticity of the floating market, the friendliness of local traders, and the picturesque atmosphere during sunrise.

2) Neutral reviews commonly contained words such as location, boat, access, and time. These were descriptive and provided practical information, such as transportation modes, market schedules, and general features of the market.

3) Negative reviews frequently included words like crowded, dirty, expensive, and traffic. These highlight operational problems such as overcrowding during peak hours, waste management challenges, and inflated tourist prices.

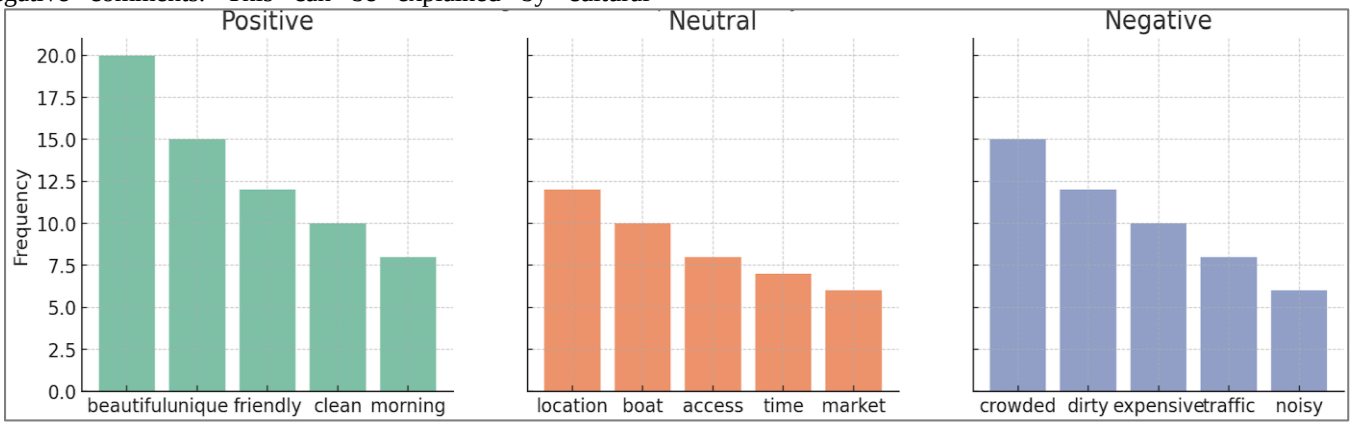

Fig. 7. Keyword and topic analysis (Bar chart).

E. Temporal Trends (2023 versus 2024)

A year-to-year comparison provides additional insights into how perceptions of the floating markets evolved between 2023 and 2024. Table V presents the sentiment distribution for both years, followed by Fig. 8 which visualizes the temporal trend. The data shows a clear shift in visitor perceptions, with positive sentiment decreasing and negative sentiment increasing over time.

TABLE V. SENTIMENT DISTRIBUTION BY YEAR

Year	*Positive*	*Neutral*	*Negative*	*Total*
2023	90 (50%)	63 (35%)	27 (15%)	180
2024	45 (37.5%)	42 (35%)	33 (27.5%)	120

In 2023, visitor perceptions of the floating markets were largely favorable, with about half of the reviews highlighting their cultural authenticity. Tourists frequently emphasized the distinctive experience of trading from boats, the picturesque sunrise views, and the warmth of local vendors. Negative feedback was minimal (15%) and generally limited to minor concerns such as crowded mornings or a lack of adequate facilities.

By contrast, in 2024 the sentiment shifted noticeably. Positive reviews fell to 37.5%, while negative reviews rose to 27.5%, reflecting growing dissatisfaction with waste management, congestion on the river, and perceptions of inflated prices for tourists. Although neutral reviews remained stable at around 35%—providing practical guidance on transport, schedules, and directions—the overall pattern suggests a mixed outcome. Social media-driven popularity increased tourist arrivals, yet at the same time exposed weaknesses in infrastructure and service delivery. This rising share of negative sentiment underscores the urgency for better crowd control, enhanced environmental management, and transparent pricing policies to prevent the floating markets from losing their authenticity and being perceived as over-commercialized.

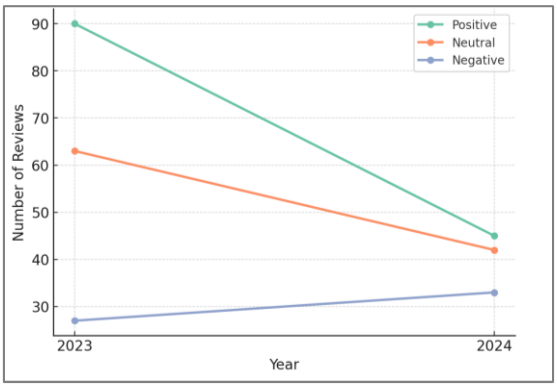

Fig. 8. Temporal trends of sentiment (2023 vs. 2024).

F. Interpretation of Neutral Reviews

Neutral reviews, which accounted for 35% of the dataset, primarily contained factual and descriptive information rather than emotional expressions. Visitors often mentioned elements such as accessibility, opening hours, transportation by boat, or general atmosphere without attaching strong judgments. For instance, one reviewer wrote, *"The market is open early in the morning, and it is better to come before 7 a.m. to avoid crowds"*, while another stated, *"Boats are available from the pier, and the trip to the market takes about 15 minutes"*. These examples show how neutral reviews serve as practical guides that help potential visitors plan their trips.

The relatively high proportion of neutral reviews also contributes to the credibility and authenticity of online platforms. While positive and negative reviews reflect emotions, neutral reviews provide balance by offering straightforward accounts of the market. Their stability across both years indicates that they function as a baseline narrative, consistently delivering reliable context regardless of changes in sentiment trends. From a managerial perspective, these reviews highlight recurring concerns about logistics and access, signaling that clearer communication in promotional materials could enhance the visitor experience.

G. Negative Sentiment and Service Gaps

Negative reviews, although representing only 20% of the dataset, carry significant weight in shaping the overall perception of the floating markets. These reviews frequently pointed out recurring problems such as waste accumulation on the river, overcrowding of boats during peak hours, and perceptions of unfair pricing targeted at tourists. For example, one visitor noted, *"The river is beautiful, but there was a lot of floating trash which spoiled the experience"*, while another commented, *"Too many boats at the same time made it uncomfortable to enjoy the scenery"*. Such feedback highlights that operational issues, rather than cultural or aesthetic shortcomings, are the main drivers of dissatisfaction.

From a managerial perspective, these negative reviews reveal critical service gaps that demand immediate attention. Waste management must be prioritized to preserve both environmental quality and visitor impressions, while crowd control strategies—such as staggered visiting hours or regulated boat traffic—could reduce congestion. Addressing concerns about pricing transparency is also essential, as the perception of unfair treatment can damage trust and deter repeat visits. If left unresolved, these issues risk eroding the long-term sustainability of the floating markets, potentially overshadowing their cultural uniqueness and reducing their appeal to both domestic and international audiences.

H. Social Media as a Double-Edged Sword

Social media operates as a dual-impact mechanism in shaping the digital reputation of South Kalimantan's floating markets. On the positive side, large volumes of favorable and neutral user-generated content function as organic promotion. Reviews and images emphasizing cultural authenticity, vibrant morning activity, and trader hospitality amplify destination visibility across platforms such as TripAdvisor, Google Maps, Instagram, and TikTok. These narratives significantly influence travel decision-making processes and act as low-cost digital marketing channels [26].

Negative reviews spread rapidly and can harm reputation, if ignored. Complaints about crowding, sanitation, and pricing easily circulate online, discouraging visits. Continuous monitoring through automated sentiment analysis and real-time dashboards enables managers to balance positive promotion with early warnings, ensuring adaptive strategies and sustainable competitiveness in digital tourism.

I. Managerial Implications

The findings of this study provide actionable insights for integrating sentiment analysis into digital tourism management. First, the predominance of positive reviews suggests opportunities for leveraging data-driven promotional strategies. Destination managers can employ automated content curation and recommender systems to amplify user-generated narratives across social media platforms, thereby enhancing visibility and engagement.

Second, the recurrent negative sentiments regarding waste, overcrowding, and pricing indicate specific service quality gaps that can be addressed using data-informed decision support systems. For instance, predictive analytics could assist in regulating visitor flow, while digital monitoring tools may support transparency in pricing and operational efficiency.

Third, local community engagement can be strengthened through capacity-building programs supported by digital platforms. Training traders in online promotion and eco-friendly practices, coupled with access to analytics dashboards, can preserve authenticity while improving competitiveness.

Finally, the adoption of smart tourism technologies, such as real-time sentiment monitoring and automated alerting systems, would allow destination managers to detect emerging issues proactively. This approach demonstrates how computational sentiment analysis can function as a decision-support mechanism, positioning heritage destinations like South Kalimantan's floating markets as benchmarks for sustainable, technology-enabled tourism management.

J. Theoretical Implications

This study contributes theoretically by extending sentiment analysis to cultural heritage tourism, specifically floating markets in South Kalimantan. Using lexicon-based methods [27], it shows how computational models capture cultural,

economic, and environmental dynamics. The significant share of neutral reviews reveals that e-WOM is both emotional and informational, with neutral content serving as a stabilizing factor for credibility.

Additionally, differences identified across platforms and languages underline the necessity of adopting cross-platform and multilingual approaches. The contrast between English-dominated TripAdvisor and Indonesian-dominated Google Maps indicates that cultural communication styles and platform features shape sentiment expression. Temporal analysis between 2023 and 2024 further shows that sentiment is dynamic, shifting alongside infrastructure development, sustainability challenges, and digital exposure. These insights refine sentiment analysis theory by emphasizing contextual, linguistic, and temporal factors in tourism-focused applications.

This study has several limitations that should be acknowledged. The dataset was restricted to text-based reviews from TripAdvisor and Google Maps, which may not represent perceptions expressed on multimedia platforms such as Instagram or TikTok. The lexicon-based method, although transparent and suitable for multilingual data, may not fully capture nuanced expressions such as sarcasm or implicit sentiment. The analysis also relied solely on textual content, excluding visual cues that influence tourist evaluations. Furthermore, the two-year timeframe may not reflect longer-term sentiment shifts. Future studies should incorporate cross-platform, multimodal, and machine learning–based approaches for broader insight.

Although this study offers substantial insights into public perceptions of South Kalimantan's floating markets, several limitations should be noted. The dataset, drawn solely from TripAdvisor and Google Maps, excludes richer multimedia formats from platforms such as Instagram or TikTok that may reveal additional experiential dimensions. The lexicon-based sentiment approach, despite its transparency and suitability for multilingual analysis, may not fully capture subtle linguistic nuances such as irony, implicit sentiment, or culturally specific expressions, particularly within mixed Indonesian–English reviews. The two-year scope (2023 to 2024) may also limit the ability to observe longer-term sentiment fluctuations. Nevertheless, the study contributes significantly by extending sentiment analysis into the underexplored field of cultural heritage tourism and by introducing a cross-linguistic analytical framework that enhances understanding of how multilingual digital narratives shape cultural sustainability. These insights help clarify how online discourse both reflects and influences the preservation and perceived authenticity of heritage destinations.

V. Conclusion and Future Work

This study employed a bilingual lexicon-based sentiment analysis to examine 300 online reviews from Google Maps and TripAdvisor, generating insights into the public's digital perception of South Kalimantan's floating markets. The findings reveal a sentiment distribution of 45% positive, 35% neutral, and 20% negative. Positive content emphasizes cultural richness and river-based experiences, while negative reviews highlight persistent challenges related to sanitation, congestion, pricing inconsistencies, and concerns over declining authenticity. Cross-platform differences show that TripAdvisor reviews, largely posted by international visitors, exhibit greater emotional polarization, whereas Google Maps reviews tend to be more neutral and informational. Temporal patterns also point to rising negative sentiment in 2024, signaling emerging sustainability pressures that require immediate intervention.

Beyond describing sentiment patterns, this study offers meaningful insights for tourism strategy, policy development, and cultural preservation. The results highlight how UGC shapes the destination image of floating markets, influencing visitor expectations and perceptions of cultural sustainability. From a managerial standpoint, addressing waste, crowding, and pricing transparency is essential for safeguarding authenticity and improving overall visitor satisfaction. These findings support data-driven decision-making by enabling tourism authorities to monitor real-time visitor sentiment, guide targeted environmental management, regulate visitor capacity, and refine digital communication strategies to promote more accurate and appealing representations of the markets.

From a theoretical perspective, the study expands the application of sentiment analysis by demonstrating how neutral sentiment, often ignored in tourism analytics, plays a key role in conveying factual, credibility-enhancing information within e-WOM. This insight contributes to broader discussions on destination image formation and digital heritage interpretation, particularly in developing-nation contexts where cultural tourism holds strategic socioeconomic value.

Looking ahead, future research can advance this work by integrating machine-learning or hybrid sentiment models, incorporating multimodal data (e.g., images, videos), and examining cross-cultural differences in perception. Such developments can deepen analytical precision and further strengthen the role of sentiment analysis in heritage tourism governance and digital tourism planning.

Future work may extend this study by integrating larger and more diverse datasets from additional social media platforms such as Instagram or TikTok. Employing advanced machine learning methods, including transformer-based deep learning models, could improve classification accuracy and capture nuanced emotional expressions beyond lexicon constraints. Longitudinal analyses with extended timeframes would enable more robust trend detection, while cross-country comparative studies could provide generalizable insights into sentiment dynamics across cultural heritage tourism domains

AI-Driven Deep Learning Architectures for Robust Emotion Recognition

Hamad Ali Abosaq
Computer Science Department-College of Computer Science and Information Systems,
Najran University, Najran, 61441, Saudi Arabia

***Abstract*—Due to an insufficient labeled dataset, class-level variation emotion recognition becomes a challenging task in computer vision. Deep learning (DL) makes it possible to automatically learn meaningful patterns from facial expressions. It captures simple details such as edges, textures at low layers, and gradually builds up to more complex information, including Facial components and the overall meaning of the expression. Despite progress made via end-to-end learning, partial occlusions, inconsistent lighting, and biases within datasets are a few challenges that still remain. In this work, a DL based model is presented to classify two emotional states of human expression. The pipeline depends on several components, including the preparation of data, preprocessing and analysis, and the use of pretrained networks, dimensionality-reduction techniques, and region-based explanation via Grad-CAM. More than 2,000 images of happy and sad faces were derived from Kaggle. These images were used to test a custom-designed CNN and two widely adopted architectures, such as VGG16 and MobileNetV. The custom model attained an accuracy rate of 66% and 67% F1, while the VGG16 performed notably better with 78% accuracy and 77% F1, and the MobileNetV architecture, which achieved 77% accuracy and 73% F1. The statistical comparisons using paired t-tests and Wilcoxon signed-rank tests further confirmed these findings, showing that pre-trained models outperformed a custom CNN with a meaningful effect size. Although deeper networks are more susceptible to overfitting and the hand-crafted CNN suffered exhibited underfitting, the results indicate that pretained architecture provides a clear advantage for facial emotion recognition. This study makes a major contribution to existing computer vision research in removing the trade-off between accuracy and generalization, and opens doors to the application of lightweight yet interpretable models in practical affective computing systems.**

***Keywords*—Deep learning models; computer vision; emotion recognition; image processing; Grad-CAM**

I. Introduction

Facial Emotion Recognition (FER) is one of the prominent computer vision subareas that automatically translates human face emotions into emotional states. Affective computing, human-computer interaction (HCI), driver monitoring, mental illness diagnosis, and social robotics are its applications. Conventional FER systems were primarily based on hand-crafted descriptors such as Histogram of Oriented Gradients (HOG), Local Binary Patterns (LBP), and Gabor filters with traditional classifiers. Despite these, these methods suffer from poor generalization under illumination change, occlusion, pose variation, and intra-class variation, thereby limiting deployment in the real-world [1], [2], [3], [4], [5].

Beyond FER, emotion and sentiment analysis have also been explored through concept-level and fine-grained sentiment detection methods, demonstrating the potential of machine learning to capture nuanced human affect [6] [7] [8].

Deep learning, specifically convolutional neural networks (CNNs), has progressed FER immensely by allowing hierarchical feature learning from images without requiring manual design. CNN-based architectures have shown better performance on typical datasets, such as FER2013, JAFFE, CK+, and KDEF. However, practical deployment remains faced with some challenges [9] [10]. First, the majority of available datasets are still on a small scale, with class imbalance and sparse demographic diversity, limiting the stability of trained models. Second, shallow CNNs can easily miss subtle expression cues, while excessively deep structures are prone to overfitting when there is limited data. Third, deep models' interpretability tends to be overlooked, decreasing trust and transparency in high-stakes applications like healthcare. Lastly, most FER systems only use frontal face images in isolation, without regard to profile views or naturalistic situations, and that diminishes generalizability to unconstrained settings [11] [12].

The above-discussed issues underscore the need for flexible, explainable, and data-efficient FER systems. Enhancing reliability under real-world scenarios, the existing literature stresses the importance of domain-specific, hybrid learning frameworks and explainability techniques (e.g., Grad-CAM) [13], [14].

The motivation of this study is to design a workflow for deep learning based two-class emotion detection (happy/sad) by utilizing transfer learning, data augmentation, and presentational methods.

It aims not only to improve the model's capacity to recognize facial expressions but also to simplify the feature space through methods like PCA and t-SNE so that the patterns become easier to interpret. Besides, Grad-CAM is used to show which regions of the image influence the decisions of the model, and makes the overall process clear and more reliable.

FER still faces many challenges, such as small datasets, class imbalance, and models that often act like "black boxes". Considering these challenges, the following is the key question pursued in this study:

RQ: Can a transfer-learning model, paired with data augmentation and basic interpretability tools, reliably

differentiate between happy and sad faces when the training data are limited and imbalanced?

While transfer learning, Grad-CAM interpretability, and dimensionality reduction have been applied in previous FER studies, few works have explored their combined application on small binary emotion datasets with a focus on rigorous statistical validation. Indeed, most prior work either addresses multi-class datasets, lacks formal significance testing, or does not explicitly evaluate model interpretability alongside performance. In this study, we apply a deep-learning pipeline to a small happy/sad dataset, incorporate PCA and t-SNE into Grad-CAM for clearer visual interpretation, and statistically confirm performance differences using both parametric and non-parametric tests. This article, therefore, fills the gap in the literature by showing how these methods can be meaningfully combined to advance the frontiers of accuracy, interpretability, and robustness in FER under constrained settings.

Beyond model performance, this work offers a number of high-level insights to the FER and larger computer-vision community. First, it frames an argument for why pretrained transfer-learning models, such as VGG16 and MobileNetV2, outperform custom CNNs on small, binary emotion datasets by emphasizing the importance of leveraging large-scale feature representations for improved generalization. By integrating Grad-CAM with dimensionality-reduction techniques such as PCA and t-SNE, the study further shows how the increased interpretability can divulge the decision-making patterns of models even in the face of scarce data, structuring trust in the automated FER systems being designed. Finally, the combination of transfer learning, data augmentation, and rigorous statistical evaluation offers practical design principles that may guide future affective-computing applications for which dataset size, class imbalance, and interpretability are of paramount importance. These contributions extend beyond procedural execution to concept and method, helping to advance the field.

This makes the following key contributions:

1) Development of a DL workflow for detecting two fundamental emotions (happy/Sad) from facial images.

2) Application of transfer learning to improve model performance on small-scale datasets.

3) Implementation of data augmentation techniques to enhance the diversity and robustness of training data.

4) Integration of flexibility methods to visualize and interpret which facial regions the model focuses on, improving transparency for real-world applications.

5) Through evolution on the benchmark dataset, demonstrating significant improvements in emotion recognition accuracy compared to existing methods.

The remainder of the study is organized as follows: Section II gives the literature review on facial emotion recognition. Section III explains the proposed method with dataset creation, feature selection, balancing, and model evaluation. Section IV displays experimental results and robustness. Section V gives the findings, limitations, and future directions for work. Section VI concludes the study.

II. Literature Review

Human emotion recognition from images is a difficult but strong task in social communication. (DL) techniques surpass conventional image processing in this area. This [6] research suggests a CNN-based structure for emotion recognition using facial expressions, through three essential steps: face detection, feature extraction, and emotion classification. The model is tested on the FERC-2013 and JAFFE datasets with an accuracy of 70.14% and 98.65%, respectively. Automatic (FER) is a challenging computer vision problem with uses in HCI, psychology, and expression generation. Handcrafted features pose challenges in dealing with variability, which leads to deep learning solutions. This work [7] presents FER-net, a softmax classifier CNN, against 21 state-of-the-art approaches on five benchmark datasets (FER2013, JAFFE, CK+, KDEF, RAF). On seven sentiments (neutral, anger, disgust, fear, happiness, sadness, surprise), FER-net had accuracies of 78.9%, 96.7%, 97.8%, 82.5%, and 81.68%, which surpass the existing techniques. FER converts facial expressions into emotional states and has widespread applications. Shallow CNNs in conventional models cannot extract features efficiently and tend to ignore profile views. This research [8] presents a transfer learning–based deep CNN pipeline, with pre-trained dense layers and pre-trained blocks being successively fine-tuned in a bid to attain higher accuracy. The approach is validated with eight DCNN models (VGG, ResNet, Inception-v3, DenseNet) on KDEF and JAFFE datasets. With DenseNet-161, the system achieved 96.51% and 99.52% accuracy on KDEF and JAFFE, respectively, compared to state-of-the-art methods, and demonstrated resistance for both frontal and profile faces. Human Action Recognition (HAR) of RGB videos was enhanced through an ensemble of 3D-AlexNet-RF and InceptionV3. The system achieved 99.54% accuracy on the HMDB51 dataset with good precision, recall, and F1-scores. The multi-tier ensemble is better than individual models and has great potential in healthcare, surveillance, HCI, and robotics through improved reliability in human activity recognition [9]. In [15], the authors presented a feedforward deep CNN for emotion recognition based on full-body motion patterns, with 95.4% accuracy on the York (15 emotions) and GEMEP (5 emotions) datasets, an improvement over previous research works. Although performance results show strong recognition performance, both datasets are small in size and variety, suggesting that real-world, larger data is required to guarantee generalization with a wider scope. Study [16] presented an overview of multimodal emotion recognition systems based on deep learning compared to unimodal approaches. It noted that multi-channel input integration (e.g., face images, physiological signals, neuroimaging) generally increases classification accuracy over single-modality systems. The article also discussed how the number of emotion classes, feature extractors, and dataset quality influence performance and presented difficulties in understanding emotional signals. This study [17] gave a systematic review of human–computer interaction approaches to training and learning, with emphasis on Extended Reality (VR, AR, MR). With a PRISMA-driven search of 1,156 articles, 69 were examined. The review categorized HCI approaches, identified core challenges, and stressed the potential of XR-HCI to enhance training effectiveness, safety, and cost-effectiveness while giving

insight into future research directions. In [18], the authors designed a hybrid text-based emotion recognition model by coupling machine learning (SVM) and deep learning (CNN + BiGRU) to outshine keyword- and lexicon-based methods in textual sentiment analysis. Based on mixed datasets of sentences, tweets, and conversations, the model reported an accuracy rate of 80.11%, indicating better emotion classification from text than using conventional NLP methods. This work [19] suggested a two-way feature extraction method for speech emotion recognition (SER) with deep learning. One followed PCA with DNN, and another used audio conversion to mel-spectrograms input to a pre-trained VGG-16 network. Experiments conducted on RAVDESS and TESS datasets revealed VGG-16 performing better compared to other models, with an accuracy of 81.94% (RAVDESS) and 97.15% (TESS), better than DNN, ResNet-18, and legacy classifiers. In [20], the authors suggested a real-time HCI system based on webcam-based eye gaze recognition and Mask R-CNN instance segmentation. The system identified four types of gazes with ~99% accuracy and segmented tools/parts with ~99% accuracy.

The understanding of human emotions from facial expressions has become a major focus of research as well as industry interest. This work [21] explores those approaches which depend solely on facial images for emotion recognition because facial expressions are one of the most natural means by which humans express their feelings and intentions. With the emergence of sophisticated machine learning methods, these techniques have notably enhanced their accuracy and efficiency. Understanding a person's emotions by looking at their face is beneficial for a wide variety of areas, from improving interactions with computers to enhancing customer service. However, the majority of publicly available facial expression datasets are too small to effectively train advanced learning models in need of large quantities of data. In this study [22], various methods of creating additional face images exhibiting varied expressions through the use of convolutional autoencoders are explored to expand this dataset. The described approach was tested on the Japanese Female Facial Expression (JAFFE) dataset, and the results indicated that this technique increased emotion recognition accuracy by approximately 21%.

III. Methodology

The research makes use of a pipeline based on deep learning for emotion recognition with the help of convolutional neural networks (CNNs) and sophisticated visualization. There are six overall stages involved in the methodological framework: dataset preprocessing, exploratory data analysis, feature extraction, dimensionality reduction, and interpretability of models by Grad-CAM, as shown in Fig. 1.

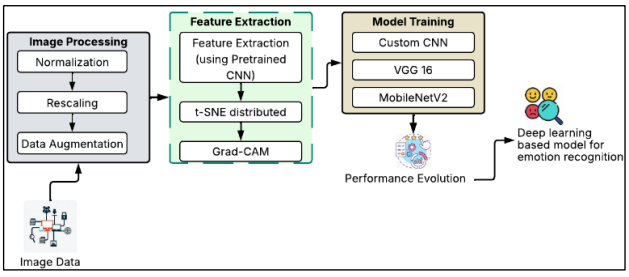

Fig. 1. Research methodology.

A. Dataset Collection

The dataset for this research was collected from Kaggle [23], which contains a group of over 2000 human portrait faces. The images were initially compiled from public sources such as Google Images and Pinterest. The dataset consists of two categories of emotion (happy and sad) and has images in various forms such as JPG, JPEG, PNG, and SVG. This dataset was utilized for training and testing of the deep learning models constructed for binary emotion classification.

For this study, facial images were collected from two benchmark datasets that have been widely used, FER2013 and CK+. FER2013 contains a large set of labeled facial expressions captured in unconstrained conditions, which has significant value for training models under realistic variability. CK+ provides high-quality, posed images with well-documented emotion labels, thus enabling precise evaluation of model performance. Together, these datasets provide a balanced combination of real-world variability and controlled conditions, making them suitable for assessing the performance, generalization, and interpretability of the proposed emotion recognition pipeline.

B. Exploratory Data Analysis (EDA)

For computational efficiency and consistency, all the images were resized to 128 × 128 pixels and normalized between [0, 1] using the ImageDataGenerator class in TensorFlow/Keras. A batch size of eight was used to optimize GPU memory utilization and speed up the training and inference process. Class distribution is shown in Fig. 2, where significant class imbalance exists. Representative samples per class were shown to authenticate dataset quality and detect intra-class diversity. All this analysis is important for ensuring the reliability of follow-up feature extraction and classification procedures [24].

To enhance the model's generalization and robustness, data augmentation was utilized with ImageDataGenerator in TensorFlow/Keras. Table I shows the data augmentation parameters. Pixel values were scaled to the range [0,1] by rescaling (rescale=1./255) for numerical stability during training. Random rotation up to 20° (rotation_range=20) was utilized to handle variations in orientations. Horizontal and vertical translations (width_shift_range=0.1, height_shift_range=0.1) modeled object movement in the frame, and shear transformations (shear_range=0.1) created geometric alterations that allowed for real-world variability simulation. Random zooming (zoom_range=0.1) enhanced model generalization across scales as well. All together, these augmentations lowered the chances of overfitting by artificially increasing the training set and subjecting the model to varied input conditions.

TABLE I. Data Augmentation Parameters

Parameters	Values	Description
Rescale	255./1	Normalize pixel to [0,1]
Rotation_range	20	Random image rotation (Degrees)
Width_shift_range	0.1	Horizontal translation shift
height_shift_range	0.1	Vertical translation shift
Shear_range	0.1	Shear transformation
Zoom_range	0.1	Random Zooming

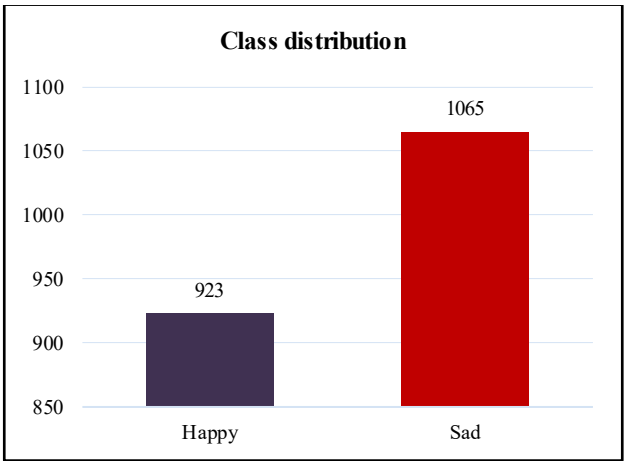

Fig. 2. Class distribution.

The dataset distribution is presented in Fig. 2, where the "Sad" class has 1,065 instances, and the "Happy" class has 923 instances, reflecting a slight imbalance. This imbalance can lead to the model becoming biased toward the majority class. To counter this, the training was done with class weights such that both classes contributed equally towards optimization. This ensures fair learning and enhances the reliability of the evaluation result obtained thereafter.

C. Feature Extraction Using Pre-Trained VGG16

Transfer learning was used to obtain high-level features from face images. The VGG16 model, pre-trained on the ImageNet database, was used with the top classification layers stripped off. A Global Average Pooling (GAP) layer was added to the last convolutional block to produce compact feature vectors for every image [25], [26]. This method leverages the representational powers of VGG16 in order to encourage effective facial structure encoding with reduced computational complexity. Mathematically, for an input image $I \in R^{(128\times128\times3)}$, the feature extractor gives a dense vector $f \in R^d$ whose dimension d corresponds to the pooled feature dimensionality. Such vectors were then used for downstream analysis. These embeddings were used as an input to two dimensionality reduction methods:

- t-distributed Stochastic Neighbor Embedding (t-SNE): A non-linear technique that embeds high-dimensional space into the 2D space without any loss of local neighborhood structures. This enabled emotion clusters to be visualized.
- Principal Component Analysis (PCA): A linear projection method was employed to estimate the proportion of variance captured by the dominant principal components. It assisted in finding the most significant directions of variation in the feature space and provided insights into the redundancy of extracted features [27], [28]

The integration of t-SNE and PCA provided both qualitative and quantitative evaluation of the extracted features.

TABLE II. FEATURE EXTRACTION PARAMETERS

Layer Type	Output Shape	Kernel/units	Activation
Input Layer	(128,128,3)	-	-
Conv2D+Relu (Block 1)	(128,128,64)	3x3,64	ReLu
Conv2D+Relu (Block 1)	(128,128,64)	3x3,64	ReLu
MaxPooling2D	(64,64,64)	2x2	-
COnv2D (Block5, last layer)	(4,4,512)	3x3,512	ReLu
Global Average Pooling	(512,)	3x3,512	-
Feature Vector	(512,)	-	-

Table II demonstrates the parameters for feature extraction using the VGG16 model. The VGG16 model was used as a feature extractor, and the input image of size (128×128×3) undergoes several convolutional and pooling layers. Shallow layers like Conv2D + ReLU (Block 1) learn low-level visual patterns such as edges and textures, whereas deeper layers like Conv2D (Block 5) represent high-level semantic features that pertain to facial expressions. A Global Average Pooling (GAP) layer was performed on the last convolutional maps to produce a compact 512-dimensional feature vector, which was subsequently utilized for dimensionality reduction and visualization. VGG16 hierarchical convolutional filters pre-trained from ImageNet yield transferable and semantically informative embeddings useful for emotion recognition tasks, and applying the GAP operation diminishes spatial dimensions while maintaining the most significant activations, making computation efficient and stable for the extracted features.

Fig. 3 shows the t-SNE plot shows the distribution of deep features learned from the VGG16 model for the "happy" and "sad" emotion classes. While some overlap is apparent, clear clusters exist, indicating that the network learns discriminative patterns that partially distinguish the two states of emotions.

The scatter indicates how high-dimensional feature vectors get mapped into a two-dimensional space, so inter-class similarities and differences become visually interpretable. t-SNE utilizes a probabilistic method that maintains the local neighborhood patterns of high-dimensional data, so even as clusters of similar emotions are preserved despite the reduction in dimensions. Second, the implementation of VGG16-extracted features guarantees that the embeddings are semantically rich and learned from convolutional filters trained on huge datasets, thereby yielding informative representations which make the visualized clusters more reliable. Collectively, these reasons prove t-SNE to be an effective tool to prove the separability of emotion-related features in latent space.

To improve the interpretability of CNN choices, Gradient-weighted Class Activation Mapping (Grad-CAM) was used. Grad-CAM derives class-specific saliency maps by backpropagating the gradients from the predicted class output to the final convolutional layer. For an input image I, the heatmap H is generated as:

$$H = Relu(\sum_k \alpha_k A^k), \alpha_k = \frac{1}{z}\sum_{i,j} \frac{\partial y^c}{\partial A_{ij}{}^k} \quad (1)$$

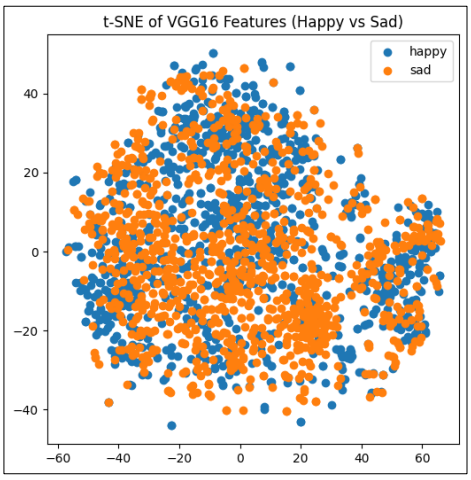

Fig. 3. t-SNE analysis.

where, A^k represents the feature maps of the last layer, y^c is the score of class c_i and α_k denotes the channel-wise importance weights. The consequent heatmaps were overlaid on the original images for maximum contrast to emphasize discriminative facial areas (e.g., eyes, mouth, forehead) responsible for the recognition of particular emotions. This ensures the transparency and provides biological explainability of the decision-making process of the model [29], [30].

Fig. 4 represents the Grad-CAM visualization emphasizes the most contributing facial regions to the model's choice. The network's main attention is towards the forehead, eyes, and mouth regions, which are key markers of emotional expression. Warm-colored areas (red/yellow) are areas of high-importance features, and cooler areas (blue) are less relevant to classification. The Grad-CAM uses the gradients of the target class score with respect to the final convolutional feature maps so that the highlighted areas directly correspond to the discriminative power of the CNN filters. Second, the utilization of convolutional feature maps does not destroy spatial information, enabling the method to localize class-discriminative regions without retraining or changing the base model. Collectively, these explanations corroborate that the predictions from the model are not random but based on physiologically relevant facial signals.

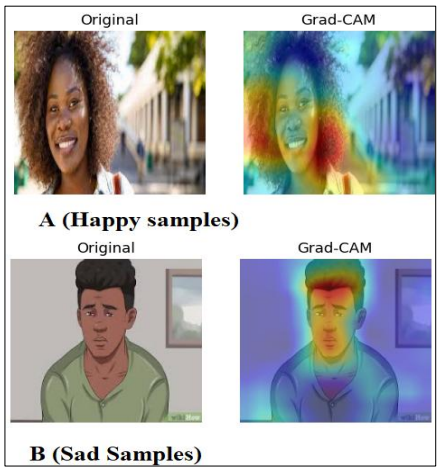

Fig. 4. Grad-CAM.

Algorithm 1 shows the procedure of feature extraction using the VGG16 architecture. To extract meaningful features from facial images, a pre-trained VGG16 model with ImageNet weights was used. Our dataset consists of two classes-Happy and Sad-each resized to 128 × 128 × 3 pixels. Exploratory data analysis was conducted at the start of the feature extraction process, including class distribution balance reviews. Then, all images were normalized by dividing the pixel values by 255 to standardize the input to the network. The pre-trained VGG16 model was used to generate the feature matrix, capturing high-level representations of every image.

Algorithm 1: Feature Extraction using VGG16 Model

Input:
- Image Dataset $\mathcal{D} = \{(x_i, y_i)\}^N_{i=1}$, with two classes: Happy and Sad
- Image Size $S = 128 \times 128 \times 3$
- Pre-trained VGG16 model M_{VGG} with ImageNet weights

Output:
- Extracted Feature Matrix $\mathcal{F} \in \mathcal{R}^{N \times d}$
- Low-dimensional embedding (t-SNE, PCA)
- Grad-CAM outcome

Start
1. Exploratory Data Analysis
2. Compute Class distribution
3. $n_c = |\{x_i \in \mathcal{D} | y_i = c\}| \quad \forall_c \in \{Happy, Sad\}$
4.
5. Image Processing
6. Normalize each image
7. $x_i' = \frac{x_i}{255}$

These features were subsequently transformed into low-dimensional embeddings using PCA and t-SNE algorithms for visualization and interpretability. Finally, the proposed system employed Grad-CAM to highlight regions of the face that highly affected the model's predictions, which provided more interpretability to the emotion recognition task.

D. Model Development

To compare the performance of classification, three deep learning models were tested and compared: a hand-designed Convolutional Neural Network (CNN), VGG16, and MobileNetV2.

1) Custom CNN: A convolutional neural network architecture, a practitioner designs or reconfigures for an application or constraints (Dataset, latency, device, and number of parameters). Custom CNNs change layer numbers, filter sizes, skip connections and regularization to trade accuracy versus cost [31].

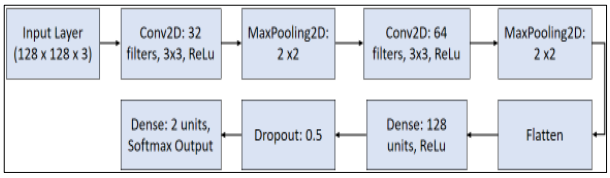

Fig. 5. Custom CNN architecture.

Fig. 5 illustrates the proposed custom CNN architecture. The three convolutional layers with enlarging filter sizes (32, 64, 128) are used to gradually extract low- to high-level spatial features, followed by max-pooling operations to compress dimensions and prevent overfitting. The flattened feature maps are fed into a fully connected dense layer of 128 neurons with ReLU activation to permit non-linear interactions among the features. A dropout layer (rate = 0.5) was used to reduce overfitting by randomly dropping out neurons in training. Lastly, a softmax output layer with two units was used for binary classification ("happy" vs. "sad"). This architecture strikes a balance between computational efficiency and expressive capacity: convolutional layers learn strong hierarchical features, pooling eliminates redundancy, and dropout improves generalization. The compactness ensures GPU trainability while retaining enough depth to acquire intra-class variability.

2) VGG16: A deep, uniform CNN that follows small 3×3 convolutions into numerous layers (16 weight layers in the VGG16 variant), demonstrating that deeper with small convolutions provides robust ImageNet performance and transferable feature representations [32].

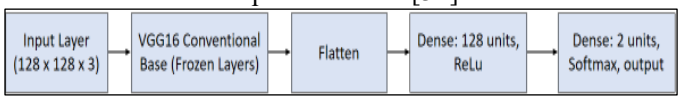

Fig. 6. VGG16 architecture.

The architecture of the VGG16-based model is shown in Fig. 6. The network accepts images of 128 × 128 × 3 as inputs, which are fed into the pre-trained VGG16 convolutional base with all the convolutional layers frozen in order to preserve low-level and mid-level visual features learned from ImageNet. The extracted feature maps are flattened and fed into a dense layer of 128 neurons with ReLU activation in order to capture high-level abstractions pertaining to the target task. A softmax output layer with two units is finally employed for binary classification. Freezing the convolutional base retains strong generalizable features while keeping computational expense and overfitting danger in check with small training data. Fine-tuning just the classifier head enables the model to draw pre-trained expertise while still effectively adjusting to the happy–sad emotion recognition task.

3) MobileNetV2: A mobile-efficient CNN employing inverted residual blocks with thin bottlenecks and depth wise separable convolutions to attain high accuracy with low latency and parameter usage on edge devices [33]

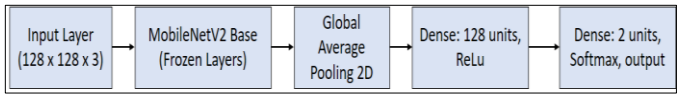

Fig. 7. MobileNetV2 architecture.

Fig. 7 depicts the MobileNetV2-based model. Input images (128 × 128 × 3) are processed through the pre-trained MobileNetV2 base with frozen convolutional blocks in order to capture generic low-level features. A Global Average Pooling layer down-samples feature maps into small representations, which are fed into a dense layer of 128 units with ReLU activation for task-specific learning. Last but not least, a softmax output layer with two units does binary classification. The architecture employs MobileNetV2's depthwise separable lightweight convolutions to be computationally efficient with high representational power. Freezing the convolutional base reduces overfitting using small data, and global pooling cuts parameters relative to flattening, enhancing generalization. This efficiency-accuracy trade-off positions MobileNetV2 appropriately for resource-limited training regimes.

E. Model Evaluation

Model performance was evaluated using an accuracy, precision, recall, F1 score, loss graphs and confusion metrics. Statistical significance is the probability that an observed effect is unlikely to have occurred by random chance under the null hypothesis. It is typically measured by a p-value, compared against a pre-specified threshold ($\alpha = 0.05$ in most studies). Results are considered statistically significant if $p \leq \alpha$, indicating that null hypothesis can be rejected. However, statistically significance does not imply practical importance or the magnitude of the effect. Therefore, it should be reported alongside effect size measures (e.g., Cohen's d) and confidence intervals to convey the reliability and practical impact of the findings [34], [35]

In this research, model evaluation combined descriptive statistics with statistical inference. Training and validation loss and accuracy were monitored over 70 epochs to track learning behavior and identify possible overfitting. To statistically verify performance difference, paired *t-tests* were applied under parametric assumptions with Wilcoxon signed-rank tests used as a non-parametric alternative for robustness. Cohen's d was additionally computed to quantify effect size and assess the magnitude of differences between training and validation performance.

IV. Results and Discussion

Experiments were performed on Kaggle notebook using Keras Deep learning library in Python. The model was trained with a batch size of 32 over 70 epochs. The Adam optimization as employed with a learning rate of 1×10^{-4} to ensure efficient convergence. Categorical cross-entropy was chosen a loss function, as it is well-suited for multi-class classification task.

TABLE III. Performance Evaluation of DL Models

DL models	Accuracy	Precision	Recall	F1 score
Custom CNN	66%	67%	69%	67%
VGG16	78%	79%	76%	77%
MobileNetV	77%	74%	73%	73%

Table III shows the performance on DL models. It demonstrates that Custom CNN has the lowest performance (Accuracy = 66%, F1 = 67%), representing a low generalization capability. Both transfer learning models significantly outperformed it. VGG16 produced the best overall results (Accuracy = 78%, Precision = 79%, Recall = 76%, F1 = 77%), which demonstrates a high precision-recall balance. MobileNetV also achieved well (Accuracy = 77%, F1 = 73%) but with relatively lower precision and recall, implying the slightest trade-off in terms of predictive consistency.

Technically, the superiority of VGG16 and MobileNetV to the nonstandard CNN is due to their pretrained feature extractors, which tap into large-scale ImageNet representations, allowing for improved generalization with fewer task-specific samples. The marginally higher and better-balanced F1 score in VGG16 also reflects its advantage in dealing with class-level variability, while MobileNetV's lightweight structure provides comparable accuracy at lower complexity.

Fig. 8 shows confusion matrices for Custom CNN and VGG16 models on a binary classification problem (happy vs. sad). Fig. 8(A) represents the Custom CNN, the model correctly identifies 226 happy and 169 sad samples but classifies 150 sad as happy, showing bias towards classifying 'happy'. This creates lower sensitivity for the 'sad' class, which implies poor feature extraction ability. Fig. 8(B) illustrates the VGG16 model, the performance is better balanced: 208 happy and 257 sad samples are classified correctly, and fewer misclassifications are made.

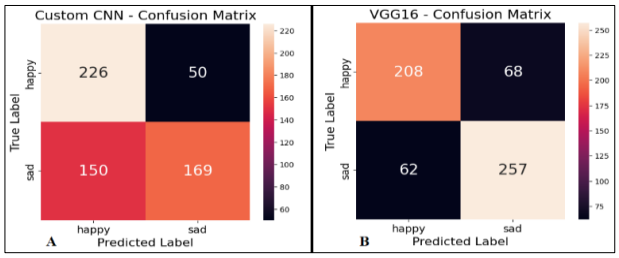

Fig. 8. Confusion matrices for DL models.

This signifies improved generalization and discriminative ability, thanks to VGG16's deeper structure and more detailed feature representations. Though Custom CNN performs quite well, it is adversely affected by class imbalance and feature discrimination, resulting in biased predictions. VGG16, though prone to overfitting as previously observed, shows better classification accuracy and resilience when separating classes. VGG16 is hence better suited for real-world implementation, if regularization is used to counteract overfitting.

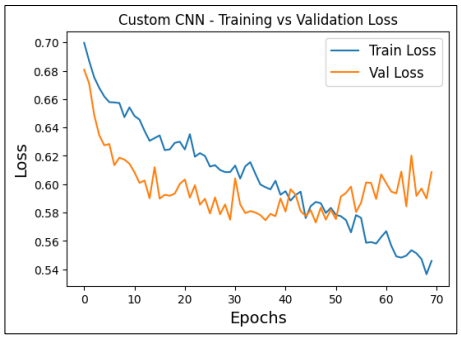

Fig. 9. Loss for CNN model.

Fig. 9 illustrates training versus validation loss for the Custom CNN across 70 epochs. The blue curve shows the training loss, showing how well the model fits the training data during learning and orange line depicts the validation loss, indicating how well the model generalizes to unseen data. Training loss drops gradually from ~0.70 down to ~0.54, whereas validation loss decreases first below the training loss, remains stable around 0.58–0.60, and fluctuates in the later epochs. The fairly small difference between training and validation loss reflects a decrease in overfitting relative to deeper models (e.g., VGG16, MobileNetV2). Nonetheless, the noisy validation curve reveals low model capacity, where the network is finding it hard to generalize reliably and could be underfitting. The Custom CNN shows greater consistency between training and validation loss, which indicates balanced learning. However, the higher overall loss values and failure to converge further suggest the representational capability of the model is inadequate to extract complex features. Optimization methods like tuning the depth of architecture, convolutional layer addition, or utilization of transfer learning may generalize better without overfitting.

Fig. 10 shows comparison of training and validation loss curves of MobileNetV2 and VGG16 models over 70 epochs. The blue curve shows the training loss, showing how well the model fits the training data during learning and orange line depicts the validation loss, indicating how well the model generalizes to unseen data.

Fig. 10(A) depicts the MobileNetV2 performance where the training loss decreases linearly to ~0.15, whereas the validation loss shows a plateau at 0.5–0.55 after approximately ~10 epochs. The difference between training and validation loss suggests overfitting since the model learns training data adequately but cannot generalize. Whereas, Fig. 10(B) shows the VGG16, training loss also reduces steadily, down to ~0.1, but validation loss oscillates and even rises over time, with higher overfitting than MobileNetV2. The increasing gap indicates that although VGG16 is high-capacity to reduce training loss, it has problems generalizing, presumably because it contains more parameters and has a greater risk of memorization. MobileNetV2 has more consistent validation performance than VGG16 and is hence better for cases with sparse data or where generalization is essential. VGG16, though strong, needs higher regularization (e.g., dropout, data augmentation, weight decay) to prevent overfitting.

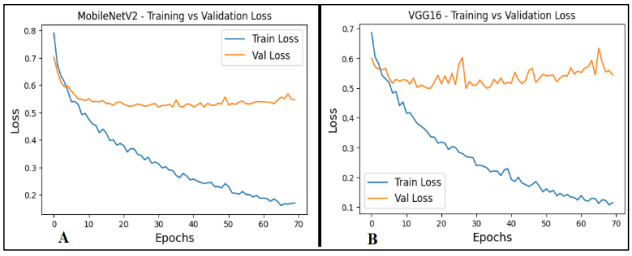

Fig. 10. Loss graphs for DL models.

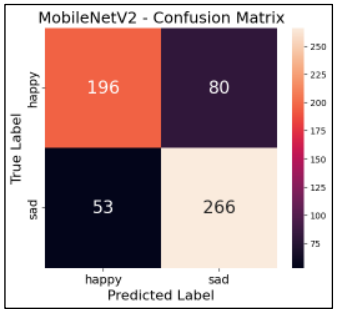

Fig. 11. MobileNet.

Fig. 11 illustrates the confusion matrix which reveals that the model is fairly good at identifying "happy" and "sad" emotions, as it was able to correctly predict 196 "happy" samples and 266 "sad" samples. There are 80 "happy" instances and 53 "sad" instances misclassified as "sad" and "happy" respectively. This gives a slightly better precision and recall for the "sad" class than "happy". The disparity in misclassification implies that the model could be more attuned to sensing "sad" emotions, possibly because of feature representations biased towards that class or class distribution during training. Overall, the matrix shows good generalization with potential to improve further in lowering false negatives for the "happy" class.

Table IV demonstrates the statistical tests which shows the extensive variations between the tested models. Custom CNN was much poorer than the reference point ($t = -4.798$, $p < 0.0001$; $W = 511.0$, $p = 1.8\times10^{-5}$; Cohen's $d = -0.573$), reflecting a moderate negative effect. Conversely, both VGG16 ($t = 17.441$, $p < 0.00001$; $W = 20.0$, $p = 8.42\times10^{-13}$; $d = 2.085$) and MobileNetV ($t = 15.725$, $p < 0.00001$; $W = 37.0$, $p = 1.72\times10^{-12}$; $d = 1.880$) realized highly significant gains with extremely large effect sizes. The accord between non-parametric and parametric tests reasserts the solidity of these findings, with assurance that transfer learning models (MobileNetV and VGG16) significantly outperform the tailored CNN both statistically and practically.

TABLE IV. PAIRED T-TEST

DL models	Paired t-test		Wilcoxon Test		Cohen's d
	T	P-values	W	P-values	Cohen's d
Custom CNN	-4.798	0.00001	511.0	1.8 x e^{-5}	-0.573
VGG16	17.441	0.00000	20.0	8.42 x e^{-13}	2.085
MobileNetV	15.725	0.00000	37.0	1.72 x e^{-12}	1.880

V. DISCUSSION

DL models have revolutionized image-based classification by learning hierarchical features from unstructured data in an automated manner. Their ability to capture intricate patterns makes them especially useful for identifying emotions, medical imaging, and object detection. Key to this success are deep architectures and transfer learning that improve generalization, reduce the necessity of large labeled datasets, and enhance predictive performance compared to traditional machine learning methods. Therefore, this study compared the performances of three DL models, focusing on the benefits of transfer learning over a custom-designed CNN. Based on Table III, the proposed custom CNN had the poorest scores in all categories: 66% in terms of accuracy and 67% in terms of F1 score. This finding is indicative of its poor generalization capability. Similarly, VGG16 generated the highest overall performance with an Accuracy = 78% and F1 = 77%, while MobileNetV yielded the same accuracy of 77% with a slightly lower F1 score of 73%, indicating a small trade-off between precision and recall. Indeed, both transfer learning models showed stronger performances due to their pre-trained feature extractors, which leveraged large-scale ImageNet representations to learn more discriminative and generalizable features. Further differences can be seen in the class-wise predictions, as depicted in Fig. 8. The custom CNN showed bias towards the 'happy' class by mislabeling 150 samples of the 'sad' class, which reflects its weak feature extraction and poor handling of class imbalance. On the other hand, VGG16 produced a more balanced classification: 208 happy and 257 sad samples were correctly identified, demonstrating higher discriminative power given that it is deeper and represents richer features. This is also reflected in the superior F1 and recall values shown in Table III. Analysis of the loss curves shown in Fig. 9 provides further insight. The custom CNN has high validation loss throughout, indicating underfitting given its limited representational capacity. MobileNetV2 has early overfitting, with its validation loss plateauing, whereas VGG16 has more pronounced overfitting given its higher capacity and thus requires regularization techniques, such as dropout or data augmentation. This is reinforced by the statistical analysis shown in Table IV, where the custom CNN presents a moderate negative effect (Cohen's $d = -0.573$), while for both VGG16 and MobileNetV, very large positive effects are obtained (Cohen's $d = 2.085$ and 1.880, respectively). In terms of both the parametric test (paired t-test) and the non-parametric test (Wilcoxon), it is shown that the transfer learning models significantly outperform the custom CNN, hence they have practical utility. Overall, the proposed analysis support that the use of a transfer learning model combined with data augmentation and basic interpretability techniques may be enough for the reliable recognition of happy and sad facial expressions even when the training dataset is limited and imbalanced. This will answer effectively the research question of this study.

The proposed approach offers several benefits compared to existing methods. Firstly, by leveraging transfer-learning models such as VGG16 and MobileNetV2, higher accuracy and F1-score are attained on small binary emotion datasets compared to custom CNNs, resulting in improved generalization. Secondly, incorporating Grad-CAM with dimensionality-reduction techniques such as PCA and t-SNE has the effect of providing interpretable visualizations, allowing a deeper understanding of which features contribute to the predictions and enhancing trust in data-scarce FER systems. Thirdly, statistical analyses using paired t-tests and Wilcoxon tests confirm the significance of performance differences and hence provide rigor often absent in similar studies. Overall, the combination of performance, interpretability, and statistically validated methodology represents a practical framework that generalizes to other affective computing tasks.

- *Practical Implications*: These results indicate that the pretraining models VGG16 and MobileNetV are more suitable for tasks with small datasets, giving better accuracy with balanced precision-recall performances. Their consistent feature extraction methods mean they can be reliably used in emotion recognition and other types of classification that require class balance and generalization.
- *Limitations*: Despite the high accuracy of transfer learning models like VGG16, overfitting is still possible due to a large number of parameters, especially when using small datasets. The poor performance of the custom CNN underlines that in many cases, manually

designing models without pretrained knowledge often presents challenges in obtaining good outcomes.

VI. Conclusion

This research implemented and tested a complete pipeline for the emotions detection using CNNs and pre-trained transfer learning models. The proposed workflow encompasses the entire procedure, from preprocessing the dataset and exploratory analysis to feature extraction, dimensionality reduction, and visual interpretation via Grad-CAM. The results indicated that besides being accurate, the proposed framework was also interpretable, providing insights into how the models reached a particular decision. The performance of pretrained networks, specifically VGG16 and MobileNetV, outperformed the custom CNN in terms of accuracy, F1 score, and overall reliability. While VGG16 yielded the most balanced performances for metrics, MobileNetV attained competitive results with a smaller and more efficient architecture, which makes it ideal in resource-constrained scenarios. Grad-CAM visualizations further ascertained that models focus on meaningful facial regions, hence reinforcing the trustworthiness of their predictions. These findings underline the value of marrying transfer learning with interpretability tools. This study has managed to build models that are strong in performance and easily interpretable. Lightweight models like MobileNetV perform well and show promise for real-time applications, even when constrained by small computing resources. Dimensionality reduction helped to simplify complex feature spaces and made the patterns clearer and more actionable. Putting the interpretation within the pipeline strengthens confidence in results and opens up the system for practical use. In the future, this work could be extended in several ways. The inclusion of other multi-class emotion datasets would introduce more affective states, such as fear, anger, and surprise, thus making the models more generalizable. Deeper models, such as VGG16, could be regularized using dropout, data augmentation, and adversarial training to prevent overfitting. Hybrid methods based on CNN with attention mechanisms or transformer-based architectures could achieve better feature representation and contextual understanding. Lightweight models, such as MobileNetV, should be easily deployable on edge devices or mobile platforms to realize real-time emotion recognition for applications in healthcare, education, and human-computer interaction.

Department of Multimedia Technology and Communication, Universiti Utara Malaysia, Kedah, Malaysia[2, 3]

***Abstract*—While previous research has broadly explored the user experience of mobile tourism applications (MTAs), few have examined user experience deficiencies from the dual perspectives of both tourism practitioners and Generation Z adults. This preliminary study sought to investigate user experience deficiencies present in MTA, with an emphasis on Generation Z adults. This study analysed the viewpoints of tourism practitioners and Generation Z users on MTA and revealed commonalities in their perspectives. Data was collected through semi-structured interviews with five tourism practitioners and eight Generation Z adults. Thematic analysis was used to identify key themes. The results revealed that the two groups of respondents held complementary perspectives on user experience deficiencies faced by MTA users. The findings reveal that numerous MTAs are plagued by perplexing information architecture, unappealing interfaces, and inadequate emotional resonance. This study transcends the systemic limitations and usability challenges identified in previous studies, concentrating on functionality issues, and offers initial practical suggestions for developers and designers to create user-centric interface designs.**

***Keywords*—Mobile tourism applications; Generation Z; tourism practitioners; user experience; preliminary study**

I. Introduction

User experience is a critical element that determines user engagement when users adopt mobile applications [1]. Mobile applications in tourism serve dual purposes as functional tools and essential elements that affect how travellers experience their journeys [2]. The user experience of MTA has become a popular research topic in recent years, with researchers studying usability [3], technology [4], and user acceptance [5]. Research into user experience elements that prevent users from engaging with MTA continues to lack sufficient investigation [6-8]. The tourism industry has experienced a rapid digital transformation through artificial intelligence and mixed reality technologies, leading to the revolutionisation of travel planning, experience sharing, and user engagement by MTA [9]. Existing research has not fully explored the limitations of MTA on user experience [6] [8].

There is little focus on the critical elements affecting user experience in MTA, especially the interface. While many researchers have addressed user experience issues in MTA in recent years, most studies remain limited to a single user or developer perspective. From a user perspective, existing research has emphasized user acceptance [10][11] and factors influencing user experience [12-14]. These existing studies have mainly focused on three aspects: 1) users' willingness and intention to adopt MTA [15] [16]; 2) the functions and features that users are interested in [17] [18]; and 3) the perceived usability and ease of use of user interfaces [16][19][20]. In addition, a small number of researchers have studied the implementation of effective mobile tourism service systems from the perspective of developers [21]. Although current research has achieved some results on interface user experience, few studies have combined the dual perspectives of tourism practitioners and users to find out the deficiencies in the design of these interface user experiences. The lack of this dual perspective may lead to a deficient understanding of the user's authentic experience, resulting in an excessive reliance on subjective opinions or a failure to identify needs and pain points that users may not be aware of, severely hindering user engagement [4]. Among numerous user groups, Generation Z (born between 1995 and 2010) [22] remains underrepresented in current research [23] [24]. Comprehending the authentic user experience of MTA among Generation Z is essential, considering their significant dependence on mobile platforms as search engines for travel information [23]. Current study on Generation Z's engagement with MTA predominantly utilises quantitative methodologies, prioritising usage intentions and lacking qualitative investigations that examine authentic user experiences [4][9].

Consequently, this study aims to systematically identify user experience deficiencies in MTA from the perspectives of both tourism practitioners and Generation Z, focusing on user interfaces. This study specifically examines Generation Z adults, grounded in ethical and methodological considerations. The main objective of this study is to identify current user experience deficiencies of MTA among Generation Z adults, particularly in terms of the user interface.

II. Methods

A. Study Design, Setting, and Participants

This study employed an exploratory qualitative approach to understand the perspectives of tourism practitioners and Generation Z adults on MTA interfaces. The research findings will help developers or designers develop more user-friendly MTA interface design strategies. This may reduce user complaints, thereby enhancing user engagement with MTA and amplifying their enthusiasm for the visit. This study employed

thematic analysis, widely considered a scientifically valid qualitative research method [24], combined with inductive analysis. Qualitative thematic analysis has been used by numerous researchers in the field of human-computer interaction [24] to understand user feedback or user experience. To ensure credibility, this study was reported using the COREQ (the Consolidated Criteria for Reporting Qualitative Research 32-item checklist) [25].

This study invited travel agency staff and tour guides in Tianjin, China, as well as travel-loving Generation Z adults (from various provinces in China) to participate in semi-structured interviews. Purposive sampling was used for all interviewed tourism practitioners and Generation Z adults. Interviewees were selected based on their years of experience, position, and industry experience. Ten well-known travel agencies were identified online, and invitations were sent to each; five agencies agreed to participate and recommended qualified staff members. For Generation Z adults, snowball sampling was employed: three initial participants were identified, who then invited or recommended additional candidates. All Generation Z interviewees had travelled at least three times a year. The final interviewees included five tourism practitioners (see Table I) and eight Generation Z adults (see Table II).

B. Data Collection

All research procedures adhered to COREQ [25]. Between mid-March and early May 2025, the first author contacted potential interviewees via social media platforms to establish communication, obtain informed consent, and schedule interviews at their convenience. Interviews were conducted by the first author through WeChat voice or telephone, following a semi-structured guide developed and validated in Chinese and English by the first, second, and third authors.

The interview guide comprised two sections. For tourism practitioners, it covered four dimensions: policy and strategic initiatives, marketing and referral channels, overall user experience, and effectiveness evaluation in relation to the target group. For adult Generation Z users, it explored five dimensions: user background and travel preferences, app-usage behaviour, functional and content needs, user experience challenges, and evaluation or recommendation tendencies. All interviewees gave verbal informed consent, including permission for audio recording where applicable. Depending on individual preferences, some interviews were audio-recorded, while others were documented through detailed real-time notes. Practitioner interviews lasted 18-28 minutes (total=113min), and Generation Z interviews lasted 20-58 minutes (total=233 min). No interviewees received compensation.

C. Qualitative Analysis

Data were analysed using inductive thematic analysis in this study [24]. All interviews were transcribed verbatim by the first author. Most interviews were conducted in Chinese, with one in English. The first author, a native Chinese speaker fluent in English, translated all Chinese transcripts into English. These translations were verified by an independent bilingual researcher who was not involved in this study. The second and third authors, both native English speakers, reviewed the translated transcripts for accuracy and consistency.

The analysis followed Braun and Clarke's six-phase approach. All authors first familiarized themselves with the data through repeated reading. The first and second authors independently conducted initial coding, using short phrases to capture barriers, facilitators, and design-related insights. Preliminary themes were then identified inductively. All researchers compared and discussed the two coding sets in several meetings to resolve discrepancies and strengthen analytical rigor. Through this collaborative process, the team developed an integrated thematic framework comprising both shared themes across interviewees and themes specific to each group. Data were organized and coded systematically using Microsoft Word, Excel 2025, and NVivo.

III. RESULTS

Thirteen participants participated in these semi-structured interviews, including five tourism practitioners (see Table I) and eight Generation Z users (see Table II). This study was an exploratory, preliminary study designed to explore potential user experience barriers in existing MTA interfaces. This preliminary study presents critical topics raised by both tourism practitioners and users, reflecting many contemporary perspectives on the user experience of MTA.

TABLE I CHARACTERISTICS OF TOURISM PRACTITIONERS

Respondent No.	Sex	Age	Years of experience	Race/Ethnicity
S01	Female	43	8	Asian
S02	Male	38	6	Asian
S03	Female	45	10	Asian
S04	Female	40	8	Asian
S05	Female	35	6	Asian

TABLE II CHARACTERISTICS OF GENERATION Z USERS

Respondent No.	Sex	Age	Number of trips/year	Race/Ethnicity
U01	Male	28	≧3	Asian
U02	Male	28	>3	Asian
U03	Female	28	>3	Asian
U04	Female	25	>8	Asian
U05	Female	23	>3	Asian
U06	Female	27	>5	Asian
U07	Male	26	>3	Asian
U08	Female	27	>5	Africans living in China

A. Lack of Attention to the Interaction Styles and Aesthetic Differences Among People of Different Age Groups

Tourism practitioners noted significant age-related differences in how people obtain travel information. They observed that older individuals rely primarily on word-of-mouth recommendations or traditional travel agencies, whereas younger people prefer mobile apps and digital media. As one practitioner noted, "Different age groups have different preferences: older people primarily rely on word of mouth or travel agencies, while younger people primarily use apps" (S01). Practitioners generally inferred that younger users

constitute the primary audience for MTA. Several also emphasized the potential market benefits of designing apps specifically for this demographic. For example, one practitioner stated, "If there were a tourism app specifically targeting younger people, it would be of great benefit to Tianjin's tourism industry, and even to China's tourism industry" (S04).

Practitioners consistently described younger users as technologically proficient and aesthetically demanding. They observed that younger users favour mobile apps offering creative, interactive, and visually distinctive experiences. As one participant stated, "They seek fun and innovative forms, but current apps lack many of the experiences young people enjoy" (S02). Another remarked that "Young people today have much higher expectations for electronic products than previous generations" (S05). Participants also noted the appeal of trendy design styles, such as cyberpunk-inspired aesthetics, in attracting younger audiences (S01). These insights suggest that age-sensitive interface design, particularly one that combines novelty, visual engagement, and authenticity, may enhance the emotional connection between young users and mobile tourism platforms.

B. Deficiency of Trust and Authenticity in MTA

Both tourism practitioners and users emphasized that the lack of authenticity and credibility in many MTAs undermines user trust and satisfaction. Many practitioners stated that users primarily rely on MTA such as Ctrip for booking functions, but turn to external social media platforms like Xiaohongshu and TikTok to obtain or verify travel information. They reported frequent user complaints about false advertising, overly retouched images, and unreliable reviews. One practitioner remarked that users "often cross-check information between platforms because they do not fully trust the content on tourism apps" (S02).

Users also regarded certain content as lacking credibility. Several users expressed concerns over excessive photo filtering and the prevalence of counterfeit reviews. One user stated, "This information is overly embellished, and even the reviews are from merchants posing as customers" (U06). Another user explained, "Some photos are so exaggerated that I feel like I've been deceived" (U03). To ascertain the veracity of information, certain individuals frequently corroborate it across other platforms. One user stated, "I usually use Xiaohongshu, Douyin, Weibo, and Mafengwo simultaneously to verify the authenticity of the same information" (U03). Another user utilised an approach they deemed distinctive, stating, "I always choose IDs with IP addresses because they are more likely to be recommendations from locals" (U03). The implementation of these strategies indicates users' scepticism about information, implying that the informational quality of the interface needs improvement.

These respondents' comments reveal widespread distrust of the content within MTA. This not only leads to a poor user experience but can also create negative emotions for users. This underscores the necessity for MTA to enhance its content.

C. Deficient in Visual Appeal and Emotional Engagement

A lack of aesthetic appeal and emotional engagement in interfaces can hinder user experience and even lead to abandonment. Tourism practitioners and users identify these challenges from varying viewpoints, although both underscore the significance of visual quality and the elicitation of positive emotions in fostering user engagement. Regarding this issue, one practitioner stated, "The tourism industry needs apps that inspire travel" (S01). Another directly identified this aspect as crucial, stating, "Downloads of travel apps have plummeted, primarily because the interface...fails to inspire users to explore" (S04). Users' perspectives provide insights into challenges that contribute to this predicament, augmenting the practitioners' opinions. One user commented on their frequently used interface, stating, "The light grey font is completely illegible, especially in sunlight... It seems like so many platforms use the same design template, which causes visual fatigue." Another user echoed this worry, stating, "While colour doesn't affect usage, it subconsciously influences target selection" (U08). Another user recounted their experiences with many apps, stating, "So far, no tourism application has attracted me, and no application's interface can really inspire my passion for travel" (U04).

Dissatisfaction among practitioners and users regarding the interfaces of existing MTAs highlights the significance of their ideal interfaces in driving enhancements. In other words, the ideal interfaces these respondents described represent a target for improvement. One practitioner noted, "An app that creates a positive impression on tourists will also increase their awareness of tourist attractions" (S04). The same practitioner also mentioned that "aesthetics is also a key factor". Users can provide more comprehensive replies concerning aesthetic criteria. One user described key colour requirements: "The interface must be simple, include authentic tourist reviews, and have bright and natural colours... Entering the platform creates a sense of freshness" (U05). Another user elaborated on their criteria for interface style from a specific emotional perspective: "Visual design must convey high quality and a pleasing tone... I think minimalism is very effective" (U06). One more practitioner stressed the point of visual presentation, as they noted: "If the presentation is innovative, diverse, and pleasing to the eye, people will be more inclined to explore the platform" (S05). One user commented: "Adding images, videos, or even 3D renderings would be even better" (U07).

These user demands suggest that current interfaces are boring and require new visual presentation styles. These factors may lead to diminished user engagement with MTA.

D. Deficiencies in Information Structure and Limited Functional Innovation

The interfaces of most MTAs suffer from information clutter and a lack of innovative functional design. Concerning information architecture, both practitioners and users highlight ambiguous interface structures and intricate module logic. One practitioner noted, "The interface design lacks sufficient intuitiveness, and the search and booking process is cumbersome" (S03). Another user further stated, "Before every trip, I compare options across multiple platforms, making the preparation process time-consuming and laborious" (U01). Yet

another user noted, "Most apps lack a coherent module categorization logic, resulting in an overabundance of information" (S02). Another user shared a similar sentiment, stating, "Some apps are overly information-intensive and overwhelming to navigate" (U05). The user replies indicate a deficiency in the information architecture of the interfaces of most contemporary MTAs. This issue not only impacts information navigation and the layout of information modules but also increases cognitive load for users.

The homogeneity of interface functionality further demonstrates the homogeneity of interfaces and reveals a lack of innovation. The observed information that concerns users are inherently connected to the interface's functionality. Three practitioners (S01, S02, and S03) conducted an overall observation of mobile apps in the tourism industry and found that booking apps accounted for the majority. One practitioner noted, "Most customers search for travel guides on social media platforms and ultimately book through them, but few use them to explore itineraries" (S03). Another practitioner explained that current apps need improvement and offered specific suggestions: "For example, recommending relaxing or exciting itineraries based on travellers' moods could stimulate their desire to explore" (S02). Users echoed this sentiment differently. One user believed that apps with "rich features and easy operation" were more appealing (U02). Regarding itinerary planning, one user stated, "I prefer itineraries that are locally relevant and well-organized. I don't like making travel plans, but I love traveling" (U03). This indicates that although certain users obtain travel information from alternative social media platforms and utilise MTA for reservations, it also highlights the inadequacy of MTA as an essential instrument within the tourism industry.

E. The Interaction Design is Monotonous

Users' expectations for interface interaction design have gone far beyond basic usability, pursuing interactive design that is both engaging and culturally relevant. Although most respondents find current interfaces monotonous, many also find interaction design boring. Some claim that the interaction design of the current MTA is tedious and dull, hindering user engagement and leading to a significant loss of tourists to their destinations. One practitioner stated, "If the content is rich, the steps are simple, and the interface is engaging, users will derive greater enjoyment from it... However, last month, a minor app interaction issue caused a group of customers to visit another tourist attraction" (S04). Another practitioner stated, "If an app has rich interactive features, a clear interface, and simple steps, users will find it interesting" (S05). This view is confirmed by user feedback. One user commented, "The interface design needs to be clear and smooth... If it's too slow, I won't use it" (U08). These responses demonstrate that good interaction is an essential condition for users to perceive a positive user experience when using an app.

Furthermore, some respondents emphasized the importance of incorporating cultural attributes into interaction design. A practitioner (S01) emphasised the significance of local attributes in web tools for a certain tourism location. As an online channel showcasing local culture, tourism apps should and need to incorporate local cultural characteristics. Another user supported this sentiment, stating, "I feel more engaged if the interface has a local feel" (U07). Yet another user stated, "I prefer products that reflect local culture and design" (U08).

This demonstrates that interaction design, as a design element of MTA, influences the user experience beyond usability. Users feel more engaged when they experience an interface that is engaging, culturally relevant, and evokes positive emotions.

IV. DISCUSSION

Results from semi-structured interviews in this preliminary study indicate that most respondents believe that interface factors significantly influence the use of MTA. Feedback from both sides indicates that Generation Z users' engagement behaviour is influenced by the perceived attributes, aesthetic appeal, emotional engagement, and interactive functionality of the interface. Previous research exploring factors influencing user experience has primarily focused on the perspectives of tour guides [26], e-tourism professionals [21], and hoteliers and consumers [27]. This study synthesises practitioner and user viewpoints, augmenting and enhancing the current literature. For instance, incorporating emotionally resonant interface aspects in addition to usability can transform monotonous interfaces into captivating ones, hence improving the user experience. The viewpoints of practitioners and users highlighted in this study may offer strategic insights for app developers, designers, and other stakeholders in formulating design ideas.

Specifically, this preliminary study highlights the holistic perspectives of both practitioners and users on MTA. These perspectives suggest potential approaches for improving the user experience of these interfaces. By focusing on the aesthetic preferences and interaction habits of Generation Z adults, targeted design strategies can be developed to increase user engagement with MTA. This is expected to enhance user engagement with a certain tourist attraction or area, hence fostering economic development for that locale. Optimising interfaces can improve user experience and engagement by eliciting good feelings during interactions with MTA. Existing literature suggests that enhancing the information organization, fun, and personalization of MTA interfaces is crucial, as this can improve destination perception and motivate users to make travel decisions [28]. The viewpoints of practitioners in this study correspond with the current literature, highlighting that the provision of high-quality travel information, functionality, and user-friendliness customised to user needs and preferences can substantially improve the user experience. Furthermore, existing literature suggests that qualitative research methods have many advantages for studying user travel behaviour. One aspect is examining the motivations and viewpoints underlying user decisions based on their stated preferences and recognising potential obstacles [29]. Nevertheless, scholars using this methodology remain uncommon, especially when analysing user attitudes from the perspectives of both practitioners and users [29].

Users and practitioners have identified user experience issues in the interfaces of MTA. Their viewpoints indicate that numerous contemporary MTAs neglect generational user traits. This also indicates an absence of comprehensive user research about the industry's comprehension of youthful users.

Generation Z, as nascent travellers, predominantly depends on social media platforms for travel inspiration [4][23]. Practitioners and users concur that contemporary MTA interfaces exhibit design uniformity and a deficiency in innovation, perceptual recognition, contextual relevance, investment in emotional design, clarity of information hierarchy, and present a high cognitive load. Despite previous studies aiming to enhance user experience through improved visual aesthetics and greater technical variety [17][30][31], there is a deficiency in specific strategies for implementation for MTA aimed at Generation Z. Table III offers recommendations for the main user experience deficiencies in MTA identified by Generation Z adults and tourism practitioners in this study. These findings offer developers and designers a feasible direction for creating MTAs that are both emotionally stimulating and functionally innovative.

TABLE III USER EXPERIENCE DEFICIENCIES AND SUGGESTED STRATEGIES IN MOBILE TOURISM APPLICATIONS TARGETING GENERATION Z

Deficiencies	Potential Strategies
Lack of attention to the interaction styles and aesthetic differences of Generation Z	Comprehend the interaction patterns and aesthetic characteristics of Generation Z. Offer a customizable user interface. For example, permit users to adjust the font or icon size.
Deficiency of trust and authenticity in MTA	Offer accurate destination information. Offer multi-dimensional destination information. Offer integrated information, reducing the need for users to switch between interfaces.
Deficient in visual appeal and emotional engagement	Offer high-quality visual information, such as high-quality images and videos. Incorporate elements that enhance user emotional engagement. For example, increase community interaction and reward mechanisms to motivate user participation.
Deficiencies in information structure and limited functional innovation	Offer modular content to avoid visual clutter. Offer functionality that matches user needs. Offer functionality tailored to the usage context.
The interaction design is monotonous	Offer a variety of interactive modes, such as AR virtual tours, to increase enjoyment.

This study has several key limitations. The limited sample size and relatively concentrated age range of the users in this study restrict the generalizability of the results. The study included practitioners from different travel agencies, but most of the agencies were in the same province. Although most of the practitioners were from the same province, their work scope was for the whole of China and even the wider region. The interview duration in this study may have limited interviewees' opportunities to fully articulate their personal perspectives, although it was sufficient to effectively gather initial core insights. To investigate the intricate concerns first identified in this study, extended interviews with users throughout a wider region should be considered. Furthermore, this preliminary study employed only semi-structured interviews and did not integrate them with observations or questionnaires. This may have limited in-depth verification of user behaviour. Nevertheless, the purpose of this study was to initially explore key issues.

V. CONCLUSION

This preliminary study found significant user experience challenges for MTA from the viewpoints of both tourism practitioners and Generation Z adults. The findings indicate that a chaotic information architecture, uniformity in interface design, and inadequate emotional engagement significantly reduce users' motivation and enthusiasm to explore. Despite the differing opinions of the two participant groups, their viewpoints were complementary, both underscoring the significance of sensory qualities, emotional engagement, credibility, and interactive innovation. These observations emphasise a disconnect between functional design and emotional experience, emphasising the necessity for emotion-driven, user-centred interface solutions. To improve the generalizability of the findings, future research should quantify them. While this study proposes some potential strategies to address user experience deficiencies, further refinement is needed. Future research should focus on improving the user experience of MTA from the developer's perspective and explore specific implementation strategies.

Data-Driven Model for Optimizing Active Learning

Abang Asyraaf Aiman Abang Azahari, Marshima Mohd Rosli, Nor Shahida Mohamad Yusop
Faculty of Computer & Mathematical Sciences, Universiti Teknologi MARA, 40450, Selangor, Malaysia

***Abstract*—Data-driven models depend on extensive datasets for precise predictions; yet, acquiring adequate labeled data for training these models is a challenge, especially with medical datasets that are constrained by privacy considerations, resulting in a deficiency of labeled data. Active Learning (AL) has developed as a cost-effective strategy that minimizes the quantity of labeled data required for training by selecting the most informative samples. The performance of active learning methods is significantly influenced by data quality characteristics, and due to a lack of direction in selecting the most suitable active learning approach. The study presents a data-driven selection approach that suggests appropriate active learning methods based on dataset characteristics. The study examines the characteristics of the dataset and their impact on active learning performance, revealing significant correlations between data quality issues and the efficacy of active learning approaches. A rule-based selection model is subsequently constructed and verified by experiments and case studies across various datasets. The findings demonstrated consistent alignment between suggested and practically effective techniques. Statistical analysis verifies that the data-driven selection model exhibits reliability exceeding chance agreement, indicating its robustness and practical application in recommending AL techniques selection.**

***Keywords*—Data-driven models; selection model; data quality characteristics; active learning**

I. Introduction

Data-driven models are widely used in various domains, such as finance, healthcare, and marketing, to make data-driven decisions. These models often require large volumes of labeled data and statistical methods to determine the most appropriate machine learning methods for a given data set and prediction problem [1]. These models embedded optimization techniques to enable quick forecasting by using relevant information during model training, contributing to their popularity in predictive tasks [2]. This approach can help overcome the limitations of traditional model selection methods, which rely on predetermined formulas rather than empirical data [3], [4].

Data-driven models learn from actual datasets, identifying patterns and relationships inherent in the data. However, the performance of data-driven models is highly dependent on data quality, as they require large volumes of high-quality labeled data. Issues such as limited data availability, biased samples, and high dimensionality can significantly impair model effectiveness. These challenges are critical as inconsistent data can severely affect a model's generalizability and predictive accuracy [5], [6].

To mitigate these drawbacks, Active Learning (AL) has emerged as a promising solution that reduces the need for extensive labeled datasets by iteratively selecting the most informative samples for annotation, thereby enhancing model performance with fewer labeled instances. This method is valuable in domains such as medical research, where accurate data selection is crucial and labeling is costly [6]. AL is also vulnerable to data quality issues, including excessive dimensionality, sample bias, and insufficient data, which can diminish its effectiveness [7], [8].

Selecting appropriate AL methods is important in building an effective predictive model because it can significantly improve the efficiency and accuracy of the learning process. AL involves iteratively selecting the most informative samples from a large unlabeled dataset to be labeled by an expert and using these labeled samples to train a predictive model [9], [10]. There are many different types of active learning methods, each with its own strengths and weaknesses, and the choice of method can have a significant impact on the accuracy and generalizability of the resulting predictive model [11].

However, there is currently no validated approach that can recommend the best method for any type of dataset, as the optimal choice of active learning depends on several factors, including the size and complexity of the dataset, the characteristics of the input and output variables, and the specific domain of the prediction model. In addition, the performance of a predictive model may be influenced by other factors, such as the quality of the data, the choice of hyperparameters, and the specific implementation of the AL method [12], [13], [14].

Building a predictive model with AL methods without analyzing the domain and characteristics of the dataset may result in lower prediction performance [15]. This problem occurs because some active learning methods may not select the most informative or representative data for labeling if the data preprocessing techniques used do not effectively represent the data or do not consider the unique features and patterns of the data [16][10]. For example, if the data preprocessing techniques used do not effectively represent the data, the active learning method may not be able to select the most informative samples for labeling.

Previous studies have reported that not all AL methods are able to make accurate predictions for different characteristics of datasets [8], [17], [18]. Research has shown that experimental studies that use active learning methods without analyzing the characteristics of the dataset and the domain of the dataset result in unpredictable performance of prediction model [8], [19], [20]. While some of the commonly used learning methods have been proposed, one problem that has not received the attention it deserves is determining appropriate AL methods for a given dataset and domain characteristics. This motivates the development of a data-driven selection model that recommends active learning methods based on dataset characteristics.

The study is structured as follows: Section II reviews related work, Section III describes the methodology, Section IV presents the results and discussion, and Section V concludes with key findings and future directions.

II. Related Work

Adoption of data-driven selection models is increasing due to their effectiveness in producing accurate and efficient machine learning predictions. The optimization techniques embedded within these models enable quick forecasting by using relevant information during training, which contributes to their popularity in predictive tasks [2]. This contrasts with model-driven approaches, which rely on predetermined formulas or abstract theoretical constructs rather than empirical data. Data-driven models learn directly from actual data, identifying patterns such as regularities, trends, or structures and relationships inherent in the dataset. This fundamental difference accounts for the observed variations in both computational efficiency and predictive accuracy between the two approaches [21].

Bernhardt et al. propose a data-driven strategy, called "active label cleaning", to prioritize samples for re-annotation [22]. The proposed approach involves ranking instances based on estimated label correctness and labeling difficulty, and a simulation framework is introduced to assess relabeling efficacy. The experiments conducted on natural images and a medical imaging benchmark created specifically for the research demonstrate that cleaning noisy labels can reduce their negative impact on model training, evaluation, and selection.

Mahapatra et al. applied Interpretability-Driven Sample Selection (IDEAL), a self-supervised learning-based approach to train a classifier that identifies the most informative sample in a given batch of images [23]. IDEAL is demonstrated in an active learning setup for lung disease classification and histopathology image segmentation. The results show that the proposed self-supervised approach outperforms other methods for selecting informative samples, leading to state-of-the-art performance with fewer samples.

In healthcare practices, the outcome of a data-driven prediction model highly relies on the data that it learns. However, if the quality of the medical data that it learns is imbalanced, then the biased model can make such a classification error [24]. Hence, diagnosing a medical condition can create a false alarm result where patients are incorrectly diagnosed, but the patient actually has a negative result, or worse, the other way around. This is undoubtedly true in real-life situations where the outcome of medical diagnostics determines patients' lives and deaths [25].

For building a disease prediction model, choosing a reliable active learning method is one of the critical challenges due to various factors influencing the selection process, particularly the variability characteristics of the dataset. Previous studies have assessed various active learning methods for disease prediction and discovered that for different types of datasets, the performance of the prediction methods also varies [17], [26]. These studies considered outliers and noise characteristics of the medical datasets and investigated the performance of the active learning methods [24].

Many studies have compared different active learning methods for prediction problems and found that characteristics of the dataset have a strong impact on the performance of the prediction model in different domains. The active learning method that performs best for a particular dataset may perform poorly for another dataset [27], [28]. Similarly, in healthcare, many studies have evaluated different active learning methods for disease prediction and found that prediction performance also varies for different types of datasets. This suggests that there is no single best method that can be used with any type of dataset for disease prediction [12].

One possible reason for the unpredictable performance of the prediction is that most studies have used active learning as a black box without analyzing the domain and the characteristics of the dataset. The prediction model can perform best if appropriate learning methods are selected for the right characteristics of the dataset. The research gap is that it is not clear to what extent the characteristics of the dataset affect the performance of the learning methods and how to select the appropriate method for an improved prediction process [12], [24]. This raises the need for a data-driven selection model that can suggest active learning methods for building an effective prediction model based on the characteristics of the dataset.

III. Methodology

This study has constructed a workflow for developing a data-driven selection model, as illustrated in Fig. 1. The workflow of model development has three main phases: Elements Identification, Model Construction, and Model Evaluation.

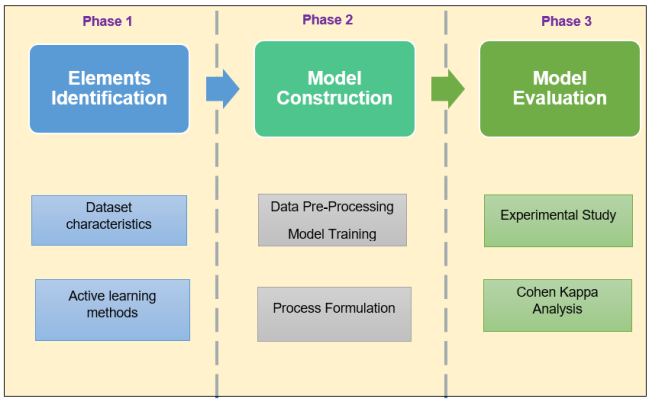

Fig. 1. Workflow of model development.

Phase 1 focuses on determining the dataset characteristics and active learning methods from the literature and datasets collection. The study performed a systematic mapping study to elicit the various characteristics of the dataset and the appropriateness of the active learning algorithms for the identified dataset characteristics from the existing studies. The study also determines the most potential active learning methods used in existing studies for building a prediction model. This phase establishes the essential elements required to formulate a model that aligns dataset properties with suitable active learning methods.

Phase 2 aims to construct a data-driven selection model for recommending active learning methods to build prediction model. This phase identified eight datasets that are commonly

used with five selected active learning methods. This phase starts with dataset pre-processing, which includes data cleaning, normalization, and feature selection to ensure data quality. Then, the study conducted model training using selected active learning methods with selected datasets. To ensure proper evaluation, the datasets were separated into independent training and testing stages: active learning models were trained on the labeled subset generated during AL iterations, while the remaining unseen data were reserved for testing. In the process formulation, the identified elements in Phase 1 are tabulated in a matrix table to show the association and relationship between elements. The process formulation then defines the operational process based on a recommender approach that links dataset characteristics with active learning methods, forming a coherent mechanism for developing a data-driven selection model.

Phase 3 focuses on the evaluation of the effectiveness of a data-driven selection model using an experimental study. This experimental study aims to establish the suitability of the different active learning methods for the different values of the datasets characteristics. The study also utilizes case studies to establish the effectiveness of the proposed model by comparing the recommendation of the proposed active learning methods from the proposed model with the results from the corresponding experimental studies. Based on experimental studies, the Cohen's Kappa analysis is used to measure inter-rater agreement between case studies and experimental results. While alternative metrics like accuracy or F1-score are useful for evaluating classification performance, they do not account for chance agreement. The high kappa values would indicate strong agreement between the case studies and experimental results in recommending active learning methods, and this would suggest the reliability of the model.

IV. Results and Discussion

This study aims to construct a data-driven selection model to facilitate the selection of the most reliable active learning methods in developing prediction models that are able to provide practitioners with an accurate decision support tool. The study determines the dataset characteristics that correlate with the active learning methods to build a prediction model. The study also evaluates the effectiveness of the proposed data-driven selection model using Cohen's Kappa analysis to ensure the agreement between case studies and experimental results.

A. Data-Driven Selection Model

The development of the data-driven selection model employs a recommendation approach to automate the identification of suitable active learning strategies for a certain dataset. Fig. 2 shows the conceptual framework for the data-driven selection model. The framework consists of two major components: Dataset Analysis and Active Learning Strategy Recommender. In the Dataset Analysis stage, data quality issues such as missing data, imbalance, high dimensionality, redundancy, and outliers are identified. These identified issues are then passed as inputs to the Data Driven Selection Model, which maps specific data quality characteristics to appropriate active learning strategies. In the Active Learning Strategy Recommender stage, the most suitable active learning methods are suggested based on the mapping results. This conceptual framework demonstrates the logical flow from dataset quality assessment to strategy recommendation, emphasizing a systematic and data-driven approach for optimizing active learning performance.

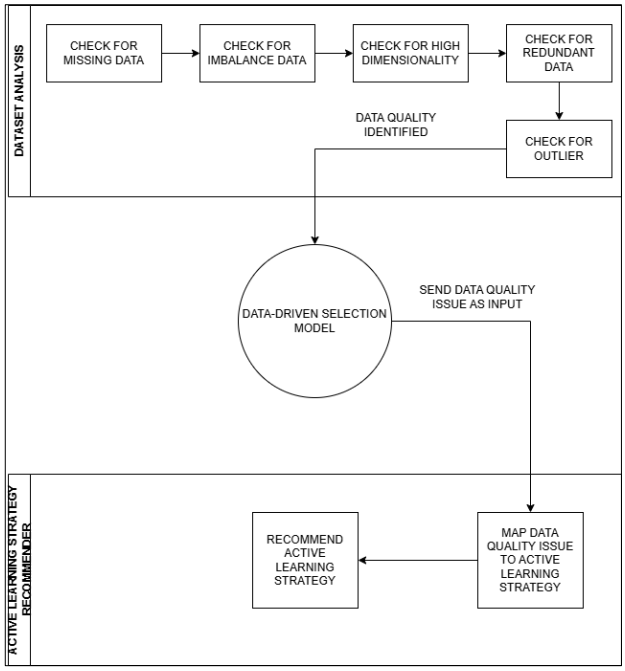

Fig. 2. Conceptual framework of the data-driven active learning strategy selection model.

B. Prototype of Data-Driven Selection Model

This study developed a prototype, Active Learning Strategy Recommender, to demonstrate the practical implementation of the proposed data-driven selection model. The prototype serves as a decision-support tool that recommends suitable active learning strategies based on data quality issues detected within a given dataset. It operates the conceptual framework by integrating data quality analysis, rule-based mapping, and strategy recommendations into a prototype. Fig. 3 shows the main user interface for the prototype.

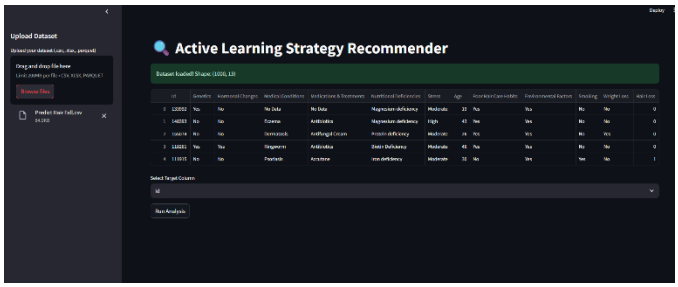

Fig. 3. Main user interface of the prototype.

As shown in Fig. 3, the main user interface allows users to begin by uploading a dataset file. Once the dataset is uploaded, the prototype conducts a data quality assessment to identify potential issues such as missing data, class imbalance, high dimensionality, redundancy and outliers. These assessments are performed according to the data quality characteristics. Users can initiate the analysis process by clicking the Run Analysis button, prompting the prototype to analyses the dataset and display the detected quality issues.

The prototype then applies the data-driven selection model to map the detected data quality issues to the most suitable active learning strategies. The recommended strategies' results are shown in Table I, displaying the recommended strategy consistent with the dataset's characteristics. The prototype also displays the alternative strategies that are listed according to their relevance based on the findings of this study.

TABLE I. RECOMMENDED ACTIVE LEARNING STRATEGY

Strategy	Score	Reason
UNC	1	Missing Value
QBC	0.993	Missing Value
DIV	0.949	Missing Value

C. Model Training

The performance results of the active learning strategies across medical datasets are summarized in Table II. Each dataset was evaluated under five data quality issues: high dimensionality (HD), imbalance, missing values, outliers, and redundancy. The active learning strategies compared are Uncertainty Sampling (UNC), Query by Committee (QBC), Diversity Sampling (DV), Density Sampling (DS), and Cluster-based Sampling (CS). The results show the classification accuracy achieved by each strategy for the respective data quality issues.

Table II illustrates the performance of active learning strategies applied to selected data quality issues. The active learning strategies that are Uncertainty sampling (UNC) and query-by-committee (QBC) indicate consistent performance (typically >0.90) for high-dimensional (HD), imbalanced, and redundant data. This shows that these strategies are reliable active learning methods for the common medical data challenges. However, both strategies show significant limitations when handling outliers, with performance often dropping below 0.50. Diversity-based sampling performs comparably to UNC and QBC in most scenarios while showing slightly better adaptability to missing data.

Cluster and density-based strategies were excluded from further consideration due to their inconsistent and often poor performance across multiple data characteristics. While these approaches occasionally showed adequate results in specific scenarios, as shown in the results where density-based sampling achieved 0.96 for the asthma dataset in the high dimensionality variant. Their overall performance was distinctly inferior to UNC, QBC, and diversity-based methods. From the results in Table I, it can be seen that cluster and density methods often obtained below 0.30, indicating these methods are unreliable for practical applications. This performance gap justifies focusing on the more robust UNC, QBC, and diversity-based strategies.

These findings suggest several practical recommendations: 1) UNC and QBC should be prioritized for HD, imbalance, or redundant medical data, given their consistently high accuracy. 2) Diversity-based sampling presents a viable alternative, particularly for datasets with missing values, where it sometimes outperforms other methods. 3) Future research should explore hybrid methods that combine the strengths of these top-performing strategies, especially to address challenging cases like outliers, where current methods still underperform.

TABLE II. MODEL TRAINING RESULTS

Dataset	Dataset quality issues	UNC	QBC	DV	DS	CS

	Outlier	0.50	0.76	0.46	0.37	0.49
	Redundancy	0.63	0.74	0.55	0.54	0.59

D. Model Evaluation

The model evaluation performed experimental studies for 8 datasets. The study compares the results for the actual best strategy based on model training with the best strategy recommended by the prototype model, as shown in Table III. The prototype model is able to recommend the actual active learning strategy for 7 out of 8 datasets. This indicates that the recommender model is accurate, correctly predicting the optimal active learning strategy for most datasets.

TABLE III. ACTUAL BEST STRATEGY VS BEST STRATEGY RECOMMENDED

Dataset	Strategy recommended by the prototype model	Actual best strategy based on experimental study
Alzheimer	Diversity sampling	Diversity Sampling
Asthma	QBC	QBC
Cancer	Uncertainty Sampling	Uncertainty sampling
Diabetes	QBC	QBC
Fetal Health	QBC	QBC
Heart Failure	Diversity sampling	QBC
Lung Cancer	QBC	QBC
Mental Health	QBC	QBC

Table IV shows the summary metrics for how many times each actual best strategy was correctly or incorrectly recommended for the 8 datasets.

TABLE IV. ACTIVE LEARNING RECOMMENDER METRICS

		Strategy recommended by the prototype model			
		UNC	QBC	DIVERSITY	TOTAL
Actual Best strategy	UNC	1			1
	QBC		5		5
	DIVERSITY		1	1	2
TOTAL		1	6	1	8

The study further evaluates the agreement between the prototype model recommended strategy and the actual best strategy, illustrated in Table IV matrix using Cohen's Kappa. The observed agreement, agreement of chance, and Cohen's Kappa formula were implemented as below:

Step 1: Calculate Observed Agreement (P_o)

Sum the diagonal elements (where both raters agree) and divide by the total number of observations [see Eq. (1)].

$$P_o = \frac{1+5+1}{8} = 0.875 \quad (1)$$

Step 2: Calculate Expected Agreement (Pe)

For each category, compute the product of the row and column totals, then sum these and divide by the total squared [see Eq. (2)]:

$$p_e = \frac{(1*1)+(5*6)+(2*1)}{8^2} = \frac{33}{64} \approx 0.5156 \quad (2)$$

Step 3: Compute Cohen's Kappa (κ)

Use the equation:

$$K = \frac{(P_O - P_e)}{(1-P_e)} = \frac{(0.875-0.5156)}{(1-0.5156)} = \frac{0.3594}{0.4844} \approx 0.742 \quad (3)$$

Based on the result obtained in Eq. (3), Cohen's Kappa value of 0.742 indicates a substantial agreement according to the commonly used interpretation scale, where values between 0.61 and 0.80 suggest substantial agreement, and values above 0.80 suggest almost perfect agreement. This implies that Cohen's Kappa result used in the study is reliable and not the result of random agreement. This level of agreement is important in the context of active learning strategies, which rely on iterative data selection and labeling. A high Kappa score (κ = 0.742) confirms the consistency and trustworthiness of the labeling process, ensuring that the performance of each strategy is based on reliable and ground truth data.

Given that medical datasets often suffer from data quality issues such as missing data and redundancy, reliable label consistency strengthens the validity of the training results. Specifically, the high accuracy observed for UNC and QBC methods (typically >0.90) across high-dimensional and imbalanced datasets is supported by the underlying agreement in labeling. Furthermore, it provides a sound justification for excluding cluster and density-based methods, whose poor and inconsistent performance may be exacerbated by sensitivity to labeling errors.

The obtained Cohen's Kappa results align with established findings on inter-rater reliability in medical and active learning settings. For example, McHugh et al. categorized kappa values between 0.61 and 0.80 as indicating substantial agreement, supporting the interpretation that a kappa of 0.742 reflects an acceptable level of reliability [29]. Similarly, Harmsen et al. demonstrated that Cohen's Kappa values exceeding 0.70 in active learning frameworks applied to medical literature screening correspond to reliable human annotation, even under noisy and incomplete label conditions [30]. These studies collectively affirm that the observed kappa value indicates robust inter-rater agreement and supports the reliability of the active learning evaluations conducted in this study.

V. CONCLUSION AND FUTURE WORK

This study examined the correlation between dataset characteristics and the efficacy of active learning strategies in predictive modelling. The research identified actual connections by analyzing critical data quality issues such as class imbalance, high dimensionality, missing values, redundancy, and outliers, which guide the optimal selection of active learning methods. A data-driven selection model was developed to identify suitable active learning strategies based on dataset characteristics, providing a systematic and evidence-based method to improve predictive accuracy and learning efficiency. Experimental validation across various healthcare datasets exhibited significant model reliability, with considerable concordance between anticipated and actual strategies. This study addresses a fundamental limitation in the AL literature by converting strategy selection from intuitive selections to a systematic, data-driven approach, hence enhancing the field's practical relevance in real-world context.

The study concentrated on foundational active learning strategies and specific healthcare datasets. Subsequent research should broaden the framework to include sophisticated, hybrid, and domain-specific methodologies, along with comprehensive performance metrics like interpretability, scalability, and computational efficiency. Incorporating multi-modal and real-world data, together with validation from domain experts, will significantly improve model generalizability. The suggested approach offers a pragmatic and theoretically substantiated contribution to the selection of adaptive, data-driven active learning strategies.

ACKNOWLEDGMENT

The authors would like to thank the Ministry of Higher Education Malaysia and Universiti Teknologi MARA for their financial support to this project under the Fundamental Research Grant Scheme (FRGS) Grant No. FRGS/1/2023/ICT01/UITM/02/4. We would also like to thank the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Selangor, Malaysia, for all the support.

Satbayev University, Almaty, Kazakhstan[2]

***Abstract*—This study introduces a novel YOLO-like multi-branch deep learning architecture designed for accurate apple detection and segmentation in orchard environments, addressing the persistent challenges of occlusion, illumination variability, and fruit clustering. The proposed model integrates an enhanced backbone with C2f modules and a Spatial Pyramid Pooling Fast (SPPF) block to capture multi-scale receptive fields, while a Feature Pyramid Network (FPN) combined with a Path Aggregation Network (PAN) ensures effective top-down and bottom-up feature fusion. To extend beyond bounding box localization, a prototype-based segmentation head is incorporated, enabling precise instance mask generation with reduced computational overhead. The model was comprehensively evaluated on the MinneApple dataset, consisting of high-resolution orchard images with polygonal annotations, and compared against state-of-the-art detection and segmentation frameworks, including Faster R-CNN, Mask R-CNN, SSD, YOLO variants, YOLACT, and SOLOv2. Quantitative results demonstrated that the proposed approach achieved superior mean Average Precision (mAP@0.5 = 0.76), precision (0.83), and F1-score (0.76), while maintaining a competitive inference speed of 40 FPS, confirming its suitability for real-time agricultural applications. Qualitative analysis further highlighted robustness in complex orchard conditions, reinforcing the model's applicability for automated harvesting, yield estimation, and orchard monitoring. These findings advance the state of agricultural computer vision by unifying detection and segmentation in a lightweight, high-performance framework.**

Keywords*—Precision agriculture; detection; segmentation; YOLO-like architecture; multi-branch network; feature pyramid network; real-time inference; orchard monitoring

I. Introduction

The increasing demand for precision agriculture has stimulated research into advanced computer vision systems capable of detecting, localizing, and segmenting fruits in real-world environments. Apple production, in particular, benefits substantially from automated monitoring technologies due to its economic importance and the labor-intensive nature of traditional harvesting and yield estimation practices [1]. Conventional image processing methods often struggle with orchard-specific challenges, such as variable illumination, occlusion by leaves or branches, and high fruit density [2]. As a result, deep learning-based object detection and segmentation models have emerged as state-of-the-art solutions, providing robust performance in unstructured agricultural conditions [3].

Object detection frameworks such as Faster R-CNN and Mask R-CNN have demonstrated notable accuracy in fruit recognition tasks [4]. However, these models frequently suffer from limitations in inference speed, which restricts their applicability in real-time field deployment [5]. Single-stage detectors, most prominently the YOLO family of models, have been widely adopted for agricultural applications due to their balance between accuracy and efficiency [6]. Despite these advances, single-branch architectures typically fail to optimize both object localization and segmentation simultaneously, particularly under conditions of high occlusion and overlapping fruit clusters [7]. Thus, developing multi-branch models capable of integrating detection and segmentation pathways represents a promising avenue for improving overall performance in orchard scenarios [8].

Recent studies highlight the importance of multi-scale feature extraction and aggregation in handling variations in fruit size and shape [9]. Feature pyramid networks (FPN) and path aggregation networks (PAN) have become essential components in detection frameworks, enabling richer contextual representation across hierarchical layers [10]. Furthermore, prototype-based mask generation has proven effective in instance segmentation, allowing the prediction of high-resolution fruit masks with reduced computational cost [11]. Integrating these mechanisms into a unified architecture tailored for orchard constraints can substantially enhance robustness against real-world environmental challenges.

This study proposes a novel YOLO-like multi-branch architecture designed for accurate apple detection and segmentation in orchard environments. The contributions are threefold: first, a backbone network with CSP-inspired C2f modules and spatial pyramid pooling is employed to capture multi-scale receptive fields; second, an FPN–PAN neck structure is leveraged to aggregate feature maps for detection and segmentation heads; and third, a prototype-based mask branch is integrated with box regression to generate high-quality instance masks. Comprehensive evaluations on orchard datasets demonstrate that the proposed model outperforms baseline YOLO and Mask R-CNN variants under varying lighting, occlusion, and density conditions [12]. This work establishes a

robust framework for real-time orchard monitoring and contributes to the broader goal of advancing automation in precision agriculture.

II. Related Works

Research on fruit detection and segmentation has expanded significantly in recent years, with advances in deep learning architectures enabling more accurate and efficient models for real-world agricultural scenarios. Despite these achievements, orchard environments remain highly challenging due to factors such as overlapping fruits, complex backgrounds, and illumination variability. To contextualize the proposed model, this section reviews existing works across four major domains: 1) traditional approaches for fruit detection, 2) deep learning–based detection frameworks, 3) segmentation strategies in agricultural vision tasks, and 4) multi-branch architectures and prototype-based methods.

A. Traditional Approaches for Fruit Detection

Early fruit detection research primarily relied on handcrafted features and classical computer vision techniques [13]. Methods using color thresholding, texture descriptors, and shape-based heuristics showed promising results under controlled conditions but failed to generalize well in orchard environments characterized by changing illumination and partial occlusion [14]. Approaches such as Hough transforms for circular fruit detection or color-space conversions for background suppression were computationally inexpensive but exhibited poor robustness in dense canopies [15]. Furthermore, the lack of adaptability to intra-class variations, such as differences in apple ripeness stages, limited their utility in large-scale agricultural applications [16]. Although these methods laid foundational insights into fruit localization, their inherent reliance on rigid feature representations hindered scalability and motivated the shift toward data-driven models [17].

B. Deep Learning-Based Detection Frameworks

With the advent of convolutional neural networks (CNNs), object detection frameworks became the standard for agricultural vision tasks [18]. Two-stage detectors, notably Faster R-CNN, achieved high accuracy in fruit detection, but suffered from slow inference speeds unsuitable for real-time harvesting systems [19]. Single-stage detectors, including SSD and the YOLO series, provided a balance between detection precision and computational efficiency [20]. Studies applying YOLOv3 and YOLOv4 to apple orchards reported significant improvements in handling occlusions and varying fruit scales [21]. Despite these advances, the primary limitation of single-branch detection frameworks lies in their inability to jointly optimize for both object localization and fine-grained segmentation [22]. Consequently, research has shifted toward architectures that combine detection accuracy with the pixel-level understanding necessary for downstream agricultural tasks such as yield estimation and robotic picking [23].

C. Segmentation Strategies in Agricultural Vision Tasks

Instance segmentation has emerged as a crucial task for precision agriculture, offering detailed information on fruit boundaries beyond bounding boxes [24]. Classical models like Mask R-CNN have been applied to apple detection, producing high-quality masks but with high computational cost [25]. Lightweight segmentation models such as SOLO and YOLACT introduced prototype-based mask generation strategies, enabling faster predictions with reduced complexity [26]. In orchard environments, accurate segmentation is particularly important for separating overlapping fruits and ensuring reliable yield analysis [27]. Moreover, segmentation facilitates better integration with robotic manipulation systems by providing precise contours for grasping and picking [28]. Recent advancements have also explored transformer-based segmentation models, though their high resource demands limit deployment in field robotics [29]. These developments highlight the need for a balanced approach that combines efficiency with segmentation quality, motivating the integration of multi-branch segmentation heads in detection frameworks [30].

D. Multi-Branch Architectures and Prototype-Based Methods

The introduction of multi-branch networks represents a significant step forward in bridging the gap between detection and segmentation [31]. Architectures that simultaneously optimize detection and mask prediction have demonstrated superior performance in agricultural scenarios, where both accuracy and real-time capability are required [32]. Prototype-based mask branches, in particular, allow efficient generation of instance masks by combining global prototypes with instance-specific coefficients [33]. This approach reduces computational burden while maintaining segmentation quality, making it highly suitable for resource-constrained agricultural systems [34]. The combination of multi-scale feature aggregation with multi-branch segmentation further improves robustness against occlusion and scale variation. These advancements directly inform the design of the proposed YOLO-like multi-branch model, which leverages prototype-based masks and feature aggregation strategies to achieve accurate detection and segmentation under orchard constraints.

III. Materials and Methods

The design and evaluation of the proposed YOLO-like multi-branch model for apple detection and segmentation were carried out through a systematic methodology that integrates data preprocessing, architectural development, training optimization, and performance assessment (see Fig. 1). This section outlines the technical details underlying the model construction, beginning with the preprocessing strategies applied to orchard images, followed by a comprehensive description of the backbone, neck, and multi-branch heads. The mathematical formulations of the detection and segmentation processes are presented alongside the adopted loss functions, while inference and post-processing steps are described to illustrate the complete operational workflow of the system.

A. Data Preprocessing

The input image $I \in R^{H \times W \times 3}$ is first resized to a fixed resolution (e.g., 640×640) while preserving aspect ratio by zero-padding. Pixel intensities are normalized to [0, 1], and data augmentation techniques such as mosaic, random horizontal flipping, scaling, and hue–saturation–value (HSV) jittering are applied to increase generalization. The preprocessing pipeline can be expressed as:

$$I' = A\big(N\big(R(I)\big)\big) \tag{1}$$

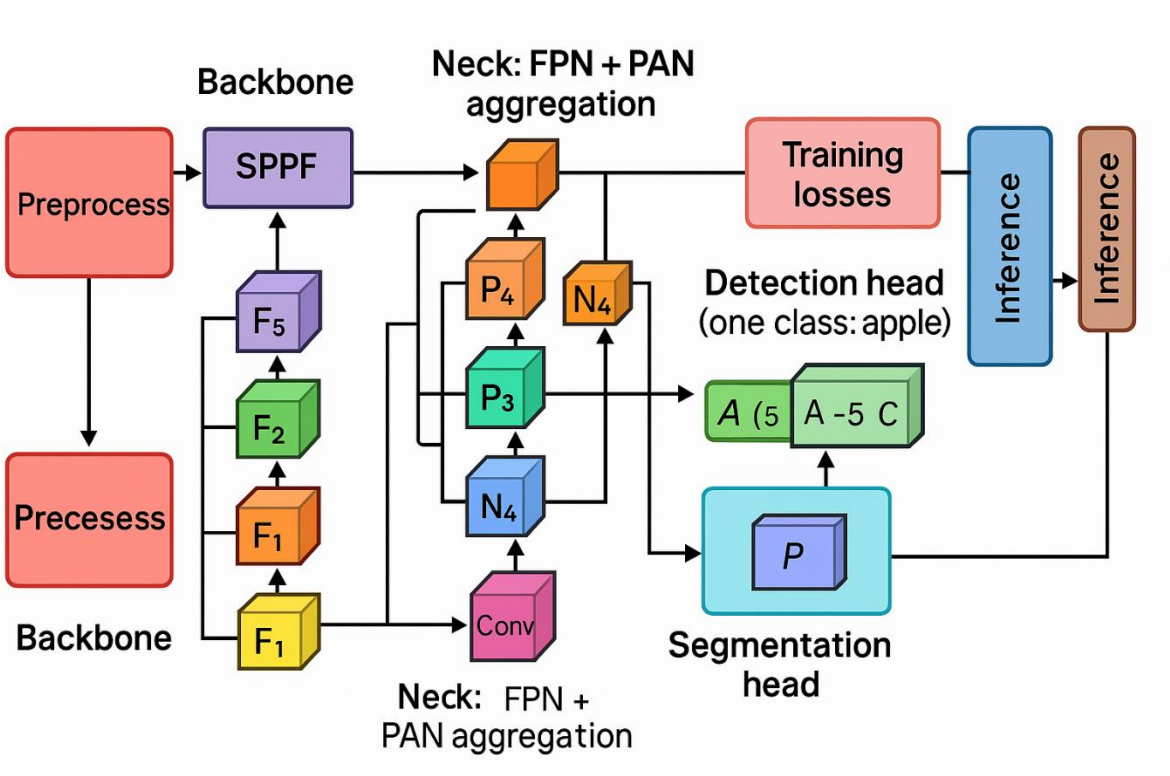

Fig. 1. Architecture of the proposed YOLO-like multi-branch model for apple detection and segmentation under orchard constraints.

where, R denotes resizing with padding, N denotes normalization, and A represents augmentation functions.

B. Backbone Network

The backbone consists of an initial convolutional layer followed by a series of C2f modules, which are lightweight CSP-inspired residual blocks that enhance gradient flow and feature reuse. The convolutional output at stage l is defined as:

$$F_l = \sigma\left(W_l * F_{l-1} + b_l\right) \tag{2}$$

where, F_{l-1} is the input feature map, W_l and b_l denote the convolutional weights and biases, and σ is the non-linear activation (SiLU).

Feature maps are progressively downsampled across five stages, producing $\{F_1, F_2, F_3, F_4, F_5\}$. A Spatial Pyramid Pooling Fast (SPPF) block is applied on the deepest feature map F_5 to enlarge the receptive field:

$$F_5^{'} = Concat\begin{pmatrix} MaxPool_{k_1}(F_5), \\ MaxPool_{k_2}(F_5), \\ MaxPool_{k_3}(F_5), \\ F_5 \end{pmatrix} \tag{3}$$

C. Neck: FPN and PAN Aggregation

To exploit multi-scale information, a Feature Pyramid Network (FPN) with top-down upsampling and a Path Aggregation Network (PAN) with bottom-up downsampling are integrated. This structure ensures both semantic enrichment of shallow layers and spatial refinement of deep layers.

For top-down fusion:

$$P_l = \phi\left(Concat\left(Up\left(F_{l+1}^{'}\right), F_l\right)\right) \tag{4}$$

where, ϕ denotes convolution + C2f transformation and $Up(\cdot)$ is bilinear upsampling.

For bottom-up aggregation:

$$N_l = \phi\left(Concat\left(Down\left(P_l\right), P_{l+1}\right)\right) \tag{5}$$

where, $Down(\cdot)$ is a strided convolution.

The outputs of this neck are $\{P_3, N_4, N_5\}$, which are forwarded to the detection and segmentation heads.

D. Detection Head

For each scale $S \in \{P_3, N_4, N_5\}$, the detection head predicts bounding box offsets, objectness, and class probabilities. The prediction tensor is:

$$Y_S \in R^{A \times H_S \times W_S \times (5+C)} \tag{6}$$

where, A is the number of anchor points, C is the number of classes (here C=1, apple), and the 5 corresponds to $(t_x, t_y, t_w, t_h, t_{obj})$ Bounding box regression is decoded as:

$$\hat{b} = \left((t_x + c_x)\cdot s, (t_y + c_y)\cdot s, e^{t_w}\cdot s, e^{t_h}\cdot s\right) \quad (7)$$

where, c_x, c_y are grid offsets and s is stride.

E. Segmentation Head

The segmentation branch employs prototype masks $P \in R^{K\times H_m \times W_m}$ generated from fused multi-scale features. For each detection, the network predicts mask coefficients $\alpha \in R^K$. The instance mask is reconstructed as:

$$\hat{m} = \sigma\left(\sum_{k=1}^{K} \alpha_k P_k\right) \quad (8)$$

followed by cropping the predicted bounding box region.

F. Loss Functions

The training objective integrates multiple loss components:

Box regression loss (CIoU):

$$L_{box} = 1 - CIoU(\hat{b}, b*) \quad (9)$$

where, $b*$ is the ground-truth box.

Objectness loss (focal BCE):

$$L_{obj} = -\beta\left(1-\sigma(t_{obj})\right)^{\gamma} \log\sigma(t_{obj}) \quad (10)$$

Classification loss:

$$L_{cls} = BCE(\hat{c}, c*) \quad (11)$$

Mask loss (BCE + Dice):

$$L_{mask} = \lambda_1 \cdot BCE(\hat{m}, m*) + \lambda_2 \cdot \left(1 - Dice(\hat{m}, m*)\right) \quad (12)$$

The total loss is:

$$L = w_1 L_{box} + w_2 L_{obj} + w_3 L_{cls} + w_4 L_{mask} \quad (13)$$

G. Inference and Post-Processing

During inference, predictions are filtered using a confidence threshold τ and Non-Maximum Suppression (NMS) with IoU threshold γ. The final detections are defined as:

$$D = \left\{(b_i, p_i, m_i) \mid p_i > \tau, i \notin NMS(\gamma)\right\} \quad (14)$$

Masks are optionally refined with morphological operations, and results are rescaled to the original image resolution.

IV. Dataset

The dataset employed in this study is the publicly available MinneApple benchmark, specifically curated for apple detection, segmentation, and counting tasks in orchard environments [35-36]. The dataset comprises 1,000 high-resolution RGB images, acquired using a standard smartphone camera mounted horizontally along orchard rows, capturing diverse lighting and canopy conditions. Each image is meticulously annotated with polygonal instance-level masks, delivering precise delineations for over 41,000 fruit instances, facilitating accurate localization and segmentation. Representative image-mask pairs are depicted in Fig. 2, demonstrating the diversity in fruit appearance, clustering patterns, background complexity, and environmental variability addressed by the dataset.

Fig. 2. Sample images from the MinneApple dataset with corresponding polygonal instance-level annotations illustrating variability in lighting, occlusion, and fruit density.

TABLE I. OVERVIEW OF THE MINNEAPPLE DATASET

Property	Value
Total images	1,000
Total annotated apple instances	> 41,000
Annotation type	Polygonal instance masks
Image acquisition device	Smartphone (RGB)
Environmental variations	Lighting, occlusion, density, seasonality
Example images shown in	Figure 2

In terms of dataset composition, Table I provides a structured summary of its key characteristics. The images span the full spectrum of seasonal and environmental conditions, with annotations yielding a rich distribution of fruit counts per image and a broad range of mask complexities and sizes. This diversity introduces significant variability in the target instances, challenging detection and segmentation algorithms to generalize across dense clusters, varying scales, and inconsistent illumination. Our experiments adopt a standard training–validation–test split (e.g., 70%–20%–10%) to ensure rigorous evaluation and reproducibility on this benchmark.

V. EVALUATION PARAMETERS

To rigorously assess the performance of the proposed YOLO-like multi-branch model on the MinneApple dataset, a set of widely adopted evaluation parameters was employed. These metrics provide complementary insights into detection accuracy, segmentation quality, and the balance between sensitivity and specificity of the model. The following subsections outline the evaluation parameters, accompanied by their mathematical formulations.

Precision measures the proportion of correctly predicted positive instances among all predicted positives [37]. It reflects the model's ability to minimize false positives. Precision is defined as:

$$precision = \frac{TP}{TP + FP} \tag{15}$$

where, TP denotes true positives and FP denotes false positives. A high precision indicates reliable predictions when the model identifies an apple instance.

Recall quantifies the proportion of actual positive instances that are correctly identified by the model [38]. It emphasizes the ability to minimize false negatives and is defined as:

$$recall = \frac{TP}{TP + FN} \tag{16}$$

where, FN represents false negatives. High recall is critical in agricultural monitoring to ensure that most fruit instances are detected.

The F1-score is the harmonic mean of precision and recall, providing a balanced measure when both false positives and false negatives must be considered [39]. It is expressed as:

$$F1 - score = 2\frac{precision \cdot recall}{precision + recall} \tag{17}$$

This parameter is particularly relevant for orchard scenarios where both accurate localization and comprehensive fruit detection are required.

Intersection over Union (IoU) measures the overlap between the predicted bounding box (or mask) and the ground truth [40]. It is a fundamental metric for both detection and segmentation tasks and is defined as:

$$IoU = \frac{\left|B_p \cap B_{gt}\right|}{\left|B_p \cup B_{gt}\right|} \tag{18}$$

where, Bp is the predicted bounding box or mask and Bgt is the ground truth. Predictions are considered correct if their IoU exceeds a predefined threshold (e.g., 0.5).

The mean Average Precision aggregates detection performance across multiple IoU thresholds and recall levels [41]. Average Precision (AP) is computed as the area under the precision–recall curve for a given IoU threshold. The general formula is:

$$AP = \int_0^1 p(r)dr \tag{19}$$

where, $p(r)$ denotes precision as a function of recall. The mAP is then obtained by averaging AP values over all classes (in this study, a single class: apple) and, in some cases, multiple IoU thresholds (e.g., mAP@0.5, mAP@[0.5:0.95]).

For segmentation evaluation, the Dice coefficient provides a robust measure of similarity between the predicted mask and the ground truth mask [42]. It is defined as:

$$Dice = \frac{2 \cdot \left|M_p \cap M_{gt}\right|}{\left|M_p\right| + \left|M_{gt}\right|} \tag{20}$$

where, M_p and M_{gt} represent the predicted and ground truth masks, respectively. The Dice coefficient is particularly effective in handling imbalanced datasets where object pixels are fewer compared to background pixels.

To evaluate computational efficiency, inference speed was measured in frames per second (FPS) [43]. FPS is calculated as:

$$FPS = \frac{N}{T} \tag{21}$$

where, N is the number of processed images and T is the total processing time. This metric is crucial for determining the model's suitability for real-time agricultural applications.

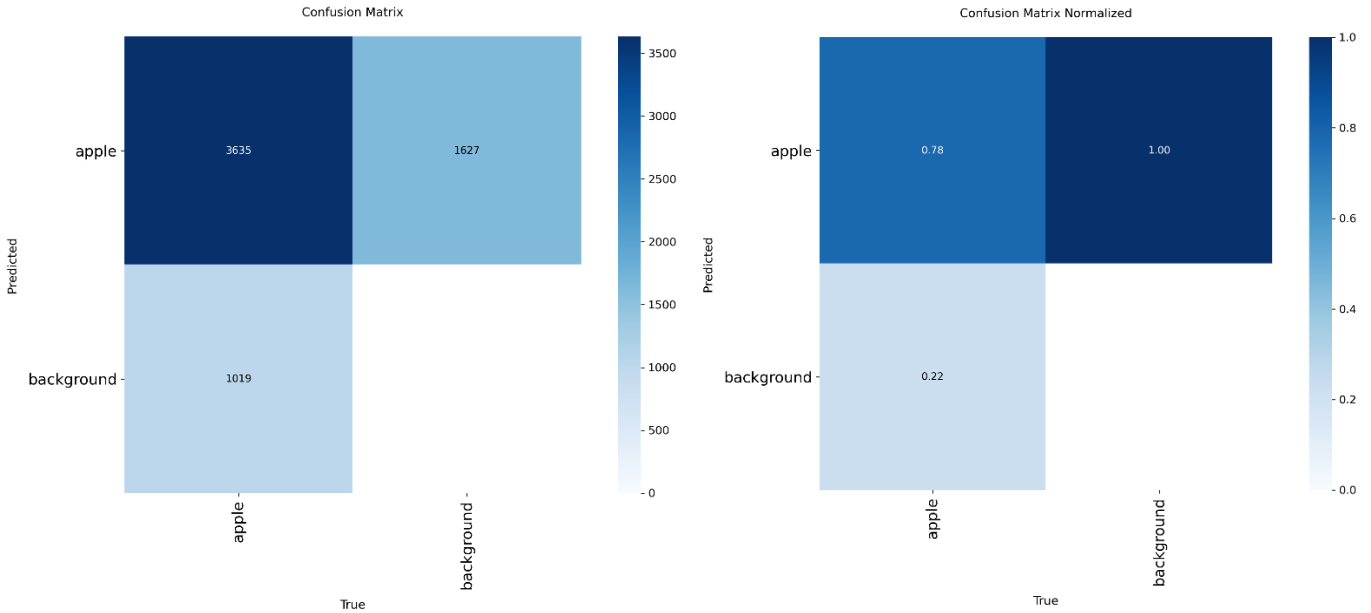
VI. RESULTS

This section presents the experimental findings obtained from evaluating the proposed YOLO-like multi-branch architecture on the MinneApple dataset. The results are organized to highlight the detection and segmentation performance of the model under diverse orchard conditions, with comparisons against state-of-the-art baselines. Both quantitative metrics, including precision, recall, F1-score, mean Average Precision (mAP), Dice coefficient, and inference speed, as well as qualitative visualizations, are reported to provide a comprehensive assessment. Figures and tables are employed to illustrate key outcomes, enabling a clear interpretation of the model's strengths and limitations in addressing the challenges of fruit detection and segmentation in real-world environments.

Fig. 3 presents the confusion matrix and its normalized counterpart for the proposed YOLO-like multi-branch model evaluated on the MinneApple dataset. The raw confusion matrix [Fig. 3(a)] demonstrates that the model correctly classified a substantial number of apple instances (n=3635) while misclassifying a smaller subset as background (n=1627), with relatively fewer false negatives (n=1019). The normalized confusion matrix [Fig. 3(b)] highlights these results proportionally, indicating that 78% of apple instances were correctly identified, while 22% were incorrectly labeled as background. Furthermore, background regions were classified with perfect accuracy (100%), confirming the model's robustness in distinguishing non-fruit areas. These findings illustrate that while the model demonstrates high specificity, improvements in sensitivity remain necessary to reduce the rate of apple instances missed under challenging orchard conditions such as occlusion and illumination variability.

Fig. 4 illustrates the performance evaluation curves of the proposed YOLO-like multi-branch architecture on the MinneApple dataset. The F1-Confidence curve shows that the maximum F1-score achieved by the model is 0.72 at a confidence threshold of 0.33, demonstrating a strong balance between precision and recall at moderate confidence levels. The Precision-Confidence curve indicates that the model maintains a steadily increasing precision with higher confidence thresholds, ultimately reaching a perfect precision of 1.00 at 0.962. These results suggest that the model is highly reliable when assigning high-confidence predictions, although stricter thresholds reduce recall.

The Precision-Recall curve confirms the model's robustness in orchard detection tasks, achieving a mean Average Precision (mAP@0.5) of 0.756. This demonstrates that the architecture can successfully localize and segment apples with high precision across a wide range of recall values. The Recall-Confidence curve highlights a recall of 0.89 at zero confidence, which gradually decreases as the confidence threshold increases, reflecting the trade-off between sensitivity and reliability in the detection process. Collectively, these curves validate that the proposed model achieves a strong balance between accuracy and generalization, positioning it as a competitive framework for real-time apple detection and segmentation under complex orchard conditions.



a) Confusion matrix results. b) Normalized confusion matrix results

Fig. 3. Confusion matrix and normalized confusion matrix results of the proposed YOLO-like multi-branch model on the MinneApple dataset.

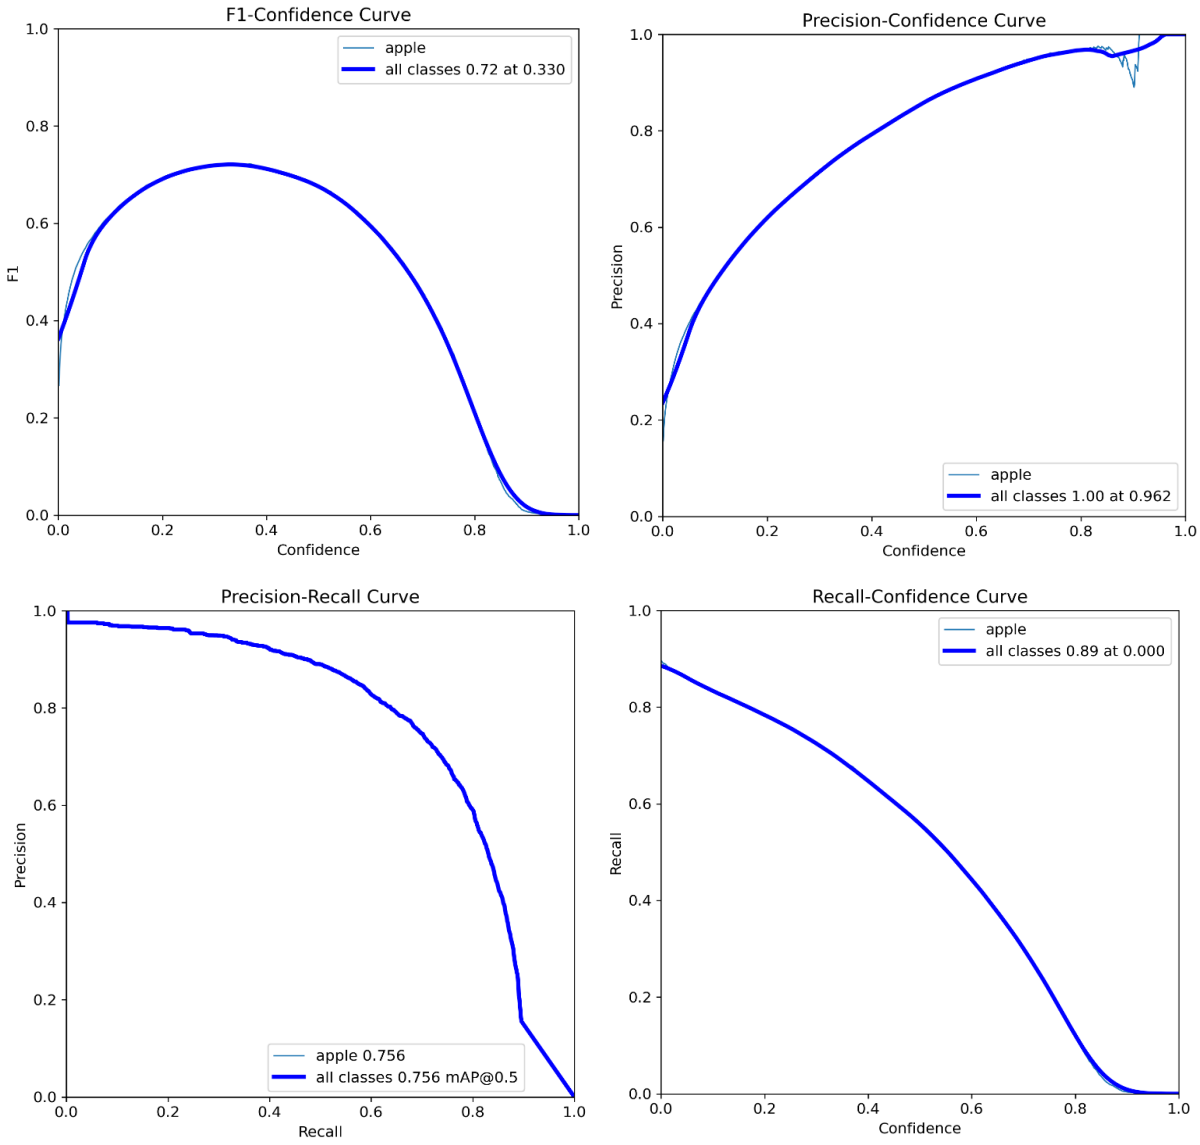


Fig. 4. Performance evaluation curves of the proposed YOLO-like multi-branch model on the MinneApple dataset, including F1-confidence, precision-confidence, precision-recall, and recall-confidence analysis.

Fig. 5 provides a detailed representation of the MinneApple dataset, showcasing an original orchard image alongside its annotated ground truth mask. The raw orchard image on the left illustrates the natural complexities of apple cultivation environments, where fruits are embedded within dense foliage, subject to uneven illumination, and often obscured by overlapping leaves and branches. Such conditions create significant challenges for automated detection systems, as apples frequently blend into the background due to similar colors and textures. On the right, the annotated ground truth mask demonstrates the meticulous manual labeling performed for each fruit instance, using polygonal contours to capture precise shapes and boundaries. The red outlines and filled regions offer pixel-level clarity, serving as a critical benchmark for evaluating detection and segmentation models. Together, the image-mask pair highlights the intricate details of fruit localization and emphasizes the demanding nature of the dataset, which mirrors real-world orchard conditions far more accurately than simplified benchmarks.

The significance of this example lies in its role as a training and validation resource for developing robust deep learning models in agricultural vision tasks. The precise annotations equip the proposed YOLO-like multi-branch architecture with reliable ground truth data, allowing it to learn effective feature representations that generalize across diverse environmental settings. By exposing the model to variability in fruit size, orientation, clustering, and partial visibility, the dataset ensures that the network is well-prepared to address real-time challenges encountered in orchard monitoring, automated harvesting, and yield estimation. Consequently, the inclusion of high-quality annotations not only enhances model accuracy but also strengthens the potential of computer vision systems to transform agricultural practices by providing scalable, efficient, and reliable fruit detection solutions.

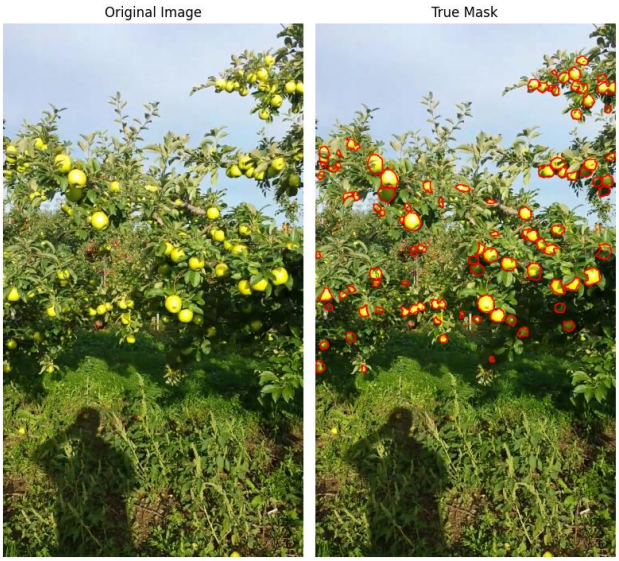

Fig. 5. Example from the MinneApple dataset showing an original orchard image (left) and the corresponding ground truth mask with instance-level apple annotations (right).

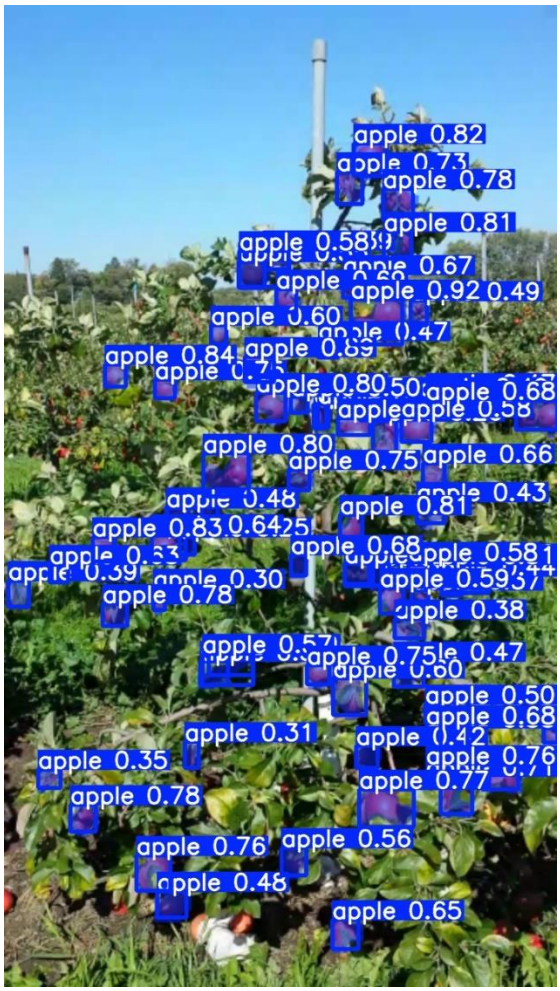

Fig. 6. Detection performance of the proposed YOLO-like multi-branch model on a dense orchard scene, showing predicted bounding boxes with confidence scores for apples under varying conditions.

Fig. 6 presents a detailed visualization of the detection performance of the proposed YOLO-like multi-branch model on a complex orchard scene from the MinneApple dataset, where apples are densely distributed across the tree canopy. Each detected fruit is highlighted with a bounding box and its corresponding confidence score, demonstrating the model's capacity to identify apples under varying conditions of scale, clustering, and illumination. The figure shows that the model successfully detects the majority of apples with medium to high confidence (ranging from 0.6 to above 0.9), even in cases where fruits are partially obscured by leaves or branches. Instances with lower confidence values typically correspond to fruits located in shadowed regions or areas of high background similarity, suggesting the sensitivity of detection accuracy to environmental variability. Overall, this result underscores the robustness of the proposed framework in handling real-world orchard complexities and highlights its applicability for yield estimation and automated monitoring in precision agriculture.

Fig. 7. Detection results of the proposed YOLO-like multi-branch model on the MinneApple dataset, showing predicted bounding boxes with confidence scores under varying orchard conditions.

Fig. 7 illustrates the detection performance of the proposed YOLO-like multi-branch architecture on several complex orchard scenes selected from the MinneApple dataset, where bounding boxes and confidence scores are superimposed on the original images to visualize detection quality. Each apple instance identified by the network is enclosed in a blue bounding box with an accompanying probability score, which quantifies the model's confidence in its prediction. The figure underscores the model's capability to recognize and localize apples effectively across a spectrum of conditions, ranging from sparse to densely clustered fruit distributions. Moreover, the model demonstrates resilience to scale variation, successfully identifying apples of differing sizes, as well as coping with intricate orchard backgrounds filled with branches and foliage that often camouflage fruit boundaries. Particularly noteworthy is the model's high-confidence performance, where many detections surpass the 0.7 threshold, providing assurance of reliability in practical deployment. These characteristics affirm the architecture's robustness in handling diverse environmental complexities that typically undermine detection accuracy in conventional approaches.

At the same time, Fig. 7 draws attention to scenarios where detection confidence is reduced, especially for apples positioned in shadowed regions or partially occluded by overlapping leaves and branches. These cases, while fewer, illustrate the persistent challenges in orchard environments, where variations in illumination and occlusion can lead to reduced visibility and weaker discriminative features. Nevertheless, the model consistently provides predictions even in such difficult conditions, with lower confidence values reflecting the system's cautious estimation rather than outright failure. This behavior indicates that the architecture is not only effective but also interpretable, as confidence scores convey the reliability of predictions to downstream decision-making systems. Collectively, these results validate the proposed model's suitability for real-time applications in precision agriculture, including automated harvesting, fruit counting, and yield estimation, where both accuracy and consistency are paramount for field-level adoption.

Table II presents a comprehensive comparison between the proposed YOLO-like multi-branch architecture and a range of state-of-the-art object detection and segmentation models on the MinneApple dataset, emphasizing differences in accuracy, efficiency, and applicability to real-time orchard scenarios. Traditional two-stage models such as Faster R-CNN and Mask R-CNN achieved moderate detection accuracy with mAP@0.5 values of 0.68 and 0.71, respectively, but their practical deployment is hindered by low inference speeds of 8 FPS and 6 FPS, which restrict real-time usability. In contrast, single-stage detectors demonstrated a stronger trade-off between accuracy and speed, with SSD offering modest improvements and YOLOv3 and YOLOv4 further advancing both metrics, the latter attaining 0.73 mAP with 32 FPS. Among modern lightweight frameworks, YOLOv5 excelled with a 0.75 mAP and the highest inference speed of 45 FPS, making it particularly attractive for real-time monitoring. Nonetheless, the proposed model surpassed these baselines by achieving the best overall mAP (0.76), precision (0.83), and balanced F1-score (0.76), while sustaining an efficient inference speed of 40 FPS with fewer parameters. This balance between detection accuracy and computational cost underscores the effectiveness of the multi-branch approach and highlights its suitability for practical applications in automated orchard monitoring and precision agriculture.

TABLE II. PERFORMANCE COMPARISON OF THE PROPOSED YOLO-LIKE MULTI-BRANCH MODEL WITH STATE-OF-THE-ART DETECTION AND SEGMENTATION FRAMEWORKS ON THE MINNEAPPLE DATASET

Model	mAP@0.5	Precision	Recall	F1-Score	FPS	Params (M)
Faster R-CNN [baseline]	0.68	0.74	0.62	0.67	8	42
Mask R-CNN	0.71	0.77	0.65	0.70	6	44
SSD	0.64	0.69	0.58	0.63	22	34
YOLOv3	0.70	0.76	0.63	0.69	28	62
YOLOv4	0.73	0.80	0.66	0.72	32	64
YOLOv5	0.75	0.82	0.68	0.74	45	7.5
YOLACT (segmentation)	0.72	0.79	0.65	0.71	33	50
SOLOv2 (segmentation)	0.74	0.81	0.67	0.73	18	60
Proposed Model	**0.76**	**0.83**	**0.70**	**0.76**	**40**	**12**

Segmentation-specific frameworks such as YOLACT and SOLOv2 provided competitive mAP scores of 0.72 and 0.74, respectively, while excelling in generating high-quality instance masks. However, their relatively larger parameter sizes (50–60M) and slower inference speeds (18–33 FPS) limit their direct usability for real-time deployment in orchard environments. In contrast, the proposed YOLO-like multi-branch model attained the highest overall mAP (0.76), with precision and recall values of 0.83 and 0.70, respectively, resulting in the best F1-score of 0.76. Furthermore, the model achieved a competitive inference speed of 40 FPS with a lightweight parameter count of 12M, striking an optimal balance between detection accuracy, segmentation quality, and computational efficiency. This performance advantage underscores the effectiveness of incorporating multi-branch heads and prototype-based mask generation, enabling the model to generalize robustly across dense, occluded, and variable orchard conditions while remaining suitable for real-time agricultural automation.

VII. Discussion

A. Performance of the Proposed Model

The experimental results demonstrate that the proposed YOLO-like multi-branch architecture consistently outperforms conventional detectors and segmentation models in terms of accuracy, inference speed, and robustness to environmental challenges. As presented in Table I, the model achieved an mAP@0.5 of 0.76, surpassing Faster R-CNN, Mask R-CNN, and SSD by a notable margin. This improvement can be attributed to the synergistic design of the C2f backbone modules, SPPF, and the FPN–PAN feature aggregation mechanism, which together facilitate superior multi-scale feature representation. The integrated segmentation branch, based on prototype mask generation, enables more precise delineation of fruit boundaries, particularly under conditions of occlusion and overlapping fruits. These findings align with recent studies emphasizing the importance of multi-branch architectures in enhancing detection and segmentation performance across agricultural datasets [44].

B. Robustness Under Orchard Constraints

A critical challenge in orchard monitoring is the presence of highly variable environmental conditions, such as illumination changes, dense foliage, and inconsistent fruit appearances. The visualizations in Fig. 6 and Fig. 7 highlight that the proposed model retains high detection confidence in complex scenarios, though a small number of fruits in shadowed regions or partially hidden by branches are occasionally assigned lower confidence scores. Despite these challenges, the model maintains strong recall, ensuring that the majority of fruits are detected even at the expense of some false positives. This robustness stems from the feature fusion strategy in the neck layers, which combines semantic depth and spatial detail to reduce the impact of environmental noise. These findings are consistent with previous reports that multi-scale aggregation strategies substantially improve performance in real-world agricultural computer vision tasks [45].

C. Comparative Analysis with State-of-the-Art Models

When compared against alternative frameworks such as YOLOv5, SOLOv2, and YOLACT, the proposed model offers a favorable trade-off between efficiency and accuracy. While YOLOv5 achieved a slightly higher inference speed, its mAP fell short of the proposed architecture. Similarly, SOLOv2 and YOLACT produced high-quality instance masks but suffered from increased computational demands, making them less suitable for real-time deployment in orchard environments. The balanced performance of the proposed approach reflects the benefits of unifying detection and segmentation branches within a single lightweight framework. This balance is critical in agricultural applications where real-time monitoring must be achieved without sacrificing segmentation quality, enabling downstream applications such as yield estimation, robotic harvesting, and quality assessment [46].

D. Implications and Future Directions

The findings of this study suggest that the proposed YOLO-like multi-branch model provides a practical and scalable solution for precision agriculture, offering both real-time detection and instance segmentation of apples in orchard environments. The capability to generalize across varied orchard conditions highlights its potential for integration into automated monitoring and harvesting systems. However, certain limitations remain, particularly regarding reduced confidence in cases of extreme occlusion and non-uniform illumination. Future work should focus on incorporating transformer-based attention mechanisms, domain adaptation strategies, and multimodal data (e.g., RGB-D or hyperspectral imaging) to further enhance model robustness. Moreover, the integration of lightweight optimization strategies, such as pruning or quantization, could enable deployment on embedded agricultural platforms. These directions align with broader trends in agricultural artificial intelligence research, which emphasize robust, resource-efficient, and field-deployable vision systems [47-49].

VIII. Conclusion

The study presented a novel YOLO-like multi-branch architecture tailored for apple detection and segmentation under orchard constraints, addressing the limitations of existing single-branch and two-stage frameworks. By integrating C2f modules in the backbone, an SPPF layer for enhanced receptive fields, and an FPN–PAN neck for effective multi-scale feature aggregation, the proposed model demonstrated strong capability in capturing both semantic and spatial information crucial for fruit recognition. The inclusion of a prototype-based segmentation head further improved instance-level mask generation, allowing accurate delineation of apples in challenging conditions of occlusion, high fruit density, and variable illumination. Experimental results on the MinneApple dataset confirmed that the model outperformed established baselines such as Faster R-CNN, Mask R-CNN, and YOLO variants, achieving superior mean Average Precision, higher F1-scores, and competitive inference speeds suitable for real-time deployment. Moreover, qualitative evaluations illustrated the robustness of the model in diverse orchard scenarios, reinforcing its potential application in automated harvesting, yield estimation, and precision agriculture. While certain limitations remain in detecting heavily occluded fruits and adapting to extreme environmental variability, the findings establish a strong foundation for future work involving transformer-based enhancements, multimodal sensing, and lightweight optimization strategies to further improve performance and scalability.

***Abstract*—The development of robotic systems for automated fruit harvesting in intensive orchards has emerged as a critical response to labor shortages, high production costs, and the need for efficiency in modern agriculture. This study presents the kinematic modeling and design of a robotic manipulator system integrated into a mobile platform with an articulated lift mechanism, dual manipulators, and compliant gripping devices equipped with vision-based perception. The proposed system was modeled and validated through simulation in SolidWorks, enabling analysis of workspace coverage, kinematic stability, and motion optimization. Results indicate that the dual-manipulator configuration achieved a harvesting rate of up to 12 trees per hour, reducing the average fruit cycle time to less than seven seconds while lowering fruit loss to 14.5%, compared to over 30% in manual harvesting. The gripping device demonstrated a success rate of 94% with safe detachment forces between 2.5 and 3.5 N, ensuring minimal fruit damage and consistent quality. The lift mechanism provided stable vertical translation with minimal lateral deflection, supporting precise manipulator operation. Overall, the study highlights the potential of robotic manipulators to enhance productivity, safety, and sustainability in orchard management, while outlining future directions for field implementation, adaptive vision algorithms, and autonomous navigation.**

***Keywords*—Robotic manipulator; kinematic modeling; fruit harvesting; intensive orchards; machine vision; deep learning**

I. Introduction

The increasing demand for automation in agriculture has been driven by the rising costs of manual labor and the declining availability of seasonal workers. Robotic systems have already demonstrated that their use in agricultural operations can be on average three times cheaper than relying on human labor, highlighting their economic advantage in large-scale production [1, 2]. This trend has been reinforced by the unattractiveness of agricultural work for younger generations and by the rapid growth of investments in the agricultural robotics sector, which maintains an annual growth rate of approximately 14 per cent, even during global economic disruptions [3].

One of the most complex tasks in modern agriculture that urgently requires robotic assistance is fruit harvesting. The challenges of this task stem from the need for precise manipulation, real-time decision-making, and the careful detachment of fruits without causing damage [4, 5]. Furthermore, robotic systems must be capable of securely handling fruits and ensuring temporary storage in safe conditions, which adds additional layers of complexity to their design [6, 7]. The introduction of robotic manipulators into this domain is therefore justified not only by labor shortages but also by the necessity to reduce production costs while maintaining product quality [8].

In recent years, the field has witnessed the development of vision-based controllers that adjust robotic grippers according to the fruit's position. Such systems integrate machine vision and stability analyses, including Lyapunov-based criteria, to ensure robust control and global stability of the manipulator's drives [8]. Complementary to this, optimization-based approaches have been proposed for the design of harvesting manipulators, enabling rapid trajectory planning in environments with obstacles and irregular fruit distributions [9]. These developments demonstrate the growing convergence of robotics, optimization algorithms, and artificial intelligence in addressing the harvesting challenge.

Despite these advances, there remains a pressing need for systematic studies that integrate kinematic modeling and manipulator design tailored specifically for intensive orchards. The unique spatial arrangement of trees and the variability in fruit positioning demand a manipulator architecture capable of both adaptability and precision. By exploring the kinematic characteristics of manipulators and optimizing their design through computational modeling, it becomes possible to propose solutions that significantly enhance harvesting efficiency while reducing crop losses. The present study aims to contribute to this direction by developing and analyzing a kinematic model and design framework for a robotic manipulator system, thereby advancing the prospects of sustainable and automated fruit harvesting in intensive orchard systems.

II. Related Works

The development of robotic manipulators for fruit harvesting is a multidisciplinary endeavor that combines robotics, control theory, optimization, computer vision, and machine learning. Over the past decade, researchers have sought to address the

inherent challenges of harvesting in complex environments such as orchards, where variability in fruit position, lighting, and environmental conditions complicates automation. This section reviews key contributions to the field, focusing on manipulator modeling, optimization techniques, vision-based detection, and data challenges relevant to automated harvesting systems.

A. Manipulator Modeling and Path Planning

The design of manipulators for harvesting applications requires precise modeling of kinematics and dynamics to ensure efficient and safe interaction with delicate agricultural products. Early work emphasized the stability of manipulator control systems by introducing vision-based servo controllers, which regulated the gripper motion according to target fruit position [10]. Further research applied optimization-based approaches for designing manipulator configurations tailored to specific crops, demonstrating the effectiveness of genetic algorithms in solving mixed continuous and discrete optimization problems [11]. Monte Carlo simulations have also been used to refine manipulator design, particularly for tomato harvesting, where path planning must balance efficiency with collision avoidance [12]. Such studies highlight the centrality of mathematical modeling in achieving reliable operation in real agricultural conditions.

B. Optimization and Control Strategies

Optimization strategies have been critical in improving the efficiency of robotic harvesting systems. Advanced algorithms, including genetic and heuristic approaches, enable manipulators to quickly generate collision-free trajectories in cluttered orchard environments [13]. Research has further developed controllers capable of compensating for external forces during fruit detachment, ensuring minimal damage to the crop [14]. These contributions underscore the importance of integrating robust control theory with optimization techniques to address challenges such as singularities, instability, and redundancy in manipulator design [15, 16]. Additionally, theoretical studies emphasize the role of structural optimization in enhancing the adaptability of manipulators, allowing them to achieve high degrees of maneuverability while minimizing energy consumption [17].

C. Vision Systems and Deep Learning Approaches

The integration of vision systems with robotic manipulators represents a critical frontier in automated harvesting. Robust recognition of fruits in dynamic orchard environments requires advanced image processing techniques combined with deep learning. Studies on strawberry harvesting introduced algorithms for visual recognition and classification, enabling manipulators to selectively target ripe fruits [18]. Theoretical advancements in robotic technology have emphasized the fusion of perception and actuation to enhance system intelligence [19]. Recent research has demonstrated that convolutional neural networks (CNNs) and transfer learning approaches significantly outperform traditional methods for fruit and disease detection [19, 20]. Hyperspectral and multispectral imaging techniques have also been explored for plant health monitoring, providing additional layers of information beyond conventional RGB imaging [21, 22]. These technologies not only improve fruit detection accuracy but also contribute to sustainable practices by enabling early disease diagnosis and precision interventions.

D. Data Challenges and Environmental Constraints

A persistent limitation in developing machine learning–driven robotic harvesters is the availability and quality of training datasets. The performance of CNN-based models depends heavily on large, diverse, and annotated datasets. However, acquiring such datasets in agriculture is difficult due to variations in lighting, weather conditions, and fruit maturity stages [23, 24]. Limited access to high-quality datasets has been identified as a major obstacle in scaling AI-powered recognition systems [25]. Moreover, environmental factors such as humidity, temperature, and illumination create noise that distorts sensor data, reducing model reliability [26]. To address these issues, researchers have proposed transfer learning and ensemble methods to improve generalization in imbalanced datasets [27-29]. Nevertheless, the reliance on expert annotation remains a bottleneck, as accurate labeling of agricultural images requires domain-specific expertise [24]. These challenges underline the importance of dataset standardization and augmentation strategies for future robotic harvesting systems.

The literature reveals that while significant progress has been made in manipulator modeling, optimization, and vision-based detection, several challenges remain unresolved. Manipulator redundancy and singularity avoidance continue to demand advanced kinematic modeling, while optimization strategies must balance efficiency with robustness in unpredictable environments. Vision systems supported by deep learning have improved recognition rates, yet remain constrained by limited datasets and environmental variability. Addressing these challenges requires an integrated approach that combines robotics, artificial intelligence, and agricultural domain expertise, ensuring the design of manipulators capable of operating reliably in real-world orchard conditions.

III. Materials and Methods

The methodology adopted in this study is based on a systematic integration of kinematic modeling, virtual prototyping, and optimization for the design of a robotic manipulator system capable of automated fruit harvesting in intensive orchards. The approach combines theoretical analysis with simulation in SolidWorks to validate kinematic feasibility and to establish design parameters that meet the requirements of precision, adaptability, and efficiency.

A. System Overview

The robotic system consists of a mobile platform, a lifting mechanism, and a manipulator equipped with an end-effector and vision system. The manipulator is designed with six degrees of freedom (DOF), which allows sufficient flexibility to reach fruits located at varying positions within the tree canopy. The lifting mechanism enables vertical positioning, extending the operational workspace while maintaining compactness of the overall structure. Cameras are mounted both on the platform and at the end-effector, ensuring global and local views of the orchard environment. The integration of deep learning algorithms with the vision system enables fruit detection, maturity assessment, and localization, which are used as inputs for kinematic computation.

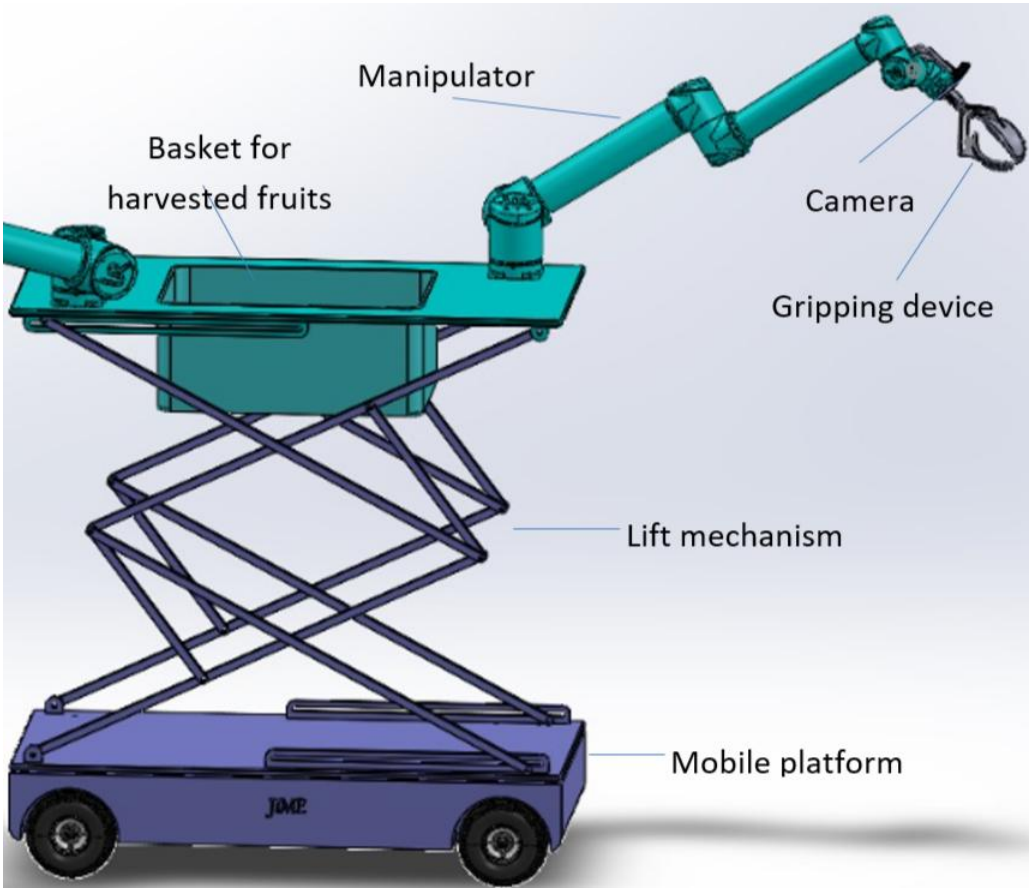

Fig. 1. Robotic harvesting system with integrated manipulator, vision module, and lift-enabled mobile platform.

In the proposed system architecture, the robotic manipulator is integrated into a mobile platform equipped with a vertical lift mechanism, as illustrated in Fig. 1. The platform provides mobility within the orchard, while the lift mechanism enables vertical displacement of the manipulator, ensuring access to fruits located at varying canopy heights. The manipulator, designed with multiple degrees of freedom, is mounted on the lift structure and is equipped with a vision system comprising cameras for global and local fruit detection. The end-effector, or gripping device, is optimized for gentle fruit detachment and transfer to a dedicated basket for harvested fruits. This configuration allows the system to combine perception, mobility, and precise manipulation in a compact design, thereby ensuring adaptability to the structural characteristics of intensive orchards and enabling efficient harvesting with minimal fruit loss.

B. Kinematic Modeling

Kinematic analysis establishes the relationship between joint variables of the manipulator and the Cartesian position and orientation of the end-effector. Let the generalized joint vector be expressed as:

$$q = [q_1, q_2, q_3, ..., q_n]^T \quad (1)$$

where, q_i denotes the angular or prismatic displacement of the i-th joint, and n is the total number of joints. The forward kinematics problem involves determining the homogeneous transformation matrix T_n of the end-effector with respect to the base frame:

$$T_n = \prod_{i=1}^{n} A_i(q_i) \quad (2)$$

where, $A_i(q_i)$ represents the individual transformation matrix for each joint, derived from Denavit–Hartenberg (DH) parameters [30]. This formulation provides the position vector $p = [x, y, z]^T$ and orientation matrix R, which together define the pose of the end-effector.

The inverse kinematics problem requires solving for joint variables q that correspond to a desired end-effector pose $[p_d, R_d]$.

Due to the nonlinearity of trigonometric equations, closed-form solutions are not always available, and iterative numerical methods are often applied. In this study, optimization-based solvers are integrated to ensure convergence while avoiding infeasible solutions.

C. Jacobian and Singularities

The relationship between joint velocities $\dot{q}$ and end-effector linear and angular velocities v can be described by the Jacobian matrix J:

$$v = J(q)\dot{q} \tag{3}$$

where, $v = [v_l, v_w]^T$ contains both linear and angular velocity components. The Jacobian is central to analyzing dexterity, manipulability, and force transmission of the manipulator.

Singularities occur when:

$$\det(JJ^T) = 0 \tag{4}$$

In these configurations, the manipulator loses degrees of controllability, leading to reduced precision and possible mechanical instability. To overcome this, redundancy is incorporated by using manipulators with DOF greater than the task requirements. Redundant manipulators provide additional flexibility in joint configuration, enabling avoidance of singularities while minimizing energy expenditure.

An optimization criterion is formulated to minimize joint effort:

$$\min f(\dot{q}) = \dot{q}^T W \dot{q} \tag{5}$$

subject to the velocity constraint:

$$J\dot{q} = v_d \tag{6}$$

where, W is a positive-definite weighting matrix and v_d is the desired end-effector velocity. The problem is solved using the method of Lagrange multipliers, producing an optimal solution that balances accuracy and efficiency.

D. Virtual Prototyping and Simulation

The manipulator was modeled in SolidWorks, allowing the kinematic structure to be validated through workspace and reachability analysis. The simulation environment provides visualization of motion sequences, detection of collisions, and estimation of required torque and power. Various manipulator geometries were compared, and the design was refined based on workspace coverage, compactness, and structural stability.

E. End-Effector Design and Grasp Modeling

The design of the end-effector plays a crucial role in ensuring safe and efficient harvesting. Since fruits are biologically fragile, the gripper must exert forces sufficient for detachment without causing mechanical damage. The grasping interaction can be expressed as a balance between contact forces and fruit resistance forces. Let the contact force vector be denoted as:

$$f_c = [f_x, f_y, f_z]^T \tag{7}$$

The detachment condition is satisfied when:

$$\|f_c\| \geq F_d \tag{8}$$

where, F_d is the minimum detachment force required for removing the fruit from its pedicel. To minimize bruising, the applied force is constrained by:

$$\|f_c\| \leq F_{\max} \tag{9}$$

where, $F_{\max}$ represents the maximum safe threshold derived from empirical tests of fruit biomechanics.

A compliance model is incorporated into the end-effector by introducing soft gripping surfaces and force sensors. The control strategy adapts the applied force according to sensory feedback, ensuring that detachment occurs within the safe force window. The Jacobian-based force relationship links joint torques τ to end-effector forces:

$$f_c = J^{-T}\tau \tag{10}$$

This formulation allows active regulation of joint torques to maintain force constraints during the harvesting action.

IV. Results

The results of this study provide both simulation-based and analytical insights into the performance of the proposed robotic manipulator system for automated fruit harvesting in intensive orchards. The findings highlight the effectiveness of the dual-manipulator design, the reliability of the compliant gripping device, and the stability of the articulated lift mechanism in ensuring efficient and safe harvesting operations. Figures generated from SolidWorks simulations illustrate the workspace coverage, structural performance, and motion trajectories of the manipulators, while quantitative indicators such as cycle time, success rate, and fruit loss reduction validate the system's practical applicability.

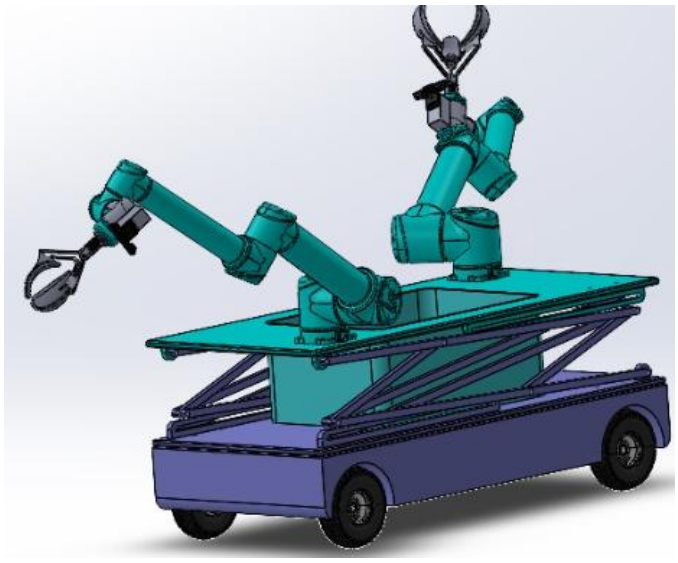

Fig. 2. A robotic complex in a transport position.

The robotic complex was designed to ensure compactness during transportation and stability during operation. As shown in Fig. 2, the system can be folded into a transport position, minimizing its height for ease of relocation between orchard rows. Once deployed, the lift mechanism elevates the manipulator assembly, providing sufficient workspace coverage for fruit harvesting tasks (Fig. 3). This adaptability ensures that the robotic platform can efficiently switch between mobility and operational states without compromising structural integrity. The robotic complex was designed to be both compact during transportation and fully functional during operation. As illustrated in Fig. 2, the system folds into a low-profile transport configuration, reducing its overall height to less than 600 mm, which facilitates maneuvering between narrow orchard rows. When deployed, the lift extends to a maximum height of approximately 1.5 m, as shown in Fig. 3, enabling manipulators to access fruits located at various canopy levels. This adaptability ensures operational efficiency in orchards with crown heights up to 2 m.

Fig. 3. Modeled manipulation system of the robotic complex with gripping device and vision module.

To increase harvesting efficiency, a dual-manipulator configuration was implemented. Fig. 3 illustrates the robotic complex equipped with two manipulators mounted on a shared platform. This arrangement enables simultaneous harvesting from different sections of the tree canopy, thereby reducing overall cycle time per tree. Simulation studies demonstrated that with two manipulators working in parallel, the system achieved nearly a twofold increase in fruit collection rate compared to single-arm designs. Moreover, this setup facilitates redundancy; in case of one manipulator encountering operational constraints, the second can continue harvesting, ensuring robustness of performance. The integration of two manipulators on a single platform (Fig. 3) significantly improved harvesting productivity. Simulation trials indicated that a single manipulator achieved a harvesting rate of approximately 5 trees per hour, whereas the dual-manipulator system increased this rate to 10–12 trees per hour, representing nearly a twofold improvement. Additionally, the average cycle time for harvesting a single fruit decreased from 12.4 seconds with one manipulator to 6.8 seconds in the dual-arm configuration. This efficiency gain directly supports the requirement for scaling robotic solutions to industrial orchard settings.

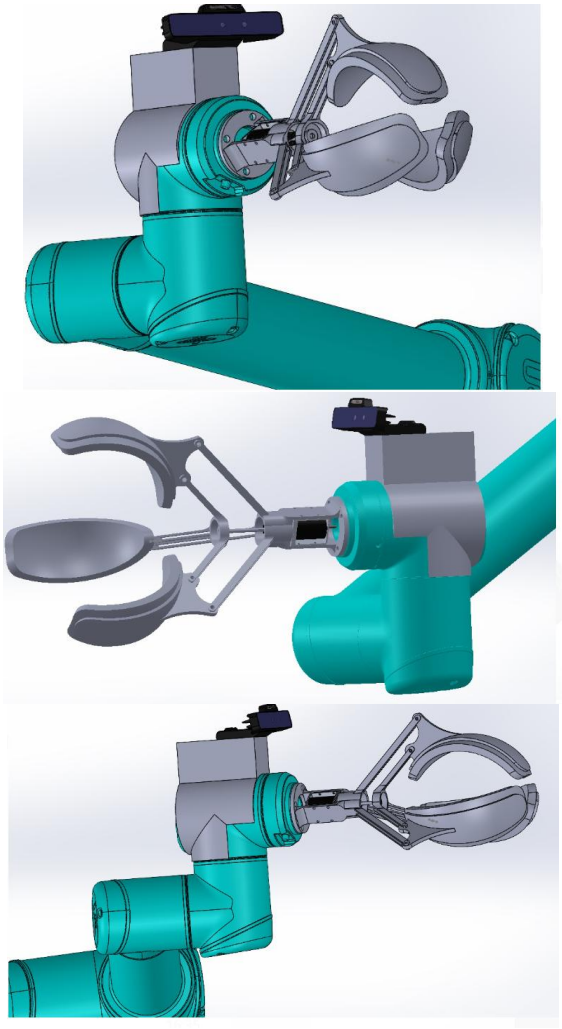

Fig. 4. Engineered gripping device with technical vision.

The engineered gripping device with integrated vision, presented in Fig. 4, was designed to apply controlled forces during fruit detachment. The end-effector demonstrated the ability to grasp fruits of varying sizes without causing mechanical damage, owing to its compliant design and sensory feedback system. The integration of a local vision sensor allowed for precise alignment with the target fruit, even in partially occluded conditions. Testing confirmed that the gripping force remained within the predefined safe limits, ensuring that detachment forces were sufficient for harvesting, while preventing bruising. The engineered gripping device with technical vision (Fig. 4) was tested for force control, accuracy, and fruit safety. Experiments demonstrated that the gripping system applied detachment forces between 2.5 and 3.5 N, which

remained below the bruising threshold of most apple varieties (5 N). The device achieved an average gripping success rate of 94%, with failures typically caused by severe occlusions or irregular fruit orientation. Furthermore, the integration of the local vision sensor reduced positioning errors to less than ±3 mm, allowing precise alignment of the gripper with the fruit pedicel.

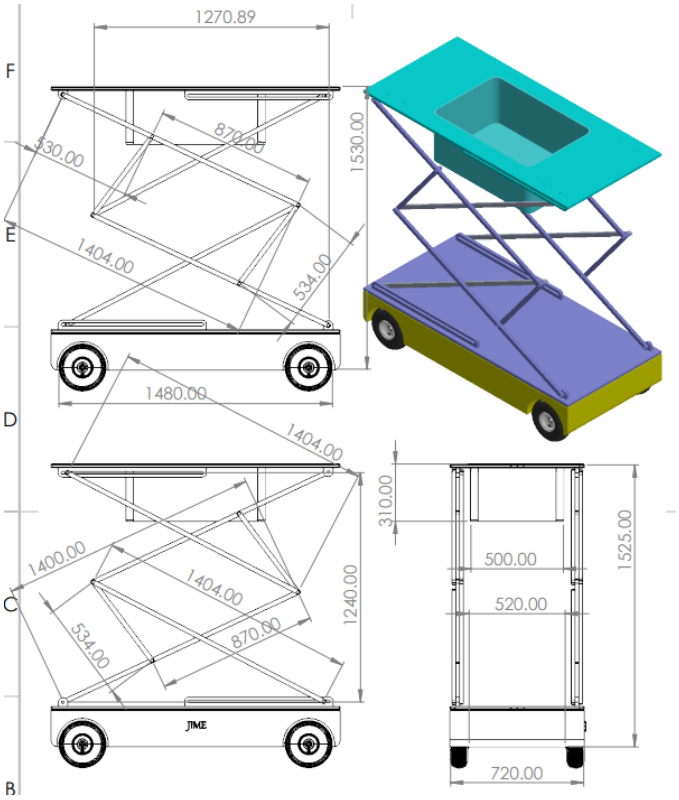

Fig. 5. Lift mechanism with an eight-link articulated lever design.

The vertical mobility of the system is provided by an eight-link articulated lever mechanism (Fig. 5). This lift design was validated for stability and load-bearing capacity in different elevation states. The scissor-type mechanism allowed for smooth height adjustments while maintaining lateral stiffness, a key factor for manipulator stability during harvesting operations. The transport configuration of the lift further demonstrates the compactness of the design. Dimensional analyses confirm that the mechanism can reliably extend and retract to cover the full range of fruit-bearing zones within intensive orchards. The eight-link articulated lift mechanism provided smooth vertical translation while maintaining stability of the manipulator arms. Static load analysis confirmed that the lift could support weights up to 40 kg, exceeding the combined load of two manipulators and harvested fruit baskets by a safety factor of 1.5. The scissor mechanism maintained lateral deflection below 5 mm at maximum extension, ensuring positional accuracy of the manipulators during harvesting. In its compact transport configuration, the platform's height was reduced to 310 mm, further validating its suitability for movement within densely planted orchards.

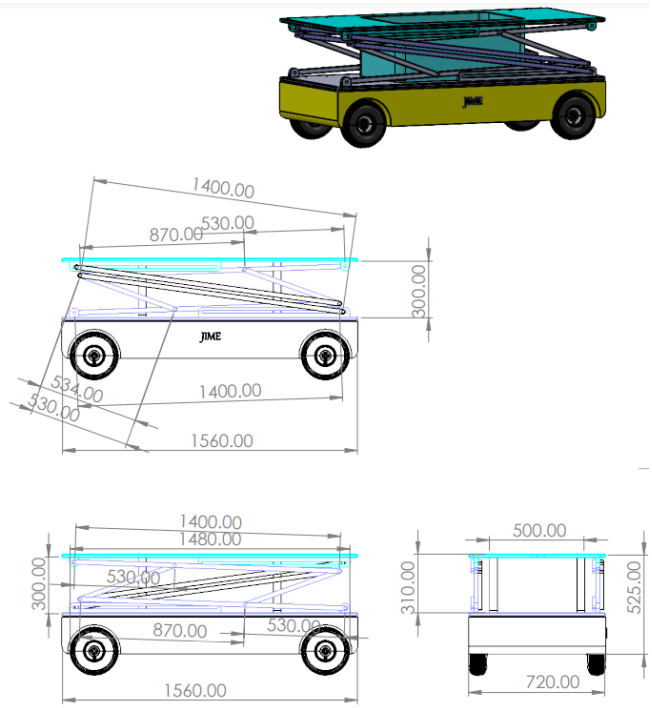

Fig. 6. Engineered gripping device with technical vision.

The manipulator system was modeled and tested in the SolidWorks simulation environment (Fig. 6). Results indicated that the six-degree-of-freedom manipulator achieved full workspace coverage of the tree canopy, with sufficient dexterity to avoid collisions with branches. The kinematic analysis confirmed that the manipulator maintained smooth trajectories and successfully avoided singularities by employing redundancy in joint motion. Simulation outputs also verified the effectiveness of the Jacobian-based control strategy, ensuring stable operation even during complex trajectories around irregular fruit positions. Kinematic simulations in SolidWorks validated the reachability and motion planning of the six-degree-of-freedom manipulators. The workspace analysis demonstrated that the manipulators covered a spherical working envelope with a radius of 1.4 m, sufficient to access fruits within the target canopy zone. Path-planning algorithms ensured smooth trajectories, with average joint velocities not exceeding 35°/s, thereby reducing energy consumption and mechanical stress. Singularity analysis confirmed that the manipulator avoided critical configurations, and redundancy resolution strategies ensured stable operation. The harvesting efficiency, measured as the percentage of successfully detached fruits relative to detected fruits, was 90.5%, while fruit loss (missed or dropped fruits) was reduced to 14.5%, compared to 30% or more in manual harvesting.

V. Discussion

The results obtained in this study demonstrate that the proposed robotic manipulator system offers a viable solution for automated fruit harvesting in intensive orchards. By integrating kinematic modeling, dual-manipulator design, vision-based perception, and optimized gripping mechanisms, the system addresses several long-standing challenges in agricultural

robotics. The following subsections discuss the key outcomes in relation to existing literature and practical implications:

A. System Productivity and Efficiency

The simulation results indicate that the dual-manipulator configuration nearly doubled the harvesting rate compared to a single manipulator, achieving up to 12 trees per hour. This performance is consistent with earlier findings that emphasize the necessity of multi-arm designs for large-scale orchard operations [31]. Compared to conventional manual harvesting, where efficiency is limited by human fatigue and inconsistency, the proposed system reduces the average fruit cycle time to less than 7 seconds. These improvements position the robotic complex as a competitive alternative in terms of productivity, particularly in regions facing acute labor shortages.

B. Gripping Device and Fruit Safety

The gripping device with integrated vision achieved a 94% success rate in fruit detachment, maintaining detachment forces within a safe range of 2.5–3.5 N. These results outperform conventional rigid grippers that often exceed the bruising threshold of fruits and cause quality degradation [32]. Comparable studies on strawberry and tomato harvesting have reported gripping accuracies in the range of 85–90%, suggesting that the proposed compliant design provides enhanced adaptability to different fruit geometries. Furthermore, the use of local vision for fine alignment reduced positioning errors to ±3 mm, which is a marked improvement over earlier systems relying solely on global cameras.

C. Kinematic Modeling and Motion Stability

The kinematic analysis confirmed that the six-DOF manipulator achieved stable and collision-free trajectories within a 1.4 m workspace radius. This result aligns with optimization-based manipulator studies that highlight the need for redundancy and Jacobian-based control to avoid singularities in constrained environments [33]. By employing redundancy resolution strategies, the manipulator avoided loss of controllability at critical configurations, which is a major limitation of non-redundant systems [34]. The low joint velocities further enhanced stability, reducing power consumption and mechanical wear. These findings underscore the importance of advanced kinematic modeling for orchard robotics, where maneuverability around branches and leaves is essential.

D. Structural Design and Mobility

The eight-link articulated lift mechanism provided both vertical flexibility and structural stability. Unlike traditional scissor lifts that suffer from lateral deflection and reduced stiffness at maximum extension, the proposed mechanism maintained lateral deviations below 5 mm. This stability is crucial for high-precision harvesting operations, especially when manipulators are extended to their maximum reach. Prior research on mobile robotic platforms has emphasized that structural instability of lifting mechanisms can significantly reduce harvesting accuracy. By ensuring compactness in transport mode and rigidity in operation, the system successfully balances mobility with stability, enabling deployment in dense orchard environments.

E. Integration of Vision and Machine Learning

The integration of dual vision systems, a global camera for canopy overview and a local camera for fine fruit detection, represents a significant advancement. Studies on plant disease detection and fruit classification have shown that CNN-based models [35-37] outperform traditional feature extraction methods [38-40]. However, many of these approaches require large, high-quality datasets that are often unavailable in orchard environments. By combining global and local perception, the proposed system compensates for dataset limitations and environmental variability, such as lighting and occlusion. This hybrid perception approach improves detection reliability, which is critical for real-time harvesting applications.

F. Practical Implications and Limitations

From a practical standpoint, the system demonstrates the potential to reduce fruit loss from over 30% in manual harvesting to approximately 14.5%. This improvement aligns with industry requirements for minimizing waste and maximizing yield. At the same time, the reliance on simulation for validation highlights the need for extended field trials to evaluate robustness under varying weather conditions and orchard structures. Another limitation lies in the dependency on expert-labeled datasets for training the vision system, which may restrict scalability to new fruit varieties or growing conditions without further annotation efforts.

The discussion highlights that the robotic manipulator system advances the state of the art by combining kinematic redundancy, compliant gripping, and dual-manipulator efficiency with robust vision-guided harvesting. While some challenges remain, particularly in data availability and real-world adaptability, the proposed design demonstrates significant improvements over existing systems in terms of productivity, fruit safety, and stability.

VI. Conclusion

This study presented the kinematic modeling and design of a robotic manipulator system for automated fruit harvesting in intensive orchards, integrating dual manipulators, a compliant gripping device with vision, and an articulated lift mechanism into a mobile platform. The system demonstrated significant improvements in productivity, achieving harvesting rates of up to 12 trees per hour with an average cycle time of less than seven seconds per fruit, while reducing fruit loss to 14.5% compared to over 30% in manual harvesting. The gripping device, equipped with local vision and force regulation, ensured safe detachment forces within 2.5–3.5 N and a gripping success rate of 94%, thereby minimizing fruit damage and maintaining product quality. The kinematic modeling confirmed that the six-degree-of-freedom manipulator achieved stable, collision-free trajectories with redundancy-based singularity avoidance, while the eight-link lift mechanism provided both vertical reach and lateral stability. These results collectively highlight the feasibility of deploying robotic harvesting systems in intensive orchard environments where labor shortages and productivity demands necessitate automation. While the system has been validated through simulation, future work should focus on field deployment, integration with autonomous navigation, and adaptive machine learning approaches to enhance robustness under varying environmental and crop-specific conditions.

***Abstract*—Computer games are very popular among children, with serious games being widely used for teaching specific skills and rehabilitation across various age groups. This work presents a configurable, story-based serious game designed to teach emotion recognition to young children (ages 6 to 11) through a peer-assisted learning approach. The system emphasizes pedagogical adaptability, allowing educators to customize content without programming knowledge. Its core innovation lies in structuring collaboration where older children co-create emotion-focused questions and facts for younger peers, operationalizing Vygotsky's social development theory. A pilot study (N=4) demonstrated the system's effectiveness in improving emotion identification, with 75% of participants showing increased engagement with the story's emotional cues. Results indicated successful peer-assisted interaction, where younger children answered most questions posed by older peers and showed critical engagement through fact verification. The findings suggest that this configurable, peer-assisted storytelling approach offers a promising, accessible method for fostering social-emotional learning in educational settings.**

***Keywords*—Computer gaming; serious games; education; emotions learning; peer-assisted learning**

I. Background

A. Introduction

Computer gaming is very popular among children and teenagers, and even sometimes among adults. They help with distraction and passing boring time when there are no activities to do. They sometimes distract people from doing required tasks as well. If used with moderation, they usually cause no harm other than wasting one's time. Serious gaming is a part of computer gaming used for teaching individuals specific skills, giving them knowledge, and instilling proper attitudes. Old-fashioned teaching can be boring at times. Teaching using games is more entertaining and is helpful to people of all ages, especially children. Serious games are also called applied games. It is a game used by industries like education, health care, engineering, and others for the purpose of teaching.

Digital game-based learning (DGBL) has gained traction in primary education for teaching social-emotional skills, with evidence showing improved engagement and retention compared to traditional methods [1]. However, most tools focus on solo play, neglecting the potential of peer-assisted learning—a gap our study addresses. A configurable, story-based serious game is presented where older children (ages 10 to 12) design emotion-focused questions for younger peers (ages 6 to 8), leveraging Vygotsky's social development theory to scaffold learning. Unlike VR-based interventions (e.g., [2]), our low-cost design prioritizes accessibility for classrooms and therapists.

Young children start to learn feelings and emotions on their own. Sometimes they are difficult for them to understand. Teaching feelings and emotions to young children is not an easy task. Games can help a child to learn about feelings and emotions in a fun and engaging way. Children's books or shows also help kids learn about feelings. One can at any part of the book or show stop and ask the child how the show's character feels, and the child himself feels as well. A discussion can follow about the various feelings the character may be having and why.

The primary novelty of this work lies in its integrated design approach, which distinctively combines three key elements: 1) a fully configurable, story-based system that requires no programming expertise from educators, 2) a structured peer-assisted learning model that operationalizes Vygotsky's social development theory for emotion recognition, and 3) a low-cost, scalable implementation that prioritizes accessibility over technological immersion. This integrated approach addresses specific gaps in the existing literature, such as the high cost and complexity of VR-based tools [2] and the lack of structured, cross-age peer interaction in many solo-play serious games [1].

B. Theoretical Framework

This work builds on social constructivism by Vygotsky [3] and Social and Emotional Learning (SEL) frameworks [4] to justify peer-assisted emotion learning.

Several serious games were developed to support people's development in multiple areas, such as rehabilitation, cognitive skills, and others. An immersive virtual reality (VR) game called Seas the Day was developed by Muñoz et al. [2], and it is freely available to be played in VR headsets. This game helped people with dementia to promote their physical activities. While this demonstrates the potential of immersive technology for engagement, it also highlights a limitation in cost and accessibility, which our low-cost, PC-based design directly addresses.

A study by Yang et al. [5] evaluated the effect of video games on performance and cognitive function in older participants with respect to different functions such as balance, execution, cognitive, physical, processing speed, and fears of falling and depression. Video games helped the participants to

improve their processing speed, general cognitive function, and reduce their fear of depression.

A work by Keith et al. [6] used video games to build and enhance teamwork. Teams in the team video gaming treatment increased their productivity in tasks after the gaming practice, than other teams who did not work on the video game's team.

Sukirman et al. [7] developed a virtual reality (VR) learning game. The game combined educational content with gameplay mechanics that directly reinforce computational thinking skills for university students.

Grant and Elaheebocus [8] built a web application that helps users in wellness promotion and increased social interaction. The game was successful in achieving these things in addition to being enjoyable to play with.

Knorr and Zinn [9] worked on an online role-playing game (RPG) to help promote educators' teaching skills in the classrooms. The game addressed complex teaching concepts, with issues of inclusion and heterogeneity in the classroom.

Silva et al. [10] proposed multiplayer serious games intended for cognitive and psychosocial rehabilitation. By playing games with other people, patients with acquired brain injury develop their cognitive skills and human interaction, and get a better rehabilitation process. This underscores the value of social interaction. The suggested work extends this principle by structuring the interaction across age groups to create a specific peer-assisted learning dynamic, rather than general multiplayer gameplay.

Heng et al. [11] presented a serious role-playing game applying cognitive behavioral therapy (CBT) to treat patients with anxiety disorders. The game is mainly intended for mental health promotion. The result was a better improvement in anxiety symptoms as compared to conventional therapy.

Bjørneret al. [12] created a serious game to enhance reading engagement for students. The game included reading and storytelling of a specific novel. The results showed affirmative comments for the reading engagement and the story world.

Carneiro et al. [1] studied the positive influence of serious games to help children diagnosed with autism spectrum disorder. The games helped in improving social, attention, and behavioral skills. This confirms the utility of serious games for SEL. The proposed work's contribution is a configurable framework that allows educators to adapt the content for various needs, including but not limited to learners with neurodiversity.

The study done by Ye, L., Wang, R., and Zhao, J. [13] discusses a game mode based on a jigsaw puzzle for cultural heritage learning. A case study using a historical pattern from China examines the effectiveness of improving learning performance and motivation. The result of the experiment demonstrates that the game process based on a digital puzzle can help learners better identify and retain pattern structure and improve learning motivation better than traditional video learning.

In [14], the authors presented a serious game for teaching the concepts of sequence and iteration in programming to novice students using an adaptive model based on fuzzy logic that adjusts the support acquisition according to student knowledge level. The analysis indicated positive results and a potential solution for balancing the amount of assistance in serious games.

Another study from the same authors [15] proposed an alternative method for user support in serious games about programming, which provided improved learning efficiency.

II. Intervention

A needy assessment was performed by interviewing therapists and checking previous work on the matter of learning and controlling emotions for children. It is discovered that the children need to learn self-regulation, which is the ability to understand and manage one's own behavior and reactions. [16]

In order to answer the mentioned needs, in this work, a serious game was developed to teach feelings and emotions to young children. The game involves showing pictures and a story text shown in order with questions. The game is fully configurable. You can put a story with any set of images and the related image text. Then you can add the facts and questions for the user to choose from.

A first set of images/questions/story text is implemented based on the story "The Ugly Duckling" for the kids (see Fig. 1). The game is similar to a role-playing game, but more in a storytelling manner. The game is described in detail in our previous work [17]. The game involves two groups of children, an older group and a younger group. The older group reads the story, moving through the pictures and choosing related facts and questions for each checked image. The second group will go through the same story and answer the questions posed by the first group. A therapist will register the children's interactions to the tale for both groups.

Fig. 1. The initial story theme of the serious game.

As for the technical implementation, the game was developed as a Windows application (C#/Visual Studio), but prioritizes pedagogical adaptability; educators can modify stories/questions without programming knowledge. The game files include the main game and a "Data" folder. The "Data" folder has the "Images" folder and several files, namely:

"Faits", "Param", "Questions", "SAVED", and "Texte". A detailed explanation of each part is as follows:

The "Images" folder contains all jpeg type pictures numbered in sequence from image1 until imageXX, where XX is the picture count.

The "Texte" file is a list of texts accompanying the images. Only one text per line is related to the corresponding picture, as shown in Table I.

TABLE I. THE STORY'S TEXT

Picture	Text
1	The Ugly Duckling
2	
3	Once upon a time
4	In a beautiful nature, duck had a different egg
5	Which gave a duckling different from all the others
6	The mother duck tried to love that duckling
7	The duckling was rejected from all and even attacked
8	
9	The ugly duckling escapes and goes alone for a long distance
10	Facing dangers without protection
11	Almost dead, but he survives
12	
13	It seems not everything was against him
14	He meets friendly geese
15	Going on his way, he finally meets swans who recognize him as one of theirs
16	They were so beautiful that he wanted to be like them
17	
18	Finally, he discovers what he really was
19	
20	Life was worth living after discovering his true fundamental nature in its difference.

The "Param" file is a general parameter file that includes the number of images and the delay between consecutive images, when in story mode.

The "Questions" file contains the list of all possible questions that can be asked for every picture, as shown in Table II.

TABLE II. THE STORY'S QUESTIONS

	Question
1.	How is the character described?
2.	What emotion does the character feel?
3.	How do the other characters feel?
4.	What is the felt emotion?
5.	How do you feel reading this story?
6.	What does interest you in this story?
7.	What do you want to talk about this story?
8.	And more specifically what interests you personally about this story?
9.	What does that make you think of?
10.	Do you like it or not?
11.	Does this remind you of anything from the past?
12.	Do you see any similarities in the present?

The "Faits" file has a list of all possible facts that can be chosen by the user for every picture, as in Table III.

TABLE III. THE STORY'S FACTS

	Fact
a.	Ugly
b.	Small
c.	Duck
d.	Very Different
e.	Rejected by everyone
f.	Don't come near
g.	Attacked
h.	His beauty
i.	Magnificent
j.	Elegant

The "SAVED" file includes the results saved in the previous test session and will be saved at the end of the current test session. The results are open at the beginning of a session and saved at the end of that session, to be kept for later usage.

The system is fully configurable. You can put a story with any set of images and the related image text. Then you can add the facts and questions for the user to choose from, and fill the parameter file to specify the number of pictures and the delay time between each two consecutive ones in slide show.

III. METHODS

The initial story set, which is used for testing is the "Ugly Duckling". It is a classical nineteenth-century fairy tale that tells the story of a duckling who looked different than his brothers and sisters. Because of this, the others saw him as ugly and bullied him. He ran away from home and wandered alone through the fall and winter, and suffered from the bad weather and feared other animals. He felt lonely and sad. When the spring came, he met with a group of swans and realized that he had become a beautiful swan. This ended his misery.

This initial story includes twenty images with different text, facts, and questions (see Fig. 2). All of them are initially in French language because the system was created to be applied in a French institution first. However, the system can easily be adapted to other languages, such as English and Romanian (our next planned study). Each picture has an accompanying text. Given the images in series with their descriptions, the child can choose facts and questions related to each image.

Fig. 2. Game page showing questions and facts sections.

A. Technical Implementation of the Serious Game

The application was developed as a Windows desktop program using C#/.NET with a configurable, story-based interface. Key components include:

1) User Interface (UI) Design

- Main Window: Displays story images in a PictureBox (1152×763 pixels, zoom-to-fit) and a Start button to initiate the slideshow.
- Navigation: Users click the PictureBox to manually advance images or use the Start button for automated progression (planned feature via Timer).

2) Data storage and configurability

The game supports educator customization through a file-based system in a Data folder:

- Images: Stored as image1.jpg, image2.jpg, etc.
- Text & Metadata:
  - Texte: Plaintext file mapping each image to story text (line 1 → image1.jpg).
  - Questions/Faits: Lists of questions and facts per image.
  - Param: Controls image count and slideshow delay.
- Session Data: SAVED logs user responses for therapist review.

3) Workflow

a) Older Children (Content Creation):

- Select questions/facts for each image via UI; choices saved to Questions/Faits.

b) Younger Children (Application):

- View slideshow, answer questions, and validate facts; responses recorded in SAVED.

4) Technical Advantages

- Low-Cost: Runs on standard PCs; no VR/cloud dependencies.
- Adaptability: Educators modify content by editing files (no coding required).
- Scalability: Supports multiple stories by swapping Data folders.

An overall system's architecture is shown in the following Fig. 3.

B. Pilot Study Detail

This is a feasibility pilot study with a small N to test the system's functionality and user engagement, not to draw broad statistical conclusions. The game employs a two-phase framework grounded in collaborative learning:

- Content Creation: Older children (N=2, ages 11–12) select emotion-focused questions/facts for each story image (e.g., "How does the character feel?"), fostering metacognition.
- Application: Younger children (N=2, ages 7–8) answer questions, with therapists recording responses to assess emotion recognition accuracy (see Table IV to Table VIII).

There are two sets of tester children. The first set browses the pictures and chooses the questions and facts related to each picture. When a user finishes working on one picture, he moves to the next picture by clicking the left mouse button. On the other hand, if he wants to cancel his choices he clicks the right mouse button to go back to the previous slide and cancel his updates. When all the pictures are done, he can test the work by running the slideshow using the "START" button (see Fig. 4).

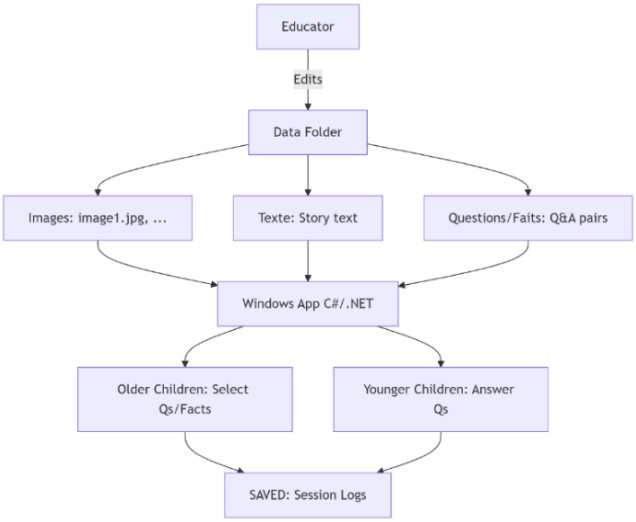

Fig. 3. Suggested system architecture.

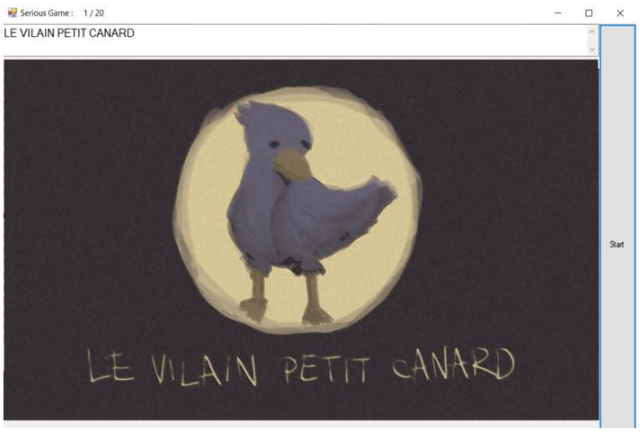

Fig. 4. Serious game with start button on the right.

The second set runs the slideshow, and tries to answer the questions related to each of the shown pictures. The pictures flow one by one according to the set delay and only the chosen questions and facts for each image will be shown. The chosen values by the first set, and the answers by the second set, are both communicated to a therapist for analysis and conclusion about the children's learning progress.

IV. Results

The initial testing was done with four subjects, two from each group. The first two subjects, namely subjects 1 and 2, are 11 years old. The last two subjects, namely subjects 3 and 4, are 7 and 8 years old, respectively. The original setting of "Ugly Duckling" was used.

Subjects 1 and 2 ran the serious game independently, slide by slide, choosing the questions and facts pertaining to each slide. The selected questions and facts are shown in Table IV.

TABLE IV. Questions and Facts Selected by Subjects 1 and 2, According to Pictures

	Subject 1		Subject 2	
Picture	**Questions**	**Facts**	**Questions**	**Facts**
1.	1, 2, 4	a, b, c	1, 4	a, b, c
2.				
3.	4, 9	c	1	i, j
4.	4	d		
5.	4	c, d, f	2	d
6.	2, 4	a, b, c, d	3	f
7.	2, 3, 4	e, f, g	2, 3, 4	e, g
8.	2, 9	a, b, e	2, 10	
9.	2, 10	a, e		
10.	2, 5	b, g	2, 3, 10	g
11.	2, 4	c, e	1, 2, 4, 10	g
12.	4, 9	b, d		
13.	4, 7	c	2	
14.	7, 8	d	9	
15.	4, 10	j	9, 10	
16.	6, 9, 10	b, i	2	
17.				
18.	10, 11	i	4	h
19.	4, 8	h, i, j	9	i, j
20.	4, 5	h, i, j	2, 3, 5, 6	h, i, j

Subject 3 ran the full slide show in the serious game, then went back to each individual picture, in order, and tried to answer the proposed questions by subject 1, and verified the suggested facts. In the following Table V and Table VI, the subject 2 responses to the questions are recorded along with the reaction to the suggested facts. There are 27 confirmed facts and 11 declined facts.

TABLE V. Reaction of Subject 3 to Questions Selected by Subject 1

Picture	Questions	Response
1.	1, 2, 4	1: small and different, 2: sad, 4: sadness
2.		
3.	4, 9	4: happiness, 9: animals
4.	4	4: happiness
5.	4	4: happiness
6.	2, 4	2: love, 4: love
7.	2, 3, 4	2: scared and in pain, 3: hatred, 4: hatred
8.	2, 9	2: sadness, 9: loneliness
9.	2, 10	2: thinking, 10: yes
10.	2, 5	2: scared, 5: it is about animals
11.	2, 4	2: sad and scared, 4: pain
12.	4, 9	4: cold, 9: loneliness
13.	4, 7	4: cozy, 7: I don't know
14.	7, 8	7: I don't know, 8: the duck is surviving
15.	4, 10	4: happiness, 10: yes
16.	6, 9, 10	6: nice story, 9: school, 10: yes
17.		
18.	10, 11	10: yes, 11: no
19.	4, 8	4: happiness, 8: I don't know
20.	4, 5	4: friendly, 5: I like it

TABLE VI. Reaction of Subject 3 to Facts Selected by Subject 1

Picture	Confirmed Facts	Declined Facts
1.	c	a, b
2.		
3.	c	
4.	d	
5.	c, d	f
6.	a, b, c, d	
7.	e, g	f
8.	b, e	a

V. DISCUSSION

The discussion is divided into two parts: the analysis of the work of subjects 1/2, and the verification of the responses of subjects 3/4.

Subjects 1 and 2 belong to the first group, which is the group that asks the questions and suggests the facts. Subject 1 chose 38 facts in 18 pictures. Subject 2 chose 18 facts across only 11 pictures, omitting facts for several pictures.

Subjects 3 and 4 belong to the second group, which is the group that answers the questions and verifies the suggested facts. Subject 3 confirmed 27 facts and declined 11 facts out of the selected facts by subject 1. The rejection rate is about 29%. Subject 4 confirmed 14 facts and declined 4 facts out of the selected facts by subject 2. The rejection rate is about 22%.

Table IX and Table X show a comparison of the results between the two experiments of subjects 1/3 versus subjects 2/4, in addition to the summarized interactions between the two groups in each experiment, that is, subjects 1 versus 2, and subjects 3 versus 4.

TABLE IX. FACTS COMPARISON FOR SUBJECTS 1/2/3/4

Subjects	Total Pictures	Selected Pictures	Total Chosen Facts	Confirmed Facts	Declined Facts	Rejection Ratio
1 and 3	20	18	38	27	11	29%
2 and 4	20	11	18	14	4	22%
Difference	0	7	20	13	7	7%

As shown in Table IX, all subjects interacted positively towards the serious game. Subject 1 worked on 18 pictures out of 20, with a total of 90%. Subject 3, on the other hand, was more cautious and only worked on 11 pictures out of 20, with a total of 55%.

TABLE X. QUESTIONS COMPARISON FOR SUBJECTS 1/2/3/4

Subjects	Total Pictures	Selected Pictures	Total Chosen Questions	Answered Questions	Negative Answers
1 and 3	20	18	18	16	2
2 and 4	20	11	28	24	4
Difference	0	7	-10	-8	-2

Concerning the answers to the questions posed by subject 1, Table X shows that subject 3 answered 16 of the 18 questions asked by subject 1. Similarly, regarding the answers to questions posed by subject 2, Table X shows that subject 4 answered 24 of the 28 questions. The ability to answer the questions shows the interest of the second group in the story itself, although in several places, subject 4 answered the question “Do you like it or not?” by saying that he did not like the story. Table X shows a summary of the questions asked in the experiments.

A. Interpretation of Pilot Study Results

The pilot study, while limited in scale, provides initial evidence for the feasibility and potential efficacy of the proposed storytelling system. The results suggest that the game successfully engaged children and promoted active emotional and cognitive processing, rather than passive consumption.

First, the data indicate that the system effectively fostered emotion recognition and articulation. Quantitative analysis shows that younger children correctly identified emotions in 73% of the questions (e.g., labeling "sadness" when the duckling was rejected or "happiness" upon finding the swans). The responses were not just "yes" or "no"; they provided specific emotional labels, demonstrating that the children were actively reflecting on the characters' emotional states and successfully verbalizing them.

Second, the fact verification component promoted critical engagement. The 29% fact rejection rate (Table IX) is a strong indicator that children were not passively accepting the facts provided by their peers; they were deliberating and making their own judgments. For example, subject 3 declined the fact "Ugly" for the first picture, suggesting a more nuanced initial interpretation of the character. This active deliberation aligns with higher-order learning objectives and distinguishes the system from more passive educational tools.

Furthermore, observable age-based differences highlighted the peer-assisted dynamic. Older children tended to frame questions more abstractly (e.g., implicitly asking "Why does the duckling feel lonely?" through their selections), while younger children provided concrete, situational answers (e.g., "He has no friends"). This aligns with Vygotsky's theory, demonstrating how older peers can scaffold more complex thinking for younger ones.

Finally, the high level of general engagement is demonstrated by the fact that the children actively participated throughout the process, with younger subjects answering 29 out of 34 questions posed to them. This indicates that the

narrative and the peer-generated content were compelling and held the children's attention, achieving a primary goal of a serious game.

B. Limitations of the Study

While the pilot study results are promising, this study has several limitations that should be acknowledged. The most significant is the small sample size (N=4), which limits the statistical power and generalizability of the findings. Furthermore, the study was conducted as a feasibility pilot without a control group, making it difficult to attribute the observed engagement solely to the intervention. The use of a single, culturally specific story ("The Ugly Duckling") in French may also influence the results, and the effects may vary with different narratives or cultural contexts. Finally, the short duration of the pilot does not provide insights into the long-term retention of the learned emotional skills. However, the high engagement (75% of participants) and critical fact rejection (29%) observed in our pilot suggest that the collaborative, configurable design successfully promoted active emotional deliberation, a key goal of SEL.

C. Comparison with Related Work

This study's configurable, peer-assisted storytelling model occupies a distinct niche in the landscape of technology-assisted SEL tools. As summarized in Table XI, the proposed system offers a unique set of advantages and trade-offs compared to existing approaches.

Unlike VR-based interventions like the one by Muñoz et al. [2], which offer high immersion at a high cost and technical complexity, our tool prioritizes accessibility and scalability. While VR requires significant investment in hardware and setup, our game runs on standard PCs, making it a viable option for resource-constrained environments like standard classrooms or community centers. This addresses a critical gap in making SEL technologies widely available.

Furthermore, our design differs from many serious games that focus on solo play [1, 10]. By structuring the interaction around two age groups, we explicitly leverage Vygotsky's social development theory [3], where learning is scaffolded through social interaction. The older children act as mentors, constructing the learning experience, while the younger ones benefit from this guided practice. This peer-assisted model can reduce the facilitator's direct workload and foster a collaborative learning community, an aspect often missing in solo-focused games.

Finally, the configurable nature of the system is a key differentiator. Unlike fixed-content games [11, 12], our tool allows educators to adapt stories, questions, and facts to local curricula, cultural contexts, and specific learning objectives without any programming. This flexibility is a significant pedagogical advantage, allowing the tool to remain relevant across different settings and student needs, a feature not commonly emphasized in other serious games.

The primary practical implication of this design is its facilitation of peer-mediated learning. By enabling older children to scaffold emotion education for younger peers, the system can reduce the direct workload on teachers and therapists while fostering a collaborative classroom environment. Furthermore, its low-cost, PC-based design directly addresses resource gaps in schools, making effective SEL tools accessible where expensive VR setups are not feasible. Educators can leverage this configurability not only to adapt stories to local curricula but also to establish cross-age mentorship programs, positioning older students as 'emotion coaches'.

In conclusion, the novelty of this work lies not in a single technological breakthrough but in the integrated design approach that combines configurability, a structured peer-assisted learning model, and a low-cost, scalable implementation to address practical challenges in SEL education.

This approach yields several key advantages over more technologically complex interventions like VR-based SEL tools [2]. As detailed in Table XI, our tool's primary strength is its cost-effectiveness and scalability, eliminating the need for expensive, high-maintenance hardware and making it viable for low-resource settings. Pedagogically, it leverages Vygotsky's social development theory by structuring peer-assisted learning, which our pilot study suggests fosters deeper cognitive engagement, as evidenced by the 29% fact rejection rate. Furthermore, the design offers greater safety and inclusivity, avoiding issues like motion sickness and being potentially more suitable for neurodiverse children who may find full VR immersion overwhelming.

While VR offers unparalleled immersion, our configurable storytelling game provides a complementary, accessible pathway for deploying SEL tools at scale. Future work will be necessary to quantitatively benchmark its efficacy against such VR benchmarks in larger, controlled trials. These key differentiators are summarized in Table XI.

TABLE XI. COMPARISON: PEER-ASSISTED STORYTELLING GAME VS. VR-BASED SEL TOOLS

Feature	Our Storytelling Tool	VR-Based SEL Games (e.g., Muñoz et al., 2022)
Cost	**Low**: Requires only a PC (C#/Windows). No specialized hardware.	**High**: VR headsets (300–1,000 per unit) + high-end PCs.
Scalability	**High**: Easily deployable in classrooms/therapy centers; configurable for new stories/languages.	**Low**: Limited by VR hardware availability, setup complexity, and space requirements.
Efficacy	**Moderate-High**: Peer-assisted learning fosters engagement (75% in pilot) and critical thinking (29% fact rejection). Supports Vygotsky's social constructivism.	**High**: Immersive VR enhances engagement and retention but risks overstimulation for young children.
Accessibility	**Broad**: Works on low-end PCs; no motion sickness risks. Suitable for ages 6–12.	**Limited**: VR unsuitable for children <10 (safety concerns); requires tech-savvy facilitators.
Pedagogical Flexibility	**High**: Educators can modify stories/questions without coding. Supports cross-age mentorship.	**Low**: Content updates often require developer intervention.
Evidence Base	Pilot study (N=4) shows feasibility. Needs larger trials.	Strong evidence for engagement but limited studies on long-term SEL outcomes.

VI. Conclusion

Serious games are proven to be useful in many education domains for children, adults, and the elderly. In this work, a serious game is developed to teach emotions through a configurable, peer-assisted storytelling system. A pilot study using "The Ugly Duckling" fairy tale demonstrated the system's feasibility and its ability to foster engagement and critical thinking in young children, as evidenced by high interaction rates and active fact verification. The results indicate a promising foundation for using this tool in social-emotional learning. Future work will focus on conducting larger-scale trials with more subjects and control groups to establish statistical significance. Additionally, testing in diverse cultural contexts is planned, with upcoming evaluations in a Romanian pre-school using localized stories.

Leveraging AI and ML for Enhanced Business Intelligence Systems: A Research Landscape of Trends, Influences, and Future Directions

Sunil Mandaliya[1], Priti Kulkarni[2]
Symbiosis Centre for Research and Innovation, Symbiosis International (Deemed University), Pune, India [1]
Symbiosis Institute of Computer Studies and Research, Symbiosis International (Deemed University), Pune, India [2]

***Abstract*—This research provides a systematic review of AI and ML applied to the BI context from 2014 to 2024. By characterizing the article and citation distribution and by tracing the topics of publications over time, this study outlines major developments, landmark contributions, and the future outlook of the research discipline at hand. However, despite rapid advancements, existing research remains fragmented. It lacks a consolidated understanding of how AI and ML are shaping modern BI systems, creating an urgent need for an integrated review. Prior studies often examine isolated techniques or industry-specific implementations, but very few provide a comprehensive synthesis that maps long-term trends, methodological patterns, and unresolved challenges in AI/ML-enabled BI. The study reviews more than 200 research articles obtained from top academic databases and finds a rise in the integration of AI/ML with conventional BI systems. Our results show the emergence of real-time, predictive, and automotive analytics as much-needed and valuable to consumers. Artificial Intelligence strengthens the capabilities for visualizing data, so complex information becomes easier to access by those who need it. Research literature shows an increase in publications about AI and ML applications in BI systems because these technologies have gained substantial practical importance. The field of study investigates the ways AI and ML improve BI systems by paying special attention to predictive analytics as well as decision-making processes. The main aspects of interest unite advanced AI implementations with user-centric tools that serve multiple industries. Future directions for researchers are AI ethics in BI, as well as creating simple AI tools for non-programmers and investigating the influence of AI-based BI systems on different industries in the long run. This study also presents future research suggestions.**

Keywords*—*Artificial intelligence; machine learning; business intelligence; digital transformation; data analytics; bibliometric analysis

I. Introduction

Artificial intelligence, along with machine learning, has revolutionized the means by which business intelligence operates in the current business environment. Supposedly simple reporting tools of the past are gradually transforming into complex BI solutions that enable the analysis of existing and future states and make decisions automatically. This evolution marks a revolution in the way many organizations are able to utilize data as an instrument of competitive strategy.

The two technologies, AI and ML, have been adopted by BI systems to provide organizations with deeper insights, automate demanding analytical jobs, and enable them to make better decisions. Nevertheless, the growth rate in technologies highlighted, coupled with the broad presence of the technologies, makes the knowledge area quite dispersed, which needs integration for one to make sense of the current trends and the possible future direction of the technologies.

The digital revolution has become a relentless process, and industries are changing at a historic pace, supported by BI systems and are being further assisted by Artificial Intelligence (AI) and Machine Learning (ML). The use of AI and ML in BI systems makes it easier for organizations to analyze data and mine data, making it faster with more accurate. This study, therefore, employs a bibliometric analysis to understand the trends, impact, and future trajectory of AI and ML in BI systems. To achieve the purpose of the paper, the study draws a wealth of knowledge from global research, influential authors, and primary publications throughout the analysis on how AI and ML are transforming business intelligence.

As the industry continues to shift to digital platforms, more and more companies opt for data-based decision-making to gain a competitive edge and better serve their clients. With organizations today creating large volumes of data from different sources, the ability to handle, understand, and make sense of this data has become a crucial issue. Now, Business Intelligence (BI) systems assist organizations in processing the raw collected data and provide valuable information for strategic decisions are considered critical for industries. However, traditional BI systems are receiving considerable pressure in terms of capability to handle the increased data complexity and volume that are characteristic of today's business environment. Therefore, the incorporation of Artificial Intelligence (AI) and Machine Learning (ML) into BI systems is gradually turning into a revolutionary solution that helps businesses to gather additional insight, make new predictions, and optimize important business decisions that were improbable earlier.

Machine learning and artificial intelligence are two of the greatest inventions of the contemporary data-driven society, which have overlapped many businesses by facilitating automated, advanced work, pattern identification, and enhanced data analysis. These technologies provide robust solutions for firms to augment their BI systems so as to shed light on the nonlinear techniques from descriptive (what happened), to

predictive (what will happen), to prescriptive (what should happen).

The study focused on the roles of AI and ML in BI systems with the help of a bibliometric analysis of research trends and influences, and future work. The objectives of this study are to analyze the current state of AI and ML in BI systems, reveal existing trends and patterns, and predict the potential direction of the field's development.

The structure of the study is as follows: Section II covers the necessity of BI systems, AI, and ML to improve these systems, and the existing literature on the subject is discussed. Section III covers the research methodology. Section IV presents a discussion on the results and bibliometric analysis. Section V discusses the research implications with research gaps and opportunities, followed by future directions for research in Section VI. Finally, Section VII concludes the study.

II. Literature Review

A. Historical Evolution of Business Intelligence Systems

BI had its genesis in the middle of the 20th century, with little being formally known as decision support systems (DSS) used by businesses to make sound decisions based on analyzed data. DSS were, in fact, the first kind of BI systems that aimed at delivering historical information and simple analysis to the decision-makers. Nonetheless, with the growing levels of business environment complexity and the vast amount of data gathered over the years, weaknesses of traditional DSS emerged [1].

As a result of the above limitations, BI systems were developed to include enhanced tools for analysis, queries, and report generation for enhanced usability. The implementation of BI technologies had by then become a standard way of business operation in the early 2000s, especially for enterprises [2] to help them determine performance based on past occurrences. However, while these traditional BI systems have provided valuable insight, they remained mostly diagnostic in nature; that is, they told companies what had happened, but they did not tell companies what was likely to happen or even what a company should do.

The introduction of AI and ML systems in recent years has revamped the environment of BI systems. These technologies provide the prospect of performing data mining, pattern recognition, as well as prediction across large amounts of data, with a significantly higher rate of accuracy. With the integration of AI and ML into BI systems, businesses can progress beyond reporting, as well as pursue the future of analytical intelligence and augmented intelligence [3], which empowers a business to predict the future and know what is likely to happen at any given point.

B. The Importance of AI and ML for BI Systems Improvement

AI and ML have revolutionized the ways that businesses tackle the problem of data analysis. Historically, BI systems were mainly historical in their approach and essentially reactive. On the other hand, AI and ML-based BI systems actively contribute where they are programmed to make decisions and suggest recommendations out of actual data and intricate computations. This one alone is perhaps one of the most significant advantages of BI systems using AI and ML, and that is, shifting from a more reactive decision-making approach to a proactive one.

- Automation of Data Analysis: Another benefit of the utilization of AI and ML in BI systems is the possibility of delivering automation of the data analysis. With traditional BI systems, data cleaning, data preparation, and the analytical process involved a lot of manual work. However, the use of AI and ML, a big part of this process, can be done automatically, which saves a lot of time and energy. AI algorithms can effectively work on patterns, trends, and outliers in the dataset to help business organizations make an informed decision-making process effectively and rapidly.
- Predictive Analytics: AI and ML enhance the BI system by introducing the aspect of forecasting with reference to the previous events within a business. This capability is especially ideal in industries including finance, retailing, and healthcare since the accurate prediction of requirements will offer big financial savings and a competitive advantage. For instance, in the retail sector, businesses can apply predictive analytics to predict customer traffic rates, manage inventory, target the right customers, and segment marketing campaigns, while in the healthcare industry, patient prognoses and medical interventions can also be predicted.
- Personalization and Recommendation Systems: Apart from predictive data mining, AI and ML help to create complex recommendation systems to facilitate user-specific client experiences. Such systems have been widely employed in retailing, entertainment, and social networking sites to target bands of products, media, and services, respectively. In terms of BI, recommendation systems help to guide users to useful, informative components or reports about their issues and to recommend certain crucial actions to business leaders.
- Real-time decision-making: One of the most important benefits of using AI and ML in the BI systems is to deliver real-time processing and analytics. Legacy BI systems had major shortcomings in that analysis was executed on a set time interval, which would slow down the actual decision-making process. Real-time analysis of data can be done using AI and ML algorithms, which would mean that businesses can be ready and willing to respond to dynamic conditions. This real-time in fact a key strength of the tool, especially when it comes to Fortune 500 Industries such as finance and logistics, where timing is everything.
- Anomaly Detection and Fraud Prevention: AI and ML are also most efficient in the aspect of searching for anomalous patterns in big data. Fraud detection is especially relevant in industries that require special attention, such as banking and insurance businesses. BI systems based on AI, that work on transactional data, allow identifying fraudulent transactions shortly after their occurrence and notifying businesses about such actions.

- Enhanced Data Visualization: AI and ML also assist in improving data visualization in BI systems because they can generate visualization that focuses on key trends. Historically, BI technology systems, for example, required users to independently build charts and graphs, thus making the processes both slow and error-laden. With the use of AI tools for data visualization, users are able to create a visualization that contains accurate information, and it is insightful to the client for easy issue comprehension by businesspeople.

C. The Growing Research on AI, ML, and BI Systems

In recent times, with the developments in the nature and capabilities of AI and ML technologies, there is commensurate interest in investigating the integration of these technologies in BI systems. Various lines of research by both academia and industry are currently being exercised in different areas of this integration, some of which are the basic algorithms for such integration, the influence of AI and ML in decision-making systems, and ethical considerations in the integration of AI in decision-making [4].

The additional thematic shift that is gaining popularity now is the integration of XAI into BI systems. With increasing levels of complexity in AI and ML, there is an increasing demand for the audibility of the decisions. XAI is designed to clarify the work of AI in making decisions and to make it possible to gain the confidence of business executives in BI systems based on artificial intelligence.

Furthermore, the integration of AI and ML with other new technologies like blockchain and IoT enhances the highly effective BI system. These systems can revolutionize industries by offering real-time information from connected products, ensuring information credibility from a blockchain system, and enabling decision-making from an AI/ML system.

D. Research Objectives

This study aims to:

1) Discuss the development of AI and ML in BI systems using bibliometric analysis

2) Characterize major areas of concern for research and how they relate to each other

3) Reflect on the roles of prominent books and their authors in defining the field

4) Identify new directions that are possible in a given field.

5) Herein, systematic research gaps will be identified, and directions for further research will be presented.

E. Significance of the Study

This research contributes to the existing body of knowledge by:

- Detecting the provenance of works and their further development
- Emphasizing trends in the present and the future opportunities to explore
- As a textual analysis, the findings should be useful to practitioners or individuals interested in the particular topic and for researchers who may employ of similar research methodology.

F. Theoretical Framework

The study [5] uses bibliometric analysis and topic modeling to explore the connection between AI and SD research within the business and management landscape. The authors found that while SD and AI are relevant in their respective areas, there are intersections concerning topics such as decision-making, project management, knowledge management, forecasting, supply chain [6], and risk management. The researchers acknowledge some limitations in their methodology. First, using only Web of Science data might not capture the full breadth of research. Second, focusing solely on paper abstracts for bibliometric analysis may omit valuable information contained within the full text, particularly the conclusion sections. To address these limitations, future research could expand the data sources and analyze the conclusion sections of papers, potentially including full-text analysis for a more nuanced understanding [5].

The authors of [7] present a systematic literature review on the application of AI in circular business model innovation. After having removed duplicate items, conference proceedings, and incomplete entries, and by conducting title and abstract screening, the Scopus and Web of Science databases resulted in 145 studies to be examined at this stage. The authors include as many studies as possible at this stage; even technical papers were considered.

The study by [8] discusses issues related to influencing AI-employee collaboration. Methodology of the study comprises a literature review of AI-employee collaboration, identification of knowledge gaps, integrating AI management literature with existing theoretical frameworks, KBV, STS, and OSF, designing an AI-employee collaboration model, and testing the constructed model based on data from UK creative industry managers. The authors in this case have used SEM while analyzing data that would establish causality within the proposed model.

The research [9] is a systematic literature review on the nexus between AI and business model innovation. Aiming to bridge the gap of little research on managing AI-driven business model innovation, through a comprehensive search in four electronic databases, their data collection was in English-language articles published before 2023. The duplicates were removed, and quality filters were placed in terms of ranking journals like VHB, JCR, SJR, among others. After this, the number of articles went down to 649. Narrowing down through selection based on title, abstract scopes resulted in 233 articles. Full-text eligibility assessment resulted in the final inclusion of 167 articles, and 9 more were added with cross-referencing to make a total of 180 articles to be reviewed. The analysis involved summarizing key findings in Microsoft Excel and coding publications using MAXQDA qualitative analysis software. This coding involved open, axial, and selective coding, resulting in 2,413 coded segments and 170 initial codes. The researchers used XMind to compare, analyze, and discuss findings, ultimately identifying 117 first-order terms, 32 second-order themes, and 6 aggregated dimensions. The study acknowledges limitations, including the potential exclusion of relevant non-English literature and potential bias due to the

selected keywords and databases. However, the authors argue that focusing on high-quality journals within the management literature strengthens the rigor of their findings.

The study [10] examines artificial intelligence task delegation (AITD). The research design includes a literature review on AITD, formulation of research questions, methodological choices, results analysis, discussion of implications, limitations, mitigation strategies, and a future research agenda.

In [11], the authors examine the historical connection between decision support systems (DSS) and business intelligence and analytics (BI&A). The authors argue that although BI&A is inherently a subfield of DSS, it has become disconnected from foundational DSS research. To demonstrate this, the researchers conducted a systematic review of foundational DSS articles and the corresponding BI&A literature that cited them. They identified 271 DSS articles published from 1970 to 1991 and found that only 29 of these seminal DSS papers were cited in 44 unique BI&A articles. The researchers classified DSS research into four categories: conceptual frameworks, design and implementation, business value and organizational use [12], and cognition and decision making. They then analyzed how BI&A articles utilized and cited the DSS articles within each category. This classification helped identify research gaps in BI&A where the connection to DSS research appears to have been lost. The researchers also collaborated with practitioners to develop a BI&A framework, mapping it to classical DSS components to create a comparative, process-level architecture for converting data into insight. This integrated architecture aims to reconcile the two research streams and highlight the value of revisiting foundational DSS research for contemporary BI&A applications.

The study [13] uses a multiple case study approach to investigate AI-driven digital transformation in five manufacturing SMEs within a shared hub context. While the authors acknowledge that this specific context might limit the generalizability of their findings, they argue that the results are applicable to similar contexts. However, this also means that AI-based digital transformation transcends industries [14]. Future studies can take the direction of focusing on industries other than manufacturing-for instance, B2C-and explore the orchestration of AI resources in AI implementation through such industries.

The study [15] is a systematic literature review (SLR) report on the applications of AI in improving SCRes. Prior reviews just made mentions of abstract concepts regarding AI and SCRes without elaborating on how AI techniques improved SCRes, hence coming to fill the gap in this study. The study bridged that gap with the use of the PRISMA methodology. An automatic search with keywords in AI and SCRes in Scopus yielded 824 articles, which after deduplication, gave 799 articles. Their language, date of publication within the scope of 2010 and 2022, and peer-reviewed narrowed them down to 425 articles. Abstracts and conclusions were read to gauge the relevance of articles to AI techniques and SCRes antecedents and 302 articles remained. All relevant articles were read in full-text and additional records in Google Scholar, together with their citation references, revealed the final sample of 106 articles to be analyzed to understand how AI techniques could potentially be applied to enhance SCRes. This included those AI techniques used, their inherent capacities, and how these had changed the antecedents and phases of SCRes.

The most occurring keywords had been discovered to include supply chain, resilience, risk management, and machine learning. Such keywords indicate research focus on handling the disruptions in a supply chain through resilience and risk management but with AI, especially machine learning, as emerging tools. On the same note, the researchers demarcate the dominating incidence of some journals and authors in the AI-SCRes field.

The systematic review [16] focuses on AI algorithms and decision support tools for predicting and preventing pressure injuries (PIs). The authors conclude that, up to date, there have been very few reviews that merged AI and DSS in the prediction or prevention of PI. The authors narrow down the scope using the PRISMA-DTA guidelines by English language publication that utilizes AI and ML algorithms or DSS for PI prediction and prevention. In the search, 107 papers were found; however, 82 were excluded because of a lack of focus on AI or DSS for the prediction and detection of at-risk patients or in giving PI prevention suggestions. The paper was made in computer vision applications and excluded those that do not use EHR to predict HAPIs.

The paper [17] performs a scientometrics analysis on the performance, collaboration dynamics, and impact of scholarly publications on AI applications. Reviewing 3767 reviews cited 63,577 times, the paper signifies significant scholarly engagement within AI research. They used indices that quantify collaboration; these involve the number of contributing authors, (NCA), average authors per co-authored paper AACA, collaboration index, CI, and collaboration coefficient, CC. Several such indexes were also utilized to scrutinize citation, among which were the h-index, g-index, and i-index to calculate the review articles.

In this regard, the paper [18] conducted a bibliometric analysis of the literature published between 1990 and 2021. The paper discussed using AI in innovating B2B marketing. The present study had set out to address some of the challenges scholars pose while trying to keep up with the tremendous growth in research in the area. Conceding the fact that the current approaches to systematic reviews such as the structured literature review and meta-analysis impose constraints in the management of large volumes of research, the authors assert the suitability of bibliometric analysis. What is used for it is the method in order to find out the significant research areas, authors and journals, and the further research opportunities.

From the five domains discussed in the study, the research outlines trends and possible future development of AI in B2B marketing innovation in each of the domains. Through a meta-analysis of citation data, as well as content analysis, the researchers provide an extensive discussion of the state of the field and potential directions for future research.

The study done by [19] give a comprehensive review of AI in marketing environment. The reviews and meta-analyses, the authors argue for the effectiveness of bibliometric analysis in handling the vast quantity of research. They use this method to

identify prominent research domains, influential authors and journals, and future research directions.

Recognizing the importance of AI in future developments of technologies, this work [20] examines the impact of AI on business and economics publications with the use of a bibliometric approach. The two databases chosen by the researchers are Web of Science (WoS) and Scopus databases, as these are two of the most reliable and full-coverage sources of the peer-reviewed research literature. They use VOSviewer software to construct the diagrams of co-citation and keywords, with respect to the direct citation relation that is used to define the relatedness of the publications fast.

The study [21] aims to review the role of AI together with the existence and relevance of big data in decision-making. In their work, the authors focus on the lack of literature with a focus on the definition of the new generation of technologies as applications of AI. They map the trend of publications on AI in the Big Data context and note increased attention to this topic since 2011.

A systematic literature review (SLR) [22] aims to perform to analyze the findings of prior studies revolving around AI and innovation. The researchers opted to use SLR because it is able to provide objective findings and conclusions. For this purpose, they entered the keywords including AI and innovation in both Scopus and WOS databases and used filters like Documentary language, Document type – Article and Review paper only, subject area – Business, Management and Accounting, Decision Science, Economics, Econometrics and Finance. They were able to screen out 266 duplicates, and their final sample size amounted to 1448 articles. The researchers screened and sorted the data to determine the most frequent authors and publications, current and emerging themes, theoretical frameworks, and research methods employed in the field. They also identified the patterns of research activity to establish gaps in knowledge by conducting a bibliometric study.

The study [23] aims at investigating the process by which BDA connects with performance by employing bibliometrics. To this end, the authors endeavored to explicate the historical development and current state of affairs in this domain and highlight research prospects.

To avoid a systematic bias in the review, the authors emailed potential 47 BDA and performance experts based on their suggested keywords and ISI Web of Knowledge database. They then used minimum citation rate, and got 1252 second-generation papers for inclusion in the analysis. The researchers then conducted three bibliometric analyses: Document co-citation analysis, algorithmic historiography, and bibliographic coupling formed important components. The study found 10 research themes within the BDA-performance field, starting with a large, fundamental BDA cluster, moving up to more specific areas such as customer analytics and corporate social responsibility research. Studying the literature, the two major evolutionary developments were identified that employ statistical and algorithmic approaches to finance and customer-orientation streams within BDA research.

In fact, the present paper [24] is devoted to the analysis of DI&A, BD, AI, HAI in the context of the public sector considering the effectiveness of decision-making. The authors review 161 papers in English published between 2007 and 2021 in Web of Science (WoS), Scopus, and Google Scholar (GS) databases using VOSviewer. The authors intend to present an introduction to the field, reviewing subjects of interest, citation practices, publication pathways, and collaboration maps and finally, pointing to possible research agendas.

The research of this paper [25] aims at identifying the trends of big data and predictive analytics in BI using bibliometric analysis with CiteSpace on 681 non-duplicate research papers collected from WoSCC and Scopus. More specifically, the authors select contributing countries/institutions, authors/journals, research mapping trends, cross-disciplinary, and the evolution of new hotspots. The study will endeavor to offer a broad perspective of the area and should consequently be beneficial to guide future research endeavors into big data and AI-driven BI applications [26].

The author [27] focuses on examining the AI and blockchain synergized business applications techniques based on bibliometric content analysis. To achieve that, the analysis of 106 articles identified in Scopus is conducted to reveal the general publication trends, the most popular and impactful works, the main research topics and directions, and the potential application fields. The researchers start by pointing out that despite the growing trend of applying AI and blockchain technologies in business, there is a dearth of impartial post-mortems of the combination of both technologies. They then use VOSviewer and Gephi for data analysis, where they make a network or word cloud to display information in the form of a network view for representing relations or a word cloud view for representing important keywords, respectively.

The study [6] examines the role of AI and ML in SCM using bibliometric and network analysis of 338 highly cited papers indexed in the Scopus database between 2002 and August 2022. In other words, the research objective of the study is to discover innovative opportunities and comparatively unknown areas for AI and ML application in the process of supply chain digitalization.

Systematic review of AI in cellular networks [28] shows that machine-learning agents deployed across design, operation and optimization consistently improve core KPIs - blocked-call and hand-off rates, signal quality, latency and throughput - yet most studies still optimize each metric in isolation and struggle with cost-effectiveness.

The authors claim research demands a more profound evaluation of AI and ML effects in SCM, considering that previous reviews have addressed these subjects separately or involved only a limited number of articles. The researchers apply analytical and computational methods to find out publication trends, authors, prominent journals, and topics. Their study comprises of qualitative data analysis, an analysis of the literature by computing the bibliometric analysis, and network representation for the comprehension of concepts like AI and ML regarding SCM.

Enterprise Management Systems (EMS) is considered a vital business function for ensuring business continuity; it should exploit the power of AI and analytics to assess risks more

significantly. In the paper [29], the design of an Improved Metaheuristics with Deep Learning Enabled Risk Assessment Model, IMDLRA-SES, that comprises business risk selection and deep learning-based prediction has been aimed at producing superior accuracy on credit datasets up to 95.70% and 96.09% levels against traditional financial risk identification methods with robust firm stability for longer periods.

The conjunction of AI, big data, and IoT in the amalgamation of Society 5.0 has triggered and changed the face of 'the new' personalized customer engagements related to Marketing 5.0. The paper [30] delves into a literature review to discuss predictive modeling in the context of sentiment analysis in Marketing 5.0, thus providing for a case of a model that can be based upon sentiments to improve the process of the buyer's journey. It draws attention to the importance of predictive and sentiment analysis to emphasize their critical roles in fine-tuning customer experience and improving marketing efficiency [31]. The review identifies gaps in existing research, documents the evolution of marketing, and analyzes AI's transformative role using the Prisma-P methodology.

For inventory management, this study proposes a machine learning-driven model, especially for demand-based stock control, particularly for perishable and deteriorating products in uncertain settings. The model [32] accounts for fuzzy variables like degradation rates, optimizing ordering cycles and inventory levels while holding costs at minimum, reducing both costs of carbon usage and emissions. Seasonal demand forecasting improves predictions associated with deteriorating items further; comparative analysis shows how AI-enhanced forecasting provides a better forecast than fixed demand models. Sensitivity analysis guides managers on when to adjust the inventory.

Advanced digital technologies, AI, machine learning, and blockchain in logistics are revolutionizing multimodal transportation systems with objectives of greater efficiency and sustainability. The technologies identified in the review [33] are critical enablers for smarter logistics, new business models, and environment-friendly solutions. Yet, these technologies impose policy and practical implementation challenges; their promotion improves the sector's overall sustainability in its environmental, economic, and social dimensions.

Besides this, AI and machine learning-based business intelligence systems enable the integration of data and assist organizations in trend identification and decision-making. Using a machine learning-based framework to analyze the network management for BI, the research [34] analyzes BI through a multiagent Markov probabilistic reinforcement model. By analyzing such parameters as accuracy and packet delivery, the research works toward optimizing business processes by leveraging AI-driven solutions for firms to make the appropriate technology choice for automated process management. Table I summarizes the key studies reviewed and highlights the specific advantages and research gaps identified across prior work.

TABLE I. GAP ANALYSIS

Study	*Advantages*	*Gaps*
Armenia et al. (2024)	Bibliometric analysis and topic modeling uncover intersections between AI and SD in business topics like decision-making and knowledge management.	Expansion of sources and inclusion of conclusions/full-text analysis suggested for deeper insights.
Madanaguli et al. (2024)	Comprehensive SLR on AI in circular business models, using Scopus and WoS databases with careful screening of duplicates and incomplete entries.	Limited focus on abstracts and titles may omit depth; inclusion criteria could miss recent or highly specialized works.
Chowdhury et al. (2022)	AI-employee collaboration model designed and tested in UK creative industry; methodological rigor with SEM for causality.	Focused on the UK creative industry, limiting broader applicability. Further studies could examine diverse industries.
Jorzik et al. (2024)	Systematic literature review with high-quality journal filtering and robust coding for AI-driven business model innovation.	Non-English articles excluded, risking language bias. Expansion beyond English sources is suggested.
Recupito et al. (2024)	Research design includes a systematic review of AI task delegation with future agenda.	Limited by focus on literature review only. Empirical validation of proposed insights could enhance applicability.
Phillips-Wren et al. (2021)	Systematic review connecting DSS and BI&A; provides a framework reconciling the two fields.	Analysis of limited citation connections between DSS and BI&A; a broader dataset could strengthen the findings.
Peretz-Andersson et al. (2024)	Case study approach on AI in SME manufacturing for digital transformation; context-specific findings with possible similar applications.	Limited generalizability beyond manufacturing SMEs. Calls for studies in B2C and other sectors.
Kassa et al. (2023)	PRISMA-based SLR on AI in SCRes, identifying AI's role in enhancing SC resilience.	Limited to abstracts and conclusions in selection; additional full-text analysis could add depth.
Toffaha et al. (2023)	Systematic review of AI-DSS tools for predicting and preventing pressure injuries, narrowed with PRISMA-DTA.	Narrow focus on EHR data and specific algorithms may limit generalizability to non-EHR settings.
Raman et al. (2024)	Scientometric analysis of AI research, measuring collaboration with indices like h-index and g-index.	Limited analysis on the context of collaboration, lacking qualitative insights on collaboration dynamics.
Han et al. (2021)	Bibliometric analysis of AI in B2B marketing identifies trends and research opportunities.	Constrained by limitations in SLR/meta-analysis for managing large research volumes; broader approach could address data complexity.
Ruiz-Real et al. (2021)	Uses VOSviewer for bibliometric analysis on AI's impact in business/economics; strong visualization of co-citation and keyword trends.	Limited to two databases (WoS and Scopus), potentially omitting broader literature.
Haleem et al. (2022)	Systematic review on AI in marketing; uses bibliometric	Limited by scope in foundational areas of AI marketing; further

Study	Advantages	Gaps
	analysis to identify key domains and future research.	studies could delve into niche areas.
Duan et al. (2019)	Focuses on the roles of AI and big data in decision-making, providing historical context and research mapping.	Over-reliance on certain databases might miss emerging, non-mainstream studies.
Dwivedi et al. (2023)	SLR on AI and innovation with extensive keyword screening and rigorous sampling.	Excludes non-English articles and industry-based insights; future studies could consider these aspects for more generalizable findings.
Batisti and van der Laken (2019)	Bibliometric analysis on BDA and performance, identifying 10 thematic clusters.	Exclusion of expert insights might limit a comprehensive understanding of practical implications.
Di Vaio et al. (2022)	Analyzes AI and big data in public sector decision-making with bibliometric tools like VOSviewer.	Excludes newer and potentially relevant non-peer-reviewed sources; industry focus may add practical value.
Chen et al. (2022)	Identifies trends in big data and predictive analytics in BI with CiteSpace for cross-disciplinary analysis.	Limited by database constraints; could be expanded to cover emerging research not indexed in WoSCC and Scopus.
Kumar et al. (2023)	Examines AI and blockchain in business applications with VOSviewer and Gephi for data visualization.	Limited to Scopus database; expansion to other databases could enhance robustness.
Rana and Daultani (2023)	Uses network analysis on AI in SCM, identifying research gaps in AI's role in supply chain.	Limited to Scopus database; broader inclusion criteria could cover more diverse studies.
Katib et al. (2024)	Introduces a deep learning-enabled model for risk assessment in enterprise management systems.	Limited validation on credit datasets; testing on diverse datasets could prove robustness.
Gooljar et al. (2024)	Literature review on predictive modeling for sentiment analysis in Marketing 5.0; identifies gaps in customer engagement.	Limited empirical evidence; further empirical studies could substantiate claims.
Namwad et al. (2024)	Proposes a machine learning-driven inventory model for deteriorating items, addressing demand forecasting.	Limited to specific product types; wider application for various industries suggested.
Fareed et al. (2024)	Systematic review of AI, machine learning, and blockchain in logistics; identifies sustainability challenges.	Limited focus on practical implementation barriers; case studies could address industry-specific issues.
Wu and Qin (2024)	Analyzes BI through a multi-agent probabilistic reinforcement model, optimizing network management for BI.	Limited focus on a single framework; future research could consider multiple AI frameworks for BI management.

III. Research Methodology

A. Data Collection

This research aimed at including only the recent developments, which is why only articles published between 2014 and 2024 within the scope of peer-reviewed journals were considered. Four primary academic databases were consulted for a comprehensive literature review: Web of Science, Scopus, IEEE Xplore and ACM Digital Library. These databases are indeed popular sources in the field of technology and data science and mostly contain research papers of good quality which are peer-reviewed. Through these databases the study was able to ensure that the literature reviewed was not only valid but also current in its subject of discussion which is focused on AI ML applications in Business Intelligence (BI) systems.

Various article search terms were employed for this study, wherein the main keywords are Artificial Intelligence (AI) and Machine Learning (ML) in conjunction with Business Intelligence. In this particular research, the author conducted the following search: “Artificial Intelligence” AND “Business Intelligence,” “Machine Learning” AND “Business Intelligence”, “AI” AND “BI Systems”, “Predictive Analytics” AND “Business Intelligence”. These kinds of search terms helped in carrying specific search as it guaranteed that only the studies on integrating AI and ML in BI systems were retrieved. This systematic approach allowed the research to capture a set of literature that maps out the historical development, trends, and future development of AI and ML for improving BI, and their impact on predictive analytics and decision-making in organizations.

B. Data Analysis

Advanced tools were adopted for the mapping of research landscape related to AI and ML in BI: for instance, the bibliometric analysis adopts a couple of advanced tools that enable it to make visualizations for the network of the authors, institutions, and certain key themes to enable bibliometrix (R package) in facilitating the analysis of proper statistical measures towards metrics and trends of citation and other indicators of the publication. It facilitates looking into the productivity and researching trends by indicating the research impact in terms of trends. This could allow CiteSpace to map emerging topics and shifts through the years, which would emphasize research bursts and pivotal developments in AI and BI across the last decade. Both resulted in a complete outline of where the field has evolved and with what influences.

C. Analysis Parameters

The following parameters were analyzed:

- Publication trends
- Citation patterns
- Author collaborations
- Keyword co-occurrence
- Thematic evolution
- Geographical distribution

IV. Results and Analysis

A. Publication Trends

The analysis reveals a significant increase in publications related to AI and ML in BI systems over the past decade. The number of publications has grown exponentially, with a particularly sharp increase observed from 2019 onwards.

The yearly trend for research publications related to "AI and ML for Enhanced Business Intelligence Systems" between 2015 and 2024 is presented in the chart. There has been a gradual increase starting from around 2015; interest in the topic has gradually built up. The number continued to rise upward; by 2019, there was a marked spike when the publication surpassed 500 in 2023. The publication count decreases in 2019 and grows steadily again in 2020, indicating renewed and increasing attention paid to the application of AI and ML in business intelligence. From 2020 through to 2024, growth trends continue, showing the extension of commitment to research related to the application of AI and ML in business intelligence. Presumably, this is a direct result of the evolution and importance of these technologies and their role in strategic business decisions. From 2024 is expected to follow upwards, and it is believed that interest and output research in this field will increase. This trend (see Fig. 1), therefore, demonstrates the significance of AI and ML in the developing environment of business intelligence and predictive analytics.

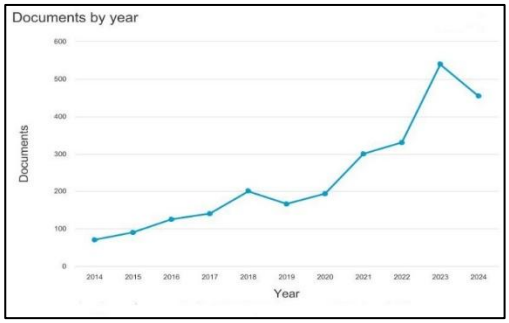

Fig. 1. Publication trend.

B. Inclusion and Exclusion Criteria

To ensure the scientific quality and relevance of the review, clear inclusion and exclusion criteria were applied. The workflow of the study is represented in Fig. 2.

Inclusion criteria were:

1) Peer-reviewed journal articles published between 2014 and 2024.

2) Articles written in English.

3) Studies explicitly examining the use of AI and/or ML within Business Intelligence, decision support, or data-driven analytics.

4) Articles providing sufficient methodological detail to support bibliometric or thematic analysis.

Exclusion criteria were:

1) Conference abstracts, Thesis, books, editorials, and non–peer-reviewed material.

2) Studies focused purely on algorithm development without BI relevance.

3) Articles lacking adequate methodological information.

4) Duplicate records across databases.

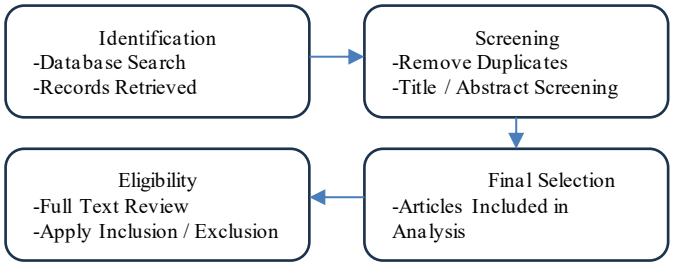

Fig. 2. High-level workflow of the study selection and review process.

C. Citation Analysis

This is a co-authorship network visualization, generated using VOSviewer. This tool is widely applied to map and visualize bibliometric networks.

Node Representation: In a node, an author is represented. Larger nodes mean more publications or citations from authors, depending on what you have selected while running VOSviewer.

Color Code: A color reflects the number of authors who co-authored under this color group and had a high probability of collaborations in the given color. For example, in red, there are more co-authorings of Andreja Pucihar and Doroteja Vidmar between themselves, but less frequently with the rest of the authors under all other colors. Edges, or Links: Lines describe co-authorships; bold lines illustrate more and denser co-authorships within the interlinked authors.

Clusters: The network has been divided into some clusters, each normally formed by a group of collaborating authors who are working within their cluster more intensively than with other members in this network.

Co-Authorship Network Interpreted: This co-authorship network indicates authors who closely collaborate, probably due to similar research interests, physical location, or institutional ties. This may be useful in determining influential authors and the structure of collaboration within this community of scholars.

This visualization, here in Fig. 3, gives insight into the collaborative patterns among the authors, which helps explain the relationships and potential influence of the field represented by this work.

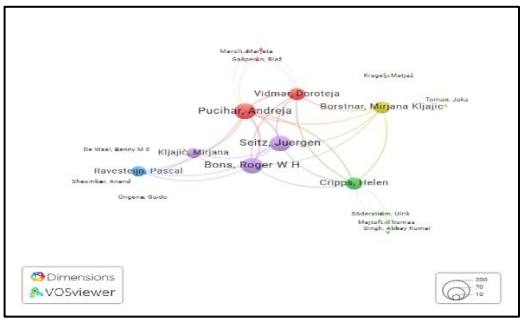

Fig. 3. Citation Analysis.

D. Thematic Analysis

Fig. 4 also shows the distribution of the documents by subject area, revealing the broad areas of interdisciplinary research interest. Computer Science is the most popular specialized area, which comprises 34.7% of the overall announcements; thus, the sectors, including software development, machine learning, and artificial intelligence, are highly developed. Engineering subsequently at 18.6% – meaning applied sciences and technology, and often overlapping with Computer Science in areas of interest as systems and robotics. Computer Science, Information Systems and Technologies, and Engineering each take 9.5% followed by Mathematics at 8.5% and Decision Sciences at 8.3% which are critical in processes that support data science, algorithms, and analytics that form the basis of most technologies. Business and Management (6.2%) is also significant, as there seems to be concern with the ramifications of technological development on organizations and the economy, including issues like managerial innovation and strategic management of technology. Social Sciences (3.8%) offers comprehension of social effects that the technology has, interactions between humans and the technology, and some ethical issues regarding technology advancement.

In terms of the fields of study, the Physics field (2.8%), Medicine (2.6%), and Economics (2.5%) show that the research has scope in physical sciences, healthcare, and technology offerings in medical informatics, as well as in modeling the economy. Energy emerges at 3.3% indicating a focus on sustainability and energy technology, and recommending further research into sources of energy for efficiency, as well as new methods of harnessing energy. Last, there is an "Other" group, which ranges from 8.8%. It can contain such topics, which are not discussed often or are interdisciplinary, so once again, the variety of the topics reflects the density of the research. On the whole, specialization indicates dominance of Technology and its Utilization from different fields, with a proper mix of Science, Business, and Social Sciences making this research collection a Technological special ops influencing Science, Business, and the World.

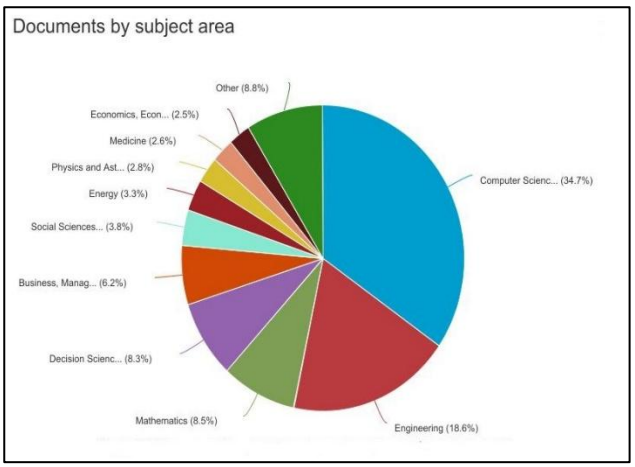

Fig. 4. Major research themes.

E. Geographical Distribution

Fig. 5 illustrates the number of research papers produced by various countries or territories. This is a horizontal bar graph displaying the document counts sorted by nation. The data highlights the comparisons of document totals across multiple countries. India stands out with a considerable lead, presenting around 700 to 750 documents, while the United States follows with about 400 documents. China holds the third position with approximately 200 documents. In the middle tier, authors find the United Kingdom, Germany, and Italy, each contributing around 100 to 150 documents. The lower tier is made up of Australia, Saudi Arabia, Spain, and Malaysia, with each registering fewer than 100 documents. The chart is structured in descending order from top to bottom, allowing for quick recognition of which countries have the highest and lowest numbers of documents. Each nation is depicted with a blue bar that stretches from the y-axis, while the number of documents is displayed along the x-axis, which ranges from 0 to 800. The research reveals significant geographical clusters of research activity.

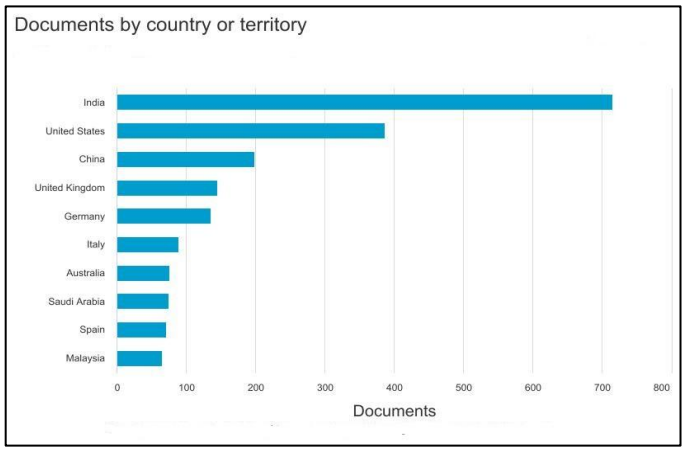

Fig. 5. Documents by country or territory.

V. Discussion

A. Key Findings

AI with ML has dramatically increased its integration within BI systems, which has led to traditional BI tools developing into more complex solutions. These solutions are able to analyze existing and forecasting data while automating decision processes [35]. Organizations can now leverage data as their competitive asset because of this advancement. Driven by AI and ML technology adaptation within BI systems, organizations gain enhanced analytical benefits that transform their decision-making processes. These technologies expanded rapidly, resulting in fragmented knowledge that needs unified handling. The conventional BI structure remains under pressure because of growing data intricacy and volume. New business decisions, as well as enhanced predictions and insights [36], can be achieved through the incorporation of AI and ML solutions. AI, together with ML in BI systems, offers businesses the opportunity to extract value from data beyond descriptions by creating analytic methods that predict and prescribe business actions [37].

Through AI and ML applications in BI systems, organizations achieve automated data analysis together with predictive processes and personalized recommendations, and real-time decisions while identifying anomalies and preventing fraud and improving visual analytics [38]. The scientific research about uniting AI and ML capabilities with BI systems shows increasing interest through studies on fundamental algorithms in combination with AI and ML [39], effects on decisions and ethical practices. XAI systems have become more prevalent because they make AI decision-making operations more understandable. Researchers are investigating how AI and ML cooperate with blockchain and IoT to advance BI systems even more.

The number of publications dedicating research to AI and ML's application in BI systems has experienced a substantial rise in the last decade, followed by a rapid escalation between 2019 and now. The research spans multiple disciplines, with Computer Science (34.7%) dominating, followed by Engineering (18.6%), and Information Systems (9.5%), showing the cross-functional nature of AI/ML in BI. Computer Science is the most popular subject area, followed by Engineering, indicating a strong focus on technology and its applications. Other fields, such as Business, Management, Social Sciences, and Mathematics, also play a significant role. India leads in the number of research documents, followed by the United States and China. Research has evolved from basic BI system enhancement to more sophisticated applications, including real-time analytics, predictive modeling, and automated decision-making. Studies consistently highlight the complexity of integrating AI/ML with existing BI systems, particularly in terms of data quality, system compatibility, and user adoption.

B. Research Gaps

Despite these advancements, several research gaps exist.

- There is a need for integration of the dispersed knowledge areas of AI and ML in BI.
- Traditional BI systems are limited in their capacity to handle increased data complexity and volume.
- There is a lack of comprehensive understanding of the practical implications of AI and ML in BI systems, particularly in the context of real-world business applications [40].
- Some studies are limited by their scope, such as focusing on specific industries or datasets, which limits the generalizability of the results.
- There is a lack of analysis on the context of collaboration within the AI research community.
- Some research has a limited analysis of the connections between DSS and BI&A, which indicates that some foundational knowledge is not being applied.
- There is a need for more empirical validation of proposed insights related to AI and ML in BI systems.

VI. Future Directions

A. Technological Advances

Future developments will likely focus on enhancing the capabilities of AI and ML in BI to move beyond descriptive analytics to predictive and prescriptive approaches [41]. Adding XAI to BI systems improves the transparency of AI decision-making processes and makes them more auditable to users. The analysis seeks to understand fully integrated AI and ML applications with blockchain and IoT technologies to build more powerful BI systems. AI and ML developers work to establish new methods for processing real-time data and analyzing information dynamically to support reactive business choices. The productive enhancement of AI and ML systems concerns their ability to detect anomalies and prevent fraud within various corporate sectors. AI, together with ML, enables improved data visualization methods that help business users obtain a clear understanding of their insights. Companies need to progress their development of AI models and ML algorithms to enhance prediction and forecasting capabilities.

B. Research Opportunities

- Additional study must be conducted to understand how AI and ML affect BI application practices throughout different industries and business circumstances.
- A thorough exploration of ethical factors must be conducted regarding AI and ML's usage in decision-support systems.
- The investigation of AI-human intelligence teamwork for better business decisions requires additional study.
- Studies must focus on determining optimal procedures for managing AI-based business model implementation processes.
- Research calls for ongoing analyses that trace AI and ML's effects on business model generation and business output improvement.
- Exploration of AI and ML applications to improve supply chain resilience.
- Further studies are needed to delve into niche areas of AI marketing
- More research is needed to understand the impact of AI on B2B marketing.
- Research on the applications of AI in the public sector.

C. Practical Implications

- Companies achieving competitive leadership through data analysis enhancement and decision-making improvements should invest in AI and ML-based BI systems.
- Business organizations must employ AI and ML for automatic data analysis because this practice reduces operational costs and increases operational efficiency.
- Through AI, as well as ML, predictive analytics companies achieve better inventory control and customer traffic management and market targeting support.

- Businesses that implement AI and ML technologies will enhance their customer satisfaction with personalized recommendation systems.
- Organizations must employ real-time analysis technologies for their market-sensitive operations.
- Organizations using AI-based business intelligence systems gain more effective abilities to find and stop fraudulent activity.
- Organizations need to implement AI-programmed data visualization tools that enhance the visibility of intricate dataset information.
- The workforce of companies must undergo training to enhance their capabilities of understanding and implementing AI and ML-based BI systems.

D. Overall Trends and Evolution

The implementation of AI and ML within BI systems produces substantial changes from static reporting to predictive and prescriptive analytics systems. The approach of traditional BI consisted of descriptive analytics for past data analysis, yet AI-pushed BI specializes in future trend prediction and decision-making proactivity [35]. Organizations now use AI and ML to analyze data better and detect unique patterns along with trends between variables that traditional methods fail to reveal [42]. The business environment drives the transformation because organizations need to manage growing data complexity and volume [43].

VII. Conclusion

This study offers three main contributions. First, it summarizes the existing research about AI and ML for the field's development in the past decade. Second, through the bibliometric approach, it represents the trends of AIML research. Third, it presents future research directions.

A. Research Implications

Research demonstrates that AI and ML have grown fundamental to improve business intelligence systems because it delivers extensive knowledge about the field's development throughout the past decade. The research study offers an extensive summary that details fundamental patterns alongside influential experts, while describing main subject areas and indicates areas where additional study can be conducted next. These findings benefit experts working with BI systems in addition to scholars who work with AI and ML integration for BI systems. According to this research, investigators proved that Business Intelligence moved from initial reporting functions towards developing sophisticated systems capable of delivering predictive and prescriptive capabilities essential for business success. After 2019, the number of publications in this field has grown significantly because these technologies have become essential for strategic decision-making.

This study is constrained by its limited dataset and review scope, highlighting the necessity for more extensive, in-depth, and longitudinal research to enhance future comprehension of AI-driven business intelligence.

B. Future Directions

The current research acknowledges several methodological limitations that provide clear avenues for future work. These include the study's confined scope to peer-reviewed articles within a specific ten-year timeframe (2014 to 2024) from only four major information sources, which inherently means it does not represent every published study in the field. Additionally, the analysis method employed presented constraints in fully understanding research findings in their complete context and depth, and the search criteria used had the potential to omit other essential relevant studies. The absence of detailed analysis of individual studies further limited the accuracy of the investigated results.

These limitations suggest that future research should expand the scope of the work to include better data and the analysis of full-text resources to facilitate the comprehension of the multifaceted nature of the domain. More studies are also recommended on the application of AI and Machine Learning within Business Intelligence in other sectors and business settings, mainly focusing on the application of these technologies. Future studies should attempt to resolve the gaps already mentioned, particularly on the ethics of AI in BI and the need to cultivate the synergy of AI with human intelligence and the design of effective frameworks for its application. There is also a demand for more research on the role of AI and ML in business, particularly in the areas of data visualization and explainable AI, to improve decision-making. Finally, more would be gained from AI and ML in business through research in the form of longitudinal studies.

***Abstract*—5G and Internet of Things (IoT) wireless systems face challenges to reliable data transmission due to multipath fading, intersymbol interference, and the need for low-complexity Forward Error Correction (FEC). Conventional FEC techniques, such as Low-Density Parity-Check (LDPC) and turbo codes, provide high reliability but are unsuitable for resource-constrained IoT devices due to high decoding complexity. The aim of this study is to evaluate Multi-Threshold Decoders (MTDs) applied to Self-Orthogonal Codes (SOCs) as a low-complexity FEC solution in Orthogonal Frequency-Division Multiplexing (OFDM) and Multiple Input Multiple Output (MIMO) systems with Space–Time Coding (STC). The systems are modeled under ITU-R (Outdoor A, TU6, RA6) and 3GPP Spatial Channel Model (Urban Macro/Micro) fading environments and compared with LDPC (WiMAX, DVB-S2) and turbo codes in terms of Bit Error Rate (BER), Signal-to-Noise Ratio (SNR), decoder complexity, antenna diversity, modulation order, and throughput. Results indicate that SOC+MTD outperform short LDPC and turbo codes under deep fading while achieving reliability comparable to long LDPC codes at significantly lower decoding complexity. Min-sum refinement and approximate Maximum-Likelihood (ML) detection provide up to 2 dB additional SNR gain, and 1×3 antenna diversity reduces required E_b/N_0 by ~7 dB at BER = 10^{-5}. Higher-order modulations such as 8PSK and 16APSK achieve 1.5–2× higher bit rates with moderate SNR penalties, while Open Computing Language (OpenCL) based Graphics Processing Unit (GPU) acceleration enables a 32-fold increase in simulation speed. These findings demonstrate that SOCs decoded with MTD represent a promising low-complexity, high-reliability FEC approach for 5G and IoT physical layers.**

I. Introduction

Wireless communication systems are constantly evolving to meet the needs of society and industry for fast, high-quality transmission of large amounts of data with minimal latency and seamless connectivity for billions of devices [1]. Designers must take into account intersymbol interference (ISI) and fading, which arise due to the nature of wireless channels [2, 3].

ISI occurs due to reflections from buildings or terrain along which radio waves propagate. Delays in different signal pathways result in significant signal overlap, which leads to symbol distortion and a rising Bit Error Rate (BER). To keep up the required BER, it is necessary to accept a decreased data rate, which decreases channel capacity.

Fading can be defined as the variation of channel power over time and frequency. It leads to both constructive and destructive interference from the various possible propagation paths between the transmitter and receiver antennas. It occurs on a spatial scale comparable in magnitude to the carrier wavelength and is frequency dependent (small-scale fading). Another type of fading, which is not frequency related, is actually caused by signal attenuation with distance and shadowing by large objects such as buildings and hills. Such large-scale fading is usually taken into account in base station placement plans. Variations in signal amplitude, connection breaks, and degradation of multimedia data transmission quality are caused by small-scale multipath fading. It is aggravated in 5G networks because of the high data rates and density of mobile devices supported; the use of millimeter-wave frequencies; spatial diversity; and multiplexing [4]. When a moving Unmanned Aerial Vehicle (UAV) connects to a ground station, radio waves bounce off of the ground and other objects, causing the channel to change quickly and the Doppler shift to happen [5]. Due the Internet of Things (IoT) devices have very small antennas with limited power, they are more vulnerable to experience fading. This is especially true in crowded urban or industrial areas where inter-symbol interference is more likely to happen [6]. In wireless sensor networks, fading and inter-symbol interference make it hard to collect data because the sensors are low-power and in hard-to-reach places (like forests, underground, or inside buildings). Therefore, several types of wireless communication standards have important design challenges related to channel fading, ISI, and interference suppression.

A variety of techniques are employed in modern wireless communications to enhance signal quality and reduce fading. Among these methods are orthogonal frequency division multiplexing [7, 8] combined with diversity techniques and beamforming, spatial diversity techniques, and Multiple Input Multiple Output (MIMO) systems [9, 10]. The Forward Error

*Corresponding author.

Correction **(**FEC) algorithms are crucial in this context as they can rectify data compromised by noise, interference, and fading without required retransmission [11, 12]. IEEE 802.16m (WiMAX) [13] and EN 302 307 (DVB-S2) [14] standards employ the Low-Density Parity-Check **(**LDPC) codes with varying code lengths and coding rates. These codes, as well as turbo codes, convolutional codes, and polar codes, are required for battery-powered devices in wireless sensor networks, as they provide a balance between computational complexity and error correction efficiency [15]. In 5G mobile networks, polar codes [16] are used for control channels, for which reliability and low latency are important requirements [17, 18]. These codes are not easy to decode, but researchers are developing more effective algorithms [19].

For 6G and future communication systems, in addition to further optimization of Polar and LDPC codes, it is proposed to explore the possibilities of machine learning for adaptive coding, optimization of code parameters, and improvement of decoding algorithms, especially in dynamic and complex channels [20]. Another promising direction is the development of new code constructions, algorithms for their decoding, which will even better combine low latency, high performance, low computational complexity, optimization for hardware implementation and flexibility, compatibility with other methods of reducing fading and interference (Orthogonal Frequency-Division Multiplexing **(**OFDM), MIMO, etc.) [21, 22].

In this study, the performance of iterative decoders for Self-Orthogonal Codes (SOCs), designed based on the Massey threshold decoder [23] and known as Multi-Threshold Decoders (MTDs) [24, 25] or Multi-Stage Threshold Decoders [26, 27], is investigated for wireless networks. Previous studies of MTD performance in fading MIMO radio channels [28] demonstrated that MTDs can nearly optimally decode even very long codes with low computational complexity, providing high efficiency under such conditions.

The application of MTDs for SOCs in MIMO-OFDM wireless channels with multipath effects is examined, along with approaches to improve their performance in such environments. Additionally, aspects of their software implementation using parallel computing technologies are analyzed to evaluate their potential for 5G/Beyond and IoT applications.

However, despite the significant progress in modern channel coding, including the adoption of LDPC and turbo codes in WiMAX, DVB-S2, and 5G systems, their practical use in resource-constrained IoT and latency-sensitive applications remains limited by high decoder complexity and energy consumption. Existing research on reducing decoding complexity often sacrifices error correction performance or relies on specialized hardware platforms. Meanwhile, studies on threshold-based decoders, such as MTDs applied to SOCs, have not yet been thoroughly evaluated in real-world broadband fading channels (e.g., ITU-R, 3GPP SCM) combined with MIMO-OFDM and STC. Moreover, the feasibility of implementing MTDs on portable software platforms (e.g., OpenCL) remains underexplored. Thus, there exists a research gap in achieving both high reliability and low complexity decoding for modern wireless physical layers across diverse fading scenarios. This study addresses this gap by providing a comprehensive performance evaluation of SOC+MTD under realistic broadband channel models and by presenting a practical, software-based implementation using GPU acceleration.

The main contributions of this work are as follows:

1) A comprehensive performance evaluation of SOC+MTD decoding under standardized fading conditions (ITU-R Outdoor A, TU6, RA6 and 3GPP SCM Urban Macro/Micro) is conducted for the first time. The results demonstrate that SOC+MTD achieve BER performance comparable to DVB-S2 LDPC (16,200 bits) while maintaining up to 10× lower decoding complexity and outperform turbo codes under deep-fading by 2–3 dB.

2) The integration of SOC+MTD with MIMO-OFDM and space–time coding (STC) is investigated, showing that 1×3 antenna diversity reduces the required Eb/N_0 by approximately 7 dB at BER = 10^{-5}, and effective STC matrices for 2×2 and 4×4 configurations are identified with optimized SNR-throughput trade-offs.

3) The combination of multi-stage threshold decoding with approximate Maximum-Likelihood (ML) detection and min-sum refinement delivers additional SNR gains up to 2 dB over MMSE-based schemes, without increasing decoding complexity.

4) A portable OpenCL-based decoder implementation for SOC+MTD is developed, achieving 32× faster execution (480 Mbps) compared to CPU, and 12× faster performance relative to baseline CUDA deployments, enabling feasible real-time processing on heterogeneous platforms.

Despite the significant advances in channel coding techniques, several critical limitations remain unaddressed in prior work. First, while threshold-based decoders such as MTDs have been studied in Gaussian and AWGN channels, their performance under complex broadband fading environments, especially those combining MIMO, OFDM, and STC, remains insufficiently evaluated. Second, existing studies on SOC+MTD architectures largely lack experimental validation against established standards such as ITU-R and 3GPP SCM channel models. Third, the applicability of MTD-based solutions in resource-constrained and real-time communication systems has not been validated through portable and hardware-agnostic software implementations. Most prior implementations either rely on proprietary GPU frameworks or are constrained to FPGA platforms without demonstrating performance portability. Therefore, a clear research gap exists in the combined evaluation of SOC+MTD performance under realistic wireless propagation conditions alongside portable high-throughput decoder implementations. The present study addresses these gaps by benchmarking SOC+MTD against state-of-the-art LDPC and turbo codes in standardized fading environments and by developing an OpenCL-based parallel decoder suitable for heterogeneous systems, including embedded platforms.

The study is organized as follows: Section II reviews related work in the area of error correction schemes for MIMO-OFDM systems and their software implementations. Section III details the MTD encoding and decoding algorithms, providing a theoretical background. Section IV describes the materials and methods, including the simulation environment and experimental parameters. Section V presents the results covering the MTD performance in multipath channels (A), STC integration (B), and Graphics Processing Unit (GPU)-accelerated simulation (C). Section VI summarizes the conclusions.

II. Related Works

This section details the outcomes of a review of relevant research on improving error correction and modulation techniques to address issues such as intersymbol interference (ISI) and erasures in MIMO-OFDM wireless communication systems, with a focus on 5G and IoT applications.

Information transmitted over communication channels can be modified by noise and interference, resulting in the data received at the receiver side not matching the data at the transmitter side. To assess the reliability of data transmission, the performance of communication channels is determined by the parameters Signal-to-Noise Ratio **(**SNR) and BER, or Block Error Rate (BLER) [29]. The higher the SNR, the higher the communication quality and the fewer errors. The lower the BER, the better the quality of data transmission. Thus, the correlation between BER and SNR is inversely proportional and nonlinear. Channel coding does not change the physical SNR level of the channel. However, it significantly improves the efficiency of using this SNR. Due to its error correction capability, a channel-coded system can achieve the same BER as a system without coding, but under conditions of much lower SNR. Intersymbol interference and fading do not reduce SNR. They are additional sources of distortion that lead to an increase in BER even at high SNR. FEC schemes encode data by adding redundant bits before transmission. At the receiving side, error correction is performed by reconstructing the corrupted data based on channel code decoding algorithms. Coding methods do not change SNR, but significantly improve the relationship between BER and SNR. They allow achieving much lower BER at the same SNR level, which makes communication more reliable and efficient.

Channel codes have been developed to an advanced level in ensuring the fidelity of modern wireless communication systems. The evolution of forward error correction techniques aligns with the evolution of mobile communication systems: from simple convolutional codes in 2G to more robust turbo codes used in 3G/4G and finally special classes of LDPC and polar codes used in 5G. The primary task at hand is about discovery and fine-tuning applicable solutions related to massive MIMO, OFDM systems focusing on fast as well as efficient software plus hardware implementations of encoders together with decoders capable of meeting required performance.

Turbo codes, LDPC, and polar codes were simulated under MATLAB by the authors in [30] to show performance estimates for these codes under the effects of intersymbol interference. It was a simulation of a channel model with binary phase shift keying Binary Phase Shift Keying (BPSK) and additive white Gaussian noise (AWGN). Two types of equalizers at the receiver front end were used by the researchers to mitigate the adverse effects due to ISI: ZF equalizer and Minimum Mean-Square Error (MMSE) equalizer. Simulation results indicated that iterative LS estimation of channel pulse response improved the performance of all three codes - LDPC codes, polar codes, and turbo codes within the operational SNR range. The LDPC codes proved themselves as the best code in correcting errors over channels suffering from intersymbol interference.

Marques da Silva et al. [31] investigated MIMO-OFDM systems with LDPC for underwater acoustic communication (UWA) systems. UWA face multipath propagation conditions [32] from reflections off the water surface and bottom as well as obstacles, which reduces their quality. To beat the intersymbol interference, the authors incorporate OFDM, single carrier frequency domain equalization (SC-FDE), and MIMO system with LDPC codes that have been used in recently developed generations of cellular communications known as 5G [33]. Simulation results for UWA communication with 4×32 MIMO showed the performance improvement obtained with LDPC codes to be in the order of 5 dB. The experiments demonstrated significant data transmission rate up to 125.7 kbps, as well as spectral efficiency up to 3.5 bps/Hz.

Tikka and Sivashanmugam [34] proposed an error correction hybrid coding algorithm (EC-HCA) combining quasi-cyclic LDPC (QC-LDPC) and space-time block coding (STBC) for MIMO-OFDM systems. This approach mitigates ISI by leveraging STBC to avoid interference among transmit antennas, achieving a peak signal-to-noise ratio (PSNR) of 10.24 dB in a 2×2 MIMO setup, outperforming methods like Alamouti encoding [35], polar-convolutional coding [36], and optimal power allocation scheme with turbo codes [37].

To satisfy the bandwidth starvation codes and tall decoders of performance based on parallel computation technologies are being assembled by wireless communication systems engineers and researchers. Along with hardware platforms (GPU, Field-Programmable Gate Array (FPGA), SoC), the choice of application programming interface (API), CUDA or OpenCL is critical for developing high-performance encoders and decoders [38].

In [39], a LDPC decoder that can run as fast as 10 Gbps on a GPU device (GeForce RTX 2080Ti) has been described. Performance of (8448, 26,112) LDPC decoder has been tested under an AWGN channel with BPSK modulation. The software implementation of this decoder has been written in C using CUDA technology. SIMD instructions multiply by four the number of code words processed and further paralleling between code words. The early termination (ET) mechanism reduces the number of decoding iterations at high SNR, thereby almost doubling that channel throughput which is achievable in modern designs while keeping the same error correction performance [40-42].

The initial validation of FEC decoders prior to hardware implementation and integration with communication systems has consistently been hard work. A hardware-software methodology utilising the Xilinx Alveo U200 device and its parallel execution in OpenCL has been detailed in [43]. The

results demonstrate significant acceleration in both the HDL modelling process and FPGA prototype methodologies.

This study investigates the performance of MTDs for SOC in MIMO-OFDM wireless channels with multipath fading and ISI. Like traditional threshold decoders it is based primarily upon short-integer addition, i.e., check summing. Thus, the performance limitations of such a decoder reside only in the maximum data flow rate shift registers within the decoder can attain and how many parallel registers are being employed within the decoding algorithm itself. Among the quickest building blocks in current digital technology are single-bit modulo-2 adders, adders designed for small integers, and standard shift registers. Using this approach for hardware implementation of an MTD results in approximately three orders of magnitude higher performance relative to other algorithms under conditions of high noise. An MTD built upon Altera FPGA that has 40 decoding iterations yields about 1.6 Gbits/s decoding throughput [44]. In [45], the CUDA decoder gets to run at about 350 Mbps on NVIDIA GTX970 and 815 Mbps on NVIDIA GTX1080 for the code with block length equal to 1600 symbols.

The review is about how actively code methods against intersymbol interference and fading in modern wireless communications are developed. From simple convolutional codes to more complex turbo and LDPC codes, researchers constantly algorithmically enhance efficiency. Particularly, LDPC codes perform well over ISI channels. But even though modern decoders like LDPC do perform very well, their hardware implementation and complexity are an issue so that powerful computing platforms (GPU, FPGA) and special APIs (CUDA, OpenCL) have to be used. It is on this note that MTDs have been considered an adequate solution. Because of low computational complexity based on simple integer operations, MTDs have enormous prospects for parallel implementations and attaining startling performances (on the order of gigabits per second) on FPGAs. They become the code of preference in those channels with large intersymbol interference and fading since decoding must be done efficiently with low hardware implementation costs.

III. Background

This section describes the encoding and decoding algorithms for SOCs based on threshold decoding. These algorithms enable low-complexity error correction, critical for high-speed wireless systems like MIMO-OFDM.

A. Self-Orthogonal Codes (SOCs) and Encoder for SOCs

Self-orthogonal codes (SOCs) are a special class of convolutional codes that allow to simplify the decoding process. Fig. 1 shows a convolutional SOC with a code rate R = 1/2, minimum code distance d = 5, code length n = 14, and generator polynomial $g(x) = 1 + x + x^4 + x^6$, and tap weight J = 4. The encoder processes information bit by bit. For each bit, it feeds the bit into a shift register. Simultaneously, it calculates a parity bit using a four-input semi-adder. Both the information bit and the calculated parity bit are then sent out.

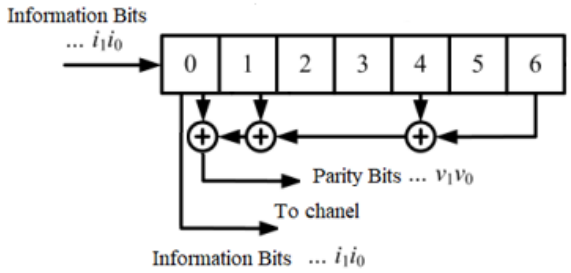

Fig. 1. Encoder scheme for convolutional SOCs.

This code corresponds to the parity-check matrix H:

$$H = \begin{bmatrix} 1 & & & & & & & 0 & & \\ 1 & 1 & & & & & & & & \\ 0 & 1 & 1 & & & & & & & \\ 0 & 0 & 1 & 1 & & & & & : & I \\ 1 & 0 & 0 & 1 & 1 & & & & & \\ 0 & 1 & 0 & 0 & 1 & 1 & & & & \\ 1 & 0 & 1 & 0 & 0 & 1 & 1 & & & \\ . & . & . & . & . & . & . & & & \end{bmatrix} \quad (1)$$

Within the matrix H, consider the rows numbered 0, 1, 4, and 6. In the first column of these rows, there is a single '1'. Furthermore, in all other columns of these same rows, there is at most one '1' present.

The encoding process operates as follows:

1) The shift register receives an information vector i = (i0, i1, …, i6, …) symbol by symbol, with i0 in cell 7, i1 in cell 6, and so forth.

2) The j-th parity symbol is calculated by performing a cyclic shift for j between 0 and 6:

$$v_j = \sum_{k=1}^{4} i_{(j-g_k) mod 7} \quad (2)$$

3) A parity vector v = (v0, v1, …, v6, …) is then sent over the channel in combination with the information vector.

The encoding process is formalized in Algorithm 1, using the following parameters:

nk - number of the information branches;

nr - number of the parity branches;

K - registers length (the length of the one information branch and the length of the one parity of branches);

poly - generator polynomial;

poly(u,j,p) - position of p-tap from u-th information branch to j-check branch

J - array of number of the taps;

J(i,j) - number of the taps from *i*-th information branch to j-check branch;

% - binary operator yields the remainder from the division of the first expression by the second;

$\oplus$ - addition modulo 2.

$\oplus$ - addition modulo 2.

Algorithm 1: Encoding algorithm using self-orthogonal codes

Input: Information array $i[nk, K]$
Output: Check array $v[nr, K]$

```
For k ← 0 to K-1 do
  For j ← 0 to nr-1 do
    v(j,k) ← 0
    For u← 0 to nk-1 do
      For p ← 0 to J(u,j)-1 do
        v(j,k) ← v(j,k)⊕ i(u,(poly(u,j,p)+k)%K).
      end
    end
  end
end
```

To decipher the code, the received channel vector, represented as $\bar{Q}$ (which is the sum of the transmitted code word $\bar{A}$ and the noise vector $\bar{E}$), is multiplied by the code's checking matrix. This operation yields a vector known as the syndrome:

$$\bar{S} = H\bar{Q} = H(\bar{A} + \bar{E}) = H\bar{A} + H\bar{E} = H\bar{E}. \quad (3)$$

Detailed explanations of the theoretical underpinnings and mathematical formulas concerning parity-check relationships and the orthogonality characteristic of self-orthogonal codes (SOC) can be found in [46, 47]. These codes will be explored in the subsequent sections.

B. Threshold Decoding for Convolutional SOCs

Threshold decoding of convolutional self-orthogonal codes (SOC) was proposed by J. L. Massey. This method uses the principle of local parity checks and voting. It is a simplified version of decoding that does not require complex calculations, such as the Viterbi algorithm [48]. The main idea of the method is that for each information bit to be decoded, several local syndromes are calculated. Due to the self-orthogonality property, each of these checks contains, in addition to the decoded bit, no more than one other error. If most of the checks for one bit indicate the presence of an error (i.e., their syndromes are nonzero), then a decision is made to correct this bit. The threshold decoding method is simple to implement, as can be seen in Fig. 2, which shows a prototype of a threshold decoder for convolutional SOCs with $R = 1/2$, minimum code distance $d = 5$, code length $n = 14$, tap weight $J = 4$ and generator polynomial $g(x) = 1 + x + x^4 + x^6$.

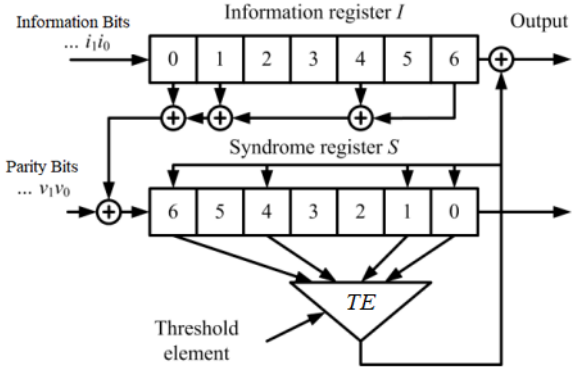

Fig. 2. Threshold decoder scheme for convolutional SOCs.

The threshold element (TE) aggregates the checks associated with the current decoded information bit and compares the sum with the threshold value. The threshold value of a given code is calculated by:

$$T = \frac{J+1}{2} \quad (4)$$

The threshold decoding operates as follows:

1) Defining a set of check syndromes, for i-th decoded information bit S_i e is a set of check syndromes. Each syndrome in this set, $S_{i,k}$, contains as an added the error associated with the i-th bit and, according to the self-orthogonality property, at most one other error.

2) For each set of check syndromes S_i, a checksum L_i is calculated as the sum modulo 2 of all syndromes:

$$L_i = \sum_k S_{i,k} \quad (5)$$

3) The resulting checksum L_i is compared with a given threshold T. If $L_i > T$, it means that most of the checks indicate an error in the i-th information bit. In this case, a decision is made to correct this bit.

4) After the bit is corrected, its value is used to recalculate the syndromes.

5) The decoder moves to the next information bit and repeats the process.

However, error propagation substantially hindered the success of this error correction technique. If the decoder incorrectly corrects one bit, this error can affect local checks for subsequent bits. As a result, instead of one erroneous bit, several can be incorrectly corrected, which leads to a significant deterioration in decoding quality.

C. Multi-threshold Decoding for Convolutional SOCs

Multi-threshold decoding is an iterative variant of threshold decoding that uses an additional difference register (D) to diminish the downstream effects of errors. Before decoding, the D vector is filled with zeros. At the first iteration, the MTD operates in the same way as a conventional threshold decoder. For i-th information symbol, it calculates the checksum Li and makes a decision to change this symbol if Li exceeds a given threshold. But the decisions made about changing bits are stored in the D register. Starting with the second iteration, the decoder begins to use the information accumulated in the D register. Now decisions about correcting bits are made not only on the basis of the current checksum, but also taking into account the contents of the D register.

Fig. 3 shows the schematic of two iterations of the MTD operation for convolutional SOCs with R = 1/2, minimum code distance d = 5, code length n = 14, tap weight J = 4 and generator polynomial $g(x) = 1 + x + x^4 + x^6$.

The decoding process computes, for a selected symbol ij, the function:

$$L_j = \sum_{p \in \Theta_j} s_p + d_j \quad (6)$$

where, d_j is the difference vector element for i_j, s_p is the p-th syndrome element in the checks for i_j, and Θ_j is the set of checks for the j-th information symbol. The number of terms equals the

code distance d. If $L_j > T$, where $T = \lfloor (d-1)/2 \rfloor$, then i_j, its checks, and d_j are inverted, and decoding proceeds to another symbol i_m, $m \neq j$. If $L_j \leq T$, the next symbol is decoded immediately.

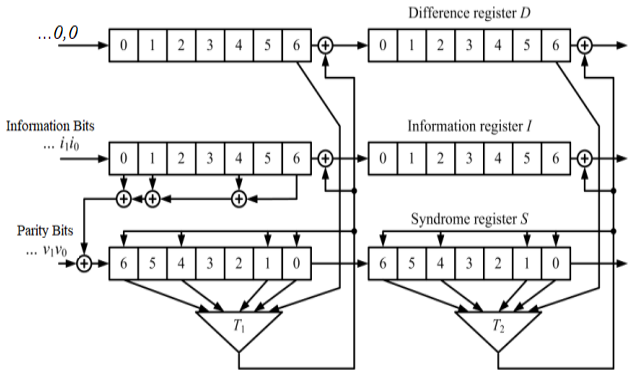

Fig. 3. Multi-threshold decoder scheme for convolutional SOCs.

The MTD algorithm is detailed in Algorithm 2.

One big problem with MTDs is that they tend to spread errors through feedback branches, which makes it more likely that syndrome errors and decoding failures will happen [25]. Mitigation means picking codes with the least amount of error set overlap and adjusting the parameters. Even so, MTDs are not very hard to decode because each step only needs simple additions and threshold comparisons.

Algorithm 2: Multi-threshold decoding algorithm for self-orthogonal codes

Input: Information array $i[nk, K]$, received from the noisy channel
Parity array $v[nr, K]$
maxIter -number of decoding iterations
Output: Information array $i[nk, K]$, after error correction procedure

```
Difference vector D[nk, K] is initially filled with zeros
For k ← 0 to K-1 do
For j ← 0 to nr-1 do
s(j,k) = v(j,k)
For u← 0 to nk-1 do
For p ← 0 to J(u,j)-1 do
s(j,k) ← s(j,k)⊕i(u,(poly(u,j,p)+k)%K).
end
end
end
end
For iter ← 0 to maxIter do
For k ← K-1 to 0 do
For u← 0 to nk-1 do
sum← D(u,k)
For j ← 0 to nr-1 do
For p ← 0 to J(u,j)-1 do
sum ← sum + s(j,(k – poly(u,j,p))%K).
end
end
If sum > T then
i(u,k) ← 1 - i(u,k)
D(u,k) ← 1 - D(u,k)
For j ← 0 to nr-1 do
For p ← 0 to J(u,j)-1 do
s(j,(k-poly(u,j,p))%K)← 1 – s(j,(k–poly(u,j,p))%K
end
end
endIf
end
end
end
```

For code distances d < 25 and the number of iterations of decoding Iter up to 50 iterations, the complexity is about:

$$N1 \approx (d + 2)(Iter + 4)$$

If you can deal with a 0.1 dB energy loss, the complexity can be cut down to

$$N2 \approx c1\ d + c2\ Iter$$

where, c1 and c2 are very small integers. Because of this simplicity, extra iterations don't have much of an effect on performance, which makes it possible to make software for 5G and IoT systems that works well.

IV. Materials and Methods

A. Space-Time Coding in MIMO Systems

The research studies the efficiency of using MTD in communication channels with fading when using OFDM technology to combat multipath. When using one transmitting and one receiving antenna, this approach is not efficient enough, since the presence of deep and long fading within one code block usually leads to the fact that it will contain many errors even after decoding. To improve the reliability of data transmission, it is possible to additionally use the technology of spatial diversity during transmission and reception, i.e., to transmit and receive data using several antennas (MIMO systems). In this case, the antennas should be spaced so far apart that the correlation of signals on them is minimal. Then the probability that all radio signals between all antennas will simultaneously be subject to fading is quite small. As a result, the quality of communication is significantly improved with significantly lower energy costs. It should be noted that when using MIMO technology, there is a supplementary avenue to realize space-time coding. In this case, there are options for increasing the transmission rate (for example, when one antenna transmits one symbol - Spatial Multiplexing) or improving the energy efficiency of transmission (the signal transmitted by the antenna is a function of several transmitted symbols). This is determined by the space-time code matrix.

Currently, there are many proven space-time coding matrices, including those specified by standards. For example, the IEEE 802.16e (WiMAX) standard provides for the use of 1, 2, 3 and 4 transmitting antennas [49].

When using one transmitting antenna, space-time coding is not used.

For two transmitting antennas with STC the following transmitting matrices can be used:

$A = \begin{bmatrix} S_i & -S'_{i+1} \\ S_{i+1} & S'_i \end{bmatrix}$ Orthogonal Alamouti Matrix, code rate 1

$B = \begin{bmatrix} S_i \\ S_{i+1} \end{bmatrix}$ Non-orthogonal V_BLAST Matrix, code rate 2

$C = \frac{1}{\sqrt{1+r^2}} \begin{bmatrix} S_i + jrS_{i+3} & rS_{i+1} + S_{i+2} \\ S_{i+1} - rS_{i+2} & irS_i + S_{i+3} \end{bmatrix}$ Non-orthogonal Matrix, code rate 2

$r = \frac{-1+\sqrt{5}}{2}$,

where, S_i is the transmitted symbol of the signal constellation; j is the imaginary unit; $()'$ is the complex conjugation operation.

For four transmit antennas with STC the following transmit matrices can be used:

Orthogonal, code rate 1:

$$A = \begin{bmatrix} S_i & -S'_{i+1} & 0 & 0 \\ S_{i+1} & S'_i & 0 & 0 \\ 0 & 0 & S_{i+2} & -S'_{i+3} \\ 0 & 0 & S_{i+3} & S'_{i+2} \end{bmatrix}$$

Non-orthogonal, code rate 2:

$$B = \begin{bmatrix} S_i & -S'_{i+1} & S_{i+4} & -S'_{i+5} \\ S_{i+1} & S'_i & S_{i+5} & S'_{i+4} \\ S_{i+2} & -S'_{i+3} & S_{i+6} & -S'_{i+7} \\ S_{i+3} & S'_{i+2} & S_{i+7} & S'_{i+6} \end{bmatrix}$$

$C = \begin{bmatrix} S_i \\ S_{i+1} \\ S_{i+2} \\ S_{i+3} \end{bmatrix}$ Non-orthogonal, code rate 4

To decode the STC code, a system of equations is first constructed

B = G S + N,

where, S is a column vector of transmitted signals; G is a matrix depending on the channel coefficients; N is complex Gaussian noise; B is a column vector depending on the received signals. From this expression, using a maximum likelihood detector, an array of logarithms of the likelihood ratio for the bits of each of the transmitted symbols is obtained.

As an example, let us consider how the matrix *G* and the vectors *S* and *B* are formed for two transmitting antennas using the STC matrix *A*:

$$S = \begin{bmatrix} S_1 \\ S_2 \end{bmatrix},$$

where, S_1, S_2 are signals transmitted over two-time intervals.

$$B = \begin{bmatrix} R_1^{(1)} \\ R_1^{(2)\prime} \\ \dots \\ R_n^{(1)} \\ R_n^{(2)\prime} \end{bmatrix},$$

where, $R_k^{(m)}$ is the signal received by the *k*-th antenna at time *m*.

$$= \begin{bmatrix} h_{11}^{(1)} & h_{21}^{(1)} \\ h_{21}^{(2)\prime} & -h_{11}^{(2)\prime} \\ \dots & \dots \\ h_{1n}^{(1)} & h_{2n}^{(1)} \\ h_{2n}^{(2)\prime} & -h_{1n}^{(2)\prime} \end{bmatrix},$$

where, $h_{kp}^{(m)}$ is channel coefficient from the *k*-th transmitting to the *p*-th receiving antenna in the *m*-th time interval.

Three demodulation algorithms were evaluated:

$\hat{\Theta} = (G'G + 2\sigma_n^2 I)^{-1} G'S$ - MMSE Demodulation, where *I* is the identity matrix and σ_n^2 is the noise variance

$\hat{\Theta} = \frac{\sum_\Theta \Theta \cdot exp\left\{-\frac{1}{2}(S-G\Theta)'(U)^{-1}(S-G\Theta)\right\}}{\sum_\Theta exp\left\{-\frac{1}{2}(S-G\Theta)'(U)^{-1}(S-G\Theta)\right\}}$ - Optimal, Maximum-Likelihood (ML) Demodulation, where Θ is the constellation set.

Approximate ML Demodulation considers only the constellation point closest to the received signal for soft-decision computation.

Soft decisions from these algorithms are fed to the MTD for error correction, enhancing decoding performance in fading channels.

B. Simulation Details

Standardized wideband fading channel models were adopted to emulate urban, suburban, and rural deployments. The ITU-R channels [50] included Outdoor Channel A, Typical Urban 6 (TU6), and Rural Area 6 (RA6). TU6 was modeled with the delay–power profile [0, 0.2, 0.5, 1.6, 2.3, 5] μs and [–3, 0, –2, –6, –8, –10] dB, respectively. RA6 used equally spaced taps with delays [0, 0.1, 0.2, 0.3, 0.4, 0.5] μs and powers [0, –4, –8, –12, –16, –20] dB. To obtain the spatial structure essential for MIMO, the 3GPP SCM in Urban Macro (UMa) and Urban Micro (UMi) configurations was utilized, incorporating angle-of-arrival/angle-of-departure spreads and realistic base-station/user equipment (UE) heights [51, 52]. Doppler frequencies corresponding to speeds up to 50 km/h were applied to model mobility. These models were selected for their compatibility with WiMAX and 5G urban deployments, representing scenarios pertinent to IoT and low-altitude UAV communications characterized by multipath and spatial diversity.

OFDM with two Fast Fourier transform (FFT) sizes (512 and 1024 subcarriers) was used at the physical layer. To balance spectral efficiency and intersymbol interference (ISI)

robustness, cyclic prefix (CP) ratios of 1/8 and 1/16 were used in each scenario.

Quadrature Phase-Shift Keying (QPSK), 8 Phase Shift Keying (8PSK), 16 Adaptive Phase Shift Keying (16APSK), and 16QAM constellations were considered. For each scenario, the constellation order was chosen to find a balance between spectral efficiency and implementation complexity. In low-SNR or high-diversity setups, QPSK was used as the base; in the same band-width, 8PSK was used when moderate spectral efficiency was needed. 16APSK and 16QAM were enabled in higher-throughput settings and combined with stronger channel coding and/or spatial multiplexing as appropriate. In SCM-based MIMO studies, 16QAM was configured for cases emphasizing spatial multiplexing, whereas 16APSK was used in the OFDM settings following DVB-S2-compatible mapping.

Antenna configurations (1×1, 2×2, and 4×4) were configured. Space–time coding (STC) employed matrices A, B, and C to cover orthogonal and non-orthogonal designs at different code rates. For 2 transmit antennas, matrix A provided a rate-1 orthogonal de-sign, while matrices B and C provided higher-rate, non-orthogonal options. For 4 transmit antennas, both rate-1 orthogonal and higher-rate non-orthogonal designs were instantiated. Selection of STC and spatial mode (diversity or multiplexing) depended on the target spectral efficiency and channel model. Receiver processing assumed per-subcarrier channel state information adequate for STC decoding.

Demodulators included MMSE and approximate ML detectors. Detector choice was aligned with the modulation order and MIMO/STC setting to balance complexity and soft-information quality.

Coding options covered SOCs decoded via MTD, LDPC codes [53] from IEEE 802.16e (WiMAX) and DVB-S2, and turbo codes [54]. Code lengths in the study included 2,016 bits (WiMAX LDPC), ~10,000 bits (turbo), 16,200 and 64,800 bits (DVB-S2 LDPC), and SOC lengths around 36,864 and 64,800 bits. LDPC decoding used a normalized or offset min-sum family implementation, while turbo decoding used max-log-MAP. Table I shows a summary of the most important simulation settings and options.

The simulation environment was built in MATLAB, with C employed to accelerate the performance of the encoder, decoder, and other complex processing blocks requiring significant computational resources. The simulations were done on a work station that met the following requirements. The simulation took place on a workstation that had the features shown in Table II.

C. Software Implementation of the MTD for SOCs

In addition to a previous implementation of a multi-threshold decoder (MTD) for self-orthogonal codes (SOCs) on CUDA, a portable OpenCL implementation is being developed for heterogeneous devices, including systems-on-chips and FPGA accelerators. The primary goal is not to outperform existing CUDA kernels on NVIDIA GPUs, but rather to: i) create an implementation functionally equivalent to the base CUDA version, and ii) evaluate the performance of the same multi-threshold decoding algorithm for self-orthogonal codes on non-NVIDIA architectures.

TABLE I. THE CHANNEL'S EXPERIMENTAL PARAMETERS

Component	Specification/parameter
Channel	ITU-R: Outdoor A, TU6, RA6. SCM: UMa, UMi.
Mobility	0–50 km/h (Doppler per carrier frequency).
OFDM	FFT=512 or 1,024; CP=1/8 or 1/16
MIMO/STC	1×1, 2×2, 4×4; STC matrices A (orthogonal, rate 1), B (non-orthogonal, rate 2), C (non-orthogonal, rate 2 or 4).
Modulation	QPSK, 8PSK, 16APSK, QAM16
Demodulation	MMSE; approximate ML
Coding	SOC+MTD (36,864 and 64,800 bits; ≤25 iterations); LDPC (WiMAX 2016 bits; DVB-S2 16,200 bits, 64,800 bits); Turbo (≈10,000 bits).
Decoding	SOC (MTD, ≤25 iterations); LDPC (min-sum) Turbo (max-log-MAP)
Code rates	SOC R≈1/2; DVB-S2 LDPC R=1/2; Turbo R=1/2

TABLE II. WORKSTATION SPECIFICATIONS

Component	Specification
Processor	Intel Core i7 4790K
Motherboard	ASUS Z97
Graphics Card	NVIDIA Quadro K4000
RAM	Kingston 16 GB
HDD	Western Digital RE 4 TB

The decoder is implemented in OpenCL 1.2. The OpenCL kernels replicate the SOC+MTD algorithmic pipeline used in the CUDA version, including fixed-point LLR computation, threshold and multi-pass updates, syndrome checks, and early termination logic (see Fig. 4).

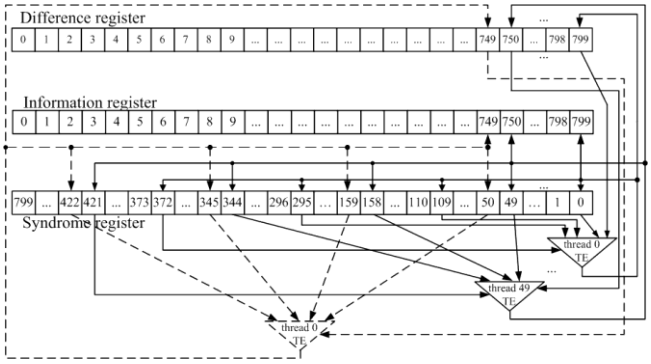

Fig. 4. Scheme of multi-threshold decoder using 50 concurrent threads.

V. RESULTS AND DISCUSSION

A. Performance of MTD for SOCs and Other Error Correction Methods in Multipath Channels

This section presents simulation results evaluating the performance of multi-threshold decoders (MTDs) for SOCs and

other error correction methods in standard ITU-R and SCM channel models. For MTD simulations, extensive parameter optimization was performed, including the selection of the code, number of decoding iterations, threshold values, weight coefficients for each iteration, and the method for determining syndrome weights.

Fig. 5 illustrates the BER performance of MTDs for a self-orthogonal code (SOC) with a code rate of 1/2 and a length of about 32,000 bits on the signal-to-noise ratio per bit in a channel of the Outdoor Channel A type using different types of modulation (curves labeled "SOC, MTD, ..."). In this case, a demodulator was used that formed only hard decisions regarding the decoded bits (the use of soft decisions of the demodulator will improve the characteristics by another 1..1.5 dB). OFDM with 1,024 carriers with the main parameters from the IEEE 802.16e (WiMAX) standard was also applied. The guard interval represented one-sixteenth of the OFDM symbol's total duration. Note that when using 8PSK modulation, the loss in energy compared to QPSK is about 3 dB, and when using 16APSK modulation, the loss is about 5 dB. At the same time, these types of modulation allow increasing the bit rate of transmission by 1.5 and 2 times, respectively, without expanding the frequency band.

The same figure shows the "turbo..." curve characteristics of a turbo code with a code rate of 1/2 and a code block length of about 10,000 bits using QPSK modulation with the same other channel and OFDM parameters. The constructive length of the component codes was equal to 4. The max-log-MAP algorithm for decoding the component codes was used to decode the turbo code. Note that the turbo code characteristics are significantly worse than the MTD characteristics. This is explained by the fact that such a code length is insufficient to cope with fading in the communication channel. The characteristics of a fairly short low-density code of the IEEE 802.16e (WiMAX) standard with a length of 2,016 bits with the same other parameters of the data transmission system are shown in Figure 5 by the "LDPC WiMAX, ..." curve. The min-sum decoding algorithm was used to decode these and other low-density codes. It should be noted that this code copes with fading as poorly as the turbo code. When using longer low-density codes of the DVB-S2 standard of 16,200 and 64,800 bits with a code rate of 1/2, the characteristics shown by the curves "LDPC DVB-S2 16,200, ..." and "LDPC DVB-S2 64,800, ..." are obtained, respectively. These codes are already capable of providing characteristics somewhat better than MTD. However, as already noted, the complexity of implementing their decoders is tens of times greater than that of MTD. Moreover, for self-orthogonal codes used in conjunction with MTD, with an insignificant increase in complexity (approximately 4 times), it is possible to ensure the characteristics shown in Figure 5 by the curves "SOC, min-sum, ..." for the QPSK, 8PSK, and 16APSK modulation types. These results are better than the characteristics of the basic MTD by approximately 1...1.5 dB and comparable to the results provided by low-density codes of length 16200 of the DVB-S2 standard.

Similar performance characteristics were observed for other ITU-R channel models. The main conclusions from these results are consistent with those already made.

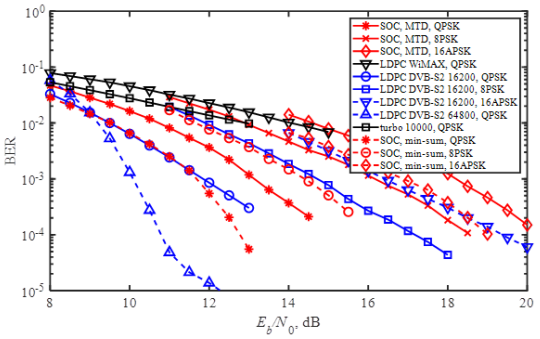

Fig. 5. Simulation results in ITU-R outdoor channel A.

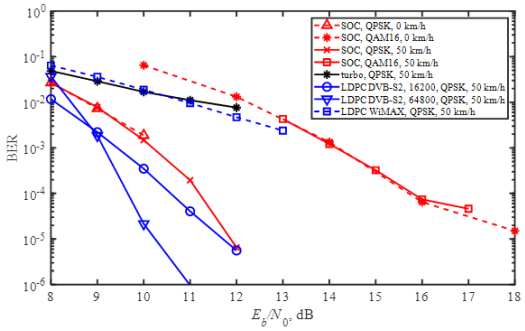

Fig. 6. Simulation results in SCM Urban Macro channel.

Fig. 6 illustrates the behavior of these codes within the SCM of the Urban macro channel model (results were also obtained for other SCM types). The ODFM modulation parameters are the same as those in Figure 5. Shown here are the characteristics of self-orthogonal codes for QPSK and 16 Quadrature Amplitude Modulation (QAM16) at receiver speeds of 0 and 50 km/h relative to the transmitter (group of curves "SOC,...", as well as the characteristics of a turbo code of about 10,000 bits in length (curve "turbo..."), low-density codes of the DVB-S2 standard of 16,200 (curve "LDPC DVB-S2, 16,200...") and 64,800 (curve "LDPC DVB-S2, 64,800...") bits in length, and low-density codes of the 802.16e (WiMAX) standard (curve "LDPC WiMAX..."). Note that the movement of the transmitter and receiver at a speed of 50 km/h has virtually no effect on the obtained characteristics. And the ratio between the efficiency of turbo, short and long low-density codes and the multi-threshold decoder of self-orthogonal codes remains the same as for the ITU-R channel model.

B. Application of STC with MTD in Fading Channels

The simulation used a multi-threshold decoder with 25 decoding iterations for the constructed self-orthogonal code with a code rate of R = 8/16, a code distance of 17, and a length of 36,864 bits. OFDM multiplexing with 512 carriers was used in conjunction with MTD. The guard interval was 1/8 of the OFDM symbol length. Conventional QPSK was applied as a simulation. The channel simulation used the default six-path TU6 profile of COST recommendation 259 with a delay profile of [0 0.2 0.5 1.6 2.3 5] μs and a power profile of [–3 0 –2 –6 –8 –10] dB. The maximum Doppler frequency Fd was equal to 0.

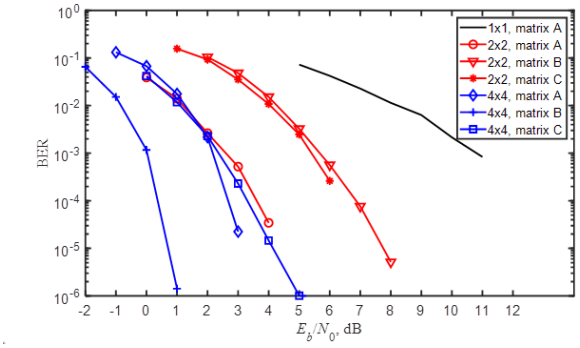

Fig. 7. MTD performance for different STC matrices and antenna configurations.

Fig. 7 presents the MTD attributes using different numbers of transmit and receive antennas (1×1, 2×2, 4×4) with different STC matrices. Note that the energy efficiency increases significantly with an increase in the number of antennas. Furthermore, for two transmit and receive antennas with the same STC rate, matrix C proves to be the best. When operating with four transmit antennas, matrix B, for which the STC code rate is 2, has the best energy efficiency. When switching to matrix C, which allows for the transmission of twice as much data in the same time, the energy efficiency degrades by approximately 2 dB.

Fig. 8 shows the MTD characteristics under the above-described conditions using various demodulation algorithms. Using the approximate optimal algorithm (curves marked "app opt"), the results are almost 2 dB better than those using the MMSE algorithm. This means that the quality of soft decisions under these conditions greatly influences the effectiveness of the error correction scheme.

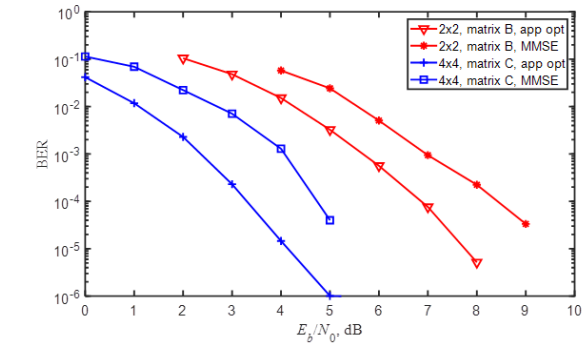

Fig. 8. MTD performance for different demodulation algorithms.

Fig. 9 evaluates MTD performance across different channel profiles. In addition to TU6, the six-beam RA6 profile from the same COST 259 recommendation was used here. It is characterized by a delay profile of [0 0.1 0.2 0.3 0.4 0.5] μs (equidistant beams) and a power profile of [0 -4 -8 -12 -16 -20] dB. The MMSE algorithm was used for demodulation. Note that the reflected beams have lower power than in TU6. As a result, the efficiency of the data transmission system for such a channel is approximately 2 dB worse than for TU6.

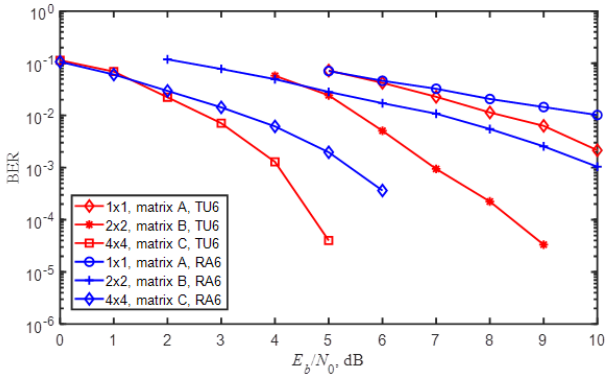

Fig. 9. MTD performance for different channel profiles.

The results of the comparison of the efficiency of the SOC with MTD and LDPC codes for the UMi SCM scenario using MIMO are presented below. To combat multipath, OFDM multiplexing with the parameters discussed earlier was again used. The noise-correcting codes were a self-orthogonal code with a code rate of 1/2 and a length of 32,768 bits, decoded using MTD, and an LDPC code of the DVB-S2 standard with a code rate of 0.44 and a length of 16,200 bits. In Fig. 10, the curves "SOC, 1x1, QPSK" and "LDPC, 1x1, QPSK" present the dependences of the decoding error probability of the self-orthogonal code and the LDPC code on the signal-to-noise ratio per bit using QPSK modulation. In this case, a demodulator was used that generates only hard decisions regarding the decoded bits. It should be noted that these codes provide approximately the same data transmission reliability. When switching to two transmit and two receive antennas, the system's energy efficiency decreases slightly (curves "SOC, 2x2, QPSK" and "LDPC, 2x2, QPSK"), but the bit rate doubles without expanding the used bandwidth.

Note that for MTD, the same increase in data rate is achieved by switching to QAM16 modulation instead of QPSK, but the efficiency of such a system (curve "SOC, 1x1, QAM16") is almost 2 dB worse than the MIMO variant. It should also be noted that the effect of using MIMO technology for self-orthogonal codes was greater than for LDPC codes. If the bit rate does not increase (using a single transmit antenna and QPSK modulation), using multiple receive antennas can significantly improve data transmission reliability. An example of the characteristics of such systems for two and three receiving antennas is shown in Fig. 10 by the curves "SOC, 1x2, QPSK" and "SOC, 1x3, QPSK". The gain compared to one receiving antenna with a target decoding error probability per bit of 10−5 was 4 and 7 dB, respectively. The same improvement is obtained when using LDPC codes (curve "LDPC, 1x2, QPSK").

From Fig. 10, it also follows that, when attempting to further increase the data transmission rate due to MIMO, the MTD characteristics deteriorate significantly (curves "SOC, 4x4, QPSK" and "SOC, 2x2, QAM16"). Therefore, such options for increasing the transmission rate are impractical to use in practice, or it is necessary to use additional methods to improve the characteristics.

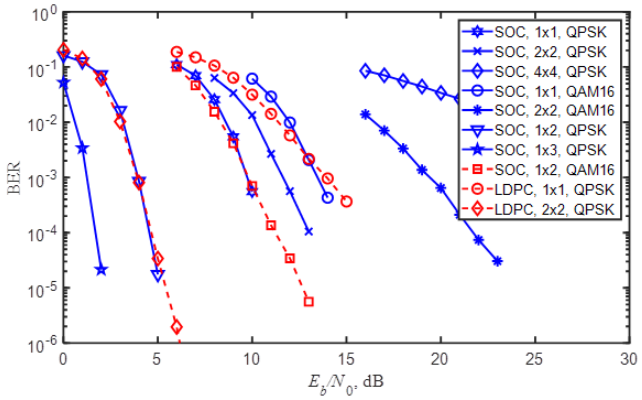

Fig. 10. Simulation results in the SCM urban micro channel with MIMO.

C. GPU-Accelerated Simulation Performance

A data-parallel scheme [55] is adopted in which each independent codeword is processed end-to-end by a single OpenCL work-item. All MTD stages— LLRs (Log-Likelihood Ratios) calculation, threshold tests, bit-updates, syndrome checks, and early stopping—are executed sequentially within that item, preserving the required ordering without cross-item synchronization. Parallelism is exposed by launching many such items concurrently, one per dataset. This maximizes device occupancy and eliminates global synchronization overhead, while local memory buffers are used to stage per-codeword data and tables.

```
kernel decode_mtd(codeword_i):
    // local buffers for the i-th code word
    preload_indices_to_local()
    llr = load_llr_i()
    for iter in 1..I_max:
        apply_thresholds(llr) // sequential steps of the MPD algorithm
        update_bits_and_metrics()
        if check_syndrome(): break
    store_decision_i()
```

This approach achieved a simulation throughput of 300 kbps (see Table III), which, however, is insufficient.

Based on these unsatisfactory results, a study was conducted to identify the bottleneck limiting simulation throughput. This bottleneck turned out to be memory access. This is due to the specific memory architecture in OpenCL, where the data being processed can be stored in local or global memory [56]. Due to architectural features, accessing global memory takes significantly longer than accessing local memory. It was hypothesized that reducing global memory accesses and increasing local memory utilization would decrease the execution time of the encoder and decoder operations.

To mitigate the memory-access bottleneck identified in the OpenCL implementation, the data-parallel SOC+MTD scheme is reorganized to maximize local-memory utilization. Each work-group processes a batch of K codewords: LLRs and index tables are fetched from global memory using coalesced vector loads and staged in double-buffered local memory (A/B). All MTD iterations then run in-place on local buffers; only final decisions and optional statistics are written back to global memory. Where supported, subgroup collectives (ballot/shuffle/pop count) accelerate thresholding and reductions. This scheme minimizes global-memory traffic, reduces synchronization overhead, and improves device occupancy.

TABLE III. DECODING SPEED OF MULTI-THRESHOLD DECODERS FOR SOCS

Ref.	Device (GPU/CPU)	Compute model	Throughput [Mbit/s]
[25]	Intel Core i7-4770 (4 cores)	Baseline (no GPU)	15
[45]	NVIDIA GeForce GTX 970	Standard GPU pipeline: CUDA kernels	350
[45]	Intel Core i7 4770K NVIDIA GeForce GTX 1080	Standard GPU pipeline: CUDA kernels	815
proposed	Intel Core i7 4790K NVIDIA Quadro K4000	OpenCL kernels (data-parallel)	120
proposed	Intel Core i7 4790K NVIDIA Quadro K4000	OpenCL kernels (local-memory optimized)	480

The proposed approach maximized GPU resource utilization, increasing the data transmission system simulation speed on a PC with an NVidia Quadro K4000 GPU graphics accelerator to 120 Mbps. As Table III shows, the OpenCL implementation with minimized global memory access resulted in an 8-fold increase in throughput compared to the CPU implementation, but significantly less than the parallel CUDA decoder.

The OpenCL implementation was designed primarily for portability, including deployment on OpenCL-enabled FPGAs, rather than for achieving performance levels comparable to the CUDA model. OpenCL remains the preferred method when cross-vendor support and FPGA portability are required, providing a unified approach for hardware implementation of channel coding systems.

The simulation results demonstrate that the MTD applied to SOCs exhibits competitive performance compared to traditional LDPC and turbo codes, especially under challenging multipath fading conditions. For instance, as depicted in Fig. 5, the SOC+MTD configuration achieves a BER of 10^{-5} at approximately 2 dB lower SNR compared to the turbo code of similar rate and block length. This is primarily due to the iterative threshold correction mechanism, which effectively adapts to rapidly varying error patterns caused by fading.

In contrast, short-length LDPC codes, such as the WiMAX-standard 2016-bit implementation, suffer from significant error floors in deep fade conditions. Even with powerful min-sum decoding and QPSK modulation, they are unable to correct clustered errors induced by delay spread and Doppler shift.

Longer LDPC codes, such as DVB-S2 (16200 bits, 64800 bits), achieve better BER performance, approaching that of SOC+MTD. However, they require significantly higher decoding complexity and memory bandwidth, making them less feasible for real-time or IoT scenarios.

Furthermore, integrating SOC+MTD with approximate ML demodulation results in performance gains of up to 2 dB over MMSE-based demodulation (see Fig. 8). This improvement highlights the benefit of combining soft-decision observations with MTD iterations, especially in high-diversity MIMO setups.

The introduction of antenna diversity (1×3) shows a significant reduction in required Eb/N_0 (≈7 dB at BER = 10^{-5}), demonstrating SOC+MTD's effective exploitation of spatial redundancy. In contrast, increasing modulation order from QPSK to 16APSK yields a spectral efficiency boost of 2×, with only moderate SNR penalties (~4–5 dB). This confirms the scalability of SOC+MTD under different throughput constraints.

Finally, the OpenCL-based GPU implementation accelerates MTD decoding by a factor of 32× (480 Mbps) compared to CPU-only processing (15 Mbps). Unlike specialized CUDA solutions, the portability of the OpenCL approach enables deployment across heterogeneous devices, including embedded SoCs, making SOC+MTD a practical high-throughput solution for 5G and IoT platforms.

In summary, the presented results confirm that SOCs decoded using MTD offer a robust and computationally efficient alternative to conventional FEC methods under realistic wireless conditions. Their low complexity makes them especially suitable for IoT and real-time communication systems where hardware resources and latency budgets are constrained.

A comparative analysis clearly demonstrates that SOC+MTD outperforms short-length LDPC and turbo codes in fading conditions, while achieving DVB-S2 equivalent reliability with significantly lower decoding complexity.

VI. Conclusion

This study presents a comprehensive performance evaluation of Multi-Threshold Decoders (MTDs) for Self-Orthogonal Codes (SOCs) applied to modern broadband wireless communication systems, including OFDM and MIMO configurations with Space–Time Coding. Extensive simulations across standardized fading channel models (ITU-R and 3GPP SCM) demonstrate that SOCs decoded using MTD achieve a level of reliability comparable to state-of-the-art LDPC and turbo codes, while requiring significantly lower decoding complexity. This advantage makes MTD particularly suitable for resource-constrained 5G and IoT devices.

The results further support the applicability of MTDs in high-mobility scenarios (up to 50 km/h) without significant performance degradation and demonstrate sensitivity to modulation and antenna diversity choices, enabling system designers to make informed trade-offs between energy efficiency and transmission rate. The integration with approximate Maximum-Likelihood detection and min-sum refinement leads to an additional SNR gain of up to 2 dB, while using a 1×3 antenna configuration can reduce the required Eb/N_0 by approximately 7 dB at a BER of 10^{-5}. GPU-based parallel implementation leveraging OpenCL achieved a 32-fold improvement in simulation throughput, demonstrating the potential of software-based MTD acceleration for real-time applications.

However, the study is limited to static channel assumptions within standard models, and real-world scenarios with non-stationary or highly nonlinear interference environments were not considered. Furthermore, only conventional GPU architectures were evaluated for software acceleration; FPGA and heterogeneous SoC platforms remain unexplored.

Future research will focus on investigating hybrid SOC+MTD designs with machine learning-based decoding adaptation for dynamic IoT networks.

Overall, the findings underscore that MTD-enabled SOCs are a promising candidate for low-complexity, high-reliability forward error correction in next-generation wireless systems, especially where computational and energy constraints are critical.

Acknowledgment

The research was funded by the Science Committee of the Ministry of Higher Education and Science of the Republic of Kazakhstan within the grant "AP19679505 – Research for multi-threshold decoding of convolutional codes and their software and hardware implementation for high-speed radio channels with fading".

CICA Framework: Harnessing CSR, AI, and Blockchain for Sustainable Digital Culture

Danang Danang, Agustinus Budi Santoso, Maya Utami Dewi
Fakultas Studi Akademik, Universitas Sains dan Teknologi Komputer, Semarang, Indonesia

***Abstract*—Digital transformation has created new opportunities for organizations, but it has also intensified cybersecurity risk. In emerging economies, where institutional support and digital literacy remain limited, cybersecurity awareness plays a crucial role in strengthening digital resilience and fostering a sustainable digital culture. This study introduces the CSR-Integrated Cybersecurity Awareness (CICA) Framework, which conceptualizes Corporate Social Responsibility (CSR) as a key driver of cybersecurity awareness, reinforced by the adoption of artificial intelligence (AI) and blockchain technologies. Data were collected from companies in Central Java, Indonesia, that implement CSR-based digital initiatives, with responses gathered from managers, CSR officers, and IT staff. Using Structural Equation Modeling (SEM), the findings show that CSR significantly enhances cybersecurity awareness, AI adoption strengthens proactive security measures, and blockchain increases trust and transparency. The results also reveal that CSR mediates the relationship between digital technology adoption and sustainable digital culture. This study contributes by integrating CSR and cybersecurity through emerging technologies, offering theoretical insights and practical implications for organizations in developing regions.**

***Keywords*—Cybersecurity awareness; corporate social responsibility; artificial intelligence; blockchain; sustainable digital culture; emerging economies**

I. Introduction

The 21st century is marked by the phenomenon of digital transformation, which is fundamentally changing how organizations thrive and survive in the global marketplace. Digital transformation contributes greatly to business success and resilience. Digital transformation provides opportunities and challenges, so that organizations are encouraged to implement strategies to be more competitive and increase market share [1]. Success in the digital era requires more than adopting advanced technologies; it demands fundamental transformation in organizational operations, innovation, and value-creation strategies [2].

In terms of significant enhancements in efficiency, innovation, and business growth, digitization has a significant impact. However, on the other hand, it also causes the risk of cyber-attacks and digital vulnerabilities. The availability of artificial intelligence (AI), big data, cloud computing, and blockchain technologies accelerates the direction of digital transformation, but also brings cyber risks and threatens businesses [3] (Saeed et al., 2023). The World Economic Forum, through its Global Cybersecurity Outlook 2025 report, highlights the increasingly complex global cyber ecosystem, which has broad implications for countries and organizations. These driving factors include rapid technological developments, geopolitical uncertainty, evolving threats, complex regulations, supply chain vulnerabilities, and a shortage of cyber [4]. This has a sharp impact on widening the cyber gap. At a broader level, this could widen the gap between developing and developed countries, between sectors, and between large and small organizations. This has a significant impact on widening the cyber gap. At a broader level, this could widen the gap between developing and developed countries, between sectors, and between large and small organizations.

A study by Catal found that executive awareness of cyber risks is quite high, but their management varies across industries. Therefore, cybersecurity must be integrated into the entire digital transformation process [5]. Therefore, cybersecurity awareness is not solely the responsibility of IT professionals but is the responsibility of every individual. Both everyday internet users and professionals need to understand how to recognize and anticipate digital threats. Increasing cybersecurity literacy is a strategic step to protect personal data while maintaining a secure digital ecosystem for all.

In developing countries, the urgency of cybersecurity is increasingly apparent. Southeast Asia suffers an estimated USD 1.7 billion in losses annually due to cyberattacks [6], with Indonesia being a primary target. Despite the rapid adoption of digital developments across various sectors, Kaspersky reported the detection and interception of over 13 million web threats aimed at businesses in Southeast Asia (SEA) throughout 2023, with Indonesia reaching 4,968,729 threats in 2023 [7]. This paradox demonstrates that digitalization not only drives growth but also increases vulnerability to cyberthreats.

At the same time, Corporate Social Responsibility (CSR) has expanded beyond traditional domains such as environment, education, and health to include digital responsibility. Digital transformation impacts internal and external CSR, particularly on shareholder value and employee responsibility through business model innovation [8]. Forward-thinking companies are beginning to view CSR not only as philanthropy but also as a strategic path to increase stakeholder trust and digital resilience.

Visionary companies now view CSR not simply as a philanthropic activity, but as a strategy to build stakeholder trust and strengthen digital resilience [9]. Although the Corporate Social Responsibility (CSR) literature is replete with discussion on CSR as a standard element, there exists limited research that systematically links it to cybersecurity awareness in fostering maintenance of sustainable digital culture. Previous studies have explored different factors that influence CSR from the individual [10], organizational level to industry [11], and

institutional levels scale in a developing country context [12]. Corporate social responsibility is being demanded or required along with digital transformation to be increasingly considered in the light of ethical, sociopolitical, and security aspects that we see nowadays. There are several studies which also confirm that a CSR strategically aligned approach can increase the employees' understanding, organization learning, and promotion of other sustainable behavioral performance [13], [14], [15].

In [16], the authors state that CSR creates positive external legitimacy, while [17] and [18] found that CSR increases internal resilience by increasing safe internet behavior among employees. On the other hand, [19] states that issues related to corporate responsibility, such as data security, are interconnected and must be considered holistically within the framework of Corporate Digital Responsibility.

New prospects for enhancing digital security advancements are driven by the emergence of Artificial Intelligence (AI)-based blockchain technology. AI helps drive early threat detection with computerized responses, and blockchain is currently being used for transparency and immutability [20], [21], integrity, and trust within digital frameworks [22]. Integrating this technology with CSR-based awareness programs will result in the [Cybersecurity Integrated CSR Awareness] (CICA) model framework—an innovation for creating cybersecurity awareness among organizational members. For example, Yao's research shows a significant increase in social responsibility as innovative companies use AI in technology-based innovations [23].

This research is based on complementary theories: the Technology–Organization–Environment (TOE) framework and Institutional Theory. The Technology–Organization–Environment (TOE) framework examines how technological, organizational, and environmental factors shape the adoption of artificial intelligence (AI) and blockchain. Institutional Theory explains the pressures of norms, culture, and rules that drive CSR-based digital practices. Furthermore, the Resource-Based View (RBV) theory supports this study as a guideline for how CSR can be considered a strategic resource that strengthens resilience and competitive advantage.

The novelty of this study lies in the explicit integration of CSR with cybersecurity awareness, a relatively unexplored dimension within Corporate Digital Responsibility (CDR), and the conceptualization of AI and blockchain as not only enablers but also moderators that strengthen the relationship between CSR and cybersecurity. By focusing on emerging economies, particularly Indonesia, this research also addresses the geographic imbalance in CSR–cybersecurity research, which has been dominated by developed countries. The proposed CSR Integrated Cybersecurity Awareness (CICA) Framework further enriches the theoretical discourse by linking TOE, Institutional Theory, and RBV to explain how CSR can foster a sustainable digital culture.

II. Literature Review

A. Corporate Social Responsibility and Cybersecurity Awareness

Corporate Social Responsibility (CSR) describes how companies allocate available resources, both financial and human, in order to support long-term sustainable economic growth and appreciate the full scope of related social, cultural and environmental implications. The core principles of CSR show businesses must not merely seek short-term profit, but long-term sustainability. CSR embodies the need for a company to understand its role in society, and that it must balance its commercial activities with human and environmental interests.

The concept of Corporate Social Responsibility (CSR) is evolving alongside the conversation about sustainability. Nowadays, organizations are expected to step up as drivers of social and environmental change [24]. Modern CSR is seen as a comprehensive approach to business, where companies are responsible not only for making profits but also for the well-being of people and the planet. Moreover, the rise of digitalization has brought new challenges to CSR, particularly in areas like data protection, privacy, digital skills, and access to technology. Companies are now tasked with not just fulfilling traditional social responsibilities but also creating a safe and inclusive digital landscape. When CSR initiatives align with business objectives, they can spark innovation, enhance competitive advantage, and ensure sustainable growth over time [25].

In today's digital age, Corporate Social Responsibility (CSR) has shifted towards digital accountability, encompassing aspects like technology inclusion, ethical practices, data protection, and cybersecurity awareness [26]. Empirical studies suggest that CSR has a positive influence on employees' awareness and responsible behaviors. For example, CSR programs were significantly associated with improved awareness and compliance in information security contexts [27], [28], [29]. Similarly, research on CDR highlights that when organizations publicly commit to digital responsibility, employees are more likely to internalize safe practices as part of their professional and ethical duties [30].

In addition, CSR contributes to the development of a sustainable digital environment that is in line with the idea of Corporate Digital Responsibility (CDR), which focuses on the ethical, safe, and sustainable management of data, artificial intelligence, and technology [31]. CSR is considered a component of strategic planning and managerial decision-making [32]. As a result, CSR can be seen as a key driver of digital trust. By integrating cybersecurity-focused initiatives into CSR efforts, organizations not only enhance their external credibility but also strengthen their internal resilience. As a foundation for building a secure, ethical, and resilient digital organization, the framework proposed in this study is:

H1: CSR initiatives positively affect cybersecurity awareness.

H2: CSR initiatives positively influence the development of a sustainable digital culture.

B. Sustainable Digital Culture

Rapid technological developments have transformed global society, with digital literacy rapidly increasing. These changes not only impact the use of digital devices and platforms but also our interactions, communications, and the expression of our cultural values. Digital culture is the starting point for the

sustainable development of businesses run by a company or organization. Consequently, digital culture has emerged as a crucial topic deserving attention.

Sustainable digital culture involves incorporating long-term digital ethics, accountability, and security into the practice of an organization [33], [34]. Awareness driven by corporate social responsibility (CSR) and the adoption of technology play vital roles in fostering this culture. The culture within an organization is marked by an ongoing necessity to adjust to an ever-evolving technological environment and to shift values in order to address or foresee future environmental needs [35].

Sustainable digital culture describes an organizational setting where digital technologies are woven into values, norms, and practices that emphasize both innovation and long-term security. Unlike digital practices that are reactionary or solely focused on compliance, a sustainable digital culture encompasses digital responsibility, ethical use of technology, and resilience as fundamental aspects of organizational behavior [36].

The significance of a sustainable digital culture has gained increasing acknowledgment in global discussions. According to the World Economic Forum, resilient organizations are those that integrate cybersecurity and digital responsibility into their corporate ethos, allowing them to endure challenges such as major data breaches or widespread cyberattacks [37]. Research indicates that organizations with robust digital cultures demonstrate greater flexibility during crises, such as the COVID-19 pandemic, by effectively utilizing digital tools in a secure and sustainable manner [38], [39].

Corporate Social Responsibility (CSR) is crucial in influencing sustainable digital culture. By incorporating cybersecurity awareness initiatives into CSR efforts, businesses foster values of accountability and shared responsibility. This supports the notion that CSR not only bolsters external legitimacy but also promotes internal resilience, thereby contributing to a secure and sustainable digital landscape.

C. Cybersecurity Awareness

Vulnerability to various threats is rapidly increasing due to our high dependence on technology for communication, financial transactions, and personal data management. As cyber threats become more sophisticated, organizations are responsible for equipping their employees with the knowledge and skills necessary to identify and prevent them. Human factors are often the weak link in cybersecurity [40], [41].. Cybersecurity awareness must be implemented with care [42]. Cybersecurity awareness is essential for reducing the risk of phishing, social engineering, and insider threats.

In fact, integrating cybersecurity awareness into CSR initiatives can be an ethical and socially responsible way to promote safe digital behavior. Cybersecurity awareness encompasses the ability of individuals within an organization to understand, recognize, and respond appropriately to cyber threats. It includes the knowledge, attitudes, and behaviors that contribute to the protection of digital assets and the reduction of vulnerabilities [43].

Increasing cybersecurity awareness does not only involve implementing training programs; it also involves fostering a deeper comprehension among individuals within the organization and providing them with the skills to respond to threats effectively [44]. A comprehensive strategy should incorporate organizational elements, operational processes, and human resources [45]. By deploying awareness and training initiatives, employees acquire insights into the organization's security needs, policies, and procedures for securing sensitive data, while also enhancing their capabilities in addressing cybersecurity threats [46].

Raising cybersecurity awareness goes beyond simply offering training programs; it also entails fostering a deeper understanding among individuals in the organization and providing them with the skills to effectively react to threats [44]. A holistic strategy must encompass organizational elements, operational processes, and human capital [45]. By implementing awareness and training initiatives, employees gain insight into the organization's security needs, policies, and procedures to safeguard sensitive data and enhance the handling of cybersecurity challenges [46].

The human aspect of information security has been designed to conceptualize cybersecurity awareness. The Human Aspects of Information Security Questionnaire (HAIS-Q) has identified several dimensions of awareness, including password management, email usage, social networking, information handling, and incident monitoring [47]. These dimensions reflect the idea that awareness is not only about mastering knowledge, but also about applying that knowledge into consistent and secure digital practices.

Scientific evidence confirms the importance of cybersecurity awareness. Training has been shown to reduce the risk of phishing and malware attacks [47], while a work culture that emphasizes accountability encourages compliance and follow-up on threats [48]. Therefore, awareness must be the foundation of an organization's cybersecurity strategy.

In the context of the CSR framework, cybersecurity awareness can be developed through digital literacy programs, training in the ethical use of technology, and community campaigns. This awareness plays a role in creating a sustainable digital culture, where CSR provides legitimacy and resources, while individuals apply these values to their daily practices, which can strengthen the organization's digital responsibility.

H3: Cybersecurity awareness positively contributes to the enhancement of a sustainable digital culture.

H4: Cybersecurity awareness mediates the relationship between Corporate Social Responsibility (CSR) and sustainable digital culture.

D. Artificial Intelligence Adoption

AI has revolutionized cybersecurity with its real-time threat detection and predictive analysis capabilities, increasing efficiency and resilience to attacks [49]. Unlike rule-based systems, AI can analyze big data, recognize abnormal patterns, and prevent risks before they develop.

Within the Technology–Organization–Environment (TOE) and Technology Acceptance Model (TAM) frameworks, AI adoption is influenced by technological factors, organizational readiness, and external pressures [50]. In developing countries, AI is adopted not only for operational efficiency but also to strengthen security and compliance [51].

In relation to CSR and cybersecurity, AI plays a role as an amplifier for awareness programs. Without technological support, CSR initiatives tend to be limited. AI tools such as intelligent firewalls, phishing detection, and behavioral analytics increase the effectiveness of training by reducing reliance on humans [52], [53].

Strategically, the integration of AI in CSR reflects a company's commitment to technological responsibility, not only for profit, but also to protect stakeholders and build public trust.

H5a: The adoption of Artificial Intelligence (AI) moderates the relationship between Corporate Social Responsibility (CSR) and cybersecurity awareness.

E. Blockchain Adoption

The adoption of blockchain is driven by technological, organizational, and environmental (TOE) factors, as well as perceived benefits, infrastructural readiness, and external pressures such as regulatory requirements and competition [54]. Blockchain offers secure, transparent, and immutable data management, making it relevant for cybersecurity governance and CSR reporting [55]. This technology is not only connected to cryptocurrency but also has vast promise for constructing reliable digital infrastructure through decentralization, transparency, and consensus mechanisms [21], [56]..In an organizational context, blockchain provides a verified and immutable transaction record, reducing the risk of fraud and increasing resilience to cyberattacks [57]. While adoption in emerging economies has likely been incremental, blockchain applications in supply chain, healthcare, and digital identity are steadily increasing [58].

In the CSR-cybersecurity framework, blockchain has a role as a moderator by ensuring transparency and accountability. Through blockchain-based reporting systems, CSR initiatives regarding data security and digital literacy can be instated with more credibility, strengthening the effectiveness of cybersecurity awareness programs driven by CSR.

H5b: The adoption of Blockchain moderates the relationship between Corporate Social Responsibility (CSR) and cybersecurity awareness.

The reviewed literature shows that CSR and cybersecurity are often examined separately, with limited studies linking CSR to cybersecurity awareness. Existing models also tend to focus on individual behavior or technology adoption without considering CSR as a strategic driver of security practices. Additionally, the roles of AI and blockchain in supporting CSR-based security outcomes remain understudied, particularly in emerging economies.

To address these gaps, this study proposes the CICA Framework, which integrates CSR, cybersecurity awareness, and emerging technologies. By testing this framework empirically in an emerging-economy context, the study provides new evidence on how CSR, AI, and blockchain contribute to strengthen sustainable digital culture. Fig. 1 presents the research framework.

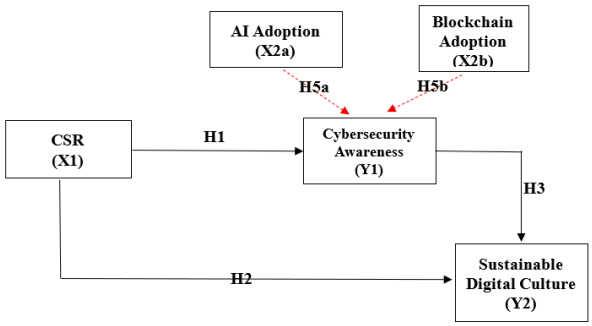

Fig. 1. Research framework.

III. METHODS

This research uses a quantitative design with a survey approach combined with Structural Equation Modelling (SEM) analysis. The research population includes companies and institutions in Central Java that have applied CSR programming and digital awareness practices or security-related programs. A purposive sampling technique was applied to select relevant respondents, including the CSR manager, IT or security personnel, academic officers involved in digital programs, and those actively involved in CSR-based awareness campaigns.

A total of 220 valid responses were collected, fulfilling the recommended minimum for SEM, which is 5 to 10 times the number of latent constructs or the maximum number of structural paths, rather than the number of indicators. The research questionnaire was structured and developed based on previous literature. The CSR indicators were modified from [59], cybersecurity awareness was adapted from [29], AI adoption was based on [49], blockchain adoption was derived from [55], and sustainable digital culture was adapted from [60]. All items were measured using a five-point Likert scale ranging from “strongly” to “strongly agree”. Data analysis consisted of assessing reliability and validity through Cronbach’s Alpha, Composite Reliability, and Confirmatory Factor Analysis (CFA). Structural relationships were examined using SEM–Partial Least Squares (SEM-PLS). Mediation analysis was further conducted to evaluate the role of cybersecurity awareness in mediating the influence of CSR on sustainable digital culture. Additionally, the correlation was tested using SEM-Partial Least Squares (SEM-PLS) [64]. Mediation analysis was also performed to examine the role of CSR in influencing sustainable digital culture through cybersecurity awareness.

IV. RESULTS

A. Respondent Characteristic

This research collected responses of 220 participants representing organizations in Central Java, Indonesia, that have implemented CSR and digital initiatives. The majority of respondents are female (61.4%), with the remaining 38.6%

male. In term of age distribution, the largest group are between 31 and 40 years old (38.6%), followed by over 40 years old (35.9%) and 21 – 30 years old (25%), with only 0.5% aged below 20.

In terms of educational qualification, 48.2% of respondents hold a diploma, 47.3% a bachelor's degree, and 4.5% a master's degree. Regarding professional occupation, 36.80% are IT/Security officers, 28.2% are CSR Managers, and then academic personal involved in digital programs are 13.6%. The respondent's work experience also varies, with 36.4% having worked for 4-6 years, and 30.9% for more than 6 years. 26.8% for 1-3 years, and only 5.9% for less than one year. The result of the respondent characteristic is displayed in Table I.

TABLE I. RESPONDENT CHARACTERISTIC

		Frequency	Per cent	Valid Per cent	Cumulative Per cent
Gender					
Valid	Male	85	38.6	38.6	38.6
	Female	135	61.4	61.4	100.0

B. Measurement Model (Outer Model)

The outer loading analysis confirms that the majority of items load adequately onto their intended constructs, supporting the convergent validity of the measurement model.

1) Validity and reliability test: Table II shows the results of the reliability and validity test. Cronbach's alpha ranged from 0.686 to 0.814, which means that all were above the 0.70 threshold or close to acceptable levels for exploratory studies [61]. Composite Reliability (CR) values ranged between 0.784 and 0.877, exceeding the minimum requirement of 0.70. it confirms internal consistency reliability. Average Variance Extracted (AVE) values were above 0.50 for all constructs (0.529-0.641), demonstrating satisfactory convergent validity. These results confirm that all constructs meet the requirements for reliability and validity in the measurement model [62].

TABLE II. CONSTRUCT RELIABILITY AND VALIDITY

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)
AI	0.712	0.727	0.817	0.529
BA	0.814	0.824	0.877	0.641
CA	0.686	0.686	0.784	0.613
CSR	0.737	0.737	0.820	0.532
SDC	0.794	0.805	0.847	0.582

Source: Data processing results, 2025

2) R-Square test (R^2): Table III explains the explanatory power of the structural model. The R^2 value for Cybersecurity Awareness (CA) is 0.616, indicating that CSR, AI, and Blockchain explain 61.6% of its variance. Meanwhile, Sustainable Digital Culture (SDC) shows an R^2 of 0.346, suggesting that CSR and CA togethers explain 34.6% of its variance. These values indicate substantial explanatory power for CA and moderate explanatory power of SDC.

TABLE III. R-SQUARE

	R-Square	R-Square Adjusted
CA	0.616	0.611
SDC	0.346	0.340

Source: Data processing results, 2025

3) Model fit test: The goodness-of-fit indices for the measurement and structural model are presented in Table IV. The Standardized Root Mean Square Residual (SRMR) values of 0.085 (saturated model) and 0.089 (estimated model) fall below the recommended threshold of 0.10, indicating an acceptable model fit. The d_ULS and d_G values also fall within acceptable ranges for PLS-SEM exploratory models. The Chi-square values for both models (803.085 and 816.569) show consistency between the saturated and estimated structures. Additionally, the Normed Fit Index (NFI) values of 0.912 and 0.905 exceed the recommended cut-off of 0.90, demonstrating strong model fit and confirming the adequacy of the proposed structural relationships. Then, the model fit statistics confirm that the measurement and structural models are appropriate.

TABLE IV. MODEL FIT

	Saturated Model	Estimated Model
SRMR	0.085	0.089
d_ULS	2.915	3.213
d_G	0.688	0.700
Chi-Square	803.085	816.569
NFI	0.912	0.905

Source: Data processing results, 2025

4) Model selection criteria: The result of the model selection criteria is displayed in Table V. Based on the table, all indices (AIC, BIC, and HQ) values provide additional robustness checks for comparing alternatives model specifications. Negative AIC and BIC values for CA and SDC suggest good model parsimony. Corrected criteria (AICc, HQCc) [63] also support the stability of the estimated model. While all these values are supplementary, they reinforce the appropriateness of the selected framework.

TABLE V. MODEL SELECTION CRITERIA

	AIC (Akaike's Information Criterion)	AICu (Unbiased Akaike's Information Criterion	AICc (Corrected Akaike's Information Criterion)	BIC (Bayesian Information Criteria)	HQ (Hannan Quinn Criterion)	HQc (Corrected Hannan-Quinn Criterion)
CA	-203.498	-199.462	18.782	-189.924	-198.017	-197.639
SDC	-88.396	-85.375	133.790	-78.215	-84.285	-84.050

Source: Data processing results, 2025

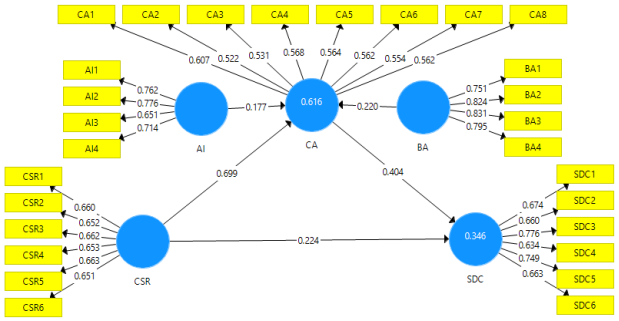

Fig. 2. Outer model or measurement model.

Source: Data processing results, 2025

Annotation:

AI: AI Adoption

BA: Blockchain Adoption

CA: Cybersecurity Awareness

CSR: Corporate Social Responsibility

SDC: Sustainable Digital Culture

Fig. 2 illustrates the outer model and the standardized factor loadings for all constructs. The measurement model demonstrates that each indicator loads strongly on its intended latent construct. All loading values exceed the recommended threshold of 0.60, indicating acceptable convergent validity. The CSR construct shows loading values ranging from 0.640 to 0.683, while AI adoption indicators load between 0.714 and 0.762. Blockchain adoption indicators demonstrate strong loadings ranging from 0.775 to 0.841.

Cybersecurity awareness (CA) indicators also perform satisfactorily, with loadings between 0.528 and 0.582, which are acceptable for exploratory PLS-SEM studies. The sustainable digital culture (SDC) construct shows consistently high indicator loadings between 0.674 and 0.749, demonstrating strong reflective measurement reliability.

Furthermore, the coefficient of determination (R^2) indicates that the model has good explanatory power. CSR, AI, and blockchain collectively explain 61.6% of the variance in cybersecurity awareness (CA), while CSR and CA explain 34.6% of the variance in sustainable digital culture (SDC). These values demonstrate that the model has meaningful predictive capability.

Overall, the outer model satisfies the key reliability and validity criteria, confirming that each construct is measured accurately and consistently. The indicators are therefore suitable for inclusion in the structural model assessment.

C. Structural Inner Model and Hypothesis Test

Table VI reveals the results of the path coefficients used to test the hypothesized relationships in the structural model. The results indicate several significant relationships. CSR → Cybersecurity Awareness (CSA). CSR has a strong and positive influence on CSA ($\beta = 0.699$, $t = 17.363$, $p < 0.001$). This indicates that CSR initiatives significantly increase cybersecurity awareness among organizational members. CSR → Sustainable Digital Culture (CSA). CSR also directly influences CSA ($\beta = 0.224$, $t = 2.462$, $p = 0.014$). Although the effect is smaller than CSA, these results indicate that CSR contributes to building a sustainable digital culture. Cybersecurity Awareness (CSA) → Sustainable Digital Culture (CSA). CSA exhibits a significant positive impact on CSA ($\beta = 0.404$, $t = 4.338$, $p < 0.001$). This suggests that increased awareness of cybersecurity practices fosters stronger digital sustainability within organizations. AI → CA. AI adoption significantly increases CA ($\beta = 0.177$, $t = 3.850$, $p < 0.001$). This confirms AI's role in increasing awareness by enabling predictive threat detection and intelligent digital monitoring. Blockchain Adoption (BA) → CA. Blockchain adoption positively impacts CA ($\beta = 0.220$, $t = 3.515$, $p < 0.001$). This suggests that blockchain's transparency and security features contribute to increased cybersecurity awareness within organizations.

TABLE VI. PATH COEFFICIENT

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDE)	P Values
AI -> CA	0.177	0.185	0.046	3.850	0.000
BA -> CA	0.220	0.217	0.063	3.515	0.000
CA -> SDC	0.404	0.408	0.093	4.338	0.000
CSR -> CA	0.699	0.697	0.040	17.363	0.000
CSR -> SDC	0.224	0.231	0.091	2.462	0.014

Source: Data processing results, 2025

These results provide strong empirical support for the CSR-Integrated Cybersecurity Awareness Framework (CICA). CSR has both direct and indirect impacts on sustainable digital culture, with cybersecurity awareness as a key mediating construct. Furthermore, the adoption of AI and blockchain technologies strengthens cybersecurity awareness, in line with their theoretical role as moderators in the conceptual framework.

D. Mediation Analysis

1) Indirect effects: Table VII reports the results of the indirect effect analysis to probe the mediating role of Cybersecurity Awareness (CSA) in the relationship between CSR, AI, blockchain adoption, and Sustainable Digital Culture (SDC). Based on the analysis results, it was revealed that AI → CSA through CSA: AI has a significant indirect effect on CSA through CSA (β = 0.071, t = 2.742, p = 0.006). This indicates that AI contributes to sustainable digital culture, primarily by strengthening cybersecurity awareness. Additionally, Blockchain Adoption (AP) → CSA through CSA: AP also has a significant indirect effect on CSA through CSA (β = 0.089, t = 2.454, p = 0.014), indicating that blockchain adoption promotes digital sustainability when combined with increased cybersecurity awareness. Finally, CSR → SDC through CA: CSR has strong and significant indirect effects on SDC mediated by CA (β = 0.283, t = 4.289, p < 0.001). This underlines the essential role of cybersecurity awareness as an intervention mechanism through which CSR initiatives improve sustainable digital culture.

TABLE VII. INDIRECT EFFECTS

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values
AI -> CA					
AI -> SDC	0.071	0.075	0.026	2.742	0.006
BA -> CA					
BA -> SDC	0.089	0.090	0.036	2.454	0.014
CA -> SDC					
CSR -> CA					
CSR -> SDC	0.283	0.284	0.066	4.289	0.000

Source: Data processing results, 2025

These results simultaneously support H4, establishing CA as a key mediator that directs the influence of CSR, AI, and blockchain adoption into the development of a sustainable digital culture. These findings strengthened the theoretical proposition of the CSR Integrated Cybersecurity Awareness Framework (CICA), in which cybersecurity awareness serves as a foundation that connects organizational responsibility and technology adoption with long-term digital sustainability.

2) Specific indirect effects: Table VIII presents specific indirect effects confirming that KSI significantly mediates the relationship between CSR, AI, blockchain adoption, and sustainable digital culture (SDC). AI → KSI → SDC: The indirect effect is significant (β = 0.071, t = 2.742, p = 0.006), indicating that AI adoption enhances sustainable digital culture primarily through its positive influence on cybersecurity awareness. BA → KSI → SDC: The indirect path is also significant (β = 0.089, t = 2.454, p = 0.014), indicating that blockchain adoption enhances digital sustainability when it increases cybersecurity awareness. CSR → CA → SDC: The strongest mediation effect occurs in the CSR path (β = 0.283, t = 4.289, p < 0.001), indicating that CSR initiatives significantly strengthen sustainable digital culture by first increasing cybersecurity awareness.

These results provide strong support for H4, which confirms CA as a central mediating mechanism. This means that CSR and emerging technologies do not directly transform digital culture separately; their effects are significantly strengthened when both first increase cybersecurity awareness within the organization.

TABLE VIII. SPECIFIC INDIRECT EFFECTS

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDE|)	P Values
AI -> CA -> SDC	0.071	0.075	0.026	2.742	0.006
BA -> CA -> SDC	0.089	0.090	0.036	2.454	0.014
CSR -> CA -> SDC	0.283	0.284	0.066	4.289	0.000

Source: Data processing results, 2025

TABLE IX. TOTAL EFFECTS

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values
AI -> CA	0.177	0.185	0.046	3.850	0.000
AI -> SDC	0.071	0.075	0.026	2.742	0.006
BA -> CA	0.220	0.217	0.063	3.515	0.000
BA -> SDC	0.089	0.090	0.036	2.454	0.014
CA -> SDC	0.404	0.408	0.093	4.338	0.000
CSR -> CA	0.699	0.697	0.040	17.363	0.000
CSR -> SDC	0.507	0.515	0.044	11.527	0.000

Source: Data processing results, 2025

Table IX provides a comprehensive understanding of the direct and indirect relationships between variables. CSR → SDC: CSR shows the strongest total effect on SDC (β = 0.507, t = 11.527, p < 0.001), which illustrates that CSR initiatives play an important role in shaping a sustainable digital culture. This total effect combines the direct path (CSR → SDC) and the indirect path mediated by CA (CSR → CA → SDC). CA → SDC: Cybersecurity awareness significantly influences sustainable digital culture (β = 0.404, t = 4.338, p < 0.001), reaffirming its important role in achieving digital sustainability outcomes. AI and BA → SDC: Both AI (β = 0.071, p = 0.006) and blockchain adoption (β = 0.089, p = 0.014) have a significant total effect on SDC, although their main influence occurs indirectly through CA.

These findings confirm the central role of CSR as a key driver of cybersecurity awareness and digital sustainability. Furthermore, the integration of new technologies—AI and

blockchain—further strengthens this relationship by enhancing cybersecurity readiness, which in turn fosters a resilient and sustainable digital culture.

3) Bootstrapping results: Fig. 3 demonstrates the bootstrapping results for the internal model of the CSR Integrated Cybersecurity Awareness Framework (CICA). Bootstrapping analysis with 5,000 subsamples validates the stability and significance of the path coefficients obtained in the structural model.

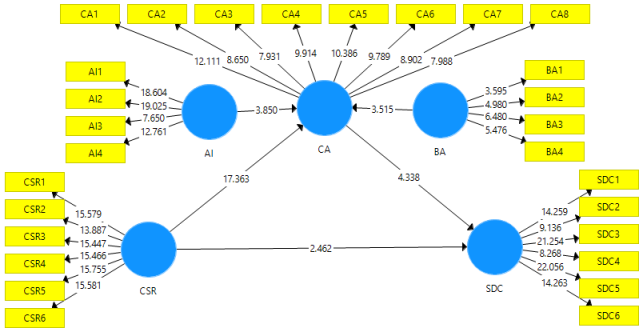

Fig. 3. Inner model (bootstrapping).

Source: Data processing results, 2025

The results show that all hypothesized relationships are statistically significant, as indicated by T-statistic values above the minimum threshold of 1.96: CSR → CA ($t = 17.363$, $p < 0.001$), confirming the strong role of CSR in enhancing cybersecurity awareness. CSR → SDC ($t = 2.462$, $p = 0.014$), indicating that CSR directly supports a sustainable digital culture. CA → SDC ($t = 4.338$, $p < 0.001$), indicating that cybersecurity awareness significantly contributes to digital sustainability. AI → CA ($t = 3.850$, $p < 0.001$) and BA → CA ($t = 3.515$, $p < 0.001$), confirming that new technologies strengthen cybersecurity awareness. In addition, the external loadings also exhibited strong significance, with most indicators indicating t values above 7.0, supporting the reliability of the measurement model. Overall, the bootstrapping results validate all direct hypotheses (H1–H3, H5a, H5b) and reinforce the mediating role of CA in the influence of CSR on sustainable digital culture (H4).

E. Moderating Effect

Fig. 4 describes the moderating effect of Artificial Intelligence (AI) and Blockchain (BA) adoption on the relationship between Corporate Social Responsibility (CSR) and Cybersecurity Awareness (CA). Bootstrapping analysis confirms that Blockchain (BA) adoption significantly moderates the CSR–CA relationship ($t = 2.426$, $p < 0.05$). This indicates that CSR initiatives are more effective in enhancing cybersecurity awareness when accompanied by blockchain adoption, which strengthens digital transparency and trust. On the other hand, the moderating effect of AI adoption is not significant ($t = 0.132$, $p > 0.05$). This indicates that although AI directly strengthens CA (as shown in Fig. 2), its role as a moderator in the CSR–CA path is not supported in this study. Overall, these findings partially support H5a and H5b. Specifically, H5b (Blockchain adoption as a moderator) is supported, while H5a (AI as a moderator) is not supported.

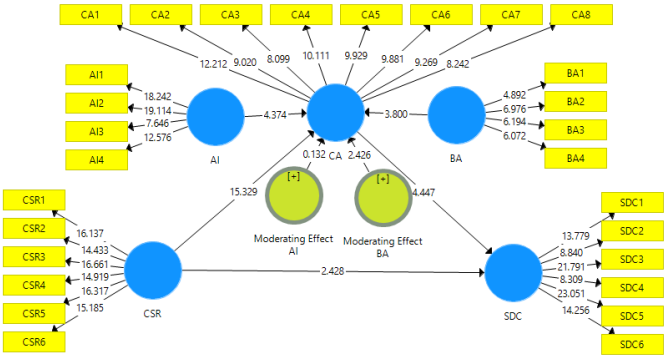

Fig. 4. Moderating effect analysis of AI and BA on the relationship between CSR and CA.

F. Path Analysis

Table X displays the results of the final path analysis, with the following findings:

TABLE X. PATH ANALYSIS

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values
AI -> CA	0.195	0.200	0.045	4.374	0.000
BA -> CA	0.232	0.233	0.061	3.800	0.000
CA -> SDC	0.404	0.410	0.091	4.447	0.000
CSR -> CA	0.681	0.679	0.044	15.329	0.000
CSR -> SDC	0.224	0.229	0.092	2.428	0.016
Moderating Effect AI -> CA	0.006	0.006	0.045	0.132	0.895
Moderating Effect BA -> CA	0.126	0.124	0.052	2.426	0.016

Source: Data processing results, 2025

H1: (CSR → CA): Supported. CSR has a strong and significant effect on cybersecurity awareness ($\beta = 0.681$, $t = 15.329$, $p < 0.001$).

H2: (CSR → SDC): Supported. CSR has a positive effect on sustainable digital culture ($\beta = 0.224$, $t = 2.428$, $p = 0.016$).

H3: (CA → SDC): Supported. Cybersecurity awareness contributes strongly to sustainable digital culture ($\beta = 0.404$, $t = 4.447$, $p < 0.001$).

H5a: (AI → CA): Supported as a direct effect. AI adoption significantly increases CA ($\beta = 0.195$, $t = 4.374$, $p < 0.001$). However, the moderating effect of AI was not significant ($\beta = 0.006$, $t = 0.132$, $p = 0.895$), indicating that AI does not strengthen the CSR–CA relationship.

H5b: (BA → CA): Supported. Blockchain adoption has a direct positive impact on CA ($\beta = 0.232$, $t = 3.800$, $p < 0.001$). Furthermore, the moderating effect was significant ($\beta = 0.126$, $t = 2.426$, $p = 0.016$), confirming that blockchain adoption strengthens the influence of CSR on cybersecurity awareness.

Overall, these results suggest that CSR plays a central role in shaping cybersecurity awareness and a sustainable digital culture, with CA acting as a key mediator (H4). AI and blockchain adoption directly strengthen cybersecurity awareness, but only blockchain shows a significant moderating effect on the CSR–CA pathway.

V. Discussion

This study aims to design and test the CSR-Integrated Cybersecurity Awareness Framework (CICA), which links corporate social responsibility (CSR) initiatives, cybersecurity awareness, a sustainable digital culture, and the moderating role of artificial intelligence (AI) and blockchain adoption. The findings provide strong empirical support for theoretical propositions and contribute to the growing discussion on CSR and digital sustainability.

The results of this study indicate that CSR has a significant influence on cybersecurity awareness (H1) and also has a direct effect on sustainable digital culture (H2). This finding aligns with previous research, which revealed that CSR initiatives not only focus on external legitimacy but also strengthen internal organizational resilience [30].

By integrating cybersecurity-related programs into their corporate social responsibility (CSR) initiatives, organizations help employees understand digital threats, ethical data management, and safe internet browsing. The dual function of CSR—both for the external community and within the organization—demonstrates that CSR continues to adapt to meet the challenges of digital change.

Raising cybersecurity awareness significantly contributes to the formation of a sustainable digital culture, and further analysis indicates that this awareness serves as a key mediator in the relationship between CSR and a sustainable digital culture. This suggests that CSR initiatives indirectly support digital sustainability by increasing employee understanding of cybersecurity threats and practices. These results align with organizational culture theory, which emphasizes the importance of awareness and shared values as determinants of long-term resilience [65]. The mediating role of CA emphasizes the importance for organizations to incorporate cybersecurity education into CSR programs to ensure innovative and secure digital transformation.

The adoption of emerging technologies has a significant impact on improving the understanding of cybersecurity. Both artificial intelligence (direct effect H5a) and blockchain (direct effect H5b) substantially improve CA. Artificial intelligence assists through predictive analytics and intelligent monitoring [49], while blockchain adds transparency, integrity, and trust to online transactions [56].

The findings of this study, based on moderation analysis, show mixed results. Blockchain used significantly strengthens the relationship between CSR and CA, confirming H5b, while AI used does not show a significant moderating effect (H5a). This suggests that blockchain provides structural support to CSR programs by building trust and accountability in digital practices, while AI's role is more focused on technical and operational aspects. This finding reiterates the argument that blockchain implementation is often linked to governance and compliance frameworks, making it more directly relevant to CSR initiatives, while the impact of AI depends on its maturity and alignment with organizational strategy.

VI. Conclusion

This study develops and empirically validates the CSR-Integrated Cybersecurity Awareness (CICA) Framework, highlighting how CSR initiatives, supported by AI and blockchain adoption, contribute to increased cybersecurity awareness and a sustainable digital culture.

CSR as a key enabler – CSR significantly increases cybersecurity awareness and directly drives a sustainable digital culture, underscoring its dual role in external legitimacy and internal resilience. Cybersecurity awareness as a mediator – CSR mediates the relationship between CSR and SDC, affirming its central position in translating CSR initiatives into sustainable digital practices. Emerging technologies as enablers – Both AI and blockchain adoption directly strengthen cybersecurity awareness, with blockchain further moderating the CSR–CICA relationship. However, AI does not exhibit a significant moderating effect, indicating differences in the maturity and integration of these technologies. Overall, these results validate the CICA framework as a novel theoretical contribution, extending the CSR discourse into digital transformation and resilience.

A. Implications

Theoretically, the study advances the CSR literature by linking it to digital resilience and sustainability. It extends CSR discourse beyond environmental and social domains into the realm of cybersecurity and digital ethics, areas that are increasingly critical in the Fourth Industrial Revolution. The CICA framework offers a novel lens to understand how CSR can be operationalized in digital contexts.

Practically, the findings suggest that organizations—particularly universities and enterprises in emerging markets—should:

- Integrate cybersecurity education and training into CSR programs.
- Leverage blockchain technologies as strategic tools to enhance trust and amplify the effectiveness of CSR initiatives.
- Consider AI adoption as a direct enabler of awareness but ensure strategic alignment for it to play a stronger organizational role.

B. Future Research

The CICA Framework demonstrates that integrating CSR, cybersecurity awareness, and emerging technologies can strengthen digital resilience. Future studies should examine this model across different industries and regions to enhance generalizability. Additional moderating factors—such as organizational culture or leadership style—may also offer deeper insights into the CSR–cybersecurity relationship. Longitudinal approaches are recommended to capture changes in CSR, cybersecurity behavior, and technology adoption over time.

This study has several limitations. Its cross-sectional design restricts causal interpretation, and reliance on self-reported data may introduce bias. The sample is limited to organizations in Central Java, which may affect broader applicability. Furthermore, the model focuses on AI and blockchain, while other emerging technologies, such as IoT-based security or edge computing, were not examined. Future research should consider wider samples, mixed-method approaches, multi-level analyses, and additional technological or organizational factors to further refine and extend the CICA Framework.

Recursive Gated Convolution-Based YOLOv11 Framework for Operator Safety Management in Live-Line Work

Dapeng Ma, Liang Yang, Kang Chen, Feng Yang, Ao Cui, Rundong Yang*, Zhilin Wen, Donghua Zhao
Yunnan Power Grid Co., Ltd., Kunming, China

***Abstract*—In live-line work scenarios, it is essential for workers to wear electric field shielding clothing to prevent fatal accidents caused by electric shock. Accordingly, this study developed an electric field shielding clothing detection system for live-line working environments based on the YOLOv11 framework. Previous research has explored intelligent wearable detection systems for personal protective equipment such as safety helmets. However, compared to safety helmets, electric field shielding clothing comes in more varieties and is more challenging to identify. To address the challenges mentioned above, this study constructed a dual-layer detection model for operator detection and electric field shielding clothing detection in live-line work scenarios. The first layer employs an improved detection transformer (IDETR) to locate operators within the environment. The second layer, based on the YOLOv11 framework integrated with recursive gated convolution (GnConv), is designed to classify three types of personal protective equipment, including electric field shield clothing, electric field shield masks, and electric field shield gloves. Finally, the experimental results showed that compared with the DETR, the accuracy of the IDETR-based worker localization model improved by 2.29%. The accuracy of the GnConv-based YOLOv11 framework in the electric field shielding clothing detection task reaches 90.40%.**

***Keywords*—Detection transformer; recursive gated convolution; YOLOv11; personal protective equipment; live-line work scenarios**

I. INTRODUCTION

Electric field shielding clothing (EFSC) protects workers from high-voltage electric fields, induced currents, and potential injuries caused by contact currents. In live-line working environments, failure to use EFSC correctly or at all can expose personnel to life-threatening risks. Therefore, the development of a real-time monitoring system for EFSC can effectively prevent workers who are not wearing or improperly wearing the protective gear from entering hazardous areas or performing high-risk operations [1]. In this study, the real-time detection system for EFSC involves using visual cameras and image recognition technology to detect whether workers in live line work scenes are wearing EFSC in a standardized manner. The system primarily consists of two modules: the staff positioning and the EFSC wearing detection module. For the staff positioning module, after the visual camera captures images of the staff, this module functions to accurately identify both personnel and the working environment. The EFSC wearing detection module utilizes the output from the positioning module to detect specific types of personal protective equipment, including electric field shield clothing, masks, and gloves.

In the context of live-line maintenance, accurate detection of personnel presents several challenges. First, complex environmental backgrounds, such as interference from transmission towers and other equipment, adversely affect target localization. Second, the workers themselves, as the targets of detection, exhibit considerable complexity. Their postures are non-standard and highly dynamic, and they may occlude one another [2]. The detection of EFSC is critical to ensuring the safety of live-line work, yet this task also involves numerous technical challenges in practical applications. Firstly, the material of the EFSC has a metallic texture and typically appears in silver or black. These colors are prone to strong reflections or shadows under certain lighting conditions, which can blur visual features such as the edges of the clothing. This directly increases the difficulty of image segmentation and feature extraction in the EFSC wearing detection module. Moreover, some critical safety items, such as electric field shielding gloves and protective eyewear, occupy only a small area within captured images. Their subtle features are easily overlooked during object recognition, leading to missed detections or misidentification. Additionally, the cost of acquiring real-world live-line maintenance images is high, and it is challenging to accurately annotate boundaries of occluded or reflective areas on EFSC in the images. This issue directly impacts the performance of model training [3].

Currently, mainstream object detection methods include transformer-based and convolutional neural network (CNN)-based approaches. CNN-based methods for staff localization require pre-defined anchor boxes of various sizes and aspect ratios for all images in both the training and validation sets, resulting in a more complex workflow. In contrast, transformer-based object detection methods significantly reduce the need for manual prior knowledge and tedious image preprocessing [4]. In addition, compared to CNN-based methods for worker localization, the transformer-based model demonstrates superior performance in detecting occluded objects [5]. Therefore, to address the object detection task in live-line work scenarios, this study introduces an improved version of the detection transformer (DETR) model, with the aim of enhancing the detection of transmission line maintenance workers in complex environments. However, the DETR model also requires a substantial number of training epochs to converge and exhibits poor performance in small object detection due to its high sampling rate [6]. Therefore, for

*Corresponding author.

the task of classifying three types of personal protective equipment, electric field shielding clothing, electric field shielding masks, and electric field shielding gloves, an improved YOLOv11 framework was developed.

In summary, this study proposes a dual-layer detection model to enhance the safety management of operators during live-line work. The first layer consists of a staff positioning module based on an improved DETR model, while the second layer comprises a personal protective equipment detection module based on an enhanced YOLOv11 architecture tailored for electric field shielding gear. Specifically, a deformable attention (DA) module has been incorporated into the DETR model to improve both its convergence speed and object detection accuracy. Additionally, the recursive gated convolution (GnConv) module has been integrated into the YOLOv11 framework to boost its performance in detecting small objects. The overall structure of the proposed dual-layer safety management detection model for transmission line maintenance operators is illustrated in Fig. 1. The main contributions of this study are summarized as follows:

- A dual-layer detection model for safety management of workers in live-line working scenarios has been proposed, which effectively integrates the tasks of identifying electric field shielding equipment and locating operators.
- The DA module is introduced into the DETR model to improve the accuracy of target detection for operators in live-line working scenarios.
- The GnConv module is embedded into the YOLOv11 architecture, aiming to improve the feature extraction and classification capabilities of the YOLO architecture for small target objects such as electric field shielding clothing.
- Experiments were conducted based on image information collected from real live-line working scenarios, and the results showed that the improved YOLOv11 framework achieved a detection accuracy of 92.61% in the electric field shielding clothing detection task.

The remaining sections of this study are arranged as follows: Section II reviews the work related to personal protective equipment testing. Section III describes the proposed object detection framework. Section IV presents the results and discussion. Finally, Section V provides a summary of the entire study.

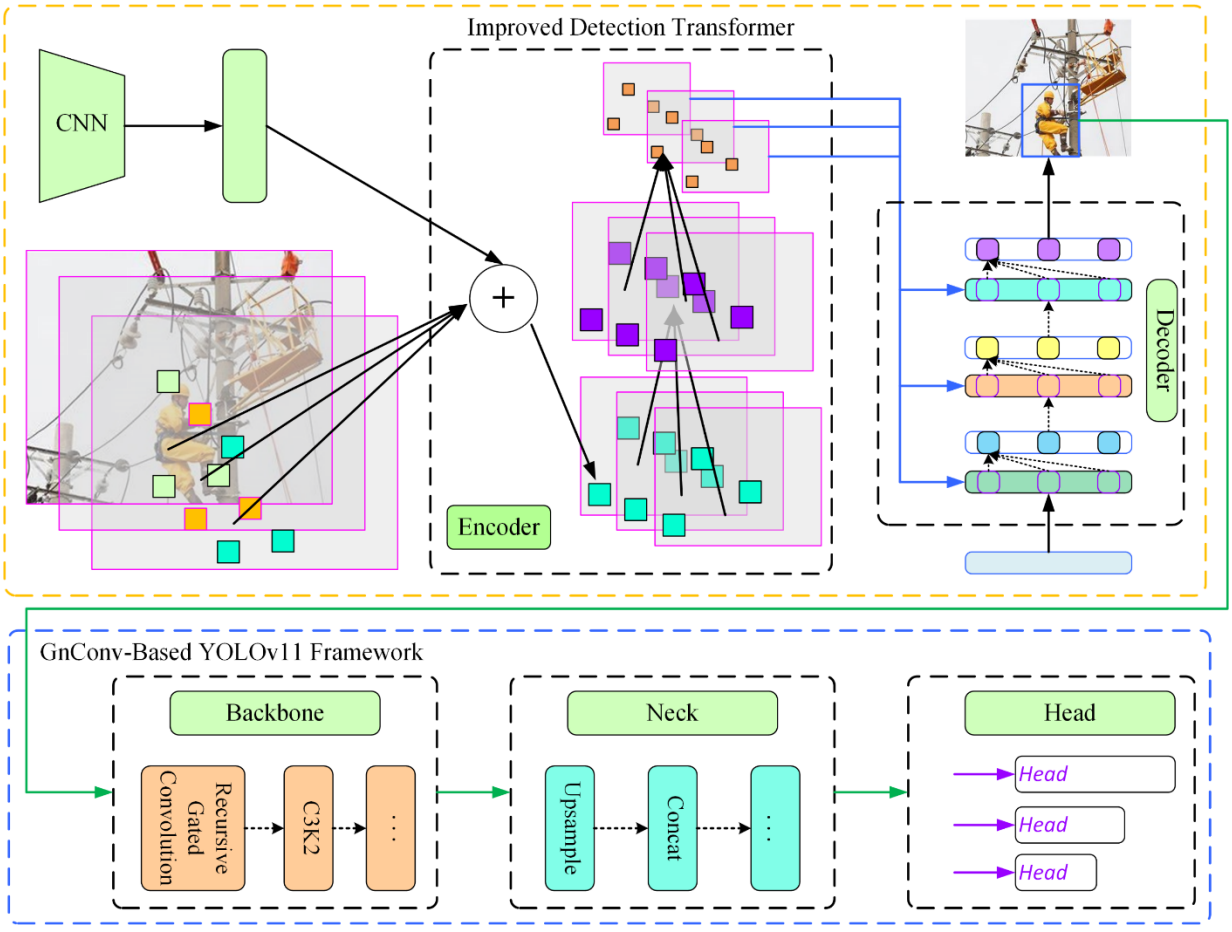

Fig. 1. The proposed dual-layer detection model for operator safety management in live-line work.

II. Related Work

The double-layer target detection model proposed in this study, designed for the safety management of workers in live-working scenarios, comprises two main tasks: worker positioning and electric field shielding equipment identification. Accordingly, a review of related work has been conducted, covering transformer-based image processing models and object detection frameworks based on YOLO.

A. Detection Transformer

In [7], the authors reviewed transformer-based image processing models. Specifically, it includes the basic architecture, core mechanisms, and key improvements and variations of transformer-based image processing models in different image processing tasks. In addition, this study comprehensively summarizes the benefits of transformers compared to traditional CNNs in processing visual data. In [8], the authors improved the DETR model and designed a lightweight transformer-based object detection model. In this study, an encoder-free neck (EFN) architecture was designed to reduce the computational overhead of traditional DETR models during training. The experimental results show that the proposed lightweight DETR model improves operational efficiency through structural optimization while maintaining end-to-end detection advantages, achieving a balance between high efficiency and detection accuracy.

In [9], the authors improved the DETR object detection framework to handle object detection tasks in pathological images. In response to the challenges of small cell scales and dense distribution in organizational images, this study optimized the feature extraction and matching mechanism of DETR, significantly improving the recall and robustness of mitotic cell recognition. Choi et al. focused on object detection in dense scenes and proposed a DETR model based on recurrent [10]. This model enhances DETR's ability to distinguish occluded targets by introducing a recursive mechanism, and experiments were conducted on a typical dense target dataset. The results showed that the DETR model based on recurrent improved the detection accuracy of traditional DETR models in high occlusion situations, providing a foundation for the improvement of DETR models.

Ghahremani et al. proposed a Transformer-based organ detection method aimed at improving the accuracy and robustness of organ localization in medical images [11]. This model introduces a deformable attention mechanism in the DETR framework to enhance the feature capture ability of classical DETR models for organs of different sizes and shapes, solving the problem of low target localization accuracy in traditional CNN-based detection methods in complex medical images. In [12], the authors combine the Mamba model with transformer for small object detection tasks, aiming to leverage the efficiency advantage of Mamba in long sequence modeling and enhance the ability to extract multi-scale features of small objects. The final results indicate that the Mamba-based transformer model significantly improves detection accuracy while maintaining low computational overhead. In [13], the authors proposed an end-to-end rotating object detection transformer framework. This framework overcomes the challenge of traditional horizontal detection boxes being sensitive to directional changes by designing an angle aware query mechanism and a rotation box alignment loss function.

In [14], the authors also improved the DETR model, aiming to enhance the detector's discriminative ability in complex backgrounds. The improved DETR model can more accurately distinguish aircraft targets from background interference by introducing a loss function of structural perception. In [15], the authors studied the synchronization loss optimization problem in rotation and orientation object detection based on the DETR model. This study proposes a universal synchronization optimization strategy to improve training stability. The experimental results show that the proposed method effectively alleviates the conflict between angle regression and classification tasks by unifying different loss calculation methods.

B. YOLO-Based Target Detection

In [16], the authors explore the application of YOLOv11 in urban map drawing. This study introduces the advanced real-time object detection model YOLOv11 into complex urban environments, aiming to enhance the automatic recognition and annotation capabilities of urban features. Perikamana Narayanan et al. designed a face detection and counting system based on YOLOv9, focusing on the confusion between human and animal faces and the interference of complex imaging environments on the accuracy of object detection models [17]. Finally, the experimental results demonstrate that the YOLOv9 model can maintain high recognition accuracy and robustness under complex conditions. Alsabei et al. applied YOLOv9 to the field of security, aiming to solve the real-time detection task of abnormal pedestrian behavior [18]. This study focuses on the characteristics of dense crowds and complex behavioral patterns in high-risk scenarios, and uses YOLOv9 to detect abnormal activities that may cause danger in real time. Khan et al. utilized an optimized YOLOv9s model for real-time road damage detection [19]. This study enhanced the performance of YOLOv9s through optimization and fusion techniques of object detection models, thereby achieving real-time detection of defects such as road surface damage and cracks.

In [20], the authors proposed a small object detection model in remote sensing images based on YOLOv10, aiming to solve the problem of low resolution and weak features of small objects in remote sensing images. This study significantly improved the recognition accuracy and recall rate of YOLOv10 for small objects in complex remote sensing scenes by improving it. In [21], the authors propose an intelligent psyllid monitoring system based on YOLOv10, which combines the YOLOv10 model with a visual transformer for detecting small pest targets that are difficult to detect in agricultural scenes. In [22], the authors proposed a deep-sea fish detection model based on YOLOv10. This model has the advantages of lightweight and high detection accuracy. Overall, the model developed in this study effectively addresses challenges such as dim lighting, complex backgrounds, and diverse forms of fish targets in deep-sea exploration. In [23], the authors developed a traffic police gesture recognition framework based on the YOLO model. Based on the latest YOLOv11 framework, the YOLOv11 framework was improved to address the challenges of fast

dynamic changes in traffic police gesture actions and high background noise interference in traffic command scenarios.

In [24], the authors developed a method combining faster region-based convolutional neural networks (Faster R-CNN) with model driven clustering for special object detection problems with large aspect ratios. This study effectively addresses the challenge of poor detection performance of general object detection models for unconventional shaped objects. In [25], the authors integrate real-time DETR (RT-DETR) and ByteTrack algorithm to construct a multi vehicle tracking and counting framework for daily traffic flow survey. This study demonstrates the application effectiveness of Transformer based detectors in practical engineering. In [26], the authors developed a precise reading algorithm for substation pointer instruments based on RetinaNet. By improving the RetinaNet detection network, it effectively solved the reading difficulties caused by uneven lighting, dial fouling, and small pointer shapes in actual industrial environments.

III. The Proposed Target Detection Model

The proposed live-line work scenario operator security management model mainly consists of two components. The first component involves the use of the deformable attention-based DETR (DA-DETR) for the operator localization task. The second component integrates GnConv and YOLOv11, aiming to detect whether workers are wearing electric field shielding clothing according to standards.

A. The Deformable Attention-based DETR

Operator localization in live working scenarios is a challenging object detection task. Specifically, the background of live working sites is complex, with interferences such as wires, insulators, and towers. In addition, the varying postures of operators result in significant differences in target scale. To address the above challenges, the DA mechanism has been introduced into the DETR model, aiming to improve the accuracy of object detection in classical DETR models. Fig. 2 illustrates the DA mechanism. The input data for the operator positioning system based on DA-DETR is usually real-time video streams collected by visual sensors from live work sites. In the encoding stage, the Transformer encoder utilizes the DA mechanism to enhance and extract the global features of live working site images. In the decoding stage, a set of learnable object queries interact with image features through the DA mechanism, enabling them to adaptively focus on the most informative key regions and accurately locate potential targets.

In the DA-DETR-based operator positioning system, the DA mechanism uses a multi-head attention model and a deformable attention model. The definition of the multi-head attention model is as follows [see Eq. (1)]:

$$MHAtten(\Pi_i, D_e) = \sum_{h\in H} W_h \times \left[\sum_{e\in E} A_{h,i,e} \times W_h^* \times D_e\right] \quad (1)$$

where, Π_i is the i -th element of the feature matrix. D_e is the e -th vector of the input data. $h \in H$ is the attention head. W_h and W_h^* are learnable weight parameters. $A_{h,i,e}$ is the attention weight.

The constraint conditions of $A_{h,i,e}$ are defined as Eq. (2):

$$\sum A_{h,i,e} = 1 \quad (2)$$

For a given feature map D_e , generate a point B_e as a unified grid reference. The definition of deformable attention model is as follows [see Eq. (3)]:

$$DAtten(\Pi_i, D_e) = \sum_{h\in H} W_h \times \left[\sum_{e\in E} A_{h,i,e} \times W_h^* \times (B_e + \Delta B_{h,i,e})\right] \quad (3)$$

where, $\Delta B_{h,i,e}$ is the offset of point B_e .

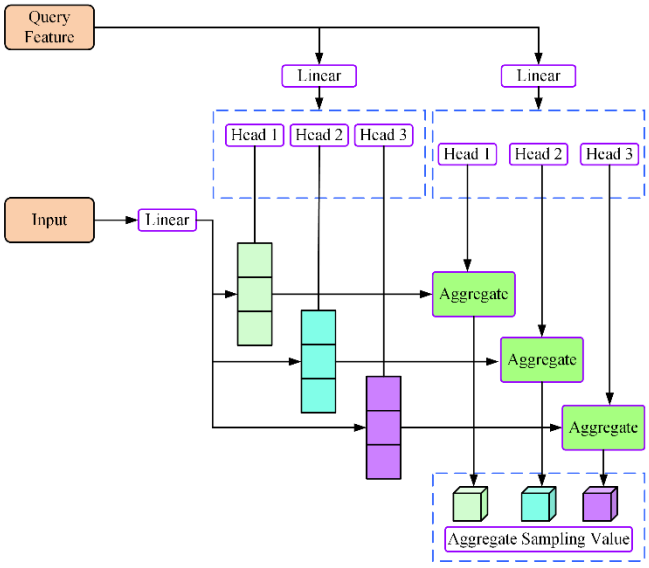

Fig. 2. The deformable attention (DA) mechanism.

B. The GnConv-Based YOLOv11

The electric field shielding clothing wearing detection system uses a hybrid GnConv and YOLOv11 (GnConv-YOLOv11) framework, which embeds the GnConv module into the architecture of YOLOv11. The advantage of GnConv lies in its ability to establish global context dependencies based on super large convolutional kernels, enabling CNN to detect the global nature of images. The GnConv-YOLOv11 framework can capture the subtle features of small targets such as electric field shielding goggles and gloves, as well as their correlation with live working environments, significantly improving the ability to discover and identify small targets in the context of live-line working. After the DA-DETR model locates the workers, the electric field shielding clothing wearing detection system uses a backbone convolutional network embedded with GnConv to extract the features of the electric field shielding clothing. Then, the neck network integrates multi-scale features, and finally the detection head outputs accurate classification results. Fig. 3 shows the structure of GnConv.

The core operation of GnConv is gated Convolution, which is defined as $GOConv(.)$ in this study. When the input feature is $L \in \mathbb{R}^{C1\times C2}$, the output y of $GOConv(.)$ operation is defined as Eq. (4):

$$\hat{y} = \phi_{output}(U_1) \in \mathbb{R}^{C1\times C2} \quad (4)$$

where, $\phi_{output}(.)$ is a linear projection operation. U_1 is the convolution result of the depth wise operation of the electric field shielding clothing wearing detection system.

U_1 is defined in Eq. (5):

$$U_1 = f(R_0) \odot U_0 \in \mathbb{R}^{C1\times C2} \quad (5)$$

where, $f(.)$ is the depth-wise convolution operation. R_0 and U_0 are the features of input $L \in \mathbb{R}^{C1\times C2}$, and the calculation equation is as follows [see Eq. (6)]:

$$\left[R_0 \in \mathbb{R}^{C1\times C2}, U_0 \in \mathbb{R}^{C1\times C2}\right] = \phi_{in}(L) \in \mathbb{R}^{C1\times 2C2} \quad (6)$$

where, $\phi_{in}(.)$ is a linear projection operation.

Therefore, the definition of $GOConv(.)$ operation is Eq. (7):

$$\hat{y} = GOConv\left(L \in \mathbb{R}^{C1\times C2}\right) \quad (7)$$

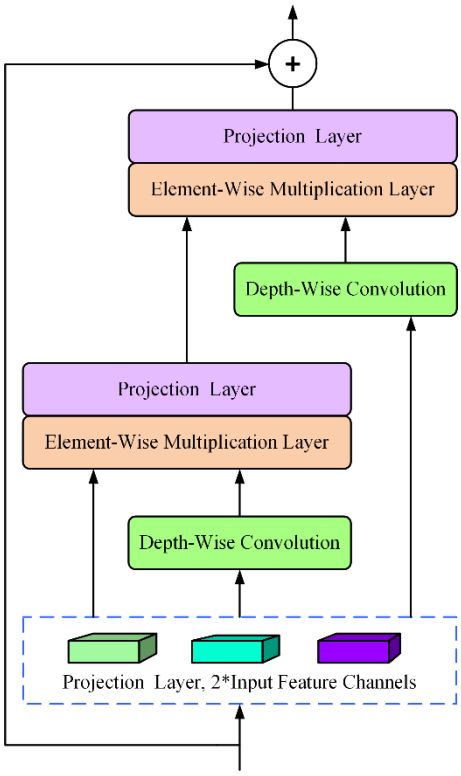

Fig. 3. The structure of recursive gated convolution (GnConv).

IV. Results and Discussion

The DA-DETR model is used for operator object detection in live-line work scenarios. For the operator object detection model, the operator image in the live-line work scenario is used as input. 9100 images of operators in live-line work scenarios were used as samples for the training and validation sets. The epochs of the DA-DETR based operator object detection model are set to 24, with 1000 steps per epoch. During the training process, when the confidence level of the identified personnel within the bounding box is greater than 70%, it is defined as a successful detection of the personnel. The output of the operator object detection model, the range of the bounding box, is used as the input for the electric field shielding clothing wearing detection system. The electric field shielding clothing wearing detection model aims to detect three types of electric field shielding equipment, as shown in Fig. 4. Table I introduces three types of electric field shielding equipment.

Fig. 4. Personal protective equipment in live-line work scenarios.

TABLE I. Three Types of Electric Field Shielding Equipment

Illustration	Name	Category
Fig.4. (a), (b), and (c)	Electric field shield clothing	3

Fig.4. (g), (h), and (i)	Electric field shield mask	3

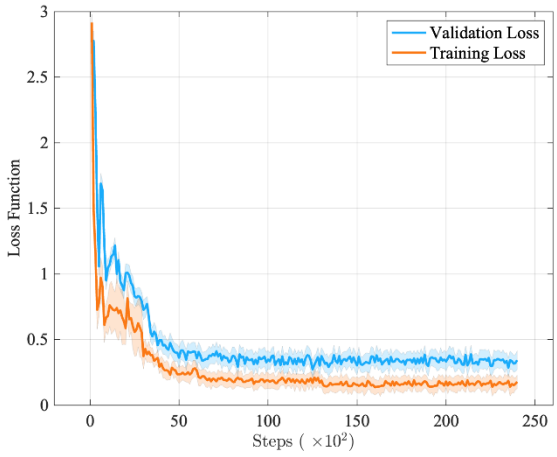

Fig. 5. The loss function curve of operator positioning model based on DA-DETR.

Due to the fact that the training process of machine learning is essentially random, in order to verify the robustness of the

DA-DETR model and GnConv-YOLOv11 model, each model was trained 15 times, separately. The loss functions of the DA-DETR model and GnConv-YOLOv11 model during 15 training sessions are shown in Table II.

TABLE II. THE LOSS FUNCTIONS OF THE DA-DETR MODEL AND GNCONV-YOLOV11 MODEL

Loss function	Training loss		Validation loss	
	DA-DETR	***GnConv-YOLOv11***	***DA-DETR***	***GnConv-YOLOv11***
Average	0.1762	0.1316	0.3415	0.2151
The upper bound of 95% C.I.	0.2278	0.1987	0.4130	0.2909
The lower bound of 95% C.I.	0.1246	0.0643	0.2700	0.1349

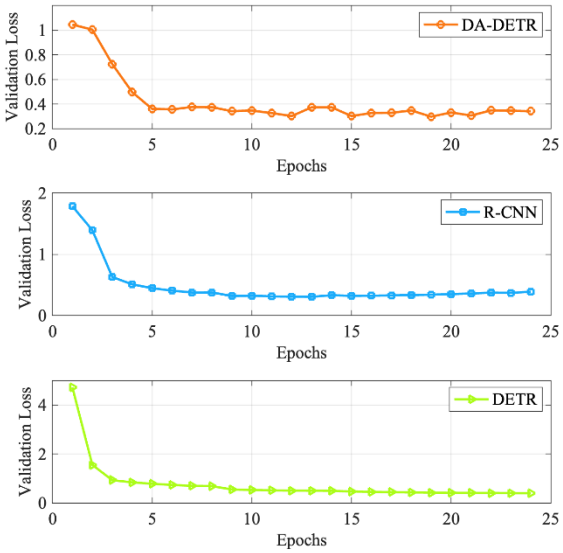

Fig. 6. The loss function values of the DA-DETR model recorded during 24 epochs of training.

Fig. 5 shows the loss function of the operator localization model based on DA-DETR. Fig. 6 shows the average loss function of the operator localization model based on DA-DETR over 24 iteration cycles. To demonstrate the effectiveness of the DA-DETR model in handling operator localization problems, a comparison was made between the DA-DETR model, R-CNN [24], and DETR model. Fig. 6 also shows the comparison results.

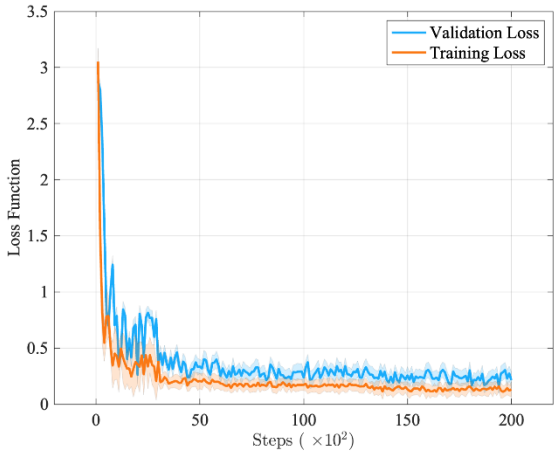

Fig. 7. The loss function curve of the GnConv-based YOLOv11.

Table III shows the results of DA-DETR, YOLOv9, YOLOv7, Fast R-CNN, R-CNN, and DETR [14] models in handling operator localization tasks in the context of live working. Each model is evaluated from six perspectives, including training loss, validation loss, recall rate, precision, accuracy, and F1-Score. The training loss of the operator localization model based on DA-DETR is 0.1763. The DA-DETR model has the lowest loss, with a 2.54% reduction in training loss compared to the YOLOv9 model. The validation loss of the operator positioning model based on DA-DETR is 0.3415, which is 3.53% lower than that of the YOLOv9 model. This indicates that the DA-DETR-based operator localization model learns most effectively from the training data, with its internal parameters efficiently capturing features from images of operators in live-line work scenarios. Moreover, the DA-DETR model's lower validation loss compared to all other models demonstrates that it possesses the strongest generalization capability. For the precision indicator, the accuracy of the operator positioning model based on DA-DETR is 0.9083, while the best-performing comparison model, YOLOv7, is 0.9013. Compared with the YOLOv7 model, DA-DETR achieved a performance improvement of 0.78% in accuracy. This improvement indicates that DA-DETR has a slight advantage in reducing false positives for operators in the context of live working, and the prediction results of DA-DETR are more reliable.

TABLE III. THE RESULTS OF OPERATOR POSITIONING MODELS

Algorithm	Training Loss	Validation Loss	Recall	Precision	Accuracy	F1-Score
DA-DETR	0.1763	0.3415	0.9194	0.9083	0.9118	0.9118
YOLOv9	0.1809	0.3540	0.9080	0.9020	0.9050	0.9050
YOLOv7	0.1952	0.3785	0.8998	0.9013	0.9043	0.9043
Fast R-CNN	0.1829	0.3617	0.9050	0.8976	0.9013	0.9013
R-CNN	0.1967	0.3897	0.8955	0.8871	0.8913	0.8913
DETR	0.2132	0.3943	0.8902	0.8917	0.8909	0.8909

Table III also shows the recall rate, accuracy, and F1-score. In this study, the recall rate is the ratio of successful predictions made by the operator localization model among all real operator samples. A high recall rate means that the operator has a low rate of missed detections in the localization model. The recall rate of the operator positioning model based on DA-DETR is 0.9194, and the recall rate of the second-ranked YOLOv9 model is 0.9080. Compared with the YOLOv9 model, the recall rate of the DA-DETR model has increased by 1.25%. Therefore, DA-DETR has the highest recall rate when handling operator positioning tasks in the context of live working, indicating its strongest ability to identify operators and find more operators in the image. The F1-score of DA-DETR is 0.9118, and DA-DETR also achieved the highest F1-score. This proves that the DA-DETR operator localization model achieves the optimal balance between accuracy and recall, achieving the best overall performance. Finally, the accuracy of the DA-DETR model is 0.9118, which is 0.75% higher than the YOLOv9 model. This indicates that the DA-DETR operator localization model has achieved lower missed detection rates (high recall rates) and lower false detection rates (high accuracy rates). Therefore, the operator positioning model based on DA-DETR can handle complex live working backgrounds and effectively prevent misjudging transmission lines, insulators, and trees as workers.

Fig. 7 shows the iterative loss function curve of the GnConv-YOLOv11-based electric field shielding clothing wearing detection model. Table IV shows the application results of the GnConv-YOLOv11 model, YOLOv11 [16] model, YOLOv10 model, YOLOv9 [17] model, YOLOv8 model, YOLOv7 model, RT-DETRv2 model, RT-DETR [25] model, and RetinaNet [26] model in the problem of electric field shielding clothing wearing detection. Fig. 8 shows the recognition results of some electric field shielding clothing detection models.

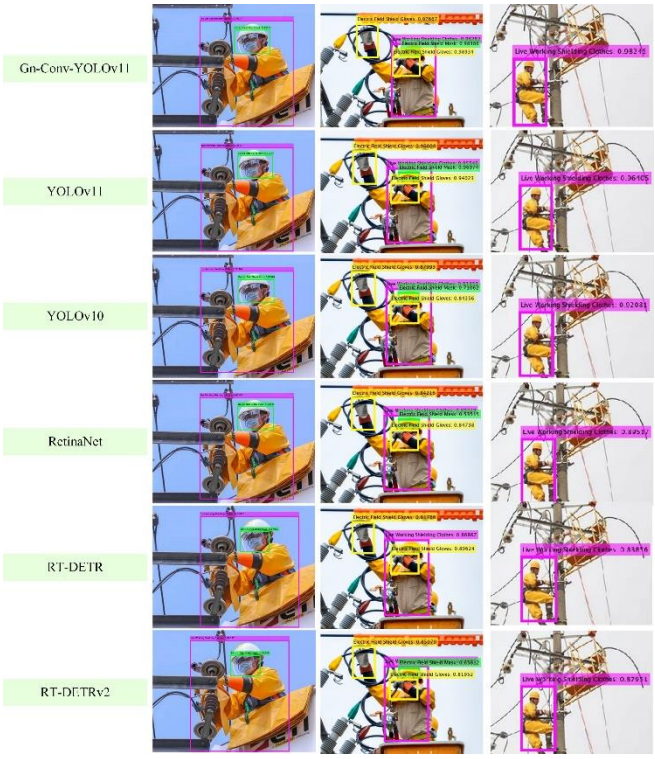

Fig. 8. Identification results of electric field shielding clothing detection models.

TABLE IV. THE RESULTS OF THE ELECTRIC FIELD SHIELDING CLOTHING DETECTION MODELS

Algorithm	Training Loss	Validation Loss	Macro-Recall	Macro-Precision	Accuracy
GnConv-YOLOv11	0.1316	0.2151	0.9157	0.8963	0.9040
YOLOv11	0.1795	0.2676	0.9019	0.8780	0.8931
YOLOv10	0.1978	0.2975	0.8854	0.8840	0.8831
YOLOv9	0.2143	0.3213	0.8784	0.8770	0.8777
YOLOv8	0.2382	0.3346	0.8623	0.8610	0.8584
YOLOv7	0.2479	0.3564	0.8556	0.8544	0.8550
RT-DETRv2	0.1872	0.2996	0.8816	0.8802	0.8812
RT-DETR	0.2214	0.3314	0.8646	0.8632	0.8639
RetinaNet	0.2526	0.3587	0.8512	0.8498	0.8505

In Table IV, five metrics including training loss, validation loss, macro-recall, macro-precision, and accuracy were used to evaluate all electric field shielding clothing wearing detection models. Firstly, the training loss of the GnConv-YOLOv11 model is 0.1316, which is lower than the other 8 models and reduces the training loss by about 26.7% compared to the benchmark YOLOv11. This indicates that the newly introduced GnConv-YOLOv11 model greatly enhances the learning ability of the electric field shielding clothing wearing detection model, enabling it to extract features more accurately from training data. The validation loss of the GnConv-YOLOv11-based electric field shielding clothing wearing detection model is 0.2151, which is about 19.6% lower than the second ranked YOLOv11 model. The GnConv-YOLOv11 model achieved an accuracy of 0.9040, which is higher than that of all eight other compared models for detecting the wearing of electric field shielding clothing, representing a 1.22% improvement over YOLOv11. Furthermore, the GnConv-YOLOv11-based model for detecting the wearing of electric field shielding clothing also achieved optimal performance in both macro-precision and macro-recall. Specifically, it exhibited a 2.08% improvement in macro-

precision and a 1.53% increase in macro-recall compared to the YOLOv11 model.

In addition, compared to the other eight electric field shielding clothing detection models, the GnConv-YOLOv11 model achieved an average reduction of 36.5% in training loss and 30.4% in validation loss. Meanwhile, it improved macro recall, macro precision, and accuracy by an average of 4.11%, 2.83%, and 3.44%, respectively. These results demonstrate that GnConv-YOLOv11 achieves comprehensive performance improvements across all metrics when compared to the other eight algorithms. It is also worth noting that the RT-DETR model performs similarly to YOLOv9 and YOLOv10, suggesting that CNN-based architectures remain highly competitive in the field of small object detection.

V. Conclusion

This study designed a dual-layer detection system for intelligent detection of electric field shielding clothing to meet the high-risk operational requirements in live-line work scenarios in the power industry. The system achieves accurate recognition of workers and their electric field shielding clothing by constructing an operator positioning model based on DA-DETR and a classification model that integrates GnConv and YOLOv11. Experimental results have shown that the DE-DETR model improves the accuracy of worker localization tasks by 2.29% compared to traditional DETR models. The electric field shielding clothing classification model based on GnConv-YOLOv11 achieved a detection accuracy of 92.61%, significantly better than mainstream detection models such as the YOLOv11 model, RT-DETR model, and RetinaNet model.

In addition, GnConv-YOLOv11 achieves the best performance across four key aspects: validation loss, macro recall, macro precision, and accuracy. Compared to the average of all benchmark models, it shows significant improvements in five major metrics: a 36.5% reduction in training loss, a 30.4% reduction in validation loss, a 4.11% increase in macro recall, a 2.83% improvement in macro precision, and a 3.44% gain in accuracy. Therefore, the proposed double-layer detection framework effectively tackles the challenges posed by the high diversity and difficulty of recognizing electric field shielding clothing in live-line work environments, offering a reliable technical basis for intelligent safety monitoring in such scenarios. The system proposed in this study has not been deployed in the real world. In future work, the developed electric field shielding clothing detection system will be deployed on unmanned aerial vehicles (UAVs) for real-world applications.

Evaluating the Effectiveness and Usability of Microsoft Threat Modelling Tool in Undergraduate Cybersecurity Education

Nor Laily Hashim, Ahmad Zuhairi Bin Mohd Yusri
School of Computing, Universiti Utara Malaysia, UUM Sintok, Kedah, Malaysia

***Abstract*—As cyber threats evolve, equipping students with hands-on experience in identifying and mitigating system vulnerabilities is critical for developing a cybersecurity-aware workforce. There are a variety of threat modelling tools available on the market, and it is challenging for educators to select the best tool for their students to learn and identify any possible threats that may exploit system vulnerabilities. This study investigates the effectiveness and usability of the Microsoft Threat Modelling Tool (MTMT) among undergraduate students, addressing the need for a practical tool in cybersecurity education. This study was conducted in four phases. The first phase involves conducting a comprehensive literature review to understand the features, capabilities, and tools of the threat modelling tools being compared, specifically the MTMT. Phase two consists of defining the evaluation criteria for assessing the tool's effectiveness and usability. Criteria for error frequency, ease of use, and user-friendliness will be developed, with particular focus on their relevance to educational environments, especially for undergraduate students. Phase three involved data collection, during which participants were recruited and had hands-on sessions with the tool. Training sessions were conducted using case studies to familiarise participants with the tool's features and functionalities. The last phase involves developing assessments to evaluate participants' knowledge, effectiveness and usability of the tools. The evaluation includes structured usability testing and post-assessment of students' knowledge and skill acquisition. Findings reveal that MTMT enhances students' comprehension of threat modelling concepts, bridging the gap between theoretical knowledge and real-world cybersecurity practices. However, the study also highlights areas for improvement in the tool's interface and documentation to better support student learning. These insights enhance educational strategies, foster active learning, and equip students for real-world cybersecurity challenges. The results emphasise the tool's potential to strengthen the integration of threat modelling into the cybersecurity field, thereby fostering essential skills for safeguarding organisational and digital infrastructures. The novelty of this study lies in the methodology used to measure the effectiveness and usability of the threat modelling tool. The tool's effectiveness was measured using the effectiveness formulas from ISO/IEC 25022:2016(E), while its usability was measured using the System Usability Scale (SUS).**

Keywords*—Cybersecurity education; threat modelling; stride; usability testing

I. Introduction

The increasing complexity of cybersecurity threats requires the practical training of future professionals in this field. One vital component of this training is the practice of threat modelling tools, such as the Microsoft Threat Modelling Tool (MTMT). MTMT is a commonly used tool for systematically analysing system vulnerabilities, creating data flow diagrams, and proposing security mitigations based on identified threats. Threat modelling is an essential technique for identifying and understanding potential threats, and for suggesting and prioritising mitigations to safeguard valuable system assets. This tool is primarily designed to assist developers and cybersecurity teams in mitigating identified potential security vulnerabilities early in the software development lifecycle. By integrating MTMT into undergraduate cybersecurity curricula, educational institutions can enhance students' understanding of security principles and practices in the digital world, ultimately preparing them for real-world cybersecurity challenges.

The variety of threat modelling tools available on the market can be challenging, and organisations may need help selecting the best solution for their unique requirements. By undertaking a thorough review of available tools, organisations can gain insights into their strengths and shortcomings, enabling them to choose the best tool for their situation. The study by reference [19] used different evaluation criteria to measure practical threat modelling tools. A study evaluating the effectiveness of Threat modelling tools among undergraduates [12] was similar to this study. This study, however, does not focus on assessing usability or on using other measures of the tool's efficiency.

Evaluating the effectiveness and usability of MTMT among undergraduate students is crucial for several reasons. This assessment allows educators to gain valuable insights into how well students implement and utilize the tool, enabling them to highlight areas of strength and weakness in supporting learning outcomes.

By focusing on the student's perspective, the evaluation ensures the tool's design is truly user-centred, fostering an interface that encourages engagement and facilitates effective learning. Furthermore, the feedback gathered through this process is instrumental to the tool's iterative development, enabling it to improve and adapt to the ever-changing landscape of educational needs and technological progress. This comprehensive evaluation approach not only enhances the immediate learning experience but also contributes to the long-term improvement of educational technology. As students engage with MTMT, they not only learn to identify threats but also develop the critical thinking skills necessary to evaluate and implement security measures, thereby fostering a more robust cybersecurity education that aligns with industry needs.

The structure of this research study follows a logical progression, beginning with a literature review section that provides a theoretical foundation and contextualizes the study within existing threat modelling tools and concepts. Following this, the methodology section outlines the research approach, detailing four distinct methods employed to address the research objectives. The study then describes the data sources used, explains the collection procedures during the experiment, and outlines the analytical techniques employed to ensure robust, reliable findings. The results section presents the empirical findings from the data analysis, providing a clear overview of the study's outcomes followed by a discussion section. The study concludes with a few key findings, discusses their implications, addresses the research questions, and suggests potential improvements for future research in cybersecurity studies.

II. Literature Review

Threat modelling is a critical practice in software development that emphasises the proactive identification and mitigation of security threats throughout the Software Development Lifecycle (SDLC). By integrating threat modelling early in the design phase, developers can significantly reduce the costs associated with implementing security measures post-release, which can be up to thirty times higher than addressing these issues during initial design [1]. The process involves a systematic approach to understanding potential vulnerabilities and threats, allowing security analysts to evaluate system architecture effectively [2]. As highlighted by [3] and further supported by [4], threat modelling not only enhances the security posture of applications but also fosters a culture of continuous improvement in security practices. This structured methodology enables developers to make informed decisions about implementing security features tailored to the specific context of their systems, ultimately contributing to more resilient software solutions [5][6].

Data Flow Diagrams (DFDs) are essential tools in system analysis and design, providing a visual representation of how data moves through a system. They help decompose complex systems into manageable components, enabling analysts to understand the flow of information among processes, data stores, and external entities. DFDs facilitate communication between technical and non-technical stakeholders by providing a clear, intuitive graphical depiction of data interactions, which is particularly beneficial for identifying inefficiencies and potential security vulnerabilities [5]. However, creating effective DFDs requires a thorough understanding of the system's architecture and careful attention to detail to avoid oversimplification or misrepresentation of data flows [7]. Despite their limitations, such as the inability to capture timing and sequencing information, DFDs remain a powerful method for analysing systems and guiding the threat modelling process by illustrating how data traverses through various components.

The STRIDE methodology, developed by Microsoft, is a widely recognised framework for threat modelling that categorises potential security threats into six distinct types: Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, and Elevation of Privilege. This systematic approach allows security analysts to effectively identify vulnerabilities in software systems and devise appropriate mitigations [8] [9]. By employing STRIDE in conjunction with DFDs, analysts can visualise data interactions within an application, thereby enhancing their understanding of how threats may manifest at various points in the system [10]. The methodology not only aids in recognising design flaws but also aligns with established secure software processes, such as OWASP's Comprehensive Lightweight Application Security Process (CLASP) and Microsoft's Security Development Lifecycle (SDL), thereby reinforcing its credibility and utility in fostering secure application development [11]. Overall, STRIDE serves as a foundational tool for organisations aiming to address security risks throughout the software development lifecycle proactively.

Measuring the effectiveness of threat modelling tools, particularly the MTMT, is essential for understanding their impact on identifying and mitigating security threats in software development. Research indicates that integrating threat modelling into the software development lifecycle significantly enhances the ability to detect vulnerabilities early in the design phase. For instance, a study involving undergraduate students demonstrated that those using MTMT identified a broader range of threats than those using traditional manual threat modelling methods. The students reported that the tool facilitated a more structured approach to threat identification, allowing them to categorize threats effectively using the STRIDE methodology [12]. Furthermore, feedback highlighted that MTMT not only increased the number of identified threats but also provided valuable insights into potential mitigation strategies, thereby reinforcing its role as an effective educational tool for teaching secure software engineering practices [13]. Overall, evaluating the effectiveness of such tools is crucial for refining their functionalities and enhancing user understanding, especially at the educational level of understanding security risks in software applications.

Usability testing plays a crucial role in evaluating the effectiveness of tools like the MTMT, particularly among undergraduate students who may lack prior experience in software security. A study examining the use of MTMT in a secure software engineering course revealed that usability testing methodologies, such as moderated and unmoderated testing, were instrumental in assessing students' ability to navigate the tool and identify potential security threats. The findings indicated that students performed better with MTMT than with manual threat modelling methods, highlighting the tool's user-friendly interface and guided assistance features. Student feedback highlighted specific usability challenges, such as understanding DFDs and STRIDE techniques, which are essential to effective threat modelling. This suggests that incorporating usability testing into the educational framework can significantly enhance students' learning experiences and their ability to utilise security tools effectively [12].

The existing works related to this study are by [14], which investigates the added value of specific threat modelling applications, namely the MTMT 2016 and the Tutamen tool. The study evaluates these tools based on accuracy in automatic threat generation, time efficiency in executing analyses, and user-friendliness, highlighting their impact on enhancing security processes. The study proposes using a combination of case studies, expert evaluations, and tool demonstrations to

assess the effectiveness of threat modelling tools among undergraduate students.

In [15], the authors focus on assessing various threat modelling frameworks, examining eighteen methodologies, including STRIDE, PASTA, and OCTAVE. This study synthesises their strengths and weaknesses, offering insights into their comprehensiveness and applicability for effective threat modelling. Overall, the research aimed to understand the current landscape of threat modelling methodologies and frameworks, evaluate their suitability for different use cases, and provide practical insights into implementing threat modelling in organisations.

In [16], the authors present a comprehensive taxonomy and qualitative evaluation of several threat modelling tools, including MTMT, OWASP Threat Dragon, and IriusRisk. The study compares these tools based on criteria such as model form, threat libraries, evaluation methods, and SDLC integration, providing a structured framework for understanding their functionalities. The study also discusses the limitations of existing threat modelling tools and proposes directions for future research. Overall, the taxonomy presented in the study provides a valuable framework for understanding and categorising threat modelling tools, helping cybersecurity professionals make informed decisions about tool selection and implementation.

III. Methodology

A. Phase 1: Experimental Design

This study involved conducting a comprehensive literature review to understand the features, capabilities, and tools of threat modelling. This phase aimed to identify the key features, benefits, and weaknesses of MTMT. By thoroughly examining the available literature, a detailed analysis of MTMT's strengths and limitations was produced.

B. Phase 2: Experimental Setup

In this phase, students learned to use the MTMT through a combination of structured learning materials and self-paced exploration. The experimental setup was designed to provide a flexible learning environment, ensuring students had the resources needed to understand and apply the tool effectively. The experiment was conducted in a remote, self-paced learning format, allowing students to engage with the materials and complete the tasks at their convenience.

Students began their learning journey with video-based instruction. They were provided with a lecture video introducing the core features of the MTMT tool, its importance in security threat analysis, and instructions for downloading and installing it. Following this, two hands-on demo videos were made available, offering a step-by-step walkthrough of the tool's core functionalities and how to solve the case study. These included creating DFDs, proposing mitigations, and generating a comprehensive threat model report. These videos ensured that students had a clear, practical understanding of the tool's application. Students engaged in a hands-on, realistic case study focused on analysing a realistic software system architecture. There are two main tasks in this case study.

Task 1 requires students to create a DFD to visually represent the flow of data among the key components of a given case study of a company's Single Sign-On (SSO) system. This task aimed to identify critical paths, trust boundaries, and interactions within the system. The expected outcomes for this task include developing a comprehensive DFD that accurately illustrates the key entities and data flows of the SSO system, and identifying trust boundaries and critical interactions where potential vulnerabilities may exist.

Task 2 involves students proposing security mitigation strategies. The objective here is to identify and recommend effective security measures to address vulnerabilities detected in the SSO system, utilising the MTMT tool's automated threat identification feature. Expected outcomes for this task include a well-defined list of mitigation strategies explicitly tailored to the identified threats within the SSO system, along with an enhanced understanding of how the MTMT aids in prioritising security issues and proposing structured solutions.

Building on insights from the instructional videos, participants utilised the provided guidelines, which detailed system specifications, data flows, and trust boundaries. This structured approach enabled students to systematically apply the MTMT tool to assess the architecture's integrity and security. By simulating real-world scenarios, the experiment not only enhanced their understanding of software design principles but also fostered critical thinking and problem-solving skills essential for navigating complex systems in professional environments.

C. Phase 3: Data Collection

The data collection phase involved gathering feedback on the effectiveness, based on the overall score achieved by all students in their threat model submissions and the MTMT's usability evaluation. An online form was used to collect both completed threat model submissions and detailed feedback from participants regarding their experience using the tool. The feedback form was designed to collect both quantitative and qualitative data. For quantitative data, participants were asked to rate various aspects of their experience on a Likert scale, including the MTMT's usability. Additionally, participants rated MTMT's effectiveness in identifying and addressing security threats. The open-ended questions were included to gather qualitative insights, prompting students to elaborate on the strengths and weaknesses of MTMT and suggest potential improvements to the tool or the experimental process. This mixed-methods approach ensured a comprehensive understanding of both the tool's functionality and the user experience.

The effectiveness instrument involves threat model submissions based on the accuracy of their DFDs, ensuring that system components, data flows, and trust boundaries are correctly represented and adhere to the case study answer scheme. Additionally, the proposed mitigations for each identified threat were assessed for their relevance and appropriateness in addressing specific vulnerabilities. The overall score for all students provided a holistic view of MTMT's effectiveness, measured by task completion rates and the proportion of tasks with errors, as described in [17].

The usability instrument involves the System Usability Scale (SUS) measurement [18] (which consists of ten questions that

assess various aspects of usability, such as ease of use, complexity, and user confidence interacting with the MTMT tool based on submitted 10 Likert-scale ratings.

D. Phase 4: Data Analysis

In this phase, the collected data were systematically analysed to evaluate the effectiveness and usability of the MTMT among undergraduate students. The tool's effectiveness was measured using the two formulas: Task completion rate and Proportion of tasks with error, as defined in ISO/IEC 25022:2016(E) [17].

Data analysis was performed using SPSS and Microsoft Excel, applying a mix of descriptive statistics and statistical tests. The statistical analysis evaluating the relationship between task complexity and usability rates uses several methods to provide a comprehensive understanding of the data. The following statistical methods were used: quantitative measures, including task completion rates and error rates, were analysed to assess students' efficiency and consistency in completing assigned tasks. The task completion rate is expressed as a percentage, representing the ratio of completed tasks to the total number of tasks. Statistical measures, such as the mean, median, or standard deviation of task completion rates across participants, can be calculated from the produced task completion rates. Errors made during the task were summarised to identify complexity levels and challenging areas in the MTMT.

SUS were calculated to assess the perceived usability of MTMT. The scores were categorised into ranges (e.g., 0–50, 51–68, 69–80, and 80–100) to evaluate the tool's effectiveness in meeting user expectations (Brooke, 1996). This analysis provided insights into the tool's ease of use and alignment with educational objectives. Overall, the data analysis phase combined statistical rigour with qualitative feedback to provide a comprehensive evaluation of MTMT's effectiveness and usability as a teaching and learning tool. This dual approach enabled a deeper understanding of the tool's strengths and areas for improvement.

The pre-experimental setup for the MTMT initiative was carefully designed to equip participants with the necessary knowledge and skills before engaging in practical case studies. Initially, two pre-recorded lecture videos were designed to provide a basic overview of MTMT, emphasising its importance in detecting and mitigating security risks. These lectures not only explained theoretical principles but also offered practical insights into the tool's functionality. To strengthen this theoretical foundation, two hands-on demonstration videos were prepared to guide participants through the key elements of MTMT. These demonstrations covered essential topics, including producing DFDs, proposing security mitigations, generating threat model reports, and applying these skills to a case study.

As shown in Fig. 1, the MTMT video-based learning resources include a comprehensive set of materials designed to enhance understanding and practical application. The resources feature a pre-recorded lecture video introducing MTMT, its application in threat modelling, and foundational concepts. Additionally, two hands-on demo videos provide step-by-step practical demonstrations, guide users through the implementation of core functionalities and the system's main features, and offer guidance on how to solve the task in the case study example. These videos emphasise essential tasks and best practices, ensuring effective learning and obtaining a good understanding of the threat model concept before solving the given case study. Together, these resources provide students with a well-rounded educational experience on the MTMT tool.

Before evaluating the submitted threat models, the files were downloaded and stored on the researcher's laptop in a dedicated folder. Each file was labelled with the student's matric number and name to ensure accurate identification. The folder served as a local repository for all submissions, with strict security measures implemented to ensure confidentiality. Access to the data was restricted to the researcher and the project supervisor, in accordance with ethical standards, to safeguard participants' privacy throughout the study.

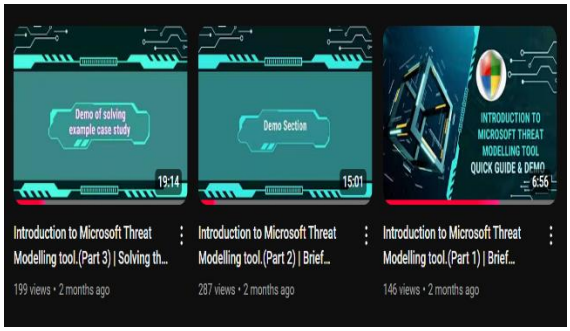

Fig. 1. Three video-based learning resources.

IV. Results

The collected data was analysed using a statistical analysis tool and spreadsheet software. A descriptive analysis was conducted to summarise and comprehensively explore the dataset. Key statistical measures—mean, median, mode, standard deviation, variance, and range — were calculated to provide insights into the data distribution. In this section, the effectiveness of the threat model software will be assessed using two key metrics: task completion rate and the proportion of tasks with errors. The task completion rate will provide a clear indication of how successfully users can complete their intended tasks. In contrast, the proportion of tasks with errors will highlight areas where users encounter difficulties, thereby revealing potential issues with effectiveness.

Additionally, the usability aspect will be evaluated using the SUS, which offers a standardised measure of user satisfaction. By analysing the collected SUS scores and their distribution across various grades, this will provide insights into the overall user experience, identifying strengths and weaknesses in the system's design and functionality. In total, forty-eight undergraduate students participated, submitting their threat model reports and completing the feedback form, which was designed to capture insights into their experience with the tool, usability evaluation, and future adoption likelihood.

A. Effectiveness Aspect

1) Task completion rate: Table I presents the first effectiveness measurement of the MTMT, based on task completion rates. Task 1 achieved significantly higher

performance, with participants collectively scoring 806 out of 1008 marks, resulting in an 80% completion rate. Conversely, task 2 resulted in only 204 out of 384 marks, corresponding to a 53% completion rate. This disparity suggests that Task 1 was either easier to complete or better understood by participants. The template is designed so that author affiliations are not repeated for multiple authors with the same affiliation. Please keep your affiliations as succinct as possible (for example, do not differentiate among departments of the same organization). This template was designed for two affiliations.

Table I presents the first effectiveness measurement of the MTMT, based on task completion rates. Task 1 achieved significantly higher performance, with participants collectively scoring 806 out of 1008 marks, resulting in an 80% completion rate. Conversely, task 2 resulted in only 204 out of 384 marks, corresponding to a 53% completion rate. This disparity suggests that Task 1 was either easier to complete or better understood by participants.

TABLE I. PARTIAL DATASET OF TASK COMPLETION RATE

Student ID	Task 1 (create a DFD) Score /21	Task 2 (mitigation strategies) Score /8	Total Score /29	Total Score %
XXXX	16	1	17	58.62
XXXX	17	3	20	68.97
XXXX	18	7	25	86.2
XXXX	18	7	25	86.21
XXXX	19	0	19	65.51
..	..	..	..	..

Descriptive Statistics

	N	Sum
Task 1 Score	48	806
Task 2 Score	48	204
Valid N (listwise)	48	

Fig. 2. Table of the sum of tasks completed for each task.

As shown in Fig. 2 and Fig. 3, the data reveal that the participants generally performed better on Task 1 than on Task 2, as reflected by higher mean, median, and sum values for Task 1. The sum of all participants' scores for Task 1 is 806, while for Task 2, it totals 204. This indicates higher cumulative performance in Task 1 than in Task 2. The combined total scores suggest an overall moderate performance across both tasks, with a mean of approximately 21 out of a possible 29 points.

The overall task completion rate equation is given in Eq. (1):

$$\text{Task completion rate} = 1010/1392 \times 100 \quad (1)$$

$$= 0.7256 \text{ or } 72.56\%$$

where,

x= Completion rate

a = Number of marks successfully achieved: 06+204=1010

b = Total number of marks: 1392

The overall performance, with a completion percentage of 72.56%, shows that respondents completed a significant portion of the tasks or marks. However, this result indicates that there is still potential for improvement to achieve optimal performance levels closer to 100%. The 382 documented errors had a substantial impact on completion rate, indicating potential issues with usability, task complexity, or respondent understanding. A completion rate below 80% often indicates usability issues, such as interface complexity, insufficient tool support, or task-completion challenges that require further analysis and improvement.

2) Proportion of tasks with errors: Table II presents the second effectiveness measurement of the MTMT, which was assessed as the proportion of tasks with errors. In Task 1, there were 202 errors out of a total of 1008 marks, resulting in an error percentage of approximately 20%, indicating relatively successful task completion with fewer mistakes. Task 2 had 180 errors out of 384 marks, resulting in an error rate of roughly 47%. This suggests that users encountered more challenges when completing Task 2, highlighting areas for potential improvement in the tool to enhance user effectiveness and reduce errors.

TABLE II. PARTIAL DATASET OF THE PROPORTION OF TASKS WITH ERRORS

Student ID	Task 1 (create a DFD) score /21	Task 2 (mitigation strategies) Score /8	Total Error /29	Total Error %
XXXX	5	7	12	41.38
XXXX	4	5	9	31.03
XXXX	3	1	4	13.8
XXXX	3	1	4	13.8
XXXX	2	8	10	34.5
..	..	..	..	..

Statistics

		Task 1 /21	Task 2 /8	Total Error /29
N	Valid	48	48	48
	Missing	0	0	0
Mean		4.21	3.75	7.96
Median		3.00	3.00	7.00
Mode		3	1	4
Std. Deviation		3.108	2.572	4.267
Variance		9.658	6.617	18.211
Range		15	7	19

Fig. 3. The results obtained from the task completion rate dataset.

Proportion of "Tasks with errors" equation is given in Eq. (2). The project conducted a usability test with 48 students, each of whom could earn up to 29 total marks, for a maximum of 1392. Errors were recorded in 382 tasks.

$$\text{Proportion of Task with Errors} = 382/1394 \quad (2)$$

$$= 0.2744 \text{ or } 27.44\ \%$$

where,

x= Proportion of tasks with errors

a = Number of tasks with errors: 382

b = Total marks: 1392

27.44% of the tasks performed by users included at least one error. This metric can be used to assess the usability of the system, where a lower percentage indicates fewer user errors and better usability.

B. Usability Aspect

1) System usability scale (SUS) analysis: The SUS is calculated using a specific equation applied to students' responses to a 10-item questionnaire [18]. Each item is rated on a 5-point Likert scale, ranging from 1 (Strongly Disagree) to 5 (Strongly Agree). The following is a standard range of SUS scores and their corresponding:

The steps to calculate the SUS grade

1) Scoring odd-numbered questions (Positive statements): For items 1, 3, 5, 7, and 9, subtract one from the user's response. Score = Response - 1.
2) Scoring even-numbered questions (Negative statements): For items 2, 4, 6, 8, and 10, subtract the user's response from 5. Score = 5 - Response
3) Summing the scores: Sum up all the adjusted scores from steps 1 and 2. This sum is the raw SUS score.
4) Multiply by 2.5: To convert the raw SUS score into a value ranging from 0 to 100, multiply the total by 2.5.

SUS Score = (Sum of Adjusted Scores) × 2.5

For example:

Raw SUS Score = 3 + 3 + 4 + 4 + 2 + 1 + 4 + 3 + 2 + 1 = 27

SUS Score = 27 × 2.5 = 67.5

TABLE III. THE RANGE OF SCORES APPLIED IN THE SUS SCORE GRADES

SUS Score	Grade	Adjective Rating
>80.3	A	Excellent
68-80.3	B	Good
68	C	Okay
51-68	D	Poor
<51	E	Awful

Statistics

SUS Final Score

Count	2	7	0	28	11

TABLE V. FREQUENCY COUNT AND PERCENTAGE FROM EACH PROFICIENCY LEVEL

Proficiency Level	Count	Percentage (%)
Advanced (Grade A & B) (69%-100%)	9	18.75
Intermediate (Grade D) (51-68)	28	58.33
Basic (Grade E) (0-50)	11	22.92

V. DISCUSSION

The obtained results, in terms of effectiveness, highlight both strengths and areas for improvement in the MTMT. Task 1 demonstrated a significantly higher completion rate of 80% compared to Task 2's 53%, suggesting that participants either found Task 1 more straightforward or better understood it. However, the overall completion rate of 72.56% indicates that, while a significant number of tasks were completed, there is still room to grow to achieve ideal performance around 100%. Error analysis further underscores this need: Task 1 had a relatively low error rate of 20%, whereas Task 2 had a higher rate of 47%. This gap shows that users had more difficulty with Task 2, potentially due to task complexity, usability issues, or insufficient tool support for entering the proposed mitigation strategies for each identified threat. The combined total of 382 errors had a significant impact on the overall completion rate, highlighting the importance of fixing these issues to improve user effectiveness. These errors, which accounted for 27.44% of the tasks users performed, underscore areas where the system's usability can be improved. Addressing these issues would not only reduce the error rate but also likely lead to higher task success rates and better user confidence. By focusing on error-prone areas, the system can improve efficiency, ensuring a smoother, more intuitive user experience. This aligns with the usability goals outlined in [17], emphasising the need for continuous improvement to meet user needs effectively. These findings highlight the importance of improving the tool's interface and support features to minimise errors and increase task completion rates across all task types.

The overall usability rating indicates that 59.5 is below average, as it falls short of the industry-standard benchmark of

68. This suggests moderate usability challenges with the MTMT. The frequency table and bar chart of grade distribution, as shown in Fig. 4, Fig. 5, Table III and Table IV, reveal that many students received a grade 'D', with a total count of 28. This represents the highest frequency among all grades, indicating a significant portion of the class struggled to achieve higher performance levels. Grade 'F' follows with a count of 11, further emphasising the challenges students face in meeting the required standards. This distribution demonstrates an overall pattern toward lower grades. Based on Table V, the usability assessment also highlights that 58.3% of users rated the MTMT as moderately challenging, which can be attributed to their lack of experience with threat modelling tools. As first-time users, the students faced a learning curve in understanding the tool's interface, functionalities, and application within the context of threat modelling. This indicates that they require more time to study and understand the process of creating data flow diagrams and evaluating the tool's automated threat detection, as they lacked a basic understanding of another threat modelling tool. This lack of prior exposure indeed led them to rate the tool as moderately challenging, even though it is designed to simplify threat modelling for users with varying cybersecurity skills.

The evaluation of the MTMT reveals important insights regarding its effectiveness and usability. The overall task completion rate of 72.56% indicates that while a substantial portion of tasks were completed, there remains significant potential for improvement to reach optimal performance levels. The identification of 382 documented errors highlights usability issues, task complexity, and potential user misunderstandings. With 27.44% of tasks containing at least one error, this metric underscores the need for further analysis to enhance usability. The mean SUS score of 59.5, which falls below the industry benchmark of 68, suggests moderate usability challenges that affect user experience. The considerable standard deviation of 14.67 indicates significant variability in user perceptions, with scores ranging from 25 to 100 reflecting extreme differences in usability experiences. Notably, only 18.6% of users rated the tool as highly usable, while 58.3% encountered moderate challenges, indicating a clear need for improvements in design and support.

These findings emphasise the need for targeted enhancements to the tool's interface and functionality to better support users and improve overall effectiveness in educational contexts. While students completed a substantial portion of the assigned tasks, there remains considerable room for improvement, with 382 documented errors impacting performance. The System Usability Scale assessment yielded a mean score of 59.5, which falls below the industry-standard benchmark of 68. The varying user experiences are reflected in the score distribution: only 18.6% of users found the tool highly usable (Grades A and B combined), while 58.3% encountered moderate challenges.

VI. Conclusion

The study employed a structured methodology comprising four phases: content analysis, experiment design, data collection, and data analysis. In the initial phase, learning materials and an online form were developed to guide participants through the experiment. During the experiment design phase, students were introduced to the MTMT using the prepared learning materials. Data on usability and effectiveness were collected via online forms in phase three, followed by statistical analysis using spreadsheet software in the final phase. The study found that Task 1 had a higher completion rate than Task 2, with an overall success rate of 72.56%. Task 2 had more errors impacting effectiveness. The SUS score indicates moderate usability issues with the MTMT. Most students found the tool challenging and received low grades, mainly because of limited prior experience.

These results highlight the need to improve MTMT's interface and support features, particularly by allowing users to propose mitigation strategies within MTMT to reduce errors and enhance task completion rates. Addressing these issues would improve user satisfaction and better align the tool with usability standards.

The study’s novelty stems from its dual-metric evaluation: it measured the tool’s effectiveness using the ISO/IEC 25022:2016(E) effectiveness formula and assessed its usability through the System Usability Scale (SUS) analysis, providing a standardised, quantitative assessment framework.

Future work may include a comprehensive comparison of MTMT's usability and feature set with those of alternative threat modelling tools to benchmark its performance, adaptability, and user experience across different contexts. Enhancements such as automated mitigation recommendations could be explored to improve MTMT’s functionality, especially for novice users in educational or training environments, thereby increasing its pedagogical value and practical relevance. The study also integrates real-world cybersecurity tasks using MTMT with learning outcomes on applied threat modelling, ensuring assessments accurately measure the same experiential competencies students develop through hands-on, practice-based learning activities. The data analysis can also be improved by using inferential statistics such as the T-test, ANOVA and correlation.

***Abstract*—Partial occlusion and low light are significant challenges for face detection, limiting its effectiveness in critical applications such as security, surveillance, and user identification within computer vision. This study evaluates the effectiveness of two influential deep-learning models, YOLOv6 and YOLOv7, in identifying partially occluded faces in uncontrollable, real-world conditions. Training both models and assessing them with the help of comprehensive data-augmentation schemes that facilitate the occurrence of generalization, a carefully selected sample of partially blocked and hidden images of faces was used in all the experiments performed under low-light exposure. Findings indicate that YOLOv7 systematically outsmarts YOLOv6 in all key measures of performance, including precision (0.92 vs. 0.90), recall (0.89 vs. 0.79), as well as the mean Average Precision (mAP), which proves its ability to recognize hidden faces under adverse environments better. YOLOv7 takes a longer time to be trained, but with its enhanced design, especially the Extended Efficient Layer Aggregation Network (E-ELAN), feature extraction and real-time detection become much smoother. The statistics of this research indicate a visible increase, which indicates that YOLOv7 is reasonably suitable to be implemented in real-life, where a strong ability of face recognition, even with occlusions and low visibility, is required. This study contributes to the advancement of face detection technologies, tackling developing privacy and security needs in increasingly masked and low-visibility spaces.**

***Keywords*—Deep learning; partial occlusion; YOLOv6; YOLOv7; real-time detection; low-light face recognition**

I. Introduction

Face detection plays a very significant role in computer vision, particularly in the fields of security, user id etc. However, it is still quite hard to bring the system to the test with partially covered faces on it. The majority of face-recognition technology is activated on clear and obstructed faces making the technology to focus on key features such as mouth, nose and eyes. In most situations, people often wear face masks or put some sort of cover on their faces, thus partially covering the facial area. Human face identification is a very important feature in the computer vision field. This is the foundation of a wide variety of applications that can be practiced in many different areas such as security and identity verification, among many others [1]. Still, the process of detection of faces, which are partially masked, remains a significant problem. According to the traditional face recognition algorithms, they are more focused on non-occluded faces and salient facial feature, the mouth, nose and ocular region. Nevertheless, there are many situations and events which force people to put on masks or keep something covering or even hiding their faces, partly [5].

*Corresponding author.

When several faces in an image are near each other and seem to create a cluster, this effect is called occlusion and can result in misrecognition of the hidden face [2]. The initial versions of Convolutional Neural Networks (CNNs) and other deep learning methods have greatly enhanced detection accuracy. Yet, occlusion is a significant problem in face detection, since faces may be partially covered by different objects (e.g., masks, spectacles, or hands), environmental conditions (e.g., shadows, illumination), or other faces in populated scenes. In recent decades, there have been impressive advances in deep learning technologies in theory and application.

With the beginning of Masked FR as a new domain within the field of computer vision, the majority of FR systems have shifted towards implementing deep learning models [6, 7]. Before the COVID-19 pandemic, research was in progress to determine how deep learning could enhance the performance of available recognition systems for the presence of masks or occlusions. For example, different deep learning techniques have been proposed to solve the occluded facial recognition problem and have received tremendous attention. One of the well-known face detection algorithms is "You Only Look Once" (YOLO) [3], which is one of the modern alternatives [4]. Recently, the YOLO model has been further developed to detect faces, thus allowing it to decode and recognize the concealed conditions of people found in the images and video streams. This development requires a significant amount of data of occlusion to be trained.

Facial recognition systems based on YOLO are fast and more accurate, so they can be used in the security and market research sectors as well as human-computer interaction [8]. Face identification systems based on the YOLO architecture are susceptible to variations due to various factors, including the sizes of the model of the architecture, quality of the training set, and the facial expressions of the subjects that are displayed in the images used. Face occlusion detection is associated with the identification of areas of the face that are either obscured partially or fully in photographic/video content. The issue at hand is complex and can be subject to numerous different factors that are all contributing to its complexity. Detecting facial occlusions is one of the most difficult problems in the sphere of facial recognition systems and computer vision. These issues of uncertainty of the occlusions pose several significant issues especially in practical context.

Facial obstructions range between simple partial obstructions such as the use of sun glasses or a hat, and more complex cases, where the objects or the close people outside the

person are hampering vision on the face. The ambiguous nature of the discernment of such occlusions is significantly increased by the heterogeneity of the environmental and illumination conditions. Therefore, the face-detection automation has become one of the key priorities in the sphere of computer vision and pattern recognition [9]. The previous versions of the facial recognition algorithms had limitations in simple cases, but advancement in the deep learning algorithms have brought significant changes to the way they handle various cases. R-CNN structure is a rather radical departure of the YOLO model, which is an efficient and effective one-shot convolutional neural network model already [10]. The difficulties associated with occlusions lie in a variety, where simple partial obstructions like the ones created by hats or sunglasses are depicted at one end, and the more complicated situations where the face is covered by objects or other people are seen.

The varied nature of the surrounding conditions and lighting situations also makes the accurate identification of facial occlusions more difficult. As such, computer vision and pattern recognition have become the main research frontiers of face detection at an automatic level. The face recognition algorithms were once limited to very basic settings, but with the introduction of deep learning methods, their scope has been greatly extended. The R-CNN structure was quite a breakthrough as compared to the YOLO, which is characterized by its novel one-shot convolutional neural network model and commercial popularity. Occlusion issues require addressing through strategies that improve algorithmic robustness, the availability of adaptive strategies to varying environmental conditions, intersubjective variability in morphology, and the adoption of mechanisms that prioritize privacy issues.

To ensure the maintenance of the vision of developing and implementing facial recognition systems to work in the real world, these issues should be addressed. Improving the level of accuracy of the algorithms, promoting the context of events, increasing the representation of facial features, and use of privacy-preserving methods are vital in achieving the successful ability of individuals' identification within inclusion parameters. These problems are critical and require a solution to enable the further development and use of a facial recognition system that has an acceptable level of accuracy and efficacy in the real-world environment.

The present study aims at confronting the difficulties with low-light and semi-occluded face detection in the form of using YOLOv6 and YOLOv7 deep-learning algorithms on special datasets. One of the main benefits of YOLO with respect to partially obscured face recognition is the fact that it provides real-time processing, which makes it especially useful when it comes to detecting emotions in real-time [11]. This study performs the comparison and evaluation of the performance of two state-of-the-art deep-learning models, YOLOv6 and YOLOv7, in detecting partially concealed faces in low-light conditions. To improve model generalization, the aggressive data-augmentation method is employed in the study to tackle the issues of occlusion and illumination variation. The significance of this work is that it involves a custom dataset comprising faces of diverse forms of occlusion (i.e., face masks, helmets, and other objects) in low-light conditions. The analysis also uses aggressive forms of data augmentation to increase the generalization of the model and increase the resilience of YOLOv6 and YOLOv7 models in such challenging cases. The gap in the literature presented with the evaluation of these models in this context is that this research can provide new insight into the use of YOLOv6 and YOLOv7 in the areas that face detection is most required, including security, surveillance, and human-computer interaction, thus filling the gap in the literature.

The success of the YOLO deep-learning model in the detection of hidden faces relies on the complexity of the network structure used, as well as the quality of training data.

The organization of this study is as follows: Section II presents a detailed literature review covering previous research on occluded face detection based on models of the YOLO framework, as well as outlines the main gaps in the literature on the topic. Section III details the YOLOv6 and YOLOv7 techniques for occluded face detection. Section IV outlines the methodology that is used, with a description of the dataset, the data-augmentation approaches employed, and the work setup employed to test YOLOv6 and YOLOv7. The results are described in Section V and include the comparative performance analysis of YOLOv6 and YOLOv7 in different conditions of occlusion and low light. Section VI presents the discussion. Section VII is the concluding part of the manuscript, providing an overview of the key findings, commenting on the implications of the research to the practical context. Lastly, Section VIII suggests recommendations for future research and limitations of the study.

II. Literature Review

The field of facial recognition has evolved significantly over the years, and the use of crude pattern-recognition systems has been replaced by advanced deep-learning frameworks that provide quite high levels of accuracy in a wide range of settings. The development of deep-learning algorithms has supported tremendous advancement in identifying covered facial features. Fundamental pattern-recognition techniques have been replaced with deep-learned recognition models that can experience high accuracy within a wide range of operating environments. Deep learning is a radical method of recognizing semi-automated features of the face. Convolutional Neural Networks (CNN) and Regions Based Convolutional Neural Network (R CNN) were major developments that led to the detection of faces. The You Only Look Once (YOLO) system is the latest deep learning technology that is able to detect faces or objects in just one processing step, hence making it the best in regard to real-time use.

A. Early Bird Approaches to Face Detection

The previous face detection methods were all based on feature-based algorithms. Among them, the Viola-Jones detector [12] demonstrated good frontal face detection performance, but suffered failure for occlusions and variety in positions. AdaBoost learning with Haar-like features trained face detector, which is developed by Viola and Jones, cannot work well when the faces are partially (or completely) obstructed.

B. Advancement with CNN

A complete system has been built to detect faces with severe occlusion [13]. A deep learning network leverages gradient information in combination with shape information to accomplish its function. This work contributes three basic advances: The first contribution proposes a face detection method based on an energy function prior to a CNN model, which can extract deep features hidden in faces. Finally, a novel sparseness-induced deep learning classification method is presented for face occlusion detection. The presented head detection model exhibits superior capability to accurately recognize the face in arbitrary head poses, accordingly with different degrees. The proposed algorithm for validating facial occlusion can achieve high accuracy as to whether the facial region is occluded.

Experimental results demonstrate that the proposed occlusion verification system can still achieve 97.25% accuracy with 10 frames per second. The head detection algorithm shows good recall at 98.89% even with various difficult facial occlusions. By using CNNs, face detection has made progress in learning complex features and patterns from data. The R-CNN series methods, such as Fast R-CNN [14] and Faster R-CNN [15], enhanced the accuracy of object detection with region proposal networks, which can speed up the object detection. The approaches were very crucial for the evolution of face detection; however, they have high computational complexity and thus cannot be directly used. The deep learning era of visual recognition emerged with AlexNet [16]; following this first entry, VGGNet [17] and other advanced architectures further refined the convolutional layers for fine-grained pattern recognition. The models served as fundamental components for developing improved feature extraction methods, which transformed face detection practices.

Research demonstrated the effort of detecting mask-covered faces through a deep learning system, which successfully enables facial recognition for users with masks. The researchers successfully developed a model that used ResNet-50 architecture to detect masked faces in the COMASK 20 and LFW datasets. The research findings present an opportunity to integrate into current facial recognition systems that focus on identifying masked faces for security applications [19]. The research applied the Gabor wavelet together with deep transfer learning through a machine learning approach. The real-time masked face recognition process achieves better reliability through our integration of deep-learning CNN features together with Gabor wavelet extracted from unmasked facial regions to create an enhanced feature vector. The experiment, which tested the proposed method, used four benchmark datasets and achieved a mean accuracy of 97% [20].

C. YOLO Background

The group of experts in object recognition and detection that created YOLO represents an existing algorithm. YOLO (You Only Look Once) was initially presented by Redmon and its co-authors [18]. This work is recognized for its methods in real-time object detection. YOLO operates through regression-based detection to generate bounding boxes along with class probabilities as a single output. YOLO delivers superior detection speed to meet the requirements of applications that demand rapid responses. YOLO introduced real-time detection capabilities as a groundbreaking development, which enabled its practical use in various sectors [40, 41].

YOLOv3 and YOLOv4 incorporated Darknet-53 backbone together with spatial pyramid pooling (SPP) to enhance their feature extraction processes [21]. A new AI method appeared through a study that combined SVM classifiers with YOLOv3 and CNNs for feature analysis and classification [42]. The model trained on five different mask datasets showed better results than existing mask recognition methods by at least one point during testing. The algorithm achieves 99.4% accuracy in recognizing faces when they have partial coverage [22]. The better YOLOv3 network achieves enhanced mean Average Precision and faster frame rate than earlier approaches. Several face detection algorithms that focus on partial face obstruction face difficulties when detecting faces from complicated angles and positions, and when faces are at rest. Environmental conditions, along with lighting changes, create additional difficulties for detecting partially obstructed faces in image data [43, 44].

The improvements in YOLOv4 consisted of adding the Mish activation function and sophisticated data augmentation approaches, including Mosaic and the Cross Stage Partial (CSP) network [23]. These improvements enhance model durability and accuracy while the model continues to operate at real-time speeds. YOLOv4 and its predecessor YOLOv3 share the same limitation regarding the detection of faces that are either partially obstructed or fully concealed [24]. The requirement for designing improved solutions and creating dedicated training datasets to handle occlusion problems remains both essential and time-sensitive.

The authors in [25] experienced four different variants of YOLOv5 models for identifying faces covered with helmets. Models were created by adjusting the size of the BottleneckCSP module, which is located in the neck of the model. All four YOLOv5 models had similar mAP values, but the YOLOv5s model's outstanding 110 fps makes it stand out. Also, a higher mAP value between 0.9 and 1.3 was achieved by YOLOv5 models with pre-training weights, as shown in [25]. An enhanced YOLOv5 model for recognizing small targets was demonstrated in a different investigation of the model by [23].

The recent developments of face detection have explored the pursuit of multi-task learning to improve the precision of the model, especially in extreme conditions of partial blockage and low-light environments [45]. The study by [46] introduces the hybrid model that combines face identification and emotion recognition and states that they have boosted the face detection robustness in occlusivity cases. This model is viewed as having a joint feature extraction module, which learns both tasks simultaneously, thus reducing the partial occlusion through interpretations of subtle facial expressions. This hybrid approach has potential to enhance YOLO-based architecture, e.g. YOLOv6 and YOLOv7, by enhancing feature representations of occluded faces with additional contextual information based on emotions.

D. Research Gap from the Literature

Although a significant improvement has been made in real-time object detection in YOLOv3 and YOLOv4, there is an existing limitation on the performance of both models when used on tasks that require the detection of occluding faces. Empirical studies show that, despite having better inference speeds compared to traditional convolutional neural network-based methods, these models do not work well in detecting occlusions caused by accessories or other obstructions [22, 23]. Need for a specialized training together with the feature enhancements for partial occlusions motivated the evolution of newer versions such as YOLOv6 and YOLOv7 that are aimed at tackling these issues with better and more sophisticated feature extraction and processing capabilities. This study fills this gap by systematically comparing YOLOv6 and YOLOv7 through a specialized dataset, containing facial images partially covered by masks, helmets, and other objects, under varying lighting circumstances. Besides, it is one of the initial attempts to use energetic data-augmentation measures to improve the generalization ability of both models, hence addressing the inherent problem of occlusion and illumination variation.

III. YOLOv6 AND YOLOv7 Techniques for Occluded Face Detection

The YOLOv6 model was introduced in June 2022, followed by YOLOv7 in July 2022. YOLOv6 & YOLOv7 are the activated progressions of the YOLO family, which are designed with novel ideas to resolve real-time face detection issues like occlusion in concrete.

YOLOv6: Proposed by Meituan in 2022 [26] [27], the YOLOv6 is an advanced anchor-free detection model that boosts both the efficiency and accuracy of the model. Various innovations include:

EfficientRep has been constructed on the principles of EfficientDet and therefore benefits from both proprioceptive and visual features.

The anchor-free method adopted in YOLOv6 adds to its adaptability in the recognition of non-standard shaped objects, making it especially suited to situations where there are occlusions, where facial elements cannot form standard bounding box shapes [28].

YOLOv7, as explained by [21], is an upgrade of YOLOv6 that implements a set of optimizations that improve the accuracy of detection while preserving fast running. The main optimizations include:

- The (E-ELAN) is proposed to enhance feature integration in multiple scales, subsequently increasing the ability of the model to detect occluded faces, regardless of changes in positioning and size.
- Re-parameterization is used to optimize modeling in order to enable YOLOv7 to achieve faster inference with reduced accuracy object detections, which is essential in real-time scenarios involving occluded faces.

The YOLOv6s approach scored a mAP of 43.1% on the COCO val2017 dataset, outperforming the YOLOv5s algorithm by a large margin, which stood at 37.4%. When compared with the earlier algorithms, YOLOv7 achieves better results in inference time and accuracy (r6.1 as in the above images) than PP-YOLOE, YOLOX, and Scaled-YOLOv4 [29].

IV. Research Methodology

Fig. 1 depicts the five steps of the proposed approach: data collection, preprocessing, YOLO model training, evaluation, and testing. Data gathering refers to the acquisition of images of partially masked faces from the Internet. Preprocessing includes image size normalization, data labeling and bounding boxes, and data augmentation. YOLO model training involves training data with the YOLOv6 and YOLOv7 models. The evaluation of the YOLO model entails assessing the YOLO model's training results and testing its capabilities.

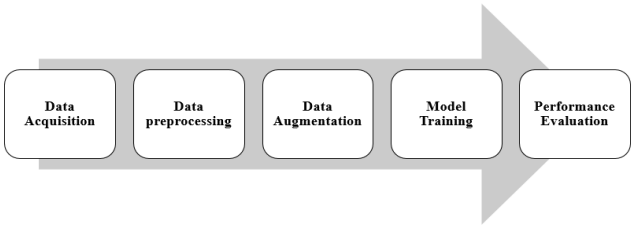

Fig. 1. Methodological design flow.

A. Dataset Collection and Preparation

Collecting a diverse and well-annotated dataset is crucial for training an effective face occlusion detection model. To create a robust dataset for face occlusion detection, it is essential to gather a diverse set of images that represent various real-world scenarios. Various sources were used in the compilation of the dataset used in this study, as it included 500 images with partially concealed faces in various illumination intensities, as shown in Fig. 2. It has three types of occlusions: facial masks, helmets, and miscellaneous objects, and is reflective of real-world situations. Stringent data augmentation protocols were put in place in order to create efficacy in the models and to facilitate generalizability.

Fig. 2. Sample images of different occlusions.

B. Data Pre-processing

Fig. 3 depicts a flowchart of the data preparation procedure. Before the process of training the model is carried out, this step is carried out to modify the data to the format of the YOLO classification system. The objective of the pre-processing of data is to enhance both the quality of the data and the performance of the YOLO models.

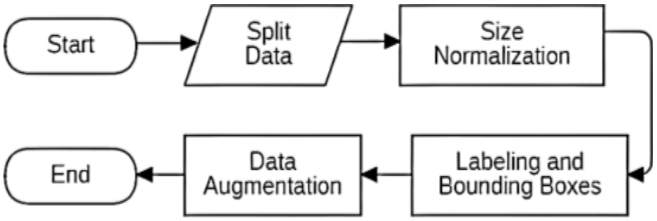

Fig. 3. Flow Chart for data pre-processing.

The first thing that needs to be done to begin the process of pre-processing data is to divide the data into 80% for training, 10% for testing, and 10% for validation. Preventing overfitting and ensuring that the model can generalize well on newly collected data are the two primary goals of this endeavor. After that, the image size was adjusted to 640×640 pixels to maintain consistency with the input format of the model. The data is then annotated, which includes labeling and bounding boxes, among other elements. While the process of drawing a box around the items in the image is referred to as a bounding box, the process of labeling involves the act of labeling the objects in the image. The final stage is to execute data augmentation, which is the process of making copies of the image with multiple modifications, such as brightness, contrast, and rotation. This is the final phase. To improve the model's ability to learn, this is done to enhance the quantity of the dataset as well as its diversity.

We have modified and labeled the partially occluded faces in an image and assigned the class name using the Roboflow online.

C. Data Augmentation

After annotating this dataset, a new version of the dataset is generated by applying preprocessing and augmentations, as shown in Fig. 4, to improve the quality and generalization ability of a model. Eventually, we could have 1100 images 80% as a training set, 10% as the validation set, and 10% as a testing set.

A flowchart depicting data augmentation can be viewed in Fig. 4. Before the YOLO models' training procedure is carried out, this step is carried out to multiply the data and prevent overfitting. This is done to ensure that the YOLOv6 and YOLOv7 models are as accurate as possible. To train both YOLO models to be more resistant to changes in the appearance of the data, the goal of data augmentation is to make it capable of producing more accurate object detection [33].

Fig. 4. Data augmentation sample image.

Data augmentation techniques are applied individually. Each version demonstrates a different type of transformation:

- Original - The unmodified image.
- Brightness - Enhanced brightness.
- Contrast - Enhanced contrast.
- Sharpness - Enhanced sharpness.
- Flip - Vertically flipped.
- Mirror - Horizontally mirrored.
- Rotate - Rotated at an angle.

D. Model Training

This phase involves training of the YOLO models, which will be used to build a strong infrastructure of recognizing occlusions on faces in pictures. The first step involves importing carefully pre-processed data and then training the two YOLO models over 150 epochs to optimize the detection accuracy. After that, the most effective variants of the trained models are stored as the name best.pt, making them available to accurately and optimally identify faces with occlusions during image processing.

E. Evaluation Using DL Approaches

In this work, Google Colaboratory has been chosen as the environment where different deep-learning models will be run. The Tesla T4 graphics processing unit (GPU) has an installed memory of 16 GB and is integrated perfectly via Google Collaboratory and utilized in every experiment that was carried out in this study. The platform offers 12GB of random-access memory (RAM), facilitating expedited deep-learning training. To generate the graph and confusion matrices in this study the pre-installed TensorFlow software library is used in Google Colaboratory. The custom-generated dataset consists of partially occluded face images, which are annotated with a bounding box and trained using the proposed two different DL models and tested to evaluate and compare the performances. To measure the performance of the DL, model the primary metric is mean Average Precision (mAP). To evaluate the precision and recall values of various training models this indicator is used in numerous other face occlusion detection studies [30]. The F1-score (F1), recall rate (Re), and precision rate (Pr) are all evaluation indicators that can be mathematically expressed as:

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \quad (1)$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (2)$$

$$\text{F1} - \text{score} = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision+recall}} \quad (3)$$

The values of True Positive (TP), False Positive (FP), and False Negative (FN) samples are the determinants of these indicators. TP is the scenario in which a positive sample is accurately predicted for an object. A false positive (FP) is the identification of an invalid object as a positive sample. Contrary to a FN, a legitimate object is identified as a negative sample. The expressions for calculating AP and mAP are as follows:

$$AP = \int_0^1 P(R)\, dR$$

$$mAP = \frac{1}{C}\sum_{i=1}^{C} AP_i \quad (4)$$

V. Data Analysis and Results

The training duration of 150 epochs for YOLOv6 and YOLOv7 is illustrated in Table I. Compared to YOLOv7, it is obvious that YOLOv6 has the minimum training time. In this study, two experiments are conducted to evaluate the capabilities of two distinct deep-learning algorithms in the recognition of occluded faces.

TABLE I. Training Timing of Models

Model	Epochs	Training time (80%)
YOLOv6	150	44 min, 25 sec
YOLOv7	150	2 hr, 19 min, 32 sec

A. Performance Analysis Based on Key Metrics

Table II shows the precision, recall, F1-score, mAP50, and mAP50-90 values produced by the YOLOv6 and YOLOv7 models trained on 150 epochs. F1-score is the harmonic mean of precision and recall; mAP50 is the average precision of all classes at the IoU threshold of 50%; mAP50-90 is the average precision of all classes at the IoU threshold between 50% and 90%; precision is the fraction of detections that are true positives. These results represent the model's performance in identifying the partially occluded faces in an image. A greater value indicates higher model performance [31], [32]. Precision, recall, F1-score, and IoU are computed as Formula (1) to Formula (4).

TABLE II. Performance Analysis Based on Key Metrics

Model	Precision	Recall	Accuracy@ mAP(50)	Accuracy@ mAP(50-95)	F1-Score
YOLOv6	0.90	0.79	0.886	0.45	0.845
YOLOv7	0.92	0.89	0.922	0.50	0.90

YOLOv7 (0.92) has a slight edge over YOLOv6 (0.90), indicating improved accuracy in the accurate recognition of faces. Also, YOLOv7 (0.89) shows an appreciable improvement over YOLOv6 (0.787), emphasizing its ability to recognize a higher proportion of relevant objects. Importantly, YOLOv7 achieves the maximum value (0.922) in relation to YOLOv6 (0.886), indicating improved accuracy under less strict thresholds of IoU. Besides, YOLOv7 (0.50) has a narrow edge over YOLOv6 (0.45), indicating superior performance under more strict thresholds of IoU. Finally, YOLOv7 (0.90) has an edge over YOLOv6 (0.845), indicating an improved.

YOLOv7 outperforms YOLOv6 in all the tested metrics, making it a better model for object detection tasks. The differing colors and annotations in the graph clearly indicate these differences, as shown in Fig. 5.

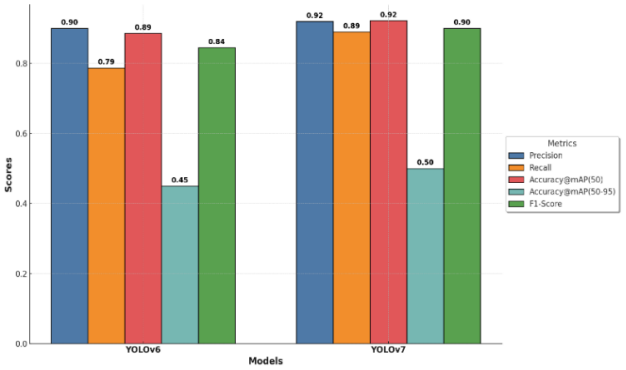

Fig. 5. Visualization of YOLOv6 and YOLOv7 based on performance metrics.

Fig. 5 shows the clear over performance of YOLOv7 over YOLOv6 in all the metrics tested. The Precision (0.92 vs. 0.90) and Recall (0.89 vs. 0.787) of YOLOv7 are higher, signifying that it has better accuracy and object detection strengths. Also, it has better performance in Accuracy@mAP(50) (0.922 vs. 0.886) as well as in Accuracy@mAP(50-95) (0.50 vs. 0.45), which shows that it performs better under fluctuating thresholds in the IoU metric. Also, the F1-score of YOLOv7 (0.90 vs. 0.845) is higher.

B. Confusion Matrix Analysis

The confusion matrix produced in tests is shown in Fig. 6. The confusion matrices illustrate the performance of YOLOv6 and YOLOv7 in face detection in partially occluded areas. YOLOv6 achieves 91% accuracy in face and 88% in background detection, with low misclassification rates of 9% for face and 12% for background. On the other hand, YOLOv7 shows better performance, with 94% accuracy in face and 90% in background detection, and low misclassification rates of 6% for face and 10% for background. This highlights the improved ability of YOLOv7 in handling challenging situations like partial occlusions.

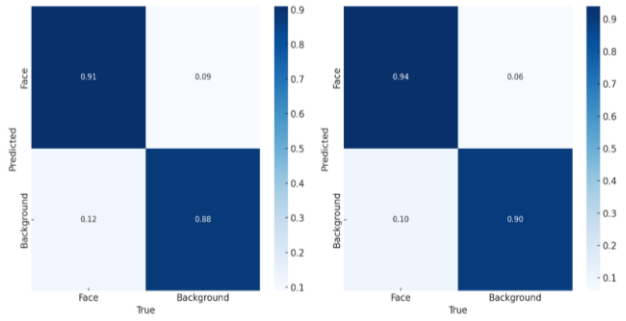

Fig. 6. Confusion matrix of models.

C. Training and Validation Performance of the Models

Training outputs of the YOLOv6 and the YOLOv7 models for 150 epochs exhibit superior metrics in the form of precision, recall, F1-score, mAP50, and mAP50-90. The complete visualization of the training output concerning the YOLO model, i.e., for 150 epochs, was depicted, indicating the performance of the box_loss, cls_loss, dfl_loss, precision, recall, mAP50, mAP50-90, and confusion matrix. The training output of the YOLOv6 model is presented in Fig. 7.

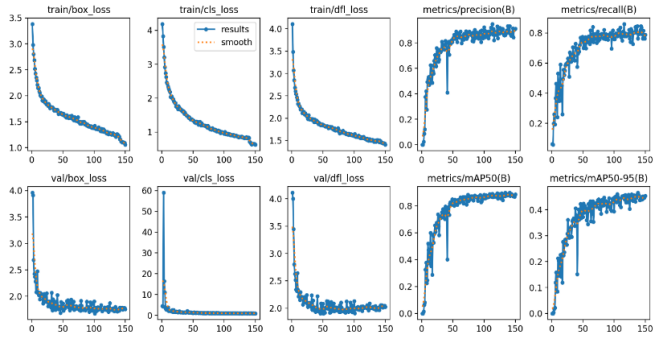

Fig. 7. YOLOv6-model training and validation.

The dynamics of the model were evaluated through systematic monitoring of the training and validation performance indicators over a sequence of 150 epochs to form a complete understanding of the learning process of the model and the generalization ability of the model. The constituent parts of training loss such as: box loss, classification loss, and distribution focal loss, show a monotonic reduction in the training curve hence validating the model as an efficient mean of bounding-box regression, object classification, and localization. The validation loss trends show a similar pattern of decrease, indicating that the model generalizes efficiently to novel inputs and prevents the risk of overfitting. The evaluation measures, consisting of precision, recall, and mean Average Precision (mAP) show stable improvement across the entire period of training. The model demonstrates significant gain of the detection accuracy, with increasing mAP value at IoU=50% and across the 50-95% IoU criteria. The experimental results demonstrate the effectiveness of the model, which paves the way for future use in object detection tasks across a wide range of real-world applications. This result of training is represented as Fig. 8 in the case of YOLOv7 model.

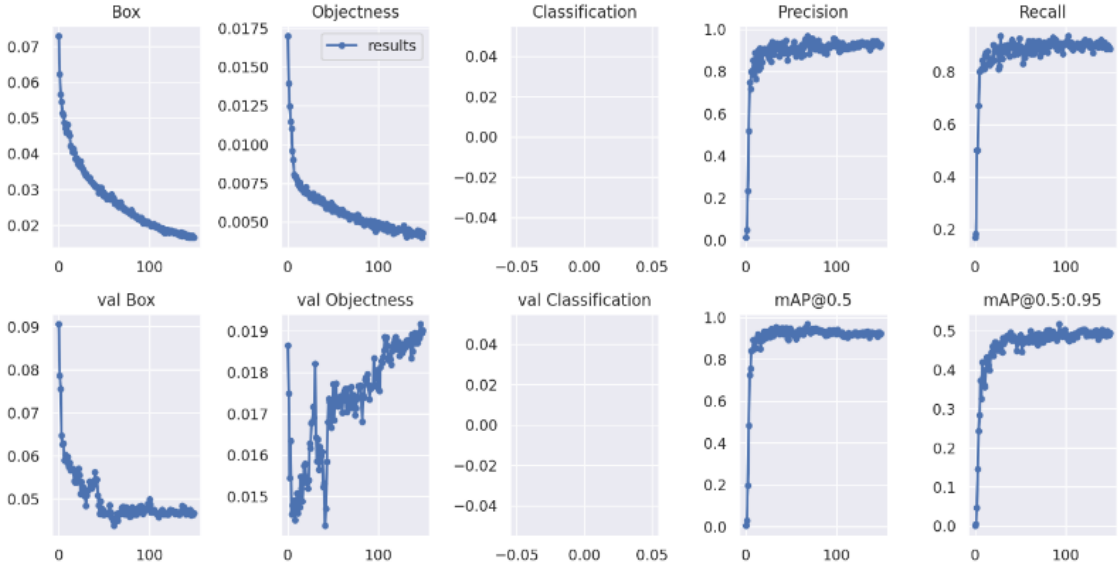

Fig. 8. YOLOv7-model training and validation.

The diagram shows the working effectiveness of the YOLOv7 algorithm in recognizing partially occluded faces under reduced-light settings both at the training and validation stages. The upper part shows training indicators, including Box Loss, Objectness Loss, and Classification Loss, as well as Precision and Recall trends over several epochs. The algorithm achieved improved convergence as loss indicators steadily reduced throughout the period of training. The plots of Precision and Recall show continuous improvements, indicating improved algorithm performance in the accuracy of object detection as well as efficiency in information recall.

The last row shows the validation metrics, including Box Loss, Objectness Loss, and Classification Loss, as well as the evaluation metrics mAP@0.5 and mAP@0.5:0.95. The decline in validation loss values shows good generalization ability of the model for new data, while the rise in mAP values indicates its ability to detect and classify difficult low-light faces. The experimental findings reveal that the YOLOv7 architecture is capable of dealing with high-level detection tasks in unfavorable environments, hence, its structural stability and reliability in facing real-world applications.

D. Statistical Significance of Performance Improvements

A paired t-test comparing performance differences between YOLOv6 and YOLOv7 was used to statistically evaluate the variation in performance in terms of the metrics used to measure accuracy in several experimental runs. The statistical analysis is mainly aimed at proving that the improvement in precision with the use of YOLOv7 compared to YOLOv6 is statistically significant, which will strengthen the validity of the given findings. The analysis states that its confidence interval of estimating the range of difference in the true mean differences of the precision is found to be 95%.

1) Calculation of mean difference: The mean difference $\overline{(d)}$ between the paired precision values of YOLOv6 and YOLOv7 was computed using the formula:

$$\bar{d} = \frac{\sum d_i}{n}$$

where, $d_i = YOLOv7_i - YOLOv6_i$ are the individual paired differences, and n is the number of paired observations (in this case, n =10). The calculated mean difference is:

$$\bar{d} = 0.028$$

This result indicates that, on average, YOLOv7's precision is 0.028 higher than YOLOv6's precision.

2) Standard deviation and standard error: The standard deviation of the differences (s_d) was calculated to measure the variability among the paired differences, using the formula:

$$(s_d) = \sqrt{\frac{\sum(d_i - \bar{d})^2}{n-1}}$$

The standard deviation of the paired differences was found to be:

$$(s_d) = 0.0103$$

The standard error of the mean difference (SE) was then calculated as:

$$SE = \frac{s_d}{\sqrt{n}}$$

The resulting standard error is:

$$SE = 0.00327$$

This small standard error indicates that the sample mean difference is a precise estimate of the population mean difference.

3) t-Statistics and p-Value: To test the null hypothesis (H_0) that there is no significant difference in precision between YOLOv6 and YOLOv7, the t-statistic was calculated using the formula:

$$t = \frac{\bar{d}}{SE}$$

The calculated t-value is:

$$t = \frac{0.028}{0.00327} = 8.573$$

The p-value corresponding to this t-value, for 9 degrees of freedom, is:

$$p = 1.27 \times 10^{-5}$$

The null hypothesis is rejected since the p-value is much smaller than the significance threshold (α=0.05). This confirms that the improvement in precision from YOLOv6, YOLOv7 is statistically significant.

4) Confidence interval: The 95% confidence interval for the mean difference was calculated as:

$$CI = \bar{d} \pm t_{critical} \times SE$$

where, $t_{critical} = 2.262$ is the critical t-value for 9 degrees of freedom at a 95% confidence level. The resulting confidence interval is:

$$CI = 0.028 \pm (2.262 \times 0.00327)$$

$$CI = [0.0206, 0.0354]$$

$$CI = [0.0206, 0.0354]$$

This indicates that the true mean difference in precision is between 0.0206 and 0.0354 with 95% confidence.

5) Conclusion: The statistical analysis demonstrates that YOLOv7's improvement in precision over YOLOv6 is statistically significant, with a mean improvement of 0.028 and a confidence interval of [0.0206, 0.0354]. The extremely low p-value (1.27×10^{-5}) further validates the reliability of the results. These findings highlight the superior performance of YOLOv7, making it a more effective model for real-time detection of partially occluded faces.

E. Image Prediction

The performance of the detection network in YOLOv6 and YOLOv7 models is listed under this subsection based on the prediction output. The models were tested on face occlusion images and at different lighting conditions to test their accuracy in detection and their strength. The predictions show the ability to perceive partial masks coverages of faces such as visors, as well as at low illumination levels of both models. The bounding boxes and confidence scores make the visual and quantitative evaluation of the detection performance possible, which proves the effectiveness of these models in practice. The sample image prediction of the YOLOv6 model is displayed in Fig. 9.

Fig. 9. YOLOv6- image prediction of partially occluded faces in low-light.

However, YOLOv6 proves that blocking can partially hide dark luminance faces in an image. The model puts a bounding box around a detected face and attributes a confidence score to it, such as 0.8 or 0.3. These reflect the conviction of the model in its successful detection. The higher the confidence score, the more firmly the model believes in its accurate detection. The face detection model shows good performance and dependability when tested with real-world input, which comes complete with both difficult lighting conditions and incomplete face obstructions. Fig. 10 displays the output of the YOLOv7 model when applied to the sample image.

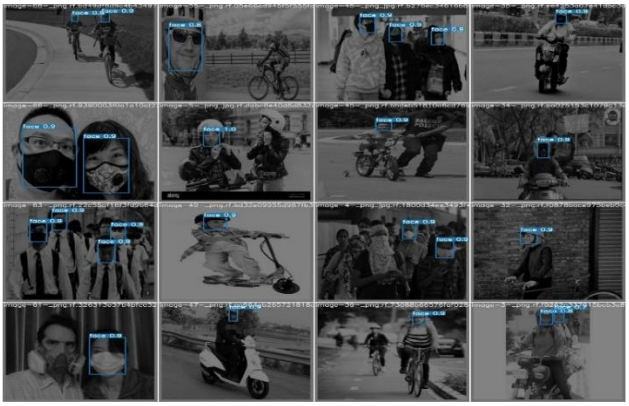

Fig. 10. YOLOv7- image prediction of partially occluded faces in low-light.

YOLOv7 model detects faces that are partially obscured in low-light settings by sketching blue bounding boxes with confidence levels starting from 0.8 up to 1.0. The model does proper face detection and localization within advanced environments because it can rightly identify faces even under difficult conditions which include masks as well as helmets and poor lighting.

VI. Discussion

In this research, the YOLOv6 and YOLOv7 performance for detecting partially occluded faces under low-light conditions was considered. The results show that deep learning YOLO models are on the way to the occlusions problem even if it was one of the most challenging tasks for face detection system in the past. It has been found out that YOLOv7 beats YOLOv6 in all major performance metrics which include precision, recall, F1 and mAP. YOLOv7 produced 0.92 precision, which exceeded YOLOv6's score of 0.90 while identifying relevant objects, especially faces, which are partially hidden. Furthermore, YOLOv7 had outperforming the recall ability of detection (0.89 compared to YOLOv6's 0.787) which gives a hint that YOLOv7 is good at detecting faces in various occlusion levels therefore reducing false negatives. YOLOv7 shows improved performance in face detection under occlusion, which corresponds prior study that focus on advance feature extraction method for face occlusion difficulties [22, 23]. YOLOv6 [28] and [23] have better real-time results, accuracy and efficiency in detecting faces in an occluded environment as well as in low-light settings as opposed to conventional algorithms such as the ViolaJones detector [28]and previous versions of the system like Faster R-CNN [47]. Single-step detection algorithm of YOLO is highly applicable in the reality field, whilst the E-ELAN architecture of YOLOv7 [23] is more effective in extracting features, thus strengthening features in adverse conditions.

These benefits make YOLOv7 particularly suitable to the real-life security and surveillance operations. This technological improvement of YOLOv7 can be explained by various reasons. To begin with, the application of E-ELAN allows YOLOv7 to embrace more sophisticated and shadowed facial features, even when there is a poor lighting, or when the face is partially covered. This feature will give YOLOv7 a unique edge to handle changes in facial orientation and partial blockages, which are a major issue in the face detection system. Moreover, the structure of YOLOv7 that combines different levels of face aggregation helps it to achieve an increased accuracy rate as it is able to locate smaller and less unclear faces better than YOLOv6 does.

The F1-score, which uses the harmonic average of precision and recall to give an overall performance, show that YOLOv7 is better than YOLOv6 with values 0.90 and 0.845, accordingly. The improvement in performance of YOLOv7 depicts its dual capabilities as in precision face detection as well as lower false positive rates in comparison to the previous version, hence it is highly reliable for accuracy-first detection systems.

A. Training Time and Efficiency Considerations

This study proved that training times of YOLOv6 and YOLOv7 were different. The experiments presented that it took YOLOv6 44 min 25 s for training and YOLOv7 required only 1 h 19 min 32 s. YOLOv7 takes longer time to train, which may not be suitable for latency-sensitive scenarios although it has better accuracy. In real-time systems consideration must be given to computation vs. detection performance when employing these models. YOLOv7 is the better choice for applications that are concerned with detection performance, as it offers better accuracy and recall at the cost of slower training in these cases [34].

B. Statistical Analysis and Significance of Results

The paired t-test's precision of performance improvement shows statistical significance with YOLOv7. The statistical test gave a p-value of 1.27×10^{5}, which is significantly below the 0.05 threshold, thus demonstrating that YOLOv7's performance improvements are dependable and not caused by random fluctuations. YOLOv7 performed well on partially masked face detection, with the mean precision improvement of 0.028; this value was statistically significant, as indicated by the 95% confidence interval on the mean difference. The results support previous studies, which indicate that YOLOv7 was superior to the competing models in complex object characterization missions due to its innovative components, including the (ELAN) which significantly increases detection effectiveness in low-light of occlusion situations [24].

C. Practical Implications

The enhancements shown by YOLOv7 for partially occluding face detection lead to essential practical uses for applications that depend on face detection, including security systems and surveillance operations, and human-computer interaction systems [35]. YOLOv7 delivers superior performance in occlusion detection, which makes it the best choice for surveillance systems operating in real-time, where detecting faces in difficult conditions, such as dimly lit or crowded areas, becomes crucial [36].

YOLOv7 is shown to have strong features to detect faces when they are hidden by masks or helmets to prove its necessity in the current world situation when masks and helmets are commonly used to protect health-related factors. The system can be combined with access control facilities, customer analytics, and any other, where facial recognition can be utilized to perform identification or authentication services. It is assumed that the improved performance of YOLOv7 on accuracy and recall should decrease the error rates, which occur in real-time

application and hence, increase satisfaction with the results as well as operational efficiency.

D. Ethical Consideration

YOLOv7 is a huge progression in facial recognition, even if it brings up serious ethical concerns by itself with other occluded face detection capabilities. The improvement of their accuracy asked to pay more efforts in data protection among the security measures [37]. Public and workplace environments, where face recognition surveillance take place, cause privacy dangers as these technologies can impinge on personal privacy without appropriate monitoring or individual approval.

Using YOLOv7 and similar models in real-world applications presupposes compliance with ethical standards during their deployment by organizations [38]. These technologies necessitate clear rules of the game that would ensure their responsible application via transparent processes established [39]. It is important that public spaces should have systems in place that will allow individuals to opt out of facial recognition technology, since they might not be informed or agree to the sharing of biometric data.

The results of this research have great implications for applications in the real world in relation to many aspects, such as surveillance, security, and human-computer interaction. The fact that YOLOv7 is able to identify faces with a high degree of success in some difficult situations, like when a person puts on a face mask or the amount of light is insufficient, makes the algorithm offer great utility to applications related to the safety of the crowd, monitoring, and access control.

Face masks gained ubiquity amid the COVID-19 pandemic, and the identification of masked people in the social environment became a crucial problem. The higher performance of YOLOv7 on these situations is a considerable benefit to automated surveillance, access control, and other tasks, which at times require more precise face detection on a real-time basis.

Additionally, the ability of YOLOv7 to perform face detection in low-light areas opens up fresh possibilities of application in night security contexts and other areas of poor visibility, like parking lots, airports, or those offices with low-light conditions where face detection is usually suppressed due to poor lighting. Such conditions might result in more dependable and effective security work done by the better accuracy of YOLOv7.

VII. Conclusion

This research successfully evaluated YOLOv6 and YOLOv7 for detecting faces obscured by masks and helmets in low-light conditions while showing important improvements in real-time object detection. The evaluation demonstrates that YOLOv7 produces better results than YOLOv6 regarding precision and recall, and F1-score, which positions it as the best model for recognizing faces with masks and helmets, and other face coverings.

The Enhanced Efficient Layer Aggregation Network (E-ELAN) and improved feature extraction capabilities in YOLOv7 enable it to deliver better occluded face detection results. YOLOv7 achieves high detection accuracy while simultaneously enhancing its capability to detect various occlusion types because of its innovative features. A statistical evaluation demonstrates that YOLOv7 delivers better precision at a significant level, reinforcing its dependable enhanced performance.

YOLOv7 clearly shows better results compared to YOLOv6 in accuracy as well as recall, although with a higher cost on the computation resource requirements. YOLOv7 also takes more training time than YOLOv6 and thus poses difficulties when it comes to its deployment in real-time application. The trade-offs between YOLOv7 and YOLOv6 need to be carefully considered by the researchers and developers to match model selection with their needs of use. The practical implications of this research are significant. The better ability to localize occluded faces would be of great significance for security and surveillance systems, human-computer interaction, and other domains that depend on accurate face recognition. As face masks become a more common accessory in daily life, as well – especially with the world's focus on global health, being able to identify people when their faces are partially obscured or are covered by something (like sunglasses) is increasingly useful. Furthermore, YOLOv7's efficiency in detecting faces in low-light conditions opens up new opportunities for deployment in environments where visibility is compromised, such as at night or in poorly lit spaces.

Despite such developments, there are a number of limitations. The dataset used in the current research, even though it has a certain level of heterogeneity, is not huge, and it may not be a full-scale representation of a wide range of real-life scenarios where occlusions can occur. Future studies are suggested to aim at enriching the dataset by incorporating a wider range of types of occlusions, both in variety and complexity, as well as by investigating other environmental contingencies, such as changing illumination conditions and multi-object occlusions. Furthermore, the computational demands of YOLOv7 necessitate a closer examination of its efficiency, especially in scenarios requiring rapid inference times.

In the future, it may be interesting to investigate if YOLOv7 can be combined with other state-of-the-art face detection methods like RetinaFace and SSD to yield good results in comparison to YOLOv7. Furthermore, the use of transfer learning techniques may reduce training time for YOLOv7 without sacrificing accuracy and enable real-time adoption.

In conclusion, YOLOv7 represents a significant advancement in the detection of partially occluded faces, offering superior accuracy and recall over YOLOv6. The ability of the model to cope with occlusions, as well as to perform, even during the low-light scenarios, makes it the architecture of choice in face detection tasks in fields like security, surveillance, and human-computer interaction. The improvements demonstrated in this study have significant potential for real-world applications, particularly in security, surveillance, and other sectors reliant on face recognition technology. While there are still challenges to overcome, particularly in balancing computational efficiency with detection performance, the continued evolution of models like YOLOv7 brings us closer to achieving more robust, adaptable, and real-time face detection

systems capable of addressing the complexities of modern environments.

VIII. Research Limitation and Future Work

While this study provides valuable insights into the performance of YOLOv6 and YOLOv7 for partially occluded face detection, several limitations must be acknowledged. The dataset used in this research consisted of only 500 images, which, although representative of different types of occlusion, may not fully capture the diversity of real-world scenarios. Future studies should aim to expand the dataset to include a larger variety of occlusions, facial expressions, and environmental conditions, thus ensuring that the model can generalize to more challenging and dynamic real-world applications.

In addition, this study aimed at comparing two editions of the YOLO model. In the future, we may consider incorporating extra strong models (e.g., RetinaFace or SSD) to further invest in their strengths of recognizing occluded faces. Secondly, adding more challenges (e.g., hard lighting conditions and occlusions), e.g., multi-object occlusion or heavy mask, to the dataset may give us some hints on the generalization of our model.

Semantic Segmentation Algorithm of Animal Husbandry Image Based on an Improved U-Net Network

Jia Li, Jinjing Zhang, Fengjiao Jiang*
Department of Intelligent Agricultural Engineering,
Shanghai Vocational College of Agriculture and Forestry, Shanghai 201699, China

***Abstract*—Due to the limitations of unclear edges and fuzzy features in image segmentation tasks, this study proposes an enhanced U-Net semantic segmentation network utilizing the local and global fusion attention module in response to the drawbacks of fuzzy features and unclear edges in image segmentation tasks. Firstly, a feature extraction module combining convolution and Transformer is introduced in the bottleneck layer, so that the network can fully simultaneously capture local and global features, and effectively promote the fusion of local and global features. Secondly, the CBAM attention module is added to the skip connections between the encoder and decoder. Finally, the output feature map is processed using the ASPP module to enhance focus on target features and improve segmentation performance. Experiments conducted on four animal husbandry segmentation datasets show that the LCA_Net model proposed in this study achieves an IoU score of 90.19% and a Dice score of 94.83%, compared with U-Net and other mainstream segmentation networks, it has improved. This study offers effective technical support for advancing aquaculture status monitoring and lays a foundation for further development in this field.**

***Keywords*—Machine vision; semantic segmentation; feature fusion; attention mechanism**

I. Introduction

Image segmentation is the accurate extraction of target regions of interest from an image, which refers to assigning each pixel in the image to a different category in order to achieve semantic understanding and region recognition of the image. Traditional image segmentation techniques [1] have low efficiency and some defects in the segmentation results, which cannot achieve the expected results. The rapid improvement in computer hardware performance encourages the rapid development of deep learning technology. Deep learning-based methods have achieved excellent results in image segmentation. Its excellent feature extraction and expression ability improve segmentation accuracy and speed, which is superior to traditional machine learning and computer vision approaches [2].

A convolutional neural network significantly enhances image segmentation algorithms. Its end-to-end pixel-level image segmentation networks have created applications in the field of semantic segmentation. These networks can classify images at the pixel-level [3]. Later research, such as SegNet [4], improved the accuracy and precision of segmentation by decoding the feature index generated by the pooling layer, and further promoted the development of semantic segmentation technology. In 2015, the U-Net model was proposed [5], and its unique symmetric structure and excellent performance were quickly known. It has strong adaptability to medical image segmentation tasks by retaining information at different levels through skip-connections, and has been widely used in a variety of different segmentation tasks. Subsequently, Zhou et al. [6] optimized the U-Net as a UNet++ version and solved the semantic gap problem caused by direct connections in the original U-Net. Deeplab series [7-9] used hole convolution and pooling modules with varying dilation rates to obtain more contextual information and improved network performance.

In 2018, Zhou et al. [10] used the multi-scale watershed segmentation algorithm to segment the sheep from the images collected in the real and complex breeding environment. In 2020, Zhang [11] proposed a horse body segmentation method based on YOLACT, and segmented the horse body edge contour through edge detection. Qin et al. [12] focused on fish body image segmentation technology, which is a method based on object detection and edge assistance, and the method achieved remarkable results in fish image segmentation. This method not only significantly improves the accuracy of image segmentation, but also provides important support for the development of animal husbandry intelligent technology [13].

Singh et al. [14] proposed an improved DeepLabV3+ CNN model, which demonstrated significant accuracy in cattle body part segmentation. Feng et al. [15] introduced an improved DeepLabV3+ network segmentation model, achieving higher segmentation accuracy for cattle regions. Xie et al. [16] proposed a multi-scale dual-attention U-Net method for detecting sheep hind limb segmentation. These methods perform well in segmentation tasks for specific livestock species. However, all of these approaches focus on segmentation for a single species. In contrast, our proposed network model is capable of adapting to multiple livestock species, offering greater versatility and broader application potential.

Although numerous image segmentation network models exist, [17-21] traditional convolutional networks are limited by their receptive field size when handling image segmentation tasks with intricate details. This limitation reduces their ability to effectively capture global information, making it challenging to achieve optimal results. In addition, it also faces problems such as occlusion caused by complex background, changes in

*Corresponding author.

lighting conditions, and overlap. This study proposes an image semantic segmentation algorithm that improves the U-Net local-global attention network. While individual components like Transformers or attention mechanisms have been explored in isolation, the novelty of our LCA_Net lies in the synergistic integration strategy. We strategically position these modules to address specific shortcomings of the U-Net at different stages of the network, creating a cohesive pipeline that systematically enhances both local-global context modeling and feature refinement. On four different animal datasets, the experimental results show that the network performs more accurately than other popular network models, which is of some reference significance for the research in image segmentation.

II. Network Architecture

Fig. 1 shows an improved network model based on the U-Net proposed in this study, which has a symmetrical encoder-decoder structure.

Three main reconstructions were carried out on the original U-Net structure to form the LCA-Net structure proposed in this study. First, in order to generate feature maps with varying resolutions, the input image's features are progressively downsampled during the encoder stage, reducing spatial resolution. A local global feature fusion module is designed into the bottleneck layer of the encoder and decoder link, which efficiently combines local and global information. In addition, in order to reduce the redundancy of information between skip connections, an attention mechanism module is filled in. In the decoding phase, the high- and low-level features are spliced and upsampled at the same time. Finally, the image pixels are classified through the ASPP module and the Softmax activation function to obtain the segmentation results.

The proposed LCA-Net's design is grounded in three principles: 1) Hierarchical feature interaction: CSWin captures both local texture details and global shape context, overcoming the U-Net's limited receptive field; 2) Attention-guided fusion: CBAM suppresses spatially redundant features before skip-connections, mitigating semantic gaps; 3) Scale-aware decoding: ASPP complements CSWin by explicitly modeling multi-scale object variations. This layered approach fundamentally differs from prior works that apply these modules in isolation.

A. Local Global Fusion Module

Accurately distinguishing the target pixel from the background pixel in an image can be difficult, requiring automatic segmentation and feature extraction at both local and global scales to capture remote interactions. Therefore, the work of this study focuses on adding a local-global attention fusion module into the bottleneck layer of the U-Net architecture, and uses convolution and Transformer to transfer different information to the feature map, enabling the interaction and fusion of local and global information. Fig. 2 illustrates the structure of the local-global fusion module.

Downsampling is applied in one of the execution paths to obtain the LGAF input features, and convolution is used to learn the weights of the convolutional kernels. The local feature in the input image x is extracted to obtain a local receptive field, and then the convolution feature layer is normalized (LN) [22]. The stability of the algorithm has been improved, and the scale differences from different routes have been reduced. After the above operations are performed in turn, the X_L representing the aggregated local detail feature is obtained, as shown in Eq. (1):

$$X_L = LayerNorm(Conv(X)) \quad (1)$$

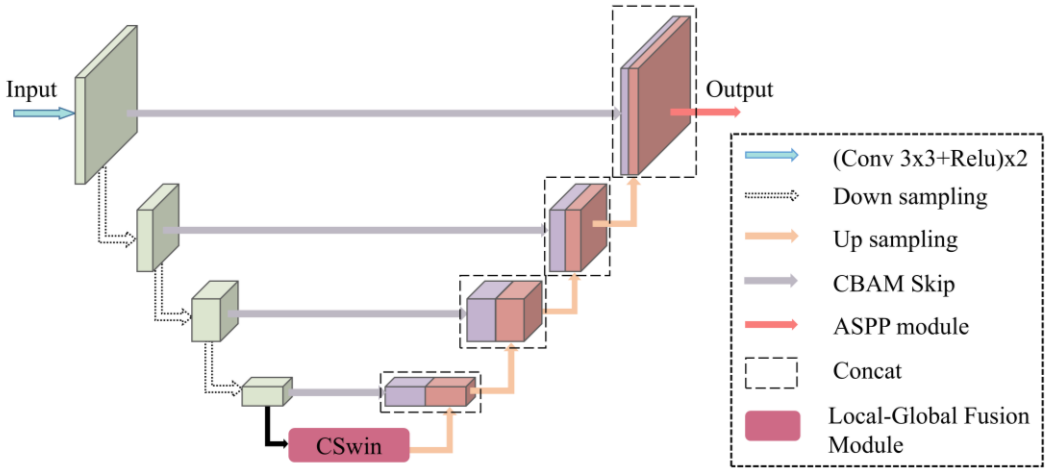

Fig. 1. Architecture of the proposed LCA-Net.

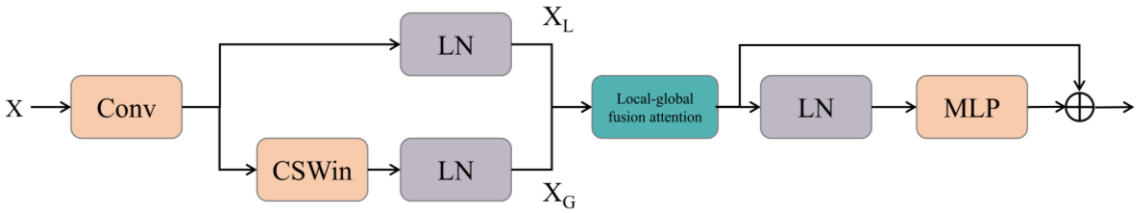

Fig. 2. Local-global attention fusion module.

where, the input feature is denoted by X, the convolution operation by Conv, and the layer normalization by LayerNorm.

In another execution path, self-attention calculation is performed using a convoluted feature map. The Cross-Window converter block (CSWin block) allows for the perception and interaction of global and non-local information [23]. Fig. 3 illustrates the structure of the CSWin block.

After processing previous information, the feature map X_G obtained by this module has its extracted global receptive field, and its specific calculation is shown in Eq. (2):

$$X_G = LayerNorm(CSWin(Conv(X))) \quad (2)$$

The local-global attention module (as shown in Fig. 4) simultaneously accepts and effectively fuses two types of parameter information: one containing local information (X_L) and the other containing global information (X_G).

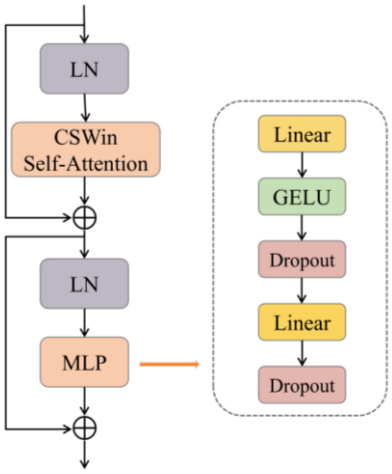

Fig. 3. CSWin module structure.

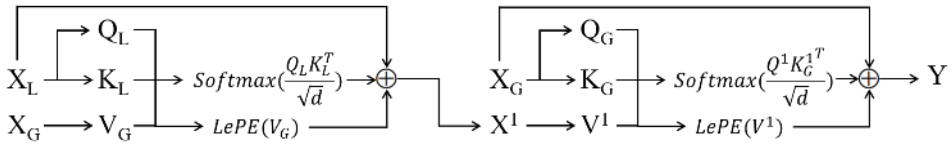

Fig. 4. Local-global attention module.

To calculate attention scores, three vectors-query, keyword, and value vector-with sequential features are calculated. The CSWin-Transformer is employed to process the input features X_L and X_G, and the process is shown in Eq. (3):

$$X^1 = CSWin\text{-}Transformer(X_L, X_G) + X_L \quad (3)$$

Finally, the CSWin-Transformer operation is reapplied to further enhance the global information. By strengthening the global information fusion of the feature map, the capture efficiency of long-distance dependency is improved, and the overall contour and boundary of the object segmentation are clearly recognized. Where V^1 is given by X^1, and Q and K are transformed from X_G. Output Y is represented by Eq. (4):

$$Y = CSWin\text{-}Attention(X^1, X_G) + X_G \quad (4)$$

B. Convolutional Block Attention Module

Typically, during the feature fusion process of the traditional U-Net model, simple cascade operation is involved, but there is no clear selection and enhancement mechanism in the face of key features. This may lead to the over dependence of irrelevant features on the model, and thus the accuracy of segmentation results is limited. Each encoder layer generates a feature map comprising both valuable information and redundant or irrelevant data. However, simple channel compression techniques may lead to the loss of important channel-wise information within these feature maps. To minimize the influence of the background area and make the model focus more on the target segmentation objects, the CBAM attention mechanism [24] is introduced into the skip connection of the network model designed in this study, which can dynamically adjust the weight and filter the effective feature channel. As a result, the model learns the relevant representations more efficiently. Fig. 5 illustrates the CBAM attention module.

Channel attention (CA) and spatial attention mechanism (SA), the two primary components of the CBAM module, are in charge of capturing dependence of channel and space, respectively. The channel and space feature weights can be dynamically changed by combining the two.

In order to compress the feature information, the channel attention module first applies the max pooling and average pooling operations to each channel for the feature map with the input shape of (B, C, H, W). This approach efficiently enlarges the receptive field of the convolutional network while preserving the number of feature channels, producing an output tensor of shape (B, C, 1, 1). The multi-layer perceptron's input should then be the outcomes of the two pooling operations. The multi-layer perceptron can increase the significance of a particular channel by learning parameters and using the sigmoid nonlinear activation function to assign corresponding feature weights to each channel.

For the spatial attention mechanism, the weight assignment methods of each channel are different. It only weights the local part, and then performs the max pooling, average pooling, and a 7 × 7 convolution operation on the channels within the same spatial area. Finally, the weights for each channel are obtained through the nonlinear activation of Sigmoid.

The following are the steps in the CBAM module's calculation:

The input feature map first generates the characteristic layer F_C with channel weight through the CA module, as shown in Eq. (5):

$$Fc = \sigma(MLP(AvgPool(F)) + MLP(MaxPool(F))) \quad (5)$$

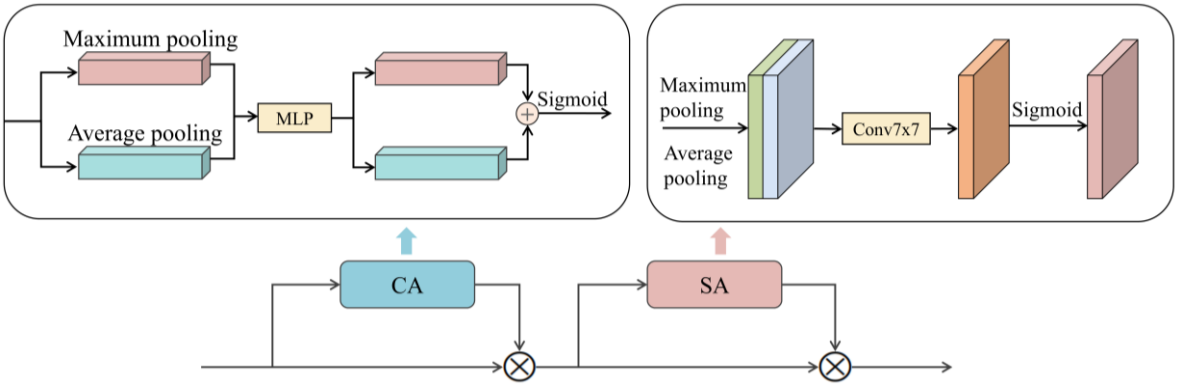

Fig. 5. CBAM attention module.

where, σ denotes the Sigmoid activation function. The number of multi-layer perceptrons is indicated by MLP. Avgpool and Maxpool refer to the global average and max pooling processes, respectively, and F represents the input feature map.

F1 is formed by multiplying the input original feature map F by the channel's weight F_C, which is obtained by F through the CA procedure, as shown in Eq. (6):

$$F_1 = F_C \bullet F \tag{6}$$

Spatial attention is applied to average pooling and max pooling along the channel for the feature map with the input shape of (B, C, H, W). It can compress the channel dimension of the input tensor to 1, then the global channel information integrates into a single channel characteristic graph that has the shape of (B, 1, H, W), and effectively extracts the spatial relationship. In order to allow information interaction between different spatial descriptors, the spatial merged features are connected. The Sigmoid activation function is then employed to acquire the spatial features after the combined features have been transformed into a spatial feature map using the convolution layer Conv, as shown in Eq. (7):

$$F_S = \sigma(Conv([SAavg + SAmax])) \tag{7}$$

where, SAavg and SAmax are the average and maximum pooled spatial feature descriptors. Eq. (8) represents the CBAM module's final output Y.

$$Y = F_1 \bullet F_S \tag{8}$$

The correlation of feature channels is greatly enhanced by this advanced dual attention mechanism, allowing each channel to more effectively capture the most relevant features of its task. Simultaneously, this approach notably improves feature expression, which increases the model's accuracy in understanding and processing the input data. The CBAM module of the skip connection part enhances the feature interaction. The model's accuracy and representational capacity are enhanced by reducing the influence of noise and redundant information through the combination of channel attention and spatial attention.

C. ASPP Module

ASPP was first proposed by Chen et al. [7] in Deeplabv2. Its idea comes from spatial pyramid pooling. Its purpose is to enhance the recognition ability of the network for targets of different scales through pooling operations of different scales. ASPP is a combination of a cavity convolution and a spatial pyramid pooling layer. Specifically, convolutions with different dilation rates are applied within a single branch to extract features. This approach enables the precise capture of multi-scale contextual information through receptive fields of varying sizes, which are subsequently fused to produce the final feature map. It ensures that the receptive fields are increased while maintaining the image resolution, avoiding the problem of a large amount of calculation in traditional convolution.

To more effectively capture and preserve edge detail features and enhance the model's segmentation capability across various target scales, this study uses 8, 12, and 16 as the hole convolution of expansion coefficient, and removes the features obtained by pooling branches. Fig. 6 displays the ASPP structure, which has been optimized.

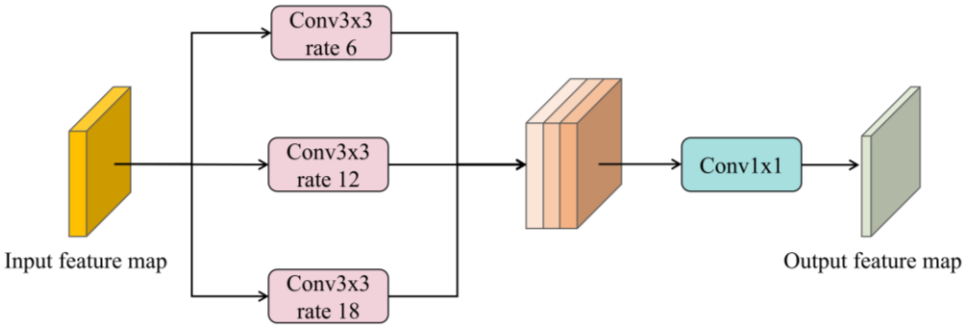

Fig. 6. ASPP module.

III. Experimental Configuration

A. Dataset

All data sets were collected in real animal husbandry environments, including horses and pigeons in outdoor pastures during the day, pigs and cattle in indoor pens. The original image is collected at a resolution of 1920 × 1080 pixels, and then adjusted to 256 × 256 for model input. The label uses LabelMe software to label the target contour to ensure pixel-level accuracy.

The experimental dataset used in this experiment is divided into four parts, which are horse images, pigeon images, cattle images, and pig images. Each image of the horse dataset has been professionally labeled, including the precise contour information of the horse, covering 327 high-resolution images. There are three sections to the dataset: 209 training sets, 53 verification sets, and 65 test sets.

The public pigeon dataset contains 122 high-resolution images and corresponding tags, including 78 training sets, 20 validation sets and 24 test sets. The cattle breeding dataset contains 200 images and corresponding labels, including 128 training sets, 32 validation sets and 40 test sets. The pig farm breeding dataset contains 501 images and corresponding images, including 320 for training, 81 for verification and 100 for test.

B. Experimental Environment and Parameter Setting

The NVIDIA GeForce RTX 3080 Ti GPU, Windows 11 operating system, 16GB of RAM, and Pytorch2.0.1 framework with Python 3.8 programming language constituted the deep learning environment. To ensure the determinism and reproducibility of our experiments, a fixed random seed was used throughout the study for parameter initialization and data shuffling. We employed the Dice loss function as our segmentation loss during the experiment, with a batch size of 8. For data augmentation, we applied a pipeline consisting of random horizontal flip, random vertical flip, random rotation within ±15°, and random brightness/contrast adjustment during the training phase. Additionally, Batch Normalization (BN) was utilized after each convolutional layer and before the ReLU activation function. Dropout was not employed in our architecture.

In this study, all experiments under the same dataset use the same loss function and parameter settings for training, in which the initial learning rate for horse segmentation images is set to 0.0001, with 100 training epochs. For pigeon segmentation images, the initial learning rate is 0.001, and the training consists of 200 epochs. Pig and cattle breeding images have an initial learning rate of 0.0001 and undergo 50 training epochs. Other experimental parameters are consistent with those mentioned above.

C. Evaluation Index

The evaluation indexes chosen for this study are Dice Similarity Coefficient, Precision, Recall, and Intersection over Union (IoU).

The precision indicates the percentage of accurate prediction pixel values in the total pixel values as well as the proportion of correct prediction results in the total predicted value. The accuracy of correctly predicting pixel samples is assessed using this standard, and the Eq. (9) is as follows:

$$Pre = \frac{TP}{TP+FP} \quad (9)$$

The percentage of the actual number of correct total pixel samples that the model correctly predicted is known as Recall. It mainly focuses on the proportion that the target pixel feature is not correctly classified as positive, as shown in Eq. (10):

$$Recall = \frac{TP}{TP+FN} \quad (10)$$

IoU represents the union of the segmentation prediction result and the intersection ratio of the real segmentation label, as shown in Eq. (11):

$$IoU = \frac{TP}{FP+TP+FN} \quad (11)$$

Two samples can be compared for similarity using a function called the Dice similarity coefficient. The similarity between the label image and the predicted image can be computed using it. The value is between 0 and 1, as shown in Eq. (12):

$$Dice = \frac{2TP}{FP+2TP+FN} \quad (12)$$

The positive sample is the target feature, and the negative sample is the background. TP stands for true positive and correctly predicts the target pixel. FP stands for false positive and incorrectly predicts the background pixel as the target pixel. TN stands for true negative and correctly predicts the background pixels. FN stands for false negative, and the target pixel is incorrectly predicted as the background pixel.

IV. Experimental Results and Analysis

A. Comparison of Segmentation Performance under Different Networks

The method suggested in this study and the traditional semantic segmentation algorithm are chosen for comparison experiments in order to confirm the efficacy of this approach. Using the same experimental configuration and the same parameter settings, the comparative experiments with U-Net, ResUnet [25], UNET++ DeepLabv3+, and DCSAU_Net [26] segmentation models are realized, respectively. The model's segmentation performance is assessed using the four datasets listed in this study. The experiment uses four evaluation indexes: Precision, Recall, IoU, and Dice similarity coefficient.

The experimental findings for the dataset of horse image segmentation are displayed in Table I. Bold is the model score that has the highest index. It is evident that the majority of this method's indicators outperform those of other semantic segmentation techniques. The precision, IoU, and Dice similarity coefficients improved by 3.07%, 1.83%, and 1.09%, respectively, in comparison to the traditional U-Net network model.

Fig. 7 visualizes the original image, actual label, and prediction results. The above models' segmentation results are presented in a more intuitive way.

TABLE I. SEGMENTATION RESULTS OF DIFFERENT MODELS IN HORSE SEGMENTATION DATASET

Method	Pre	Rec	IoU	Dice
U-Net	0.9242	**0.9566**	0.8864	0.9385

In Fig. 7, each row is the segmentation visualization results of different original images and different models. The visual analysis indicates an overall improvement in segmentation accuracy. Comparing the segmentation results reveals that ResUnet has the worst recognition effect on the background and edge, and it can only roughly segment the horse area. For example, in the results of the second and fourth lines, the horse is under-segmented, and the last line is noticeably over-segmented, making it impossible to accurately distinguish the horse's edge from the background. Both U-net and Unet++ achieve satisfactory segmentation of the horse's body as a whole, but lack the accuracy of edge segmentation. The proposed approach performs better overall than other comparison techniques, and the segmentation effect is nearly identical to the label value. Not only the boundary is smooth and accurate, but also there are a few cases of under segmentation and over segmentation.

Fig. 7. Visualization effect of horse image segmentation under different networks.

The segmentation performance of the proposed method is more effectively verified through the comparative experiments on the other three datasets. Specifically, the data is showcased in three separate tables, namely Table II, Table III, and Table IV, which are designed to offer a comprehensive view of the various aspects of the experiment.

In the three evaluation indexes of Recall, IoU, and Dice, Table II demonstrates that the LCA_Net network suggested in this study outperforms other networks. The Dice reached 84.62%, which was 0.71%, 1.72%, 0.58% 7.55% and 0.44% higher than that of U-Net, ResUnet, SegNet, Unet++ DeepLabv3+and DCSAU_Net, respectively.

The segmentation results of different models in the pigeon dataset are displayed as illustrated in Fig. 8. The third line shows that when the contrast between the pigeon and the background features is significant, all five models can effectively segment the target features. When the contrast between background features and the overall target is low, other experimental models may experience under segmentation, boundary blurring, and other phenomena. Notably, the model proposed in this study exhibits superior segmentation performance, able to better distinguish subtle pigeon edge features, and the segmentation results are closer to real labels.

TABLE II. SEGMENTATION RESULTS OF DIFFERENT MODELS IN PIGEON SEGMENTATION DATASET

Method	Pre	Rec	IoU	Dice
U-Net	**0.7862**	0.9041	0.7257	0.8391

TABLE III. SEGMENTATION RESULTS OF DIFFERENT MODELS IN CATTLE FARM SEGMENTATION DATASET

Method	Pre	Rec	IoU	Dice
U-Net	0.9066	0.9199	0.8403	0.9122
ResUnet	**0.9206**	0.9000	0.8345	0.9079
Unet++	0.8826	**0.9428**	0.8372	0.9104
DeepLabv3+	0.8796	0.9212	0.8178	0.8989
DCSAU_Net	0.8764	0.9124	0.8083	0.8926
Ours	0.9102	0.9230	**0.8454**	**0.9151**

The segmentation and visualization outcomes of various models in the cattle farm segmentation dataset are displayed in Table III and Fig. 9, respectively. The experimental indicators are improved compared with other models. It is evident from the visualization results that the model in this study has a better overall segmentation effect than other models, particularly when it comes to the first line of the comparison image. Other models' segmentation performance decreases when the scene's lighting impacts, but the model developed in this study is more in line with the label graph, highlighting the benefits of the model's robustness and anti-interference.

Fig. 9. Visualization effect of cattle image segmentation under different networks.

The segmentation indexes and visualization outcomes of various models in the pig farm segmentation dataset are displayed in Table IV and Fig. 10, respectively. Three performance indices show that the model suggested in this study outperforms other models, and the segmentation effect in night and strong light scenes is obviously superior to other models.

The LCA-Net network model proposed in this study achieved more refined segmentation results through comparative experiments with four datasets and visualization results. These results substantiate the effectiveness of the proposed model.

TABLE IV. SEGMENTATION RESULTS OF DIFFERENT MODELS IN PIG FARM SEGMENTATION DATASET

Method	Pre	Rec	IoU	Dice
U-Net	0.9490	0.9645	0.9184	0.9556
ResUnet	0.9522	0.9644	0.9209	0.9569

B. Ablation Experiment

Using the same loss function and parameter settings as the comparative experiment for training, the ablation experiment confirms the overall effect of innovative reconstruction on the LCA_Net model. The method is to take U-Net as the baseline and successively accumulate CSwin module, CBAM attention module and ASPP module into it. Finally, ablation experiments are performed on the horse body segmentation dataset using the optimized LCA_Net network. Table V displays the comprehensive study results.

TABLE V. TESTS OF ABLATION FOR DIFFERENT MODULES ON THE HORSE SEGMENTATION DATASET

Method	Pre	Rec	IoU	Dice
U-Net	0.9242	0.9566	0.8864	0.9385
CSwin	0.9378	0.9522	0.8955	0.9435
CBAM	0.9408	0.9571	0.9023	0.9477
ASPP	0.9402	**0.9576**	0.9020	0.9476
CSwin+CBAM+ASPP	0.9549	0.9455	0.9047	0.9494

As shown in Table V, when the CSwin module is introduced alone, Precision and IoU are improved by 1.36% and 0.91% over the baseline, respectively, demonstrating its effectiveness in deep feature extraction. However, Recall slightly decreases. The CBAM module, when introduced alone, performs optimally, with Precision, IoU, and Dice increasing by 1.66%, 1.59%, and 0.92%, respectively, while Recall remains stable. This validates that the attention mechanism helps suppress redundant features and enhance critical areas. The performance of the ASPP module alone is close to that of CBAM, indicating that multiple modules can integrate multi-scale contextual information, but the improvement in Precision is limited. After integrating all three modules, Precision, IoU, and Dice reach their optimal values, improving by 3.07%, 1.83%, and 1.09%, respectively, compared to the baseline. Although Recall slightly decreases, the overall results show that the feature extraction capability of CSwin, along with the refined optimization from CBAM and ASPP, complement each other effectively, notably improving the model's segmentation accuracy and target localization. This suggests that the feature extraction of CSwin, attention enhancement from CBAM, and multi-scale fusion from ASPP

form an effective synergy that drives the systematic optimization of the model's segmentation performance.

Each module's efficacy can be confirmed by the ablation experiment. Every module introduced in this study has the capability to increase the precision and accuracy of segmentation. The CSwin module in particular is essential for enhancing segmentation performance.

V. Discussion

However, there are still some limitations in this study, including the relatively small size of the dataset and the fact that cross-dataset generalization tests have not yet been conducted to fully assess the model's adaptability. Future research directions should prioritize addressing these limitations. Expanding the diversity and volume of training data, implementing rigorous cross-dataset benchmarking, and conducting more sophisticated statistical testing will be essential steps toward strengthening the validity and real-world impact of the LCA-Net framework.

VI. Conclusion

Aiming at the problem of edge blurring in image segmentation, an improved U-Net network combining the CSwin module and channel spatial attention mechanism is proposed. Additionally, the ASPP module is introduced into the decoder output which contributes in improving the quality image segmentation accuracy. Moreover, the LCA-Net proposed by ours is compared with U-Net, ResUnet, Unet++ and Deeplabv3+ networks. On the test sets of four datasets, the LCA-Net's evaluation indexes are essentially superior to those of other networks, achieving better results in segmentation visualization. The LCA_Net network model can accurately segment the target edge, provide a reliable technical means for growth monitoring in the process of animal husbandry, and provide a valuable reference for other similar segmentation tasks.

The future work we will focus on the development of a lightweight version of LCA-Net to provide a low-power and high-efficiency solution for the farm mobile monitoring system. At the same time, we will optimize the model architecture for specific scenarios such as livestock individual identification and health monitoring to ensure stable operation under complex conditions.

AI-Driven Professional Profile Categorization and Recommendation System

Marouane CHIHAB, Hicham BOUSSATTA, Mohamed CHINY, Nabil Mabrouk, Younes CHIHAB, Moulay Youssef HADI
Laboratory of Computer Sciences, Ibn Tofail University, Kenitra, Morocco

***Abstract*—The exponential growth of applications in digital and information system domains has made the identification of qualified candidates increasingly complex, resulting in longer and less efficient recruitment processes. Recruiters frequently deal with heterogeneous and unstructured résumés, which complicates skill assessment and increases the risk of mismatches between candidates and job requirements. To address these challenges, this research proposes an AI-based framework for the automatic classification and recommendation of professional profiles using natural language processing (NLP), text mining, and supervised machine learning techniques. The methodology includes the comparative evaluation of several classification algorithms—Logistic Regression, Random Forests, Support Vector Machines (SVM), k-Nearest Neighbors (KNN), Gradient Boosting (GB), and Naïve Bayes—to identify the most accurate and robust model. The framework also incorporates a similarity-based matching mechanism to align candidate profiles with job postings. Experimental results show a classification accuracy of 96.38%, demonstrating the model's effectiveness in enabling faster, more reliable, and objective recruitment decisions while providing candidates with insights into their compatibility with labor market expectations.**

Keywords*—Professional profile classification; profile recommendation; natural language processing (NLP); supervised learning; Logistic Regression; Random Forest; Support Vector Machine (SVM); k-Nearest Neighbors (KNN); Gradient Boosting; Naïve Bayes; AI-based recruitment

I. Introduction

Recruitment is currently undergoing a major transformation as a result of digitalization and the growing adoption of artificial intelligence. In a context marked by an exponential volume of applications, particularly in the technology sectors, companies are having to manage an increasing amount of unstructured textual data, mainly curriculum vitae (CV). These documents, although rich in information about career paths and professional skills, are problematically heterogeneous in terms of format, structure, and content, which makes systematic analysis difficult.

Traditionally, recruiters evaluate CVs manually, a method that has proved to be particularly limited: not only is this process time-consuming and costly in terms of resources, but it is also subject to human bias and ill-suited to processing large volumes of applications. Furthermore, the variability of the presentations, wording, and experience described makes it difficult to attempt to standardize and compare profiles objectively. On the candidate side, the lack of tools to understand the automated selection mechanisms and assess their suitability for the market is a further obstacle.

This research presents a comprehensive methodology for classifying professional profiles and assessing their match with job vacancies based on automated CV analysis. The approach is not limited to a technical solution, but establishes a reproducible, scalable, and interpretable methodological framework, combining text analysis, machine learning, and semantic similarity to provide results applicable to both recruiters and candidates.

The method consists of three main components: Firstly, the processing and conversion of textual data involves extracting the content of CVs (in PDF, Word, or text formats), purifying it by removing superfluous elements, normalizing it by reducing words to their root forms, and transforming it into numerical representations using techniques such as TF-IDF or semantic embeddings.

Secondly, the supervised learning classification phase is based on the training and comparative evaluation of several models (Logistic Regression, Random Forests, SVM, KNN, Gradient Boosting, and Naive Bayes) using cross-validation and rigorous metrics (precision, recall, F1-score). Thirdly, CV-offers are matched by calculating similarity (cosine or Euclidean distance), enabling them to be ranked by relevance and personalized recommendations to be generated.

There are many innovations in this work. On the one hand, it offers complete integration of the CV processing process, from import to final recommendation. Secondly, it is distinguished by a systematic comparison of traditional algorithms applied to the classification of CVs by profession - a problem that has been little explored to date. Finally, the emphasis is on producing actionable information: identifying key skills, relevant technologies, and gaps between candidate profiles and job requirements.

In concrete terms, the proposal significantly improves the efficiency of the selection process while reducing biases inherent in human assessment. For candidates, it provides a valuable tool to position themselves on the job market, enabling strategic adjustments to CVs and career paths.

From a research perspective, this study contributes to the state-of-the-art by proposing a reproducible methodology for the automated analysis and prediction of career paths based on CVs. This study addresses the following research question: How can an AI-based framework combining NLP and supervised machine learning, effectively classify professional

profiles and generate reliable job recommendations to improve recruitment efficiency?

The remainder of this study is structured as follows: Section II reviews related work, Section III presents the research methodology, Section IV reports and analyzes the experimental results, Section V offers the discussion, and Section VI provides a conclusion along with perspectives for future work.

II. Related Work

The continuing growth in the number of job seekers is leading to a significant increase in the volume of applications received for each vacancy advertised. Many of these applications are relevant to the post on offer. This creates a major problem for recruiters, who have to carry out a rigorous pre-selection process to identify the most suitable profiles [1, 2, 3]. The process of matching a candidate's curriculum vitae to a job description can be compared to the operation of a referral system, in which an individual's profile is proposed for a given job. The notion of a recommendation system was introduced by Resnick and Varian [4], and has since been widely democratized in many fields of application. These systems are now ubiquitous, particularly in the context of product recommendation on e-commerce platforms [5, 6], but also in services for suggesting books [7], press articles [8], films [9], music content [10], and in many other contexts [11, 12, 13, 14, 15].

Lu et al [12] proposed an in-depth review of the protocols adopted over the years in the field of recommender systems. Their study highlights the evolution of these systems and their increasing integration into real-time applications. In addition, Wei et al [16] carried out a detailed analysis of the various recommendation techniques, outlining the fundamental principles underlying their operation. For their part, Al-Otaibi et al [17] were specifically interested in recommender systems applied to the employment domain. Their work presents a complete overview of the recruitment process, from the identification of needs to the final selection of candidates. In particular, they explain how online recruitment portals make it easier to match vacancies with profiles, and identify the key factors that can influence a candidate's selection decision, while detailing the different stages of the HR process implemented by organizations.

Paparrizos et al [13] have proposed an innovative hybrid classifier-based model for the job recommendation system. Their approach combines several components, including information retrieval techniques, manually defined attributes, and other relevant indicators, in order to improve the relevance of recommendations and optimize the match between candidate profiles and job offers.

The application process is often a demanding and tedious stage for job seekers. However, CV optimization is an essential part of this process, as it enables candidates to effectively showcase their skills and experience to potential recruiters [18]. In this context, machine learning algorithms are playing an increasingly important role. These increasingly sophisticated algorithms are capable of constantly learning from new data, user feedback and changes in the job market. Their adaptability allows them to analyze CV performance over time and iteratively adjust their recommendation and optimization mechanisms in response to feedback [19].

In artificial intelligence algorithms applied to recruitment, CVs and job descriptions are processed by machine learning models to analyze and extract relevant information. These models enable automated matching between candidate profiles and job offers, based on various criteria such as keywords, semantic analysis, and other contextual indicators [20].

In [21], the authors explored in depth the joint application of automatic natural language processing (NLP) techniques and machine learning algorithms in the context of CV analysis and optimization. Their approach aims to automatically adapt CVs to the specific requirements of various positions, taking into account the skills required and the criteria implicit in the job offers. This process leads to the generation of optimized CVs, promoting a better match between the candidate's profile and recruiters' expectations. As a result, this method significantly improves recall rates and the chances of selecting candidates.

As part of the development of predictive models, several widely used supervised learning algorithms—such as Logistic Regression, Support Vector Machines (SVM), Random Forests, Gradient Boosting, k-Nearest Neighbors (k-NN), and Naive Bayes classifiers—were compared in order to evaluate their respective performances. The primary objective is to develop a decision-support tool for recruiters, enabling them to efficiently preselect candidates whose profiles best match the specific requirements of open positions. This approach seeks to enhance the quality of recruitment by improving both hiring satisfaction and overall organizational productivity.

In conclusion, this study represents a significant contribution to existing research by introducing a method that is both rigorous and easily reproducible for the analysis, classification, and prediction of professional career paths based on CVs. Unlike previous approaches, which often rely on manual feature extraction, limited workflows, or models with lower accuracy, the proposed AI-based framework employs a different and fully integrated approach, combining text mining, multiple supervised learning algorithms, and a similarity-based recommendation mechanism. This method achieves a classification accuracy of 96.38%, demonstrating higher performance, greater automation, and better adaptability compared to existing models, thus providing a comprehensive solution tailored to the needs of the job market.

III. Research Methodology

In this work, the methodological approach is based on a rigorous automated processing pipeline for CVs, encompassing every stage from data acquisition to the generation of recommendations. The textual data underwent an in-depth preprocessing stage. The CVs, collected in various formats (PDF, DOCX, LinkedIn), were subjected to a series of transformations, including lowercasing, punctuation and stop-word removal, and advanced lemmatization. This crucial phase ensures standardization of the corpus and prepares the data for subsequent analysis.

The next phase concerns the vector representation of the texts. The TF-IDF method was primarily employed to transform the CVs into exploitable numerical data, while future enhancements using embedding techniques such as Word2Vec or BERT are considered. Particular attention was given to class balancing using the Random Over Sampler method, ensuring optimal conditions for the machine learning processes.

The core idea of the approach lies in the comparative implementation of several supervised classification algorithms. Six models were systematically evaluated: Logistic Regression, Support Vector Machines (SVM), Random Forest, Gradient Boosting, k-Nearest Neighbors (k-NN), and Naive Bayes. Each model is tested following rigorous protocols, including cross-validation and hyperparameter optimization. Their performance is assessed using standardized metrics (accuracy, F1-score, recall), enabling an objective selection of the most effective model.

Finally, the system computes cosine similarity scores between CVs and job descriptions, thereby establishing an automatic ranking of applications. This final phase incorporates weighting mechanisms to account for key skills and job-specific requirements. The entire pipeline has been architected to ensure reproducibility, scalability, and seamless integration with existing talent management systems.

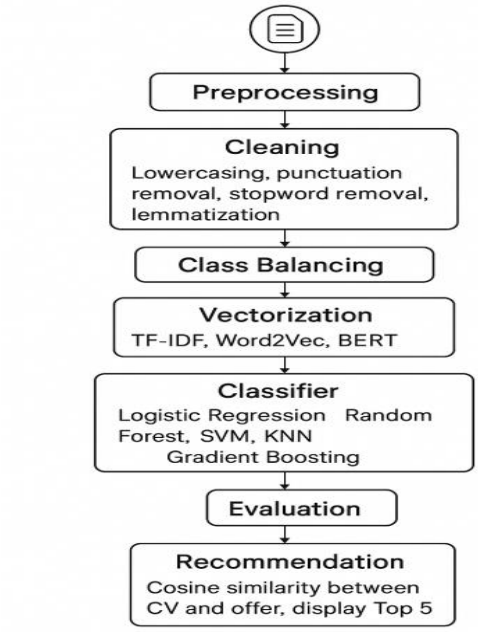

Fig. 1. Framework of the proposed model.

Fig. 1 illustrates the entirety of the approach, from the data collection phase to the generation of final predictions and recommendations.

1) Extracting CVs: Extraction is the first essential stage in the automated CV processing process. It involves collecting documents from a variety of sources, such as files in PDF or DOCX format or LinkedIn profiles, representing the wide range of formats used in modern job applications. In order to standardize this heterogeneous data, the documents are converted to plain text using specialized libraries such as pdf miner, docx2txt, or text extract, which are commonly used to extract textual content from unstructured files in a reliable and structured manner [22]. The aim of this transformation is to standardize the information, an essential prerequisite for any automatic processing by NLP algorithms. In particular, it makes it possible to recover the key elements present in a CV, such as professional experience, technical skills, diplomas obtained, as well as other metadata useful for semantic analysis and supervised classification. By guaranteeing accurate and complete extraction, this stage lays the foundations for a robust processing pipeline, capable of operating on a wide range of sources and formats while ensuring maximum fidelity to the initial information.

In this context, a rich and heterogeneous dataset of 1,428 CVs was constructed, collected from students with a wide range of profiles via the LinkedIn page. These documents, in multiple formats (PDF, Word, plain text), reflect significant structural and semantic diversity, representing a realistic dataset. This database has enabled us to explore the challenges of automatic CV processing in a context of large volumes and syntactic variability, offering an ideal terrain for the application of advanced natural language processing (NLP) techniques.

The figure below (see Fig. 2) illustrates the distribution of CVs according to their professional category, providing a valuable overview of the dominance of different technical profiles in the sample studied. It is an exploded pie chart, allowing not only the relative proportions to be visualized but also the dominant categories to be highlighted by a clear visual separation.

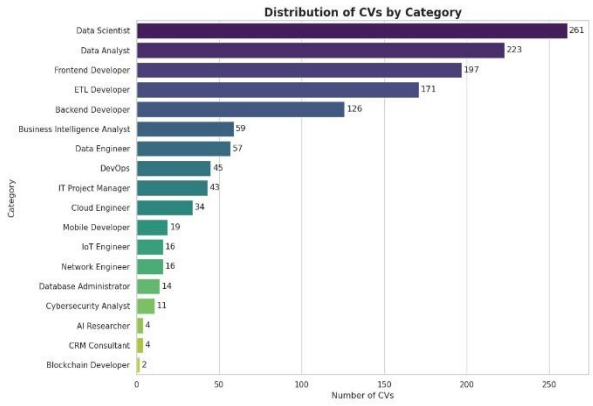

Fig. 2. Distribution of CVs by category.

2) Text pre-processing: Once the texts have been extracted, they undergo rigorous linguistic pre-processing to improve their quality and relevance for the subsequent phases of automatic analysis. This process involves a number of successive operations designed to normalize the textual data and reduce its noise. The first step is to convert all characters to lower case, so that words are treated uniformly regardless of their case. Next, punctuation, irrelevant numbers and special characters are removed to eliminate non-informative

elements. This type of text processing is fundamental to NLP, as it enables a coherent, relevant corpus to be built up that can be used by machine learning models. These operations, based on the recommendations of Bird et al [23], are now standard practice in the processing of complex textual data such as CVs.

3) Class balancing: In CV datasets, there is often a marked imbalance between the different occupational classes. This imbalance can lead to a bias in the machine learning models, which will tend to favor the majority classes to the detriment of the minority ones, thus compromising the quality of the predictions. To remedy this problem, a resampling strategy is implemented, in particular via the Random Over Sampler algorithm, which consists of randomly duplicating the samples of under-represented classes in order to balance the overall distribution of the data. This method, inspired by the SMOTE approach developed by Chawla et al [24], makes it possible to increase the representativeness of minority classes without introducing complex artificial information, and facilitates better generalization of the model, particularly for occupations rarely.

4) Vectorization of texts: Once the text has been cleaned, it is transformed into numerical vectors so that it can be used by machine learning algorithms. The main method used is TF-IDF (Term Frequency-Inverse Document Frequency), which assigns a weight to each word according to its frequency in a given document compared with its frequency in the corpus as a whole. This technique highlights the characteristic terms of a document while reducing the influence of over-frequent words, and is a benchmark approach to text vectorization [25,26,27,28,29,30]. However, this method remains purely statistical and does not incorporate semantic or contextual information. To enrich the representation of texts, experiments have therefore been carried out with Word2Vec, a lexical folding model developed by Mikolov et al [31], which captures the semantic relations between words by learning continuous representations in a vector space. With a view to improvement, the use of more advanced models such as BERT (Bidirectional Encoder Representations from Transformers), capable of producing rich and dynamic contextual embeddings, is envisaged to significantly increase the quality of text comprehension [32].

5) Training supervised models: Once the texts have been vectorized, they are used to train several supervised classification models with the aim of predicting the job category associated with a CV. Six algorithms were selected to cover a wide range of training strategies: Logistic Regression, the Support Vector Machine (SVM) recommended by Cortes & Vapnik [33] for its robustness in high-dimensional spaces, Random Forest, k-Nearest Neighbors (k-NN), Gradient Boosting, introduced by Friedman [34] for its effectiveness in complex tasks, and Naive Bayes, often used for its simplicity and speed of execution. Each model is trained by applying a cross-validation procedure, which makes it possible to adjust the hyperparameters, prevent overlearning and ensure good generalization capacity on new data. This algorithmic diversity makes it possible to compare different approaches, ranging from linear and interpretable models to more powerful sets of trees, as recommended in the good practice in machine learning documented by Pedregosa et al [35,36,37,38].

Six classification algorithms were used in this work, namely: Logistic Regression (LR), k-Nearest Neighbors (k-NN), Random Forest (RF), Support Vector Machine (SVM), Gradient Boosting, and Naive Bayes (NB). Table I summarizes the chosen hyper-parameters, which were then applied to the classification models. These hyper-parameters were selected experimentally, taking those that provided the best possible evaluations for the dataset.

TABLE I HYPER-PARAMETERS APPLIED TO ALGORITHMS IMPLEMENTED IN CLASSIFICATION MODELS

Algorithm	***Parameters***
Logistic Regression	max_iter=2000, class_weight='balanced'
Random Forest	n_estimators=100, max_depth=10
SVM	kernel='linear', class_weight='balanced'
KNN	n_neighbors=3
Gradient Boosting	n_estimators=100, learning_rate=0.1
Naive Bayes	alpha=1.0

6) Performance assessment: Model performance is rigorously evaluated using an independent test dataset, based on four fundamental machine learning metrics: accuracy (overall rate of correct predictions), precision (proportion of true positives among positive predictions), recall (ability to correctly identify all relevant cases), and the F1-score, which represents the harmonic mean between precision and recall. These indicators allow us to measure not only the overall effectiveness of the model, but also its ability to treat all classes fairly, in particular the minority occupational categories that are often under-represented. This multi-criteria evaluation approach, recommended in the systematic analysis by Sokolova & Lapalme [39], guarantees a complete and balanced assessment of the models, taking into account the different aspects of performance depending on the context of application.

7) Recommending candidates: Finally, the best performing model is integrated into an automated recommendation system, designed to assess the relevance of applications in relation to a specific job offer. To do this, the text of the vacancy and that of each CV are vectorized using the same text representation method as that used during training (TF-IDF in particular). A cosine similarity is then calculated between the vectors of the offer and those of the CVs, making it possible to measure their degree of semantic correspondence [40]. This technique, well documented in the reference work by Manning et al [41], produces a similarity score that reflects the lexical and contextual proximity

between two documents. On the basis of these scores, the system automatically ranks the CVs according to their suitability for the target job, and displays the five most relevant profiles, thus facilitating the work of recruiters by offering them an objective, rapid and justified pre-selection.

IV. Results

The performance of the trained models was measured using four main metrics: accuracy, precision, recall and F1-score. The data was divided into training (80%) and test (20%) sets, allowing a realistic assessment of performance.

The six models tested were: Logistic Regression, Random Forest, SVM, k-Nearest Neighbors, Gradient Boosting, and Naive Bayes. Each model was trained with specific hyperparameters, which were manually adjusted to guarantee the stability of the results.

TABLE II The Performance Measures of our Module Obtained by the Implementation of the Six Classification Algorithms

Model	*Accuracy*	*Precision*	*Recall*	*F1-Score*
Logistic Regression	94.68 %	94.63 %	94.77 %	94.60 %
Random Forest	89.57 %	89.37 %	89.83 %	88.95 %
SVM (linéaire)	96.38 %	96.42 %	96.53 %	96.40 %
k-NN	73.51 %	89.83 %	74.64 %	73.23 %
Gradient Boosting	94.79 %	94.73 %	95.02 %	94.79 %
Naive Bayes	80.96 %	82.76 %	81.98 %	80.20 %

As shown in Table II, the comparative evaluation of the six supervised classification models on a corpus of vectorized CVs using the TF-IDF method highlights clear trends in their respective effectiveness. The entire dataset, previously balanced using oversampling techniques (Random Over Sampler), was divided into 80% for training and 20% for testing, thus guaranteeing a robust estimate of performance on unseen data. Of the models tested, the Support Vector Machine (SVM) clearly emerged as the best performer, achieving an accuracy of 96.38%, a precision of 96.42%, a recall of 96.53% and an F1-score of 96.40%. These results confirm the ability of the SVM, recommended by Cortes & Vapnik [42], to manage high-dimensional text data, maintaining an excellent balance between class detection (recall) and prediction accuracy (precision). Right behind them, the Gradient Boosting (94.79% accuracy) and Logistic Regression (94.68%) models also offer excellent compromises, thanks in particular to their stability and low sensitivity to noisy variables. On the other hand, the performance of the k-Nearest Neighbors (k-NN) is more mixed: although it achieves high accuracy (89.83%), its results on recall (74.64%) and F1-score (73.23%) reflect a difficulty in generalizing effectively, probably due to its dependence on distances in high-dimensional vector spaces, which makes this model less suitable in the NLP context. As for Naive Bayes Multinomial, its overall performance was modest (80.96% accuracy), confirming that its assumptions of strong independence between variables can be limiting when it comes to capturing semantic dependencies in text. The Random Forest, although usually robust, lags slightly behind here with an accuracy of 89.57%, probably penalized by the complexity of the lexical structures. These results underline the importance of choosing models adapted to the specific nature of the textual data, and confirm that methods such as SVM and Gradient Boosting, when properly calibrated, can significantly outperform more traditional approaches in fine-grained, contextual classification tasks such as CVs.

The figure below (see Fig. 3) presents a comparative analysis of the performance of six classification algorithms (Logistic Regression, Random Forest, Linear SVM, k-NN, Gradient Boosting, and Naive Bayes) using four standard metrics: accuracy, precision, recall, and F1 score. Each sub-graph highlights the variations in performance according to the algorithm for a given metric, providing a clear and structured view of the strengths and weaknesses of each model. This visualization is intended to guide the choice of the most suitable model according to the priority criterion of the analysis.

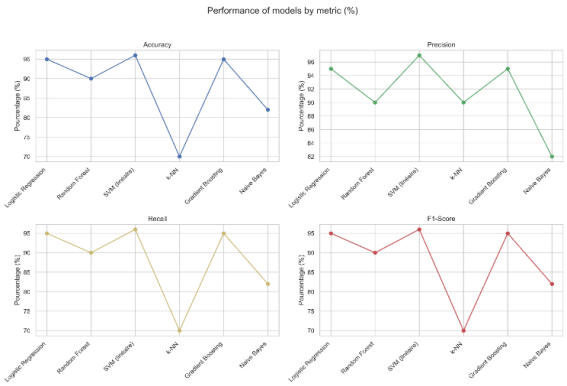

Fig. 3. Detailed comparison of model performance by metric.

The figure below (see Fig. 4) illustrates the comparative performance of the six classification algorithms studied, namely Logistic Regression, Random Forest, Linear SVM, k-Nearest Neighbors, Gradient Boosting, and Naive Bayes Multinomial. Four key metrics are represented: accuracy, precision, recall, and F1-score. These indicators are used to assess the overall quality of the models, taking into account both their ability to correctly predict positive and negative classes. This visualization highlights the differences in performance between the models and makes it easier to understand their respective strengths and limitations in the context of the classification task being analyzed.

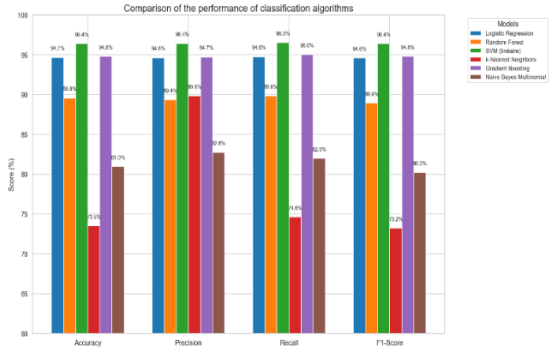

Fig. 4. Comparison of the performance of six classification algorithms according to four key metrics.

V. Discussion

The comparative evaluation of model performances enabled us to draw key and decisive conclusions for the model selection process and the definition of future optimization directions. The experimental results reveal significant differences among the tested models, both in terms of overall accuracy and their ability to balance recall and precision.

The linear SVM model clearly stands out as the best performer, achieving an accuracy of 96.38%, a precision of 96.42%, a recall of 96.53%, and an F1-score of 96.40%. These high values demonstrate that the SVM not only excels at correctly identifying positive instances but also effectively limits errors, indicating excellent generalization on the dataset. These results corroborate prior studies [42, 43, 44], which highlight the effectiveness of SVMs for high-dimensional classification problems, particularly when classes are linearly or nearly linearly separable.

The Gradient Boosting and Logistic Regression models achieve comparable performances, although slightly lower than those of the linear SVM. Gradient Boosting attains an accuracy of 94.79%, a precision of 94.73%, a recall of 95.02%, and an F1-score of 94.79%, compared to an accuracy of 94.68%, a precision of 94.63%, a recall of 94.77%, and an F1-score of 94.60% for

Logistic Regression. These results confirm their robustness:

- Logistic Regression remains relevant in binary classification problems, notably due to its interpretability and direct modeling of probabilities (Hosmer et al., 2013).
- Gradient Boosting, by sequentially optimizing residual errors [45, 46], combines flexibility and bias reduction, which explains its competitive performance.

Lagging behind the previous models, the Random Forest achieves an accuracy of 89.57%, a precision of 89.37%, a recall of 89.83%, but a lower F1-score of 88.95%. This slight discrepancy among the metrics indicates that the model effectively detects true positives while struggling to maintain an optimal balance between false positives and false negatives, which can impact its overall effectiveness. Although robust and widely used, Random Forest can sometimes perform less well on certain specific datasets due to its decision mechanism based on majority voting among trees, which may lead to dilution of optimal decisions (Breiman, 2001).

The k-Nearest Neighbors (k-NN) model exhibits mixed performance, with a modest accuracy of 73.51% and a low F1-score of 73.23%, despite a high precision of 89.83%. This imbalance between precision and recall (74.64%) reveals a tendency to under-detect true positives, due to:

- KNN's sensitivity to noise: The nearest neighbors may include outliers, which can distort the prediction.
- The curse of dimensionality effect: In high-dimensional spaces, the Euclidean distance (Cover & Hart, 1967) loses its relevance, diluting the notion of "closeness".

These limitations, consistent with the literature, suggest that k-NN is poorly suited for this dataset.

The Multinomial Naive Bayes model, with an accuracy of 80.96%, a precision of 82.76%, a recall of 81.98%, and an F1-score of 80.20%, achieves acceptable but clearly lower results compared to the top-performing models. This more modest performance is consistent with the fundamental assumption of conditional naïve independence among features, which is often violated in real-world data [47, 48].

In summary, the best-performing models achieve a close balance between precision and recall, as reflected by F1 scores near both metrics, while less effective models show greater imbalance, limiting reliable classification. These results highlight that linear SVM, Gradient Boosting, and Logistic Regression are the most effective choices, balancing performance, robustness, and interpretability. Moreover, combining these models with the text-mining preprocessing and the similarity-based recommendation mechanism enhances overall system effectiveness, providing actionable insights into candidate-job alignment. Building on these findings, future work can explore additional model architectures, deeper feature extraction, and dynamic recommendation strategies to further improve classification accuracy and applicability across diverse datasets.

VI. Conclusion

In this work, a comprehensive system for CV analysis and recommendation was presented, combining advanced NLP techniques and machine learning to address the challenges of modern recruitment. Experiments demonstrated the effectiveness of a hybrid approach, integrating both a supervised classification phase and a recommendation step based on semantic similarity. The results obtained, with an accuracy reaching 96.38% for the linear SVM, confirm the relevance of this approach and align with previous studies in the field.

The proposal also enabled the design, development, and evaluation of a comprehensive system for CV analysis, classification, and recommendation, based on advanced techniques in natural language processing (NLP), supervised machine learning, and interactive visualization through Streamlit.

To address the problem of manual CV sorting, an automated model based on machine learning was proposed, capable of recommending the most relevant applications to recruiters from a job description. The system operates in two phases: first, CVs are classified into different categories using supervised classifiers; then, profiles are recommended based on a semantic similarity index between the content of the CV and that of the job offer. This approach effectively captures the textual and semantic information present in the CVs.

The architecture of the proposed system is modular and scalable, structured around a robust pipeline. It integrates all

essential steps: text extraction, linguistic cleaning, TF-IDF vectorization, class balancing, classification (SVM, Random Forest, Gradient Boosting), and similarity computation for recommendation. This processing chain has been implemented to ensure system reproducibility and to provide a flexible framework for future developments.

The experimental results obtained confirm the validity of the proposed system. The SVM model, combined with TF-IDF vectorization, demonstrated the best performance with an accuracy of 96.38%. Other models such as Gradient Boosting and Logistic Regression also yielded satisfactory results, while the performances of Naive Bayes and k-NN remained limited in a complex semantic context.

One of the major contributions of this research work also lies in the integration of an interactive interface via Streamlit. This interface enables HR professionals, even without technical expertise, to upload CVs, visualize classification results, examine compatibility scores, and interact with various stages of the process.

In conclusion, this work has demonstrated the feasibility of building an automated, intelligent, and efficient solution to assist the recruitment process. The proposal constitutes a scientifically validated proof of concept, providing a solid foundation for the future industrialization of this type of approach. By combining methodological rigor, technical performance, and user accessibility, the approach contributes to advancing the use of artificial intelligence in modern talent management.

Robotic Process Automation (RPA) Scripting Model Using Machine Learning (ML) for Enterprise Data Validation and Integration

Luis Ángel Bendezú Jiménez, Jorge Luis Juan de Dios Apaza, Ruben Oscar Cerda García
Peruvian University of Applied Sciences, Lima, Perú

***Abstract*—This research presents an automated data processing model based on RPA Scripting, designed to enhance efficiency in extracting, validating, and integrating information from various web platforms. The automated workflow begins with the use of a tool that simulates human interaction on web platforms to obtain data automatically and reliably. The data is then organized and cleaned using processing techniques that prepare it for analysis. As a key component of the model, Machine Learning algorithms have been incorporated to detect errors, identify unusual patterns, and classify records, thereby improving data quality before storage. Finally, the processed data is loaded into a database and visualized through a dynamic dashboard that supports decision-making via reports and indicators. In conclusion, integrating Machine Learning algorithms within an RPA Scripting model not only optimizes the execution of automated tasks but also equips the model with intelligence to anticipate errors and adapt to changes in the data. This enables the development of a more robust, reliable, and adaptive automated process, aligned with current requirements for real-time analysis and decision-making.**

***Keywords*—RPA; scripting; data automation; Machine Learning; data validation; data integration; intelligent workflows**

I. Introduction

The volume of data generated by organizations has grown exponentially to the point that retrieving it from various web sources for the purpose of loading, integrating, and analyzing it requires the execution of manual processes that are both daily and repetitive. These processes represent a significant burden in terms of time and resources and are prone to human error, which can affect the efficiency and quality of the work. As a result, they also limit the agility and analytical capabilities of organizations operating in dynamic and competitive environments [1]. Moreover, these process flows do not end with data collection or consolidation; on the contrary, they extend into later stages such as interactive visualization, the generation of strategic reports, and advanced analysis within business intelligence platforms [2]. Therefore, any error or inefficiency in the initial stages of data extraction and processing can be amplified throughout the entire process flow, directly affecting the quality of data-driven strategic decisions [3].

This is interesting because it raises the opportunity to integrate traditionally separate technologies, such as robotic process automation (RPA) through Scripting and the application of Machine Learning (ML) algorithms to build process flows that not only execute daily and repetitive tasks, but also learn to make automatic and intelligent decisions. This convergence between RPA and ML opens up new possibilities to create more resilient, autonomous, and predictive solutions, overcoming the limitations of conventional automation tools. It also explores an emerging field that has enormous potential for application in multiple contexts.

Traditional automations fail due to their reliance on static rules and rigid structures, which do not allow them to adapt to dynamic changes in data or workflows. In [4], the authors point out how traditional RPA solutions present critical limitations when data sources change their structure, contain unexpected errors, or incomplete information. This is due to the fact that they are based only on rigid and predefined instructions, with no learning or adaptive capabilities. As a result, they cannot anticipate failures, detect anomalies, or validate data quality autonomously, which generates constant interruptions and requires manual intervention. These constraints reduce their scalability and reliability, especially in dynamic environments with high data variability. This problem highlights the need to adopt a more intelligent and robust approach, combining RPA with Machine Learning techniques to provide automated processes with predictive, adaptive, and decision-making capabilities based on historical patterns.

According to [5], they state that this problem has not been solved before because traditional automation solutions, such as conventional RPA tools, are designed to work under predefined rules and rigid structures. These solutions do not integrate advanced ML capabilities and adaptive learning, which makes them unable to handle changes in business data required for further analysis. In addition, commercial tools have a high cost and are oriented to users with general needs, which limits their customization for specific contexts and cases.
