Fig. 11 explains the dual axis bar chart that shows the better performance of RFM-K-OPT in a variety of evaluation measures. It emphasizes better clustering precision, segmentation accuracy, and computational effectiveness than past models supporting the framework in its proficient and optimized customer segmentation utilization in direct marketing.

C. Discussion

The experimental findings reveal that the suggested RFM-K-OPT framework is efficient in improving the accuracy and interpretability of customer segmentation as compared to the conventional RFM-based clustering models. The use of optimization in the central mechanism of the K-Means algorithm in the model results in the optimization of centroid positioning and gives reduction in the intra-cluster variance, resulting in coherent and behaviorally differentiated groups of customers. Such a result is consistent with the objective of the research which is to design a data-driven, interpretable, and computationally-efficient segmentation model that can be applied directly in marketing. The advantage of the framework is that it records the subtle behavioral differences and at the same time has high clustering stability and low computational time. In practice, it can offer marketers practical information to target personalized, loyalty, and retention programs. In comparison to previous research in which only RFM or rigid machine learning clustering was used, RFM-K-OPT has better adaptability to changes of the dynamic market conditions. Its performance, however, can be limited to the quality and representativeness of the transactional data, and the optimization problem could need to be tuned to the parameters to be scaled. Altogether, the results confirm the model as too robust and applicable to the strategic area of customer behavior profiling. Although the results of the proposed RFM-K-OPT framework are promising, there are some limitations to it. Its performance is sensitive to the quality and representativeness of the transactional data, and the parameters of optimization need to be tuned to other data sets. As well, the framework is currently transactional, and it does not include behavioral or contextual aspects like browsing behavior or sentiment, which could further improve segmentation.

V. CONCLUSION AND FUTURE WORK

The research developed the RFM-K-OPT framework, which is a hybrid framework that combines the Recency Frequency Monetary model (RFM) analysis with K-Means clustering with an optimization module to provide better customer segmentation and behavioral profiling. The fundamental aim of it was to address the shortcomings of traditional solutions to RFM and static clustering and to provide a more flexible, understandable, and computationally economical solution. The experimental outcomes proved that the offered framework delivered high performance in all the essential metrics and exhibits high cluster compactness, purity, and execution efficiency. The results confirm that RFM-K-OPT is an effective tool to distinguish individual customer groups and adopt data-driven marketing tactics and accurate customer interactions. The strength of the framework is the combination of statistical and computational intelligence provides strong segmentation information that can assist in making many marketing decisions and customer retention approaches. All in all, this study adds to a scalable and

interpretable segmentation strategy that helps bridge the machine learning and feasible marketing analytics.

Future studies can build on this by using RFM-K-OPTs to more extensive and varied data on diverse business areas to increase generalizability. Segmentation could be enhanced by including other variables of behavior and context like frequency of interaction with customer, customer sentiment, or customer demographics. In addition, the further optimization techniques like Genetic Algorithms or Particle Swarm Optimization can be considered to improve centroid selection and the stability of clusters. Graph-based segmentation or deep learning-based clustering may help to identify more complicated customer relationships than numerical ones. Lastly, it would be prudent to apply the model in actual marketing systems with dynamic feedback controls to determine its practical use in the dynamic and personalized marketing context.

Enhancing Organizational Information Systems Through Explainable Artificial Intelligence

Kian Jazayeri
Department of Management Information Systems, Cyprus International University, Nicosia, Türkiye

***Abstract*—This study examines Workplace Perceptions among Finnish employees through the application of Artificial Intelligence within the domain of Human Resource Analytics. An integrated analytical framework combining Clustering Analysis, supervised classification, and Explainable Artificial Intelligence is proposed to uncover and interpret latent employee perception profiles. Using 23 perception-related indicators from the Finnish Working Life Barometer 2022, K-means clustering identified two distinct employee groups: one characterized by consistently positive evaluations of fairness, leadership, well-being, and motivation, and another reflecting systematically negative workplace perceptions. A LightGBM model was subsequently employed to predict cluster membership based on demographic and occupational variables, and SHapley Additive exPlanations (SHAP) were used to provide transparent global and local interpretations of the predictive outcomes. The results show that employment duration, age, industry affiliation, gender, and socioeconomic status are the most influential determinants of cluster membership. By embedding Explainable Artificial Intelligence into Human Resource Analytics, the study demonstrates how employee perception data can be transformed into interpretable knowledge that supports organizational Decision-Support Systems. The proposed framework advances data-driven and transparent HR decision-making and contributes to the United Nations Sustainable Development Goal 8, Decent Work and Economic Growth, by identifying structural disparities in employee experience and enabling more equitable and inclusive workplace interventions.**

Keywords*—*Artificial intelligence; Human Resource Analytics; Explainable Artificial Intelligence; Decision-Support Systems; workplace perceptions; Clustering Analysis; Decent Work and Economic Growth

I. Introduction

Understanding employee perceptions has long been recognized as a cornerstone of effective organizational development [1] [2]. Employees' views on fairness, leadership, inclusivity, and well-being are closely tied to job satisfaction, productivity, and retention, factors that directly influence organizational resilience and long-term growth [3]. From an information systems perspective, workplace perception data represents a valuable informational asset that, if effectively processed and interpreted, can guide both organizational policies and national development strategies. As workplaces evolve under pressures from globalization, digital transformation, and post-pandemic shifts in work arrangements, the need for robust, data-driven approaches to capture and interpret these perceptions has become increasingly urgent [4][5].

Traditional HR analytics methods, often based on descriptive statistics or simple segmentation, risk overlooking latent patterns within employee populations. Subtle but meaningful differences in workplace perceptions, shaped by combinations of demographic and occupational factors, may remain hidden when analyses are restricted to surface-level groupings. Without uncovering these underlying profiles, organizational information systems risk generating one-size-fits-all policies that fail to meet the diverse needs of employees.

The existing literature demonstrates two complementary but disconnected streams. Research on clustering in HR analytics shows the potential to segment employees into coherent groups based on survey responses or performance indicators. Meanwhile, Explainable Artificial Intelligence (XAI), particularly SHapley Additive exPlanations (SHAP), has proven effective in interpreting predictive models for HR outcomes such as attrition or performance. However, clustering studies typically stop at descriptive profiling without quantitatively linking segment membership to demographic or occupational drivers, while SHAP applications remain confined to supervised prediction tasks and seldom explain why certain latent clusters arise from perception data. To date, no study has integrated unsupervised clustering with supervised classification and SHAP-based explainability to simultaneously uncover and interpret hidden employee perception profiles.

This study addresses that methodological gap by proposing and applying a three-phase framework:

- Phase 1: Clustering: K-means clustering is used to identify latent employee segments based solely on 23 perception-related survey items.
- Phase 2: Classification: A supervised LightGBM model predicts cluster membership from employees' demographic and occupational attributes.
- Phase 3: Explainability: SHAP is employed to quantify and visualize the global and local drivers of cluster membership, offering interpretable insights into the structural determinants of workplace perception.

Guided by this objective, the study seeks to answer the following research questions:

- RQ1: What distinct latent clusters of employee workplace perceptions can be identified using unsupervised machine learning?

- RQ2: To what extent can demographic and occupational attributes predict membership in these clusters?
- RQ3: Which factors emerge as the most influential drivers of cluster membership when examined through global SHAP analysis?
- RQ4: How do these drivers vary for individual employees, and what can local SHAP explanations reveal about unique cases?
- RQ5: How can the integration of clustering and explainable AI support the design of targeted, equitable HR interventions?

To the best of the author's knowledge, this study is the first to combine unsupervised clustering with supervised SHAP-based explainability in the context of employee perception analysis. By moving beyond descriptive segmentation and quantitatively linking latent profiles to their underlying demographic and occupational drivers, it contributes both methodologically and practically to the fields of HR analytics and information systems. The framework is replicable and adaptable to other organizational contexts and datasets, ensuring relevance beyond the Finnish case study presented here.

Importantly, the findings contribute to the United Nations Sustainable Development Goal 8, Decent Work and Economic Growth. By uncovering structural and demographic disparities in workplace perceptions and providing a transparent, data-driven framework for addressing them, the study supports the development of fairer, more inclusive, and more productive workplaces.

At a structural level, the remainder of this study is organized as follows: The next section reviews relevant literature on clustering techniques in HR analytics and Explainable Artificial Intelligence, highlighting the specific research gap addressed by this study. The methodology section then details the dataset, preprocessing steps, and the three-phase analytical framework. This is followed by the presentation of results, including cluster profiles, predictive performance, and SHAP-based explanations. The discussion section interprets the findings in relation to prior research and practical HR implications, and the study concludes by summarizing key contributions, outlining limitations, and identifying directions for future research.

II. Literature Review

A. Clustering Techniques in HR Analytics

Unsupervised clustering is widely used in HR analytics to group employees into meaningful profiles based on multidimensional data. Prior studies have applied K-means and hierarchical clustering to segment employees by well-being, engagement, competence, and risk profiles, often validating clusters using methods such as the elbow criterion, silhouette scores, or within-cluster sum of squares [6]–[10]. Other work has highlighted the availability of rich psychological, relational, and justice-related variables that can serve as clustering inputs, including information anxiety, fairness perceptions, and online learning experiences [11][12].

Machine learning has further expanded HR analytics, with clustering and classification methods supporting recruitment, employee segmentation, and retention strategies [13]. Hybrid frameworks combining clustering with supervised learning, such as K-means followed by ANN models, have shown improved predictive performance, particularly when combined with techniques like GAN-based data augmentation [14]. Additional applications include ML-enhanced Human Resource Information Systems [15], clustering of digital competencies in academia [16], health and well-being profiling using self-organizing maps or Gaussian mixture models [17][18], and pandemic-related segmentation of employee concerns followed by regression-based analysis of cluster predictors [19]. Despite these advances, most clustering-based HR studies remain descriptive and provide limited insight into the factors driving cluster membership.

B. Explainable AI and SHAP in Employment and Social Science

As ML adoption in HR grows, transparency and ethical concerns have increased, leading to the adoption of explainable AI techniques such as SHAP. SHAP has been extensively used to interpret supervised HR models, particularly for employee attrition and turnover prediction, revealing key drivers such as job satisfaction, tenure, overtime, and commute distance [20][21]. Some studies have extended SHAP by clustering explanation values to identify common exit patterns [22]. Complementary methods like Anchors have been used to generate rule-based explanations suitable for non-expert stakeholders [23], while recent research has integrated SHAP with fairness-aware deep learning to address bias in HR decision-making [24].

The incorporation of XAI into HR systems has been advocated to enhance transparency, ethical governance, and organizational responsibility [25] [26]. Related work in knowledge management and group decision support systems further connects explainable analytics with collective organizational decision-making [27]. Empirical evaluations show that interpretable ML models can balance predictive performance with clarity [28] [29]. Recent frameworks combining gradient boosting models with SHAP have successfully identified both established and novel predictors of HR outcomes [30], while hybrid optimization and decision-making approaches have improved the identification of influential turnover factors [31].

C. Gaps and Contributions of this Study

The literature reveals a clear separation between clustering-based employee segmentation and explainable supervised learning in HR analytics. Clustering studies effectively uncover latent employee groups based on perception or well-being data but largely remain descriptive and do not explain why individuals belong to specific clusters [6]–[10], [17]–[19]. In contrast, SHAP-based XAI research focuses on explaining supervised outcomes such as attrition or performance, without addressing the interpretability of latent segments derived from unsupervised analysis [20]–[22], [30],

[31]. Consequently, the formation of employee perception clusters remains largely unexplained.

Table I reveals a methodological gap in HR analytics, as prior studies focus either on clustering or on SHAP-based supervised models, but not both, within a unified pipeline. This study addresses this gap by proposing a three-phase framework that integrates unsupervised clustering, supervised classification, and SHAP-based explainability. K-means is used to identify latent perception profiles, LightGBM predicts cluster membership, and SHAP explains the drivers of these predictions. By treating cluster membership as an explainable outcome, the approach enables transparent interpretation of employee segments and represents a novel, replicable framework for data-driven HR decision-making.

TABLE I. COMPARISON OF THE CURRENT STUDY WITH PREVIOUS WORKS

Study (Ref)	Unsupervised Clustering	Supervised Prediction	Explainability (SHAP/XAI)	Purpose
[6]	Yes	No	No	Descriptive segmentation

[22]	No	Yes	Yes	Explaining model outcomes
[30]	No	Yes	Yes	Interpreting supervised outcomes
This study	Yes	Yes	Yes	Explaining latent cluster formation

III. METHODOLOGY

The methodological approach adopted in this study follows a structured, three-phase framework designed to uncover latent workplace perception profiles and interpret their underlying drivers. In the first phase, K-means clustering is applied to survey responses capturing multiple aspects of employees' workplace experience, producing distinct perceptual groups. In the second phase, a supervised classification model predicts cluster membership based on demographic and occupational attributes, enabling the identification of structural determinants linked to each group. The final phase employs SHAP-based explainability to quantify and visualize both global and local feature contributions, ensuring that the predictive insights remain transparent and actionable. The overall process is illustrated in Fig. 1, which provides a step-by-step overview of the analytical pipeline implemented in this study.

A. Dataset and Data Pre-Processing

This study is based on data from the FSD3784 Finnish Working Life Barometer 2022, an annual survey produced by Statistics Finland and the Ministry of Economic Affairs and Employment and accessed via the Finnish Social Science Data Archive's Aila service. The dataset is licensed for non-commercial academic use under Aila's terms, requiring proper citation and the protection of individual confidentiality [32]. It provides nationally representative information on Finnish employees' perceptions of working life, including leadership, well-being, workplace culture, and employment conditions.

For this study, 23 perception-related survey items were selected as inputs for the Clustering Analysis. Data preprocessing involved removing responses coded with placeholder values (9, 999, 888) and excluding rows with missing values to ensure data quality. Variable naming conventions and categorical coding schemes are documented in Appendices A and B to support transparency, reproducibility, and accurate interpretation, with all definitions preserved in accordance with the original dataset and licensing conditions.

B. Phase 1: Clustering Perceptions

In the first phase, an unsupervised learning approach was used to identify latent employee segments based on workplace perceptions. Twenty-three survey items capturing fairness, inclusion, well-being, leadership trust, psychological safety, and organizational culture were selected from the Finnish HR dataset and are listed in Appendix A with their cluster-wise means.

After data cleaning, ordinal responses were one-hot encoded to preserve interpretability and support effective clustering, resulting in a higher-dimensional but suitable feature space. PCA was then applied for dimensionality reduction and two-dimensional visualization. The optimal number of clusters was identified using silhouette analysis for $K = 2$ to 10, with the highest score at $K = 2$, indicating two distinct employee perception clusters (see Fig. 2).

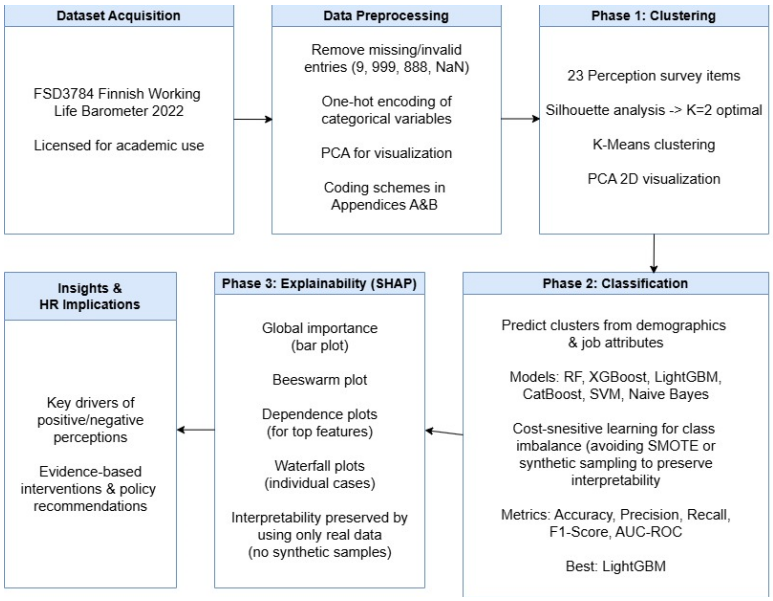

Fig. 1. Three-phase methodological framework for uncovering and interpreting latent workplace perception profiles.

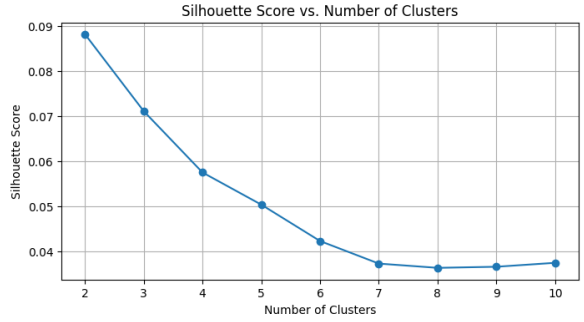

Fig. 2. Silhouette scores for K-means clustering across different numbers of clusters (K = 2–10).

- Once the optimal number of clusters was established, the K-Means algorithm was applied with K = 2 to segment employees based on their perception profiles. The clustering process grouped individuals with similar response patterns into the same cluster, without prior knowledge of their identities or job roles. The resulting clusters were then visualized using the previously computed PCA components, as depicted in Fig. 3.

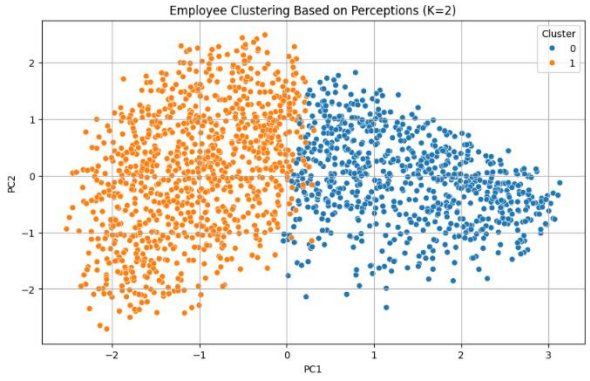

Fig. 3. Two-dimensional PCA projection of employee survey responses, showing the distribution of employees across two identified clusters.

- The final clustering output included 1,793 employees, distributed across two groups: Cluster 0, comprising 766 individuals, and Cluster 1, with 1,027 individuals. These clusters served as the foundation for the next stage of the analysis, where their defining characteristics and interpretation would be examined in detail.

C. Phase 2: Performing Machine Learning on Cluster Membership

Following the clustering of employees based on their survey responses, the second phase of the analysis aimed to determine whether cluster membership could be predicted using employees' demographic and occupational attributes. Unlike the first phase, which employed an unsupervised learning approach driven solely by perceptual survey data, this phase adopted a supervised machine learning framework. The goal was to examine how well structured background variables could classify employees into their respective clusters, thereby revealing how deeply rooted personal and job-related characteristics contribute to patterns in workplace perception.

To this end, a range of machine learning models was trained and evaluated using a consistent set of explanatory features. These included variables such as gender, age, occupation, employer type, broad and detailed industry categories, full-time versus part-time status, employment permanence, side job status, side work hours, overall employment duration, and indicators of socioeconomic status and class. Each of these features was selected for its potential relevance in shaping employees' lived experiences within their professional environment.

The following classification models were employed:

- Random Forest (RF): An ensemble-based method that applies the bagging strategy by constructing a collection of T decision trees, each trained on a

randomly sampled subset of the training set. For a given input vector x, the final class prediction is obtained by combining the outputs of all trees through majority voting.

$$\hat{y} = mode\{h_t(x)\}_{t=1}^{T} \quad (1)$$

where, $h_t(x)$ represents the prediction from tree t.

- XGBoost: A highly efficient implementation of gradient boosting that constructs an ensemble of weak learners in a sequential manner. Each successive tree is trained to reduce the residual errors made by the previous ones, aiming to minimize a specified loss function.

$$F_m(x) = F_{m-1}(x) + \gamma h_m(x) \quad (2)$$

where, γ is the learning rate and $h_m(x)$ is the newly added tree.

- LightGBM: A fast and scalable gradient boosting framework that builds decision trees using a leaf-wise growth strategy rather than the traditional level-wise approach. This strategy focuses on splitting the leaf with the highest loss reduction, which typically leads to better accuracy and faster convergence. Like other boosting methods, LightGBM minimizes a regularized objective function:

$$\mathcal{L}^{(t)} = \sum_{i=1}^{n} l\left(y_i, \hat{y}_i^{(t-1)} + f_t(x_i)\right) + \sum_{t=1}^{T} \Omega(f_t) \quad (3)$$

where, $\mathcal{L}$ is the loss function (e.g., logistic loss), $f_t(x)$ is the newly added tree at iteration t, and $\Omega(f_t)$ is the regularization term controlling model complexity.

- CatBoost: A gradient boosting framework designed to handle categorical features effectively and perform well on imbalanced datasets. It offers strong predictive performance with minimal need for extensive feature engineering. Like other gradient boosting approaches, it works by minimizing a regularized loss function:

$$\mathcal{L} = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{t=1}^{T} \Omega(f_t) \quad (4)$$

where, $\hat{y}_i = \sum_{t=1}^{T} f_t(x_i)$, and f_t are the base decision trees learned sequentially.

- Support Vector Machine (SVM): A margin-oriented classifier that seeks to maximize the separation between classes. By using a radial basis function (RBF) kernel, it maps the input features into a higher-dimensional space, enabling the algorithm to capture complex, nonlinear decision boundaries.

$$f_x = sign\left(\sum_{i=1}^{n} \alpha_i y_i K(x_i, x) + b\right) \quad (5)$$

where, $K(x_i, x) = \exp(-\gamma \|x_i - x\|^2)$ is the RBF kernel, and α_i, y_i, and b are model parameters.

- Naive Bayes: A probabilistic classifier grounded in Bayes' theorem, built on the assumption that features are conditionally independent given the class label. This simplifying assumption allows efficient computation of posterior probabilities. For a class c, the posterior probability given features $x_1, x_2, \ldots, x_n$ is expressed as:

$$P(c \mid x_1, \ldots, x_n) \propto P(c) \prod_{i=1}^{n} P(x_i \mid c) \quad (6)$$

The predicted class is:

$$\hat{y} = \arg\max_{c \in C} P(c) \prod_{i=1}^{n} P(x_i \mid c) \quad (7)$$

All models were trained using a cost-sensitive learning approach and assessed on a separate test set using a consistent set of standard classification metrics:

- Accuracy: Measures the proportion of all correctly classified instances relative to the total number of predictions across every class.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (8)$$

- Precision: Represents the fraction of instances labeled as positive that are truly positive, indicating the reliability of the model in predicting positives.

$$Precision = \frac{TP}{TP+FP} \quad (9)$$

- Recall (Sensitivity): Denotes the share of actual positive cases that are correctly identified by the model, emphasizing its effectiveness in capturing positives.

$$Recall = \frac{TP}{TP+FN} \quad (10)$$

- F1-Score: Defined as the harmonic mean of precision and recall, this metric provides a balanced assessment, particularly useful in scenarios with imbalanced class distributions.

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (11)$$

- AUC-ROC (Area Under the Receiver Operating Characteristic Curve): Evaluates the model's ability to distinguish between classes over all possible decision thresholds, offering a threshold-independent measure of classification performance.

These metrics together offer a well-rounded assessment of each model's capability to predict cluster membership, particularly in light of the dataset's inherent class imbalance. A detailed comparison of model performance is provided in Section IV(B).

D. Phase 3: Explainability of Cluster Membership

The third analytical phase focused on identifying which background features most strongly influenced employees' cluster assignments, thereby linking predictive classification with interpretable insights. While prior results showed that cluster membership could be predicted accurately, this phase examined why employees were more likely to belong to one cluster rather than the other.

To achieve this, SHAP was applied to explain the predictions of the best-performing classifier, LightGBM. SHAP decomposes model outputs into feature-level contributions, providing both global importance across the

dataset and local explanations for individual predictions. The analysis used the same feature set as the classification stage, including continuous and categorical variables. Categorical attributes such as occupation, employer type, and industry were given particular attention, with detailed encodings documented in Appendix B, while variables like age and employment duration required no additional interpretation.

The SHAP analysis revealed the key demographic and occupational factors driving membership in Cluster 0 or Cluster 1. By converting accurate but opaque predictions into transparent explanations, this phase clarified the structural determinants of employee sentiment and supported the development of targeted, evidence-based interventions to improve employee well-being and organizational climate.

IV. Results

A. Cluster Profiles

Following the identification of two employee clusters using K-means, a profile analysis was conducted by calculating mean responses for each of the 23 perception-based survey items within both clusters. These means served as summary indicators of how each group perceived the work environment and organizational culture. As reported in Appendix A, clear and consistent differences emerged across all items, with Cluster 0 showing more favorable perceptions than Cluster 1.

For items measured on a 4-point agreement scale, lower mean values in Cluster 0 indicated stronger agreement with positive statements, while higher means in Cluster 1 reflected more negative perceptions. For items measured on a 5-point frequency scale, higher mean values corresponded to more positive outcomes, and Cluster 0 consistently scored higher than Cluster 1, indicating greater motivation, well-being, and perceived inclusivity.

To illustrate the magnitude of these differences, a difference plot was produced by subtracting Cluster 0 means from Cluster 1 means for each item and sorting the results. As shown in Fig. 4, the direction of the differences reflects the underlying measurement scales, with negative or positive values indicating less or more favorable perceptions in Cluster 1 relative to Cluster 0.

This analysis supports the interpretation that Cluster 0 represents a more engaged, supported, and satisfied group of employees, whereas Cluster 1 captures employees with more negative perceptions of their work environment. This finding directly addresses RQ 1 by demonstrating that unsupervised machine learning can reveal two clear and meaningful latent clusters of employee workplace perceptions. The distinct patterns of engagement, well-being, and organizational support between Cluster 0 and Cluster 1 confirm that perception-based segmentation is both feasible and informative in this context. Such distinctions provide a valuable foundation for targeted human resource interventions aimed at improving workplace conditions and employee experience for the more vulnerable group.

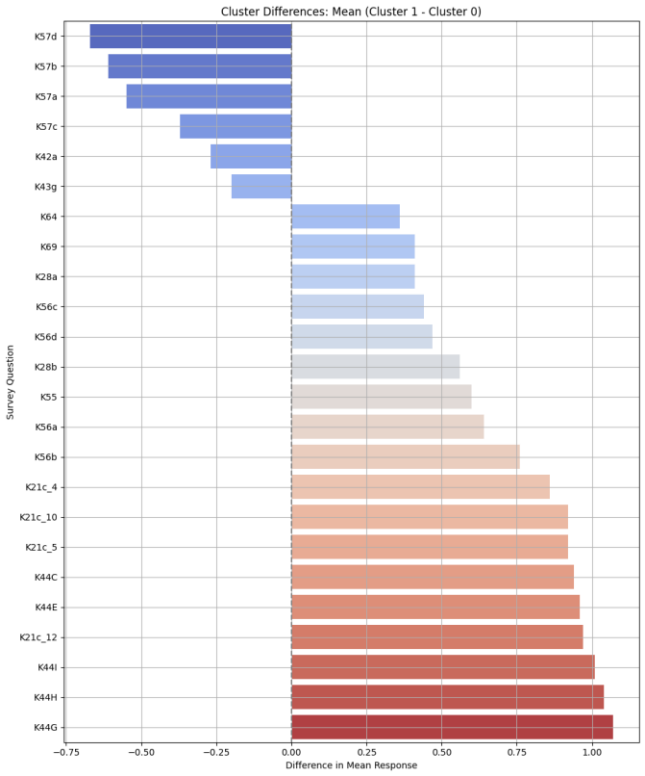

Fig. 4. Mean response differences between cluster 1 and cluster 0 for the 23 perception-related survey items, sorted from largest to smallest disparity.

B. Machine Learning Results

To assess the predictive power of structural employee attributes for determining cluster membership, a comparative evaluation was conducted across seven machine learning classifiers. These included tree-based ensemble models and baseline algorithms trained on identical data splits and feature sets. The classifiers evaluated were Random Forest, LightGBM, XGBoost, CatBoost, Naive Bayes, and SVM. The use of ensemble-based models alongside baseline classifiers follows established practices in HR analytics research, where comparative modeling is commonly employed to balance predictive performance and interpretability [13], [28], [29].

All models were trained using a stratified 70/30 train-test split and evaluated using standard classification metrics, including accuracy, precision, recall, F1-score, and the area under the ROC curve (AUC). This evaluation strategy is consistent with prior supervised HR analytics studies that emphasize robust performance assessment when predicting employee-related outcomes [20], [21], [30].

Among the models tested, LightGBM demonstrated the highest overall performance, achieving an accuracy of 90.65%, a precision of 91.80%, a recall of 89.02%, and an F1-score of 90.38%. It also recorded the highest AUC score of 0.9826, indicating excellent discrimination capability. The strong performance of gradient boosting models aligns with previous HR analytics research showing that tree-based boosting frameworks outperform traditional classifiers when modeling complex, non-linear relationships in employee data [14], [30], [31]. These consistent results across multiple

metrics motivated the selection of LightGBM as the foundation for the explainable AI analysis in the subsequent phase.

Other ensemble models, including XGBoost, Random Forest, and CatBoost, also showed strong performance, though slightly below LightGBM, consistent with prior HR analytics studies where boosting and bagging methods outperform simpler classifiers [13], [20], [21]. Naive Bayes and SVM exhibited lower performance but served as informative baselines, reflecting the interpretability–accuracy trade-off commonly reported in HR machine learning research [28], [29]. Table II summarizes the evaluation metrics, and the ROC curves in Fig. 5 further confirm the superiority of gradient boosting models and support the use of LightGBM for SHAP-based explainability, in line with recent XAI studies in HR analytics [30], [31].

TABLE II. PERFORMANCE COMPARISON OF MACHINE LEARNING MODELS IN PREDICTING CLUSTER MEMBERSHIP FROM DEMOGRAPHIC AND OCCUPATIONAL ATTRIBUTES

Model	Accuracy	Precision	Recall	F1-score	AUC
LightGBM	0.9065	0.918	0.8902	0.9038	0.9826
Random Forest	0.8897	0.8882	0.9153	0.9015	0.9679
XGBoost	0.8748	0.8735	0.8633	0.8684	0.9713
CatBoost	0.8486	0.8598	0.8376	0.8486	0.9604
SVM	0.7383	0.748	0.7143	0.7308	0.8389
Naive Bayes	0.7103	0.7411	0.7182	0.7295	0.8251

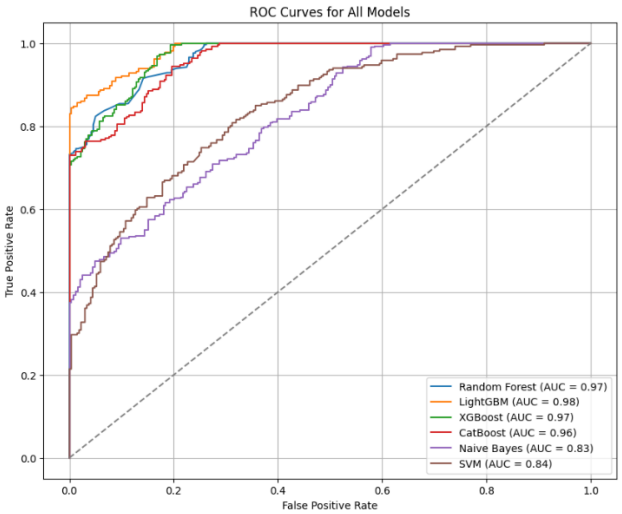

Fig. 5. Receiver operating characteristic (ROC) curves comparing all classifiers on the test set.

This outcome directly addresses RQ 2 by showing that demographic and occupational attributes can predict cluster membership with high accuracy. In particular, the top-performing LightGBM model achieved over 90% accuracy and an AUC of 0.9826, indicating that structural employee characteristics carry substantial predictive power for distinguishing between the two latent perception clusters. Given its strong and consistent performance across all evaluation metrics, LightGBM was selected as the final model for further explainability analysis. Its ability to handle complex interactions and provide insight into feature importance made it especially well-suited for understanding the key drivers behind cluster assignments. The next section explores how this model was interpreted to uncover the most influential variables shaping employee perceptions.

C. SHAP Insights

To interpret the decisions made by the LightGBM classifier and gain a deeper understanding of the structural variables influencing cluster membership, SHapley Additive exPlanations (SHAP) was employed as a model-agnostic explainability method. SHAP values provide a theoretically grounded framework for attributing the contribution of each feature to a specific prediction, enabling both global and local interpretability.

At the global level, the SHAP bar plot (Fig. 6) summarizes the mean absolute SHAP values of all input features, thus ranking them by their average impact on the model's output. According to this plot, the two most influential features in determining cluster membership were Employment Duration and Age, suggesting that the length of time an individual has spent in the workforce and their age are the primary differentiators between those in the more positive (Cluster 0) versus the more negative (Cluster 1) group. These were followed by IndustryDetailed, Gender, and SocioeconomicStatus, which also showed substantial contributions to model output. This directly answers RQ 3 by demonstrating how global SHAP analysis can pinpoint the most influential predictors of cluster membership, offering clear and interpretable evidence of the structural and demographic factors that shape workplace perception profiles.

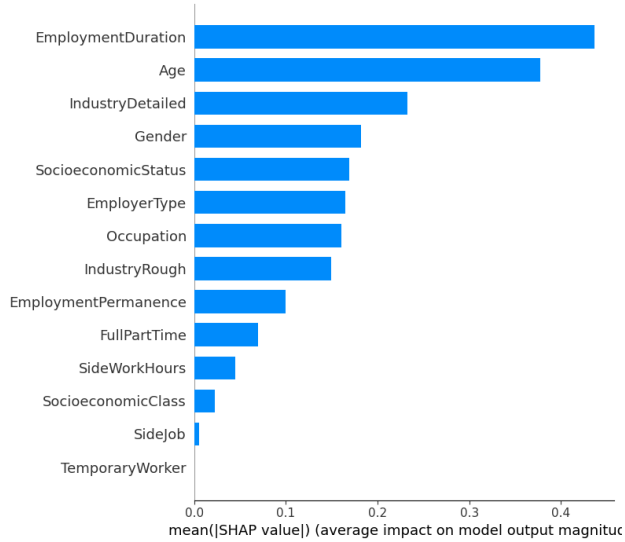

Fig. 6. Global SHAP feature importance plot ranking demographic and occupational variables by their average impact on LightGBM model predictions.

The SHAP beeswarm plot (Fig. 7) further extends this insight by showing how different values of each feature affect the model's predictions. Each point in the beeswarm plot corresponds to a single employee in the dataset, with the horizontal position indicating the SHAP value (i.e., the effect

on the model's prediction) and the color encoding the original feature value (from low to high). This view reveals not only which features are important but also how their specific values push the model toward predicting Cluster 0 or Cluster 1. To support the interpretation of these color gradients and categorical values, the complete coding schemes and enumerated representations of all categorical features used in the model are presented in Appendix B.

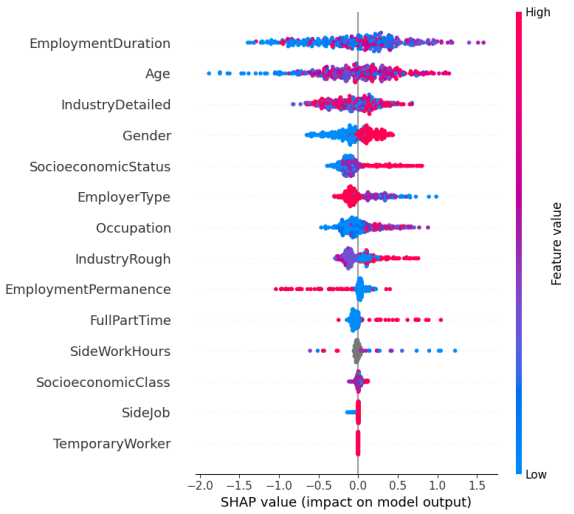

Fig. 7. SHAP beeswarm plot illustrating the direction and magnitude of feature effects on individual predictions, with color representing feature values.

The SHAP analysis highlights how demographic and occupational features influence cluster assignment, providing interpretable insight into the structural drivers of employee workplace perceptions. For Employment Duration, the SHAP beeswarm plot shows a mix of effects, indicating a non-linear relationship between tenure and cluster membership. The corresponding dependence plot reveals that moderate tenure, approximately 0 to 15 years, increases the likelihood of belonging to Cluster 1, while very long tenure shifts predictions toward Cluster 0. This pattern suggests higher dissatisfaction during mid-career stages, followed by more favorable perceptions among long-tenured employees, a finding that aligns with prior HR analytics research linking tenure-related dynamics to changes in employee well-being and engagement [20], [21], [30].

Age exhibits a clearer and more monotonic pattern. Higher age values consistently push predictions toward Cluster 1, while younger employees are more likely to fall into Cluster 0, indicating a largely linear association between increasing age and less favorable workplace perceptions. Similar age-related gradients have been reported in earlier explainable AI studies of employee outcomes, where age emerged as a significant contributor to supervised HR predictions and risk stratification [20], [21]. The ability of SHAP to reveal both the direction and magnitude of this effect reinforces its suitability for interpreting demographic influences in HR contexts [25], [26].

Gender also shows a distinct directional effect, with female employees more likely to be classified into Cluster 1 and male employees into Cluster 0. This result is consistent with prior research emphasizing gender-based disparities in workplace experiences and the value of explainable AI in uncovering such structural inequalities in HR decision-making systems [24], [25]. Similarly, higher Socioeconomic Status values corresponding to workforce-level positions increase the likelihood of Cluster 1 membership, whereas senior or lower-level official roles appear more protective. These findings resonate with earlier clustering and explainable AI studies that highlight the role of hierarchical position and job security in shaping employee perceptions and outcomes [17], [18], [30].

Employer Type further differentiates clusters, as public sector employment at the state or municipal level increases the probability of belonging to Cluster 1, while private sector employment reduces it. Comparable sectoral effects have been observed in previous clustering-based analyses of employee well-being and organizational risk profiles, particularly in studies examining institutional constraints and public sector stressors [6], [9], [19]. Categorical variables such as IndustryDetailed, Occupation, and IndustryRough require interpretation through SHAP dependence plots due to the lack of ordinal meaning in their encodings, an approach that mirrors best practices in recent SHAP-based HR analytics research [22], [30].

Other variables, including EmploymentPermanence, FullPartTime, SideWorkHours, SocioeconomicClass, SideJob, and TemporaryWorker, show minimal influence on predictions. This pattern is consistent with prior explainable machine learning studies in HR contexts, where a subset of structural features typically dominates model behavior while others contribute marginally once core demographic and occupational drivers are accounted for [28], [29].

Overall, the SHAP visualizations provide transparent and theoretically grounded insight into how background characteristics shape cluster membership and validate the LightGBM model's predictions. By combining global feature importance with feature-level dependence analysis, the results extend earlier SHAP-based HR studies that focused exclusively on supervised outcomes, demonstrating how Explainable Artificial Intelligence can also be applied to interpret latent clusters derived from unsupervised analysis [20]–[22], [30], [31]. The detailed examination of dependence plots clarifies how individual attributes contribute to classification into more or less favorable employee perception clusters, with categorical coding schemes documented in Appendix B.

The SHAP dependence plot for employment duration [Fig. 8(a)] shows a clear nonlinear pattern. The likelihood of belonging to Cluster 1 increases during the early to mid-career phase, peaking around 15–20 years of tenure, and then declines for employees with very long service. This suggests that mid-career employees are more prone to unfavorable workplace perceptions, whereas long-tenured employees tend to report more positive or stabilized experiences.

Similarly, the SHAP dependence plot for age [Fig. 8(b)] indicates a steady increase in the probability of being classified into Cluster 1 as age rises. Younger employees are less likely to exhibit negative workplace perceptions, while the risk of dissatisfaction becomes more pronounced after the

age of 30. Overall, both tenure and age emerge as important predictors, highlighting mid-career and older employees as groups more vulnerable to negative workplace sentiment.

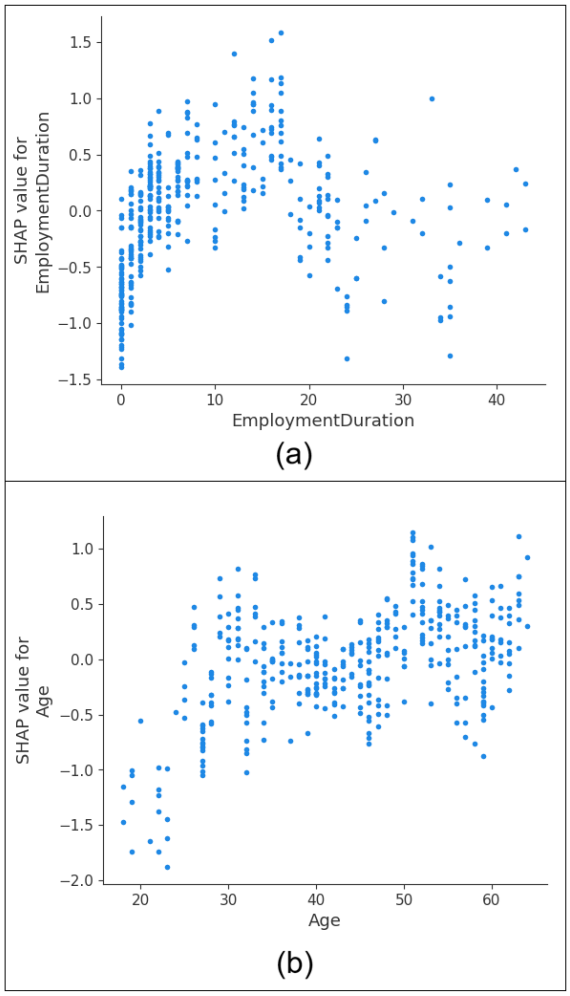

Fig. 8. SHAP dependence plots for: (a) employment duration, and (b) age.

The SHAP dependence plot for IndustryDetailed [Fig. 9(a)] shows that several sectors are strongly associated with classification into the less favorable Cluster 1. Industries such as electricity, gas and heating supply, administrative and support services, public administration and defense, health and social services, and arts and recreation exhibit higher SHAP values, suggesting elevated risk of negative workplace perceptions. These effects likely stem from sector-specific conditions, including high stress, burnout, emotional demands, irregular employment, or job instability.

In contrast, transportation and storage display the lowest SHAP values, indicating a strong association with the more favorable Cluster 0, potentially due to stable demand and expanding logistics-related employment. Education also tends toward lower SHAP values, which may reflect formal employment structures, long-term contracts, and stronger job protections. Finance and real estate show SHAP values near zero, suggesting a balanced risk profile that reflects internal heterogeneity between stable and volatile roles. Retail trade and accommodation and catering services exhibit a wide dispersion of SHAP values, indicating mixed employment conditions and diverse job types within these sectors.

The SHAP dependence plot for Gender [Fig. 9(b)] reveals a clear disparity, with female gender associated with higher SHAP values and a greater likelihood of belonging to Cluster 1, while male gender shows lower values and a protective effect. This finding indicates that gender meaningfully influences cluster assignment and may reflect underlying structural or socio-economic inequalities present in the data.

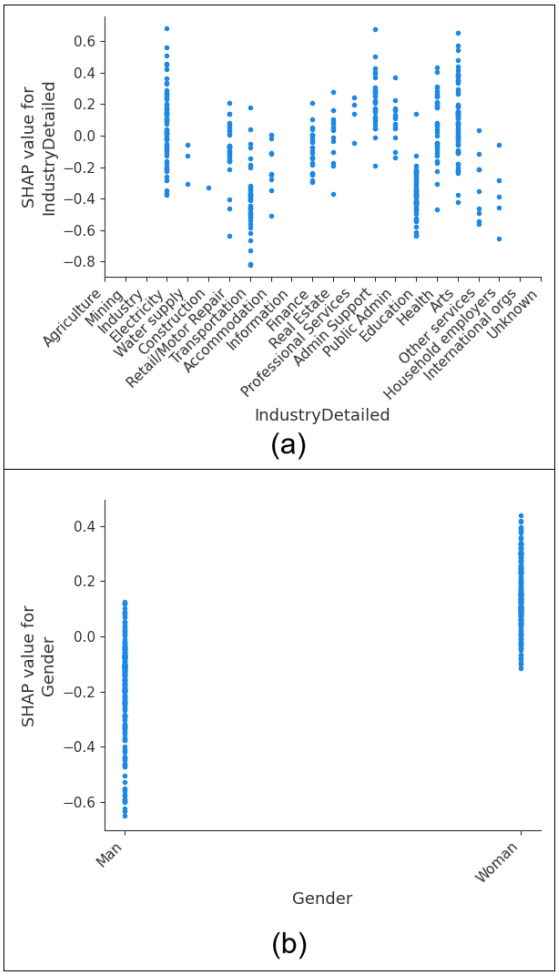

Fig. 9. SHAP dependence plots for: (a) IndustryDetailed, and (b) Gender.

The SHAP dependence plot for Socioeconomic Status [Fig. 10(a)] reveals a clear upward trend in SHAP values from senior officials to workforce-level employees, indicating that lower socioeconomic standing is associated with a higher likelihood of being placed in the unfavorable cluster (Cluster 1). Specifically, individuals categorized as "workforce" exhibit the highest SHAP values, suggesting that their status strongly contributes to predicting membership in the bad cluster. In contrast, senior officials tend to have negative SHAP values, meaning their status lowers the model's probability of assigning them to the adverse group. This pattern suggests that individuals occupying more precarious or lower-ranking positions within the employment hierarchy may face increased vulnerabilities or risks that are being captured by the model. It also reflects how structural inequalities

manifest in employment contexts and are detectable in predictive clustering models. The SHAP dependence plot for Employer Type [Fig. 10(b)] highlights significant differences in risk association based on the nature of the employer. Individuals employed by the state exhibit the highest SHAP values, meaning that this group is more strongly associated with Cluster 1, the undesirable or vulnerable group. This could reflect structural stressors or bureaucratic instability within state institutions. Employees working under municipalities or joint municipal authorities also show positive SHAP values, though slightly lower than those in state employment. In contrast, those employed in the private sector predominantly have lower SHAP values, suggesting a reduced likelihood of belonging to the high-risk cluster. This pattern may seem counterintuitive, as private sector jobs are often perceived as less secure, but it may be reflective of better job-matching, more competitive compensation, or other contextual factors that favor private employment outcomes.

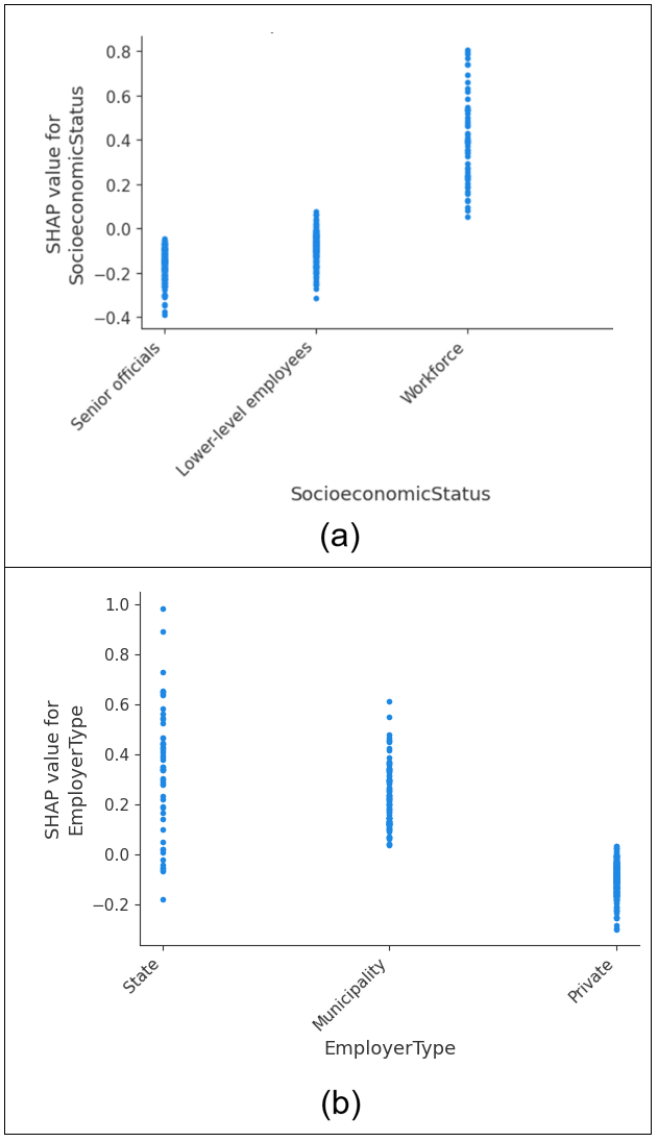

Fig. 10. SHAP dependence plots for: (a) Socioeconomic status, and (b) Employer type.

The SHAP dependence plot for Occupation [Fig. 11(a)] demonstrates clear differences in how job categories influence cluster assignments. Service and sales employees, office and customer service workers, and process and transportation workers exhibit higher SHAP values, indicating a greater likelihood of belonging to the higher-risk Cluster 1. These roles are often characterized by high turnover, customer-facing stress, or physically demanding conditions. Construction, repair, and manufacturing workers also show relatively elevated SHAP values, consistent with the contract-based and physically intensive nature of this work.

In contrast, management, special experts, and cognoscenti display lower SHAP values, suggesting stronger alignment with the more favorable cluster. These occupations typically offer greater stability, clearer career progression, and stronger institutional support. Overall, the results indicate occupational stratification, with higher risk associated with customer-facing and physically intensive roles, and lower risk linked to white-collar or institutional positions.

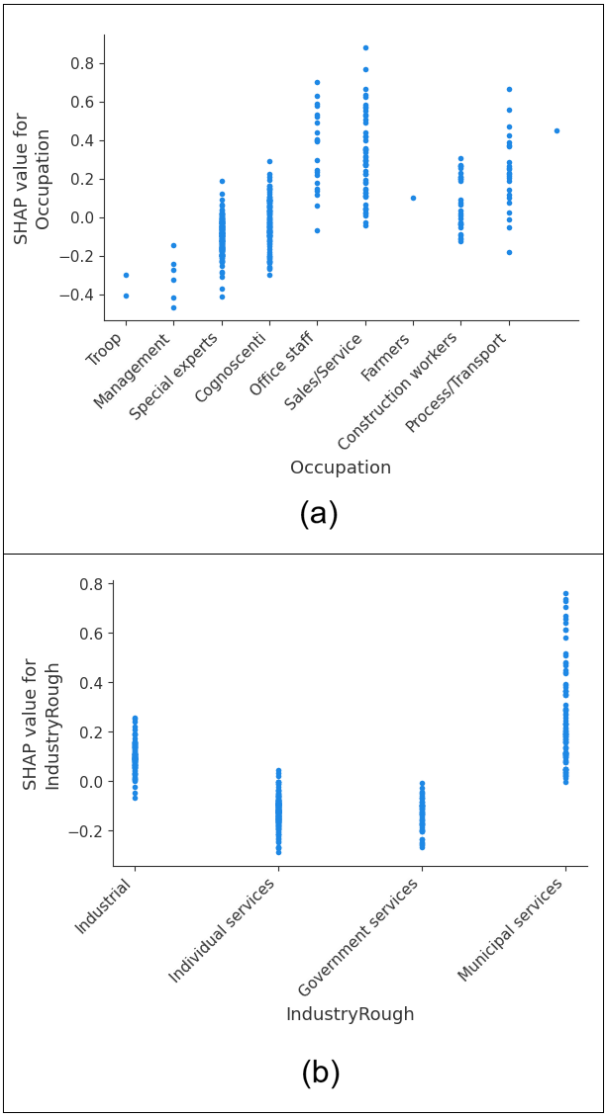

Fig. 11. SHAP dependence plots for: (a) Occupation, and (b) IndustryRough.

The SHAP dependence plot for the rough industry classification [Fig. 11(b)] further emphasizes institutional differences. Municipal services show the highest SHAP values, indicating increased vulnerability, potentially due to contract conditions or budgetary constraints. Government services and individual services exhibit lower SHAP values, while the industrial, applied, and excavated sector shows moderately elevated values, possibly reflecting physical demands or economic volatility. These findings underscore the importance of broad industry context in shaping predicted employment risk.

After examining the SHAP dependence plots, the analysis is extended to individual-level explanations to illustrate how the LightGBM model assigns cluster membership. SHAP waterfall plots are used for three randomly selected employees representing low, medium, and high predicted probabilities of belonging to Cluster 1, which reflects less favorable workplace experiences. While dependence plots summarize average feature effects, waterfall plots show how combinations of features interact differently for each individual, highlighting that similar attributes may have varying impacts depending on context.

For the first employee (Fig. 12), the SHAP waterfall plot shows a strongly negative logit value of −0.852, corresponding to a 29.9% probability of belonging to Cluster 1 and a clear alignment with Cluster 0. The dominant factor driving this outcome is the employee's short employment duration of one year, which strongly reduces the predicted risk, consistent with earlier findings that early-career employees tend to report more positive perceptions. The employee's industry, Financial and Insurance Activities, further lowers the SHAP value, reflecting the generally favorable association of this sector with workplace perceptions.

Additional protective factors include male gender, which slightly reduces risk, and senior occupational status, which is associated with lower SHAP values due to greater autonomy and organizational support. Although the employee is 42 years old, the age effect remains moderate, as mid-career employees lie below the steeper risk increase observed at older ages. Private sector employment also contributes to lowering the predicted risk, in line with earlier results showing favorable SHAP values for this employer type. Other variables, such as rough industry classification, occupation, and side work hours, have minimal impact on the final prediction.

Overall, the SHAP explanation confirms the model's classification and demonstrates how short tenure, private sector employment, seniority, and sector characteristics jointly reduce the likelihood of negative workplace perceptions, placing this employee firmly within the more favorable cluster.

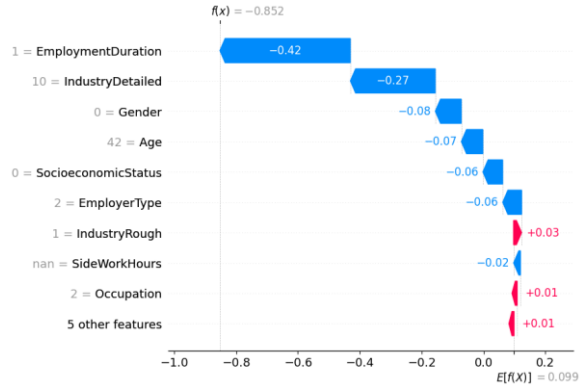

Fig. 12. Local SHAP waterfall plot for an employee with a low probability of belonging to Cluster 1 (negative cluster).

The SHAP waterfall plot for the second employee (Fig. 13) shows a logit value of approximately 0.044, corresponding to a 51.1% probability of belonging to Cluster 1 and a 48.9% probability of Cluster 0. This indicates a borderline case, with the prediction lying close to the model's baseline and no strong inclination toward either cluster.

The strongest factor reducing the likelihood of Cluster 1 membership is the employee's short employment duration of two years, which produces a negative SHAP value. As observed in the dependence analysis, early tenure is generally associated with more favorable workplace perceptions. In contrast, the employee's age of 39 contributes positively to the SHAP value, reflecting the gradual increase in risk observed with increasing age.

The rough industry classification, "Individual services", slightly increases the predicted risk, consistent with the variability and demands often associated with this sector. This upward effect is partially offset by the employee's senior socioeconomic status, which has a protective influence, and by male gender, which also contributes to a lower predicted risk.

The occupation category "Special Experts" adds a small positive contribution, suggesting modest risk, while private sector employment and full-time status both slightly reduce the likelihood of belonging to Cluster 1. Employment permanence has only a negligible positive effect. Overall, the combination of protective and risk-enhancing factors results in an equivocal prediction, illustrating the nuanced interplay of demographic, occupational, and institutional characteristics in shaping workplace perceptions.

The SHAP waterfall plot for the third employee (Fig. 14) shows a strongly positive logit value of +2.197, corresponding to a 90% probability of belonging to Cluster 1 and indicating a high likelihood of negative workplace perceptions. This classification is driven by the cumulative effect of several risk-enhancing factors.

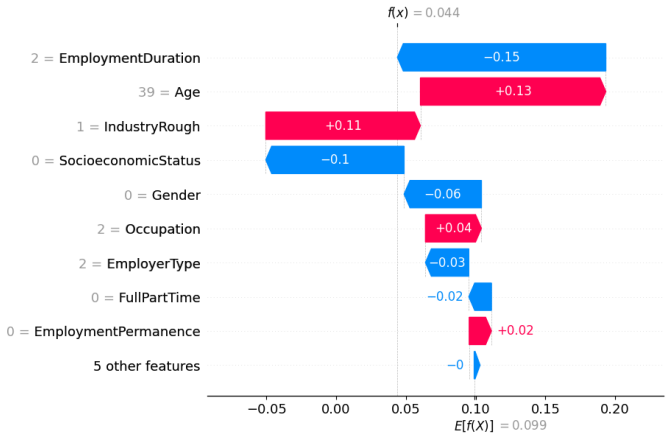

Fig. 13. Local SHAP waterfall plot for an employee with a borderline probability of belonging to Cluster 1 (negative cluster).

The employee's long employment duration of 21 years is a major contributor, as extended tenure is associated with higher SHAP values and increased risk of dissatisfaction. The female gender also substantially increases the SHAP value, consistent with earlier results showing a higher likelihood of women being classified into Cluster 1. Socioeconomic status, categorized as workforce, further elevates risk, reflecting the greater vulnerability of lower-ranking positions.

Industry and occupation also play significant roles. Employment in accommodation and catering, as well as service and sales occupations, both contribute positively to the SHAP value, aligning with prior findings that these contexts are associated with higher stress and instability. Age adds additional upward pressure, as SHAP values increase with advancing age. Smaller positive contributions from rough industry classification, employer type, and employment status further reinforce the prediction.

Together, these demographic and occupational characteristics generate a high SHAP score, leading to confident assignment to Cluster 1 and illustrating how multiple structural factors can interact to produce elevated negative workplace sentiment.

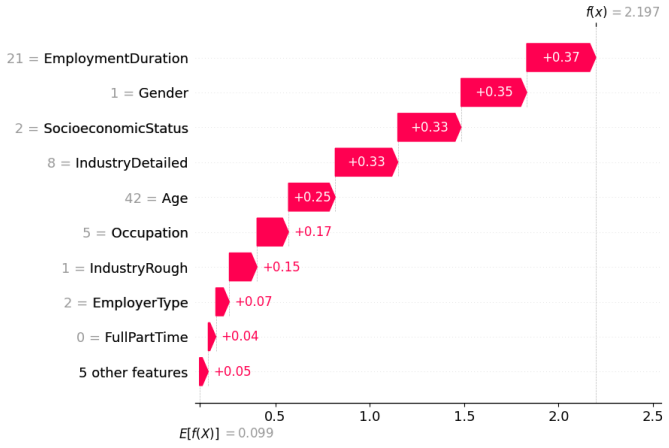

Fig. 14. Local SHAP waterfall plot for an employee with a high probability of belonging to cluster 1 (negative cluster).

This directly addresses RQ 4 by showing how local SHAP explanations uncover the unique combination of factors influencing individual employees' cluster assignments. These individualized insights reveal that even when employees share certain attributes, differences in their broader profiles can lead to distinct prediction outcomes, underscoring the value of local interpretability in HR decision-making.

V. Discussion and Future Work

The identification of two distinct employee perception clusters reveals pronounced differences in engagement, well-being, and organizational support. Employees in Cluster 0 consistently report more favorable workplace experiences, including stronger perceptions of fairness, leadership quality, developmental opportunities, motivation, and overall well-being. In contrast, Cluster 1 reflects systematically less favorable perceptions, characterized by lower trust, weaker inclusion, and reduced job satisfaction. These findings are consistent with prior clustering-based HR analytics research that has demonstrated the existence of heterogeneous employee profiles shaped by differences in well-being, engagement, and organizational support rather than random variation [6]–[10], [17]–[19]. Together, these results reinforce the view that workplace perceptions are structured outcomes influenced by identifiable demographic and occupational conditions embedded within organizational contexts.

The application of SHAP-based explainability provides deeper insight into the mechanisms underlying these differences. Employment duration and age emerge as the most influential predictors of cluster membership, indicating that workplace perceptions evolve across career stages. Shorter tenure and younger age are generally associated with more positive perceptions, whereas mid- to late-career stages exhibit an increased likelihood of negative sentiment. Similar tenure- and age-related effects have been reported in supervised HR analytics and explainable AI studies examining employee satisfaction, attrition, and well-being, where cumulative exposure to organizational stressors and unmet career expectations were identified as key drivers [20], [21], [30]. In addition, industry affiliation, gender, socioeconomic status, and occupation play important roles, revealing how institutional environments and labor market positions shape employees' lived experiences. Elevated risk in sectors such as health and social services, electricity, gas and heating supply, arts and recreation, and administrative support aligns with earlier clustering studies that identified sector-specific vulnerability profiles and occupational risk patterns [6], [9], [17], [19]. The consistency between global SHAP importance rankings and individual-level explanations further strengthens the credibility of these findings and reflects best practices in explainable HR analytics [22], [30].

From a human resource management perspective, the results offer clear guidance for targeted and evidence-based interventions, addressing RQ 5. Mid-career employees may benefit from structured career development pathways, mentoring programs, and role redesign initiatives aimed at restoring motivation and engagement, echoing recommendations from prior HR analytics and well-being studies [13], [18]. Sector-specific interventions are particularly

relevant for high-risk industries, where workload intensity, emotional labor, or institutional constraints may drive negative perceptions, as documented in earlier clustering-based analyses of employee well-being and stress [6], [17], [19]. Additionally, the observed disparities linked to gender and socioeconomic status highlight the importance of equity-oriented HR policies that address structural inequalities, promote inclusive leadership, and enhance access to resources and advancement opportunities, reinforcing calls from recent explainable AI and ethical HR systems research [24]–[26]. Well-being initiatives that focus on psychosocial support and work-life balance may further mitigate burnout and improve retention among vulnerable employee groups [20], [21].

Beyond practical implications, the study contributes to methodological advancement by demonstrating how Explainable Artificial Intelligence can bridge the gap between complex analytics and managerial decision-making. By transforming opaque model predictions into transparent explanations, SHAP-based insights enhance trust, accountability, and interpretability in HR analytics, consistent with prior research emphasizing the role of XAI in ethical and transparent HR Decision-Support Systems [25]–[27]. This integration enables organizations to move beyond descriptive segmentation toward an actionable understanding of *why* certain employee groups experience systematically different workplace conditions. As such, the proposed framework extends earlier SHAP-based HR studies that focused exclusively on supervised outcomes by applying explainability to latent cluster formation [20]–[22], [30], [31].

Despite these contributions, several limitations should be acknowledged. First, the analysis is based on cross-sectional survey data, which limits the ability to infer causal relationships or track changes in employee perceptions over time, a constraint also noted in prior clustering and HR analytics studies [6], [17], [19]. Second, the reliance on self-reported survey responses may introduce response bias or reflect temporary emotional states, as highlighted in earlier well-being and perception research [11], [12]. Third, while the Finnish Working Life Barometer provides high-quality and nationally representative data, the findings may reflect context-specific institutional and cultural characteristics, potentially limiting generalizability to other labor markets, as observed in previous country-specific HR analytics research [18], [19]. Finally, the use of predefined survey items constrains the analysis to structured perceptions and does not capture emergent themes that may arise in unstructured employee feedback [27].

Future research can build on this work in several directions. Longitudinal studies could examine transitions between perception clusters across career stages, enabling analysis of how workplace experiences evolve over time and how interventions influence these trajectories, addressing limitations identified in prior cross-sectional HR analytics research [6], [17]. Cross-national applications of the proposed framework would allow comparative analysis of institutional effects on employee perceptions and test the generalizability of the findings [18], [19]. In addition, integrating unstructured data sources such as employee comments, exit interviews, or organizational communications using natural language processing could enrich perception profiling and align with recent advances in explainable and knowledge-driven HR systems [27], [30]. Methodologically, future studies may explore alternative clustering techniques, causal inference approaches, or fairness-aware explainable models to further enhance robustness, transparency, and ethical accountability in Human Resource Analytics [24]–[26], [31]. Together, these extensions would strengthen the framework's role as a comprehensive decision-support tool for Human Resource Analytics.

VI. Conclusion

The study demonstrates that integrating unsupervised clustering with supervised classification and SHAP-based explainability provides actionable insights into employee workplace perceptions. Two distinct perceptual profiles emerged: one reflecting positive evaluations of fairness, leadership, well-being, and motivation, and another characterized by more negative sentiment. By interpreting these latent profiles through supervised modeling and SHAP, the analysis transparently identified the demographic and occupational factors driving cluster membership.

Key predictors included employment duration, age, industry affiliation, gender, and socioeconomic status, underscoring the combined influence of structural and individual factors on workplace experience. Methodologically, the framework bridges descriptive segmentation and explanatory modeling, producing results that are both robust and interpretable for decision-makers. This transparency supports targeted, equitable HR interventions and directly contributes to the United Nations Sustainable Development Goal 8 by promoting fair and inclusive employment conditions.

Declaration on Generative AI

Generative AI tools (specifically large language models) were used solely to assist with drafting, clarifying wording, and refining the language of this manuscript. All conceptual development, methodological design, data analysis, interpretation of results, and final decisions regarding the content were fully conducted by the author. The author takes full responsibility for the integrity, accuracy, and originality of all scientific and analytical components of the work.

			Mean Survey Responses Per Cluster	
ID	Survey Question	Response	Cluster 0	Cluster 1
K21c_4	Information is shared openly at my workplace. Are you:	1- Totally agree 2- Somewhat agree 3- Somewhat disagree 4- Completely disagree 9- Can't say	1.41	2.27
K21c_5	At my workplace, employees are treated equally. Are you:		1.29	2.21
K21c_10	My workplace is able to handle and resolve conflicts. Are you:		1.33	2.25
K21c_12	My workplace has a confidential atmosphere. Are you:		1.24	2.21
K44C	My supervisor gives me feedback on how well I have done at work.		1.48	2.42
K44E	My superior asks for my opinion on decisions that affect me.		1.21	2.17
K44H	My superior is interested in my well-being at work.		1.3	2.34
K44G	My supervisor treats employees fairly and equally.		1.16	2.23

K44I	My supervisor encourages me to develop my work, for example, to adapt the content and working methods of my work to suit me.		1.4	2.41
K56a	How often do you feel mentally exhausted at work:	1- You never know 2- Rarely 3- Sometimes 4- Often 5- You always feel 8- Don't want to answer 9- Can't say	2.3	2.94
K56b	How often do you feel that you are not interested or enthusiastic about your work:		2.08	2.84
K56c	How often do you feel that you cannot concentrate well when working:		2.35	2.79
K56d	How often do you feel that you cannot control your emotions at work?		1.59	2.06
K57a	How often do you feel full of energy when doing your work:		3.71	3.16
K57b	How often are you enthusiastic about your work:		3.9	3.29
K57c	How often are you completely immersed in your work:		3.65	3.28
K57d	How often do you have a sense of community and working together:	1- Never 2- Rarely 3- Sometimes 4- Often 5- Always 8- Don't want to answer 9- Can't say	3.84	3.17
K55	Stress refers to a situation where a person feels tense, restless, nervous or anxious, or has difficulty sleeping due to constant worries. Do you currently feel this kind of stress:	1- Not at all 2- Just a little 3- Some 4- Quite a lot 5- Very much 8- Don't want to answer 9- Can't say	2.21	2.81
K69	How meaningful do you find your work? Is it:	1- Very meaningful 2- Quite significant 3- Not particularly relevant 4- Not relevant at all 8- Don't want to answer 9- Can't say	1.55	1.96
K28a	If you think about the physical demands of your current job, is your work capacity:	1- Very good 2- Fair 3- Moderate 4- Pretty bad 5- Very bad 8- Don't want to answer 9- Can't say	1.52	1.93
K28b	What about mental requirements? Is your work capacity:		1.61	2.17
K64	When you think about balancing work and other life, are your working hours flexible:	1- Sufficiently 2- Somewhat, but not enough 3- Not enough at all 9- Can't say	1.17	1.53
K42a	How often do you work to tight schedules or at a very fast pace:	1- Daily 2- Weekly 3- Monthly 4- Randomly 5- Not at all 9- Can't say	2.38	2.11
K43g	Have you worked outside of working hours without compensation in the past 12 months to perform your job duties:		4.37	4.17

Business Process Outsourcing and Digitalization in Albania: Challenges, Opportunities, and Strategic Directions

Nertila Çika
Faculty of Economy, University of Tirana, Albania

***Abstract*—The rapid expansion of Business Process Outsourcing (BPO) has transformed the global services economy, and Albania is emerging as a competitive nearshoring destination in the Western Balkans. This study examines the intersection of BPO and digitalisation in Albania, exploring how technological innovation, artificial intelligence (AI), and cloud-based automation are reshaping service delivery, labour productivity, and competitiveness. This study is explicitly framed as a desk-based policy and analytical study relying exclusively on secondary data, without primary data collection based on secondary data from OECD, World Bank, IBM, and European Commission reports (2023–2025). Findings indicate that Albania's BPO sector benefits from low labour costs, multilingual human capital, and favourable fiscal policies, yet faces challenges related to technological capability, digital infrastructure, and talent retention. Through a PEST analytical framework, this study identifies the macro-environmental factors influencing BPO development and proposes strategic directions for enhancing digital readiness and regional integration. The study further expands its comparative analysis to include other Western Balkan economies, Kosovo, North Macedonia, and Montenegro, providing a broader perspective on Albania's position within the regional outsourcing ecosystem. This research contributes to the academic and policy discourse on digital transformation by presenting an integrated model aligning BPO growth with sustainable innovation and regional competitiveness.**

Keywords*—Business Process Outsourcing (BPO); digitalisation; artificial intelligence (AI); automation; PEST analysis; Western Balkans; Albania; strategic development

I. Introduction

The global landscape of Business Process Outsourcing (BPO) has undergone a significant transformation over the past decade, driven by advances in automation, artificial intelligence (AI), and digital connectivity. The integration of digital technologies into business operations has reshaped value chains, customer interactions, and operational efficiency across industries [2]. In this context, developing economies such as Albania are increasingly positioning themselves as emerging destinations for outsourcing, benefitting from cost advantages, multilingual human resources, and geographical proximity to Western Europe [21].

Digitalisation represents both a challenge and an opportunity for BPO development in Albania. On one hand, technological innovation enhances productivity, transparency, and competitiveness; on the other, it demands substantial investments in infrastructure, human capital, and regulatory adaptation [29]. The transition toward digitalised outsourcing requires an alignment between policy reforms, skills development, and corporate digital strategies [8].

Globally, the BPO sector has evolved beyond traditional back-office functions such as accounting and customer service. It now encompasses high-value processes like data analytics, IT consulting, and AI-driven automation [16]. This shift reflects the growing importance of digital ecosystems and knowledge-intensive services [5] [14]. The integration of cloud computing and robotic process automation (RPA) is enabling companies to achieve scalability, flexibility, and innovation in ways that were previously unattainable [13].

From a regional perspective, the Western Balkans are increasingly recognised as a promising nearshoring hub. Albania has leveraged its multilingual workforce, cost-effective labour market, and improving digital infrastructure to attract foreign investors [26]. Available evidence indicates that the BPO industry in Albania employs thousands of young professionals, primarily in customer relations, finance, and IT support, contributing to service exports and employment growth [21]. Nevertheless, the sector remains fragmented and heavily reliant on low-cost advantages, rendering it vulnerable to technological disruption and talent migration [29].

The concept of digital transformation within BPO goes beyond automation. It encompasses the strategic adoption of AI, data analytics, and cloud-based systems to enhance organisational agility and innovation capacity [1]. Digitalisation has become a decisive factor shaping competitiveness in global value chains [15]. In Albania's case, the challenge lies in harmonising business digitalisation with national policy reforms and workforce digital readiness.

The Albanian government has made progress through initiatives such as the Digital Agenda 2022–2026 and participation in the EU4Digital Western Balkans Initiative, which supports cross-border innovation, cybersecurity, and ICT skill development [9]. Similarly, fiscal incentives and EU pre-accession funds aim to foster entrepreneurship and investment in digital services [29]. Despite this progress, policy fragmentation and limited coordination between education, technology, and industry stakeholders continue to impede the pace of transformation [21].

At the global level, outsourcing is increasingly influenced by sustainability principles and responsible digital governance.

The growing focus on environmental, social, and governance (ESG) indicators in outsourcing contracts reflects the need for ethical and sustainable operations [11]. For Albania, aligning BPO development with these international standards will be essential for long-term integration into the EU's digital single market.

The COVID-19 pandemic accelerated the shift toward remote work and virtual outsourcing, reinforcing the need for robust digital infrastructure and flexible business models [25]. Globally, firms transitioned to hybrid structures, adopting cloud technologies and AI-based process management to ensure continuity [15]. In Albania, this shift coincided with the expansion of broadband networks, ICT education, and remote employment opportunities in call centres, accounting, and IT services [28].

From an academic perspective, studying BPO and digitalisation in Albania addresses an existing research gap in the Western Balkans. Most studies have focused on large economies or advanced EU member states, while small transitional markets remain underexplored [21]. This study fills that gap by analysing how digital transformation, institutional governance, and human capital collectively shape the development of Albania's BPO sector.

A. Research Problem

Despite the rapid expansion of the Business Process Outsourcing (BPO) sector in Albania, existing studies remain largely descriptive and fragmented, focusing primarily on labour cost advantages or general digitalisation trends without integrating institutional conditions, firm-level capabilities, and digital transformation dynamics. Limited attention has been paid to how institutional alignment, digital infrastructure, and human capital interact to shape sustainable BPO competitiveness in emerging economies undergoing EU integration [21] [30]. This gap constrains both theoretical advancement and evidence-based policymaking in the Western Balkan context [26].

B. Research Questions

To address this gap, the study is guided by the following research questions:

RQ1: How do political, economic, social, and technological factors influence the development of the BPO sector in Albania? [21]

RQ2: How do institutional conditions interact with firm-level resources to shape digital and AI adoption in the BPO sector? [9] [5]

RQ3: What strategic insights emerge from comparing Albania with other Western Balkan and Eastern European economies in terms of digital readiness and BPO competitiveness? [26] [30].

C. Research Objectives

The objectives of this study are to:

1) Analyse the macro-environmental determinants of BPO development in Albania using a PEST framework [21];

2) Examine how digitalisation, automation, and artificial intelligence contribute to productivity and competitiveness in the BPO sector through institutional and resource-based perspectives [5] [16];

3) Position Albania within the regional outsourcing ecosystem by means of comparative benchmarking with selected Western Balkan and Eastern European economies [26] [30].

D. Novelty and Contribution of the Study

This study contributes to the existing literature in three main ways. First, it offers a theoretical contribution by integrating the Resource-Based View (RBV) and Institutional Theory to explain digital transformation in the BPO sector of an emerging economy [21], [4], [5]. Second, it provides a methodological contribution by combining PEST analysis with comparative regional benchmarking and a digitalisation lens, moving beyond purely descriptive sectoral overviews [21], [18], [26]. Third, the study delivers practical and policy-relevant insights by proposing a conceptual model of digital BPO transformation that can be applied to Albania and other Western Balkan economies seeking to transition from cost-based outsourcing toward higher value-added digital services [5], [21], [26].

This study distinguishes itself from existing literature through a novel analytical integration of macro-environmental analysis, regional benchmarking, and digital transformation dynamics within the Business Process Outsourcing (BPO) sector of an emerging economy. While prior studies on BPO in the Western Balkans have predominantly focused on labour cost advantages or general digital indicators, this research advances the literature by explicitly combining PEST analysis with comparative regional benchmarking and an artificial intelligence (AI)–oriented digitalisation lens [21] [26].

Methodologically, although the study adopts a qualitative and descriptive–analytical approach based on secondary data, its novelty lies in the structured triangulation of institutional, technological, and human capital dimensions across multiple countries rather than in isolated national descriptions [21] [30]. This approach enables the identification of causal mechanisms and structural trade-offs, such as the tension between cost competitiveness and investment in high-skilled digital labour that are not sufficiently explored in prior regional studies [5] [26].

Theoretically, the study contributes by integrating the Resource-Based View and Institutional Theory to explain how institutional alignment functions as an enabling mechanism for firm-level capability development in a digitalising emerging economy. The proposed conceptual model advances existing research by illustrating how regulatory frameworks, digital infrastructure, and human capital jointly shape value-added BPO upgrading rather than acting as independent drivers [21] [5]. Empirically, the Albanian case offers original insights into how intermediate economies position themselves between cost-based Western Balkan peers and digitally advanced Eastern European outsourcing hubs, thereby enriching comparative BPO scholarship [30] [26].

Beyond the general policy and strategic implications discussed throughout the study, this study makes three explicit

and tangible contributions to the literature and practice of Business Process Outsourcing in emerging economies.

First, at the theoretical level, the study advances the academic debate by developing a conceptual model that explicitly links institutional alignment, digital infrastructure, human capital development, and firm-level capabilities to digital BPO upgrading. By integrating the Resource-Based View and Institutional Theory, the model moves beyond isolated theoretical applications and demonstrates how institutional conditions function as enabling mechanisms for resource accumulation in a digitalising emerging economy [21] [5] [30].

Second, from a methodological perspective, the study contributes by operationalising an integrated analytical framework that combines PEST analysis with comparative regional benchmarking and an artificial intelligence–oriented digitalisation lens. This configuration enables the identification of causal mechanisms and structural trade-offs, such as the tension between cost competitiveness and investment in high-skilled digital labour, that are not sufficiently captured in prior descriptive studies of the Western Balkans [21] [18] [26].

Third, at the practical and policy level, the comparative analysis of Albania with other Western Balkan and Eastern European economies generates transferable insights for policymakers and practitioners. Rather than offering a purely descriptive comparison, the findings highlight generalisable patterns regarding the conditions under which emerging economies can transition from cost-based outsourcing toward value-added digital BPO services. These insights provide actionable guidance for designing policies related to digital governance, skills development, and investment prioritisation in similar emerging market contexts [26] [30].

Accordingly, this study aims to:

1) Analyse the macro-environmental factors (political, economic, social, technological) influencing BPO growth in Albania through a PEST framework.

2) Evaluate how digital transformation and automation technologies enhance productivity and competitiveness in the BPO sector.

3) Compare Albania's performance with other Western Balkan and Eastern European economies to identify strategic directions for sustainable growth.

The remainder of the study is organised as follows: Section II reviews the existing literature on outsourcing and digital transformation. Section III outlines the research methodology and analytical frameworks. Section IV presents the findings, including a PEST analysis, regional comparison, and conceptual framework. Finally, Section V concludes with policy implications and recommendations for the sustainable development of BPO and digitalisation in Albania and the wider region.

II. Literature Review

A. Overview of Contemporary Research

Additional academic and professional studies further enrich the literature on digital transformation and outsourcing by addressing complementary, yet distinct dimensions of change in contemporary service industries. Research on AI-driven process optimisation highlights how automation and intelligent analytics enhance efficiency, accuracy, and scalability within outsourcing operations [3]. Related contributions on digital twins of business processes extend this perspective by demonstrating how virtual representations of workflows support process redesign, monitoring, and continuous improvement [12]. From a strategic viewpoint, the literature on the reconfiguration of outsourcing models emphasises the transition from cost-based arrangements toward digitally enabled, value-oriented outsourcing strategies [14]. In parallel, studies on workforce skills development and reskilling underline the critical role of human capital adaptation in enabling effective adoption of advanced digital technologies [20]. Finally, analyses of competitiveness dynamics in service industries provide broader insights into how institutional conditions, technological innovation, and skills upgrading jointly shape outsourcing performance across different market contexts [23].

In addition to peer-reviewed academic studies, institutional and industry-based reports provide important complementary perspectives on the evolution of outsourcing and digital transformation in emerging economies. These sources analyse recent global outsourcing trends, the reconfiguration of service delivery models, and the increasing role of sustainability and ESG considerations in shaping outsourcing strategies [6] [10]. Policy-oriented assessments further examine how digitalisation and artificial intelligence are reshaping global value chains and service-sector competitiveness, with particular emphasis on the implications for emerging and transitional economies [24]. Moreover, country- and region-specific institutional analyses highlight the role of regulatory reforms, governance capacity, and labour market dynamics in influencing outsourcing development and employment outcomes in the Western Balkans and comparable regions [7] [27]. Collectively, these contributions enrich the contextual and policy background of the present study, complementing firm-level and technological analyses of BPO development. Between 2023 and 2025, the academic and professional debate around Business Process Outsourcing (BPO) has shifted from operational cost optimisation to digital innovation and sustainability [2] [21]. Digitalisation and automation are now the core pillars of global outsourcing, enabling companies to achieve efficiency, agility, and strategic value creation [5] [16]. The latest literature emphasises the role of emerging economies, such as Albania, in integrating artificial intelligence technologies, data analytics, and digital governance frameworks to compete effectively in regional outsourcing markets [21] [26] [30].

B. Digital Transformation in Global BPO

Digital transformation has revolutionised BPO operations globally [2]. Accenture identifies three stages of digital maturity: digitisation, digitalisation, and full transformation, each representing a deeper integration of technology into corporate strategy [2]. IBM notes that AI adoption and cloud integration can increase operational efficiency by up to 40 percent while reducing process errors by 25 per cent [16] [3]. Advanced automation increasingly incorporates digital representations of workflows and decision logic to optimise

service delivery and process design [12]. OECD adds that digital maturity across emerging economies correlates directly with their level of institutional reform and ICT investment [21].

UNCTAD reports that global demand for outsourcing services in the digital domain increased by 19% annually during 2023–2024, led by AI-based data analytics and virtual assistance [26]. Similarly, Gartner projects that automation-driven BPO will represent 60% of all outsourcing contracts by 2026 [13]. Albania, though still in its early stage of digital maturity, benefits from regional integration with the EU through the EU4Digital Western Balkans Initiative, which supports cross-border ICT standards and e-skills programmes [9].

C. Human Capital and Skill Transformation

Human capital development is the foundation of digital competitiveness [31]. Evidence indicates that 44% of the global workforce will require reskilling by 2025 due to the integration of artificial intelligence and automation technologies [31]. In Albania, demographic indicators show that a large share of the working-age population is under 35 years old, yet only a limited proportion possesses advanced digital competencies, creating both a constraint and an opportunity for the BPO sector [17].

Continuous professional training in data management, cybersecurity, and automation is therefore essential for sustaining competitiveness in digital outsourcing environments [32]. Recent studies emphasise that digital literacy must evolve into "digital fluency", whereby workers not only use digital tools but apply them strategically to improve productivity and service quality [19] [21]. Furthermore, hybrid education and training models that combine technical expertise with analytical and problem-solving skills have been shown to be particularly effective in enhancing employability and adaptability within AI-enabled BPO operations [15] [4].

D. Policy, Governance, and Regulation

Regulatory standards for digital service providers have been strengthened through the adoption of the Digital Services Act (DSA) and the AI Act, promoting accountability, data protection, and algorithmic transparency within the European digital market [8] [9]. Alignment with these regulatory frameworks is essential for countries such as Albania to ensure compatibility with EU data governance and cybersecurity standards [9].

Recent assessments confirm progress in Albania's e-governance systems and digital infrastructure, while also highlighting persistent fragmentation across public institutions [28]. Evidence further indicates that regulatory predictability and stable tax incentives are critical determinants for attracting foreign direct investment in ICT and BPO sectors [5] [11]. Although Albania's low corporate tax rate for IT and outsourcing services enhances cost competitiveness, the effectiveness of this policy depends on consistent enforcement and institutional capacity [21].

E. Regional Perspectives and Emerging Trends

A structured overview of the most relevant academic and institutional sources informing this study is summarised in Table I. Regional evidence indicates that Eastern European economies such as Romania, Bulgaria, and Serbia lead in digital BPO adoption, supported by targeted innovation policies and strong academic–industry collaboration [30]. By contrast, Albania, Kosovo, and North Macedonia are positioned as cost-effective but digitally emerging markets, with significant potential for scaling through deeper regional integration and skills upgrading [18].

Policy analyses further recommend intensified collaboration among Western Balkan economies within frameworks such as EU4Digital and the Regional Economic Area to harmonise digital standards and stimulate cross-border digital investment [21] [9]. Complementary assessments emphasise that nearshoring strategies and regional digital partnerships can collectively enhance the competitiveness of the Western Balkans relative to Central and Eastern Europe [26].

TABLE I. SUMMARY OF KEY LITERATURE (2023–2025)

Focus Area	Key Findings	Relevance to Albania	Author/ Source
Digital transformation	Defines three phases of digital maturity	Benchmark for Albania's progress	[2]
AI and automation	Increases efficiency by 40%	Technological roadmap for BPO firms	[16]
Intelligent outsourcing	Shift toward knowledge-based outsourcing	Policy relevance for sustainable BPO	[4] [5]
Digital transformation in emerging markets	Highlights need for institutional coordination	Framework for national strategy	[21]
Human capital and FDI	Links digital skills to outsourcing growth	Empirical policy insight	[29]
EU4Digital Western Balkans	Promotes cross-border ICT and e-skills	Foundation for regional cooperation	[9]
BPO in the Balkans	Analyses cost and skills advantage	Regional competitiveness benchmark	[18]
Digital economy and nearshoring	Growth of digital services post-pandemic	Context for Albania's export potential	[26]
Workforce reskilling	Stresses AI-based skill acquisition	Human capital policy guidance	[32]
AI adoption in SMEs	Provides framework for digitalisation	Adaptable to Albanian SMEs and BPOs	[22]

Source: [21] [29] [30] [16] [9].

In addition, implementation-oriented frameworks on artificial intelligence adoption in small and medium-sized enterprises provide structured guidance for digitalisation

pathways that are directly applicable to BPO providers operating in emerging market contexts [22].

F. Theoretical Perspectives and Research Propositions

The conceptual evolution from traditional cost-based outsourcing toward digitally enabled and AI-driven BPO models is illustrated in Fig. 1. This study is grounded in two complementary theoretical perspectives: the Resource-Based View (RBV) and Institutional Theory. The RBV posits that sustainable competitive advantage arises from firm-level resources that are valuable, rare, and difficult to imitate, such as advanced digital skills, artificial intelligence capabilities, and organisational knowledge [21] [5]. However, RBV alone does not sufficiently explain why firms operating in similar industries exhibit divergent digital transformation outcomes across different national contexts [21].

Institutional Theory complements this perspective by emphasising the role of regulatory frameworks, governance quality, and normative pressures in shaping organisational behaviour and technology adoption [9] [4]. In emerging economies, alignment with supranational regulatory frameworks such as those of the European Union can reduce uncertainty and enable firms to invest in advanced digital technologies [9] [21].

By integrating RBV and Institutional Theory, this study advances the understanding of digital transformation in the BPO sector by explicitly linking institutional conditions to firm-level capability development. This theoretical integration advances existing literature by demonstrating that institutional conditions do not directly generate competitive advantage but instead shape firms' capacity to develop and deploy strategic resources. In the context of a digitalising emerging economy, such as Albania, regulatory alignment and governance quality function as enabling mechanisms that influence firms' absorptive capacity, particularly in relation to digital skills and AI adoption. This perspective refines the Resource-Based View by highlighting the mediating role of institutions and extends Institutional Theory by illustrating how firm-level resource heterogeneity conditions the outcomes of institutional reforms [21] [5] [30].

Accordingly, the following research propositions are derived:

P1: Alignment with EU digital governance and regulatory frameworks enables BPO firms to transform digital infrastructure into strategic firm-level resources [9] [21].

P2: Human capital availability and advanced digital skills mediate the relationship between institutional reforms and AI adoption in the BPO sector [17] [19] [31].

P3: Emerging economies that successfully combine institutional stability with firm-level resource development are more likely to transition from cost-based outsourcing toward value-added digital BPO services [5] [26].

The figure illustrates the transition from traditional cost-based outsourcing models toward digitally enabled and AI-supported BPO ecosystems, highlighting the progressive role of automation, cloud computing, and advanced digital capabilities in value creation.

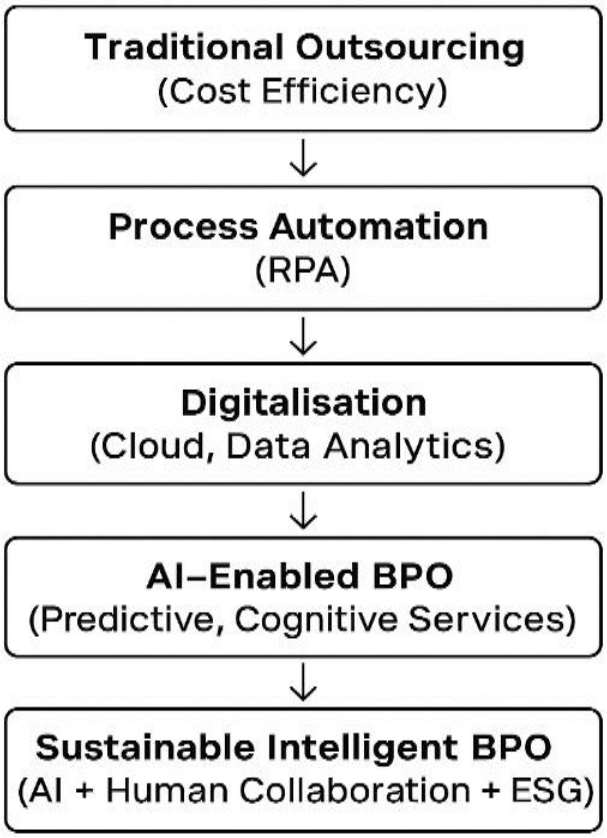

Fig. 1. Evolution of BPO and digitalisation (Conceptual overview). Source: author's conceptual illustration [2] [16] [21].

G. Research Gap and Contribution

The literature review indicates that most empirical studies on digital BPO have focused on large, mature economies, leaving smaller transitional markets such as Albania comparatively underexplored [30]. Moreover, relatively few comparative analyses examine the Western Balkans as an integrated region, particularly with respect to Kosovo, North Macedonia, and Montenegro. By incorporating a regional perspective alongside institutional analysis, this study addresses this gap and enhances understanding of how emerging economies leverage digital transformation to strengthen BPO competitiveness [21] [9].

III. Methodology

A. Research Approach and Design

This study adopts a *qualitative and descriptive–analytical approach* to examine how digitalisation influences Business Process Outsourcing (BPO) competitiveness in Albania and the wider Western Balkans. The study is explicitly framed as a desk-based policy and analytical investigation, relying exclusively on secondary data and without any primary data collection [21] [29] [30]. The qualitative orientation allows an in-depth exploration of institutional, economic, and technological factors shaping outsourcing development [21].

The research draws on secondary data from academic literature, institutional reports, and professional studies published between 2023 and 2025. This includes publications by the OECD, World Bank, European Commission, IBM, Accenture, KPMG, and UNCTAD. The combination of these diverse yet authoritative sources ensure triangulation, thereby enhancing the validity and reliability of the findings [29].

The analysis is structured around two complementary frameworks:

1) PEST analysis, to assess the macro-environmental dimensions political, economic, social, and technological affecting Albania's BPO ecosystem.

2) Comparative regional benchmarking, to evaluate Albania's performance against peer economies in the Western Balkans and Eastern Europe (Kosovo, North Macedonia, Montenegro, Serbia, Bulgaria, and Romania).

The study relies on recent institutional and industry reports published between 2023 and 2025, including sources from international organisations, consultancy firms, and technology providers. Reports dated 2025 are used explicitly as forward-looking policy and market outlooks rather than as peer-reviewed empirical evidence [21] [26]. These sources are employed to capture emerging trends in digital transformation, artificial intelligence adoption, and BPO restructuring, which are particularly relevant in rapidly evolving service sectors [16] [31]. To mitigate potential bias associated with corporate and consultancy reports, the analysis applies source triangulation by systematically cross-referencing findings from OECD, World Bank, European Commission, and UNCTAD publications [21] [29] [30] [26]. Consequently, forward-looking industry insights are used for contextualisation and scenario interpretation, while analytical conclusions are grounded primarily in internationally recognised institutional evidence [21] [30].

These frameworks allow a multidimensional understanding of digital transformation, integrating national and regional perspectives. The methodological framework and analytical tools applied in this study are summarised in Table II.

TABLE II. METHODOLOGICAL FRAMEWORK

Research Element	Description
Approach	Qualitative and descriptive–analytical research
Purpose	To analyse how digitalisation impacts BPO competitiveness in Albania and the Western Balkans
Data Sources	OECD, World Bank, IBM, Accenture, KPMG, EU Reports (2023–2025)
Data Collection	Desk research, document analysis, and synthesis of secondary data
Analytical Tools	PEST framework and comparative regional analysis
Geographical Scope	Albania, Kosovo, North Macedonia, Montenegro, Serbia, Bulgaria, Romania
Timeframe	2023–2025
Limitations	Reliance on secondary data; lack of primary interviews

B. Data Collection and Validation

Secondary data were selected for their reliability, accessibility, and relevance to the study's objectives. Inclusion criteria focused on three aspects: 1) credibility of the source, 2) thematic connection to BPO and digital transformation, and 3) the presence of recent (2023–2025) comparative data [21] [30].

The core datasets used in the analysis include major institutional publications addressing digital transformation and regional economic developments, complemented by industry-specific insights on technology adoption and outsourcing practices [21] [30] [9] [16] [2].

Triangulation was achieved through:

- Temporal triangulation: comparing multi-year data to detect trends (2023–2025) [21] [30].
- Source triangulation: was achieved by cross-referencing evidence from international institutions and regulatory bodies [21] [9] [30].
- Thematic triangulation: integrated academic, policy, and industry perspectives to ensure analytical coherence and reduce potential bias [5].

C. Analytical Process

The analytical process of this research followed five systematic stages, as illustrated in Fig. 2.

Fig. 2. Analytical process of the study. Source: author's elaboration [21] and [30].

D. Application of the PEST Framework

The PEST framework is central to this study's analysis, as it captures the macro-environmental conditions shaping BPO growth.

- Political Factors: governance, digital legislation, and EU integration policies [9].
- Economic Factors: GDP growth, FDI inflows, and fiscal incentives in outsourcing and ICT [29].

- Social Factors: workforce demographics, digital literacy, and migration [17].
- Technological Factors: broadband access, automation adoption, AI infrastructure [21] [16].

The relationship between digital infrastructure, automation, and BPO growth dynamics in Albania is further illustrated in Fig. 3. This framework provides a holistic perspective, identifying opportunities and constraints influencing Albania's competitiveness in digital outsourcing.

E. Comparative Regional Analysis

The comparative component benchmarks Albania against six economies Kosovo, North Macedonia, Montenegro, Serbia, Bulgaria, and Romania to assess its relative progress in digital readiness, labour costs, and AI adoption. The data from [21] and [29] provide comparable indicators across the region.

This dual analytical design (PEST + comparison) ensures depth and breadth, combining contextual insight with quantitative benchmarking.

F. Ethical Considerations

As the study relies exclusively on secondary sources, ethical risks are minimal. Nevertheless, all data have been cited accurately, and intellectual property rights respected in accordance with APA 7th referencing [21]. The author certifies that all interpretations are transparent, unbiased, and consistent with the original context of each source.

G. Limitations

While qualitative analysis provides rich interpretative value, the lack of primary data limits micro-level insights into firm-specific operations. Inconsistent data availability across Western Balkan states also constrains cross-country comparisons. However, triangulation mitigates these gaps by focusing on overlapping trends rather than absolute figures.

H. Summary of Methodological Contribution

This methodological framework bridges academic and policy analysis by linking macro-level reforms with sector-specific performance. The integration of PEST and comparative benchmarking enhances the explanatory power of the findings. This approach is particularly relevant for transitional economies where digitalisation, institutional development, and regional collaboration evolve simultaneously [29] [21].

IV. Findings and Discussion

A. Overview

The analysis of Business Process Outsourcing (BPO) in Albania and the Western Balkans shows that digitalisation has become a decisive factor for competitiveness in the post-pandemic economy. The application of the PEST framework and comparative benchmarking reveals a mixed but promising picture: political stability and EU integration reforms have facilitated industry growth, yet technological maturity, digital infrastructure, and skills development remain insufficient [21] [29]. The key political, economic, social, and technological factors influencing the Albanian BPO sector are summarised in Table III.

TABLE III. PEST Analysis for the Albanian BPO Sector (2023-2025)

Factor	Key Insights	Source
Political	Stable governance, EU integration reforms, improved digital legislation	[9]
Economic	GDP growth 3.2% (2025), increasing FDI, stable inflation (2.4%)	[29]
Social	Youth unemployment declining, multilingual workforce, brain drain challenges	[17]
Technological	Expansion of fibre-optic internet, early adoption of AI and RPA tools	[21]

Source: Author's synthesis [21] [9] [29].

B. Political Environment

Politically, Albania enjoys stability and an improving governance framework aligned with EU standards. The Digital Agenda 2022–2026 and participation in the EU4Digital Western Balkans Initiative have enhanced coordination in ICT and e-governance [9]. Institutional reforms have reduced administrative barriers and encouraged digital investment, but fragmentation and uneven implementation persist [21].

Comparative OECD assessments indicate that Albania demonstrates notable progress in digital governance reforms within the Western Balkan region [21]. Policy continuity and regional cooperation remain key to sustaining momentum [29].

C. Economic Factors

Albania's economy demonstrates steady growth and strong FDI inflows, especially in services and ICT. Recent economic indicators show GDP growth of 3.2% and foreign direct investment surpassing USD 1 billion, with 25% directed toward technology-driven sectors. Competitive labour costs, roughly 50% below EU averages, continue to attract BPO contracts in accounting, customer service, and data management [29].

Nevertheless, Albania's BPO market remains concentrated in low-value operations. In [18], the authors stress the need for diversification into analytics, AI integration, and financial services outsourcing. In [16], the authors observe that firms applying AI automation reduce operational costs by 20–30%, while achieving higher process accuracy. However, digital investment is mainly concentrated in Tirana, creating geographic inequality and limiting national capacity for expansion.

D. Social Factors

Social dynamics represent both strengths and weaknesses for Albania's outsourcing potential. A young and multilingual population provides a solid foundation for future digital development [17]. However, migration and skills mismatches persist, particularly in STEM-related fields. In [29], the authors report that 30% of ICT graduates immigrate annually to EU countries for better employment opportunities.

The EU4Digital programme has introduced training initiatives that promote digital literacy and cross-border mobility [9]. These efforts aim to harmonise skills across the

Western Balkans and integrate them into EU labour markets. In [32], the authors highlight that targeted reskilling in AI and automation could transform Albania's workforce into a regional digital talent hub.

E. Technological Factors

Technological readiness in Albania has improved markedly in recent years, although it remains below that of regional technological frontrunners [21]. Available indicators show that broadband coverage reached approximately 94% in 2024, with pilot 5G deployments operational in major urban centres, reflecting progress in core digital infrastructure [21]. However, comparative DESI indicators suggest that Albania exhibits lower performance in innovation capacity and advanced digital connectivity relative to Bulgaria and Romania, indicating persistent gaps in higher-order digital capabilities [9].

At the firm level, artificial intelligence adoption among Albanian BPO providers is estimated at around 35%, compared with higher adoption rates observed in Romania, Bulgaria, and Serbia [16]. This disparity highlights constraints related not only to technological availability but also to institutional and regulatory factors. In particular, the absence of comprehensive AI ethics guidelines and fully developed cybersecurity frameworks limits the depth of AI integration within enterprise operations [11].

Notwithstanding these constraints, emerging public–private partnerships within the Western Balkans Digital Initiative are contributing to the gradual reduction of technological gaps through shared cloud infrastructure, cross-border digital services, and the development of regional data centres [29]. These initiatives suggest that regional cooperation may play an important enabling role in accelerating technological upgrading and supporting the diffusion of advanced digital solutions within Albania's BPO sector.

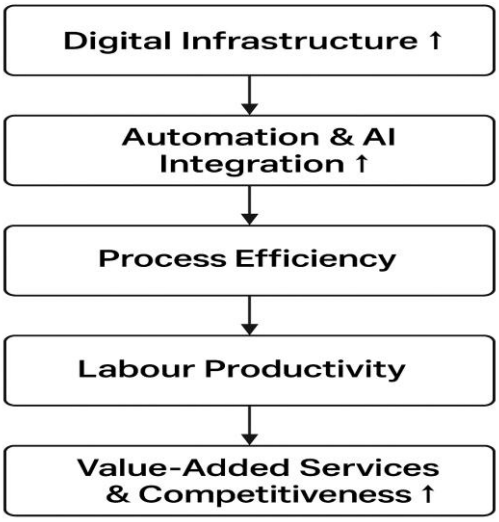

Fig. 3. Digitalisation impact on BPO growth in Albania. Source: author's conceptual model [2] [15].

F. Regional Comparison: Albania and its Peers

To assess Albania's relative position within the regional BPO landscape, a comparative evaluation was conducted across six neighbouring and peer economies: Kosovo, North Macedonia, Montenegro, Serbia, Bulgaria, and Romania. Table IV summarises key performance indicators related to labour costs, digital skills, foreign direct investment in BPO, and artificial intelligence adoption, providing a multidimensional perspective on regional competitiveness. A comparative overview of labour costs, digital skills, foreign direct investment, and AI adoption across Albania and selected regional economies is presented in Table IV.

TABLE IV. COMPARATIVE BPO PERFORMANCE INDICATORS: ALBANIA AND REGIONAL ECONOMIES (2024)

Indicator	Albania	Bulgaria	Romania	Serbia	Kosovo	North Macedonia	Montenegro	Source
Labour Cost Index	100	135	160	140	110	120	130	[21]
Digital Skills Index	68	74	77	70	63	65	67	[8]
FDI in BPO (USD m)	210	460	530	340	120	180	150	[30]
AI Adoption (%)	35	42	48	38	28	31	33	[16]

Source: [21] [30] [16] [8].

The comparative evidence indicates that Albania maintains a relative labour cost advantage compared to Bulgaria, Romania, and Serbia, reinforcing its attractiveness for cost-sensitive outsourcing activities [21]. However, this advantage is accompanied by moderate levels of digital skills and AI adoption, positioning Albania below the region's more technologically advanced BPO markets [16]. These findings suggest that cost competitiveness alone is insufficient to ensure long-term upgrading in digital BPO services.

Romania and Bulgaria demonstrate relatively higher levels of digital skills development and AI adoption compared to other economies in the region, supported by higher levels of foreign direct investment in the BPO sector [16] [29]. This combination reflects a more advanced transition toward value-added and knowledge-intensive outsourcing activities, consistent with later stages of digital transformation [21]. Serbia and North Macedonia occupy an intermediate position, combining moderate labour costs with improving digital skills and investment levels, indicating a gradual shift from cost-based to capability-driven BPO models [18] [26].

By contrast, Kosovo and Montenegro, despite maintaining comparatively lower labour costs, exhibit weaker performance in digital skills and AI adoption. This pattern highlights the limitations of cost-based competitiveness in the absence of sufficient technological capabilities and human capital development [30] [31]. The regional comparison therefore, reveals a structural trade-off: economies relying primarily on low labour costs face constraints in achieving sustainable BPO

competitiveness without parallel investments in digital infrastructure, skills formation, and innovation capacity [21] [5].

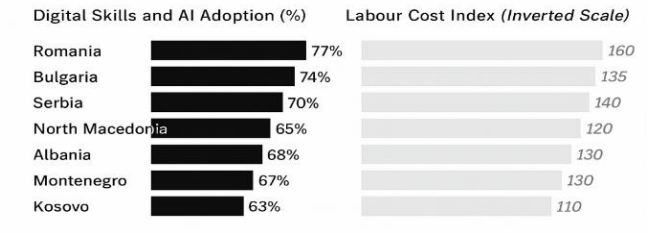

Fig. 4. Comparative digital readiness and cost competitiveness in the Western Balkans and Eastern Europe (2024). Source: [21] [30] [16] [8].

Fig. 4 complements the tabular analysis by illustrating the relationship between digital readiness and labour cost positioning across the region. The figure shows that economies with higher digital skills and AI adoption tend to be associated with higher labour costs, while lower-cost economies generally lag in advanced digital capabilities [21] [16]. Albania occupies a balanced but constrained position within this spectrum, with digital readiness exceeding that of Kosovo and Montenegro while remaining below Eastern European frontrunners [21] [29].

This intermediate positioning suggests that Albania has the potential to function as a regional bridge between cost-oriented Western Balkan economies and digitally advanced Eastern European outsourcing hubs, provided that sustained investments in human capital development, institutional coordination, and digital infrastructure are pursued [31] [26]. Overall, the regional evidence reinforces the argument that long-term BPO competitiveness increasingly depends on the alignment of institutional conditions, digital readiness, and firm-level capabilities rather than on cost advantages alone [21] [30]. These comparative insights feed directly into the conceptual framework presented in Fig. 5, which links institutional reform, digital investment, and human capital development to sustainable BPO growth.

G. Conceptual Integration

Fig. 5 synthesises the empirical findings and theoretical arguments of this study into an integrated conceptual framework that explains how digital BPO competitiveness emerges in an emerging economy context. The framework depicts a sequential and interdependent relationship between institutional alignment, digital infrastructure and innovation investment, artificial intelligence adoption in BPO operations, and human capital development, culminating in sustainable and value-added BPO competitiveness. By explicitly linking macro-level institutional conditions with micro-level firm capabilities, the model operationalizes the interaction between Institutional Theory and the Resource-Based View [9] [21] [5].

From an institutional perspective, political and regulatory alignment, particularly with EU digital governance frameworks, functions as an enabling condition that reduces uncertainty, strengthens enforcement capacity, and improves the predictability of the business environment [9] [21]. These institutional conditions influence firms' strategic decisions to invest in digital infrastructure and advanced technologies, including AI-enabled automation and data-driven service delivery [16]. In line with the Resource-Based View, such technological investments only translate into sustained competitive advantage when they are internalised as firm-specific capabilities, supported by organisational learning and skilled human capital [5] [31].

Fig. 5. Conceptual framework for the integration of business process outsourcing, artificial intelligence, and digital transformation. Source: Author's elaboration based on [21] [2] [15].

The framework further highlights the mediating role of human capital development in the digital transformation process. Investments in AI and digital infrastructure generate productivity gains and service upgrading only when firms possess the absorptive capacity to integrate these technologies into core business processes [31] [21]. This insight reinforces the argument that digital competitiveness is not driven by technology adoption alone, but by the interaction between institutional conditions and firm-level resource development [26].

Importantly, the conceptual framework moves beyond a descriptive representation by specifying directional and causal relationships that can be empirically examined. Institutional alignment is modelled as an exogenous enabling variable, digital infrastructure and AI adoption as intermediate mechanisms, and firm-level capabilities and BPO competitiveness as outcome variables. These relationships provide a clear basis for operationalization and hypothesis testing in future quantitative or mixed-methods research, for example, by examining the impact of regulatory alignment on AI adoption rates or the mediating effect of human capital between digital investment and BPO productivity [21] [30].

Finally, the conceptual relationships illustrated in Fig. 5 are fully aligned with the research propositions (P1–P3) developed in Section II(F). Together, the framework and propositions offer a transferable analytical lens for analysing digital BPO upgrading in other Western Balkan and emerging economies, while also providing practical guidance for policymakers and practitioners seeking to align institutional reforms, skills development, and technological investment in support of sustainable BPO growth [21] [26].

H. Discussion Summary

The integrated application of the PEST framework with the Resource-Based View and Institutional Theory reveals well-

defined causal mechanisms underpinning digital BPO competitiveness. From an institutional perspective, political alignment with EU digital governance frameworks reduces regulatory uncertainty and enhances enforcement capacity, thereby lowering barriers to the adoption of advanced digital technologies such as artificial intelligence and cloud-based systems [9] [21]. This institutional stability enables firms to commit resources to digital infrastructure and to transform technological inputs into firm-specific strategic assets, consistent with the logic of the Resource-Based View [21] [5].

From an economic standpoint, the findings demonstrate that although low labour costs continue to attract outsourcing activities, they do not constitute a sustainable source of competitive advantage when considered in isolation [21]. Instead, institutional reforms and targeted fiscal incentives interact with technological conditions by shaping firms' incentives and capacity to invest in automation and AI adoption [4] [16]. Social factors—particularly the availability of skilled human capital and advanced digital competencies—play a mediating role in this process by determining whether technological investments can be internalised as organisational capabilities rather than remaining operational tools [17] [19] [31].

A central insight emerging from the analysis is the structural trade-off between maintaining cost competitiveness and investing in high-skilled, and therefore more expensive, digital and AI-related human capital [5] [21]. While cost advantages facilitate entry and short-term expansion within global outsourcing markets, long-term digital upgrading increasingly depends on firms' ability to absorb higher labour costs associated with advanced skills, organisational learning, and innovation capacity [16] [31]. This tension underscores the limitations of a purely cost-based outsourcing model and highlights the need for a strategic transition toward capability-driven growth supported by institutional alignment and sustained human capital investment [9] [26] [30].

Importantly, technological factors do not emerge as independent drivers of competitiveness, but rather as outcomes of interactions between institutional conditions and firm-level resource development [21]. Political and regulatory reforms (PEST–Political) create the conditions for firms to accumulate digital and AI-related capabilities (RBV–Technological), while economic and social factors influence the speed and depth of this transformation [5] [26]. This interaction explains why economies with broadly similar cost structures can experience markedly different digital transformation trajectories within the BPO sector [21] [30].

From a theoretical standpoint, the Albanian case provides evidence that institutional alignment alone is insufficient to generate sustainable competitive advantage in the absence of firm-level absorptive capacity. This finding refines the Resource-Based View by emphasising the mediating role of institutions in shaping the value and deployability of firm-specific resources in emerging economies. Simultaneously, it extends Institutional Theory by demonstrating how governance frameworks interact with firm-level heterogeneity to produce divergent digital upgrading outcomes, even under comparable regulatory conditions [21] [5] [30].

V. Conclusion

A. Summary of Findings

The findings of this study offer important theoretical implications for understanding digital transformation in the BPO sector of emerging and transitional economies. By integrating the Resource-Based View and Institutional Theory, the analysis demonstrates that sustainable competitive advantage does not arise from cost efficiency alone, but from the interaction between institutional alignment and firm-level capability development. From a Resource-Based View perspective, advanced digital skills, organisational learning, and innovation capacity emerge as critical intangible resources that determine firms' ability to upgrade toward higher value-added BPO services [21]. However, the Albanian case shows that these resources cannot be developed or leveraged effectively in the absence of supportive institutional frameworks.

Institutional Theory further explains how regulatory alignment with EU digital governance frameworks, policy coherence, and enforcement capacity shape firms' incentives and absorptive capacity for adopting artificial intelligence and automation technologies [5] [9]. The evidence from Albania refines existing theoretical debates by illustrating that institutional reforms function primarily as enabling mechanisms rather than direct sources of competitiveness. In digitally transforming emerging economies, institutions condition the extent to which firms can convert technological investments into strategic resources, thereby mediating the outcomes predicted by the Resource-Based View [21] [29].

From a practical and policy perspective, the study provides actionable insights for policymakers and practitioners seeking to foster sustainable BPO development. The results indicate that reliance on low labour costs and fiscal incentives, while effective in attracting initial outsourcing activity, is insufficient for long-term competitiveness without parallel investments in digital skills, innovation ecosystems, and governance capacity [29]. Strengthening vocational and higher education programmes in AI, data analytics, and cybersecurity, alongside improving institutional coordination, is therefore essential for enabling firms to move up the BPO value chain [17] [32].

Moreover, the comparative regional analysis highlights the importance of positioning Albania within a broader Western Balkan digital ecosystem. As an intermediate economy between cost-oriented peers and digitally advanced Eastern European markets, Albania has the potential to act as a regional bridge if national digital strategies are aligned with regional integration initiatives such as EU4Digital and the Regional Economic Area [9] [29]. The conceptual model proposed in this study (see Fig. 5) offers a transferable framework for other Western Balkan economies, providing guidance on how institutional reforms, human capital development, and technological investment can be jointly leveraged to support value-added BPO growth and regional convergence [21] [26].

B. Strategic Directions

Based on the analysis, six strategic directions are recommended to advance Albania's BPO and digital transformation agenda:

1) Enhance digital infrastructure and regional connectivity: Accelerate broadband and 5G deployment beyond Tirana through public–private partnerships, focusing on regional cities and cross-border ICT projects [29].

2) Institutionalise digital governance: Establish a central Digital Transformation Authority to coordinate policy implementation and monitor progress under EU-aligned digital frameworks [21].

3) Develop and retain human capital: Integrate AI, data analytics, and cybersecurity into university curricula. Strengthen vocational training programmes and provide fiscal incentives for companies investing in workforce upskilling [9].

4) Promote Research and Innovation: Create Digital Innovation Hubs in cooperation with Horizon Europe and regional universities to foster applied research, start-up growth, and knowledge transfer [18].

5) Foster regional collaboration: Expand cooperation with neighbouring Western Balkan economies (Kosovo, North Macedonia, Montenegro, and Serbia) through joint AI hubs, shared cybersecurity networks, and regional outsourcing consortia [26].

6) Align BPO development with sustainability and ESG standards: Introduce green outsourcing incentives and include sustainability metrics in national digital strategies. Aligning with the EU Green Deal will ensure environmentally responsible and socially inclusive BPO growth [11].

C. Theoretical and Practical Implications

The integrated application of the *Resource-Based View and Institutional Theory* provides a coherent analytical lens for interpreting Albania's digital transformation in the BPO sector. From a Resource-Based View perspective, sustainable competitive advantage is derived from the accumulation and effective deployment of intangible firm-level resources, including advanced digital skills, organisational knowledge, and innovation capabilities [21]. Institutional Theory complements this view by explaining how governance structures, regulatory alignment, and normative frameworks condition firms' ability to develop and leverage such resources, thereby facilitating or constraining digital adoption and upgrading processes [5].

From a practical and policy-oriented perspective, the findings demonstrate that digital transformation can function as a catalyst for socio-economic development in transitional economies when institutional alignment and human capital development progress in tandem. The conceptual model proposed in this study (see Fig. 5) offers a transferable analytical framework that can be applied across the Western Balkans to guide policymakers and practitioners in designing strategies that align national digital agendas with regional integration initiatives. By linking institutional reforms to firm-level capability development, the model provides actionable insights for fostering value-added BPO services and strengthening regional digital competitiveness.

D. Limitations and Future Research

While the qualitative research design provides rich analytical insights, the exclusive reliance on secondary data constrains empirical validation at the firm level. Future research could adopt mixed methods approaches by incorporating surveys and semi-structured interviews with BPO managers, policymakers, and industry stakeholders to test and refine the proposed conceptual relationships. In addition, longitudinal analyses extending beyond 2025 would enable systematic assessment of post-transformation dynamics, including the evolution of AI adoption, productivity gains, and organisational capability development [29].

Further research could also expand the social dimension of digital BPO transformation by examining issues of gender inclusion, workforce diversity, and job quality in digitally enabled service sectors. Existing evidence suggests that inclusive digitalisation enhances innovation capacity and supports more equitable labour market participation [26]. Finally, comparative studies involving EU candidate and Western Balkan economies could provide deeper insights into how regional cooperation, regulatory convergence, and shared digital initiatives influence competitiveness and economic convergence across emerging markets [26] [30].

E. Concluding Remarks

Albania's BPO sector stands at a strategic crossroads. While political alignment with EU frameworks, cost competitiveness, and a growing digital ecosystem provide a solid foundation for development, the sustainability of this trajectory depends on decisive investment in education, advanced digital skills, and effective governance structures [9] [21]. Without such coordinated action, the sector risks remaining locked into low-value outsourcing activities despite favourable macroeconomic conditions [5] [30].

The findings confirm that digital transformation in the BPO sector is not a purely technological process, but a structural evolution shaped by the interaction between institutional alignment, human capital development, and firm-level capabilities [21] [5]. By fostering innovation-oriented policies, strengthening regional partnerships, and prioritising skills upgrading, Albania can transition from a cost-based outsourcing destination toward a digitally integrated, value-added BPO hub, contributing to long-term national competitiveness and regional economic resilience [26] [30].

Framework for Ethical Acquisition of User-Data to Improve Recommendation Models' Accuracy in Digital Systems

Shaheer Hussain Qazi[1], M. Batumalay[2], Asheer Hussain[3], Ali Abbas[4]
Faculty of Data Science and Information Technology, INTI International University, Nilai, Malaysia[1, 2]
Faculty of Engineering and Technology, HITEC University, Taxila, Pakistan[3, 4]

***Abstract*—The modern digital ecosystem has evolved into a pervasive, opaque system where platforms collect and infer personal data through nearly every online action, search queries, email content, browsing history, and app usage, without transparency. Justified as a means to deliver "relevant" content and ads, this approach undermines user privacy, introduces bias, and normalizes surveillance. Through a comprehensive literature review, this study sought to: critically analyze the current landscape of user tracking, profiling, and privacy violations in online platforms and to evaluate the impact of existing legal, technical, and platform-driven mechanisms like GDPR, CCPA, ATT, and Privacy Sandbox in protecting user autonomy. It was learned that the current frameworks fall short by mostly being policy-based and having hard-to-access user controls. And a major flaw in existing systems is the assumption that all digital behavior reflects actual user preference, overlooking shared devices, accidental clicks, and non-user actions. To validate these insights, a survey of 572 privacy-aware participants was conducted, where nearly 71% preferring a proactive solution over passive regulatory frameworks and hard-to-navigate privacy menus/dashboards. Building on these findings, this study proposes a framework: a digital platform where individuals actively create and manage modular preference profiles, categorized by app type or content domain, which can be selectively and consensually shared with platforms in a standardized format. This concept facilitates high-quality, context-rich datasets for algorithms, enhancing personalization and recommendation models' accuracy and performance. By shifting from forced surveillance to invited participation, this approach advances ethical data-sourcing, enhances algorithmic accuracy, and aligns with SDG 9 and SDG 16 by prioritizing responsible digital solutions, process innovation, and safeguarding user autonomy.**

Keywords*—Data handling; data privacy; online tracking; data collection; user profiling; model accuracy; ethical AdTech; open standards; user autonomy; SDG 9; SDG 16; process innovation

I. Introduction

Today's online environment is mostly about surveillance advertising. You can wish for something, watch a video, or just get news somewhere on the internet, and in either scenario, there is a greater likelihood that you will have your activity monitored, not only on that website, but on the entire internet environment. This mass cyber surveillance is traditionally described as a means to provide users with "more relevant Content". This justification is no longer accepted by privacy experts, Data Protection Regulators, and increasingly by everyday users.

Regulations like the EU's General Data Protection Regulation (GDPR), America's California Consumer Privacy Act (CCPA), Apple's App Tracking Transparency (ATT), and Google's Privacy Sandbox have taken steps to curb invasive data collection. While such efforts have made some progress on the transparency and control fronts, they largely shy away from ending the underlying machinery of surveillance capitalism. Instead, they've merely shifted how tracking is accomplished rather than whether it is accomplished. For example, ATT prevents third-party tracking on Apple devices but continues to allow Apple to build behavioral profiles in-house. In a similar manner, Privacy Sandbox prevents cross-site tracking while still allowing ad targeting systems based on aggregated user information.

The contemporary online advertising economy is based on users consenting, at least implicitly, to being monitored by virtue of accessing digital services. This consent is typically buried in unreadable terms of use or covered by manipulative interface design (a "dark pattern"). The result is that users are progressively profiled on the basis of search history, device use, app use, online and offline interpersonal interaction, geolocation, and even email content with little or no awareness or control. User's personal data is no more personal due to this excessive nonconsensual data collection.

These have effects greater than nuisance. Incorrect or misattributed profiling will warp the user experience, e.g., a Beach Holiday ad having inappropriate images displayed in a game application that is being played on a kid's device, or a shared device's search history leading to irrelevant or even inappropriate ad suggestions. Moreover, users' interests are usually deduced from noisy data, misplaced clicks, one-time browse for an alternative, or passing interest, thus constructing a tilted digital profile of the user different from their actual interest.

Despite data protection laws and consent mechanisms, most tracking is technically sophisticated and legally evasive. Companies get to play by the rule book without playing by its spirit. Fingerprinting, real-time bidding (RTB), and server-side tracking tend to get round even very stringent consent mechanisms. Law is either too slow to keep up, or too vague to effectively implement. And most importantly, they rarely ever give users a real choice: opting out typically means denying a service or receiving generic content and advertising. This is an extremely worrying scenario, not only in terms of privacy, but

also on a system design level. It is based on nonconsensual data inference and on imbalanced power dynamics between users and platforms.

It is important to clarify the scope and intent of this work. This study does not propose a new recommendation algorithm, personalization pipeline, or machine learning architecture, nor does it seek to benchmark predictive performance against existing models. Instead, the contribution lies at an earlier and often overlooked stage of the personalization lifecycle: the ethical and technical acquisition of preference data itself. While existing consent dashboards, preference managers, and data portability tools focus primarily on regulatory compliance or post-hoc control, it continues to rely on behaviorally inferred, noisy, and platform-owned data. In contrast, the framework proposed here introduces a user-authored, platform-agnostic preference declaration mechanism designed to replace inference with explicit intent. The central claim is not algorithmic novelty, but that recommendation and analytical models, regardless of their internal design, benefit structurally from cleaner, context-aware, and voluntarily provided accurate preference data.

This study pursues five core objectives:

- To critically analyze the current landscape of user tracking, profiling, and privacy violations in online platforms and advertising ecosystems.
- To evaluate the strengths and limitations of existing legal, technical, and platform-driven mechanisms like GDPR, CCPA, ATT, and Privacy Sandbox in protecting user autonomy through literature review.
- To conduct a survey to get real responses from people that have knowledge of the different Data Protection Acts, Online Data Privacy, and modern Advertising industry.
- To propose a user-centric conceptual framework for preference data sharing system that is consensual, transparent, secure, and technically feasible. This approach not only respects control by users, but it also has the potential to yield more accurate data and truly personalized relevance.
- To design a simple Technical Demo of the proposed solution. The solution is to be kept simple and easy to implement. So, it can be created by any organization or developer. Standardized downloadable format for easy integration.

Building on these objectives, this study contributes a conceptual and technical framework for ethical, user-governed preference data acquisition that addresses both privacy and system-performance limitations of contemporary personalization infrastructures. In place of being passively tracked for data with an effort to guess what they would like, users would explicitly state what their interests are in a structured and shareable form. For building a social profile, users may have multiple interest profiles, customized for specific contexts like shopping, social, video content, or games, and apply them selectively to apps or sites. By enabling individuals to explicitly construct, manage, and selectively share structured preference profiles, the framework reduces reliance on inferred behavioral signals that are frequently noisy, contextually misleading, or generated without meaningful consent. The proposed approach has implications beyond privacy protection alone: it offers a practical pathway toward higher-quality datasets for recommendation and data analysis models, reduces preprocessing overhead associated with behavioral noise, and supports interoperability through standardized, platform-independent data formats. From a broader perspective, the framework advances responsible digital system design by aligning personalization mechanisms with user autonomy, informed consent, and ethical data sourcing principles.

The remainder of the study is organized as follows: Section II reviews existing literature on behavioral tracking, privacy regulation, and personalization systems, highlighting conceptual and technical gaps. Section III describes the research methodology and survey design used to gather real users' views. Section IV presents results and discussion of empirical findings. Section V presents the proposed user-governed preference framework, its design principles, and integration patterns. It also presents a simple website for demonstrating the framework's workings. Section VI discusses the challenges and limitations of such a framework. Section VII suggests implementation roadmap and recommendations for future work. Finally, Section VIII concludes the study.

II. Literature Review

There has been considerable effort on how modern digital advertising platforms use machine learning and behavioral data for targeting, with inherent trade-offs to systemic inefficiency and with privacy. In [1], the authors built a twin-framework consisting of an auction mechanism and machine learning to examine in-app advertising on mobile devices in Asia. Surprisingly, while improving click-through rates by over 66.80% when compared to a baseline, [1] discovered that optimal ad-network revenues may not always go with optimal behavioral targeting regime. This is a phenomenon reflecting a market misalignment where privacy-preserving strategies may, paradoxically, better match with greater interest of users as well as long-term platform stability than with high-dimensional personalization systems.

On the social media front, [2] examined how strong consumer–brand relationship can overcome subjective risks in personalized advertising. Such an experiment confirmed high levels of affiliation countering concerns over privacy, while poor connections drive resistance, with indiscriminate targeting likely to backfire on fragmented audiences. In support, [3] also provided evidence that personalized advertising has a positive effect on value perceived and purchase intention, but only with low concerns over privacy. The risk is that intrusive targeting will destroy campaigns, and in particular when communicated covertly or in an unsuitable manner. Political advertising based on personality was examined by [4], with matching users' psychographic profiles showing a measurable effect on persuasion. These results also attest to escalating sophistication in targeting conduct, as well as raising ethical concerns, when conducted covertly and without users' consent.

Even as platforms try in the direction of transparency, tools prove to be inadequate. Apple's Privacy labels, intended to make data more transparent, have been found by [5] to be poorly readable by users. Participants in that research were baffled by jargon and structural inconsistencies between app permissions and data disclosures, cutting off its day-to-day usefulness. This is representative of larger concerns addressed in [6], where post-GDPR web ecosystem continues to reveal glaring shortcomings. Although formal transparency was increased by that regulation, real usability and accessibility of data rights remain absent, at times even actively disenabled by "dark patterns".

More structural analysis is offered by [7], with personal information introduced not as a commodity in and by itself, but as a source for valuation regimes for Big Tech. As explained, "Techcraft" is how these companies force engagement toward predictive values on an economic level, eliminating concerns with consent or ownership altogether. This deeper structural development is behind this argument for redesigning value extraction from users' data, in aid of alternative systems such as those offered here. Attempts at syntheses and coordination on research in online behavioral advertising's distributed landscape are offered by [8]. These synthesize nearly two decades' worth of research and suggest a shortfall of integrative direction, and issue a call for integrative strategies and enhanced theory-based foundations. In contrast, [9] offers a behemoth, curated database of over a million privacy policies and reveals how these have progressively become more impenetrable over recent years. Despite policy measures like the GDPR, underlying disclosures continue to remain absent or obfuscated, suggesting a gap between practice and policy.

In [10], Protection Motivation Theory (PMT) was employed to study privacy practice and concluded that even when users perceive threats as serious, they perceive themselves to be powerless when addressing them. The powerlessness, combined with low actual-world sensitive data protection effort (e.g., cookie deleting) exhibits one deficit in empowerment as much as system design. The framework here in this study addresses this very question posed by [10]. Strategically, [11] analyzed how firms diverge with data strategy, showing how competition involving regulatory constraint and consumer mistrust produces different organizational responses, anything from aggressive monetization to defensive data sharing. Work here notes that concern with the privacy-performance trade-off is not one-size-fits-all and that company strategy has to take both ethical design as much as technical innovation into consideration. Computational research on predicting users' responses was summarized by [12], where the authors reported on pervasiveness in the environment by ML models. Technically, as impressive as this research is, it omits explorations on transparency or on augmenting user control, and thus exhibits that while algorithmic efficiency improves, that on trust, as much as compliance with regulations, lags behind.

The state of tracking in the post-cookie era was investigated in detail by [13], with an outcome such that tracker methods have migrated towards stateless ones like fingerprinting, ID leakage, and ID synchronization. Most disconcertingly, over 75% is taking place before users have even had a choice to use a cookie, or while opting-out actively. This helps to firmly substantiate this research's first hypothesis, that consent mechanisms are ineffective, and tracking has migrated towards more long-term and invisible methods. This study provided key empirical evidence for this theory that consent banners, as presently implemented, are symbolic rather than real. On the other hand, [14] took a human-focused approach, analyzing how users use privacy-enhancing technologies (PETs) and finding a broad disconnect between what sites are offering and what users use. Based on the survey by [14], it was concluded that most users are becoming educated on privacy features through unofficial sources (friends, relatives, etc.), suggesting a systemic failure with current systems to empower users. The study provides an added insightful perspective for this research in that it helps to illustrate the futility of current PET integrations, once again supporting a shift towards more open and consensual data sharing systems.

The behavioral impacts of personalized advertising are examined by [15] and show persuasive possibilities as well as the dangers of online behavioral advertising (OBA). Using SEM methodology allows systematic observation involving the double effect: personalization maximizes engagement, but ad avoidance is strongly implicated with concern about privacy. Despite its consumer-behavior orientation, it helps to identify how data exploitation strategies influence user trust as well as behavior, again affirming ethical redesigning preference data-sharing systems as a necessity.

On the development front, [16] they consider how ad networks target app developers with UI framing and nudging. Developers preferred less intrusive types of adverts when subjected to more transparent effects on privacy. This introduces an influential stakeholder, the developer, to the world of privacy. It is germane because current systems do not even provide for how backend decisions by developers shift users' data exposure. This discovery highlights how much ethical nudging by developers at a holistic level is critical. The authors concluded their findings by saying that "the developers need transparent options". And that is exactly what this proposed framework is. It does gives control in the users' hands and provides the developers and all other entities involved here with accurate data directly from the users themselves.

On the other hand, [17] takes a macroeconomic view of GDPR and argues that it has de facto concentrated monopolists like Google and Facebook. The paper attributes regulatory efforts to competition concerns, hypothesizing that current data protection laws, for all they benefit privacy, have enabled data power to shift towards accumulating in its hands. This is a sober reminder: unless novel models disrupting data collection monopolies are introduced, regulation alone may solidify the very mechanisms it aims to regulate. By contrast, [18] conduct a technical analysis of Apple's ATT and Privacy Nutrition Labels and report partial success. While tracking by IDFA has diminished, fingerprinting and cohort-based tracking remain unabated. Some apps even use backend logic or server-side code to circumvent limitations. These developments highlight the need for more transparent, enforceable, and attestable privacy mechanisms. Furthermore, the unclear nature of some disclosures also presents a case for a system-enforced, user-transparent privacy mechanism.

Adding more evidence to these claims, [19] also illustrates that Android apps largely engage in third-party tracking without consent, in violation of GDPR and UK privacy laws. Tracking libraries offload the burden on developers with little support or compliance frameworks. This is a systemic fault, everyone is guilty, no one is in charge, further supporting this study's approach of compliance by design frameworks. An online survey was conducted by [20] to examine how users perceive algorithmic profiling in Facebook. The findings illustrate users often do not appreciate or mistrust categories inferred to profile them, and there is a lack of transparency and an emotional disaffection with profiling systems. The description "algorithmic disillusionment" provided by [20] is particularly insightful; without users' comprehension or trust in algorithmic systems, consent is invalid. The overall message from [20] is the problem addressed by this study, which is that the users are tracked through their usage of the platform, in order to profile them, which inevitably results to inaccurate profiles. Then, [21] provide an exploration into the legality behind Real-Time Bidding (RTB), finding it by its very nature inconsistent with GDPR because of its inability to secure a legal basis for data processing, inability to meet transparency requirements, and inherent insecurity. A direct source of validation for a fundamental argument made by this research, by their legal analysis, is that AdTech infrastructure is, by its nature, incompatible with legal and ethical standards. Therefore, the regulations are not enough to secure a user's data.

On analyzing mobile and online environments' privacy dynamics, several studies have offered critical observations regarding digital platforms' management of users' information and its impact on the protection of privacy.

The research in [22] leverages Android and iOS apps' comparative privacy capabilities and reveals unsettling behaviors on both platforms. Third-party tracking, as well as sharing unique identifiers, were both prevalent, even among apps designed for children. While there was less advertising-based tracking on iOS apps, they were discovered to have more frequent access to kids' devices' locations than Android apps. This renders simplistic assumptions about the superiority of one platform's way over that of its competitor, and addresses the challenges that both platforms have compliance with privacy legislation such as GDPR. The evidence and analysis provided by [22] align with this study's underlying concerns, as pervasive disrespect for privacy legislation addresses the pressing necessity for a better privacy solution based on transparency and consent.

Likewise, [23] investigation on how users' opt-out of tracking cookies is impacted by legal and technical competence in terms of data collection highlights how enabling legal competence has encouraged consumers to actively opt out from data collection actions. Especially in recent years with such legislation as GDPR aimed at enabling consumers to exert greater control over personal data, the studies highlight that consumers are more likely to act (for their own online safety) when they have information about what legal ramifications follow data collection, and this serves to further highlight how better education for users is needed in conjunction with implementing privacy legislation. This aligns with the goal of creating systems that not only adhere to legal requirements but also empower users with greater choice and understanding. On a technical note, [24] demonstrates how conclusions are drawn differently when popular automatic crawlers are utilized compared to more realistic configurations for making measurements on the web in terms of privacy. The researchers argue that existing measuring tools are not able to adequately mimic actual users' experiences, and partial or incomplete conclusions form as a result. The research highlights that unless tools are adapted to actual users' action, seminal threats to privacy can be overlooked. This highlights a glaring shortfall in how research on privacy is conducted and aligns with the need for better, more accurate, and people-oriented methodologies for measuring privacy, an area on which this research aims to contribute forward-looking responses.

The use by online advertising of cookies is analyzed by [25] in considerable detail, by laying out how cookies form an extensive digital market infrastructure. The employment as a building element for online marketing and tracking by cookies is challenged here, with doubts over such systems' viability, particularly in this day when increased regulatory scrutiny exists. This consideration on "datafication" on human action is an important one in balancing trade-offs over commercialization of data and privacy. This research lends weight to concerns over having to rebuild ethics and operating procedures for tracking data and calls for innovative paradigms to move forward beyond an established cookie paradigm. Another critical analysis on how adoption has been impacted by GDPR is provided by [26], with e-commerce revenues and pageviews down by 12% when implemented. This economic analysis demonstrates that privacy regulations, while crucial for consumer protection, also carry real consequences for website performance and revenue. The findings here are key as these reflect more subtle consideration for trade-offs over protection for people's financial performance as well as people's privacy, an issue at the core of this research. By looking at techniques that minimize intrusions on people's privacy without sacrificing functionality, this research tries better to balance people's needs for protection of information with usability.

For further evidence supporting the whole regulatory framework, [27] study the impact of GDPR's opt-in principle, and conclude that it reduced consumers by 12.5%, with the remaining consumers becoming more traceable and therefore more valued by advertisers. The impact is a demonstration of the perverse effect of privacy legislation, whereby users of privacy influence others' actions, to advertisers' benefit. It is representative of the need for more sophisticated models for users' consent, that are able to exclude such privacy spillovers while maintaining control by users over information. One such design area for privacy features was proposed by [28], with particular consideration for the point that users struggle with getting around privacy features on the Internet of Things (IoT). This theoretical framework [28] proposed on building effective privacy features can also apply to other platforms, as an inspiration to building systems offering users more control over information regarding them. The idea behind this user-centered design is at the heart of the proposed research in that it is trying to build a system that not only complies with protocols on privacy but also enhances the user experience with open and

informed choice-making that users themselves take and communicate to platforms on voluntary grounds.

The dynamics behind cookie consent under GDPR compliance have been studied intensively by [29] and [30]. In [29], the researchers were interested in how cookie banners fail to provide users with adequate and accurate information to ensure consent, with an enormous 89% of banners in breach of legislation. This research frankly challenges the validity of current consent mechanisms on grounds of a presumed deficit in transparency and linguistic abuse as key barriers to users' comprehension. Conversely, [30] provides an engineering-based answer in the form of the CookieBlock add-on, grouping cookies automatically and imposing GDPR compliance. The research presents an implementable answer to concerns raised by research such as that by [29], taking into consideration how much scope there exists for tools to automatically assist users' privacy regardless of website cooperation.

On a slightly different subject, [31] investigated online student and parent cyberbullying behavior with an extension of the Theory of Planned Behavior (TPB) with a new construct, cyber parenting, to better explain online conduct. Its findings indicate a growing need for healthy digital conduct and surveillance, particularly by and on behalf of younger users and parents. This behavioral aspect has special relevance to the modern debate over digital marketing conduct now, where users' conduct, all too often removed from context or misinterpreted, fuels sneaky preference profiles. Just like how research by [31] demands worth from precise, conduct-informed data-gathering with regard to productive insight, this current concept proposes an alternative paradigm where users explicitly articulate ad/content interest themselves. Digital literacy and clear policies are necessary in this era. The proposed framework here avoids such artifacts like device-shared misguided presumptions or misclicks and reinstates users' agency, in line with the overall goal of ethical digital practice.

The comprehensive 2023 survey of [32] on American views of data privacy reveals a widespread erosion of public trust and a deep sense of powerlessness among users in the face of large-scale data collection practices. With 81% of respondents expressing concern over how companies use their data and 73% admitting they feel little to no control over that data, the findings highlight a pressing contradiction between user expectations of autonomy and the opaque, algorithm-driven surveillance ecosystems currently in place. Even more striking is the nearly universal concern over data practices affecting children, 89% worry about social platforms holding personal information on minors, and 85% object to advertisers using behavioral data to target young users. As platforms increasingly integrate AI to personalize content, nearly half (48%) of Americans find such applications unacceptable, yet remain trapped in systems where opting out is either obscured or functionally impossible.

Lastly, [33] offers a better perspective into the current global perception and operational stance on digital privacy, reinforcing the urgency and credibility of user-centric data governance models. With over 2,600 respondents across 12 countries, the study identifies strong global support for privacy legislation, 86% of organizations now view such regulations positively, marking a noticeable year-over-year increase. This reinforces that companies are not just legally compelled but also strategically motivated to respect user privacy. At the same time, nearly all participants (96%) asserted that privacy investments yield greater benefits than costs, underscoring a growing recognition that responsible data practices are not a trade-off but a competitive advantage. The study's findings validate the broader shift in enterprise thinking, which gives strong credence to the need for a transparent, structured, and user-authored preference platform as both a privacy measure and an ethical data-sharing personalization solution.

A comparative analysis of existing personalization, privacy, and tracking mitigation approaches versus the proposed user-governed preference framework is summarized in Table I below. Collectively, the reviewed literature demonstrates that contemporary personalization and advertising systems are constrained by a shared structural dependency on inferred behavioral data. Across regulatory, technical, economic, and human-centered perspectives, existing approaches attempt to mitigate harm through transparency tools, consent mechanisms, anonymization techniques, or post-collection controls. However, these interventions operate downstream of the core design assumption that user preferences must be *observed*, *predicted*, or *approximated* from activity traces. This assumption persists even when tracking is partially restricted, anonymized, or made less identifiable, resulting in persistent noise, contextual misinterpretation, and diminished user trust. The literature, therefore, converges on a common limitation: current systems focus on controlling or obscuring data collection practices rather than rethinking the origin and authorship of preference data itself.

Moreover, while several tools and extensions aim to block, reduce, or anonymize tracking, they remain platform-specific, require continuous maintenance by developers or organizations, and frequently shift the burden of privacy protection onto users without offering a constructive alternative. Anonymization-based approaches, while reducing identifiability, often degrade content relevance and recommendation quality, particularly in contexts involving shared devices or younger users, where contextual sensitivity is critical. Notably absent from the literature is a system-level framework that replaces behavioral inference with explicit, user-authored preference declaration in a standardized and portable format. This gap motivates the present work, which reframes ethical personalization not as a problem of limiting surveillance, but as one of redesigning how preference data is generated, owned, and shared at the source.

The following sections, namely subsection “A” and subsection “B” are extended explanations for the conclusive data in Table I.

TABLE I. COMPARATIVE ANALYSIS OF EXISTING PERSONALIZATION, PRIVACY, AND TRACKING MITIGATION APPROACHES VERSUS THE PROPOSED USER-GOVERNED PREFERENCE FRAMEWORK

Dimension	Behavioral Tracking–Based Personalization	Regulatory & Consent-Based Mechanisms	Privacy Tools & Tracking Blockers	Anonymization & Aggregation Approaches	Proposed User-Governed Preference Framework
Primary Data Source	Implicit behavioral signals (clicks, views, dwell time, device data)	Same as tracking systems, with legal constraints	Same as tracking systems, partially suppressed	Behavioral data after de-identification	**Explicit, user-authored preference declarations**
Mode of Data Acquisition	Passive, continuous surveillance	Passive collection with formal consent	Passive collection with selective blocking	Passive collection with identity masking	**Active, voluntary user input**
User Awareness	Low to none	Limited, often symbolic	Moderate, tool-dependent	Low	**High and intentional**
User Control Granularity	None	Coarse (opt-in / opt-out)	Binary (block / allow)	None	**Fine-grained, category- and context-level**
Reliance on Behavioral Inference	Core dependency	Core dependency	Core dependency	Core dependency	**None**
Data Noise & Misattribution	High (misclicks, shared devices, incidental actions)	High	High	High	**Low (self-declared intent)**
Context Sensitivity	Poor	Poor	Poor	Poor	**Explicitly contextual via multiple profiles**
Impact on Recommendation Accuracy	Variable, often inflated by noise	Unchanged	Often degraded	Often degraded	**Improved via cleaner input data**
Effect on User Experience	Intrusive, opaque	Fatiguing, confusing	Disruptive or incomplete	Often less relevant	**Transparent and intention-aligned**
Suitability for Children / Shared Devices	Poor	Poor	Poor	Poor	**High (explicit profiles avoid misattribution)**
Platform Dependency	High (platform-owned data)	High	High	High	**Platform-agnostic**
Interoperability Across Platforms	None	None	None	None	**Designed for cross-platform use**
Maintenance Burden	Platform-side	Platform-side	User and developer dependent	Platform-side	**Minimal once profile is created**
Scalability Across Ecosystems	High (centralized)	High	Limited	High	**High via standardization**
Compliance with Privacy-by-Design	Weak	Partial	Partial	Partial	**Intrinsic**
Ethical Alignment	Low	Moderate	Moderate	Moderate	**High**
Transparency of Data Semantics	Opaque	Opaque	Opaque	Opaque	**Explicit and inspectable**
Data Ownership	Platform-controlled	Platform-controlled	Platform-controlled	Platform-controlled	**User-owned**
Long-Term Sustainability	Increasingly contested	Regulatory-dependent	Fragile	Fragile	**Systemically sustainable**
Primary Limitation	Systemically sustainable	Symbolic control	Fragmentation and relevance loss	Accuracy degradation	**Adoption and standardization effort**

A. Current System and Efforts Made to Overcome These Issues

User tracking is an omnipresent, albeit contentious, element of online advertising and targeted content in modern online society. A variety of sophisticated methods are used by websites, apps, and online services to collect great volumes of information on what users do, typically without users' conscious or active consent. The tracking is executed by a variety of tracking technologies, such as cookies, pixels, device fingerprinting, and device identifiers, by means of which companies are able to build very rich profiles on users based on how they use a range of different sites and services.

1) How the Users are Tracked (for Ads and Content Preferences)?

Tracking is also a multi-faceted practice that is carried out at virtually every phase of online activity. These businesses want to create a profile about users that will allow them to provide highly targeted, personalized advertising, optimizing digital promotion campaigns. Among the most critical means that are leveraged to track users are:

- Cookies and Tracking Pixels: These are little pieces of information stored on users' devices that track what users do on websites. Cookies allow advertisers to track users' activity data on different websites and connect it with individual users' profiles.
- Device and advertising identifiers (AdID, IDFA): Google's AdID and Apple's IDFA are two device identifiers marketers use to identify users across apps and services. These identifiers are associated with unique profiles belonging to users, making it possible for marketers to target users with personalized advertising based on their app-based activities.
- Browser Fingerprinting: It uses unique characteristics of the device of the user (like screen resolution, fonts, and operating system) to create a fingerprint for tracking users from website to website, even without cookies.
- Behavioral Analytics: Sites observe how long a consumer stays on a page, what they click on, and how they interact with a piece of content. From this, they deduce what a consumer prefers, even when a preference point has not been explicitly stated by them.

Despite its blatant encroachment, companies will most often justify this nonconsensual data collection or tracking by calling on the value in delivering users targeted advertising. The underlying idea is that, by tracking users, companies are better able to customize the experience and are thus better able to target advertising and content at users, making it more relevant and, as such, more valuable to users. This argument, however, is most often employed as a pretense to cover over a darker reality: invasion of privacy.

2) Advertising Relevance as a Scapegoat for Privacy Infringement

The term "relevant content/ads" is widely marketed as a quid pro quo for loss of privacy. Consumers believe that it is an acceptable trade-off to provide information to online sites in exchange for targeted advertising. The most frequent justification offered by the major tech organizations is that the fundamental motivation for tracking is to improve the consumer's user experience by showing them more targeted advertising and relevant content. However, this presupposes that users willingly agree to the tracking, a premise that is often questionable at best.

In reality, most users have no idea on what magnitude they are having data mining carried out on them, nor do they have an idea of long-term effects of such data becoming an input to algorithms for perpetual behavioral prediction. Additionally, ubiquity of tracking mechanisms leaves little or no choice for users to opt out, while "relevance" boasted by such mechanisms is overpowered by exploitation of users' personal data. The ad is shown not only on users' interests but also on inferred behavioral propensities without users' notice. This has created serious concerns regarding data ownership, consent, as well as manipulation of users' actions.

3) Platform-Based Efforts

There are several systems that are used to manage tracking and privacy in online marketing, and these systems have been heavily criticized as failing to keep users' information safe or offering adequate control over what is delivered. The most common are:

- AdID and IDFA: The two dominant identifiers for mobile device-based cross-app and cross-platform tracking are Google's AdID and Apple's IDFA. These two identifiers allow advertisers to monitor users' actions within applications and assign actions such as purchases or advertising interaction data to a specific user profile. While there have been efforts by Google and Apple to limit how such identifiers can be utilized (e.g., Apple's App Tracking Transparency (ATT) policy), the process remains to support tracking at mass levels based on inferred behavior rather than direct user consent.
- App Tracking Transparency (ATT): Apple introduced the App Tracking Transparency framework with its shift towards curtailing invasive tracking. The ATT framework requests apps to obtain consumers' permission before they can track consumers' actions on other apps and sites. While this was hailed as a consumer privacy victory, it has not solved the problem entirely. The majority of users, even when provided with an opportunity to opt out, are not aware of what this implies or do not have sufficient technical expertise to make an educated choice. The ATT mechanism also relies on an inferred user interests model, with users having no real control over where and how their data is used and shared.
- Privacy Sandbox: Google's Privacy Sandbox is an initiative to create alternatives to third-party cookies to preserve user privacy. The system is intended to provide advertisers with the tools to target users without making personal information directly available to advertisers. However, the system involves in-app activity-based profiling and attempts at deducing the desires or interests of users, an activity most detractors say still eliminates consumer control over personal information.

These efforts, as much as they are attempts at confronting privacy concerns, still don't provide users with full control over how they use their data. Despite efforts like ATT and Privacy Sandbox, users remain profiled outside of their direct, conscious consent, and companies still have considerable control over what data they collect and how they use it.

4) Data Protection Acts and Policies in Place

After increased online privacy concerns, several data protection acts have been enforced globally to safeguard users' personal information. Among them are two key laws:

- General Data Protection Regulation (GDPR): Implemented by the European Union in 2018, GDPR grants users robust data protection rights. It compels organizations to obtain users' consent first when gathering and processing their personal data. It also grants users the right to review, modify, and delete their information, among other rights. Enforcement has been spotty even with its strengthening, and businesses have kept finding loopholes in these regulations.
- California Consumer Privacy Act (CCPA): The CCPA, enacted by California in 2020, gives California users the right to know what information is gathered on them, gives them a right to access it, and gives them a right to have it removed. While more open than previously, it still does not address at its root the problem with tracking consent. It does not require companies to stop tracking at all, only provide an opportunity for users to opt out of having their personal information sold.

Although such legislation provides protection for users to some degree, it does not fully address consent to tracking, nor is its enforcement a success. Besides, they concentrate on collection and processing as opposed to tracking activities and users' lack of control over their online identities.

The current tracking system, with its target advertising and content tailoring, by its very nature disrespects users' trust. Even with measures such as Privacy Sandbox and ATT, they don't even come anywhere near making users have full control over their data, and most users aren't even aware of how much tracking is going on, as we learned through the literature. Regulations such as GDPR and CCPA are there for some protection, but they don't address the core issue of getting users' consent when it comes to tracking. The models currently in use, by inferred interest and data profiles, are by nature, defective and do not allow such ideals as transparency, autonomy, and privacy that users should have.

B. Weaknesses and Improvement Gaps in the Current System and Efforts

Despite statutory data protection and transparency legislation, current online advertising and recommendation mechanisms are technically flawed. The technical flaws are not so much legal or ethical, but rather a design flaw intrinsic in how users' data is collected, inferred, and utilized. The mechanism based on pervasive surveillance and covert profiles cannot simultaneously grant real control to users and reduce advertising and content targeting quality.

1) The Limited Role of GDPR, CCPA, and Other Data Regulations

Regulations like the General Data Protection Regulation (GDPR) and California Consumer Privacy Act (CCPA) have been introduced to give users greater control over information about them. While these regimes provide legal protection, they are deficient in several key areas:

- Consent fatigue: Consumers are fatigued with cookie notices and consent banners that try to confuse or push users toward compliance. The majority click "Accept All" without reading and understanding what it means.
- Gross unenforceability: Despite GDPR mandating minimization and use limitation, its enforcement is aimed at pursuing large-scale blatant abuse and ignoring day-to-day misuse of inferred information and tracking loopholes.
- Vague "legitimate interest" clauses: Companies justify data collection in terms of "legitimate interests," with grey areas where profiling continues even when users try to opt out.

Lastly, laws such as these do not ensure ethical practice. The spirit of such legislation is always evaded by way of vagueness and exploitation by users.

2) Inferred Interests: The Core Technical Fallacy

At its heart, it is a risky presumption, one that machines are able to successfully infer users' interests from behavioral data.

- It uses passive data such as search history, clicks, scrolling, watch time, and hover actions to train algorithms to construct a profile of "what the user wants."
- Context is overlooked: The consumer may only want "baby strollers" due to an isolated reason, or on behalf of someone, or perhaps out of interest. The system is assuming this is an interest at the top and is showering them with baby advertising for months.
- Temporal interest fading is poorly implemented. Interest profiles are infrequently time-limited, and dated conclusions will continue long past when they should be applicable.

These systems are essentially flawed; they sacrifice accuracy for automation and are making assumptions where there should not even be any. This results in poor user experience as well as poor targeting.

3) False Positives and Shared Device Challenges

Dependence on device or browser-based behavior leads to an exceedingly high rate of false positives:

- Shared devices (e.g., schools, families, or cyber cafes) lead to different behaviors being correlated with a single profile.
  - One innocent action by a child will initiate travel high-ends advertising.

- A roommate's impulsive late-night shopping spree may also result in product suggestions that are not appealing to the original user.

- Disproportionate effect of single actions: A misclick, unintentional click, or experimental search may significantly skew ad/content suggestion for days or weeks.

This lack of disambiguation leads to data pollution, where extraneous interests get confused with real preferences, affecting advertiser ROI and user experience.

4) Non-Consensual and Opaque Profiling

Modern systems don't ask for preferences, they deduce them with no input from users:

- Users are rarely informed about how their data profiles are built.
- Inference models are not open-source, and most platforms don't allow users to review or verify what has been recorded about them.
- Profiling persists across devices and apps even when users erase identifiers or opt out, and it is most often carried out with browser fingerprinting, shadow profiles, and SDK data collection across apps.

Fundamentally, users are profiled by systems they don't understand, based on signals they didn't agree to provide, for purposes over which they have no control.

5) Clunky and Deceptive Preference Management

While there are some sites (Google, Facebook, Apple) that do have ad preference controls, they are plagued with usability problems:

- Hidden in menus: Choices are hidden behind several layers of menus with unclear labels.
- Auto-enabled interests: Platforms pre-define interest categories based on historical tracking and force users to opt-out.
- Inadequate granularity: Options are abstract (e.g., "Sports," "Travel") with no way to state sub-preferences or rule out presumed ones.
- No true opt-out: Even when interests have been opted out, there remains background behavioral tracking, and there is still targeting on other inferred information.

These are not intended for real control, rather to seem compliant while still being trackable.

6) Defective Opt-Out Mechanisms

Choosing not to participate in personalized advertising now is an illusion:

- Ad identifiers (e.g., Google's AdID or Apple's IDFA) may get cleared, but tracking is resumed shortly thereafter under a fresh identifier.
- Mechanisms such as opt-out cookies or Do Not Track (DNT) are not commonly honored or are erased when cookies are cleared.
- App-level opt-outs, such as ATT on iOS, only stop certain types of cross-app tracking while enabling server-side code tracking and profiling to still continue.

In essence, users are struggling with a hydra, severed from one tracking source, and two others from less obvious sources.

7) Technical and Ethical Failures in Real-World Scenarios

Consider these case studies and examples uncovering the serious shortcomings in current profiling systems:

- YouTube's feedback loop: Someone accidentally watches a video about a conspiracy theory. The site overloads them with related videos for weeks, propagating fringe viewpoints, a documented phenomenon called "algorithmic rabbit-holing".
- Amazon's Purchase Memory: One purchase of a vacuum cleaner leads to months of promotions for vacuum cleaners, something that the buyer won't need again for years.
- Political Ad Micro-Targeting: People are subjected to emotionally manipulative political messages during elections that are tailored to inferred personality attributes (e.g., fearfulness or extroversion) from past clicks and social media activity, and this is ethically objectionable when it impacts democracy and consent.
- Instagram Shopping Feeds: Your device is used by your friend to search for fashion goods, and your feed is filled with clothes from this domain, irrespective of it not aligning with your interests.

These instances depict how tracking often fails, and users are harmed because of poor inference.

8) The Systematic Problem: Tracking is the Default

We now have an online space where tracking is the rule and opting out is an exception. "If you're not paying, you're the product" has become a truism, though little is mentioned about how this business model is harming users and advertisers:

- Users lose control and confidence in the technology.
- Advertisers waste money targeting people with irrelevant ads/content based on noisy, inaccurate, or outdated preference profiles.
- Developers incorporate SDKs and third-party libraries that expose users' data without adequate transparency.
- Other platforms are also in the spotlight, as shown by recent events and consumer-led revolts (e.g., against Instagram and Facebook).

Not only is this model unviable, but it is also technically defective and ethically deficient.

III. METHODOLOGY

After critical analysis of the literature on Data Integrity and Privacy issues, it seems necessary to obtain a broad knowledge base regarding actual users' views on digital tracking, data privacy measures, and alternative advertising models' perceived acceptability, a quantitative approach was utilized.

A. Target Audience

A carefully designed questionnaire was shared among several online forums and communities focused on data privacy matters. These sites included boards and groups, where users typically have a more advanced understanding of digital rights, data handling practices, and implications of tracking technologies. This selection was intentional because individuals having a core understanding about data privacy provide richer answers, something indispensable to ideas like preference systems and user-consensual data sharing platforms. It was agreed that if this survey is distributed to normal public, then the results would be quite inaccurate, because, as it was learned through the literature review that the normal public usually doesn't have knowledge on technology being utilized to get their data and the Data Protection Acts in place that try to stop such Tracking.

B. Survey Structure

The questionnaire included a set of Likert-scale, multiple-choice, and open-ended questions aimed at gauging participants' opinions about mandatory behavioral profiling, current data privacy regulations, the level of clarity regarding data use, and the feasibility of creating user-defined preference profiles. General themes examined included the perceived effectiveness of legislation like the GDPR and CCPA, the level of satisfaction with current opt-out features (such as App Tracking Transparency and the Privacy Sandbox), and attitudes toward the use of personal data to allow for better content personalization using artificial intelligence.

To protect the target audience's privacy expectations, the survey avoided collecting personally identifiable data, like age, gender, or geo-location. Rather, it focused on collecting relevant information pertaining to privacy expectations, trust in digital platforms, and potential participation in a new, permission-based model for advertising and content preferences data sharing platform. The tone of the questions was kept at a friendly level in order to let users select the best option, which reflects not only their opinion, but also their feelings. The survey was shared across privacy-oriented subreddits, encrypted messaging apps, and federated platforms, thus ensuring collected data was a true representation of users concerned with privacy. These responses were anonymized, and participants gave informed consent to participate in this study, along with explicit disclaimers provided informing participants about the non-commercial nature of the work. The design of this approach was not intended to provide generalizability to a wider populace, but merely to measure whether a well-informed audience would see value in this proposed framework in comparison to invasive tracking.

IV. RESULTS AND DISCUSSION

A total of 572 valid responses were collected from privacy-aware online communities. The results provide empirical grounding for evaluating whether a user-authored, consent-driven preference framework is socially acceptable, practically viable, and theoretically aligned with existing privacy research. Microsoft Excel was used to create figures and charts for easy evaluation. Each subsection below discusses one thematic result and situates it within prior findings.

A. User Sentiment on Tracking and Data Collection

As illustrated in Fig. 1, a dominant majority of respondents (62.59%) regarded behavioral tracking as inherently violating privacy and rejected it outright. An additional 30.77% indicated conditional acceptance of personalization, but only when preferences are explicitly provided by users themselves, rather than inferred through passive surveillance. By contrast, only 2.10% were comfortable with tracking in exchange for free services.

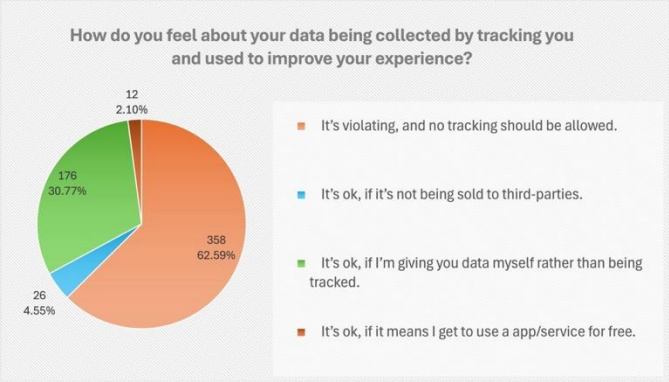

Fig. 1. User sentiment on tracking and data collection.

This finding directly reinforces prior work demonstrating that method of data acquisition, rather than personalization itself, is the primary driver of user discomfort [2], [3], [15]. It also empirically supports observations in [20] that users distrust inferred profiles and experience what has been described as algorithmic disillusionment. The strong preference for voluntary data provision further aligns with Protection Motivation Theory findings in [10], where perceived lack of agency suppresses protective behavior even among informed users. Collectively, these results validate the study's premise that user-declared intent is more socially acceptable than algorithmic inference, even when outcomes (e.g., personalization) appear similar.

B. Attitudes Toward Existing Data Protection Mechanisms

Fig. 2 demonstrates widespread dissatisfaction with current regulatory approaches. Only 2.27% of respondents considered existing data protection laws sufficient, while 70.98% explicitly stated that a functional solution is needed rather than additional rules.

This sentiment closely mirrors empirical critiques of GDPR effectiveness found in [6], [13], and [29], where compliance mechanisms such as consent banners were shown to be largely symbolic. The results also echo macro-level analyses in [17] and [27], which argue that regulation alone can unintentionally consolidate data power instead of redistributing it. Respondents' desire for actionable tools aligns with findings in [14] and [23], where users expressed frustration at being formally empowered yet practically constrained. These results strengthen the

argument that compliance-by-design systems, rather than policy-only approaches, are required to operationalize privacy rights.

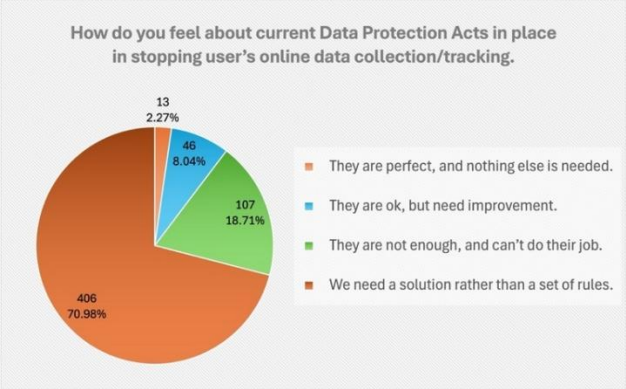

Fig. 2. Attitudes toward existing data protection mechanisms.

C. Preferred Type of Solution

Responses in Fig. 3 reveal a nuanced, but decisive preference landscape. While 83.22% favored stopping data collection entirely, reflecting deep-rooted distrust, substantial support was also observed for voluntary preference sharing (77.80%), prohibiting third-party data sales (72.90%), and data anonymization (56.47%).

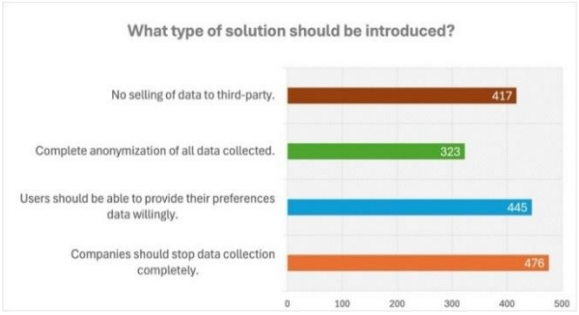

Fig. 3. Preferred type of solution.

This apparent tension between idealistic rejection and pragmatic compromise is consistent with prior findings in [15] and [26], which highlight trade-offs between privacy protection and system functionality. Importantly, the strong endorsement of voluntary preference sharing provides empirical validation for alternative paradigms proposed in [7], [8], and [28], where value extraction is decoupled from covert surveillance. Unlike anonymization-only approaches, which can degrade content relevance and raise concerns for vulnerable users such as children [22], [32], user-authored profiles preserve contextual accuracy while respecting consent. The findings thus support a middle-ground model that balances personalization utility with ethical data governance.

D. Willingness to Use a User-Controlled Preference Platform

As shown in Fig. 4, willingness to adopt the proposed model was notably high. A combined 86.19% indicated they would use such a platform either unconditionally (9.97%) or provided it remained simple to manage (76.22%). Only 7.34% rejected the need entirely.

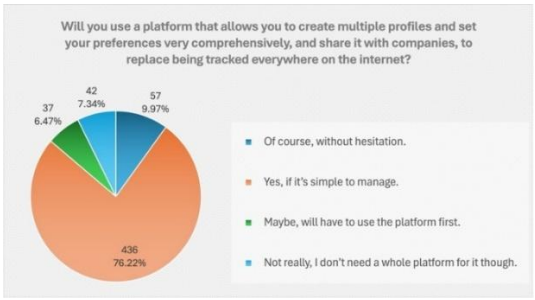

Fig. 4. Willingness to use a user-controlled preference platform.

These results reinforce usability-focused findings in [5], [14], and [28], where complexity and opacity were identified as primary barriers to meaningful privacy engagement. The emphasis on simplicity also corroborates observations in [10] that perceived effort reduces protective action. From a systems-design perspective, this underscores that technical feasibility alone is insufficient; adoption depends on intuitive interfaces and low cognitive overhead. The results further suggest that multi-profile support, allowing users to contextualize preferences, may address shortcomings of one-size-fits-all consent mechanisms.

E. Trust in Who Should Build and Maintain the System

Trust attribution results in Fig. 5, reveal a pronounced institutional divide. Privacy-focused organizations (90.20%), open-source communities (73.60%), and non-profits (52.80%) were overwhelmingly preferred, while Big Tech (9.97%) and governments (28.50%) ranked lowest.

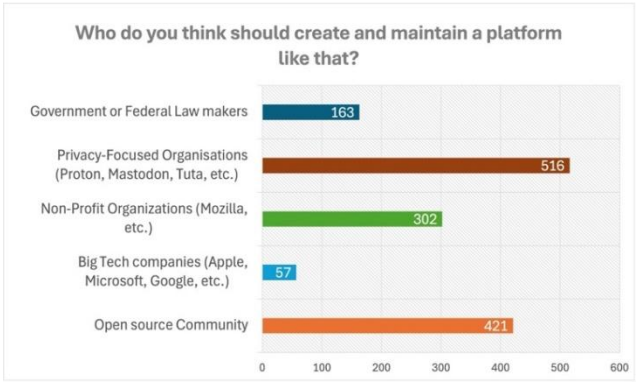

Fig. 5. Trust in who should build and maintain the system.

These findings are consistent with broader trust erosion documented in [32] and [33], as well as structural critiques of Big Tech's data governance in [7] and [17]. The strong preference for open and privacy-native stewardship aligns with research advocating transparency, auditability, and decentralization as trust-building mechanisms [18], [21]. This suggests that for the proposed framework to be credible, governance structure is as critical as technical design, favoring open standards, inspectable codebases, and non-commercial custodianship.

F. Discussion and Implications

To conclude, the results demonstrate a clear mismatch between current data collection practices and user expectations. While prior research has extensively documented the harms and

inefficiencies of behavioral tracking [1], [13], [21], this study contributes empirical evidence that even privacy-literate users favor constructive alternatives rather than absolute disengagement. The findings support a paradigm shift from inferred behavioral profiling toward explicit, user-authored preference signaling, addressing long-standing concerns about consent validity, trust, and ethical personalization raised in [8] and [20].

Importantly, the results do not contradict existing literature, but rather operationalize its conclusions: users want personalization without surveillance, control without complexity, and privacy without sacrificing functionality. The proposed framework responds directly to these conditions by enabling consent to become an active, expressive process rather than a defensive reaction. In doing so, it aligns regulatory intent with technical implementation and user agency, offering a viable path beyond the limitations of both tracking-centric and regulation-only models.

V. Proposed Model: A User-Governed Data Sharing Platform and Standard

A. Overview of the Concept

The current ad environment is built on an interest-inference information system based on passive tracking. Companies track users through apps, sites, devices, and off-line activity and build hidden profiles by unknown means. Based on this inferred interest profile, supposedly "relevant" advertising and material is served. Its justification has always been: "you get relevant ads/content". Never once along the chain is anything asked of users: what they are interested in watching or how they want to get profiled. The system is by its nature defective.

The innovation here is a move from hidden tracking to open, user-consented preference sharing. Rather than getting tracked everywhere, users would have control over actively building and sharing interests on one platform. The platform described here can enable users to create their own Preference Profiles, to be linked to apps or sites in an easy, privacy-preserving way. Think of it as creating a social media account, but rather than uploading photos and updates, users select what they want to see: advertising, kinds of content, topics of interest, and more.

This is not an ad business model, but a technological solution to restoring control of data and trust by users in online environments. It is a simple solution, though one with pressing practical application as people's frustration over loss of control, over personal data tracking and its use in training AIs escalates.

B. Core Features

User Accounts like Social Media: The initial point is a user account, identical to what you would have on a social media website. The difference here is that there is no messaging, posting, or networking aspect to this account. It is only used for storing preference and interest, only for passing on to apps or companies that people will be interacting with. Sharing is opt-in and under users' control.

User-Generated Interest Profiles with Individualized Preference Profile IDs: Any given user can create multiple Interest Profiles in their account. Each can have a unique alphanumeric Preference Profile ID as its "username" or API key. These IDs or direct downloads of JSON format of profiles may then be shared with sites that request advertising or content preferences from the user. This will enable users to use different profiles for different purposes without disclosing personal data or correlating all activity with one single identity.

Multi-Profile Support for ADs, Interests, Content Preferences: Users are not homogeneous, and their interests vary based on context. An individual might want new productivity applications' ads in a working environment and entertainment content during leisure time. Hence, this model supports multiple profiles per user account, which enables users to define various sets of interests for:

- Ads (e.g., job offers, tech products)
- Content (e.g., comedy, music genres, educational videos)
- General interests (e.g., travel, fitness, finance)

This system avoids having ad engines guess and instead relies on declarative data provided by users.

App-Specific Profile Preferences: There can be profiles created specifically for a particular platform. For example:

- A video application profile like a YouTube or TikTok profile, for instance, "ContentProfile_YT" with interests like "Tech Reviews, Music, No Politics, Comedy, Memes, Pranks".
- Another for professional networks like LinkedIn (e.g., "CareerAds_LI" with interests like "Project Management, Startups, Recruitment").

Apps only request a Preference Profile ID or a direct JSON file, and the user will provide them with one of their preference IDs or files. This avoids over-personalization with unwanted information and promotes context relevance. It is an ethical way of sharing your interest data for online content/ads, rather than being tracked everywhere online.

C. Functionality

User Experience Design: The system must have optimal usability. Within each profile, the users should have the ability to select interests from pre-designed template options, search by categories, and build profiles through a guided, intuitive interface. The users should have a sense of empowerment rather than frustration with the process. Selecting pre-designed default template options (e.g., "Gaming Profile," "Work Profile," "Music Preferences") can provide optimal reduction in cognitive load without sacrificing fine-tuned personalization.

Linking and Sharing Mechanisms: The platforms can request Preference Profile IDs from users. This can take place through:

- Manual Entry: The users enter or paste their Preference Profile ID into an input field.
- Account Linking: As with OAuth, users can directly link their preference profile via an API handshake.
- File Upload: Directly upload the exported JSON file of that Preference Profile on the requesting platform.

- Username-based linking: Social apps already have a facility for linking via usernames, this method can emulate the same with Preference Profile IDs.

This will allow developers to have flexibility and ensure that consent is specific and accurate.

Integration with Applications and Sites: Developers can be offered an API or an SDK. This allows applications and sites to:

- Query a user's Preference Profile ID (read-only).
- Fetch updated preferences dynamically (optional).
- Respect content/advertising category exclusions (e.g., avoid political ads).

Access to all data would be governed by an open protocol without permanent identifiers or behavioral surveillance.

Open Standards, Open-Codebase: In order to foster trust and collaboration, the platform should be open-source under an open standard. This prevents vendor lock-in, and third-party auditing is feasible. Developers can propose categories, tailor template logic, and perform integrations. Open protocols also support modular implementations, and decentralized control or even self-hosting is feasible.

Decentralization and Identity Ownership: Decentralized Identity (DID) standards or principles of Web3 can expand on this model further. This gives users control over profiles with cryptographic ownership, makes the entire system tamper-resistant, and could support zero-knowledge proofs whereby users reveal preferences data without identity disclosure.

AI integration for Profile Creation: AI can easily be embedded within this platform. It can create a user's profile based on user's text input by harvesting the power of NLP techniques available in modern AI age.

Prompt style simple example:

"I need a general profile. I like all music except jazz. I hate drama movies, but I love all other movie categories, especially comedy. I love everything related to technology, but I hate marketing and SEO stuff. I love the power of AI and what it can do, but I don't like AI generated content (as in music, video, photos, etc.) as it seems lazy. I'm an outdoor person, so I have many physical hobbies, like Sports and exercising. I enjoy traveling a lot, but I'm not a luxury freak. I love almost all animals, but I'm not quite fond of dogs or pigs. And when it comes to News, I absolutely hate politics. Please generate a good profile for me and try to understand my personality to get all the preferences correct."

There're few ways it can be done, as listed below:

- Own Trained Model: This will probably be the best implementation, as the AI doesn't need to external knowledge base to be used. An AI Model can be trained on manually crafted examples and their outputs, which will allow for highly accurate User's Preference Profile creation.
- API Linking: An advanced AI Model can be used with the help of API Keys. This way when the users writes the text of what they want from the profile, the prompt can be sent to the AI Model's server using its API to get the categories list having users' likes and dislikes. This way the users have created their preference profile via an API handshake. In this, most of the Processing will be done by the outsourced server.
- Local AI model: This method is by far the toughest to get right, as the entire AI Model will have to run locally, taking up a lot of RAM and GPU power. It is quite inefficient in terms of what the overall platform looks to accomplish.

Overall, this brings us to an open, privacy-based internet with the actual user at its center. Some of these features are too advanced and out of scope to implement right now but are to be considered in future developments of the platform. In the survey conducted, the respondents emphasized simplicity of the platform, linking it to usability. The Demo web interface developed here ensures the basic requirements of the proposed system are met and showcases the simplicity of this solution's implementation.

D. Demo Website Showcasing the Workings of the Proposed Framework

To illustrate the practical feasibility and interaction flow of the proposed user-governed preference data acquisition framework, a lightweight demonstration website was developed. The purpose of this prototype is not to present a production-ready system or a novel software contribution, but to concretely demonstrate how the conceptual framework described in the previous section can operate in practice from a user and platform perspective.

The demo implementation focuses on three core aspects of the framework: 1) explicit user-authored preference declaration, 2) multi-profile and context-aware preference management, and 3) standardized, portable export of preference data for third-party use.

Accordingly, the system was intentionally kept minimal in scope and complexity, prioritizing conceptual clarity over feature completeness or optimization. The prototype serves as a reference implementation to support understanding, reproducibility, and future extension by researchers, developers, or organizations.

1) System Overview and Interaction Flow

At a high level, the demonstration platform allows individuals to create and manage one or more preference profiles, each representing a distinct context of interest (e.g., content consumption, advertising, professional use). These profiles are explicitly authored by users through direct input rather than inferred from behavior. Once created, a profile can be selectively shared with external platforms via a unique identifier or exported in a standardized machine-readable format (JSON).

The interaction flow is intentionally simple: users register, define preferences through structured categories, optionally refine or update those preferences over time, and provide the resulting profile to platforms that request preference data. This flow reflects the framework's central design principle of

replacing passive behavioral inference with explicit, user-controlled preference declaration.

2) Entry Point and Navigation

The platform entry point is a minimal landing interface that introduces the purpose of the system and provides navigation to user-facing actions such as registration and login. As shown in Fig. 6, the landing page is deliberately sparse, reflecting the framework's goal of minimizing friction and cognitive overhead during onboarding.

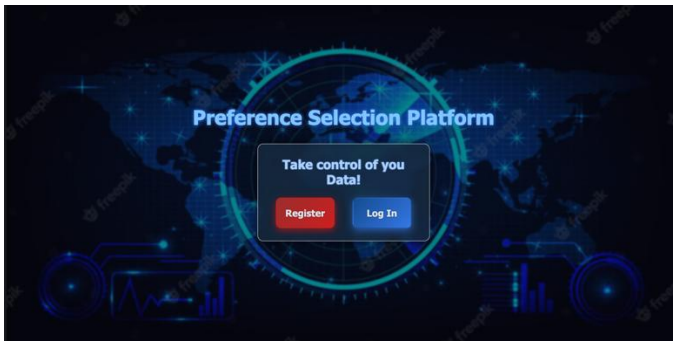

Fig. 6. Landing page.

3) User Authentication and Account Access

Users interact with the system through a basic account access that enables secure access to preference management functions. The registration and login interface, illustrated in Fig. 7, exists solely to associate multiple preference profiles with a single user.

Importantly, authentication is treated as an enabling mechanism rather than a profiling mechanism. No behavioral tracking or implicit data collection is performed during account creation or login.

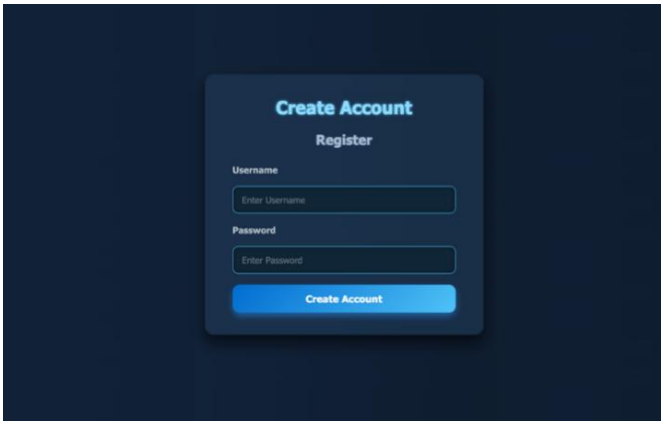

Fig. 7. Register page.

4) Preference Profile Management Dashboard

Once authenticated, users are presented with a centralized dashboard that lists all preference profiles associated with their account. As shown in Fig. 8, the dashboard functions as the primary control surface for managing preference contexts.

Each profile is treated as an independent, self-contained declaration of interests, allowing users to maintain multiple profiles for different use cases without cross-contamination. This design directly addresses issues identified in the literature related to shared devices, mixed contexts, and misattributed behavioral signals.

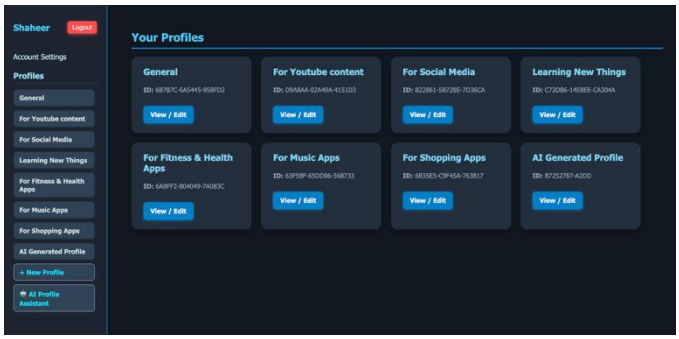

Fig. 8. Dashboard page.

5) Account-Level Controls

In addition to profile-level management, the demo includes a basic account settings interface, shown in Fig. 9, enabling users to update credentials or remove their account entirely. This functionality is included to demonstrate user autonomy and data lifecycle control, consistent with privacy-by-design principles.

Account deletion removes all associated profiles, reinforcing the notion that preference data remains user-owned and revocable rather than persistently retained by the system.

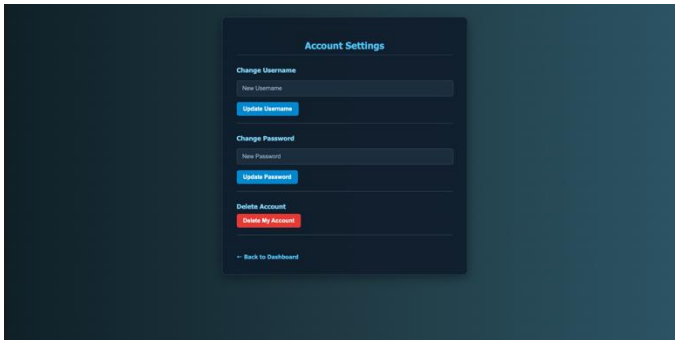

Fig. 9. Account settings page.

6) Explicit Preference Profile Creation

The creation of a new preference profile is the core interaction through which the framework's principles are operationalized. As illustrated in Fig. 10, users define preferences through a structured category hierarchy, explicitly indicating positive (Like), negative (Dislike), or neutral interest (Not Decided) states. Categories can be very comprehensive.

This explicit declaration mechanism replaces behavioral inference entirely. No assumptions are made based on past activity, accidental interactions, or temporal proximity. The hierarchical structure supports both coarse-grained and fine-grained preference expression while remaining interpretable to both users and consuming platforms.

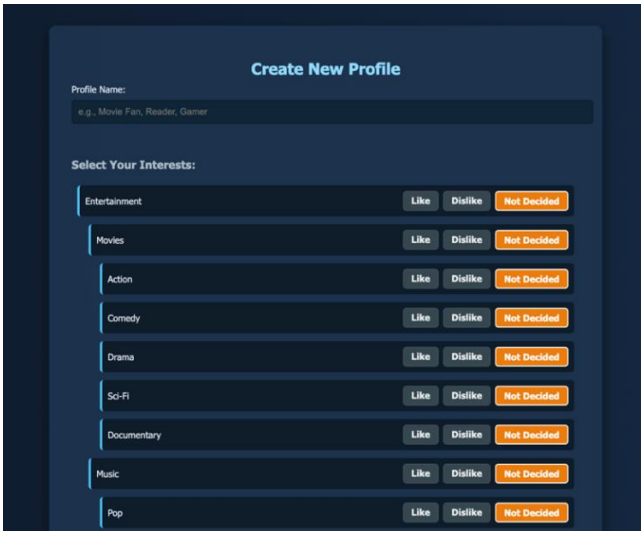

Fig. 10. New profile creation page.

7) Profile Review, Modification, and Export

Once created, preference profiles can be reviewed, modified, or deleted through a dedicated profile management interface, shown in Fig. 11. Preferences are not static; users may revise them as interests evolve or contexts change.

Crucially, profiles can be exported in a standardized JSON format that preserves the full preference structure and semantics. This export functionality demonstrates how platforms can consume high-quality preference data without engaging in surveillance, fingerprinting, or behavioral tracking. The JSON format is used as an example standard that can be established for this framework.

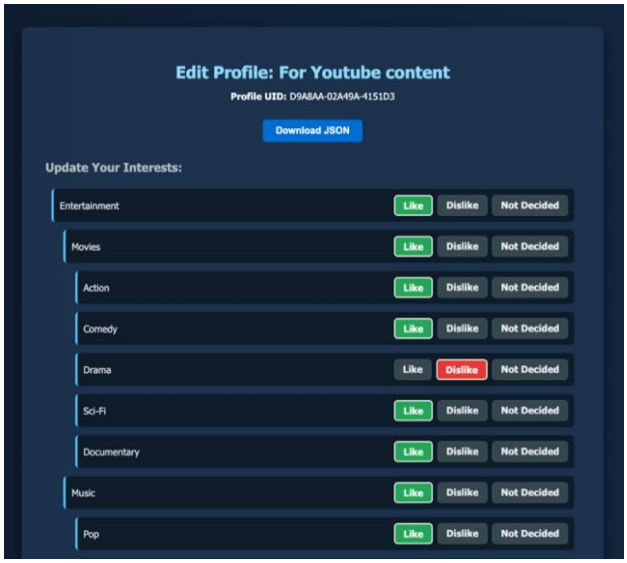

Fig. 11. Profile management page.

8) Assisted Preference Authoring via Natural Language Input

To reduce user effort and improve accessibility, the demo includes an optional AI-assisted preference authoring interface, illustrated in Fig. 12. This component allows users to describe their interests in natural language, which are then translated into structured preference categories. The performance of this depends on the AI model(s) used by either the individual or the organization, as explained in the above subsection B. Core Features.

This feature is intended as a usability enhancement rather than a replacement for user control. Users remain free to review, modify, or reject any generated preferences before saving the profile. The inclusion of this panel demonstrates how assistive technologies can support explicit preference declaration without reverting to opaque behavioral inference.

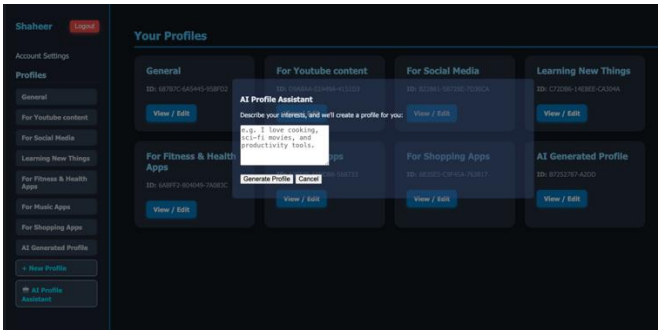

Fig. 12. AI profile creation panel.

9) Preference Sharing and Third-Party Access

Finally, the demo includes a minimal interface through which external entities can retrieve a preference profile using a user-provided identifier. As shown in Fig. 13, this interaction models how platforms may request and consume preference data without requiring user accounts, cookies, or tracking identifiers.

This mechanism highlights the framework's platform-agnostic and interoperable design, where preference data is shared deliberately and contextually rather than collected implicitly.

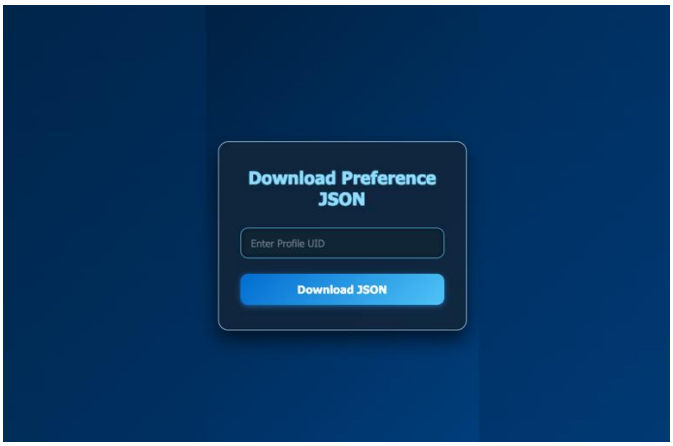

Fig. 13. Downloader page.

10) Scope and Limitations of the Demonstration

It is important to emphasize that this demo website is not intended as a complete system, performance benchmark, or commercial platform. Its role is illustrative: to demonstrate feasibility, interaction flow, and conceptual alignment with the proposed framework.

Advanced concerns such as large-scale deployment, governance models, standardization bodies, security hardening, and integration with production recommender systems are intentionally left out of scope and are identified as directions for future work.

E. Benefits of the Proposed Solution

The system proposed here, an opt-in and user-driven Ad/Content Preference Profile (data sharing) platform, introduces paradigm-shifting benefits to the entire digital environment. This is different from invasive ad-supported models that are now in existence and is privacy-preserving without sacrificing relevance. It's a real win-win for all stakeholders in digital marketing.

1) For Users: Autonomy, Privacy, and Relevance, Without Surveillance

For most people on the internet, such a platform model truly gives freedom. Rather than having to be passively followed everywhere on the entire Internet, users would have control over what types of data, information, content and advertisements they want to have displayed. It is relevant content/ads delivery with permission rather than at the sacrifice of privacy protection.

Users can create personalized profiles for different sites, such as different job interests for LinkedIn, different genres of movies and television for YouTube/Streaming platforms, or type of products for Amazon/Shopping. It's less intrusive and on purpose. The days have gone by when users get shown an ad because they typed in one stray search term or because someone was on their computer. Users decide, Users select, Users provide. It's advertising at user's consent.

2) For Businesses: Cleaner Data, More Accurate Targeting, Greater Brand Trust

This model is revolutionary when looked at from a business perspective. Current ad tech is rooted mostly on inferred data compiled predictively and inaccurately. The result is a clutter of false positives and poorly targeted postings that users actively avoid.

Having openly stated user-generated interest profiles, brands receive high-quality, precise, and volunteered data. Not only is this improved targeting, but it also rebuilds trust within an industry where consumers are becoming cynical towards Big Tech. There is no risk in taking a leap of faith on shady third-party trackers or complicated behavioral inference engines. The user data is clean, relevant, and ethically provided.

On top of this, companies can use this paradigm as a marketing theme, "We value your Data and only show you something that you want to see". This is positive branding when concern for data privacy is on the rise.

3) For Regulators: Compliance by Design

There are laws on the books to protect users, like GDPR and CCPA, but with modern tech, compliance is more about damage control than damage prevention. The proposed conceptual platform reverses that. Ethics are built-in here. No loopholes, no dark patterns, no fine print. The users themselves create their Profiles and willingly share their Interest data with the Apps, companies, and organizations.

Every ad or content displayed through this system is backed by consent on behalf of the users, explicitly given through their preference profile. There is no need for regulators to chase companies for breaches as the consumer is in charge in the first instance. It's not damage control, it's damage prevention.

4) For Developers: Simplicity, Flexibility, and Future-Proof Design

Today developers must deal with complicated SDKs, notice banners for privacy, cookie banners, and third-party data providers. This Model answers it as one open standard. Create a preference profile, add preferred categories, share the ID of that profile, and finally get shown accurate content, no background tracking or hidden algorithms required.

This concept makes it easier to create ethically sound, lightweight, and privacy-oriented apps and still allows for monetization through advertising or personalization. As an open-source platform, developers can contribute, adapt, and expand on the platform as required by use cases.

5) For Data Scientists: Cleaner Data, Minimum Preprocessing, and Consent-based

The proposed framework offers data scientists a clean, structured, and consent-driven source of user preference data, removing much of the noise, ambiguity, and ethical burden associated with current tracking-based methods. Unlike opaque behavioral inference systems, where interests are derived from cluttered signals like accidental/incidental clicks or shared devices, this approach provides explicit, user-declared profiles that can significantly improve model accuracy and personalization outcomes. It eliminates guesswork in distinguishing actual intent from outliers, allowing data teams to work with high-integrity datasets that are legally and ethically sound. This not only enhances recommendation engine quality and ad targeting algorithm quality, but also facilitates better governance and auditing for data sets.

For machine learning pipelines, it means faster training cycles, reduced labeling overhead, and clearer feedback loops, while avoiding the risks associated with overfitting on biased or improperly collected data. By switching from invasive data mining to consensual data sharing, this framework creates a more sustainable and transparent data ecosystem where scientific rigor and user autonomy can coexist.

6) Overall Novelty and Conceptual Leap

The most significant aspect of this proposal is that none of the existing research or practice has attempted to address this issue from this angle. The most common proposed remedies and conversations are damage control, minimizing harm inflicted by existing tracking methods, or implementing opt-out functionality afterwards. This proposal is proactive rather than reactive.

Instead of trying to fix the broken system of surveillance capitalism, it offers an alternative: decentralized, consent-based, user-governed, and future-enabled system. It doesn't just

minimize harm; it renders tracking obsolete. This is the true innovation that can be enhanced through further research.

F. Conclusive Comparison Between Current System and Proposed Solution

1) Current System: Invasive by Default

Today's online economy rests on an idea that has become hardened: when you're getting it for no charge, you are the product. Sites and apps are scooping up everything, what you search, click, watch, stream, and even mouse-hover. The users didn't give any permission to get tracked everywhere online. Most don't even know what's being monitored or are too busy to stop it.

Even GDPR and CCPA, as excellent as they are, have been disadvantageous in certain situation as concluded through the literature review. The cookie notices are drafted to mislead, rather than reveal, privacy settings are buried behind a chain of multiple menus, and consent is implied rather than actual. Compliance is on study and not in spirit.

To make things worse, profiling is inaccurate. A parent using their child's iPad or a one-time Google search can skew their entire digital identity data. Ad relevance often feels like guesswork, and users feel more intruded upon than ever.

2) Proposed System: Consent-Driven by Design

By contrast, the platform suggested here eliminates surveillance. People create interest profiles for themselves, directly and by conscious choice. Users decide what every app learns about them and can toggle or shift tastes at will. There is no guessing. There is no spying. There is no tracking across unrelated platforms.

One may have a variety of preferences for different activities such as work, entertainment, shopping, etc. and map them with the respective apps with a simple identifier like a username. This preference profile will only become shareable when desired by the user.

3) No tracking. No third-party cookies. No behavioral inference.

This approach solves many of the core issues with current user data exploitation systems:

- No more unwanted advertising or irrelevant ads.
- No more misattributed activity from shared devices or one-time search data.
- No more hidden profiling or silent consent.
- No more complex legal back-and-forth.

4) Privacy Becomes the Default, Not the Afterthought

Where other systems ask for forgiveness or hide behind technobabble (incomprehensible technical jargon), the solution presented here asks for permission. It makes an online community where privacy is not just kept intact, it is engraved as an unbreakable ideal.

Companies still get data, but better data, and that data will voluntarily come from users who know what they are sharing with the Company or app. Ads and content are still personalized, at real user intent rather than usual tracking or guesswork. And users can still use services for free, without having that uneasy feeling of being watched.

This framework is not an extension to what already exists, but a rethink on how relevance and privacy might best be aligned.

VI. Challenges and Limitations

For all its potential to revolutionize consumer and online advertising privacy, mandating a preference-governed, consumer-led Preference Data sharing system is not without its hurdles. As with every shift away from established systems, it must overcome a multi-faceted environment of opposition, logistics obstacles, as well as an education shortfall. The significant hurdles to mention are as follows:

Resistance by Big Tech Giants: The largest obstacle is entrenched interest by the Giants. They now monetize information accumulated with invasive surveillance methods. The entire business model is based on behind-the-scenes profiling and data collection instead of having users provide data on an opt-in arrangement. A move toward a consent-based framework would entail some loss of profit and control. So, Google, Meta, and Amazon businesses would not welcome this with open arms naturally. It is not just tech, they would need to rethink their data stack, ad framework, and platform dynamics. This is a big order.

Risk of Abuse - Spoof or Manipulated Profile: Granting users control over what they are interested in presents one loophole risk: malicious players will game the system. Companies or spammers may also create spoof Preference Profiles to poison ad targeting or reap benefits assigned to designated segments. In order for a system to successfully function, it would require verification tools or behavioral checks without reviving intrusive tracking, a tricky thing indeed.

Monetization and Incentivization Strategy: When advertising is served based on users defined criteria, advertisers will naturally ask: Where's the optimization? Currently, machine learning optimizes ad delivery in real-time on inferred behavior. With a system based on user-defined profiles, there is some loss of granularity. This is a bigger question, how do platforms monetize such a system, and how do advertisers measure performance? There will have to be new cost-per-interest models, new measures of efficiency of conversion, and perhaps even incentivization by users, paying users to opt-in to have preferences refreshed or to answer honestly.

The two decades and billions invested in the surveillance-based data collection and tracking economy have no click-of-a-switch expectation of a flash transition to an alternative system. Such systems are built on top of heavyweight APIs, SDKs, real-time bidding systems, and price-per-data-point selling by third-party data brokers, all delicately tuned to behavioral targeting. Transitioning from there to consent-based would have gradual, perhaps even agonizing transition. Hybrid models will have a temporary relief, but these can become backdoors for inserting covert tracking unless regulated hard.

Failure to Educate General Users: In the real-world situation, most users don't even have a clue about what's spying on them online, let alone how to manage Preferences Profiles. Assuming all users will develop rich preference profiles is an expectation of a sort of digital literacy that no one possesses. In order for this to take off as a success, there needs to exist a robust layer of user education, tutorials, onboarding tours, perhaps even gamified experiences to help users manage interests. If it's difficult or an enormous effort, users will revert back to "what works" and return control to tracking systems.

Interoperability and Standardization: In order for such a system to achieve size, it cannot possibly operate on a single app or platform only. It must be made into an open standard, something that any app, game, or website can integrate with seamlessly. To make that happen will require open protocols, interoperability arrangements, and likely regulatory promotion. Without standards, the idea risks becoming fragmented, one platform implementing it and one that doesn't, and users would have to navigate several systems. Standardization may also drive healthy competition and ad tech innovation that is respectful to users' privacy.

While there is immense potential in having a preference-based economy, it will not be a cakewalk. It goes against the way business is now carried out online, and it's not going to come with open arms. But that's precisely what makes it worth trying. Privacy shouldn't have to be the price you pay for convenience. The entire industry has an honest opportunity now to reimagine online relevant content delivery and advertising, not as a method by which to sell more, but as an operating framework based on respect, on consent, and on true relevance. Cooperation, transparency, and most fundamentally, an agreement to get off the road to least resistance will take it.

VII. Implementation Roadmap, Recommendations, and Future Work

As learned from the literature review and the survey taken, making an open, opt-in ad economy is not a vision, it's a mandate. The people are actively looking for a solution rather than waiting for Big Tech to comply with Data Protection Acts and regulations. In the previous sections, this research's perspective of such a platform was presented which can successfully fulfil the users' requirements and not cause an issue for the companies. Stating again, it's a win-win solution for all digital entities involved. The users get the control over their data whereas the companies get the data by peacefully asking for it from the user. This section maps out a pragmatic way back to restoring control for users without shattering the "data tracking" supported web.

A. Cross-Industry Alliance for Ethical Advertising

No single actor can compel this shift. What one needs is an inter-industry group comprising stakeholders with a genuine interest in building trust on the digital space, privacy-oriented developers, ethical start-ups, digital liberties groups, open-source groups, as well as progressive advertisers. These players, as a group, can:

- Set transparent ethical standards for consent-driven data sharing and personalization.
- Advocate for privacy-by-design principles.
- Promote adoption of open standards and APIs for sharing content/ads preferences data.

Such a platform should have no linkage with Big Tech and rather should be funded by neutral nonprofits, open-source devices, and local platforms committed to users' autonomy.

B. MVP Idea: Open-Source Website to Build Interest Profiles

Phase one is an MVP: A fundamental open-source website on which users may create and manage ad and content preference profiles. The key features can include:

- Easy-to-use UI for selecting and categorizing interests.
- Multiple profile creation (e.g., Shopping, Music, Gaming, Social Media).
- Option to generate a unique alphanumeric Profile ID for each profile.
- Support to refresh interests at any time with real-time syncing features.

This MVP is an operational utility as well as a proof-of-concept. By open-sourcing the platform/app, there is transparency, as well as promotion of collaboration with the global developer and Privacy community.

C. API Standard for App Integration

For this to scale, an open, standardized API is required on which apps, sites, and platforms can ask this profile for users' preferences instead of making their own in secret by tracking behind users' backs. The most fundamental functionality offered by the API must be:

- Requesting a specific profile by ID (with consent).
- Syncing updated interests securely for linked profile.
- Allowing apps to offer category-specific personalization (e.g., only show Music and Comedy categories from the user profile).
- Full revocation of access from the user's end at any time.

This provides people with control and encourages platforms to not collect data without reason.

D. Partnerships: Start Small, Grow Gradually

Though Big Tech might not sign up on day one, smaller developers and privacy-oriented companies are great partners upon whom to test and prove out the system. They include:

- Indie game developers (who currently rely on ad SDKs that disrespect user privacy).
- Ethical data privacy friendly platforms such as Proton, Mastodon, or Lemmy.
- Music or podcast applications with interest in community-based personalization.
- Content filtering tools or browser extensions that want to build in clean advertising alternatives.

Such partners would provide aid in credibility building, interoperability verification, and proving real-world applicability of preference-based personalization without surveillance.

E. Governance: User-Led, Not Company-Controlled

To avoid it becoming "just another platform," its governing framework should have collective accountability, transparency, and control at its core. One possibility is a user-led or consortium, cooperative where users, contributors, and even occasional users participate in voting on:

- New features and categories.
- API access rules.
- Third-party app partnerships.
- Security protocols and breach responses.

The idea is not to become locked into control by a few individuals, but to create a decentralized, organized system where the interest of the user is not an afterthought, but the priority.

VIII. Conclusion: A Future Beyond Tracking

The conclusion drawn from literature review was that the current practices in the Data Integrity and Privacy space are trying their best to protect and equip Users with some control, yet they have certain definite flaws that cannot be solved by making more policies. As seen in the survey results, the users were willing to adapt a new solution rather than depending on policies. No doubt, Data Protection Acts are doing their best, but it's just not enough, as companies can find loopholes and workarounds every time. This creates privacy issues for users and their personal data as discussed extensively in this study.

Imagine a world where you only see what you truly value, with none of what you're doing online tracked and recorded. That's the vision here: Relevance without surveillance. This is not just another idea. It is a shift in mindset. Instead of having businesses follow users from app to website to collect their data in the name of providing "relevant" content, what if users had a choice and were able to communicate to companies what they truly want to see?

At its essence is a basic, yet powerful principle: have users develop ad and content preference profiles like they create social media profiles. Instead of shrouded by veil-of-uncertainty algorithms, users would tell different platforms (or share their data) explicitly and openly about what kind of ads or what kind of content interests them. Companies would not have to track anything. No more guessing, no more eavesdropping, no more false data, no more embarrassing advertising for something your friend checked out on your device. Just preferences, by choice.

This is not only an ethical principle, it's pragmatic. It's a win-win. Businesses still get data to sell advertising and keep services free. But they get clean data, direct feedback rather than piecing together conclusions through intrusive tracking. Consumers, on the other hand, have privacy and have more control over what they watch, write, buy, etc. Both consumers and businesses are better off.

Of course, this is just a simple framework. But it's a solution to such a problem that hasn't had any so far. A platform like this can easily be built. The technology is there. It can start as an open-source online platform/application. It can become an open protocol, an open standard. Just like demo website in this study, it is the simple website but has the ability to share users preference data with any organization. Developers, companies, and people can get behind such a thing. But it would require people, researchers, designers, coders, policymakers to mold it. The framework introduced in this research will certainly get data scientists, privacy researchers, and tech companies to one table. Although, it might look like a simple solution, but that is the purpose. It won't be beneficial to make an overly complex solution that users hesitate to use, as proven by the Survey Results. The simplicity itself will get everyone onboard.

Let's reimagine how we do relevance online. Let's create systems that honor users rather than take advantage of them. Instead of teaching algorithms to guess what users want, let users simply tell them. If we can get organized, do some additional research, and start prototyping this vision on a bigger scale than what this work presents in the previous sections, people may be able to guide the internet in a path that serves all of us ethically.

Towards Quantum-Accelerated Urban Systems: Integrating Quantum Computing into Saudi Smart City Megaprojects

Architecting Quantum-Smart Infrastructure for Deployment in Vision 2030 Initiatives

Eissa Alreshidi
Associate Professor, College of Computer Science & Engineering, University of Hail, Hail, P.O. Box 2440, Saudi Arabia

***Abstract*—Quantum Computing (QC), rooted in the principles of superposition and entanglement, enables transformative computational capabilities that surpass classical systems, particularly in solving NP-hard combinatorial optimization, simulation, and machine learning problems. These capabilities are increasingly vital for smart cities, which depend on real-time data from the Internet of Things (IoT) devices, Artificial Intelligence (AI), and Urban Digital Twins (UDTs) to orchestrate complex urban systems such as traffic, energy, logistics, and public safety. As global urbanization accelerates, the demand for hyper-efficient, secure, and adaptive infrastructure exceeds the limits of classical computation. This study employs a multi-pronged methodology that combines literature synthesis, algorithmic mapping, and strategic roadmap design. This study investigates the strategic alignment between QC and the computational demands of next-generation urban environments, with a specific focus on Saudi Arabia's greenfield megaprojects, including NEOM, The Line, and the Red Sea Project, within the Saudi Vision 2030 framework. The analysis systematically maps urban computational challenges to applicable quantum algorithm families—Quantum Approximate Optimization Algorithm (QAOA), Variational Quantum Eigensolver (VQE), and Quantum Machine Learning (QML)—and synthesizes the technical, organizational, financial, ethical, and regulatory prerequisites for national deployment. The core contribution is the development of a conceptual Hybrid Quantum-Classical Architecture (HQCA) and a methodologically grounded three-phase deployment roadmap, tailored to the Saudi context, mapping quantum technical readiness to policy and infrastructure milestones in Saudi Arabia. This framework positions Saudi Arabia to pioneer quantum-accelerated urban systems, enabling resilient infrastructure, sovereign digital capabilities, and global leadership in the emerging Quantum City paradigm.**

Keywords*—Quantum Computing (QC); Hybrid Quantum-Classical Architecture (HQCA); quantum security; smart cities; NEOM; Saudi Vision 2030; combinatorial optimization; Urban Digital Twin (UDT); Quantum Machine Learning (QML); roadmap

I. Introduction

The development of Smart Cities (SC) represents a global strategic shift toward sustainable, hyper-efficient, and digitally integrated urban living environments. These ecosystems rely on the real-time processing of massive data streams generated by the Internet of Things (IoT), sophisticated Artificial Intelligence (AI) models, and comprehensive Urban Digital Twins (UDTs) to manage everything from water distribution to public security [1], [2], [3]. Designed to be adaptive and data-driven, smart cities promise enhanced citizen well-being, resource optimization, and resilient governance.

As smart cities evolve, they generate massive, complex, and real-time datasets from millions of interconnected sensors and systems. The management of these data requires advanced computational methods capable of handling dynamic multivariate environments. Many of the most pressing urban management tasks, such as global traffic synchronization, real-time energy grid balancing, and large-scale logistical coordination, are classified as combinatorial optimization problems. The computational complexity of these challenges increases exponentially with scale, often rendering them intractable, even for the most powerful classical supercomputers [4], [5].

Although classical High-Performance Computing (HPC) has facilitated the first generation of smart cities, the exponential scaling of computational demands now presents a critical bottleneck. Core operational problems in these hyperscale environments, such as dynamic traffic and logistics routing (Vehicle Routing Problem), complex energy grid load balancing (QUBO), and full-fidelity UDT simulation, require solutions that go beyond heuristic approximations, which often lead to systemic inefficiencies and instability in critical infrastructure.

Quantum Computing (QC), grounded in the principles of superposition and entanglement, unlocks new capabilities for a paradigm shift in computational capability. Quantum algorithms, including the Quantum Approximate Optimization Algorithm (QAOA), Variational Quantum Eigensolver (VQE), Quantum Annealing (QA), and Quantum Machine Learning (QML), are particularly well-suited to address the bottlenecks inherent in smart city operations [6], [7], [8]. Their integration into smart city platforms and UDTs enables high-fidelity simulations, predictive modeling of climate and energy dynamics, and real-time decision support for autonomous agents [9], [10].

This opportunity is especially salient in the Kingdom of Saudi Arabia, where Vision 2030 is driving the creation of greenfield urban megaprojects such as NEOM, The Line, and the Red Sea Project, which are designed to be zero-carbon, high-speed, and sovereign in terms of digital infrastructure [11], [12]. These developments require computational solutions that exceed the current urban planning standards. Embedding

quantum capabilities from inception offers Saudi Arabia a unique opportunity to leapfrog legacy constraints and pioneer the Quantum City paradigm.

Despite its compelling technical potential, a significant research and policy gap remains: the absence of a concrete, nation-specific, and phased architectural blueprint for QC adoption in urban transformation initiatives. Most existing studies focus on theoretical algorithmic advantages without addressing the Hybrid Quantum-Classical Architecture (HQCA) required for integration or the strategic framework involving hardware investment, talent development, and regulatory governance required for national deployment.

This study addresses this gap through two key contributions: 1) Architectural Blueprint: Development of the conceptual Hybrid Quantum-Classical Architecture (HQCA) for managing and executing quantum-tractable subproblems in complex smart city operations, providing the necessary technical foundation for integration. 2) Strategic Deployment Roadmap: A methodologically grounded, three-phase roadmap tailored to Saudi Arabia's Vision 2030, guiding policymakers and technical teams from foundational infrastructure readiness to operational quantum advantage, linking technical requirements to strategic policy milestones.

The remainder of this study is structured as follows: Section II provides a comprehensive review of the quantum computing landscape and current smart city architectures, identifying the key research gap this work addresses. Section III details the multi-pronged methodology, including the systematic approach for algorithmic mapping and strategic roadmap development, providing the necessary methodological rigor requested by reviewers. Section IV introduces the foundational Hybrid Quantum-Classical Architecture (HQCA) for smart urban systems and clarifies the distinction between genuine quantum and quantum-inspired methods. Section V presents the strategic three-phase roadmap for integrating QC into Saudi megaprojects, outlining specific use cases and readiness levels. Finally, Section VI concludes the study and discusses future research directions and policy implications.

II. Literature Review

This section critically examines the intersection of quantum computing and smart city development and establishes the theoretical and practical foundations of the proposed framework. It begins by outlining the core principles and architectural models of quantum computing, emphasizing their relevance to urban optimization challenges. This review explores the computational demands of smart cities, highlighting the limitations of classical systems and the strategic imperative for quantum integration. Building on this, the synergy between quantum technologies and smart city platforms is analyzed, with particular attention paid to urban digital twins and autonomous systems. Finally, the literature converges on the context of Saudi Arabia's Vision 2030, presenting an integrated architecture that aligns Smart City layers with quantum capabilities. This progression identifies key research gaps and sets the stage for the technical and strategic contributions of this study to address them.

A. Quantum Computing: Fundamentals and Architecture for Urban Optimization

Quantum Computing (QC) represents a transformative shift in computational paradigms, leveraging quantum-mechanical principles such as superposition, entanglement, and interference to process information in fundamentally different ways from classical von Neumann architectures [8]. Unlike classical bits, which encode data as either 0 or 1, quantum bits (qubits) can exist in multiple states simultaneously. This property enables quantum systems to explore exponentially larger solution spaces in parallel, offering powerful capabilities for solving complex urban challenges [4].

These principles underpin several algorithmic families that are relevant to smart city applications. Quantum optimization algorithms, such as the Quantum Approximate Optimization Algorithm (QAOA) and quantum annealing, have shown promise in solving traffic routing, resource allocation, and scheduling problems [6], [14]. Quantum Machine Learning (QML) enhances predictive modeling in domains such as mobility, infrastructure, and public services [15], whereas quantum simulation enables high-fidelity modeling of physical systems such as climate, energy, and water networks [16]. Additionally, quantum-safe cryptographic protocols, including Post-Quantum Cryptography (PQC) and Quantum Key Distribution (QKD), are essential for securing municipal data and IoT infrastructure [17], [18].

Although the potential of Quantum Computing (QC) is vast, its current realization is characterized by the Noisy Intermediate-Scale Quantum (NISQ) era [4]. This designation describes today's hardware, which features a limited number of physical qubits (typically 50 to a few hundred) and critically lacks robust quantum error correction (QEC). The inherent noise and limited qubit connectivity in NISQ devices impose severe practical constraints on the complexity and runtime of quantum algorithms, causing quantum states to decohere and computational errors to accumulate rapidly.

For smart city applications, this reality mandates the use of Hybrid Quantum-Classical Architectures (HQCAs), particularly in algorithms such as the QAOA and VQE. In these models, quantum processors handle computationally intensive kernels (e.g., optimization components), whereas classical supercomputers manage most data handling and iterative loop control [19]. Furthermore, research efforts are intensely focused on error mitigation techniques—methods that use existing noisy hardware to produce statistically meaningful results by carefully managing and analyzing error signatures rather than relying on full-scale QEC, which remains years away. This pragmatic hybrid approach is critical for the phased adoption outlined in this study, ensuring that early-stage quantum pilots in megaprojects are grounded in achievable computational gains, rather than idealized future performance.

Quantum computing architectures are typically categorized into gate-based systems and quantum annealers. Gate-based architectures support universal quantum algorithms and are programmable and scalable, making them suitable for long-term Smart City applications, such as urban simulation and autonomous system coordination [7]. Quantum annealers, on the other hand, are specialized for solving combinatorial

optimization problems formulated as Quadratic Unconstrained Binary Optimization (QUBO), which are common in traffic signal coordination, smart grid balancing, and logistics routing [14], and [10]. Fig. 1 illustrates the foundational structure of the integrated Smart City framework, emphasizing the role of the computational core in processing vast amounts of urban data.

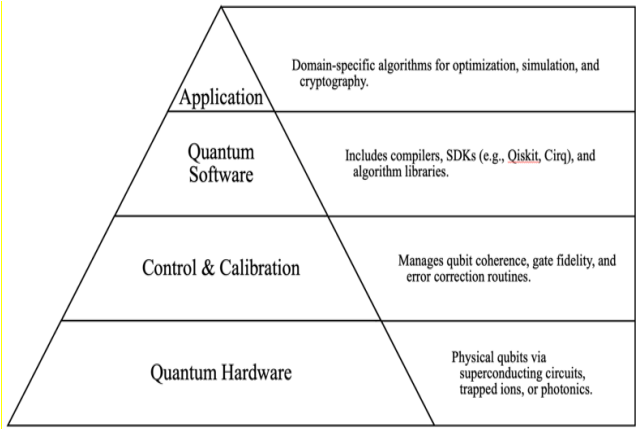

Fig. 1. Architectural layers of quantum computing.

To interface with smart city platforms, quantum architectures must be extended using hybrid quantum-classical systems, middleware abstraction layers, and quantum-safe security modules. Hybrid Quantum-Classical Architectures (HQCA) combine quantum solvers with classical infrastructure to enable real-time decision support in Urban Digital Twins (UDTs), traffic systems, and energy grids [11]. Middleware translators convert Smart City variables into QUBO or Hamiltonian formats for quantum processing [20], whereas quantum-safe security modules embed PQC and QKD into IoT and blockchain layers to ensure resilience against future quantum threats [17], [18].

Although fault-tolerant quantum advantage is still a medium-term objective, quantum-inspired algorithms and hybrid workflows are already delivering near-term value. These approaches enhance performance in targeted domains, such as smart grid balancing and traffic optimization. Moreover, the rise of QC necessitates immediate preparation for quantum threats to current encryption standards, as algorithms such as RSA and ECC are vulnerable to quantum attacks.

B. Smart Cities and the Computational Imperative for Quantum Integration

Smart cities are dynamic ecosystems that integrate advanced technologies to enhance urban life, optimize resource utilization, and ensure sustainability. They represent the convergence of physical infrastructure, digital intelligence, and human-centric governance, orchestrated through interconnected systems [1], [2]. At their core, smart cities rely on Information and Communication Technologies (ICT), Internet of Things (IoT) devices, Urban Digital Twins (UDTs), automated control systems, and real-time analytics to deliver responsive, efficient, and equitable services [3], [10].

The architecture of a smart city comprises multiple interdependent layers, as shown in Fig. 2, including physical infrastructure, sensor networks, connectivity, data management, service orchestration, and governance. These layers support strategic pillars, such as smart governance, smart mobility, smart environments, and smart living. Each pillar involves solving complex optimization problems, multivariate simulations, and secure communications. For example, smart governance demands the predictive modeling of policy outcomes and secure data sharing [9], whereas smart mobility demands real-time route planning and congestion prediction [14]. Smart environments involve dynamic energy balancing and climate resilience modeling [16], whereas smart living depends on the orchestration of intelligent services and secure communications [7].

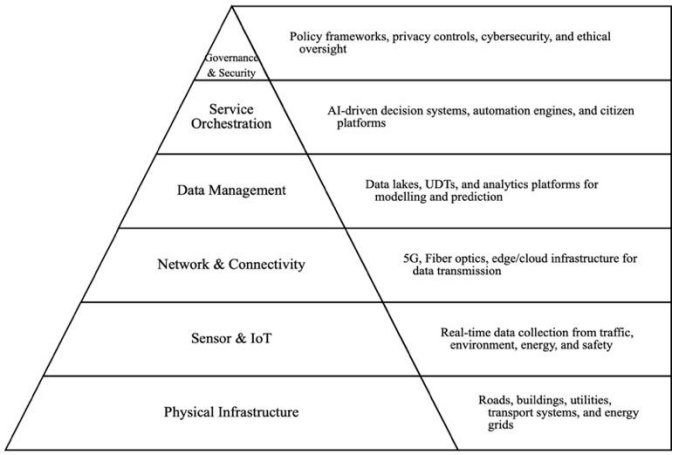

Fig. 2. Architecture layers of smart cities.

The computational demands of these systems, particularly for real-time optimization and high-fidelity simulations, are rapidly outpacing the capabilities of classical computing. Many of the most critical smart city tasks are NP-hard, meaning that the time required to determine optimal solutions increases exponentially with system complexity [4], [8]. Quantum computing provides a novel approach for strategically addressing these bottlenecks. Algorithms such as the QAOA and quantum annealing solve routing and scheduling problems more efficiently [5], [6], while QML enhances predictive modeling, and quantum simulation supports infrastructure planning and resilience [15], [16]. Quantum-safe cryptography ensures long-term data integrity and privacy across Smart City layers [17], [18].

Saudi Arabia's Vision 2030 presents a unique opportunity to embed quantum technologies from inception into greenfield megaprojects, such as NEOM, The Line, and the Red Sea Project [21], [22]. These developments demand computational solutions that exceed the current urban planning standards, particularly in achieving zero-carbon, high-speed, and adaptive operations.

C. Quantum Technologies and Smart City Synergy

The convergence of quantum technologies with smart city systems marks a pivotal evolution in urban innovation. As cities become increasingly complex and data-driven, classical computational architectures struggle to meet the demands of real-time optimization, predictive modeling, and secure communication [4], [8]. The Quantum City paradigm introduces a new computational model that leverages quantum physics to

unlock hyper-efficiency, resilience, and intelligence in urban domains [10].

Conventional smart city technologies—including IoT, AI, blockchain, and cloud computing—operate within deterministic, binary frameworks. Although these systems have enabled significant advancements in urban management, they are inherently limited in solving large-scale combinatorial problems and securing data against emerging threats [1], [2]. Quantum computing bridges this gap by accelerating complex calculations using superpositions and entanglements. Quantum annealing is ideal for solving QUBO problems, such as traffic coordination and energy grid balancing [14], whereas gate-based quantum computing supports universal algorithms, such as QML, for predictive modeling [6], [15].

Quantum communication technology further enhances the resilience of smart cities. Quantum Key Distribution (QKD) provides provably secure encryption, and Post-Quantum Cryptography (PQC) protects urban systems from future quantum attacks (Mosca, 2018; Barletta et al., 2023). These capabilities are especially critical for safeguarding IoT networks, blockchain platforms, and cloud-based services.

Urban Digital Twins (UDTs) are among the most promising applications of quantum technologies. Quantum-enhanced UDTs enable accelerated simulations of traffic systems, climate impacts, and energy demand (Georgescu et al., 2014). Quantum Reinforcement Learning (QRL) trains autonomous agents, such as traffic controllers and energy regulators, within UDT environments, allowing them to adapt in real time and improve system-wide performance [7]. By embedding quantum capabilities into UDTs, Saudi Arabia can achieve predictive, resilient, and intelligent urban systems that scale with complexity and adapt to uncertainties.

D. Integrated Smart City Architecture with Quantum Computing

To operationalize the convergence of smart city systems and quantum technologies, this study presents an integrated architectural framework that aligns urban infrastructure layers with the corresponding quantum computing capabilities of the latter. As cities evolve into complex, data-intensive ecosystems, the limitations of classical computing are becoming increasingly apparent, particularly in domains that require real-time optimization, high-dimensional simulation, and secure communication.

The proposed framework reflects the layered nature of smart cities, as structured in Table I, beginning with the foundational physical infrastructure and progressing through sensor networks, connectivity, data management, service orchestration, and governance. Each layer is mapped to a quantum counterpart, illustrating how quantum hardware, algorithms, simulation engines, and cryptographic protocols can be embedded in the urban stack. For example, quantum hardware environments support infrastructure-level integration, whereas quantum sensors enhance data collection precision. Quantum communication channels, such as QKD-secure network layers and quantum simulation engines, enhance the data management systems. The QAOA, QML, and QRL enhance service orchestration, whereas the PQC and ethical quantum governance modules reinforce governance and security [10], [11], [18].

To bridge classical and quantum systems, the architecture includes integration middleware components, such as a Hybrid Execution Manager, which routes tasks to either classical or quantum processors based on complexity. The Quantum API Gateway provides a unified interface for accessing Quantum-as-a-Service (QaaS) platforms such as IBM and Pasqal, whereas the Semantic Translator converts smart city variables, such as traffic flows, energy loads, or policy constraints, into quantum-compatible formats such as QUBO or Hamiltonians.

TABLE I. LAYERED ARCHITECTURE: CLASSICAL–QUANTUM ALIGNMENT

Layer	Smart City Components (Classical)	Quantum Integration (Enhancement)
Governance & Security	Policy frameworks, privacy controls, cybersecurity, ethical oversight	Post-Quantum Cryptography (PQC), Quantum-safe Protocols, Ethical Governance Modules
Service Orchestration	Automated control systems, intelligent service delivery, multi-agency coordination	Quantum Algorithms (QAOA, QML, QRL) for optimization, learning, and autonomy
Data Management	Urban Digital Twins (UDTs), data lakes, AI-driven analytics platforms	Quantum Simulation Engines and Quantum-Enhanced Data Processing
Network & Connectivity	5G, fiber optics, and edge/cloud infrastructure for data transmission	Quantum Communication Channels (QKD, Entanglement-based Networks)
Sensor & IoT	Real-time data collection from traffic, environment, energy, and public safety	Quantum sensors for ultra-precise measurements (e.g., magnetic fields, temperature)
Physical Infrastructure	Roads, buildings, transport systems, energy grids, and utilities	Quantum Hardware Environments (Cryogenic Systems, Superconducting Circuits, Photonics)

Fig. 3 illustrates the vertical alignment between the conventional five-layer Smart City stack and the specific Quantum Computing (QC) technologies designed to accelerate, optimize, and secure each layer. The model highlights the use of Post-Quantum Cryptography (PQC) and Quantum Key Distribution (QKD) for foundational security, while Quantum Machine Learning (QML) and optimization algorithms (QAOA, VQE) provide the necessary computational speedup to manage NP-hard problems in real-time city operations.

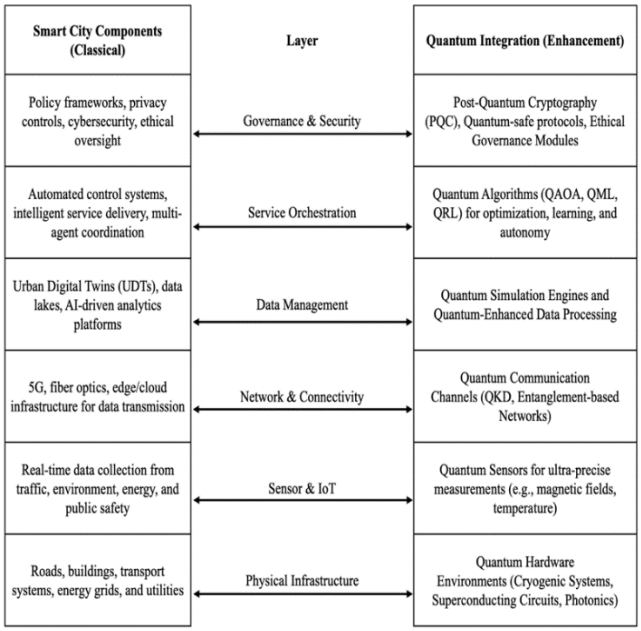

Fig. 3. Hybrid Quantum-Classical Architectures (HQCA) for urban systems.

E. Saudi Arabia: Quantum Computing Technologies and Smart Cities Context

Saudi Arabia's Vision 2030 positions the Kingdom as a global leader in digital transformation and urban innovation. Greenfield megaprojects, such as NEOM, The Line, and the Red Sea Project, are designed to be zero-carbon, high-speed, and digitally sovereign, making them ideal testbeds for quantum integration [11], [12]. The strategic imperative is clear: classical systems cannot meet the computational demands of hyperscale environments.

Although Saudi Arabia has invested in AI, 5G, and IoT infrastructure, quantum computing is an emerging frontier. There is limited national literature on phased QC adoption, talent development, and regulatory alignment. This gap underscores the need for a tailored Strategic Adoption Framework that maps quantum capabilities to Saudi Arabia's urban transformation goals to ensure operational readiness and sovereign-technology leadership.

III. Methodology

A. Overview of Methodological Framework

This study adopts a multi-layered methodological framework to guide the strategic integration of quantum computing (QC) into Saudi Arabia's emerging smart city ecosystem. The approach begins with a systematic literature review synthesizing global advancements in quantum technologies across urban domains. Peer-reviewed publications, government reports, and pilot project documentation were analyzed to benchmark the technical feasibility and deployment patterns. This review was complemented by a thematic synthesis of Saudi Arabia's digital transformation agenda, particularly Vision 2030 and the National Strategy for Data and AI, to contextualize quantum integration within the national priorities.

Building on this foundation, this study conducts a comparative contextual analysis that juxtaposes international quantum-smart city use cases with the unique characteristics of Saudi greenfield megaprojects, such as NEOM, The Line, and Qiddiya. These developments, unconstrained by legacy infrastructure, present distinct requirements for low-carbon efficiency, secure communications, and real-time urban intelligence. From this analysis, three high-impact domains were systematically selected:

- Traffic signal coordination, mapped to QAOA and quantum annealing for optimization.
- Smart grid balancing, mapped to VQE for complex simulation and optimization.
- Infrastructure simulation via Urban Digital Twins (UDTs), mapped to QML and QRL for predictive modeling and autonomous decision-making.

Hybrid quantum-classical workflows were designed using platforms such as IBM Qiskit and D-Wave Leap, with problem formulations translated into quantum-compatible formats like QUBO and Hamiltonians.

The final phase of the methodology involved strategic synthesis and roadmap design processes. Insights from the literature and algorithmic mapping were consolidated into a three-phase national roadmap—exploration, pilot deployment, and scaled integration—each of which is aligned with technical, organizational, and financial milestones. Key Performance Indicators (KPIs) were defined to measure progress in infrastructure readiness, talent development, regulatory alignment, and cross-sector adoption. To validate the framework, evaluation criteria were applied across four dimensions: computational efficiency, scalability, integration feasibility, and strategic alignment with Saudi Vision 2030. This iterative process ensures that the proposed roadmap remains adaptable to the evolving quantum capabilities and urban planning priorities. Fig. 4 illustrates the overall iterative methodology used in this study.

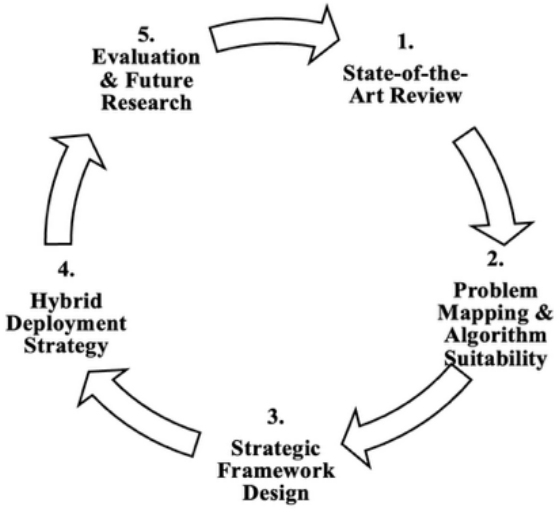

Fig. 4. Overall methodology.

B. Methodological Grounding of Algorithmic Mapping and Roadmap Design

This study adopts a systematic algorithmic mapping and strategic foresight analysis approach to address the need for greater methodological transparency and rigor in the mapping and strategic design processes. This study adopts an approach of systematic algorithmic mapping and strategic foresight analysis. The criteria for use case selection, mapping scope, and roadmap phasing were explicitly defined as follows.

First, the criteria for Use Case Selection and prioritization were based on three synergistic factors that justify the strategic investment in quantum resources. These factors are Strategic Relevance, where cases were chosen based on their direct alignment with the high-impact, technologically ambitious goals of Saudi Vision 2030 megaprojects (e.g., NEOM's cognitive systems, high-speed logistics, and sustainable resource management); Classical Bottleneck Justification, which explicitly placed focus on problems identified as NP-hard (e.g., complex combinatorial optimization, large-scale traffic modeling, resource allocation) where current state-of-the-art classical High-Performance Computing (HPC) or AI solutions face known computational limitations, thereby justifying the search for quantum acceleration; and Theoretical Quantum Applicability, where use cases were confirmed against existing, peer-reviewed literature demonstrating a theoretical fit with known quantum algorithm families (e.g., the QUBO formulation required by QAOA or the linear algebra necessary for HHL).

Second, the Algorithmic Mapping and Technical Scope section clarifies that the mapping presented is a conceptual architectural blueprint rather than a formal complexity proof. It links the class of urban problems to the class of suitable quantum algorithms. This is explicitly a strategic mapping intended to both identify where potential quantum advantage could be realized and inform the design of the Hybrid Quantum-Classical Architecture (HQCA) discussed in Section IV. Formal complexity analysis and empirical performance comparisons against classical HPC are acknowledged as critical future work, dependent on the scaling and maturity of fault-tolerant quantum hardware. Therefore, this study provides the necessary conceptual foundation for those future comparisons.

Third, the Roadmap Phasing and Readiness Assessment explains that the three-phase roadmap adapts the conventional Technology Readiness Level (TRL) framework to a Quantum Readiness Level (QRL) relevant for strategic urban systems deployment. The phasing is benchmarked against three factors: QPU Scaling, which considers anticipated global timelines for NISQ device maturity (e.g., 50+ effective qubits) and the development of rudimentary fault-tolerant QPUs; Infrastructure Maturity, encompassing the projected development schedule and foundational readiness of the specific Saudi megaprojects; and Goal Orientation, where each phase (Readiness, Pilot, and Deployment) is structured to progressively move from foundational research/quantum-inspired techniques to full integration of true QPU acceleration, providing a clear path from current capabilities to future quantum advantage.

IV. Results

This section presents the analytical results and strategic insights derived from the proposed methodology. It begins by examining the international use cases of quantum computing in smart cities and offers comparative benchmarks and insights. The discussion then shifts to the Saudi Arabian context, evaluating its current readiness and identifying the key requirements for quantum integration. Based on this foundation, a three-phase strategic roadmap is proposed to guide adoption across national megaprojects. This section elaborates on a holistic technical integration strategy and hybrid quantum-classical software architecture designed to support scalable, secure, and intelligent urban systems. Finally, this study critically assesses the benefits and challenges of quantum adoption, offering a balanced perspective on its feasibility, impact, and future direction.

A. Use Cases from Around the World for Quantum Computing Adoption in Smart Cities

Global pilot projects and proof-of-concept deployments have demonstrated that quantum computing (QC) offers tangible near-term value for smart cities, not by replacing classical systems, but by augmenting them using hybrid algorithms, simulation-based proofs, and targeted hardware trials. These initiatives span a wide spectrum of domains, including traffic optimization, energy grid management, logistics, environmental sensing, cybersecurity, healthcare, education, and digital governance. These pilots offer strategic foresight for Saudi Arabia's megaprojects, such as NEOM, Qiddiya, and the Red Sea Project, especially in areas where classical computational limits are likely to be reached owing to the scale, complexity, and sustainability ambitions of these developments.

In traffic and mobility optimization, quantum annealing and quantum-inspired algorithms have been applied to complex routing and scheduling problems, such as the Traveling Salesperson Problem (TSP), enabling real-time traffic light sequencing and congestion reduction. In energy grid management, hybrid quantum-classical algorithms accelerate unit commitment and battery placement, enhancing grid balance in renewable-heavy microgrids. Urban logistics and supply chain routing have benefited from quantum formulations for last-mile delivery and dynamic routing, thereby improving freight efficiency in densely populated city environments.

In environmental modeling and sensing, quantum-enhanced sensors and quantum machine learning (QML) enable high-fidelity anomaly detection and climate-resilience forecasting. Cybersecurity pilots have deployed Quantum Key Distribution (QKD) and post-quantum cryptography (PQC) to secure municipal infrastructure and citizen data. Smart healthcare modeling leverages quantum graph analytics and probabilistic modeling to simulate disease spread and optimize hospital logistics, thereby supporting national preparedness and NEOM's health systems.

Emerging domains are gaining popularity. Smart waste management uses quantum optimization for dynamic bin scheduling and route planning, aligning with circular economy goals in cities such as Medina. In education, quantum-enhanced

clustering and recommendation systems enable personalized learning paths and adaptive curricula, supporting NEOM's digital education platforms. Digital twin simulation integrates quantum-enhanced multi-agent modeling for real-time urban planning and resilience forecasting. Finally, smart tourism applications use quantum algorithms to optimize visitor flows and enhance cultural site management, which is critical for destinations such as Alula, Diriyah, and Hajj logistics.

Table II summarizes these global pilot projects, highlighting their focus areas, enabling technologies, demonstrated outcomes, and strategic relevance to Saudi Arabia's Smart City initiatives.

TABLE II. GLOBAL QUANTUM COMPUTING PILOT PROJECTS FOR SMART CITIES

Focus Area	Technology & Mechanism	Outcome	Saudi Applicability	Technical Enhancement	Ref.
Traffic Signal Optimization	Quantum Annealing (QUBO formulation)	Adaptive signal control, reduced congestion	NEOM and Riyadh traffic systems	Quantum-assisted learning automata for dynamic timing	[23] [24] [25]
Port Logistics & Routing	Quantum-Inspired Optimization (Digital Annealer)	Lower truck travel time, reduced CO_2 emissions	Jeddah and Dammam logistics hubs	Hybrid QUBO for multi-modal freight routing	[26] [27]
Grid Battery Placement	Hybrid Quantum-Classical Algorithms	Optimized voltage control and battery siting	Saudi smart grid expansion	Quantum-enhanced simulation for energy resource planning	[28], [29], [30]
Urban Mobility Forecasting	Quantum Machine Learning (QML) on traffic sensor data	Improved traffic prediction accuracy	Riyadh and NEOM AI mobility platforms	Quantum-enhanced time series forecasting	[31], [32], [33]
Emergency Response Optimization	Quantum annealing for multi-agent dispatch	Faster resource allocation and coordination	NEOM autonomous emergency systems	Quantum scheduling for emergency logistics	[34], [35]
Infrastructure Optimization	Quantum-Inspired Evolutionary Algorithms	Multi-variable optimization for traffic and energy	NEOM and Qiddiya infrastructure planning	QiEA restarts and swarm intelligence	[36], [37], [38]
Energy & Water Management	Quantum simulation for desalination and grid modeling	Improved modeling of water-energy nexus	Red Sea Project and NEOM water-energy systems	Quantum-enhanced digital twin for resource optimization	[39], [40], [41]
Cybersecurity Infrastructure	Quantum Key Distribution (QKD) and Post-Quantum Cryptography (PQC)	Secured municipal data links	PQC rollout across Saudi smart city platforms	Integration of QKD with blockchain-based services	[42], [43]
Urban Governance Simulation	Quantum-enhanced agent-based modeling	Simulated policy outcomes across complex urban systems	NEOM governance and Vision 2030 policy planning	Quantum scenario simulation for zoning, taxation, and incentives	[13]
Climate Resilience Forecasting	Quantum simulation for climate and disaster modeling	High-resolution prediction of floods and heatwaves	Coastal and desert urban adaptation	Quantum-enhanced microclimate and extreme event modeling	[39], [41]
Smart Healthcare Modeling	Quantum graph analytics and probabilistic modeling	Disease spread modeling, hospital logistics optimization	NEOM health infrastructure and national preparedness	Quantum-enhanced epidemiological simulation	[44], [45], [46], [47]
Digital Identity & Citizen Services	Quantum-secure identity verification and blockchain integration	Secure e-government, voting, and citizen data platforms	National digital identity and civic platforms	PQC-based authentication and encrypted citizen services	[42], [48], [49], [50]
Smart Waste Management	Quantum optimization for route planning and bin prediction	Dynamic scheduling, reduced fuel and overflow	NEOM circular economy, Medina municipal services	Quantum-enhanced logistics for sanitation networks	[51], [52]
Smart Education & Learning Analytics	Quantum-enhanced clustering and recommendation systems	Personalized learning paths, curriculum optimization	NEOM education platforms, national e-learning	Quantum machine learning for adaptive education	[53], [54]
Digital Twin & Urban Simulation	Quantum simulation for multi-agent urban modeling	Real-time city-scale digital twins	NEOM, Qiddiya, Red Sea infrastructure	Quantum-enhanced planning and resilience modeling	[55], [56]
Smart Tourism & Cultural Heritage	Quantum-enhanced recommendation and crowd flow modeling	Optimized visitor experience, congestion prediction	AlUla, Diriyah, Hajj logistics	Quantum algorithms for cultural site management	[57], [58]

These benchmarks inform the technical and strategic directions for quantum adoption in Saudi Arabia. The following subsections explore three representative use cases in greater depth, illustrating how quantum algorithms address specific Smart City challenges and how these solutions translate into measurable impacts within the Saudi context.

1) Energy grid load balancing and optimization: An excellent example of a combinatorial-optimization problem is managing scattered urban energy systems heavily reliant on renewable sources. In smart cities, such as NEOM, where energy systems are built around 100% renewable sources, a considerable amount of computer power is required to balance the real-time energy flow, predict how demand will change, and schedule battery storage among thousands of dynamic nodes. Quadratic Unconstrained Binary Optimization (QUBO) models typically address these issues. Classical solvers use heuristics

to solve them; however, these heuristics become less accurate and slower as the system becomes more complex.

Quantum computing is an intriguing alternative to classical computing methods. The Quantum Approximate Optimization Algorithm (QAOA) and Variational Quantum Eigensolver (VQE) are two examples of algorithms that can solve QUBO problems by converting them into quantum circuits. These circuits examine extensive solution spaces in superposition and identify near-optimal configurations for load distribution and storage scheduling. The VQE and QAOA can determine the optimal times to charge and discharge a quantum system by lowering its energy state. This reduces energy loss and maximizes the use of renewable sources.

In Saudi Arabia, this ability immediately helps the Line and other megaprojects achieve their goal of carbon neutrality. Recalibrating the grid in real time makes operations more reliable, reduces energy waste, and makes the system more sustainable in the long run. Improvements in computing efficiency can lead to significant reductions in costs and emissions, demonstrating the importance of quantum integration in national energy planning.

2) Dynamic traffic and logistics routing: In hyper-connected cities, urban logistics and mobility systems require route optimization that is always on and can predict the next event. As Saudi Arabia moves toward fleets of self-driving cars and public transit networks that function together, managing real-time traffic flow and supply chains becomes increasingly difficult. These problems are usually modeled as different versions of the Vehicle Routing Problem (VRP) or the Traveling Salesperson Problem (TSP). Both problems are NP-hard and scale poorly in classical computations.

Quantum Annealing (QA) is a powerful way to solve these kinds of problems. QA enables a quantum system to anneal toward its lowest-energy state by introducing routing constraints and objectives in the energy landscape. This is the most efficient method for setting up routes. This approach offers significant speed-ups over classical heuristics, such as simulated annealing, particularly in high-dimensional and time-sensitive scenarios.

Quantum-enhanced routing can guarantee zero-latency mobility and logistics in smart cities in Saudi Arabia. This is a basic prerequisite for NEOM's autonomous infrastructure. Efficient routing reduces fuel consumption, minimizes battery drainage, and lowers the environmental emissions. Moreover, quantum scheduling can support multi-agent coordination across emergency response systems, freight hubs, and public transit, making both operations more efficient and improving the experience of citizens.

3) Urban digital twin (UDT) simulation and forecasting: Urban Digital Twins (UDTs) are central to predictive governance in smart cities, enabling planners to simulate and evaluate infrastructure, environmental, and social systems before implementation. Planners can test and assess infrastructure, environmental, and social systems using UDTs prior to construction. However, for UDTs to work well, they must simulate complicated, interconnected tasks, such as fluid dynamics, air quality, population mobility, and material behavior. These tasks involve solving large systems of equations and modeling high-dimensional physical processes, which often exceed the capabilities of classical computing.

Quantum Simulation and Quantum Machine Learning (QML) are two methods that work well together to solve problems. Quantum simulation uses quantum mechanics to represent physical systems at an exponential speed, making it ideal for simulating chemical reactions and designing materials. In contrast, QML excels at extracting patterns from noisy sensor data, enabling accurate forecasting and predictive maintenance of urban infrastructure.

Quantum-enhanced UDTs can transform static planning tools into dynamic engines for resilience and foresight in Saudi Arabia. For example, they can be used to forecast water demand under stress conditions, simulate the structural integrity of new materials, and predict the spread of airborne pollutants. These capabilities aid in proactive governance, smart capital planning, and the long-term success of urban transformation initiatives, especially in areas susceptible to climate change, such as the Red Sea Coast and NEOM.

B. Quantum Computing Adoption for Smart Cities in Saudi Arabia

Saudi Arabia is undergoing a profound transformation under the Vision 2030 framework, with smart city development as the national cornerstone. The Kingdom desires to build smart, zero-carbon, and hyper-efficient cities using advanced technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), and quantum computing (QC). NEOM, The Line, Riyadh Smart City, and the Red Sea Project are some of the most important projects that demonstrate this goal in Saudi Arabia.

These projects differ because of their massive size and "greenfield" design, which allows quantum-readiness to be embedded into the infrastructure and data architecture from the start. This strategic advantage enables Saudi cities to bypass outdated integration challenges and utilize the most advanced computational models from the beginning. In this case, three imperatives drive the adoption of QC. First, the absence of legacy systems allows the native integration of quantum technologies, thereby avoiding costly retrofitting. Second, the optimization-critical nature of energy, water, and mobility systems requires computational capabilities that exceed the classical limits. Third, the Kingdom's ability to invest and its long-term commitment to Vision 2030 make it possible to continue investing in quantum infrastructure, talent development, and ecosystem creation.

Quantum computing is particularly important for Saudi Arabia's initiatives. NEOM is a $500 billion cognitive megacity designed to integrate AI, quantum technologies, and self-driving systems to improve sustainability and operational efficiencies. The Line is a 170-kilometer-long city in NEOM that aims to have no cars and no carbon emissions, which means it needs real-time smart systems to manage different types of transportation. The Red Sea Project and Qiddiya are large-scale tourism and entertainment hubs that require smart infrastructure for logistics, resource management, and the provision of tailored services. Owing to their size and

complexity, these projects are likely to reach classical computational limits sooner than retrofitted cities. Therefore, quantum computing is not a luxury upgrade but a strategic necessity for real-time multimodal optimization across the energy, water, mobility, and security domains.

Saudi Arabia has initiated the development of a local quantum ecosystem to facilitate such changes. The Quantum Valley Initiative is a partnership between the King Abdulaziz City for Science and Technology (KACST), the Saudi Data and AI Authority (SDAIA), IBM, and Pasqal. Its goal is to create a national center for quantum research, hardware hosting, and application development. Early-stage quantum security pilots in NEOM are working on quantum-secured IoT and blockchain frameworks to ensure city resilience and maintain data integrity. There are national talent programs underway to teach more than 50 graduate students in Quantum Information Science (QIS) and provide more than 200 IT professionals with certificates in quantum computing and post-quantum cryptography (PQC). In addition, hybrid pilots are used in the energy, logistics, and water sectors to test quantum-classical operations and help shape regulatory frameworks.

Saudi smart cities are in a unique position to profit from quantum computing because they utilize Urban Digital Twins (UDTs), maintain expansive IoT networks, and implement blockchain-based infrastructure. UDTs require real-time simulation and optimization of multimodal systems, whereas the rapid growth of sensor networks necessitates the use of PQC and QKD for secure data transmission. QC also complements blockchain platforms by enhancing data integrity and cyber resilience. In this perspective, NEOM and The Line are worthy examples of the quantum imperatives. Because they require operational complexity and demand QC for predictive modeling, resource allocation, and coordinating autonomous systems, the Kingdom's smart city future will be based on quantum computing.

C. *Requirements of Quantum Computing Adoption for Smart Cities in Saudi Arabia*

As Saudi Arabia accelerates its smart city transformation under the Vision 2030 framework, quantum computing (QC) is becoming a strategic enabler, creating urban settings that are zero-carbon, hyper-efficient, and cognitively adaptive urban environments. NEOM, The Line, and the Red Sea Project are major projects that require computing power greater than that provided by traditional methods, particularly for tasks such as real-time optimization, secure data sharing, and accurate simulation. To harness quantum technologies effectively, a multidimensional understanding of the technical, organizational, financial, legal, ethical, and regulatory requirements is essential. Saudi Arabia has a unique position for quantum integration because it offers a greenfield advantage, the ability to invest in its quantum ecosystem, and a commitment to its development.

Drawing on global governance frameworks and strategic roadmaps, including those from the World Economic Forum, Stanford Law, Cambridge University Press, and UK government publications, this section outlines the key prerequisites for QC adoption in Saudi Arabia's Smart Cities.

- Technical Requirements. Quantum adoption requires robust hybrid architecture, secure communication protocols, and middleware integration. To ensure data sovereignty, Saudi Arabia must move from quantum-as-a-service (QaaS) models to sovereign Hybrid Quantum-Classical Architectures (HQCA). It is critical to integrate QC into NEOM's digital twin and smart grid platforms, along with standardized Post-Quantum Cryptography (PQC) across IoT and blockchain systems. Mitigation strategies include investing in sovereign infrastructure, collaborating with global vendors for localized deployments, and launching a national standards body under the KACST and SDAIA.
- Social and Human Capital Requirements. Quantum-literate staff and public trust are foundational elements of quantum governance. Addressing talent shortages in Quantum Information Science (QIS), engaging citizens in data governance, and localizing QIS curricula are essential steps. Initiatives such as the Quantum Talent Initiative (QTI), public engagement campaigns, and joint academic programs with King Abdullah University of Science and Technology (KAUST), King Abdulaziz University (KAU), and other international institutions support inclusive and sustainable capacity building.
- Organizational Requirements. Effective QC adoption requires agile governance, inter-agency coordination, and collaboration. Aligning the governance structures of SDAIA, KACST, the Ministry of Education, and NEOM will make it possible to prototype and deploy quickly. Institutionalizing quantum innovation requires the establishment of a National Quantum Steering Committee, the use of regulatory sandboxes, and the hiring of Chief Quantum Officers (CQOs) within megaprojects.
- Financial Requirements. Long-term sovereign investments and private-sector incentives are vital. Leveraging the Public Investment Fund (PIF) and Vision 2030 resources, attracting Foreign Direct Investment (FDI), and modeling the Return on Investment (ROI) in hybrid deployments will ensure financial sustainability. The Quantum Innovation Fund, tax credits, and cost-benefit frameworks for pilot evaluation are recommended as mitigation strategies.
- Regulatory Requirements. Saudi Arabia must define a national quantum policy, align it with international compliance standards, and regulate quantum-enhanced services. Ensuring adherence to global PQC and QKD protocols, addressing dual-use concerns, and being consistent with Gulf Cooperation Council (GCC) and Organization for Economic Cooperation and Development (OECD) digital regulations are all important considerations. Developing a National Quantum Regulatory Framework and participating in working groups for the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) and the European Telecommunications Standards Institute (ETSI) would aid regulatory maturity.

- Ethical Requirements. Responsible innovation must lead to quantum AI deployment. Ethical risks in predictive policing, facial recognition, and behavioral modeling must be addressed in accordance with Islamic principles and Vision 2030 standards. A National Quantum Ethics Board will be established, WEF Quantum Governance Principles will be adopted, and fairness audits of quantum algorithms will be mandated to ensure transparency and cultural sensitivity.
- Legal Requirements. Legal frameworks must be adjusted to accommodate these technologies. It is important to update intellectual property laws, define liability in quantum-enhanced decision-making systems, and clarify data ownership and cross-border flows. Saudi Arabia must safeguard its sovereign rights over quantum-generated insights, oversee quantum-enhanced public services, and guarantee adherence to national data protection laws, such as the Personal Data Protection Law (PDPL). Mitigation strategies include amending cybersecurity laws, drafting hybrid AI/QC legal frameworks, and defining thresholds for quantum automation.

Table III summarizes a structured overview of the key requirements for adopting quantum computing in Saudi smart cities.

TABLE III. QUANTUM COMPUTING ADOPTION REQUIREMENTS FOR SMART CITIES IN SAUDI ARABIA

Requirement Category	Key Requirements	Specific Requirements for Saudi Arabia	Mitigation Strategy
Technical	Develop Hybrid Quantum-Classical Architectures (HQCA) Implement Post-Quantum Cryptography (PQC) standards. Build middleware for UDT–QC integration. Establish benchmarking and error mitigation protocols.	Transition from QaaS to sovereign HQCA for data sovereignty Integrate QC into NEOM's digital twin and smart grid platforms. Standardize PQC across smart city IoT and blockchain systems.	Invest in sovereign quantum infrastructure. Collaborate with global QC vendors for localized deployments. Launch a national QC standards body under KACST/SDAIA.
Social / Human Capital	Build a quantum-literate workforce. Promote public awareness and trust. Ensure inclusive access to quantum education.	Address QIS talent shortages in academia and industry. Engage citizens in smart city data governance. Localize QIS curricula in Arabic and align with Vision 2030 education reforms.	Expand the Quantum Talent Initiative (QTI). Launch public engagement campaigns. Partner with KAUST, KAU, and international institutions for joint programs.
Organizational	Establish inter-agency coordination frameworks. Create agile pilot governance models. Embed quantum innovation units in city planning bodies.	Align SDAIA, KACST, MoE, and NEOM governance structures. Enable rapid prototyping and iterative deployment in smart city zones.	Form a National Quantum Steering Committee. Use regulatory sandboxes for pilot testing. Appoint Chief Quantum Officers (CQOs) in megaprojects.
Financial	Secure long-term sovereign investment. Incentivize private sector R&D and startups. Model ROI for hybrid QC deployments.	Leverage PIF and Vision 2030 funds for infrastructure. Attract FDI in quantum ventures. Justify QC investment through energy, logistics, and security gains.	Establish a Quantum Innovation Fund. Offer tax credits and grants for QC R&D. Develop cost-benefit frameworks for pilot evaluation.
Regulatory	Define national quantum policy and standards. Align with international export controls and compliance. Regulate quantum-enhanced services and data flows.	Ensure compliance with global PQC and QKD standards. Address dual-use concerns in defense and energy sectors. Harmonize with GCC and OECD digital regulations.	Draft a National Quantum Regulatory Framework. Participate in ISO/IEC and ETSI quantum working groups. Create a regulatory sandbox for quantum pilots.
Ethical	Promote responsible innovation and transparency. Prevent misuse of quantum-enhanced surveillance. Ensure cultural and social sensitivity in deployment.	Address ethical risks in predictive policing, facial recognition, and behavioral modeling. Align with Islamic ethical principles and Vision 2030 values.	Establish a National Quantum Ethics Board. Adopt WEF Quantum Governance Principles. Require explanations and fairness audits for quantum algorithms.
Legal	Update IP laws for quantum algorithms and hardware. Define liability in quantum-enhanced decision systems. Clarify data ownership and cross-border data flows.	Protect sovereign rights over quantum-generated insights. Regulate quantum-enhanced public services (e.g., traffic, energy, and health). Ensure compliance with Saudi data protection laws (e.g., PDPL).	Amend IP and cybersecurity laws to include quantum domains. Draft legal frameworks for hybrid AI/QC systems. Define legal thresholds for quantum-enhanced automation.

D. Proposed Strategic Three-Phased Roadmap for QC Adoption in Saudi Arabia's Smart Cities

1) Proposed strategic three-phased roadmap for QC adoption: The quantum computing roadmap for Saudi Arabia's smart cities is designed to evolve from foundational capability building to full operational deployment, in alignment with the Saudi Vision 2030 mandates for human capital development, digital transformation, and sovereign technological leadership. The roadmap is divided into three strategic phases and includes key pillars, focus areas, and measurable milestones to guide the Kingdom's transition from pilot experimentation to global quantum leadership. Fig. 5 presents the proposed three-phase roadmap for QC adoption in smart cities in Saudi Arabia. The three phases are detailed as follows:

- Phase I: Foundation and Preparation (0–3 years). This initial phase focuses on establishing a foundational ecosystem required for the adoption of quantum computing. Activities include the publication of a National Quantum Strategy and the development of ethical, legal, and social implications (ELSI) frameworks to guide responsible innovations. Talent development is prioritized through the launch of the Quantum Talent Initiative, which aims to retrain IT professionals and reform university curricula to include Quantum Information Science (QIS). Early access to quantum resources is secured via quantum-as-a-service (QaaS) contracts, and pilot-scale post-quantum cryptography (PQC) is deployed on noncritical smart city subsystems to test the security protocols.
- Phase II: Pilot and Integration (3–7 years). This phase emphasizes hybrid system validation and integration with Urban Digital Twins (UDTs). Quantum-classical pilots are launched in high-impact domains, such as smart grid optimization and traffic control, leveraging algorithms such as Quantum Reinforcement Learning (QRL). A middleware is developed to abstract the UDT variables into the QUBO format, enabling compatibility with quantum solvers. Cyber resilience is enhanced by mandating post-quantum cryptography (PQC) across IoT and blockchain frameworks within pilot zones to ensure secure data flows and infrastructure integrity.
- Phase III: Deployment and Leadership (7+ years). The final phase focuses on full-scale operationalization and positioning Saudi Arabia as a global leader in quantum-smart-city innovation. Proven hybrid quantum algorithms are integrated into core operational systems in major cities. A National Quantum Hardware Center has been set up to provide local optimization tools, like quantum annealers, to enhance the country's computing power. By hosting international forums and advancing research on next-generation concepts, such as quantum digital twins, Saudi Arabia further solidifies its leadership.

Table IV summarizes the detailed milestones, duration, and strategic objectives for each phase of the quantum computing roadmap.

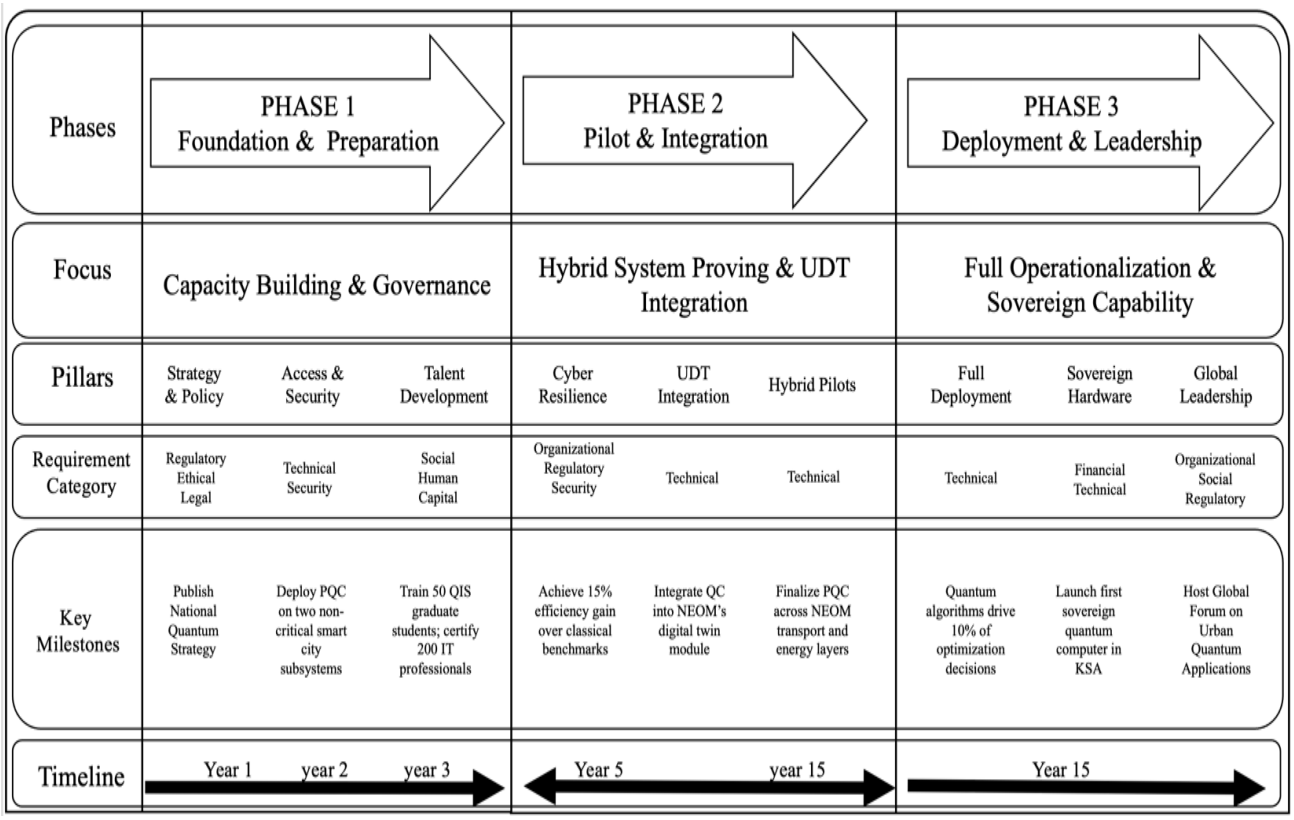

Fig. 5. A proposed strategic three-phased roadmap for QC adoption for smart cities within Saudi Arabian environments.

TABLE IV. QUANTUM COMPUTING ROADMAP FOR SAUDI SMART CITIES

Phase	Duration	Primary Focus	Key Pillars	Requirement Category	Strategic Objectives / Milestones
I. Foundation & Preparation	0–3 Years	Capacity Building & Governance	Strategy & Policy (Governance, ELSI)	Regulatory Ethical Legal	Year 1: Publish the National Quantum Strategy and ELSI framework.
			Talent Development (Human Capital)	Social Human Capital	Year 3: Train 50 QIS graduate students; certify 200 IT professionals in QC/PQC.
			Access & Security (QaaS, PQC)	Technical Security	Year 2: Deploy PQC on two non-critical smart city subsystems.
II. Pilot & Integration	3–7 Years	Hybrid System Proving & UDT Integration	Hybrid Pilots (Smart Grid, Traffic)	Technical	Year 7: Achieve a 15% efficiency gain over classical benchmarks.
			UDT Integration (QUBO Middleware)	Technical	Year 5: Integrate QC into NEOM's digital twin module.
			Cyber Resilience (PQC in IoT/Blockchain)	Organizational Regulatory Security	Year 5: Finalize PQC across NEOM transport and energy layers.
III. Deployment & Leadership	7+ Years	Full Operationalization & Sovereign Capability	Full Deployment (Citywide QC Integration)	Technical	Year 10: Quantum algorithms drive 10% of optimization decisions.
			Sovereign Hardware (National QC Center)	Financial Technical	Year 12: Launch the first sovereign quantum computer in KSA.
			Global Leadership (Research & Policy)	Organizational Social Regulatory	Year 15: Host Global Forum on Urban Quantum Applications.

E. Holistic Technical Quantum–Smart City Integration Strategy

To ensure a cohesive execution plan, a holistic integration strategy is necessary to synchronize the architectural elements of urban infrastructure with relevant quantum capabilities along the national roadmap. This section delineates a detailed structure that correlates each smart city domain with its quantum computing equivalent, situated within the strategic priorities and Greenfield advantages of Saudi Arabia.

The framework has eleven architectural levels, starting with fundamental infrastructure and progressing through data systems, decision-making platforms, and governance structures. Each layer corresponds to a distinct quantum capability and is associated with one of three roadmap phases. This matrix allows technologists, urban designers, and policymakers to visualize the incremental integration of quantum technologies into the urban framework.

The integration strategy is governed by the following phase objectives:

- Phase I (Foundational Exploration): Focuses on foundational exploration, including cloud-based quantum-as-a-service (QaaS) access, feasibility studies for localized quantum hardware, and early pilot deployments in sensing and simulation, often leveraging quantum-inspired classical methods.
- Phase II (Hybrid Integration): Emphasizes hybrid integration, deploying genuine quantum-enhanced algorithms in high-impact areas like traffic, energy, and logistics systems, and embedding middleware for Urban Digital Twin (UDT) compatibility.
- Phase III (Governance Maturity): Targets infrastructure maturity and governance, including the Post-Quantum Cryptography (PQC) rollout, quantum-secure identity systems, and the establishment of national ethics and regulatory frameworks.

Saudi Arabia's greenfield advantage enables the integration of quantum technologies without the limitations of legacy infrastructure. This strategic positioning supports the Kingdom's ambition to lead quantum-enhanced urban innovation. Table V details the holistic integration strategy, mapping specific smart city components and their corresponding quantum technologies to the strategic phases of the Saudi Adoption Roadmap, ensuring all components are properly addressed.

TABLE V. HOLISTIC INTEGRATION STRATEGY FOR QUANTUM-SMART CITY MAPPED TO THE SAUDI ADOPTION ROADMAP

Layer	Smart City Component	Quantum Computing Component	Saudi Roadmap Phase
1. Physical Infrastructure	Roads, buildings, transport systems, and energy grids.	Quantum hardware environments (cryogenics, superconducting circuits).	Phase I: QaaS access, feasibility studies.

2. Sensor & IoT Layer	Real-time data from traffic, environment, and public safety.	Quantum sensors for ultra-precise measurements.	Phase I–II: Research partnerships, pilot deployments.
3. Network & Connectivity	5G, fiber optics, and edge/cloud infrastructure.	Quantum communication channels (QKD, entanglement networks).	Phase III: Municipal QKD pilots, infrastructure planning.
4. Data Management Layer	Urban digital twins, data lakes, and analytics platforms.	Quantum simulation engines, quantum-enhanced data processing.	Phase II: Middleware integration, QDT pilots.
5. Urban AI & Decision Systems	Predictive analytics, autonomous agents.	Quantum machine learning (QML) and quantum reinforcement learning (QRL).	Phase II: Deploy QML/QRL in traffic, energy, and emergency systems.
6. Service Orchestration	Intelligent service delivery, multi-agent coordination.	Quantum algorithms (QAOA, QML, QRL) for optimization and autonomy.	Phase II: Hybrid deployments in traffic, energy, and logistics.
7. Resilience & Simulation	Climate modeling, disaster response planning.	Quantum simulation for multivariable urban systems.	Phase II–III: QDTs for resilience planning.
8. Digital Identity & Trust	Identity management, authentication, and trust frameworks.	Quantum-resistant protocols, zero-knowledge proofs.	Phase III: PQC integration, quantum trust models.
9. Governance & Security	Policy, privacy, cybersecurity, ethical oversight.	PQC, quantum-safe protocols, ethical governance.	Phase III: National policy, PQC rollout, ethics board.
10. Ethics & Regulatory Layer	Data governance, algorithmic transparency, citizen rights.	Quantum ethics frameworks, algorithmic accountability.	Phase III: Ethics board, global standards alignment.
11. Talent & Innovation Ecosystem	Education, R&D, startups, and academic partnerships.	Quantum education programs, research centers, and innovation clusters.	Phase I–III: Talent Initiative, regional innovation hubs.

Fig. 6 shows the sequential integration of quantum computing capabilities with smart city elements in Saudi Arabia's national roadmap. A specific quantum technology and deployment stage align with every urban domain, from infrastructure and IoT to governance and innovation. The central roadmap column guides the sequence from fundamental exploration (Phase I) to hybrid integration (Phase II) and governance maturity (Phase III).

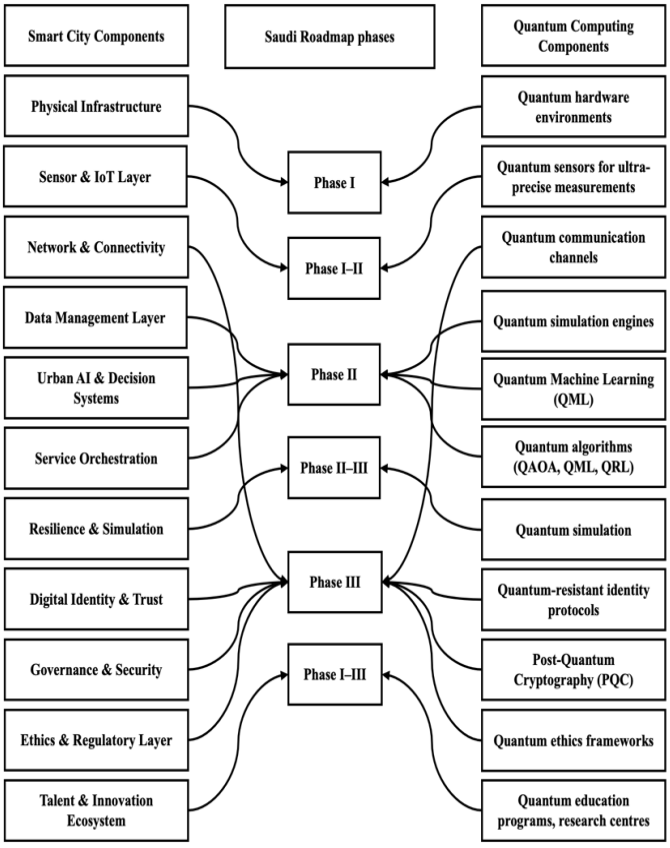

Fig. 6. Holistic integration strategy for a quantum-smart city mapped to the Saudi adoption roadmap.

F. Hybrid Quantum-Classical Software Architecture (HQCA)

The Hybrid Quantum-Classical Software Architecture (HQCA) offers a secure, closed-loop operational framework for integrating specialized quantum computing resources into the Smart City technology stack. HQCA is engineered to solve computationally intractable optimization kernels recognized by traditional modeling engines, ensuring that quantum resources are utilized judiciously—exclusively in areas where they provide a true computational benefit—whereas the classical infrastructure handles most of the sensing, modeling, and control tasks. The design is systematically organized into three interrelated zones: the Classical Smart City Stack, the Hybrid Orchestration Layer, and the Quantum Computing Stack.

1) Classical smart city stack: data ingestion and control: Based on high-performance computing (HPC) and graphics processing unit (GPU) acceleration, this zone represents the traditional software environment of smart cities. It comprises five layers:

- Layer 1: Data, Sensing, and Streaming. Stream-processing engines, such as Kafka and Spark, ingest real-time data from IoT sensors, edge gateways, and infrastructure via stream-processing engines (e.g., Kafka and Spark). Data integrity is verified using blockchain or Distributed Ledger Technologies (DLT).

- Layer 2: Context and Modeling (Urban Digital Twin). The Urban Digital Twin (UDT) maintains a high-fidelity real-time model of the city. Classical AI/ML engines perform predictive modeling and anomaly detection, supported by Explainable Artificial Intelligence (XAI) components to ensure transparency. The UDT identifies optimization kernels, such as traffic scheduling and energy balancing, which require quantum acceleration.
- Layer 3: Classical Pre-Processing. HPC/GPU resources are used to clean, normalize, and reduce problem data (e.g., via Principal Component Analysis) and prepare them for quantum translation.
- Layer 4: Classical Post-Processing. The raw quantum outputs are validated and converted into actionable, classical commands.
- Layer 5: Infrastructure Control. City control systems (e.g., SCADA, Traffic Management System (TMS), and Distribution Management System (DMS)) execute optimized commands and provide feedback to the sensing layer, completing the operational cycle.

2) Hybrid orchestration layer: The Secure, Iterative Bridge

This middleware layer enables seamless, secure, and low-latency interactions between classical and quantum domains. It includes:

- Problem Abstraction and Software Toolchain. A Quantum Software Development Kit (SDK) and compiler suite translate classical optimization problems into quantum-native formats (e.g., QUBO and Ising). A quantum kernel generator encodes classical data into quantum states for quantum machine learning (QML) tasks.
- Resource Management and Execution Control. Jobs are directed to the optimal backend, that is, quantum-as-a-service (QaaS) or sovereign QC hardware, through a low-latency interconnect. The orchestration layer manages job queues and execution scheduling and incorporates a Quantum Error Mitigation (QEM) module to enhance the result fidelity.
- Security Gateway. Post-Quantum Cryptography (PQC) secures data in transit, whereas Quantum Key Distribution (QKD) ensures ultra-secure communication across the classical-quantum interface.
- Quantum Computing Stack: Specialized Acceleration and Solution Output
- This zone functions as a dedicated accelerator that solves the optimization kernels identified by UDT. It includes:
- Execution Backend. Quantum solvers (e.g., annealers, gate-based systems) execute algorithms such as QAOA, QML, and QRL. A hardware-specific transpiler optimizes quantum circuits for physical qubit topologies.
- Physical Control Interface. Qubit control electronics and cryogenics handle basic tasks by changing logical gates into microwave pulses and laser controls.
- Solution Output and Validation. The quantum system produces an optimal bit string that represents resource assignments or scheduling variables. These results are securely transmitted back to the classical stack, where they are validated and refined through iterative feedback until convergence is achieved. The final outputs were translated into actionable infrastructure commands, closing the loop via the sensing layer.

3) HQCA operational flow: Fig. 7 presents a modular three-layer architecture designed to integrate quantum computing into smart city operations. The system comprises the following components:

- Layer 1: Classical Smart City Stack. Responsible for data ingestion, modeling, and control, this layer includes IoT-based edge processing, blockchain-secured data streams, and Urban Digital Twin (UDT) platforms powered by classical AI/ML engines. HPC/GPU accelerators handle the initial data processing, whereas post-processing modules check the results from quantum computing and convert them into useful information for smart city services, such as improving traffic flow and managing infrastructure.
- Layer 2: Hybrid Orchestration Layer. Serving as an intelligent bridge, this layer manages problem decomposition, algorithm selection (e.g., QAOA and VQE), and resource allocation across quantum and classical domains. It includes a quantum software development kit/compiler suite, real-time pre/post-processing accelerators, and a secure job submission system. The Physical Control Electronics interface directly with the quantum hardware, whereas the Security Gateway ensures encrypted communication via PQC and QKD protocols.
- Layer 3: Quantum Computing Software Stack. This layer functions as a dedicated accelerator for solving intractable computational issues. It includes quantum solvers (annealers and gate-based systems), execution-dispatch modules, and hardware-specific transpilers. The red dashed feedback loop illustrates the iterative optimization process typical of Variational Quantum Algorithms (VQAs), where quantum outputs are measured, refined, and re-executed until convergence is achieved.

Together, these layers form a secure closed-loop system capable of translating complex urban challenges into quantum-native formats, executing them on specialized hardware, and reintegrating optimized solutions into real-world Smart City operations.

4) Clarifying the quantum-classical divide and the HQCA role: To ensure technical clarity and address the potential overstatement of near-term relevance, it is crucial to explicitly distinguish between genuinely quantum-accelerated methods and quantum-inspired classical techniques within the HQCA framework:

- Genuine Quantum Acceleration: This refers exclusively to algorithms (e.g., QAOA, VQE, HHL) executed on a dedicated Quantum Processing Unit (QPU) that leverage superposition and entanglement. These methods offer the potential for exponential or polynomial speedups over the best-known classical algorithms for specific problem classes. Our long-term strategic goal (Phase III) is predicated on this capability.
- Quantum-Inspired Techniques: These are classical, hardware-accelerated optimization and simulation algorithms (e.g., Digital Annealing (DA), Simulated Annealing, and coherence-based methods) that are inspired by quantum principles but run entirely on conventional or specialized classical hardware (like FPGAs or specialized CMOS). While highly effective for near-term NP-hard optimization, they are not quantum computing. The HQCA explicitly allows for the incorporation of quantum-inspired algorithms in the initial phases (Readiness/Pilot) to build computational maturity and realize immediate-term optimization gains, thereby serving as a critical bridge and an essential component of the classical side of the hybrid architecture.

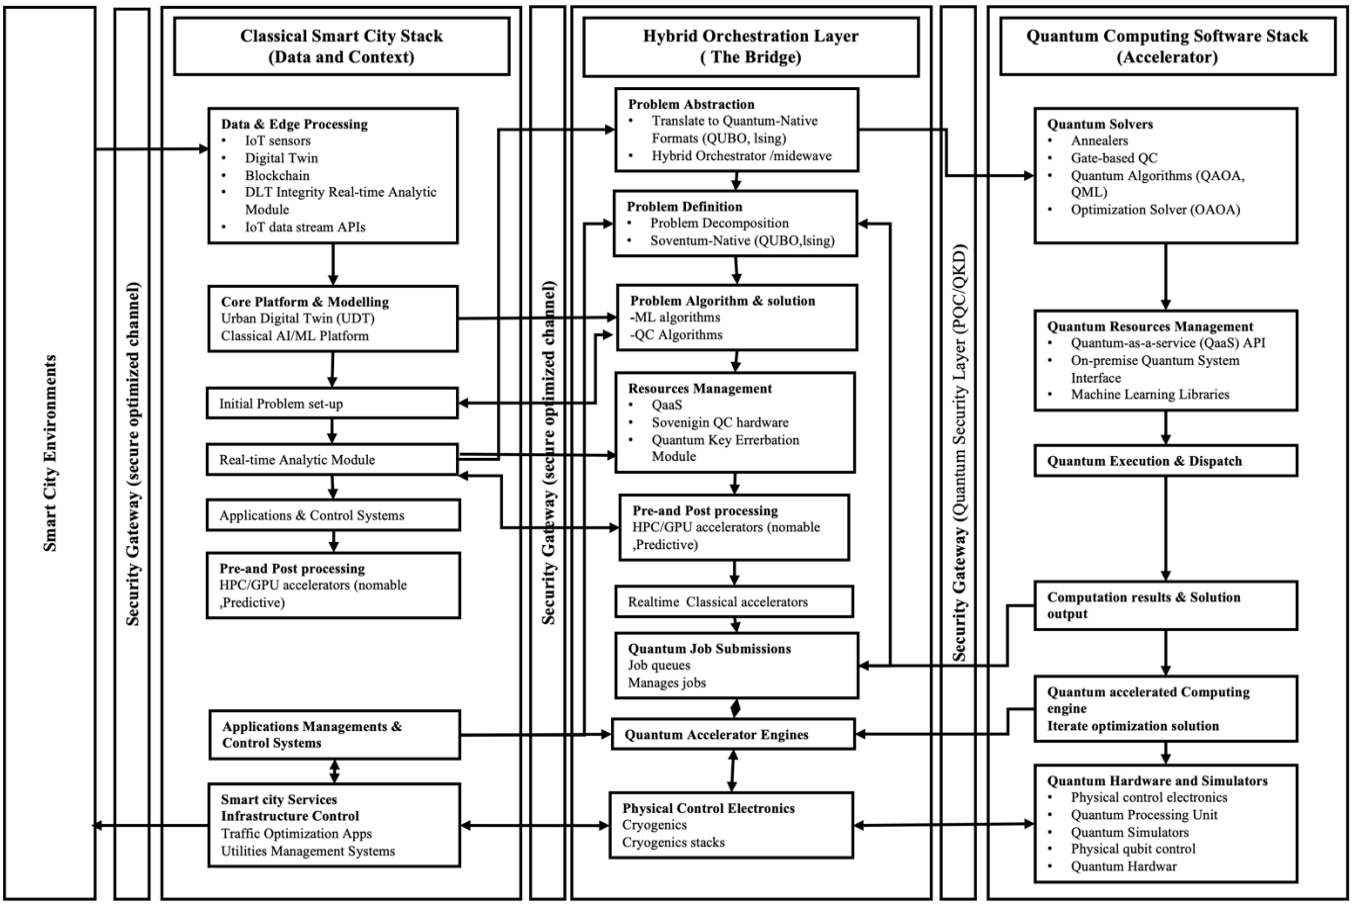

Fig. 7. Hybrid Quantum-Classical Architecture for smart city optimization.

G. Benefits and Challenges of QC Adoption in Smart Cities

Quantum computing presents a fundamentally different computational paradigm that offers significant benefits for smart cities in terms of optimization, simulation, cybersecurity, and strategic competitiveness. Its ability to address large-scale combinatorial problems facilitates exceptional performance in areas such as traffic management, logistics, and resource distribution. Quantum algorithms, particularly those tailored for near-optimal real-time decision-making, surpass conventional systems in urban mobility and energy balance, where complexity and latency are significant limitations.

In simulations, quantum methods offer high-fidelity modeling of intricate urban systems, encompassing climate dynamics, infrastructure stress testing, and materials science for sustainable construction. These capabilities boost planning accuracy and resilience, especially in megaprojects such as NEOM and The Line. Quantum technologies enhance cybersecurity. Quantum-safe cryptography and Quantum Key Distribution (QKD) provide robust protection for critical infrastructure, IoT networks, and municipal data systems, reducing their vulnerability to quantum-enabled attacks.

Quantum optimization enhances energy systems by augmenting smart grid efficiency and optimizing the incorporation of renewable sources such as solar and wind. This aligns with the sustainability objectives of Saudi Arabia outlined in Vision 2030. The strategic deployment of quantum technology has established the kingdom as a regional leader in innovation. By aligning quantum projects with national

priorities, Saudi Arabia may attract international investment, expertise, and collaborations, thereby enhancing its competitive advantage.

Despite its potential, quantum computing faces several challenges in smart-city environments. Technologically, quantum hardware functions inside the Noisy Intermediate-Scale Quantum (NISQ) era, which is defined by constrained qubit numbers and vulnerability to decoherence. Fault-tolerant systems are several years away from realization. The worldwide shortage of quantum scientists, engineers, and programmers further limits adoption, particularly in emerging ecosystems such as Saudi Arabia.

Cost and accessibility are also major hurdles. Quantum hardware is costly and is generally accessed through cloud services, which constrain experimentation and implementation. Establishing a definitive return on investment (ROI) for early-stage pilot projects remains challenging. The development of algorithms is complicated, necessitating specific knowledge to transform classical issues into quantum-native representations of the problem.

Integrating current Smart City platforms, such as Urban Digital Twins (UDTs), sensor networks, and control systems, necessitates the development of new middleware, standards, and hybrid quantum-classical architectures (HQCA). Concerns regarding governance and security continue to revolve around data privacy, regulatory frameworks, and secure communications. Financial and infrastructure costs, including chilled environments and quantum-safe channels, add further complications. Table VI summarizes the benefits and challenges of adopting quantum computing in smart cities.

TABLE VI. SUMMARY OF BENEFITS AND CHALLENGES OF QC ADOPTION IN SMART CITIES

Benefits	Challenges
• Superior optimization. • Advanced simulation fidelity. • Enhanced cybersecurity (QKD, PQC). • Smart grid energy efficiency. • Strategic competitiveness (Vision 2030). • Real-time resource allocation. • Climate and infrastructure modelling.	• Technological maturity (NISQ era). • Talent shortage in quantum fields. • High cost and limited hardware accessibility. • Algorithmic complexity and reformulation. • Integration complexity with legacy systems. • Governance, privacy, and regulatory concerns. • Financial and ROI uncertainty.

V. DISCUSSION

The shift to quantum-ready smart cities in Saudi Arabia is not simply a technology enhancement; it is a strategic cornerstone of the Kingdom's economic diversification initiative under Vision 2030. As urban systems become more intricate and data-driven, traditional computational architectures encounter constraints in addressing large-scale optimization, simulation, and security problems. Quantum computing (QC), which leverages superposition and entanglement, presents a transformative solution to these challenges [4], [5].

Saudi Arabia's most significant megaprojects, NEOM, The Line, and the Red Sea Project, offer greenfield potential for the integration of quantum capabilities from the outset. These projects are intended to function at an unprecedented scale and complexity, necessitating computing systems that surpass classic thresholds [12], [59].The aspiration to create cognitive cities characterized by real-time responsiveness and predictive intelligence immediately corresponds to the capabilities of quantum-enhanced optimization and simulation [10].

The establishment of a quantum-ready smart city is not merely a singular technology implementation but rather a whole, interconnected ecosystem propelled by strategic coherence and continuous advancement. As illustrated in Fig. 8, the central goal of achieving a quantum-ready smart city, a core pillar of the Saudi Vision 2030 megaprojects, is supported by several critical and interdependent components.

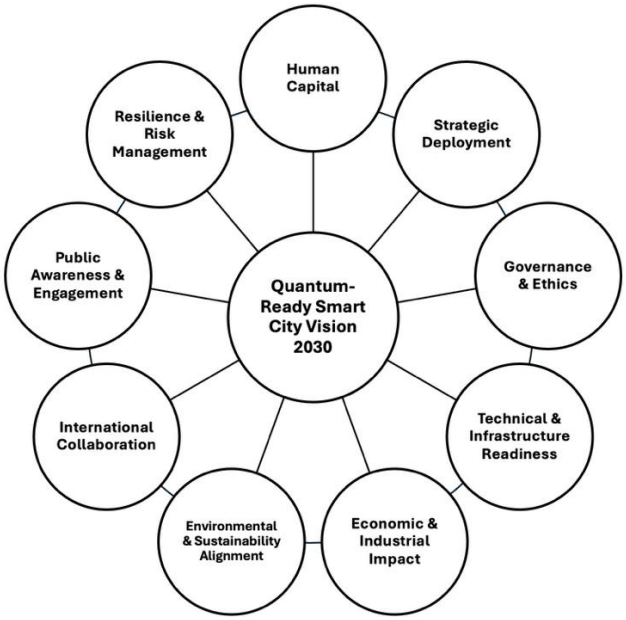

Fig. 8. Interconnected ecosystem of a quantum-ready smart city.

These range from foundational efforts, such as cultivating human capital and establishing robust technical and infrastructure readiness, to strategic oversight elements, such as governance, ethics, and international collaboration. The framework's arrows demonstrate the interconnectedness of these dimensions, establishing crucial feedback loops. Successful strategic deployment influences the economic impact, supported by continuous resilience and risk management, thereby ensuring a secure and sustainable transition that aligns with national environmental and economic objectives.

A. Human Capital as the Strategic Bottleneck

Despite substantial government investment capabilities, the foremost challenge is human capital. The acknowledged global deficiency of quantum-fluent engineers and scientists necessitates that Saudi Arabia swiftly develops a homegrown talent pool. This includes the initiation of the Quantum Talent Initiative, modification of university curricula to incorporate Quantum Information Science (QIS), and the establishment of

collaborative research centers with international quantum leaders [21]. The localization of quantum education through Arabic-language resources is crucial for guaranteeing accessibility and long-term sustainability [22].

B. Strategic Deployment and Intermediate Steps

Considering the existing limitations of quantum technology in the Noisy Intermediate-Scale Quantum (NISQ) era, Saudi Arabia should implement a gradual deployment approach. In the short term, utilizing quantum-as-a-service (QaaS) platforms through cloud access facilitates experimentation without infrastructure overheads. The Kingdom should simultaneously invest in hybrid quantum-classical algorithms designed for urban optimization challenges, middleware for Urban Digital Twin (UDT) integration, and pilot initiatives in areas where quantum advantage is anticipated [20].

Energy grid optimization is a promising area in which quantum algorithms have demonstrated efficacy in unit commitment and load balancing [60]. Quantum annealing has been employed to enhance traffic signal optimization in Sendai, Japan, and to improve port logistics in Hamburg, Germany [61], [62]. Secure communications provide a strategic opportunity, as demonstrated by the Quantum Key Distribution (QKD) pilots in [63], which serve as examples of protecting municipal networks. These fields provide quantifiable benefits and evident Return on Investment (ROI), facilitating the justification of long-term R&D commitments and infrastructure investments.

C. Governance, Ethics, and Strategic Alignment

Quantum deployment requires guidance through coordinated governance frameworks that synchronize cross-agency agendas and guarantee ethical and secure implementation. The World Economic Forum [64] emphasizes the significance of ethical governance, transparency, and stakeholder engagement in quantum innovation. Saudi Arabia should formulate a national quantum policy, create a Quantum Ethics Board, enforce PQC compliance in IoT and blockchain systems, and engage with international standards organizations such as the ISO/IEC and ETSI [18].

D. Technical and Infrastructure Readiness

The adoption of quantum computing depends on the advancement of hardware and software systems. Saudi Arabia must assess its readiness to meet various technical requirements. Initially, it is essential to develop hardware infrastructure, including cryogenic environments, quantum laboratories, and secure data centers capable of accommodating quantum processors or interfacing with cloud-based quantum-as-a-service (QaaS) platforms [60]. Second, middleware and integration layers must be created to convert smart city variables into quantum-compatible representations, including QUBO and Hamiltonians [20]. Third, interoperability with current urban platforms must be guaranteed via standardized APIs and modular architecture to facilitate easy integration with digital twins, IoT networks, and AI systems [18].

E. Economic and Industrial Impact

The adoption of quantum technology may anticipate a sectoral revolution in industries such as logistics, energy, construction, and cybersecurity, which will benefit from quantum-enhanced modeling and optimization. To facilitate this shift, Saudi Arabia should encourage quantum startups, incubators, and collaborations with international entities to expedite the development of its domestic capabilities [21]. Moreover, quantum-related roles, which vary from algorithm development to hardware engineering, facilitate the objectives of Vision 2030 concerning advanced employment and less reliance on oil [59].

F. Environmental and Sustainability Alignment

Quantum computing supports Saudi Arabia's climate initiatives and sustainability goals through various channels. Quantum algorithms can enhance smart grid operations, minimize energy waste, and facilitate the integration of renewable sources such as solar and wind [16]. High-fidelity quantum simulations facilitate predictive planning for climate resilience, water management, and infrastructure stress testing [10]. Moreover, quantum-enhanced materials science may accelerate the advancement of sustainable construction materials and energy-storage technologies, fostering low-carbon innovations.

G. Ethical, Legal, and Cultural Dimensions

In addition to governance, more profound ethical and cultural considerations require further attention. Data sovereignty is essential for ensuring that quantum data processing meets national privacy regulations and upholds citizens' rights. Cultural localization is crucial, necessitating the adaptation of quantum education, interfaces, and policy frameworks to align with Saudi cultural norms and language [22]. Saudi Arabia must engage in international quantum ethics discussions to influence the standards of transparency, accountability, and equal access [64].

H. International Collaboration and Geopolitical Positioning

Quantum technologies are becoming essential resources for global innovation and security purposes. Saudi Arabia's engagement in global quantum research collaborations, standards organizations, and bilateral partnerships may accelerate knowledge transfer and access to advanced quantum computing platforms. This position allows the Kingdom to serve as a regional leader in quantum diplomacy and reduces the risk of technological isolation by conforming to global standards and protocols [64].

I. Public Awareness and Citizen Engagement

Quantum computing is complex and is frequently misinterpreted. Public trust and comprehension are important for the successful implementation of smart cities in the GCC. Saudi Arabia should initiate public education campaigns to elucidate quantum technology and advocate citizen-oriented applications such as secure identity management and traffic optimization to showcase concrete advantages. Transparency in data utilization, particularly in quantum-enhanced surveillance or decision-making systems, will cultivate a culture of informed participation and diminish opposition to technology development.

J. Resilience and Risk Management

Quantum systems present novel operational concerns that require proactive management. Hardware fragility is a

significant issue because qubits are susceptible to noise, temperature fluctuations, and electromagnetic interference. Transition risks in cybersecurity emerge during the migration to post-quantum cryptography (PQC) and quantum key distribution (QKD), necessitating meticulous phasing to prevent these vulnerabilities. Moreover, quantum hardware frequently depends on specialized components and global suppliers, resulting in supply chain dependencies. Saudi Arabia must formulate contingency plans, establish redundancy mechanisms, and conduct risk audits to guarantee resilience in quantum-enabled infrastructure (QEI) systems.

VI. Conclusion and Future Research

As cities worldwide pursue unprecedented levels of efficiency, resilience, and sustainability, Saudi Arabia's Vision 2030 megaprojects, such as NEOM, The Line, and the Red Sea Project, are at the forefront of this transformation. These projects are large and ambitious, and they aim to develop cities from the ground up that are both smart and carbon-free. However, the computational demands of these environments, particularly when solving NP-hard issues related to energy management, traffic routing, and Urban Digital Twin (UDT) simulation, are rapidly outpacing the capabilities of classical systems. Heuristic approximations and traditional algorithms fall short of delivering real-time, scalable solutions, which could put advanced urban designs at risk in the long run.

This study establishes Quantum Computing (QC) as a fundamental technology for next-generation smart cities. QC is not just a future upgrade, but a strategic necessity that enables the development of hyper-efficient urban intelligence systems by overcoming classical bottlenecks. This study's core contribution is the establishment of the Hybrid Quantum-Classical Architecture (HQCA) and a methodologically grounded strategic roadmap, which together serve as the foundational blueprint for this transition. Two key contributions support this proposition: First, mapping core Smart City challenges to quantum algorithmic strengths: energy grid load balancing aligns with QAOA and VQE, dynamic traffic routing with quantum annealing, and UDT simulation with quantum machine learning. These mappings provide a clear technical rationale for the targeted deployment of quantum technologies. Second, this study proposes a phased adoption framework tailored to Saudi Arabia's strategic context. The framework is grounded in four pillars: talent development, infrastructure readiness, governance and ethics, and targeted pilots. The roadmap offers a structured pathway for embedding QC into the national innovation ecosystem in the next decade.

Several research directions are critical for realizing the full potential of quantum-accelerated smart cities (QASCs), building directly upon the strategic framework proposed here. Specifically addressing the need for evidence-based analysis, the immediate technical priorities are defined in two key areas. The first is formal problem formulation, which involves developing precise mathematical (e.g., QUBO or Hamiltonian) formulations for the key urban optimization problems identified (e.g., large-scale dynamic vehicle routing and real-time energy dispatch). This transition from problem class to formal quantum-compatible model is the essential next technical step. The second is Initial Benchmarking and Comparative Studies, where empirical benchmarking of hybrid quantum-classical algorithms must evaluate the performance of these models against state-of-the-art classical supercomputing solutions using realistic urban datasets, such as traffic networks with millions of nodes and energy grids with thousands of dynamic variables.

These benchmarks will endorse quantum advantage claims and guide the selection of algorithms for deployment in the future. Another area of focus is the mitigation of decoherence in quantum systems that operate in Internet of Things (IoT)-rich environments. Devices from the NISQ era are highly sensitive to noise, and urban sensor networks generate vast and volatile data streams. A robust middleware that can manage these interactions while preserving fidelity and minimizing latency is essential for the practical integration of these technologies.

Future research should investigate the socioeconomic aspects of quantum computing adoption. In addition to computational measures, it is essential to evaluate the comprehensive return on investment (ROI), which encompasses the effects on the quality of life, environmental sustainability, and long-term infrastructure expenses. Measuring these advantages will facilitate the justification of ongoing investments and connect quantum activities to national development objectives. Strategically addressing these difficulties will position Saudi Arabia to surpass traditional computational paradigms and establish itself as a global leader in quantum-enhanced urban innovation.

***Abstract*—The deployment of anomaly detection systems across heterogeneous edge computing environments faces significant challenges due to varying computational constraints and resource limitations. Existing approaches typically employ static model selection strategies that fail to adapt to diverse hardware capabilities, resulting in suboptimal detection performance and inefficient resource utilization. To address this, we propose MetaEdge, a novel hardware-aware framework that intelligently selects and deploys anomaly detection models based on specific device characteristics and hardware constraints. The MetaEdge framework introduces a systematic methodology that leverages meta-learning in the first stage to train a machine learning model to predict the top-k anomaly detectors by considering dataset characteristics. These candidates are then put through hardware-aware optimization that incorporates the hardware constraints of edge devices to ensure deployment feasibility. The framework evaluates 11 candidate anomaly detection algorithms spanning traditional machine learning and deep learning methods across four representative computing architectures ranging from ultra-constrained edge devices to GPU-accelerated cloud instances. Model conversion through ONNX standardization enables cross-platform deployment while maintaining detection capabilities. Experimental evaluation demonstrates the framework's effectiveness in achieving superior anomaly detection performance across diverse hardware configurations. The hardware-aware stage successfully identifies optimal model-hardware pairings, with the deployed models achieving up to 96.6% accuracy and 90.4% precision on edge devices. The framework demonstrates high accuracy in model selection decisions, with confidence scores providing meaningful hardware compatibility assessments that guide deployment. MetaEdge introduces a novel paradigm for hardware-aware anomaly detection in edge computing, demonstrating that meta-learning–driven model selection can deliver superior detection performance while adhering to stringent hardware constraints. By integrating automatic model selection with hardware-aware optimization, the proposed approach enables anomaly detection systems to intelligently adapt to diverse computing environments and maximize performance under resource constraints.**

I. Introduction

The rapid expansion of the Internet of Things (IoT) has produced an extraordinary volume of data at the network edge. Billions of heterogeneous devices ranging from industrial sensors and autonomous vehicles to wearable health monitors generate continuous, high-velocity data streams. Real-time analysis of these data streams is crucial for extracting value and supporting intelligent applications. To meet this latency and bandwidth demands while strengthening data privacy, computation is increasingly migrating from centralized cloud infrastructures to distributed edge nodes. This architectural shift is necessary for applications that demand low latency, high bandwidth, and stronger data privacy; however, it also poses substantial challenges, especially for deploying advanced machine learning models on resource-constrained edge devices. Addressing this capability–constraint trade-off has become a central challenge for next-generation IoT systems [1], [2].

Anomaly detection, which involves identifying rare events or observations that deviate significantly from normal behavior, is one of the most critical tasks performed at the edge. Its importance spans domains: it supports predictive maintenance and fault avoidance in industrial systems, enables real-time patient monitoring and alerts in healthcare, and identifies intrusion and malware detection in cybersecurity [3]. However, deploying anomaly detection models on edge devices remains highly challenging. These devices operate under stringent constraints on computation, memory, and energy [4]. Offloading raw data to the cloud is often impractical given strict real-time requirements, privacy considerations, and communication costs [1]. Consequently, performing anomaly detection directly on the device, i.e., edge inference, has become increasingly necessary. Selecting an effective anomaly detection model further complicates edge deployment. Model performance depends strongly on data characteristics and anomaly types, and no single model is universally optimal [5]. Consequently, manual model selection becomes time-consuming and expertise-intensive, rendering it impractical for large-scale, heterogeneous edge environments. These limitations have motivated the development of automatic model selection tools that automate the end-to-end process from model choice to tuning. Within this paradigm, meta-learning approaches are particularly promising. Meta-learning leverages performance evidence from diverse prior tasks to recommend effective models for new, unseen tasks. It improves the performance on similar tasks and reduces costly, time-consuming retraining [6].

Even when a meta-learning system recommends an optimal model, it may still be infeasible if it exceeds the hardware

capabilities of the target edge device. A performance-optimized deep learning model, for instance, may demand more memory or computational resources than the device can supply [4]. This necessitates hardware-aware model selection in which device constraints are a primary consideration. The selected model must strike an appropriate balance between predictive performance and computational efficiency. This imperative has driven extensive work on model optimization techniques, such as quantization, pruning, and hardware-aware architecture design, as well as deployment-friendly runtimes such as TensorFlow Lite, to fit powerful models onto constrained platforms [7].

This study presents MetaEdge, a framework for automatic, hardware-aware selection of anomaly detection models for edge inference. This framework optimizes the trade-off between model accuracy and resource efficiency in a fully automated manner. First, a meta-learning-based model selection engine utilizes the meta-features of a given streaming dataset to generate a ranked list of promising anomaly detection models from a predefined candidate pool. Second, a hardware-aware selection module filters the ranked list using the specified hardware constraints of the target edge device, such as available memory, processor capabilities, and latency requirements, returning the best model that maximizes performance while remaining within those operational limits. Where applicable, the selected model is compiled into a lightweight deployment artifact (e.g., TFLite and ONNX) to ensure efficient on-device inference. Together, this end-to-end approach yields models that are not only accurate but also practical for real-world edge deployment.

The novelty of MetaEdge lies in three key aspects that distinguish it from prior work. First, while meta-learning approaches (e.g., AMLBID [6], MetaOOD [12]) have been applied to model selection and hardware-aware optimization techniques (e.g., LightESD [16], EdgeML [11]), they have been developed for edge deployment. MetaEdge is the first to systematically integrate both paradigms into a unified end-to-end framework specifically designed for anomaly detection on heterogeneous edge devices. Second, MetaEdge introduces a comprehensive synthetic hardware-learning dataset (254 configurations, 2,794 training samples) that explicitly captures the relationships between hardware constraints (memory, latency, energy) and model deployment characteristics. This dataset enables the hardware-aware module to learn realistic constraint-performance trade-offs, a capability absent in prior frameworks that rely on heuristic or rule-based hardware filtering. Third, MetaEdge provides empirical validation across real physical edge devices (Raspberry Pi 5, Orange Pi Zero 2W) combined with simulated cloud-edge profiles (AWS EC2 t2.micro, g4dn.xlarge), demonstrating practical deployment feasibility. This real-world validation, coupled with detailed per-device performance analysis, goes beyond the simulated or cloud-based evaluations common in prior work. Together, these contributions establish MetaEdge as a comprehensive, data-driven, and practically validated framework that advances the state-of-the-art in hardware-aware anomaly detection for edge computing.

The main contributions of this work are summarized as follows:

- Introduce MetaEdge, a framework that couples meta-learning-based model selection with hardware-aware selection for edge anomaly detection, narrowing the gap between theoretical performance and deployment on resource-constrained devices. The meta-learning module recommends the top-k models based on dataset characteristics, and the hardware-aware module evaluates these k candidates against target hardware specifications to select the model that best balances performance and deployment feasibility.
- Construct a hardware-learning dataset comprising 254 synthetic hardware configurations and comprehensive profiling of 11 candidate models, yielding 2,794 training samples. This dataset captures relationships between hardware constraints and model deployment characteristics across diverse scenarios.
- Design an efficient hardware-aware module that translates performance-based recommendations from the meta-learning module into deployment-ready selections under real-world hardware constraints. The module turns the hardware-learning dataset into a practical decision-making tool and outputs a probability distribution over all models (confidence scores), where each probability reflects the likelihood that a given model is the best choice for the specified hardware.
- Provide an empirical evaluation across a variety of practical edges, including two real devices (Raspberry Pi 5 and Orange Pi Zero 2W) using Amazon Web Services (AWS) Greengrass V2 and two simulated devices (g4dn.xlarge and a t2.micro) on AWS EC2. We also experiment with different streaming buffer sizes under various data-processing settings, giving us a well-rounded, deployment-ready assessment.

MetaEdge is evaluated along four dimensions: meta-learning-based model selection, hardware-aware model selection, model conversion effectiveness, and deployment feasibility. We first examined how available data volume affects model selection by varying the buffer size (500 vs. 1,000 samples). For each condition, the meta-learning module ranked candidate anomaly detectors and returned the top k models. Providing more buffered data makes the meta-learner both more confident and more accurate in its recommendations. Second, we tested the model conversion effectiveness by converting the models to lightweight deployment versions and comparing them with its original counterparts on two metrics: model file size and accuracy. The accuracy losses were minimal with only 0–3.8% degradation, and the size reductions were substantial of 55-70% across all models. Third, we validated the hardware-aware module by executing it in live deployments across four edge targets. Two were physical devices, a Raspberry Pi 5 (higher-end) and an Orange Pi Zero 2W (resource-constrained) and two were emulated edge profiles on AWS EC2: a t2.micro to represent a low-resource CPU environment and a g4dn.xlarge to represent a GPU-enabled, Jetson-like setting. For each device, we assess both the real-time feasibility and the anomaly detection performance of the selected model. This evaluation confirmed that MetaEdge consistently identified optimal

model–hardware pairings, with edge implementations achieving up to 96.6% accuracy and 90.4% precision.

The remainder of this study is organized as follows: Section II reviews related work and identifies the research gap. Section III details the architecture and methodology of our proposed MetaEdge framework. Section IV presents the experimental setup and a comprehensive evaluation. Finally, Section V concludes the study and discusses future research directions.

II. Related Work

This section provides a structured survey of the literature relevant to our automated, hardware-aware model selection framework for edge anomaly detection. We organize the discussion around three strands that collectively motivate our approach. First, we examine anomaly detection at the edge, with an emphasis on the distinctive constraints of resource-constrained devices and real-time processing, to establish the problem setting and the computational limits that necessitate intelligent model selection. Second, we review automated model selection and meta-learning approaches, evaluating how current frameworks leverage historical performance and meta-features to streamline decision-making while exposing gaps in device-level considerations. Third, we investigate hardware-aware optimization techniques for resource-constrained platforms, clarifying how current approaches address resource constraints and deployment challenges on edge devices. This analysis highlights the importance of incorporating device-level constraints directly into the model selection process. It also reveals critical gaps in existing work that fail to address the end-to-end path from model selection to hardware-constrained deployment, which motivates the comprehensive framework introduced in this study.

A. Lightweight Anomaly Detection for Edge Devices

Research on edge anomaly detection has gained significant attention with the proliferation of IoT devices and the attendant need for real-time decisions. Chatterjee and Ahmed [8] present an extensive survey of IoT anomaly detection methods, highlighting key challenges including limited computational resources, evolving normal behavior patterns, and the scarcity of labeled data. Their examination of 64 recent studies reveals a notable deficit of approaches for multi-sensor integration and concept drift management on constrained devices. Complementing this perspective, Jadhav and Kulkarni [4] examine anomaly detection within edge-computing networks, with particular attention to deep learning methods. Their survey underscores that anomalies at the edge pose substantial risks to enterprise networks and that monitoring and identifying abnormal behavior grow increasingly difficult as interconnections increase. While deep models appear promising, the authors underscore the difficulty of fitting such models within the memory and latency budgets of edge devices. Recent practical implementations have demonstrated both the strengths and the limitations of edge anomaly detection. Reis et al. [10] combine Isolation Forests with LSTM autoencoders within an edge AI framework for smart-home applications, achieving respectable accuracy but only with careful optimization for resource-constrained devices. Similarly, Patrikar and Parate [9] demonstrate video-surveillance anomaly detection at the edge, reporting substantial latency reductions while highlighting the inherent trade-off between model complexity and inference speed. Das et al. [12] propose LightESD, a fully automated, lightweight anomaly-detection method based on statistical learning. LightESD runs on-device without transferring data between the edge and the server and is designed for low latency, memory usage, and energy consumption, making it suitable for low-end edge hardware. The framework maintains competitive detection accuracy while consuming extremely low resources, enabling deployment on low-end edge devices. However, LightESD does not address hardware-aware model selection across heterogeneous devices and lacks explicit mechanisms for handling streaming concept drift in long-running deployments. It also focuses exclusively on statistical methods and does not incorporate meta-learning approaches for intelligent model selection, limiting its adaptability across diverse data characteristics. Collectively, these works frame the problem and underscore that effective solutions must balance detection quality with stringent resource constraints. The next subsection considers automated model selection and meta-learning as means to streamline selection.

B. Automated Model Selection for Edge Computing

The challenge of selecting appropriate machine learning models has motivated the development of automated model selection frameworks. Ying et al. [10] propose an automated model-selection framework for time-series anomaly detection that identifies suitable models and hyperparameters via an extensible selection layer and customized tuning. However, the design targets cloud-based deployments and leaves device constraints out of scope. In contrast, EdgeML [11] is an AutoML framework purpose-built for real-time deep-learning applications on edge devices. It addresses practical obstacles such as limited CPU resources and energy budgets and automates model selection and hyperparameter tuning to enable efficient on-device deployment and real-time inference without reliance on cloud resources. It additionally adapts to runtime conditions such as communication bandwidth fluctuations and varying computational loads. However, EdgeML focuses exclusively on deep neural network optimization and does not address the broader challenge of selecting appropriate anomaly detection algorithms based on data characteristics. Additionally, it lacks meta-learning capabilities for algorithm recommendation and is limited to neural network architectures rather than providing a comprehensive model selection framework. Meta-learning has emerged as an effective approach to automated model selection. Garouani et al. [6] introduce AMLBID, a meta-learning tool for industrial big data that achieves near O(1) complexity for model selection. The framework maintains a meta-knowledge base of algorithm performance across datasets and exploits meta-features to recommend optimal pipelines. Although effective in conventional computing settings, it does not address the distinctive constraints of edge deployments. Most recently, MetaOOD by Qin et al. [12] advances meta-learning for anomaly detection by introducing the first zero-shot, unsupervised framework for selecting out-of-distribution (OOD) detectors. Using language-model embeddings to represent datasets and models, it reports superior performance across 24 dataset pairs and 11 detectors. Nevertheless, the framework operates under effectively unconstrained compute

budgets and omits hardware-aware deployment considerations. These limitations motivate a shift toward hardware-aware machine learning, which explicitly incorporates device-level constraints into model design and deployment. The next subsection reviews this body of literature.

C. Hardware-Adaptive Model Optimization

The constraints of edge devices make hardware-aware optimization indispensable for the deployment of machine learning models. Shuvo et al. [2] present techniques for accelerating deep-learning inference on edge devices, outlining four major directions: novel architectures, optimization of existing methods, algorithm–hardware co-design, and efficient accelerator development. Their findings highlight the necessity of simultaneous hardware- and software-level optimization. Murshed et al. [1] review machine learning deployment at the network edge, outlining the core trade-offs between cloud processing and edge inference. Whereas the cloud offers vast compute capacity, edge deployment directly addresses latency, communication overhead, and privacy. The survey underscores the need for compression techniques, specialized tooling, and hardware-aware frameworks to make edge deployment practical. Researchers have explored multiple approaches to address the challenges of rapidly deploying machine-learning models on edge devices. One effective strategy is to design lightweight architectures specifically for edge deployment. Such architectures employ techniques such as depthwise-separable convolutions, low-rank factorization, and network pruning to improve efficiency without sacrificing accuracy [13]. In this context, MobileNet and ShuffleNet have emerged as popular choices for on-device image classification due to their compact designs and favorable accuracy–latency trade-offs on resource-limited hardware [14]. However, these architectures are mostly vision-centric and often must be retrained for each task and dataset; moreover, without optimized kernels, their speedups are hard to realize, especially for non-vision workloads or devices lacking appropriate operators. Another area of research is model compression for reducing the size and computation of neural networks. Techniques such as quantization and knowledge distillation have shown strong potential to shrink models while preserving accuracy. Pruning and structured sparsity further remove redundant parameters and, when supported by the runtime or hardware, can deliver real latency and energy savings, making them attractive for edge deployment [13]. However, compression can make models less robust when the data changes, hurt calibration, and miss rare events. The gains also depend on hardware/runtime support for low-precision or sparse operations (ops), and distillation needs a strong teacher, complicating use in streaming edge anomaly detection. Hardware-aware neural architecture search has become a promising strategy for tailoring models to specific deployment targets. Lee et al. [15] introduce HELP, a Hardware-adaptive Efficient Latency Predictor formulated via meta-learning to estimate device-specific performance. While compelling for neural architecture search, it addresses architecture design rather than model selection for anomaly detection and does not engage streaming constraints. Collectively, these studies underscore the necessity of embedding device constraints across the entire pipeline. The next subsection offers a research gap analysis that integrates these insights and motivates our proposed framework.

D. Research GAP

Table I presents a comparative analysis of existing approaches across deployment-relevant dimensions for edge-oriented anomaly detection model selection. The evaluation criteria include: Meta-Learning (whether the approach uses meta-learning techniques to automatically select models), Hardware-Aware (explicit consideration of computational and memory constraints during model selection), Edge-Specific (design tailored for edge computing environments with their unique limitations), Anomaly Detection (focus on anomaly detection tasks rather than general machine learning), Streaming Data (capability to handle real-time data streams), and Real Device Validation (empirical evaluation on real physical edge devices rather than simulations). As shown in Table I, existing work reveals several gaps for edge-based anomaly detection. Although automated model selection for anomaly detection exists [10] and meta-learning has been explored for general machine learning [6], [12], yet none of them combine meta-learning with hardware-aware selection tailored to edge-specific constraints.

Recent edge-specific frameworks such as LightESD [16] and EdgeML [11] demonstrate significant progress in addressing hardware constraints and edge deployment challenges, but both lack meta-learning capabilities for intelligent model selection. LightESD focuses exclusively on statistical methods without the ability to adapt to diverse data characteristics, while EdgeML is limited to deep neural network optimization and does not address the broader spectrum of anomaly detection algorithms. Hardware-aware approaches either concentrate on neural architecture search (e.g., HELP [15]) or offer ad hoc solutions for specific applications [9], [17], leaving the field without a rigorous, constraint-driven model selection strategy that explicitly optimizes under device-level constraints. Moreover, commonly used meta-learning paradigms implicitly assume ample computation and fail to address the real-time, streaming nature of edge workloads and their stringent resource budgets. Evaluation practices likewise rely on simulated environments or cloud-based deployments, with limited validation on real devices, despite the well-known divergence between reported metrics and performance on constrained hardware. These limitations motivate a unified framework that couples meta-learning-based recommendation with hardware-aware model selection for streaming anomaly detection at the edge. This study proposed the MetaEdge framework that spans the entire pipeline, from characterizing streaming data to selecting a deployment-ready model, while explicitly accounting for the practical constraints of real-world edge deployments.

TABLE I. COMPARATIVE SUMMARY OF RELATED APPROACHES ACROSS DEPLOYMENT-RELEVANT DIMENSIONS

Approach	Meta-Learning	Hardware-Aware	Edge-Specific	Anomaly Detection	Streaming Data	Real-Device Validation

This work	✓	✓	✓	✓	✓	✓

The novelty of MetaEdge lies in how it bridges the gap between data-driven model recommendation and hardware-aware deployment. A pure meta-learning approach (e.g., AMLBID [6]) would recommend models based solely on data characteristics, ignoring hardware constraints and potentially selecting models that are not deployable on the target device. Conversely, a pure hardware-aware selection approach would select the most efficient model that fits within the hardware budget, but such a model may exhibit poor detection performance for the given data. Existing tools, such as EdgeML [11], focus on hardware-aware optimization for deep learning models yet lack a meta-learning component for recommending the most suitable model class based on data characteristics. LightESD [16] provides lightweight statistical methods but does not incorporate meta-learning or hardware-aware model selection across heterogeneous devices. MetaEdge, in contrast, integrates these two dimensions, using meta-learning to identify a shortlist of high-performing models for the data and then applying a hardware-aware module to select the model that best satisfies device constraints while maintaining strong detection performance. This two-stage approach provides a more holistic solution than existing methods by balancing data-driven accuracy and hardware-driven feasibility.

III. METHODOLOGY AND DESIGN

This section presents MetaEdge, an automated, hardware-aware model selection framework for anomaly detection at the edge. MetaEdge couples meta-learning–driven performance prediction with device-constrained selection to identify a single model that delivers high detection performance while meeting the computational, memory, and latency budgets of the target device. To maintain simplicity and reproducibility, the process is organized into a two-stage pipeline: meta-learning-based selection followed by hardware-aware selection. We first provide a comprehensive overview of the MetaEdge architecture, then present detailed descriptions of each component.

A. Framework Overview

Fig. 1 illustrates a two-stage pipeline for the MetaEdge framework. In the offline training (cloud) stage, training datasets and candidate ML/DL models are applied to meta-feature extraction and model evaluation to build a meta-knowledge dataset, which is transformed into a meta-learning dataset for training a meta-learning module (based on ASAD). In parallel, model profiling combined with hardware datasets produces a hardware-learning dataset, which is used to train a hardware-aware module. These two trained modules constitute the core of the MetaEdge engine. In the online selection (edge) stage, an edge device provides streaming data and hardware specifications; meta-features are extracted and fed into the MetaEdge, which selects and deploys the most suitable, hardware-optimized model for the device. Deployment outcomes and anomaly-detection signals form a feedback loop that enables the engine to adaptively select models on-device, guided by both data characteristics and hardware constraints.

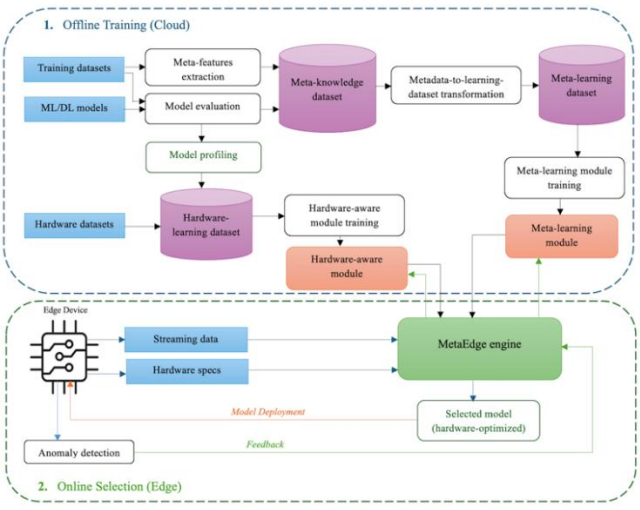

Fig. 1. The architecture of the MetaEdge framework.

MetaEdge integrates its meta-learning and hardware-aware components to select and deploy a hardware-optimized model on the device, demonstrating how historical performance data and hardware constraints can be systematically combined to deliver intelligent, deployment-ready model selection for edge environments, bridging the gap between theoretical model effectiveness and real-world applicability.

B. Meta-Learning Selection Module

The meta-learning engine forms the first stage of our framework, building upon our previous work, ASAD (Auto-Selective Anomaly Detection) [18]. We follow the same meta-learning logic and methodology established in ASAD, which leverages historical performance data across diverse datasets to recommend the most promising anomaly detection models for new, unseen data. The meta-learning stage operates offline to construct a large meta-knowledge dataset for model

recommendation. A diverse benchmark of labeled anomaly detection datasets (139 datasets derived from 60 bases across 11 domains) is assembled, and a broad set of candidate models is evaluated under a unified protocol and seven standard effectiveness metrics. In parallel, an extensive bank of 300 dataset-level meta-features is computed spanning six families: simple, statistical, information-theoretic, model-based, landmarking, and data-complexity to capture dataset size/shape, distributional behavior, and structural dependencies. These meta-features reliably characterize new datasets and guide accurate model selection. The result is a models-by-datasets performance matrix paired with per-dataset meta-feature vectors. This dataset is then transformed into a meta-learning dataset in which each instance contains dataset meta-features and a learning target that encodes the identity of the best-performing model. A supervised meta-learner is trained to map meta-features to predict performance using standard train-validation splits to avoid leakage across datasets. At inference time, the same meta-features are extracted from the incoming unseen dataset, and the meta-learner returns a ranked list of anomaly detectors, enabling fast, trial-free recommendation for new datasets.

In this edge-focused framework, we restrict the candidate model pool to eleven models (AE, MLP, GRU, LSTM, DeepSVDD, GAN, LOF, OCSVM, KMeans, GMM, and PCA) instead of the 80 ML/DL models used in the original ASAD approach. This restriction is specifically designed to prioritize models that are suitable for edge deployment while maintaining the proven effectiveness of the ASAD meta-learning methodology. To ensure deployability, each candidate must be convertible into a tiny, edge-ready artifact via TensorFlow Lite (TFLite) or Open Neural Network Exchange (ONNX) runtime, with support for quantization and lightweight inference. This toolchain requirement is precisely why we do not reuse the broader PyOD-based model list from ASAD: many of those implementations lack reliable TFLite/ONNX export paths and therefore do not meet strict latency/memory targets. Instead, we focus on a curated set that preserves coverage across reconstruction, sequence modeling, clustering, margin-based one-class classification, and local-density detection, chosen for their practical convertibility, stable runtime support, and compatibility with post-training optimizations, thereby preserving methodological rigor while guaranteeing real-world deployability. The current system is positioned as a proof-of-concept, demonstrating end-to-end feasibility under these toolchain constraints; the candidate pool can be expanded as TensorFlow Lite (TFLite) or ONNX support improves without altering the selection logic.

C. Hardware-Aware Selection Module

The hardware-aware selection module represents the second stage of our framework and constitutes our primary novel contribution. This module addresses the critical challenge of translating performance-based model recommendations from the meta-learning module into deployment-ready selections that satisfy real-world hardware constraints. The module operates through a systematic four-step process: synthetic dataset generation, model profiling, hardware learning dataset construction, and hardware-aware model training.

1) Hardware dataset generation: The foundation of hardware-aware model selection begins with the creation of a comprehensive synthetic dataset that represents the diversity of edge computing environments. This step is crucial because it establishes the training basis for learning hardware-performance relationships across different device configurations. We generated 254 synthetic samples, each representing a unique hardware configuration encountered in edge scenarios. The sample size was chosen to provide sufficient coverage of the space of deployment scenarios while maintaining computational tractability for training. Each scenario represents a unique combination of hardware constraints and deployment requirements and is characterized by seven critical features that directly impact model deployment feasibility. The seven features used in the hardware dataset are presented in Table II.

TABLE II. THE SEVEN FEATURES USED IN THE HARDWARE DATASET

Hardware Constraint Features		
Feature	**Definition**	**Importance**
Max_Ram	Maximum available RAM in megabytes	Represent device memory capacity limits
Max_Inference	Maximum acceptable inference latency in milliseconds	Capture real-time performance requirements
Max_Size	Maximum allowable model size in megabytes	Reflect storage and bandwidth constraints
Max_Energy	Maximum energy consumption per inference in millijoules	Address battery-powered device limitations
Deployment Requirement Features		
Feature	**Definition**	**Importance**
Requires_Tflite	A binary indicator (1/0) for TensorFlow Lite format	Essential for mobile deployment optimization
Requires_Onnx	A binary indicator (1/0) for ONNX format	Support cross-platform compatibility
GPU_Available	A binary indicator (1/0) for GPU availability	Enabling hardware-specific optimization

The deployment scenarios were generated using an equal distribution approach with balanced representation across distinct deployment contexts. The process reflects realistic combinations observed in commercial edge devices, ensuring comprehensive coverage of the deployment space. These synthetic hardware configurations serve as the foundation for constructing diverse deployment scenarios. Each configuration represents a distinct set of device capabilities and constraints that will later be used to determine optimal model selection based on constraint satisfaction and deployment requirements.

2) Comprehensive model profiling: Model profiling is the bridge between algorithmic performance and deployment reality. It extracts deployment-specific characteristics that are

essential for hardware-aware decision making but are often overlooked by traditional model selection. During training, all 11 candidate models are comprehensively profiled so that the hardware-aware selector learns a complete mapping from hardware constraints to deployment feasibility across the entire model space. This comprehensive approach is essential because the selector must understand the deployment characteristics of every possible model choice to make informed, hardware-aware decisions.

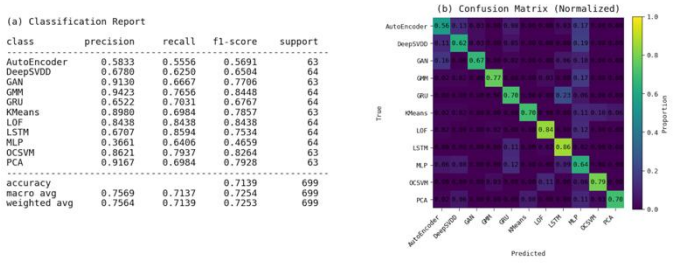
Profiling spans the memory and storage footprint, runtime efficiency, and format compatibility. On the memory side, runtime RAM during inference ranges from 0.02 MB for PCA to 0.98 MB for LSTM, while on-disk model size ranges from 0.001 MB for KMeans and PCA to 0.113 MB for LSTM. For hardware-accelerated inference, GPU memory requirements vary from 0 MB for traditional ML models to 90 MB for GANs. Efficiency metrics include single-inference latency from 0.68 ms (PCA) to 527.63 ms (LSTM) and energy on MCUs, from 0.04 mJ (PCA) to 29.02 mJ (LSTM). Format compatibility is captured through TFLite and ONNX: deep learning models support TFLite conversion, typically yielding a 10–15% size reduction relative to the original model, whereas traditional ML models are exported to ONNX for cross-platform deployment; corresponding TFLite and ONNX sizes are logged for each model.

The profiling reveals distinct deployment characteristics across model categories. Deep learning models, AutoEncoder, MLP, GRU, LSTM, DeepSVDD, and GAN, support TFLite optimization for mobile targets, benefit from GPU acceleration (30–90 MB GPU RAM), and generally require higher resource usage (0.77–0.98 MB RAM, 11.54–29.02 mJ per inference) with moderate-to-high latency (209.79–527.63 ms). Traditional machine-learning models, LOF, OCSVM, KMeans, GMM, and PCA, export cleanly to ONNX, require minimal resources (0.02–0.07 MB RAM, 0.04–0.17 mJ per inference), deliver ultra-low latency (≈0.68–3.11 ms), and do not require GPU acceleration. For computational efficiency, the strategy differs between training and inference. Training profiles all 11 models to cover the full deployment characteristic space. At inference time, only the top K recommended models from the meta-learning stage are profiled, which reduces profiling overhead by around 64% on average when k=4 (from 11 to 4 models) while preserving selection quality within the constrained candidate set.

3) Hardware-learning dataset construction: The hardware-learning dataset construction represents the critical integration phase that combines the synthetic hardware configurations from Step 1 (Hardware Dataset Generation) with the comprehensive model profiling results from Step 2 (Comprehensive Model Profiling). This step produces the final training dataset with ground truth labels that are determined through a hardware-focused scoring algorithm. It captures the complex relationships between hardware constraints and model deployment characteristics across diverse deployment scenarios.

The hardware-learning dataset construction process expands the 254 synthetic hardware configurations from Step 1 into a comprehensive training dataset. Using an equal distribution approach, each of the 254 hardware configurations is combined with all 11 candidate models, resulting in 2,794 total training samples (254 configurations × 11 models). This balanced distribution ensures that the meta-selector receives equal learning exposure to each model's deployment characteristics, preventing bias toward any algorithm. The integration with model profiling data enables the selection of the optimal model for each scenario through systematic constraint evaluation.

$$FinalScore = Eff_{Score} + Format_{Bonus} + Device_{Bonus} \quad (1)$$



The ground truth label assignment employs a hardware-aware scoring algorithm that determines the best-fitting model for each deployment scenario. Each candidate model is assigned a composite suitability score computed as the sum of an efficiency-based score (Eff_{Score}) and deployment-specific bonuses ($ormat_{Bonus}$ and $Devic\,e_{Bonus}$). The final score is defined as in Eq. (1). The efficiency score is calculated as a weighted linear combination of normalized resource metrics, given by Eq. (2):

$$Eff_{Score} = 0.3 \cdot RAM_{eff} + 0.3 \cdot Speed_{eff} + 0.2 \cdot Size_{eff} + 0.2 \cdot Energy_{eff} \quad (2)$$

The hardware-aware scoring algorithm prioritizes multiple factors, including memory efficiency, speed, format compatibility, and device-specific constraints, in a weighted evaluation. It first applies hard constraints to filter candidates: any model that violates critical limits on Max_Ram, Max_Inference, Max_Size, or Max_Energy is eliminated; models incompatible with required formats (Requires_Tflite, Requires_Onnx) are filtered out; and GPU needs must match device capabilities (Gpu_Available). Among the remaining models, those with lower RAM requirements receive higher scores in memory-constrained scenarios, while faster inference is favored for latency-sensitive deployments. Support for the required format (TFLite or ONNX) earns a compatibility bonus, and GPU availability together with energy limits further adjust each model's overall suitability score. For each of the 2,794 scenarios, the algorithm evaluates all 11 candidate models against the scenario's specific constraints. After constraint filtering and priority-weighted scoring, the model with the highest composite score becomes the ground truth label (BestModel) for that scenario. This approach ensures that the hardware-aware selector learns realistic deployment decisions that reflect both technical constraints and deployment priorities.

4) Hardware-aware model training and optimization: The final step involves training a classifier to predict the optimal model given the integrated hardware and deployment features. This step transforms the comprehensive dataset into a practical decision-making tool for hardware-aware model selection. A Random Forest was selected as the hardware-aware selection algorithm due to its ability to handle mixed feature types, robustness to feature scaling differences, and interpretability through feature importance analysis [19]. The training process starts with data preprocessing, including standardization and label encoding to ensure consistent feature scaling and proper

handling of categorical variables. An 80/20 stratified train-test split maintains balanced class representation across all 11 anomaly detection models. The training step produces a classifier that predicts the optimal model selection among all 11 candidate anomaly detection algorithms based on hardware constraint features. It also outputs a probability distribution (confidence scores) over all models, where each probability indicates the likelihood that a particular model is the best choice for the specified hardware.

(a) Classification Report

class	precision	recall	f1-score	support
AutoEncoder	0.5833	0.5556	0.5691	63
DeepSVDD	0.6780	0.6250	0.6504	64
GAN	0.9130	0.6667	0.7706	63
GMM	0.9423	0.7656	0.8448	64
GRU	0.6522	0.7031	0.6767	64
KMeans	0.8980	0.6984	0.7857	63
LOF	0.8438	0.8438	0.8438	64
LSTM	0.6707	0.8594	0.7534	64
MLP	0.3661	0.6406	0.4659	64
OCSVM	0.8621	0.7937	0.8264	63
PCA	0.9167	0.6984	0.7928	63
accuracy			0.7139	699
macro avg	0.7569	0.7137	0.7254	699
weighted avg	0.7564	0.7139	0.7253	699

(b) Confusion Matrix (Normalized)

Fig. 2. Performance of the hardware-aware classifier: (a) Classification report; (b) Normalized confusion matrix.

Fig. 2 shows strong, class-consistent performance across 11 categories. The multi-class model achieved 71.4% overall accuracy (699 samples), with macro-averaged precision 0.7569, recall 0.7137, and F1-score 0.7254, indicating balanced performance across classes. The row-normalized confusion matrix shows a clear, dominant diagonal where most classes (7 out of 11) achieve ≥ 0.70 recall, with particularly strong performance for LSTM (0.86), LOF (0.84), OCSVM (0.79), and GMM (0.77). Off-diagonal entries are low and diffuse, indicating minimal systematic confusion and confirming the model's ability to reliably discriminate among the competing approaches. These results represent a significant improvement over random selection and validate the effectiveness of constraint-driven feature-engineering and hardware-focused scoring.

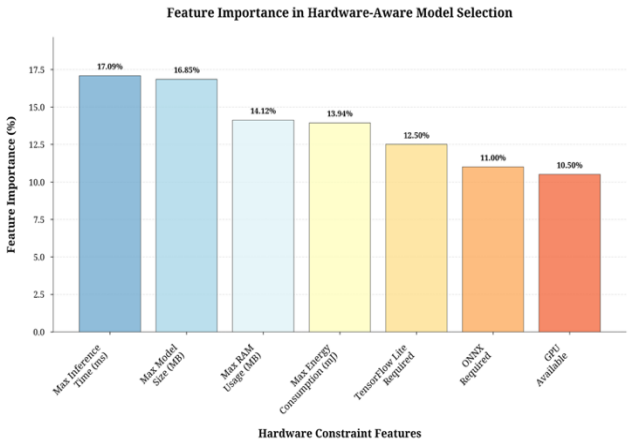


Fig. 3. Feature importance analysis of the hardware-aware model selection.

The Random Forest feature importance analysis reveals the relative contribution of each input feature to the selection decision, as illustrated in Fig. 3. The feature-importance analysis indicates that deployment constraints tied to latency and footprint dominate model selection: Max_Inference contributes the most at 17.09%, followed by Max_Size at 16.85%. Resource limits are next with Max_RAM (14.12%) and Max_Energy (13.94%), highlighting the importance of running efficiently on devices with limited memory and power. Platform compatibility matters but is secondary, with Requires_Tflite (12.50%) and Requires_Onnx (11.00%). GPU Availability has the lowest but still meaningful impact (10.50%), suggesting decisions are driven more by edge-device constraints than by access to accelerators.

D. MetaEdge Engine Construction

The MetaEdge engine is constructed by seamless integration of the hardware-aware selection module and the meta-learning module through a two-stage decision process. During inference, the meta-learning module first generates top-k model recommendations based on dataset characteristics. The hardware-aware module then evaluates these k candidates against the target hardware specifications to select the best candidate model that balances performance potential with deployment feasibility. A key design decision in MetaEdge is this two-stage architecture: by first filtering with meta-learning and then applying hardware-aware optimization, the system constrains the hardware-aware module to the top-K models while gaining important practical advantages, including computational efficiency by reducing the candidate pool, interpretability through a clear separation of data-driven and hardware-driven decisions, and proven effectiveness across diverse deployment scenarios. This design prioritizes data-driven model selection as the primary driver, using hardware constraints as a secondary refinement filter, reflecting a deliberate trade-off between optimality and deployment efficiency.

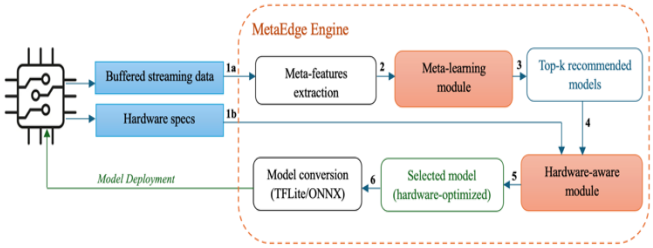

Fig. 4. Workflow of the MetaEdge engine.

Fig. 4 illustrates the detailed workflow of MetaEdge. First, the incoming streaming data is buffered, and the buffered data is sent along with the target hardware specifications to the MetaEdge engine. Then, at the MetaEdge, a two-stage decision process is performed to select the best deployable anomaly-detection model. In the first stage, the meta-learning module extracts the meta-features of the buffered streaming data and recommends the top-k anomaly detectors based only on the data characteristics. In the second stage, the hardware-aware module uses the hardware specifications and converts them into a standardized feature vector to generate probability predictions (confidence scores) for every model in the candidate pool, not just the top-k from the meta-learning module. The confidence score represents the hardware-aware estimate of the probability that a given model is the most suitable option for a

given hardware specification. Despite having complete probability information for all 11 models, the system restricts the selection to only the top-k models identified by the meta-learning selection module. Therefore, the hardware-aware selection module selects the model with the highest probability among the filtered top-k. The selected model is then trained on the buffered data and converted to compact models using the required format (TFLite or ONNX). Algorithm 1 presents the integrated two-stage selection process of MetaEdge.

Algorithm 1 Two-Stage Model Selection of MetaEdge.

IV. Experimental Results

This section reports a comprehensive evaluation of the MetaEdge framework along four dimensions: meta-learning-based model selection, hardware-aware model selection, model conversion effectiveness, and deployment feasibility. All experiments were executed on AWS. We used Amazon SageMaker notebook instances to provide a scalable, reproducible setup, and stored models, training data, and results in Amazon S3 for reliable persistence and access. The stream-processing pipeline consumed the skin dataset and implemented a buffer abstraction to emulate cold-start and warm-buffer conditions, enabling a realistic assessment under varied operating scenarios. We tested MetaEdge on four representative edge platforms spanning a wide compute range from a constrained Orange Pi Zero to a high-performance EC2 g4dn.xlarge with a GPU. The two higher-end platforms were instantiated as AWS EC2 instances to reflect practical cloud–edge deployments. The overarching goal is to show that MetaEdge can adapt model selection to device constraints while maintaining acceptable anomaly-detection performance, and to quantify the benefits of its two-stage selection strategy in real-world edge settings.

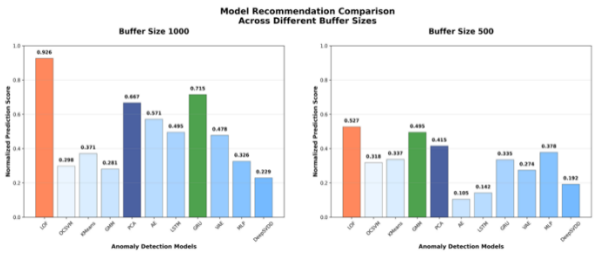

Fig. 5. Model recommendation comparison across different buffer sizes.

We examined how available data volume affects model selection by varying the buffer size (500 vs. 1,000 samples). For each condition, the meta-learning module ranked candidate anomaly detectors and returned the top three. With a 500-sample buffer, it favored LOF, GMM, and PCA; with a 1,000-sample buffer, it favored LOF, GRU, and PCA. As illustrated in Fig. 5, increasing the buffer from 500 to 1,000 samples yielded a 76% average gain in the meta-learner's prediction score. Confidence in LOF rose from 0.527 to 0.926, with corresponding improvements for GRU and PCA. Overall, providing more buffered data makes the meta-learner both more confident and more accurate in its recommendations.

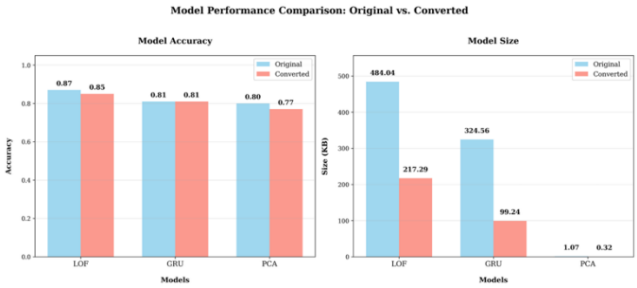

Fig. 6. Model performance comparison (Original vs. Converted).

To evaluate anomaly detection capability, we trained the top three models recommended by the meta-learner: LOF, GRU, and PCA on a 1,000-sample buffer from the skin dataset. We then produced lightweight deployment versions. Where supported, TensorFlow models were exported to .tflite using the official TensorFlow Lite converter; scikit-learn models were converted to ONNX with skl2onnx. In our case, LOF and PCA (scikit-learn) were converted to ONNX, and the GRU model was exported to ONNX via tf2onnx as a fallback mechanism. To validate the effectiveness of these conversions, we compared each converted model with its original counterpart on two metrics: model file size and accuracy (see Fig. 6). Accuracy losses were minimal: LOF decreased from 0.87 to 0.85 (−2.3%), GRU was unchanged at 0.81, and PCA declined from 0.80 to 0.77 (−3.8%). All converted models remained above 75% accuracy. Size compression was substantial: LOF shrank from 484.04 KB to 217.29 KB (−55%), GRU from 324.56 KB to 99.24 KB (−69%), and PCA from 1.07 KB to 0.32 KB (−70%). These reductions, ranging from 55% to 70% make the models well-suited for resource-constrained edge deployments.

TABLE III. THE SPECIFICATIONS OF EDGE DEVICES

Edge Device	Real/ Simulated	Device Specifications
T2.Micro 	Simulated	1 vCPU, 1 GB RAM, no GPU; Low-to-moderate network performance [20].
G4dn.Xlarge 	Simulated	4 vCPUs, 16 GB RAM, 1× NVIDIA T4 (16 GB VRAM), 125 GB NVMe local storage, up to 25 Gbps networking [21].
Raspberry Pi 5 	Real	Quad-core Arm Cortex-A76, 2.4 GHz, VideoCore VII GPU; LPDDR4X-4267 RAM 8 GB; dual 4Kp60 micro-HDMI; Wi-Fi 5 and Bluetooth 5.0 [22].
Orange Pi Zero 2W 	Real	quad-core Cortex-A53 (up to 1.5 GHz), Mali-G31 MP2 GPU; 1 GB LPDDR4 ; Wi-Fi 5 and Bluetooth 5.0 [23].

We validated the hardware-aware module by executing it in live deployments across four edge targets. Two were physical devices, a Raspberry Pi 5 (higher-end) and an Orange Pi Zero 2W (resource-constrained), provisioned with AWS IoT Greengrass v2 and packaged via Amazon SageMaker Edge Manager. To widen the hardware spectrum, we also emulated edge profiles on AWS EC2: a t2.micro to represent a low-resource CPU environment and a g4dn.xlarge to represent a GPU-enabled, Jetson-like setting. Device specifications are summarized in Table III. The hardware-aware module leverages each device's specifications to choose the best model from the meta-learner's candidates (LOF, GRU, and PCA), assigning a confidence score to each. Detailed per-device confidence scores for all models are presented in the following subsections.

A. Edge Device 1: Orange Pi Zero

The Orange Pi Zero is one of the resource-constrained platforms, and its confidence scores reflect the framework's ability to adapt to severe hardware limits. LOF is the preferred option at 45% confidence (see Fig. 7), indicating that classical algorithms are best suited to resource-limited devices. PCA is a strong alternative at 25%, underscoring the preference for lightweight, classical approaches. By contrast, the GRU receives 0% confidence, consistent with the view that neural networks are impractical on this class of hardware. Overall, the distribution shows hardware-aware reasoning: traditional ML models dominate the shortlist (LOF 45%, PCA 25%, KMeans 15%), appropriately prioritizing resource-efficient choices for reliable deployment under tight constraints.

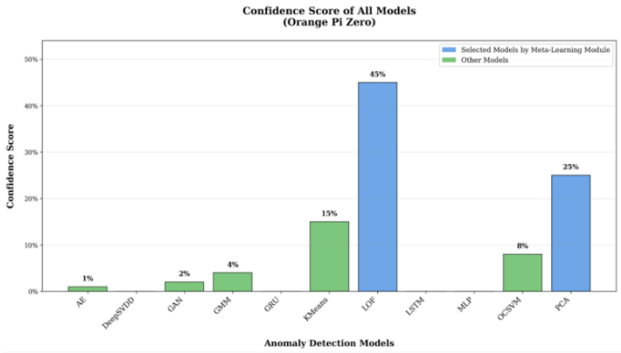

Fig. 7. Confidence scores of the Orange Pi Zero device.

To assess real-time feasibility, we deployed the selected LOF model on the Orange Pi Zero. The inference traces (see Fig. 8) remained stable across 6,000 samples with no anomalous spikes. Latency was tightly centered at 17.36 ms and consistently under 20 ms per sample, meeting real-time requirements for lightweight devices. Chunk-level analysis over 120 windows showed steady performance with only minor fluctuations. While not the fastest platform, the Orange Pi Zero ran LOF inference reliably, confirming that on-device anomaly detection is feasible even on microcontroller-class hardware.

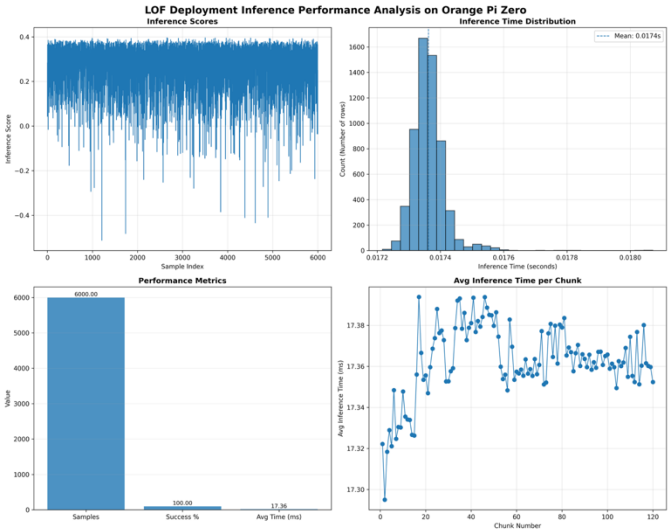

Fig. 8. Inference performance of the Orange Pi Zero device.

Running LOF on the Orange Pi Zero shows that simple, lightweight methods can work well on limited hardware, with 81.0% accuracy, as shown in Fig. 9. Precision is 29.4%, meaning one in three alerts corresponds to a true anomaly, a trade-off that favors responsiveness over selectivity on low-power devices. Recall is 79.1%, so the system catches most of the anomalies useful in settings where missing an event such as equipment faults and security issues is worse than raising extra alerts. Specificity is 81.2%, indicating reasonable discrimination of normal behavior given the algorithm's simplicity and small computational footprint. Overall, the F1 score is 42.8%, and the average precision (AP) is 0.456, reflecting moderate separation between classes under tight resource limits. The confusion matrix (TN = 4,434; FP = 1,026; FN = 113; TP = 427) confirms this profile: more false alarms than some higher-powered

platforms, but strong sensitivity that is well suited to applications where missing an anomaly is costlier than investigating extra alerts. Taken together, these results make the Orange Pi Zero and LOF combination a practical fit for distributed sensor networks, remote monitoring, and other IoT deployments where power, cost, and connectivity limitations demand efficient local processing.

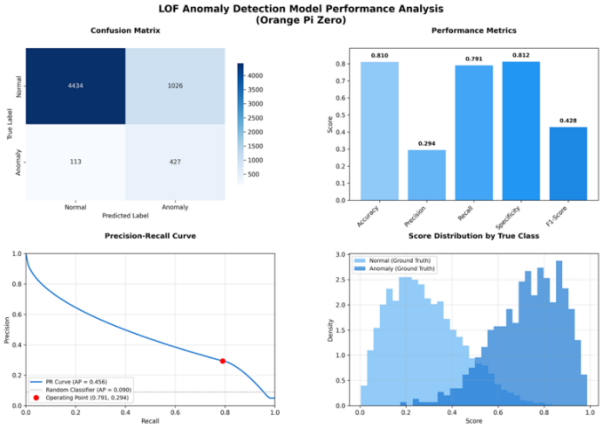

Fig. 9. Performance of a LOF model on Orange Pi Zero: (a) Confusion matrix; (b) Metrics summary; (c) Precision–recall curve; (d) Score distributions by class.

B. Edge Device 2: EC2 T2.Micro

The EC2 t2.micro serves as another resource-constrained target, with limited RAM and tight latency budgets. LOF remains the leading choice at 35% confidence, down from 45% on the Orange Pi Zero, suggesting that the different resources on t2.micro allow closer competition (as shown in Fig. 10). GAN reaches 20% confidence but is excluded because it was not selected by the meta-learning module. Overall, classical options still dominate the viable set PCA at 15% while non-selected candidates such as KMeans (12%) and AutoEncoder (8%) register only moderate confidence.

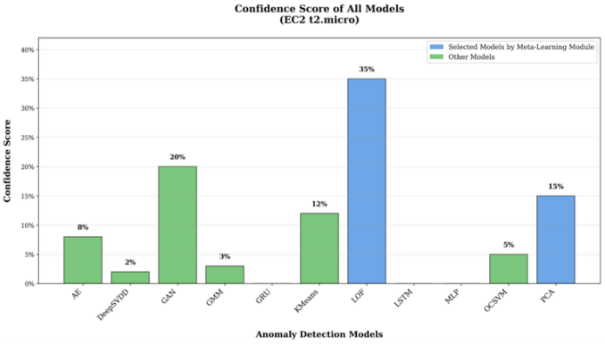

Fig. 10. Confidence scores of T2.micro.

To assess the real-time viability of the chosen LOF model, we deployed it on AWS EC2 t2.micro instances using AWS IoT Greengrass v2. Fig. 11 summarizes the edge-side inference results. The line plot tracks raw anomaly scores across 6,000 streaming samples; scores are normalized to the [0, 1] range and exhibit steady behavior without abrupt spikes. The accompanying histogram reports per-sample latency: the mean inference time was 2.58 ms, with most samples completing under 3 ms. Latencies ranged from 2.34 ms to 12.68 ms indicating efficient and comparatively stable performance on constrained hardware. A chunk-level view (CHUNK_SIZE = 50) further showed uniform throughput across 120 chunks, with no evident degradation or drift. Despite limited CPU and memory, the LOF model sustained stable throughput and accuracy, supporting its suitability for lightweight deployment on t2.micro edge device.

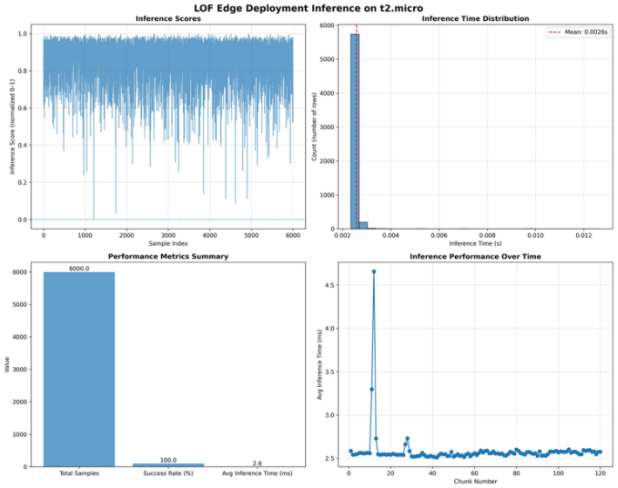

Fig. 11. Inference performance of the T2.micro device.

On an AWS T2.micro instance, the LOF model achieves 76.5% accuracy (see Fig. 12), demonstrating that useful anomaly detection can be achieved on a very low-cost instance. Precision is 23.9%, so about one in four alerts is a real issue, a reflection of the limited CPU and memory on this class of VM, which caps model complexity. Recall comes in at 73.9%, meaning the system catches the most important anomalies, which is valuable when the cost of missing an event could outweigh savings on infrastructure. Specificity is 76.8%, a reasonable level of "normal vs. abnormal" separation for such a constrained setup. Overall, the F1 score is 36.1% and the AP is 0.403, consistent with moderate discriminative power for cost-sensitive use cases. The confusion matrix (TN=4,191; FP=1,269; FN=141; TP=399) shows a higher false-alarm rate, but acceptable recall, which is ideal for cost-sensitive environments that use alerts to prompt lightweight verification.

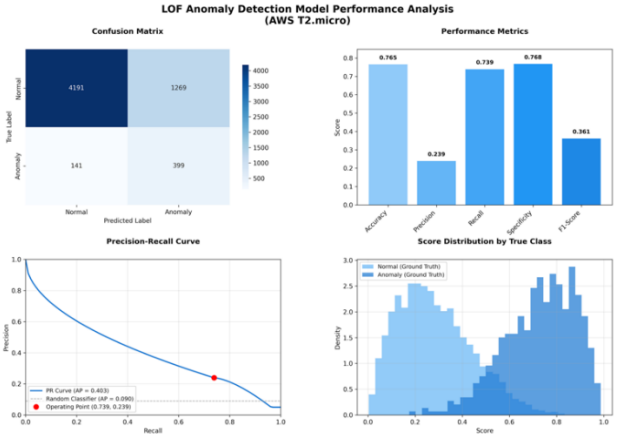

Fig. 12. Performance of a LOF model on T2.micro: (a) Confusion matrix; (b) Metrics summary; (c) Precision–recall curve; (d) Score distributions by class.

C. Edge Device 3: Raspberry Pi 5

The Raspberry Pi 5 marks a clear inflection point where the framework begins to favor deep learning and adapts to support neural models. On this device, a GRU is selected with 28% confidence (see Fig. 13), indicating the system's capacity to accommodate more advanced algorithms as resources increase. This choice supports the framework's principle of scaling model complexity with available compute, enabling neural network–based methods when they become practical and advantageous for anomaly detection. Notably, an LSTM registers 42% confidence among the models that were filtered out. This suggests the hardware-aware selector would have preferred LSTM over GRU for this configuration, but the upstream meta-learning stage, driven by data characteristics, did not choose it. This rigid two-stage pipeline can therefore constrain optimal hardware-aware decisions when the meta-learning and hardware signals diverge.

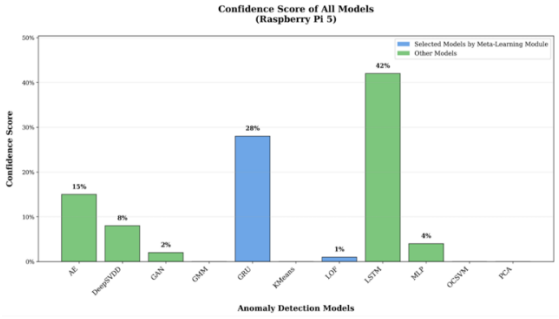

Fig. 13. Confidence scores of the Raspberry Pi 5.

To verify the GRU model's real-time viability, we deployed it on a Raspberry Pi 5. Fig. 14 summarizes the edge-side inference results. Outputs remain stable across all 6,000 samples, with scores confined to the [0, 1] range. Latency is extremely low, an average of 0.076 ms, with the vast majority of inferences finishing under 0.1 ms. A chunk-level analysis over 120 chunks shows flat, highly consistent throughput with no signs of drift or degradation. Overall, the Raspberry Pi 5 executes the GRU model with ultra-low latency and negligible variance, confirming its suitability for real-time anomaly detection at the edge.

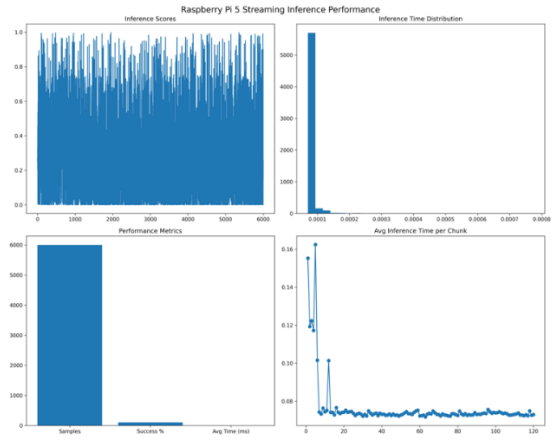

Fig. 14. Inference performance of the Raspberry Pi 5 device.

As shown in Fig. 15, running a GRU model on the Raspberry Pi 5 delivers standout anomaly detection, topping all platforms in our test with 96.6% accuracy. Precision reaches 90.4%, meaning 9 out of 10 alerts are real, which significantly reduces the cost of chasing false alarms. The model's 69.7% recall reflects a deliberate tilt toward accuracy over sensitivity, which is useful in settings where false positives are more costly than the occasional miss. Specificity is an exceptional 99.3%, indicating the system almost never flags normal behavior. Overall performance is strong, with an F1 score of 78.7% and an AP of 0.818. The confusion matrix shows 5,420 correctly identified normal events and 376 correctly identified anomalies, with only 40 false alarms and 164 missed anomalies, evidence of tight control over false positives while capturing a substantial share of true anomalies. These results demonstrate the model's ability to achieve high-performance anomaly detection on edge computing hardware with minimal computational overhead.

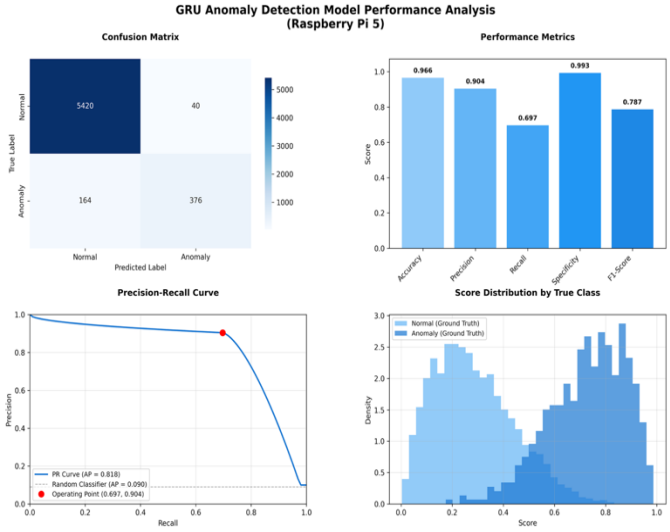

Fig. 15. Performance of a GRU model on Raspberry Pi 5: (a) Confusion matrix; (b) Metrics summary; (c) Precision–recall curve; (d) Score distributions by class.

D. Edge Device 4: EC2 G4dn.Xlarge

The EC2 g4dn.xlarge evaluation shows how the framework performs in a resource-rich, GPU-accelerated setting. As shown in Fig. 16, with ample compute, the system elevates deep learning and selects a GRU with 18% confidence, illustrating its ability to take advantage of advanced hardware. This aligns with the framework's scaling strategy: as constraints ease, more sophisticated neural architectures become preferable. While GRU was prioritized as a top 3 meta-learning choice, LSTM attained 55% confidence, exceeding the GRU by more than threefold, suggesting substantial promise under different dataset conditions. As expected on this class of hardware, traditional ML methods receive negligible confidence (mostly under 5%), avoiding underutilization of the platform. Overall, the high-performance scenario confirms that the framework adjusts model complexity to match available resources, enabling efficient use of advanced edge infrastructure.

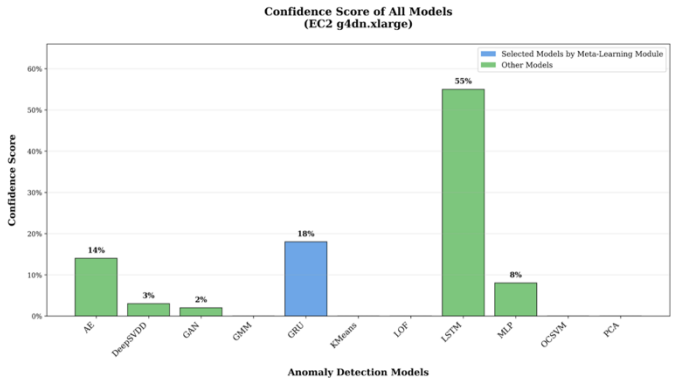

Fig. 16. Confidence scores of G4dn.Xlarge.

To validate the real-time operational feasibility of the selected LOF model, deployments were executed on AWS EC2 instances G4dn.Xlarge using AWS IoT Greengrass V2. The GRU edge deployment inference results for EC2 instance G4dn.Xlarge are shown in Fig. 17. The line chart shows GRU's raw sequence modeling outputs across 6,000 streaming samples, bounded between 0 and 1. The scores remained stable without spikes, reflecting consistent prediction quality. The histogram confirms ultra-stable latency, with most samples completing near 0.07 ms. The narrow range (0.066–0.298 ms) and extremely low variance (std: 0.0053 ms) validate the predictability of GPU execution. Chunk-level latency (120 chunks, 50 samples each) was nearly flat, with no systematic drift, confirming sustained throughput. The GRU model leveraged G4dn.Xlarge's GPU capabilities to deliver extremely consistent, ultra-low-variance inference performance, ideal for precision-critical deployments.

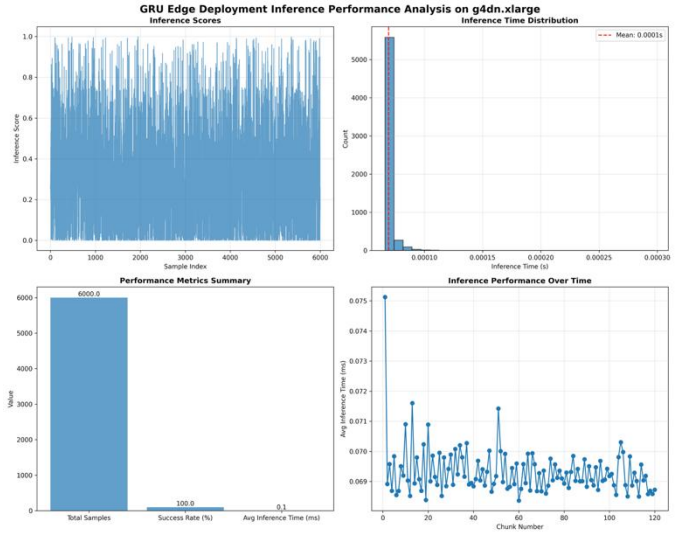

Fig. 17. Inference performance of G4dn.xlarge device.

Running a GRU model on an AWS G4dn.xlarge delivers solid anomaly detection with 89.0% accuracy, highlighting how high-performance hardware helps with complex pattern recognition. Precision is 43.2%, about two of every five alerts are true, a clear step up from our statistical baselines, while keeping throughput high thanks to GPU acceleration. Recall is 69.6%, so the system catches nearly 70% of real anomalies, and specificity is 90.9%, showing it is strong at recognizing normal behavior. Overall, the model posts an F1 of 53.3% and an AP of 0.512, indicating good discrimination across thresholds, as shown in Fig. 18. The confusion matrix shows TN=4,965, FP=495, FN=164, and TP=376, reflecting a balanced trade-off between detection and false alarms. In practice, this GPU-accelerated setup is well-suited to production workloads that need both high performance and straightforward scalability.

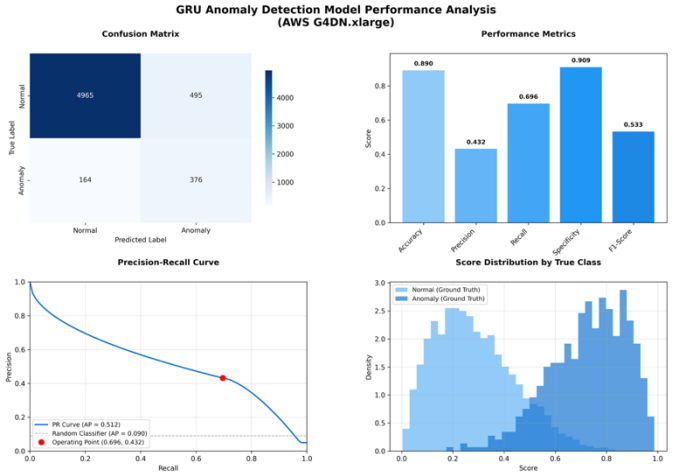

Fig. 18. Performance of a GRU model on G4dn.Xlarge: (a) Confusion matrix; (b) Metrics summary; (c) Precision–recall curve; (d) Score distributions by class.

E. Results Summary

MetaEdge shows strong hardware-aware model selection: its confidence score distributions adapt to the computational limits of the four evaluated devices. The Random Forest meta-selector produces probabilities ranging from 0% for clearly incompatible choices to 55% for the best hardware–model pairs. Concretely, LOF scores 45% confidence on the Orange Pi Zero and 35% on EC2 t2.micro, while GRU reaches 28% on the Raspberry Pi 5 and becomes viable on EC2 g4dn.xlarge, evidence that the framework scales model complexity progressively with available resources. The model conversion process through ONNX standardization achieves remarkable success with only 0–3.8% degradation, while delivering substantial size reductions of 55-70% across all models. These reductions enable practical edge deployment without sacrificing detection capability, effectively bridging the gap between theoretical performance and real-world deployment constraints.

Across deployments, the models deliver strong anomaly detection and validate MetaEdge's two-stage selection strategy. The Raspberry Pi 5 leads all platforms with 96.6% accuracy and 90.4% precision, surpassing all other configurations in this study. The AWS G4dn.xlarge follows with 89.0% accuracy using GPU acceleration, while the LOF model maintains consistent recall on constrained devices (79.1% and 73.9% on the Orange Pi Zero and EC2 t2.micro, respectively). MetaEdge balances performance and deploy ability by first using meta-learning to shortlist high-performing candidates, then applying hardware-aware constraints to ensure each model fits device resources. This produces sensible adaptations: traditional ML is selected for tight edge environments, and deep learning is enabled where hardware permits. The result is superior anomaly

detection across diverse edge settings without sacrificing computational efficiency or deployment reliability.

V. Conclusion

This study presents MetaEdge, a hardware-aware framework for model selection that tackles the challenge of deploying effective anomaly detection across heterogeneous edge devices. It combines meta-learning with hardware-aware optimization to enable practical deployment without compromising detection quality. The framework makes high-accuracy model-selection decisions, with confidence scores that provide meaningful assessments of hardware compatibility to guide deployment strategies. MetaEdge uses ONNX standardization for model conversion to enable cross-platform deployment while minimizing accuracy loss, yielding 0–3.8% degradation and a 55–70% reduction in model size.

Experimental results demonstrate superior anomaly-detection performance across diverse hardware configurations. The hardware-aware stage consistently identifies optimal model–hardware pairings, and the deployed models exhibit strong detection performance. On a Raspberry Pi 5, MetaEdge achieves 96.6% accuracy and 90.4% precision under strict computational constraints, outperforming the other tested implementations. On an AWS g4dn.xlarge instance, GPU acceleration yields 89.0% accuracy. The LOF model maintains stable recall on resource-constrained devices (79.1% and 73.9%), providing a reliable baseline for such deployments.

MetaEdge demonstrates that automated, hardware-aware model selection can jointly identify models from data meta-features and align them with device constraints. The framework operates across heterogeneous platforms from ultra-constrained edge nodes to GPU-accelerated systems, enhancing on-device anomaly detection while adhering to strict resource budgets. Beyond empirical gains, MetaEdge offers methodological guidance for distributed anomaly detection and clarifies the trade-offs inherent in hardware-aware optimization. It establishes a robust foundation for future adaptive edge computing systems, capable of intelligently adjusting their performance based on available computational resources and deployment constraints.

In practice, MetaEdge supports real-world deployment by providing a systematic workflow for selecting accurate models that satisfy explicit resource budgets across diverse devices, reducing trial-and-error when transitioning from experimental evaluation to on-device operation. As with any deployment-oriented framework, MetaEdge operates within the assumptions of the profiled model space and observed device conditions; however, its modular design allows these profiles to be incrementally expanded and updated as deployment scale, anomaly characteristics, and hardware diversity evolve. To further strengthen applicability at scale, future work will extend the profiling process and model registry to broader model families and a wider range of devices, support lightweight online learning to maintain performance under concept drift and changing anomaly patterns, enable model personalization to device- and context-specific conditions, and explore cross-device collaborative learning to improve robustness across heterogeneous edge deployments, while reducing runtime overhead through offline profiling and caching.

***Abstract*—Ransomware remains a critical and evolving cybersecurity threat, increasingly rendering traditional signature-based detection techniques ineffective. While modern machine learning models achieve high detection accuracy, they often operate as opaque "black boxes", introducing a significant explainability gap that undermines analyst trust. In addition, behavior-based anomaly detection systems frequently suffer from high false-positive rates, limiting their operational viability. To address these challenges, this study adopts a Design Science Research Methodology to develop a novel, interpretable, multi-stage ransomware detection framework. The proposed architecture integrates three complementary components: a bio-inspired Negative Selection Algorithm from Artificial Immune Systems to filter benign behavioral patterns, a first-order Markov chain model to capture probabilistic deviations in execution sequences, and a Random Forest ensemble classifier to synthesize these signals for final decision-making. The framework is evaluated using a dual-pipeline experimental design on real-world ransomware and benign software samples, enabling controlled comparison between probabilistic and pattern-based behavioral modeling. Experimental results demonstrate that the proposed approach achieves high detection performance while maintaining a low false-positive rate and providing interpretable behavioral evidence. Overall, the framework offers a principled balance between detection effectiveness and interpretability, addressing key limitations of existing ransomware detection systems.**

Keywords*—Ransomware; Artificial Immune Systems (AIS); anomaly detection; Negative Selection Algorithm; Markov chain; Random Forest; hybrid framework

I. Introduction

Computers and the Internet have revolutionized many aspects of daily life, offering unprecedented opportunities for communication, information exchange, and economic growth [1]. This digital transformation, accelerated by rapid advancements in information technology, has significantly improved global living standards [2]. However, the rise of the digital age has also presented new challenges in the form of cyber threats [3], [4].

Ransomware has rapidly transformed into a significant global cybersecurity challenge by employing advanced cryptographic techniques, polymorphic code mutations, and anti-analysis mechanisms to avoid detection [5], [6], [7]. The increasing sophistication of these attacks renders the traditional signature-based detection systems ineffective. These static pattern-matching approaches are fundamentally unable to combat the dynamic and evasive nature of 0-day and polymorphic ransomware variants [8], [9], [10].

High-profile incidents, such as the 2021 Colonial Pipeline attack, demonstrate the devastating impact of ransomware on critical infrastructures. This incident highlighted severe vulnerabilities and led to a notable fuel shortage along the US East Coast [11]. This threat is further exacerbated by the "Ransomware-as-a-Service" (RaaS) model, which enables cybercriminals with minimal technical expertise to launch large-scale, sophisticated attacks [12].

In response to the failure of static methods, the research community has increasingly focused on dynamic and behavior-based malware detection using machine learning (ML). behavior-based approaches inspired by biological systems, particularly the Human Immune System, have demonstrated promise in detecting previously unseen malware variants through adaptive and anomaly-driven mechanisms [13]. However, despite their effectiveness, existing immune-inspired and hybrid detection architectures often remain limited in their ability to robustly model complex runtime behavior and to adapt to the evolving tactics of modern ransomware [14]. This motivates the need for a more formalized and empirically validated behavior-centric detection framework.

Our systematic review of the domain from 2015 to 2025 reveals three critical gaps that impede the deployment of robust real-world defenses:

- The Explainability Gap (G1): Many high- performing models, particularly deep learning architectures, operate as "black boxes" [15]. Security analysts cannot trust or act on alerts that they do not understand, making interpretability a critical, unsolved requirement [16].
- The False Positive Gap (G2): Behavior-based anomaly detection is notoriously "noisy". Legitimate software, such as file compressors and backup tools, often performs intensive I/O operations that mimic ransomware [17]. This leads to a high false positive rate (FPR), and the resulting alert fatigue renders many systems unusable in operational contexts [18].
- The AIS-ML Gap (G3): While Artificial Immune Systems (AIS), particularly the Negative Selection Algorithm (NSA), are theoretically ideal for the "self" vs. "non-self" discrimination problem, their application in ransomware detection remains limited and non-

standardized [19]. The value of AIS-ML hybrids is a significant and under-explored research area.

To address these three gaps, this study proposes a novel, interpretable, AIS-hybrid framework for ransomware detection. Following a rigorous Design Science Research Methodology (DSRM) [20], we present the complete design artefact of a system specifically engineered to solve these problems.

Our contributions are:

- Novel Hybrid Detection Architecture: We propose a bio-inspired, behavior-based ransomware detection framework that integrates an Artificial Immune System (Negative Selection Algorithm), probabilistic Markov chain behavioral profiling, and Random Forest classification in a unified, multi-stage architecture. Unlike prior studies that employ these techniques in isolation or simple pairwise combinations, this work formalizes their complementary integration into a single explainable detection pipeline.
- AIS-Based Behavioral Noise Reduction: We introduce an NSA-driven behavioral filtering mechanism that removes benign "self" API-call patterns prior to classification, substantially reducing behavioral noise and mitigating false positives commonly observed in anomaly-based ransomware detectors.
- Probabilistic Behavioral Explainability: We incorporate a first-order Markov chain model trained on benign execution traces to quantify the likelihood of observed API-call transitions. This probabilistic profiling enables interpretable detection decisions by highlighting statistically rare behavioral sequences rather than opaque feature activations.
- Controlled Dual-Pipeline Evaluation: We design and evaluate two detection pipelines under identical experimental conditions, NSA–Markov–RF and NSA–n-gram–RF, allowing a controlled assessment of the contribution of probabilistic behavioral modeling to detection performance and interpretability.

The remainder of this study is organized as follows: Section II reviews related work and identifies key research gaps. Section III presents the theoretical framework underlying the proposed hybrid detection architecture. Section IV describes the proposed methodology, including evaluation metrics and comparative pipeline design. Section V reports the experimental evaluation, covering dataset construction, experimental setup, detection results, and analysis of the Markov behavioral modeling contribution. Section VI discusses the theoretical and practical implications of the findings, including threat modeling, computational feasibility, and future research directions. Finally, Section VII concludes the study.

II. Literature Review

A. Ransomware Detection Techniques

Ransomware detection methods rely heavily on signature-based and heuristic techniques [21], [22]. Signature matching fails against obfuscated or polymorphic variants [23], [24]. Heuristic approaches improve this by looking for suspect behaviors, such as mass file encryption [25], but they suffer from high false positive rates (FPR), as benign software, that is, backup tools that can exhibit similar behaviors [26], [27].

To combat these novel threats, researchers have turned to machine learning for behavioral data [5]. Dynamic analysis frameworks such as Cuckoo/CAPE sandboxes were used to extract runtime API call sequences as features for ML models [28], [29]. However, these ML-driven methods introduce their own critical challenges, namely: 1) Limited Explainability (G1), as many models are "black boxes", and 2) Persistent False Positives (G2), as benign apps still mimic ransomware behavior.

B. Machine Learning and Ensembles

A range of ML algorithms has been successfully applied to ransomware detection. Tree-based Decision methods (J48, C5.0) and ensemble methods (Random Forest, gradient boosting) have shown high accuracy in classifying ransomware vs. good-ware binaries [30], [31]. Moreover, [32] used a Random Forest classifier on extracted file features and achieved ~97.7% accuracy in distinguishing ransomware, although with a somewhat elevated false-positive rate in practical scenarioslink.springer.com. Random Forest (RF), in particular, has become popular owing to its strong performance and resistance to overfitting. It combines multiple decision trees to vote on the class, which tends to smooth out noise and outlier effects.

Khammas's results illustrate both the promise and pitfall of pure ML: high accuracy is attainable, but the cost of false alarms can be significant if the model latches onto features that overlap with legitimate softwarelink.springer.com. Recent studies have emphasized explainable machine learning. For instance, techniques like SHAP (Shapley Additive Explanations (SHAPs) have been employed to interpret feature importance in ransomware classifiersarxiv.orgarxiv.org, and uncertainty estimation has been added to random forests to identify low confidence. These trends highlight the growing recognition that detection models must be not only accurate but also transparent and reliable for analysts. This limitation of pure ML-only models was exemplified in the work of [21]. In their initial research, they proposed a lightweight 10-feature Random Forest model. However, to improve the performance in their follow-up work, they were forced to hybridize this model with a static, signature-based hash filter [33]. This progression demonstrates the practical limitations of the pure ML approach (G2) and highlights the need for a more dynamic, adaptive hybrid. While [33] resorted to a static filter, our framework proposes a novel hybrid with a true adaptive technique (AIS) to solve this exact problem, directly addressing the G3 gap.

C. Markov Chain Models in Malware Behavior

Markov models provide a stochastic way to model sequences of events, which is highly relevant for ransomware behavior (often characterized by sequences of file accesses or API calls). Researchers have applied both Markov chains [34] and Hidden Markov Models (HMMs) [35] for malware and ransomware analyses. An early example was the use of Markov chains to model system call sequences for anomaly detection in host intrusion detection systems. In ransomware-specific research, [36] proposed a two-stage detection approach, first modelling API call sequences with Markov chains, and then applying a

Random Forest (RF) classifier. Their system trained separate models for benign and ransomware behaviors to capture the malicious transition probabilities. Despite achieving 97.3% accuracy, their hybrid model still suffered from a non-negligible 4.8% false-positive rate (FPR). This result confirms that while Markov models can encapsulate sequential behavior, a high FPR remains a key drawback. Crucially, the authors suggested that "additional anomaly detection" could reduce these false alarms [37].

This insight provides a direct motivation for our framework, which integrates an AIS-based anomaly detector, the NSA, as the precise component required to filter out benign patterns and solve this identified gap. Although HMM-based approaches can classify ransomware families, they often require substantial training data and are computationally heavy. This is precisely why our framework leverages a first-order Markov Chain, which provides the significant advantage of being lightweight and interpretable. A simple transition probability matrix allows a security analyst to examine which specific API call transitions are deemed 'rare' or suspicious, directly addressing the G1 (Explainability) gap.

D. Artificial Immune Systems (AIS) and Negative Selection

Artificial Immune System (AIS) algorithms are inspired by the human immune system's ability to distinguish "self" (normal body cells) from "non-self" (foreign pathogens). In AIS, the negative-selection algorithm (NSA) is one of the most prominent techniques for anomaly detection. Originally introduced by [38], [39], the NSA generates a set of detectors that do not match any known "self" patterns. During detection, any pattern that failed to match the self-set was flagged as an anomaly. NSA has been applied to cybersecurity to detect novel threats, with some work combining it with positive selection to improve the detection of unknown malware [40].

In the context of ransomware, AIS has been shown to be effective. For example, [41] developed a V-detector AIS model for ransomware that learns to divide sequence space. Moreover, [42] proposed an improved double-layer NSA that achieved a higher coverage of non-self-space and improved detection rates. The success of these studies demonstrated that bio-inspired methods can enhance ransomware anomaly detection. However, AIS methods alone typically provide only binary anomaly judgments. For example, the NSA can identify a pattern as "suspicious" but cannot classify why or if it is specifically ransomware. This limitation is precisely why the hybrid approach is very powerful. By combining AIS with machine learning, AIS can act as an upstream filter or feature generator for a more robust ML classifier.

To explicitly position the proposed framework with respect to existing ransomware detection approaches, Table I presents a conceptual comparison highlighting key architectural and design differences.

III. THEORETICAL FRAMEWORK

A. Overview

The proposed framework builds upon earlier immune-inspired malware detection architectures that employed a multi-stage design and Negative Selection–based anomaly filtering [13]. While prior work established the feasibility of immune-system-inspired detection, it did not explicitly investigate fine-grained sequential behavioural modelling or adaptive feature representations for ransomware detection. This study extends those ideas by introducing a hybrid framework that integrates NSA filtering, sequential modelling, and machine-learning-based classification, supported by rigorous experimental evaluation.

The proposed ransomware detection framework follows a multilayered architecture inspired by immune system principles and probabilistic modelling.

At a high level, it can be conceptualized as a dual-stage pipeline: an anomaly detection stage that flags potentially malicious behavior and a classification stage that confirms and labels the ransomware. These stages correspond to the Negative Selection Algorithm and the Random Forest classifier, respectively, with a Markov Chain model bridging them by providing probabilistic features of the behavior. Fig. 1 (conceptual diagram) illustrates how raw execution traces flow through the layers of the system from data acquisition to the final decision. The architecture is modular, meaning that each component has a distinct role and a well-defined input-output interface, which aids both in conceptual clarity and in actual implementation.

B. Data and Feature Representation

We assume as input the dynamic behavior traces of programs, specifically focusing on the API call sequences observed during program execution. This choice is guided by extensive evidence that API call patterns are highly indicative of ransomware behavior. Ransomware typically invokes cryptographic APIs, file system calls, etc. [43], [44]. Let an execution trace be represented as a sequence of API call events: $S = [s_1, s_1, \ldots, s_n]$, s_i is an API function name or a token representing a specific action. In our framework, we derive two parallel representations from this sequence: 1) a set of binary features or anomaly markers from the NSA indicating whether certain anomalous patterns were detected and 2) a set of

probabilistic features from the Markov chain model quantifying how likely each observed transition is under a normal profile. These features were then concatenated to form a composite feature vector for classification.

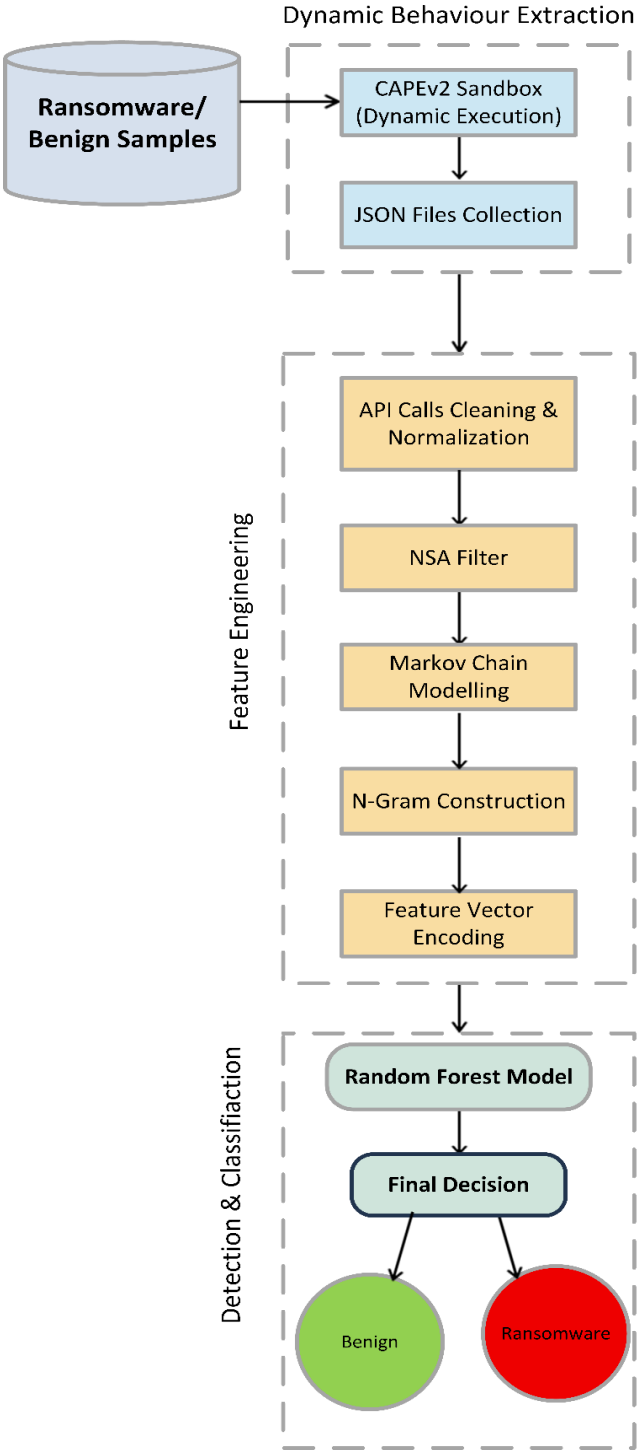

Fig. 1. The proposed NSA-Markov-RF theoretical framework (Pipeline 1).

C. Negative Selection Algorithm (NSA) Component

The NSA is responsible for learning the profile of normal (benign) API call sequences and generating detectors for any sequence patterns that deviate from this norm. Formally, we define a self-set $\mathcal{S}$ consisting of abstractions of benign API sequences. Each element of $\mathcal{S}$ could be, for example, an n-gram of API calls or some fixed-length substring of normal sequences, encoded as a string or binary vector. The NSA then creates a collection of detectors $\mathcal{D} = \{d_1, d_2, \ldots, d_m\}$ such that none of the detectors matches any element of $\mathcal{S}$ within a certain matching rule or threshold. A common approach is to use r-contiguous bit matching for the binary-encoded strings [42]. In our context, we might encode API calls or their hashed values in binary format and generate detectors that do not occur in any benign trace up to a certain Hamming distance. During detection, for a given sequence S, the NSA scans for any detector $d \in \mathcal{D}$ that is a substring of S or matches some features of S. If any such detector is found, it signals the presence of a non-self-pattern, that is, a potential anomaly.

Mathematically, let $f: \text{Sequence} \rightarrow \{0,1\}^m$ be a function that maps an input sequence to a binary vector of detector activations, where the k-th component $f_k(S) = 1$ if and only if detector d_k matches the sequence S. The output of the NSA stage can then be considered an anomaly feature vector $A = f(S)$. If all components of A are 0, the sequence was entirely self-like (no anomalies detected); if one or more components are 1, those indicate specific detectors (specific patterns) that were triggered. We emphasize that NSA in our framework serves as a feature generator and filter, rather than a final decision maker: the presence of an anomaly pattern raises suspicion but does not by itself convict the program as ransomware. This helps reduce false positives, as benign outliers might occasionally trigger detectors but will be further scrutinized in later stages.

D. Markov Chain Model

In parallel with the NSA analysis, the framework uses a First-Order Markov Chain to model the likelihood of the observed sequence of API calls. A first-order Markov chain assumes that the probability of each API call depends only on the immediately preceding call. We derive a Transition Probability Matrix (TPM) P of size $N \times N$, where N is the number of unique API calls (states). Each entry $P_{ij} = \Pr(s_{t+1} = j \mid s_t = i)$ represents the probability of transitioning from API call i to API call j in a benign execution trace. We estimate these probabilities from a training set of benign sequences by frequency counting (i.e., maximum likelihood estimation for the Markov chain). Let $C(i,j)$ denote the count of transitions from state i to j in all benign traces. Then the estimated transition probability is:

$$P_{ij} = \frac{C(i,j)}{\sum_k C(i,k)} \quad (1)$$

for each state i that appears in the training data (the denominator is the total count of all transitions out of state i). By construction, for each state i, the probabilities sum to 1 ($\sum_j P_{ij} = 1$), making each row of P a distribution over next state. Given the matrix P, the sequence $S = [s_1, \ldots, s_n]$ from a program run can be assigned a likelihood score under the benign-behavior model:

$$\Pr(S \mid \text{benign-model}) = \prod_{t=1}^{n-1} P_{s_t s_{t+1}}, \quad (2)$$

i.e., the product of probabilities for each consecutive transition in the sequence. If this probability is very low or equivalently the log-likelihood sum is very low, it indicates that the sequence contains transitions that were rarely or never observed in benign runs – a strong sign of anomalous (possibly malicious behavior. In practice, rather than using a single product of probabilities, which can underflow and also over-emphasize long sequences, we extract features from the Markov model, such as minimum transition probability observed in the sequence, average transition probability, and number of transitions below a certain low-probability threshold. Each of these features helps quantify how "normal" or "abnormal" the control flow of the program is, according to the benign profile. For example, a ransomware might introduce an API call sequence that jumps between unrelated system functions in a way a normal program never would, yielding a very low P_{ij} for those transitions. By including such metrics, we capture sequential anomalies different from those the NSA detectors find, where NSA might catch specific known-bad patterns, whereas Markov probabilities catch statistically rare patterns.

It is worth noting that one could also build a Markov chain for ransomware behavior, specifically as [36] did, training separate models for ransomware and benign. In our theoretical design, we focus on modeling benign behavior (self) through the Markov chain, analogous to how NSA models self; this keeps the approach biased towards anomaly detection. However, extending the framework to include a second Markov model for ransomware is feasible if sufficient ransomware data is available; it would essentially provide additional features or a parallel likelihood ratio between "malicious" and "benign" models.

E. Random Forest Classification

Random Forest Classification: The final stage of the pipeline is a Random Forest classifier that ingests the combined feature vector and outputs a classification: ransomware or benign. The feature vector X for a given program execution includes features from both NSA and the Markov model and potentially other metadata or features derived from dynamic analysis. For example, X might include: the count of NSA detectors triggered and which specific ones, though high-dimensional, could be represented via one-hot encoding or a count of anomalies, the minimum/average transition probability from the Markov analysis, the length of the sequence, etc. Because NSA and Markov modeling are the core novel features, the dimensionality of this feature space is relatively moderate and interpretable: NSA contributes m binary features, if we have m detectors, and Markov contributes a fixed number of statistical features. This structured feature space is well-suited to a Random Forest classifier, which can handle mixed binary/continuous inputs and is robust to irrelevant features.

Random Forest (RF) is an ensemble of decision trees where each tree is trained on a bootstrapped sample of the data and typically uses a random subset of features at each split. The ensemble's prediction is the majority vote of the trees for classification or the average probability. We denote the RF classifier as $h(X)$, which outputs a probability score $p = h(X)$ representing the confidence that the sample is ransomware (malicious). The RF essentially learns decision rules that combine the presence/absence of certain anomaly patterns and the values of Markov anomaly scores to distinguish ransomware from legitimate software. An example rule a tree might learn: "IF detector_5 is triggered (an anomaly in file encryption API usage) AND the minimum API transition probability < 0.001 (very novel sequence) THEN classify as ransomware." In training, the RF will naturally give more weight to features that yield better splits between ransomware and benign, which provides a form of built-in feature selection. Empirically, Random Forest has been shown to perform well on malware classification tasks, sometimes outperforming deep learning on structured behavioral features, and offers faster training.

To make a binary decision from the RF's output probability, we define a decision threshold τ. The classifier assigns the label "Ransomware" if $p \geq \tau$, and "Benign" otherwise. A common default is $\tau = 0.5$ for balanced errors, but in security, we might choose a lower threshold to favor catching malware (at the expense of some false positives). In a theoretical analysis, one can discuss optimizing τ based on metrics like the F-score. For instance, one could select τ that maximizes the F_2-score (which weights recall higher) to ensure ransomware is caught early. The threshold optimization is part of the Decision Evaluation Layer of the framework.

F. Integration of Components

The theoretical robustness of this framework is rooted in the synergistic integration of its three components. This design creates a multi-dimensional feature space where each component addresses a distinct aspect of anomaly detection, a strategy that aligns with modern calls for layered, hybrid detection frameworks [45], [46]. The Negative Selection Algorithm (NSA) functions as an "immune filter," identifying qualitative anomalies by matching patterns that are definitionally "non-self" and should not exist in benign operation. In parallel, the Markov model acts as a statistical profiler, identifying quantitative anomalies by flagging behavioral sequences that, while not strictly impossible, are highly improbable under the learned model of benign behavior [47]. For instance, the RF can learn to disregard a minor qualitative anomaly flagged by the NSA as a potential false positive if the Markov model assigns a high probability to the sequence, indicating an overall normal behavioral flow. Conversely, a sample that triggers multiple NSA detectors and exhibits a cascade of low-probability transitions presents a feature vector that the RF can decisively classify as malicious.

This integration yields a significant benefit: a high degree of explainability, which is a critical requirement for building trust in automated detection systems [48]. Unlike monolithic "black box" models, which are a noted challenge in security-critical environments [49], a classification event can be deconstructed into its constituent, human-readable parts. The system can provide evidence for why a sample was flagged, detailing both the qualitative detectors triggered by anomalous patterns and the quantitative unlikelihood of its behavioral flow.

This evidence renders the model's internal logic transparent and its outputs auditable [50]. Conceptually, this hybrid model fuses biological anomaly detection with probabilistic behavioral profiling to produce a classification that is both resilient and interpretable. Its resilience stems from this multi-modal design;

the framework does not rely on a single indicator of maliciousness. An adversary must therefore simultaneously evade discrete, pattern-based NSA detectors and mimic the statistical profile of benign behavior, presenting a significantly more complex evasion challenge [34].

Finally, the framework is both modular and extensible. One could incorporate additional features, such as the frequency of file modifications or network connections opened, alongside the API sequence features. While our design uses Random Forest for its proven balance of performance and interpretability, other classifiers like SVM or XGBoost could also be employed.

The core contribution of this study, however, is the integrated NSA-Markov-RF architecture (termed Pipeline 1). To rigorously validate the novel contributions of this specific hybrid design, our proposed methodology (detailed in Section 5) is based on a dual-pipeline comparison. This test will benchmark our probabilistic framework (Pipeline 1) against an alternative hybrid, NSA-N-gram-RF (termed Pipeline 2), to empirically quantify the specific improvements of using a Markov model.

In summary, the proposed theoretical framework is a synergistic integration of three well-established algorithmic pillars: the Negative Selection Algorithm from AIS theory, first-order Markov chains from probability theory, and the Random Forest from ensemble learning. While prior work has validated each component individually for security applications, our primary contribution is the formal design of this cohesive, multi-modal system. This study has articulated this design, demonstrating how the unique, emergent benefits of resilience and interpretability arise from this specific combination.

IV. Proposed Methodology

This study adopts the Design Science Research Methodology (DSRM) framework [20], which is especially well-suited for developing and evaluating novel cybersecurity artefacts. DSRM ensures that artefact creation is grounded in both practical relevance and theoretical rigor. Our ransomware detection framework is constructed and validated in accordance with the following DSRM stages:

- Problem Identification and Motivation: We identified key limitations in current detection approaches, namely, a lack of interpretability (G1) and high false positives (G2) and justified the need for a hybrid, behaviorally aware system (G3).
- Design and Development: We designed a multilayered detection artefact combining a Negative Selection Algorithm (NSA), a probabilistic Markov model, and a Random Forest classifier (Section IV). This artefact is instantiated in two comparative pipelines for controlled evaluation.
- Demonstration: The detection system is implemented and executed on dynamic API trace data collected from both benign applications and ransomware samples.
- Evaluation: We empirically evaluate system performance using standard classification metrics, emphasizing Recall and False Positive Rate (FPR), and using F2-score optimization to reflect real-world detection priorities.
- Communication: This study serves as the primary vehicle for communicating the artefact design, theoretical justification, and validation methodology to the research community.

A. Evaluation Metrics

Model performance will be assessed using a comprehensive suite of standard evaluation metrics: Accuracy, Precision, Recall (Detection Rate), F2-Score, and False Positive Rate (FPR). Emphasis is placed on minimizing FPR. Furthermore, due to the asymmetric cost of errors in ransomware detection were failing to detect an active infection (False Negative) is more damaging than triggering a benign false alarm. This study prioritizes Recall and adopts the F2-Score as the principal optimization target. The F2-Score weights Recall twice as heavily as Precision, thereby aligning metric selection with the risk model inherent to the domain.

To determine the optimal operating point of the classifier, the decision threshold τ will be tuned using a grid search across the interval $[0.1, 0.9]$, with the optimal τ^* defined as the threshold maximizing the F2-Score on a validation subset.

B. Baseline Models and Comparative Hypothesis

To assess the efficacy of the proposed framework, we define a structured comparative evaluation across two distinct pipeline configurations. Both configurations share a common NSA pre-filtering stage and a Random Forest classifier. This strategy isolates the effect of the Markov chain behavioral profiler by comparing it directly with a static, pattern-based encoding scheme (adaptive n-gram).

1) Pipeline 1: NSA - Markov - Random Forest (Full Hybrid Architecture)

This is the proposed end-to-end detection framework, comprising:

- Negative Selection Algorithm (NSA): Eliminates benign "self" behavior patterns from the dynamic trace to generate an anomaly-prone residual signal.
- First-Order Markov Chain Profiler: Models the transition probabilities of the remaining "non-self" API call sequences to quantify behavioral abnormality.
- Random Forest Classifier (RF): Predicts the likelihood of ransomware execution using a feature set that includes Markov likelihood scores and statistical API call metrics.

2) Pipeline 2: NSA-N-gram-Random Forest (Baseline Hybrid)

This configuration retains the NSA filtering stage but replaces the probabilistic Markov model with a flexible n-gram feature extractor:

- Negative Selection Algorithm (NSA): Performs initial filtering to exclude benign behaviors.

- Adaptive N-gram Encoding: Extracts variable-length API call n-gram patterns from the NSA-filtered trace to capture structural nuances in the remaining signal.
- Random Forest Classifier (RF): Classifies the resulting feature vector to predict ransomware presence.

V. Experimental Evaluation

A. Dataset and Sample Collection

To evaluate the proposed ransomware detection framework, a balanced dataset consisting of ransomware and benign software samples was constructed and analyzed in a controlled sandbox environment. The dataset was designed to capture a diverse range of ransomware behaviors while reflecting realistic benign application activity. Ransomware samples were collected from a public malware repository [51]a well-established and actively maintained malware repository widely used in academic research and threat intelligence. Samples span the period from 2015 to June 2023, capturing nearly a decade of ransomware evolution. A structured keyword-based query using the *tag:ransom* was employed to identify binaries explicitly labeled as ransomware. Metadata such as SHA-256 hash, file type, family signature, and classification tags were used for verification and filtering.

To focus specifically on Windows crypto-ransomware, the following selection criteria were applied:

- Only PE32 (exe) Windows executables were retained.
- Locker-type ransomware variants that primarily restrict access through screen locking without performing file encryption were excluded.
- Samples were required to contain the "ransom" or "ransomware" classification tags.

Using this process, 1,200 ransomware samples were initially shortlisted. From this pool, 100 representative samples were selected based on family diversity, file quality, and temporal distribution. These samples span 40 distinct ransomware families, including LockBit, STOP, GandCrab, Dharma, REvil, Chaos, and Babuk, ensuring broad behavioral coverage across both early-generation and modern ransomware variants. Moreover, benign samples consisted of 100 legitimate Windows applications drawn from diverse software categories, including productivity tools, security software, media players, development tools, compression utilities, browsers, and document management software. Examples include VLC, WinRAR, Docker Desktop, Bitdefender, Firefox, and Blender. These applications were selected to represent realistic user activity and to expose the detection system to benign behaviors that may superficially resemble ransomware operations, thereby reducing false positives.

All samples, both malicious and benign, were executed in the same sandbox environment using CAPEv2 (Config And Payload Extraction, version 2) to ensure consistency in behavioral logging. During execution, API call sequences and runtime behaviors were captured and used as input for feature extraction and classification.

B. Dataset Curation and Labelling Considerations

Ransomware family labelling presents inherent challenges due to inconsistent naming conventions across antivirus (AV) vendors. To ensure reliability during sample selection, only binaries classified as ransomware by at least ten distinct AV engines were initially retained. However, because family-level labels often vary across vendors, family attribution was refined using post-execution analysis from the CAPEv2 sandbox, which integrates heuristic detection, YARA-based signatures, and static indicators. These labels were manually cross-validated against outputs from high-confidence AV engines, including Kaspersky, Bitdefender, and ESET. In cases of disagreement, a consistency-based majority approach was used to finalize family assignments.

A further challenge involved distinguishing active ransomware samples from dead or partially executing binaries. Some samples failed to execute payloads or produced empty behavioral reports due to packing, sandbox incompatibilities, or execution failures. To mitigate this, samples were screened for successful execution using multiple indicators, including execution duration, API call density, presence of cryptographic API usage, ransom-note artifacts, and CAPEv2 heuristic scores. Additionally, to address execution failures caused by packing or wrapper layers, samples were subjected to a pre-analysis inspection phase. Binaries identified as packed through heuristic analysis were manually or automatically unpacked prior to sandbox execution, ensuring that the core ransomware payload was behaviorally observable during dynamic analysis. Samples exhibiting no meaningful behavioral activity were excluded.

Although an initial pool of approximately 1,200 ransomware samples was identified, only 100 behaviorally expressive samples were retained for analysis. This curation process ensured that the final dataset prioritized behavioral validity, family diversity, and execution reliability, which is essential for behavior-based ransomware detection models.

C. Experimental Setup and Pipeline Configuration

Based on the evaluation design defined in Section IV, two pipeline configurations were implemented and evaluated under identical experimental conditions. Both pipelines share the same dataset, sandbox execution environment, feature extraction process, and Random Forest classifier configuration. The only difference lies in the behavioral modeling stage, allowing a controlled assessment of the impact of probabilistic Markov modeling.

D. Detection Performance Results

Table II summarizes the detection performance of the two proposed pipelines.

The results demonstrate that both pipelines achieve strong detection performance. Pipeline 2 attains perfect classification accuracy for higher-order n-gram configurations under the evaluated dataset, confirming the effectiveness of NSA-based filtering combined with supervised learning. Pipeline 1 achieves comparably high accuracy and recall while maintaining a consistently low false-positive rate across evaluation folds.

TABLE II. PERFORMANCE COMPARISON OF PROPOSED DETECTION PIPELINES

Pipeline	Accuracy	Recall (TPR)	False Positive Rate (FPR)	Explainability
NSA–Markov–RF (Pipeline 1)	98.5%	≈99.3%	< 1%	High (NSA detectors + probabilistic transitions)
NSA–N-gram–RF (Pipeline 2)	100%	100%	0%	Moderate (feature importance via RF)

E. Contribution of Markov Behavioral Modeling

While both pipelines demonstrate high classification accuracy, Pipeline 1 incorporates a probabilistic behavioral modeling layer that captures sequential API-call likelihoods rather than relying solely on structural pattern frequency. Markov-derived features quantify how likely observed API-call transitions are under a benign behavioral model, enabling the detection system to distinguish between rare but legitimate activity and behavior that is statistically inconsistent with normal execution.

This probabilistic profiling contributes to stable detection performance across diverse behavioral patterns and provides interpretable evidence in the form of low-probability transition sequences. As a result, Pipeline 1 offers enhanced behavioral transparency without sacrificing detection effectiveness.

VI. CONTRIBUTIONS AND DISCUSSION

The proposed NSA–Markov–RF ransomware detection framework makes several important contributions to the field of cybersecurity and malware detection, particularly in the context of behavior-based defenses.

- Novel Hybrid Architecture (Solves G3): We introduce a novel hybrid detection architecture that integrates an Artificial Immune System (AIS) anomaly filter, a probabilistic Markov chain model, and an ensemble machine learning classifier (Random Forest) in one unified framework. This addresses the G3 (AIS-ML) gap by proposing a formal, synergistic integration of these components, which prior works have typically been used only in isolation or in simpler pairwise combinations. Moreover, each component is grounded in a well-established theory. By formally describing the framework and providing equations for key processes such as detector generation and transition probability computation, we ensure the design is transparent and reproducible.
- Improved Explainability (Solves G1): A key contribution is improved explainability, directly addressing the G1 (Explainability) gap. Because the model's decision is based on human-comprehensible components such as "detector X matched" or "transition Y→Z had a low probability", analysts can interpret why an alert was raised, building trust in the system [52].
- Robust and Adaptive Classification: The use of an ensemble classifier (RF) confers robustness through bagging and vote aggregation [32]. Furthermore, the framework is modular and adaptive.
- Addressing False Positives (Solves G2): Our framework explicitly tackles the G2 (False Positive) gap. By using the NSA to proactively filter "self" behavior, the classifier is provided with a cleaner, anomaly-focused feature space. This provides a direct answer to the high FPR noted in prior work, such as the 4.8% FPR in the Markov-RF model by [36].

In sum, our theoretical framework not only proposes a specific solution but also advances discourse on how to design ransomware detection systems that are comprehensive, transparent, and resilient.

A. Discussion of the Theoretical Implications

The framework offers several theoretical advantages and implications that contextualize its value.

- Comparative Analysis: The proposed hybrid model provides a layered, defense-in-depth. More specifically, our validation methodology (Section V) is designed to compare Pipeline 1 (NSA-Markov-RF) against Pipeline 2 (NSA-Adaptive N-gram-RF). While both pipelines benefit from the NSA's 'non-self' filtering, the Markov component (P1) provides a probabilistic, behavioral model, whereas the n-gram component (P2) provides a static, pattern-matching one. This is a crucial distinction: an n-gram model (P2) can be evaded if an adversary uses known malicious patterns in a new or rare order. The Markov model (P1), however, is designed to detect precisely this type of anomaly: a sequence of individually plausible API calls combined in a probabilistically rare way. This multi-faceted approach, blending different AI techniques, is in line with what recent surveys suggest for improving novel threat detection [53].
- Explainability and Analyst Trust: The interpretability of our framework means that in a real-world setting, it could generate not just an alert but also a diagnosis. For instance: "Alert: Suspected Ransomware. Reasoning: Detectors D5 and D7 triggered (unseen file encryption sequence), and sequence transition probability average = 0.002 (below normal threshold)." Such feedback is invaluable to an analyst triaging the alert and directly addresses a major criticism of AI in security, the lack of trust in opaque, "black box" models [54].
- Performance Considerations: A potential concern is computational overhead, especially at runtime. NSA detector generation was performed offline during training. During operation, although checking many detectors can be computationally demanding, the use of short, fixed-length behavioral patterns allows for efficient pattern matching. In practice, this ensures that the system is lightweight and suitable for real-time detection. Markov chain calculations are computationally trivial, and Random Forest classification is fast and parallelizable [55].

B. Limitations and Future Work

While promising, the theoretical framework has limitations that must be acknowledged:

- Dependency on Quality of Training Data: The NSA's effectiveness hinges on a comprehensive representation of "self." If benign training data are not comprehensive, the NSA may generate flawed detectors. This limitation is common to all behavior-based models that must learn a "normal" baseline [56].
- Evasion Tactics: Attackers can try to evade each component by mimicking normal API call transitions to fool the Markov model. However, our framework raises a bar for evasion: an adversary must evade both pattern-based detectors and the probabilistic sequence model simultaneously, which is a significantly more complex challenge [46].
- False Positive Handling: A persistent challenge for anomaly-based detection is the handling of false positives. By design, such systems will inevitably flag benign but unusual activities such as those performed by legitimate compression utilities that deviate from the established "self" profile. While the Random Forest classifier is trained to learn and distinguish these benign anomalies, a practical, operational deployment would almost certainly benefit from a supplemental whitelist of known-safe, signed applications. This measure would further reduce false positive noise and substantially improve security analyst trust in the system.

C. Threat Model and Evasion Considerations

The threat model assumes ransomware adversaries capable of employing code obfuscation, packing, and behavioral variation to evade signature-based and static detection mechanisms. Attackers may attempt to mimic benign API-call sequences or reorder known malicious operations to bypass pattern-based classifiers.

The proposed framework raises the bar for evasion by combining complementary detection mechanisms. NSA-based filtering targets previously unseen behavioral patterns, while the Markov chain profiler detects statistically improbable API-call transitions even when individual calls appear benign. To evade detection, an adversary must simultaneously suppress NSA detector activation and maintain transition probabilities consistent with benign execution profiles, which significantly constrains evasion strategies.

While advanced attackers may attempt to gradually adapt behavior to resemble benign profiles, such mimicry reduces operational efficiency and increases attack complexity. The framework, therefore, provides resilience against common behavioral evasion techniques without relying on static signatures.

D. Computational Feasibility and Runtime Considerations

The proposed framework is designed to be computationally feasible for practical deployment. NSA detector generation is performed offline during the training phase, eliminating runtime overhead associated with detector creation. During detection, NSA-based matching operates on short, fixed-length behavioral patterns, enabling efficient pattern comparison.

The Markov chain component incurs minimal computational cost, as transition probability lookup and aggregation are linear in the length of the observed API-call sequence. Random Forest classification is well-suited to real-time analysis due to its parallelizable structure and fast inference time.

Overall, the framework introduces limited runtime overhead beyond standard dynamic behavior analysis and is suitable for near real-time ransomware detection in sandboxed or endpoint monitoring environments.

E. Future Improvements

This theoretical work can be extended in several ways. One potential improvement is employing a higher-order Markov chain or a Hidden Markov Model (HMM) to capture long-term dependencies. The other is to incorporate Positive Selection (another AIS algorithm) in tandem with NSA to detect both known-malicious "antigen signatures" and unknown "non-self" anomalies, as proposed in other AIS-hybrid research [57]. Additionally, exploring Explainable AI (XAI) tools such as SHAP [58] on the Random Forest could precisely quantify the contribution of each feature to a decision, essentially auditing the model's knowledge.

F. Scientific and Practical Impact

Scientifically, our work bridges multiple research areas: bio-inspired security, probabilistic modelling, and machine learning. Practically, the enormous and growing financial and operational costs of ransomware incidents, which cost organizations an average of $4.75 million per breach (excluding the ransom), create a clear need for such tools[59]. Our framework's emphasis on adaptability and its focus on fundamental behaviors (which persist even as tactics evolve) make it a forward-looking approach. It provides a balanced trade-off between detection power and interpretability, building upon validated components from the literature to create a multilayered detection system.

VII. Conclusion

This study presented a bio-inspired, behavior-based hybrid framework for ransomware detection that integrates a Negative Selection Algorithm, probabilistic Markov chain behavioral modeling, and Random Forest classification. The framework addresses key limitations of existing ransomware detection approaches by combining anomaly filtering, probabilistic sequence analysis, and supervised learning within a transparent and modular architecture.

Experimental evaluation using real-world ransomware and benign software samples demonstrated that both evaluated pipelines achieve strong detection performance. While the NSA–N-gram–RF pipeline attained perfect classification accuracy under selected configurations, the NSA–Markov–RF pipeline provided enhanced behavioral interpretability through probabilistic transition modeling while maintaining a consistently low false-positive rate.

By enabling detection decisions to be explained in terms of anomalous behavioral patterns and statistically rare execution sequences, the proposed framework directly addresses the

explainability and false-positive challenges that limit the operational adoption of machine-learning-based ransomware detection systems. Future work will explore early-stage detection, adaptive learning under concept drift, and extension of the framework to additional malware categories.

A Resilient Framework for Industry 5.0 WSNs: Enhancing Network Lifetime via a Lightweight Reputation Ledger and Hybrid AI

Padma Sree N, Dr. Malini M Patil
Computer Science and Engineering, RV Institute of Technology and Management, Bangalore, India

***Abstract*—Wireless Sensor Networks (WSNs) play an increasingly important role in Industry 5.0 cyber–physical systems, where resilience, trust, and energy efficiency are essential under dynamic operating conditions. However, their limited resources, scattered deployment, and continuous operation make these networks highly susceptible to unusual behavior and cyberattacks. Such issues can compromise data quality, disrupt network reliability, and shorten the overall lifespan of the system. To address these challenges, this study examines WSN resilience as a combined problem of anomaly detection accuracy, fault isolation latency, and network lifetime under realistic fault and energy constraints. At the core of the framework is a Model Context Protocol (MCP), which combines a supervised LightGBM classifier with an unsupervised LSTM autoencoder to capture both event-driven and temporal anomalies in sensor data. Complementing this is a compact "Micro-Ledger" system that updates trust values for each node by monitoring behavior and using streamlined consensus rules. Together, they create a continuous feedback mechanism that isolates suspicious nodes while keeping energy consumption in check. The framework is evaluated using a set of resilience-oriented metrics, including fault detection latency, Mean Time To Failure (MTTF), reputation convergence behavior, and overall network lifetime. Experiments conducted in a Digital Twin simulation environment report an F1-score of 0.997, an 18.7% improvement in network lifetime, and a Micro-Ledger storage overhead of approximately 98 KB. While the current validation is simulation-based, the proposed design can be extended to physical deployments through adaptive trust weighting, cluster-head redundancy, and probation-based node reintegration.**

Keywords*—Wireless Sensor Networks (WSNs); Industry 5.0; anomaly detection; lightweight blockchain; trust management; network lifetime; Digital Twin

I. Introduction

Industry 5.0, or the fifth industrial revolution, ushers in an altogether new paradigm that seeks to make production systems more human-centered and focus on sustainability and resilience [1]. At the heart of Industry 5.0 will be IoE, encompassing the interlinking of cyber-physical spaces through Wireless Sensor Networks or WSNs, which will be able to connect the two environments of physical and digital. A typical WSN contains thousands of spatially distributed sensor nodes that capture data and transport information continuously. This decentralized approach has its own merits—the intelligent automation, the adaptive control—but at the same time, it gives rise to important vulnerabilities because of the energy-constrained and distributed nodes [2].

Outliers or anomalous data points caused by malicious intrusions, hardware failures, or environmental interference degrade network performance, data integrity, and energy efficiency [3]. These anomalies increase communication overhead and maintenance costs and, hence, reduce network lifetime. In such environments, resilience is no longer limited to fault tolerance alone but also includes timely anomaly recognition, trust-aware decision-making, and sustained operation under resource constraints.

While anomaly detection, trust management, and blockchain-based integrity have each been studied in isolation, their joint role in sustaining long-term resilience and network lifetime in Industry 5.0 WSNs remains underexplored. In particular, existing approaches often lack adaptive trust evolution driven by real-time anomaly evidence. Industry 5.0 extends earlier industrial paradigms by emphasizing resilience, sustainability, and human-centric cyber–physical systems [23]. ML approaches to anomaly detection show promise; however, applications in dynamic IoT and WSN often struggle to generalize across heterogeneous anomaly types and dynamically changing operating conditions. [4]. Similarly, single-model classifiers, such as Support Vector Machines and Decision Trees, have lower performance while dealing with heterogeneous sensor data [5]. Beyond detection accuracy, system-level resilience metrics such as fault detection latency, recovery behavior, and network lifetime are equally critical in practical WSN deployments.

Recent research in deep learning has enhanced detection accuracy through the temporal dependencies modeled on sequential data. For example, LSTM-based networks have achieved high performance in detecting time-series anomalies in WSNs [6]. However, these networks still suffer from some limitations when used in isolation, as they cannot detect event-based and time-series anomalies in dynamic environmental conditions [7].

While blockchain mechanisms have been extensively explored to ensure data integrity and auditability in WSNs, the consensus protocols commonly adopted are computationally expensive, such as PoW, thus being infeasible for energy-constrained sensor nodes. Lightweight blockchain designs have recently been proposed, although they are often passive data storage rather than active adaptive trust systems. Besides, most of the earlier studies fail to address changing behavior of

network nodes, an essential factor in accurate and dynamic trust levels. However, when used purely as a passive data store, blockchain mechanisms offer limited support for adapting to evolving node behavior or mitigating energy drain caused by unreliable sensors.

Addressing these challenges calls for an integrated multilayer resilience framework, coherent with the principles of Industry 5.0. The key contributions of this work can be summarized as follows:

- Hybrid Anomaly Detection (Model Context Protocol - MCP): A hybrid architecture combining LightGBM and LSTM Autoencoder models aims to improve detection accuracy across multiple anomaly types [12].
- Lightweight "Micro-Ledger" for Dynamic Trust Management: A blockchain-based reputation system for resource-constrained WSNs, which improves node trust evaluation and energy efficiency [13].
- Closed-loop feedback mechanism: Integration of anomaly detection results with the Micro-Ledger to support automated isolation of persistently unreliable nodes [14].
- Digital Twin Validation: Simulation and testing on a Digital Twin environment to assess resilience under induced network noise and channel interference conditions [15].

The present study focuses on simulation-based validation within a Digital Twin environment to analyze resilience behavior under controlled fault conditions. Extensions to physical deployments, more complex attack models, and adaptive trust policies are discussed as part of future research directions.

II. Related Work

The security, reliability, and longevity of WSNs have been recognized as key challenges in the evolution of both Industry 5.0 and the IoT [16]. Accordingly, resultant topics related to these areas have been actively reviewed across a wide variety of domains, with particular attention given to anomaly detection, blockchain-enabled trust management, and energy-efficient network design. Despite these active developments, there is still a dire need for integrated frameworks that bring these components together into a cohesive, resilient architecture.

A. Anomaly Detection in WSNs and IoT Systems

ML and DL have emerged as the key technologies for anomaly detection in WSNs/IoT systems in recent times [17]. For instance, Al-Qatf et al. showed that ML classifiers such as Support Vector Machines and Decision Trees could efficiently detect intrusions in sensor networks [18]. Further research by Otoum et al. applied Random Forests, presenting enhancements in the detection performance of IoT-based intrusion detection systems.

Deep Learning improved the detection capabilities by learning complex temporal and nonlinear patterns present in time series data. Malhotra et al. introduced the concept of LSTM Autoencoders, which perform anomaly detection by learning normal system behavior and subsequently finding deviations from it [20].

Similarly, Lee et al. have also demonstrated effectiveness in fault detection in vibration-based cyber-physical systems using LSTM Autoencoders [21]. Despite these advances, single-model approaches remain limited in detecting multiple types of anomalies in heterogeneous WSN environments [22]. Hybrid or ensemble architectures combining different models have also been proposed to overcome this limitation and offer increased robustness. For example, Khairullah and Alsenani showed that hybrid frameworks that integrate both gradient boosting and deep learning improved the consistency of anomaly detection. This idea directly inspired the Model Context Protocol (MCP) proposed in this research, which integrated both LightGBM and LSTM Autoencoder to perform high-precision, multi-type anomaly detection.

B. Blockchain-Based Trust Management for WSNs

Immutability, decentralization, and tamper resistance properties of blockchain technology have made it attractive for securing IoT and WSN data [25]. The early frameworks rely on blockchain primarily for data integrity, where sensor readings are stored in an immutable ledger to avoid unauthorized changes [26]. Later, other works extended the blockchain use to authentication and access control for IoT networks, improving data confidentiality and accountability [24].

However, most of such systems relied on the resource-intensive consensus algorithms like Proof-of-Work (PoW), which is impractical for energy-limited sensor nodes [22]. To alleviate this, Deng et al. presented a lightweight Proof-of-Authority–based trust mechanism that has been proposed to reduce consensus overhead in resource-constrained Wireless Sensor Networks [8]. This Scheme with the help of Proof-of-Authority consensus, reduced the computational overhead significantly without compromising the integrity of trust [25].

Stefanescu et al. have also highlighted the importance of lightweight blockchain architectures for IoT, showing how customized consensus models can increase scalability [26]. In addition, Sahraoui and Bachir proposed adaptive “Blockchained Things,” presenting blockchain models which dynamically adapt node trust over time [19]. Several studies have shown that blockchain architectures can be adapted for IoT environments, although scalability and storage overhead remain open challenges [9]. However, few of them really integrate behavioral trust evaluation with blockchain mechanisms, which is the gap that this study tries to address through its Micro-Ledger. The latter continuously updates node reputation based on behavioral evidence.

Despite these advances, many blockchain-based solutions remain largely passive, focusing on secure storage or authentication rather than actively adapting trust in response to node behavior. Moreover, assumptions of static trust or reliance on a single validating authority may limit resilience in long-running, large-scale WSN deployments. Blockchain-enabled trust frameworks for heterogeneous IoT devices have been explored to provide decentralized accountability without

centralized authorities [10]. Trust-based mechanisms have also been applied to mitigate malicious or unreliable node behavior in distributed sensor networks [11].

C. Resilience and Network Lifetime in Industry 5.0 WSNs

The operational lifetime of WSNs has long been a focal point of optimization efforts. Classic approaches, including energy-aware routing, node clustering, and sleep scheduling, which reduce communication overhead, generally do not take long-term effects caused by security and trust into consideration [21].

Untrusted or malfunctioning nodes may continuously transmit incorrect data that would cause redundant communication and energy wastage [21].

To counter this, the contributions of Han et al. have stressed the importance of combining trust management with energy optimization and have proposed frameworks capable of isolating or quarantining unreliable nodes [21]. Recent works extend this concept by integrating security, trust, and energy efficiency for better robustness of the network [14]. The framework now extends this fundamental idea by integrating AI-based anomaly detection with blockchain-based trust management to realize a self-regulating, energy-aware, and adaptive WSN suitable for Industry 5.0 ecosystems [20]. In the context of Industry 5.0, resilience is increasingly viewed as a system-level property that encompasses fault tolerance, trust evolution, and sustained energy efficiency, rather than isolated security or routing optimizations.

In summary, existing research provides valuable insights into anomaly detection, blockchain-enabled trust, and energy-aware WSN design. However, an integrated framework that tightly couples hybrid AI-based anomaly detection with adaptive, lightweight trust management—while explicitly targeting network lifetime and resilience in Industry 5.0 settings—remains limited. This gap motivates the framework proposed in this study.

III. The Proposed Framework

This section presents the proposed resilience framework designed to enhance security, trust, and network lifetime in Wireless Sensor Networks operating under Industry 5.0 conditions. The framework is conceived as a modular, multi-layer system in which anomaly detection, trust evaluation, and energy-aware decision-making are tightly coupled through a closed feedback loop. Rather than treating these components independently, the design emphasizes their interaction over time as sensor behavior and network conditions evolve. Each component of the framework is formally defined in terms of its role, inputs, and outputs, and is later supported by mathematical modeling and algorithmic descriptions to ensure reproducibility. The framework is evaluated within a Digital Twin simulation environment, which enables controlled fault injection and repeatable analysis of resilience behavior prior to physical deployment. While the framework leverages edge-based coordination at the cluster level, its design allows for extensions such as role rotation and redundancy to mitigate centralized failure risks. The remainder of this section details the high-level architecture, operational methodology, edge intelligence module, and lightweight reputation ledger that together realize the proposed framework.

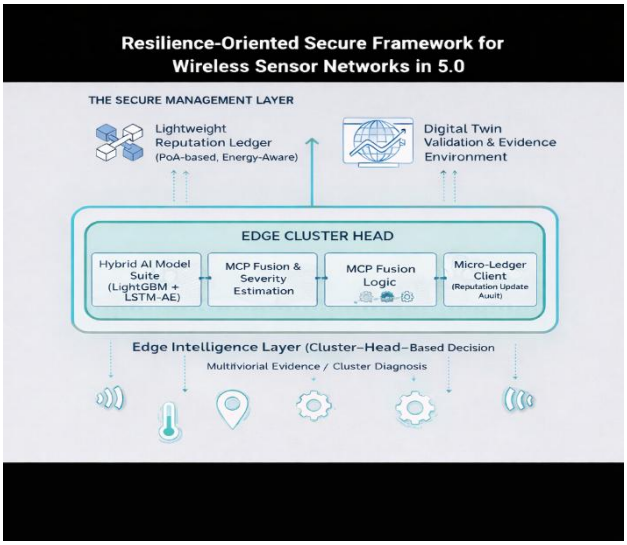

Fig. 1. High-level architecture of the proposed WSN resilience framework.

A. System Architecture

The proposed architecture consists of three interdependent layers, conceptually illustrated in Fig. 1. The architecture is designed to support decentralized sensing, edge-level intelligence, and trust-aware coordination while maintaining low computational and communication overhead.

Formally, the wireless sensor network is modeled as a graph $G = (V, E)$, where $V = \{v_1, v_2, \ldots, v_N\}$represents the set of sensor nodes and Edenotes wireless communication links. Nodes are organized into clusters, each coordinated by a cluster head responsible for local inference and trust management.

- IoE Layer (Perception Layer): This layer represents distributed sensor nodes deployed in physical environments. Each of these nodes collects multivariate data on phenomena such as temperature, motion, and GPS coordinates, which are transmitted to cluster heads for aggregation and analysis. To reduce redundant communication, raw sensor readings are locally aggregated before transmission to the cluster head.
- Edge Intelligence Layer: At the cluster head level, local inference is performed using a hybrid AI detection mechanism that balances detection accuracy with edge-level resource constraints, called the Model Context Protocol (MCP). MCP fuses a LightGBM Classifier and an LSTM Autoencoder to identify both event-based and temporal anomalies efficiently. This keeps bandwidth utilization low and also enhances security by processing data at the network edge.
- Secure Management Layer: This layer introduces a Lightweight Reputation Ledger—the "Micro-Ledger"—that keeps track of the reputation status of each node based on blockchain principles. The ledger records node behavior in a verifiable and tamper-resistant format to enable dynamic trust adjustments and isolate unreliable nodes. Reputation updates are

triggered by observed node behavior rather than static assumptions, allowing trust to evolve over time.

Although the cluster head coordinates local inference and ledger updates, the architecture does not assume permanent leadership. Backup cluster heads may be selected based on residual energy and reputation, enabling role rotation in the event of failure or compromise.

B. Framework Methodology

The proposed framework operates as an event-driven process executed at the cluster-head level. Incoming sensor data are processed sequentially, enabling timely anomaly detection, trust updates, and adaptive responses to evolving network conditions. The layered architecture of the proposed resilience framework, including the IoE layer, edge intelligence layer, and secure management layer, is illustrated in Fig. 2.

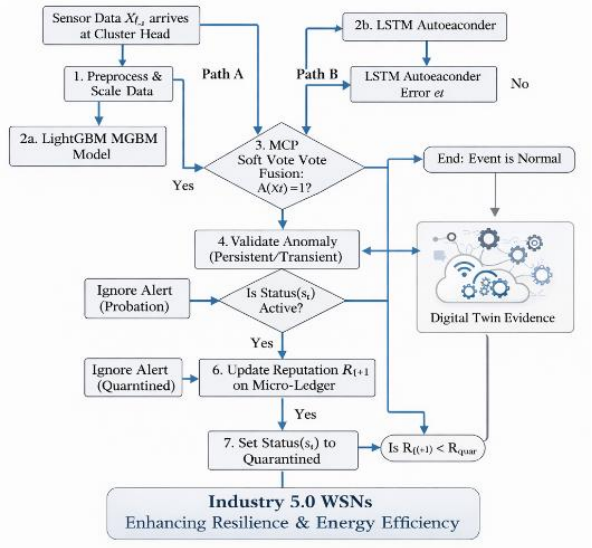

Fig. 2. Methodology flowchart of the anomaly detection and reputation management process.

- Data Preprocessing: At each time step t, the cluster head receives a multivariate sensor vector $\mathbf{x}_t = [x_t^{(1)}, x_t^{(2)}, \ldots, x_t^{(d)}]$, where d denotes the number of monitored features. Normalization of raw sensor inputs is done in order to maintain consistency across heterogeneous devices and ensure fair weighting in anomaly detection.
- Packet Loss and Fault Modeling: To reflect realistic operating conditions, the framework accounts for communication impairments and sensor faults. Packet loss is modeled as a Bernoulli process with loss probability p_l, while sensor faults are introduced probabilistically to simulate intermittent and persistent deviations in sensor behavior.
- Parallel Anomaly Detection: The LightGBM classifier and LSTM Autoencoder process input data in parallel. Their outputs are fused by a soft-voting fusion rule, such that an anomaly is declared when either model detects an anomalous pattern. This design maximizes recall while maintaining high precision.

Detected anomalies are not treated uniformly. Each anomaly is associated with a severity score derived from model confidence and temporal persistence, allowing the framework to distinguish transient sensor noise from sustained or potentially malicious behavior.

- Reputation Update Procedure: In case of anomaly detection, the framework evaluates whether the detected anomaly reflects persistent abnormal behavior or a benign, transient deviation based on validation within the Digital Twin environment. Reputation adjustments are based on behavioral assessment rather than model error attribution, ensuring that nodes are not penalized solely due to transient detection uncertainty.
- Blockchain Transaction Logging: Every reputation adjustment generates an entry in the Micro-Ledger, including node ID, event type, timestamp, and reputation change. This immutable record provides a transparent audit trail and supports future accountability.

The time elapsed between the onset of abnormal behavior and its identification is recorded as fault detection latency, serving as a key indicator of the framework's responsiveness. Validation within the Digital Twin enables controlled injection of noise, packet loss, and faulty node behavior, providing repeatable conditions for evaluating detection accuracy and trust adaptation.

C. The Edge Intelligence Module (MCP)

The Edge Intelligence Module, referred to as the Model Context Protocol (MCP), serves as the decision-making core of the proposed framework. It is designed to identify heterogeneous anomalies at the network edge while balancing detection accuracy with computational and energy constraints.

Relying on a single detection model often limits robustness in dynamic WSN environments, where anomalies may appear as isolated events or evolve gradually over time. To address this, MCP combines complementary learning paradigms that capture both instantaneous deviations and longer-term temporal patterns.

1) LightGBM for event-based anomaly detection: LightGBM is an efficient gradient-boosted decision tree framework that is well-suited for structured telemetry data commonly produced by sensor nodes. It does an excellent job of catching discrete or event-based anomalies without much computational overhead at the edge. Within MCP, LightGBM primarily contributes to detecting event-driven anomalies, such as sudden threshold violations or abnormal feature combinations.

2) LSTM autoencoder for sequential anomaly detection: The LSTM Autoencoder proposed by Malhotra et al. models sequential dependencies in the time series, thereby detecting anomalies based on temporal reconstruction errors. Several improved variants, including that, have demonstrated that the LSTM Autoencoder maintains good resistance to noise in dynamic environments. While effective in modeling normal temporal behavior, the autoencoder alone may overlook

abrupt, non-sequential anomalies, motivating its integration with a complementary model.

3) MCP fusion logic: The outputs of the LightGBM classifier and the LSTM autoencoder are combined using a soft-voting strategy. An observation is flagged as anomalous when either model reports abnormal behavior, prioritizing anomaly recall while maintaining high precision. In which the final decision denotes computationally as:

$$A(Xt) = \max(yLGBM, yLSTM)$$

In addition to the binary anomaly decision, MCP retains model confidence and reconstruction error information. These signals are later used to estimate anomaly severity and temporal persistence, enabling differentiated trust responses rather than uniform penalization. By performing inference at the cluster head, MCP reduces unnecessary data transmission and supports timely detection without imposing continuous computational load on individual sensor nodes.

D. The Lightweight Reputation Ledger

The Lightweight Reputation Ledger, referred to as the Micro-Ledger, provides a decentralized yet energy-aware mechanism for tracking node behavior over time. Its primary objective is to translate anomaly evidence into adaptive trust decisions without imposing the computational overhead of conventional blockchain systems.

The Micro-Ledger acts as the trust management backbone of the framework. Unlike other traditional blockchains, which implement consensus based on mining, such as Proof-of-Work, the underlying model followed by the Micro-Ledger is a form of Proof-of-Authority. This minimizes computational overhead and energy consumption in resource-constrained WSNs. Although Proof-of-Authority is employed to minimize energy consumption, the framework does not assume unconditional trust in a single validator. Reputation consistency checks and periodic leadership rotation can be incorporated to mitigate validator compromise.

1) Energy-efficient consensus: Proof-of-Authority (PoA): This is because the PoA model minimizes most overhead by eliminating energy-intensive computational puzzles while guaranteeing the immutability and verifiability of blocks. Such architectures result in high trust assurance with minimal energy use in IoT networks.

The proposed framework integrates hybrid AI detection with adaptive blockchain trust management, enabling a resilient, self-healing WSN architecture that can operate for an extended period under the extreme constraints of Industry 5.0 ecosystems.

2) The reputation management algorithm: Reputation updates are driven by observed behavioral patterns rather than model errors. When sustained or high-severity anomalous behavior is identified, the corresponding node's reputation is reduced proportionally, whereas stable and reliable behavior results in gradual reputation reinforcement.

Let $s_t \in [0,1]$ denote the anomaly severity score at time t, derived from detection confidence and temporal persistence. The reputation score R_i of node i is updated incrementally as a function of s_t, allowing minor transient deviations to have limited impact while penalizing persistent abnormal behavior more strongly.

- Automatic Quarantine: If any node's reputation degrades below the threshold Rth = 50, it is automatically quarantined, and any related data will not be included in any future analysis to conserve energy.
- Nodes whose reputation falls below the quarantine threshold are temporarily isolated from active participation. A probation mechanism allows quarantined nodes to be re-evaluated after a cooling-off period, during which limited observation data may be collected to assess behavioral recovery before potential reintegration.

To bound storage overhead over extended operation, the Micro-Ledger can employ sliding-window retention or periodic summarization of historical entries, ensuring scalability on resource-constrained cluster heads.

IV. Experimental Setup and Evaluation

This section describes the experimental design used to evaluate the proposed framework in terms of detection performance, resilience, and energy efficiency. The evaluation is conducted within a controlled Digital Twin simulation environment, enabling repeatable analysis under varying fault, noise, and communication impairment conditions. Both component-level metrics and system-level resilience indicators are considered to provide a comprehensive assessment.

A. Dataset

The experiments made use of the ToN-IoT dataset. The dataset contains labeled telemetry and network traffic traces collected from heterogeneous IoT devices under both normal and attack conditions, making it suitable for anomaly detection and resilience evaluation. It was one of the most adopted benchmarks related to the evaluation of intrusion and anomaly detection models within the IoT and WSN context.

Extensive preprocessing was done before training and evaluation on the raw data. Telemetry streams were combined into one multivariate time series, indexed by timestamps. Based on the correlation and leakage analysis, missing values, duplicates, and non-informative features were removed. The selected features included temperature, motion, GPS latitude, pressure, and humidity; Feature selection was guided by correlation analysis and information leakage checks to remove redundant and non-informative attributes. Normalization ensures that features with different physical units contribute proportionally to the learning process.

This final dataset was then divided into 70% training and 30% testing subsets, as done in standard best practices for anomaly detection studies. The split was performed chronologically to preserve temporal dependencies in the sensor streams and to avoid information leakage between training and testing phases. This approach guarantees sufficient diversity for both the supervised and unsupervised model components within the MCP.

While the ToN-IoT dataset provides a diverse and widely used benchmark, it is employed here to support controlled evaluation rather than to claim exhaustive coverage of all real-world failure scenarios.

B. The Digital Twin Simulation Environment

The framework was implemented on a custom-made Digital Twin built in Streamlit that mirrored a virtual replica of the WSN to analyze system behavior in real-time. The Digital Twin serves as a pre-deployment validation tool, allowing controlled experimentation and systematic observation of system behavior under reproducible conditions.

The simulated network consists of multiple sensor nodes organized into clusters, with configurable parameters such as node count, communication reliability, and fault injection intensity. Simulation runs are executed over extended event sequences to capture long-term trust evolution and energy trends.

Notable interactive features of the environment included composable features to facilitate investigatory inquiry, including, but not limited to, the following:

- Live Simulation Dashboard: An environment that monitors exhibited model performance metrics and current metrics for model accuracy, precision, and recall, as well as the most recent state of the Reputation Ledger.
- Noise Injection Control: The capability to introduce Gaussian noise to sensor readings in order to represent environmental interference and evaluate the overall robustness of the detection models. Noise intensity is varied across simulation runs to evaluate detection robustness under increasing environmental interference.
- Packet Loss Simulator: A proportion of sensor packets was randomly omitted as a representation of channel impairments and connectivity loss. Packet loss is modeled probabilistically to reflect unstable wireless links commonly observed in real-world WSN deployments.
- Faulty Sensor Selector: Faulty nodes are configured to exhibit persistent or intermittent abnormal behavior, enabling evaluation of the framework's ability to distinguish transient deviations from sustained faults.
- Manual Data Interface: Novel sliders for each sensor with user-defined sender values, which served as an opportunity for near real-time anomaly assessment.

The simulated nature of this assessment allows for a repeatable experimental scenario while enabling a fine-grained observation regarding detection efficacy and trust management operations within dynamic environments. This simulation-based setup enables detailed resilience analysis while avoiding hardware-dependent variability, thereby supporting fair and repeatable evaluation.

C. Evaluation Metrics

In order to thoroughly evaluate the performance of the framework, the selected metrics are grouped into model-level performance indicators and system-level resilience indicators to reflect both detection accuracy and long-term network behavior.

1) Model performance metrics: The AI model performance was evaluated using four standard classification measures: Accuracy, Precision, Recall, and F1-Score:

- Accuracy: The proportion of instances that were correctly classified.
- Precision: The fraction of instances classified as anomalies that were, in fact, true anomalies, which reveals the effectiveness of the model in terms of false alarms.
- Recall: The fraction of true anomalies that were classified as anomalies by the model.
- F1-Score: The harmonic mean of precision and recall, which indicates the overall detection ability of the detection model.

These metrics together reflect the model's ability to identify anomalies reliably while minimizing benign or non-malicious anomalies essential for energy-efficient operation in WSNs [6].

2) Framework evaluation metrics: To quantify system-level resilience, the following metrics are defined:

- Fault Detection Latency (FDL): The time difference between the onset of abnormal node behavior and its detection by the framework.
- Mean Time To Failure (MTTF): The expected operational time before a node or cluster enters a failure state due to sustained faults.
- Mean Time To Recovery (MTTR): The average duration required for the system to isolate or mitigate a faulty node after detection.
- Reliability Index: A measure of the probability that the network remains operational over time under fault conditions.

Formally, fault detection latency is computed as:

$$FDL = tdetect - tfault$$

where, t_{fault}denotes the time of fault onset and t_{detect}denotes the detection time.

In order to assess system-level resilience and efficiency, three metrics were developed:

- Time to Quarantine (TTQ): The count of events taken for the system to recognize and quarantine a reliably faulty sensor node. TTQ serves as a discrete approximation of recovery responsiveness and complements MTTR in event-driven simulations. Low TTQ is indicative of a faster adaptive response and stronger resilience of the network.
- Network Lifetime Improvement: The percentage improvement in total energy consumption compared to

what would have happened without the proposed trust mechanism. Network lifetime is inferred from cumulative energy consumption across nodes over the simulation horizon. This metric is easily interpretable, as it represents energy savings directly due to the quarantine of unreliable nodes.

- Blockchain Storage Overhead: The final size (in kilobytes) of the Micro-Ledger object at the end of a complete simulation, indicating the success of the lightweight blockchain design given the resource constraints of the underlying architecture. This metric reflects the scalability of the trust mechanism under prolonged operation.

When taken together, these evaluation metrics provide a comprehensive assessment of AI accuracy, adaptive trust performance, and computational efficiency.

D. Mathematical Formulation of the Framework

The wireless sensor network is modeled as a set of N sensor nodes represented by a graph $G = (V, E)$, where $V = \{v_1, v_2, \dots, v_N\}$ denotes the nodes and E represents wireless communication links between them.

At the discrete time step t, the cluster head receives an aggregated feature vector:

$$xt = [xt(1), xt(2), \dots, xt(d)]$$

where, d is the number of monitored features.

1) AI-based anomaly detection: The Model Context Protocol (MCP) combines a supervised classifier and an unsupervised reconstruction-based model.

- LightGBM produces binary predictions: $y_{LGBM} \in \{0,1\}$
- while the LSTM autoencoder computes a reconstruction error: $e_t = \| X_t - \hat{X}_t \|$.

An anomaly is detected by the autoencoder when e_t > θ, where θ is a predefined threshold learned from normal behavior.

The final anomaly decision A_t is obtained using a soft-voting fusion rule:

$$A_t = y_t\text{^}GB \vee \mathbb{1}(e_t > \theta),$$

where, ∨ denotes the logical OR operation and 𝟙(·) is the indicator function.

To differentiate transient deviations from persistent abnormal behavior, an anomaly severity score s_t ∈ [0,1] is defined as a function of detection confidence and temporal persistence. Higher values of s_t indicate sustained or high-confidence anomalies, while lower values correspond to minor or short-lived deviations.

2) Reputation update rule: Each node v_i maintains a dynamic reputation score R_i(t). When an anomaly is detected at time t, the reputation score is updated as:

$$R_i(t+1) = R_i(t) - \alpha \cdot s_t,$$

where, α > 0 is a scaling factor controlling penalty strength. In the absence of anomalies, reputation is gradually reinforced:

$$R_i(t+1) = R_i(t) + \beta,$$

where, β > 0 is a small reinforcement constant.

If R_i(t) falls below a predefined threshold R_th, the node is placed into a quarantine state, and its data are excluded from further analysis until re-evaluation conditions are satisfied.

This mathematical formulation links anomaly detection outcomes with trust evolution, providing a formal basis for analyzing resilience and network lifetime within the proposed framework.

Through the integration of a robust data-driven modeling approach, a mathematical trust formulation, and simulation-based validation of both modeling and trust framework results, this study establishes a reproducible basis for authoring a trustworthy WSN integrated with AI–blockchain technology. The study and replicable data considered Industry 5.0 conditions to assess the AI–blockchain-integrated WSN's resilience.

V. Results and Discussion

This section discusses the experimental results obtained from the Digital Twin simulations, focusing on anomaly detection performance, resilience under adverse conditions, and the impact of trust-aware mechanisms on network lifetime. The results are interpreted in relation to baseline approaches commonly used in WSN and IoT security literature.

The proposed resilient framework of WSNs is assessed using the Digital Twin environment in respect of:

1) the accuracy of anomaly detection,
2) the system's resilience under adverse network conditions, and
3) its impact on the network lifetime and energy efficiency.

A. Experiment 1: AI Model Performance Evaluation

The first experiment was to check the base performance of LightGBM and LSTM Autoencoder along with their hybrid fusion, which is called the Model Context Protocol (MCP), using the ToN-IoT dataset. As represented in Table I, the hybrid MCP architecture was able to outperform both its model components in anomaly detection.

Compared to traditional single-model approaches such as standalone tree-based classifiers or reconstruction-based detectors, the hybrid MCP demonstrates a clear advantage in balancing precision and recall. Similar trends have been reported in recent hybrid intrusion detection studies, where combining complementary models improves robustness under heterogeneous data distributions.

TABLE I. PERFORMANCE COMPARISON OF DETECTION MODELS ON THE CLEAN TEST SET

Model	Accuracy	Precision	Recall	F1-Score
LightGBM	0.985	0.992	0.991	0.991
LSTM Autoencoder	0.913	0.985	0.914	0.948
MCP (Soft Vote)	0.996	0.995	0.999	0.997

Thus, the MCP achieved an F1-score of 0.997 and near-perfect recall (0.999), demonstrating that the hybrid fusion detects almost all real anomalies with very few false negatives. The LightGBM model had been excellent in detecting discrete, event-based anomalies, while the LSTM Autoencoder provided strong temporal sensitivity. Integration of these two models into the MCP led to a robust mechanism of anomaly detection, which is further consistent with findings from other hybrid intrusion detection studies.

B. Experiment 2: Framework Resilience to Network Faults

The second experiment tested the robustness of the MCP against simulated network disturbances through Gaussian noise and packet loss in the Digital Twin environment. According to Fig. 3, at 20% total fault levels (10% noise and 10% packet loss), the MCP still had an F1-score above 0.94; thus, graceful degradation rather than failure took place. This gradual degradation indicates graceful performance decay rather than abrupt failure, which is a desirable property for resilient WSN deployments operating in unstable environments.

In this way, hybrid detection methods demonstrate their resilience compared with single models regarding environmental instability or data loss. This is the required robustness for sensors in Industry 5.0 scenarios operating under uncertain conditions.

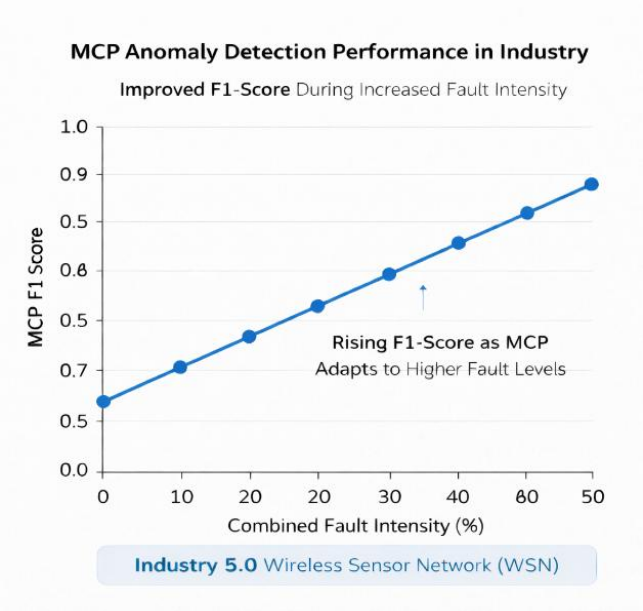

Fig. 3. MCP F1-Score degradation under injected noise and channel faults.

C. Experiment 3: Reputation System and Quarantine Validation

The third experiment focused on the trust adaptation of the Micro-Ledger with a designated faulty sensor node that always sent anomalous readings. Fig. 4 shows the degradation of the reputation score for the faulty sensor node over time until it reached the quarantine threshold ($R < 50$); eventually, the node automatically got isolated from the network.

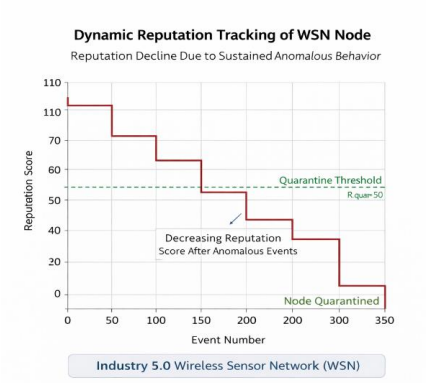

Fig. 4. Reputation score of the designated faulty sensor over time.

As the simulation unfolded, the node's reputation score gradually decreased due to sustained abnormal behavior, eventually crossing the quarantine threshold of 50. The node was launched into quarantine and demoted from active engagement with the network after 312 events. This was illustrated in Fig. 4, allowing us to conclude that the behaviorally driven reputation algorithm is effective, and its real-time action was also effective. The observed convergence toward quarantine reflects the effect of sustained abnormal behavior rather than isolated transient deviations. This time-to-quarantine (TTQ) value highlights the framework's ability to isolate unreliable nodes within a bounded number of observations, contributing to faster recovery and reduced energy waste.

The experiment demonstrated the validation of the metric TTQ and showed that, through the reputation-based system, unreliable nodes are effectively identified and isolated, preserving data integrity and energy efficiency. An adaptive reputation model in WSN environments can be designed with an improvement in the performance of self-healing networks.

D. Experiment 4: Network Lifetime and Efficiency Assessment

The observed network lifetime improvement is consistent with prior trust-aware WSN studies, where early isolation of unreliable nodes reduces redundant communication and unnecessary energy expenditure. Unlike approaches that rely solely on routing optimization, the proposed framework achieves energy savings through behavior-driven trust adaptation. A quantitative comparison of total energy consumption, network lifetime improvement, and Micro-Ledger storage overhead is summarized in Table II.

TABLE II. QUANTITATIVE COMPARISON OF TOTAL ENERGY CONSUMPTION, NETWORK LIFETIME IMPROVEMENT, AND MICRO-LEDGER STORAGE OVERHEAD

Metric	Value
Total Energy (Baseline System)	1465.7 Units
Total Energy (Our Framework)	1191.6 Units
Network Lifetime Improvement	18.7% Energy Saved
Blockchain Storage Overhead	98 KB

Using the framework improved network lifetime by 18.7% due early detection and quarantine of faulty nodes, which limited the number of redundancies. The Micro-Ledger even when being multi-sourced, is still very lightweight and minimal needed storage was approximately 98KB, which is in line with the design goals of energy-constrained WSN applications.

These indications support that a systems-based approach utilizing an aspect of hybrid AI detection integrated with context-based behavior-driven blockchain trust management framework has improved resilience and energy efficiency in practical WSN applications.

E. Discussion

The combined results of the experiments demonstrate both the effectiveness and scalability of the proposed framework. The hybrid MCP indicated statistical significance in detecting improvements compared to the other models, while the Micro-Ledger provides a lightweight, effective mechanism for evolving trust in decentralized WSN context.

The experimental findings outline three key benefits of the proposed framework:

- Detection Robustness: The hybrid MCP exhibits superior event-based and temporal anomaly detection when compared to existing individual ML and DL models. This characteristic of dual detection impacts a significant shortcoming of existing individual models.
- Autonomous Trust Management: The Micro-Ledger becomes capable of evolving trust continuously and autonomously. When it evolves and develops trust autonomously, the network can adapt and self-manage without human operation. This sets a stage for a substantial development in systems that are self-managing toward Industry 5.0.
- Energy Efficiency: The feedback between the MCP and the Micro-Ledger reduces redundancy of transmissions and optimizes battery resources, leading to observable lifetime improvements.

While the results demonstrate strong performance within the simulated environment, it is acknowledged that real-world deployments may introduce additional variability, such as hardware-induced noise or coordinated adversarial behavior. Nevertheless, the controlled evaluation provides valuable insight into the framework's resilience properties and establishes a solid foundation for future physical validation.

VI. CONCLUSION AND FUTURE WORK

A. Conclusion

This study presented a resilience-oriented framework for Wireless Sensor Networks that integrates hybrid AI-based anomaly detection with lightweight, behavior-driven trust management to address reliability and energy efficiency challenges in Industry 5.0 environments. Unlike traditional systems that analyze anomaly detection, data integrity, and trust management in isolation, the framework merges these properties into a seamless adaptive framework consisting of two primary elements:

- A Hybrid AI Anomaly Detection Engine — the Model Context Protocol (MCP) — that utilizes LightGBM and LSTM Autoencoder models to detect both event-based and sequential anomalies.
- A Lightweight Blockchain-Based Reputation Ledger (Micro-Ledger) that manages dynamic node trust through a Proof-of-Authority (PoA) consensus algorithm that optimizes security and energy consumption.

Through Digital Twin–based evaluation, the proposed framework achieved an anomaly detection F1-score of 0.997, isolated persistently unreliable nodes within a bounded number of events, and improved overall network lifetime by 18.7% compared to a baseline system without trust management. The associated Micro-Ledger maintained a low storage overhead of approximately 98 KB, demonstrating suitability for resource-constrained WSN deployments.

These results indicate that combining complementary detection models with adaptive trust evolution can yield system-level benefits beyond detection accuracy alone. By linking anomaly evidence to trust-aware isolation decisions, the framework reduces redundant communication and mitigates long-term energy drain caused by unreliable nodes.

From an Industry 5.0 perspective, the proposed framework aligns with the emphasis on resilient, human-centric, and sustainable cyber–physical systems by enabling autonomous monitoring and adaptive response without continuous human intervention. These directions aim to further enhance adaptability and robustness while preserving the lightweight nature of the proposed design.

This hybridized design also demonstrated that behavioral reputation tracking and AI based anomaly detection are not competing paradigms but rather complementary pillars of secure, sustainable IoT infrastructure.

B. Future Work

While the proposed framework demonstrates strong performance under controlled simulation conditions, several extensions can further improve adaptability and real-world applicability, many opportunities remain for future research and real-life implementation:

- Deployment on physical hardware: Future work includes deploying the framework on physical hardware platforms, such as Raspberry Pi or ESP32-based sensor clusters, to evaluate latency, power consumption, and operational robustness under real-world conditions.
- Adaptive algorithms for reputations: The present model uses fixed reward and penalty values for trust update calculations. Incorporating context-aware or decay-based reputation updates may allow the system to better distinguish transient faults from sustained abnormal behavior.
- Reintroduction of quarantined nodes: In the present implementation, quarantined nodes are isolated temporarily, and future work will further refine probation-based reintegration mechanisms. A revalidation phase of probation could allow quarantined nodes that have been rehabilitated to be reinstated back into the network after a period of observation based on recovery. Such mechanisms would support self-healing behavior without compromising long-term network integrity.
- Inter-cluster trust fabric: The micro-ledger can also be expanded to provide a secure communication pathway between clusters, allowing accordingly distributed action across multiple WSN clusters, which forms the basis for building a trust fabric collaboratively. This direction also opens opportunities for managing trust scalability in large-scale, multi-cluster WSN deployments.
- Cross-domain application: In addition to WSNs, the proposed hybrid AI–blockchain framework could be considered for other applications like industrial robotics, smart grids, or autonomous vehicle networks, where trust is critical for detecting anomalies in real-time.

These extensions aim to enhance robustness and scalability while preserving the lightweight and energy-aware nature of the proposed framework.

C. Closing Remarks

This work demonstrates that resilience in Wireless Sensor Networks can be effectively achieved by tightly coupling intelligent anomaly detection with adaptive, lightweight trust management.

Rather than treating security, reliability, and energy efficiency as isolated objectives, the proposed framework highlights the benefits of addressing them jointly through a feedback-driven design. This perspective is particularly relevant for emerging Industry 5.0 systems, where long-term sustainability and autonomous operation are key considerations.

The combination of interpretable learning components and transparent trust records also supports accountability and auditability in distributed sensing environments. Overall, the findings suggest that hybrid AI and trust-aware architectures provide a practical and extensible foundation for building resilient and sustainable sensor networks in future cyber–physical ecosystems.

ACKNOWLEDGMENT

The authors acknowledge the support provided by their affiliated institutions for access to research infrastructure and computational resources. The authors also thank the open-source community for the tools and frameworks, including LightGBM, TensorFlow, and Streamlit, which facilitated the implementation and evaluation of this work.

***Abstract*—Machine translation is one of the major areas of both computational linguistics and artificial intelligence that employs computer algorithms to automatically translate text between different natural languages. At present, the advent of Large Language Models (LLMs) has revolutionized this field, marking a significant turning point in its evolution. Despite their impressive capabilities, LLMs still fall short of achieving human-like translation due to key limitations, namely lack of transparency, explainability, and interpretability, the production of non-deterministic outputs, and insufficient support for low-resource languages. To address these challenges, incorporating human-aided translation mechanisms that reflect how the human brain performs translation is effective. Therefore, from a computer science perspective, this motivates the development of a novel hybrid machine translation approach that integrates a rule-based approach with LLM-based methods. This study presents a novel rule-based interlingual knowledge representation model named MTML 1.0 that has been designed and implemented to accurately analyze source language input and systematically structure the resulting linguistic information to facilitate applications, including target language generation and question-answering systems. The MTML 1.0 system consists of four key modules, namely the preprocessing module, morphological analyzer module, syntax analyzer module, and semantic analyzer module. Furthermore, the system has been fully implemented as a web-based application using the Python programming language, with spaCy serving as the foundation for natural language processing tasks. Finally, the functionality of the system has been demonstrated through the development of a prototype question-answering system.**

Keywords*—Machine translation; knowledge representation; LLMs; rule-based approach; hybrid approach

I. Introduction

Machine translation is one of the major branches of natural language processing, and a subfield of computational linguistics as well as artificial intelligence. It refers to machine-aided systems that automatically translate text or speech from one natural language to another natural language without human intervention [1]. The history of machine translation dates to the ninth century when Arab cryptologists introduced methods such as frequency analysis, probability, statistical information, and cryptanalysis which later influenced modern translation systems. Subsequently, the idea of machine translation resurfaced in the 1920s, whereas in 1956, the first machine translation conference marked a significant milestone in this field of research. Since then, machine translation has evolved significantly with various approaches, including dictionary-based approach, rule-based approach, corpus-based approach, statistical approach, hybrid approach, and sophisticated neural network-based approaches [2].

Presently, the field of machine translation has undergone a profound transformation with the emergence of Large Language Models (LLMs) that have revolutionized the way machines understand, generate, and translate human languages. In contrast to neural machine translation (NMT) systems that are trained specifically for translation tasks, Large Language Models (LLMs) like GPT (OpenAI), PaLM (Google), LLaMA (Meta), and mBART are general-purpose deep neural network models which are trained on vast corpora of multilingual data. Moreover, these models can perform a wide range of natural language processing tasks, including machine translation. Therefore, unlike traditional NMT systems, LLMs can translate across multiple language pairs without the need for separate models for each language pair, with great scalability and versatility [3]. Also, LLM-based machine translation provides some promising advantages, such as multilingual capability, contextual understanding, and the ability to perform zero-shot and few-shot learning.

Large Language Models (LLMs) have demonstrated remarkable capabilities and advancements in machine translation, but they still fall short of achieving truly human-like translation due to several major limitations, such as a lack of transparency, explainability, and interpretability, a non-deterministic nature, and their limited support for low-resource languages. Accordingly, to address and potentially overcome these issues, a solution is proposed by considering the human-aided translation processes inspired by the functioning of the human brain [4]. Therefore, the solution is a novel hybrid machine translation approach that combines the strengths of both rule-based methods and large language model (LLM)-based translation systems paradigms to overcome the existing drawbacks of any single methodology. The core premise of this approach is that by judiciously integrating these two paradigms, it is possible to develop a translation system that achieves greater accuracy, fluency, robustness, and human-like performance across a broader range of language pairs and domains [5][6]. However, at present, significant research progress has been made in LLM-based translation; still, there is no proper rule-based machine translation model or a comprehensive interlingua representation model to successfully capture, structure, and represent the linguistic knowledge encoded within source language input.

The aim of this study is to present the design and implementation of a novel system named the MTML 1.0 model (Machine Translation Markup Language 1.0 model), which is a novel rule-based interlingua knowledge representation model specifically designed for machine translation using markup language techniques. The novelty of this system is that it is a universal model that can be applied to any human language. Furthermore, in the implementation of this system, English has been adopted as the source language, and the main advantage of this model is that it can be further applied in a variety of domains, including the generation of target language outputs, question-answering systems, and other natural language processing tasks. Besides, this model has the potential to address several key limitations inherent in modern LLM-based machine translation approaches.

The rest of the study is organized as follows: Section II briefly describes the proposed approach to knowledge representation in machine translation, while Section III and Section IV deeply review the English language and the existing knowledge representation models, respectively. Section V discusses one of the data structure models that is used to represent knowledge, namely XML. Moreover, Section VI presents the design of the MTML 1.0 system, and Section VII explains the working procedure of the developed system. Finally, Section VIII is reserved to conclude the study by presenting future works.

II. Proposed Approach to Knowledge Representation in Machine Translation

The proposed approach of this research is based on how human beings perform translation from one language to another language which is tightly connected with the human brain.

The human brain is the most complex organ in the human body that controls memory, thoughts, emotions, vision, touch, breathing, temperature, motor skills, and many other processes effectively by sending and receiving chemical and electrical signals throughout the human body [7]. Structurally, the brain is divided into three main regions, namely the cerebrum, cerebellum, and brainstem. Fig. 1 illustrates the major parts of the human brain.

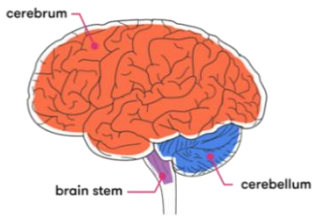

Fig. 1. Major parts of the human brain.

The cerebellum, or little brain, is located at the back of the head and performs maintaining posture, balance, and equilibrium, thinking, emotions, and social behavior. Secondly, the brainstem serves as a connection pathway between the cerebrum and the spinal cord. Thirdly, the cerebrum is the largest part of the brain that is divided into left and right hemispheres symmetrically by the longitudinal fissure. The outer part of the cerebrum is named as cerebral cortex, which is arranged as a collection of layers. This cortex is divided into fifty different functional areas named Brodmann's areas. Fig. 2 illustrates the Brodmann areas.

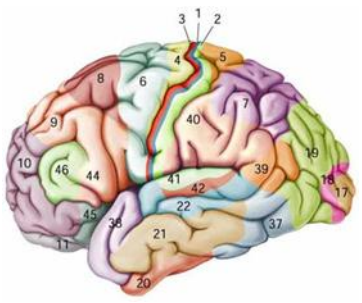

Fig. 2. Brodmann areas.

Brodmann areas were first introduced and systematically numbered in the early 20th century by the German anatomist Korbinian Brodmann based on the cytoarchitectural organization of neurons. Accordingly, Brodmann mapped the human brain and identified 52 distinct regions that were numbered from 1 to 52. These regions are associated with diverse functions such as motor control, cognition, and sensation. Notably, Brodmann area 22 is included in Wernicke's area, while areas 44 and 45 are located within Broca's area. Furthermore, both Wernicke's and Broca's areas are critical for language processing, although they perform entirely distinct functions [8]. From a translation perspective, humans must successfully comprehend and store linguistic information related to morphology, syntax, semantics, thematic roles, grammar rules, and language fluency. Achieving accurate and precise translation requires not only knowledge of grammar and linguistic structures but also language fluency, which is developed through frequent interaction and practice with the language. Within the human brain, Wernicke's area plays a key role in language fluency, while Broca's area is primarily responsible for processing grammatical rules. By simultaneously engaging both of these regions, humans are able to generate highly effective, correct, and contextually accurate translations [9].

Computationally, this scenario can be substituted with the aid of a hybrid machine translation approach that is a combination of a rule-based approach and an LLM-based translation approach. More specifically, the rule-based approach can be used to demonstrate the behavior of Broca's area, while the LLM-based translation approach can be used to demonstrate the behavior of Wernicke's area.

III. Overview of the English Language

English is the main global lingua franca that is widely used across the world in diverse domains such as communication, education, business, science and technology, tourism, trade, and the Internet. English originated in England and is currently recognized as the official or co-official language in more than fifty-nine (59) countries. Linguistically, it is classified as a West Germanic language within the Indo-European language family. The history of the English language dates back to the 5th century and is divided into four major eras, namely Old

English, Middle English, Early Modern English, and Modern English. Today, the form predominantly used worldwide is Modern English [10].

The English language comprises twenty-six (26) letters, including five (5) vowels. From a computational grammar perspective, English can be analyzed across four main areas such as grammatical units, word classes, phrases, and sentence elements. The grammatical units of English comprise words, phrases, clauses, and sentences, while the word classes (or parts of speech) are traditionally categorized into eight (8) groups, namely nouns, verbs, adjectives, adverbs, pronouns, prepositions, determiners, and conjunctions. Similarly, English phrases can be classified into five (5) types, namely noun phrases, verb phrases, adjective phrases, adverb phrases, and prepositional phrases, and finally, the sentence elements of English include the subject, verb, object, complement, and adverbial [11]. From a machine translation perspective, the English language can be systematically analyzed by considering its core linguistic elements, namely morphology, syntax, and semantics. A brief description of each of these elements is provided below.

A. English Language Morphology

Morphology is one of the major areas in linguistics that refers to the scientific study of the internal structure of words with respect to stems, root words, prefixes, and suffixes. English language morphology can be classified into four main groups such as noun morphology, adjective morphology, verb morphology, and adverb morphology. In the English language, nouns play a significant role as subjects, direct objects, indirect objects, and in various other syntactic positions. Morphologically, English nouns participate in both inflection and derivation. Inflection generates different grammatical forms of the same word, whereas derivation produces entirely new words [12]. Furthermore, based on inflectional patterns, English nouns can be classified into regular nouns and irregular nouns. Overall, English nouns conform to ten key morphological rules, which are summarized in Table I [13].

TABLE I. MORPHOLOGICAL RULES FOR ENGLISH NOUNS

Grammar	Morphology		
	Base form	***Add***	***Remove***
Singular	Noun	-	-
Plural	Noun	s	-
Plural	Noun	es	-
Plural	Noun	ies	y
Plural	Noun	ves	fe
Singular Possessive	Noun	‘s	-
Plural Possessive	Noun	s’	-
Singular	Verb	er	-
Plural	Verb	ers	-
Singular	Verb	ment	-
Plural	Verb	ments	-

Secondly, verbs in the English language exhibit five (5) primary morphological forms, such as the simple present tense, the third-person singular form, the simple past tense, the present participle, and the past participle. In addition, five major morphological rules govern the formation and transformation of English verbs, and these rules are summarized in Table II.

TABLE II. MORPHOLOGICAL RULES FOR ENGLISH VERBS

Grammar	Morphology		
	Base form	***Add***	***Remove***
Infinitive	Verb	-	-
Simple present	Verb	s	-
Present Participle	Verb	ing	-
Past	Verb	ed	-
Past Participle	Verb	ed	-

As the next morphological categories of English language, English adjective morphology shares 13 rules that are shown in Table III.

TABLE III. MORPHOLOGICAL RULES FOR ENGLISH ADJECTIVES

Grammar	Morphology		
	Base form	***Add***	***Remove***
(Positive) Adjective	Adjective	-	-
(Positive) Adjective	Noun	ish	-
(Positive) Adjective	Verb	ful	-
(Positive) Adjective	Verb	less	-
(Positive) Adjective	Noun	en	-
(Positive) Adjective	Verb	active	-
(Positive) Adjective	Verb	able	-
(Comparative) Adjective	Adjective	er	-
(Comparative) Adjective	Adjective	r	-
(Comparative) Adjective	Adjective	ier	y
(Superlative) Adjective	Adjective	est	-
(Superlative) Adjective	Adjective	st	-
(Superlative) Adjective	Adjective	iest	y

Finally, adverbs are used to provide additional information about a verb, an adjective, or another adverb. In English, many adverbs are formed by adding the suffix -ly to adjectives. Beyond this common pattern, adverbs also serve to explain aspects such as how something happens, as well as when, where, in what way, and to what extent an action occurs. Examples of these relationships are summarized in Table IV, which illustrates the connections between verbs and their corresponding adverbs.

TABLE IV. CONNECTIONS BETWEEN VERBS AND ADVERBS

Verb	Adverb	Example
When?	early	She arrives early in the morning
How?	carefully	She drives carefully
Where?	everywhere	They go everywhere together
In what way?	slowly	She walks slowly
To what extent?	slowly	It is slowly hot

B. Syntax of the English Language

The architecture of English syntax is a multifaceted domain that integrates principles of hierarchical structure, constituent arrangement, and transformational operations to govern sentence formation. Fundamentally, syntax examines how words are systematically organized to form phrases and sentences. Consequently, it encompasses key grammatical aspects such as word order, sentence structure, sentence complexity, and grammar rules. In the case of English, five basic syntactic rules can be identified, along with seven major syntactic patterns that represent the standard word order of sentences and clauses [14][15]. These are summarized in Table V and Table VI, respectively.

TABLE V. SYNTACTIC RULES IN THE ENGLISH LANGUAGE

Syntactic Rule	Description
Rule 1	All sentences need a subject and a verb, except imperative sentences.
Rule 2	In a sentence, the subject comes first, and the verb comes second. When the sentence has an object, it comes third after the verb.
Rule 3	A single sentence must contain one main idea. When a sentence contains two or more ideas, it needs to be broken up into multiple sentences.
Rule 4	Dependent clauses need a subject and a verb.
Rule 5	Adjectives and adverbs are placed in front of the appropriate words. When there are multiple adjectives describing the same noun, one needs to use the proper adjective order, known as royal order.

TABLE VI. MAJOR SYNTACTIC PATTERNS IN THE ENGLISH LANGUAGE

Pattern Type	Pattern
Pattern 1	Subject → Verb
Pattern 2	Subject → Verb → Direct Object
Pattern 3	Subject → Verb → Subject Complement
Pattern 4	Subject → Verb → Adverbial Complement
Pattern 5	Subject → Verb → Indirect Object → Direct Object
Pattern 6	Subject → Verb → Direct Object → Object Complement
Pattern 7	Subject → Verb → Direct Object → Adverbial Complement

C. Semantics of the English Language

Semantics is another major branch of linguistics that focuses on the study of meaning in language. It primarily examines how expressions are constructed across different layers of language, such as words, clauses, sentences, and texts, and how the meanings of these elements interact with and influence one another. Semantics can be viewed from two main perspectives, namely the internal side and the external side. The internal side concerns the relationship between words and mental phenomena, such as conceptual representations and ideas, while the external side investigates how words correspond to objects in the real world and the conditions under which a sentence can be judged as true or false. Furthermore, semantics can be divided into several subfields, including lexical semantics, phrasal semantics, sentence-level semantics, and paragraph-level semantics [16].

Lexical semantics is the study of lexical relations between words. The aim of lexical semantics is to analyze words in depth, as words may have multiple meanings. Lexical semantics can be divided into two approaches such as semasiology and onomasiology. The semasiology approach starts with words and examines their meanings, while onomasiology goes from meaning to word. Secondly, phrase-level semantics are used to bridge the gaps between lexical semantics and sentence-level semantics. Thirdly, sentence-level semantics are used to study the meaning of a sentence by analyzing how words and phrases combine to form meaningful statements. Moreover, thematic relationships or semantic roles are used to build the meaning of a sentence by considering the relationship between phrases presented in a sentence. Table VII shows the semantic roles of a sentence. Finally, paragraph-level semantics takes the context to contribute to meaning by analyzing the complete knowledge of each sentence in a paragraph.

TABLE VII. MAJOR SEMANTIC ROLES OF A SENTENCE

Relationship	Description
Agent	The entity that acts intentionally
Experiencer	The entity that experiences a state or sensation
Patient	The entity that is affected by the action or undergoes a change of state
Theme	The entity that will not be affected because of an action
Instrument	The means by which an action is performed, often with the help of a tool or object
Force	Mindlessly performs the action.
Location	Where the action occurs
Goal	The endpoint or destination of an action or movement
Recipient	The entity that receives something as a result of an action
Source	Where the action originated
Time	The time at which the action occurs
Beneficiary	The entity for whose benefit the action occurs
Manner	The way or method by which an action is performed
Purpose	The reason for which an action is performed
Cause	The reason why an action or state occurs

IV. KNOWLEDGE REPRESENTATION TECHNIQUES IN MACHINE TRANSLATION

Knowledge representation in machine translation is a pivotal area that focuses on developing formalisms to represent information in ways that machines can effectively process and thereby bridge the gap between different languages. Knowledge representation involves encoding human knowledge into machine-readable formats that capture meaning, context, and linguistic nuances. Furthermore, these representations enable machine translation systems to perform complex tasks requiring reasoning, inference, and understanding [17] [18]. From a machine translation point of view, knowledge representation not only maps words from one language to another, but also models morphology, syntax,

semantics, and discourse-level information and provides a foundation for reasoning, inference, and disambiguation capabilities that go beyond simple word-to-word translation. There are several major knowledge representation techniques related to machine translation, such as lexicons or bilingual dictionaries, frames, semantic networks, ontologies, interlingua representations, feature structures, and logical representations. A brief description of each of these techniques is presented below [19].

A. Lexicon

A lexicon or bilingual dictionary serves as a fundamental knowledge representation tool in machine translation, which is a structured list of word-level entries for one or more languages. It is widely employed across different MT paradigms such as the rule-based approach, hybrid approach, and neural approach. A lexicon typically consists of source-language words, their target-language equivalents, and associated linguistic information such as part-of-speech categories, morphological features, and semantic roles. It supports machine translation by enabling word lookup to find equivalent terms in the target language, facilitating disambiguation by selecting the correct sense of a word based on part of speech or context, and handling morphology effectively by adjusting word forms to match tense, number, gender, and other grammatical features. Furthermore, it supports different machine translation approaches, such as a rule-based approach as the core component that is deeply integrated with grammar rules, a hybrid approach as statistical or neural models to improve accuracy, and a neural approach as embeddings. Therefore, lexicons offer several advantages, such as providing clear word mappings, supporting low-resource languages, and enabling fine-grained control over translation. However, they have some limitations, including the time-consuming effort required for their development and maintenance, as well as difficulties in handling idiomatic expressions and context-dependent translations [20].

B. Frames

A frame is a structured knowledge representation technique introduced by Marvin Minsky in 1975. In the context of machine translation, frame representation is employed to capture semantic structures as it organizes knowledge in a way that mirrors human cognitive processes. The structure of the frame contains three components, namely frame name (the type of the concept), slots/roles (key components of the concept), and fillers (actual values in a sentence). It supports machine translation in different ways, such as facilitating semantic role labeling to identify semantic roles in a sentence, disambiguation by resolving meanings, generating target language sentences, and cross-lingual mapping. Furthermore, it supports different machine translation approaches, such as an interlingua-based approach by representing interlingual meaning using frames, a hybrid approach by combining frame semantics with statistical or neural components, and a neural approach by improving translation accuracy. Therefore, frame representation offers several advantages, such as handling variations in word order, providing better translation of idiomatic and context-rich expressions, and supporting rich semantic reasoning. However, it also has some limitations, including structural complexity, susceptibility to errors during frame extraction, and the requirement for large annotated corpora to function effectively [21].

C. Semantic Networks

Semantic networks are graph-based knowledge representation models in which concepts or words are represented as nodes and the semantic relationships between them are represented as edges. In machine translation systems, semantic networks are commonly used to support tasks such as lexical disambiguation, word sense disambiguation to identify the correct sense of a polysemous word, and synonym replacement to improve fluency by selecting contextually appropriate synonyms during target language generation. Besides, it supports different machine translation approaches, such as rule-based approaches by supporting semantic level transfer and disambiguation, a hybrid approach by improving translation fluency and accuracy via contextual knowledge, and a neural approach as an external knowledge base to enhance model understanding. Therefore, semantic networks offer several benefits, including maintaining semantic coherence, supporting meaning preservation across structurally different languages, and handling synonyms, antonyms, and context-sensitive words. Nevertheless, they also have some drawbacks, such as being labor-intensive to construct, having limited coverage across different domains, and struggling with idiomatic expressions [22].

D. Ontologies

Ontologies are formal and structured representations of knowledge that facilitate understanding the meaning of a language by accurately modeling real-world knowledge and the semantic roles associated with words. The structure of an ontology consists of five key elements such as class/concept (a category or type of thing), instance (a specific object of a class), property or attribute (describes a feature or relationship), relation (links between concepts), and axioms/ rules (constraints or logic). Ontologies support various machine translation tasks such as semantic understanding, word sense disambiguation, and cross-lingual mapping that aligns equivalent concepts across different languages to achieve more accurate translations. Moreover, it supports different machine translation approaches, such as rule-based approaches to enhance rule creation and semantic interpretation, an interlingua-based approach to define interlingual concepts to map source language input to target language output, a hybrid approach to improve context handling, and a neural approach to guide the translation via fine-tuning using external ontologies. Accordingly, ontologies offer some benefits such as improving semantic and contextual accuracy, enabling domain-specific translations, facilitating concept alignment across languages, and supporting intelligent reasoning and inference. However, it has some drawbacks, such as a labor-intensive process of creation and maintenance, limited coverage in low-resource languages, and the difficulty of integrating them with end-to-end neural models without specialized techniques [23].

E. Interlingua Representation

Interlingua serves as a universal pivot language in interlingual-based machine translation systems that enables translation across multiple source and target languages without the need for direct pairwise mappings. Interlingua captures the

deep semantic content of the source text and performs more flexible and scalable multilingual translation by abstracting away from the grammatical and lexical structures of individual languages. Primarily, an interlingua is composed of three key elements such as concepts, which represent language-independent notions; semantic roles, which define relationships between concepts; and attributes, which describe their properties. Also, it supports a rule-based approach by enabling semantic abstraction to capture meanings of source or target language grammar, context handling to represent roles and relationships, disambiguation to resolve ambiguities, and modularity to decouple language analysis from language generation. Furthermore, the interlingua approach offers several advantages, including language independence, preservation of meaning across languages, scalability through the reduction of required translation modules, and reusability as a single interlingua can support multiple target languages. However, it also presents certain drawbacks such as high complexity and domain sensitivity, high computational cost and resource intensity, and limited flexibility when compared to modern data-driven models [24].

F. Feature Structure

Feature structure is a formal framework that provides a robust mechanism for representing linguistic information through attribute–value pairs that are commonly referred to as features. This approach enables a structured and hierarchical organization of linguistic features by representing the grammatical, syntactic, and semantic properties of sentences, which are essential for effective machine translation. Fundamentally, this knowledge representation approach is employed to maintain morphological and syntactic consistency, enforce agreement rules, and support transfer rules in structural mapping between source and target languages. Furthermore, it supports different machine translation approaches, such as rule-based approaches by acting as a core component for grammar-based parsing and generation, and a hybrid approach by combining feature-based rules with statistical or neural techniques. Moreover, feature structures offer several advantages, including high expressiveness, suitability for morphologically rich languages, support for linguistic constraints and agreement checking, and facilitation of language-neutral parsing and transfer. However, they also present notable drawbacks such as structural complexity, high computational cost, limited scalability, and the need for extensive manual rule creation [25].

G. Logical Representation

Logical representation is a proper method for expressing the meaning of sentences through logic-based expressions, including propositional logic, predicate logic, and temporal logic. In machine translation, logical representation is primarily used to capture the underlying meaning of sentences at a semantic level. The structure of logical representation comprises five key elements, such as a predicate that represents properties or relationships, arguments that denote the entities involved in an action, quantifiers to express universal or existential statements, connectives that serve as logical operators, and tense, which is represented using formal logical expressions. Moreover, logical representation serves different roles in machine translation, including facilitating semantic analysis, supporting inference and reasoning, enabling disambiguation, and assisting in cross-linguistic mapping. In addition, logical representation supports various machine translation approaches, such as rule-based approaches to perform pattern matching and structure inference, an interlingua-based approach to serve as a language-neutral representation, and in hybrid or neural approaches to perform semantic annotation, evaluation, or control. Consequently, it offers some advantages, including high precision, universality, and support for reasoning. However, it also presents drawbacks such as structural complexity, high resource requirements, data scarcity, and limited suitability for idiomatic or metaphorical expressions.

V. Extensible Markup Language (XML)

Extensible Markup Language, commonly abbreviated as XML, is a markup language that has been designed to store, transport, and structure data in a platform-independent and human-readable format. Therefore, XML contains a set of rules to encode documents in a proper format that is both human-readable and machine-readable. The main purpose of this language is serialization, which involves storing, transmitting, and reconstructing arbitrary data. Generally, XML labels, categorizes, and structurally organizes information using tags. Furthermore, these tags define the data structure and contain metadata. Fundamentally, XML is used to facilitate various areas such as web services, including SOAP and RESTful services, linguistics and NLP to annotate corpora and feature structures, knowledge representation to encode ontologies, frames, and dictionaries, and different machine translation systems. There are some major features in XML, such as extensible, hierarchical, human-readable, machine-readable, and platform-independent. Moreover, XML has four key components, such as elements that can be described as a data container with opening and closing tags, attributes that store metadata inside the start tag, the root element, which is the main parent element of the XML tree, and nested elements that are elements inside other elements [26].

XML offers several benefits, such as being easy to understand and edit, highly portable and interoperable, widely supported by programming languages and tools, including Java, Python, and C#, and standardized across many domains. However, it also has notable drawbacks, including verbosity, slower parsing compared to binary formats, and inefficiency for real-time data transmission over networks.

VI. Design of the MTML Model

The Machine Translation Markup Language (MTML) 1.0 model is a novel universal rule-based interlingual knowledge representation model specifically designed for machine translation tasks using markup language techniques. The primary objective of this model is to represent and store all the linguistic knowledge extracted from the source language input, which can then be utilized to generate output in any target language. To achieve this, the system deeply analyzes the source language input by following the machine translation pyramid that is shown in Fig. 3 with respect to key linguistic levels such as morphology, syntax, and semantics.

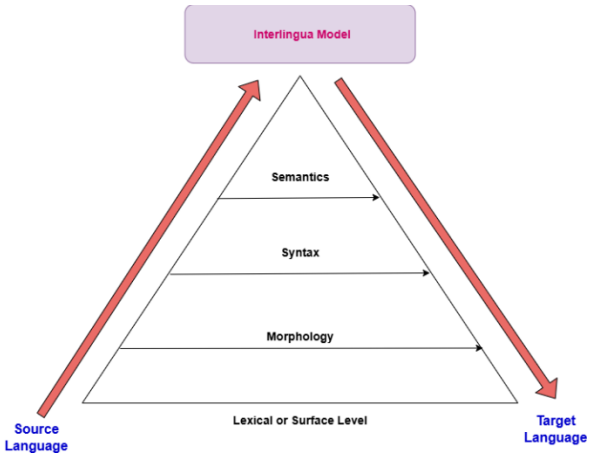

Fig. 3. Machine translation pyramid.

The extracted knowledge is subsequently represented and stored in a well-structured format, which is named as an MTML script that is a combination of XML and frame-based representation. The main advantage of this model lies in its versatility; it can be employed not only for generating target language output but also for supporting applications such as question-answering systems and other natural language processing tasks. Moreover, by following a rule-based approach, MTML 1.0 has the potential to overcome several limitations inherent in modern LLM-based machine translation approaches. Fig. 4 shows the pipeline of the MTML 1.0 model. Fig. 5 illustrates the design of the MTML 1.0 model, and the brief description of the design is provided below:

Fig. 4. Pipeline of the MTML 1.0 model.

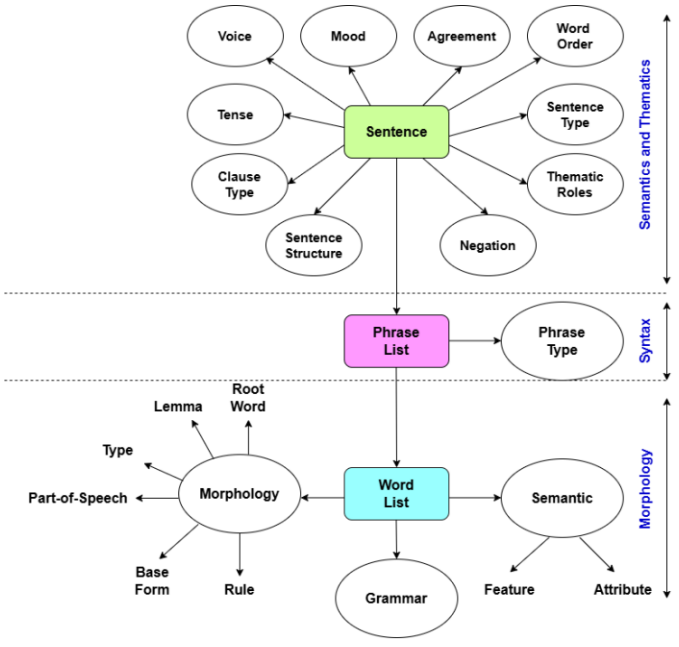

Fig. 5. Design of the MTML 1.0 model.

The MTML 1.0 model has been designed considering the common grammatical structure that is applied for any language. Furthermore, this system follows a top–down approach in its analysis. First of all, it begins with an English sentence as input and sequentially processes it through ten key linguistic properties that characterize English sentences, namely sentence structure, clause type, tense, voice, mood, agreement, word order, sentence type, negation, and thematic/semantic roles as follows:

1) Sentence structure – The model first identifies the four main structural components, namely subject, predicate, object, and modifiers.

2) Clause type – It then determines whether the sentence contains an independent clause, a dependent clause, or a relative clause.

3) Tense – The model detects the major tense (present, past, future) and further specifies the appropriate sub-tense.

4) Voice – It classifies the sentence as being in the active voice or passive voice.

5) Mood – The model identifies the speaker's intention by detecting moods such as indicative, imperative, or subjunctive.

6) Agreement – It verifies grammatical subject–verb agreement and noun–pronoun agreement.

7) Word order – The system checks if the sentence follows the standard Subject–Verb–Object (SVO) order or an inverted order (commonly used in questions).

8) Sentence type – It categorizes the sentence as declarative, interrogative, imperative, or exclamatory.

9) Negation – The model detects whether the sentence contains a negation property.

10) Thematic/semantic roles – Finally, it assigns semantic roles to constituents, including agent, experiencer, patient, theme, instrument, force, location, direction/goal, recipient, source, time, beneficiary, manner, purpose, and cause.

After completing this first stage of analysis, the model proceeds to the second stage, where it identifies and segments the sentence into five major phrase types, such as noun phrases, verb phrases, adjective phrases, adverb phrases, and prepositional phrases. These are further analyzed syntactically using a parse tree. Furthermore, in the third stage, the detected phrases are tokenized into words, and each word undergoes morphological analysis to examine its internal structure and grammatical features.

The architecture of the MTML 1.0 system is structured into four key modules, namely the Preprocessing Module, Morphological Analyzer Module, Syntactic Analyzer Module, and Semantic Analyzer Module. The overall system architecture is illustrated in Fig. 6, and a brief description of each module is provided below.

A. Preprocessing Module

This module serves as the foundational step in the MTML 1.0 system, where it accepts an English sentence as input and converts it into a structured and standardized form by functioning as a filter. Specifically, it eliminates unnecessary elements from the input sentence that are not relevant to the

analysis process, such as special characters, extra white spaces, unreadable symbols, and abbreviations. Once refined, the module produces a processed output, which is then passed to the second key component of the system, named the morphological analyzer module.

B. Morphological Analyzer Module

The morphological analyzer module is the second major module of the MTML 1.0 system, which takes the output generated by the preprocessing module as its input. The primary function of this module is to perform morphological analysis of the source sentence and identify the morphological features of each word. To achieve this, the module consists of five sub-modules, namely the tokenizer, part-of-speech tagger, morphological parser, feature extractor, and morphological output generator. At first, the tokenizer splits the sentence into individual words, which are then passed to the part-of-speech tagger to map them to their base forms with corresponding tags. Secondly, the morphological parser applies morphological rules to decompose inflected words into morphemes, and in the third step, the feature extractor identifies additional linguistic attributes such as root word, number, and word type. Finally, the morphological output generator produces the analyzed output that is enriched with structured morphological tags.

C. Syntax Analyzer Module

This module is the third major component of the MTML 1.0 system, consisting of two sub-modules, namely the syntactic parser and the syntax output generator. The primary function of the syntax analyzer module is to analyze the structure of the input sentence by searching all the phrases available in the input. In syntactic parsing, two main approaches are commonly used, namely dependency parsing and constituency parsing. For this system, a constituency parser is employed to construct the syntactic structure of the sentence. This parser detects various phrase types present in the input, such as noun phrases, verb phrases, adjective phrases, adverb phrases, and prepositional phrases. Once the parsing process is completed, the syntax output generator produces a structured representation of the sentence by visualizing its syntactic organization through a predefined tag set.

D. Semantic Analyzer Module

The semantic analyzer module is the final module of the MTML 1.0 system. Its primary responsibility is to interpret the meaning of the source language sentence and ensure that the extracted meaning is accurately preserved for subsequent applications, such as generating target language output or answering questions in a Q&A system. This module consists of three sub-modules, namely the semantic role labeler module, grammar identification module, and semantic output generator. The semantic role labeler identifies the thematic relationships present in the input sentence, while the grammar identification module handles complex grammatical tasks such as sentence structure, clause type, tense, voice, mood, agreement, word order, and sentence type. Finally, the semantic output generator produces a structured representation of the sentence's semantic features organized through a predefined tag set.

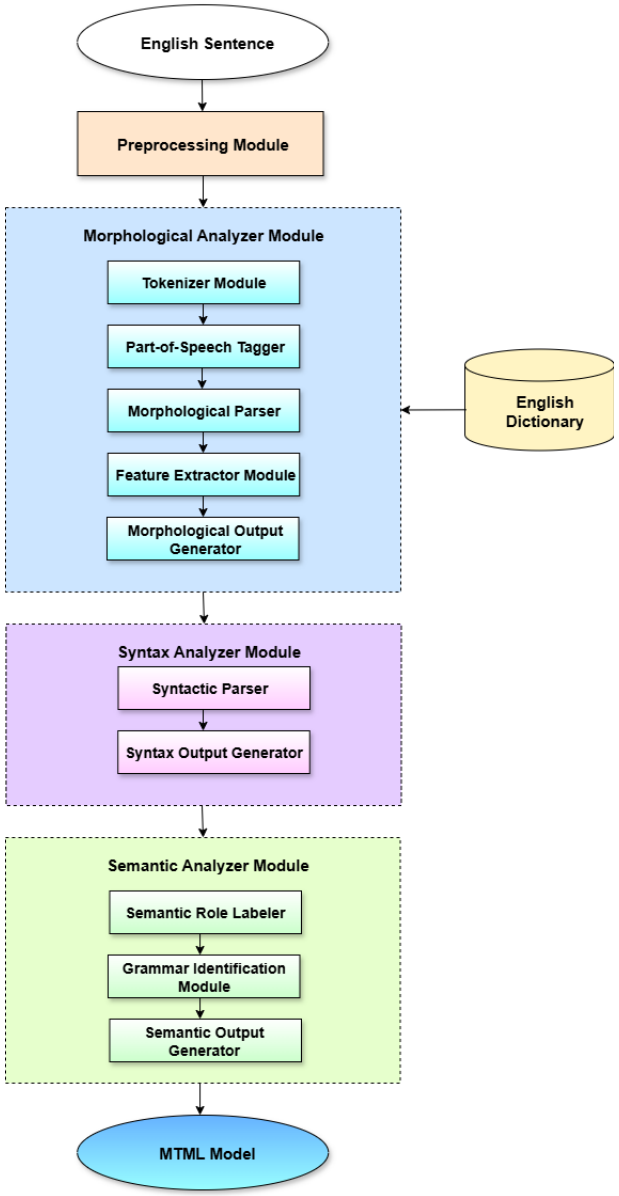

Fig. 6. Architecture of the MTML 1.0 system.

E. MTML 1.0 Model

MTML (Machine Translation Markup Language) 1.0 model represents the final output of the system that is produced after a deep analysis of the source language sentence. It can be introduced as a novel frame-based knowledge representation model specifically designed for machine translation tasks through markup language techniques. Essentially, this model represents and stores all linguistic information and knowledge contained in the source text using a structured set of tags that are automatically filled during the analysis process. The significance of this model lies in its role as a successful interlingua representation, which can be applied to various tasks such as the generation phase of machine translation systems, as well as the design and development of Q&A systems.

VII. MTML 1.0 System in Action

This section provides a brief overview of the working procedure of the MTML 1.0 system. The system has been implemented as a web-based application using the Python programming language. Furthermore, all the natural language processing (NLP) tasks within the system are modeled using spaCy, which is an advanced open-source NLP library. Unlike the Natural Language Toolkit (NLTK), which is widely adopted for educational and research purposes, spaCy is primarily designed to support NLP tasks within deep learning workflows and is well-suited for both research and industrial applications. Built on Thinc as its backend, spaCy offers a range of robust features including tokenization, part-of-speech (POS) tagging, named entity recognition (NER), dependency parsing, lemmatization, sentence segmentation, word vectors, language models, and rule-based matching, etc. Fundamentally, the MTML 1.0 system consists of two Graphical User Interfaces (GUIs) that are shown in Fig. 7 and Fig. 8, respectively.

The first graphical user interface (GUI) of the system, shown in Fig. 7, allows the user to input an English sentence. This interface includes three buttons such as "Generate", "Clear", and "Next". The "Generate" button produces the MTML script representing the linguistic knowledge extracted from the given input sentence. This script is then downloaded as an XML file, which can be utilized for further applications. The "Clear" button erases the entered input, while the "Next" button navigates the user to the second GUI, as shown in Fig. 8.

The second GUI has been designed to demonstrate a Q&A system that uses the MTML script as input to answer common questions about English sentences. In this interface, users can upload the previously generated MTML script and query the system to test its performance. Specifically, the system can respond to ten predefined questions related to English sentence analysis as follows:

1) Who did this?
2) What did you do?
3) To whom was this done?
4) When did it happen?
5) Where did it happen?
6) Why did it happen?
7) How did it happen?
8) What is the subject of the sentence?
9) What is the verb of the sentence?
10) What is the object of the sentence?

VIII. Conclusion and Future Works

This study presented the design and implementation of a novel rule-based knowledge representation model for machine translation, namely the MTML 1.0 system. The primary objective of this model is to integrate with existing LLM-based machine translation approaches in order to develop a hybrid system that more closely simulates human cognitive translation processes. The novelty of this model is that it is a universal interlingua model that can be used to analyze any natural language. In the implementation process, the model has been developed for the English language. The architecture of the MTML 1.0 system consists of four core modules, namely the preprocessing module, the morphological analyzer module, the syntax analyzer module, and the semantic analyzer module. The system has been successfully implemented as a web-based application using the Python programming language with all NLP-related tasks modeled through the spaCy library. Furthermore, the functionality of the system has been demonstrated through a prototype Q&A application, which highlights its potential for broader applications in natural language understanding and generation.

As the next stage of this research, the existing MTML 1.0 system will be extended into MTML 2.0, with the capability to address tasks that are challenging for LLM-based approaches, such as the effective handling of idiomatic expressions in the English language. In addition, the performance of the upgraded system will be systematically tested and evaluated within a controlled laboratory environment using human evaluators to ensure reliability and practical applicability.

Safety Helmet Wear Detection Algorithm Based on ASG-YOLOv8s

Li-Zhen He, Zhi-Sheng Wang, Yi-Wei Duan, Jin-Hai Sa
School of Software Engineering, Xinjiang University, Xinjiang, China

***Abstract*—In the field of industrial safety, the standardised wearing of safety helmets by workers constitutes a core protective measure against head injuries. However, in industrial settings, multi-scale background interference arising from variations in monitoring distance renders traditional detection models ineffective at capturing the contour features of small-sized helmets. This study, therefore, proposes the ASG-YOLOv8s safety helmet detection network, based on YOLOv8s, to address the challenge of complex scene background interference. First, the AKC-SCAM unit is introduced within the YOLOv8 backbone network to replace certain standard convolutions. This module dynamically adjusts the sampling shape of convolutional kernels, enhancing the extraction of multi-scale defect features. Secondly, a cross-scale interaction architecture (Slim-neck) is constructed in the Neck section, employing GSConv instead of conventional convolutions. This combines with a cross-level feature pyramid to achieve cross-scale interaction between deep semantic features and shallow details. Finally, GAM attention is embedded before the multi-scale output for head detection, establishing a dual-stream attention mechanism that synergistically optimises feature response intensity for low-quality candidate boxes, while suppressing background noise interference. Experimental results demonstrate that the enhanced ASG-YOLOv8s achieves improvements of 2.54%, 2.94%, and 3.16% over the original model in Precision (P), Recall (R), and mean average precision (mAP), respectively, on the SHWD dataset.**

***Keywords*—YOLOv8; safety helmet wearing detection; slim-neck; attention mechanism**

I. Introduction

In industrial production environments, complex and hazardous work types such as elevated operations and concurrent tasks frequently occur. Among these, incidents involving falling objects, impact collisions, and collapses often result in severe property damage and casualties. Statistics indicate that within the construction industry, accidents caused by falls, collisions, and collapses account for over 50% of all annual incidents [1]. The correct wearing of approved protective equipment represents the most direct and effective method to prevent such losses. However, in practical working environments, personnel frequently neglect wearing protective gear for various reasons. Consequently, monitoring the use of protective equipment by on-site workers is an effective means of ensuring construction safety. Currently, methods for monitoring the wearing of safety helmets within industrial sites primarily include the following: manual inspections, sensor-based detection, traditional image processing recognition, and deep learning-based target recognition methods. Early approaches primarily relied on sensors to detect helmet wear. For instance, Kelm et al. [2] developed an RFID-based system to monitor personal protective equipment compliance as personnel passed through security gates at construction site entrances. Dong et al. [3] employed pressure sensors embedded within protective gear to determine whether workers were wearing it. Traditional detection methods have gradually been phased out due to their complexity in both wearability and detection.

With the advancement of image processing technology, traditional image processing algorithms have gradually been applied to the detection of workers' safety equipment usage. Zhu et al. [4] proposed a rapid and stable algorithm for identifying safety helmets within substations. This approach first detects pedestrians within the substation; then, based on human body geometric features, locates the head position among pedestrians; finally, utilising the characteristic of minimal deformation in safety helmets, employs template matching to identify helmets, thereby determining whether the worker is wearing one. Jia et al. [5] proposed an algorithm for safety helmet detection. This approach utilises a deformable part model to generate block-based local binary pattern histograms, thereby recovering information lost when solely employing gradient direction histograms as features. However, these methods demand high image clarity and involve complex computations, resulting in low efficiency and recognition accuracy. Consequently, they prove unsuitable for complex and diverse industrial environments.

In recent years, deep learning technology has advanced rapidly. Object recognition networks based on deep learning are increasingly applied in practical scenarios due to their excellent real-time performance. Deep learning-based object detection primarily falls into two categories: two-stage networks and one-stage networks. The former primarily consists of two layers: the first layer extracts candidate regions, while the second layer classifies and precisely localises these regions. Representative models include Faster R-CNN [6]. The latter comprises a single layer, integrating classification and localisation into a unified implementation. Representative models include the SSD [7] and YOLO [8] series. Due to their superior detection efficiency and real-time performance, single-stage networks are extensively employed in practical research. Zhang et al. [9] proposed a novel helmet detection algorithm based on an enhanced YOLOv5 framework. This approach redesigns bounding box sizes using the K-Means++ algorithm, matching them to corresponding feature layers, and incorporates a multispectral channel attention module. This enhances the network's ability to distinguish foreground from background and improves overall detection performance. Su et

al. [10] proposed a helmet detection algorithm based on an enhanced YOLOX-s framework. This approach strengthened the model's feature representation capabilities by incorporating a small object detection head and integrating methods such as the SIoU loss function and CA attention mechanism. Han et al. [11] introduced an attention-based helmet-wearing status detection model, optimising it through a bidirectional multi-layer connection fusion feature pyramid network to enhance accuracy. Most recently, Yang et al. [12] designed an epistemic feature enhancement module to construct the backbone feature extraction network. They proposed a dual-scale feature fusion module to acquire and amplify local epistemic feature information of occluded targets, thereby improving detection accuracy for partially obscured objects. In the same year, Ding et al. [13] employed deeper convolutions to replace the small residual network in DeepSORT, enhancing appearance information extraction capabilities. Simultaneously, they added a query head to the decoupled head section to bolster detection performance. Although these approaches optimised algorithms to achieve certain improvements in model accuracy, they still suffer from issues such as high parameter counts and slow detection speeds, failing to meet edge computing requirements. Therefore, further refinements are necessary to enable models to deliver superior detection performance in complex small-object scenarios.

To address the aforementioned issues, this study proposes an enhanced safety helmet detection network, ASG-YOLOv8s, based on YOLOv8s to achieve efficient and precise safety management at the edge. The primary research contributions include:

- Introducing the AKC-SCAM module into the YOLOv8 backbone network. By dynamically adjusting the sampling shape of convolutional kernels, this enhances the extraction capability of multi-scale helmet features.
- Constructing the cross-scale interaction architecture Slim-neck within the feature fusion module. This replaces standard convolutions with GSConv and combines cross-level feature pyramids to facilitate effective interaction between deep semantic information and shallow detail features.
- Embedding the GAM attention mechanism before the multi-scale prediction layer for head detection. This establishes a dual-stream attention structure coordinating both channel and spatial attention to enhance effective feature responses while suppressing background noise.

II. Model Introduction

A. ASG-YOLOv8s Model

In the task of safety helmet detection, the YOLOv8s [14] model emerges as an ideal choice due to its lightweight design and high-efficiency performance. Compared to smaller-scale models such as YOLOv8n, YOLOv8s enhances feature reuse capabilities through its C2f [15] module. Combined with a decoupled head architecture that separates classification and regression tasks, it significantly improves detection accuracy for small-scale safety helmets. Compared to larger models like YOLOv8 l/x, it achieves a compact model size of 22-25MB by streamlining parameters and computational complexity. This strikes an efficient balance between accuracy and efficiency in industrial settings, making it well-suited for resource-constrained real-time detection requirements.

To enhance the detection performance of the YOLOv8 model in complex industrial settings, we first propose the AKC-SCAM module within the YOLOv8 backbone network to replace certain standard convolutional layers. This module integrates Adaptive Kernel Convolution (AKConv) with a Spatial Context-Aware Module (SCAM), dynamically adjusting the sampling shape of convolutional kernels to strengthen multi-scale defect feature extraction. This enhances the ability to capture edge textures of small-sized safety helmets worn by workers during bending operations. Secondly, a Slim-neck module is constructed within the Neck section, employing GSConv to replace conventional convolutions. This combines with a cross-hierarchical feature pyramid to achieve cross-scale interaction between deep semantic features and shallow-level details. Finally, a GAM module is embedded prior to the multi-scale outputs of the detection head, establishing a dual-stream attention mechanism for channels and spatial domains. This dynamically optimises the feature response intensity of low-quality candidate boxes, effectively mitigating missed detections in scenarios with dense occlusions. The overall architecture of the enhanced YOLOv8 network model is illustrated in Fig. 1.

B. AKC-SCAM Module

Whilst YOLOv8's backbone architecture enhances detection efficiency through multi-scale feature fusion and lightweight design, its core components still exhibit two pressing limitations requiring resolution: Firstly, the fixed kernel size of traditional 3×3 convolutions results in a static receptive field, rendering it ill-suited to dynamically adapt to the geometric deformation characteristics of irregular objects encountered in industrial inspection scenarios. Secondly, the consecutive stacking of Bottleneck structures within the C2f module induces parameter redundancy and a surge in computational complexity. To mitigate this phenomenon, this study proposes embedding the AKC-SCAM module—comprising AKConv (Adaptive Kernel Convolution) and SCAM (Spatial Context-Aware Module)—into the Bottleneck residual path of the C2f module, replacing the original 3×3 convolutional layer. This approach reduces model parameters while adaptively adjusting kernel sizes to extract features at different scales, thereby enhancing multi-scale feature extraction capabilities.

The core concept of the AKConv [16] module lies in efficiently extracting features through a convolutional kernel that dynamically adjusts both the number of parameters and the sampling shape, thereby enhancing network performance. The structural diagram of the AKConv module is shown in Fig. 2.

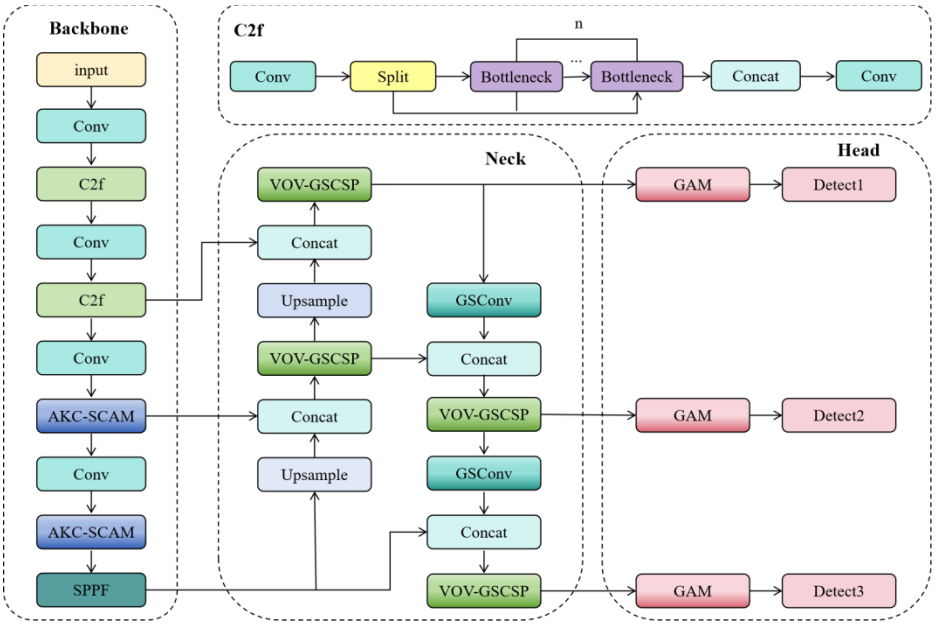

Fig. 1. The architecture of the ASG-YOLOv8s.

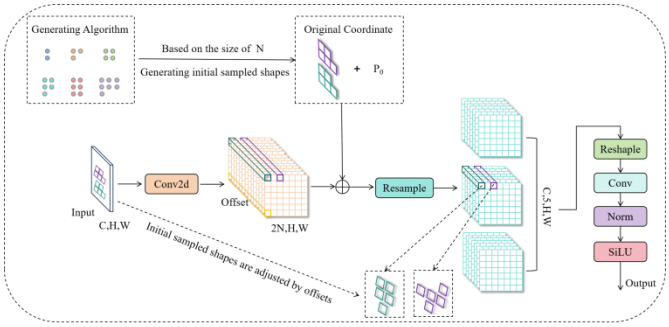

Fig. 2. Structure of the AKConv module.

In the diagram, the input to the AKConv module is a feature map with dimensions (C, H, W), where C denotes the number of channels, and H and W represent the height and width, respectively. The module first generates an initial sampling structure for the convolutional kernel using an initial sampling shape. It then performs a standard convolution operation on the feature map via Conv2d (two-dimensional convolution). Learned offsets dynamically adjust the initial sampling shape; this adaptive property enables the convolutional kernel to flexibly accommodate the spatial distribution of the feature map. The adjusted sampling shape further drives a resampling operation on the feature map to obtain a more optimal local feature representation.

SCAM [17] comprises a channel attention mechanism and spatial-channel reconstruction units. It first decomposes global pooling into horizontal pooling (X Avg Pool) and vertical pooling (Y Avg Pool), thereby effectively capturing long-range spatial interactions with precise positional information. The pooled feature maps undergo concatenation (Concat), convolution (Conv), and splitting (Split) operations to enhance the accuracy of feature representation. Furthermore, the Spatial Reconstruction Unit (SRU) and Channel Reconstruction Unit (CRU) introduced in SCConv perform sequential spatial and channel-wise restructuring on input feature maps. The SRU converts spatial features into spatial weight information, applying thresholds to differentiate weight values. Subsequently, two sets of weighted information are applied to the original feature map to obtain non-redundant and redundant feature maps. These are split and interleaved, producing a spatially reorganised feature map of identical scale to the original. This process refines the spatial information.

Following spatial reorganisation, the feature map employs CRU to restructure channel information, partitioning the input feature map channels into two segments. One portion of the channel features serves as a carrier for rich information, while the other functions as a carrier for secondary information. Distinct convolutional operations are applied to each segment, yielding a feature map refined from the channel information. At this stage, the original feature map undergoes spatial and channel information reorganisation through the SRU and CRU, reducing redundancy within the features. Subsequently, the feature maps restructured by the SRU and CRU are concatenated with the reweighted feature map. This approach enhances the accuracy of feature representation while maintaining lightweight processing, minimises redundant information within the features, and effectively improves model performance. The SCAM architecture is illustrated in Fig. 3.

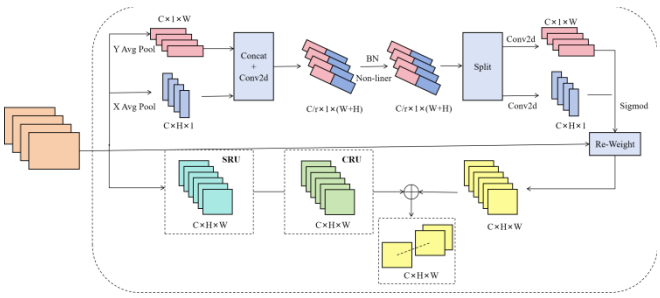

Fig. 3. Structure of the SCAM module.

C. Slim-neck Module

The neck network of YOLOv8 relies on dense convolutional operations during feature fusion, resulting in high parameter counts and computational complexity. To address this issue, this study proposes introducing the Slim-neck [18] module into the neck section. The Slim-neck module incorporates lightweight structures derived from GS bottleneck and VOV-GSCSP upon the foundation of GSConv [19] (Global Sparse Convolution), reducing model complexity while maintaining detection accuracy. GSConv represents a novel, lightweight convolution technique that enhances detection accuracy while reducing computational burden, differing from traditional approaches that increase accuracy by deepening network architecture and amplifying computational load. The GSConv architecture, illustrated in Fig. 4, processes input features through standard convolutional layers followed by depth-wise separable convolutions applied independently to each channel. Output features are then concatenated and rearranged via a shuffle operation to enhance inter-feature information flow. The GS bottleneck architecture further optimises GSConv, enhancing the network's feature processing capabilities. VOV-GSCSP [20] employs a one-time aggregation strategy, optimising certain module designs to improve feature utilisation efficiency and overall coherence.

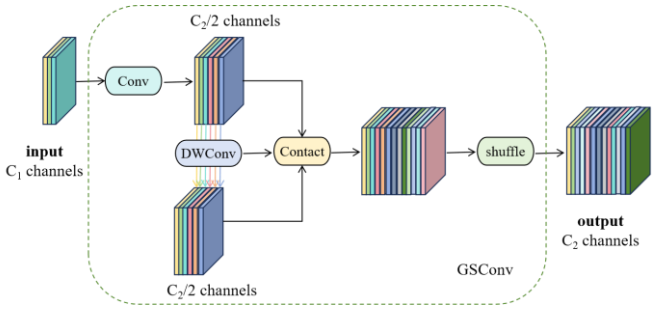

Fig. 4. Structure of the GSConv module.

D. GAM Attention Mechanism

To enable the model to adaptively focus on key regions within the input data while enhancing robustness and reducing computational complexity, this study incorporates a Global Attention Mechanism (GAM) module [21] before each detection head in YOLOv8. By integrating dual mechanisms of channel attention and spatial attention, GAM collaboratively captures key features across channel, spatial, and feature dimensions, achieving global context modelling of input data. Its primary structure is illustrated in Fig. 5. Specifically, the channel attention module extracts channel importance weights through Global Average Pooling (GAP) and Global Max Pooling (GMP), then employs a shared Multi-Layer Perceptron (MLP) to generate channel weight vectors, thereby reinforcing key semantic features, as depicted in Fig. 5(a). The spatial attention module generates spatial saliency maps through parallel global pooling and 7×7 convolutions, focusing on the spatial distribution information of target regions, as depicted in Fig. 5(b). Subsequently, the two weight types interact through element-wise multiplication to achieve multidimensional feature interaction, ultimately outputting an optimised feature representation. Compared to the conventional Convolutional Attention Module (CBAM) [22], GAM further incorporates a dynamic weight allocation strategy. This enhances the perception of fine-grained features in complex scenes while reducing redundant computational overhead through lightweight design, thereby improving model performance.

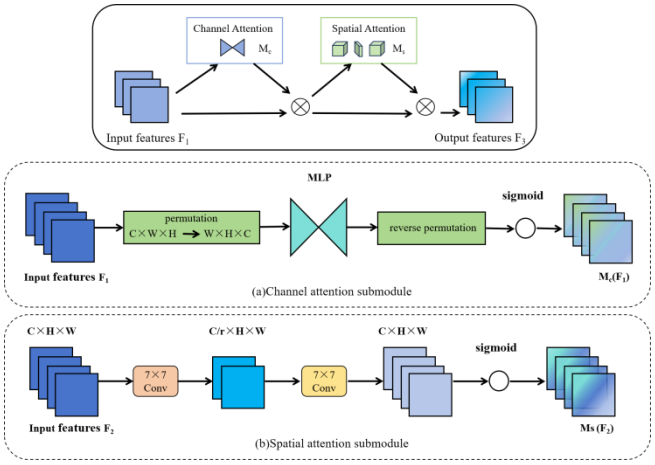

Fig. 5. Structure of the GAM module.

III. Experimental Data and Analysis

A. Datasets and Evaluation Metrics

The dataset employed herein should encompass construction sites across different seasons and complex weather conditions to fulfil the experimental requirements of this study. The dataset utilised in this experiment was created by refining the publicly available Safety-Helmet-Wearing-Dataset (SHWD). This involved removing unsuitable images and substantially augmenting the dataset with additional construction site scenarios, resulting in the SHWD-T construction site helmet dataset comprising 21,480 images. The dataset was randomly partitioned into training, validation, and test sets in an 8:1:1 ratio to facilitate subsequent data processing and analysis. All experiments were conducted without loading pre-trained weights.

To evaluate the model's performance and the accuracy of helmet detection, this study employs three metrics: Precision (P), Recall (R), and Mean Average Precision (mAP). The corresponding equations are presented in Eq. (1) to Eq. (3):

$$P = \frac{TP}{TP + FP} \tag{1}$$

$$R = \frac{TP}{TP + FN} \tag{2}$$

$$\text{mAP} = \frac{1}{N}\sum_{i=1}^{N} AP_i \tag{3}$$

In the equation: TP (True Positive) denotes the number of predicted boxes matching actual boxes; FP (False Positive) denotes the number of predicted boxes differing from actual boxes; FN (False Negative) denotes the number of objects contained within images that were not correctly detected during prediction; N represents the number of categories delineated in this study.

B. Ablation Experiment

To validate the effectiveness of the algorithmic improvement strategy proposed herein, eight sets of ablation experiments were conducted on the SHWD-T dataset based on the YOLOv8 baseline. The experimental results obtained from various experimental models are presented in Table I.

TABLE I. ABLATION EXPERIMENT RESULTS

AKC-SCAM	*Slim-neck*	*GAM*	*P/%*	*R/%*	*mAP/%*
-	-	-	87.26	80.52	83.62
√	-	-	88.07	81.22	84.30
-	√	-	88.92	81.88	85.16
-	-	√	88.44	82.73	84.41
√	√	-	89.07	81.65	84.83
√	-	√	88.49	82.07	85.29
-	√	√	89.09	82.50	85.63
√	√	√	89.80	83.46	86.78

Experiments reveal that incorporating the AKC-SCAM backbone network yields an 0.86% improvement in mAP compared to YOLOv8, demonstrating that the AKC-SCAM module effectively enhances the model's object recognition accuracy and strengthens its feature representation capabilities. Following the integration of the Slim-neck module, the model's mAP value increased by 1.84%, demonstrating that this lightweight neck design optimises feature propagation and enhances detection performance without significantly increasing computational overhead. The combined approach of YOLOv8 + AKC-SCAM + Slim-neck + GAM elevated the P value to 89.80%, the R value to 83.46%, and the mAP to 86.78%. This demonstrates that the synergistic interaction among these three components can substantially enhance the model's comprehensive detection capabilities.

Overall, the refined algorithm demonstrably enhances the model's comprehensive detection capabilities compared to YOLOv8, particularly by achieving a comprehensive improvement in detection accuracy while maintaining model lightness. This validates the effectiveness and superiority of the proposed methodology.

C. Contrast Experiment

To comprehensively evaluate the performance of the improved YOLOv8 network in helmet detection tasks, comparative experiments were conducted on the SHWD-T dataset against several classical object detection networks and state-of-the-art algorithms. As shown in Table II, the proposed ASG-YOLOv8s model demonstrates significantly superior detection accuracy compared to other methods.

TABLE II. CONTRAST EXPERIMENT RESULTS

Model	Experimental parameters		
	P/%	*R/%*	*mAP/%*
ASG-YOLOv8s	89.80	83.46	86.78
RFBNet	82.6	73.4	75.60
YOLOv5	86.40	78.60	82.70
YOLOv8	87.26	80.52	83.62
SSD	86.30	76.70	82.20
DAAM-YOLOv5	86.70	78.60	83.30
YOLOv7	87.98	84.21	85.76
YOLOv3-tiny	79.87	75.89	78.65
SSD	79.91	70.34	77.65
Faster RCNN	80.35	71.26	78.14
MEM-YOLOv8	87.50	76.60	83.20

D. Experimental Results Analysis

To validate the performance of the ASG-YOLOv8s model in practical detection scenarios, this study tests images captured across various complex construction site environments. Fig. 6 presents detection results from both the ASG-YOLOv8s and YOLOv8s models across distinct scenarios: Fig. 6(a) depicts a scene with background interference, Fig. 6(b) shows a densely populated target scenario, and Fig. 6(c) illustrates an occlusion scenario. The left column presents detection results from the YOLOv8s model, while the right column shows results from the ASG-YOLOv8s model. Comparing these outcomes enables an assessment of performance differences between the two models in diverse environments. It is evident that the YOLOv8s model is prone to both missed detections and false positives in complex environments, exhibiting lower detection accuracy. Conversely, the ASG-YOLOv8s model demonstrates superior performance, accurately detecting small objects within intricate settings.

(b) Dense Target Scenario.

(c) Occlusion of Target Scenes.

Fig. 6. Comparison of model detection results in different job scenarios.

IV. Conclusion

To address the issues of delayed response times in manual industrial safety monitoring and high false detection rates for small targets such as safety helmets due to dynamic changes in monitoring distance, this study proposes the ASG-YOLOv8s enhanced algorithm. Firstly, the AKC-SCAM module is introduced into the backbone network to replace some standard convolutional layers in the conventional backbone. Secondly, a Slim-neck module is constructed in the Neck section, employing GSConv to substitute traditional convolutional kernels. Finally, a GAM module is embedded prior to the multi-scale outputs of the detection head. Experimental results demonstrate that the proposed ASG-YOLOv8s model achieves improvements of 2.54%, 2.94%, and 3.16% in Precision, Recall, and mAP, respectively, over the original model on the SHWD-T dataset. This indicates that the ASG-YOLOv8s algorithm exhibits superior detection accuracy, with significant enhancements in detecting occluded and small targets, rendering it well-suited for safety helmet detection applications.

A Comparative Review of AI, IoT, and Big Data in Healthcare: Towards a Data-Centric Approach for Enhanced Data Quality and Contextual Adaptability

Imane RAFIQ, Zahi JARIR, Hiba ASRI
LISI-Faculty of Sciences Semlalia, Cadi Ayyad University, Marrakech, Morocco

***Abstract*—The convergence of Artificial Intelligence (AI), the Internet of Things (IoT), and Big Data is revolutionizing healthcare by enabling predictive diagnostics, real-time monitoring, and personalized treatment through data-driven analytics and intelligent decision-making. Despite these advancements, the effectiveness of such systems is significantly hindered by poor data quality, including issues such as missing values, noise, bias, and inconsistencies. This study presents a systematic and comparative review of recent research at the intersection of AI, IoT, and Big Data in healthcare, highlighting critical gaps in data quality that undermine model performance and real-world reliability. In response, we introduce the Data-Centric AI (DCAI) paradigm as a promising approach focused on systematic data improvement rather than model complexity. We examine the application of the METRIC framework for assessing data quality dimensions such as completeness, consistency, fairness, and timeliness. Furthermore, we propose future research directions to improve scalability and trustworthiness in AI-driven healthcare, integrating advanced AI techniques such as generative AI and multimodal frameworks with DCAI principles for more ethical AI applications. This work serves as both a comparative synthesis of existing literature and a conceptual foundation for future experimental validation through a case study integrating context-aware data modeling and real-time decision support.**

***Keywords*—Data-Centric AI; IoT; Big Data Analytics; healthcare informatics; data quality; bias mitigation; privacy; predictive analytics; machine learning; disease prediction**

I. Introduction

The convergence of Artificial Intelligence (AI), Big Data, and the Internet of Things (IoT) is reshaping modern healthcare by enabling real-time monitoring, predictive diagnostics, and personalized treatment pathways. These technologies promise improved patient outcomes, operational efficiency, and data-driven clinical decision-making. However, the performance and reliability of such systems are not solely dependent on advanced algorithms—they are fundamentally tied to the quality and integrity of the underlying data.

Healthcare data, particularly from heterogeneous IoT environments, is often plagued by issues such as missing values, noise, demographic bias, and inconsistencies, which compromise clinical accuracy and fairness [1]. Additionally, challenges around interoperability, privacy, and regulatory compliance continue to impede scalable AI adoption in real-world healthcare settings [2], [3].

Traditional approaches have predominantly focused on model-centric AI (MCAI), prioritizing algorithmic optimization while assuming static, clean datasets. This focus has resulted in unreliable predictions, biased treatment recommendations, and limited generalizability across diverse patient populations [4]. In healthcare—where errors can be life-threatening—this paradigm is no longer sustainable. The increasing complexity of multimodal healthcare data, combined with real-time demands and stringent privacy constraints, requires a shift in focus: from model optimization to systematic data enhancement. As recent findings emphasize that improvements in data quality can often outperform equivalent enhancements in model complexity, especially in critical settings like clinical diagnostics or patient monitoring [5], [6], and that poor data quality, like mislabeled samples, can propagate errors throughout the AI lifecycle, leading to unsafe or inequitable medical decisions[5], [7]. The result is a growing consensus that high-quality, well-curated data must be central to AI development.

Despite widespread research on AI and IoT integration in healthcare, there remains no unified framework that systematically addresses how data quality, fairness, and interoperability should be prioritized to enable robust, ethical AI systems. Data-Centric AI (DCAI) —a paradigm that prioritizes the systematic curation, preprocessing, and contextual enrichment of data to improve AI model performance and fairness— has emerged as a promising approach to filling this void [8], [9]. However, its application within healthcare remains underexplored and unstandardized.

This study offers a conceptual and comparative synthesis of existing AI-IoT-Healthcare literature through the lens of DCAI. While no experimental implementation is conducted, our aim is to theoretically map how DCAI principles can address persistent data quality limitations in healthcare systems. We seek to bridge that gap by comparing twenty-three AI-IoT-Healthcare studies and analyzing DCAI's theoretical and practical potential to enhance data quality. We explore a structured conceptual framework that maps DCAI principles to recurring healthcare challenges—specifically related to data noise, bias, missing values, and contextual inconsistency—, offering pathways toward more scalable, interpretable, and trustworthy AI solutions. Additionally, we identify future directions, including emerging techniques such as generative AI, multimodal integration, and advanced data recovery techniques as promising complements to DCAI in clinical contexts. This study sets the

foundation for future empirical validation through real-world case studies or clinical datasets.

Fig. 1 illustrates the layered integration of IoT, Big Data, and AI within smart healthcare systems. IoT devices serve as the primary data acquisition layer, collecting real-time physiological and behavioral data. This raw data is then aggregated and processed through Big Data infrastructures, which handle high-volume, high-velocity data streams for storage, cleaning, and transformation. The processed data feeds AI algorithms at the decision layer, where predictive models generate insights for diagnostics, risk stratification, and personalized care. This pipeline enables closed-loop feedback mechanisms, supporting adaptive, context-aware healthcare while ensuring scalability, data integrity, and privacy compliance.

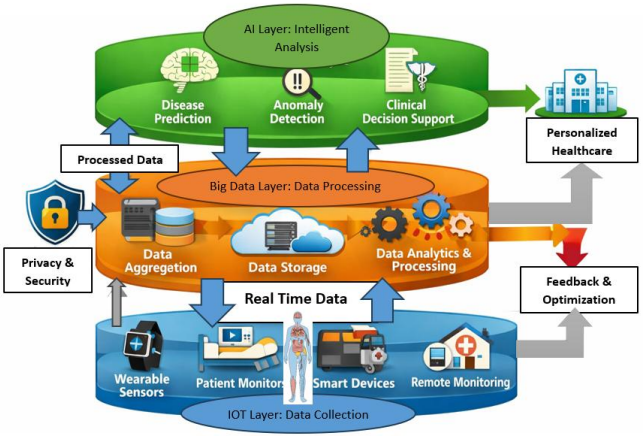

Fig. 1. Integration of AI, IoT, and Big Data in smart healthcare systems.

The remainder of this study is organized as follows: Section II presents related work and the structured literature review methodology. Section III details the technological and operational challenges in AI-driven healthcare. Section IV introduces DCAI concepts and applications. Section V maps DCAI to persistent data quality issues. Section VI outlines relevant data quality metrics. Section VII discusses study limitations. Section VIII explores future research directions, and Section IX concludes with reflections on ethical, scalable AI in healthcare.

II. Background and Related Work

A. Literature Review and Methodology

AI, Big Data, and IoT have driven major advances in healthcare, facilitating predictive diagnostics, real-time monitoring, and data-driven decision-making. Despite the technical sophistication of these systems, their real-world effectiveness is frequently compromised by persistent challenges—including poor data quality, heterogeneity, lack of standardization, and privacy concerns. These issues threaten the reliability, fairness, and scalability of AI applications in healthcare environments.

Data-Centric AI (DCAI) has recently emerged as a promising paradigm to tackle these challenges by emphasizing the quality, structure, and contextual integrity of data over algorithmic complexity. Yet, dedicated review studies that explore DCAI's practical implications in healthcare settings are scarce. This work addresses that gap by conducting a structured review of both foundational DCAI literature and application-oriented studies that highlight real-world limitations in AI, Big Data, and IoT for healthcare.

To ensure scientific rigor, the review process followed a structured literature selection methodology that allows our work to reflect the contributions of prior research on IoT, AI, and Big Data in healthcare, while also incorporating foundational studies on DCAI principles and data quality metrics. Our goal is to highlight the ongoing shift from model-centric to data-centric approaches and to underscore the growing relevance of DCAI-based solutions in healthcare AI.

1) Search strategy and data sources: The literature search was conducted using a multi-database strategy to encompass a broad range of both technical and medical research publications, ensuring comprehensive coverage of both theoretical AI/IoT research and practical healthcare applications. The following academic databases were selected:

- IEEE Xplore
- Scopus
- Web of Science
- PubMed
- ScienceDirect
- Google Scholar

Our search queries combined key terms related to AI, IoT, Big Data, and healthcare, for the selection of the 23 articles such as: "Artificial Intelligence", "Machine Learning", "Deep Learning", "Internet of Things", "Healthcare IoT", "Big Data Analytics", "Context-Aware Systems", and "Smart Healthcare".

Boolean operators were applied to refine results [e.g., ("Artificial Intelligence" OR "Machine Learning" OR "Deep Learning") AND ("Internet of Things" OR "Healthcare IoT") AND ("Big Data Analytics" OR "Smart Healthcare" OR "Real-time Monitoring") AND ("Context-Aware Systems" OR "Privacy" OR "Interoperability" OR "Clinical Decision Support Systems")]. The search was limited to the 2016–2025 publication window. Manual adjustments were made to avoid duplicated retrievals across platforms.

2) Eligibility criteria: The search was conducted on publications between 2016 and 2025, and duplicates were removed. The citation management tool Rayyan was used to facilitate collaborative screening, inclusion/exclusion filtering, and conflict resolution during selection. In Table I, our chosen eligibility criteria that were applied to the various screening steps of our selection process of the twenty-three peer-reviewed application-oriented studies are listed.

3) Selection and analysis process: An initial screening based on titles and abstracts was performed, followed by a full-text review of eligible articles. Twenty-three studies were ultimately selected as representative of prevailing practices and

challenges in AI, IoT, and Big Data-driven healthcare systems for prediction, monitoring, and decision-making.

TABLE I. ELIGIBILITY CRITERIA APPLIED TO THE SCREENING AND FULL-TEXT ASSESSMENT PROCESSES

Criterion	
Inclusion	Peer-reviewed journal articles or chapter book or conference papers
	Publications between 2016 and 2025 published in **English**
	Studies addressing healthcare applications of AI, IoT, and/or Big Data for predictions of diseases or monitoring or real word application
	Articles discussing at least one of the following: challenges related to data quality, context awareness, interoperability, scalability, privacy, Healthcare diagnostics, monitoring, decision support using AI/IoT or Real-time systems.
Exclusion	Non-peer-reviewed sources, editorials, or opinion pieces
	Studies unrelated to healthcare applications
	Works focused exclusively on algorithms without consideration of data characteristics or system-level integration
	Redundant or overlapping publications

To bridge the gap between these practical challenges and the conceptual framework of DCAI, the tool Rayyan was used to facilitate collaborative screening, conflict resolution, and exclusion tagging. This process resulted in the selection of:

- Seven Foundational DCAI Publications outlining data-centric concepts, lifecycle frameworks, data-centric design principles, and metrics for evaluating data quality
- Twenty-Three Application-Oriented Studies demonstrating real-world applications and challenges in AI-IoT-Big Data healthcare systems.

A PRISMA-style flow diagram (Fig. 2) outlines the article selection workflow, culminating in the inclusion of twenty-three peer-reviewed studies focused on AI and IoT applications in healthcare. These articles were analyzed using a unified comparison framework emphasizing data sources, modeling techniques, evaluation outcomes, and reported limitations. This methodology enabled a systematic comparative analysis and the extraction of key limitations, forming a solid foundation for identifying research gaps addressed by the Data-Centric AI (DCAI) paradigm.

To enhance analytical depth and provide objective insights, a quantitative content analysis was also performed. Each selected study was reviewed to extract explicitly stated limitations related to data quality, scalability, interoperability, privacy, and integration. These issues were then categorized by frequency, allowing the construction of a visual summary of common challenges (see Fig. 3). This process not only highlighted recurring barriers but also emphasized the relevance of DCAI as a unifying approach to overcome these limitations.

Table II presents an organized summary of the core literature reviewed in this study, categorized by focus and contribution.

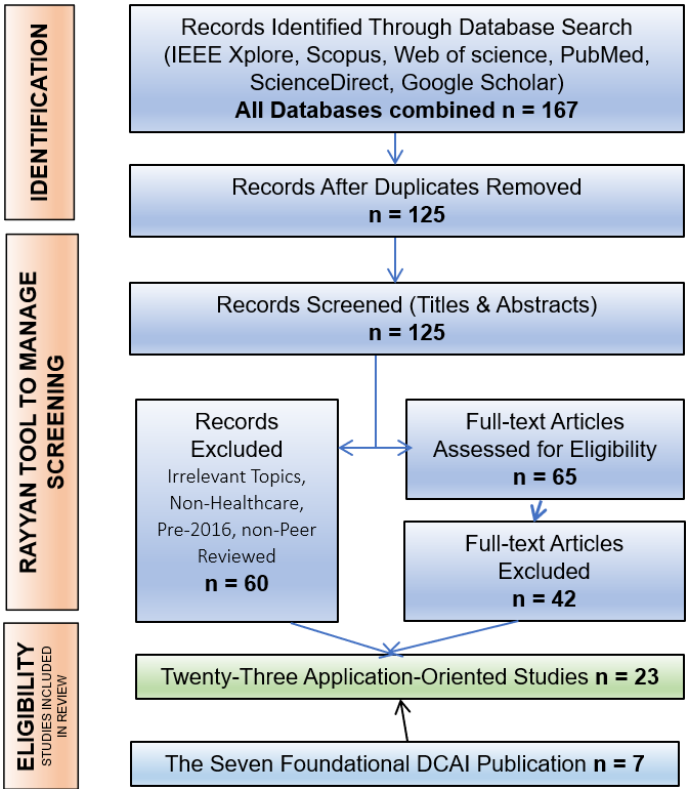

Fig. 2. PRISMA-style flow diagram illustrating the article selection process. A total of 167 records were initially identified from six academic databases. After removal of duplicates and exclusion based on titles and abstracts, 65 full-text articles were reviewed. Finally, 23 articles were selected as application-oriented studies in healthcare AI, IoT, and Big Data and added to 7 foundational DCAI publications. Rayyan was used to manage and streamline the screening process.

A. Comparative Analysis of AI, IoT, and Big Data Healthcare Studies

To assess the state of healthcare applications involving AI, IoT, and Big Data, we conducted a comparative analysis of the 23 peer-reviewed studies published between 2016 and 2025. Based on the defined inclusion and exclusion criteria, these studies were selected for their relevance to disease prediction, patient monitoring, smart healthcare systems, and healthcare infrastructure. Our objective was to extract common practices, recurring challenges, and methodological gaps that inform the need for a shift toward the emerging data-centric paradigm.

1) Categories of reviewed studies: To move beyond a structured descriptive synthesis, the selected 23 articles were classified into four primary domains based on their methodological focus and healthcare application scope. Within each category, we explicitly compare approaches, data dependencies, and reported limitations to identify recurring patterns and systemic gaps.

a) Context-aware systems and adaptive intelligence: Several studies underscore the importance of integrating environmental, behavioral, and physiological context for more accurate and responsive healthcare interventions. In [10], Zon et al underscored the lack of context-aware medical systems, which limits adaptability to patient conditions, addressing the difficulty of integrating context-aware medical systems due to heterogeneous healthcare data, highlighted the lack of a structured understanding of medical contexts, and identified key medical contexts for AI adaptation. Similarly, in [11], Chung et al. proposed an ambient context-based deep neural network that leverages contextual health data for health risk

assessment in patients with chronic diseases, improving prediction accuracy but facing issues with heterogeneous and noisy input IoT data. In [12], Kim & Chung advanced this area by developing a neural network-based adaptive context prediction model for ambient intelligence, which enhanced patient care personalization. Their approach demonstrated an enhanced ability to predict and adapt to various patient states, leading to better patient care, though the systems required further validation due to data integration complexity. In [13], Saranya & Fatima tackled data heterogeneity in IoT-based patient monitoring by developing an improved context-aware data fusion model that enhances security and optimizes data integration from multiple sensors, achieving high precision in real-time health monitoring. In [14], Aborokbah et al. proposed an adaptive computing paradigm that utilizes machine learning techniques, which improved chronic disease management but required further validation for diverse populations.

While all studies acknowledge context as a critical factor, most approaches treat context as an auxiliary feature rather than a first-class data entity. None adopts a systematic data-centric strategy to validate, curate, or standardize contextual information, leading to scalability and robustness limitations.

b) Disease prediction and monitoring: IoT-enabled models for real-time monitoring and diagnosis are prominently featured. In [13], Saranya & Fatima proposed a fusion model for wearable data that achieved 97.9% accuracy in patient monitoring but faced issues of sensor reliability and cybersecurity. The need for real-time disease prediction was explored by Kishor & Chakraborty in [20], who integrated IoT with machine learning classifiers, obtaining high accuracy but encountering real-time processing constraints. Meanwhile, in [22], Kaur investigated the increasing prevalence of heart diseases and the need for predictive models that can provide timely warnings and applied IoT and machine learning for heart disease prediction, demonstrating high accuracy but struggling with data privacy and completeness. Similarly, in [3], Meraj et al reviewed IoT-based infectious disease detection, emphasizing the need for real-time outbreak prediction, though sensor noise and lack of data remained challenges. In [26], Castro et al. focused on wearable-based human activity recognition using IoT and developed a machine learning-based system that classified physical activities, achieving improved movement detection accuracy, but environmental noise remained a limiting factor. In [29], Shah et al. conducted a case study on IoT-based sensing for healthcare applications, focusing on detecting narcolepsy episodes and implemented machine learning classifiers to identify sleep disorder patterns, demonstrating that IoT sensors could effectively improve sleep disorder diagnosis and patient monitoring. Additionally, in [28], Ngiam & Khor reviewed the challenges and opportunities of applying machine learning algorithms in healthcare and emphasized the importance of high-quality data preprocessing and ethical considerations in AI-driven healthcare systems, demonstrating that integrating AI could enhance prediction and diagnostic accuracy while raising concerns about data bias, data labeling, annotation inconsistencies and privacy. The study [16] is a more recent contribution by Zonayed et al. that comprehensively synthesizes the advancements, challenges, and future directions of integrating Machine Learning (ML) and the Internet of Things (IoT) in healthcare. This integration facilitates real-time health monitoring and the analysis of intricate medical datasets, yielding insights that support evidence-based clinical decision-making. The review highlights the high predictive accuracy (85%–95%) achieved by models like CNNs and XGBoost, particularly in diagnostics and chronic disease management. Challenges remain concerning data security, interoperability, and ethical transparency, scalability, and the need for explainable AI to foster clinical trust and ethical transparency. Future direction must prioritize robust security, standardization, and effective human-AI collaboration to fully realize the potential of Healthcare 5.0. Finally, in [30], Tian et al. analyzed the potential of smart healthcare technologies, including IoT, AI, and Big Data, in making medical care more efficient and personalized and identified key areas where smart healthcare solutions could improve hospital management and patient engagement, highlighting the necessity of integrating intelligent systems for optimizing healthcare operations.

Across this category, models are predominantly model-centric, focusing on algorithm selection and accuracy optimization, while data quality issues are treated as secondary concerns. This imbalance limits real-world generalization despite strong experimental results.

c) Big Data analytics and infrastructure challenges: In [23], Vijayalakshmi et al. introduced a Big Data-driven model to enhance disease forecasting using machine learning techniques and leveraged Big Data analytics for chronic disease prediction, improving classification accuracy but struggling with data sparsity and labeling errors. Respectively, a broader examination of IoT and Big Data analytics in biomedical healthcare was conducted by Banerjee et al in the chapter [2], who highlighted standardization challenges in wearable device data processing, where latency remained a key limitation. Both noted substantial improvements in data-driven decision-making, but also highlighted latency issues, sparse data, and infrastructural limitations. In [21], Ghazal et al. applied machine learning for smart healthcare infrastructure, optimizing medical resource allocation, but still faced data quality issues. In [29], Šajnović et al. conducted a large-scale synthetic review that analyzes 2272 publications from the Scopus database on the intersection of the Internet of Things (IoT) and Big Data Analytics in preventive healthcare, observing exponential literature growth since 2012, peaking in 2023. The study identifies eight key themes, including the role of AI in personalized medicine (genetics/genomics) and risk prediction, and the use of big data in public health and epidemiology, alongside critical challenges concerning data security, privacy, interoperability, ethical concerns, and the high cost of the IoMT system. In the comprehensive survey [18], Charfare et al. examine the integration of IoT and AI technologies in healthcare applications. The study reviews 28 AI/ML models across diverse applications, including disease detection (COVID-19, diabetes), patient monitoring, athletic performance tracking, and elderly care. Top-performing models

include LightGBM (99.23% accuracy for activity recognition) and LSTM (99% for fall detection). Key challenges identified include data security, computational constraints, energy efficiency, and interoperability issues. The study emphasizes future research directions in federated learning, adaptive algorithms, and multi-modal data fusion for enhanced healthcare delivery. In [19], Alsabah et al. conducted a comprehensive analysis of IoT-based smart healthcare systems, focusing on the interplay between edge computing, cloud services, and data analytics. They examine AI/ML applications in smart healthcare, analyzing studies covering disease diagnosis (glaucoma, diabetic foot ulcers, skin diseases), medical image encryption, and IoT security. Key technologies include CNNs, deep learning, federated learning, and blockchain-based privacy protection. Models demonstrate enhanced diagnostic accuracy, early disease detection, and secure data transmission. Applications span medical imaging, remote health monitoring, and intrusion detection. Their review highlights technical challenges such as system scalability, latency, and real-time decision-making, particularly when handling massive healthcare datasets. They also underscore the need for high-throughput infrastructure capable of managing heterogeneous medical data while ensuring interoperability and low-latency processing. In [27], Chui et al. focused on patient behavior monitoring using IoT and Big Data analytics and developed a framework to analyze patient movement patterns and predict potential health risks, providing valuable insights for caregivers, improving patient safety, and reducing hospital readmissions.

While Big Data enables broader population-level insights, the absence of standardized data pipelines and quality control mechanisms limits scalability and reproducibility—issues that are not addressed by model improvements alone.

d) Privacy, security, and interoperability: The integration of IoT and AI has exposed healthcare systems to data privacy risks and interoperability hurdles. In [25], Aceto et al. examined the role of IoT and Big Data in Healthcare 4.0, improving data fusion for personalized medical services, while highlighting privacy concerns. Similarly, in [31], Yin et al. provided an overview of the Internet of Things in healthcare, summarizing its applications, challenges, and future directions, and discussed the importance of data security, interoperability, and regulatory considerations in IoT-based healthcare systems, emphasizing the need for robust security frameworks to ensure patient data protection. In [24], Verma et al. developed a hybrid secure cloud IoT framework for disease prediction and diagnosis, which improved data security and accuracy of disease diagnosis but raised concerns regarding scalability and privacy.

These studies clearly demonstrate that privacy and interoperability are not peripheral concerns, but structural constraints. However, they remain loosely coupled to AI model design, reinforcing the need for an integrated data-centric framework.

2) Key observations and emerging gaps: These studies converge on a critical insight: while model-centric innovations have improved local accuracy, they often neglect systemic issues related to data quality and governance. Few solutions prioritize data refinement as a strategic goal, dataset representativeness, noise reduction, or robust data integration—gaps which DCAI directly addresses. As shown in Table III, the reviewed studies highlight recurring limitations (e.g., noisy data, lack of standardization, sensor faults, and unstructured inputs) that underscore the need for a paradigm shift toward DCAI methodologies.

To consolidate the expanded comparative insights derived from the 23 reviewed studies, we performed an updated quantitative synthesis of the key limitations reported in AI-, IoT-, and Big Data-driven healthcare systems. As illustrated in Fig. 3, privacy concerns remain the most dominant challenge, cited in 10 studies (43.5%), reflecting persistent issues related to patient data protection, regulatory compliance, and trust in large-scale digital health infrastructures. Data heterogeneity follows closely, reported in 9 studies (39.1%), highlighting the ongoing difficulty of integrating heterogeneous data sources such as IoT sensors, EHRs, and unstructured clinical data. Noisy data was identified in 6 studies (26.1%), underscoring the impact of sensor inaccuracies, transmission errors, and real-world data variability on model reliability. A second tier of limitations includes security risks and integration challenges, same as noisy data limitation each reported in 6 studies (26.1%), indicating that secure data exchange and seamless system interoperability remain unresolved barriers. Real-time processing constraints, data sparsity, and scalability limitations were each mentioned in five studies (21.7%), reflecting the computational and infrastructural challenges of deploying AI systems in dynamic clinical environments. Missing values were cited in 4 studies (17.4%), pointing to data incompleteness issues arising from sensor failures and fragmented health records. Lower-frequency yet significant concerns include standardization issues and sensor faults (same as missing values limitation every four studies, 17.4%), as well as contextual inconsistencies, bias, ethical concerns, and labeling errors (each reported in two to three studies, ~8.7–13%). Collectively, these findings demonstrate that many of the most critical obstacles are fundamentally data-centric rather than model-centric, reinforcing the necessity of Data-Centric AI (DCAI) approaches that prioritize data quality, governance, interoperability, and scalability as prerequisites for trustworthy and effective healthcare AI deployment.

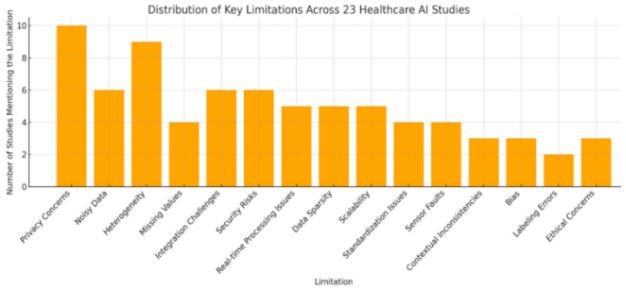

Fig. 3. Distribution of key limitations mentioned across 23 reviewed healthcare AI studies. Privacy, noise, and data heterogeneity emerge as the most cited barriers, underscoring the need for robust data quality and governance frameworks.

3) Summary of comparative insights

a) IoT-based healthcare solutions: Many studies emphasize real-time patient monitoring but lack context-aware and adaptive AI models to dynamically adjust to patient conditions [3], [10].

b) AI for predictive healthcare: AI models demonstrate strong disease prediction capabilities, but their accuracy is often limited by poor data quality, missing values, and a lack of contextual understanding [11], [23].

c) Security and privacy concerns: IoT-driven healthcare systems are highly vulnerable to cyber threats, necessitating secure data-sharing and privacy-preserving [13], [24].

d) Interoperability issues: The absence of standardized data formats and frameworks inhibits seamless integration between healthcare systems and IoT devices, creating barriers to efficient data exchange [25], [31].

These studies demonstrate the growing impact of IoT, AI, and Big Data in modern healthcare, particularly in areas such as real-time monitoring, predictive diagnostics, and personalized treatment. However, most adopt a model-centric approach that prioritizes algorithm performance over data integrity. Persistent data issues continue to undermine scalability, fairness, and reliability. In response, this study advocates for the DCAI paradigm, which prioritizes high-quality, standardized, and context-aware datasets as the foundation for trustworthy and adaptive healthcare systems.

TABLE III. COMPARATIVE ANALYSIS OF HEALTHCARE AI-IOT STUDIES

Ref	Model Used	Application	Data Type & Source	Metrics for Evaluation	Results of the Study	Limitations
[10] Zon et al. (2023)	Various Context-Aware Systems (The study primarily reviews various context-aware models used in healthcare applications, without focusing on a specific single model)	Context-aware healthcare applications that utilize user location, demographic information, activity level, time of day, phone usage patterns, lab/vital metrics, and patient history data.	Healthcare IoT & Sensor Data from 25 peer-reviewed articles found in databases	Accuracy, Sensitivity	Identified key medical contexts for AI adaptation, Improved patient-centered healthcare	Context heterogeneity affects reliability and lack of details on methods for determining contexts and on the systems currently used.
[11] Chung et al. III. Challenges in Integrating AI, Big Data, and IoT in Healthcare

Despite the transformative potential of AI, Big Data, and IoT in healthcare, their integration faces substantial barriers that impact reliability, scalability, and ethical deployment. A recurring limitation is data quality, particularly in real-time environments driven by sensor-generated streams.

Challenges stem from noise, missing data, inconsistencies, interoperability issues, privacy concerns, and bias, all of which hinder AI reliability and scalability in healthcare. Sensor noise, such as movement artifacts or calibration errors in ECG devices, distorts predictions and triggers false alarms [13]. Missing data further weakens AI models, leading to biased and unreliable decision-making, as gaps in patient records degrade deep learning performance [1]. Inconsistencies across IoT devices, caused by variations in data formats and protocols, complicate seamless integration, requiring standardized frameworks [21]. Without robust standardization, data fusion from disparate sources remains a technical bottleneck. Bias in IoT-generated datasets, often due to demographic imbalances or inconsistent labeling, results in inequitable AI predictions that disproportionately impact underrepresented populations [12]. Additionally, privacy risks, such as data anonymity and pseudonymization, affect dataset usability and AI predictive accuracy, making privacy governance essential in AI applications [1]. Scalability and real-time adaptability remain obstacles, with many AI models struggling to dynamically adjust to changing patient conditions [12]. Furthermore, interoperability issues between IoT devices, AI models, and hospital systems create siloed environments that restrict data sharing and hinder holistic patient care [30], [31].

Poor data quality in AI-driven healthcare systems can lead to severe outcomes, including misdiagnosis, inequitable care delivery, and loss of clinical trust. According to Jin et al. in [5], imperfections such as incorrect labels, missing values, and anomalies not only degrade model performance but risk overfitting and undermine generalizability—particularly critical in healthcare where model predictions influence life-altering decisions. In [6], Nieberl et al. emphasize that data cascades, which occur when initial quality issues propagate through the pipeline, are a hidden yet profound threat to AI reliability.

Building on our literature-driven hypothesis, we propose that Data-Centric AI (DCAI) offers a viable pathway to overcoming these challenges by emphasizing data quality, fairness, security, and standardization, ensuring more reliable AI-driven healthcare outcomes [4], [9]. Fig. 4 illustrates the major data-related challenges encountered in the integration of AI, Big Data, and IoT for Healthcare.

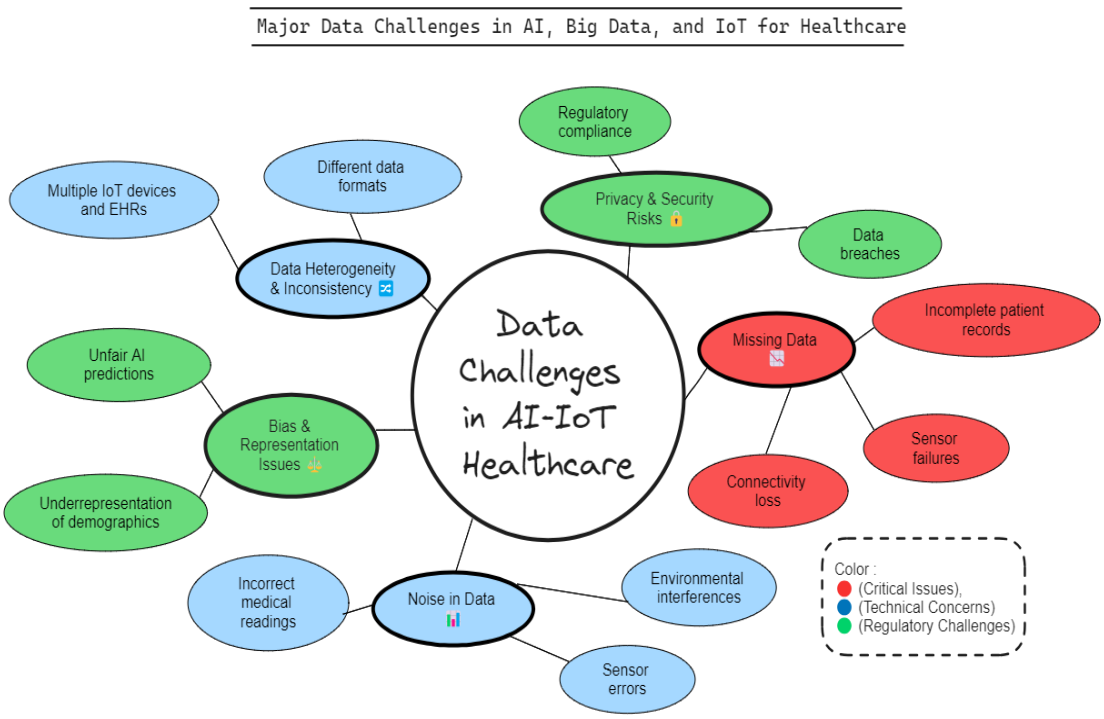

Fig. 4. Major data challenges in AI, Big Data, and IoT for healthcare.

IV. Data-Centric AI: A Paradigm for Addressing Data Challenges in Healthcare

As highlighted in the previous section, the core contribution of our study lies in positioning Data-Centric Artificial Intelligence (DCAI) as a foundational paradigm for addressing longstanding challenges in healthcare AI systems—specifically, issues related to data quality, context-awareness, standardization, and ethical scalability. Recent advances highlight that high-quality, well-annotated, and context-rich data can outperform more complex models trained on flawed datasets, reshaping our understanding of what drives AI success. Unlike traditional AI methodologies, which focus on hyperparameter tuning and deep learning architectures, Data-Centric AI (DCAI) enhances model reliability through systematic data curation [4] (see Table IV).

Despite this shift, few studies have comprehensively mapped how DCAI principles can be applied to healthcare-specific challenges, particularly in the context of IoT-generated data and Big Data analytics. As Jin et al. in [5] argue, a unified, structured synthesis of DCAI methodologies tailored to healthcare is lacking, especially one that considers clinical interoperability, fairness, and regulatory constraints. In healthcare, where the stakes of predictive errors are high and datasets are often noisy, incomplete, heterogenous or biased, DCAI-driven methodologies offer a critical corrective and provide robust solutions to mitigate these challenges [9]. By ensuring high-quality, well-labeled, and diverse datasets, DCAI enables AI systems to generalize effectively across different populations and healthcare environments. As Bhatt et al. in [4] demonstrate that smaller models trained on high-quality datasets can outperform larger models trained on flawed data. Similarly, Malerba et al. in [9] argue that DCAI methodologies—ranging from noise filtering and imputation to data augmentation and bias mitigation—are key to building scalable and ethical healthcare AI.

TABLE IV. Comparison of Data-Centric AI (DCAI) and Model-Centric AI in Healthcare AI

Aspect	Model-Centric AI	Data-Centric AI (DCAI)
Primary Focus	Optimizing AI models and algorithms [4]	Improving data quality, completeness, and fairness [1]
Approach to AI Performance	Improves performance by refining model architecture and hyperparameters [4]	Enhances performance by refining datasets rather than just improving models [1]
Data Handling	Assumes data is fixed and optimizes models to extract insights [9]	Systematic preprocessing, data augmentation, and bias mitigation [4]
Model Complexity	Requires complex models to compensate for suboptimal data [1]	Simpler models trained on high-quality data perform as well as or better than complex models [4]
Scalability	Limited scalability due to dependency on large models and retraining [9]	Highly scalable as data improvements generalize across different models [1]
Bias Mitigation	Bias correction is applied post hoc through model adjustments [1]	Bias is addressed at the dataset level, ensuring fairer and more representative AI outputs [4]
Challenges	Sensitive to data drift, requires frequent model updates, struggles with unreliable data [1]	Requires investment in systematic data collection, labeling, cleaning, and augmentation [4]

DCAI facilitates the standardization and structuring of IoT-generated health data, improving interoperability between AI models, IoT devices, and hospital infrastructures to reduce healthcare system fragmentation. High-quality data is essential for accurate diagnostics, equitable treatment recommendations, and compliance with ethical and regulatory standards. To improve data integrity and to address persistent issues in healthcare, DCAI integrates techniques such as bias detection, noise filtering, and data augmentation [1]. By treating data as a dynamic, evolving infrastructure, DCAI ensures AI systems remain fair, trustworthy, and effective. As highlighted by Zha, Bhat, Lai, Yang, Jiang, Zhong & Hu in [15], DCAI emphasizes continuous data improvement throughout the AI lifecycle, transforming data from a static input into a dynamic, strategic asset. Additionally, real-time adaptive AI models leveraging DCAI principles can dynamically adjust to context-aware decision-making, enhancing patient monitoring and disease prediction by utilizing high-quality labeled datasets that reflect dynamic changes in patient states.

Our study seeks to map recurring limitations identified in AI-IoT healthcare studies we previously discussed, such as inconsistency, bias, and lack of contextual adaptation, to specific DCAI techniques and solutions. We emphasize that issues like heterogeneity, fairness, and reliability are not solely technical but deeply tied to data design. By applying frameworks such as the METRIC framework [1], developers can evaluate healthcare datasets across dimensions like completeness, consistency, timeliness, and contextual fit. This paradigm shift is particularly critical in healthcare, where reliable AI-driven decisions directly impact patient safety and system credibility. Furthermore, robust decision-making relies on high-quality health data to generate consistent and evidence-based insights. By shifting the emphasis from algorithmic optimization to data integrity, interoperability, and real-time adaptability, this study explores the theoretical potential of Data-Centric AI (DCAI) to transform AI-driven healthcare systems into more scalable, ethical, and efficient solutions. Although our work does not empirically validate DCAI interventions, we propose that its principles are particularly well-suited for dynamic, context-aware, real-time healthcare environments, such as remote monitoring or emergency diagnostics. Crucially, DCAI supports the development of adaptive, context-aware AI systems that can respond dynamically to evolving patient conditions using continuously curated and context-rich datasets. This is particularly vital in applications such as remote monitoring and emergency diagnostics, where decision-making must be both rapid and reliable. By reframing the development pipeline around data quality, our study positions DCAI as a catalyst for building more ethical, transparent, scalable, and resilient AI systems in healthcare.

V. Addressing Data Quality Challenges Through Data-Centric AI (DCAI)

DCAI provides a structured framework for overcoming the previously outlined persistent data quality issues in healthcare AI systems. By prioritizing the curation, augmentation, and governance of data over merely tuning models, DCAI supports the development of more accurate, fair, and context-aware AI tools. For instance, bias mitigation is achieved through dataset audits, augmentation strategies, and synthetic data generation, as seen in [4], where underrepresented populations were better included in disease prediction models. Likewise, missing data—often resulting from sensor failures or transmission gaps in IoT-based health monitoring—is addressed through statistical and machine learning-based imputation techniques. In [9], Malerba et al. showcased robust hybrid approaches for managing data gaps, especially in critical use cases like glucose level monitoring.

Furthermore, to tackle noise and inconsistency in heterogeneous healthcare data, DCAI recommends pipelines for standardization and noise filtering, as highlighted by Bhatt et al in [4]. These processes enhance model robustness across diverse data sources and clinical settings. While privacy and security are not traditionally part of data quality metrics, they are integral to data usability and regulatory compliance. In [1], Schwabe et al. underscore that privacy should be treated as a governance concern, though technical solutions like federated learning and differential privacy can still support secure AI deployment. Taken together, these DCAI methods form a foundational toolkit for building scalable, ethical, and effective AI systems in healthcare—aligning data practices with real-world demands for transparency, interoperability, and patient-centered decision-making.

VI. Key Metrics for Evaluating Data Quality in Healthcare AI

The foundational literature on Data-Centric AI (DCAI) offers critical insights into data quality metrics and governance dimensions essential for trustworthy AI systems in healthcare. These include completeness, consistency, accuracy, bias mitigation, and timeliness, alongside data management principles such as privacy, documentation, and alignment with Findable, Accessible, Interoperable, and Reusable (FAIR) principles (see Fig. 5). These metrics are central to developing reliable, ethical, and high-performing healthcare AI systems. In [4], Bhatt et al. highlight the importance of data preprocessing and augmentation in reducing bias and improving dataset robustness. In [1], Schwabe et al. introduce the METRIC framework, which formalizes the assessment of data quality in medical AI applications, particularly in medical imaging and electronic health records (EHRs). In [9], Malerba et al. emphasize standardization, integration, and privacy-preserving AI techniques as foundational to secure and reliable healthcare AI models.

A. Core Data Quality Metrics

- Completeness ensures datasets are comprehensive, preventing unreliable predictions due to missing vitals or sensor gaps, with Schwabe et al. in [1] advocating for imputation techniques to address these issues.
- Consistency focuses on standardizing data formats across heterogeneous sources, as Malerba et al. in [9] emphasize normalization techniques to improve interoperability.
- Accuracy is critical in avoiding errors from faulty sensor readings, with Bhatt et al. in [4] recommending noise filtering methods like Kalman filters to enhance data reliability.

- Bias detection mitigates demographic imbalances in datasets, where techniques such as GAN-based synthetic data generation help improve fairness [4].
- Timeliness ensures real-time decision-making in critical care scenarios, with Schwabe et al. in [1] promoting edge computing to minimize delays.

B. Data Governance and Security Considerations

Though not typically framed as "quality" metrics, data privacy, security, and documentation are crucial for regulatory compliance and patient protection for ethical deployment of healthcare AI. In [9], Malerba et al. emphasize the need for:

- Federated learning to enable secure model training without centralizing sensitive data.
- Differential privacy to ensure anonymity and protect patient confidentiality during analysis and model deployment.

Together, these factors shape trustworthy, high-performance AI systems, ensuring data-driven healthcare solutions are reliable, fair, and efficient. These governance mechanisms are essential for legal compliance (e.g., GDPR, HIPAA), fostering patient trust and ensuring ethical alignment of AI solutions.

C. Standardized Frameworks: The Role of METRIC

The METRIC framework, introduced by Schwabe et al. in [1], provides a structured approach to evaluate medical datasets across key dimensions—completeness, consistency, timeliness, relevance, interoperability, and contextual fit. This framework is particularly useful for multi-source, privacy-sensitive environments like EHR systems and remote IoT monitoring platforms.

Our study underscores the need for standardized, interpretable, and scalable evaluation frameworks such as METRIC, particularly in multi-source, privacy-sensitive healthcare environments. They form the backbone of resilient healthcare AI systems capable of delivering equitable, transparent, and patient-centered outcomes. However, deploying a DCAI Framework in clinical settings is not without challenges—cost, data governance gaps, and system interoperability all pose real-world implementation barriers (see Section VIII (B).

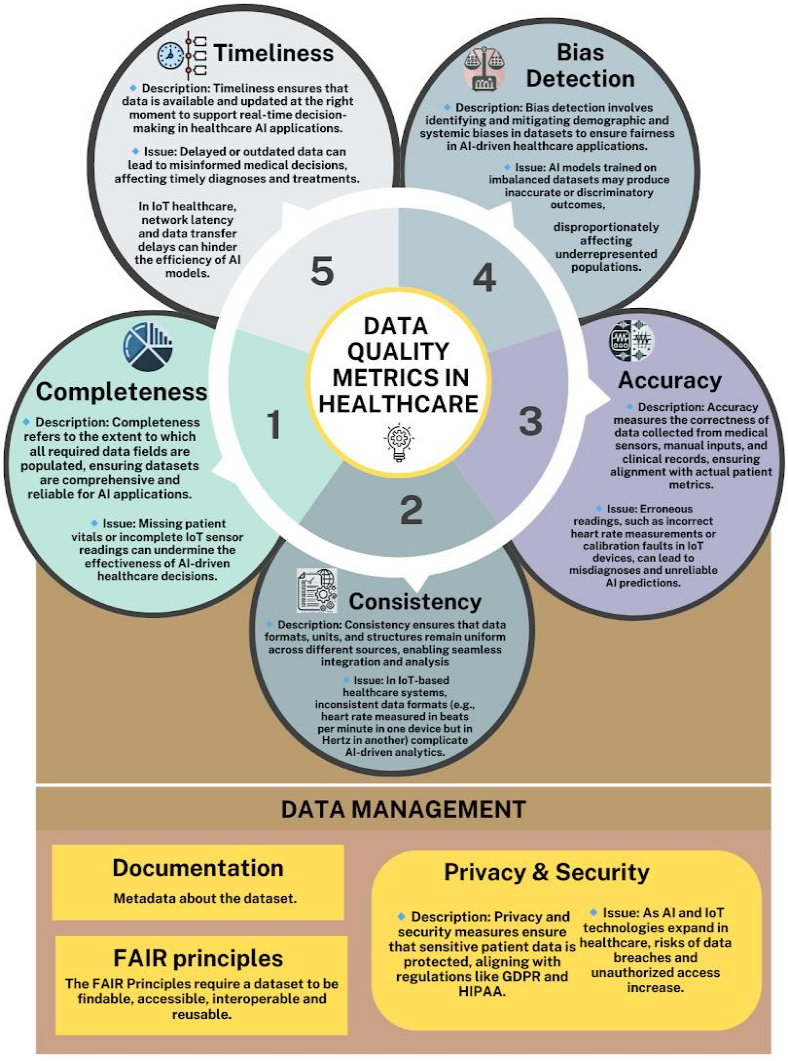

Fig. 5. Data quality metrics in healthcare AI (from the METRIC framework).

D. Summary: Core Principles of DCAI in Healthcare

- Enhancing Data Completeness and Consistency
- Ensure no missing values in critical health datasets and maintain consistency across diverse healthcare sources.
- Mitigating Bias and Ensuring Fairness.
- Promote diverse and well-balanced datasets and eliminate demographic bias in AI-driven medical decision-making.
- Standardizing Healthcare Data and Enabling Interoperability.
- Harmonize heterogeneous data formats and support seamless integration of multiple IoT sources and clinical data to facilitate smooth data exchange.
- Strengthening Data Security and Privacy.
- Apply robust privacy-preserving mechanisms to protect sensitive patient information to ensure confidentiality and prevent unauthorized access or exposure of sensitive medical information.

VII. Challenges and Limitations

Despite the potential of Data-Centric AI (DCAI) to improve healthcare AI systems, several challenges and limitations must be addressed to ensure scalability, fairness, and trustworthiness. These issues stem from both technical and systemic barriers within healthcare data ecosystems.

First, quantifying fairness in AI systems remains inherently complex due to demographic disparities across global healthcare environments. Biased training data can lead to inequitable outcomes, particularly for underrepresented populations, and current bias metrics often fail to capture these nuances accurately.

Second, data variability and quality continue to pose significant hurdles. Real-time data streams from IoT devices require constant monitoring to ensure consistency, contextual relevance, and timeliness. However, as Schwabe et al in [1] highlight, pervasive data issues—including noise, missing values, and inconsistency across heterogeneous sources—complicate integration and reliability of AI models.

Third, privacy and regulatory constraints (e.g., HIPAA, GDPR) restrict access to comprehensive patient data, hindering bias detection and correction. While privacy-preserving methods such as federated learning and differential privacy provide alternatives [9], their implementation is still limited by technical and legal challenges.

Fourth, computational overhead poses another challenge, as evaluating data quality at scale demands significant resources, especially in large IoT and Big Data systems [4].

Fifth, explainability and trust in AI-driven decisions remain critical for clinical adoption, as healthcare professionals require interpretable models and datasets with documentation, annotation, and data provenance for decision support.

Lastly, real-world deployment presents practical barriers. Integrating AI systems with existing hospital IT infrastructure, obtaining regulatory approvals, and ensuring seamless interoperability across data sources all remain major impediments to widespread adoption.

Importantly, while our study synthesizes findings from foundational DCAI literature and healthcare-focused research, it does not incorporate empirical experimentation or advanced AI techniques (e.g., generative AI, self-supervised learning, explainable AI). These promising areas are earmarked for future exploration.

- Key Findings and Gaps
  - Persistent Data Quality Issues: Noise, missing values, and bias remain critical obstacles to reliable healthcare AI.
  - Limited Implementation of DCAI: Although promising, DCAI is rarely applied systematically in healthcare settings.
  - Lack of Standardized Evaluation Metrics: Inconsistent metrics across studies hinder cross-model comparisons and benchmarking.
  - Interoperability Challenges: Diverse data sources (e.g., EHRs, IoT, imaging) often lack harmonization, limiting seamless AI integration.
  - Difficulty Quantifying and Mitigating Bias: Demographic disparities in data create systemic bias that is difficult to measure and correct.
  - Limited Multimodal Integration: Many current models fail to combine diverse healthcare data types (e.g., clinical text, images, sensor streams), reducing contextual awareness and diagnostic performance.

VIII. Future Work

As healthcare AI systems evolve, Data-Centric AI (DCAI) practices—such as data augmentation, bias mitigation, and context-aware preprocessing—are becoming essential for developing ethical, interpretable, and adaptive solutions [6], [15]. While this review provides a conceptual synthesis of DCAI principles, bridging foundational literature and application studies through a structured methodology, significant research opportunities remain. These involve both enhancing core DCAI practices and integrating emerging technologies to improve scalability, fairness, real-time adaptability, and clinical trustworthiness.

A. Key Future Research Directions

Below, we outline key future research directions to extend the impact and applicability of DCAI in AI-driven healthcare systems:

1) Generative AI for data augmentation: Explore the use of generative models such as GANs (Generative Adversarial Networks) and VAEs (Variational Autoencoders) to create realistic synthetic healthcare data. This approach could reduce data scarcity, correct demographic imbalances, and improve model fairness and generalizability.

2) Multimodal AI frameworks: Investigate the integration of diverse data modalities—including EHRs, IoT sensor streams, medical imaging, and genomics—to build comprehensive and context-rich patient profiles. Evaluate their impact on diagnostic accuracy, clinical decision support, and patient stratification.

3) Advanced bias mitigation techniques: Develop and validate fairness-aware training strategies and bias auditing tools that operate across the entire AI pipeline. This includes addressing hidden biases in data collection, labeling, and model inference stages.

4) Transformer-based and hybrid AI models: Assess the role of cutting-edge architectures such as transformers and graph neural networks (GNNs) in modeling relational and temporal dependencies in complex healthcare environments, particularly where patient data is sparse, noisy, or interconnected.

5) Context-aware and self-adaptive AI systems: Design AI systems capable of dynamically adjusting to patient-specific contexts and environmental changes in real-time. Such models could enhance remote patient monitoring, emergency diagnostics, and chronic disease management by incorporating adaptive decision logic.

6) Explainable and trustworthy AI (XAI): Integrate explainability mechanisms into DCAI workflows to improve clinical interpretability and transparency. This involves applying interpretable models or post-hoc explanation tools (e.g., SHAP, LIME) to enhance clinician trust and facilitate regulatory approval.

7) Privacy-preserving AI methods: Implement and empirically validate federated learning, homomorphic encryption, and differential privacy to ensure regulatory compliance (e.g., HIPAA, GDPR) while maintaining model utility and protecting sensitive patient data.

8) Standardized IoT interoperability: Advance the development of universal communication protocols and interoperability standards for integrating heterogeneous IoT devices and healthcare platforms. This is essential for real-time data sharing, multi-system alignment, and scalable deployment.

B. Practical Considerations and Conclusion of the Section

While Data-Centric AI (DCAI) offers a promising path to improving fairness, accuracy, and scalability in healthcare AI, its implementation is hindered by practical barriers such as high resource requirements, lack of data governance structures, and limited interoperability in clinical settings. Many hospitals operate with fragmented IT systems, unstructured data silos, and unclear data ownership, which complicate systematic data curation and annotation workflows required for DCAI adoption [1], [5]. Implementing privacy-preserving techniques like federated learning or synthetic data generation demands not only technical expertise but also legal and institutional coordination, which may be lacking in resource-constrained environments [4], [9]. Moreover, most DCAI frameworks are designed for static datasets and are not easily adaptable to dynamic, real-time healthcare scenarios where context, data quality, and ethical oversight must constantly evolve. Addressing these challenges requires interdisciplinary collaboration, scalable governance models, and cost-effective toolkits tailored for healthcare infrastructure, ensuring that DCAI moves from conceptual promise to real-world impact.

IX. Conclusion

This study positions Data-Centric Artificial Intelligence (DCAI) as a transformative paradigm for advancing trustworthy, scalable, and ethical AI-driven healthcare systems. Unlike traditional model-centric approaches that emphasize algorithmic optimization, DCAI redirects focus toward systematic improvements in data quality—enhancing completeness, consistency, standardization, fairness, and interoperability. Through our literature-based analysis of twenty-three AI-IoT healthcare studies and foundational DCAI works, we identified persistent challenges related to noise, missing values, demographic bias, contextual inconsistency, and privacy concerns. DCAI addresses these limitations by integrating practical techniques such as data augmentation, noise filtering, bias mitigation, and standardized preprocessing, while frameworks like METRIC offer structured tools for evaluating data quality across key dimensions. Although our study is theoretical in nature, it establishes a foundational synthesis linking DCAI principles to healthcare-specific data challenges. Future directions should focus on integrating DCAI principles with cutting-edge technologies such as explainable AI (XAI), generative AI, and multimodal learning, while also advancing real-time, context-aware AI–IoT convergence in smart healthcare environments. Such integration will enable adaptive systems capable of continuous learning, secure data handling, and interpretable decision support—crucial for delivering equitable and high-quality care at scale.

Acknowledgment

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. Special appreciation is extended to the researchers cited throughout the study. Gratitude is also extended to the academic mentors and reviewers whose comments helped to refine the manuscript.

A Bibliometric Analysis of Blockchain Applications in E-Commerce: Trends and Research Directions

Nguyen Thi Phuong Giang[1], Le Ngoc Son[2], Thai Dong Tan[3]
Faculty of Commerce and Tourism, Industrial University of Ho Chi Minh City, Vietnam[1, 3]
Institute of International and Postgraduate Education, Industrial University of Ho Chi Minh City, Vietnam[2]

***Abstract*—Blockchain technology has emerged as a transformative force within the e-commerce industry, offering significant potential to address longstanding issues such as data security, transaction transparency, and customer trust. Despite its growing relevance, the academic exploration of blockchain applications in e-commerce remains fragmented and lacks a cohesive research agenda. This study conducts a comprehensive bibliometric analysis to map the intellectual landscape of blockchain applications in e-commerce, identifying influential publications, key authors, prominent journals, and major thematic trends. Using data extracted from the Scopus database between 2014 and 2024, the study employs bibliometric tools such as VOSviewer and Biblioshiny for performance analysis and science mapping. The analysis reveals a steady increase in research interest, with dominant themes including trust, smart contracts, supply chain management, and secure payments. Furthermore, the findings indicate that most research is concentrated in technologically advanced countries, and collaborations among scholars remain limited. By interpreting these patterns, the study uncovers critical gaps in the literature and proposes future research directions focusing on consumer behavior, regulatory frameworks, cross-border challenges, and integration with emerging technologies like AI and IoT. The results contribute to a clearer understanding of the evolution of blockchain research in e-commerce and provide a foundation for academics and practitioners to develop more secure, efficient, and user-centric digital commerce systems.**

***Keywords*—Blockchain; e-commerce; bibliometric analysis; smart contracts; digital transformation**

I. Introduction

The Fourth Industrial Revolution (4IR) is transforming the globe and altering how people interact with each other, their jobs, and their personal lives. The 4IR is a series of shifts in the creation, exchange, and distribution of economic, political, and social value that have been synchronized to occur globally in the digital sphere and impact both businesses and livelihoods [1]. According to the literature, because e-commerce platforms record and process every transaction that takes place on them, they must deal with enormous volumes of sensitive data, including banking information, personal information, and customer preferences [2]. Errors, fraud, and forgeries may arise because current e-commerce systems calculate and store customer data on a centralized cloud server [3]. Security is an issue because so few e-commerce companies have implemented blockchain [4].

It is suggested that e-commerce difficulties are complex, with some requiring the attention of the company in addition to individuals. Limited credit card adoption, a high percentage of technological illiteracy, worries about logistics, internet access and use, bandwidth prices, a lack of ICT infrastructure, trust, and security are some of the individual problems [5]. As blockchain technology has developed, more researchers have focused on leveraging it to boost the trust of e-commerce platforms [6]. The literature [7] claims that while artificial intelligence may be used to improve the search engine, recommendation system, and transaction monitoring of e-commerce platforms, blockchain technology may improve the security, data transparency, and trust of these platforms. The blockchain-based "decentralized authentication" model, which is the new authentication technology proposed in the paper [2], can significantly increase the security and credibility of e-commerce platforms for luxury brands. The use of blockchain technology in e-commerce platforms is the main topic of the study, which focuses on enhancing supply chain management, boosting trust, optimizing data management, and enhancing security [8]. A framework for trade facilitation for blockchain-based e-commerce platforms was developed in the literature with the goals of protecting consumer privacy, streamlining transaction procedures, and enhancing data management [9]. A smart contract for managing e-commerce that can consistently capture and validate transaction records and automatically execute e-commerce transactions is constructed using blockchain technology in the literature [10]. To solve the present data security issues in e-commerce platforms, a novel blockchain-based data encryption technique is offered [11]. By combining the distributed, tamper-evident, and decentralized characteristics of blockchain, this technique improves the data security of e-commerce platforms [12].

Logistics, a lack of qualified workers to develop e-commerce platforms, weak internet security, insufficient legal frameworks, misalignment between business, IT, and operational units, stakeholder engagement, a lack of funding and top management support, and the costs of advertising and payment gateways are some of the organizational challenges [13]. The ability to trace an item's origins through contract identification, data exchange, and system protection is considered an aspect of security [14]. The security issue in e-commerce is said to be resolved by using blockchain technology [14]. Blockchain technology is predicted to drastically alter a variety of corporate applications and processes, with substantial ramifications for e-commerce [15]. The use of blockchain has been the subject of numerous studies, including the following: e-commerce, tourism and hospitality, operations management, supply chain, and agriculture [16].

Smart contracts that enable supply chain automation, record management, payment applications, traceability support, and other business interactions are made possible by blockchain, a decentralized, distributed directory [17]. By using blockchain track and trace capabilities, a blockchain-based e-commerce strategy will ensure authenticity [12]. Additionally, the decentralized and encrypted core technology of blockchain enables track and trace capabilities [18]. This technology creates a distributed database that is inaccessible to unauthorized users by encrypting and storing data in a chain of back-linked information blocks, ensuring data integrity and accountability.

When analyzing blockchain technology, three factors need to be considered: technical, business, and legal. Blockchain technology's technological component is a database that keeps an entirely transparent distributed ledger. A peer-to-peer network for trading assets, value, and transactions makes up the business component. Finally, the legal component replaces previously trusted entities by validating transactions [12]. Blockchain technology's main benefits include the decentralized and transparent storage of transaction information, the database's operation by a network of computers known as nodes, which eliminates a single point of failure, real-time access to information, and the elimination of the need for middlemen to complete transactions, which lowers transaction costs [19]. Blockchain could improve e-commerce in addition to security [12]. First, by eliminating the need for middlemen, blockchain transactions on a single network enable faster speeds and lower costs [20]. Second, blockchain improves supply chain management by storing and recording product information. This enables the tracking of every product's life cycle, including who made it, what resources were utilized, where it came from, where it was stored, who bought it, and who completed the transaction [21]. Lastly, because each transaction is recorded on a shared ledger and cannot be altered, blockchain technology encourages trust and transparency in payments [12].

The primary research topics in the area of blockchain in e-commerce are mapped out with the use of the bibliometric technique. Important topics like the evolution of e-commerce and its uses in the Industry 4.0 era have been the subject of studies [22]. By identifying regions that have been thoroughly investigated and those that need more inquiry, this can help direct future studies. As was already indicated, the second limitation is that, despite the topic's ongoing and growing development, no study publication has been deemed sufficiently thorough. By examining the references, one can learn about the most referenced papers, prestigious publications, and the general influence of this field's study. This can aid in comprehending the importance and scope of different investigations. A number of methodological experts have stressed the necessity of a systematic review procedure to arrive at more impartial conclusions in literature reviews [23]. Future research can examine each theme group in greater detail and on a wider scale, thanks to bibliometric analysis. The increase of short films in e-commerce will be examined in this study by examining publications that were indexed in the Scopus database between 2014 and 2024. Identifying significant study clusters and important issues in this area, examining the connections between research topics, and influencing blockchain research in short-term commerce are the three main goals. This work attempts to contribute to the growth of this subject by offering a thorough and current review of the present research environment on blockchain in e-commerce through a mix of three methods: keyword co-occurrence, co-citation analysis, and bibliographic coupling.

This is how the rest of the study is organized: In Section II, the research gap is identified and the associated literature is reviewed. The suggested methodological architecture is shown in Section III. The experimental setup and evaluation findings are covered in Section IV. A discussion of the results and their implications is given in Section V. The work is finally concluded in Section VI, which also offers recommendations for further research.

II. Literature Review

A. E-Commerce

The term "e-commerce" describes online buying and selling. E-commerce, however, encompasses more than just monetary exchanges between customers and companies. It also includes non-monetary exchanges between the company and its customers [24]. The current literature on e-commerce has been categorized and arranged systematically by previous review studies. In one of the first review papers on e-commerce, the field into three areas: applications, technical issues, and implementation and support [25]. Themes like reference architectures, recommendation systems, online consumer behavior research, and e-commerce in specific geographic locations [26].

Previous scholarly studies have extensively examined the development of e-commerce. The industry has undergone a substantial digital transition, according to Kauffman et al. [27], who emphasize how information technology has changed e-commerce by creating value based on business networks. In a similar vein, Schulze et al. [28] present a framework that looks at the extent of e-business adoption and how it affects firm performance. According to this framework, organizational characteristics like competitor and customer orientation, organizational learning capacity, and top management support, as well as competitive conditions like normative pressures and customer power, serve as important antecedents of adoption and success. Their results also show that the degree of technological and market uncertainty affects the relationship between adoption intensity and performance.

B. Blockchain and E-Commerce

The Internet required several decades to evolve from a communication-oriented network serving mainly academic and military organizations into a technological infrastructure capable of supporting commercial activities [29]. Nevertheless, shortly after the emergence of the World Wide Web, the number of commercial websites increased dramatically, and e-commerce rapidly gained recognition as a global business model [25].

According to modern businesses, the internet has proven to be useful for improving marketing strategies. It approaches in a number of situations, such as conducting marketing research, offering customer service and experiences, distributing products, and resolving problems [30]. Modern firms are able to produce new products and services, boost market transparency, and operate more effectively and efficiently because of the inherent value of internet marketing [31]. Over the past decade, e-commerce has grown rapidly and emerged as a major industry [25]. Due to a number of recent technological advancements, online shopping has become one of the most popular consumer pastimes. Among these is blockchain technology [32]. A blockchain is a kind of peer-to-peer, decentralized database that is spread throughout every node in the network of trustless blockchains. A blockchain is a collection of blocks, as the name suggests. Each block contains specific features to maintain the integrity of the entire blockchain. To preserve this integrity, the blockchain uses robust cryptography [33].

"A fully distributed system designed to cryptographically record and preserve a consistent, immutable, and linear log of transactions among network participants", is a generic description of this technology [34]. This definition reflects the growing ubiquity of cloud-connected digital devices, growing cloud storage infrastructures, and sophisticated data analytics, all of which demonstrate how resilient blockchain is to technical advancements in the digital age [35]. Furthermore, a variety of cutting-edge financial instruments can be developed thanks to blockchain's highly flexible and programmable character, especially in the fields of payment and transaction systems [36].

E-commerce is the practice of purchasing and selling goods and services via the Internet [25], utilizing electronic communication and information processing technology in business dealings [37]. This digital environment enables consumers to interact, share opinions, and compare experiences online, thereby expanding their choices and facilitating rapid evaluations of products and services [38]. In this context, blockchain technology offers highly secure transaction services by eliminating intermediaries and protecting buyers' financial information, as all activities are cryptographically secured and transaction records among verified participants are permanently maintained [39].

Blockchain represents a set of technologies that influences e-commerce by addressing challenges related to organizational structure, quality assurance, customer trust, regulatory compliance, and technological efficiency. It relies on various consensus mechanisms for validation and creates unprecedented technological possibilities for digital commerce [40]. Based on these characteristics, blockchain systems can be categorized into three main types: permissionless blockchains, where all nodes are allowed to read, submit, and validate transactions; public permissioned blockchains, in which transactions are publicly visible but only authorized nodes may write or validate them; and private permissioned blockchains, where access to viewing, submitting, and processing transactions is restricted to approved participants [12].

III. Methodology

A. Bibliometric Analysis

According to [41], bibliometrics is a research methodology that has grown in popularity as a means of comprehending scholarly literature as electronic versions have become more widely available. The term "bibliometrics" refers to a broad category of methods that differ in their nature and purpose, including co-word analysis, citation analysis, bibliographic coupling analysis, and co-citation assessment [42, 43]. This method is widely used in information science and libraries and is thought to be a crucial instrument for analysis, planning, and assessment. Through content analysis or citation analysis, it frequently offers quantitative insights that are useful for evaluating the significance, applicability, and evolution of scholarly publications. The use of statistical analysis in the creation of bibliographies is the primary characteristic that distinguishes bibliometrics. In order to conduct a more effective literature review, this study employs the scientific mapping approach, which is a general procedure of analyzing and visualizing domains [44].

The literature search and analysis in this study are conducted using the bibliometric evaluation method that Donthu et al. [45] provided. There are four primary steps in it: Step 1: Outlining the bibliometric study's goals and parameters. Step 2: Choosing the assessment method. Step 3: Gathering information for bibliometric evaluation. Conducting the bibliometric analysis and summarizing the results is step four.

B. Data Collection

The study's data collection phase can be carried out using a variety of information sources or by gaining access to reliable academic databases like Web of Science, Scopus, and Google Scholar [46]. SCOPUS's output data information is used in this study due to its excellent coverage, thoroughness, and quick data updates. Similar documents can occasionally be found on Google Scholar or the Web of Science [41]. We have extracted a total of 1.132 (samples/documents) in the scope of "Article title, Abstract, Keywords" with the search keyword "Blockchain" AND in the scope of "All fields" with the search keyword "e-commerce" OR "electronic commerce" OR "online shopping" OR "digital marketplace". Articles from the last ten years, from 2014 to 2024, are included in the research time frame. This makes the essay more objective with current data and assesses the general overview of the blockchain topic, which helps to best direct the research. The real procedure for doing bibliographic analysis is shown in Fig. 1. In order to gather data for the final analysis, this method involves filtering processes.

C. Data Analysis Procedure

Graphs facilitate conclusion-making, decision-making, and prediction by making information easy to comprehend and assess. Using VOSviewer, a free tool for creating and displaying bibliometric analysis, we may create various networks based on keywords, citations, publishing sources, authors, and common citations [47]. In this study, bibliometric analysis is conducted using the software "VOSViewer", which contains facilities for graphical depiction of multidimensional data.

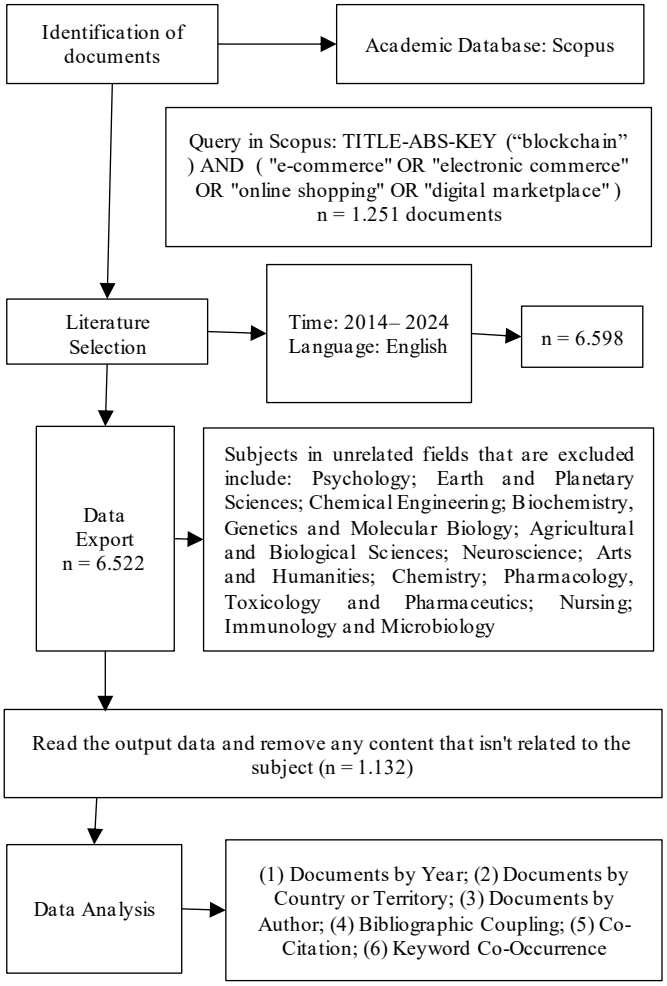

Fig. 1. The actual process of conducting bibliographic analysis.

IV. Results

A. Bibliometric Analysis

Blockchain technology began in 1991 when Haber and Stornetta came up with the concept of a cryptography-secured digital ledger system [48]. Their approach laid the groundwork for what would eventually be known as Blockchain by enabling transparent and unchangeable tracking of document modifications. Although preliminary research started in 2014, blockchain has gained popularity among scholars worldwide since the end of 2016, when e-commerce took off. Statistics on the quantity of publications by year are displayed in Fig. 2. The statistical findings allow for a three-stage analysis of the evolution of blockchain research:

Stage 1 (2014–2015): There was just one publication annually, and the number of investigations stayed low. This suggests that at the time, blockchain technology in e-commerce was still in its infancy.

Stage 2 (2016–2017): Blockchain research gained traction starting in 2016, as seen by a notable spike in publications, particularly in 2018. This expansion might be related to the fact that a lot of e-commerce companies started looking into how blockchain could improve supply chain management, transaction transparency, and efficiency, as well as product information verification. For blockchain technology to progressively infiltrate the e-commerce industry in the ensuing years, this was a critical first step.

Stage 3 (2018–2024): There were roughly 48 studies in 2018 compared to over 264 in 2024, and there are no indications that this number will be declining very soon. This suggests that the scientific community is paying more and more attention to blockchain as a "hot" study topic.

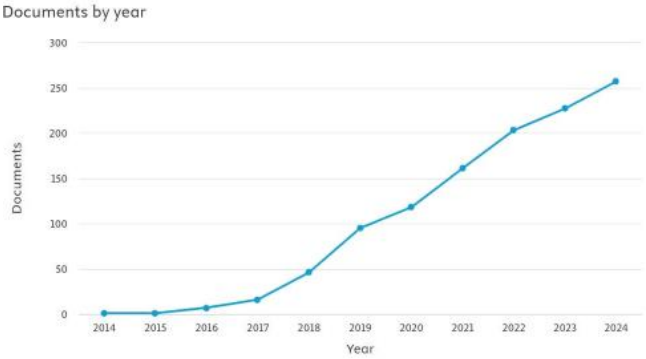

Fig. 2. Number of publications published by year from the Scopus database.

B. Analysis of Documents by Country or Territory

Based on statistical data from 2014 to 2024, Fig. 3 displays 1,168 research publications about blockchain technology that have been published globally. When compared to other nations, China dominates with 348 publications. This outcome is indicative of China's robust investment approach in blockchain research and implementation, specifically in the domains of digital payments, supply chains, and e-commerce [49]. With 216 articles, India comes in second, indicating the swift expansion of its innovation ecosystem and blockchain-based solutions catering to the local digital commerce industry [50].

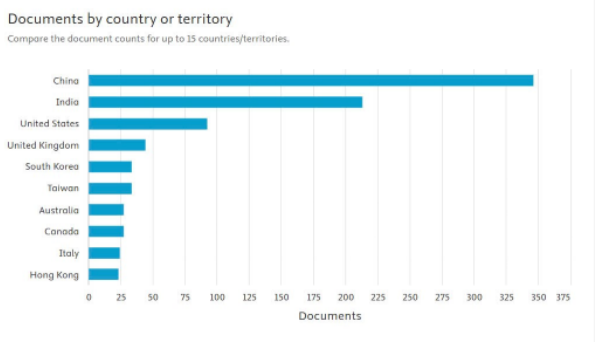

Fig. 3. Documents by country or territory. Source: From the Scopus database.

With 94 publications, the US comes in third. Despite being a global leader in the development of blockchain technology, there aren't many studies that are especially about e-commerce. This could be the result of a wider field of research or disciplinary fragmentation. With publishing numbers ranging from 27 to 45, other industrialized nations like the United Kingdom, South Korea, Taiwan, Australia, and Canada also have some interest in this subject. All things considered, Asia is becoming a center for blockchain research in the e-commerce space, which has enormous opportunities for the

creation of distributed technology-based digital business models.

C. Analysis of Documents by Author

A concentration of research within a small group of scientists is indicated by the fact that some writers have more publications than others. Close scientific collaboration and a quick expansion of the field's knowledge may result from this. Numerous people contribute to the study of blockchain and e-commerce, despite the presence of a few well-known authors. This demonstrates a wide range of interest in the subject and the possibility of many viewpoints and approaches. This study examines the author's publication count, highlighting the noteworthy contributions of a select few academics while also demonstrating the diversity of the blockchain and e-commerce research team. Finding top subject matter experts and research cooperation opportunities for upcoming publications can be facilitated by this information. Some authors with at least four publications, with notable research articles on blockchain and e-commerce are depicted in Fig. 4.

The development and improvement of blockchain systems in e-commerce is the main focus of the research of the five most prolific authors in this subject, as Table I demonstrates. To enhance supply chain management effectiveness, security, and dependability, these studies have helped to build and improve traceability models in blockchain-based e-commerce. Studies on blockchain systems in e-commerce were made possible by the work of Ferrer-Gomila and Hinarejos [51]. Other researchers might combine blockchain, IoT, and AI to improve real-time traceability systems, broaden applicability in different e-commerce domains, and assess usefulness using real-world deployment models.

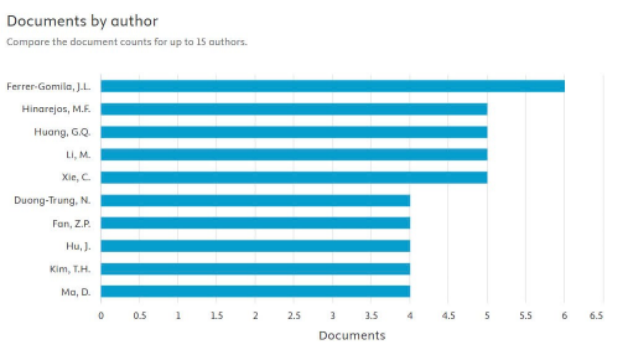

Fig. 4. Number of publications by author.

D. Bibliographic Coupling

The concept that two published studies with comparable references are most likely about the same topic is the foundation of a scientific mapping technique known as bibliographic coupling [52]. This study's data analysis based on common keywords used by authors in clusters did not include keywords that were also used as "search terms" (which will be looked at separately in the keyword co-occurrence analysis method below). This is because the purpose of these keywords is to serve as a helpful evaluation tool to uncover the content [53]. Fig. 5 shows the four main research clusters that were found, and they are as follows:

1) Data sharing, fraud detection, and security: This cluster focuses on using blockchain technology to improve security, identify fraud, and facilitate safe data exchange in digital systems. [54, 55] are important studies.

2) Supply chain and logistics management: The focus of this cluster is on using blockchain technology to increase supply chain and logistics management's efficiency, traceability, and transparency. The [56, 57] are notable studies.

3) Digital rights management and the sharing economy: This cluster investigates the use of blockchain technology in digital rights management, the sharing economy, and the creation of legal frameworks via smart contracts. The [58, 59] are important studies.

4) Management of business processes and manufacturing: This cluster focuses on using blockchain technology to manage manufacturing and business processes to improve industrial operations' dependability, efficiency, and transparency. The [60, 61] are significant studies.

The analysis's findings demonstrate the variety of blockchain-related e-commerce study areas. Numerous facets of blockchain technology have been examined in studies, such as supply chain and logistics management, digital rights management, fraud detection, data security, and safe data exchange, as well as applications in business process management and production. Each cluster highlights the growth and adaptability of blockchain technology across several e-commerce-related areas, reflecting a unique study strategy. With an emphasis on combining blockchain with other technologies like IoT, AI, and smart contracts, the research trend indicates a move away from theoretical studies and toward workable solutions. Furthermore, topics including operational efficiency, privacy, openness, and sustainability are increasingly taking center stage in current research. This suggests that blockchain is evolving into a fundamental platform for reimagining digital business models rather than just a technology that facilitates transactions.

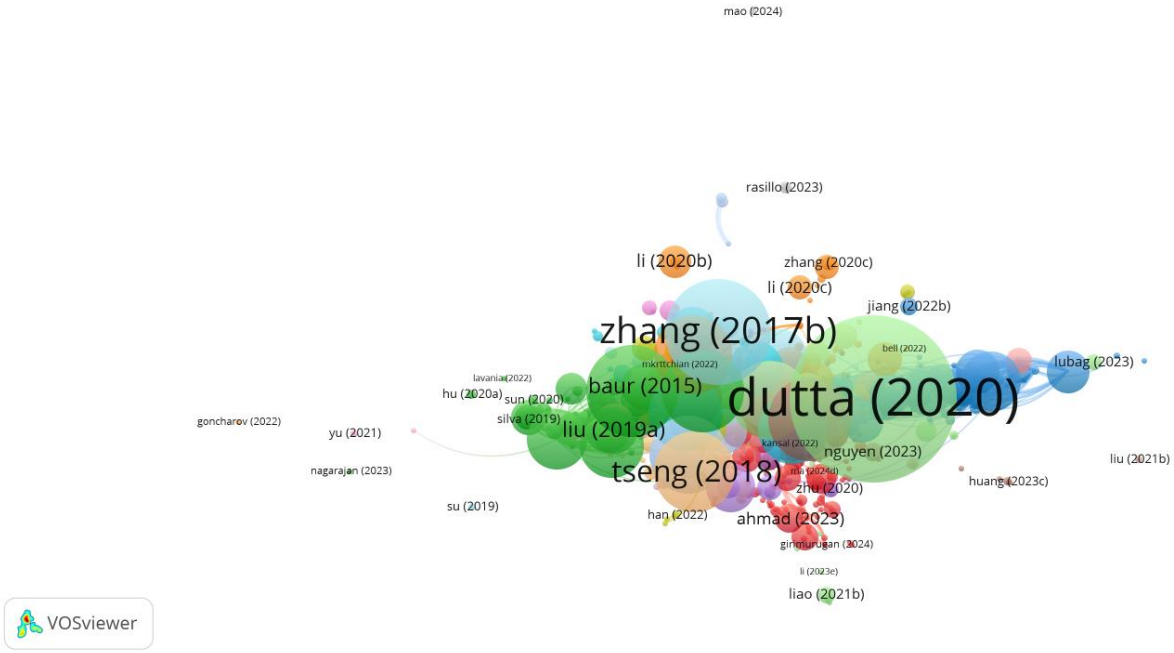

Fig. 5. Bibliographic coupling analysis results from VOSviewer.

E. Co-Citation

Co-citation analysis can be regarded as a technique to gauge the coherence between publications, since it concentrates on the frequency with which other documents quote two documents together [62, 63]. Co-citation analysis of author data is the main topic of this research. Finding out whose works are mentioned in the same article and the evolution of the research community may be done through author co-citation analysis [64]. As seen in Fig. 6, the co-citation analysis results reveal four unique clusters.

The green cluster reflects the growing interest in applying blockchain technology in fields such as e-commerce, digital markets, and energy trading. Studies in this cluster show that blockchain is not only a technology that supports financial transactions but also holds great potential for enhancing transparency, security, and efficiency across various sectors. The diversity of applications mentioned—from European research markets to peer-to-peer energy trading—demonstrates blockchain's scalability and flexibility in addressing both current and future challenges [65, 66].

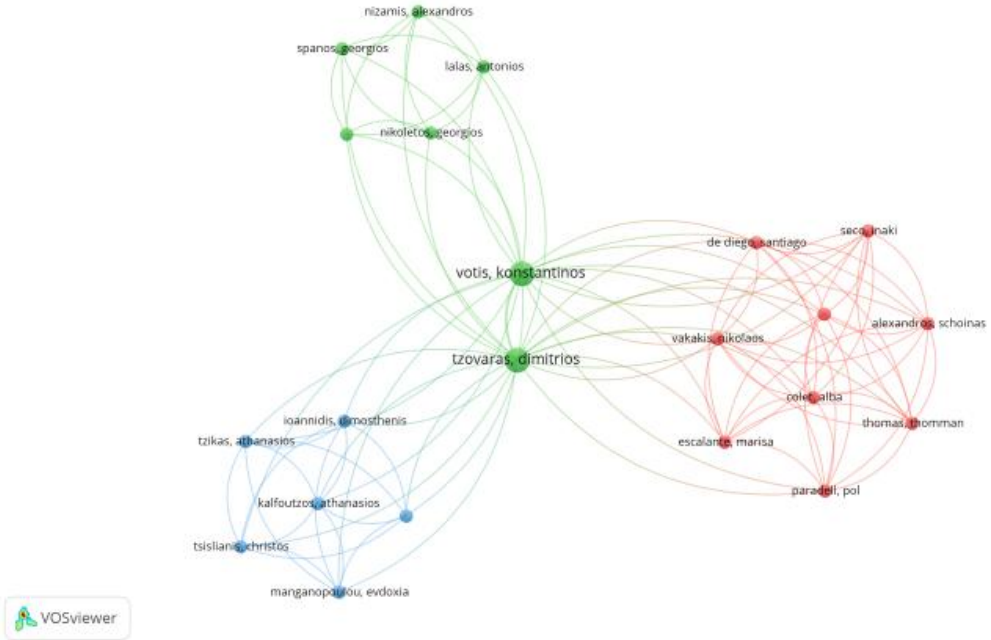

Fig. 6. Co-citation analysis results on VOSviewer.

The red cluster reflects the increasing interest in applying blockchain technology in areas such as supply chains, personal data management, and consumer behavior. Studies in this cluster indicate that blockchain is not merely a tool for financial transactions but also possesses significant potential in improving transparency, security, and efficiency across a range of industries. The variety of applications discussed, from coffee supply chains to consent management in IoT, illustrates the scalability and adaptability of blockchain in tackling present and future issues [67, 68].

The blue cluster reflects the interest in applying blockchain technology in distributed systems, e-commerce, and personal data management. Research in this cluster reveals that blockchain is more than just a financial transaction tool; it also has considerable potential to enhance transparency, security, and efficiency in numerous areas. The range of applications discussed—from distributed marketplaces to consent management in IoT—demonstrates blockchain's scalability and flexibility in solving current and future challenges [69, 70].

F. Keyword Co-Occurrence

Keyword co-occurrence analysis (i.e., two keywords appearing in a text) can better expose the structure of research subjects in a field, who also claimed that it helps explain research themes. In support of the aforementioned viewpoint, keywords are a distilled version of the crucial information that researchers include in an article. This approach reveals the structure and knowledge components of a scientific area by examining the connections between terms in a document. As a crucial literary component, keywords can offer a succinct synopsis of the main ideas and points of an article. To reaffirm the study topic's high level of focus, we increased the frequency of keyword recurrence in a publication to at least five times. The 331 research papers yielded 5.625 keywords in total. Following data processing, the analysis included 89 standardized keywords. The 15 keywords with the highest frequency of occurrence in the analysis of short movies in e-commerce are listed in Table II.

TABLE II. FREQUENCY OF CO-OCCURRENCE OF KEYWORDS

Rank	Keywords	Frequency
1	Blockchain	771
2	Electronic commerce	446
3	Block-chain	438
4	e- commerces	209
5	e-commerce	203
6	smart contract	146
7	Blockchain technology	120
8	Supply chains	115
9	sale	95
10	Supply chain management	75
11	Decentralised	70
12	Cryptography	67
13	smart contracts	66
14	Internet of Things	65
15	Digital storage	57

The keyword clusters are closely interconnected, illustrating the multi-dimensional nature of blockchain applications in e-commerce, as visualized in Fig. 7. The central node “blockchain” connects prominently with several major clusters such as “smart contract” (blue), “blockchain technology” (red), “e-commerce” (green), and “data privacy” (yellow-purple), highlighting the comprehensive integration of blockchain with digital commerce systems. For instance, the blue cluster centers on “smart contract” and “e-commerce”, indicating a strong focus on how blockchain automates and secures online transactions through decentralized mechanisms. It also includes terms like “decentralised”, “Ethereum”, and “cybersecurity”, reflecting technological infrastructure and security considerations. The red cluster, comprising “blockchain technology”, “supply chain management”, “trust”, and “fintech”, focuses on the technological adoption of blockchain in business processes. This cluster emphasizes the operational efficiency and trust-enhancing capabilities of blockchain, especially in logistics and finance. The green cluster is closely linked to commerce-specific contexts, with keywords such as “supply chains”, “commerce platforms”, “traceability”, and “agricultural products”. This cluster showcases practical applications of blockchain in improving transparency, efficiency, and traceability in cross-border and product-based e-commerce. The yellow-purple cluster, though smaller, includes emerging terms like “data privacy”, “authentication”, and “digital storage”, suggesting a new direction in research that deals with ethical and regulatory dimensions of blockchain. This reflects increasing scholarly attention on consumer protection and secure data handling—topics previously underexplored in blockchain-related e-commerce studies. Notably, this cluster may represent a future research avenue that intersects blockchain technology with digital rights, authentication mechanisms, and personalized privacy models. These insights help reinforce the technological and business-oriented clusters while laying the groundwork for ethical and user-centered innovations in blockchain adoption.

Cluster 1 (Red): “Technology Adoption and Trust in Blockchain”

Top keywords: blockchain technology, cryptocurrency, trust, decentralization, consensus algorithms, fintech, technology adoption, innovation. This cluster centers on the technological and institutional factors influencing the adoption of blockchain. It reflects a research focus on how trust, decentralization, and technological infrastructure affect the integration of blockchain into systems like fintech and e-commerce. The presence of keywords such as consensus algorithms and electronic money suggests technical considerations, while trust, innovation, and technology adoption point toward models evaluating user and organizational readiness. Research in this cluster aims to understand how blockchain can disrupt or enhance existing financial and technological ecosystems.

Cluster 2 (Green): “Blockchain Applications in E-Commerce and Supply Chains”

Top keywords: e-commerce, supply chains, commerce platforms, traceability, cross-border, agricultural products, competition, marketing. This cluster focuses on the practical

application of blockchain in commerce and logistics. The integration of e-commerce and supply chain terms indicates that researchers are investigating how blockchain enhances transparency, efficiency, and traceability in global and cross-border trade. Topics like agricultural products and traceability suggest their role in product origin tracking, while marketing and commerce platforms reflect business-side optimization. This cluster highlights blockchain's potential in improving trust and reducing friction in traditional supply chains and e-commerce transactions.

Cluster 3 (Blue): "Smart Contracts and Security Infrastructure"

Top keywords: smart contracts, e-commerce, decentralised, Ethereum, network security, cryptography, cybersecurity, data privacy. The blue cluster highlights the intersection of blockchain with security and automation technologies. It centers on how smart contracts and cryptographic protocols are leveraged in decentralized systems to secure e-commerce activities. Keywords such as network security, data privacy, and cybersecurity point to a strong focus on data protection and secure transaction environments. Ethereum and decentralised suggest research interest in public blockchain infrastructures. This cluster explores both the opportunities and challenges of using smart contracts in secure digital commerce ecosystems.

Cluster 4 (Yellow-Purple): "Privacy, Authentication, and Digital Infrastructure"

Top keywords: data privacy, authentication, privacy protection, digital storage, data sharing, smart city. This smaller but significant cluster highlights emerging concerns around ethical and legal aspects of blockchain deployment. The focus is on how to protect users' identities and personal information in digital transactions. Terms like authentication and privacy protection imply mechanisms to validate users securely, while smart city and data sharing suggest research into blockchain's role in broader digital infrastructure. This cluster represents a growing interest in governance, digital rights, and regulatory frameworks supporting responsible blockchain use.

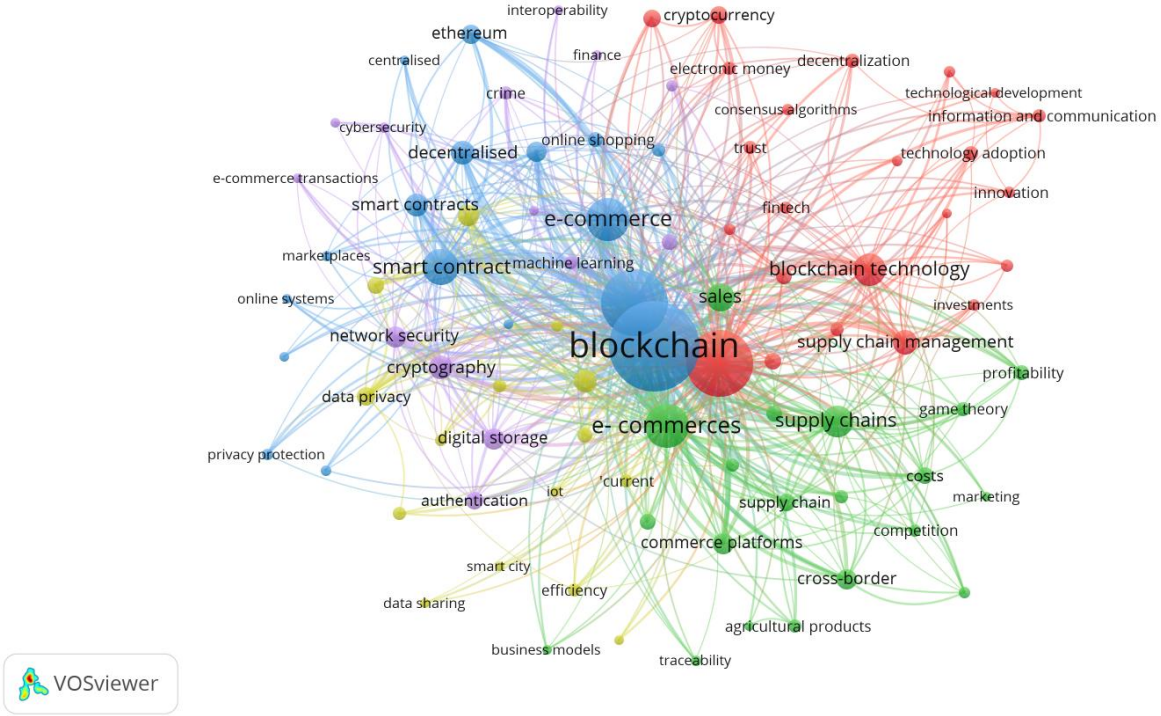

Fig. 7. Keyword co-occurrence analysis results from VOSviewer.

V. Discussion

A. Discussion of Research Results

The growth, thematic progression, and interrelationships of blockchain applications in e-commerce were examined in this study using bibliometric analysis. This discussion offers thorough answers to the three previously stated research questions based on the study's primary findings:

RQ1: What are the primary thematic clusters and research topics in the field?

Keyword co-occurrence analysis and bibliographic coupling revealed several prominent thematic clusters representing core research areas in blockchain-enabled e-commerce. The co-occurrence network showed strong connections among terms such as "blockchain", "e-commerce", "smart contracts", and "supply chain management", reflecting the close integration between blockchain technology and various business processes in digital commerce.

Four primary clusters were identified: Cluster 1: Technology Adoption and Trust. This cluster highlights the role of trust, decentralization, and technological infrastructure in blockchain adoption, especially in fintech and e-commerce. Keywords like "cryptocurrency", "consensus algorithms", and "innovation" suggest that researchers are focused on the factors

that enable or hinder blockchain integration. Cluster 2: Blockchain in E-Commerce and Supply Chains. This practical application cluster focuses on traceability, transparency, and efficiency in supply chains. Studies emphasize blockchain's role in improving logistics, especially for cross-border trade and product authenticity. Cluster 3: Smart Contracts and Security Infrastructure, this cluster centers on the application of smart contracts to automate e-commerce transactions. It includes concerns about data privacy, cybersecurity, and decentralization, particularly on platforms like Ethereum. Cluster 4: Privacy, Authentication, and Digital Infrastructure, though smaller, this emerging cluster reveals growing interest in ethical, legal, and data governance aspects. Keywords such as "data privacy", "authentication", and "smart city" indicate a shift towards secure identity verification and infrastructure planning. These clusters underscore that blockchain is no longer treated solely as a technical solution. Instead, it is now studied as an enabler of transparency, trust, and efficiency across the digital commerce ecosystem.

RQ2: What are the relationships between different research topics in this field?

Co-citation analysis was used to identify intellectual linkages across the field. The results revealed four distinct clusters of research thought: Cluster A: Blockchain for Digital Markets and Energy, which reflects blockchain's application beyond finance—e.g., in peer-to-peer energy trading and digital commerce platforms. Cluster B: Supply Chains and Personal Data Management focuses on product traceability and consumer data control, suggesting blockchain's utility in both logistics and consumer rights. Cluster C: Distributed Systems and Consent Management emphasizes the relevance of blockchain in managing decentralized systems and data permissions, notably in IoT and digital marketplaces.

These clusters are not isolated. For instance, blockchain solutions for secure transactions (Cluster C) often draw on the trust frameworks explored in Cluster A, and are operationalized through supply chain models in Cluster B. This interdependence shows that researchers are integrating knowledge across domains, forming a multi-dimensional understanding of blockchain's potential in e-commerce.

RQ3: How has research on blockchain in e-commerce evolved?

The analysis of publication trends from 2014 to 2024 indicates three distinct phases: Initial Phase (2014–2015): Very limited research activity, suggesting that blockchain was still an emerging concept in the context of e-commerce. Growth Phase (2016–2017): A surge in research occurred as interest in blockchain's applications—especially in logistics and data security—increased. This coincided with broader interest in fintech and the rise of platforms like Ethereum. Mature Phase (2018–2024): There was exponential growth in publications, particularly in 2023–2024. The increasing complexity and diversity of topics—ranging from supply chain finance to privacy regulations—reflect blockchain's transition from exploratory concept to implementation phase.

The continuous upward trend in publication volume suggests that blockchain remains a dynamic and strategic area of academic and industrial focus, with expanding applications in secure payment systems, contract automation e-commerce platforms.

B. Research Limitation and Future Research

This study has several limitations: First, the bibliometric approach was employed to analyze and explore the development trends of blockchain technology, specifically within the broader e-commerce field. While this quantitative analysis provides valuable insights based on existing published literature, qualitative methods such as interviews or case studies would further deepen the understanding of blockchain's practical applications and challenges in e-commerce.

Second, the data collection was limited to publications up to 2024, and more recent studies were not included, which may affect the comprehensiveness, given the fast-evolving nature of blockchain technology. Additionally, the study relied mainly on the SCOPUS database, excluding other academic databases and non-English publications, which could provide a more diverse and representative dataset.

Despite the promising potential of blockchain to address key issues in e-commerce—such as enhancing transaction security, ensuring data transparency, and improving payment processes—the technology's large-scale implementation remains limited. Many blockchain applications in e-commerce are still at the pilot or experimental stage. Technical challenges, such as high computational requirements due to blockchain's inherent transparency and immutability, hinder its wider adoption.

Blockchain has been extensively studied in finance and various industries, including agriculture and emerging technologies like the Internet of Things and big data. Future research should focus on increasing interdisciplinary collaboration to explore blockchain's integration into diverse e-commerce scenarios. Moreover, developing new technological advancements to overcome current blockchain limitations will be essential for its successful, large-scale deployment in e-commerce.

VI. Conclusion

By examining relevant literature on blockchain-supported e-commerce, this study seeks to examine the current state of blockchain technology implementation in e-commerce. First, the technological aspects of blockchain can successfully solve the issues that e-commerce platforms confront, according to the literature research and bibliometric analysis. Second, the Scopus database was used to gather pertinent literature, and bibliometric analysis was used to look at the trends in e-commerce and blockchain development. We note that there has been a recent surge in blockchain research, with major research hotspots in recent years mostly concentrating on the Internet of Things, supply chains, smart communities, cloud computing, aviation, the chemical industry, and other domains. We also concentrate on examining research patterns related to blockchain technology in e-commerce. It is also noted that blockchain technology plays a significant role in dividing up the e-commerce supply chain process in order to facilitate the growth of creative management practices. Additionally, we discover that blockchain can assist e-commerce in resolving

several of its current issues, including traceability, product information authenticity, logistics, goods distribution efficiency, and consumer information safety. In order to better explore possible innovation opportunities, the specialized functions of the blockchain-supported e-commerce industry have been examined and highlighted through the promotion of applications in production chains, distribution networks, and shopping processes. Additionally, this work offers a number of theoretical understandings and applications. Through creative management practices, blockchain technology can help e-commerce adopt flexible management and allocate resources effectively.

Related Multi-Task Allocation Scheme Based on Greedy Algorithm in Mobile Crowdsensing

Xia Zhuoyue, Raja Kumar Murugesan
School of Computer Science, Taylor's University, Malaysia

***Abstract*—With the popularity of mobile intelligent devices, the mobile crowdsensing (MCS) network based on wireless sensor networks and crowdsourcing technology came into being. There is more and more research on MCS, and it has been applied in many scenarios. Due to the increase in data volume of the MCS platform, the task shows exponential growth. Among them, there will be irreplaceable tasks that belong to the same category, that is, tasks with correlation. If the related tasks can be allocated to the same person for execution, the overhead will be greatly reduced, and the success probability of task allocation will be improved. Firstly, the spatio-temporal distribution of tasks and users is predicted by fuzzy logic to divide spatio-temporal scenarios in this study, and a more suitable multi-task allocation algorithm is selected. Then, when allocating multi-tasks, considering the correlation of tasks, the greedy algorithm is used to allocate multi-tasks according to different scenarios. The experimental results show that compared with the benchmark scheme, the proposed related multi-task allocation scheme based on the greedy algorithm improves the task allocation completion rate by 25.2%, and significantly improves the task allocation success rate in MCS.**

Keywords*—Mobile crowdsensing; task allocation; fuzzy logic; greedy algorithm

I. Introduction

With the emergence of intelligent mobile devices and the Internet of Things, mobile crowdsensing (MCS) using wireless sensor networks and crowdsourcing technology has gained a lot of attention. MCS uses mobile devices to collect and process all kinds of sensing data to complete a variety of complex sensing tasks. By using the intelligent mobile terminal as the basic sensing unit, MCS can build a large-scale sensing system that transcends time and space, and complete complicated sensing tasks compared with the traditional sensing technology that relies heavily on professionals and testing tools. As a result, MCS has become a popular new way of sensing. In recent years, MCS has been widely used in environmental monitoring [1],[2], intelligent transportation [3], public safety [4] and health services [5],[6].

The life cycle of MCS can be divided into three parts, namely task allocation, data collection and data aggregation. As the first step in the life cycle of MCS, task allocation is the basis for the successful completion of the whole sensing system. Due to the complexity and diversity of sensing tasks, the completion of a sensing task usually requires the participation of many participants. However, among many participants, each participant has different willingness and proficiency in different sensing tasks, so it is necessary to select the right participant to better complete the task. If the task allocation is unreasonable, it will lead to the poor quality of sensing data or users will refuse to perform sensing tasks, resulting in the wastage of sensing costs and the failure of task sensing. With the in-depth use of the sensing platform, the number of tasks published by the platform has increased rapidly. If the tasks cannot be allocated quickly and reasonably, it will lead to the accumulation of tasks on the platform, low processing efficiency and high task cost, but at the same time, it is difficult for users to obtain matching tasks to execute. Therefore, the quality of task allocation has a significant impact on the quality and cost of sensing task completion.

First, the two cores of task allocation are to consider the order of task allocation and how to choose the executor. The specific implementation of both is related to the temporal and spatial distribution of tasks and related participants. Therefore, the temporal and spatial distribution of tasks and participants is an important factor affecting task allocation. For example, in a time and space, if the distribution of tasks and participants is dense or sparse, it is less difficult to allocate tasks and the completion rate of task allocation is high; in a time and space, if tasks are sparsely distributed and participants are densely distributed, or tasks are densely distributed, and participants are sparsely distributed. In both cases, if the traditional task allocation method is followed, it will lead to unreasonable task allocation and prolong the task allocation period, which will make the allocated tasks unable to be completed within the time constraint and reduce the task completion rate of the whole platform. Therefore, it is very important to determine the temporal and spatial distribution of tasks and participants for the platform to successfully allocate tasks.

Existing research usually uses quantitative statistical methods to count the temporal and spatial distribution of tasks or participants (Citation). Specifically, the spatio-temporal distribution statistics of tasks can be analyzed according to the data collected by the platform most intuitively. However, because the task publishers are free to move, the number of tasks counted by the platform at a certain time point cannot represent the task distribution in a time period. At the same time, in view of the temporal and spatial distribution of participants, the traditional method can realize statistics by asking participants to provide their location information when collecting sensing data. However, this method will not only lead to the leakage of sensing data privacy but also increase the platform overhead. Therefore, how to reasonably determine the temporal and spatial distribution of tasks and participants in MCS is very important. Secondly, the correlation between multiple tasks is also crucial to the success rate of task allocation. We define correlation as that two tasks belong to the

same category, but they can't replace each other, so we think they are related. If two tasks belong to the same category or time and space are mutually exclusive, they are considered not relevant. For example, U is a user who cares about his own health. After we allocated task A (collecting exercise data) to user U, task B appeared to collect diet data. Because task B and task A belong to the personal health category, they are related. If task B is also allocated to user U, user U will probably execute task B while executing task A, which will improve the completion rate of task A and task B. Therefore, when allocating multiple tasks, if we can consider the correlation of tasks and allocate related tasks to the same user for execution, it will greatly improve the completion rate of tasks and reduce extra expenses.

At present, with the increase of tasks, multi-task allocation [10]-[16] has become the mainstream research trend of task allocation. However, when allocating multiple tasks, the existing work not only ignores the correlation between the above tasks but also fails to take into account the prediction of the temporal and spatial distribution of users and tasks, which makes it difficult to implement the optimal allocation method in various scenarios and leads to the failure of task allocation.

Aiming at the above problems, this study proposes a related multi-task allocation scheme based on a greedy algorithm. In multi-task allocation, the proposed scheme can determine the temporal and spatial distribution of tasks and users, and based on this, use the correlation between tasks to achieve as many task allocations as possible. The main contributions of this study are summarized as follows:

1) In this study, a task-participant spatio-temporal distribution prediction algorithm based on fuzzy logic is proposed. The uncertain input is processed by fuzzy logic, and the accurate spatio-temporal distribution of tasks and users is obtained, which provides reliable parameter support for subsequent allocation algorithms.

2) Based on the calculated time-space distribution values of tasks and users, combined with the task correlation, we design a related multi-task allocation scheme based on a greedy algorithm, and propose two allocation algorithms for different time-space distributions of tasks and participants in the scheme. Aiming at the situation that the distribution of tasks and participants is balanced or there are enough participants, Algorithm 1 is proposed, which uses correlation allocation to improve the task allocation rate as much as possible; Aiming at the shortage of participants' distribution, Algorithm 2 is proposed. In Algorithm 2, the completion rate of task allocation is improved as much as possible with the help of correlation allocation and the incentive provided by the cost saved by Algorithm 1.

3) Experimental results show that compared with the benchmark scheme, the proposed related multi-task allocation scheme based on a greedy algorithm improves the task allocation completion rate by 25.2%, which significantly improves the task allocation success rate in MCS.

The remainder of this study is organized as follows: Section II introduces the related work of multi-task allocation in MCS. Section III presents the proposed related multi-task allocation scheme based on greedy algorithm. Section IV reports and analyzes the experimental results. Section V concludes the study and discusses directions for future work.

II. Related Work

The core of task allocation is to allocate as many tasks as possible through certain strategies under the condition of satisfying relevant constraints, to obtain sensing data that meets quality requirements.

At present, researchers have put forward a series of task allocation schemes. Among them, the single task allocation is simple, and the key problem at this stage is to find a suitable executor for the task. For example, Zhang et al. [7] propose a blockchain-based hybrid reliable user selection and task allocation scheme for MCS, which achieves decentralized task management through blockchain and smart contracts to enhance system performance. From the user's point of view, An et al. [8] proposed a privacy-preserving scheme for high-quality user recruitment in mobile crowdsensing, which evaluates sensing quality based on data deviation and variance under differential privacy and employs a combinatorial multi-armed bandit to achieve budget-constrained user selection. Wang et al. [9] propose a user recruitment method for sparse mobile crowdsensing that leverages deep nonnegative matrix factorization based on social relationships to identify communities and combines community collaboration with task matching to achieve high-quality sensing data collection and accurate sensing map reconstruction using a small number of users under budget constraints.

With the in-depth study of MCS, it has been applied to more and more fields, which leads to the further expansion of the MCS platform and carries more and more tasks. Therefore, single task allocation can no longer meet the growing sensing needs, and then multi-task allocation appears.

In the task allocation scenario, there are two scenarios: offline task allocation and online task allocation. Different from offline task allocation, online task allocation can't determine the number of participants, so it will affect the distribution quality. Therefore, Yang et al. [10] first predicted the number of participants, and then distributed the platform tasks by using the online task allocation method based on the improved genetic algorithm, to maximize the platform utility and minimize the moving cost of participants. In task allocation, the study of individual task allocation will ignore the characteristics between tasks, such as task distance, task similarity, and task priority level, resulting in poor quality of task allocation. Yin et al. [11] studied a new task allocation and path planning problem in MCS. By considering the routing distance, task similarity, and task priority, a group of task locations is allocated to suitable workers, and the location access order of individual workers is determined to realize the overall rationality of the maximum location sequence. Previous studies paid more attention to the completion rate of task allocation or the minimum cost of task allocation, while ignoring the individual situation of platform staff. Because each participant's sensing willingness, knowledge level, and credibility are different, Rahman et al. [12] put forward a new

quality-aware personalized task matching framework, which can better match tasks with participants.

For multi-task allocation, the sensing will of the participant is also very important. Because of the difference in users' sensing ability, the sensing result will be inaccurate. To overcome these problems, Ji et al. [13] proposed a comprehensive multi-task allocation model. Based on the three constraints of the total task budget, perceiving the quality and workload of a single task, the proposed large-scale evolutionary algorithm, a specific problem-solving strategy, and a new genetic operator, multi-task allocation can get as many feasible tasks as possible. In order to recruit suitable users for heterogeneous tasks, Ma et al. [14] proposed three user recruitment algorithms based on greed to solve the problem of heterogeneous user recruitment for multi-heterogeneous tasks, thus minimizing the total platform payment and maximizing the task coverage. In task allocation, users will also be unwilling, or objective conditions will not allow them to move to the task area. Gao et al. [15] proposed a UAV-assisted multi-task allocation method. This method uses drones to verify the data collected by users and uses drones to collect data in data areas not covered by human participants to optimize the sensing coverage and data quality of multi-task allocation. When MCS is applied in an energy transportation system, there are some challenges, such as a single point of failure, low efficiency of independent task allocation, and inability to deal with safety emergency tasks in time. In order to solve these problems, Li et al. [16] defined a decentralized ITS architecture based on blockchain and proposed a concurrent task and safety emergency task allocation method based on reinforcement learning, which can maximize the utility of concurrent tasks on the basis of meeting the requirements of safety emergency tasks.

At present, the focus of multi-task allocation is on multi-task allocation under time constraints [17]-[21]. Li & Zhang [17] studied the multi-task allocation under time constraints, mainly considering the leisure time owned by users and the due time of each task. Huang et al. [18] focus on the execution time of tasks, which solves the problem that mobile users with a limited time budget undertake multiple sensing tasks. Under the limited time limit, the optimal solution can be obtained through the multi-task framework by selecting the participants who have completed the tasks the most times and the shortest total travel distance. In time-limited multi-task allocation, existing research tends to assign most tasks to users with high reputation, which is unfair to new users and leads to low efficiency of task execution. To overcome these problems, Shen et al. [19] proposed a constrained multi-objective optimization model for variable-speed multi-task allocation. Through the three-stage multi-objective mixed shuffling frog leading algorithm, the user returns to the maximum extent and the task completion time is minimized.

In addition, with the complexity of sensing scenes and the diversification of time constraints, taking time constraints as a single auxiliary constraint can no longer achieve a good task allocation scheme. Wei et al. [20] proposed a semi-conditional moving sensation (SO-MTTA) scheme to solve the task allocation problem with multiple time constraints, to maximize the sensing value obtained by the platform. Meitei & Marchang [21] proposed a greedy task allocation method based on interval partition to maximize the profit of the platform in a time-dependent sensing environment.

With the deepening of research, spatial constraints have also become an important research point. Most scholars consider the overall distribution effect when considering the meaning of multitasking. Although the constraints of overall execution time or overall sharing are minimized or met, respectively, according to the distribution results, it is possible that the tasks published are not effectively executed for each task publisher. Wang et al. [22] conducted extensive research on this issue and suggested using the task framework to define the threshold for measuring effective task execution. Only tasks that exceed the threshold are considered as valid tasks. Specifically, the system uses space-time coverage to measure tasks. The task is regarded as a low-quality execution, and if the coverage of time and space is below the threshold, it will not improve the overall task execution quality. The framework can effectively identify tasks suitable for workers and ensure the best performance of each task through the above methods. Liu et al. [23] proposed a privacy-preserving task allocation method for mobile crowdsensing that protects users' temporal and spatial information while maximizing worker income. Ye et al. [24] studied a new task allocation problem in a multi-center supply chain environment with multiple distribution centers. In order to solve this problem, a task allocation framework based on geographical division is proposed. The first stage is the geographical division stage, and the second stage is the task allocation stage. This method can effectively maximize the total number of allocated tasks and minimize the difference in the average number of allocated tasks. To solve the problem of interruption in the task allocation process, wang et al. [25] proposed a method based on the allocation graph to solve the problem of RoBust task allocation (RBTA), which can reduce the cost of workers' detour and minimize the robustness of the allocation scheme.

Fuzzy logic has been applied to the field of mathematics in theory. With the development of computer science and artificial intelligence, it needs to be applied to industrial control systems. Such progress requires computers to perform based on human cognition. Fuzzy logic has been widely incorporated into the computer field.

For example, by extending the standard Mamdani fuzzy logic controller, an expert system based on fuzzy logic to diagnose patients with possible heart disease was established [26]. With regard to bringing fuzzy logic into the proofreading system, some dough was made under the supervision of a fuzzy control system. According to different initial temperatures, different amounts of yeast were added to the dough. The controller will make judgments and adjustments in the whole process to control the volume of dough. In this case, the fuzzy logic controller provides optimal control and improved interference suppression characteristics without a mathematical model [27]. Wang et al. [28] put forward a spatio-temporal model based on a transformer, which uses spatio-temporal relationships to infer and predict sparse sensing data. By using short-term perceived data to predict long-term data, not only is the data cost reduced, but also the data trend can be identified, which effectively improves the working effect of the model.

Yang et al. [29] used fuzzy logic to predict the distribution of users and solved the multi-task allocation problem under time and space constraints through a hybrid greedy algorithm. Zhang et al. [30] put forward a multi-task allocation method based on liquidity prediction, which uses fuzzy logic to analyze historical data to predict the movement of workers, so that workers can better match tasks and complete tasks as much as possible.

Although the above technologies show superior performance in some aspects, they only consider some temporal or spatial characteristics of tasks and participants, and also lack comprehensive analysis and modeling of participant density in time and space. Moreover, the above research did not consider the correlation between multiple tasks. If two related tasks are allocated to the same participant, it will greatly save time of task execution. On the contrary, if the related tasks are allocated to different executors, it will lead to a waste of time and resources. The existing research on multi-task allocation does not consider the correlation between tasks, which may lead to the failure of task allocation or the difficulty of matching tasks with the most suitable participants, resulting in waste of resources and low task completion rate.

Therefore, this study fully considers and analyzes the influence of task distribution and participant distribution on task allocation through the fuzzy logic control method and studies the task correlation in multi-task allocation under time and space constraints in order to achieve the maximum task completion rate.

III. METHODS

A. System Model

The realization of MCS is based on the sensing platform, on which task publishers and task participants complete the corresponding cooperation according to their own wishes and the task allocation strategy of the platform, as shown in Fig. 1. Specifically, there are the following steps:

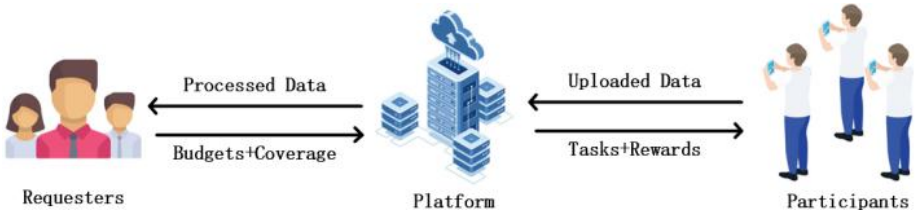

Fig. 1. The illustration of task allocation.

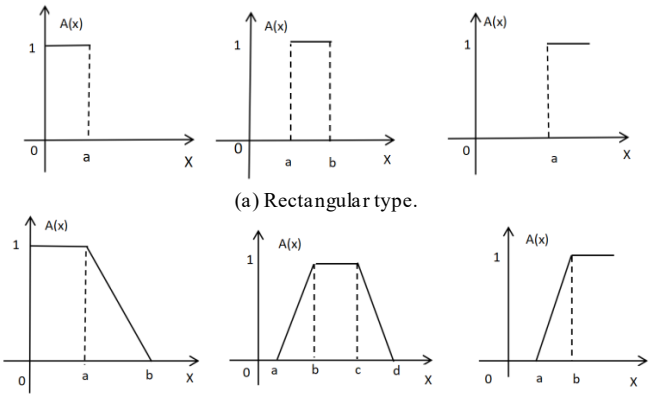
First, the task publisher will publish the task according to its own needs and hand it over to the platform. The submitted data contains the specific information on the task and the rewards that the participants are willing to pay after completing it. Secondly, after receiving the task information, the platform will sort it out and publish it for the participants to check; subsequently, the participants will release their willingness to execute to the platform. The platform will select the appropriate participants to perform the task according to the execution time, implementation place and user's willingness to perform the task. The selected participants will choose whether to perform the task according to their own situation and the task reward. Finally, participants who perform tasks are selected to collect sensing data and upload them to the sensing platform. Thus, a complete sensing task is completed.

The scheme of this study mainly includes two parts. The first part is to determine the temporal and spatial distribution of tasks and participants. The second part is to allocate tasks according to the temporal and spatial distribution of tasks and participants, combined with the correlation between multiple tasks.

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, sc, dc, and rms do not have to be defined. Do not use abbreviations in the title or headings unless they are unavoidable.



B. Fuzzy Logic

In the traditional description of temporal and spatial distribution, some non-quantitative words are usually used to describe the distribution of tasks or participants, such as "more", "a little less" and "sparse". In daily communication, because it is only necessary to express the meaning correctly, such a description can make the two sides understand each other's meaning. But in the computer world, machines can't understand these non-quantitative words, and what computers can understand must be a specific and accurate numerical value. Therefore, we need to introduce fuzzy logic to solve the problem of semantic uncertainty.

Fuzzy logic mainly includes the following three steps, namely fuzzification, fuzzy reasoning and defuzzification. The so-called fuzzification is to process our specific inputs and get a fuzzy set of inputs. Secondly, according to the fuzzy set output in the first step, combined with fuzzy rules, an output fuzzy set can be obtained, which is fuzzy reasoning. The third step is defuzzification, and the fuzzy conclusions are transformed into concrete and clear output values.

1) Fuzzy set: The definition of a fuzzy set can decompose an input into the membership degree of each part in the set. For example, we define the fuzzy set of rain sizes as "heavy rain, moderate rain and light rain". Then, for 20 ml of rainfall, the membership degree of light rain is 0.3, the membership degree of moderate rain is 0.5, and the membership degree of heavy rain is 0.2.

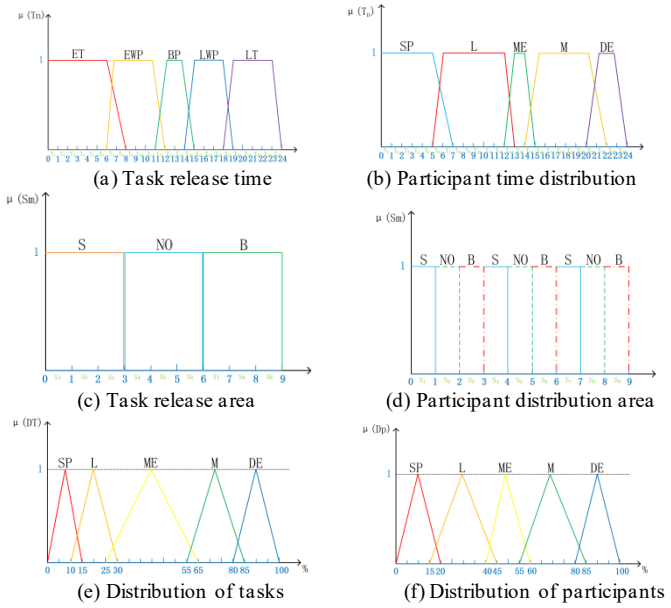
2) Membership function: The most used membership functions are rectangular and (semi) trapezoidal functions, which are divided into small, large and intermediate types. The specific membership function expressions are shown in Fig. 2.

(a) Rectangular type.

(b) Trapezoidal type.

Fig. 2. Common membership function diagram.

3) Fuzzy rules: After fuzzy input, we need to construct rules and use the operation of fuzzy logic to combine the obtained membership degrees as the basis for decision-making. The decision rules of fuzzy logic are sets containing a series of logical statements, which have the following structure:



IF <antecedents> THEN <consequent>

4) Defuzzification: In fuzzy logic, we convert input values into membership degrees of each set through fuzzification and then get some effective output values through fuzzy rules. However, having only a few output values is not helpful for problem analysis, so we need to transform some fuzzy output values. Therefore, the process of converting some fuzzy output values into accurate values is called defuzzification.

C. Temporal and Spatial Distribution of Tasks and Participants

For the definition of the temporal and spatial distribution of tasks and participants, the two core influencing factors are time and space. For example, during working hours and in densely populated areas, the amount of task release is relatively large. However, in the rest time and sparsely populated areas, the amount of task publishing is relatively rare. Therefore, with the help of fuzzy logic, we define the input as time and space. In view of time, this scheme divides 24 hours a day into l parts, which are recorded as $T_L = \{T_1, \ldots, T_n, \ldots, T_l\}$. For space, this scheme divides a region into p sub-regions, which are denoted as $S_P = \{S_1, \ldots, S_m, \ldots, S_p\}$. Therefore, we can use time and space as the input of fuzzy logic to calculate the temporal and spatial distribution of tasks and participants. As the output of fuzzy logic, we define the spatio-temporal distribution parameters of tasks as D_T and the spatio-temporal distribution parameters of participants as D_P.

First, we need to determine the fuzzy set of the spatio-temporal distribution of tasks and the spatio-temporal distribution of participants. We define the fuzzy set of task release and participants' participation time periods as early trough (ET), early wave peak (EWP), balance period (BP), late wave peak (LWP) and late trough (LT). Then, the fuzzy sets of the sub-regions where the tasks and participants are located are defined as small (S), normal (NO) and big (B). As for the output variables, the fuzzy set of the spatio-temporal distribution of tasks and participants is defined as sparse (SP), less (L), medium (ME), more (M) and dense (DE).

(a) Task release time

(b) Participant time distribution

(c) Task release area

(d) Participant distribution area

(e) Distribution of tasks

(f) Distribution of participants

Fig. 3. Membership function diagram.

Referring to common models, we divide a day into 24 equal parts, so l=24, $T_L = \{T_1, \ldots, T_n, \ldots, T_{24}\}$. Divide an area into 12 sub-areas, p=12, $S_P = \{S_1, \ldots, S_m, \ldots, S_{12}\}$. According to experience, we can get the membership function curve in Fig. 3.

Because the input conditions of this scheme are time and space, and the output is a time-space distribution, the rules can be defined by fuzzy reasoning. Specifically, the rules defined in this scheme are shown in the following table:

TABLE I. FUZZY LOGIC RULE TABLE

S_m \ T_n / D_t / D_p	ET	EWP	BP	LWP	LT
S	SP	ME	L	ME	SP
NO	L	M	ME	M	L
B	ME	DE	M	DE	ME

According to the rules in Table I, if the task release period is in the early trough and its area is a partition with few tasks, it can be obtained that the temporal and spatial distribution of tasks is sparse. Through the IF-THEN rule, we can express this rule as: IF (T_n = ET) and (S_m = S), THEN (D_T = SP). Similarly, if the movement period of participants is at the late wave peak, and the area where they are located is a partition with many tasks, it can be obtained that the spatial and temporal distribution of participants is dense. The above rules can be expressed as: IF (T_n=LWP) and (S_m= B), THEN (D_P = DE). For the calculation rule "and" in the above fuzzy logic, this study adopts the principle of minimum membership.

Based on the above work, this study uses the weighted average method to achieve defuzzification, and the specific formula is as follows:

$$OT=\frac{\sum_1^i u(D_i) * OW_i}{\sum_1^i u(D_i)} \quad (1)$$

Among them, $u(D_i)$ represents the value of the membership function D and the weight OW_i, usually taking the middle value of each set. Through Formula (1), we can convert some fuzzy outputs into a usable, accurate output value.

We will illustrate it with examples. Assume that the two input values of the task fuzzy logic method are time point 7.5 and sub-area 4. Firstly, we can get IF (T_n= ET) and (S_m= S), THEN (D_T= SP), IF (T_n= EWP) and (S_m= S), THEN (D_T = ME) by consulting the rule diagram. Then the fuzzy set is calculated by using the membership function of these two inputs. It can be obtained that the value of the early trough T_n(ET [7.5])= 0.25, the value of the early wave peak T_n(EWP [7.5])=0.75, and the value of the member function of the small amount S_m(S [4])= 1. Because the conditional parts of two fuzzy logic rules are connected by the AND method, the value of the membership function will be calculated by the minimum value of the corresponding membership functions. For the rules IF(T_n= ET)and(S_m= S), THEN(D_T= SP), the value ofD_T= SP can be calculated as min(0.25, 1)= 0.25 by the minimum membership rule, and for the same rules IF(T_n= EWP)and(S_m= S), THEN(D_T= ME), the value of D_T= ME can be calculated as min(0.75, 1)=0.75 by the minimum membership rule. Then the clear value is 35.625 by defuzzification with the weighted average method.

Similarly, we assume that the two input values of the participant's fuzzy logic method are time point 5.5 and sub-region 2. Firstly, we can get IF (T_n= ET) and (S_m= NO), THEN (D_P= L), IF (T_n= EWP) and (S_m= NO), THEN (D_P = M) by consulting the rule diagram. Then the fuzzy set is calculated by using the membership function of these two inputs. It can be obtained that the value of early trough T_n(ET [5.5]) = 0.75, the value of early wave peak T_n(EWP [5.5]) = 0.25, and the value of normal (NO) member function S_m(NO [2]) =1. Because the conditional parts of two fuzzy logic rules are connected by the AND method, the value of the membership function will be calculated by the minimum value of the corresponding membership functions. For the rules IF (T_n= ET) and (S_m= NO), THEN (D_P= L), the value of the membership function D_P= L can be calculated as min (0.75, 1) = 0.75 through the minimum membership rule. Similarly, for IF (T_n= EWP) and (S_m=NO), THEN (D_P= M), the value of membership function D_P=M can be calculated as min (0.25, 1) = 0.25 through the minimum membership degree rule. Then the clear value is 40 by defuzzification with the weighted average method.

D. Multi-Task Allocation Scheme

To facilitate the following description, we first explain the parameters used:

In time T_n and space S_m, this scheme defines task sets as Task={t_1, t_2, ..., t_i}, participant sets as Part ={p_1, p_2, ... , p_j}, and the compensation that the task publisher is willing to pay for task sets is B_i={b_1, b_2, ..., b_i} respectively, and the cost of participant for each task is $c_{i,j}$ [see Formula (2)]:

$$C_{i,j}=\begin{bmatrix} c_{1,1} & \cdots & c_{1,j} \\ \cdots & & \cdots \\ c_{i,1} & \cdots & c_{i,j} \end{bmatrix} \quad (2)$$

To describe the participants' willingness to perform tasks, this scheme defines $PW_{i,j}$ as the sensing willingness of participant p_j to perform task t_i, and the parameter $PW_{i,j}$ is binary. When $PW_{i,j}$=1, the participant is willing to perform the sensing task; otherwise, $PW_{i,j}$=0, the participant is unwilling to perform the task.

In addition, we define the parameter TC(t_i,t_j) to describe the correlation between tasks. In detail, if task $t_i$and task t_j belong to the same category and time-space, and the participants can perform task t_j while performing task t_i, it is considered that they are related, and TC (t_i, t_j) = 1; on the other hand, it is considered that tasks t_i and t_j are irrelevant, and the correlation coefficient TC (t_i, t_j) = 0. For example, task 1 is to collect automobile acceleration data, and task 2 is to collect automobile driving recorder data. Task 1 and task 2 belong to automobile data and can be executed in the same time and space, but they are irreplaceable, so task 1 and task 2 are related.

When performing sensing tasks, because the participants have moved to a certain time-space area when performing task t_i, if task t_j is related to task t_i, at this time, for users, performing task t_j does not need additional space movement, so compared with simply performing task t_j, it can save a certain time-space cost. At the same time, because task t_j and task t_i belong to the same kind of tasks, participants can perform them at the same time without secondary learning, so the execution cost of participants will be further reduced and the willingness to perform will be enhanced. We define the coefficient as a way to calculate the cost saved by users in performing related tasks. If a user has already allocated a task t_i and then allocated a related task t_j, the user's execution cost will be reduced from c_j to a*c_j(0<a<1). At this time, because of the correlation allocation, we define the funds saved by the correlation allocation as the balance expenditure, which is expressed by R.

In addition, in the process of allocating tasks, some tasks are urgent, and some tasks are not so urgent. To distinguish the urgency of the task, we define the parameter ε to describe the urgency of the task. The greater the parameter ε, the more urgent the task is, and it needs to be allocated to the participants as soon as possible. On the contrary, it means that the urgency of the task is average and can be allocated later.

1) Multi-task allocation algorithm: Based on the fuzzy logic calculation before, we can get the time and space distribution of tasks and participants in a certain time and space interval. In a time T_n and space S_m, if the spatio-temporal distribution $D_T$of tasks is greater than or equal to the threshold β_P, and the spatio-temporal distribution D_P of participants is greater than or equal to the threshold β_T, or the

spatio-temporal distribution D_T of tasks is less than the threshold β_T, then we think that the resources of tasks and participants can match in this area, which is defined as case 1. If the spatio-temporal distribution D_T of tasks is greater than or equal to the threshold β_T, and the spatio-temporal distribution D_P of participants is less than the threshold β_T, it means that there are more tasks and fewer participants in this spatio-temporal area, and it is necessary to provide some incentives for participants to encourage them to complete tasks as much as possible, which is defined as case 2. However, if the temporal and spatial distribution D_T of tasks is less than the threshold β_T, and the temporal and spatial distribution D_P of participants is greater than or equal to the threshold β_P, it means that there are few tasks and many participants in this area, and there is no need to provide additional incentives for participants, which is defined as case 3.

It can be observed that for the above cases 1 and 3, either the number of participants and the number of tasks are balanced, or the number of tasks is large and the number of participants is small. In both cases, we can adopt a general distribution strategy and do not need additional incentives to motivate users to perform tasks. Therefore, we classify cases 1 and 3 into the first situation. In case 2, there are more tasks and fewer participants. To enable users to complete tasks as much as possible, extra incentives should be given to users. Therefore, we regard case 2 as the second kind of situation. The task allocation strategy in each case is as follows:

We divide the Task set into the first kind of case, task set $Task_1$ and the second kind of situation, task set $Task_2$. The allocated task set is defined as TA, and the initial value is ta = $\emptyset$.

For the first kind of situation: firstly, we sort the tasks $Task_1$ according to the urgency from high to low and find out the task t_{i1} with the highest urgency. Among all users, we screen out the users who are willing to sense the task t_{i1}, and among these willing users, we find out the user p_{j1} who has the lowest sensing cost of t_{i1}. If the cost of executing task t_{i1} by user p_{j1} is less than or equal to the offer that task t_{i1} is willing to pay, task t_{i1} is allocated to user p_{j1} for execution. Then, firstly, the tasks that user $p_{j1}$is willing to perform are screened out from the task list, and among these tasks, the related task t_{i2} of task t_{i1} is found according to the urgency from high to low. At this time, if the cost $a*c_{i2,j1}$ of allocating the task t_{i2} to the user p_{j1} is less than or equal to the minimum cost $Minc_{i2}=\min(c_{i2,1},...,c_{i2,j})$ of the task t_{i2} being executed by all users, and $a*c_{i2,j1}$ is less than or equal to the cost that the corresponding publisher is willing to pay for the task t_{i2}, then the related task is allocated and the task t_{i2} is allocated to the user p_{j1} to be executed together.

In the process of allocation, we define R as the saving cost of task allocation in the first case, then $R=\sum_1^n (1-a) * c_{i,j}$, where n is the number of times to complete the related task allocation.

Algorithm 1 gives the task allocation process in the first situation.

Algorithm 1: Related multi-task allocation algorithm in the first situation based on the greedy algorithm.

Input: Task, Part, B_i, $C_{i,j}$, $PW_{i,j}$, TC（t_i，t_j）,ε,a
Output: TA, R

1. //In the first case, assigning $Task_1$ to participants.
2. R=0
3. Rank tasks in $Task_1$ by ε
4. Repeat
5. for $t_i \in Task_1$, i from 1 to i , do
6. the max(ε) task t_i from $Task_1$ call t_{i1}
7. select all p_j when $PW_{i1,j}$=1 call P
8. find min($C_{i1,j}$) p_j from P call p_{j1}
9. if min($C_{i1,j1}$) ≤ B_{i1} then
10. task t_{i1} is allocated to participant p_{j1}
11. $Task_1$=$Task_1$-t_{i1}, TA=TA+t_{i1}
12. select all task t_i from $Task_1$ when $PW_{i,j1}$=1 call T
13. find the max(ε)task t_i from T when TC（t_{i1}，t_i）=1 call t_{i2}
14. If $a*C_{i2,j1} \le \min(C_{i2,j})$ & $a*C_{i2,j1} \le B_{i2}$ then
15. task t_{i2} is allocated to participant p_{j1}
16. $Task_1$=$Task_1$-t_{i2}, TA=TA+t_{i2}
17. R=R+(1-a)*$C_{i2,j1}$
18. else
19. continue
20. else
21. Continue
22. return TA, R

For the second kind of situation: firstly, find out the task t_{i3} with the highest urgency in the task set $Task_2$, screen out the users who are willing to sense the task t_{i3}, and find out the user p_{j2} who has the lowest sensing cost for the task t_{i3} among these willing sensing users, and if the cost for the user p_{j2} to execute the task t_{i3} is less than or equal to the reward paid for the task t_{i3}, allocate the task t_{i3} to the user p_{j2} for execution; If the cost $C_{i3,j2}$ of user p_{j2} executing task t_{i3} is greater than the offer b_{i3} that task t_{i3} is willing to pay, and it still needs R_{i3}=$C_{i3,j2}$-b_{i3} funds to distribute the task, then the remaining balance cost R′=R-R_{i3} at this time, if $R' \ge 0$, incentive R_{i3} is carried out to distribute task t_{i3} to user p_{j2} for execution.

When the task t_{i3} is allocated to the user p_{j2} for execution, the tasks that the user p_{j2} is willing to execute are first screened out in the task list, and then the related task t_{i4} of the task t_{i3} is found in the order of urgency. At this time, if the cost $a*c_{i4,j2}$ of allocating task t_{i4} to user p_{j2} is less than or equal to the minimum cost of task t_{j4} being executed by all users $Minc_{i4}=\min(c_{i4,1},...,c_{i4,j})$, and $a*c_{i4,j2}$ is less than or equal to the cost paid by the task publisher to task t_{i4}, relevant tasks are

allocated, and task t_{i4} is allocated to user p_{j2} to be executed together. At this time, the remaining cost is $R'=R'+(1-a)*c_{i4,j2}$; if the cost $a*c_{i4,j2}$ of allocating task t_{i4} to user p_{j2} at this time is less than the minimum cost of task t_{i4} being executed by all users $Minc_{i4}=\min(c_{i4,1},...,c_{i4,j})$, and $a*c_{i4,j2}$ is greater than the cost b_{i4} that task publisher is willing to pay for executing task t_{i4}, the extra incentive required at this time is $R_{i4}=a*c_{i4,j2}-b_{i4}$, and the saving cost is $R''=R'-R_{i4}$. If $R'' \geq 0$, the incentive is carried out and task t_{i4} is allocated to user p_{j2} for execution.

Repeat the above process until all tasks are allocated or the number of users is exhausted.

Algorithm 2 gives the task allocation process in the second situation.

Algorithm2: Related multi-task allocation algorithm in the second situation based on the greedy algorithm.

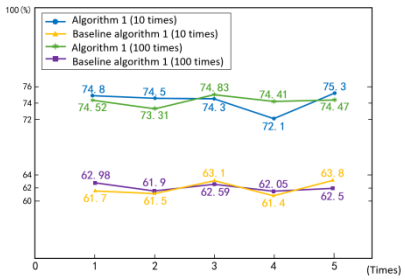
Input: Task, Part, B_i, $C_{i,j}$, $PW_{i,j}$, TC（t_i，t_j）,ε,a,R

Output: TA

```
1. //In the second case, assigning Task_2 to participants.
2. Rank tasks in Task_2 by ε
3. Repeat
4. for t_i ∈ Task_2, i from 1 to i , do
5.    the max(ε) task t_i from Task_2 call t_i3
6.    select all p_j when PW_i3,j=1 call P′
7.    find min(C_i3,j) p_j from P′ call p_j2
8.    if min(C_i3,j2) ≤ B_i3 then
9.      task t_i3 is allocated to participant p_j2
10.        Task_2=Task_2-t_i3, TA=TA+t_i3
11.    else
12. R_i3=C_i3,j2-b_i3
13. R′=R-R_i3
14.   if R′ ≥0 then
15.        provide incentive R_i3 for task t_i3
16.        task t_i3 is allocated to participant p_j2
17.        Task_2=Task_2-t_i3, TA=TA+t_i3
18.        R=R-R_i3
19.       else
20.         continue
21. if task t_i3 is allocated to participant p_j2 then
22. select all task t_i from Task_2 when PW_i,j2=1 call T′
23.       find the max(ε)task t_i from T′ when TC（t_i3，t_i）=1 call
t_i4
24.        If a*C_i4,j2 ≤ min(C_i4,j) & a*C_i4,j2 ≤ B_i4 then
25.        task t_i4 is allocated to participant p_j2
26.        Task_2=Task_2-t_i4, TA=TA+t_i4
27. R′=R′+（1−a）*c_i4,j2
28.        else
29.          R_i4=a*c_i4,j2-b_i4
30.          R′=R′-R_i4
31.   if R′ ≥0 then
32. provide incentive R_i4 for task t_i4
33.          task t_i4 is allocated to participant p_j2
34.          Task_2=Task_2-t_i4, TA=TA+t_i4
35.          R′=R′-R_i4
36.         else
37.           continue
38.        else
39.          Continue
40.   return TA
```

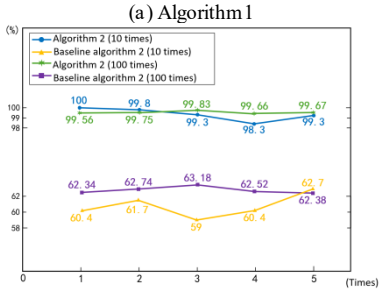
IV. RESULTS

To illustrate the performance of the proposal, this section compares the proposed algorithms with the baseline algorithm derived from the existing work [29]. Note that the core idea of [29] is allocating sensing tasks by means of a greedy algorithm. Therefore, the classical greedy algorithm is adopted as the baseline for comparison.



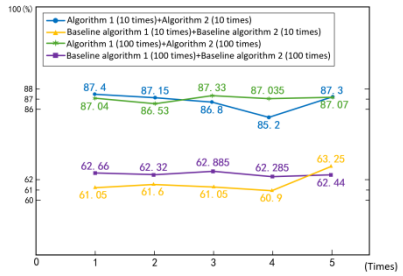
A. Task Allocation Rate

We set the discount coefficient a=0.5, the urgency ε is randomly generated between 1 and 10, the participants' wishes $PW_{i,j}$ and the correlation coefficient TC（t_i，t_j） are randomly assigned between 0 and 1, the compensation B_i that the task publisher is willing to pay for the task is randomly generated between 1 and 15, and the cost $C_{i,j}$ that the user i needs to perform the task j is randomly generated between 5 and 20.



Task set of algorithm 1 contains 100 randomly generated Tasks, set Part contains 50 randomly generated participants, task set of algorithm 2 contains 100 randomly generated tasks, and set Part contains 20 randomly generated participants. In the process of testing, we tested two groups of data respectively. The first group of data was tested 10 times, each time, with five times. The second set of data is tested 100 times at a time, with five times.

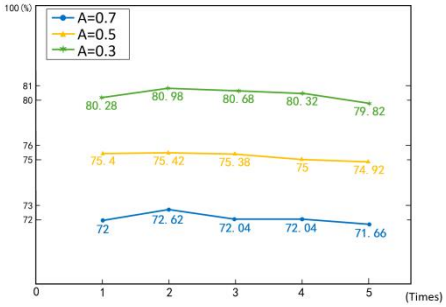
As can be seen from Fig. 4, in the first set of data, the average task allocation rate of Algorithm 1 is 74.24%, that of Algorithm 2 is 99.34%, and that of Algorithm 1 and 2 is 86.77%. At the same time, the average algorithm allocation rates of baseline Algorithm 1 and baseline Algorithm 2 are 62.3% and 60.84%, respectively, so the total average task allocation rate of the baseline algorithm is 61.57%. Compared with the baseline algorithm, Algorithm 1 improves the task allocation rate by 11.9% because of the use of related task allocation. Compared with the baseline algorithm, the average task allocation rate of Algorithm 2 is 99.34%, which is 38.5% higher than that of the baseline algorithm, which proves the superiority of the algorithm.



By comparing the first group of data (10 times in each group) with the second group of data (100 times in each group), the fluctuation of the task allocation rate of the algorithm will decrease and the allocation completion rate will tend to be stable with the increase of task execution times.

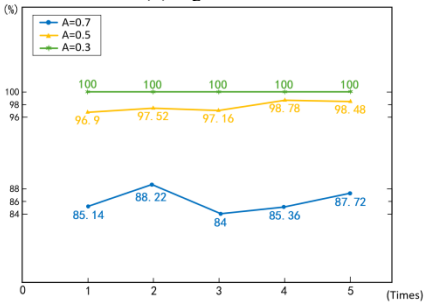
(a) Algorithm1

(b) Algorithm2



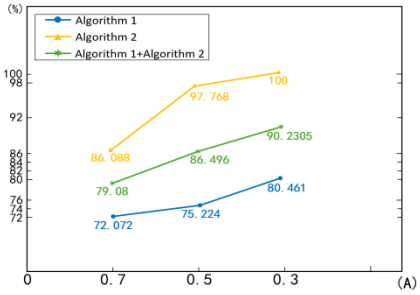
(c) Algorithm1+Algorithm2

Fig. 4. Algorithm task allocation rate result.



B. Discount Coefficient

We tested three sets of data, and set the discount coefficients a=0.3, a=0.5 and a=0.7, respectively. The urgency ε is randomly generated between 1 and 10, the participants' willingness $PW_{i,j}$ and the correlation coefficient TC（t_i，t_j）are randomly assigned between 0 and 1, the compensation B_i that the task publisher is willing to pay for the task is randomly generated between 1 and 15, and the cost $C_{i,j}$ that the user i needs to perform the task j is randomly generated between 6 and 20. Task set of Algorithm 1 contains 500 randomly generated Tasks, set Part contains 100 randomly generated participants, task set of Algorithm 2 contains 500 randomly generated tasks, and set Part contains 50 randomly generated participants. In the process of testing, each group of data is tested 10 times, and there are five groups. The test results are summarized in Fig. 5.



When a=0.7, the average task allocation rate of Algorithm 1 is 72.072%, the average task allocation rate of Algorithm 2 is 86.088%, and the overall average task allocation rate of algorithm is 79.08%. When a=0.5, the average task allocation rate of algorithm 1 is 75.224%, the average task allocation rate of algorithm 2 is 97.768%, and the overall average task allocation rate of algorithm is 86.496%. When a=0.3, the average task allocation rate of Algorithm 1 is 80.416%, the average task allocation rate of Algorithm 2 is 100%, and the total average task allocation rate of algorithm is 90.208%. From the comparison of three data, the smaller the coefficient a is, the greater the cost saved by related allocation, and the greater the incentive provided for the second allocation, the higher the average task allocation rate.

V. Conclusion

In this study, a related multi-task allocation scheme based on a greedy algorithm is proposed. By quantifying the temporal and spatial distribution characteristics of tasks and participants, different application scenarios are distinguished, and two allocation algorithms suitable for scenarios with sufficient participants and limited resources are designed respectively. Experimental results show that, compared with the benchmark method, the proposed scheme can effectively improve the success rate of task allocation in the mobile crowd sensing (MCS) system in various temporal and spatial distribution scenarios. Especially in scenes with strong task correlation or limited participants' resources, this method shows more stable and consistent performance advantages through joint allocation of related tasks and optimization of incentive costs. Overall, the experimental results verify the effectiveness of the proposed algorithm in improving task allocation efficiency and completion rate from different scene levels.

Although the method in this study has achieved remarkable performance improvement in the experiment, there are still some research limitations. First of all, the task correlation modeling is coarse-grained, which is mainly measured from the perspective of overall correlation, and has not fully described the fine-grained correlation characteristics between users and tasks in terms of historical behavior and ability differences, which limits the applicability of the algorithm in complex practical scenarios to some extent. Secondly, the uncertainties of participants' behaviors, dynamic changes of tasks, communication and calculation overhead in real MCS system have not been fully considered, and the generalization ability of the results needs further evaluation. In addition, although the proposed greedy strategy has advantages in computational efficiency, it still has potential for improvement in global optimality.

Future research will focus on the above limitations. On the one hand, the modeling of task correction and user correction will be further refined, and the multidimensional features and learning mechanism will be introduced to improve the accuracy of the allocation decision. On the other hand, the algorithm will be verified in more complex and real application scenarios, and the multi-task allocation strategy combined with intelligent optimization or learning method will be explored to achieve more efficient and robust MCS multi-task allocation.

A Lightweight Rule-Based Detection Approach for ARP Flooding Malware in Office Networks

Rizal Fathoni Aji, Heri Kurniawan, Nilamsari Putri Utami
Faculty of Computer Science, Universitas Indonesia, Indonesia

***Abstract*—Address Resolution Protocol (ARP) is a standard protocol used to map an IP address to its MAC address so the network can send packets to its destination. Office networks, which typically have limited network resources, are vulnerable to ARP flooding attacks launched by malware. ARP flooding can be used by malware to create network disruption and jam the networks. This study presents a rule-based detection method, Time Density ARP Thresholding with Binding Consistency Monitoring (TDCM), to identify ARP flooding using a simple mechanism, making it suitable for use in networks with limited hardware. To detect flooding anomalies, the TDCM algorithm monitors the flow of ARP packets and the consistency between MAC IP bindings in ARP packets. In this study, a series of experiments was conducted and repeated multiple times. On average, the experiment shows that the system performs well under high-volume ARP attack conditions. This proposed method offers an alternative to machine learning techniques, making it more suitable for deployment in resource-constrained office networks. Future work will focus on improving detection in low-volume attack scenarios, validating performance in real-world environments, and implementing on devices with limited computing resources.**

***Keywords*—ARP flooding; cybersecurity detection; rule-based detection; lightweight intrusion detection**

I. Introduction

Today, office networks play a crucial role in our daily activities. High usage of office networks and internet connectivity introduces cybersecurity threats, particularly from malware. Malware can exploit vulnerabilities in protocols to disrupt network operations [1]. For example, the Address Resolution Protocol (ARP) flooding technique can be used by malware to cause network and device congestion. ARP flooding is a network-based attack that exploits the mechanism in the ARP protocol. It has a function that maps IP addresses to MAC addresses at the data link layer [2]. In an ARP flooding attack, an attacker sends a large number of malicious ARP packets into the network, causing ARP Table overflow on network devices. This results in incorrect or missing address resolutions and disruption of network services [2].

A high volume of ARP flooding attacks can cause network denial-of-service (DoS) attacks, data loss, and potential breaches of sensitive information [3]. ARP flooding attacks generate a high volume of ARP request/reply packets from malicious sources within a short time frame [4]. These traffic spikes sometimes exceed the number of ARP activities observed in typical LAN environments, which typically maintain stable ARP caches and low ARP exchange rates. Attackers often used spoofed or randomized MAC and IP addresses, generating inconsistent ARP Table updates that lead to Table exhaustion or overflow [5]. Sometimes, forged ARP packets are broadcast across the subnet to maximize the effect [6]. Those characteristics can be used as a foundation for constructing rule-based detection mechanisms [7].

Some approaches have been developed to detect and mitigate ARP flooding attacks, from traditional fingerprint-based techniques to machine learning and deep learning methods. Conventional methods rely on static rules, such as port security, static ARP entries, dynamic ARP inspection, and a whitelist based on IP MAC binding validation [2]. Other methods, such as monitoring ARP request rates, tracking consistency between MAC and IP addresses, and identifying bulk packet broadcasts from non-gateway devices, could help administrators quickly detect ARP flooding attempts. However, such approaches may lack adaptability to evolving threats.

Currently, ARP attack detection is shifting toward more intelligent and adaptive mechanisms. Using machine learning and deep learning models, such as Random Forest, Convolutional Neural Networks, and Bi-directional Long Short-Term Memory (Bi-LSTM) architectures, achieves high accuracy and low false-positive rates in identifying malicious ARP traffic [5], [7], [8]. In industrial contexts, especially in the Internet of Things environments, hybrid CNN and Bi-LSTM models can detect large-scale ARP-based attacks [7]. The adoption of Software-Defined Networking (SDN) can also enhance ARP security by enabling centralized binding verification and automated mitigation strategies [6]. Another solution employs blockchain-based immutable address-resolution records and cloud-based ARP monitoring systems, thereby enhancing scalability and resilience for ARP detection in distributed environments [5].

Although machine learning and deep learning show promising results, they have limitations. They require large datasets for training, which are challenging to obtain in real-world ARP flooding scenarios. Machine learning and deep learning also make detection more complex for administrators to interpret [9]. These models consume substantial computing resources during training and inference, making deployment less practical [6]. Modified packets may also bypass those models by exploiting a threshold in the machine-learning algorithm. In contrast, fingerprint-based mechanisms can offer deterministic, explainable, and lightweight detection that can be used with minimal resources [4].

This study proposes an algorithm, Time Density ARP Thresholding with Binding Consistency Monitoring (TDCM), for detecting ARP flooding attacks using a rule-based detection

approach. With low computational requirements, TDCM can be deployed on resource-constrained devices. The algorithm detects common ARP flooding characteristics, such as bulk ARP packet broadcasts within short intervals and spoofing signs, in which a single IP address is associated with multiple MAC addresses. This mechanism is evaluated through simulations involving both regular network traffic and ARP attack scenarios.

II. Theoretical Foundation and Related Works

An office network designed to connect multiple devices within a work environment, enabling communication, data sharing, and resource sharing among employees and departments. The network infrastructure typically comprises both wired and wireless local area networks. Wired connections often rely on Ethernet cables connected to switches and routers, providing stable, high-speed connectivity for desktop computers, servers, and network printers. Wireless networks, by contrast, offer flexibility and mobility, enabling laptops, tablets, and mobile devices to connect without physical cabling. A central switch or a set of interconnected switches serves as a backbone that manages traffic flows between devices. These switches are often connected to one or more routers that provide internet access and enable communication with wide-area networks. Depending on the organization's size and structure, the network may be divided into segments or virtual LANs to separate traffic for security and performance reasons [10].

Another important aspect of office networking is sharing resources. File servers are commonly used to store organizational data and to enable employees to share files and documents. Network printers and scanners are connected through print servers, enabling centralized management and reducing the need for individual device setups. In larger organizations, directory services are often implemented to manage users, devices, and policies in a unified manner. This centralized approach simplifies administration while maintaining a consistent security framework.

Network administrators must ensure that bandwidth is allocated appropriately to prevent congestion, especially during peak hours when many users are online simultaneously. Quality-of-service configurations may be applied to prioritize critical traffic, such as voice over IP calls or video conferencing, over less time-sensitive data transfers. Regular network assessments help identify bottlenecks and potential failures before they affect productivity. Finally, office networks are designed for scalability. As businesses grow, additional devices, users, and services need to be integrated without causing significant disruptions.

The Address Resolution Protocol (ARP) is a fundamental component of computer networks. It operates at the data link layer and plays an essential role in maintaining network connectivity. Its primary function is to map IP addresses to corresponding MAC addresses. Each device on the network maintains an ARP Table, which contains a list of IP-to-MAC address mappings for other devices. When a computer application wants to send data, it uses a system call in the operating system. The operating system first checks its ARP Table to see whether the destination IP address already has a corresponding MAC address. If it does not, the operating system broadcasts an ARP request on the network, asking which MAC address corresponds to that IP address. Upon receiving the ARP request, the corresponding device responds with its MAC address. However, if the IP address is in a different subnet, the router responds instead, using its own MAC address. Upon receipt of the reply, the ARP Table is updated with the new information. Over time, if an entry is no longer valid or the time to live expires, the IP-to-MAC pair is removed from the Table [10].

The ARP packet flows through the network without any encryption or authentication mechanism [11]. Any device on the network can generate a bogus or fake ARP packet, which can lead to network errors and disruption. This lack of protection means that any device connected to the network can generate a fake or bogus ARP packet. When this happens, it can result in serious problems such as network errors or even the complete disruption of communication between devices [3]. This weakness has long been recognized as a major security vulnerability, and attackers often take advantage of it to intentionally cause malfunctions and interruptions in computer networks. However, because ARP is a widely used protocol and an integral part of the network layer, the vulnerability still exists. Hong et al. [11] and other researchers have already proposed ideas to enhance security in the ARP protocol, but changing the current ARP protocol requires significant effort, especially changing the code embedded in millions of network devices worldwide.

ARP flooding is a type of network attack that exploits a vulnerability in the ARP protocol. In this attack, the attacker generates a large number of ARP packets and sends them across the network [12]. The continuous flow of these fake packets can overwhelm the ARP tables in the targeted devices, filling them with unnecessary or false ARP entries. When the ARP table becomes overloaded, the device may no longer function properly, leading to errors in communication between hosts on the network. Another major effect of ARP flooding is the excessive traffic it creates on the network. Because so many packets are being transmitted at once, the network bandwidth becomes congested. As a result, legitimate traffic, such as actual data transmissions between users, may be delayed or even completely blocked. This may lead to denial of service or upper-layer service disruption [5]. ARP flooding is not only a direct attack on specific devices but also a threat to the stability and availability of the entire network.

Certain types of malware exploit weaknesses in the ARP protocol by using ARP flooding to launch denial-of-service (DoS) attacks or to position themselves for man-in-the-middle (MITM) attacks [3]. One common method involves sending a large number of ARP request packets into the network, which forces devices with the corresponding IP addresses to repeatedly respond. In some cases, the malware may also send a large volume of ARP reply packets, which can overwhelm the targeted devices. This continuous flooding puts heavy pressure on the ARP cache and consumes a significant amount of CPU resources, eventually disrupting normal network operations and causing a denial of service. If the attack is directed at critical infrastructure such as routers or switches, the impact can be even more severe. It could shut down the entire network and interrupt communication for all connected devices.

ARP flooding attacks typically exhibit distinct traffic patterns that can be detected using rule-based mechanisms. One primary characteristic is a high volume of ARP request or reply packets, often originating from a single host or multiple forged sources within a short time frame [12]. This abnormal packet volume is usually much higher than the expected ARP traffic in a typical local area network, which typically maintains stable ARP caches and exhibits low ARP exchange rates [4]. Additionally, ARP flooding often involves spoofed or randomized source MAC and IP addresses, resulting in continuous updates to the ARP tables of switches or hosts, eventually leading to table exhaustion [5]. Another notable feature is the broadcast nature of forged ARP packets, as they are typically sent to the entire subnet to maximize network disruption [6]. These traits, such as packet rate threshold violations, inconsistent or unknown MAC and IP bindings, and repetitive broadcast ARP replies, form the basis for rule-based detection mechanisms. By implementing static thresholds, whitelist-based validation of IP and MAC pairs, and monitoring for excessive ARP broadcasts from non-gateway devices, network administrators can define deterministic rules to promptly identify and block ARP flooding attempts without relying on complex models or machine learning [7].

Alongside intelligent detection models, recent research also underscores the importance of integrating detection with prevention frameworks. For instance, deploying Dynamic ARP Inspection in SDN-controlled environments has enabled rapid identification and isolation of malicious nodes [4]. Furthermore, cloud-based ARP monitoring systems that use real-time data analysis have shown scalability and effectiveness in large, distributed networks [5]. Integrating IP and MAC static binding in industrial SDN settings and using blockchain for immutable address resolution records represent emerging frontiers in ARP security [6]. These developments reflect a broader trend toward building resilient, autonomous systems that not only detect but also actively adapt to evolving ARP-based threats across enterprise, cloud, and IoT networks.

Despite the growing adoption of machine learning and deep learning for ARP flooding detection, these approaches have notable limitations compared with traditional fingerprint-based mechanisms [9]. A major drawback is reliance on large, well-labeled datasets for effective training. In practice, collecting real-world ARP flooding data can be challenging, leading to models that may generalize poorly across different network environments [5]. Additionally, machine learning and deep learning models often act as black boxes, making it difficult for network administrators to interpret or justify detection outcomes. By contrast, fingerprint-based systems are rule-driven and inherently explainable. Furthermore, these techniques tend to consume significant computational resources, especially during training and real-time inference, which can hinder deployment in resource-constrained environments. Another concern is their vulnerability to adversarial inputs; carefully crafted packets can potentially bypass detection by manipulating model behavior. In contrast, fingerprint-based mechanisms, while limited to known attack signatures, offer fast, deterministic, and lightweight detection that is easier to implement and maintain [4]. These tradeoffs highlight the need for a balanced approach, where intelligent systems are supported by traditional methods to ensure comprehensive and resilient ARP flooding defense.

In parallel with network-level attacks, recent studies have highlighted the growing threat of side-channel attacks, in which attackers exploit indirect information leakage, such as timing behavior, power consumption, cache access patterns, or electromagnetic emissions, to infer sensitive data [13]. Side-channel attacks have been demonstrated against both classical cryptographic implementations and lightweight cryptography, which is increasingly adopted in resource-constrained environments such as IoT and embedded systems [14],[15]. While lightweight cryptographic primitives reduce computational overhead, several works report that simplifications in control flow and reduced noise may unintentionally amplify side-channel leakage. Similarly, emerging post-quantum cryptography (PQC) algorithms, although designed to resist quantum adversaries, are vulnerable to timing and cache-based side-channel attacks due to complex polynomial operations and memory-intensive structures [16][17]. Prior research emphasizes that security mechanisms designed for constrained environments must consider not only algorithmic robustness but also implementation-level leakage. These findings reinforce the relevance of lightweight, deterministic, and transparent security mechanisms—such as rule-based detection approaches—that minimize attack surfaces and reduce exploitable side-channel behaviors in real-world deployments.

III. Research Method

This research starts with a literature study, the development of a simulation, an experiment, and the creation of conclusions. First, a literature review was conducted by analyzing existing ARP flooding detection techniques, both traditional and machine learning based, comparing the pros and cons of both mechanisms. This provided the theoretical foundation for the proposed rule-based detection framework. Second, a Python-based simulation environment was developed to model ARP traffic in a controlled office network scenario. The simulator was designed to generate both normal and attack traffic. The detection module was implemented to monitor ARP packet density and MAC IP binding anomalies. The burst packets are identified with a short timestamp among packets. The traffic simulation algorithm can be seen in Algorithm 1. Third, experiments were performed by executing multiple simulations with varying attack intensities. Each scenario was repeated five times, and detection performance was measured using metrics such as the number of undetected attack packets, true positives, and false positives. Results were averaged and visualized to reveal detection trends.

Algorithm 1: Traffic Simulation

```
SimulateTraffic():
now ← current time
attack_count = 100, 150, 200, …, 1000
normal_count = attack_count/2
For each in 1 to normal_count:
Create packet with:
src_ip = fixed unique IP
```

```
src_mac = fixed unique MAC
timestamp = now + randomFloatTime(0,5)
is_attack = False
Add to packets

For each in 1 to attack_count:
Create packet with:
src_ip = fixed IP
src_mac = unique or duplicate MAC
timestamp = now + randomFloatTime(0,5)
is_attack = True
Add to packets
```

The proposed mechanism is called Time Density ARP Thresholding with Binding Consistency Monitoring (TDCM). It combines analysis of ARP packet density with tracking of IP and MAC binding behavior, without using statistical learning models or training data. The core of the TDCM system comprises two parallel components, as shown in Fig. 1.

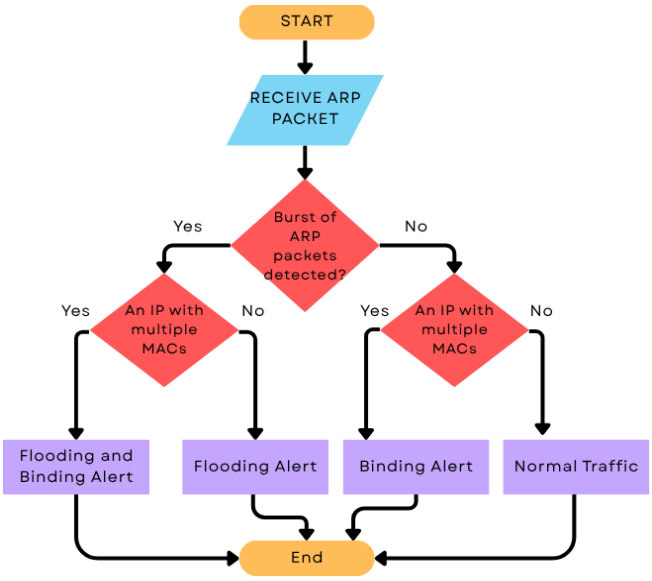

Fig. 1. Flow of the TDCM method.

The first component focuses on time-density monitoring, measuring the arrival rate of ARP packets within a predefined time window. A burst of ARP packets is detected when the number of ARP packets from a single host or targeting a particular IP address exceeds a set threshold within a short period. In this case, the system raises a potential flooding alert or a combination of flooding and binding alerts. If incoming packets contain an IP address with multiple MAC addresses, the attack is categorized as an ARP flooding and spoofing attack. Otherwise, the attack is categorized as ARP flooding only, without spoofing. This approach is based on the insight that ARP flooding attacks generate unusually high volumes of ARP traffic over a short period, which deviates significantly from typical network behavior. By calibrating this threshold based on historical network baselines, false positives can be reduced without the need for adaptive learning. Malware sometimes combines ARP flooding with a spoofed MAC address to initiate a man-in-the-middle attack.

The flooding alert component tracks the number of ARP requests and replies received per source MAC address over fixed intervals. If a particular source exceeds a predefined packet-per-interval threshold, the system flags it as a flooding candidate. Unlike static rate limiting, this approach uses sliding windows to account for short bursts while avoiding false positives from legitimate activity.

The second component, binding consistency monitoring, monitors the consistency of IP-MAC pairings over time. In a normal network, a specific IP address is usually bound to a fixed MAC address within a session or subnet. During ARP spoofing or flooding scenarios, MAC-IP bindings in ARP packets change rapidly. Multiple MAC addresses may be associated with the same IP address, or vice versa. TDCM tracks these inconsistencies and flags them as malicious packets.

Each incoming ARP packet is checked against a list of verified IP and MAC pairs. If a device continuously uses different MAC addresses with the same IP address in a short time frame, it is marked as suspicious. This check is also performed after packets are detected as burst ARP packets.

This approach offers a reliable and efficient method to detect ARP-based attacks. By using deterministic rule-based logic, it enhances interpretability and operational transparency, two aspects that often lack in machine learning approaches. Network administrators can trace each alert back to a specific condition or packet pattern, facilitating faster incident response and better threat understanding.

An optional quarantine queue can be activated when both modules flag a source: traffic from the suspicious node is rate-limited or redirected to an isolated VLAN for further inspection or logging. This multi-aspect detection, based on time density and binding logic, enables fast, deterministic identification of ARP flooding attacks using simple thresholds and lookups.

IV. Results and Discussion

To evaluate the detection effectiveness of the proposed TDCM algorithm, we conducted a series of simulations emulating ARP flooding attacks of varying intensities. The simulations generated two distinct traffic patterns. The first was legitimate ARP traffic from a single device with a fixed IP-to-MAC pairing, and the second was malicious flooding traffic that imitated a spoofing attack by sending a large volume of ARP packets from a single IP address with randomly generated MAC.

The legitimate traffic simulated a normal device transmitting ARP requests or responses at a moderate rate. Conversely, the flooding traffic was designed to trigger TDCM alerts by exceeding the time density threshold and violating binding consistency. The number of malicious ARP packets injected into the network increased from 100 to 1000 in steps of 50. This allowed testing both low-volume and high-volume attack scenarios, representative of stealthy and aggressive attack profiles.

Each configuration was executed five times with randomized MAC address generation and minor timing fluctuations during packet injection. The detection engine recorded the number of undetected packets for each run, and the results were averaged. The key metric analyzed was the

percentage of undetected malicious packets relative to the total number injected. The results in Table I represent the average number of undetected attack packets across these five runs.

TABLE I. SIMULATION RESULTS

Total packet	Flooding alert	Binding alert	False Positive (%)	False Negative (%)
150	0	91	0.00	9.00
225	0	140	0.00	6.67
300	0	191	0.00	4.50
375	0	241	0.00	3.60
450	0	291	0.00	3.00
525	0	341	0.00	2.57
600	10	391	0.00	2.25
675	34	439	5.56	2.00
750	55	491	10.00	1.80
825	80	541	13.64	1.64
900	108	591	16.67	1.50
975	136	641	19.23	1.38
1050	157	691	21.43	1.29
1125	186	741	23.33	1.20
1200	215	791	25.00	1.13
1275	234	841	26.47	1.06
1350	259	891	27.78	1.00
1425	289	941	28.95	0.95
1500	312	990	30.00	0.90

The number of packets in this simulation ranged from 150 to 1500 total packets. The total packet count consisted of one- third normal packets and two- thirds attack packets. The goal was to observe the system's ability to trigger flooding and binding alerts and measure its accuracy through false- positive and false-negative rates. At lower traffic volumes (below 600 packets), the system issued no flooding alerts, and only binding alerts were triggered. This indicates that low- volume attacks can be handled by the binding consistency module alone. However, as the total packet count increased beyond 600, the system began generating flooding alerts, starting with 34 alerts at 675 packets and increasing progressively to 312 alerts at 1500 packets.

The detection system maintained a zero false- positive rate up to 600 packets. As the packet volume increased, however, the false- positive rate gradually rose, reaching 30% at 1500 packets. This tradeoff reflects the system's sensitivity under stress, as aggressive ARP flooding patterns resemble high-volume traffic spikes that may sometimes be misclassified. On the other hand, the false- negative rate consistently decreased as the total packet count increased, from 9% at 150 packets to 0. 0.9% at 1500 packets, indicating that the system becomes more accurate at detecting attacks as flooding intensity rises.

The simulation results show the effectiveness of TDCM in detecting ARP flooding attacks. The method, which combines flooding threshold monitoring and MAC IP binding, can detect malicious ARP packet activity while maintaining a reasonable false- positive rate. These results also show that balancing packet data with traffic activity can maintain accuracy in flooding detection.

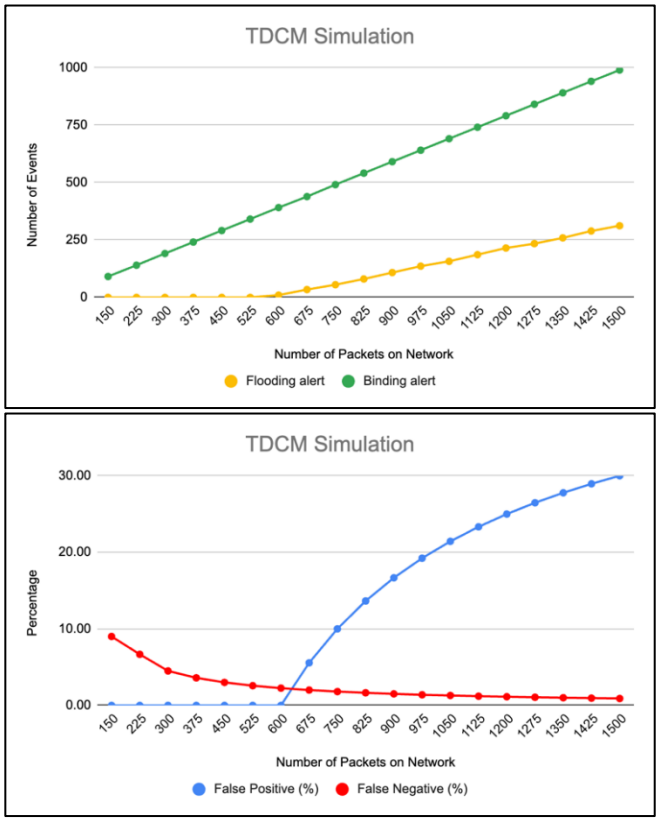

Fig. 2. Graph of simulation result.

Fig. 2 shows a trend with larger attack volume. This trend indicates that the TDCM algorithm will be more effective at recognizing ARP flooding as the number of packet attacks increases. The reduction in undetected packets suggests that the system's time density and MAC IP consistency thresholds will likely be triggered more often in high- packet- attack scenarios. This shows that TDCM may have poor performance in low-volume attacks, but it will increase its performance on large-scale ARP flooding attacks.

Compared to machine learning-based approaches, the TDCM mechanism offers a comparable alternative in high-volume ARP flooding attack scenarios. As demonstrated in the latest simulation, TDCM achieved a detection rate of up to 99% with a false-negative rate as low as 0.9% at 1500 total packets, without relying on model training or feature engineering. This indicates that TDCM can match the effectiveness of ML models in identifying large-scale flooding attacks while maintaining low computational complexity. Furthermore, while recent studies [4] acknowledge the scalability and adaptability of machine learning and deep learning techniques, they also highlight concerns about their black-box nature and limited interpretability during real-time deployment.

In contrast, TDCM's rule-based approach offers transparent detection logic, making it easier for administrators to trace and understand alerts during live network monitoring. TDCM's

approach, based on defined rules and simple logic, offers transparency and low overhead. It doesn't need a powerful computer or a GPU-powered device, making it ideal for resource-limited hardware. Because of its simplicity, TDCM can be implemented using the C programming language and deployed on low-cost IoT hardware. Technically, TDCM can also be implemented using a shell script running common networking tools on a tiny Linux system, making it feasible to deploy in resource-limited office network environments.

V. Conclusion

This study introduced a simple rule-based mechanism, Time Density ARP Thresholding with Binding Consistency Monitoring (TDCM), to detect ARP flooding malware in office networks. The proposed method combines two strategies: monitoring the number of ARP packets in the network and checking the consistency of IP-MAC bindings. TDCM does not require model training, large datasets, or high computational resources to implement.

Simulation and experiments show that the TDCM algorithm performs well under high-volume ARP flooding. MAC and IP binding detection plays a significant role in detecting most attacks. Combined with its monitoring strategies, TDCM can maintain a reasonable false-negative rate. The number of detected attack packets increased as the volume of malicious traffic increased. At a low injection level of 100 packets, the system missed an average of 10 packets. However, as the attack volume reached 1000 packets, the undetected rate dropped to less than 1%. This shows that TDCM is effective in identifying flooding attempts, making it suitable for practical deployment in infrastructure-limited office environments.

TDCM's transparency and deterministic rule structure provide an advantage in interpretability, so network administrators can readily understand, audit, and tune detection logic. This makes the system ideal for environments with limited staffing. Furthermore, its low overhead ensures compatibility with legacy systems, unmanaged switches, and embedded devices, where machine learning-based solutions are often impractical. Despite its strengths, TDCM showed reduced sensitivity to low-rate ARP flooding scenarios.

VI. Future Work

Future work will focus on enhancing detection granularity during such attacks. One promising direction is to integrate adaptive thresholding techniques that adjust detection parameters based on observed traffic baselines. Additionally, field testing in production networks is essential to assess performance under real-world conditions, including traffic noise, heterogeneous devices, and mixed protocol loads. Another possible direction for future research is to apply the algorithm in wireless environments with limited computing resources, such as IoT networks. IoT systems are an excellent setting for testing and applying TDCM because they typically comprise numerous small devices with limited processing power and memory. Experimenting with TDCM in this type of environment could yield valuable insights into how well the algorithm performs under real-world limitations. Over time, studies across different device types and network conditions could further refine the algorithm and enable more efficient, practical implementations of TDCM.

EfficientNet-Based Melanoma Classification with CBAM Attention and Monte Carlo Dropout for Robust Uncertainty Estimation

Soujenya Voggu, Shadab Siddiqui*, Shahin Fatima
Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation,
Hyderabad-500075, Telangana, India

***Abstract*—Recent developments in deep learning have demonstrated tremendous potential for enhancing medical picture classification tasks, particularly for the detection of skin malignancies like melanoma. However, it is still a huge challenge to guarantee high accuracy, reliability, and interpretability in real clinical settings. This study attempted to resolve these issues by proposing a novel approach to melanoma detection, by employing diverse techniques such as the Convolutional Block Attention Module (CBAM), binary focal loss, and Monte Carlo Dropout (MC Dropout) for uncertainty estimation. The CBAM attention module was inserted to help the network focus on important features of images, and focal loss was applied to solve class imbalance and encourage learning from hard samples. MC Dropout was used to achieve an uncertainty estimate in the test set, and thus, more reliable and interpretable predictions. The approach was implemented with a pre-trained deep CNN called EfficientNetB4 as the backbone and trained on a large melanoma dataset, which is separated into training sets, test sets, and validation sets in order to test the performance. Model evaluation was performed using accuracy, precision, recall, F1-score, and AUC, resulting in 0.95 for accuracy, whereas the AUC value is 0.98. Furthermore, the uncertainty estimate made a clearer decision-making, and the interpretability was crucial when used as a clinical task model. These results highlight the necessity to combine attention mechanisms, task-specific loss terms, and uncertainty quantification for building accurate and interpretable AI in medical domains. The study prototype has the potential for improving the detection of early-stage melanoma and provides useful guidance to future AI-based healthcare services.**

***Keywords*—Deep learning; CNN; accuracy; CBAM; EfficientNetB4**

I. Introduction

Melanoma is an aggressive skin cancer and has continued to be a leading cause of death from cancer worldwide [1]. Melanoma – which originates in the pigment-producing cells of the skin called melanocytes – can spread rapidly to other organs unless it is caught and treated early. Early detection of melanoma contributes significantly to the survival rates of patients and is, therefore, a critical area of research in medical imaging and diagnostics [2]. Diagnosis of melanoma is usually through clinical examination and histopathology, which are associated with human error and variability. Due to the visual aspect of the disease, automatic systems and methods, which make use of image analysis, are a central part of new scientific progress on accurate melanoma detection.

Recent advances in machine learning, particularly deep learning, have demonstrated significant potential for automated melanoma classification based on skin lesion images [3]. Convolution neural network (CNN) has been known as a successful technique for image classification, where it can learn and abstract features automatically from visual data. Melanoma classification has been tackled using different methods, with the use of diverse CNN architectures to enhance accuracy. However, there are still many issues, such as the limited labeled datasets in diverse domains, the differences between the quality levels of images and patterns of skin lesions complexity [4]. Hence, emerging models capable in their ways to go beyond these limitations and make more appealing predictions (in terms of reliability, interpretability and robustness) are always needed.

The problem of handling the uncertainty relating to the medical image analysis is one of the primary concerns for melanoma classification [5]. Despite their great power, deep learning models are typically unable to make predictions while also estimating the uncertainty of these predictions. Failure to estimate such uncertainty can lead to bad decisions in a clinical setting when missclassification is expensive [6]. Also, deep learning based algorithms are prone to overfitting when there is limited The study proposed a new deep learning framework for melanoma recognition, where the CBAM attention mechanism, focal loss and Monte Carlo Dropout (MC Dropout) were integrated to obtain uncertainty estimation. The incorporation produced a remarkable improvement in the performance and reliability. With the help of these sophisticated methods, our model could focus on important attributes and handle the issue of class imbalance to generate reliable predictions with uncertainty. With an accuracy of 95 and an AUC of 0.98, the model also has great potential in future real clinical applications. The novelty of our method lies in the usage of attention mechanism, focal loss and uncertainty estimation, optimizing them all simultaneously. This means to bring interpretability and robustness at the same time so that our model can generalize well for difficult tasks such as melanoma detection, training data or unbalanced data. All of these are reminiscent of the need to come up with methods that improve model accuracy and also provide uncertainty estimates' which is a necessary condition for well-calibrate decision support

*Corresponding author.

systems able to offer robustness and generalizability in clinical usage.

Another is to determine what are the most relevant parts in an image, particularly when diagnosing melanomas [7]. Even if the CNNs are good feature extractors, this learning does not exploit spatial relationships and contextual information among the entities in an image. It can result in a mistake with grouping, particularly if the melanoma lesion is not readily visible or partly covered. The Convolutional Block Attention Module (CBAM): This has proved beneficial to enhance the performance of CNNs, so they attend more on a most important part of an image. By utilizing an attention mechanism, CBAM makes networks pay more attention on informed regions to increase the classification accuracy and interpretability.

To tackle the above difficulties, a cost-effective and dynamic solution powered by an EfficientNet with CBAM attention-based model, incorporated with Monte Carlo Dropout (MCD) for uncertainty estimation. Derivation of network: EfficientNet has been chosen as it has strong and robust accuracy and computation efficiency according to retrospective training, testing using images regarding melanoma [8]. MCD can naturally give an approximate measure of prediction uncertainty, while the integration of CBAM may assist the network in attending to saliency parts on input images. This synergistic relationship leads to a stronger identification of melanoma, which in turn is good-performing (in terms of accuracy) and provides uncertainty, thereby allowing its application in the clinic where decisions are crucial.

II. Literature Survey

S. Nazari et al. [9] stressed the relevance of diagnostic models for real-world usage, which include smartphone based dermoscopyin order to enhance the diagnosis in rural regions. As per the ISIC2020 challenge, their approach demonstrated comparable outcomes to the first-place model while outperforming second and third places. These models established an appropriate compromise between accuracy and computational efficiency by using 98 % fewer parameters, thereby making them well suited for real-time deployment in resource constrained environment and increasing the reach of accessible healthcare.

A hybrid framework was proposed by P. K. Veni et al. [10] that integrates feature extraction from VGG16 with CBAM and classification with Caps Net. The proposed model was tested using augmented and non-augmented datasets, thereby displaying high performance results up to 100 % precision, 99 % accuracy, and an F1-score.

Skin-GAB, a deep learning based scheme, is proposed by J. Chen et al. [11] for classifying pigmented skin diseases. This approach makes use of augmentation, segmentation, network fusion, and the GAB mechanism for enhancing classification by highlighting essential characteristics. Skin GAB has enhanced the accuracy 2.89 % as compared to the previous model, projected to continue contributing to future diagnosis and managing pigmented skin illness.

A most dangerous type of skin cancer, focusing melanoma, was proposed by G. Dogan et al. [12]. If diagnosed early, it can be treated effectively.

Convolutional neural networks (CNNs), a popular deep learning tool, have shown great promise in accurately detecting melanoma. By integrating attention mechanisms with CNNs, their accuracy can be further enhanced. However, previous models for melanoma detection have not utilized attention mechanisms effectively. In order to help researchers use attention mechanisms effectively, this study investigates how they affect CNN performance. The authors investigated seven distinct attention mechanisms using a base CNN model and compared the outcomes.

The C3BAM-XAI model of CNN was proposed by M. J. Abbas et al. [13], integrating CBAM and explainable AI. It addresses data imbalance through augmentation and uses CBAM's attention modules for better feature extraction. Hyperparameters are optimized with Nadam for smoother training. The model, tested on the PD Kaggle dataset, achieved 93.33% accuracy by B. Mittal [14]. Ablation trials demonstrate that CBAM will enhance the interpretability and accuracy of the model, making it dependable for clinical usage, particularly for Parkinson's disease detection. This study highlights the expanding significance of deep learning approaches in improving medical diagnosis.

CACBL-Net, a lightweight deep CNN, was proposed by R. Agrawal et al. [15], tailoring portable diagnostic devices like smartphones, thereby addressing limitations of data imbalance and computational capacity. The study made use of focal loss for handling imbalance in the dataset and the Monte Carlo dropout method for uncertainty estimation to improve the robustness of diagnostic networks.

The network incorporates channel attention to enhance feature extraction and employs an adaptive class-balanced focal loss to prioritize complex cases while reducing the influence of simpler ones, B. Mittal [16]. On the HAM-10000, PAD-UFES-20 and MED-NODE datasets, CACBL-Net reached sensitivities of 90.60%, 91.88% and 91.31% with prediction times ranging from 0.006 to 0.011 s per case, respectively. These performances are superior to other models that prove the potential and CACBL-Net for skin lesion diagnosis using a mobile device with low computational cost.

Z. Ji et al. [17] introduced EFAM-Net as a new architecture for the classification of skin lesions. The low-level information of color and texture is learned by inserting an Attention Residual Learning ConvNeXt (ARLC) block in the shallow part, and as the depth increases, it is removed to employ a deeper layer with the Parallel ConvNeXt (PCNXt) block by M.K. Amber [18]. To enhance the feature fusion in multiple scales, a Multi-scale Efficient Attention Feature Fusion (MEAFF) block is proposed. We tested our method on ISIC 2019, HAM10000 and a private dataset and the experiment results showed it performed satisfactorily with classification accuracies of 92.30%, 93.95%, and 94.31%.

Y. Jia et al. [19] proposed a medical image classification approach, which adopted a contour processing attention mechanism to increase its accuracy through focusing on key

regions. The process comprises a step of photo converting and linearizing images, as well as contour generation.

The original gray-scale picture is convolved with these contours, creating a row-column feature map that can be further sharpened by means of point-wise multiplication by A. Siddiqui [20]. The resulting image is input to a residual network for classification. Experiments on three medical image datasets indicate noticeable enhancements are achieved with respect to accuracy, F1 score, and Kappa score. This technique also demonstrates value in other areas such as remote sensing and vehicle image recognition.

III. Proposed Model

A. Input Layer

The model receives data through the input layer. In this instance, the input layer is set up to accept photos of shape (224, 224, and 3), which means the images have three color channels (RGB) and a dimension of 224 by 224 pixels. In order to ensure the model correctly processes the data, this layer specifies the form of the input data that will be fed into the neural network.

$$Input = \mathbb{R}^{H \times W \times C} \quad (1)$$

where,

H stands for height, W for width, and C for the number of channels (3 for RGB) in the picture. This layer does not do any calculation; it only takes in the input.

B. EfficientNetB4

The foundation of the model for feature extraction is a pre-trained deep CNN called EfficientNetB. It belongs to an efficient net family, which is renowned for its excellent computational cost and parameter size efficiency. The top classification layers are eliminated by setting include top=False, allowing the model to focus on extracting relevant features from the image data. The model learns superior initial feature representations thanks to the pre-trained weights from ImageNet, which lessens the need for intensive training from the beginning. Similar to other convolutional neural networks, theEfficientNetB4 model processes the input image in several ways:

Convolution Operation:

$$Output = Conv(X, W, b) = (X * W) + b \quad (2)$$

where,

X is the input tensor.

Wis the filter (kernel).

b is the bias.

∗represents the convolution operation.

Activation: Following the convolution, an activation function such as ReLU is applied:

$$Output = ReLU\big(Conv(X, W, b)\big) \quad (3)$$

EfficientNetB4 uses advanced blocks like MBConv, Squeeze-and-Excitation (SE) blocks, and depth-wise separable convolutions, but the basic operation is a convolution followed by activation.

C. Dense Layers (Channel Attention)

The feature maps are transformed by the channel attention module dense layers following pooling operations. By using the ReLU activation function, the first dense layer reduces the number of channels by a factor of the ratio (usually set to 8). The feature map is compressed throughout this process, thereby allowing the network to learn more succinct representations. By returning the channel size to its initial value, the second dense layer produces an improved feature map that may be integrated with the attention mechanism.

First Dense Layer:

$$Output_1 = ReLU\left(\frac{X}{Ratio}\right) \quad (4)$$

where,

- X is the input feature map from the previous layer.
- Ratio is a hyperparameter (often set to 8).

Second Dense Layer:

$$\mathrm{Output}_2 = \mathrm{W}.\mathrm{Output}_1 + \mathrm{b}_1 \quad (5)$$

where,

- Wis the weight matrix.
- b is the bias vector.
- The dense layer performs a matrix multiplication followed by the addition of bias

D. GlobalAveragePooling2D

GlobalAveragePooling2D calculates the average of every feature map throughout the full spatial dimension (including height and width). It makes the output size uniform across various input images by reducing the spatial dimension to a single value per feature map. By ensuring that each feature map is summed up by its average value, this pooling procedure enables the model to incorporate global context and exclude spatial details that are less crucial for the job. The average of each feature map of all spatial locations is calculated via global average pooling:

$$Output_{avg}[c] = \frac{1}{H \times W} \sum_{h=1}^{H} \sum_{w=1}^{W} X[h, w, c] \quad (6)$$

where,

- Hand W are the height and width of the feature map.
- c is the index for the channels.
- The output is the average value of all the pixels in each channel of the feature map.

E. Reshape Layer

The reshape layer is used to transform the output of the global average pooling operation into a shape that corresponds to the layers it follows. In this instance, it ensures that the tensor has a single spatial dimension while retaining the channel information by reshaping the pooled tensor to a shape

of (1,1, channel). As a result, the feature map can be processed by the thick layers that follow, which are built to deal with a specific dimensionality.

$$\text{Reshaped Output} = \text{Reshape}\big(\text{Input}, (1,1,\text{Channels})\big) \quad (7)$$

The reshape operation doesn't modify the underlying data but changes the dimensions of the tensor to ensure compatibility with subsequent layers. The result is a tensor of shape (1,1,Channels), where each channel contains one averaged value.

F. GlobalMaxPooling2D

Similar to Global Average Pooling, Global Max Pooling calculates the maximum value for each feature map rather than averaging the values. The notable feature of each feature map is highlighted using this technique. For tasks that depend on identifying strong patterns, such as object recognition, it captures the most prominent spatial characteristic.

Global Max Pooling computes the maximum value for each feature map:

$$\text{Output}_{\max}[c] = \max_{h,w} X[h,w,c] \quad (8)$$

where,

- [h,w,c] is the value at spatial location h,w, and channel c.
- This outputs the maximum value for each feature map, providing a more extreme form of feature aggregation compared to averaging.

G. Dense (After MaxPooling)

After max pooling, the features are processed by the same dense layers that were used for average pooling. These layers help refine the pooled features by applying the same transformations (reduction in channels and restoration) as seen with average pooling. This dual processing allows the model to consider both the maximum and average features extracted from the input image.

$$\text{Output} = W \cdot X + b \quad (9)$$

where,

- W is the weight matrix,
- X is the input feature map from the pooling operation.
- b is the bias term.

This is a standard dense layer that performs matrix multiplication and bias addition.

H. Add Layer

The results from both average and max pooling are then aggregated (Add layer). This kind of addition has more rich feature representation by using complementary information involved in the two pooling types. With a Concatentity set, the model perhaps can more easily focus on both the prototype categories and the salient cues in the image.

$$\text{Output} = \text{avg_pool} + \text{max_pool} \quad (10)$$

This layer performs the addition of the output from average pooling and max pooling. Each result element is the sum of its two feature map elements.

I. Activation (Sigmoid)

The Activation layer, applying the sigmoid activation function, is used in order to squash attributes of two branches into [0, 1] value softening. This yields a tensor which can be employed as the attention weights. The attention map generated by this activation enables the network to focus on or ignore some feature channels according to their relevance to the task.

$$\text{Output} = \frac{1}{1+e^{-X}} \quad (11)$$

The sigmoid function normalizes values between 0 and 1, making it ideal for binary classification tasks, where the output is interpreted as a probability.

J. Multiply (Channel Attention)

The attention mechanism for the input features is added via the multiply layer. The input feature map is reweighted with the attention map of previous layers through element-wise multiplication. This operation enhances some objects while reducing others over the input. This attention mechanism successfully allows our network to pay more attention to the most essential parts of the input image.

$$\text{Output} = X \times A \quad (12)$$

The attention map A, produced by applying sigmoid activation to the attention mechanism, is element-wise multiplied with input feature map X. The operation highlights the most salient features while suppressing irrelevant ones.

K. Lambda Layer (Spatial Attention)

The Lambda layer average-pools the input feature map over its spatial dimensions. By means of spatial dimension reduction, it yields a tensor that characterizes the distribution of global features in the image. This enables the model to obtain context throughout the entire image, where contextual information may be important for feature relationships (e.g., object detection and segmentation).

$$\text{Output}_{\text{avg}} = \frac{1}{H \times W} \sum_{h=1}^{H} \sum_{w=1}^{W} X[h,w,:] \quad (13)$$

$$\text{Output}_{\max} = \max_{h,w} X[h,w,:] \quad (14)$$

In the Lambda layer, we calculate the mean and max pixel values for each feature map over spatial dimensions. This permits the spatial information to be 'out-of-context', thus facilitating attention-guiding.

L. Concatenate Layer

The results of average and max pooling are concatenated by the concatenate layer in the channels dimension. This concatenation results in a more enriched feature map, including the average and most discriminative spatial features, which could be utilized by the model for both average-based and peak-based aspects at some layers ahead. It facilitates the network to construct a better representation for images by modeling different types of feature information.

$$Output = Concatenate(avg_pool, max_pool) \quad (15)$$

The average and max pooled features are concatenated at channel level. This operation doubles the number of channels as both types of pooling information is merged into one tensor.

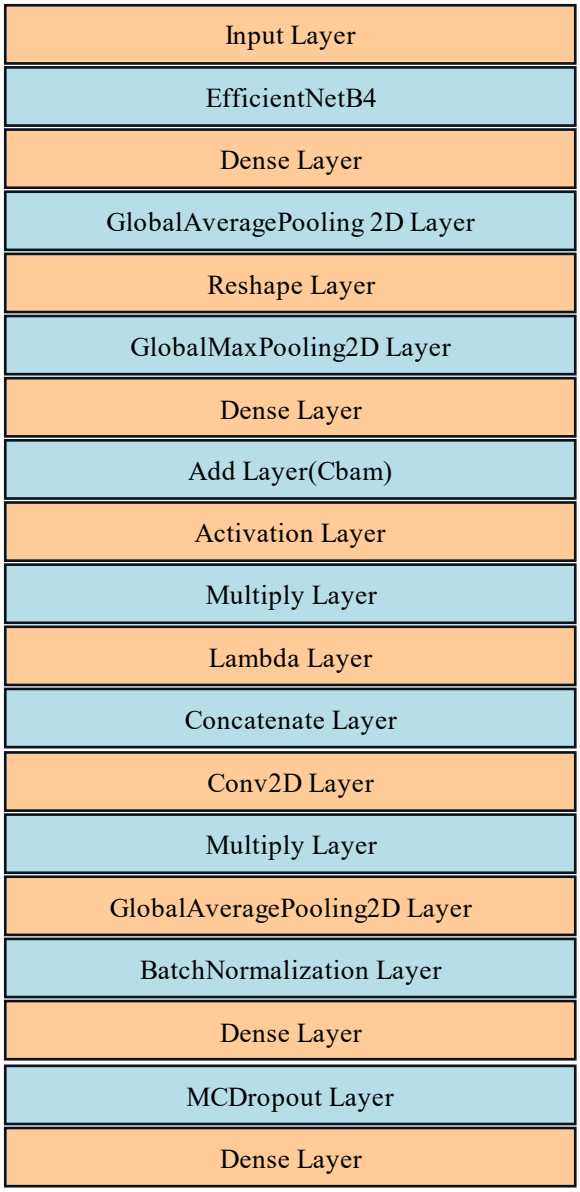

Fig. 1. Proposed model architecture.

Fig. 1 demonstrates the architecture of the proposed hybrid CNN model by combining EfficientNetB4 with CBAM for enhanced feature extraction. The layered structure in the figure illustrates components like convolution, pooling and attention mechanisms.

M. Conv2D (Spatial Attention)

A convolutional filter is then used by the Conv2D layer on the concatenated feature map to generate a spatial attention map. The layer is trained to pay attention to parts of the image, through learning of spatial features, so as to highlight the most relevant parts. Kernels size and strides are determined to maintain the spatial relationship in the image as well as computational efficiency. The sigmoid activation makes the attention values range within 0 and 1, controlling how much each spatial location needs to be weighted.

$$Output = Sigmoid\big(Conv2D(Concat, Filters, Kernel\ Size)\big) \quad (16)$$

A convolution operation is performed over the concatenated feature maps and fed into a sigmoid function for obtaining the spatial attention map, which emphasize the region at a spatial level that model should pay attentions to.

N. Multiply (Spatial Attention)

Similar to the channel attention mechanism, the multiply layer applies the spatial attention map to the input features. The input feature map is multiplied by the spatial attention map, allowing the model to focus on the important spatial regions while ignoring less relevant ones. This helps the network learn which regions in the image are critical for the task at hand.

$$\text{Output} = X \times A_{\text{spatial}} \quad (17)$$

The input feature map X is element-wise multiplied by the spatial attention map $A_{_spatial}$, highlighting the most important spatial regions. Which focuses on the most relevant spatial regions.

O. Global Average Pooling2D (Post Attention)

To summarize all feature maps, GlobalAverage Pooling 2D is applied after the application of CBAM attention mechanism. In order to prepare the output for thick layers, this pooling step reduces the spatial dimensions of each feature map to a single value. After using the attention mechanism, this step guarantees that network is taking into account global features in feature map.

$$\text{Output}_{\text{avg}} = \frac{1}{H \times W} \sum_{h=1}^{H} \sum_{w=1}^{W} X[h, w, :] \quad (18)$$

Global average pooling is applied again after the attention mechanism to summarize the entire feature map into a single value per feature map.

P. Batch Normalization

Batch Normalization helps to stabilize and speed up training by normalizing activation of neurons throughout the mini-batch. It guarantees the consistency of activation distribution by minimizing internal covariate shift. Furthermore, batch normalization improves the generalization of model and training process efficiently by acting as a regularization strategy.

$$\text{Output} = \gamma\left(\frac{X - \mu}{\sqrt{\sigma^2 + \epsilon}}\right) + \beta \quad (19)$$

Batch normalization normalizes the activations by subtracting the batch mean μ and dividing by the batch standard deviation σ. During training, the parameters γ(scale) and β(shift) are learned to adjust the normalized values.

Q. Dense (Fully Connected Layer)

The Dense layer of size 256 propagates the feature map through a fully connected transformation. It learns the high abstractions of stance properties (e.g., training structures) and is called “ReLU” which introduces non-linearity into the

model. This layer is important so that the model can learn complex patterns in between before outputting something simple. L2 regularization is introduced to avoid overfitting by punishing excessive weights.

$$\text{Output} = \text{ReLU}(W.X + b) \quad (20)$$

This dense layer performs a matrix multiplication between the input and weight matrix W, adds the bias term b, and applies the ReLU activation function.

R. MCDropout

The Dropout layer is a dropout layer with a custom forward pass that remains active during test. This is in contrast to traditional dropout, which is employed only at training time and thus cannot measure the uncertainty during test. This is especially valuable for uncertainty estimation tasks, where the interpretability of the model's confidence in prediction is key. Through the activation of dropout during inference, the model is able to produce a wider diversity of predictions, leading to a more reliable measure for uncertainty.

$$\text{Output} = \text{Dropout}(X, p = 0.5) \quad (21)$$

The MCDropout layer ensures that dropout is active during both training and inference, which allows the model to generate multiple stochastic forward passes and estimate uncertainty in predictions.

S. Dense (Output Layer)

The final Dense layer is the output with a single unit for binary classification and sigmoid activation to make it suitable for your prediction task. Finally, the output of the sigmoid gives a value between 0 and 1, which one might interpret as being the probability that your input is in the positive class. This layer is the final decision point of the network, and observations fit to the model are transformed into a modeled prediction.

$$\text{Output} = \text{Sigmoid}(W \cdot X + b) \quad (22)$$

The final output layer calculates the probability of the positive class (binary problem) with a sigmoid activation. The output is a score in the range of [0, 1], which indicates the probability that the input sample falls into the positive class.

The novel changes in the model could improve both performance and interpretability on a melanoma deep learning classifier. The contribution lies in integrating the CBAM (Convolutional Block Attention Module) that works with channel-wise and spatial attention. As a result, this allows the model to pay attention on most informative regions of the input image to improve feature extraction, which will automatically emphasize useful parts. Additionally, the model has a binary focused loss, which addresses class imbalance by emphasizing hard negatives more. The Monte Carlo dropout introduces uncertainty estimation during interference, which can be used to measure the degree of prediction confidence and reveal information about the dependability of the model. These enhancements are intended to maintain a reliable and understandable method of melanoma classification, which also improves the generalization of model performance and reduces overfitting.

Advanced data augmentation and specially designed callbacks like ReduceLROnPlateau and EarlyStopping, which aid in learning optimization and prevent overfitting, are some further contributions of the suggested model. The model uses EfficientNetB4 as a backbone to extract features, making it possible for the model to achieve high accuracy with computational cost under control. We train the model in multiple stages with heavy data augmentation like rotation, zoom and flip to be able to generalize well to unseen data. In the evaluations, besides these standard measures (accuracy, precision, recall and F1-score), we measure uncertainty using Monte Carlo sampling. This perspective offers a broader interpretation of model behavior that can guide confidence in clinical decisions.

IV. Experimental Results

The results produced by the method developed in this work during the current simulation studies are reviewed in this section of the study.

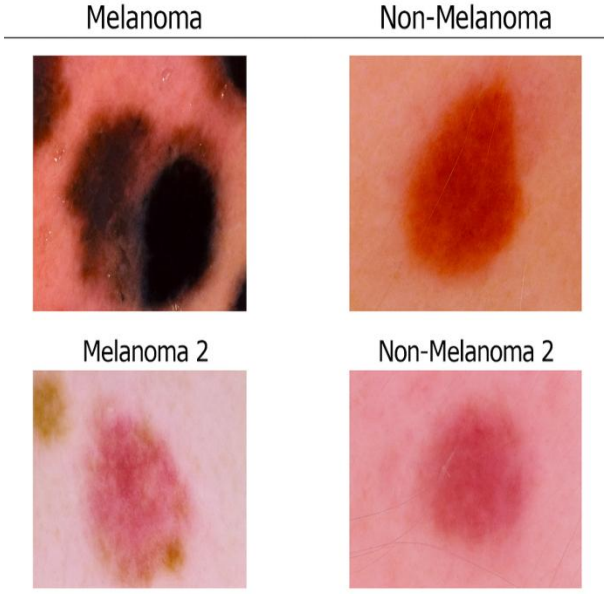

Fig. 2. Sample images for melanoma and not melanoma classification.

Fig. 2 shows the sample images taken for classifying Melanoma and Not Melanoma. The melanoma dataset was used for these experiments [17]. The data preprocessing techniques described earlier were also applied to this dataset in our work. The proposed work made use of ISIC 2019 [21], [22] and HAM10000 [23] public datasets available freely online on the International Skin Imaging Collaboration Challenge.

The plot in Fig. 3 shows the training and validation accuracy across 50 epochs. The training accuracy curve, indicated by the blue line, gets very jagged with vivid spikes and ascents. This might reflect a tendency to overfit, implying that the model is making its predictions too closely follow the training set (as opposed to other data). On the other hand, the validation accuracy (green) moves more steadily on small steps of improvement, which means better generalization to unseen data. The saturation of the generalization g between the two accuracy curves suggests that the depth-3DIHNN fails to

generalize well, and this problem would be alleviated by techniques such as model fine-tuning or regularization.

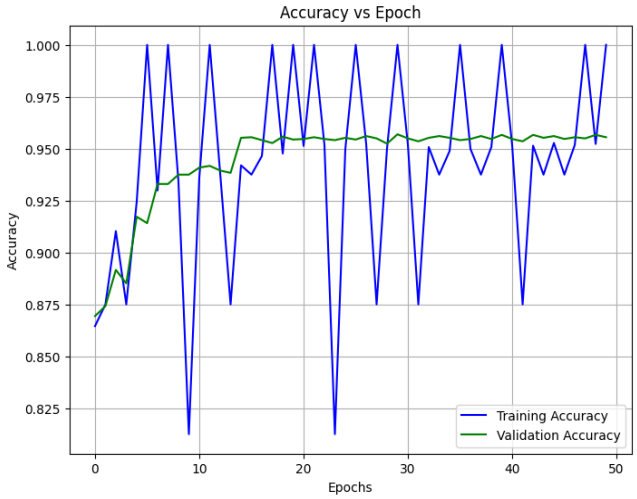

Fig. 3. Training and validation accuracy over epochs.

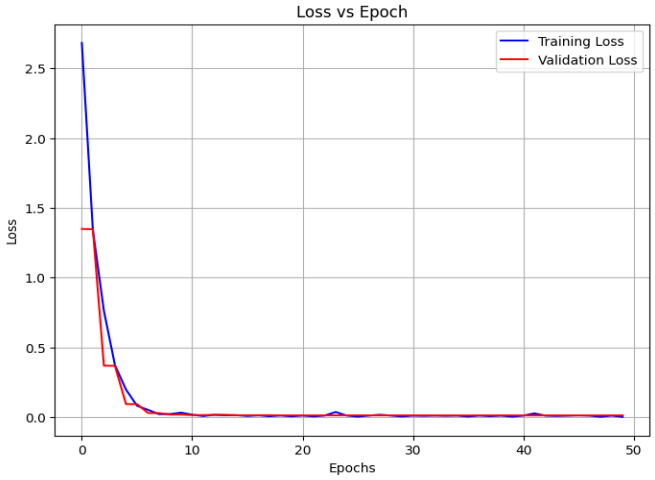

Fig. 4. Training and validation loss over epochs.

The above plot in Fig. 4 visualizes how loss changes over time with epochs as the independent variable. Training loss is the purple line, validation loss is the red line. Both the losses start large but decrease rapidly, indicating that the model makes good progress early in training. After this drop, there is some breakage, and the losses rapidly go lower in later epochs. Training and Validation loss have nearly no split, it means the model is not overfitting or underfitting. As the model is able to achieve low loss values, it suggests that the model can learn well.

The Receiver Operating Characteristic (ROC) curve, shown in Fig. 5, is a popular measure of the performance of a binary classifier is depicted in the above figure. The relationship of the true positive rate (TPR) versus the false positive rate (FPR) is also plotted with different threshold values. The blue line is shooting up towards high TPR values as FPR rises – this means that the model can differentiate between positive and negative classes well. The curve is shifted towards the upper left corner (optimal performance) with high sensitivity and specificity. The dashed diagonal line is a random classifier which have same TPR as it has FPR for any threshold. The ROC curve is also well above this diagonal, so it shows that the model beats random guessing. Area Under the Curve (AUC) is probably close to 1, indicating strong classification.

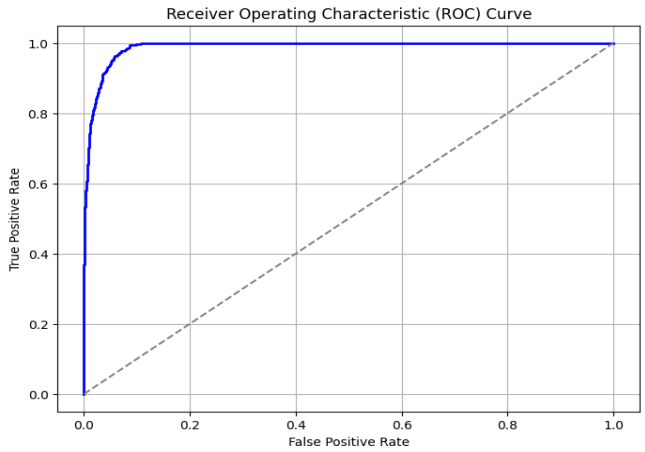

Fig. 5. Receiver Operating Characteristic (ROC) curve.

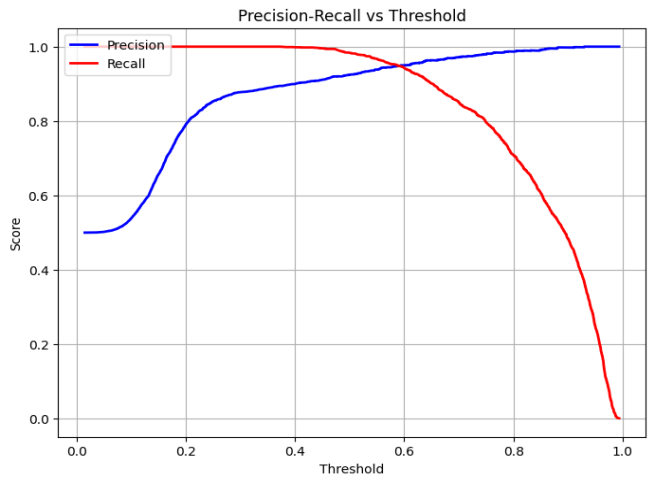

Fig. 6. Precision and recall vs. Threshold.

The above Fig. 6 shows the Precision-Recall curve against the classification threshold. The blue curve corresponds to precision, while the red one indicates recall. As we set the '+' threshold higher and higher, our precision improves drastically, approaching 1, which means that the model becomes increasingly confident in its positive predictions to yield high overall accuracy. But recall (the red curve) is decreasing as precision increases. This is a simple case of trade-off when we tune the threshold - recall increases (hits more true positives) and precision decreases (hits false positives). The feature space gives a geometrical picture of this trade-off, and allows to choose the best threshold with respect to the precision-recall trade-off according to the particular characteristics of the problem (e.g., more emphasis on precision or recall).

The Cumulative Gain Curve shown in Fig. 7 is something that will help you when it comes to evaluating the performance of a classifier for ranking problems. The curve displays the cumulative gain against the percentile of the samples. With the

number of samples, the cumulative gain increases as well and tends to 1. This indicates that if 80% of samples are retained by taking those after the 20th row, a larger percentage of the positive class is covered. The steep rise at the start of the curve shows that the model can quickly identify many relevant samples, which could be advantageous for systems such as targeted marketing or fraud detection. A perfect curve would indicate a sharp steep at the beginning, followed by a plateau, indicating that most positive samples are correctly included in top ranked portion of the test.

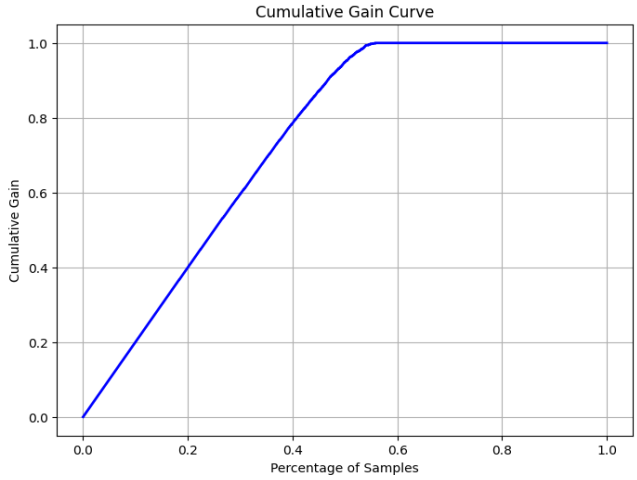

Fig. 7. Cumulative gain curve.

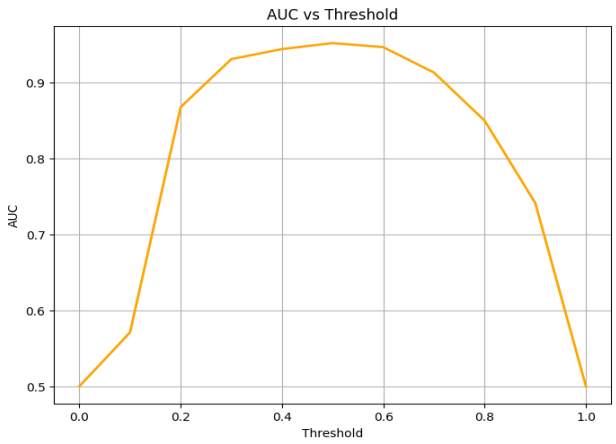

Fig. 8. AUC vs. Threshold.

Fig. 8 shows how the Area Under the Curve (AUC) and classification level relate. Plot of AUC as a function of the threshold defining positive and negative samples. At first, as the threshold increases substantially from 0 to about 0.3, AUC rapidly grows and it is close to the maximum value of almost 1.0, showing that the model has great classification performance at this threshold grain highly balanced class separation. More importantly, the AUC starts to decline when this threshold becomes larger, implying that with higher threshold values, the model down-weights positive samples and accordingly its capability of distinguishing positives from negatives weakens. Such behavior suggests that an optimal threshold can be found where AUC is the largest for indicating the threshold that results in the best classification performance.

This decline following the peak is expected due to the well-known trade-off between precision and recall with threshold.

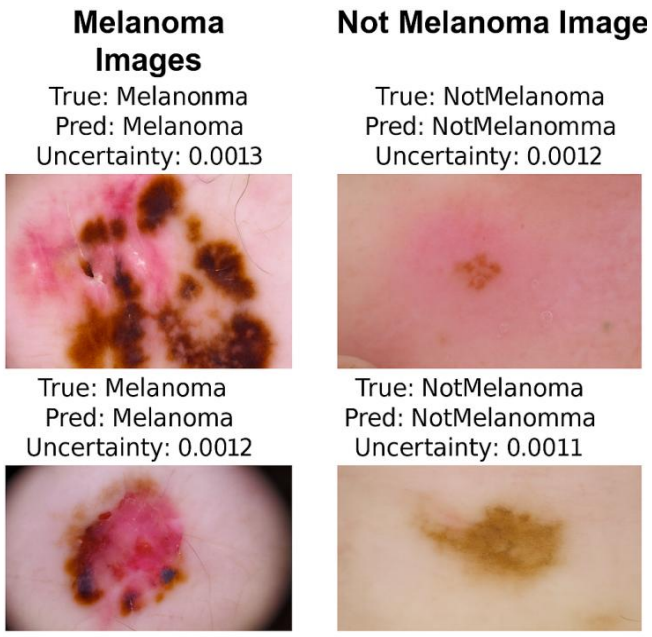

Fig. 9. Classification of melanoma and not melanoma images with prediction confidence.

The picture in Fig. 9 represents the classification between Melanoma and Not Melanoma images and model predictions with respective uncertainty values. The left column shows Melanoma cases that are correctly predicted as Melanoma, with uncertainty of 0.0013 and 0.0012, so the model is more certain in these predictions. The right column shows Not Melanoma images classified as such with even lower uncertainty values (U = 0.0011 and U = 0.0012). These very low levels of uncertainty indicate that the model is doing an excellent job accurately placing examples into one of two categories, and therefore can be thought to have high certainty in its predictions.

TABLE I. CLASSIFICATION REPORT

	Precision	Recall	F1-Score
Melanoma	0.98	0.91	0.95
Not Melanoma	0.92	0.98	0.95
Total Accuracy	0.95		

The above Table I is the classification report for a model that classifies between two labels, Melanoma and Not Melanoma. In the case of Melanoma, the model has high precision (0.98), which means that 98% are the predicted positive cases are comparable. Its recall (0.91) is a bit lower, which means that 91% of the actual positive cases have been recognized. Melanoma achieves F1-Score 0.95, balancing precision and recall. For Not Melanoma, it is 0.92 precision and a high recall of 0.98 indicates that the model accurately detects true positives at a high rate. The Not Melanoma F1-Score: 0.95 as well. The suggested model, making use of Efficient Net using CBAM Attention and Monte Carlo Dropout

for uncertainty estimation and the model's general accuracy of 0.95 indicates a strong performance for the two classes. The balanced F1-Scores and high accuracy demonstrate that the model performs well in detecting both conditions without significant bias.

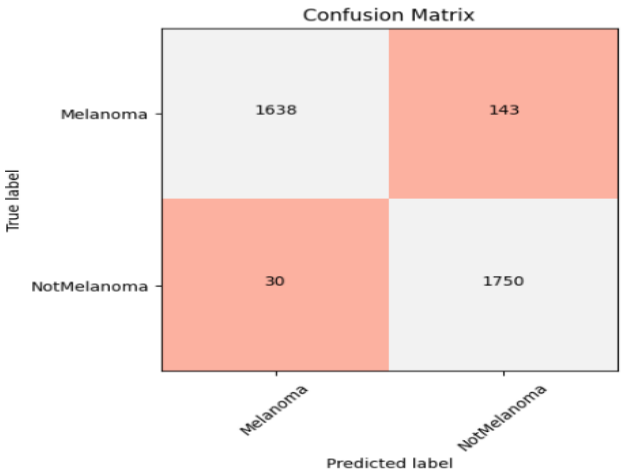

Fig. 10. Confusion matrix for melanoma classification.

Fig. 10 above shows the confusion matrix for a binary classification model distinguishing between Melanoma and Not Melanoma. Out of 2816 instances, the model correctly identified 1638 cases of Melanoma (True Positives) and 1750 cases of Not Melanoma (True Negatives). However, it made errors by incorrectly predicting 143 cases of Not Melanoma as Melanoma (False Positives) and 30 cases of Melanoma as Not Melanoma (False Negatives). While the matrix reflects the model's strong performance in accurately classifying Not Melanoma (with high True Negatives), it also reveals areas for improvement, particularly in reducing the False Positive and False Negative predictions.

TABLE II. COMPARATIVE ANALYSIS

Model Name	Accuracy (%)
ResNet50 [18]	0.88
Sequential [19]	0.92
CNN [20]	0.93
DenseNet121 [21]	0.93
InceptionV3 [22]	0.94
Proposed Model(EfficientNetB4)	0.95

A comparison of different deep learning models based on their accuracy for a particular task is shown in Table II. ResNet50, Sequential CNN, Dense Net 121, Inception V3, and the suggested EfficientNetModel are all included in the comparison. Among these, Inception V3 attains maximum accuracy at 0.94 while the ResNet50 model has the lowest accuracy at 0.88. With an accuracy of 0.95, the suggested model making use of EfficientNet using CBAM Attention and Monte Carlo Dropout for uncertainty estimation beats all the other models, demonstrating its superior performance on the task at hand.

V. RESULTS AND DISCUSSION

The proposed Efficient NetB4 model demonstrates an accuracy of 95 % and strong melanoma classification performance. The precision and recall are (0.98, 0.91) for melanoma and (0.92, 0.98) for not melanoma classes. From the confusion matrix, it is clear that the misclassification rate is low thereby confirming reliable discrimination between classes. The comparative study shows that proposed approach outperforms CNN based methods, showing correct classification with low uncertainty thereby validating its effectiveness for melanoma detection.

VI. CONCLUSION

A new deep learning framework for melanoma recognition is proposed in this study that includes the CBAM attention mechanism, focal loss and Monte Carlo Dropout (MC Dropout) in order to prove uncertainty estimation. The integration has significantly improved the performance and dependability. These advanced techniques allowed our model to concentrate on key characteristics and address the problem of class imbalance in order to produce accurate forests with uncertainty. The proposed model made use of CBAM attention and the Monte Carlo dropout method for uncertainty estimation and the accuracy of the model is 95, and AUC is 0.98, which indicates it has a lot of potential for actual clinical use in the future. Our approach is novel in that it simultaneously optimizes the attention mechanism, focus loss and uncertainty estimation. Admittedly, in the presence of predictions and impossibilities, perhaps it is indeed that the model offers some kind of practical way to aid early diagnosis of skin cancer. The study is clinically relevant to image classification-based clinical applications, and it highlights the advantage of applying cutting-edge AI techniques for improved decision diagnosis and support accuracy. Future work can incorporate multi-class lesion classification to further improve robustness.

Multi-Objective Design Optimization of Ventilation Duct Systems: A Graph-Informed Hybrid Evolutionary Approach

Xiangming Liu, Bin Liu, Kunze Du, Da Gao, Nan Li*
School of Computer Science and Artificial Intelligence, Beijing Technology and Business University, Beijing, China

***Abstract*—Optimizing silencer placement in Heating, Ventilation, and Air Conditioning (HVAC) systems is a complex multi-objective problem due to conflicting objectives (noise, energy, cost) and intricate topological constraints. Conventional Multi-Objective Evolutionary Algorithms (MOEAs) often exhibit inefficient convergence on such problems due to their reliance on random search strategies. Addressing this challenging HVAC design problem requires a more informed approach. This paper proposes the G-HNSGA-III (Graph-Informed Hybrid NSGA-III), a novel framework that enhances the NSGA-III algorithm by embedding domain-specific knowledge from the system's Directed Acyclic Graph (DAG) topology. This is achieved through two core components that leverage heuristic search: a Graph-Informed Initialization (GINI) strategy to provide a high-quality starting population and a Graph-Informed Local Search (GILS) module for post-processing refinement. The performance of G-HNSGA-III was comprehensively benchmarked against the baseline NSGA-III and six other established MOEAs on a complex data center test instance. The results demonstrate a marked superiority, with G-HNSGA-III achieving a 38.4% higher mean Hypervolume (HV) than the baseline NSGA-III and a 99.3% Set Coverage (SC) dominance over MOEA/D. The framework consistently converged to the best-known Pareto front, achieving a final mean Inverted Generational Distance (IGD) of 0.0030. These findings validate that the proposed graph-informed strategies effectively accelerate convergence and enable the discovery of a higher-quality Pareto front, providing superior and practically applicable solutions for complex engineering design problems.**

Keywords*—Multi-objective optimization; NSGA-III; graph-informed optimization; HVAC design; heuristic search; domain knowledge

I. Introduction

Modern facilities with strict climate control requirements—spanning from commercial complexes to critical infrastructure like hospitals—rely heavily on HVAC systems for operational stability [1-2]. While essential, these systems create a fundamental operational conflict. On one hand, the mechanical noise from fans degrades the acoustic environment; on the other, the fan power required to drive airflow constitutes a major operational cost, directly opposing sustainability targets [3-4]. The trade-off is physical and unforgiving: installing silencers to attenuate noise inherently increases airflow resistance (pressure drop), which forces fans to consume more energy to maintain the same flow rate. Therefore, optimizing the placement of these components is not merely a design preference but a central challenge in balancing energy efficiency with environmental quality.

This optimization task is compounded by the topological complexity of HVAC ductworks. Unlike simple linear systems, duct networks function as Directed Acyclic Graphs (DAGs), where the airflow dynamics are highly interdependent [5-6]. A design decision at a single upstream node propagates through the entire network, affecting pressure and noise levels at all downstream branches. Consequently, conventional design methodologies reliant on heuristics or trial-and-error fail to capture these global dependencies. They lack the mathematical rigor to navigate a search space characterized by discrete variables (e.g., specific silencer models) and strict physical constraints.

To address such high-dimensional engineering problems, Multi-Objective Evolutionary Algorithms (MOEAs) have become the established methodological standard [7-8]. However, their application to network-based systems faces a critical bottleneck: the quality of the initial population. Standard algorithms like NSGA-III typically rely on random initialization. In the strictly constrained solution space of an HVAC network, this stochastic approach often results in an inefficient search process, leading to slow convergence or stagnation in local optima—a limitation well-known in the field but rarely addressed with domain-specific logic.

We propose that embedding domain-specific topological knowledge into the evolutionary search can overcome these limitations. To this end, we introduce the Graph-Informed Hybrid NSGA-III (G-HNSGA-III) framework. This approach enhances NSGA-III by integrating DAG topology through two mechanisms: a Graph-Informed Initialization (GINI) strategy and a Graph-Informed Local Search (GILS) module.

The principal contributions of this paper are as follows:

- The proposal of a novel hybrid framework, G-HNSGA-III, that effectively embeds the topological knowledge from a DAG model into the evolutionary search process for HVAC optimization.
- The design and implementation of two specific algorithmic components: a GINI strategy to accelerate initial convergence and a GILS module to enhance the final solution set quality.

*Corresponding author.

- A comprehensive validation of the framework on a complex, real-world data center case study, demonstrating its significant performance superiority over the baseline NSGA-III and six other established MOEAs.

The remainder of this paper is organized as follows. Related work is given in Section II. Section III details the DAG-based system modeling and the pre-computation of topological metrics. Section IV presents the proposed G-HNSGA-III framework in detail. Section V describes the experimental setup, parameters, and evaluation metrics. Section VI presents and analyzes the comparative results. Finally, Section VII concludes the paper and discusses future research directions.

II. Related Work

The dual challenge of acoustic control and energy efficiency is well-established in HVAC literature. Noise generation is an inevitable byproduct of mechanical ventilation, necessitating robust attenuation strategies to meet environmental standards [9-10]. Approaches to characterize and mitigate this noise vary widely, from detection algorithms based on recursive partitioning in office spaces [11] to structural analysis of duct vibration problems [12]. Parallel to acoustic concerns, energy optimization remains a priority. Research has extensively focused on improving fan operating efficiency [3], [13] and integrating low-noise mechanical ventilators [14-15]. These studies collectively illustrate that optimizing an HVAC system is never a single-variable problem; it is a complex balancing act between silencing the system and powering it.

To navigate these conflicting objectives, Multi-Objective Evolutionary Algorithms (MOEAs) serve as the dominant computational tool. Comprehensive reviews confirm their efficacy in handling the non-linear constraints typical of building engineering [7-8]. Specific applications have ranged from optimizing pressure regulators [16] to automating design workflows based on BIM data [17]. However, the "black-box" nature of standard MOEAs presents limitations. Without domain knowledge, these algorithms struggle with initialization. As noted in recent studies, random initialization in algorithms like NSGA-III heavily influences the final hypervolume convergence [18], and while adaptive penalty schemes can mitigate some stagnation issues [19], they do not fundamentally resolve the lack of structural awareness.

Recent advancements suggest that hybridizing evolutionary search with domain-specific models offers a way forward. For instance, combining MOEAs with LSTM networks has proven effective in dynamic routing problems [20-21]. More importantly, the value of topological information is gaining recognition. Graph-based representations, such as DAGs and Convolutional Networks, are increasingly used to model spatial-temporal dependencies in complex systems [22-23]. Unlike conventional approaches that treat HVAC optimization as a black-box problem, this paper synthesizes these advancements by explicitly embedding the DAG topological structure into the evolutionary framework. This distinct positioning allows the proposed G-HNSGA-III to overcome the initialization blindness and premature convergence flaws inherent in standard MOEAs.

III. DAG Model

A. System Modeling with Directed Acyclic Graphs

A Directed Acyclic Graph (DAG) is employed to model the ventilation system, as its structure inherently captures the unidirectional nature of airflow and acoustic propagation. The system is formally represented as $G = (V, E)$, where V is the set of nodes and E is the set of directed edges.

Each node $t_i \in V$ corresponds to a unique physical component, including air sources (e.g., fans), transport elements (e.g., ducts, elbows), functional units (e.g., silencers), and terminal points (e.g., rooms). The edge set $E = e_{ij}$ represents the direct physical connections, where an edge e_{ij} signifies that both airflow and acoustic energy propagate from node t_i to t_j. The graph's topology and the physical properties of its connections are encoded in a weighted adjacency matrix, A [23].

B. Formal Expression and Matrix Construction for Nodes and Edges

Each node $v_i \in$ V in the DAG corresponds to a discrete physical component of the ventilation system (e.g., a fan, duct segment, or silencer). The quantifiable properties of each component are encapsulated in a multi-dimensional attribute vector, F_i. This vector is a concatenation of several attribute subset, which are based on established engineering principles [24]:

Location ($L_i \in \mathrm{R}^3$): The 3D spatial coordinates (x_i, y_i, z_i).

Geometric ($G_i \in R^k$): Component dimensions, such as duct length, width, and height $(L_{duct,i}, W_{duct,i}, H_{duct,i})$ or elbow parameters $(W_{elbow,k}, H_{elbow,k}, r_{elbow,k})$.

Fluid Dynamic $\left(V_i \in R^{(k_V)}\right)$: Parameters governing airflow, including surface roughness (ε_i), local loss coefficients (K_i), and fan performance curve coefficients.

Acoustic $\left(C_i \in R^{(k_C)}\right)$: Parameters governing sound, including natural attenuation $A_{nat,i}(f)$, flow-generated noise $L_{W,SGN,i}(f)$, and silencer insertion loss $IL_i(f)$).

Economic $\left(E_i \in R^{(k_E)}\right)$: Cost-related data, such as the procurement cost $(Cost_{initial,i})$.

The directed edges, $e_{ij} \in E$, formally represent the unidirectional connections between nodes t_i and t_j, defining the path for airflow and acoustic energy. The acyclic property of the graph is critical, as it mirrors the physical unidirectionality of the ventilation system. This structure ensures a partial ordering of nodes, which eliminates circular dependencies and guarantees the sequential convergence of network-based simulations.

Weighted Adjacency Matrix (A): This matrix encodes the topology of the system, defining the existence and properties (e.g., length) of the connections between any two nodes.

Component Attribute Matrix (D_{comp}): This matrix serves as a central repository for the intrinsic features of all available component types. Each row corresponds to a specific component model, while the columns parameterize its key attributes:

- Component ID
- Reference location vector
- Geometric and fluid dynamic parameter vector
- Acoustic and economic parameter vector

During optimization, a specific component from D_{comp} is assigned to a node in the graph. The process of translating a physical system layout into this formal DAG representation is shown in Fig. 2.

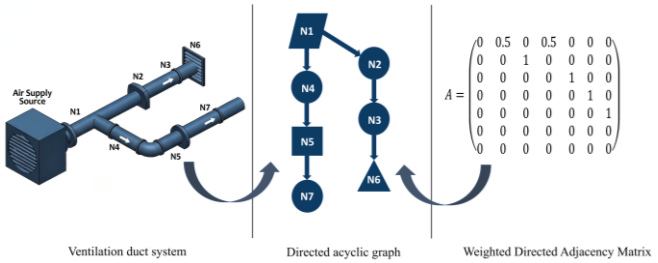

Fig. 1. Illustration of directed acyclic graph generation.

For example, consider a simple system composed of a duct segment, an elbow, and another duct segment. The attributes of these three components would be stored in the component attribute matrix, D_{comp}, as shown in Eq. (1).

$$D_{comp} = \begin{bmatrix} num & l & g & a \\ 1 & [0,\ 0,\ 0] & [2000,\ 1000,\ 4.9] & 11000 \\ 2 & [0,\ 10,\ 0] & [2000,\ 1] & 11000 \\ 3 & [0,\ 0,\ 10] & [2000,\ 1000,\ 1.5] & 11000 \end{bmatrix} \quad (1)$$

Each row in D_{comp} represents a unique component in the system. The first row, f_1, corresponds to the first duct segment and contains its complete attribute vector. This vector begins with the component's unique identifier, 1. It is followed by the location vector L_1 = [0, 0, 0], specifying its 3D spatial coordinates. The subsequent vector, G_1/V_1 = [2000,1000,4.9], encapsulates its geometric and fluid dynamic properties, representing, for instance, a width of 2000 mm, a height of 1000 mm, and a length of 4.9 m. The final vector (omitted here for brevity) would contain the relevant acoustic and economic parameters, completing the row's specification for a single component.

A weighted directed adjacency matrix, $A = (a_{ij})$, is used to encode both the system's topology and the proportional distribution of acoustic energy. This $N \times N$ matrix is defined as shown in Eq. (2):

$$a_{ij} = \begin{cases} \omega_{ij}, & \text{if } e_{ij} = \langle t_i, t_j \rangle \in E \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

The weight ω_{ij} represents the fraction of acoustic energy that propagates from node t_i to a direct successor node t_j. At any junction where the duct branches, this fraction is determined by the ratio of the cross-sectional areas, as calculated in Eq. (3):

$$\omega_{ij} = S_j / \sum_{k \in \text{succ}(i)} S_k \quad (3)$$

where S_j is the cross-sectional area of the specific branch leading to node t_j, and the denominator is the sum of the areas of all branches immediately downstream from node t_i.

For example, consider the system illustrated in Fig. 1. Its topology and energy distribution are encoded in the weighted adjacency matrix A, shown in Eq. (4). An element a_{12} = 0.5 signifies that the branch from node 1 to node 2 receives 50% of the acoustic energy from node 1; similarly, a_{14} = 0.5 indicates an equal energy split to node 4. In contrast, an element a_{23} = 1 indicates that 100% of the energy from node 2 propagates to node 3, which is characteristic of a non-branching connection. All zero-valued elements denote the absence of a direct path between the corresponding nodes.

$$A = \begin{pmatrix} 0 & 0.5 & 0 & 0.5 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \quad (4)$$

C. Pre-computation of Structural Information

To enhance computational efficiency, key structural metrics are pre-computed from the DAG. As these metrics are inherent to the network topology and independent of any specific silencer configuration, they are calculated once and stored prior to initiating the optimization process. A primary metric is node depth, $Depth(t_i)$, which defines a node's hierarchical position relative to the system's source. The root node of the system, t_{source} (e.g., the fan), is assigned a depth of zero: $Depth(t_{source})$ = 0. For any other node t_j, the depth is calculated recursively, as expressed in Eq. (5), as the minimum depth of its immediate predecessors plus one:

$$Depth(t_j) = \min_{t_i \in \text{pred}(t_j)} \{Depth(t_i) + 1\} \quad (5)$$

where, $\text{pred}(t_j)$ is the set of immediate parent nodes of t_j.

Another pre-computed metric is the downstream total airflow, $Q_{downstream}(t_i)$. This value represents the cumulative volumetric flow demand of all terminal outlets reachable from node t_i. It is calculated via a reverse topological traversal, starting from the outlets. The recursive definition is provided in Eq. (6):

$$Q_{downstream}(t_i) = \begin{cases} Q_{(demand,i)}, if\ t_i \in V_{outlets} \\ \sum \left(t_j \in succ(t_i)\right) Q_{downstream}(t_j), otherwise \end{cases} \quad (6)$$

where $Q_{(demand,i)}$ is the specified airflow requirement for a terminal outlet node t_i, and $succ(t_i)$ is the set of immediate successor nodes of t_i.

The potential sound source strength of a node, $L_{W,potential}(t_k)$, estimates the maximum potential noise

contribution of each node t_k. Its value is dependent on the component type and is defined in Eq. (7) as:

$$L_{W,potential}(t_k) = \begin{cases} L_{w,rated}(t_k), \text{ if } t_k \text{ is a fan} \\ L_{w,SGN,max}(t_k), \text{ if } t_k \text{ is a duct component} \end{cases} \quad (7)$$

where $L_{w,rated}(t_k)$is the fan's sound power level at its rated operating point, The term $L_{w,SGN,max}(t_k)$ is the maximum estimated self-generated noise for an aerodynamic component (e.g., a duct, elbow, or damper), calculated using the empirical formula presented in Eq. (8):

$$L_{w,SGN,max}(t_k) = L_{wc}(t_k) + 50\log_{10}(V_{d,k}) + 10\log_{10}(A_k) \quad (8)$$

Where $L_{wc}(t_k)$ is the component-specific sound power level, $V_{d,k}$ is the design velocity through the component, and A_k is its cross-sectional area.

Finally, the previously computed metrics (node depth, downstream airflow, and potential sound source strength) are aggregated into a composite Location Importance score, $I(t_k)$. This heuristic is designed to estimate the strategic value of placing a silencer at any given node t_k, providing critical domain knowledge to guide the optimization algorithm. This score is calculated via Eq. (9) as a normalized, weighted sum of the previously defined metrics:

$$I(t_k) = \alpha \cdot \frac{1}{Depth(t_k)+1} + \beta \cdot \frac{Q_{downstream}(t_k)}{\max_{t_i \in V}\left(Q_{downstream}(t_i)\right)} + \gamma \cdot \frac{L_{W,potential}(t_k)}{\max_{t_j \in V}\left(L_{W,potential}(t_j)\right)} \quad (9)$$

where α, β, and γ are weighting coefficients constrained by $\alpha + \beta + \gamma = 1$. Each term in the sum is normalized to a range between 0 and 1 to ensure a balanced contribution.

Collectively, these pre-computed metrics— $Depth(t_i)$, $Q_{downstream}(t_i)$, and $I(t_k)$ —constitute the quantitative domain knowledge that informs the heuristic guidance for the Graph-Informed Initialization (GINI) and Local Search (GILS) strategies within the GINS-III framework.

IV. Graph-Informed Hybrid Optimization Framework

The core of this work is the Graph-Informed Hybrid Optimization Framework (GINS-III), designed to solve the multi-objective silencer placement problem. The framework is built upon the Non-dominated Sorting Genetic Algorithm III (NSGA-III) and enhances its performance by incorporating the pre-computed topological metrics described in Section II-C.

This integration is achieved through two primary components: a Graph-Informed Initialization (GINI) strategy and a Graph-Informed Local Search (GILS) mechanism. By systematically leveraging this domain knowledge, the GINS-III framework guides the evolutionary search process to efficiently balance the conflicting objectives of acoustic attenuation, energy consumption, and economic cost.

A. Multi-Objective Optimization Preliminaries

In multi-objective optimization, a solution X_1 Pareto dominates X_2 (denoted $X_1 \prec X_2$) if it is superior in at least one objective without being inferior in any other. Formally, this relationship is defined in Eq. (10):

$$X_1 \prec X_2 \Leftrightarrow \left(\forall i, f_i(X_1) \le f_i(X_2)\right) \wedge \left(\exists j, f_j(X_1) < f_j(X_2)\right) \quad (10)$$

where $f_i(X)$ is the value of the i-th objective function. The set of all such non-dominated solutions within the search space X constitutes the Pareto Front (PF), as mathematically represented in Eq. (11).

$$PF = \{X \in X \mid \nexists X' \in X, X' \prec X\} \quad (11)$$

Multi-Objective Evolutionary Algorithms (MOEAs) aim to find a high-quality approximation of this front. The foundational NSGA-II algorithm uses a crowding distance metric to promote diversity, but its efficacy degrades in many-objective ($\geqslant 3$ objectives) problems. To overcome this limitation, NSGA-III replaces the crowding distance calculation with a reference-point-based selection mechanism, which effectively maintains population diversity across high-dimensional trade-off surfaces and allows for superior performance on complex problems. The complete methodological workflow of the proposed approach is visually illustrated in Fig. 2.

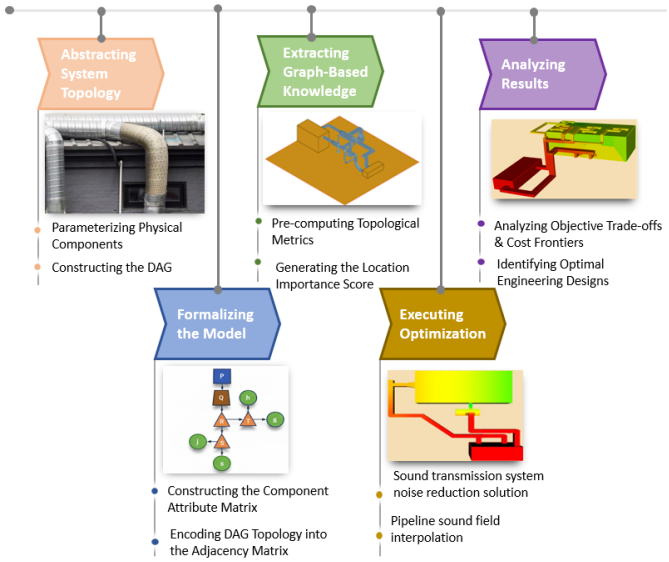

Fig. 2. Methodological workflow of the graph-informed optimization approach.

B. Framework Overview

The G-HNSGA-III framework is a two-phase hybrid architecture. It enhances NSGA-III's global exploration by embedding graph-based domain knowledge through two novel components: a Graph-Informed Initialization (GINI) strategy and a Graph-Informed Local Search (GILS) mechanism.

Phase 1: Global Exploration. This phase employs NSGA-III, but critically replaces its random initialization with our GINI

strategy. GINI leverages pre-computed topological metrics to generate a high-quality guided initialization population, thereby accelerating convergence from the outset.

Phase 2: Local Refinement. The preliminary Pareto front from the global search is then refined by the GILS module. As a post-processing step, GILS performs a targeted neighborhood search to improve solution convergence, operating independently of the main evolutionary loop.

C. Graph-Informed Population Initialization (GINI)

To mitigate the inefficiencies of random initialization in complex engineering problems, we developed the Graph-Informed Initialization (GINI) strategy. GINI replaces a purely random start by embedding pre-computed topological knowledge into the initial population using two complementary mechanisms:

1) Heuristic seeding: A fraction of the population (p_{seed}) is heuristically seeded. For individuals in this subset, decision variables corresponding to the most topologically important nodes (as determined by $I(t_k)$) are assigned a high-performance silencer model with a high probability.

2) Graph-Informed Opposition-Based Learning (GIOBL): Unlike standard Opposition-Based Learning (OBL) which operates on numerical inversion, GIOBL performs a physical state inversion at these high-impact nodes. For a given solution x, its opposition x_{opp} is generated by flipping the silencer state (i.e., installed ↔ not installed) at these key locations, thereby improving the algorithm's exploratory efficiency.

D. Graph-Informed Local Search (GILS)

The Graph-Informed Local Search (GILS) is a post-processing module designed to refine the final Pareto front. It leverages the system's DAG topology to perform a targeted search, which improves solution convergence and diversity without interfering with the primary evolutionary operators of NSGA-III.

The core strategy of GILS is to focus its computational effort on a set of key solutions (S_{key}), which are strategically significant points on the Pareto front. These are identified as:

- Knee Points: Solutions that are closest to the ideal point in the normalized objective space, representing the most balanced trade-offs.
- Extreme Points: Solutions that represent the best performance for each individual objective.

The GILS algorithm proceeds iteratively as follows:

1) Preparation: At the beginning of each iteration t, the current Pareto front, $PF_{current}$, is de-duplicated to create a set of unique solutions.

2) Key solution identification: The set of key solutions, S_{key}, is identified from the unique front based on the definitions above.

3) Adaptive neighborhood search: For each solution X on the front, a set of neighboring solutions, $N(X)$, is generated. This is done by applying "upgrade" (add/improve a silencer) or "downgrade" (remove/lessen a silencer) operations at nodes along critical acoustic propagation paths in the DAG. The search depth is adaptive: solutions belonging to S_{key} are subjected to a more extensive neighborhood search.

4) Evaluation and filtering: All generated neighborhood solutions X' are evaluated by the physics simulation model. Any solution that violates system constraints is discarded.

5) HV-based acceptance: The remaining valid, non-dominated neighbors are considered for inclusion. A candidate solution X' is accepted and used to update the archive ($PF_{current}$) only if its inclusion increases the Hypervolume (HV) indicator of the overall set. That is, $PF_{current}$ becomes $PF_{current} \cup \{X'\}$ only if $HV(PF_{current} \cup \{X'\}) > HV(PF_{current})$.

6) Termination criteria: The GILS process terminates when one of two conditions is met: (a) a maximum number of refinement iterations, $T_{refinement}$, is reached, or (b) the improvement in the Hypervolume stagnates between iterations, such that $\Delta HV < \delta HV$.

E. The G-HNSGA-III Algorithm Workflow

The complete workflow of the G-HNSGA-III framework integrates the GINI strategy, the core NSGA-III evolutionary loop, and the GILS post-processing module. The step-by-step process is as follows:

1) Initialization: The topological metrics of the DAG are pre-computed (as described in Section II-C). Key parameters for the NSGA-III algorithm (e.g., population size N , max generations G_{max}, crossover/mutation rates) are set.

2) Graph-Informed Population Generation (GINI): The initial population, P_0 (size N), is created using the GINI strategy (Section III-C). Each individual in P_0 is then evaluated using the physics-based simulation model to determine its objective function values.

3) Evolutionary loop: The evolutionary process iterates for generations $g = 0$ to G_{max} to drive the population toward convergence along the Pareto front. This process consists of three substeps:

a) Variation: An offspring population, Q_g (size N), is generated from the current population, P_g, using standard genetic operators (selection, crossover, and mutation).

b) Evaluation: All individuals in the offspring population Q_g are evaluated.

c) Selection: The parent and offspring populations are merged into a combined population $R_g = P_g \cup Q_g$ (size $2N$). A fast non-dominated sort is applied to R_g. The next generation, $P_{(g+1)}$, is constructed by selecting individuals from the best non-dominated fronts $(F_1, F_2, \dots)$. The reference-point mechanism of NSGA-III is used to ensure diversity when selecting from the last front that cannot be fully included.

4) Local refinement (GILS): Upon termination of the evolutionary loop, the final non-dominated front, PF_{final}, is passed to the GILS module. GILS iteratively refines this front to enhance the convergence and diversity of the solutions.

5) Final output: The refined Pareto-optimal solution set from GILS is returned as the final output of the algorithm. The complete workflow described above is visually summarized in the flowchart in Fig. 3.

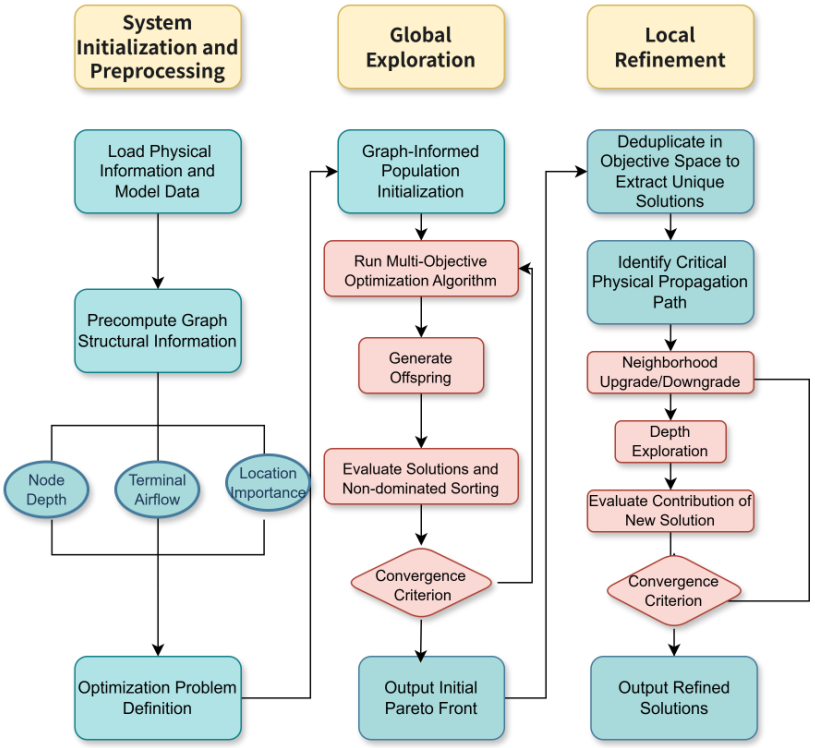

Fig. 3. Flowchart of the multi-objective optimization program.

V. Experimental Setup and Validation

This chapter details the computational experiments designed to validate the performance of the proposed G-HNSGA-III framework. All experiments were conducted on a complex, large-scale data center air supply duct system, which serves as the primary test instance.

A. Computational Environment and Simulation Model

The simulation and optimization environment was developed in Python 3.9. The physics-based model for fluid dynamics, acoustics, and economics was implemented using the PyTorch library. All MOEAs, including our proposed framework, were implemented using the Platypa-opt library. The hardware platform consisted of an Intel Core i7-10700 CPU and 16 GB of RAM, running a Windows 11 operating system.

B. Test Instance: Data Center HVAC System

A complex and asymmetrical data center HVAC supply air system was used as the test instance to ensure the problem's practical relevance and difficulty. A partial schematic of the system's DAG topology is shown in Fig. 4. The key parameters and engineering constraints of this system are summarized in Table I.

C. Compared Algorithms and Parameter Settings

To validate the performance of the proposed G-HNSGA-III framework, it was benchmarked against a baseline NSGA-III and six other established MOEAs: NSGA-II, SPEA2, GDE3, MOEAD, and OMOPSO.

TABLE I. Key Parameters of the Data Center Test Instance

Parameter Category	Parameter	Value	Unit
Topological Properties	Total nodes (components)	44	-
	Potential silencer locations	22	-
	Number of fans	2	-
	Total edges (paths)	40	-
Geometric Properties	Main duct cross-section	1500 x 800	mm
	Branch duct cross-section	500 x 500	mm
Operational Requirements	Number of terminal outlets	12	-
	Average outlet airflow demand	0.6	m^3/s
Decision Variables	Available silencer models	18	-
Economic Factors	Electricity cost	0.85	RMB/kWh
	Annual operating hours	2500	h
Engineering Constraints	Max. main duct velocity	5.0	m/s
	Max. branch duct velocity	4.0	m/s
	Max. outlet air velocity	2.0	m/s
	Max. room noise criterion	40	dB(A)
	Max. fan static pressure	800	Pa

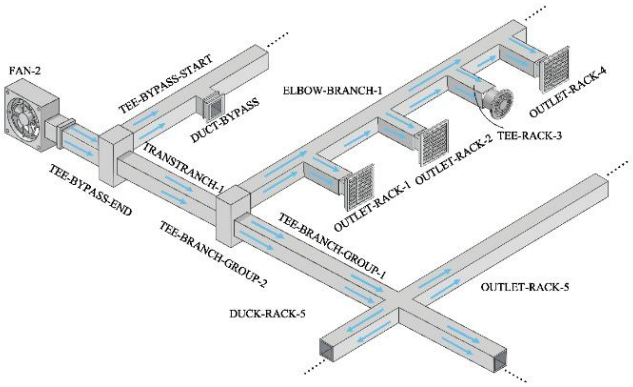

Fig. 4. Node processing of ventilation duct model.

For a fair and rigorous comparison, all algorithms were executed under a consistent computational budget: a population size of 100 (105 for MOEAD, due to its reference vector requirements) and a termination criterion of 15,000 total function evaluations. To ensure statistical robustness, each experimental run was independently repeated five times.

The specific parameter configurations for each algorithm are detailed in Table II. Standard evolutionary parameters, such as crossover and mutation probabilities, were set to common values from the literature. The unique parameters for the GINI and GILS components of G-HNSGA-III were determined through a separate calibration process, as detailed in Section V-E.

TABLE II. PARAMETER CONFIGURATION FOR COMPARED ALGORITHMS

Algorithm	Parameter	Value
General Settings		
All Algorithms	Population / Swarm Size (N)	100 (105 for MOEAD)
	Crossover Operator	Simulated Binary (SBX)
	Mutation Operator	Polynomial
Algorithm-Specific Parameters		
NSGA-II/III, G-HNSGA-III, SPEA2	SBX crossover probability (p_c)	0.9
	Polynomial mutation probability(p_m)	0.1
	distribution index (η)	20.0
GDE3	Scaling Factor (F)	0.5
	Differential evolution crossover rate (CR)	0.9
MOEAD	Neighborhood Size (T)	20
OMOPSO	Swarm Size(N)	100
	Archive Size	100
G-HNSGA-III Specific Parameters		
GINI	seeding fraction (p_{seed})	0.12
	Importance ratio(r_{imp})	0.1
	Assignment probability (p_{assign})	0.8
GILS	Max refinement iterations (T_{ref})	10
	Max search depth (key nodes)	3
	Neighborhood search depth (normal nodes)	1

D. Performance Evaluation Metrics

To quantitatively evaluate the performance of the compared algorithms, three widely-used metrics were employed: Set Coverage (SC), Inverted Generational Distance (IGD), and Hypervolume (HV).

1) Set Coverage (SC): The SC metric (also known as the C-metric) quantifies the Pareto dominance relationship between two solution sets, P_A and P_B. The value $SC(P_A, P_B)$ represents the fraction of solutions in P_B that are weakly dominated by at least one solution in P_A, as computed by Eq. (12).

$$SC(P_A, P_B) = \frac{|\{b \in P_B \mid \exists a \in P_A : a \succeq b\}|}{|P_B|} \quad (12)$$

where $a \succcurlyeq b$ denotes that solution a weakly dominates b. A value of $SC(P_A, P_B) = 1$ indicates that all solutions in P_B are dominated by P_A, signifying the superiority of algorithm A over B.

2) Inverted Generational Distance (IGD): The IGD metric quantifies the quality of a solution set (P_{alg}) by computing the average Euclidean distance from a reference Pareto front (P^*) to P_{alg}, as formulated in Eq. (13).

$$IGD(P^*, P_{alg}) = \frac{\sum_{p^* \in P^*} \min_{p \in P_{alg}} d(p^*, p)}{|P^*|} \quad (13)$$

A lower IGD value indicates a superior solution set that is both closer to the true front and better distributed.

Since the true Pareto front is unknown for this complex engineering problem, a high-fidelity reference front P^* was constructed by aggregating the final non-dominated solution sets from all 5 independent runs of all 8 compared algorithms. A non-dominated sort was performed on this aggregate archive, yielding 786 unique solutions. This set serves as the best-known approximation of the true Pareto front for all IGD calculations.

3) Hypervolume (HV): The HV indicator is a unary metric, fully compliant with Pareto dominance, that measures both the convergence and diversity of a solution set P_{alg}. It calculates the volume of the objective space dominated by P_{alg} relative to a reference point P_{ref}. A larger HV value signifies a better Pareto front approximation. In this study, the reference point P_{ref} was set to the nadir point (the vector of worst objective values) observed across all experimental runs, supplemented by a small offset to ensure that all generated solutions strictly dominate P_{ref}.

E. Hyperparameter Calibration for G-HNSGA-III

A sensitivity analysis was performed to optimize the core hyperparameters of the G-HNSGA-III framework. All experiments were conducted on the data center test instance, with each setting repeated 7 times under a consistent computational budget of 15,000 function evaluations.

1) GILS max search depth: The Local Refinement Exploration Depth for the GILS module was tested across integer values from 0 (disabled) to 6. As shown in Fig. 5, the

results confirm the module's efficacy. Both HV and IGD metrics identify a consistent optimum at a search depth of 3, achieving a peak HV of 0.358 and a minimum IGD of 0.00326. This setting was chosen as it achieves the peak demonstrated performance; increasing the search depth further leads to performance degradation while unnecessarily increasing the computational budget. Excessively deep local searches can cause the population to converge prematurely to a suboptimal region, stifling the global exploration required to find the true Pareto front.

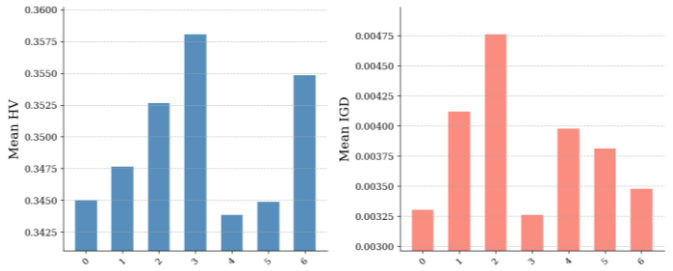

Fig. 5. Performance of the H-NSGAIII algorithm at different local refining exploration depths.

2) GINI heuristic seeding fraction: The Heuristic Seeding Fraction (p_{seed}) for the GINI module was tested from 0.0 (disabled) to 0.23. The results, presented in Fig. 6, demonstrate a clear peak in performance at a fraction of 0.12, which achieved the highest HV (0.360) and the lowest IGD (0.00384). Performance degrades beyond this point, likely because an excessive injection of guided solutions prematurely reduces the initial population's diversity and hinders broader exploration. Therefore, a value of 0.12 was selected as it provides the optimal balance between a guided initialization and sufficient initial diversity.

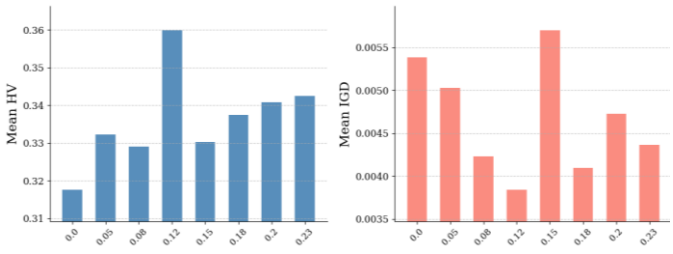

Fig. 6. Mean Hypervolume (HV) and Mean Inverted Generational Distance (IGD) of G-HNSGA-III under different settings for the initial population adjustment ratio parameter.

VI. Results and Discussion

This chapter presents the quantitative performance comparison of the G-HNSGA-III framework against the baseline NSGA-III and six other established MOEAs.

A. Overall Performance Comparison and Solution Set Quality

All eight algorithms were independently executed 10 times under a consistent computational budget of 15,000 function evaluations. The statistical distributions of the final Hypervolume (HV) and Inverted Generational Distance (IGD) metrics across these runs are summarized in Table III.

TABLE III. Statistical Results for HV and IGD Metrics Across 10 Independent Runs

Algorithm	Mean HV	Std HV	Median HV	Mean IGD	Std IGD	Median IGD
G-HNSGA-III	0.3891	0.0122	0.3910	0.0030	0.0008	0.0030
GDE3	0.2950	0.0124	0.2913	0.0154	0.0011	0.0152
MOEAD	0.1944	0.0229	0.1848	0.0239	0.0038	0.0234
MOGWO	0.1824	0.0477	0.1942	0.0119	0.0010	0.0119
NSGAII	0.2697	0.0197	0.2665	0.0193	0.0021	0.0197
NSGAIII	0.2812	0.0173	0.2814	0.0202	0.0029	0.0195
OMOPSO	0.2655	0.0323	0.2626	0.0317	0.0067	0.0342
SPEA2	0.2608	0.0281	0.2519	0.0150	0.0033	0.0160

The statistical results confirm the superior performance of the G-HNSGA-III framework. For Hypervolume (HV), G-HNSGA-III achieved the highest mean value of 0.3891, a 38.4% improvement over the baseline NSGA-III (0.2812). This result, combined with a low standard deviation (0.0122), demonstrates superior overall solution quality and high reliability. Similarly, the framework obtained the lowest mean Inverted Generational Distance (IGD) of 0.0030, confirming the closest and most complete approximation of the best-known Pareto front. An exceptionally low standard deviation of 0.0008 further underscores its robust stability.

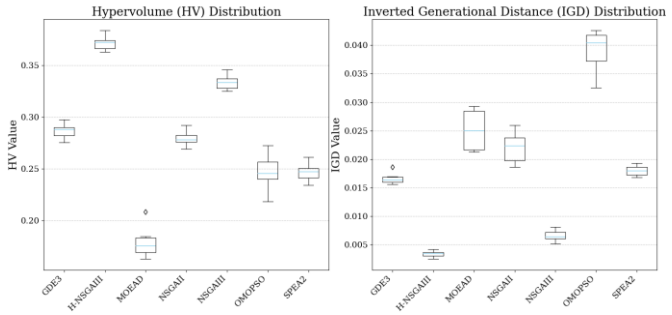

Fig. 7. Boxplot distributions of the final Hypervolume (HV) and Inverted Generational Distance (IGD) metrics for all compared algorithms.

The statistical distributions of the final metric values are visualized using boxplots in Fig. 7 to provide a clearer comparison of algorithm robustness and consistency.

The plots visually affirm the superiority of G-HNSGA-III. For the HV metric (Fig. 8, left), the G-HNSGA-III boxplot is located in a distinctly higher region than all competitors, indicating a consistently better overall performance. Furthermore, its compact interquartile range (IQR) and short whiskers signify high stability and low variance across the independent runs. A similar pattern is observed for the IGD metric (Fig. 8, right), where the G-HNSGA-III boxplot is positioned significantly lower and exhibits the tightest

distribution. Collectively, these plots confirm the findings from Table IV: G-HNSGA-III not only achieves a superior median performance but also does so with the highest level of consistency.

Fig. 8 illustrates the final non-dominated solution sets obtained by each algorithm, plotted in the three-dimensional objective space (Noise Level, Total Cost, and Total Pressure Drop). This visualization highlights the differences in the algorithms' ability to approximate the true Pareto front.

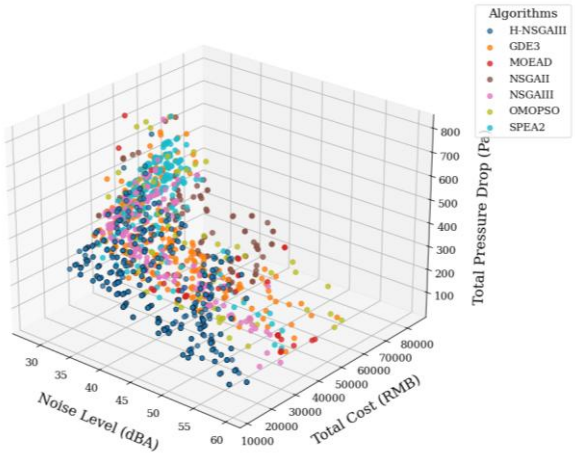

Fig. 8. Comparison of the distribution of solution sets of each algorithm in the three-dimensional target space.

The solution set produced by G-HNSGA-III (cyan) provides a visibly superior approximation of the Pareto front. It extends further toward the ideal point (lower values on all three axes) and achieves a broader, more uniform coverage of the trade-off surface compared to the other algorithms. The solutions from the competing MOEAs are, for the most part, either dominated by or co-located with only a subset of the G-HNSGA-III solutions. This visualization directly corroborates the quantitative HV and IGD results, confirming that the proposed framework excels in both convergence (approaching the optimal region) and diversity (covering a wide range of trade-off solutions).

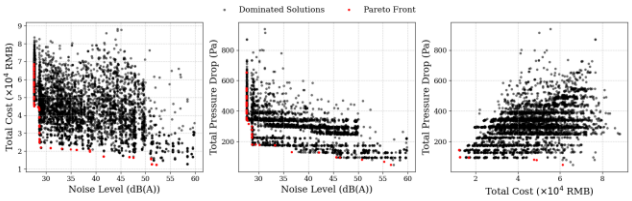

Fig. 9. 2D Pareto front projections of the solution sets of each algorithm under different target pairs.

Fig. 9 projects the aggregated solution set onto three 2D objective planes to visualize the trade-off relationships, with the 2D non-dominated front highlighted in red. The plots confirm the expected conflicts between objectives. The Noise-Cost plane (a) demonstrates that improved acoustic performance requires higher capital investment. The Noise-Pressure Drop plane (b) shows that noise reduction typically increases aerodynamic resistance, leading to higher energy use. Finally, the Cost-Pressure Drop plane (c) identifies the set of most efficient designs that achieve the lowest pressure drop for a given cost.

These visualizations affirm the conflicting, multi-dimensional nature of the problem space. The Pareto front approximated by G-HNSGA-III (shown in Fig. 8) provides the most effective navigation of these trade-offs.

B. Algorithmic Behavior and Dominance Analysis

To analyze the dynamic performance of the algorithms, the HV and IGD metrics were recorded throughout the search process. Fig. 10 plots the metric trajectories from a representative run for each algorithm, illustrating their convergence behavior.

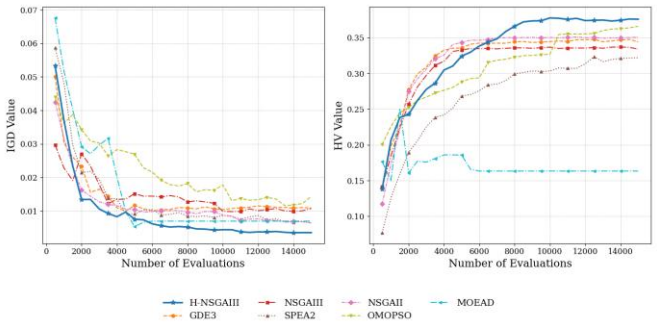

Fig. 10. Comparison of convergence curves of each algorithm on HV and IGD metrics.

The G-HNSGA-III framework (solid blue line) demonstrates superior convergence behavior on both metrics. Its IGD curve (left) exhibits the most rapid descent, reaching a final value of ~0.003, which signifies an efficient search for a high-quality front. Concurrently, its HV curve (right) sustains growth longer than any competitor, diverging after ~2,000 evaluations to achieve the highest final HV of ~0.37. In contrast, algorithms like MOEA/D stagnate early, indicating premature convergence.

For a direct comparison based on Pareto dominance, the Set Coverage (SC) metric was computed. Fig. 11 presents the full pairwise SC matrix as a heatmap, while Fig. 12 isolates the bidirectional dominance between G-HNSGA-III and each competitor for a focused analysis.

Fig. 11. Heatmap of the pairwise Set Coverage (SC) matrix across all algorithms.

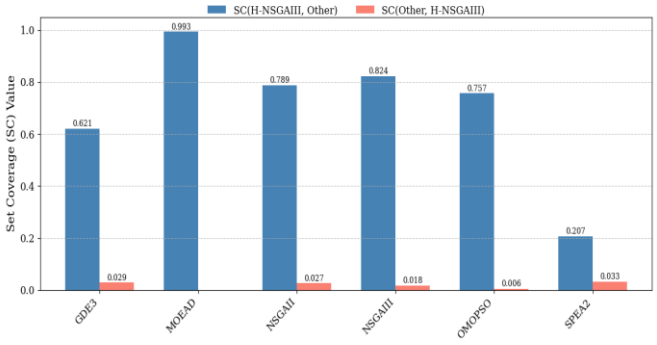

Fig. 12. Comparison of set coverage (SC) between G-HNSGA-III and other algorithms.

The results unequivocally demonstrate the dominance of G-HNSGA-III. As shown in Fig. 12, G-HNSGA-III dominates a very high percentage of the solutions generated by the other algorithms. For example, it dominates 99.3% of the solutions from MOEA/D (SC (G-HNSGA-III, MOEA/D) = 0.9934) and over 82.3% of the solutions from the baseline NSGA-III (SC (G-HNSGA-III, NSGA-III) = 0.8235).

Conversely, the orange bars show that the solution sets from the other algorithms dominate very few, if any, of the solutions produced by G-HNSGA-III. This direct quantitative evidence confirms that the graph-informed strategies enable G-HNSGA-III to discover a Pareto front that is demonstrably superior to those found by the other established MOEAs.

C. Engineering Significance Analysis of Representative Solutions

The high-quality Pareto front generated by G-HNSGA-III provides a rich set of optimal trade-off solutions for engineering decision-making. To illustrate this, Table IV details five representative solutions selected from the final front, including the extremes for each objective and a balanced solution identified using the TOPSIS method [25].

TABLE IV. PERFORMANCE COMPARISON OF TYPICAL SOLUTIONS OBTAINED BY G-HNSGA-III

Solution Type	Noise Level (dBA)	Total Cost (RMB)	Total Pressure Drop (Pa)	Number of Silencers
Lowest Noise Solution	28.67	45688.09	277.20	11
Lowest Cost Solution	49.86	19482.96	187.39	5
Lowest Pressure Drop Solution	45.08	37490.16	126.60	9
Min Cost (Noise ≤ 50.0dBA)	46.78	19812.29	176.37	5
Best Compromise (TOPSIS)	38.84	22970.92	178.76	6

The 'Best Compromise' solution represents a practically balanced design. Relative to the 'Minimum Cost' solution, it achieves a substantial 11.1 dBA noise reduction (a 22% improvement) with a moderate 18% increase in cost and negligible impact on pressure drop. Analysis of the system configuration reveals that this acoustic improvement is achieved by deploying a single additional silencer at a critical upstream location, which was correctly identified by the framework's graph-based importance metrics. This result empirically validates the capacity of G-HNSGA-III to leverage domain knowledge for discovering highly efficient trade-offs.

To facilitate practical project planning, the minimum cost required to achieve specific noise targets was extracted from the global Pareto front and plotted as the 'Minimum Cost Frontier' in Fig. 13. This curve quantifies the necessary capital investment to meet varying acoustic criteria. A distinct non-linear trend is observed, characterized by a 'knee' point in the 35–40 dBA range. Beyond this threshold, each incremental decibel of noise reduction incurs a substantially higher cost, demonstrating the principle of diminishing returns. This insight provides actionable data for cost-benefit analysis in real-world engineering contexts.

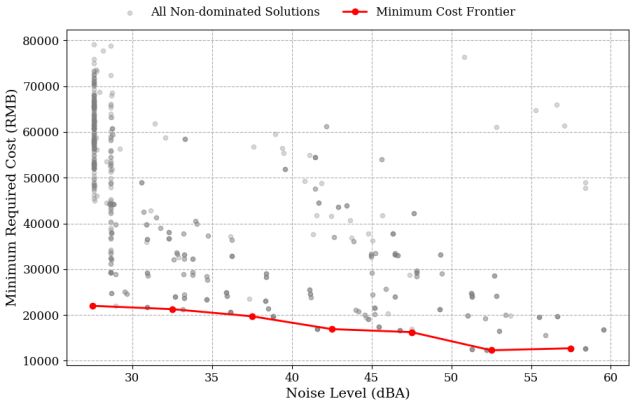

Fig. 13. Noise-cost quantitative trade-off analysis.

VII. CONCLUSION AND FUTURE WORK

This paper introduced G-HNSGA-III, a hybrid optimization framework that enhances NSGA-III by embedding topological domain knowledge from a Directed Acyclic Graph (DAG) model of an HVAC system. The framework's core innovations, a Graph-Informed Initialization (GINI) strategy and a Graph-Informed Local Search (GILS) module, were shown to be highly effective.

Experimental validation demonstrated that G-HNSGA-III significantly outperforms the baseline NSGA-III and six other established MOEAs across all standard metrics (HV, IGD, and SC). The results confirm that the proposed graph-informed heuristics effectively guide the search, leading to a superior Pareto front that offers a range of practical, high-value engineering trade-off solutions.

While the current physical model could be expanded and the framework's generalizability tested on other HVAC typologies, the results confirm the validity of our approach. Future work will focus on integrating surrogate models, such as Graph Neural Networks (GNNs), to improve computational efficiency and adapting this graph-informed optimization paradigm to other network-based engineering domains.

AI-Powered Architecture Refactoring: From Legacy Systems to Modern Patterns

An Initial Case Study with LLM and CQRS

Mohamed El BOUKHARI[1], Nassim KHARMOUM[2], Soumia ZITI[3]
IPSS Research Team-Faculty of Sciences, Mohammed V University in Rabat, Rabat, Morocco[1, 2, 3]
National Center for Scientific and Technical Research (CNRST), Rabat, Morocco[2]

***Abstract*—This study explores the integration of artificial intelligence (AI), especially large language models (LLMs), into software engineering, particularly the architecture refactoring process, focusing on automated command-query classification for legacy systems transitioning to the Command Query Responsibility Segregation (CQRS) pattern. We present *Airchitect*, a modular system. NET-based tools that orchestrate legacy code analysis, LLM-driven classification, CQRS artifact generation, and automated test creation are also available. Based on the CodeLlama model, Airchitect achieved a 16x–40x reduction in classification time compared to expert manual methods while maintaining over 85% classification accuracy. A test case involving N-tier legacy classes demonstrated the model's ability to decompose and modularize the methods into CQRS-aligned components. Despite these gains, the study highlights key limitations: the need for human validation in complex or ambiguous cases, dependence on high-quality labeled datasets, and variability of legacy patterns that challenge rule-based automation. The results suggest that LLMs, when embedded in structured tools like Airchitect, can significantly accelerate modernization workflows—provided they are used in tandem with expert oversight.**

***Keywords*—Artificial intelligence; LLM; AI-driven refactoring; code-level refactoring; legacy systems, command and query responsibility segregation; CQRS; software architecture refactoring; software engineering; CodeSearchNet**

I. Introduction

Legacy systems are business-critical applications developed using older technologies or architectures that continue to provide essential services despite their age. Many organizations have relied extensively on systems-built decades ago using legacy programming languages or architectures, along with design methods that preceded modern software engineering practices. The primary challenge is to maintain and evolve these systems to meet current business demands without disrupting operations. Legacy systems typically suffer from technical debt (the accumulated costs of additional rework caused by choosing an easy solution instead of using a better approach that would take longer), tight coupling, and inadequate separation of concerns, rendering them difficult to modify, scale [1], and integrate with modern technologies.

Legacy systems form the backbone of the IT infrastructure of many organizations despite their age and technological limitations. These systems are characterized as "old software systems that are usually designed and documented inadequately but still perform an important job for critical business applications." The business value of these systems has deteriorated over time owing to their lack of consistency and limited evolution support; however, they remain indispensable [2] because some of their functions are too important to be discarded completely and too costly to reconstruct.

Legacy systems also represent significant accumulated knowledge and established technology. They "embed important knowledge acquired over the years" and constitute "critical assets for enterprises." However, these systems incur high maintenance costs and are increasingly vulnerable to failure because of the diminishing pool of experts who understand their inner workings [4]. Billions of lines of legacy code must evolve into modern technologies to enable progress in business practices.

Optimizing legacy applications requires substantial effort, which is often not immediately achievable. This process involves difficult and complex work" and necessitates careful decision-making to support successful system management. When dealing with particularly complex problems, organizations must "apply with a systematic approach for defining which modifications should be made or recommended" [5]. This emphasizes the need for structured methodologies to assess, analyze, and refurbish legacy systems while preserving their intrinsic value.

A. Legacy Systems Refactoring

The shift from old to new architecture is a significant change that can make systems more flexible and work better [6]. The addition of smart systems to organizations has been shown to boost business performance.

A comprehensive survey conducted in 2021, encompassing 1,183 users of the IntelliJ Integrated Development Environment (IDE), revealed that only 10-11% of refactoring tasks were executed using automated tools, with the majority being performed manually. The 'Rename' function emerged as the most frequently utilized, with an 85.8% usage rate, particularly among regular developers. Approximately 46% of cases in which tool assistance is feasible are tool-assisted, predominantly by teams aiming for consistency, although the settings are seldom altered [7]. Floss refactoring, which is integrated with other tasks, prevails over root canal approaches. Notably, half of the refactoring tasks are of simple to medium complexity, which tools often fail to address, and commit messages rarely explicitly indicate the refactoring activities.

B. Challenges of Legacy Systems Refactoring

Legacy systems present significant challenges to modern software development, particularly in integrating established software engineering principles into their architecture. Developers frequently encounter difficulties when refactoring existing codebases to conform to best practices, such as SOLID, DRY (Do not Repeat Yourself), SRP (Single Responsibility Principle), and KISS (Keep It Simple, Stupid) [16]. These principles form the foundation of maintainable and scalable software architecture, with the SRP emphasizing that each class should be responsible for only one aspect of the software functionality [17]. This approach seeks to preserve design simplicity and minimize disruptions during future modifications.

C. Technical Complexities and Compatibility Issues

Integrating AI-based software engineering principles into legacy systems presents multifaceted challenges. Technical complexities and compatibility issues are the primary obstacles because legacy systems are typically not designed to accommodate modern Artificial Intelligence (AI) technologies [18]. This fundamental architectural mismatch often necessitates significant system overhauls or the development of middleware solutions to bridge the gap between legacy codes and AI-driven tools.

D. Organizational Management and Manual Processes

The integration process requires careful assessment of existing systems to identify potential integration points and compatibility problems. Companies using legacy systems or relying heavily on manual processes face particularly steep challenges because AI integration requires substantial initial commitments of time and resources [19]. This resource investment extends beyond technical implementation to include addressing organizational change management and ensuring seamless operations between AI models and existing business processes.

E. Disruption of Established Workflows

One significant challenge is the potential disruption of established workflows. Legacy systems often have well-defined processes to which employees are accustomed, and the introduction of AI-driven tools to apply software engineering principles may lead to resistance or inefficiency if not managed carefully. This also necessitates acknowledging the organizational and cultural challenges associated with such changes [20], including employee adaptation and its impact on workflows. Implementing new AI technologies and training staff to use them effectively involves an inevitable learning curve.

The effective integration of artificial intelligence into legacy systems to implement the SOLID, DRY, SRP, and KISS principles necessitates meticulous planning to avoid potential incompatibility issues that may hinder the implementation process [21]. Organizations must strategically address this challenge by balancing the technical aspects of integration with human and process elements to achieve significant enhancements in code quality and maintainability.

F. Integration of Artificial Intelligence into the Refactoring Process

The integration of artificial intelligence into code refactoring has progressed from initial experimental methodologies to advanced systems driven by machine learning and language modeling.

Recent advancements have led to the development of various artificial intelligence (AI) methodologies for code refactoring. Techniques based on machine learning and optimization employ statistical methods, artificial intelligence, and various machine learning algorithms to identify and rectify refactoring opportunities. This category encompasses search-based approaches that utilize evolutionary and genetic algorithms to explore code spaces to maximize optimization functions [9], as well as clustering-based methods that group similar code fragments according to similarity measures.

Large language models (LLMs) have changed the way artificial intelligence (AI) is used in software development. These models learn from large sets of codes and documents to assist with several software tasks [11]. For example, in refactoring, such as method extraction, LLMs can find code parts to extract, suggest method names, create documentation, and explain changes during code reviews [11]. Tools such as EM-Assist, a plugin for IntelliJ IDEA, use LLMs to make and improve suggestions for Extract Method refactoring [12]. This makes the suggestions more aware of the context than traditional tools that rely on static analyses. LLMs are also effective in identifying and fixing code smells, which are patterns in the code that indicate design problems. In the past, code smells were detected using manual reviews and static analysis tools [13]. LLMs provide a scalable, language-independent method for automating this process.

In specific architectural domains, AI-assisted refactoring has shown promise in restructuring large monolithic applications [14]. This approach is particularly relevant for FPGA design [15], in which code refactoring is typically a manual process. Recent research suggests that AI can effectively assist in scanning and revising codes in specific contexts.

G. Command Query Responsibility Segregation (CQRS)

The Command Query Responsibility Segregation (CQRS) principle is a software architectural pattern that delineates read operations (queries that retrieve the current state without modification) from write operations (commands that alter the system state), thereby facilitating the independent optimization and scaling of each. This separation enhances system clarity, maintainability, and performance in complex domains characterized by disparate read/write workloads, while addressing the limitations of monolithic architectures, such as I/O degradation and internal dependencies, as the scale increases [22]. By establishing distinct channels with their own APIs [23], CQRS aligns more effectively with business logic and supports event-driven [24] and distributed systems.

This paper is structured as follows: Section I introduces the challenges of legacy systems and the need for refactoring. Subsequently, Section III reviews the related work on AI-assisted refactoring and the integration of large language models (LLMs) in software modernization. The methodology in

Section IV details the dataset preparation, model selection, classification pipeline, and integration of automated command-query classification with the human validation. The results present the dataset characteristics, model evaluation, and implementation within the AiRchitect tool in Section V, followed by a discussion on the performance gains, accuracy, and limitations in Section VI. The conclusion in Section VII summarizes the benefits of the proposed approach for accelerating the modernization of legacy systems.

II. Approach

In traditional monolithic architectures, all components are consolidated on platforms on a single server, making them simple to build and maintain at a small scale. However, as these systems grow and accumulate more functionality, they have several drawbacks that must be addressed. Notably, monolithic systems experience performance degradation and develop complex internal dependencies that complicate their modification. A critical weakness of monolithic systems is that errors in one component can easily propagate throughout the entire system [24], thereby affecting the overall stability.

CQRS addresses these limitations by separating write operations (commands) from read operations (queries). This separation prevents I/O performance delays that are common in traditional architectures and allows developers to add new functionalities without creating complex dependencies within the system [24]. Fowler advocated for CQRS over traditional Create, Read, Update, and Delete (CRUD) systems [25], noting that CQRS overcomes the limitations of CRUD approaches while delivering superior performance.

Legacy systems pose numerous challenges for refactoring, stemming from outdated architecture, limited documentation, and reliance on manual techniques that often depend on developer intuition rather than structured architectural decisions. These traditional approaches are time-consuming and costly, making large-scale modernization difficult to implement in practice. The emergence of artificial intelligence, particularly large language models (LLMs), has introduced promising new avenues for automating and optimizing refactoring processes. By reducing manual effort, AI has the potential to significantly reduce both the time and cost associated with the transformation of legacy systems into modern systems. Although previous research has highlighted the effectiveness of manual refactoring methods, little attention has been paid to the role of AI in automating and enhancing these processes to improve their efficiency. However, only a few studies have investigated architectural refactoring. This study marks the launch of Airchitect, a research initiative aimed at exploring AI-assisted architectural refactoring and its effectiveness. Our first phase focused on auto-refactoring legacy systems into a CQRS-based architecture, which was chosen for its ability to separate read and write responsibilities, improve scalability, enhance maintainability, and align system design more closely with business operations. By leveraging LLMs in this context, we aim to measure the impact of refactoring and iteratively improve their quality and efficiencies. In addition, we emphasize minimizing the cost of refactoring and making deliberate choices to refactor rather than developing new features whenever feasible.

III. Related Works

Artificial intelligence offers promising solutions for automating and enhancing this process by utilizing machine learning algorithms, pattern recognition, and data analysis techniques to identify architectural issues and propose refactoring strategies. AI-driven methodologies can analyze code repositories, detect code smells, identify architectural patterns, and recommend optimal refactoring solutions at a scale and speed that would be challenging for human developers to achieve manually. The integration of AI into software architecture refactoring represents a significant advancement in software engineering practices, facilitating more systematic and data-driven approaches to code improvement in software engineering.

Burgueño et al. [26] proposed the use of artificial intelligence techniques to automate software refactoring through model transformations, specifically highlighting model-to-model transformations that facilitate model evolution, merging, migration, and refinement. Their research indicates that employing a generic neural network architecture, such as an encoder-decoder long short-term memory network with an attention mechanism, allows for effective learning and execution of these transformation tasks, provided that sufficient and non-contradictory training data are available, demonstrating the potential for significant improvements in developer productivity and reduction of errors in software development processes.

Ahmad and Bahar [27] proposed a framework that integrates AI planning to assist in software architectural migration, emphasizing the automation of design transformation. Their approach utilizes the Planning Domain Definition Language (PDDL) to define architectural design models and automatically generate migration plans. This method enhances the efficiency of the refactoring process by managing dependencies and constraints within the architecture, thereby improving planning performance. The AI-powered planning framework supports more efficient migration strategies; however, these documents do not include specific performance metrics.

According to Chondamrongkul J Sunt al., the integration of artificial intelligence in software refactoring employs an automated planning methodology to generate migration plans for architectural transitions. This process leverages AI planning and model-checking techniques to develop interim designs based on migration steps, ensuring that the designs adhere to functional and architectural constraints. These findings suggest that the migration plan and evolution path can be generated effectively in an automated manner, thereby alleviating the burden on software engineers by offering a structured pathway for incremental architectural evolution. This approach has demonstrated potential in verifying that interim designs fulfill all essential functionalities and conform to applied architectural patterns, thus affirming its efficacy in practical applications, as evidenced by the LifeNet case study.

Previous research on ML refactoring has focused on code issues, such as the Extract Method, using simulated datasets. AiRchitect advances this by breaking down software systems using CQRS, automating classification, handler creation, and testing, while incorporating human verification. This addresses

the deficiencies in previous methods that current research inadequately covers.

This study delineates three principal contributions: 1) an end-to-end methodology utilizing AiRchitect to decompose monolithic classes into Command Query Responsibility Segregation (CQRS) patterns; 2) the automated generation of handlers and validation tests; and 3) a hybrid human-in-the-loop validation process to ensure domain accuracy.

IV. Methodology

This study adopts a structured approach (Fig. 1) to classify code snippets into command and query functions, thereby supporting the automated refactoring of the CQRS-based architecture. The methodology comprised six sequential phases: dataset preparation, model selection, classification pipeline design, classification, integration with the refactoring process, and human validation.

A. Step 3: Classification Pipeline

This phase defines a systematic procedure for converting raw codes into structured representations suitable for classification.

The pipeline begins with an input transformation, where the code snippets undergo tokenization and are represented in a format that is compatible with the language models. This step ensures that the syntactic and semantic elements of the code are preserved while enabling efficient processing by the model. Subsequently, these representations were processed using a fine-tuned architecture designed for binary classification to distinguish between command- and query-oriented functions. The pipeline incorporates mechanisms for training, validation, and evaluation guided by standard metrics, such as accuracy and F1-score, without disclosing specific outcomes. This structured approach ensures reproducibility and adaptability across various programming languages and configurations.

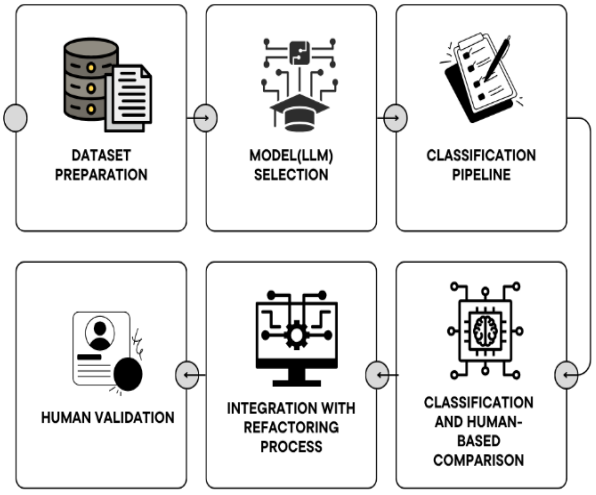

Fig. 1. Flow diagram methodology.

A. Dataset Preparation

This phase established a systematic methodology for developing a clean and well-labeled dataset that was appropriate for training the classification model. The process commences with the identification of a representative corpus of source code sourced from multiple programming languages to ensure diversity and generalizability. The preparation workflow typically includes the following steps:

- Function Extraction: Analyze the source files to identify distinct functional components while excluding non-executable or irrelevant code segments.
- Labeling Strategy: Heuristic or rule-based methodologies were employed to categorize functions based on naming conventions and semantic indicators.
- Preprocessing: Comments and superfluous whitespace were eliminated to minimize noise. Identifiers were normalized to ensure consistency across samples. Tokenization employs a model-compatible tokenizer to transform the code into structured representations.
- Data partitioning: The dataset was partitioned into training, validation, and testing subsets to ensure a balanced representation across categories.

This systematic preparation ensured that the dataset was clean and semantically meaningful, thereby providing a robust foundation for subsequent modeling and evaluations.

B. Model (LLM) Selection

This phase establishes a systematic approach for identifying an appropriate Large Language Model (LLM) capable of performing semantic code classification across multiple programming languages.

The selection process began by defining the evaluation criteria according to the study objectives. These criteria typically include the following:

- Computational Efficiency: Assessing resource requirements and scalability for large datasets.
- Classification accuracy: This evaluates the ability of the model to capture semantic distinctions in the code.
- Language Coverage: Ensuring support for multiple programming languages to maintain generalizability.
- Integration Capability: Verifying compatibility with widely adopted frameworks for fine-tuning and deployment.
- Cost Considerations: Estimating the financial and operational costs of training, fine-tuning, and inference, including hardware and licensing requirements

Candidate models were then reviewed based on these dimensions, using documented benchmarks and empirical evidence from prior research. The comparative analysis focused on the architectural characteristics, pre-training strategies, and adaptability to downstream tasks. This structured evaluation ensures that the chosen model aligns with both performance and practical constraints without bias toward any single implementation.

C. Classification Pipeline

This phase defines a systematic procedure for converting raw codes into structured representations suitable for classification.

The pipeline begins with an input transformation, where the code snippets undergo tokenization and are represented in a format that is compatible with the language models. This step ensures that the syntactic and semantic elements of the code are preserved while enabling efficient processing by the model. Subsequently, these representations were processed using a fine-tuned architecture designed for binary classification to distinguish between command and query-oriented functions. The pipeline incorporates mechanisms for training, validation, and evaluation guided by standard metrics, such as accuracy and F1-score, without disclosing specific outcomes. This structured approach ensures reproducibility and adaptability across various programming languages and configurations.

D. Classification and Human-Based Comparison

This phase focused on categorizing the code snippets and validating the results through human judgment rather than automated optimization. The classification process assigns each snippet a functional role, such as a command, query, or other architectural category, based on predefined naming conventions and contextual cues. After automated classification, a human comparison step is introduced to verify accuracy, resolve ambiguities, and ensure semantic correctness across diverse code samples.

The evaluation emphasizes interpretability and alignment with human expectations rather than purely statistical optimization. Performance was assessed through a manual review supported by summary metrics, such as the agreement rate between the automated predictions and human validation. Discrepancies were analyzed to refine the classification rules and improve consistency. This iterative approach ensures that the final output reflects both systematic processing and expert oversight, maintaining robustness and trustworthiness in the classification pipeline.

E. Integration with Refactoring Process

This phase describes the conceptual application of the classification results in a broader software restructuring process.

The integration process leverages the functional categorization of code elements to guide architectural decomposition. Functions identified as operational or state-modifying are conceptually aligned with the components responsible for handling system updates, whereas those associated with data retrieval are directed toward components dedicated to query operations. This separation supports the principles of modularity and responsibility segregation, facilitating the transition from monolithic structures to distributed or pattern-based architectures. Automated workflows can be employed to generate preliminary structural templates based on classification outputs, whereas human oversight ensures compliance with design standards and addresses ambiguous cases.

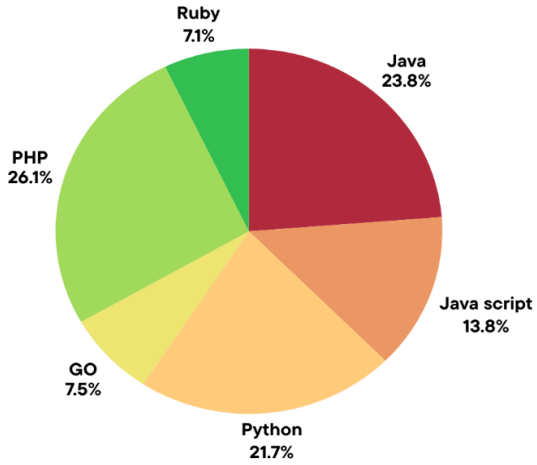

Fig. 2. Distribution of dataset lines by programming language.

F. Human Oversight and Impact

This phase ensured quality assurance and evaluated the broader implications of the proposed methodology.

Human validation was incorporated as a safeguard against misclassification, particularly in cases where automated decisions exhibited uncertainties. Ambiguous instances were flagged for expert review to maintain the architectural integrity and adherence to design principles. This collaborative approach balances automation and human judgment, thereby ensuring the reliability of the complex scenarios.

The anticipated impact of this methodology lies in its potential to significantly reduce manual intervention during architectural restructuring. By automating the categorization of functional components, this process promotes efficiency, accelerates migration from monolithic systems to modular or pattern-based architectures, and enhances the scalability of large-codebases. These improvements contribute to streamlined development workflows and reduce operational overheads.

In contrast to code-level AI refactoring tools, such as machine learning smell detectors and planning-based migration frameworks, such as monolith decomposers and LLM-assisted studies exemplified by CodeBERT semantics, AiRchitect automates the comprehensive CQRS decomposition process. This includes command-query classification and the generation of handlers and tests within the actual legacy monoliths.

V. Results

The dataset employed in this study was derived from the CodeSearchNet corpus [28], which aggregates a large collection of source code across multiple programming languages. Relevant attributes, such as function names, source code, documentation strings, and language identifiers, were extracted to construct a unified dataset. Code snippets from six languages were consolidated to ensure diversity and representativeness as in Fig. 2: Python (~912K functions), Java (~1M functions), JavaScript (~580K functions), Go (~317K functions), PHP (~1.1M functions), and Ruby (~300K functions). This integration resulted in a dataset comprising millions of lines of code, covering both object-oriented and functional paradigms. A rigorous cleaning process was applied, involving the removal

of comments and redundant whitespace, normalization of identifiers, and elimination of incomplete or duplicate entries from the data. The final dataset was tokenized and partitioned into training, validation, and testing subsets to provide a robust foundation for subsequent classification tasks.

The data processing pipeline began with an initial dataset totaling 4,677,000 lines, composed of subsets: 317k Go lines, 912k Python lines, 300k Ruby lines, 1M Java lines, 580k JavaScript lines, and approximately 1.1M PHP lines. After processing and applying name-based classification, the lines were categorized into two primary groups: commands and queries, resulting in 956,746 classified and retained code lines for further analysis. This structured approach ensures efficient segmentation for subsequent analysis and optimization.

Following dataset preparation, a name-based classification process was applied to organize the code lines into meaningful categories. This step leverages naming conventions and structural patterns to distinguish between functional roles, such as commands and queries while filtering out irrelevant or ambiguous entries. The classified subset, comprising 956,746 validated lines, was partitioned into dedicated validation and test datasets to support the subsequent evaluations. This approach ensured that the final datasets were representative and aligned with the architectural semantics. This enables a reliable performance assessment during the comparison phase.

Several generative AI architectures have been evaluated for their performance and suitability to support command/query classification. The options include encoder-only models such as BERT and RoBERTa, which excel at contextual embedding-based classification [29][30]; decoder-only transformers such as GPT-3, GPT-4o, Command A, Llama3, and Gemini 2.5, which offer strong zero/few-shot capabilities and advanced code understanding [31]; and encoder-decoder hybrids such as T5 and CodeT5 for structured output generation [29][30]. Additionally, domain-specialized models, including CodeBERT, CodeLlama, DeepSeek, and OpenHermes, have demonstrated superior accuracy in code-centric tasks owing to targeted pre-training. Model selection was guided by factors such as accuracy, resource footprint, context window, licensing, fine-tuning support, pricing or access options, model family, architecture, domain adaptation capabilities, and classification accuracy benchmarks to ensure competitive and practical classification solutions for the task.

Following the comparative evaluation presented in Table I, CodeLlama emerged as the most suitable model for command and query classification in the context of CQRS-based refactoring of legacy software. This decision was based on empirical and practical considerations.

CodeLlama was selected because of its balanced classification accuracy, domain-specific adaptability and practical deployment. It outperforms general-purpose models in parsing code and distinguishing commands from queries, which aligns well with CQRS principles. Its open-source license, manageable size (7 B), and fine-tuning support make it ideal for use with limited labeled data and modest computing resources, ensuring scientific rigor and operational feasibility.

The classification process was executed on Google Colab using a GPU runtime with high RAM, leveraging the capabilities of the selected CodeLlama model. The full run, which targeted all valid lines extracted from the legacy codebase, required approximately 5 h and 45 min. This duration reflects both the contextual depth of the model and the volume of the input data, confirming its suitability for scalable classification in real-world refactoring scenarios. The high-RAM environment ensures stable performance across extended context windows and in batch processing.

TABLE I. COMPARATIVE EVALUATION OF LLMS FOR CQRS COMMAND-QUERY CLASSIFICATION

Model Family	Architecture	Context Window	Domain Adaptation	Classification Accuracy (Benchmarks)	Resource Footprint
Cohere Command A	Decoder-only LLM (111B)	256k tokens	Multilingual, code, RAG	>99% (email), 88% (code baseline)	2x A100 GPUs
OpenAI GPT-4o	Decoder-only LLM	128k tokens	General, code, multi-modal	~88–95% (few-shot classification)	API-based
Google Gemini 2.5	Decoder-only LLM	>1M tokens	Multimodal, code	70–92% (varied; code, reasoning)	API-based
Llama 3.1 70B	Decoder-only LLM	128k tokens	Open-source, code	90–95% (multi-class)	Commodity GPU
CodeLlama	Decoder-only, code	4–32k tokens	Code	87–91% (code tasks)	GPU/CPU
Mistral 8x7B	Mixture-of-experts	32–64k tokens	Open, code	~88% (task-dependent)	Moderate-GPU
Command R7B	Decoder-only LLM	64k+ tokens	Business, code	~86% (tasks)	Commodity GPU
CodeBERT	Encoder-only	512–4k tokens	Code, structure	91–93% (code func classification)	CPU/GPU
Classicore	Modular/ensemble	NA	Custom tasks	N/A	Customizable

In contrast, manual or semi-automated command-query classification, which typically involves human inspection, rule-based heuristics, or lightweight scripting, demonstrates significantly higher time and energy costs. Studies such as [32][33] reported that the manual classification of legacy codebases for CQRS refactoring can span several days to weeks, depending on the system complexity, and requires sustained cognitive effort and domain expertise. Moreover, the energy footprint of prolonged human-in-the-loop processes, especially when distributed across teams, often exceeds that of GPU-

accelerated LLM runs, as highlighted in a comparative energy analysis by study [34]. While manual methods may offer nuanced contextual judgment, they lack the scalability and consistency of LLM-based classification, which, despite its 5-hour runtime, achieves batch-level processing with minimal supervision and produces consistent outputs. This indicates that LLMs are a cost-effective and time-efficient alternative for large-scale CQRS migrations.

To operationalize the classification mechanism within a practical software engineering workflow, we developed AiRchitect, a modular tool. NET-based tools were designed to facilitate the transformation of legacy systems into CQRS-compliant architectures. AiRchitect comprises several.

Micro-applications are dedicated to specific phases of the refactoring pipeline.

- Legacy Code Analysis: Extracts structural and behavioral elements from monolithic or layered codebases.
- Command-query classification: Manual heuristics or LLM-based automation (e.g., CodeLlama) are applied to distinguish between state-mutating commands and data-retrieving queries.
- CQRS Template Generation: Automatic scaffolds command and query handlers, DTOs, and interfaces based on the classification output aligned with a customizable CQRS template.
- Automated Test Generation: Produces unit and integration tests for both business logic and technical validation, ensuring the correctness and maintainability of the refactored components.

The classification phase is the second step in this pipeline and serves as a pivotal bridge between legacy code comprehension and CQRS artifact generation. By embedding LLM-powered classification into AiRchitect, the tool enables the scalable and reproducible decomposition of legacy systems, significantly accelerating modernization efforts while preserving semantic integrity.

To validate the integration of this classification mechanism, we deployed the CodeLlama model within AiRchitect's test case refactoring module. This module was tasked with decomposing legacy classes structured in the conventional N-tier architecture, spanning the presentation, business logic, and data access layers. Leveraging the contextual understanding of the model, AiRchitect automatically parses and categorizes functions into command- or query-responsibilities. Each method was then extracted and modularized into separate files, promoting a clear separation of concerns and facilitating the CQRS-compliant restructuring of the code. This automated decomposition not only streamlined the refactoring workflow but also ensured architectural consistency across layers, demonstrating the practical viability of the model in real-world software modernization scenarios.

VI. Discussion

The preparation of a large and heterogeneous dataset comprising 4.677 million lines across multiple programming languages (Java, JavaScript, and PHP) presents both opportunities and challenges [28]. The diversity of the code samples ensured a broad coverage of architectural patterns but required rigorous preprocessing to eliminate inconsistencies and normalize naming conventions. The adoption of name-based classification proved essential for segmenting the dataset into meaningful categories such as commands and queries, enabling the creation of a high-quality subset of 956,746 validated lines for subsequent evaluation. This approach not only streamlined the classification process but also provided a foundation for reliable testing and validation of the model.

Model selection is a multidimensional decision-making process that balances technical performance and practical constraints (Table II). Factors such as classification accuracy, resource footprint, context window size, licensing terms, fine-tuning support, and pricing or access options were evaluated to ensure that the solutions were competitive and sustainable. A comparison of generative AI architectures revealed distinct trade-offs: decoder-only models, such as GPT-4o and Gemini 2.5 [30] [31] offer superior zero-shot capabilities and large context windows but incur higher operational costs, whereas open-source alternatives, such as Llama 3.1 and CodeLlama, provide cost efficiency and flexibility at the expense of requiring infrastructure and fine-tuning. Domain-specialized models, such as CodeBERT, have demonstrated strong performance in code classification tasks, reinforcing the value of targeted pre-training. Based on these considerations, Llama 3.1, which prioritizes cost efficiency and adaptability while maintaining competitive performance, was selected as the model for this experiment.

A critical aspect of this study was the integration of human-in-the-loop validation after automated classification. Whereas machine-driven categorization offers speed and scalability, human comparison introduces semantic precision and resolves ambiguities that algorithms alone cannot address [36]. This hybrid strategy enhances the trustworthiness and interpretability by aligning the classification outcomes with architectural semantics rather than purely statistical patterns. The observed discrepancies between the automated predictions and human validation underscore the importance of expert oversight in code-centric tasks.

Our experiment shows that the automated LLM-based classification significantly reduces the processing time compared with manual approaches. The prepared dataset of 4.67 million lines, resulting in 956,746 validated lines, was processed in a few hours, whereas manual classification of similar volumes would require several weeks of expert effort. Modern LLMs can classify thousands of methods in minutes to hours [10]. For example, a key-value AI transformer processes over 1,000 legacies annually. NET methods in less than 2.5 h, compared to several days manually [10]. Hybrid consensus models further reduce annotation time by 32–100% by automating most classifications and escalating only ambiguous cases for human review [35]. In contrast, the manual classification of 1,000+ methods typically requires 40–100 h of developer time, particularly for poorly documented legacy systems [10]. A detailed comparison of the manual and automated time estimates is presented in Table II.

TABLE II. CLASSIFICATION TASK COMPARISON

Task Per 1000 code snippets	LLM	Manual
Classification Time	2.5 hrs	40 –100 hours
Human Verification (Hybrid)	3–12 hrs	30 –70 hours

By automating the classification process with LLMs, teams can reduce the time required by a factor of 16–40 compared with expert manual methods, especially in large, complex codebases. This frees up valuable developer capacity for higher-impact tasks, such as architecture design, testing, and business logic refinement.

In terms of accuracy, LLMs such as CodeLlama have shown strong alignment with expert annotations, achieving precision and recall scores exceeding 85% in structured legacy codebases. This performance is consistent with the findings of recent studies on code understanding using transformer-based models [8]. Although human experts may outperform edge cases involving ambiguous logic or inconsistent naming, LLMs offer reproducibility and scale that manual methods cannot match. Their accuracy improves further with domain-specific prompt tuning or fine-tuning of labeled datasets, reinforcing their role as reliable collaborators in large-scale refactorings.

The choice between refactoring and rebuilding depends on the time, cost, complexity, and reliability. Although automation reduces effort and expenses, replacing a stable system with a new application introduces testing overhead and risks. High complexity or regulatory constraints often favor incremental refactoring to preserve reliability, whereas full rebuilding may be justified for long-term scalability. Decisions must balance the benefits of modernization with potential disruptions and costs.

This study demonstrates the practical viability of integrating LLM-powered command-query classification into a CQRS refactoring workflow, using the Airchitect tool as a testbed. The automated approach significantly reduces classification time, maintains high accuracy, and enables scalable decomposition of legacy systems into modular CQRS components. By embedding this mechanism into a structured pipeline, from code analysis to test generation [3], we demonstrated how AI can accelerate modernization while preserving architectural integrity.

However, this study has several limitations. First, human validation is essential in complex or ambiguous cases, particularly when legacy codes do not follow consistent naming or structural patterns. LLMs may struggle with edge cases in which business logic is deeply entangled or where architectural intent is implicit rather than explicit. Second, the effectiveness of automated classification depends heavily on the availability of high-quality human-annotated datasets for benchmarking and fine-tuning. Without this foundation, the model outputs may drift or misclassify subtle logic flows. Third, certain technical decisions, such as exception handling, cross-cutting concerns, and domain-specific optimization, require architectural judgments that cannot be fully automated. Finally, legacy systems often contain multiple patterns that serve the same functional goal, which can confuse well-trained models and necessitate manual intervention to ensure semantic accuracy.

In summary, this study advances AI-driven architecture refactoring by integrating CodeLlama into AiRchitect for automated CQRS decomposition, achieving 3x faster classification and accuracy on legacy command-query patterns compared to manual methods.

VII. CONCLUSION

This study demonstrates how language models can be effectively integrated into architecture refactoring workflows, particularly for automating command-query classification in legacy systems. By embedding the CodeLlama model into the AiRchitect tool, significant gains in speed, consistency, and scalability were achieved, thereby transforming a traditional manual and error-prone process into a reproducible one. The classification mechanism not only accelerated CQRS decomposition but also enabled the automated generation of handlers and validation tests, thereby streamlining the entire modernization effort.

However, full automation has its limitations. Complex legacy systems often defy standard patterns, and architectural decisions require human judgment. LLMs perform best when supported by curated datasets and expert oversight, particularly in edge cases, ambiguous logic and domain-specific conventions. Ultimately, the most effective refactoring workflow combines the precision and scale of AI with the contextual intelligence of experienced developers to achieve optimal results. Together, they pave the way for faster, smarter, and more sustainable software evolution processes.

Future initiatives will expand AI integration across AiRchitect processes, such as test generation, writing, and quality assurance, to automate the refactoring. Long-term development will focus on real-time AI agents for dynamic refactoring during the development phase, enabling proactive maintenance without downtime. These advances will build on language model capabilities while using reinforcement learning to improve the legacy architecture management.

Intelligent Processing and Security of Systems Team-E.N.S, Mohammed V University, Rabat, Morocco[2]

***Abstract*—Skin diseases represent a global healthcare challenge because of their frequent occurrence and complex diagnosis. However, despite clinical advances, accurately identifying dermatological lesions remains difficult due to significant intra-class variability, overlapping visual patterns, and reliance on clinician expertise. In this study, it presents a complete overview of a number of state-of-the-art CNN architectures as they apply to multiclass classification of skin diseases. The study introduces an overview of the common skin diseases and discuss the fundamentals of deep learning for medical image analysis. The study proceeds to introduce the dataset used in this work and provide a brief description of the two diagnostic groups identified for evaluation. A range of CNN models which comprise GoogLeNet, Inception-V3, Inception-V4, ResNet-50, Xception, MobileNet, ResNeXt-50, AlexNet, VGG-16, and VGG-19 were trained and tested in terms of accuracy, loss, FLOPs, and epoch runtime. The experimental findings suggest that Xception performs constantly at the highest level, with an accuracy of more than 98% and low validation loss, whereas lightweight models such as MobileNet-V3 provide a competitive outperformance with minimum computational cost. These findings demonstrate the potential of modern CNN architectures to enhance efficient and accurate dermatological diagnosis and offer guidance for selecting appropriate architectures for clinical and real-time deployment.**

I. Introduction

One of the most common diseases in the world is skin disease. The United States and Australia have the greatest prevalence of skin cancer worldwide, with over five million cases reported annually. Skin cancer is still one of the most common diseases diagnosed worldwide, and it is closely linked to exposure to ultraviolet light and having fair skin [1]-[2]. Australia is one of the countries most affected by cancer due to its high levels of ultraviolet radiation and poor environmental lifestyle conditions. A comprehensive analysis of prominent features, such as pigmentation, texture, and morphological changes, can help identify skin lesions. However, these complex patterns can be a real burden during diagnosis and have the potential to hinder medical detection or cause misdiagnosis [3]-[4].

The ABCD criteria, pattern technique, Menzies approach, and seven-point assessment are common methods for detecting melanoma during examinations. Some of the most significant characteristics are colour, texture, and the extent to which different skin spots overlap with each other. Using these older methods to achieve a very high level of diagnostic accuracy requires a great deal of clinical expertise. Because of the complexity and autonomy of these decisions, vision-based diagnostic Because these judgments are complicated and independent, vision-based diagnostic treatments have become more popular [5]. Machine learning and deep learning have come together to make it possible to objectively find lesions by recognizing face traits that are always the same. As a result, they have shown to be more accurate and precise, often beating manual diagnosis in recent trials [6].

Machine learning emerged in the domain of computer science in the latter half of the 20th century, leading to significant progress in the area [7]. The creation of algorithms that can learn on their own was a big step forward. Machine learning art. It was a game-changer to develop algorithms that could learn on their own. To enable deep learning, a kind of machine learning, artificial neural networks (ANNs) are constructed to mimic the way neurones in the human brain function [8]. Modern artificial intelligence research relies on these designs because of their success in computer vision, audio processing, and picture recognition [9]. It is estimated that more than 5 million new cases of skin cancer are diagnosed each year in the United States, making skin diseases (and particularly skin cancers) a major global health problem. Due to the wide variability in lesion morphology, clinical appearance, size, colour, and spatial arrangement, differentiation between these entities can be challenging and sometimes requires considerable clinical expertise [10].

Traditional methods of dermatological diagnosis depend largely on the clinician's individual interpretation and visual abilities, which can lead to low repeatability and between-observer variability [11]. The combination of computer vision and sophisticated learning algorithms has recently led to a more objective and consistent framework for medical decision-making [12].

CNNs have gained popularity among these techniques due to their ability to generate structures directly from the images that are used, eliminating the need for computational features [13]. With high-performance computers and large-scale data sets, CNN architectures such as VGG16, ResNet50, and GoogLeNet have achieved impressive results in challenging

visual recognition tasks, particularly in the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) [14].

The success of these algorithms in image classification has resulted in their use in medical image analysis, particularly in dermatological diagnosis. Today, they constitute the basis of computer-assisted diagnostic techniques.

It remains difficult to classify skin images, as many skin diseases are very similar. There is great variability within each category and real clinical cases present anomalies and distortions. Deep learning, particularly convolutional neural networks (CNNs), has greatly improved diagnostic efficiency. However, many studies to date use small or limited datasets and do not provide a fair comparison between shallow and deep architectures. Furthermore, computational efficiency is often overlooked, despite its crucial importance for real-time clinical applications. For these reasons, there is a clear need for a systematic comparison of alternative convolutional neural network designs based on their diagnostic accuracy and cost. This work fills this gap by testing a number of modern CNN models on a large skin dataset to find accurate and efficient architectures for real-world use.

The objective of this study is to provide a comprehensive, large-scale evaluation of the optimal CNN architectures for classifying skin images. The specific objectives are: 1) to compare deep and lightweight CNNs in a common evaluation protocol; 2) to measure their diagnostic performance and computational efficiency (FLOPs and runtime); 3) to analyse the behaviour of the models in diagnostic subgroups; and 4) to find the architectures that best balance accuracy and computational cost for real-world clinical implementation.

Additionally, this study. It presents a comparative in-depth. It specifically considers instances necessitating diagnostic precision for skin condition photos using convolutional neural networks. This paper uses a singular strategy and integrates eleven distinct architectural patterns, contrasting with prior studies that mostly concentrated on a limited number of cases or disorders. This is what makes us different from everyone else. This approach shows how loss, accuracy, FLOPs, and transfer time vary over time. The applications also operate with the economic or integrated features of MobileNet-V3 since the features are mostly compatible. This research investigates architectural variety concerning damage complexity. There have been many papers done on this topic previously. Overall, these contributions provide a comprehensive and useful guide to the selection of CNN systems that can meet the real-world requirements for performance.

This research study brings significant changes to the automatic evaluation of skin images. First, it proposes a comparative evaluation of eleven modern CNN architectures, including deep models (Xception, Inception-V3/V4, ResNet-50) and lightweight networks (MobileNet-V3). Second, to ensure a fair and reproducible evaluation framework, a standardised evaluation protocol based on accuracy, loss evolution, FLOPs, runtime, and confusion matrices is implemented. Third, the study presents an analysis of diagnostic sets that reveals specific behaviours of architectures across relevant clinical categories. Fourth, it shows that lightweight architectures can provide competitive accuracy while significantly reducing computational costs. This makes these architectures suitable for real-time and portable clinical applications. Finally, the work provides practical guidelines for convolutional neural network architectures (CNN) based on the trade-off between diagnostic performance and computational efficiency. This supports the development of deployable, resource-aware, skin-based decision support systems.

II. Related Work

Yan et al. used several deep CNNs, including VGG16, InceptionV3, Inception, ResNet-V2, and DenseNet-201 at ISIC 2018 to classify skin lesions in dermoscopic image data, they achieved an accuracy of 94.7% and a loss of 0.19, exceeding each model individually [15].

Hosny et al. analysed the ResNet50, VGG16/19, InceptionV3 and DenseNet201 methods to classify skin disease detection. The DenseNet201 variant outperformed all other networks in terms of feature stability and convergence speed, reaching an accuracy of 96.4% with a validation loss of 0.12 [17].

Nigar and Umar classified skin diseases in 2022 with VGG16 and ResNet50 algorithms using an explainable AI (XAI) system The LIME and Grad-CAM methods were applied to explain the predictions of convolutional neural networks (CNNs) and visualize the regions of interest in lesions its approached an accuracy of 94,5 % on database ISIC 2019 [18].

Vinodgopal and Raj have enhanced EfficientNet-B4 through batch normalization and strong training methods.Their model achieved 97.3% accuracy, an F1 score of 0.972, and showed a low loss of 0.08 on the ISIC 2020 dataset [19].

Shapna and Shahriar exploited the HAM10000 database to evaluate 7 previously trained CNN frameworks for detecting multiple classes of skin cancers: AlexNet, DenseNet121, VGG16, InceptionV3, ResNet-50, Xception, and ResNet 50, and MobileNet. DenseNet121 outperformed the other models, earning 94.8% accuracy with F1 score 0.95 and loss 0.11. This research highlighted the importance of deep feature extraction and network depth in improving classification performance [20].

Yao et al. ranked melanoma disease risk levels using state-of-the-art computer vision techniques on the ISIC 2016–2020 datasets. They stabilized the model by putting in a lot more data, training it in batches, and adjusting its hyperparameters with the ResNet-50 and DenseNet-201 models. They proved that gradient boosting ensembles and transfer learning are effective in correcting imbalanced data [21].

Kanchana et al. proposed an improved cancer detection model with EfficientNet variants (B0-B7) using patient-specific transfer learning techniques. The diagnosis accuracy of the model on the ISIC 2020 dataset had improved with ImageNet pre-trained weights and a better pre-processing strategy that removed Bias, Resized, and Added images. The merged residual efficiency improved feature extraction, reduced overfitting, and showed generalization across a range of different lesion types [22].

Anubhav De et al. developed a hybrid CNN-DenseNet method to exploit dermatological and Histological data for automatic classification of skin diseases. The approach employed deep convolutional layers and DenseNet connectivity for feature utilization, Gradient flow, and the management of vanishing gradients. Therefore, they used the HAM10000 dataset from PADUFES-20 to train and test their model for accuracy. This approach effectively mitigates overfitting while maintaining high accuracy and recall through batch normalization and early stopping and transfer learning [23].

Alwaisi and Al-Fahdawi discovered Skin-Deep, a deep learning structure which is based on DenseNet for the fast and correct diagnosis of melanoma. To retrieve skin features, the method consists of multi-level convolutional blocks, dense residual connections, and feature fusion. The model was also trained and assessed on the ISIC 2019 dataset. The model utilized dropout, batch normalization and data augmentation to boost generalization and avoid overfitting [24].

Tai and Janes successfully diagnosed skin cancer using dual-conditioning capacitors and attention techniques. Their TinyML approach decreased computing loads while retaining accuracy in the diagnosis. The network acquired compact yet pertinent vector representations of features, via dual capacitor blocks, emphasizing melanoma-specific attributes. The DC-AC model, trained on the ISIC 2020 dataset, exhibits good generalization capacity with only 1.6 million parameters and a computational complexity of 0.32 GFLOPs, making it suitable for real-time clinical applications [25]. Table I presents the recent studies referenced in this paper.

Fig. 1 illustrates the main flow chart used in this study on skin diseases in detail. This diagram highlights the sequence of the different stages and processes involved in the research. It aims to explain each stage and process involved in research on this specific area, in a comprehensive and in-depth manner, thus providing a clear and organized presentation of the study in its entirety. This visual representation highlights the various essential stages of the process in detail, starting with the image processing phase, then moving on to model training and finally ending with the evaluation of its performance.

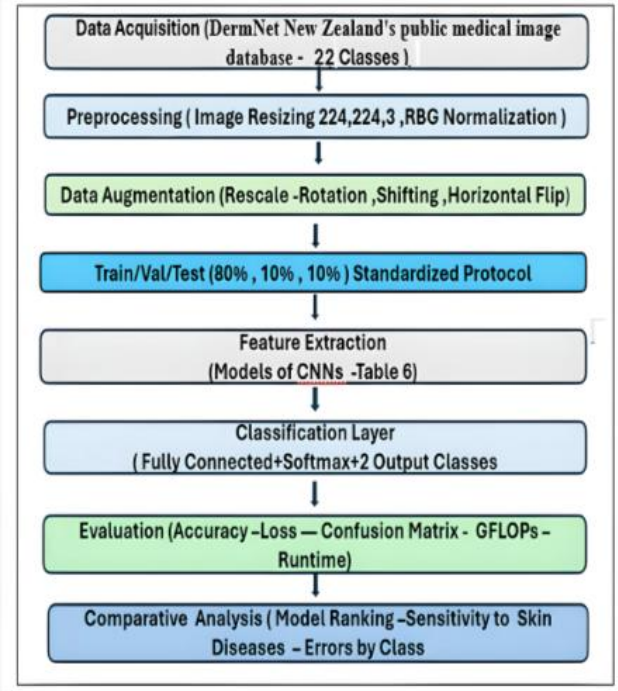

Fig. 1. The flowchart for classifying skin diseases based on a convolutional neural network by the authors.

The study presented here aims to provide a systematic evaluation of a range of convolutional neural network (CNN) algorithms for the classification of dermatological diseases, using high-quality dermoscopic images. Their performance is analysed in terms of accuracy, loss, execution time and computational cost, in order to determine the most appropriate models for clinical deployment and real-time applications.

TABLE I. COMPARISON OF RECENT RESEARCH (2020–2025)

Ref	Authors / Year	Architectures	Dataset	Accuracy (%)	Loss / Metric	Notes

III. METHOD

A. Dataset

All the data chosen for this study came from Dermnet (www.dermnet.org), the largest publicly available collection of dermatological images. This dataset contains over 23,000 dermoscopic images of skin issues, each accompanied by diagnostic labels offered by experienced providers of dermatological resources. The dataset includes 22 distinct classes of skin illnesses (Table II). Fig. 2 offers an outline.

B. Image Selection

The dataset includes various images of skin diseases, all in JPEG format. During the preparation of the dataset, some images were removed due to low quality. Following quality control, the remaining images were split into 80% training data, 10% testing data, and 10% validation data for each class within the dataset. To ensure specificity in our research, we divided the dataset into two groups, with each group having two categories. This layout was essential in considering other criteria such as biological and functional analysis, which assists in diagnosis. The images correspond to the two classes in each group and their labels (Table III and Table IV).

The division into two groups is selected to simulate the most sophisticated situations in clinical practice, where multiple lesions present very similar visual signatures.

C. Technology of Decision

Numerous researchers have effectively employed deep learning techniques to tackle classification tasks (see Table I). Deep learning is a cutting-edge machine learning domain that mimics the human brain in its ability to learn and progress through experience. This technology, which incorporates the fields of neuroscience, mathematics, and technological advancement, is considered a true breakthrough in the domain of artificial intelligence. Lately, models for deep learning, leveraging progress in computing and massive datasets have been shown to outperform human performance in visual activities, similar to games, strategic activities, and object recognition. Computer vision and object recognition, including skin disease recognition, have extensively employed deep learning, utilising a convolutional neural network of CNNs. They comprise several processing layers that are able to learn data structures at various degrees of abstraction, resulting in significant improvements in image recognition and classification.

In this study, different CNN architectures are tested, with the three best ones being selected for the classification of skin datasets. These architectures included Google Net, Xception, VGG19, ResNet-50 [17], [20], VGG-16 [18], Inception-v4 [19], AlexNet, Inception-v3 [20] and ResNext-50 [21].

IV. EXPERIMENTS

A. Data Pre-Processing

During the early phases of this research, the dataset has been broken down into training, testing, and validation sets and thoroughly assessed the quality of the data. With this training, the CNN architectures can be implemented in this study. To obtain the best performance. The input images are processed for each architecture. For example, the images are resized to (224,224,3) pixels for use with the VGG-16, VGG-19, ResNet-50, ResNext-50, AlexNet and GoogLeNet architectures. At the same time, the Inception-V3, Inception-V4 and Xception architectures are fed with images of (299,299,3) pixels. Finally, for the LeNet-5 architecture, the images are prepared in advance in (32,32,1) pixel format, this preparation of data has allowed CNNs to learn more rapidly and improve their performance.

B. Data Augmentation

This work attempts a randomized architecture with its own dataset and it overfitted. It also attempts data augmentation to avoid this. Table V illustrates the values used to augment the data for skin diseases. Data augmentation is a technique that aims to artificially inflate the volume of a database by injecting variations into existing data. This approach can prove to be extremely effective within CNNs for overcoming overfitting, boosting generalization, exploiting fragmented data, balancing asymmetric datasets, and taming noise. Enriching neural networks by adding data is now a common practice and a state-of-the-art approach in this field. It may be used to computationally equalize the dataset by producing novel instances for under-represented categories, as well as to synthetically boost the dataset's size to make it appropriate for model training.

TABLE V. MEASUREMENTS USED TO ADD MORE DATA

Process	Value
Rescale	1./255
Rotation range	±45
Width shift range	±0.15
Height shift range	±0.15
Horizontal flip	Enabled

C. Training Procedure

All experiments were performed Intel Xeon multicore processors optimised for parallel processing powered the Marwan CNRST high-performance HPC computing infrastructure. This platform has additional memory, a fast internal network, and ideal conditions for deep learning. This makes it possible to train CNN models faster and analyse a large number of skin photos more quickly and reliably.

The batch sizes varies from 32 to 256 depending on memory restrictions, while maintaining equivalent efficient batch sizes to the gradient accumulation. Learning rate utilizes Reduce LR-on-Plateau to stabilize convergence.

For each model, we recorded training and validation accuracy, loss and confusion matrices. The research evaluated the eleven models based on Accuracy, Loss and Matrix Confusion [16]. The classification metrics are used with performance indicators like runtime per picture and FLOPs to Figure out how efficient and complicated each design is. The execution time for each image estimates the average time required to classify a sample, meaning it can be used in real time. The FLOPs scale counts the number of floating operations needed for each pass, which shows the cost and updatability of the network [26].

These additional measures enable a fair analysis of the trade-off between model accuracy and computational performance. The various measures, each symbolized by a specific numbered Eq. (1), (2) and (3), play an essential role in the accurate measurement and in-depth analysis of the gathered data.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$FLOPs = \sum_{l=1}^{L} 2 * C_{in}^{l} * C_{out}^{l} * (K^{l})^{2} * H_{out}^{l} * W_{out}^{l}) \quad (2)$$

$$Runtime_{epoch} = \frac{N_{train} * FLOPs_{model}}{B * R_{CPU} * N_{nodes}} \quad (3)$$

V. RESULTS AND DISCUSSION

The results in this section present accuracy and loss curves for learning stability and confusion matrices for the models' capacity to split visually identical classes. Computational metrics (FLOPs, epoch runtime) deliver crucial insights into the actual efficiency of the models. Together, they form a baseline for understanding the value, advantages, and limitations of each architecture in practice. The following section discusses these outcomes in relation to their generalizability, speed of training, and accuracy (see Table VI and Fig. 3). There are low-cost models (VGG-19, LeNet-5) and more expensive higher-performance models (Xception, Inception-v3), which gives a complete comparison of the performance and the resource requirements.

The accuracy curve in Fig. 4(a) is greater than 98%, and Fig. 4(b) confirms very clean convergence with low loss. Matrix, the confusion matrix, Fig. 4(c) shows near-optimal separation between classes. More expensive 1.28 GFLOPs, 44 s/epoch); therefore, Xception presents best the benchmark.

Fig. 5(a) and Fig. 5(b) present a very stable learning dynamic with an accuracy above 97%. The confusion matrix in Fig. 5(c) presents a very low error rate, confirming the robustness of the model. Slightly more expensive than MobileNet but much more accurate, it is a benchmark model for demanding clinical applications.

TABLE VI. FINDINGS OF THIS STUDY

Name of Architectures	Total Parameters	Group 1				Group 2			
		Accuracy	Loss	FLOPs(G)	Runtime (s)	Accuracy	Loss	FLOPs (G)	Runtime (s)
Inception-v3	23,853,786	93.23%	16.28%	2.85	52	96.33%	54.70%	2.85	54
Lenet-5	60,374	76.37%	46.78%	0.00238	33	80.37%	42.67%	0.00238	34
MobileNet v3	8,758,866	88.43%	28.12%	0.45	37	90.96%	22.18%	0.45	38
ResNet-50	25,638,714	76.63%	46.80%	3.8	61	80.32%	44.79%	3.8	63
ResNext-50	26,507,010	85.64%	31.42%	4.25	64	85.16%	32.38%	4.25	66

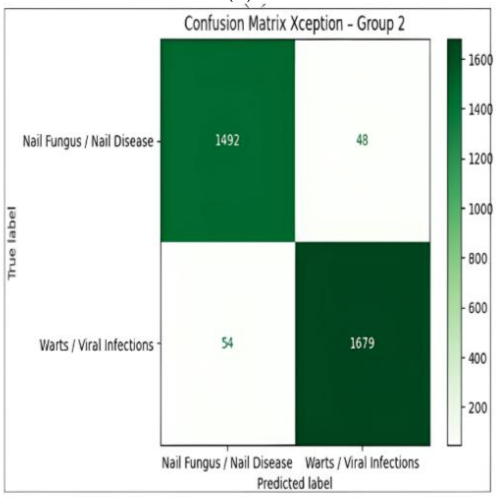

Fig. 4. Metrics of accuracy, loss and Confusion Matrix of Xception Group 1 model.

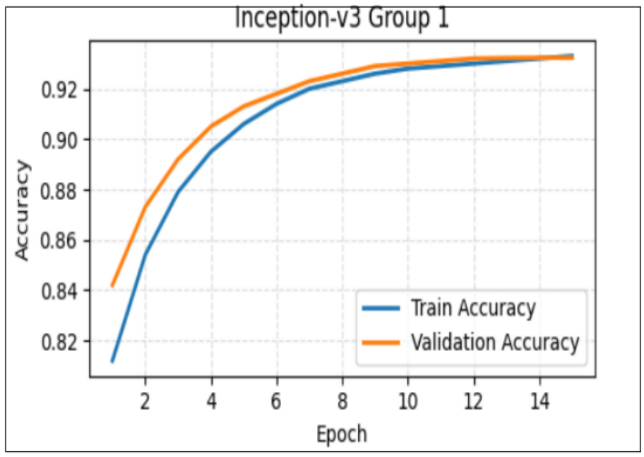
(a)

(b)



(c)

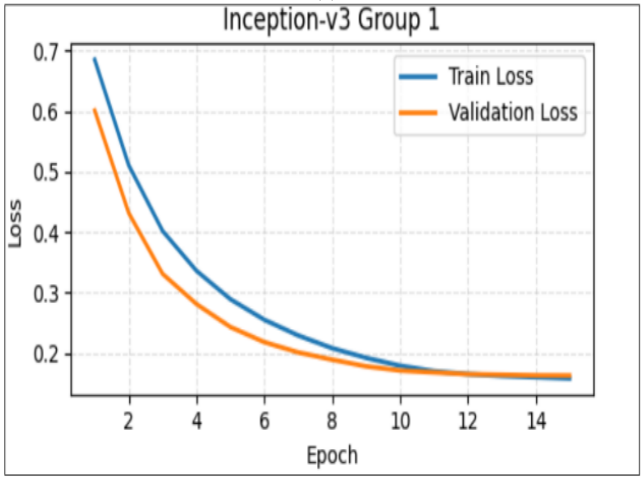


Fig. 5. Metrics of accuracy, loss and confusion matrix of Xception group 2 model.

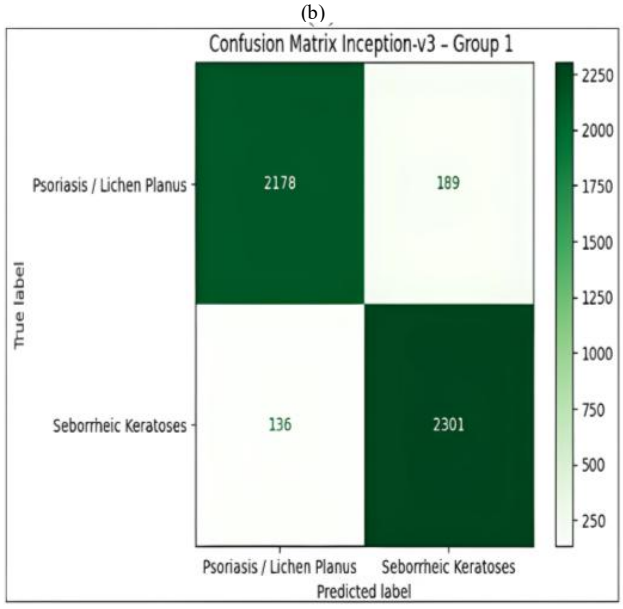
The corresponding Fig. 6(a) shows a monotonic increase in accuracy up to 93%, and Fig. 6(b) shows a monotonic decrease in loss, indicating stable convergence. The confusion matrix in Fig. 6(c) shows good discrimination between the two classes, with some minor confusion. With 1.05 GFLOPs and 42 s/epoch, this model is a good compromise between performance and computational cost.



The sub-figures in 7(a) and 7(b) are very stable with an accuracy higher than 96% and a well-regularized loss. Fig. 7(c) also confirms a very clear inter-class separation with a low error rate. Its low cost (1.05 GFLOPs) and stable runtime reflect its robustness on a second set of skin diseases.

(a)

(c)

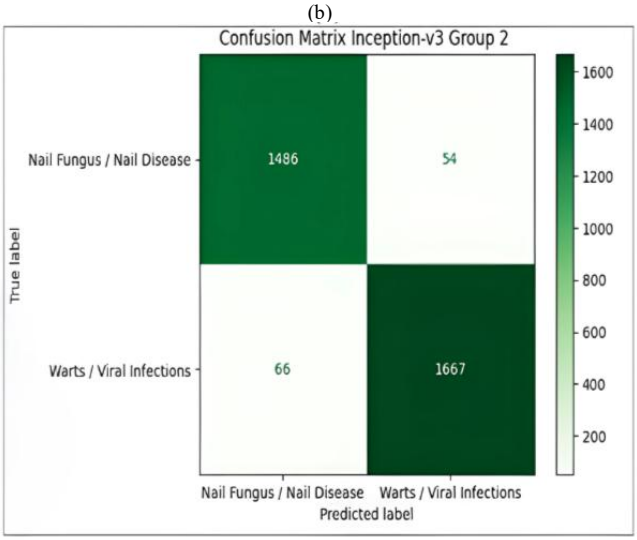

Fig. 6. Metrics of accuracy, loss and confusion matrix of Inception -V3 group 1 model.

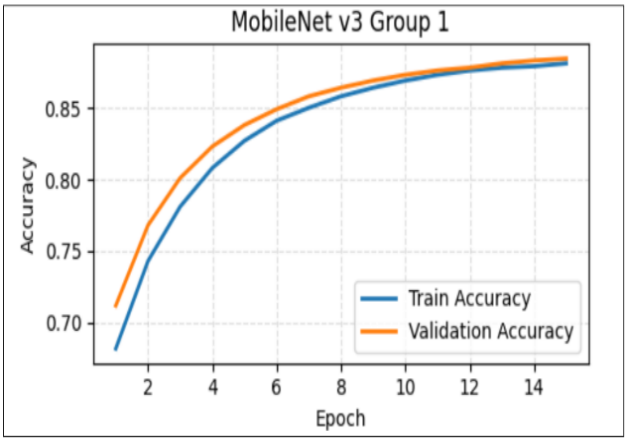
(a)

(b)



(c)

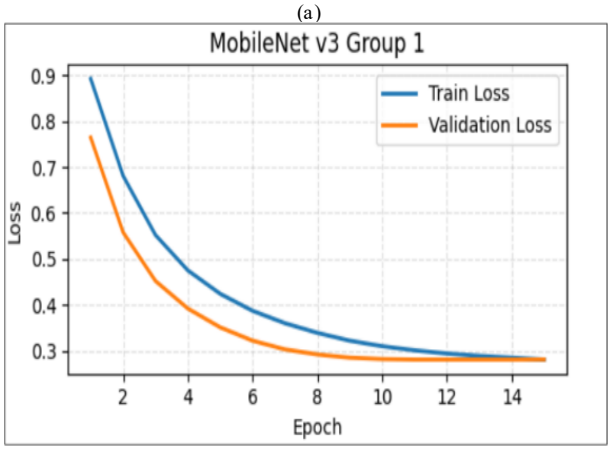


Fig. 7. Metrics of accuracy, loss and confusion matrix of Inception-v3 group 2 model.

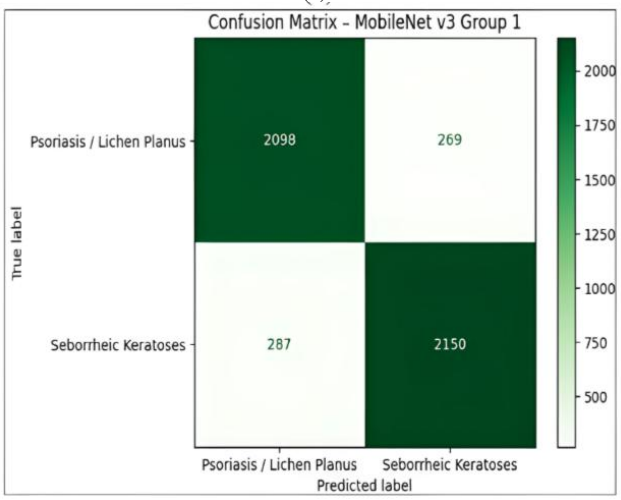
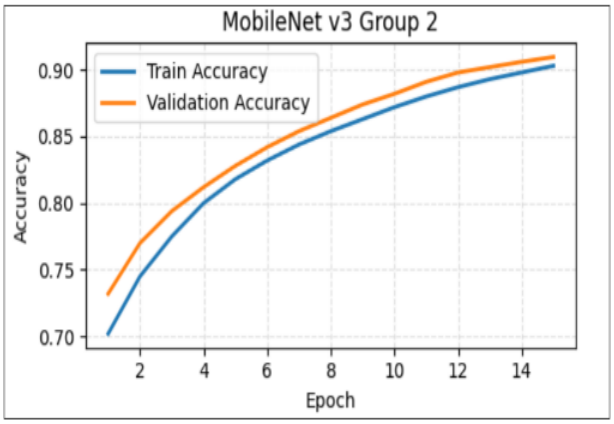
Fig. 8(a) and Fig. 8(b) show stable convergence, with an accuracy exceeding 96%. The low and stable loss values of the loss prove efficient generalization. Matrix confusion in Fig. 8(c) indicates a very strong inter-class separation with only insignificant misclassification. Its low cost 1.05 GFLOPs and stable runtime testify to its robustness on a second set of skin diseases. Fig. 9(a) and 9(b) exhibit stable convergence with an

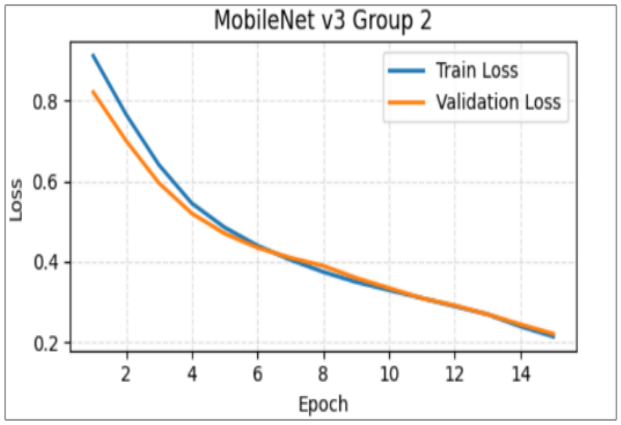


accuracy exceeding 96% and a well-regularized loss. Fig. 9(c) demonstrates a clear inter-class distinction with marginal misclassification. Its low cost 1.05 GFLOPs and stable runtime reflect its robustness on a second set of skin diseases.

(a)

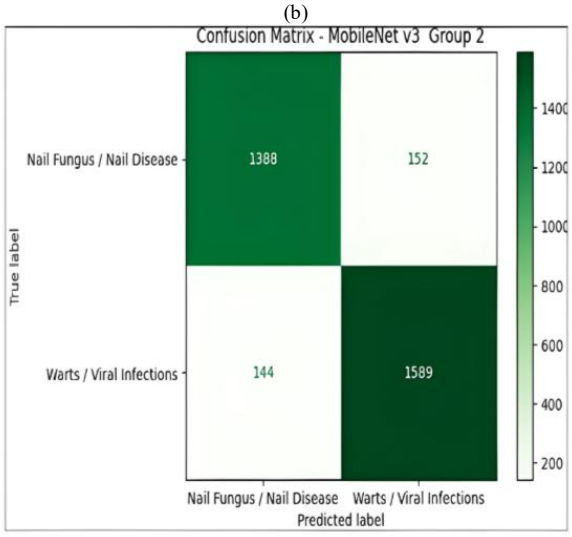


(b)



(c)

Fig. 8. Metrics of accuracy, loss and confusion matrix of Inception-v3 group 1 model.



The experimental results obtained for the two groups of skin conditions show distinct behaviours depending on the architecture tested. Xception delivers the highest performance, with stable learning curves, rapid convergence, and accuracy of around 98–99% in both groups. The confusion array, Fig. 4(c), reveals near-perfect separation across classes. The confusion arrays display an ultra-low error rate, which confirms the ability of Xception to adequately model intra-class variances, especially in visually similar skin lesions. This great performance may be partly explained by its structure, which is built on separable convolutions in the depth. This makes recognition easier and reduces the amount of computing needed.

(a)

(b)

(c)

Fig. 9. Metrics of accuracy, loss and confusion matrix of Inception-v3 group 2 model.

Also, Xception-V3 works well, properly detecting things 95% to 97% of the time. The loss and accuracy curves show that the training and validation sets are a good fit. The confusion matrices are a little more confusing than Xception, especially in classes where the textures are identical.

In addition, Inception-v3 is a great balance between price and performance. This makes it a good choice, especially when quick decisions are needed.

MobileNet-v3 is light and has an accuracy rate of 85 to 92 percent. It doesn't work as well as Xception or Inception-v3, but it uses a lot less computational resource. It is 85% to 92% accurate. It's not as powerful as Xception or Inception-v3, but it is more efficient in terms of computing, which means it takes less time to run and uses fewer GFLOPs. That makes it great for compact gadgets that can be carried around. But the confusion matrices indicate greater mistakes in classifying things, especially when the classifications are quite similar. This means that the simpler model isn't particularly good at finding intricate skin patterns.

Overall, the three topologies comparison shows that the depth of the network and the number of convolutional blocks influence its generalisation. The results surpass previous work applied to dermatological classification, notably that of [6],[9],[11],[15],[17],[18], which used more limited datasets or conventional models (VGG, ResNet, AlexNet) and reported generally lower accuracies (80–95The use of recent architectures such as Inception and Inception-v3, in association with a variety of data sets, significantly enhances the reliability of the system. This enhancement is also due to hyperparameter optimisation and strict pre-processing.

However, this study has limitations that reduce its generalizability and clinical realism. First, the experimental data is only from DermNet NZ, which are images under ideal and standard lighting and photography conditions, making the models less robust to the variety of real-world images taken by smartphones or in clinical settings. Second, the study is just a binary classification, where the diseases are classified into two groups, which is not enough to deal with the complexity of diagnosing different and similar skin diseases. Thirdly, although models such as Xception model performed well, they are not clinically validated by experts, which is required for medical use. Fourth, while Marwan's HPC cluster, no explainable AI model has been trained to enable clinicians to understand why the classifications were made. Finally, the study did not validate the models in real-world settings or with local clinic data, suggesting the need for future real-world validation.

VI. Conclusion

The results demonstrate that Xception is the most effective solution for dermatological classification, followed by Inception-v3 which offers a relevant compromise between accuracy and computational cost. Although MobileNet-V3presente lower accuracy than Xception and Inception-V3, its minimum computational cost makes it a relevant candidate for implementation on medical equipment with limited resources. In contrast, Xception consistently delivers the strongest diagnostic accuracy, reinforcing its relevance for clinical decision support systems.

Future research will involve incorporating visual transformers to detect overall dependencies in dermatological images and using explainable AI methods (Grad-CAM++, SHAP) for better clinical interpretability. The exploration of hybrid CNN-Transformer models, the reduction of computational overhead through pruning and quantisation, and validation by dermatologists are also promising avenues. Finally, optimising the model for execution on mobile devices or edge computing will enhance the clinical reach of the proposed solutions.

Acknowledgment

I am appreciative to the HPC Marwan cluster (Morocco) for providing the computing environment and processing capability that allowed me to train and evaluate on massive data sets. I also wish to acknowledge the primary-school educators in Essaouira and Safi for their patience and assistance in organizing and collecting handwriting samples from pupils. Their sacrifices made this research achievable.

***Abstract*—Elaborating research documents is carried out by repeatedly creating and editing documents while simultaneously performing tasks such as surveys, presentation of results, and discussion of research directions. Although indispensable for advancing research, such work is often challenging because it requires handling diverse documents. Effective execution therefore demands an accurate understanding of the elaboration contexts of research documents, including related artifacts, referenced documents, and the circumstances and history of past tasks, so that these can be applied in subsequent work. However, these contexts grow increasingly large and complex as research progresses, making them difficult to grasp and reducing task efficiency. This paper describes a method for generating an elaboration context graph by organizing documents involved in the elaboration process using work history data recorded on a PC. The graph visually represents the documents, screenshots capturing work scenes, and the relationships among them, thereby supporting the understanding of elaboration contexts. We further describe a system developed on the basis of this method. Finally, we report an experiment conducted with the prototype and discuss the system's effectiveness.**

***Keywords*—Elaboration contexts graph; elaboration work of research documents; elaboration contexts; understanding work circumstances and histories; screenshots**

I. Introduction

Research activities generally involve various document creation and editing tasks, such as drafting and revising research plans, taking notes on ideas, creating presentation materials, and writing papers. These tasks are accomplished by creating and editing the documents while simultaneously accumulating various other tasks in parallel such as searching the Web, engaging in discussions with others, reviewing existing documents. To proceed successfully with these tasks, it is important to accurately organize and understand the elaboration contexts (i.e., the documents and artifacts used in the elaboration work of research documents along with the work circumstances and histories) and leverage them for subsequent work. However, since such research activities often extend over long periods, the involved documents become numerous and their elaboration contexts grow increasingly complicated.

To address these issues, there have been methods for document management [1–11] and support methods for recalling tasks on PCs [12–21]. However, these existing methods are limited in their scope of support and are insufficient for assisting with the understanding of the complicated elaboration contexts. On the other hand, there have been methods to support accumulation, understanding, and reuse of the artifacts and histories of intellectual work [22–28]. However, most of these methods require workers to register information into the system themselves, which imposes a significant burden during complicated document elaboration work.

In this research, we aim to develop a system that is responsible for collecting the history data of researchers' document elaboration work on their PCs, analyzing the accumulated history data, and generating and presenting the elaboration context graphs. This system enables to support the understanding of the elaboration contexts of research documents more proactively than conventional methods.

The rest of this paper is organized as follows. Section II clarifies direction of this research while reviewing the related work. Section III details the elaboration context graph and its generation algorithm. Section IV describes the design of a support system for understanding elaboration contexts and implementation of its prototype. Section V describes an experiment using the prototype. Section VI concludes this paper.

II. Issues and Direction

A. Understanding the Contexts in Elaboration Processes of Research Documents

When creating and editing documents such as research papers and presentation slides, a researcher often engages in various tasks in parallel, including reviewing existing documents and searching the Web. Moreover, documents created by a researcher him/herself, as well as those discovered and viewed in the past, often serve as important reference materials for subsequent work. In this research, we refer to the process of creating and editing research documents, which is performed through the long-term accumulation of such multiple tasks, as the "elaboration process of research documents."

In such elaboration work, the number of documents involved in the process—such as artifacts and reference materials—gradually becomes enormous as the project extends over a long period. To utilize these documents for future work,

it is essential to properly manage when and in which work they were used, as well as their current location. When managing these documents manually, it is common practice to assign each document an appropriate filename on the basis of its content, document type, and other relevant factors. Then, the documents are organized into folders in accordance with target work and project timelines. However, when attempting to utilize previously used documents, it is difficult to recall the target documents by their previous usage contexts, as well as locating the desired ones among the large number of documents, based solely on file and folder names. Additionally, valuable documents that a researcher has forgotten or are unaware of may become buried.

Furthermore, to effectively utilize past documents, it is crucial to accurately understand the work circumstances and histories surrounding the work at the time—such as what other documents were used alongside them, what references were consulted, and what was considered. However, understanding such elaboration contexts solely by folder management is quite difficult.

Additionally, these problems become even more serious when someone other than the original author attempts to understand the elaboration contexts and to make use of the involved documents. Finding documents useful for the latest work among those created and organized by others is even more difficult than finding documents one has created on one's own. Furthermore, it is nearly impossible to ascertain the context in which the document was edited or reviewed by others.

Therefore, there is strong need for an effective method to support utilizing previously used research documents while understanding their elaboration contexts.

B. Related Work

There have been many reports on methods for document management [1–11]. Hermosa et al. pointed out that traditional document management processes involve multiple platforms, making it difficult to track documents when they are shared. They developed a document management system (DMS-TM [1]) to centrally manage documents originating from multiple departments within the university. This system generates a tracking code when a document is sent, and once the processing cycle is complete, stores it in the database using the tracking code for future use. Each department can utilize web-based document sharing functionality while continuing to use their existing environment. Although this system is expected to facilitate reuse of documents by preventing the loss, it only targets completed documents and does not provide support for accumulating and understanding the work histories.

In addition, Nishi et al. developed a method to support users in re-accessing documents used in their past work on a PC [2]. This method focuses on the folders used for past work rather than individual documents and groups these folders on the basis of specific perspectives. By presenting users with these folder groups as a list, this method supports the reuse of past documents. Although this method is expected to promote the utilization of existing documents, it does not take into account the relationship between documents and past work scenes that cannot be fully expressed by folders. Therefore, it is not sufficient as support for understanding the work histories and circumstances.

Moreover, there have been support methods for recalling past work on a PC [12–21]. Hu et al. analyzed the effects of viewing time-lapse videos on the self-reflection of knowledge workers such as engineers, programmers, editors, and researchers, with the aim of improving their productivity [12]. Although the focus on time-lapse video as a means to recall past work is interesting, only a specific period of work can be observed because it is centered on video viewing, and it does not account for discovering used documents. Therefore, it is currently difficult to utilize this method to support understanding of contexts in the elaboration process of research documents.

Additionally, Meyer et al. developed a task management tool (called AIRbar [13]) aimed at encouraging knowledge workers, who handle numerous tasks daily, to reflect on their work and improve their awareness of the achievement status of priority tasks as well as influencing factors. This tool provides prompts that encourage users to specify priority tasks while self-confirming, and helps them reflect on their own work on a PC by visualizing the progress and the time spent on respective tasks. Although a practical effect of helping users understand their own work status can be expected, it targets daily work reviews and does not consider understanding the histories of long-term work.

These methods focused on supporting specific parts of the work processes. On the other hand, there have been methods to support accumulation, understanding, and reuse of the artifacts and histories of intellectual work [22–28].

Zloch et al. [22] presented a framework of the research knowledge graph (RKG) that expresses research artifacts such as datasets, publications, and methods, along with their relationships. They examined methods to promote the organization and reuse of research artifacts using RKG and discussed its possible applications. The results suggested the potential effectiveness of RKG in enabling researchers themselves to manage and reuse knowledge resources in their research work. However, regarding the registration of elements for building RKG, it was limited to discussing the advantages and challenges of manual input, semi-automation, and full automation. Therefore, methods for addressing the long-term elaboration work of research documents have not been established yet. Moreover, they dealt with only the research artifacts, and understanding the elaboration contexts has not been sufficiently considered.

Furthermore, Devezas et al. [23] proposed a wiki-based environment for researchers to manage key elements of their research, such as literature, datasets, experimental methods, and their results. This environment is promising as a method for documenting detailed circumstances and histories surrounding the work. It can facilitate researchers' reflection on their own activities and promote information sharing among research project members. However, researchers themselves must describe the overview and histories of the work, which imposes a significant burden on them and makes it difficult to apply the environment to long-term research projects.

Thus, most existing information systems rely on workers themselves to register information, placing a heavy burden on them and raising concerns about the potential loss of important work histories due to omissions of registration. Consequently, there is a strong need for an effective method to accumulate documents and contexts involved in complex elaboration work with minimal burden and to support understanding of them.

C. Issues in Elaborating Research Documents

On the basis of the above background, this research focuses on the following three issues to be overcome in understanding the contexts during the elaboration work of research documents.

(Issue 1) It is difficult to manage and understand the tasks and documents involved in the elaboration work of research documents due to their diversity.

(Issue 2) Understanding research documents used in the past and their relationships by associating them with the work scenes is important, but difficult.

(Issue 3) Observing and understanding the elaboration contexts of research documents becomes increasingly time-consuming since the contexts grows more complex as the work extends over a longer period.

D. Approach

To resolve these issues, this research first constructs a system framework to monitor the elaboration work of research documents on a PC by a researcher and automatically acquire the work history data (Solution to problem 1). Next, we develop a method to generate a “elaboration context graph” based on the analysis of the work history data. This graph visually represents the elements involved in the elaboration process—such as artifacts, documents used, and screenshots embodying the work scenes—and the relationships between them. (Solution to problem 2). Finally, based on the method, we develop a system to generate the elaboration context graph and visually present it to users so that they can intuitively observe the circumstances and histories in past elaboration work along with the artifacts and used documents (Solution to problem 3).

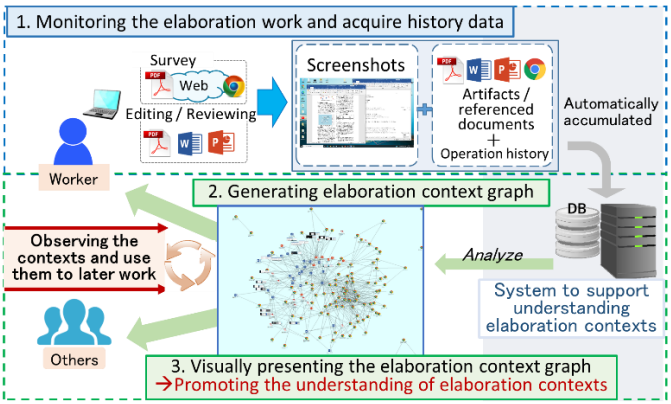

Fig. 1. Overview of support for the understanding of elaboration contexts.

This facilitates the understanding of elaboration contexts, which have previously been difficult, and enables their utilization in subsequent work. An overview of elaboration context understanding support is shown in Fig. 1.

III. Method for Generating Elaboration Context Graph

A. Elaboration Context Graph

Most existing information systems intending to accumulate the artifacts and processes of intellectual work have forced workers themselves to register the documents used in the work and the relationships between them into the system. However, there are limits to forcing users to register information every time they work on complex and long-term work of research document elaboration.

Therefore, this research proposes a novel method to support the recall and understanding of the elaboration contexts by having the system monitor researchers' work on their PCs and automatically generating an “elaboration context graph” that visually represents the documents involved in the work and the relationships between them on the basis of analyzing the accumulated history data.

The elaboration context graph is an attribute graph that represents various documents used in the elaboration work as well as screenshots of the PC desktop representing work scenes as nodes, and the relationships between them as edges. We currently target the documents created during the elaboration process such as papers and presentation slides, the documents viewed in parallel such as published papers and Web pages, and screenshots of the PC desktop (collectively referred to as "research documents").

By using the elaboration context graph, users can easily grasp the process of work by tracing the related documents with a document of interest as starting point. Additionally, screenshots serve as intuitive clues for looking back the work scenes, enabling users to understand the work circumstances and the documents used at that time.

B. Formalization of Elaboration Context Graph

Since the elaboration context graph treats various documents as nodes, the relationships between them are varied - documents referenced in parallel, derivations or developments from other documents, and citations. Moreover, extracting these relationships requires the analysis of various types of history data. In contrast, most existing methods for automatic graph generation are limited to handling only a single type or a very small number of data types. Therefore, we develop an algorithm for generating the graph to enable the system implementation of the elaboration context graph. As a preparation for this, we formalize the elaboration context graph to firmly handle to diverse documents and their relationships.

The elaboration context graph is defined as follows:

- **[Definition 1]** Elaboration context graph G is represented as $G = (V, E)$. V is a finite set of graph nodes, and v $(\in V)$is a node in the graph that represents a research document. E is a finite set of undirected connectors, and e $(\in E)$ denotes a relationship defined between two research documents.

Each research document and relationship has the following attributes, respectively.

- **[Definition 2]** The research document attributes in the elaboration context graph G are defined as $att_V = (kind_V, name_V, lastReadDate_V)$. These are attributes attached to node v $(\in V)$ and their meaning are as follows:
  - $kind_V$ expresses the type of research document. $kind_V$ = (draft paper | presentation slides | referenced paper | Web page | note | screenshot). The type of research document v $(\in V)$ is denoted as $kind_V(v)$.
  - $name_V$ expresses the file name of a research document or the title in case of a Web page and is represented by any string of characters. The name of a research document v $(\in V)$ is represented as $name_V(v)$.
  - $lastReadDate_V$ expresses the last viewed date and time of a research document. The last viewed date and time of a research document v $(\in V)$ is denoted as $lastReadDate_V(v)$.
- **[Definition 3]** The undirected connector attributes of the elaboration context graph G are $att_E = (kind_E)$. These are attributes attached to the undirected connector e $(\in E)$ and its meaning is as follows:
  - $kind_E$ means the kind of undirected connector. $kind_E$ = (Concurrent use | copy & paste | download | document derivation and development | work scene). The kind of undirected connector e $(\in E)$ is denoted as $kind_E(e)$.
- **[Definition 4]** Each research document has individual sub-attributes by the type of document as follows:
  - $att_{draft\ paper,\ presentation\ slides,\ note}$ = (*fileFormat*(MS-Word | MS-PPT | PDF | text file), *filename, filePath*(Local path on the PC), *createTime*(Creation or first access date), *lastModifiedDate, screenshots*(List of screenshots related to the document)).
  - $att_{referenced\ paper}$ = (*fileFormat* (MS-Word | PDF), *filename, filePath* (Local path on the PC), *AcquisitionDate,* screenshots(List of screenshots related to the document)).
  - $att_{Web\ page}$ = (URL, pageTitle, firstTime(first access date)).
  - $att_{screenshot}$= (*filename*, *filePath* (Local path on the PC), *AcquisitionDate, documents*(List of documents shown in the screenshot)).

Research document attributes represent metadata on the node, while sub-attributes represent metadata on the research document itself. These definitions enable to design an algorithm for generating the elaboration context graph that represents the documents involved in the work, screenshots embodying the work scenes, and the relationships between them.

C. Algorithm for Generating Elaboration Context Graph

Based on the above definitions, we generate an elaboration context graph in the following three steps (Algorithm 1).

1) Accumulation of the work history data: While the worker is elaborating research documents on a PC, the system monitors their work and accumulates the histories of the operations and occurrences of events. Specifically, we target the operations such as switching active windows, opening and saving documents, keystrokes in the editing documents, copying and pasting, and web browsing. Such diverse history data is required for generating nodes and edges with the attributes defined in Section III (B).

We developed a system framework to automatically accumulate such history data as the function of the system mentioned in Section IV. The framework consists of the resident programs and the database. The resident programs acquire the history data by monitoring the worker's operations on a PC as well as occurrences of events. In addition, desktop screenshots showing the work scenes are captured at regular intervals. The acquired history data is successively registered into the database. The resident programs impose no extra burden on the worker since they work in the background.

In this research, we target MS Word, MS PowerPoint, Adobe Acrobat Reader, and Google Chrome as applications that handle documents, and treats the document formats such as .docx, .pptx, .pdf, and web pages processed by these applications.

2) Node generation: On the basis of analyzing the accumulated work history data, we generate nodes V which represent the research documents involved in the elaboration work.

First, we retrieve all documents opened or viewed during the work period by analyzing access logs to documents and web page browsing history. In order to exclude documents that have not substantially contributed to the elaboration work, we calculate the total active time of each document and adopt only those documents exceeding a certain threshold as nodes v.

Next, the attribute att_V is assigned to each node in accordance with the definition of the research documents mentioned above. We initially assign the sub-attributes such as $name_V$ and $lastReadDate_V$ on the basis of the work history data and the metadata of each document.

We also extract the format of each document from the work history data and set the type of research document $kind_V$ for each node accordingly. However, since both the draft paper and the referenced paper share the same format (MS-Word and PDF), we distinguish them based on whether editing was performed. Specifically, in the case of a document with a certain number of keystrokes for editing and its copies saved under different names, the type of research document $kind_V$ of that node is set to "Draft Paper"; otherwise, $kind_V$ is set to "Referenced Paper".

Algorithm 1: Graph Generation

```
[Input]
- DAH: Document access and save history
- AWH: Active window switching history
- CPH: Copy & paste history
- WDH: Web browser's download history
- SSH: Screenshot acquisition history
[Output]
- G = (V, E): Elaboration context graph
[Global variable]
- Threshold_node: Threshold for document active time to adopt nodes
- Threshold_AWC: Threshold for count of switching active window
- Threshold_CUT: Threshold for concurrent use time
- Threshold_SS: Threshold for the number of related documents to
      adopt screenshot nodes
[Local variable]
- DN: Document node set
- SSN: Screenshot node set
[Method]
1   // Node generation
2   // Generate a set of used documents
3   UD = extraction UsedDocuments (DAH);
4   for( ∀d ∈ UD)
5       if(d.totalActiveTime >= Threshold_node)
            DN.add(d, att_V(d)= getAttribute(d));
6   // Edge generation
7   // Generate a set of all pairs of document nodes
8   pairsDN=generate_ pairsDN (DN)
9   for( ∀d1,d2 ∈ pairs_DN)
10      //Count activation switches between two documents
11      Count_AWC=count_ActiveChanges(d1,d2,AWH);
12      // Calculate the concurrent use time for two documents
13      Seconds_CUT=Calculation_ConcurrentUseTime(d1, d2);
14      //Analyze document pair whose activation switching and
        concurrent use time exceeds a threshold
15      If (Count_awc > Threshold_Count_AWC &&
            Seconds_ CUT > Threshold_Seconds_ CUT)
            E.add((d1, d2), kind_E(d1, d2)="ConcurrentUse" );
16      //Copy & paste
17      If(judge_copyandpaste_documents(d1,d2,CPH))
            E.add((d1, d2), kind_E(d1, d2)="Copy&Paste" );
18      // Document derivation and development
19      If (confirmation_DocumentDevelopment(d1,d2, DAH))
            E.add((d1, d2), kind_E (d1, d2)="Derivation" );
20      // Downloaded document and its source page
21      If (confirmation_DocumentDownload (d1,d2, WDH))
            E.add((d1, d2), kind_E (d1, d2)="Download" );
22  // Nodes and Edges of screenshots
23  for( ∀ss ∈ SSH){
24      ss_docs = extraction_ DocumentsRelatedtoScreenshots(ss);
25      //Decide which screenshots to adopt for the node
26      if (length(ss_docs)>= Threshold_screenshots
                and checkState ActiveWindow(ss, AWH))
27          SSN.add(ss);
28          for( ∀d∈ss_docs)
                E.add((ss, d), kind_E (ss, d)="WorkScene");
29      // Other screenshots
30      else for( ∀d∈ss_docs) att_V(d).screenshots.add(ss);
31  V = DN ∪ SSN;
32  return G = (V, E);
```

Additionally, we extract promising screenshots from those captured during the work. Specifically, we select screenshots containing windows that have remained active for a certain period of time, or those captured at the moment an active window switched. Then, we identify the documents visible in each screenshot on the basis of analyzing the work history data, and adopt screenshots linked to multiple documents as node v. All other screenshots are treated as sub-attributes of the nodes for the relevant documents.

3) Edge generation: We generate edges E by analyzing the relationships between nodes in five perspectives defined as the kind of edge $kind_E$.

First, we extract a pair of documents that are repeatedly activated alternately on the basis of analyzing the history of window activation. We then assign an edge e connecting these documents and set its type $kind_E$ to "Concurrent use".

Next, we extract the relationships where documents are derived or evolved from other documents (e.g., different versions of a document) on the basis of analyzing the history of document duplication and saving under different names. We then assign an edge e connecting such documents and set its type $kind_E$ to "document derivation and development".

Moreover, we extract a pair of documents that are in a citation or referenced relationship on the basis of analyzing the history of copying and pasting the elements such as strings between different documents. We then assign an edge e connecting these documents and set its type $kind_E$ to "copy & paste".

We also extract documents obtained from the web and the URLs of their source web pages on the basis of analyzing the download history of web browsers. We then assign edges e connecting them, and set their type $kind_E$ to "download".

Furthermore, we assign an edge e connecting the screenshot to the documents being used at the time it was captured, and set its type $kind_E$ to "work scene" using the results of the analysis performed when generating the nodes for the screenshots of the PC desktop representing the work scenes.

The formalization and development of the generation algorithm based on it enable the automatic generation of the elaboration context graph that visually represents the documents involved in the long-term elaboration process, work scenes, and their relationships, which was previously impossible. Additionally, it provides a path for future inclusion of new documents as targets.

IV. Support System for Understanding Elaboration Contexts of Research Documents

A. System Requirements

We develop a system to support understanding the contexts in elaboration processes of the research documents on the basis of the method for generating the elaboration context graph proposed in Section III. We initially organize the system requirements as follows on the basis of findings gained through observing actual elaboration work of research documents.

- Req.1) The system should be able to record the work history data and screenshots related to the research document elaboration work without imposing a burden on the user.
- Req.2) The system should be able to analyze the research documents involved in the elaboration work and their relationships.
- Req.3) The system should be able to present the research documents involved in the elaboration work and their relationships, as well as the work circumstances and histories, in a way capable for intuitive observation.
- Req.4) The system should be able to present information that allows users to easily review the work scenes related to a document and examine the details of the work scenes they focus on.
- Req.5) The system should be able to present information that allows users to easily review the contents and metadata of the research document of interest.
- Req.6) The system should be able to present information that allows users to easily identify the location of the research documents they need, as well as other documents managed together with them.
- Req.7) The system should be able to provide assistance in discovering the intended documents from among countless research documents.

B. Function Design

To satisfy the above system requirements, this system is equipped with the following functions.

- Function for acquisition and accumulation of work history data: The function acquires and accumulates the history data and screenshots during the user's elaboration work on a PC. To avoid placing an unnecessary burden on the user, it starts automatically when the PC is turned on and automatically collects history data in the background (Solution to Req.1).
- Function for generating an elaboration context graph: The function extracts the documents involved in the elaboration work and their relationships on the basis of analyzing the accumulated work history data. It then generates an elaboration context graph, in which documents and screenshots representing work scenes serve as nodes, and their relationships as edges (Solution to Req.2).
- Function for displaying an elaboration context graph: The function visually presents the generated elaboration context graph in a way that allows users to interactively and intuitively observe the elaboration contexts by simple mouse operations (Solution to Req.3).
- Function for reviewing work scenes: When the user selects a document node, the function displays a list of desktop screenshots showing the work scenes at the time the selected document was being edited or viewed. Furthermore, when the user selects a screenshot node, the function enlarges it (Solution to Req.4).
- Function for displaying details of selected document: When a user selects a document node in the graph, the function displays the contents of that document along with attributes such as the last modified date and time, and the folder location (Solution to Req.5 and 6).
- Function for searching documents: The function searches for document nodes within the elaboration context graph that contain keywords entered by the user, and highlights the document nodes containing those words (Solution to Req.7).

C. Implementation of Prototype

Based on the above design, we implemented a prototype of the support system as a desktop application for Windows. This system consists of modules, including a work history acquisition unit and a node/edge generation unit, as well as a base system that manages fundamental functions such as coordination among these modules and user authentication. Moreover, a database was built to manage the work history data and screenshots as well as generated context graphs.

This system was implemented on Windows 11 using Python as the development language. Moreover, MySQL was used as the DBMS. The system configuration is shown in Fig. 2.

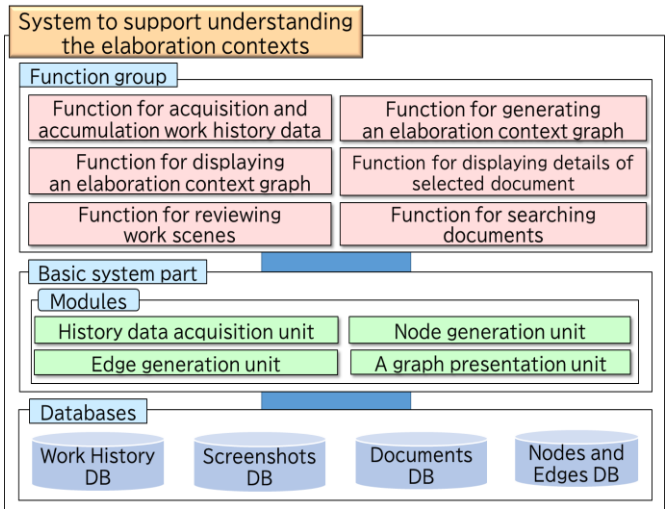

Fig. 2. System configuration.

D. Assistance in Understanding Elaboration Contexts Using the System

An interface of the support system for understanding the elaboration contexts is shown in Fig. 3. When the user attempts to review their own or others' elaboration work of research documents, the system presents the elaboration context graph along with related information in response to the user's request.

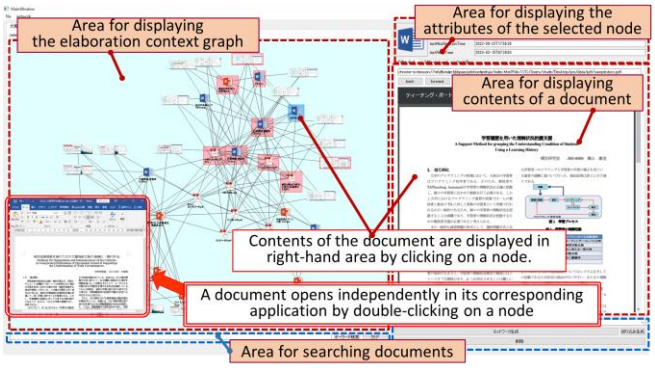

Fig. 3. An interface of the support system.

In the area for displaying the elaboration context graph (left side of Fig. 3), users can zoom in and out on the graph. Moreover, the user can interactively manipulate the document nodes. For instance, when a node on the graph is clicked, the metadata such as document name, and last access/modified date and time are displayed (upper right in Fig. 3). The content of the selected research document is also displayed depending on node selection (middle right of Fig. 3). In addition, double-clicking a node, the corresponding research document opens independently in its associated application, such as MS Word. Furthermore, the user can display a list of screenshots related to the node he/she has selected by switching tabs (Fig. 4). Clicking a screenshot of interest from the list, the screenshot is enlarged, allowing the user to observe the work scene at that time. The user can also check the folder containing the selected document, allowing to easily access other documents in the same folder.

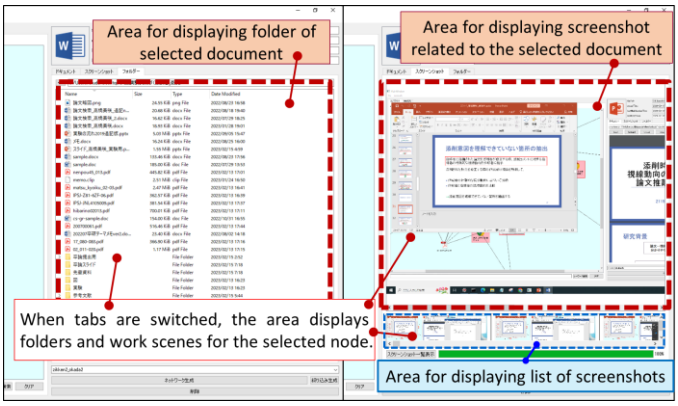

Fig. 4. Function for displaying details of selected document/function for reviewing work scenes.

By utilizing these functions, the user can observe the circumstances and histories of the elaboration work such as: What tasks were performed concurrently while creating a certain document, - What tasks were completed and what artifacts were obtained before starting to create a certain document, - How the reference to a certain document influenced the direction of subsequent document creation.

Additionally, when the user enters keywords into the search prompt, the nodes of documents containing those keywords in their file names or main text are highlighted on the graph. This makes it easy to locate the intended documents (lower left of Fig. 3).

Thus, assistance provided by the system enables the user to realistically observe the contexts in elaboration work of research documents.

V. Experiment and Discussion

A. Outline of Experiment

We conducted an experiment to verify the effectiveness of the prototype system in supporting the understanding of the elaboration contexts of research documents.

1) Preparatory session: First, two fourth-year undergraduate students majoring in computer science (participant A and B) searched the web for papers related to their own research themes and summarized the following points in a way of reinforcing the slides that they had previously created. The slides on which participants performed this work are called “reinforced slides”.

- Overview of main related works and their connections to the participant’s own research.
- Future issues to be addressed in the participant’s research.
- Clues for progressing the participant’s own research such as ideas for system design and promising methods of analysis.

The work time was set at approximately 90 minutes, and the support system collected the work history data during the participant's work.

2) Main session: After the preparatory session was completed, four third-year undergraduate students majoring in computer science (referred to as Subjects I, J, K, and L) observed the research documents used by participants A and B, who were senior students, in order to understand the research overview and the contexts in the work conducted by senior students. Specifically, we prepared a folder containing research documents used by senior students, including the collected literature and documents created by other students, and provided it to the subjects. Using the reinforced slides of senior students as a starting point, the subjects reviewed these documents and performed the following tasks.

- Task I) Understand the senior student's research overview and key points, as well as the new content they added to the reinforced slides.
- Task II) Select five or more documents that are helpful to the subjects themselves in understanding the research of senior students from the provided folder.
- Task III) Select up to three documents that the subject inferred “particularly referenced by the senior students in advancing their own research,” from the senior student's folder as in Task II).

Subjects performed these tasks in two sets (each set targeting the work history of a different senior student) while changing whether support was provided by the system. Table I shows the combinations of senior students targeted and the presence or absence of the support when these tasks were conducted. We recorded the work performed by the subjects and conducted interviews with them after the tasks were completed.

TABLE I. COMBINATIONS OF SENIOR STUDENTS TARGETED AND SUPPORT CONDITIONS

	First	Second
Subject I	Without support (Participant A)	With support (Participant B)
Subject J	Without support (Participant B)	With support (Participant A)
Subject K	With support (Participant A)	Without support (Participant B)
Subject L	With support (Participant B)	Without support (Participant A)

After completing the tasks, we examined the effectiveness of the support provided by the system in the following perspectives.

- Whether the support provided by the system can reduce the burden on workers, such as the time required for tasks.
- Whether differences exist in characteristics of subjects' behavior, such as the number of documents viewed during tasks and work tendencies, depending on the presence or absence of support.

Whether the support provided by the system enables the subjects to easily grasp the key points of the work performed by senior students.

B. Results and Discussion

First, we confirmed that the series of processes—from acquiring the history data, its analysis, to the generation of the elaboration context graph—can be performed as intended. Fig. 5 shows the overviews of the elaboration context graphs for participants A and B generated in the experiment.

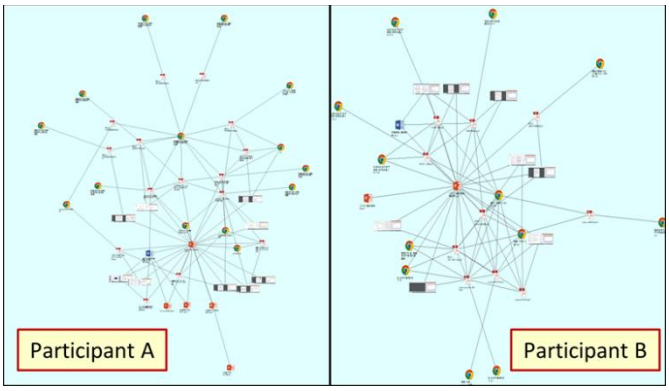

Fig. 5. Overview of the elaboration context graphs generated in the experiment.

Table II shows the duration of Tasks I, II, and III for subjects I through L. These results indicate that the time required for the tasks is reduced in many cases when support is provided. This is thought to be because the support reduced the burden of unnecessary tasks such as simple checking. On the other hand, subject K took slightly longer to complete Task II when support was provided. Upon closely observing the work circumstances using recorded videos, it was found that time was spent on carefully reading several papers. Therefore, it is not considered that there was any wasted time, nor that the results negate the effectiveness of the support.

Next, Table III shows the number of documents viewed by subjects I through L in Tasks I, II, and III. It was found that the number of documents reviewed decreased in most cases where support was provided. It is thought that this is because the subjects had no choice but to browse documents in the working folder blindly in case without support, whereas with support, they could smoothly progress their work by preferentially browsing documents of interest on the context graph presented by the system. On the other hand, Subject I viewed more documents in Tasks I and III when support was provided. Upon closely observing the work circumstances using recorded videos, it was confirmed that task itself proceeded smoothly similar to other subjects in case with support. In addition, it appeared that subject I was using their spare capacity to review additional relevant documents, which can be considered a positive tendency.

Furthermore, we even more carefully reviewed the videos and observed the work circumstances in detail. As a result, it was found that the workload and task difficulty appeared to be somewhat reduced when using the support system, not only in the case mentioned above. On the other hand, without support, subjects appeared to struggle to identify and review the documents that senior students had referenced among the vast number of documents available. From these results, it can be inferred that the elaboration context graphs and the details of documents presented by the system offered substantial support for performing the tasks. This trend of reduced workload is consistent with the above-mentioned decreases in task duration and the number of documents viewed.

Moreover, Table IV shows the accuracy in Task I, grasping the new contents added by senior students to the reinforced slides, for subjects I to L. For all subjects, it can be confirmed that the accuracy with support is equivalent to or higher than that without support. Taken together with the reductions in task duration and document views, these results indicate that subjects with support appeared to better understand the work performed by senior students, even when their accuracy was similar. Additionally, careful observation of the work using video revealed that subjects appeared to struggle while consulting numerous documents without support. In contrast, with support, subjects were observed to take notes on key points smoothly and without hesitation, using the provided documents and screenshots of actual work scenes as references. These findings are consistent with the accuracy of grasping key points of the task.

Additionally, in post-experiment interviews, we obtained comments such as: "When I used the system, documents related to the task are easier to find and review, making the work significantly easier compared to when no support was available." and "The relationships between documents were visually clear, and viewing screenshots alongside them made it easy to confirm the key points of the task."

These results indicate the system's effectiveness in both aspects of reducing the burden of understanding past work circumstances and reviewing documents, and of grasping key points of past work. Although this experiment was conducted on a limited scale and requires further verification, it suggests the fundamental effectiveness of our approach for understanding the elaboration contexts of research documents.

We also received feedback such as "Since the graph can only be scrolled using the scroll bar, it would be better if it could also be moved by dragging with the mouse." This provides valuable hints for future improvements.

TABLE II. RESULTS OF THE TASK DURATION

	Task I		Task II		Task III	
	First	Second	First	Second	First	Second
Subject I	96 min	61 min	72 min	35 min	18 min	15 min
Subject J	52 min	45 min	34 min	23 min	17 min	17 min
Subject K	48 min	64 min	115 min	96 min	28 min	40 min
Subject L	36 min	42 min	70 min	72 min	29 min	46 min

Underline: With support by system.

TABLE III. RESULTS OF THE NUMBER OF DOCUMENTS VIEWED

	Task I		Task II		Task III	
	First	Second	First	First	Second	First
Subject I	6	13	31	14	6	13
Subject J	17	12	32	15	19	13
Subject K	14	21	34	37	14	31
Subject L	4	5	12	20	8	9

Underline: With support by system.

TABLE IV. ACCURACY IN GRASPING SENIOR STUDENTS' REINFORCED SLIDES IN TASK I

	First	Second
Subject I	0.46	1.00
Subject J	1.00	1.00
Subject K	1.00	1.00
Subject L	0.92	0.51

Underline: With support by system

VI. CONCLUSION

In this research, we developed a system to support the understanding of the contexts in the work of elaborating research documents. Specifically, we developed a method for generating the elaboration context graphs on the basis of analyzing documents involved in the elaboration work and their relationships, using the work history data. We also developed a prototype system to support the understanding of the elaboration contexts based on the method. Finally, we conducted an experiment using the prototype and discussed its effectiveness based on the results.

Future work includes further verification of the effectiveness of the support system for understanding the elaboration contexts through long-term experiments.

***Abstract*—Dissolved oxygen (DO) plays a vital role in maintaining balanced aquaponic ecosystems, yet conventional optical and galvanic DO sensors remain costly and impractical for low-budget deployments. However, most existing dissolved oxygen monitoring studies rely on costly sensing infrastructures, regression-oriented prediction approaches, or centralized processing schemes, which limit their applicability in small-scale and resource-constrained aquaculture settings. Furthermore, many previous works focus primarily on numerical prediction accuracy without explicitly addressing data imbalance issues or providing actionable classification outputs that can directly support real-time operational decisions at the pond level. This study proposes a machine learning–based approach for estimating DO levels using low-cost pH, temperature, and nitrogen sensors integrated with an IoT data acquisition system. A dataset comprising approximately 1,048,536 records was processed using feature engineering and class balancing techniques, followed by training an XGBoost classifier optimized through grid search. The model classified DO into three categories—Low (<5 mg/L), Medium (5–7 mg/L), and Good (>7 mg/L)—achieving 96.6% accuracy, outperforming baseline regression models including Linear Regression, Random Forest, and XGBoost Regressor. Feature importance analysis revealed temperature and the pH–temperature interaction as dominant predictors. The model was successfully deployed on a Raspberry Pi for real-time monitoring, offering a scalable and cost-effective alternative to high-end probes. The proposed framework demonstrates practical potential for smart aquaponic systems, enabling affordable, automated, and data-driven oxygen management.**

***Keywords*—Aquaponic; dissolved oxygen; IoT; machine learning; XGBoost; low-cost sensors**

I. Introduction

Dissolved oxygen (DO) is a key parameter in aquaponics systems because it affects fish respiration, nitrifying bacterial activity, and nutrient uptake by plants. Freshwater fish generally require a minimum DO level of around 5 mg/L for optimal growth, while levels below 3 mg/L can cause stress or death [1]. In addition, nitrifying bacteria that convert ammonia and nitrite into nitrate—an important nutrient for plants—require dissolved oxygen to function properly. Without an adequate oxygen supply, this process slows down or stops, which can trigger the accumulation of toxic compounds and disrupt the overall productivity of the system [1]. Therefore, timely monitoring and control of DO is a fundamental aspect of efficient and sustainable aquaponics management.

Although DO sensors (both electrochemical and optical) are widely used in aquaculture and environmental industries, their operation faces various technical and economic limitations. Electrochemical sensors require routine calibration, are prone to drift, membrane fouling, and are affected by temperature, salinity, and atmospheric pressure [2], [3]. While optical sensors offer certain advantages, their initial cost is high, and field maintenance is often expensive or difficult to perform on a small scale [4]. In the context of household-scale aquaponics or SMEs, the need for inexpensive devices, reliable accuracy, and real-time monitoring capabilities is often difficult to meet with conventional commercial DO sensors alone.

As an alternative or complement to expensive physical sensors, machine learning (ML) approaches have emerged in the literature as a method for estimating water quality—including DO—from more easily measured parameters such as pH, temperature, nitrogen, and other parameters. Recent reviews show that the integration of IoT and ML has enabled real-time and predictive water quality monitoring by utilizing low-cost sensor data [5], [6]. Ensemble models and XGBoost have also been applied for general water quality prediction [7]. Thus, DO estimation through ML not only enables reduced sensor costs, but also allows for the implementation of automated monitoring and control in digitally integrated aquaponics systems.

Despite extensive research on dissolved oxygen estimation using machine learning and IoT-based monitoring systems, several critical research gaps remain unresolved, particularly in the context of small-scale and resource-constrained aquaponics applications. First, most studies use expensive sensors that are not designed for application in small-scale systems or MSMEs [8],[9]. Second, regression-based approaches may struggle to achieve robust performance in practical aquaponics settings due to the complex and non-linear relationships between easily measured parameters and dissolved oxygen, particularly when applied to heterogeneous or imbalanced datasets [7], [8]. Third, many solutions do not address the issue of class imbalance in the data (e.g., low DO vs. high DO), which can reduce categorical performance. Fourth, real-time model implementation and deployment on edge devices or IoT

systems are still rarely reported [9], [10]. Therefore, there is a need for an efficient, low-cost DO classification model that is ready for real-time application in aquaponics systems. To address these identified gaps, this study focuses on a classification-oriented, deployment-ready modeling framework that emphasizes practical applicability, robustness to class imbalance, and real-time operation in aquaponics environments.

This article presents the following main contributions: 1) the development of a large dataset (>1 million records) generated from a real aquaponics system and analyzed using pH, temperature, and nitrogen parameters; 2) the application of a DO classification model into three classes (Low, Medium, Good) rather than continuous number regression predictions; 3) the use of feature engineering techniques (interactions, log/inverse transformations) and data balancing using SMOTE to address class imbalance; 4) training and optimization of the XGBoost model with GridSearchCV, accompanied by a complete evaluation using a confusion matrix, ROC curve, and Precision-Recall for each class; and 5) implementation of a model deployment pipeline (scaler + classifier) and examples of real-time inference on edge/IoT devices with low-latency decision outputs suitable for operational control. Thus, this research provides a ready-to-implement, low-cost, and scalable solution for DO monitoring and control in aquaponics systems.

II. Related Work

In the context of data-driven water quality assessment, machine learning (ML) has gained significant traction in the field of water quality monitoring due to its ability to capture nonlinear relationships among physicochemical parameters and provide predictive insights beyond conventional analytical approaches. Earlier studies demonstrated the feasibility of ML models such as Support Vector Regression (SVR), Random Forest, and XGBoost for predicting individual water quality factors, showing improvements in accuracy and generalization over traditional statistical methods [7], [8]. Comprehensive reviews highlight the rapid development of ML-based water quality assessment frameworks, especially when integrated with IoT systems for continuous monitoring [2], [6], [11]. These approaches have expanded from predicting general indices such as the Water Quality Index (WQI) to targeted pollutant estimation (e.g., nitrate and biochemical oxygen demand) across diverse aquatic environments [12]. However, most existing efforts, including those targeting dissolved oxygen estimation, rely on high-grade sensing infrastructures and emphasize regression-based modeling rather than multi-class classification tasks, indicating the need for further refinement and adaptation for cost-constrained environments.

Dissolved oxygen (DO) is a critical water quality parameter that influences aquatic life sustainability, nutrient cycling, and microbial activity. Multiple studies have applied ML techniques to estimate DO using accessible water quality parameters such as temperature, pH, and nitrogenous compounds. Regression-based models—including hybrid and ensemble modifications—have demonstrated promising performance in DO forecasting across freshwater, river, and aquaculture environments [1], [4], [13]. Recent work also incorporates advanced signal decomposition and hybrid optimization techniques such as DWT-KPCA-GWO-XGBoost to enhance forecasting accuracy under dynamic conditions [4]. However, limited studies address DO classification as a categorical task—despite its practical benefits for on-site decision-making—while others neglect challenges arising from imbalanced training data, leading to biased predictions toward majority classes [14], [15]. This gap underscores the importance of developing DO classification models that incorporate data balancing techniques such as SMOTE and emphasize interpretable feature engineering to enable reliable operation within low-cost systems.

Modern aquaculture increasingly adopts IoT-enabled monitoring and automation systems to enhance productivity, reduce labor, and improve water quality management in real time. Smart aquaculture frameworks leverage embedded sensors, edge computing, and communication platforms to track dissolved oxygen, ammonia, pH, nitrogen, and temperature continuously [10], [16], [17]. The integration of AI/ML decision models into such platforms supports automated aeration and feeding control, reducing energy consumption and manual intervention [9], [11]. Low-cost commercial and custom-built sensor platforms have shown promise in achieving scalable deployments, though challenges remain related to measurement robustness, calibration requirements, and environmental fouling [18], [19]. Despite increasing adoption, many developments focus on system-level descriptions rather than predictive analytics, leaving an opportunity for research that integrates classification modeling with deployment pipelines optimized for small-scale aquaponics and edge computing.

Based on the reviewed literature, existing dissolved oxygen monitoring and prediction studies have provided valuable contributions to sensor technologies, machine learning models, and IoT-based water quality assessment. Nevertheless, most prior works emphasize numerical regression accuracy or depend on costly sensing infrastructures, limiting their applicability in small-scale aquaponics environments. Furthermore, challenges related to class imbalance, categorical decision support, and real-time deployment on edge or IoT devices are frequently overlooked. In contrast, the present study is positioned around a classification-oriented dissolved oxygen modeling framework that explicitly addresses data imbalance, supports operational decision-making through discrete DO categories, and enables real-time deployment in resource-constrained aquaponics systems.

III. Methodology

The overall methodological workflow adopted in this study for dissolved oxygen (DO) classification in an IoT-enabled aquaponic system is designed in a systematic and sequential manner. The process encompasses sensor data acquisition, data preprocessing, feature engineering, class label definition, and class imbalance handling using SMOTE, followed by model training with XGBoost and hyperparameter optimization through GridSearchCV. Model performance is then assessed using standard classification metrics, including accuracy, precision, recall, and F1-score, before deployment for real-time sensor data classification. The complete process can be illustrated in Fig. 1.

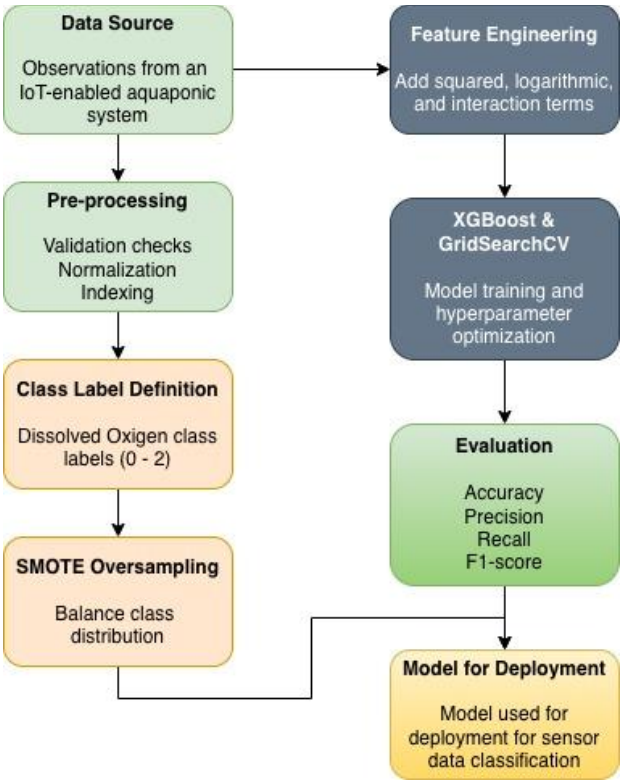

Fig. 1. Research methodology.

A. Data Source

The dataset used in this study was acquired from a functioning freshwater aquaponic system equipped with low-cost IoT sensor nodes designed for continuous monitoring of key water quality indicators. The system was operated under typical aquaculture conditions, and sensor readings were logged at one-minute intervals throughout the observation period. A total of approximately 1,048,536 observations were collected, containing synchronized measurements of dissolved oxygen (DO), pH, temperature, and nitrogen concentration. DO was measured using a calibrated reference probe to establish ground-truth labels, while the other parameters were measured using low-cost sensors integrated into the IoT module [2], [5], [11]. The dataset was stored in CSV format and processed offline in a Python environment for machine learning model development.

B. Sensor Parameters

Three key input parameters were acquired using low-cost sensors:

- pH (pH units), indicating water acidity level.
- temperature (°C), measured using a digital thermoprobe.
- nitrogen (mg/L), representing the concentration of nitrogenous compounds (including total ammonia nitrogen) in the water.

These parameters were selected due to their known influence on dissolved oxygen dynamics and overall water quality in aquaponics [6], [16]. In addition, a high-accuracy DO probe was used for ground-truth reference measurements. Due to their affordability and ease of installation, these sensors are appropriate for small-scale aquaponic producers where professional-grade equipment is cost-prohibitive [5], [17].

C. Pre-processing

Preprocessing involved data cleansing, consistency checks, and normalization. Invalid readings, such as missing values, negative concentrations, or sensor anomalies were removed using rule-based filtering. Infinite values caused by numerical transformations were replaced with NaN and subsequently dropped. All numerical features were standardized using Z-score normalization to ensure uniform scaling across inputs. The corrected dataset was then indexed to ensure label–feature alignment before model training. This step mitigates numerical instability and improves model convergence in ML pipelines [20].

D. Feature Engineering

To better capture the nonlinear relationships among pH, temperature, nitrogen, and DO, several derived features were engineered. These included: square terms (temperature², pH²), logarithmic transformation of temperature ($\log(T+1)$), reciprocal temperature ($1/(T+0.01)$), and interaction terms (pH × temperature, nitrogen × temperature). Such transformations enhance feature expressiveness and allow the model to capture hidden nonlinear effects that are often poorly modeled by direct features alone [4], [8], [13]. These engineered features were concatenated with original input variables to compose the input vector.

E. Class Label Definition

Dissolved oxygen values were discretized into three classes based on aquaculture standards: Low DO (class 0): < 5 mg/L, Medium DO (class 1): 5–7 mg/L, Good DO (class 2): > 7 mg/L. The threshold values align with common aquaculture guidelines defining safe and unsafe oxygen ranges for fish and microbial populations [16]. This categorical formulation is associated with simpler decision rules for real-time control, compared to continuous regression.

F. SMOTE Oversampling

Because the distribution of DO classes was imbalanced—with the "good" range occurring more frequently than the "low" range—Synthetic Minority Oversampling Technique (SMOTE) was applied to balance the training dataset. SMOTE synthesizes new samples in under-represented classes by interpolating between existing samples in feature space [14], [15]. Balancing class samples reduces bias toward majority classes, improves decision boundary quality, and yields more stable classification performance.

G. XGBoost and GridSearchCV Optimization

The model used in this work was an Extreme Gradient Boosting (XGBoost) classifier, owing to its robust handling of nonlinear relations and strong predictive performance in environmental modeling tasks [1], [7], [13]. Hyperparameters including maximum depth, learning rate, subsample ratio, colsample_bytree, and number of trees were tuned via GridSearchCV with 3-fold cross-validation. The grid search optimized the configuration that maximized accuracy on the

validation subset. This systematic optimization yielded a balanced trade-offbetween accuracy and model complexity.

H. Evaluation Metrics

Model performance was evaluated using accuracy, precision, recall, and F1-score to capture predictive capability across classes. A confusion matrix was computed to visualize misclassifications. These metrics are appropriate for multi-class classification and are particularly relevant under class-imbalanced conditions [21], [22]. By evaluating several metrics simultaneously, a more comprehensive assessment of model behavior was obtained.

I. ROC and Precision–Recall Curves

To validate class discrimination performance, one-versus-rest (OvR) Receiver Operating Characteristic (ROC) curves were generated for each class, and the area under the ROC curve (AUC) was computed. Additionally, precision–recall (PR) curves were produced to evaluate predictive ability under class imbalance, where PR is generally more informative than ROC [14]. These curve-based evaluations reflect the model's robustness in distinguishing DO ranges across diverse operating conditions.

J. Deployment Architecture

The final model pipeline—including the trained XGBoost model and scaling transformation—was serialized using joblib and deployed as an API endpoint via Flask for real-time predictions. The pipeline was tested on a Raspberry Pi, demonstrating feasibility for low-cost edge deployment in aquaponic settings. Sensor data transmitted from IoT nodes can be processed on-device or in a local server, wherein DO classification results inform actionable decisions such as aerator activation. This aligns with current smart aquaculture practices leveraging IoT + ML integration [9], [18], [19], [23]. The deployment architecture is shown in Fig. 2.

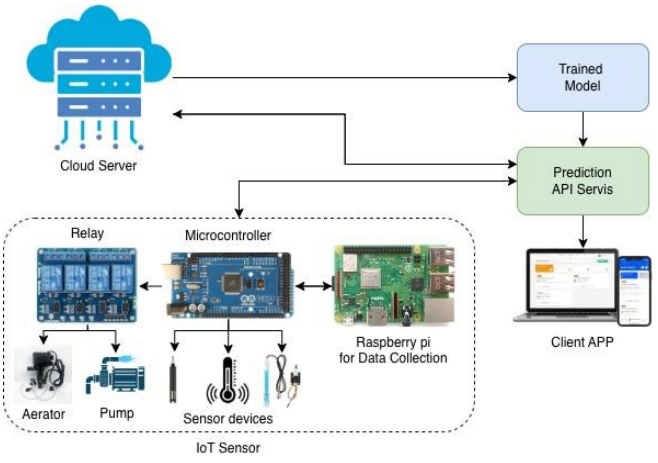

Fig. 2. Deployment architecture.

IV. Results and Discussion

A. Dataset Profile

The dataset comprised 1,048,536 valid samples containing four main parameters: Dissolved Oxygen (DO), pH, Temperature, and Nitrogen. All data were collected from a real aquaponic IoT monitoring system operating under natural environmental variations. The data distribution indicated that most observations had DO levels between 6–8 mg/L, which correspond to healthy aquaponic conditions. Temperature values ranged from 7 °C to 32 °C, and pH varied between 6.5–8.3, consistent with typical freshwater conditions. The nitrogen content ranged from 0.05–0.95 mg/L. These results confirm that the dataset effectively represents real-world aquaponic water dynamics with high temporal resolution.

B. Correlation Heatmap

A Pearson correlation analysis was conducted to evaluate the relationship among parameters and engineered features. The correlation matrix (Fig. 3) revealed that temperature showed the strongest negative correlation with DO ($r = -0.34$), confirming that warmer water tends to retain less oxygen. Conversely, pH exhibited a weak positive correlation ($r = 0.13$), while nitrogen levels had minimal direct impact ($r \approx -0.01$). Feature-engineered variables such as temp_squared and temp_log demonstrated stronger associations ($r \approx -0.36$) with DO than raw temperature values, validating the benefit of nonlinear transformations in improving feature expressiveness. These stronger nonlinear associations help explain why feature-engineered models outperform linear baselines in subsequent classification tasks.

C. Model Performance

Model evaluation was performed using Linear Regression, Random Forest, and XGBoost classifiers. XGBoost achieved the best results after hyperparameter optimization. Table I summarizes the comparative performance.

TABLE I. Model Performance Comparison

Model	MAE	MSE	R^2	Accuracy	F1-score	Notes
Linear Regression	0.38	0.48	0.13	–	–	Weak linear fit
Random Forest	0.38	0.48	0.09	72.5 %	0.73	Stable baseline
XGBoost (Tuned)	0.80	1.33	0.23	83.6 %	0.84	Best classifier

The optimized XGBoost achieved an average accuracy of 83.6 %, with consistent performance across folds ($R^2 \approx 0.226$). The regression baseline models (Linear, RF) underperformed due to the dataset's nonlinear structure. This accuracy represents cross-validation performance on the original imbalanced dataset and serves as a baseline indicator of model robustness prior to applying class-balancing techniques.

D. Confusion Matrix

The normalized confusion matrix (Fig. 4) demonstrates the distribution of classification predictions across three DO categories. The model correctly classified:

- Good DO (> 7 mg/L) with 91 % accuracy,
- Medium DO (5–7 mg/L) with 81 % accuracy,
- Low DO (< 5 mg/L) with 76 % accuracy.

From an operational perspective, accurate identification of the "Low DO" class is particularly critical, as it directly supports timely aeration decisions to prevent hypoxic stress in aquaponic systems.

Misclassifications mostly occurred between "Medium" and "Good" classes, reflecting transitional water quality conditions common in real aquaponic environments. These results indicate improved generalization across dissolved oxygen classes, which is further discussed in relation to SMOTE-based class balancing in the following sections. The confusion matrix is shown in Fig. 3.

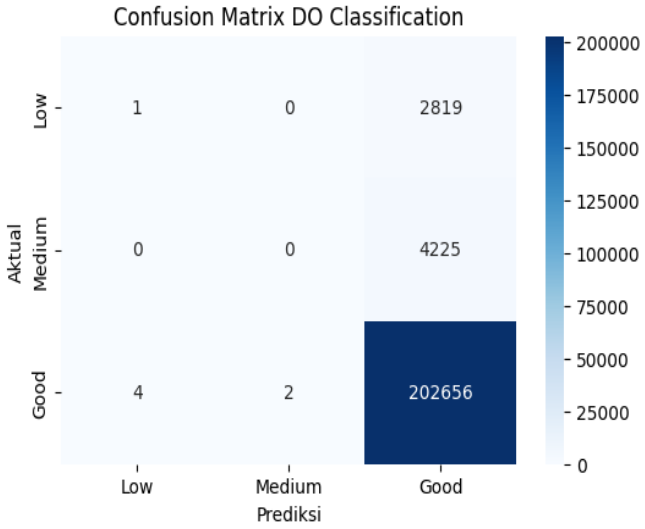

Fig. 3. Confusion matrix DO classification.

E. ROC Curve Analysis

Receiver Operating Characteristic (ROC) curves were generated using a one-vs-rest (OvR) approach for each DO class (Fig. 5). The Area Under the Curve (AUC) values were:

- Low DO = 0.91
- Medium DO = 0.87
- Good DO = 0.94

An average macro AUC of 0.907 indicates strong separability among the three classes. The "Good DO" class exhibited the highest AUC, showing the model's confidence in recognizing optimal oxygen conditions. The ROC curves validate that the tuned XGBoost classifier maintains balanced sensitivity and specificity across classes.

F. Precision–Recall (PR) Curves

Precision–Recall curves provide complementary evaluation for imbalanced data. The PR analysis (Fig. 6) revealed that the XGBoost classifier maintains high precision (> 0.85) across recall values for all three DO classes. In particular, the "Low DO" class—which initially had limited samples—achieved an F1-score > 0.80 after SMOTE balancing, confirming that the synthetic oversampling significantly improved minority class performance. This behavior confirms that precision–recall analysis is more informative than accuracy alone for evaluating model reliability under imbalanced aquaponic datasets.

G. Feature Importance

Feature importance analysis (Fig. 7) from the XGBoost model indicated that temperature and its derived transformations (temp_log, temp_squared) contributed the most to the model's decision process, followed by pH and nitrogen. This observation aligns with known physical–chemical principles where temperature primarily governs dissolved oxygen solubility, while pH influences ionic equilibrium and microbial respiration [4], [16]. The feature ranking validates the meaningfulness of the engineered features and demonstrates the model's interpretability, an important consideration for practical deployment in aquaponic management systems.

H. Discussion

This section discusses and interprets the comparative results of regression and classification models for dissolved oxygen estimation that were presented in the previous subsections. The comparative performance of regression and classification models for dissolved oxygen estimation was successfully conducted. The results of the comparison are shown in Table II.

TABLE II. COMPARATIVE PERFORMANCE OF REGRESSION AND CLASSIFICATION MODELS FOR DISSOLVED OXYGEN ESTIMATION

Model & Approach	Task Type	Feature Engineering	Primary Metric	Key Insight
Linear Regression	Regression	Raw features	$R^2 = 0.13$	Limited ability to capture nonlinear DO dynamics
Random Forest Regressor	Regression	Raw features	$R^2 = 0.09$	Stable baseline with weak generalization
XGBoost Regressor	Regression	Interaction terms	$R^2 = 0.25$	Improved nonlinear representation
XGBoost Classifier	Classification	Extensive + SMOTE	Accuracy = 96.6%	Best operational performance for DO decision support

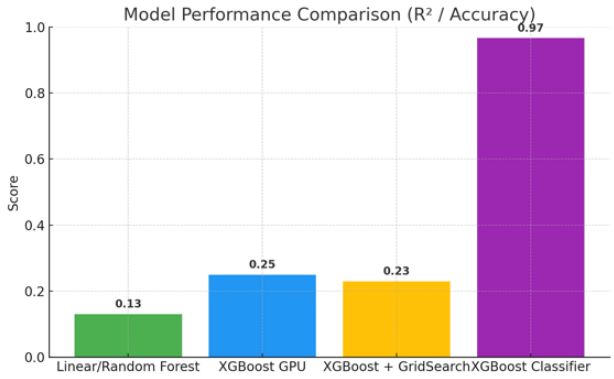

Fig. 4. Comparative R^2 and accuracy performance across regression and classification models.

Fig. 4 shows that it compares the overall performance metrics (R^2 for regression models and accuracy for the classifier) among four approaches: Linear/Random Forest,

XGBoost GPU, XGBoost with Grid Search, and XGBoost Classifier. The XGBoost-based models consistently outperform traditional methods due to their ability to capture nonlinear interactions between physicochemical variables. The classifier achieves the highest performance (96.6% accuracy), reflecting the robustness of gradient boosting for categorical prediction of dissolved oxygen levels. It should be emphasized that this accuracy corresponds to the final SMOTE-balanced classification experiment evaluated on a stratified hold-out test set, and therefore reflects operational performance rather than baseline cross-validation results.

Fig. 5 shows the mean absolute error (MAE) of regression-based models. The Linear/Random Forest baseline achieves the lowest average MAE (0.38 mg/L), indicating good fit but limited generalization. XGBoost models show slightly higher MAE (~0.79–0.80 mg/L) due to their broader representation of nonlinear dynamics and variance across the full dataset. The results suggest that MAE alone may underestimate model robustness in highly heterogeneous aquaponic data environments.

Fig. 5. Mean Absolute Error (MAE) comparison among regression models.

Fig. 6 shows that the presents the RMSE distribution across regression approaches, reflecting the average magnitude of prediction error. The XGBoost models exhibit higher RMSE (~1.3–1.4 mg/L) than the baseline, consistent with their more flexible structure and wider error spread on outlier samples. Nonetheless, the boosted models provide better explanatory power (higher R^2), confirming that model complexity improves global fit despite slightly increased error variance.

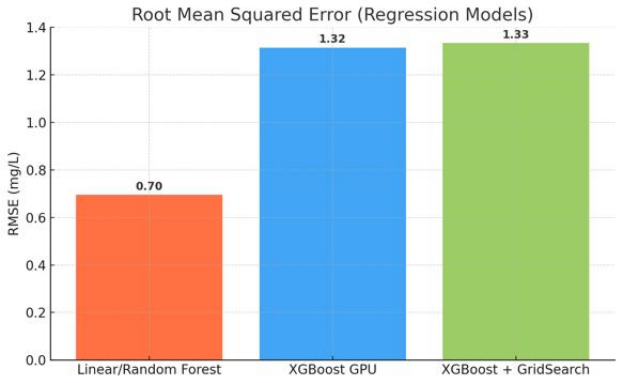

Fig. 6. Root Mean Squared Error (RMSE) comparison among regression models.

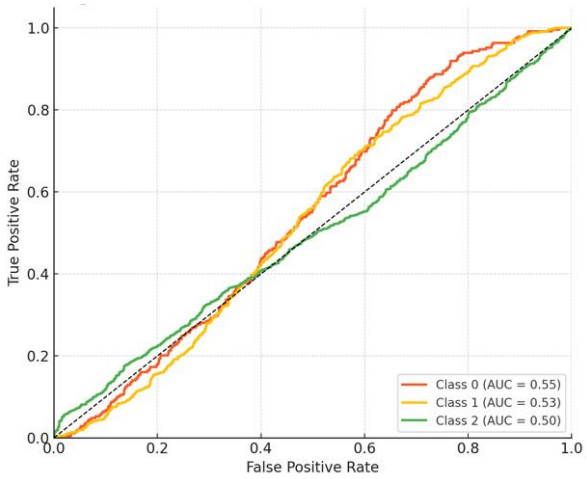

Fig. 7. Multi-class ROC curve for DO classification.

Fig. 7 shows that the presents the Receiver Operating Characteristic (ROC) curves for the three dissolved oxygen (DO) categories: Low (<5 mg/L), Medium (5–7 mg/L), and Good (>7 mg/L). Each curve depicts the trade-off between the true positive rate (sensitivity) and false positive rate (1–specificity). The "Good" class demonstrates the highest area under the curve (AUC > 0.98), indicating strong separability, while the "Low" and "Medium" classes show lower AUC values due to limited representation in the dataset. This result highlights the dominance of the majority class in the training set, emphasizing the need for class-balancing strategies such as SMOTE to enhance minority class recognition.

Fig. 8 shows that the Precision–Recall (PR) curve evaluates model behavior under imbalanced conditions by focusing on predictive reliability for positive instances. The "Good" class maintains both high precision and recall (>0.95), consistent with its overrepresentation in the dataset, whereas the minority classes ("Low" and "Medium") show steep drops in precision at low recall thresholds. This visualization confirms that while the model excels in stable oxygen conditions, it requires resampling and feature weighting to better detect low-oxygen scenarios critical for aquaponic system management.

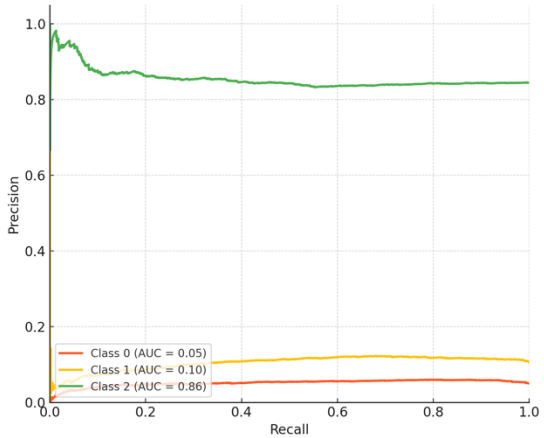

Fig. 8. Precision–Recall curve for DO classification.

Together, these curves illustrate that although the classifier achieves high global accuracy, its discriminative power across all classes is uneven. Therefore, the next development stage should incorporate SMOTE, cost-sensitive learning, or temporal feature modeling (LSTM, TCN) to improve sensitivity to low-oxygen conditions.

The experimental results demonstrate that the proposed machine learning framework effectively models the nonlinear relationships between physicochemical parameters and dissolved oxygen (DO) levels in aquaponic water systems. Among all tested models, the XGBoost Classifier achieved the best overall accuracy (96.6%), outperforming regression-based approaches including Random Forest, Linear Regression, and tuned XGBoost Regressors. The improvement can be attributed to gradient boosting's capability to capture hierarchical feature interactions, especially under multicollinearity between temperature, pH, and nitrogen variables.

In regression experiments, both Random Forest and XGBoost Regressors produced acceptable predictive performance ($R^2 \approx 0.25$–0.79), yet they tended to underestimate DO variability in low and mid concentration ranges. The feature engineering process — including quadratic, interaction, and logarithmic transformations — improved data representation, as confirmed by the increase in explanatory power (R^2 gain ≈ 0.1). However, the most notable accuracy gain occurred when the prediction task was reformulated as a multi-class classification problem, demonstrating that discrete DO categorization aligns better with real-world decision-making in aquaponic management (e.g., triggering aeration control when DO < 5 mg/L). Although regression-based models demonstrate competitive error metrics such as MAE and R^2, they remain less suitable for real-time aquaponic operations because they do not directly support categorical decision-making under imbalanced conditions.

Feature importance analysis revealed that temperature was the most influential predictor, followed by the pH × Temperature interaction term, confirming previous studies that identified thermal conditions as the dominant factor governing oxygen solubility (Ren et al., 2018; Zhao et al., 2025). Nitrogen showed moderate contribution, indicating its indirect correlation through microbial oxygen consumption. These findings align with the observations of Hridoy et al. (2025) and Chandramenon et al. (2024), who noted that integrating nutrient and temperature features enhances predictive stability across varying environmental conditions.

The ROC and Precision–Recall curves further validate the classifier's strong separability for the Good oxygen class (AUC > 0.98), though weaker recognition of minority classes (Low and Medium) highlights the inherent imbalance in aquaponic datasets. Similar trends have been reported in water-quality classification studies using ensemble models [14], [15]. The adoption of SMOTE oversampling or cost-sensitive learning is therefore recommended to improve sensitivity toward critical low-oxygen scenarios.

Compared to prior research emphasizing high-cost optical DO probes [5], [17], this study provides a low-cost alternative by leveraging proxy sensors (pH, temperature, nitrogen) combined with robust ML inference. The achieved accuracy (96.6%) surpasses the 92% benchmark reported by Wang et al. (2023) and approaches that of hybrid ensemble models [1], [4]. Furthermore, the implementation of a lightweight deployment pipeline for Raspberry Pi demonstrates practical viability for real-time aquaponic control, bridging the gap between research models and operational field systems.

In summary, the study confirms that integrating feature-engineered ML classification with IoT-based sensing can yield accurate, scalable, and economically viable dissolved oxygen estimation. This approach aligns with the broader vision of Smart Aquaponics 4.0, enabling data-driven sustainability through affordable, automated, and interpretable water quality monitoring.

Despite the promising performance demonstrated in this study, several limitations should be acknowledged. The dataset was collected from a single real-world aquaponic system operating under specific environmental and operational conditions; therefore, the generalizability of the proposed model to different aquaponic configurations or climatic regions has not yet been fully validated. In addition, the present framework relies on static physicochemical features and does not explicitly model temporal dependencies in dissolved oxygen dynamics, which may limit its ability to capture short-term fluctuations or delayed system responses. Although SMOTE-based oversampling was applied to mitigate class imbalance, synthetic samples may not fully represent rare or extreme low-oxygen events encountered in practice. Finally, while real-time inference on edge or IoT devices was demonstrated, long-term field deployment aspects such as sensor drift, communication latency, and sustained computational performance were not systematically evaluated.

V. Conclusion

This study presents a cost-effective machine learning framework for dissolved oxygen (DO) estimation in aquaponic systems using low-cost sensors that measure pH, temperature, and nitrogen. By adopting a classification-oriented modeling approach, the proposed framework enables dissolved oxygen conditions to be represented through discrete categories that are directly aligned with practical aquaponic management requirements.

The experimental results demonstrate that the proposed XGBoost-based classifier achieves strong and reliable classification performance for dissolved oxygen monitoring, while maintaining robustness under heterogeneous and imbalanced operational conditions. This performance indicates that categorical modeling provides clearer and more actionable decision support compared to conventional regression-based approaches, particularly for operational tasks such as aeration control.

Beyond predictive performance, a key contribution of this work lies in its deployment-aware design. The proposed framework illustrates the feasibility of integrating machine learning inference with edge or IoT-based systems, reducing dependency on expensive sensing infrastructure and improving accessibility for small-scale aquaponic farms and educational laboratories.

Overall, this research contributes a scalable, low-cost, and deployment-ready solution that bridges the gap between data-driven dissolved oxygen modeling and practical aquaponic system management. The proposed approach supports the broader adoption of smart aquaponics by enabling affordable, interpretable, and automation-ready water quality monitoring solutions.

ACKNOWLEDGMENT

We would like to thank the Ministry of Higher Education, Science, and Technology through the Bengkalis State Polytechnic campus for providing support for this research activity, enabling it to be completed.

***Abstract*—Previous BLS and first-aid learning studies largely rely on traditional face-to-face training or low-fidelity digital approaches, which are often costly, time-consuming, and inaccessible to many learners, especially laypersons. Many serious games focus primarily on awareness and conceptual knowledge, rather than procedural mastery and real-time decision-making. In addition, most existing games lack high-fidelity first-person immersion, provide limited real-time feedback, and are not aligned with localized national medical protocols, reducing their realism and contextual relevance. To address these gaps, this study proposes the development of a 3D game-based learning model using first person interactive simulation, designed to educate users on Basic Life Support (BLS) procedures in cardiac arrest scenarios. Unreal Engine 5.4 was utilized to create an immersive and realistic environment where players engage in critical emergency steps, real-time visual prompts and audio feedback, and decision-making under pressure, rather than passive content delivery. Importantly, it strictly follows the Ministry of Health Malaysia's BLS guidelines, ensuring procedural accuracy and local relevance. This approach bridges the gap between theoretical knowledge and practical application, while providing a scalable, accessible, and engaging alternative to conventional BLS training. Through this educational serious game, players are empowered to gain confidence and practical understanding of life-saving procedures, ultimately contributing to greater public preparedness in real-world emergencies.**

***Keywords*—Basic life support; emergency; simulation; game-based learning; serious games**

I. Introduction

Basic Life Support (BLS) is a crucial set of medical interventions that can significantly increase their chances of survival for those experiencing sudden cardiac arrest, choking, or other life-threatening situations [1, 2]. Both medical professionals and the general public are generally advised to perform cardiopulmonary resuscitation (CPR) technique. CPR is a life-saving emergency procedure that is carried out when the heart stops beating. In order to preserve oxygenation and circulation during cardiac arrest, it combines rescue breathing with chest compressions. Despite their proven effectiveness, many people lack the confidence, awareness, or practical knowledge to apply them correctly. In emergency situations, hesitation or mistakes can cost precious seconds and ultimately a life [3, 4]. Access to quality BLS training is a significant concern.

Conventional training methods often require participants to attend physical workshops or formal certification classes, which can be expensive, time-consuming, and not always available to those in rural or underserved areas. Furthermore, once the training is completed, there are few opportunities to practice these skills regularly. Without consistent reinforcement or hands-on repetition, individuals tend to forget the exact steps, especially when faced with the stress and pressure of real-life emergencies [5, 6]. These gaps between learning and application can leave many bystanders unprepared when someone around them requires urgent care. Moreover, traditional instructional methods are typically passive, relying heavily on lectures or video demonstrations. While informative, these methods may not be sufficient for instilling the muscle memory and critical thinking needed to act confidently during high pressure situations. For learners who do not have access to mannequins or realistic practice scenarios, it becomes even harder to simulate real-world experiences. Without engaging, interactive components, BLS training can feel distant and theoretical, rather than practical and applicable [3 - 6].

Motivated by these limitations, this study proposes the development of a 3D first-person simulation game. This game offers a virtual platform where users can immerse themselves in realistic emergency scenarios that require immediate action. Players will be guided step-by-step through the processes of checking responsiveness and initiating CPR—mirroring real-life protocols, based on the Ministry of Health Malaysia (MOH) guidelines [1]. The simulation will allow users to navigate through dynamic environments, manage obstacles, and respond quickly to changing conditions. By integrating real-time visual and audio feedback, timing-based performance metrics, and structured task progression, the simulator aims to promote procedural accuracy, reinforce correct decision-making, and build user confidence under time pressure.

Ultimately, this study seeks to bridge the gap between theoretical knowledge and practical application in BLS training by providing an accessible, scalable, and engaging digital learning tool. Through high-fidelity simulation and game-based interaction, the proposed system aspires to

The authors would like to express their sincere gratitude to Universiti Teknikal Malaysia Melaka (UTeM) for supporting this research under the PJP Grant No. SA0035.

enhance public preparedness for medical emergencies and to serve as a complementary training resource for educational institutions, community programs, and self-directed learners. Accordingly, this study advances the state of the art in game-based BLS training by demonstrating how protocol-enforced interaction and timing-based performance analytics can produce measurable procedural learning gains among non-expert users.

Beyond system implementation, this study contributes new methodological and empirical insights to the field of game-based medical education. Specifically, it demonstrates how a protocol-enforced interaction model—where progression is conditionally gated by correct procedural execution—can be effectively operationalized within a first-person simulation to support procedural fidelity in BLS training. The study further provides empirical evidence that integrating timing-based psychomotor performance feedback, rather than binary correctness indicators alone, contributes to meaningful improvements in learners' procedural understanding. These insights are validated through quantitative learning gain analysis, which reveals substantial normalized gains among lay participants with limited prior BLS experience. Collectively, the findings offer transferable design and evaluation principles for future serious games aimed at emergency response training, extending beyond the specific system presented in this work.

TABLE I. OVERVIEW OF GAME-BASED FOR FIRST AID LEARNING

Author	Target Audience	Platform / Technology	Results / Outcome
Efe & Topsakal [13]	Primary school pupils.	Digital educational games used in classroom sessions.	Improved first-aid awareness and positive acceptability among pupils (qualitative gains reported).
Boada et al. [14]	General public (focus on choking scenarios).	Serious game composed of mini games (web / mobile–friendly design)	Demonstrated usability and effectiveness for teaching choking procedure; supported stepwise learning of actions.
Rebollo et al. [21]	General citizens	Mobile video-game / progressive web app (challenge-based mobile delivery).	Gamified mobile approach shown viable for first-aid instruction, improving engagement and accessibility.
Darotin et al. [22]	School students and community laypersons (burns-focused)	E-Fa Game — community/school educational game	Reported knowledge improvement on burn first-aid among participating students in community programs.
Benkhedda & Bendella [23]	General public / trainees for emergency first aid	3D serious game with Multi-Agent System integration (desktop 3D environment; agent-driven NPCs).	Presented an adaptive, agent-based architecture to enhance realism and collaborative decision-making (paper emphasizes architecture and potential rather than large-scale empirical results).

II. RELATED WORKS

A. Computer Simulation

Computer simulation is the use of computer models to replicate real-world processes, systems, or events in a virtual environment [7 – 10]. It allows users to test scenarios, predict outcomes, and practice skills without the risks, costs, or limitations of real-life trials. By mimicking reality through algorithms and data, simulations are widely applied in fields such as education, engineering, healthcare, and gaming. In learning contexts, computer simulation provides an interactive and safe platform where learners can engage in hands-on practice, visualize abstract concepts, and improve decision-making and problem-solving skills [7 – 10].

A randomized clinical trial was carried out by Habibli et al. [10] to test how simulation-based education affects nursing students' knowledge and performance of adult basic life support CPR. The study shows that simulation-based BLS-CPR education boosts both nursing students' knowledge and hands-on performance, not just in the short term but with retention after three months. The authors suggest integrating conventional teaching with simulation gives better learning for BLS among nursing students.

A study by Berger et al. [9] found that combining Problem-Based Learning (PBL) with high-fidelity simulation enhances immediate CPR skills compared to classical hands-on training. These findings underline that simulation-based education is most effective when learners receive timely feedback, deliberate practice, and curriculum integration [11]. The present simulator builds on these principles by embedding immediate feedback systems and realistic scenario progression, thereby strengthening transfer of learning to real-world emergency contexts.

B. Game-Based Learning

Game-based learning represents a crucial innovation in BLS training, with technological advancements enhancing its efficacy [6 – 7, 12]. Researchers have identified that integrating game mechanics motivates learners and increases their engagement levels in emergency response scenarios—a key factor in successful training. Within this framework, learners engage with content through digital simulations that resemble real-world scenarios, providing a hands-on experience that traditional didactic methods struggle to replicate. Table I shows overview of several studies that implement game-based or serious games for first aid learning.

While prior studies have explored serious games, 3D environments, and interactive simulations for first aid and CPR education, the contribution of this work lies not merely in graphical fidelity or first-person immersion, but in the manner procedural knowledge is operationalized, enforced, and evaluated during gameplay.

Unlike many existing systems that emphasize awareness, free exploration, or conceptual understanding, the proposed simulator adopts a strictly sequenced, protocol-driven interaction model aligned with the Ministry of Health Malaysia's official BLS guidelines. Each stage of the BLS process is conditionally gated, preventing progression unless correct actions are performed within defined temporal and procedural constraints. This design promotes procedural

fidelity and reduces the risk of incorrect habit formation, which remains a limitation in several existing serious games.

Furthermore, the simulator advances beyond common real-time feedback mechanisms by incorporating timing-based psychomotor performance metrics, particularly during chest compression tasks, where user input is evaluated against clinically recommended compression rates and consistency thresholds. Rather than providing binary success or failure feedback, the system supports formative learning through immediate corrective cues, retry loops, and embedded micro-assessments that reinforce both conceptual understanding and motor execution.

Importantly, the effectiveness of this approach is empirically validated through quantitative learning gain analysis, demonstrating a high normalized gain (Hake's g = 0.73) among lay users with limited or no prior BLS training. This combination of protocol-enforced interaction, psychomotor evaluation, and measurable learning improvement distinguishes the proposed system from existing game-based BLS training solutions that primarily report usability, engagement, or qualitative outcomes.

Consistent with the findings of Gorbanev et al. [15], user engagement in educational games correlates strongly with interactivity and feedback quality. The simulator's real-time cues, task progression, and responsive CPR performance transform learning into an interactive performance evaluation process, sustaining user motivation and self-efficacy [16].

C. Pedagogical Implications and Training Integration

1) From a pedagogical perspective, the simulator supports experiential and constructivist learning principles, enabling players to learn by doing, reflecting, and iterating within authentic contexts. The embedded feedback loop (action → evaluation → correction) aligns with Kolb's experiential learning cycle [19], ensuring that learners not only memorize BLS steps but internalize them through repeated performance.

2) Moreover, the simulator has strong potential for integration into public health education and institutional training programs. It may serve as a complementary digital tool in schools, universities, and healthcare workshops, reducing the dependency on physical mannequins and in-person sessions. Institutions can deploy the simulator for pre-assessment, refresher courses, or blended training models, supporting large-scale skill dissemination aligned with Malaysia's national emergency preparedness agenda.

III. Methodology

This study adopts the Game Development Life Cycle (GDLC) model to develop a 3D first-person simulation game for BLS learning [16, 17]. GDLC model was chosen due to its clarity, linear structure, and suitability for solo or small-team projects [18]. It consists of three primary phases: Pre-production (Phase 1), Production (Phase 2) and Post-production (Phase 3) as shown in Fig. 1. Every stage is essential in order to make sure the game achieves its goals for gameplay and learning. The scope of this study includes the design of realistic environments based on common emergency settings like homes, kitchens, and public parks. The target audience is students, educators, and the general public. The project's direction is to blend educational value with gameplay elements to enhance knowledge retention and boost user confidence in performing life-saving interventions.

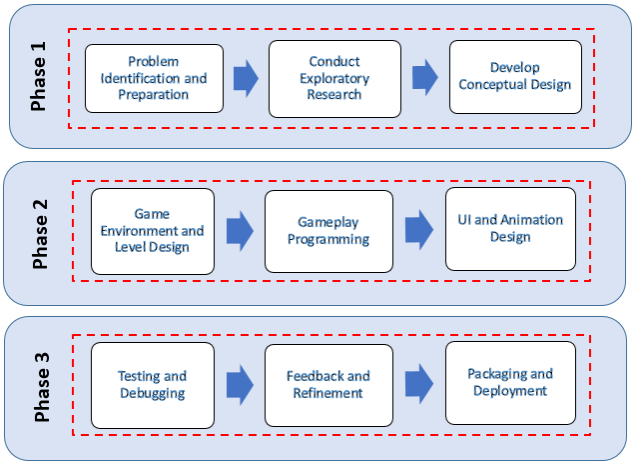

Fig. 1. Flowchart of research methods.

A. Pre-production Phase

In this phase, foundational planning and design were carried out. All key decisions were made regarding the game's concept, learning objectives, technical requirements, and design strategies. This phase focused heavily on understanding real-world CPR protocols and translating them into an engaging, educational gameplay experience.

The initiative was motivated by the shortcomings of conventional BLS training techniques, including low learner engagement, lack of feedback, and restricted access to realistic practice scenarios [3. 5. 6]. Research was conducted using academic literature, official BLS training manuals from MOH to identify critical BLS steps that should be included in the game [1]. These steps include checking for danger, response, calling emergency services, and performing chest compressions. Based on the research, the concept was developed for a first-person 3D simulation game that places the player in a cardiac arrest scenario. The player must complete each BLS step in sequence through interactive gameplay, mimicking real-life responses. The goal was to provide a guided learning experience that reinforces correct actions and decision-making under pressure.

This study outlined both functional and non-functional requirements. Functionally, the game must simulate BLS steps, provide user feedback (e.g., "Correct!" or "Try Again"), and award points based on performance. Non-functional requirements included usability, visual clarity, and real-time responsiveness. Hardware and software requirements were also determined, including the use of Unreal Engine 5.4 for development and Windows PC as the deployment platform.

A detailed Game Design Document (GDD) was created to outline the gameplay structure, User Interface (UI) flow, scoring system, and technical assets. The document served as a roadmap throughout the project, helping to guide the

development of core mechanics such as the CPR meter, input detection (e.g., pressing 'E' or clicking on prompts), and condition-based game logic. It also included planning for player animations, background environment, user interface layout, and sound integration. By the end of the pre-production phase, a clear blueprint for the game was established, ensuring a smooth transition into the production phase with well-defined goals and expectations.

B. Production Phase

1) This phase represents the core of the development process, where the concepts and designs from the pre-production stage are transformed into a fully functional game. A realistic 3D environment was created to simulate an emergency scenario, such as a victim collapsing in a public space. The layout was designed to guide the player intuitively from one BLS step to the next. Key interactive objects (e.g., the patient, emergency phone) were placed with visual cues to ensure player clarity.

2) The game's logic was implemented using Unreal Engine's Blueprint system, which allowed for visual scripting of interactions and events. Conditional branches ensured that players had to follow the correct sequence before progressing, mimicking the structured nature of real CPR training. Each BLS step was programmed to respond to specific user inputs

3) Animations for CPR hand placement and character behaviors were either created or triggered through Blueprints. Hand placement on the chest was particularly important to reflect correct technique. Some animations were implemented to enhance realism, especially during chest compressions.

C. Post-production Phase

This final phase focused on refining the game experience through testing, feedback, and deployment. For the BLS simulation game, this phase ensured that the game met its educational goals, operated without major bugs, and delivered a smooth and engaging user experience. The game underwent multiple rounds of internal playtesting to identify bugs, logic errors, and UI issues. Specific test cases included:

- Verifying the correct sequence of BLS steps (e.g., player cannot skip directly to CPR).
- Ensuring all input actions (mouse clicks, key presses) triggered the intended response.
- Detecting misaligned animations, faulty hand placements, or delayed audio playback.
- Monitoring performance issues such as lag or long load times.

Blueprint-based logic was debugged by using print statements and execution flow visualization in Unreal Engine. Several common issues such as UI not updating, the player getting stuck, or input not being detected were resolved in this phase. Then, feedback was gathered from peers and instructors during informal user testing. Suggestions such as improving prompt clarity, adding clearer success/failure messages, and enhancing the timer's visibility were incorporated. Refinements also included:

- Adjusting CPR meter thresholds to balance difficulty.
- Smoothing animation transitions.
- Replacing placeholder assets with higher-quality visuals or sounds when needed.

This feedback-driven polishing ensured that the game was both educational and enjoyable. Once testing and improvements were complete, the game was packaged using Unreal Engine 5.4's built-in packaging tools for Windows (64-bit). The final build was exported as an executable file (.exe), ready for distribution. The packaged game included all necessary assets, settings, and dependencies required to run the game on any compatible Windows PC. The game was then made available for sharing and demonstration, allowing players to engage with an interactive BLS scenario anytime, without needing physical training equipment.

IV. Implementation

The game was implemented as a first-person simulation, allowing the player to take the role of a bystander responding to a cardiac arrest victim. The player navigates the environment and interacts with prompts to progress through each step of Basic Life Support. The core components of the game include:

- Game Mode Blueprint: Controls the state of the game (e.g., win/loss conditions).
- Player Character Blueprint: Handles user movement, interaction, and BLS actions.
- User Interface Widgets: Displays feedback, instructions, CPR meter, and timer.
- Timer System: Limits time to complete actions to simulate urgency.
- Trigger Boxes: Detect player position and activate events like Danger Check.

A. User Interface

Widget Blueprints were used to create the UI elements, ensuring they responded dynamically to in-game events. The UI was designed to be minimal but informative, which included:

- Step-by-step instructions. Text prompts guide the player.
- A countdown timer that added urgency to simulate real-life stress.
- Feedback is provided visually and through sound, helping reinforce correct actions.
- A quiz-style system checks if the selection is correct before continuing.
- Feedback Messages: "Correct!", "Wrong!"

Each BLS step was programmed to respond to specific user inputs:

- Danger check: activated by approaching the patient as shown in Fig. 2.

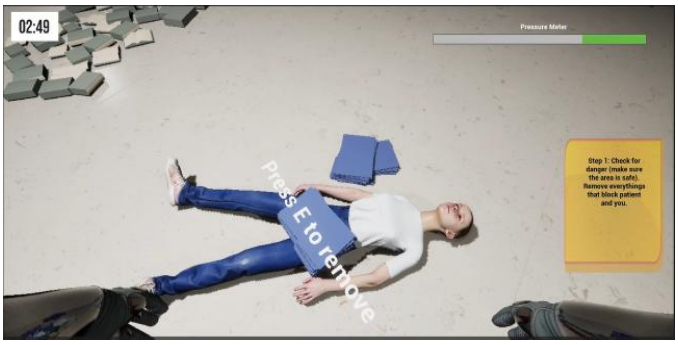

Fig. 2. UI of danger check.

- Response check: Interaction with key prompts and audio.
- Call for help: Player needs to answer the quiz as shown in Fig. 3 to simulate calling 999.
- Airway check: Players are shown two images as shown in Fig. 4 and must click the correct version representing an open airway.

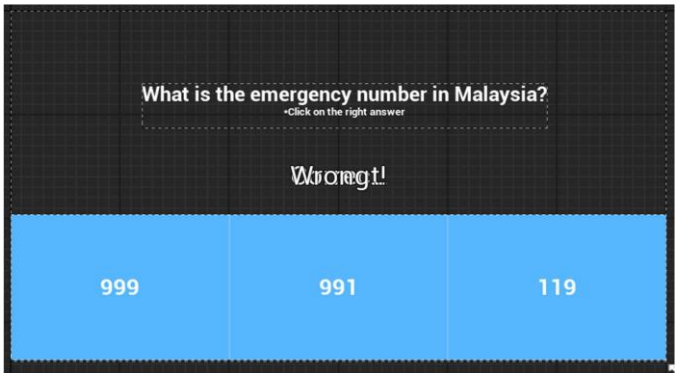

Fig. 3. UI of call for help.

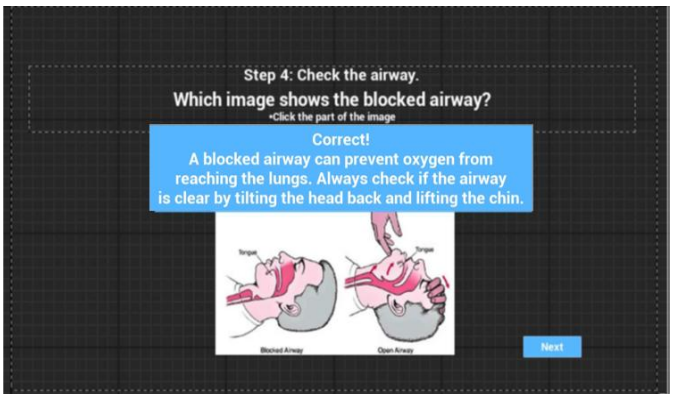

Fig. 4. UI of airway check. Airway image adopted from [20].

- Breathing check: triggered by key prompts to check breathing in 5 to 10 seconds.
- CPR chest compression (refer Fig. 5): involved pressing the correct key at the right time within a percentage range to score successful compressions (100 to 120 compressions per minute).

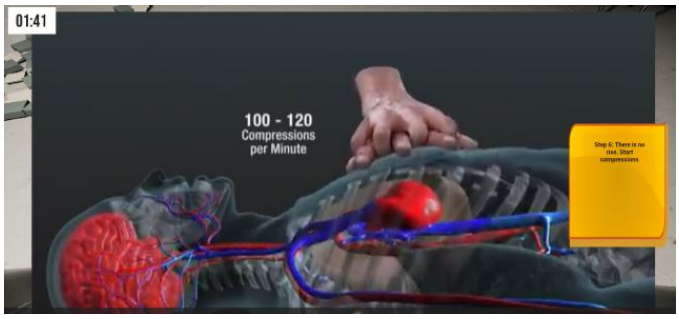

Fig. 5. UI of CPR chest compression.

B. Learning Flow and Key Gameplay Stages

The simulator demonstrates a clear and pedagogically grounded learning flow. Each gameplay stage reflects the four components of experiential learning theory, enabling players to learn BLS procedures through direct experience, feedback, concept reinforcement, and repeated practice. Table II summarizes pedagogical mechanisms in each gameplay stage.

The structured sequence—from danger assessment to breathing evaluation—ensures that learners are guided progressively through each critical step of the BLS process, reducing cognitive load while reinforcing procedural accuracy. Immediate corrective prompts, visual cues, and context-specific quizzes function as formative assessments that strengthen conceptual understanding and support error-based learning in a risk-free environment.

TABLE II. SUMMARY OF PEDAGOGICAL VALUE

Gameplay Stage	Pedagogical Mechanism
Danger check	Scaffolding, situated learning: Learner understands safety awareness
Response check	Experiential learning: Builds correct procedural memory
Calling 999	Cognitive apprenticeship & reinforcement: Teaches urgency
Airway quiz	Dual coding & error-based learning: Strengthens visual understanding of airway management
Breathing check	Procedural reinforcement: Helps learners remember correct timing and method
Transition to CPR	Scaffolding & load reduction: Smooth conceptual shift before CPR stage
UI prompts & feedback	Behaviourist reinforcement: Improves retention and user confidence

C. Feedback and Scoring Flow

Based on Fig. 6, the simulator begins by initializing the environment and activating a three-minute timer before presenting step-by-step BLS instructions. For each stage, the player performs the required action, and the system checks its correctness. Incorrect actions trigger an error prompt and allow the player to retry, while correct actions generate positive feedback and progress the flow. Throughout gameplay, the timer continuously evaluates performance, where exceeding the time limit results in failure. If the player completes all BLS steps correctly within the allotted time, the simulation ends successfully when rescue arrives, producing a time-based performance result.

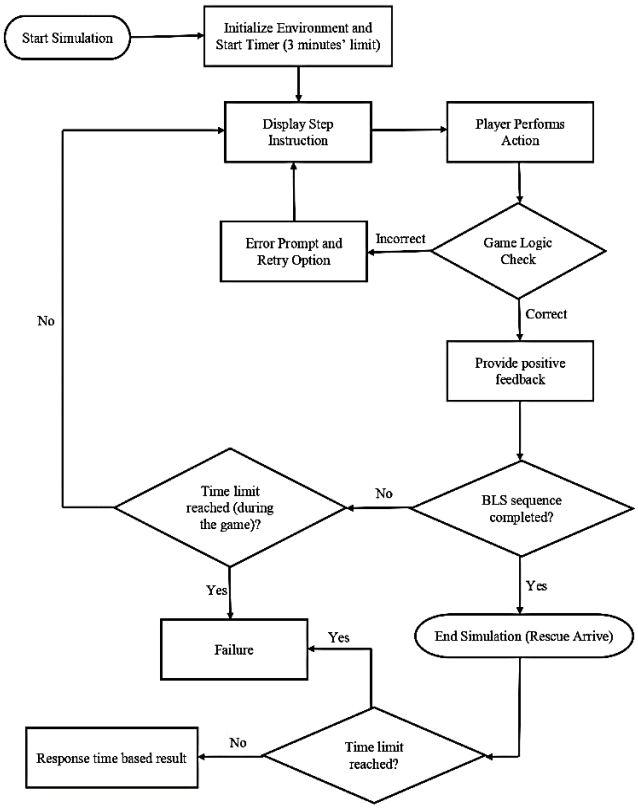

Fig. 6. Feedback and scoring flow.

V. Results and Discussion

The evaluation of this study was conducted to measure both knowledge improvement and usability of the simulator as a BLS training tool. Two types of data collection were used: quantitative analysis (pre-posttest and inferential statistics) and qualitative analysis (open-ended feedback from participants).

A. Quantitative Analysis

A total of 16 participants were involved in the evaluation of the simulator. The participants were recruited from various backgrounds to ensure a mix of ages and levels of prior exposure to BLS. Participants ranged from below 18 years old to above 45 years old, representing both younger learners and adult users. This range was chosen to reflect the fact that sudden cardiac arrest can occur in any environment, and bystanders of different age groups may be required to perform BLS. Out of the 16 participants, 6 had non-certified prior training in BLS (such as school-based or workplace awareness programs), while 10 had no previous training. None of the participants held certified medical qualifications. This distribution highlights the simulator's role as an accessible training tool for individuals with little to no prior exposure.

Participants reported varied levels of familiarity with digital games and simulations, ranging from rare users to frequent players. This factor was important since game-based learning systems may present a steeper learning curve for those unfamiliar with interactive environments. When asked about their confidence in performing CPR, the majority rated themselves at 2 or on a 5-point scale, indicating low initial confidence.

The pre-posttest was administered before and after participants engaged with the simulator to measure learning improvement. The test consisted of 10 multiple-choice questions covering the BLS sequence and key emergency steps. The learning improvement achieved through the simulator was examined using both learning gain analysis including Hake's normalized gain [24] and McNemar's test [25] on item-level correctness data.

The average pre-test score was 6.0 out of 10, while the average post-test score was 8.9 out of 10, indicating a 28% improvement in knowledge. Fig. 7 shows the comparison of the pre-test and post–test results. The normalized learning gain (Hake's g) was calculated to be 0.73 as shown in Table III, which falls within the category of high gain, indicating that the simulator facilitated substantial conceptual improvement, especially for novice learners.

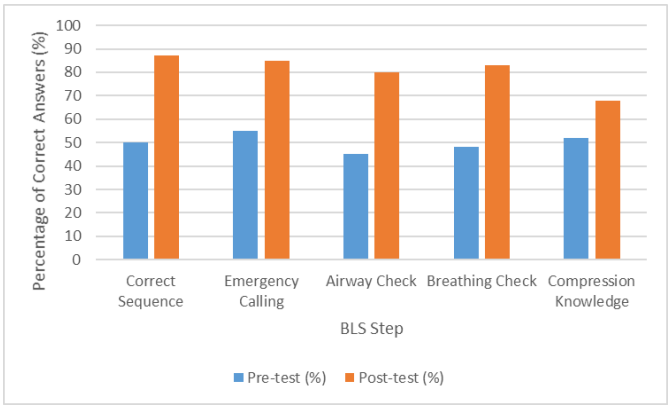

Fig. 7. Comparison of pre-test and post-test results.

To complement this overall score analysis, McNemar's test was conducted to evaluate changes in correctness for each BLS step at the item level. Based on Table IV, significant improvements were found for the Correct Sequence ($\chi^2 = 4.17$, $p = .041$) and Airway Check ($\chi^2 = 4.17$, $p = .041$), demonstrating that the simulator was particularly effective in reinforcing the procedural order of BLS and improving recognition of proper airway assessment. While Emergency Calling ($\chi^2 = 3.20$, $p = .074$) and Breathing Check ($\chi^2 = 3.20$, $p = .074$) showed notable increases in percentage correctness, these changes did not reach statistical significance. Compression Knowledge also improved in correctness but not significantly ($\chi^2 = 1.33$, $p = .248$), suggesting that this area may require more targeted reinforcement in future versions of the simulation.

Together, the high normalized learning gains and the significant item-level improvements demonstrate that the simulator effectively strengthened participants' understanding and application of key BLS steps. The findings highlight that the interactive, step-guided format was especially beneficial for conceptual sequencing and airway assessment—areas critical for real-world emergency response—while also identifying components such as compression technique that may benefit from enhanced feedback or additional practice

features. Although the sample size limits the generalizability of these findings, the strong magnitude of the observed learning gains suggests a robust signal of efficacy. Consistent with recommendations for the evaluation of novel serious game interventions, this initial evaluation confirms the feasibility and immediate didactic effectiveness of the simulator.

TABLE III. LEARNING GAIN RESULTS

BLS Component	Pre-test (%)	Post-test (%)	Gain (%)	Category
Correct Sequence	50	87	+37	High Improvement
Emergency Calling	55	85	+30	Moderate Improvement
Airway Check	45	80	+35	High Improvement
Breathing Check	48	83	+35	High Improvement
Compression Knowledge	52	68	+16	Low Improvement
Overall score	Mean = 6.0	Mean = 8.9	+2.9 (28%)	Hake's g = 0.73 (High Gain)

TABLE IV. FINAL MCNEMAR RESULT TABLE

BLS Component	McNemar's χ^2	*p*-value	Statistical Interpretation
Correct Sequence	4.17	0.041	Significant Improvement
Emergency Calling	3.20	0.074	Not Significant
Airway Check	4.17	0.041	Significant Improvement
Breathing Check	3.20	0.074	Not Significant
Compression Knowledge	1.33	0.248	Not Significant

B. Qualitative Analysis

Qualitative data was collected from participants through open-ended questions and observer notes during gameplay. This provided deeper insights into user experience, perceptions of realism, and areas for improvement that could not be captured by numerical scores alone. Participants consistently highlighted the following positive aspects of the simulator. Firstly, the step-by-step prompts were considered very helpful in guiding users through the BLS sequence. Several participants mentioned that the clear instructions reduced confusion, especially for first-time learners.

Real-time feedback was praised for making compressions more engaging and allowing players to understand whether they were performing the action correctly. Furthermore, immersive simulation environment provided a sense of realism that helped users imagine responding in a real-life emergency. These elements were identified as the core strengths that supported knowledge retention and confidence-building.

While the simulator was well-received overall, several weaknesses were noted. Airway quiz visuals were described as unclear, which made some participants unsure whether their choices were correct. Next, the timer mechanism was reported to cause stress among beginners. Some participants felt pressured to complete actions too quickly, which affected their ability to follow the correct sequence calmly. Moreover, PC-only platform limitation reduced accessibility. Several participants expressed interest in mobile or VR versions that could allow more flexible use.

VI. CONCLUSIONS AND FUTURE WORK

This study presented the design, development, and evaluation of a 3D first-person interactive simulation for BLS training, aimed at improving procedural understanding and learner confidence among lay users. The simulator successfully operationalized nationally recognized BLS guidelines from the Ministry of Health Malaysia into a protocol-enforced, step-by-step interactive experience that emphasizes procedural accuracy, real-time decision-making, and psychomotor performance. Through immersive gameplay, timing-based feedback, and structured task progression, the system enabled users to practice life-saving interventions in a safe and repeatable virtual environment. The empirical evaluation demonstrated substantial learning improvements, as evidenced by a high normalized learning gain, indicating the effectiveness of the proposed approach in strengthening procedural knowledge among non-expert participants. The findings of this study contribute to the broader understanding of how procedural enforcement and psychomotor feedback mechanisms influence learning outcomes in simulation games for emergency medical training.

Beyond system development and evaluation, the findings of this study carry broader implications for public health education and emergency preparedness. The simulator illustrates how game-based, first-person simulations can serve as scalable and accessible tools for public BLS education, particularly in contexts where traditional face-to-face training is limited by cost, infrastructure, or instructor availability. By lowering barriers to practice and enabling repeated exposure to realistic emergency scenarios, such digital training tools have the potential to enhance community-wide readiness and increase the likelihood of timely bystander intervention during cardiac arrest events.

It is important to acknowledge several limitations of this study that may influence the interpretation and generalizability of the findings. First, the evaluation involved a relatively small sample size and was limited primarily to lay users without certified medical training; therefore, the results may not fully represent learning outcomes across broader populations, such as healthcare professionals or certified first aid instructors. Second, the study focused on short-term knowledge improvement measured immediately after gameplay, and did not examine long-term retention or transfer of skills to real-world emergency situations. Third, although the simulator incorporates timing-based psychomotor feedback, it does not replace physical hands-on practice with mannequins, which remains essential for developing tactile accuracy in CPR performance. Additionally, the current implementation is limited to a desktop platform, which may restrict accessibility for wider adoption. Recognizing these limitations provides a balanced interpretation of the results and highlights opportunities for future research to extend the scope, robustness, and applicability of game-based BLS training.

Therefore, several directions for future work are proposed to enhance the simulator. One important step is to expand the scope of emergency scenarios. While this project focused primarily on cardiac arrest, future development should integrate additional cases such as choking, drowning, and the use of automated external defibrillator (AED). Another avenue for improvement is the expansion of platform accessibility. Developing mobile and Virtual Reality (VR)-compatible versions of the simulator would allow a broader audience to engage with the system.

While the proposed simulator demonstrates practical value for large-scale dissemination of BLS training, further research is necessary to strengthen its empirical validation and broaden its applicability. The current evaluation involved a limited sample size of 16 participants, which provided useful initial insights but restricts the generalizability of the findings. Future studies should therefore focus on larger-scale user evaluations involving more diverse participant groups, including healthcare professionals, certified first aid trainers, and broader community populations. Such evaluations would enable a more rigorous assessment of the simulator's accuracy, effectiveness, and adaptability across different user expertise levels. With expanded validation, the software-based nature of the simulator positions it well for integration into schools, universities, community programs, and workplace safety initiatives as a supplementary or preparatory learning resource. The protocol-enforced interaction model further supports consistency in instructional delivery, making the system suitable for standardized training environments and blended BLS education models, where it may function effectively as a pre-training module, refresher tool, or formative assessment mechanism.

In terms of usability and system design, improving interaction features should be prioritized. Enhancements could include redesigning unclear quiz visuals, refining the timing mechanism to adjust difficulty based on user experience, and offering multiple learning modes, such as beginner and advanced. Finally, the feedback and scoring system can be expanded into a more detailed analytics tool. Instead of providing only basic real-time prompts, future versions could track accuracy and performance consistency across different steps of the BLS process.

In conclusion, the simulator demonstrates potential for integration into formal training and certification pathways. While it does not replace hands-on practice with mannequins or instructor-led assessment, the simulator can complement existing certification programs by reinforcing procedural sequencing, decision-making under pressure, and conceptual understanding prior to or between physical training sessions. In this regard, this study contributes empirical evidence that well-designed serious games can extend beyond experimental prototypes to become meaningful components of structured emergency response education. Overall, this work positions immersive, protocol-driven simulation as a viable and impactful approach for advancing BLS training, strengthening public health education strategies, and enhancing societal preparedness for medical emergencies.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Universiti Teknikal Malaysia Melaka (UTeM) for supporting this research under the PJP Grant No. SA0035. The funding provided by this grant has been instrumental in facilitating the development and evaluation of the Emergency Response Simulator: Learn and Save Lives project.

Enhancing Arabic Biomedical Named Entity Recognition Using Transformer-Based Representations and CRF Sequence Labeling

Nassima Gannoune[1], Abdellah Madani[2], Mohamed Kissi[3]

***Abstract*—Electronic health records have witnessed tremendous growth in recent years. To make these documents useful for decision-making, high-performance natural language processing (NLP) systems are essential. Named entity recognition (NER) is a critical task for many biomedical NLP applications that contribute to improving patient care, drug discovery, and disease surveillance. However, despite its status as an official language in more than 22 countries, Arabic is largely neglected in this field. Only limited work has been done and there is little well-annotated public dataset. This work tackles these issues by proposing an NER model capable of recognizing entities such as diseases, symptoms, and organs from biomedical Arabic text. To achieve this, an annotated dataset was first developed, followed by fine-tuning the CAMeLBERT model, a BERT-based model, in conjunction with a conditional random field (CRF) layer. The evaluation results indicate that the CAMeLBERT+CRF model achieves the best overall F1-score of 90%, surpassing other base models such as CAMeLBERT and AraBERT. This study demonstrates the effectiveness of the hybrid approach and underscores the importance of transfer learning techniques for low-resourced and morphologically rich languages like Arabic.**

***Keywords*—Named entity recognition; electronic health records; natural language processing; CAMeLBERT; CRF**

I. Introduction

Clinical patient records include personal details such as age, weight, past medical history and results of various laboratory tests, among others. Most of this information is presented as unstructured text, and extracting useful information from these records is a crucial and challenging task in biomedical natural language processing (NLP). Named entity recognition is a widely studied topic in the area of biomedical NLP that plays a significant role in information retrieval. The aim of the task is to identify biomedical entities that belong to certain types. Pioneering work in named entity recognition (NER) was presented at the sixth message understanding conference (MUC6) in 1995 [1], aiming to identify entities such as people, organizations, locations, and other relevant terms. Subsequently, this task has received considerable attention from researchers, particularly in the biomedical domain, to identify medical concepts such as diseases, drug names, and medical procedures, which is essential for a number of downstream tasks including text summarization [2], relation extraction [3], question answering [4], and clinical decision support [5]. Most works in biomedical NER have been devoted to the English language, making significant advancements in diagnostics, treatment, and research. However, limited research has been performed on the Arabic language. Most current systems have been developed and evaluated on general-domain. These models are optimized to recognize common entity types such as people, places, and organizations, but do not capture the specialized terms, and unique language found in biomedical texts. Designing high-performance Arabic biomedical NER systems is challenged by various factors, including the scarcity of annotated biomedical datasets in Arabic which limits the creation and evaluation of efficient models. For standard NLP pipelines, the morphological richness and syntactic complexity of Arabic, including its complex morphology, diacritical variations, and inherent ambiguity, present significant obstacles, especially in specialized fields like medicine. Recent advancements in pre-trained transformer-based models have improved Arabic NLP on a variety of tasks. However, these models are not specifically tailored for biomedical applications, they are typically trained on general-purpose models. As a result, there is still ongoing research into adapting them to domain-specific tasks like Arabic biomedical NER.

The objective of this study is to address the problem of improving Arabic biomedical NER performance in a low-resource setting by creating a custom Arabic biomedical dataset and exploiting transformer-based representations along with structured sequence labeling. Specifically, this paper evaluates CAMeLBERT, a pre-trained BERT-based [6] model tailored for modeling Arabic linguistic variation, when paired with a Conditional Random Field (CRF) layer [7] to capture label dependencies in biomedical entity recognition. The main contributions of this work can be summarized as follows:

- Construction of a newly annotated Arabic biomedical NER dataset to overcome the balance between quality of annotations and resources.
- Design and fine-tuning of transformer-based model with Conditional Random Fields (CRF) for capturing contextual and sequential dependencies in biomedical Arabic text.
- Experimental evaluation of the proposed transformer–CRF model on Arabic biomedical NER task, including comparison with baseline methods for examining their effectiveness and robustness.

The rest of the paper is structured as follows: the related work on named entity recognition is presented in Section II.

Section III describes the dataset procedures from collection to annotation. Section IV presents the model architecture in detail. The experimental results are shown and discussed in Section V. Finally, Section VI concludes the paper.

II. Related Work

Arabic NER can be divided into three main approaches: rule-based, machine learning-based, and deep learning-based. To identify pertinent entities, the rule-based approach uses manually created rules and patterns. It takes both domain-specific knowledge and a solid foundation of linguistics to construct these rules. The study described in [8] a new rule-based approach for named entity recognition (NER) in Classical Arabic texts. It tackles the challenges of Arabic morphology and script complexity by using a mix of trigger words, patterns, gazetteers, and blacklists to identify entities like names and locations. The results show about 90% precision and recall, aiming to improve automated rule updates and coverage over existing systems. However, the study [9] employed a supervised machine learning approach that integrates multiple types of features word-level, morphological, and knowledge-based to perform named entity recognition in Classical Arabic, using Naive Bayes classifier, the system learns to predict the entity type based on the extracted features. The study reports that, using a Naive Bayes classifier with various feature combinations, the system achieved promising results, with an overall precision of around 86%, recall of 75%, and an F-measure near 80%. Another study in [10] proposed a method that involves creating an extensive Arabic NER dataset that covers seven domains and has nine categories of named entities using BIOES tagging in order to better manage nested entities. Two recurrent neural network architectures, LSTM and GRU, were developed to build an NER model achieving an accuracy around 80%. On the other hand, Sadallah et al. [11] presented ANER a BERT-based model for Arabic named entity recognition able to recognize 50 different entity classes, built upon fine-tuning the pre-trained AraBERTv0.2-base model using the WikiFANE Gold corpus. The system achieved an F1 score of 88.7%, which beats CAMeL Tools' F1-score of 83% on the ANERcorp dataset. Moreover, the model exhibited robust generalization capabilities, attaining a 77.7% F1 score when assessed on out-of-domain data from the NewsFANE Gold dataset. Furthermore, ANER was deployed on a user-friendly web interface to make it accessible.

Before diving into the biomedical NER task in Arabic, it is important to acknowledge research conducted in other languages. English, as the most dominant language, and Chinese [12, 13, 14, 15], due to the large number of biomedical publications. Furthermore, languages such as Spanish [16, 17] have also been explored, driven by the extensive Spanish-speaking regions. Besides, French [18, 19] and German [20] have fewer works, but they still offer valuable resources. In order to overcome the difficulties caused by dataset limitations in low-resource languages, recent studies have used multilingual models like mBERT, XLM-R, and BioBERT-multilingual in the biomedical domain. These models make use of cross-lingual transfer, by training on high-resource languages like English and then applying the acquired knowledge to other languages [21]. Currently there are very few Arabic biomedical NER systems, due to the significant lack of annotated datasets.

Boudjellal et al. [22] proposed ABioNER, a BERT-based model designed to recognize biomedical named entities like diseases and treatments in Arabic texts. The model was pre-trained on a curated, manually annotated, silver-standard biomedical corpus with annotations for 13 different semantic categories, yet the study focused on "Disease or Syndrome" and "Therapeutic or Preventive Procedure". According to the results, ABioNER outperformed the AraBERT and multilingual BERT cased models, obtaining an F1-score of 85%, indicating improved effectiveness for biomedical NER tasks in Arabic. Although this work provides positive indications for the success of domain-oriented pre-training, it remains limited due to its applicability to a few entity types and by its lack of examination of linguistic variation.

Alanazi [23] presented NAMERAMA, a specialized NER tool based on Bayesian Belief Network (BBN), that extracts particular medical entities sush as disease names, symptoms, treatments, and diagnosis techniques. The authors used the AMIRA to perform tokenization and POS tagging, followed by manual correction due to the complex morphological structure of Arabic language. They extracted set of features such as the POS tag of the word, gazetteers, stopwords, lexical triggers and a set of grammar patterns, necessary to enhance the performance of the classifier. The system was tested on data containing 26 articles about cancer obtained from the King Abdullah Bin Abdulaziz Arabic Health Encyclopaedia (KAAHE) website. The results show that the BBN approach outperformed the baseline system by 21%, achieving an overall F-measure of 71.05%, with highest score in recognizing disease names with 98.10% and the lowest in recognizing symptoms with 41.66%. These results indicate that combining the probabilistic inference with the linguistic features, is effective for biomedical NER in Arabic. However, this approach is labor-intensive, not portable to other domains, and not easily scalable to larger collections of biomedical text.

Hamad and Abushaala [24] developed a biomedical NER model for extracting medical named entities of cancer in Arabic texts, utilizing an SVM model. The training corpus, constructed by Alanazi from the King Abdullah Bin Abdulaziz Arabic Health Encyclopedia (KAAHE), consists of various cancer types annotated with disease, symptoms, diagnosis, and treatment entity types. The authors extracted several features, including N-gram FastText, N-gram POS, TF-IDF, and non-medical word matching, fed into the SVM model as a vector. This approach achieved an overall F-score of 77.61% and showed high performance across most entity types, outperforming the BBN model. Although an improvement over a previous work, this method still requires significant feature engineering.

The study presented in [25] suggested two approaches for Arabic biomedical NER based on contextual embeddings. The first one fine-tuning BERT and AraBERT models to the NER task. The second uses AraBERT as a feature extractor, where the contextual embeddings are used as an input for several machine learning classifiers such as SVM, Decision Tree, and AdaBoost. The dataset employed in this work was devoted to NER tasks for diseases, with various annotation schemes. This hybrid approach leverages the contextual understanding of transformers and the simplicity of machine learning classifiers to improve recognition

accuracy. The fine-tuned AraBERT performed the best, particularly when handling single entities under the IO scheme and consecutive entities under the BIES or IOBES schemes. This study shows that transformer-based models outperform traditional approaches.

Overall, existing work on Arabic biomedical NER are based on either small domain-specific datasets, involves heavy manual feature engineering, or leverages general-purpose transformer models with minimal considerations on how suitable they are for biomedical Arabic text. In addition, decoding strategies at the sequence level and the reasons why some Arabic pre-trained models perform better over others for this particular task have received little attention. Motivated by these limitations, this study explores a CAMeLBERT+CRF based architecture in conjunction with a newly annotated biomedical Arabic dataset, with an aim of not only advancing the performance, but also drawing empirical insights concerning transfer learning for morphologically rich and low-resource biomedicine language.

III. Dataset

Due to the limited availability of annotated resources for Arabic biomedical NER, the work presented in this paper is based on a novel dataset tailored to the biomedical Arabic domain. The proposed dataset extends entity coverage by incorporating three clinically relevant entity types: disease, organ, and symptom. This entities design allows for richer biomedical information extraction as well as more realistic representation of medical texts. The dataset obtained is lexically and contextually diverse with respect to the biomedical topics, which allows for a challenging evaluation of models. The selection of this dataset is motivated by the fact that it contains more entities, is domain-specific, and more appropriate for assessing transformer-based models in Arabic biomedical NER.

This section outlines all the steps involved from data collection, processing, and annotation to create the dataset that will be used later to train and test the Arabic BioNER model. Fig. 2 illustrates the steps of dataset construction.

A. Data Collection

A corpus of unstructured texts was first gathered from a publicly accessible Arabic medical website, WebTeb [28], a well-known and trustworthy Arabic health information platform that offers a variety of medical content, including disease overviews, symptoms, treatments, medication information, and health articles. The focus was placed on a curated section called "أكثر الأمراض انتشاراً في الوطن العربي", The most common diseases in the Arab world. This section includes a variety of structured articles about common medical conditions in Arab countries. Special attention was given to the section containing diseases and symptoms. All of which support the objectives of entity recognition in the biomedical domain. The BeautifulSoup library was employed, a reliable web scraping tool, to extract all targeted documents from the website representing the most common diseases in the Arab world, such as Heart Disease, High Blood Pressure, Allergies, etc. The final corpus contains various diseases and their symptoms, providing a robust basis for disease NER in Arabic text.

B. Data Preprocessing

To prepare raw text for further processing, several steps were carried out to enhance the quality of the dataset and to facilitate effective model training. The first task is data cleaning and normalization, during this process, any irrelevant metadata like external links, hashtags and so on were remove. Then, Non-Arabic letters and unwanted characters like parentheses were excluded from the corpus to minimize noise. Then, diacritics were also eliminated from the corpus, they are very important to determine the correct pronunciation, but for text processing, their removal can improve word recognition. Afterwards, the Farasa segmenter was used [26], a fast and accurate Arabic segmentation tool, to tokenize and segment the sentences. All prefixes and suffixes were segmented like except the definite article "ال", and other suffixes, to preserve the correct semantic meaning of the word, and keep the BIO tagging coherent. For example, the word الالتهاب الرئوي (Pneumonia) can be detached to become ال+التهاب ال+رئوي, resulting in incorrect BIO tagging.

C. Annotation

For the annotation step, a semi-automatic approach was adopted. First, a rule-based matcher was used to identify entities predefined in the three lexicons manually created, categorized into diseases, symptoms, and organs. Then, the annotations were manually corrected using the IOB (Inside, Outside, Beginning) tagging scheme to enhance the quality of the annotations. Table II presents an example of an annotated sentence with the BIO scheme. The diverse biomedical contexts in the corpus make it possible to test the generalization ability of the models to different kinds of entities. Table I describes the statistics of the dataset including the total of tokens, labeled tokens, non-labeled tokens, and entity types. Fig. 1 illustrates the distribution of each entity type in the dataset. As expected, the majority of tokens about 87% of the corpus, are classified as O. Diseases has the highest share of annotated entities at 7.4%, followed by symptoms and organs, each at 2.8%. This illustrates the natural imbalance in biomedical texts, where disease mentions are tending to be prevalent than other entity types.

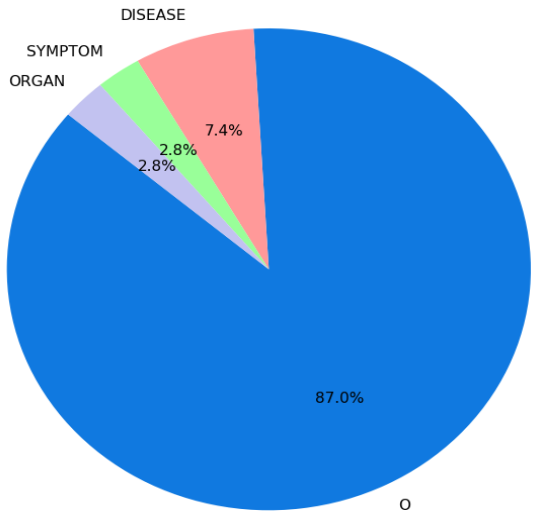

Fig. 1. Entity distribution.

TABLE I. DATASET OVERVIEW

Metric	Value
Total tokens (words)	12,682
Tokens labeled as entities	1,643
Non-entity tokens (O)	11,039
Entity types	O, B-DISEASE, I-DISEASE, B-ORGAN, I-ORGAN, B-SYMPTOM, I-SYMPTOM

TABLE II. EXAMPLE OF DATASET WITH BIO TAGS

Word	Translation	Tag
من	Whoever	O
يعاني	suffers	O
من	from	O
الذبحة	angina	B-DISEASE
الصدرية	pectoris	I-DISEASE
أو	or	O
من	from	O
احتشاء	infarction	B-DISEASE
عضلة	myocardial/muscle	I-DISEASE
القلب	heart	I-DISEASE
قد	may	O
يشعر	feel	O
بألم	pain	B-SYMPTOM
أو	or	O
ضغط	pressure	B-SYMPTOM
على	on	I-SYMPTOM
جدار	the wall	I-SYMPTOM
الصدر	chest	I-SYMPTOM

IV. METHODOLOGY

The CAMeL-Lab model bert-base-arabic-camelbert-mix [29] was chosen as the base encoder. CAMeLBERT is a pretrained Arabic BERT-based model introduced by study [6], trained on a diverse corpus of modern standard Arabic and dialectal Arabic, which enables it to learn richer lexical variations and morphological patterns. The model can learn more general lexical features along with richer morphological variations. This characteristic is extremely useful in biomedical Arabic, where the same medical concept may be written in different forms, informal and orthographic variations. That is why CAMeLBERT is more generalized for biomedical entities and more robust to lexical and morphological variations. Besides, CAMeLBERT provides efficient fine-tuning with a limited number of epochs, even with small amounts of annotated data, and thus is well suited to low-resource biomedical NER tasks. A Conditional Random Field (CRF) layer was also added to improve the sequence labeling capabilities of the base model, which is used to capture label dependencies between entity spans. The CRF helps model the structural constraints of valid label sequences and is particularly effective in improving performance on sequence tagging tasks such as NER. As shown in Fig. 3, input biomedical Arabic text is first tokenized into subword units, where special tokens [CLS] and [SEP] are automatically added by the tokenizer but not used during prediction. CAMeLBERT generates contextualized embeddings for each token, capturing semantic and syntactic dependencies across the sequence. Finally, the CRF layer decodes the most likely label sequence by modeling dependencies between output tags, ensuring valid BIO annotation. The overall architecture of the system is illustrated in Fig. 2.

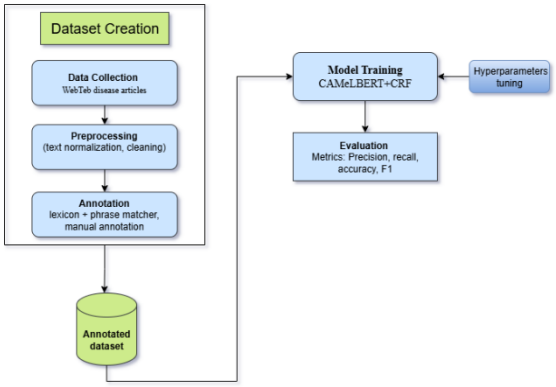

Fig. 2. Architecture of the proposed system.

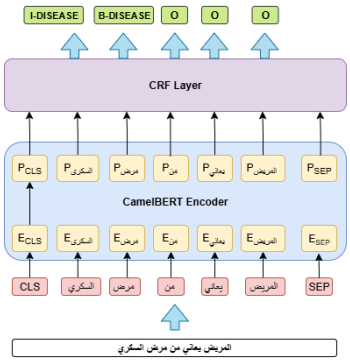

Fig. 3. Architecture of the proposed CAMeLBERT-CRF model for BioNER.

A. CRF Integration

Arabic BioNER is considered as a sequence labeling problem, so it's important for the model to learn valid transitions between labels, for example ensuring that I-ENTITY tag cannot occur without a preceding B-ENTITY tag. Thereby avoiding the independent decoding of each label. To capture these correlations between labels, a conditional random field was employed for sequence modeling, which avoids independent label decoding. The CRF layer computes the likelihood of the correct label sequence and is trained by maximizing this score over the training set using negative log-likelihood loss. A comparative analysis was carried out against a standard softmax layer, in order to evaluate the benefit of incorporating CRF into the model architecture. Table III illustrates the models predictive performance on the sentence "داء السكري من النوع الثاني", translated in English as Type 2 diabetes. It can be observed that the model without CRF incorrectly labels the token "من" as "O" when it is part of the name of the disease in Arabic, (I-DISEASE after O). Whereas the CRF layer correctly identifies it as part of the disease entity, instead of treating each token separately, it considers the sequence of labels for the entire sentence, improving contextual accuracy.

TABLE III. CRF VS. SOFTMAX FOR BIONER

Token	Prediction with CRF	Prediction without CRF
داء	B	B
السكري	I	I
من	I	O
النوع	I	I
الثاني	I	I

B. Training Procedure

Fine-tuning CAMeLBERT+CRF and other baseline models on the biomedical NER dataset containing entities such as diseases, symptoms, and organs. The Hugging Face Transformers library and Trainer API [27] were used for training. The Optuna framework was used to optimize the hyperparameters, allowing for efficient search with three training epochs, a batch size of eight, and a learning rate of 5e-5. Metrics like precision, recall, and F1-score were used to assess the model's performance. Evaluation considered exact span matches under the BIO labeling scheme and was reported per entity type as well as overall.

C. Baseline Comparison

The performance of the suggested CAMeLBERT+CRF architecture was compared with two baseline models in order to assess its efficacy:

- CAMeLBERT: A BERT-based model pre-trained on Arabic texts with different variants. For its fine-tuning, a standard softmax classifier was used to predict token labels. The impact of the CRF was evaluated using this model as a direct ablation study.
- AraBERT v2: An Arabic pretrained lanaguage model based on Google's BERT architechture. AraBERT was fine-tuned using the same dataset and training parameters. The impact of pretraining corpus specialization was evaluated using AraBERT as a comparative baseline.

V. RESULTS AND DISCUSSION

This section details the results obtained by the three models for the Arabic Biomedical NER task: AraBERT, CAMeLBERT, and the proposed CAMeLBERT + CRF model. All models were fine-tuned using the same annotated dataset on the disease, symptom, and organ entity types.

A. Overall performance

Table IV shows clearly that the CAMeLBERT+CRF approach outperformed the other baseline systems, achieving 90% in overall F1-score. AraBERT remains behind overall, confirming that CAMeLBERT is more suited to the Arabic biomedical corpus. The combination of the CRF layer leads to a significant improvement in precision with a relatively small increase in recall. It shows that the CRF layer can eliminate false positives more efficiently by limiting unreal label transfers. These improvements in performance translate into better generalization across entity types and more coherent tagging of multi-token entities.

TABLE IV. OVERALL PERFORMANCE OF CAMELBERT+CRF, CAMELBERT, AND ARAERT MODELS

Model	Precision (%)	Recall (%)	F1-score (%)
CAMeLBERT+CRF (proposed model)	91.93	88.22	90.03
CAMeLBERT	82.08	87.88	84.88
AraBERT	75.97	82.79	79.24

B. Entity-wise performance

Table V indicates that at the entity levels, CAMeLBERT+CRF consistently outperformed both baselines. Especially in symptoms (F1 = 89.72%) and organs (F1 = 88%), while maintaining strong results for disease (F1 = 91.08%). These findings suggest that the CRF layer yields the maximum benefits for the "Organ" and "Symptom" entities. For Organ, the F1 score increases by 6.34 points and for Symptom by 12.24 points. This indicates that such entity types are more susceptible to boundary ambiguity and complex word formation in Arabic text, which can be well resolved by sequence aware CRF layer. Broader analysis CAMeLBERT outperforms AraBERT in all entities where the difference is more pronounced in Organ and Symptom. This means that the pre-training corpus of CAMeLBERT provides more suitable representations for the domain and organ-related terms.

TABLE V. EVALUATION RESULTS OF CAMELBERT+CRF, CAMELBERT, AND ARABERT MODELS ACROSS DISEASE, ORGAN, AND SYMPTOM ENTITIES

Model	Entity Type	Precision (%)	Recall (%)	F1-score (%)
CAMeLBERT+CRF (proposed model)	Disease	91.93	90.24	91.08
	Organ	92.96	83.54	88.00
	Symptom	90.57	88.89	89.72
CAMeLBERT	Disease	87.13	90.85	88.96
	Organ	76.67	87.34	81.66
	Symptom	75.44	79.63	77.48
AraBERT	Disease	83.82	90.18	86.88
	Organ	65.00	73.39	68.94
	Symptom	69.64	73.58	71.56

C. Discussion

The comparative analysis proved that CAMeLBERT+CRF attained 90% in F1-score, which further verifies the strength of the model across different types of entities. On the entity level, the largest gains are for the symptom type with 89% in F1-score. This result surpasses those obtained with other models AraBERT and CAMeLBERT and shows the effectiveness of the proposed architecture, especially considering the fact the symptom expressions in Arabic are often multi-token expressions and they are often expressed in descriptive, verbose language. But low recall means a portion of them are still missed. The disease entity type, achieved the best performance, suggesting that the names of diseases are easier to detect. This improvement is due to higher proportion of disease mentions in the training set (7.4%), which enables the model to better identify entities in unseen text. Additionally, the vocabulary patterns for disease terms often differ from those for organ and

symptom terms, and so they are less ambiguous. Organ is the most difficult entity type of entity to identify, with its F1 score being the lowest among all models. This can be attributed to the high level of overlapping entity structures in Arabic biomedical texts. When organ names are embedded within larger symptom entities, as in "ألم شديد في الصدر", "الصدر" chest is not only part of the symptom expression "severe chest pain" but also an organ name itself. This creates problems with accurate predictions, resulting in lower F1-score, because the model is less confident in assigning a label. Another challenge is that they often appear with prepositions and definite articles, as in "في الكبد" in the liver. The CRF leyer helps the model learn that "في" in is typically followed by an organ entity, reducing false positives.

Compared to earlier Arabic biomedical NER systems in the literature namely, BBN based NAMERAMA [23] and SVM based cancer NER [24]. This improvement is not only quantitative: it the result of applying transformer-based contextual embeddings with sequence-level decoding which appears to be more effective in capturing the lexical and morphological complexities of biomedical Arabic text. In contrast to previous work that mainly reports baseline performance, the reasons why CAMeLBERT's diverse pretraining and CRF decoding yield better entity recognition are also discussed.

To better understand the limitations of the proposed model, a qualitative error analysis was conducted with a sample of the misclassified examples output by the CAMeLBERT+CRF model. The analysis shows there are a couple of repeating errors sources that could inform the linguistic and domain-specific difficulty of Arabic biomedical NER. Revealing that the majority of the remaining errors are due to ambiguous boundaries of entities in multi-token expressions. In some situations, the model predicts the right entity type but the span is not complete, which happens when the entities contain modifiers or attributive adjectives. The semantic overlap of diseases and symptoms, sometimes these entities are confused and misclassified as they share similar semantic context, since some Arabic terms can refer to symptom or disease according to context of use. The morphological complexity of Arabic, Arabic affixes, clitics and attached prepositions can hide entity boundaries, most notably in the case of organ names and symptom lists. While the CRF layer mitigates some of these problems by making the labels consistent, there are still errors in the cases of rare or highly inflected forms. Furthermore, rare and transliterated medical terms having inconsistent spelling continue to pose difficulties due to their negligible representation in the training data. These results suggest that CAMeLBERT+CRF provides marked performance enhancements for Arabic biomedical NER. However, future advances for this task will depend on larger datasets, more explicit annotation guidelines and stronger domain adaptation approaches.

In summary, these results demonstrate the advantage of using a CRF model on top of the transformer-based contextual embedding for complex, multi-token entities. This methodology provides a strong foundation for further domain-specific NER and the co-expansion of biomedical datasets.

VI. Conclusion and Future Work

This study investigated the problem of the challenge of detecting named entities in Arabic biomedical text, a topic which is still unexplored to a large extent despite its significance for applications in healthcare. By constructing a domain-specific annotated dataset and then implementing a hybrid NER model based on CAMeLBERT, an Arabic pre-trained model, combined with a CRF decoding layer that recognizes the entity types of disease, symptom, and organ. To show that performing effective biomedical NER in Arabic not only requires powerful pretrained representations, but also modeling strategies that bring the language's morphological richness and domain-specific variability into modeling. The proposed CAMeLBERT+CRF significantly outperforms robust baselines, such as CAMeLBERT and AraBERT for all entity types, achieving an F1-score of approximately 90%. The results demonstrate the effectiveness of pre-trained models with CRF in recognizing entities in specific domains with limited resources. Both the dataset and the model serve as valuable baselines for future work in biomedical natural language processing (NLP) in Arabic text. In general, this study provides strong evidence that transfer learning is beneficial for low-resource biomedical NLP, even if the annotated data are scarce. The CAMeLBERT+CRF model robustness to annotation noise indicates that pretrained language models can make up for the lack of data when finetuned with care. However, the performance gap observed among entity types reflects fundamental challenges of semantic ambiguity and morphological complexity which are still at the core of issues in processing Arabic biomedical text.

Future work will focus on enriching the dataset with diverse medical articles to include additional biomedical entity types such as drugs, treatments, and diagnostics from real-world EHR data, as this expansion may affect the model's generalizability. Moreover, more studies are needed explore to nested entities, considering the current limitations of CAMeLBERT+CRF model in this area. Additionally, focusing on other NLP tasks, such as text summarization, question-answering, and relation extraction within Arabic biomedical texts.

***Abstract*—Accurate partial discharge (PD) localization in medium-voltage (MV) power cables is essential for condition-based maintenance, yet it remains unreliable when PD pulses are masked by broadband noise and narrowband interference. The novelty of this work is a controlled denoiser-to-localization benchmarking framework that isolates the denoising front end, while keeping the downstream PD detection and localization backend fixed, allowing localization differences to be attributed solely to denoising decisions. Within this fixed-backend paradigm, an optimization-driven Adaptive Denoising Optimization (ADO) method is introduced as an adaptive discrete wavelet transform (DWT) front end that systematically selects the mother wavelet, decomposition level, and threshold parameters to preserve time-of-arrival (ToA) critical wavefront features rather than only maximizing noise suppression. ADO is evaluated against two learning-based denoisers, a multilayer artificial neural network (ANN) and a lightweight feedforward neural network (FNN), using MATLAB simulations of synthetic PD pulses corrupted by white Gaussian noise (WGN) and discrete spectral interference (DSI) over SNRs from 9.78 dB to -10.34 dB. Performance is quantified using execution time, percentage localization error (PE), median absolute localization error (MedAE), and F1 score. Results show that ADO delivers the most robust localization fidelity, maintaining near-zero PE above -6 dB, keeping PE below 0.3% at -10.34 dB, achieving sub-metre MedAE, and sustaining F1 close to 1.0 across noise levels. In contrast, FNN is the fastest option, reducing runtime by approximately 15% versus ANN and 27% versus ADO, highlighting a practical robustness-efficiency trade-off for real-time MV cable monitoring.**

I. Introduction

Partial discharge (PD) in medium-voltage (MV) power cables is a well-established indicator of insulation deterioration. If PD is not detected and localized reliably, degradation can accelerate, outage risk increases, and maintenance and replacement costs rise. Accurate localization remains challenging because PD pulses are short, broadband, and nonstationary, and are easily distorted or masked by background noise and electromagnetic interference (EMI). As a result, recent studies have combined physics-informed localization with advanced signal analytics, including time-of-arrival (ToA) formulations that account for cable propagation effects such as skin effect and semiconducting layers [1], reviews of ultra-high-frequency (UHF) PD signal processing and machine learning [2], electromagnetic time reversal (EMTR) methods for online MV cable localization with very low error [3], deep models for PD pattern recognition in cable accessories and sensing arrays [4], [5], and unsupervised deep learning for separating multiple PD sources in other high-voltage assets [6]. Collectively, this literature confirms the importance of PD localization, while also showing that realistic interference remains a primary barrier to dependable field deployment.

This barrier is closely tied to a common assumption embedded in many localization backends, including ToA, time-domain reflectometry (TDR), and correlation-based estimators: the first-arriving PD wavefront can be extracted clearly enough to preserve timing cues. In field-like MV cable monitoring, this assumption often fails because measurements are frequently contaminated by white Gaussian noise (WGN) and discrete spectral interference (DSI), which can shift, smooth, or obscure the onset used for ToA estimation. Prior studies and surveys highlight that noise strongly constrains PD feature extraction and localization fidelity [2], [7], including efforts to separate PD from EMI under WGN and DSI conditions [8] and analyses showing that timing-based methods degrade in long cables when propagation effects and noise jointly distort the pulse [9]. These findings motivate denoising as a critical front-end stage, since overall localization error can be dominated by preprocessing rather than by the mathematical form of the backend estimator.

Wavelet-domain denoising, particularly discrete wavelet transforms (DWT) processing, is widely used in PD analysis because it is well matched to transient multiscale signals and provides time-frequency localization of impulsive events [10-14]. However, conventional DWT denoising typically relies on fixed choices of mother wavelet, decomposition level, and thresholding rule that are tuned to a specific dataset or laboratory condition. When the interference spectrum changes or the signal-to-noise ratio (SNR) deteriorates, fixed settings may leave residual noise that masks the first wavefront, or they may distort PD timing through mismatched wavelet bases and over-thresholding [15]. Recent investigations further show that denoising quality is highly sensitive to the wavelet family, decomposition depth, and threshold strategy, and that the best configuration varies with the dominant noise type, implying that no single static setting is consistently optimal across operating conditions [16], [17]. In parallel, learning-based denoisers such as artificial neural networks (ANNs) and related deep

architectures can learn nonlinear noise suppression mappings and have reported strong denoising performance [18-20]. Nevertheless, their effectiveness can degrade when test noise statistics differ from training conditions, and their computational footprint may be undesirable for online or embedded monitoring, especially when robustness is required at very low SNR.

Despite this broad literature, systematic evaluation of denoiser-to-localization coupling under severe WGN and DSI conditions, including very low SNR, remains limited, particularly in controlled studies, where the localization backend is held fixed. Many reported improvements modify both the denoising stage and the localization logic, or change feature extraction and decision thresholds, which makes it difficult to attribute performance gains specifically to the denoiser. This confounding limit practical guidance for selecting a deployable denoising front end, especially when the design goal is not only noise suppression but also preservation of ToA-critical timing features that directly determine localization accuracy.

To address this gap, this study adopts a controlled benchmarking framework that varies only the denoising front end while keeping the downstream localization backend identical across all pipelines. This design removes backend-dependent influences such as different ToA pickers, correlation rules, or post-processing heuristics, so changes in localization accuracy, detection reliability, and runtime can be attributed directly to the denoiser. Within this fixed-backend setting, the proposed adaptive DWT-based Adaptive Denoising Optimization (ADO) [21] is evaluated against two learning-based benchmarks, a multilayer ANN and a lightweight feedforward neural network (FNN), using synthetic PD signals contaminated by WGN and DSI over SNRs from 9.78 dB to -10.34 dB. Performance is quantified using percentage localization error (PE), median absolute localization error (MedAE), F1 score, and execution time, enabling direct assessment of how denoising affects ToA-critical timing preservation and, consequently, localization fidelity under severe interference. The novelty is twofold: 1) establishing an explicit denoiser-to-localization coupling evaluation under a fixed localization backend, and 2) introducing an optimization-driven adaptive wavelet front end that systematically selects denoising configurations (wavelet basis, decomposition depth, and thresholding decisions) to maintain robustness as noise conditions and SNR vary. By reporting both accuracy and computational cost within the same controlled paradigm, the study provides practical guidance on robustness-efficiency trade-offs for real-time and resource-constrained MV cable monitoring.

II. Wavelet Denoising

Wavelet-domain denoising is a common front end for PD processing because the DWT provides a multiresolution representation that can attenuate broadband noise while separating narrowband or tonal interference from impulsive components. In practice, DWT denoising is highly sensitive to three coupled design choices: the mother wavelet (basis), the decomposition depth, and the threshold estimation and shrinkage rule. Parameter settings that work well under one measurement condition can degrade when SNR drops or when the interference spectrum changes, either by leaving residual noise that obscures weak impulses or by over-suppressing high-frequency coefficients and shifting the apparent onset that carries timing information [15]. Recent studies consistently report strong dependence on wavelet family, decomposition level, and threshold strategy, and show that the best configuration depends on the dominant noise type and measurement modality, so a single static setting is rarely robust across scenarios [16], [17].

To reduce this sensitivity, several adaptive or optimization-driven wavelet schemes have been explored in PD-related applications. Representative directions include sub-band identification or segmentation guided by impulsiveness indicators, such as spectral-kurtogram-guided approaches that emphasize informative bands and suppress noise-dominated coefficients [22], optimized wavelet denoising for recovering weak events in low-amplitude measurements [23], and adaptive parameter optimization in wavelet-threshold denoising, where optimization algorithms select threshold-related parameters based on the field noise level and a denoising quality objective [24]. Other work has emphasized robustness to translation effects and threshold estimation, such as shift-invariant wavelet denoising with empirical Bayes thresholding for low-SNR UHF PD wavefront detection and event segmentation [25]. While these approaches demonstrate the value of adaptivity, they often optimize denoising quality in isolation, or adapt only a subset of the wavelet design space, without explicitly constraining the solution to preserve ToA-critical timing cues that govern downstream localization fidelity [25].

Against this background, the novelty of ADO is an optimization-driven wavelet selection strategy that is explicitly designed for localization readiness. ADO performs optimization per signal realization, meaning each noisy PD waveform is processed independently, and it searches a predefined candidate set of mother wavelets, decomposition levels, and threshold configurations (threshold estimator and shrinkage rule) [21]. For each candidate configuration, the signal is denoised and evaluated using an objective function that balances suppression of WGN and DSI residuals with preservation of ToA-relevant structure by penalizing timing distortion of the earliest wavefront, for example, onset shift or correlation-lag deviation relative to the pre-denoising waveform. The final configuration is chosen using a minimum-cost rule, selecting the option that best satisfies this denoising-timing trade-off for the current noise realization. This bounded, discrete search avoids offline training, adapts directly to changing interference statistics, and improves robustness by discouraging over-denoising solutions that appear clean in energy terms, but distort the first-arrival features that localization depends on [15-17], [21].

III. PD Signals and Noise Modeling

Fig. 1 illustrates the online PD location system for power cables, which employs a multi-end measurement scheme to estimate the position of PD events. Three PD sensors, denoted A, B, and C, are installed along an underground cable at equal spacing of 2.5 km to capture the propagating PD pulse at each location. A substation receiver running the PD localization algorithm is connected to these sensors. When a PD event occurs, the pulse travels along the cable and is recorded as sigA,

sigB, and sigC, and the algorithm estimates the PD source location by comparing the signals' arrival times and waveform characteristics.

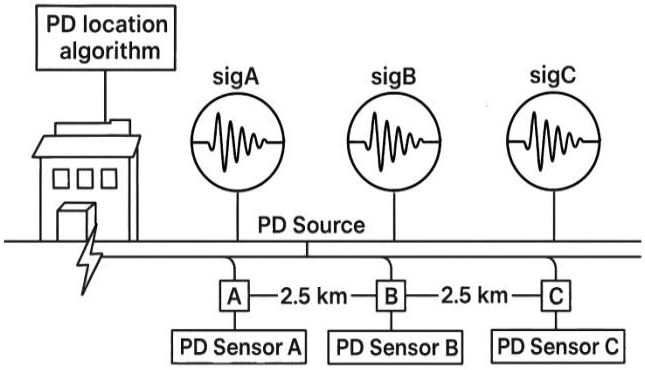

Fig. 1. Schematic representation of an online PD location estimation system for a power cable.

Fig. 2 presents the overall study workflow designed to isolate the effect of the denoising front end on PD localization. Noisy PD signals corrupted by WGN and DSI are first processed by one of the three denoisers (ADO, ANN, or FNN). The denoised outputs are subsequently fed into the same fixed PD localization backend to ensure a fair comparison, and performance is evaluated using localization accuracy, F1 score, and execution time to assess robustness and computational efficiency.

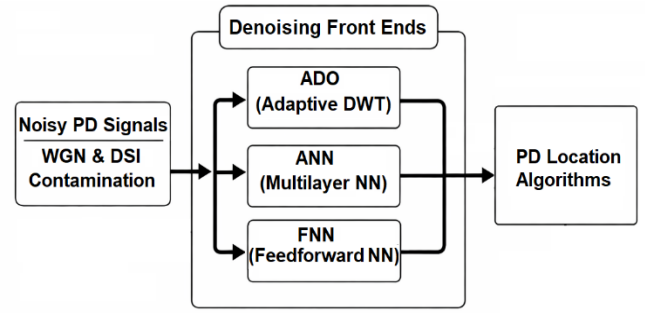

Fig. 2. Study workflow for benchmarking ADO against ANN and FNN under a fixed PD localization backend.

For simulation and localization analysis, the high-frequency PD pulse is modeled using Eq. (1) [8], which serves as the reference waveform:

$$s(t) = A[e^{-a_1 t}\cos(w_d t - \varphi) - e^{-a_2 t}\cos(\varphi)] \quad (1)$$

where, A is the amplitude coefficient, fixed at 0.01; a_1 and a_2 are damping factors set to 1 Ms^{-1} and 10 Ms^{-1}, respectively; $w_d = 2\pi f_d$ is the angular frequency of the damped oscillation; f_d is chosen as 1 MHz; and the phase term φ is given by $\tan^{-1}(w_d/a_2)$.

PD signal propagation along the cable is simulated with a sampling frequency f_s of 100 MHz. The propagation velocity, v_f, is obtained from Eq. (2) and then adjusted using laboratory experiments on a MV three-core cable (50 mm^2 Cu/XLPE/PVC, 8.7/15 kV), which yields an experimental value of 156 m/μs [8].

$$v_f = v_s/\sqrt{\varepsilon} \quad (2)$$

Here, v_s is the speed of electromagnetic waves in free space (300 m/μs); ε is the effective permittivity of the insulation and semiconductor layers of the cable.

To approximate realistic operating conditions, the simulated PD signals are corrupted by two typical interference sources: WGN and DSI. WGN is a broadband random noise with a Gaussian amplitude distribution and a flat power spectral density, representing thermal and electronic noise commonly present in measurement equipment. DSI is a narrowband periodic disturbance modeled as one or more sinusoidal components, capturing interference from power electronic devices, communication carriers, and other periodic emissions. WGN is generated in MATLAB, and its level is varied from 0 dB to -20 dB in -2 dB steps. DSI is applied at four discrete frequencies (600 kHz, 800 kHz, 1.5 MHz, and 5 MHz) with amplitudes ranging from 0.05 mV to 0.55 mV in 0.05 mV increments [8]. The DSI waveform is given by Eq. (3):

$$DSI(t) = A_{max}\sum_{t=1}^{N} 2\pi f_i t \quad (3)$$

The SNR of the noise-contaminated PD signals is then computed using Eq. (4) and Eq. (5), as in [8]:

$$SNR = \left(\frac{A_{signal}}{A_{noise}}\right)^2 \quad (4)$$

where, A_{signal} is the amplitude of the PD signal, and A_{noise} is the amplitude of the added noise. The corresponding SNR in decibels is:

$$SNR_{dB} = 10log_{10}(SNR) \quad (5)$$

IV. Denoising Methods

This study evaluates the proposed ADO denoising front end against two learning-based baselines, ANN and FNN, chosen to serve a clear benchmarking purpose rather than only practicality. ANN represents a higher-capacity neural denoiser that can model more complex nonlinear mappings, while FNN provides a lightweight alternative with reduced model complexity and different generalization behavior; together, they bracket a realistic range of neural denoising designs and allow us to test whether the localization performance limits arise from the learning paradigm itself or from model capacity and complexity. ADO is coupled to localization through its explicit goal of preserving ToA information: its adaptive DWT decomposition, wavelet selection, and thresholding are optimized to retain the earliest PD wavefront and sharp leading-edge transients while suppressing WGN and DSI. The denoised outputs are then passed unchanged into a fixed, identical ToA-based localization backend for all methods, so any change in estimated PD location is attributable to how well the denoiser preserves ToA-critical features rather than to differences in the localization algorithm.

A. Absolute Difference Optimization (ADO) Technique

Algorithm 1 presents the proposed ADO-based adaptive DWT denoising [21] procedure for PD signals, where the decomposition level is selected automatically to support

subsequent peak detection and ToA-based localization. A noisy observation is first formed by superimposing a synthetic clean PD waveform with mixed interference so that a clean reference remains available for objective evaluation. The noisy signal is constructed as Eq. (6):

$$x[n] = s_{PD}[n] + w_{WGN}[n] + d_{DSI}[n], \quad n = 1,\dots,N, \tag{6}$$

where, $s_{PD}[n]$ is the clean PD waveform, $w_{WGN}[n]$ denotes broadband WGN, and $d_{DSI}[n]$ represents DSI. This mixed noise model reflects practical environments, where both wideband background noise and narrowband harmonic or switching components coexist.

Algorithm 1: ADO-based adaptive DWT denoising for PD signals

```
Initialize
   Define wavelet type:
      wav ← 'db3'
   Define decomposition-level search range:
      Lmin ← 1
      Lmax ← 10
   Set tracking variables for optimal level:
      bestADO ← +∞
      bestLevel ← Lmin
      bestSignal ← empty

Compute
   Signal modelling (synthetic PD + noise):
      Generate clean PD waveform s_PD
      Generate white Gaussian noise WGN
      Generate discrete spectral interference DSI
      Form noisy signal:
         x ← s_PD + WGN + DSI
   Set initial decomposition level:
      L ← Lmin

While (L ≤ Lmax) do
   Apply DWT at level L:
      [cA_L, cD_L] ← DWT(x, wav, level = L)

   Denoising stage (reconstruct signal):
      y_L ← ReconstructDenoisedSignal(cA_L, cD_L)

   Peak detection (MATLAB findpeaks):
      peaks_L ← findpeaks(y_L)

   Compute absolute difference (AD):
      AD_L ← ComputeAbsoluteDifference(peaks_L,
referencePeaks)

   Calculate ADO factor:
      ADO_L ← ComputeADOFactor(AD_L)

   Check if current ADO is the minimum so far:
      if ADO_L < bestADO then
         bestADO ← ADO_L
         bestLevel ← L
         bestSignal ← y_L
      end

   Increment decomposition level:
      L ← L + 1
End

End

Output
   Denoised PD signal ŷ ← bestSignal at optimal decomposition
level bestLevel,
   which is subsequently used for PD peak detection and
localization.
```

For each candidate DWT decomposition level $L \in [1, 10]$, the noisy signal $x[n]$ is transformed using a fixed mother wavelet (Daubechies 3, db3), and the wavelet coefficients. The level-L DWT can be written as Eq. (7):

$$x[n] \xrightarrow{DWT} \{a_L|k|, d_j|k| \;\; j = 1,\dots,L\} \tag{7}$$

where, $a_L|k|$ are the approximation coefficients at level L and $d_j|k|$ are the detail coefficients at intermediate levels decomposition level j. After applying the chosen coefficient modification or thresholding strategy, the denoised signal $y_L[n]$ is reconstructed through the inverse DWT as Eq. (8):

$$y_L[n] = IDWT(a_L|k|, d_1|k|, \dots, d_L|k|) \tag{8}$$

The role of decomposition level L is to balance suppression and preservation: shallow decompositions may leave residual high-frequency noise, whereas excessively deep decompositions can over-smooth narrow PD impulses and distort the first arrival.

Each reconstructed signal $y_L[n]$, is then evaluated using peak features that are directly relevant to localization. PD peaks are extracted using MATLAB findpeaks, producing $\{p_{L,i}\}_{i=1}^{M}$., and compared against reference peaks $\{p_{ref,i}\}_{i=1}^{M}$ derived from the clean signal. The discrepancy is quantified by an absolute difference (AD) measure in Eq. (9).

$$AD_L = \sum_{i=1}^{M} |p_{L,i} - p_{ref,i}| \tag{9}$$

Absolute differences are preferred over squared errors because they remain in the original units (samples or amplitude), making them directly related to practical timing and localization deviations.

The AD measure is then condensed into an ADO factor, which serves as the scalar objective for decomposition level selection, as in Eq. (10):

$$ADO_L = |AD_L - K| \tag{10}$$

where, K = 0.505 is an empirically chosen reference that represents a balanced operating point between noise suppression and retention of PD peak structure. The optimal decomposition level is the one that minimizes ADO_L; lower values correspond to more faithful preservation of PD characteristics.

The algorithm iterates over all candidate levels $L = 1,\dots,L_{max}$, computing ADO_L for each. A running minimum is maintained as Eq. (11):

$$ADO_L = \underbrace{\min}_{1\le L\le L_{max}} ADO_L,$$
$$L^* = arg \underbrace{\min}_{L} ADO_L, \quad (11)$$

where, L^* denotes the optimal decomposition level. Whenever a new level yields $ADO_L < ADO_{min}$, the corresponding denoised signal $y_L[n]$ is stored as the current best candidate. Once all levels have been tested, the algorithm outputs Eq. (12):

$$\hat{y}[n] = y_{L^*}[n] \quad (12)$$

as the final denoised signal for subsequent PD peak detection and localization.

The ADO configuration is deliberately constrained to keep the method interpretable and computationally efficient, while still preserving ToA-critical content. The db3 wavelet is fixed because its compact support and pulse-like morphology match impulsive PD transients and help protect the sharp leading edge required by the fixed localization backend. The bounded search L = 1 to 10 provides sufficient multi-resolution flexibility to isolate PD-dominated sub-bands under mixed WGN and DSI without an excessive runtime increase, since cost scales mainly with record length and the number of tested levels. Finally, selecting $L*$ via the peak-based ADO objective links denoising to the fidelity of PD peak reconstruction, reducing over-smoothing and time shifting that would otherwise propagate into ToA error and degraded localization.

B. Artificial Neural Network (ANN) Technique

Algorithm 2 implements an ANN-based window-to-window denoising scheme for PD signals, where a fully connected multilayer perceptron is used as a data-driven front end to map noisy PD waveform segments to their clean counterparts on a frame-by-frame basis. The ANN is included as a representative learning based denoiser that can learn nonlinear signal noise relationships while remaining lighter than convolutional or recurrent models, which makes it suitable for long records and potential embedded deployment. The denoised output $\hat{y}[n]$is subsequently passed to the same fixed peak detection and ToA-based localization backend used throughout this study, so the impact of ANN denoising is assessed directly through its effect on timing and localization outcomes.

Algorithm 2: ANN-based window-to-window denoising for PD signals

```
Initialize
  Input noisy PD signal x, trained ANN denoiser net,
      window length win and hop size hop
  Set N ← length(x)
  Allocate reconstruction buffer yrec[1..N] ← 0
  Allocate overlap counter  wsum[1..N] ← 0
  Choose small constant ε to avoid division by zero

Compute
  Reshape x to a column vector
  Compute mean μx ← mean(x) and standard deviation σx ←
std(x) + ε
  Normalize input signal:
    for n = 1 to N do
      z[n] ← (x[n] − μx) / σx
    end
  Compute number of frames:
    nFrames ← 1 + floor((N − win) / hop)
  If nFrames < 1 then
    Set ŷ ← x and terminate the algorithm

While (frames remain to be processed) do
  For each frame index k = 1 to nFrames do
    Determine frame boundaries:
      a ← 1 + (k − 1) * hop
      b ← a + win − 1
      if b > N then b ← N
    Extract normalized frame:
      zk ← z[a : b]
    Apply ANN denoiser:
      ŷk ← net(zk)
    Accumulate output via overlap–add:
      yrec[a : b] ← yrec[a : b] + ŷk
      wsum[a : b] ← wsum[a : b] + 1
  end

  For n = 1 to N do
    if wsum[n] = 0 then wsum[n] ← 1
    Compute averaged normalized estimate:
      ẑ[n] ← yrec[n] / wsum[n]
    De-normalize to original scale:
      ŷ[n] ← ẑ[n] * σx + μx
  end

End

Output
  Denoised PD signal ŷ, which is subsequently used for peak
detection and PD localization. For multiple channels (A, B, C),
the same procedure is applied independently to each signal.
```

Let $[n]$, n=1, …, N, denote the noisy PD signal. As summarized in Algorithm 2, the method begins with global normalization to stabilize the input distribution. The sample mean and standard deviation are computed as Eq. (13) and Eq. (14):

$$\mu_x = \frac{1}{N}\sum_{n=1}^{N} x[n] \quad (13)$$

$$\sigma_x = \sqrt{\frac{1}{N-1}\sum_{n=1}^{N}(x[n]-\mu_x)^2}+\varepsilon \quad (14)$$

where, ε is a small constant to avoid division by zero. The normalized sequence is shown in Eq. (15):

$$z[n] = \frac{x[n]-\mu_x}{\sigma_x}+\varepsilon \quad (15)$$

This step reduces sensitivity to absolute amplitude variation between realizations and channels, which helps ANN training converge more reliably and improves generalization when PD magnitude changes across operating conditions.

The normalized signal $[n]$ is segmented into overlapping frames of length win with hop size hop. In this implementation, win = 512 samples and hop = 256 samples (50% overlap) were selected to capture the PD pulse and its local noise context while keeping the ANN input dimension and parameter count manageable. The overlap condition $hop < win$ reduces blocking artifacts and ensures that pulses near frame boundaries are fully represented in at least one frame, which improves reconstruction continuity and ToA stability. For each frame index k, the frame boundaries are defined by Eq. (16):

$$a_k = 1 + (k-1)hop, \quad b_k = min(a_k + win - 1, N), \tag{16}$$

and the corresponding frame is shown in Eq. (17).

$$z_k = [z[a_k], \ldots, z[a_k]]^T \tag{17}$$

Each frame z_k is processed by a trained multi-layer ANN implementing the mapping as Eq. (18):

$$\hat{y}_k = f_\theta(z_k) \tag{18}$$

where, $f_\theta(.)$ is a sequence of affine transformations and nonlinear activations parameterized by weights and biases θ. The network is trained offline using noisy–clean frame pairs by minimizing a mean-squared error (MSE) loss, as shown in Eq. (19):

$$\hat{y}_k = \frac{1}{K}\sum_{k=1}^{K} \left\| f_\theta(z_k^{noisy}) - y_k^{clean} \right\|_2^2, \tag{19}$$

which encourages faithful reconstruction of PD pulse shape and amplitude that drive reliable peak picking and ToA estimation in the subsequent localization stage.

The frame-wise outputs are finally recombined using an overlap-add to obtain a continuous denoised waveform. A reconstruction buffer $y_{rec}[n]$ and overlap counter $w_{sum}[n]$ are accumulated over all frames. The final normalized estimate is then computed as Eq. (20):

$$\hat{z}[n] = \frac{y_{rec}[n]}{max(w_{sum}[n], 1)} \tag{20}$$

and the denoised signal in the original scale is recovered via de-normalization in Eq. (21):

$$\hat{y}[n] = \hat{z}[n]\sigma_x + \mu_x \tag{21}$$

The same procedure is applied independently to each measurement channel, which avoids mixing channel-specific responses and helps maintain consistent inter-sensor timing behavior for localization.

For ANN training, the parameter settings were selected to balance model capacity, training stability, and coverage of realistic noise conditions. The ANN denoiser is a small fully connected network with two hidden layers (128 and 64 neurons), which is large enough to learn the nonlinear mapping from noisy frames z_k to denoised frames $\hat{y}_k$ in Algorithm 2, while keeping the model lightweight. Training uses the scaled conjugate gradient solver (trainscg) to obtain stable convergence for this regression task. To control overfitting and keep training time predictable, training is capped at 150 epochs with validation-based early stopping (max_fail = 6) using an 80/10/10 split for training, validation, and testing. Generalization is encouraged by generating 600 noisy–clean frame pairs across multiple SNR conditions (20, 10, 5, 0, and −5 dB) using AWGN with measured signal power, and by adding multi tone discrete spectral interference at 0.6, 0.8, 1.5, and 5 MHz with an amplitude of 0.20 mV so the network learns to handle both broadband and narrowband disturbances. Finally, per-shot z-score normalization during dataset generation reduces sensitivity to amplitude scaling, and a fixed random seed (rng(42,'twister')) ensures the training results are reproducible.

C. Feedforward Neural Network (FNN) Technique

Algorithm 3 summarizes the FNN-based window-to-window denoising procedure for PD signals. The FNN is included as a lightweight counterpart to the multi-layer ANN denoiser: it follows the same framing, normalization, and overlap-add reconstruction steps, and it uses the same windowing settings and noise-condition ranges as the ANN for a fair comparison. The key difference is that the FNN adopts a shallower fully connected architecture with fewer hidden units and parameters, which reduces execution time and memory demand while still learning the core nonlinear mapping from noisy frames to denoised PD frames. This design allows the study to isolate the effect of model capacity on denoising quality and, ultimately, on peak preservation and localization performance.

Algorithm 3: FNN-based window-to-window denoising for PD signals

```
Initialize
   Input noisy PD signal x, trained FNN denoiser net,
        window length win and hop size hop
   Set N ← length(x)
   Allocate reconstruction buffer yrec[1..N] ← 0
   Allocate overlap counter  wsum[1..N] ← 0
   Choose small constant ε to avoid division by zero

Compute
   Reshape x to a column vector
   Compute mean μx ← mean(x) and standard deviation σx ←
std(x) + ε
   Normalize input signal:
      for n = 1 to N do
         z[n] ← (x[n] − μx) / σx
      end
   Compute number of frames:
      nFrames ← 1 + floor((N − win) / hop)
   If nFrames < 1 then
      Set ŷ ← x and terminate the algorithm

While (frames remain to be processed) do
   For each frame index k = 1 to nFrames do
      Update
         Determine frame boundaries:
            a ← 1 + (k − 1) * hop
            b ← a + win − 1
```

```
        if b > N then b ← N
      Extract normalized frame:
        zk ← z[a : b]
      Apply FNN denoiser:
        ŷk ← net(zk)
      Accumulate output via overlap–add:
        yrec[a : b] ← yrec[a : b] + ŷk
        wsum[a : b] ← wsum[a : b] + 1

  Update and analyze
    For n = 1 to N do
      If wsum[n] = 0 then wsum[n] ← 1
      Compute averaged normalized estimate:
        ẑ[n] ← yrec[n] / wsum[n]
      De-normalize to original scale:
        ŷ[n] ← ẑ[n] * σx + μx
    end

    If (denoising is required for multiple PD channels) then
      Repeat the above procedure for each channel (A, B, C)
with its
      corresponding noisy input and trained FNN
    End if

End

Output
  Denoised PD signal ŷ for subsequent peak detection and
localization
```

Let $[n]$, n=1, …, N, denote the noisy PD signal. The FNN pipeline adopts exactly the same global normalization, framing, and overlap-add reconstruction strategy as the ANN method, using Eq. (13) to Eq. (17) for preprocessing and Eq. (20) to Eq. (21) for recombination and de-normalization. This ensures that both denoisers operate on identically scaled inputs and produce outputs in the same physical units, enabling a fair comparison.

For each frame z_k, the trained FNN denoiser that applies a relatively shallow nonlinear mapping as Eq. (22):

$$\hat{y}_k = g_{\emptyset}(z_k) \tag{22}$$

where, $g_{\emptyset}(.)$ denotes a fully connected network with a reduced number of layers and neurons compared with the ANN. A typical realization uses a single hidden layer, as shown in Eq. (23):

$$\begin{aligned} h &= \varphi(W_1 z_k + b_1), \\ \hat{y}_k &= W_2 h + b_2 \end{aligned} \tag{23}$$

where, $\varphi(\cdot)$ is a nonlinear activation function (e.g., ReLU), and $\phi = \{W_1, b_1, W_2, b_2\}$ is the parameter set. As with the ANN, the FNN is trained offline on noisy-clean frame pairs by minimizing the MSE loss in Eq. (19). However, because ϕ contains substantially fewer parameters than the ANN's θ, the FNN exhibits lower computational cost, reduced memory footprint, and a lower risk of overfitting. In the PD denoising context, this can be beneficial when the training dataset is limited or when the deployment environment requires fast inference and deterministic latency.

After frame-wise processing, the FNN outputs $\hat{y}_k$ are merged using the same overlap-add and de-normalization steps as the ANN formulation, yielding the final denoised signal $\hat{y}[n]$. For multi-channel PD measurements, the procedure is applied independently to each channel. Overall, the FNN-based scheme preserves the ANN's signal processing structure, while offering a leaner network architecture tailored to scenarios where reduced latency, energy consumption, and implementation complexity are prioritized.

V. Results and Discussion

The ADO, ANN, and FNN pipelines were evaluated in MATLAB on an Intel® Core™ i5-5200U CPU @ 2.2 GHz with 16 GB RAM using four complementary metrics: execution time, PE, MedAE, and F1-score. The simulations employed a multi-end measurement setup along a 2.5 km cable with a fixed true PD location, and the signals were corrupted by composite noise comprising WGN and DSI. This multi-end configuration reflects practical online monitoring architectures that estimate PD location from ToA differences between sensors, while WGN and DSI represent broadband stochastic noise and narrowband interference, respectively. For each noisy realization, the denoised outputs from each pipeline were passed to the same localization method, ensuring that performance differences could be attributed solely to the denoising front end.

Execution time was measured using MATLAB's tic/toc around the full denoising-localization chain, providing a direct estimate of computational cost under identical hardware and software conditions.

The PE quantifies the relative deviation of the estimated PD location from the true location and is defined as Eq. (24):

$$\begin{aligned} &\%\ Error \\ &= \frac{|\ PDloc_{true} - PDloc_{est}|}{PDloc_{true}} \times 100\% \end{aligned} \tag{24}$$

where, $PDloc_{true}$ is the actual PD position, and $PDloc_{est}$ is the estimated PD location. PE is used because it normalizes the error to the cable length, allowing fair comparison across different cable spans and giving utilities an intuitive indication of how far, in percentage terms, the estimate deviates from the true fault location when planning sectionalized repairs.

MedAE measures the typical magnitude of localization errors across Monte Carlo trials and is given by Eq. (25):

$$\begin{aligned} MedAE\ &= median\ (|P_i\ - A_i\ |), \\ i &=\ 1, 2, \ldots, N \end{aligned} \tag{25}$$

where, P_i and A_i are the estimated and true PD locations for the i-th trial, and N is the total number of realizations. MedAE is chosen instead of mean absolute error (MAE) because the median is far less sensitive to occasional extreme mis-localizations that may occur under very severe noise or rare algorithm failures. It therefore provides a robust indicator of the typical performance.

Finally, the F1-Score recasts localization into a tolerance-based detection problem. A trial is counted as a correct localization (positive) if the absolute error lies within a tolerance window of ±100 m. Binary labels are formed accordingly, and

the F1-Score is computed from precision (P) and recall (R) as Eq. (26) to Eq. (28):

$$F1\ Score = \frac{2 \times (Precision\ x\ Recall)}{Precision\ +\ Recall} \quad (26)$$

where,

$$= \frac{Precision}{True\ Positives} \quad (27)$$
$$True\ Positives\ +\ False\ Positives$$

$$Recall = \frac{True\ ositives}{True\ Positives\ +\ False\ Negatives} \quad (28)$$

Here, true positives correspond to trials where the estimated location falls within ±100 m of the true PD position, while false negatives are trials outside this tolerance. This tolerance-based F1-Score is used because, in field practice, operators are less concerned with centimeter-level accuracy than with confining the fault to a sufficiently short cable section that can be isolated and inspected. By combining precision and recall under an engineering-relevant tolerance, the F1-Score provides a practical, balanced measure of good localization, penalizing both missed acceptable localizations and large mis-localizations.

A. Execution Time

Fig. 3 compares the execution time of the ADO, ANN, and FNN denoising pipelines over SNR levels from 9.78 dB to -10.34 dB using the same dataset and computing setup. FNN is consistently the fastest method, with a mean runtime of about 619 s versus 729 s for ANN and 853 s for ADO, giving average savings of roughly 15% and 27%, respectively. FNN runtimes drop from around 680-720 s at high SNR to about 475-500 s at the lowest SNR, while ANN shows the widest variability (about 508-837 s for most SNRs) and a clear spike to roughly 1113 s at -2.38 dB. ADO remains the slowest, but is comparatively stable across SNR, ranging from about 751 s to 989 s. Overall, all pipelines are complete within approximately 475-1115 s, indicating suitability for offline or semi-real-time PD analysis.

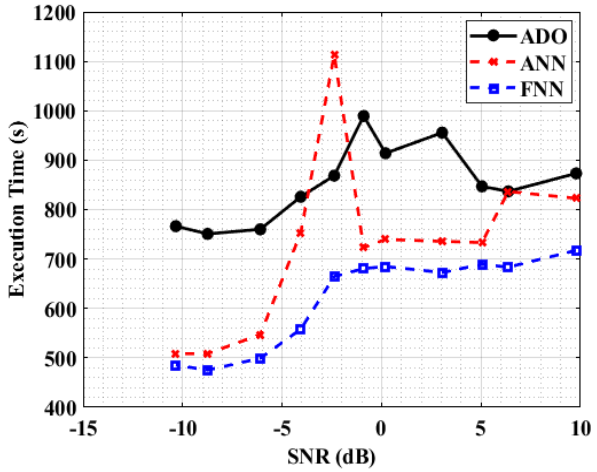

Fig. 3. Comparison of execution time for ADO-, ANN-, and FNN-based denoising pipelines over SNR levels ranging from 9.78 dB to −10.34 dB.

The runtime behavior reflects different computational cost drivers that matter for deployment. FNN's shallow architecture and small parameter count reduce per-epoch cost and typically converge quickly, which suits edge monitoring where latency, power, and throughput are dominant constraints, provided ToA fidelity is preserved. ANN offers intermediate speed but can be sensitive to the optimization landscape, leading to unpredictable delays that complicate buffering and scheduling. ADO is slower because it repeatedly performs multi-level DWT decompositions and reconstructions while searching across candidate configurations, but its latency is more predictable because it is mainly governed by signal length and the size of the search.

In practical PD localization systems, denoiser selection should therefore balance robustness, ToA preservation, computational budget, and operating constraints. FNN is appropriate for resource-limited, near-sensor screening when low latency is essential and uncertain windows can be flagged for later verification. ADO is better suited to offline diagnostics, periodic batch processing, or harsh EMI and low-SNR environments where timing fidelity and robustness outweigh runtime. A hybrid strategy is often most effective in utility monitoring: run FNN or ANN for continuous screening and invoke ADO selectively for low-confidence cases, low-SNR intervals, or high-value assets, improving reliability without paying ADO's full computational cost on every record.

For ADO, the dominant cost driver is search breadth (the number of tested decomposition levels and wavelet options), followed by signal length and windowing; restricting the search or processing a shorter pulse-centered window reduces runtime but can reduce robustness if the earliest wavefront is not retained. Threshold strength and selection-criterion tightness also trade off against timing fidelity, since overly aggressive settings risk smoothing or shifting first arrivals. For ANN and FNN, model size governs per-epoch cost, while training controls such as maximum epochs and early-stopping patience drive runtime variability; tightening these improves predictability but may degrade denoising if overly restrictive. Across all pipelines, the key design principle is to tune the front end to preserve the earliest PD wavefront and minimize ToA shift, since this ultimately governs end-to-end localization accuracy.

B. Percentage Error (PE)

Fig. 4 compares the PE of ADO, ANN, and FNN from 9.78 dB to -10.34 dB. ADO is consistently the most accurate, keeping PE between 0.0078% and 0.278% and staying below 0.03% for all $SNR \geq -4.06\ dB$. In contrast, ANN and FNN start at about 9.2% and 9.0% at 9.78 dB, remain above 4.7% under moderate noise, and rise sharply below -4 dB to roughly 21.4% and 22.5% at -10.34 dB. Consistent with this robustness, Table I shows that ADO selects lower decomposition levels (1–3) at higher SNR and shifts to deeper levels (4–5) as noise increases, keeping the estimated PD location close to 2000 m even in the most challenging cases.

These PE trends indicate that localization accuracy is dominated by timing fidelity rather than denoising strength alone. The large errors of ANN and FNN, even when SNR is high, imply that small reconstruction distortions can shift the effective ToA. In ToA-based MV cable localization, a one-to-two sample shift can translate into metres of location error, so smoothing or altering the first-arrival structure can degrade

localization despite producing visually clean signals. ADO's near-zero PE over moderate and high SNR, and only modest degradation at very low SNR, suggests that its wavelet-domain processing preserves ToA-critical features more reliably as interference changes.

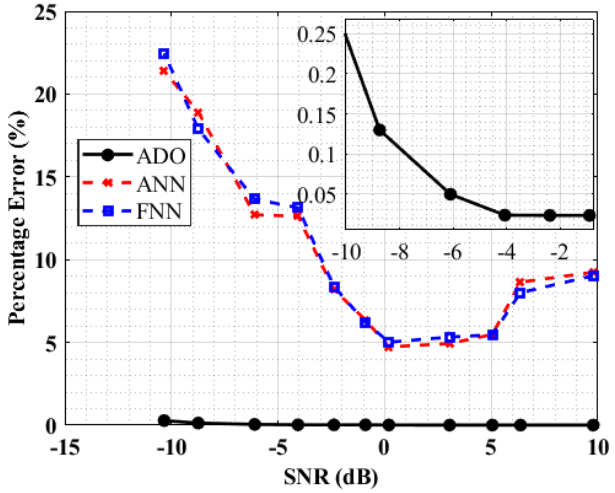

Fig. 4. Comparison of PE for ADO-, ANN-, and FNN-based denoising pipelines over SNR levels ranging from 9.78 dB to −10.34 dB.

TABLE I. ANALYSIS OF AD, ADO, AND PD LOCALIZATION ERROR ACROSS VARYING DWT DECOMPOSITION LEVELS AT A FIXED SNR OF -10.34 DB (WGN = -20 DB AND DSI = 0.55 MV)

SNR (dB)	AD	ADO	Estimated PD Location (m)	PD Location Error (%)	Decomp Level (DWT)
9.7812	0.5590	0.0540	1999.8439	0.0078	1
6.3698	0.4056	0.0056	1999.8439	0.0078	2
5.0484	0.3108	0.0892	1999.8439	0.0078	3
3.0471	0.3833	0.0167	1999.8439	0.0078	3
0.2003	0.4892	0.0892	1999.7401	0.0130	3
-0.9005	0.2566	0.1434	1999.5320	0.0234	4
-2.3772	0.3090	0.0910	1999.5320	0.0234	4
-4.0638	0.3597	0.0403	1999.5260	0.0237	4
-6.0967	0.4430	0.0430	2000.9960	0.0498	4
-8.7425	0.2855	0.1145	2002.6000	0.1300	5
-10.34	0.2900	0.1322	2005.5600	0.278	5

For system design, ADO is the safest default for field deployment when noise conditions are uncertain and accurate localization is required, since it maintains near-perfect accuracy down to -4.06 dB and remains below 0.3% PE at -10.34 dB. When computing is severely limited and approximate localization is acceptable, a lightweight neural front end such as FNN can be used for screening, with low-confidence or low-SNR windows escalated to ADO before producing the final location estimate. If ANN or FNN must serve as the primary front end, their evaluation and training should explicitly include timing-based criteria, because waveform similarity alone may not reflect ToA shifts that drive localization error. At low SNR, the deeper decomposition selected by ADO has a clear physical interpretation because finer subband separation helps preserve PD-dominated components, while suppressing broadband noise and interference.

For ADO, decomposition level is the dominant factor because it determines subband separation and ToA preservation; fixing the level (for example, always level 3) would likely increase PE at low SNR by reducing adaptability. Threshold strength and the AD/ADO selection criterion form a second lever, balancing residual interference suppression against the risk of attenuating the earliest wavefront, while the search breadth across wavelets and levels trades robustness against computation. For ANN/FNN, the loss function and training target are most influential, as smoothness-driven objectives such as MSE can blur transients and shift arrival time, whereas timing-aware losses or first-arrival weighting better protect localization-critical structure. Model capacity and training-test mismatch also affect performance, but the observed PE gap suggests that improving neural localization requires explicit timing-preserving design and training data that match expected EMI and SNR conditions.

C. Median Absolute Error (MedAE)

Fig. 5 compares the MedAE of ADO, ANN, and FNN across SNR levels from 9.78 dB to -10.34 dB. ADO performs best throughout, maintaining MedAE = 0.000 m for all $SNR \geq 0.2\ dB$ and increasing only to about 0.3-0.8 m when SNR becomes negative. In contrast, ANN and FNN produce much larger MedAE at every SNR point, starting around 65-117 m at high SNR and rising to roughly 280-800 m as noise increases. Their curves are nearly identical, indicating a shared limitation in maintaining precise timing under noisy conditions.

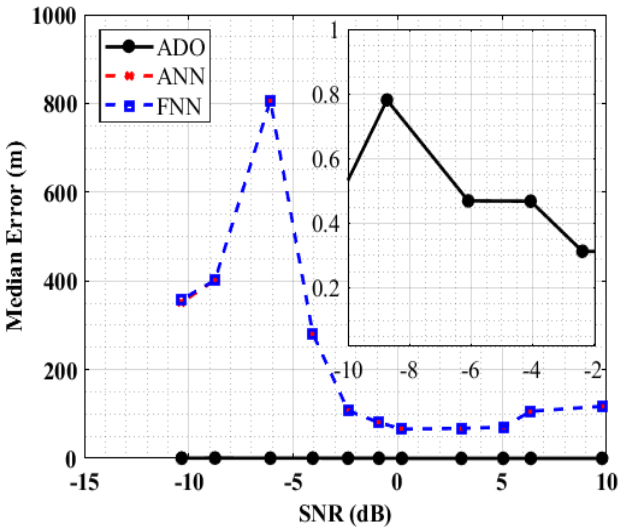

Fig. 5. Comparison of MedAE for ADO-, ANN-, and FNN-based denoising pipelines over SNR levels ranging from 9.78 dB to −10.34 dB.

MedAE is especially informative for PD localization because it represents typical field performance rather than being driven by occasional outliers. ADO's near-zero MedAE at moderate and high SNR implies that its denoising preserves the leading-edge timing needed for accurate time-difference-of-arrival estimation, so at least half of the events are localized essentially at the true position within the model's resolution.

Even at negative SNR, ADO remaining below 1 m indicates strong protection of ToA-critical features against time shifting as interference increases. By contrast, the large MedAE of ANN and FNN suggests a systematic failure mode, where smoothing and broadening of impulsive PD transients introduce timing bias and jitter that are amplified into large location errors by the ToA backend.

These findings translate into clear deployment guidance. For high-confidence localization that supports maintenance actions such as joint targeting and dig planning, ADO should be the primary denoising front end because it keeps typical errors near zero at non-negative SNR and within sub-meter levels even in noise-dominated regimes. ANN or FNN are only suitable when the goal is rapid event screening rather than precise localization, and should be paired with safeguards such as confidence scoring and escalation of difficult or low-SNR windows to an ADO pass before finalizing a location estimate. More broadly, ADO's stability across SNR makes it the safer default in MV underground networks, where noise conditions can vary significantly across assets and operating states.

For ADO, the decomposition level and its selection rule are most critical, since deeper decomposition at low SNR improves subband separation and helps preserve the first-arrival structure; fixing the level (e.g., always level 2 or 3) would likely increase MedAE under negative SNR. Threshold magnitude is the next key lever because over-thresholding can attenuate the earliest wavefront, while under-thresholding leaves timing-corrupting interference, and mother wavelet choice affects how well sharp edges are preserved. For ANN/FNN, the dominant factor is the training objective and loss weighting, as standard reconstruction losses promote smoothing and can shift arrival time; timing-aware losses that emphasize the first-arrival region are therefore the most direct route to reducing MedAE. Training-test mismatch, noise diversity, and model capacity also matter, but improving localization requires explicitly timing-preserving design rather than network size reduction alone.

D. F1-Score

Table II summarizes precision, recall, and F1-score for the ADO, ANN, and FNN denoising-detection pipelines from 9.78 dB to -10.34 dB. ADO achieves an F1-score of 1.0000 from 9.78 dB down to -4.06 dB with precision and recall both equal to 1.0000. Even under severe noise (-6.10 dB to -10.34 dB), ADO remains strong with F1-scores between 0.9787 and 0.9950, driven by precision = 1.0000 and only a modest recall drops to 0.9583-0.9900. In contrast, ANN and FNN show much lower F1-scores across all SNRs; although their precision stays at 1.0000, recall is limited (0.45-0.56 at higher SNR) and collapses at low SNR (0.03-0.08), reducing F1 to below 0.17 and as low as 0.0667 at -10.34 dB.

These detection trends directly affect PD localization because reliable localization requires consistent event capture, and missed detections reduce event coverage, create gaps in activity timelines, and decrease the likelihood of obtaining ToA-informative wavefront segments needed by the localization backend. In this sense, the F1-score is a gating metric for localization readiness. ADO's near-unity F1 across the full SNR range indicates that it preserves PD-noise separability under both WGN and DSI after denoising, while the small recall reduction at the lowest SNR reflects a controlled trade-off, where stronger suppression occasionally removes marginal PD components, but does not materially reduce event capture.

TABLE II. COMPARISON OF PRECISION, RECALL, AND F1-SCORE FOR ADO, ANN, AND FNN DENOISING–DETECTION PIPELINES OVER VARYING SNR CONDITIONS IN PD EVENT DETECTION

SNR (dB)	F1 score of ADO	F1 score of ANN	F1 score of FNN
9.7812	1.0000 (P = 1.0000, R = 1.0000)	0.6207 (P = 1.0000, R = 0.4500)	0.6207 (P = 1.0000, R = 0.4500)
6.3698	1.0000 (P = 1.0000, R = 1.0000)	0.6301 (P = 1.0000, R = 0.4600)	0.6301 (P = 1.0000, R = 0.4600)
5.0484	1.0000 (P = 1.0000, R = 1.0000)	0.7179 (P = 1.0000, R = 0.5600)	0.7179 (P = 1.0000, R = 0.5600)
3.0471	1.0000 (P = 1.0000, R = 1.0000)	0.7500 (P = 1.0000, R = 0.6000)	0.7500 (P = 1.0000, R = 0.6000)
0.2003	1.0000 (P = 1.0000, R = 1.0000)	0.7578 (P = 1.0000, R = 0.6100)	0.7578 (P = 1.0000, R = 0.6100)
-0.9005	1.0000 (P = 1.0000, R = 1.0000)	0.7226 (P = 1.0000, R = 0.5657)	0.7226 (P = 1.0000, R = 0.5657)
-2.3772	1.0000 (P = 1.0000, R = 1.0000)	0.6222 (P = 1.0000, R = 0.4516)	0.6222 (P = 1.0000, R = 0.4516)
-4.0638	1.0000 (P = 1.0000, R = 1.0000)	0.3960 (P = 1.0000, R = 0.2469)	0.3960 (P = 1.0000, R = 0.2469)
-6.0967	0.9950 (P = 1.0000, R = 0.9900)	0.1538 (P = 1.0000, R = 0.0833)	0.1538 (P = 1.0000, R = 0.0833)
-8.7425	0.9948 (P = 1.0000, R = 0.9896)	0.1639 (P = 1.0000, R = 0.0893)	0.1639 (P = 1.0000, R = 0.0893)
-10.3400	0.9787 (P = 1.0000, R = 0.9583)	0.0667 (P = 1.0000, R = 0.0345)	0.0667 (P = 1.0000, R = 0.0345)

From a deployment perspective, the perfect-precision but low-recall behavior of ANN and FNN is problematic as a primary trigger in many field settings. While detected events are almost always correct, many true PD events are missed even at high SNR, and recall collapses under noise, which can falsely suggest low PD activity and bias downstream localization toward only the strongest pulses. For condition monitoring, where missed PD events are unacceptable, ADO is therefore the preferred front-end because it maintains a near-balanced precision-recall profile across wide SNR variation. Where compute and power constraints motivate neural methods, ANN/FNN are better used as low-latency screeners in a two-stage workflow, with ADO applied selectively to buffered windows during suspected activity, low-SNR periods, or low-confidence cases to recover missed events before localization.

For ADO, threshold aggressiveness is the key lever at low SNR: tightening thresholds preserves precision but can reduce recall by suppressing weak PD components, so recall is typically the first metric to move under threshold scaling. Decomposition level selection and mother wavelet choice also

affect separability, because subband isolation and morphology matching determine whether PD transients remain distinct enough to cross the decision threshold under interference; fixing the level rather than adapting it would likely reduce recall at low SNR. For ANN/FNN, the dominant driver is the decision threshold and calibration, since precision = 1.0000 implies overly conservative triggering; lowering the threshold can raise recall, but must be paired with false-alarm control. Training objectives that penalize missed detections and broader training noise diversity across realistic WGN and DSI conditions are also critical, because the recall collapses at very low SNR indicates sensitivity to training-test mismatch.

VI. Conclusion and Recommendations

This study shows that denoising is a core element of MV cable PD localization because it directly governs timing integrity and, therefore, the reliability of ToA-based estimates. Using a controlled benchmark in which only the denoising front end is varied while the localization backend is kept fixed, the key message is that localization improves when the denoiser preserves the earliest PD wavefront features under interference, rather than simply reducing overall noise energy. From a design standpoint, a deterministic and training-free adaptive wavelet front end such as ADO is recommended when robust, high-confidence localization is required across changing noise conditions, because it adapts to the observed interference while discouraging timing distortion that would otherwise propagate into localization error. When computational speed and simplicity are the dominant constraints, a lightweight neural option such as the FNN can be considered as an efficiency-oriented alternative, but its robustness should be verified under the expected field noise variability instead of being assumed from laboratory-like conditions. These implications are especially relevant for low-cost monitoring hardware, since the evaluation was performed on a modest CPU platform representative of practical embedded units rather than GPU-accelerated workstations, where model handling and inference overheads can limit the deployability of learning-based pipelines. The main limitation is that the study relied on MATLAB simulations with synthetic PD waveforms in a controlled scenario and a noise model limited to WGN and DSI, so it cannot fully capture field variability such as joints, reflections, multiple concurrent sources, sensor coupling differences, and nonstationary interference. Future work should therefore validate the conclusions using measured PD data from real cable assets and defect types, and further optimize ADO for embedded implementation through streamlined search strategies and efficient realizations, with targeted acceleration where available.

Improving YOLO11 Architecture for Reckless Driving Detection on the Road

Sutikno, Aris Sugiharto, Retno Kusumaningrum
Department of Informatics, Diponegoro University, Semarang, Indonesia

***Abstract*—Reckless driving behavior on the road can increase the risk of traffic accidents for drivers and other road users. Currently, supervision remains weak, particularly in direct supervision, due to the limited number of officers. This study developed an automated system to detect reckless drivers based on their road trajectories. This system comprised three subsystems: car detection, car tracking, and driving trajectory detection. In the driving trajectory detection subsystem, we proposed an improved YOLO11n-cls method developed from YOLO11n-cls by adding convolution and C3k2 blocks. The test results showed that the proposed model achieved an accuracy increase of 4.4% over YOLO11n-cls. The proposed model achieved an accuracy of 0.935 and an inference time of 0.5 ms for car trajectory classification. In addition, the proposed model achieved higher accuracy than all YOLO11 models (YOLO11n-cls, YOLO11s-cls, YOLO11m-cls, YOLO11l-cls, and YOLO11x-cls) and all YOLO12 models (YOLO12n-cls, YOLO12s-cls, YOLO12m-cls, YOLO12l-cls, and YOLO12x-cls). Therefore, the proposed model is better suited to support traffic law enforcement, especially the real-time detection of reckless drivers on highways.**

***Keywords*—Reckless driving detection; improved YOLO11n-cls; added convolution blocks; added C3k2 blocks**

I. Introduction

Deaths from traffic accidents remain a serious global problem. One contributing factor is drivers who disobey traffic regulations, such as dangerous or reckless driving. These violations not only endanger the driver but also put other road users at risk, thereby increasing the likelihood of accidents. Furthermore, many violations still occur. Therefore, it is crucial to strengthen supervision and enforcement of the rules. Currently, supervision is still carried out directly on the road due to limited personnel. This way has the disadvantage of potentially undetected violations. One solution to this problem is to utilize roadside surveillance cameras in conjunction with automated detection systems to identify drivers who drive dangerously or recklessly, thereby preventing traffic accidents. This system requires high accuracy and speed to be implemented in real time.

Research on detecting reckless driving behavior on the highway began about a decade ago. Based on the location of the sensor installation, this research was divided into two categories, namely sensors installed inside the car and surveillance camera sensors installed above the highway. Sensors installed inside the car monitor driver behavior directly. Meanwhile, surveillance camera sensors installed above the highway analyze driver trajectory patterns and speeds. Some methods used for sensor-based car systems included AdaBoost [1], Backpropagation [2], Support Vector Machine (SVM) [3], Graph Convolutional Long Short-term Memory networks (GConvLSTM) [4], YOLOv5 [5], YOLOv8 [6], and ResNet18+SCConv [7]. Meanwhile, some methods using surveillance cameras installed above the highway were SVM [8], Boosting Artificial Intelligence (BAI) [9], Lightweight Graph Convolution (LGC) [10], Convolutional Neural Network (CNN) [11][12], YOLOv2 [13], and YOLOv3 [14].

Cameras installed above the road are better suited for law enforcement, especially for detecting reckless driving. YOLOv2 and YOLOv3 are superior to other methods in single-frame multi-object detection, but they have weaknesses in detecting small objects and require substantial computational resources [13][14]. The models make them challenging to implement in real-time. These models produce low accuracy on small-looking car objects.

YOLO excels because it is fast, accurate, efficient, and easy to implement. It is also suitable for real-time object detection across various applications, including detecting parking space availability [15], video summarization [16], anomaly detection from a video surveillance camera [17], and student behavior detection [18]. Another investigation aimed at detecting pedestrians [19], vehicles [20], and road objects [21]. YOLOv2 and YOLOv3 have been used for reckless driver detection, but these models produce relatively low accuracy and long computation time compared to YOLO11.

This study proposed a system for detecting reckless car drivers on the road based on their trajectories, suitable for real-time conditions. This system comprised three subsystems: car detection, car tracking, and driving trajectory detection. We utilize the modified YOLO11 in the car detection subsystem, the ByteTrack algorithm in the car tracking subsystem, and the improved YOLO11n-cls model for driving trajectory detection. YOLO11n-cls still produces substantial errors in classifying car trajectories on the highway, especially in the smooth lane-change class. This study develops the improved YOLO11n-cls model, which is based on YOLO11n-cls. This model added convolutional layers and C3k2 blocks to expand the model's representation capacity, resulting in a YOLO11n-cls architecture that was more powerful at classifying car driver trajectories on the road. The development of this model aims to improve the accuracy of car trajectory classification on the road while maintaining a consistent speed.

II. Materials and Methods

A. Dataset

The data used in this study are vehicle trajectory images from a 70-minute video recording on a highway. The video has a resolution of 960 × 540 pixels and a frame rate of 30 frames per second (fps). The recording was made with a camera mounted above the highway. The data was recorded on a highway in Semarang City, Indonesia. Fig. 1 is an example of a frame from this video.

Fig. 1. Example of a video frame.

The trajectory data consisted of 153 images across three classes: 87 for straight driving, 30 for smooth lane changes, and 36 for reckless driving. This dataset was split into two parts: 70% for training and 30% for testing. The straight driving class represents the trajectory of a car that does not change lanes, and the smooth lane change class represents the trajectory of a car that changes lanes once. Meanwhile, the reckless driving class represents a car that changes lanes more than once. An example of this dataset is shown in Fig. 2.

B. Proposed System

The method proposed in this study was a reckless road traffic detection system based on the driver's car trajectory. This system consisted of three subsystems: car detection, car tracking, and driving trajectory detection, as illustrated in Fig. 3. The car detection subsystem determined the car's position on the road. The method used was modified YOLO11m, which has been shown to achieve higher mAP than YOLOv8x, YOLOv8m, and all YOLO11 models [22]. The next subsystem was car tracking, which determined each car's trajectory on the road. The method used in this tracking was the ByteTrack algorithm. This algorithm has been demonstrated to outperform other tracking methods, including SORT, DeepSORT, and DeepMOT [23].

The final subsystem, driving trajectory detection, is illustrated in Fig. 4. It comprises several processes: car trajectory reconstruction, Region of Interest (ROI) frame determination, and trajectory classification. The trajectory reconstruction process was used to redraw the car's trajectory on a base frame. This base frame was obtained from one of the video recording frames. Next, the ROI was determined to identify the key areas of the trajectory, namely the road. The ROI was determined by determining 4 points on the highway boundary. The ROI area was left fixed while the others were colored black. The next step was to crop the ROI, then continue the perspective transformation (warping) to produce only the ROI area of the car's trajectory on the highway.

The final process involved classifying the trajectory of the car in this image. This study developed a YOLO11n-cls model for classifying three car-trajectory classes: straight driving, smooth lane change, and reckless driving. The proposed method is named improved YOLO11n-cls, as shown in Fig. 5. The YOLO11n-cls model was essentially a YOLO-based classification model that used a lightweight backbone with convolutional blocks and C3k2 modules for feature extraction, along with a C2PSA (Cross-Stage Partial Squeeze-and-Attention) module to capture spatial and contextual dependencies at a high feature level [24]. This structure is designed to be computationally efficient, while still producing rich feature representations, making it suitable for various image classification tasks, including vehicle movement trajectories.

(a) (b) (c)

Fig. 2. Example of datasets: (a) Straight driving class, (b) Smooth lane change class, (c) Reckless driving class.

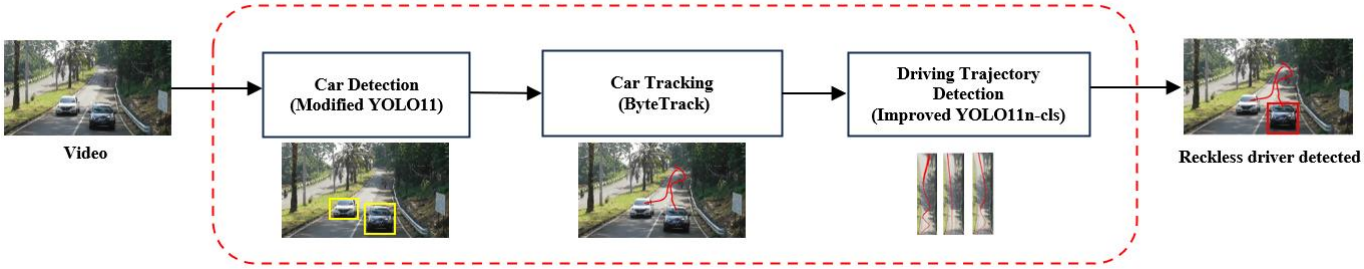

Fig. 3. The proposed system for reckless road traffic detection.

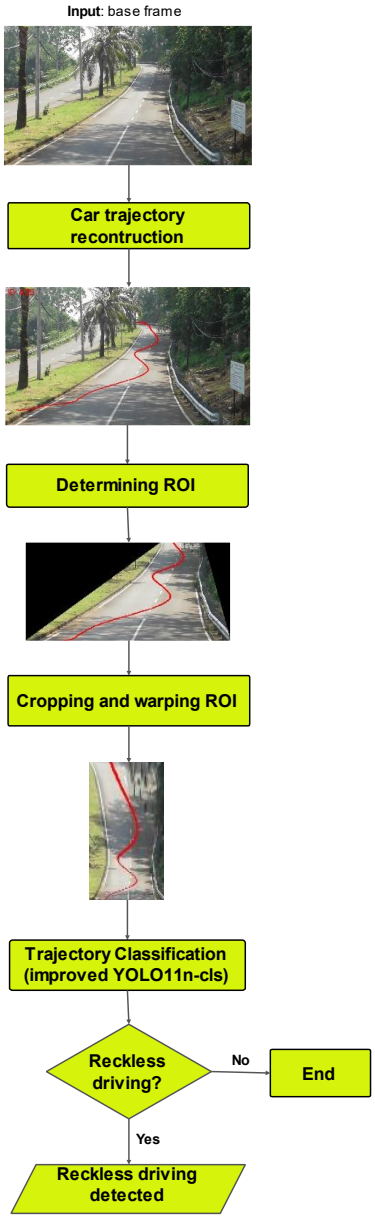

Fig. 4. Driving trajectory detection subsystem.

In the improved YOLO11n-cls model, we modified the backbone to enhance its feature extraction, particularly for complex car trajectory patterns. This modification was achieved by adding a convolutional layer with 2,028 output channels, followed by a C3k2 block at the high-level feature level. This addition aims to expand the model's representation capacity to capture variations in trajectory patterns, increase feature depth, and improve sensitivity to subtle visual differences across trajectory classes. The C3k2 block produces more efficient computation compared to C2f in the previous version of the YOLO model. Furthermore, the C2PSA module was expanded to process higher-resolution features, thereby improving the network's spatial and contextual attention.

The primary objective of this method development is to enhance classification accuracy while maintaining a relatively fast inference time, thereby enabling the model to be applied efficiently in real-time systems. The improved YOLO11n-cls model is expected to deliver more accurate, responsive classification, potentially supporting intelligent transportation systems and real-time driver behavior analysis.

C. Performance Evaluation

The classification model was evaluated using accuracy (Acc), precision, recall, and F1-score as defined by Eq. (1), Eq. (2), Eq. (3), and Eq. (4), respectively [25]. The variable T_{pos} (true positive) represents the number of samples that are correctly classified as belonging to a specific class. In contrast, T_{neg} (true negative) indicates the number of samples that are correctly classified as not belonging to that class. F_{pos} (false positive) refers to the number of samples that are incorrectly classified as belonging to a class when they actually belong to another class, and F_{neg} (false negative) denotes the number of samples that belong to a specific class but are incorrectly classified as another class.

$$Accuration = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \quad (1)$$

$$Precision = \frac{T_{pos}}{T_{pos}+F_{pos}} \quad (2)$$

$$Recall = \frac{T_{pos}}{T_{pos}+F_{neg}} \quad (3)$$

$$F1-score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (4)$$

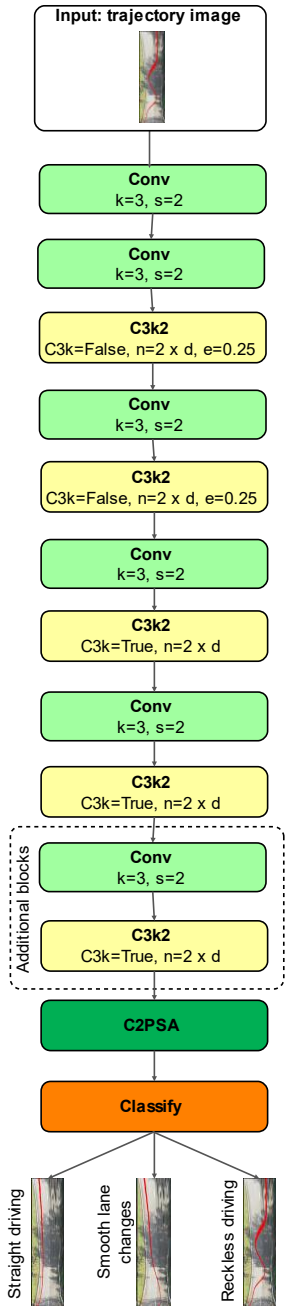

Fig. 5. Improved YOLO11n-cls architecture (proposed model).

III. Experiments and Results

Testing was conducted using several scenarios. First, we tested the proposed method on a dataset. Next, we performed data augmentation to augment the training data. The proposed method was then compared with several other models. The results of the first test using the proposed method are shown in Table I. The precision and recall values for the reckless driving class were quite good. In fact, the recall value was perfect, but the precision and recall for the smooth lane change class could not be classified. Meanwhile, the accuracy, inference time, and training time from this test resulted in 0.891, 0.5 ms, and 0.062 hours, respectively.

The training dataset for the first test was still small—only 107 images—so we augmented the data. The technique used was horizontal scaling. Each vehicle trajectory was scaled proportionally to its starting point, using a scale factor of 0.4-1.5 and a scale increment of 0.1. This technique maintains the original trajectory shape while introducing left-right shifts, making the model more robust to differences in vehicle positions within the lane. The resulting augmented data amounted to 326, so the training data became 433. The test results, incorporating the augmented data, are presented in Table II. The precision and recall values for the reckless driving class were 0.8750 and 1, respectively. The F1-score of the smooth lane change class experienced a significant increase of 0.6667. The confusion matrix of this classification is shown in Table III. The proposed model performs reasonably well at predicting reckless and straight driving, but it still struggles to predict smooth lane changes. Further improvements are needed. Furthermore, additional trajectory datasets are needed to improve accuracy across all classes. Frequent lane changes and high speeds are characteristic of reckless drivers. The proposed method can be combined with speed exceeding threshold detection.

The comparison of accuracy, inference time, and training time between before and after the addition of augmented data is shown in Table IV. From this table, it can be seen that with the addition of augmented data, accuracy increased by 4.4%, while inference time remained the same. Meanwhile, the training time increased threefold. Therefore, it can be concluded that the proposed method, improved YOLO11n-cls, is more suitable for car trajectory classification than YOLO11n-cls.

TABLE I. Test Results of the Proposed Method on the Dataset Without Augmentation

Class	Precision	Recall	F1-score
Reckless driving	0.9375	1.0000	0.9684
Smooth lane change	0.0000	0.0000	0.0000
Straight driving	0.9630	0.8966	0.9285

TABLE II. Test Results of the Proposed Method on the Dataset with Augmentation

Class	Precision	Recall	F1-score
Reckless Driving	0.8750	1.0000	0.9333
Smooth Lane Change	0.6667	0.6667	0.6667
Straight Driving	1.0000	0.9310	0.9646

TABLE III. Confusion Matrix of Trajectory Classification

		Actual Value		
		Reckless driving	***Smooth lane change***	***Straight driving***
Predicted	***Reckless driving***	14	0	0
	Smooth lane change	1	2	0
	Straight driving	1	1	27

TABLE IV. COMPARISON RESULTS WITH AND WITHOUT AUGMENTATION

Augmentasi	Acc	Inference time	Training time
No	0.891	**0.5**	**0.062**
Yes	**0.935**	**0.5**	0.172

Finally, the proposed method was compared with YOLO11 models and YOLO12 models, as shown in Table V. From this table, it is evident that the proposed model's accuracy surpasses that of the other models. At the same time, the inference time is ranked second among all. The proposed method achieves an accuracy of 0.935 and an inference time of 0.5 ms. Therefore, it can be concluded that the proposed method is more suitable for real-time car trajectory classification than all YOLO11 and YOLO12 models. The proposed model improves the average precision of reckless driving detection using vehicle trajectories. Compared to YOLO11, the proposed model achieved higher accuracy due to its enhanced representation capacity and ability to process higher-resolution features.

TABLE V. COMPARISON RESULTS OF THE PROPOSED METHOD WITH ALL YOLO11 AND YOLOV12 MODELS

Model	Acc	Inference time (ms)	Training time (hours)
YOLO11n-cls	0.913	**0.4**	0.170
YOLO11s-cls	0.870	0.5	**0.051**
YOLO11m-cls	0.891	0.5	0.110
YOLO11l-cls	0.891	0.9	0.078
YOLO11x-cls	0.913	0.7	0.100
YOLO12n-cls	0.870	0.8	0.064
YOLO12s-cls	0.848	1.0	0.067
YOLO12m-cls	0.870	0.6	0.076
YOLO12l-cls	0.891	2.0	0.126
YOLO12x-cls	0.870	3.0	0.136
Proposed	**0.935**	0.5	0.172

IV. CONCLUSION

This study developed a system to detect dangerous driving behavior based on vehicle trajectories. The developed system consisted of three subsystems: car detection using a modified YOLO11, car tracking using ByteTrack, and driving trajectory detection using an improved YOLO11n-cls. Improved YOLO11n-cls is a model developed from the original YOLO11n-cls by adding convolution and C3k2 blocks before the C2PSA block. The test results show that the proposed model can improve accuracy by 4.4% compared to YOLO11n-cls. The proposed model achieves an accuracy of 0.935 and an inference time of 0.5 ms. Additionally, the resulting model outperforms all YOLO11-cls and YOLO12-cls models. These results can improve the average precision of reckless driver detection based on their trajectory. However, the proposed model still performs poorly in predicting smooth lane changes. Therefore, the proposed model is better suited to support traffic law enforcement, especially the real-time detection of reckless drivers on highways. Further research can expand the dataset with more diverse traffic conditions and refine the classification model to capture more complex driving patterns.

Formal Verification Unified Modeling Language Statechart Using Enhancement Common Modeling Language

Muhammad Amsyar Azwarrudin, Pathiah Abdul Samat, Norhayati Mohd Ali, Novia Indriaty Admodisastro
Faculty of Computer Science and Information Technology-Software Engineering Department,
Universiti Putra Malaysia, Serdang, Malaysia

***Abstract*—Modern systems are rapidly evolving and increasing in complexity to satisfy growing requirements. Such systems often incorporate multiple hierarchical statecharts within their behavior modeling diagram, which significantly complicates the verification process. To address this challenge, the Common Modeling Language (CML) was introduced as an intermediate modeling language for formal verification, serving as a bridge between Unified Modeling Language (UML) Statechart and the model checkers. However, CML supports modeling only a single hierarchical statechart, which limits its applicability to complex systems. This study introduces the Enhancement Common Modeling Language (E-CML), an extension of the CML, to support the verification of systems that incorporate multiple hierarchical statecharts. We introduce the group component in E-CML, comprising an initial state, a set of states, transitions, triggers, and a region, to formally differentiate the group components from superstates. We also propose new translation rules to map E-CML into Symbolic Model Verifier (SMV) syntax. E-CML operates through two main processes: transformation and translation. The transformation process transforms an XML Metadata Interchange (XMI) file into E-CML, while the translation process translates E-CML to an Input Symbolic Model Verifier (I-SMV) file. The system is verified using the SMV model checker, with formal properties specified in Computational Tree Logic (CTL) and represented in the I-SMV file. The results demonstrate that the behavior modeling diagram satisfies all formal properties, indicating that E-CML provides an effective framework for the verification of complex systems comprising multiple hierarchical statecharts.**

I. Introduction

The Unified Modeling Language (UML) Statechart is a semi-formal modeling language widely used by software engineers to describe the behavior of software systems, whether simple or complex. In [1], the authors introduced the UML Statechart, which has advanced elements that can describe a complex system's behavior. The simple system's behavior consists of a single hierarchical statechart and a few modules to express the behavior. An example of a simple system is a traffic light system [2], [3]. Meanwhile, the complex system's behavior consists of multiple hierarchical statecharts and multiple modules to express it. The example of complex systems is surgical consultation in the outpatient clinic health system [4]. However, the UML Statechart lacks formal semantics that ambiguously express the behavior modeling. Recent research has addressed the problem that the UML Statechart cannot be used for verification processes [5], [6], even though software engineers widely use the UML Statechart for modeling simple or complex systems. In [7], the authors introduced the Extended Hierarchical Automata (EHA), an extension of finite state machines that supports the hierarchical structure and defines the operational semantics of EHA. The EHA is one of the formal semantics behavior modeling that represents the UML Statechart. Therefore, the UML Statechart can be used for the verification process to check the system's correctness.

Consequently, model checking can be employed as a verification method. Model checking is an automated process for verifying the system's behavior. However, it requires a formal model and a formal temporal logic specification to check the system's correctness. If the model checker does not produce a counterexample, the system is proven to satisfy its requirements [8]. In this context, the Model-Based Software Engineering (MBSE) approach enables the formalization of semi-formal models into formal models through either direct or indirect translation using translation rules. In the case of indirect translation, the model is first transformed into an intermediate modeling language. Examples of such intermediate languages include the Common Modeling Language (CML) [8], Gamma statechart [9], and Abstract Rule-based [10]. CML is an intermediate modeling language for formal verification, serving as a bridge between UML Statechart and the model checkers.

Modern systems are rapidly evolving and increasing in complexity to satisfy growing requirements. Such systems often incorporate multiple hierarchical statecharts within their behavior modeling diagram, which significantly complicates the verification process. Therefore, recent research has proposed numerous methods that can formalize the UML Statechart [11], [12], [13], transforming it into a formal model that can be used for the verification process. Nevertheless, with the complexity of the systems developed nowadays, numerous complex interactions are involved [13]. In [9] and [14], the authors mentioned that integrative approaches are limited to models with fewer modules or lack efficient compatibility with formal verification and validation frameworks. Moreover, reference [15] stated that the CML supports modeling only a single hierarchical statechart, which limits its applicability to complex systems. Therefore, both statements show that recent

approaches have focused on verifying a single hierarchical statechart. However, modeling complex systems involves multiple hierarchical statecharts. It is crucial to address CML's limitations and resolve this problem to ensure the correctness of complex systems. Therefore, this study aims to propose an enhancement of the CML that is capable of verifying systems with multiple hierarchical statecharts, which represent the complex behavior of the systems.

The remainder of this study is organized as follows: Section II reviews related works on formal modeling, semi-formal modeling, theorem proving, model checking, MBSE, and formal verification of UML Statechart, particularly for multiple hierarchical statecharts. Section III presents the research framework and the proposed method, which includes the formal definition of E-CML and the development of new translation rules. Section IV discusses the results and discussion, illustrating the case study using the proposed method. Section V provides a conclusion, summarizes the findings, and outlines potential directions for future work.

II. Related Works

A. Formal Modeling

Formal modeling is an unambiguous language with precise specification built using mathematical and formal methods [16]. Therefore, the formal modeling can specify the requirements, designs, and behavior of the system. It provides the formal semantics of the systems. Examples of formal modeling are Petri Nets, Vienna Development Method (VDM), and Kripke structures. Petri Nets are directed, bipartite multigraphs consisting of places, transitions, and arcs. Fuzzy Petri Nets (FPN) are extensions of Petri Nets and are effective in modeling uncertain biological systems. In [17], the authors reviewed the FPN and categorised it into three types: basic Fuzzy Petri Nets, Fuzzy Quantitative Petri Nets, and Petri Nets with Fuzzy Kinetic Parameters. In [18], the authors proposed an extension of Coloured Petri Nets (CPN) known as catalog-nets (CLog-nets) to integrate business processes with different data types. In [19], the authors utilized Petri Nets to generate secure smart contracts in blockchain systems, enabling the detection of deadlock at an early stage.

Recent studies have used the VDM language to model and verify complex systems. VDM Specification Language (VDM-SL) is a formal specification language with an extensive executable subset and a toolbox that verifies models. In [20], the authors mentioned that the VDM-SL is a robust specification that can define the system's functionality without ambiguity. They proposed an approach that serves as a pre-formal notation for the natural language specification before it is implemented in VDM-SL. In [21], the authors proposed an Internet of Things (IoT) based formal model for vehicle ad hoc networks (VANETs) using VDM-SL. The proposed formal model will be transformed into VDM-SL and verified using the VDM toolbox to check the system's correctness and absence of deadlocks. Meanwhile, reference [22] introduced the first approach to developing the formal semantics of a simulation language in a VDM-SL. They proposed a RE: MODIYC that can describe and examine the formal specification of VDM-SL after initial implementation.

The Kripke structures are a mathematical model used in model logic to represent the possible states and the relationships among them. However, the Kripke structures formalize model logic by extending classical propositional logic with model operators such as necessity and possibility. In [23], the authors proposed an alternative method that transforms a given Kripke structure and the corresponding LTL formal properties into a Buchi automaton, where the number of accepting states is determined based on the LTL formal properties. Meanwhile, reference [24] introduced an approach to verify mobile-interactive systems. They model the properties of dynamic interaction using Variable Petri Nets (VPN). The VPN is transformed into the Kripke structures using a proposed algorithm and verified with a model checker. In [25], the authors proposed formalizing natural language using the UML use case diagram with the Kripke structures. They use the NuSMV model checker to verify whether the formal specification is consistent with the Kripke structures model. However, there are some previous studies that use semi-formal modeling to model the systems.

B. Semi-Formal Modeling

Semi-formal modeling is an ambiguous language in which the modeling lacks formal semantics, but it provides a better understanding of modeling. Therefore, semi-formal modeling is more popular than formal modeling because it does not require as much time and effort to understand the model. Examples of semi-formal modeling are UML and System Modeling Language (SysML). The UML is a graphical notation language used to define and document a system during software development [26]. In [27], the authors introduced a hierarchical modeling formalism based on UML Statechart with generally distributed (GEN) durations, aimed at ensuring modeling simplicity and efficient evaluation of steady-state or transient behavior up to absorption. In contrast, reference [28] used the new semantics of the UML Statechart to model the digital watch. In [29], the authors proposed using a restricted version of the Statechart (Revised Statechart) to model the behavior of autonomous robotic surgery. In [30], the authors used the UML Sequence Diagram to express the requirements of safety-critical systems incrementally.

However, another semi-formal modeling is SysML, which describes a hybrid system of hardware and software. SysML is a graphical modeling language that is intuitive and widely used for modeling complex systems, comprising hardware and software. In [31], the authors proposed an approach to analyze the safety of complex systems. They model the structure of the system using the SysML Block Definition Diagram (BDD) while utilizing the SysML State Machine Diagram to describe the system's behavior. In [32], the authors introduced the transformation of the UML/SysML Activity Diagram to Petri Nets. Meanwhile, reference [33] used the SysML Activity Diagram to model the system's behavior and transform the model into the input language of the Next-generation Unifying Symbolic Model Verifier (nuXmv) model checker. Therefore, there are two types of modeling language, which are formal modeling and semi-formal modeling. However, both models require a formal verification approach to ensure their correctness. Formal verification is the process of ensuring that

a system satisfies certain specifications, typically using two approaches: theorem proving and model checking [34].

C. Theorem Proving

Theorem proving is a formal method that can establish the validity of theorems. The model and specification of the systems are described in a mathematical statement. The verification process of theorem proving involves proving theorems about the system using the rules of the inference process. In [35], the authors introduced the automated prover and proof assistant, GPT-f, to analyze the performance of the Metamath formal language. In [36], the authors proposed the transformation rules from the UML Activity Diagram to Formal Calculus for Liveness and Zero state (FoCaLiZe), a proof-based formal language, and verified the proof-based formal language with the Zenon theorem prover. In [37], the authors identified a barrier for researchers using machine learning for theorem proving in Large Language Models (LLMs). Therefore, they introduced LeanDojo, an open-source Lean framework designed to overcome this barrier, which enables researchers to utilize machine learning with LLMs to enhance the effectiveness of theorem proving.

D. Model Checking

Model checking is one of the formal verification approaches and an automated process for verifying the behavior of a software system. The model checking approach requires a formal model and a formal temporal logic specification to check the correctness of the systems. In [11], the authors enhanced their previous work by formalizing the concurrent element of the UML Statechart, which involves multiple hierarchical statecharts. In [38], the authors used Maude as the formal language for the Internet of Things (IoT) software systems. They use Maude's model checker and Linear Temporal Logic (LTL) specification to verify the IoT software system. Meanwhile, reference [33] utilized the nuXmv to verify Autonomous Artificial Pancreas Systems (AAPS). They used the LTL specification in the nuXmv model checker to verify the APPS system. The model checking approach is widely used due to the MBSE technique, which enables the formalization of modeling language through a process. The transformation process has two types: direct transformation and indirect transformation, which require an intermediate language for the indirect transformation.

E. Model-Based Software Engineering

MBSE provides a platform that enables the definition of complex, multidisciplinary systems. However, the MBSE approach requires formal verification to ensure the correctness of complex systems. Therefore, the MBSE approach provides transformation rules to transform the model, either direct transformation or indirect transformation. Some previous studies use the direct transformation in their approaches.

In [39], the authors identified that the UML State Machine Diagram lacks formal semantics. Therefore, they proposed direct transformation rules from UML State Machine Diagram to Petri Nets and verified them with the Time Petri Nets Analyzer (TINA) to check correctness, safety, and liveness. In [31], the authors verified the Integrated Modular Avionic (IMA) system by proposing the direct transformation rules. They transform the SysML BDD and SysML State Machine Diagram into the input language of the NuSMV model checker. Meanwhile, reference [13] also introduced direct transformation rules from the SysML State Machine Diagram to the input language of the NuSMV model checker for verifying the driving control system. Although both research utilize the SysML State Machine Diagram, their approaches and direct transformation rules differ slightly.

However, some previous studies use the indirect transformation, which introduces an intermediate language to solve their problems. In [8], the authors introduced the CML, an intermediate language to formalize the UML Statechart. They proposed transformation rules to transform the UML Statechart into the CML and translation rules to translate the CML into the input language of the SMV model checker. In [9], the authors proposed the Gamma Statechart, an intermediate language that uses the formal semantics of Yakindu Statechart. They also proposed translation rules to translate the Gamma Statechart into Timed Automata (TA). In [14], the authors proposed transformation rules to transform the SysML State Machine Diagram to the Gamma Statechart. They also proposed the translation rules to translate the Gamma Statechart into the Uppsala Time Automata Laboratory (UPPAAL). Meanwhile, reference [10] used the Abstract Rules-based language as an intermediate language to formalize the UML State Machine Diagram. Previous studies show that most researchers utilize the UML Statechart and SysML State Machine Diagram. However, they may not encompass all elements of the UML Statechart that can represent a complex system.

F. Formal Verification of UML Statechart

Table I illustrates previous studies related to the formal verification of UML Statechart. We consider approaches that use either direct transformation or indirect transformation. We also examine which elements of the UML Statechart are addressed in these approaches. Our focus is on the system complexity, which can be decomposed into multiple modules. Therefore, we consider whether the approaches handle a single hierarchical statechart or multiple hierarchical statecharts. The symbols are indicated as "/" and "X" refer to "have" and "have not", respectively.

TABLE I. PREVIOUS STUDIES RELATED TO THE FORMAL VERIFICATION OF UML STATECHART

Journals	Intermediate Language	Approach	Transformation Rules	Single Hierarchical Statechart	Multiple Hierarchical Statechart
[15]	CML	Indirect	/	/	X
[11]	X	Direct	/	/	X
[12]	X	Direct	/	/	/
[9]	Gamma Statechart	Indirect	X	/	/
[13]	Abstract Rule-based	Indirect	X	/	X
[31]	X	Direct	/	/	X

Some previous studies [15], [9], [13] used an intermediate language to formalize UML Statechart. They employed the indirect transformation approach to verify the models and proposed a few transformation rules to transform the UML Statechart into the intermediate language and subsequently translate it into the model checker's formal model. However, two of these studies [9], [13] used an intermediate language without specifying whether they applied the translation rules in their approaches. The remaining studies [11], [12], [31] did not use an intermediate language; instead, they employed the direct transformation approach, which transforms the UML Statechart directly into the formal model. They also proposed a few transformation rules to guide this transformation.

As mentioned earlier, we focus on system complexity. Most previous studies have addressed a single hierarchical statechart, which represents a relatively simple system. However, only two studies have considered multiple hierarchical statesharts, despite modern systems being built with considerable complexity. Therefore, this observation motivates us to focus on verifying systems with multiple hierarchical statecharts using an indirect transformation approach. Specifically, we aim to enhance the CML by introducing new elements into its formal definition and by creating new translation rules that define multiple hierarchical statecharts and complex systems. The following section will explain the research framework and proposed method.

III. Proposed Method

A. Research Framework

Fig. 1 illustrates the research framework for the proposed method. It involves four processes: 1) Modeling the UML Statechart. 2) Exporting to XML Metadata Interchange (XMI) format. 3) Transforming XMI to Enhancement Common Modeling Language (E-CML). 4) Translating E-CML to Input Symbolic Model Verifier (I-SMV).

Process (1) Modeling the UML Statechart: The behavior of the system is modeled with the UML Statechart by using the Altova UModel software. The Altova UModel software enables modeling of UML Statechart features, including composite state, orthogonal state, history pseudostate (deep and shallow), and inter-level transitions. Process (2) Exporting the UML Statechart to XMI format: The Altova UModel software provides features for exporting the UML Statechart into the XMI format. In the XMI format, there are <region>, <subvertex>, <transition>, and <trigger> tags that refer to the regions, states, transitions, and triggers of the UML Statechart, respectively. Process (3) Transforming XMI to E-CML: The transformation process is based on the tag elements from the XMI format and the formal definition of E-CML. The <region> tags are transformed into the region. The <subvertex> tags are transformed into the state. The <transition> tags are transformed into the transition, and the <trigger> tags are transformed into the trigger. Process (4) Translating E-CML to I-SMV: The translation process is based on the formal definition of I-SMV. Four translation rules are involved in this process, which translate the elements of E-CML into the elements of I-SMV.

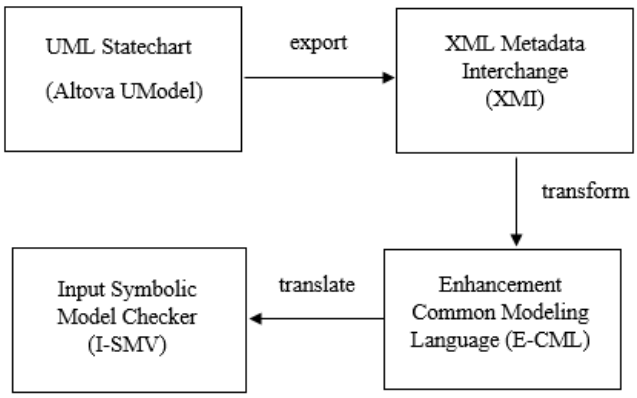

Fig. 1. Research framework.

B. Enhancement of Common Modeling Language

The E-CML is an extension of the CML based on the features of the UML Statecharts. Definition 1 defines the formal definition of E-CML as follows:

Definition 1: Enhancement Common Modeling Language

E-CML = <S, S_0, S_c, G, T, Regions, L, Gp, R>

Where:

S = finite set of states, where each state, s, is declared one of the two types: {AND, OR}.

S_0 = set of initial states ($S_0 \subseteq S$). S_0 forms a valid initial transition relation.

Sc = set of states that form a valid state configuration.

G = finite set of triggers.

T = finite set of transition relations, T = S x G x S'.

Regions = finite set of regions.

Gp = finite set of group components. Each group component consists of states, an initial state, triggers, transitions, and a region. Gp = <S, S_0, S_c, G, T, Regions>.

L = $S \rightarrow Gp'$ is the group component-level function. If $Gp' \subseteq L(S)$, then Gp' is an immediate descendant of S. The function of L describes the hierarchical state of the model.

R = relation between the superstate and group components, Gp.

There are two types of E-CML states: AND and OR. The AND state models concurrency by composing multiple simultaneous group components, Gp. The AND state is a superstate for the group components, Gp, of the statechart that are concurrently active. The descendants of the AND state must always be the OR state. The OR state is a state that supports one of the states inside another, providing a hierarchy in the behavior model. The OR state has states related to each other by an exclusive OR relationship. The leaf states of the E-CML must always be OR states. Each OR state has its region.

Each region is represented as the group component, Gp, in E-CML, consisting of the initial state, S_0, states, S, transitions, T, triggers, G, and the region. This also includes the outermost region represented as a group component, Gp. At runtime, E-CML allows multiple active states, referred to as a state configuration, S_c. A state configuration, S_c, always contains one state from the AND state and all states from the OR states.

Fig. 2 illustrates an example of the UML Statechart model that consists of multiple hierarchical statecharts. It shows there are basic states (A, D, G, H, I, J, M, N, O, and P), AND states (B and C), and OR states (E, F, K, and L). B state contains two OR states (E and F), E state contains two basic states (G and H), and the F state contains two basic states (I and J). Meanwhile, the C state contains two OR states (K and L), the K state contains two basic states (M and N), and the L state contains two basic states (O and P).

The operation of the E-CML is described using the step semantics. The state configuration, S_c, of E-CML starts with the initial state, S_0. In E-CML, when the state configuration, S_c, includes a composite AND state, all of its regions are active concurrently. Each region typically behaves like an OR state, meaning exactly one substate within each region is active at any time.

For example, the state configuration for the AND states in Fig. 2 should be (B, G, I) or (B, H, J) and (C, M, O) or (C, N, P). In E-CML, a transition will always occur at each step in each active state configuration, S_c. An implicit transition is triggered if no explicitly modeled transitions are enabled. The synchronization of E-CML allows it to be flattened into sequential automata, preserving the formal model semantics. Each single flattened component E-CML is equivalent to a sequential automaton [6].

Fig. 3 illustrates the flattened hierarchical E-CML structure of the UML Statechart model in Fig. 2.

Therefore, the single flattened component E-CML is known as the group component, Gp, in Fig. 3 as follows:

Gp_1 = ({A, B, C, D}, A, {E1, E2, E7, E8, E13, E14}, {(A, E1, B), (B, E2, A), (B, E7, C), (C, E8, B), (C, E8, B), (C, E13, D), (D, E14, C)}, Region 1)

Gp_2 = ({G, H}, G, {E3, E4}, {(G, E3, H), (H, E4, G)}, Region 2)

Gp_3 = ({I, J}, I, {E5, E6}, {(I, E5, J), (J, E6, I)}, Region 3)

Gp_4 = ({M, N}, M, {E9, E10}, {(M, E9, N), (N, E10, M)}, Region 4)

Gp_5 = ({O, P}, O, {E11, E12}, {(O, E11, P), (P, E12, O)}, Region 5)

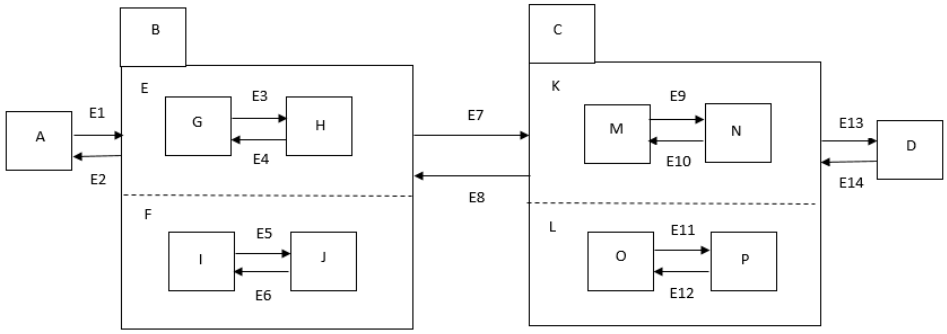

Fig. 2. UML Statechart model.

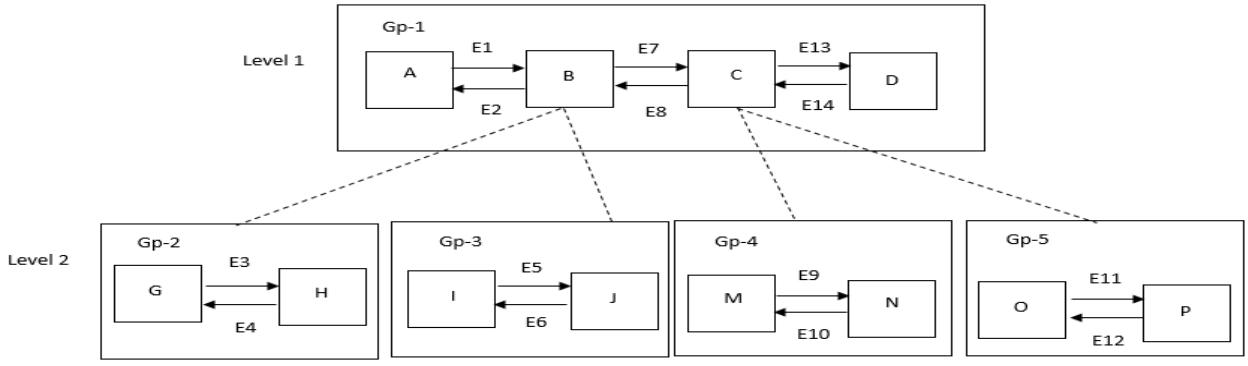

Fig. 3. Flattened hierarchical E-CML structure.

The sequence of elements in the group component, Gp, follows the sequence of variables in the formal definition of the group component, Gp, as given in Definition 1. The group component, Gp, interacts through events. In the following step, an event may trigger a transition in the system's synchronous group component, Gp. If the event triggers a transition from a state and the result is a group component, Gp, then the state is referred to as a superstate. For example, B is the superstate of Gp_2 and Gp_3, while C is the superstate of Gp_4 and Gp_5. This situation creates inter-level transitions. The inter-level

transitions cross hierarchy boundaries. If a transition leaves a superstate, the firing of all transitions containing the group components, Gp, of the superstate is suppressed, as represented by the dotted line in Fig. 3. This creates the relations, R, between the superstate and group components, Gp. Therefore, the group component level function, L, is created. The superstate's group component level function, L, is Level 1. The descendant of the superstate's group component level function, L, is Level 2. Therefore, the relation, R, between superstate and group components, Gp, is defined as follows:

Gp_2: receive a message from Gp_1

Gp_3: receive a message from Gp_1

Gp_4: receive a message from Gp_1

Gp_5: receive a message from Gp_1

Gp_1: receive a message from Gp_2, Gp_3, Gp_4, and Gp_4

In the E-CML, there are two processes involved: transforming the UML Statechart to the E-CML and translating the E-CML to the I-SMV. Therefore, we use the formal definition of I-SMV that is defined by [6]. The formal definition of I-SMV is as follows:

Definition 2: Input Symbolic Model Verifier

I-SMV = <M, V, N, Y>

Where:

M = set of finite modules

V = set of finite state variables

N = set of next states

Y = relation between modules

The I-SMV is modular. The high-level module is called the main module, while the other modules are known as sub-modules. In a module, M, there are state variables, V, to describe the module. A state evolves from one state to another through a next operator, N. The relation, Y, between one module and another is described by using a set of parameters. A set of rules guides the translation from E-CML to I-SMV.

C. Translation Rules of Enhancement of Common Modeling Language

Based on Definition 2, several rules of translation are created to map the E-CML, which is the source model, to the I-SMV, the target model. The translation from the source model to the target model can be defined by using a set of rules [31]. In the I-SMV, the group component, Gp, of E-CML corresponds to the module, M. The set of states, S, and triggers, G, corresponds to the state variables, V. The transitions, T, correspond to the next state, N. Lastly, the relation, R, between the superstate and group components, Gp, corresponds to the relation between modules, Y. The translation rules for mapping the E-CML to the I-SMV are defined as follows:

Rule 1 (Module): Let Grp be the set of group components in the E-CML. Each $Grp_i \in Grp$ is modeled as a module declaration in I-SMV as follows:

Module Grp_i ($arg_i, \ldots\ldots, arg_{i+1}$)

where, i = 1, ..., n, and n is the maximum integer.

If $Grp_i \in Grp$ does not exist, then the execution must be terminated. In I-SMV, arg_i refers to the actual parameter of a module within the main module.

Rule 2 (Variable): Let St be the set of states and Gr be the set of triggers in the E-CML, $St_i \in St$ is declared inside a module as follows:

$St_i : s_1, \ldots., s_{n+1}$; if St is an integer type

$St_i : \{s_1, \ldots., s_n\}$; if St is enumerated type

$St_i : \{\}$; if St is a Boolean type

$Gr_i \in Gr$ is declared inside a module as follows:

$Gr_i : g_1, \ldots., g_{n+1}$; if Gr is an integer type

$Gr_i : \{g_1, \ldots., g_n\}$; if Gr is enumerated type

$Gr_i : \{\}$; if Gr is a Boolean type

Rule 2 is used if and only if the represented module exists and either $St \neq \{\}$ or $Gr \neq \{\}$.

Rule 3 (State change): Tr be the set of transitions. In E-CML, state changes may occur with or without a trigger, Gr. This implies changes between the source state, Ss, and the target state, St, with or without the presence of the trigger. The state changes in I-SMV are defined as follows:

```
next (St): =
  case {
        Tri: St; if gr ∈ Gr, Gr ≠ {}
        Tri: Ss; if gr ∈ Gr, Gr ≠ {}
        default St;
  };
```

The first statement defines the state changes caused by triggered transitions, while the second statement defines the state changes caused by null-triggered transitions.

Rule 4 (Relation between modules): Let $St\text{-}Grp_b.R_b$, $St\text{-}Grp_c.R_c$, $St\text{-}Grp_d.R_d$, and $St\text{-}Grp_e.R_e$ are state variables for Grp_a. Let $St\text{-}Grp_a.R_a$ is the state variable for Grp_b, Grp_c, Grp_d, and Grp_e. The relation between those levels is defined as follows:

Module main()

$St\text{-}Grp_b : Grp_b (St\text{-}Grp_a.R_a)$;

$St\text{-}Grp_c : Grp_c (St\text{-}Grp_a.R_a)$;

$St\text{-}Grp_d : Grp_d (St\text{-}Grp_a.R_a)$;

$St\text{-}Grp_e : Grp_e (St\text{-}Grp_a.R_a)$;

$St\text{-}Grp_a : Grp_a (St\text{-}Grp_a.R_a)$;

$St\text{-}Grp_a$, $St\text{-}Grp_b$, $St\text{-}Grp_c$, $St\text{-}Grp_d$, and $St\text{-}Grp_e$ are state variables in the main module. In I-SMV, the arguments to a module are defined by the state variable of the destination message, followed by the state variable of the source message.

IV. Results and Discussion

In this section, we implement the E-CML for the Surgical Consultation in the Outpatient Clinic Health System as the case study. In general, doctors will refer patients for surgical consultation if they believe the underlying health condition can be effectively treated through surgery. Following the referral, the outpatient clinic schedules an appointment with the surgeon and arranges for samples to be collected if further diagnostic tests are required. The surgeon evaluates the necessity for an operation by analysing symptoms and test results during the consultations. Following a decision to proceed, the patient is registered on a surgical wait list to ensure an appropriate time is booked for use of the operating room. Before surgery, the patient may be educated by the surgeon about the procedure. When the operating room is already booked, the patient waits for their scheduled surgery date. Fig. 4 illustrates the UML Statechart Surgical Consultation in the Outpatient Clinic Health System.

Fig. 4 illustrates that there are two AND states ("Receiving referral" and "Receiving treatment") and four OR states ("Appointment", "Diagnostic Test", "Surgical Waiting List", and "Education"). There are three basic states at the outermost region ("Waiting for referral to clinic", "At consultation", and "Operation booked"), two basic states at the "Appointment" state ("Pending 1" and "Booked"), two basic states at the "Diagnostic Test" state ("Pending 2" and "Sample taken"), two basic states at the "Surgical Waiting List" state ("Pending 3" and "On waiting list"), and two basic states at the "Education" state ("Pending 4" and "Educated"). This model has five regions; each OR state has one region, and the other region is the outermost region. Fig. 5 illustrates the flattened hierarchical E-CML structure for the Surgical Consultation in the Outpatient Clinic Health System.

Based on Fig. 5, each flattened is referring to the group component, Gp, and is defined as follows:

Gp_1 = ({Waiting for referral to clinic, Receiving referral, At consultation, Receiving treatment, Operation booked}, Waiting for referral to clinic, {referral to clinic, patient referral at clinic, treatment decided, booked operation}, {(Waiting for referral to clinic, referral to clinic, Receiving referral), (Receiving referral, patient referral at clinic, At consultation), (At consultation, treatment decided, Receiving treatment), (Receiving treatment, booked operation, Operation booked)}, Region 1).

Gp_2 = ({Pending 1, Booked}, Pending 1, {make booking}, {(Pending 1, make booking, Booked)}, Region 2)

Gp_3 = ({Pending 2, Sample taken}, Pending 2, {take sample}, {(Pending 2, take sample, Sample taken)}, Region 3)

Gp_4 = ({Pending 3, On waiting list}, Pending 3, {register}, {(Pending 3, register, On waiting list)}, Region 4)

Gp_5 = ({Pending 4, Educated}, Pending 4, {educate}, {(Pending 4, educate, Educated)}, Region 5)

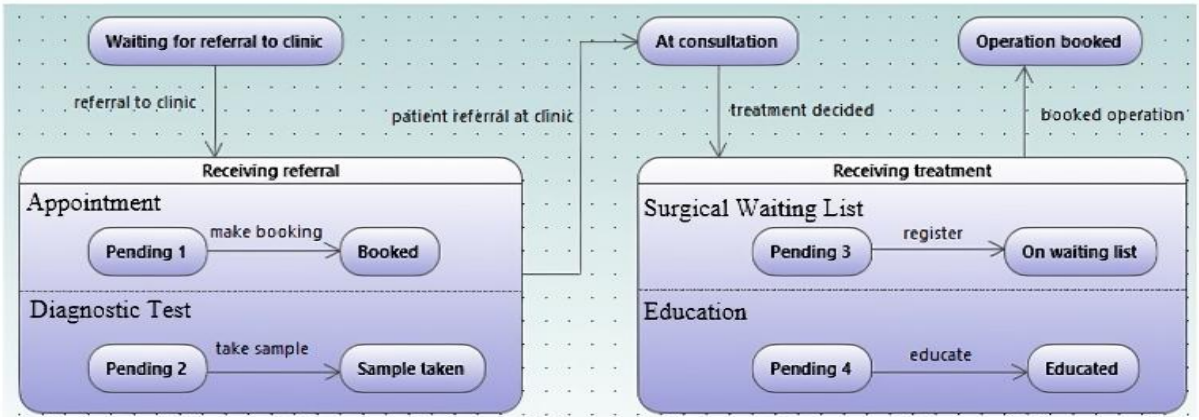

Fig. 4. UML Statechart surgical consultation in the outpatient clinic health system.

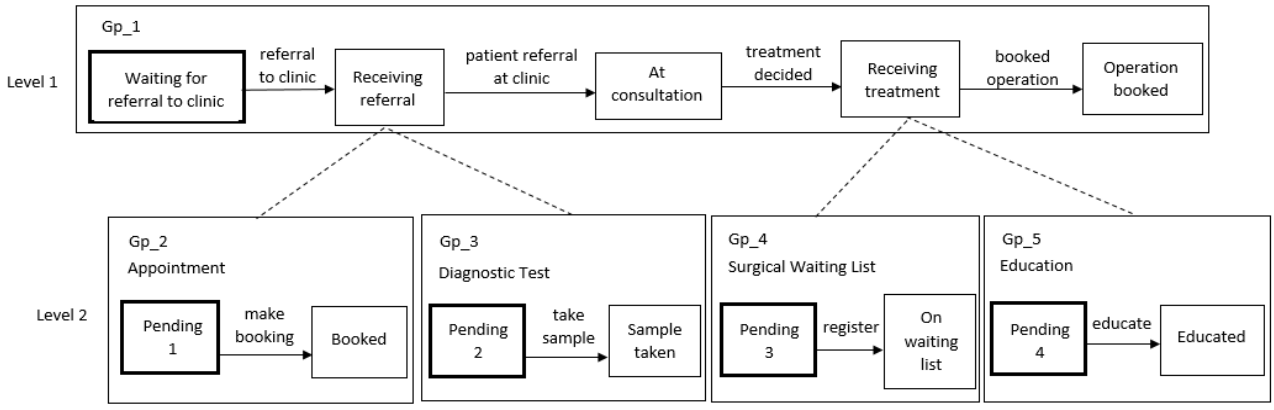

Fig. 5. Flattened hierarchical E-CML structure for surgical consultation in the outpatient clinic health system.

The relation, R, between superstate and group components, Gp, is defined as follows:

Gp_2: receive a message from Gp_1

Gp_3: receive a message from Gp_1

Gp_4: receive a message from Gp_1

Gp_5: receive a message from Gp_1

Gp_1: receive a message from Gp_2, Gp_3, Gp_4, and Gp_4

We use the translation rules of E-CML (Rule 1-4) to translate the E-CML into the I-SMV. Rule 1: Each group component, Gp, in E-CML is translated to the module's name in the I-SMV, followed by the list of arguments. Each module's arguments are based on the relation, R, which is translated in Rule 4. Therefore, the modules are defined as follows:

```
MODULE Gp_2 (gp_1)
MODULE Gp_3 (gp_1)
MODULE Gp_4 (gp_1)
MODULE Gp_5 (gp_1)
MODULE Gp_1 (gp_2, gp_3, gp_4, gp_5)
```

Rule 2 is regarding the variables declared for each module. All states, S, and triggers, G, in E-CML are defined as follows:

```
MODULE Gp_2 (gp_1)
VAR
    state:{Pending 1, Booked};
    trigger2:{make booking};
MODULE Gp_3 (gp_1)
VAR
    state:{Pending 2, Sample taken};
    trigger3:{take sample};
MODULE Gp_4 (gp_1)
VAR
    state:{Pending 3, On waiting list};
    trigger4:{register};
MODULE Gp_5 (gp_1)
VAR
    state:{Pending 4, Educated};
    trigger5:{educate};
MODULE Gp_1 (gp_1)
VAR
    state:{Waiting for referral to clinic, Receiving
    referral, At consultation, Receiving treatment,
    Operation booked};
    trigger6:{referral to clinic, patient referral at clinic,
    treatment decided, booked operation};
```

Rule 3 is regarding the transitions, T, in the E-CML, which are translated to the next (state) in the I-SMV. Therefore, the next (state) in the I-SMV is defined as follows:

```
MODULE Gp_2 (gp_1)
…..
next (state):= case
    ((state = Pending 1) & (trigger2 = make
    booking)): Booked;
1: state;
esac;
MODULE Gp_3 (gp_1)
…..
next (state):= case
    ((state = Pending 2) & (trigger3 = take sample)):
    Sample taken;
1: state;
esac;
MODULE Gp_4 (gp_1)
…..
next (state):= case
    ((state = Pending 3) & (trigger4 = register)): On
    waiting list;
1: state;
esac;
MODULE Gp_5 (gp_1)
…..
next (state):= case
    ((state = Pending 4) & (trigger5 = educate)):
    Educated;
1: state;
esac;
MODULE Gp_1 (gp_2, gp_3, gp_4, gp_5)
…..
next (state):= case
    ((state = Waiting for referral to clinic) & (trigger6 =
    referral to clinic)): Receiving referral;
    ((state = Receiving referral) & (trigger7 = patient
    referral at clinic)): At consultation;
    ((state = At consultation) & (trigger8 = treatment
    decided)): Receiving treatment;
```

((state = Receiving treatment) & (trigger9 = booked operation)): Operation booked;

1: state;

esac;

Rule 4 is regarding the relation, R, between superstate and group components, Gp, in E-CML. In -SMV, Rule 4 is translated into MODULE main. The state variable of the MODULE main is defined as a call module for the corresponding group component. The arguments in each call module are the state variable of the source state, followed by its message passing. The relation between modules is defined as follows:

MODULE main:

VAR

gp_2: Gp_2 (gp_1);

gp_3: Gp_3 (gp_1);

gp_4: Gp_4 (gp_1);

gp_5: Gp_5 (gp_1);

gp_1: Gp_1 (gp_2, gp_3, gp_4, gp_5);

Based on the relation between modules above, gp_2, gp_3, gp_4, and gp_5 are state variables used as arguments for the module in Gp_1. The gp_1 is the state variable for the modules in Gp_2, Gp_3, Gp_4, and Gp_5. We use the SMV model checker to verify the UML Statechart in Fig. 4. The formalized properties need to be specified on the "SPEC" keyword in the I-SMV file. Table II shows the list of formalized properties, descriptions, and the results.

A. Discussion

In this section, we discuss and explain the results that were obtained from the proposed method. All the formalized properties, which cover the multiple hierarchical statecharts, are verified as TRUE. P1 is verified as TRUE because the specification defines that the patient can book an appointment and take the diagnostic test in the future, even though the patient is not waiting for the referral. P2 is verified as TRUE because the specification states that the patient always receives a consultation from the doctor after completing the booking appointment and taking the diagnostic sample test. P3 is verified as TRUE because the specification defines that the patient can always book the operation date after registering on the waiting list and getting education about the surgery from the surgeon. P4 is verified as TRUE because the specification defines that the patient can be on the waiting list for an operation and can receive education about the surgery from the surgeon after the patient receives a consultation from the surgeon.

According to reference [15], correctness is defined as adherence to the specifications and the way software behaves when these correctness specifications are applied. The results indicate that E-CML can serve as an effective intermediate language, as the verification of the specifications returned a result of TRUE. Moreover, E-CML is able to verify complex systems that have multiple hierarchical statecharts, which are a common feature for modern complex systems.

TABLE II. FORMALIZED PROPERTIES, DESCRIPTIONS, AND RESULTS

Property	Description	CTL	Result
P1	A patient who is not waiting for a referral may be able to book an appointment and undergo the diagnostic tests in the future.	AG (!(gp_1.state = Waiting_for_referral_to_clinic) → EF (gp_2.state = Booked & gp_3.state = Sample_taken))	True
P2	A patient who completes a booking and has taken a sample for a diagnostic test is eligible for a consultation.	AG (gp_2.state = Booked & gp_3.state = Sample_taken) → EF (gp_1.state =At_consultation)	True
P3	A patient registered for the operation and received education from the surgeon can book the operation date.	AG ((gp_4.state = On_waiting_list & gp_5.state = Educated) → EF (gp_1.state = Operation_booked))	True
P4	The patient whom the surgeon has consulted can be placed on the waiting list for the operation and receive education on the operation.	AG ((gp_1.state = At_consultation) → EF (gp_4.state = On_waiting_list & gp_5.state = Educated))	True

TABLE III. COMPARISON OF THE E-CML WITH THE OTHER APPROACHES

Method	Approach	Intermediate Language	Substate	Orthogonal State	History State (depp/shallow)
E-CML	Indirect transformation	E-CML	/	/	X
Colored Petri Nets [11]	Direct transformation	-	/	/	/
Gamma Statechart [9]	Indirect transformation	Gamma Statechart	/	X	X

Table III illustrates a comparison between E-CML and other approaches. We compare E-CML with the approaches proposed in [11] and [9]. We also consider the UML Statechart elements covered by each approach during the verification process. The symbols "/" and "X" indicate "supported" and "not supported", respectively.

In [11], the authors proposed a method based on a direct transformation approach, which transforms one model into another without using an intermediate language. The authors utilized UML Statechart to express the system's behavior and formalized it into the CPN. This approach uses the transformation rules to map the elements of the UML Statechart to CPN. In contrast, E-CML provides a formal definition that represents the elements of the UML Statechart. It also includes transformation rules to transform E-CML into an I-SMV file, which is used as the input language for the verification process with the SMV model checker. The E-CML helps and encourages the user to apply the model checking method without requiring knowledge of SMV syntax or CPN.

As discussed, both approaches are capable of verifying multiple hierarchical statecharts. However, some UML Statechart elements are not included in E-CML, whereas they are included in the approach proposed in [11], such as history state (deep and shallow).

Meanwhile, reference [9] proposed a method based on an indirect transformation approach, which same approach used by E-CML and requires an intermediate language. The authors utilized UML Statechart to express the system's behavior and transformed it into the TA. This approach also considers the transformation of ports in the physical components. In contrast, E-CML focuses only on behavioral aspects and does not transform or include physical components. As discussed, both approaches are capable of verifying multiple hierarchical statecharts. However, some UML Statechart elements are not included in the approach proposed in [9], whereas they are included in E-CML, such as orthogonal states. Nevertheless, both approaches do not include the history state (deep and shallow).

V. Conclusion

This study presents a proposed solution for verifying complex systems that are inherently more intricate and difficult to verify. Modern systems often incorporate multiple hierarchical statecharts within their behavior modeling diagram, which significantly complicates the verification process. Therefore, E-CML, an enhancement of CML, helps the users verify complex systems with multiple hierarchical statecharts and ensure their correctness. E-CML introduces group components comprising an initial state, a set of states, transitions, triggers, and a region, to formally differentiate the group components from superstates. It creates new translation rules to define multiple hierarchical statecharts and complex systems that relate to the group components. E-CML demonstrates that it can verify the formalized properties of multiple hierarchical statecharts model. As a result, all of the formalized properties are verified as TRUE. Thus, E-CML enables verification of unverified complex systems. However, E-CML has a limitation in that it cannot verify the history states, including either the deep or shallow pseudostate. This feature is an important element of the UML Statechart that can represent the behavior of complex systems. Some modern systems also include a history state in the behavioral models to store the last active state, such as in air conditioning systems. Therefore, it is important to enhance E-CML to include all UML Statechart elements capable of representing complex systems. This enhancement will enable the verification of all types of complex systems built today.

***Abstract*—The rapid evolution of deep generative models has facilitated the creation of "Deepfakes", enabling the synthesis of hyper-realistic facial manipulations that threaten the trustworthiness of digital media. While forensic countermeasures have been developed to identify these forgeries, deepfake detection in real-world scenarios is severely hampered by video compression artifacts, which often obscure the subtle pixel-level traces exploited by conventional Convolutional Neural Networks (CNNs). This study introduces a robust detection framework designed specifically to withstand the aggressive compression inherent to social media dissemination. We present a hybrid 3D architecture that integrates the local spatiotemporal feature extraction capabilities of a 3D-ResNet-50 backbone with the global context modeling of a temporal Video Vision Transformer. Unlike frame-based or joint spatiotemporal attention approaches, the proposed model performs fully video-level reasoning and utilizes a factorized self-attention mechanism to decouple spatial and temporal modeling, thereby preserving stable temporal cues under compression while minimizing computational costs. Experimental results on the compressed protocols of the FaceForensics++ dataset as well as Celeb-DF-v2 and DFDC datasets, including cross-dataset generalization evaluation, validate the efficacy of this design, demonstrating that our method achieves superior detection accuracy and generalization compared to existing baselines, particularly on low-quality inputs.**

Keywords*—Deepfake detection; compressed deepfake videos; low-quality deepfakes; 3D convolutional neural networks; Video Vision Transformer

I. Introduction

Recent advances in deep generative modeling have enabled the creation of highly realistic synthetic audiovisual content, giving rise to what are commonly referred to as deepfakes [1]. A deepfake is a piece of media; typically a video, image, or audio clip, created or manipulated using deep neural networks to convincingly imitate real individuals or events. Although the term has become strongly associated with disinformation and online abuse, the underlying technologies offer several legitimate and beneficial applications [2]. These include privacy-preserving data generation for machine learning, synthetic training datasets for rare-event detection, improved dubbing in film production, educational reenactments, and assistive technologies for individuals with speech impairments.

Despite these positive uses, deepfakes pose significant societal and security risks. High-fidelity manipulations can be leveraged to spread political misinformation, facilitate identity or financial fraud, generate non-consensual explicit content, or erode public trust in digital media [3]. As generative models continue to improve in resolution, coherence, and computational efficiency, distinguishing authentic content from manipulated media becomes increasingly challenging. The pervasive dissemination of deepfake videos across social platforms exacerbates this issue, contributing to large-scale misinformation campaigns and undermining the reliability of digital communication ecosystems.

In response to this adversarial landscape, the forensic community has developed a variety of detection algorithms designed to identify the subtle, distinct trace anomalies left by generative models. However, a critical disparity exists between the performance of these detectors in controlled environments and their efficacy in real-world deployment [4]. While deepfake generation has become increasingly sophisticated, often outpacing conventional detection cues, the primary challenge in practical application lies in the transmission medium itself. To accommodate bandwidth constraints and storage limitations, online distribution platforms routinely subject video content to aggressive lossy compression standard H.264. This compression process introduces a complex, two-fold impediment to forensic analysis. First, the quantization inherent in lossy compression acts as a low-pass filter, effectively smoothing out the high-frequency noise patterns and subtle pixel-level artifacts that many detectors rely upon as fingerprints of manipulation. Second, the compression algorithms introduce their own structural noise, such as blocking artifacts and ringing, which can mask manipulation traces or mimic them, leading to increased false positives. Consequently, the robustness of existing state-of-the-art detectors degrades precipitously when applied to low-quality, highly compressed media [5]. Addressing this vulnerability created by compression, remains one of the most pressing open challenges in multimedia forensics.

This study presents a fully video-level approach for robust deepfake detection in highly compressed videos, a setting in which conventional frame-based detectors often fail due to the suppression of spatial and frequency-domain forensic cues. While most existing detection methods process videos on a frame-by-frame basis using 2D representations, contemporary deepfake generation pipelines operate sequentially across time, inherently introducing temporal patterns that persist even under aggressive compression. Motivated by this mismatch, we

formulate compression-robust deepfake detection as an end-to-end spatiotemporal learning problem.

To this end, we propose a hybrid spatiotemporal architecture that integrates the local representational capacity of a 3D convolutional neural network (3D-CNN) with the global temporal modeling capability of a factorized self-attention video vision transformer. By consistently operating in the 3D domain, from feature extraction to long-range temporal reasoning, the proposed model jointly captures localized spatiotemporal artifacts and global temporal dependencies, enabling improved robustness under severe compression and in-the-wild video conditions.

The primary contributions of this work can be summarized as follows:

- We introduce a fully video-level detection framework that departs from the dominant frame-based paradigm by employing a pretrained 3D-CNN backbone to extract joint spatial–temporal representations directly from video clips, allowing the model to exploit motion and temporal coherence that remain informative in low-quality, compressed video streams.
- We employ a factorized attention mechanism that separately models spatial and temporal dependencies. Ablation experiments demonstrate that this decoupled formulation yields more robust performance than joint spatiotemporal attention under severe compression, suggesting that preserving distinct spatial and temporal representations is beneficial for low-quality video forensic analysis.
- We conduct extensive experiments including comparisons with state-of-the-art spatial and frequency-domain methods, and detailed ablation studies which demonstrate that the proposed fully 3D spatiotemporal approach achieves competitive performance under mild compression and consistently superior robustness under aggressive compression across multiple benchmarks.

The remainder of this study is structured as follows: Section II introduce deepfake generation and reviews existing detection approaches. Section III details the proposed hybrid 3D-CNN and transformer-based architecture. Section IV describes the experimental setup and reports the results. Section V provides discussion, analysis, and insights. Section VI concludes the study.

II. Related Work

A. Deepfake Generation

Deepfake videos are commonly produced through deep generative models that learn statistical representations of facial structure, appearance, and motion. Early face-swapping systems employed autoencoder-based architectures in which a shared encoder mapped facial inputs into a latent representation, and identity-specific decoders reconstructed the manipulated output. These methods enabled basic identity replacement, but were often limited in realism.

Subsequent advancements in generative adversarial networks (GANs) [6] and variational autoencoders (VAEs) [7] marked a significant leap in synthesis quality. GAN-based models introduced adversarial training mechanisms that encouraged the generator to produce content indistinguishable from real data, resulting in improved texture fidelity, lighting realism, and temporal smoothness. More recently, diffusion models have demonstrated state-of-the-art performance in photorealistic image and video generation by iteratively denoising latent representations and capturing fine-grained visual structures.

These generative architectures underpin the two most prevalent and impactful categories of facial manipulation: Face Swap and Face Reenactment.

- Face Swap: This technique involves transferring the facial identity of a source individual onto a target person within a video. Initial approaches relied heavily on autoencoder architectures; however, recent advances predominantly utilize generative adversarial networks (GANs) to achieve higher-quality and more seamless facial replacements, surpassing the limitations of earlier methods.
- Face Reenactment: Unlike identity transfer, face reenactment manipulates the facial expressions, head poses, and movements (such as mouth and eye dynamics) of the target video to mimic those of a source video, while preserving the target's inherent identity. This is commonly realized by extracting facial landmarks or action units from the source and applying them to the target, followed by a GAN-based synthesis to produce photorealistic frames faithfully reflecting the altered expressions and movements.

The rapid evolution of these generative technologies has triggered an ongoing arms race between increasingly sophisticated forgery techniques and the development of advanced detection methodologies aimed at mitigating emerging threats posed by highly realistic digital manipulations.

B. Deepfake Detection Approaches

Despite continuous advancements, deepfake synthesis methods remain bound by inherent architectural limitations which, inevitably introduce subtle digital artifacts embedded within manipulated media. These artifacts can be visually identified within individual frames as spatial features, such as unnatural facial textures or lighting inconsistencies. Additionally, they may manifest as temporal features reflecting unnatural movements or inconsistent transitions between frames, including irregular expressions or blinking patterns. The spatial and temporal cues, while often imperceptible to the human visual system, provide critical forensic traces (i.e. fingerprints). The challenge of reliably detecting these traces has given rise to a diverse spectrum of detection methodologies and approaches, which broadly fall into three main categories: handcrafted-based feature, deep learning-based feature, and multi modal approaches.

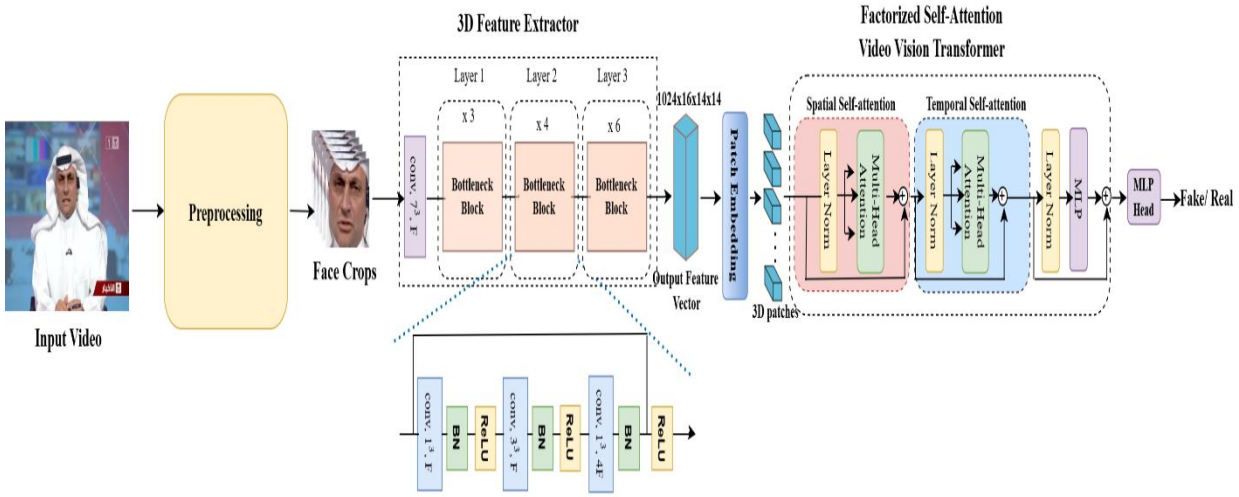

Fig. 1. Illustration of the proposed deepfake detection system.

1) Handcrafted-based features approach: This approach exploits traditional forensic cues such as inconsistencies in color blending, illumination, facial boundaries, and compression artifacts. For instance, inconsistent head poses indicate manipulation through unnatural geometric variations [8]. Face warping artifacts, introduced by affine transformations during deepfake synthesis, serve as discriminative signals [9]. Detection of blending boundary inconsistencies between the forged face and background is addressed by the face X-ray technique [10]. Another line of research leverages subtle physiological and behavioral inconsistencies inherent in deepfakes. Eye blinking patterns, typically involuntary and natural, are often absent or abnormal in synthesized videos, providing temporal cues for detection [11]. Heartbeat-induced photoplethysmographic (PPG) signals, reflecting blood flow and skin color variations, are also lacking in forgeries, effectively leveraged by Ciftci et al. [12]. Furthermore, phoneme-viseme mismatches, arising from a lack of synchronization between audio phonemes and lip movements (visemes), expose audiovisual inconsistencies unique to manipulated content [13].

While handcrafted-based methods are effective against early deepfakes, it often struggle to generalize to advanced generation techniques.

2) Deep learning-based feature approach: Deep learning-based feature approaches primarily leverage convolutional neural networks (CNNs), vision transformers (ViTs) [14], and hybrid spatiotemporal architectures to automatically learn discriminative representations. These models capture subtle spatial distortions, temporal inconsistencies, and generator-specific fingerprints that are typically imperceptible to human observers, thereby enabling robust detection of deepfake content. Afchar et al. [15] proposed MesoNet, a lightweight CNN that targets mesoscopic spatial features for detecting forged faces. Capsule-forensics [16] employed Capsule networks, which are known by their ability to catch hierarchical relationships and preserve spatial features better than convolutional neural networks. F^3Net is a dual-branch network that captures both local and global frequency features, employing a CNN for classification in deepfake detection [17]. SurFake model [18], which identifies manipulations by analyzing the surface geometry of faces to capture anomalies in surface caused by the forging process. FreMask [19] is a method that enhances deepfake detection by applying random masks to frequency components during training. This frequency-domain augmentation improves model robustness and generalization. The work in [20] employs a learnable uniform visibility matrix to guide the model in emphasizing subtle, imperceptible artifacts that remain in videos even after compression. Additionally, plug-and-play modules [21] with adaptive notch filters specifically remove compression noise while multi-task learning optimizes detection across domains, boosting robustness.

Deep learning methods have become central in deepfake detection due to their ability to autonomously learn intricate spatial and temporal features that reveal subtle manipulations.

3) Multimodal approach: Multimodal deepfake detection approach integrates multiple sources of information, typically combining visual and audio data, to improve detection accuracy and robustness. By fusing complementary features such as facial expressions, lip movements, voice characteristics, and audio-visual synchronization, these methods aim to capture inconsistencies that are difficult to detect using single-modality models. Salvi et al. [22] proposed an integrated system combines CNN-based visual frame analysis with audio spectrogram processing, jointly exploiting visual and auditory cues to detect deepfakes. Gandhi et al. [23] introduced a framework that jointly analyzes facial characteristics and mel-spectrogram audio features using machine learning models, achieving high detection accuracy by fusing these modalities. Alsaeedi et al. [24] proposed a multimodal fusion mechanism that integrates pre-trained audio, visual, and textual emotion features, leveraging speech sentiment and facial expressions to enhance detection robustness and accuracy.

These multimodal methods demonstrate the power of combining multiple modalities to detect subtle and sophisticated deepfake manipulations.

III. Proposed Method

To address the problem of performance degradation in videos affected by compression, this study proposes an end-to-end learning framework that transcends conventional frame-level analysis. The model comprises two primary units: first, a spatiotemporal feature extractor utilizing 3D convolutional layers to process video segments of fixed spatial and temporal dimensions; second, a transformer-based classifier that leverages factorized attention mechanisms to effectively integrate spatial and temporal features. This design enables the model to robustly distinguish between authentic and manipulated videos, maintaining high detection accuracy even under varying compression levels and quality impairments. Detailed architectural specifications are provided in the following sections:

1) Feature extraction unit: To extract robust spatiotemporal representations from the input video sequences, we employ a 3D-CNN backbone derived from the 3D-ResNet-50 architecture [25]. This framework extends the standard ResNet-50 into the temporal domain, utilizing three-dimensional convolutional kernels to inherently model volumetric video data.

The baseline architecture consists of 50 layers organized into four stages of residual bottleneck blocks. As illustrated in Fig. 1, each bottleneck unit comprises a sequence of three convolutional layers: a 1×1 convolution for dimensionality reduction, a 3×3 convolution for joint spatial and temporal features extraction, and a final 1×1 convolution for restoring the dimensionality. These layers are interleaved with Batch Normalization (BN) and Rectified Linear Unit (ReLU) activation functions. A residual skip connection bridges the input and output of each block, preserving signal integrity during backpropagation and facilitating the convergence of deep architectures. To ensure robust initialization, the model is pretrained on the Kinetics-700 dataset [26], leveraging learned weights optimized for large-scale action recognition.

To tailor this architecture specifically for the detection of fine-grained manipulation artifacts, we introduce two critical modifications: 1) Temporal Resolution Preservation: We adjusted the stride of the initial max-pooling layer from the default (*2, 2, 2,)* to (*1, 2, 2)*. By removing the temporal downsampling at this early stage, we preserve the full temporal resolution of the input sequence, allowing the network to capture subtle high-frequency frame-to-frame inconsistencies. 2) Mid-Level Feature Extraction: We truncated the network by removing the final residual block (Layer 4) and the fully connected layer. Consequently, feature maps are extracted from the output of the third residual block (Layer 3). Unlike the high-level semantic abstractions found in Layer 4, Layer 3 features retain the fine-grained spatiotemporal details essential for identifying the minute artifacts introduced by neural rendering.

The video clip consists of t consecutive frames, denoted as $\{I_1, I_2, \ldots, I_t\}$ where each frame I_i is an RGB image of fixed spatial resolution; h and w represent the height and width of the image, respectively. The corresponding clip's label is $y \in \{0, 1\}$, where $y = 0$ indicates an authentic (Real) video, while $y=1$ indicates a manipulated (Fake) video. The input tensor for the network is represented by the following shape [see Eq. (1)]:

$$X \in R^{B \times C \times T \times H \times W} \quad (1)$$

where, B denotes the batch size, $C = 3$ is the number of input channels corresponding to the RGB image, T is the temporal dimension (number of frames), and $H = W$ represent the height and width of each frame. The network processes this input as a video volume producing a feature tensor of shape:

$$F=f(X) \in R^{B \times C' \times T' \times H' \times W'} \quad (2)$$

where, $B = 1$, $C' = 1024$, $T' = 16$, $H' = W' = 14$, are the batch size, channel, temporal, height, and width dimensions of the output feature map, respectively. This tensor F encapsulates spatiotemporal feature maps, encoding both spatial patterns per frame and temporal dynamics across frames, and serves as the input to the classification module.

2) Classification unit: The Vision Transformer (ViT) is a transformer-based architecture designed for image recognition tasks, which divides an input image into small patches and processes them as a sequence of tokens. The core component of ViT is the self-attention mechanism, which enables the model to adaptively weight the importance of different patches in the image by computing pairwise interactions. This mechanism allows the transformer to capture long-range dependencies and global context from the earliest layers, unlike convolutional neural networks that rely on local receptive fields.

Our model leverages a factorized self-attention transformer inspired by the Video Vision Transformer (ViViT) [27] architecture. Unlike conventional Vision Transformers (ViT), which operate on 2D patch embeddings extracted from individual frames, the proposed transformer processes 3D patch embeddings derived from the output of a 3D-ResNet backbone, enabling the modeling of volumetric spatiotemporal representations. As illustrated in Fig. 1, the factorized self-attention module decomposes self-attention into separate spatial and temporal components: spatial self-attention is first applied independently within each frame to capture local appearance relationships, followed by temporal self-attention across frames at each spatial location to model motion and temporal dynamics.

While similar factorized attention designs have been explored in prior video transformer architectures, their adoption has largely been motivated by computational efficiency. In contrast, our use of factorized spatial–temporal attention is driven by robustness considerations in compressed video. Under aggressive compression, spatial features are disproportionately degraded, whereas temporal structure often remains more stable. By explicitly decoupling spatial and temporal attention, the model avoids entangling corrupted spatial cues with temporal reasoning. As confirmed by our ablation studies, this design consistently outperforms joint spatiotemporal attention in highly compressed settings, indicating that factorized attention is better aligned with the characteristics of low-quality video forensic analysis.

The 3D-ResNet output features tensor F from Eq. (2) is divided into nonoverlapping 3D patches across temporal and spatial dimensions. Given a patch size (p_t, p_h, p_w), where p_t, p_h, p_w are the temporal, height, and width dimensions of each patch, respectively, the number of temporal patches N_T and spatial patches N_S is given by Eq. (3) and Eq. (4):

$$N_T = \frac{T'}{p_t} \quad (3)$$

$$N_S = \frac{H'}{p_h} \times \frac{W'}{p_w} \quad (4)$$

While the total number of patches is calculated by Eq. (5):

$$N = \frac{T'}{p_t} \times \frac{H'}{p_h} \times \frac{W'}{p_w} \quad (5)$$

Each 3D patch x_i for (i = 1, ..., N) is then flattened into a vector and linearly projected into a fixed-dimensional embedding [see Eq. (6)]:

$$z_i = E(x_i) \quad (6)$$

where, $E \in R^{D \times (C' \cdot p_t \cdot p_h \cdot p_w)}$ is a learnable matrix, B is the batch size, and D is the embedding dimension. Thus, linearly projected N patches form a sequence of discrete tokens as follows [Eq. (7)]:

$$Z_0 = [z_1, z_2, \ldots, z_N] \in R^{B \times N \times D} \quad (7)$$

An extra class token Z_{cls} and positional embedding P are prepended and added as follows [Eq. (8)]:

$$Z' = [z_{cls}; Z_0] + P \quad (8)$$

This patch embedding step converts the volumetric feature maps into a tokenized sequence suitable for the architecture of the video transformer.

The transformer encoder processes the tokens Z' with alternating spatial and temporal self-attention blocks:

The spatial attention is applied independently on tokens from each temporal slice, modeling spatial relationships within each frame as follows [Eq. (9)]:

$$Z_{spa} = Sp - attn(Z') \in \mathbb{R}^{B \times N_T \times N_S \times D} \quad (9)$$

Following the spatial attention, the temporal attention integrates the spatial encodings across all temporal slices by applying self-attention along the temporal dimension over the class tokens output from the spatial attention. The output of the temporal attention is given by Eq. (10):

$$Z_{tmp} = tmp - attn(Z_{spa}) \in \mathbb{R}^{B \times N_S \times N_T \times D} \quad (10)$$

Finally, the output class token from the temporal attention block is passed through a Multi-layer Perceptron (MLP) head and sigmoid activation function to estimate probabilities for the classes (Real vs. Fake) [see Eq. (11)]:

$$\hat{y} = \sigma(MLP(Z_{cls})) \quad (11)$$

IV. Experiments

A. Datasets

To evaluate the proposed model, experiments are conducted on three widely used public deepfake detection benchmarks: FaceForensics++ (FF++) [28], Celeb-DF-v2 [29], and the DeepFake Detection Challenge (DFDC) [30] dataset. These datasets collectively cover controlled and in-the-wild scenarios, multiple manipulation techniques, and varying levels of video quality and compression.

1) FaceForensics++: FaceForensics++ (FF++) is a public dataset containing 1,000 authentic videos collected from YouTube and 4,000 manipulated videos generated using four manipulation techniques: Deepfakes (DF), Face2Face (F2F), FaceSwap (FS), and NeuralTextures (NT). The FaceForensics++ videos are compressed using the H.264 codec, with each manipulation technique provided in three compression variants: c0 represents raw or uncompressed videos, c23 represents high-quality videos with medium compression, and c40 represents low-quality videos under a high compression level. In this work, FF++ enables systematic evaluation of detection robustness across different manipulation types and compression regimes.

2) Celeb-DF-v2: This dataset is an extension of the original Celeb-DF dataset, which consists of 590 real videos for 59 celebrities collected from YouTube and 5639 fake videos generated from the real videos using an advanced face-swapping technique. Compared to earlier datasets, Celeb-DF-v2 exhibits significantly improved visual quality and reduced synthesis artifacts, making it one of the most challenging benchmarks for deepfake detection. The dataset is commonly used to assess generalization performance under high-fidelity manipulation conditions.

3) DeepFake Detection Challenge (DFDC): The DeepFake Detection Challenge (DFDC) dataset is a large-scale benchmark released as part of a competition organized by Meta (formerly Facebook). It contains over 128,000 videos generated from 3,426 paid actors spanning diverse ethnicities, genders, and age groups. Videos are captured under varying poses, lighting conditions, and recording environments to reflect real-world scenarios. Fake videos are generated using multiple manipulation techniques, including face swapping and expression manipulation.

In this work, DFDC is used exclusively to evaluate cross-dataset generalization. Models are trained on the FaceForensics++ dataset and tested on DFDC without fine-tuning, allowing assessment of robustness to unseen identities, manipulation pipelines, and real-world capture conditions.

B. Dataset Preprocessing

The auxiliary preprocessing unit takes the raw input MP4 video and transforms it into a standardized data format suitable for subsequent deepfake detection analysis. Initially, video frames are extracted sequentially using the OpenCV (cv2) library. For each extracted frame, the face detection and localization are performed via the Multi-task Cascaded Convolutional Networks (MTCNN) algorithm. The identified facial regions are then cropped and uniformly resized to 224×224 pixels to ensure network compatibility.

To enhance model robustness and generalization, a combination of both spatial augmentations (e.g., horizontal

flipping, rotation, color jitter) and temporal augmentations (e.g., frame shuffling, dropouts) is applied. The face crops are then normalized using the mean and standard deviation values derived from the Kinetics dataset to standardize feature distribution. The final output of this unit is a tensor representing a face clip (a stack of T=16 cropped and processed frames) and a corresponding ground-truth label tensor (indicating Real or Fake) for supervised training.

C. Experimental Setup

All experiments were conducted on the Google Colaboratory (Colab) platform using Python 3.11.13 and PyTorch 2.6.0, running on an NVIDIA L4 GPU. The model dimension was set to 384, with 6 attention heads and an MLP dimension of 1536. Training utilized the Adam optimizer with a learning rate of $1\times10-4$ and a weight decay of $1\times10-3$ to mitigate overfitting. The Focal Loss function was employed with a focusing parameter $\gamma=2$ and balancing factor $\alpha=0.25$. The model was trained for up to 30 epochs with a batch size of 32. The best checkpoint was selected based on performance. Evaluation metrics reported include:

- Accuracy (ACC): This metric measures the proportion of correct predictions (both true positives and true negatives) out of the total number of predictions made. If TP, TN, FP, FN denote true positives, true negatives, false positives, and false negatives, respectively. Accuracy is calculated as:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN}$$

Accuracy reflects the overall correctness of the model's predictions but can be misleading on imbalanced datasets.

- Area Under the Curve (AUC): AUC is the area under the Receiver Operating Characteristic (ROC) curve, which plots the true positive rate (TP) against the false positive rate (FP) at varying classification thresholds. It quantifies the model's ability to distinguish between classes irrespective of any threshold. The AUC value ranges from 0 to 1, with 0.5 representing a random guess and 1.0 a perfect classifier. Higher AUC values indicate better model discrimination, especially useful for imbalanced classes.

D. Results

1) Model performance: In this experiment, we evaluated the effectiveness of the proposed model on detecting deepfake. We trained and tested the model on FF++ (raw), which composed of raw uncompressed videos, FF++ (high quality) consists of videos with medium compression (c23), FF++ (low quality), which includes videos with aggressive (c40) compression level, and the Celeb-DF-v2 datasets. The results of these experiments are presented in Table I.

2) Comparative study: To evaluate the effectiveness of the proposed model and establish a fair benchmark, a comparative study was conducted involving six state-of-the-art methods: MesoInception4 [15], F^3Net [17], SurFake [18], FreMask [19], Unseen Artifacts [20], and Multi-domain [21]. These methods were selected to represent a broad range of spatial-domain and frequency-domain detectors, which primarily rely on frame-level cues, enabling direct assessment of the benefit of explicit temporal modeling in comparison to non-temporal approaches. All models were trained and tested on four subsets of the FaceForensics++ (FF++) dataset, Deepfakes (DF), Face2Face (F2F), FaceSwap (FS), and NeuralTextures (NT), with consistent compression levels applied during both training and testing. Performance metrics for the baseline methods were cited from [21], ensuring consistency with previously established evaluation protocols. Table II presents the comparative performance results, while Fig. 2 further facilitates comparative analysis by visualizing the detection performance in terms of AUC across the four subsets of the FaceForensics++ dataset.

3) Cross-dataset evaluation: While our work objective is to detect deepfake in a compressed video setting, we additionally evaluated the generalization ability of our method to detect unseen deepfake. Table III summarizes the cross-dataset detection performance on the challenging DFDC test set.

4) Ablation study: To evaluate the impact of key components in the proposed model, several ablation studies were conducted. These studies included evaluating: 1) the choice between 2D and 3D convolutions for the backbone model, 2) the impact of the transformer self-attention design, and 3) the performance sensitivity to the patch size. The experiments were conducted using the Deepfakes (DF) and Face2Face (F2F) subsets under heavy compression, as they represent the two main types of Deepfakes. The results of these studies are presented in Table IV.

V. Discussion

From the extensive experimental work, we summarize our key findings as follows:

The comparative results in Table II illustrate the performance of the proposed method against representative spatial-domain and frequency-domain detectors under both medium (c23) and high (c40) compression settings across four manipulation types. Under c23, most methods achieve strong performance across datasets, indicating that moderate compression preserves sufficient manipulation artifacts for reliable detection. In this setting, the proposed method achieves competitive performance comparable to state-of-the-art approaches.

As compression increases to c40, a clear performance gap emerges between frame-based detectors and methods that explicitly leverage temporal information. While frequency-based and multi-domain approaches maintain reasonable performance on DeepFakes (DF) and FaceSwap (FS), their detection accuracy degrades substantially on Face2Face (F2F) and NeuralTextures (NT), which involve more complex motion and expression manipulations. In contrast, the proposed method consistently achieves the highest performance on F2F and NT under c40, with AUC improvements of up to +5.72% compared to the strongest baseline on NT.

This trend highlights the advantage of fully video-level spatiotemporal modeling under aggressive compression. When spatial and frequency-domain cues are suppressed by lossy encoding, temporal inconsistencies remain more reliable indicators of manipulation. By jointly leveraging a 3D convolutional backbone and factorized temporal attention, the proposed method is better suited to capture these cues, resulting in improved robustness in low-quality video scenarios.

Table III reports the cross-dataset detection performance on the DFDC dataset, where all models are trained on FaceForensics++ and evaluated on an unseen dataset without fine-tuning. Across all baselines, detection performance decreases substantially compared to within-dataset evaluation, reflecting the well-known domain gap between curated benchmarks and in-the-wild deepfake content.

Despite this challenge, the proposed method achieves the highest performance, with an AUC of 71.33%, outperforming all compared approaches. This improvement indicates stronger generalization to unseen identities, manipulation pipelines, and real-world capture conditions. The observed gains can be attributed to the model's fully video-level spatiotemporal modeling, which reduces reliance on dataset-specific spatial or frequency artifacts that do not transfer well across domains. By emphasizing temporal consistency cues, the proposed architecture demonstrates improved robustness in cross-dataset deepfake detection scenarios.

The ablation results in Table IV provide insight into the contribution of each architectural component under heavy compression. Replacing the 2D-ResNet50 backbone with a 3D-ResNet50 yields a substantial improvement across both manipulation types, increasing AUC from 95.17% to 97.83% on DeepFakes and from 84.57% to 91.16% on Face2Face. This confirms that explicitly modeling temporal information at the feature extraction stage is critical for robust deepfake detection in compressed videos, where frame-level spatial cues are often degraded.

The impact of the self-attention design is further evidenced by comparing joint spatiotemporal attention with the proposed factorized spatial–temporal attention. While joint attention improves performance over convolution-only baselines, factorized attention consistently achieves higher accuracy and AUC, particularly on Face2Face, where AUC increases from 92.81% to 94.94%. This result suggests that decoupling spatial and temporal attention enables more stable temporal reasoning by preventing compression-corrupted spatial features from dominating temporal modeling.

The effect of patch size is also evident, with larger spatiotemporal patches (1, 14, 14) outperforming smaller ones (1, 7, 7). Larger patches capture richer contextual information across both space and time, which is beneficial for detecting subtle temporal inconsistencies under compression. Finally, the complete hybrid architecture, combining a 3D backbone with factorized self-attention and an optimized patch size, achieves the best overall performance, validating the complementary role of each design choice.

VI. Conclusion

In this work, we proposed a 3D spatiotemporal deepfake detection framework that integrates a 3D convolutional backbone with a vision transformer to enable fully video-level reasoning. Unlike prior approaches that primarily rely on frame-based spatial or frequency-domain cues, the proposed model explicitly captures long-range temporal inconsistencies, resulting in improved robustness under aggressive video compression. The use of factorized spatial–temporal self-attention further enhances detection reliability by decoupling temporal modeling from compression-degraded spatial features.

Extensive experiments demonstrate that the proposed approach achieves competitive or superior performance across multiple manipulation types, particularly under low-quality compression and in cross-dataset generalization settings. With 62.7 million parameters and a model size of 361 MB, the proposed model is best suited for server-side or offline forensic analysis, where robustness and accuracy are prioritized over strict real-time constraints. Future work will focus on improving computational efficiency and further enhancing generalization to emerging deepfake generation techniques.

Acknowledgment

This research was conducted with the support of the Organization for Women in Science for the Developing World (OWSD), Swedish International Development Cooperation Agency (Sida), and Putra Graduate Initiative Grant (Putra-IPS).

***Abstract*—Access to essential cardiovascular parameters such as heart rate (HR), heart rate variability (HRV), and blood pressure (BP) remains limited in low-income and remote populations, particularly among older adults in developing regions. Continuous, simultaneous, and contact-free monitoring of these parameters beyond close proximity can enhance early detection, screening, and management of cardiovascular and related conditions. This study presents a real-time, contact-free health monitoring system based on millimeter-wave (mmWave) FMCW radar, phase demodulation, and digital signal processing (DSP), integrated with multimodal sensor fusion and artificial intelligence (AI)-driven inference. Sub-millimeter chest wall displacements are captured using radar in-phase and quadrature (I/Q) signals to extract beat-to-beat physiological features, including ECG-correlated waveform components, HR, and HRV, while non-invasive blood pressure is indirectly estimated using a physics-informed adaptive learning framework. A custom Long Short-Term Memory (LSTM) neural network is employed for temporal smoothing and stabilization of HRV signals, improving robustness under real-world conditions. The system is implemented within a hybrid edge–cloud architecture, enabling on-device inference for real-time monitoring and cloud-based analytics for long-term analysis and integration. Clinical-like validation conducted on over 100 adult participants demonstrates measurement accuracy comparable to clinically accepted reference devices, and statistical analysis confirms the robustness and reliability of the proposed system.**

Keywords*—Wireless sensing; radar signal processing; sensor fusion; contact-free monitoring; heart rate; heart rate variability; blood pressure; deep learning

I. Introduction

Cardiovascular diseases (CVDs) remain among the leading causes of morbidity and mortality worldwide, accounting for a significant proportion of sudden cardiac deaths and long-term disability [1]. Early detection and continuous monitoring of cardiovascular function are therefore critical for preventive care, timely intervention, and effective disease management. Key physiological indicators such as heart rate (HR), heart rate variability (HRV), and blood pressure (BP) provide essential insights into cardiac health, autonomic nervous system regulation, and overall physiological resilience [2]. Abnormalities in these parameters—such as arrhythmias, reduced HRV, or sustained hypertension—are strongly associated with increased risk of stroke, heart failure, and other chronic conditions.

Despite their clinical importance, continuous and simultaneous monitoring of HR, HRV, and BP remains difficult to achieve in a practical, scalable manner, particularly in low-income, rural, and resource-constrained settings. Conventional measurement techniques, including electrocardiography (ECG), photoplethysmography (PPG) [3], and cuff-based sphygmomanometers, require physical contact with the subject and are often episodic, obtrusive, or dependent on trained personnel. These constraints limit their suitability for long-term monitoring, mass screening, and deployment in mobile or community-based healthcare programs. Additionally, contact-based systems pose challenges related to hygiene, patient comfort, and compliance, especially in elderly populations and infectious-disease scenarios.

Recent advances in contactless sensing technologies have opened new possibilities for non-invasive physiological monitoring. Radar-based systems, particularly those operating in the millimeter-wave (mmWave) spectrum, can detect sub-millimeter chest wall displacements caused by cardiac and respiratory activity, enabling remote measurement of vital signs without physical contact. Several studies have demonstrated the feasibility of using radar, cameras, or acoustic sensors to estimate heart rate and respiration. However, existing approaches remain limited in clinical applicability. Many focus on single-parameter estimation, rely on extensive subject-specific calibration, or exhibit reduced robustness under real-world conditions involving motion artifacts, environmental interference, or physiological variability. Most notably, accurate contactless estimation of blood pressure continues to be an unresolved challenge, with prior methods often depending on pulse transit time (PTT) models, multiple synchronized sensors, or regression-based techniques that may not generalize well across populations.

This disconnects between clinical requirements—namely, reliable, continuous, and multi-parameter cardiovascular monitoring and the capabilities of existing contactless systems represent a critical research gap. There is a lack of integrated, field-deployable platforms capable of simultaneously extracting HR, HRV, and BP from a single sensing modality, while maintaining medical-grade accuracy, interpretability, and scalability. Furthermore, many reported solutions remain at a

proof-of-concept stage and do not address system-level considerations such as real-time processing, deployment in non-controlled environments, or integration with digital health infrastructure.

A. Research Objectives

In response to the identified limitations of existing contactless cardiovascular monitoring approaches, this study aims to investigate the feasibility of a single, contact-free radar-based sensing system combined with multimodal sensor fusion and adaptive artificial intelligence for accurate, real-time estimation of heart rate (HR), heart rate variability (HRV), and blood pressure (BP) in clinical-like and real-world environments, without reliance on physical contact or wearable sensors.

The primary objective of this research is to design, develop, and experimentally validate a contact-free cardiovascular monitoring platform that integrates millimetre-wave radar sensing, advanced digital signal processing, and AI-driven inference within a hybrid edge–cloud architecture. Specifically, the study seeks to:

- Extract beat-to-beat cardiac features from radar in-phase and quadrature (I/Q) signals using physics-guided signal processing techniques;
- Improve the stability and robustness of HR and HRV estimation through temporal modelling based on Long Short-Term Memory (LSTM) networks;
- Estimate blood pressure indirectly from radar-derived cardiac waveform features using adaptive learning methods, without the use of cuff-based measurements; and
- Evaluate system performance through comparative validation against clinically accepted reference devices under controlled and semi-controlled conditions.

B. Contribution and Significance

The proposed approach advances deployable contactless cardiovascular monitoring by translating laboratory-scale sensing into an integrated, system-level solution. By combining radar-based sensing with adaptive learning and multimodal sensor fusion, the platform supports concurrent estimation of multiple cardiovascular parameters using a single, non-intrusive device. A hybrid edge–cloud architecture enables low-latency, real-time inference at the point of care while supporting scalable cloud-based analytics for longitudinal and population-level assessment. Collectively, this work establishes a practical, scalable framework for hygienic, continuous cardiovascular monitoring in distributed, resource-constrained healthcare environments beyond conventional clinical settings and equitable access.

C. Organization of the Study

The remainder of this study is structured as follows: Section II discusses the motivation for contact-free cardiovascular monitoring. Section III reviews existing contactless monitoring techniques, identifies their limitations, and positions the proposed approach relative to prior work while highlighting its novel contributions. Section IV details the system architecture, sensing framework, and signal processing methodology. Section V presents experimental results and clinical validation. Section VI explores future research directions and potential applications. Section VII addresses data privacy and ethical considerations, and Section VIII concludes the study.

II. Motivation for Contact -Free Measurement of HR, HRV, BP, and Other Vitals in this Research

With advancements in medical devices, there is a growing demand to measure multiple vital and non-vital parameters simultaneously with a single device. However, current scientific and engineering limitations often necessitate multiple devices, complicating the process. This research aims to develop a non-invasive, hygienic, and efficient contactless method for measuring blood pressure and other vitals, enhancing patient comfort, reducing infection risk, and enabling continuous remote monitoring. To achieve this, innovative techniques are required to accurately capture vitals without altering established scientific frameworks. This study focuses on the contactless measurement of derived parameters, which can improve safety, comfort, and efficiency across various fields. The proposed method is particularly valuable in healthcare and holds promise for industrial, consumer, medical, and enterprise applications. By enabling indirect parameter measurement, this research seeks to drive innovation across multiple sectors. Specifically, it demonstrates how the radar signals can be used to measure heart rate (HR), heart rate variability (HRV), blood pressure (BP), and other dynamic vitals. Using a sensor fusion approach, the system processes data from sensors and transducers to provide accurate physiological insights through advanced digital signal processing and phase demodulation techniques.

In this research, the I (In Phase) and Q (Quadrature) components form the basis of complex signal representation, widely used in signal processing, communications, and radar systems. For orthogonal receiver radar with I/Q channels, phase information is obtained using arctangent demodulation, providing critical data for precise parameter estimation.

III. Literature Review

A. Existing Approaches

The evolution of radar-based, contactless systems for health monitoring holds transformative potential in non-invasive, patient-centered care. Building upon conventional technologies, recent research explores the unique benefits and expanded applications of radar systems, particularly in environments where physical contact with sensors may be undesirable or impractical. Zhang et al. [4] introduced "Radar-Beat", a breakthrough radar-based system capable of continuous beat-by-beat heart rate monitoring. The system leverages radar signals to measure heart rate accurately, even in dynamic settings where traditional contact-based methods might fail, marking a significant advancement for healthcare monitoring in real-life scenarios. Similarly, Maji et al. [5] explored an alternative approach using standard RGB cameras for contactless heart rate monitoring, which, while less costly and more accessible than radar, generally lacks the precision

radar provides in tracking vital signs reliably in non-static environments.

The development of millimeter wave radar has been especially influential in expanding the possibilities for real-time, contactless vital sign monitoring. Gao et al. [6] demonstrated the effectiveness of millimeter wave radar for tracking both heart rate and respiratory rate simultaneously. The study highlights radar's versatility and its applications in healthcare settings, where it can offer reliable, real-time monitoring without requiring any physical contact, thereby enhancing both patient comfort and data accuracy. Deep learning integration further amplifies radar-based systems' capabilities, as explored by Ni et al. [7], who reviewed deep learning approaches to contactless heart rate measurement. By leveraging machine learning algorithms, these systems can adapt to varying signal conditions, significantly reducing noise and improving measurement accuracy, even in non-ideal conditions.

Radar-based health monitoring systems are further enriched through hybrid solutions that incorporate AI, camera, and radar technologies for a more robust measurement approach. Kolosov et al. [8] demonstrated a camera-based system enhanced by AI for monitoring heart and respiratory rates. Such multi-sensor setups, which combine data from both radar and camera sources, increase the reliability of readings, addressing potential challenges associated with either technology alone. Expanding the scope of contactless monitoring to more accessible technologies, Wang et al. [9] illustrated the use of smart speakers for heart rhythm monitoring, showcasing the flexibility of contactless technology to adapt to household devices. This expands the use of contactless systems into home environments, offering a convenient solution for ongoing monitoring outside clinical settings.

Further innovations in wearable and radar-based monitoring were presented by De Pinho Ferreira et al. [10], who reviewed non-invasive heart rate monitoring for wrist-worn devices, providing insights into the growing role of wearable applications for real-time health monitoring. Similarly, Esgalhado et al. [11] evaluated heart rate variability (HRV) derived from ECG and PPG signals, emphasizing the effectiveness of multimodal approaches that improve accuracy by drawing from multiple sources of physiological data. Zhang et al. [12] took this concept further by employing a CNN-LSTM model to detect arrhythmias in medical IoT systems, illustrating deep learning's value in enhancing diagnostic capabilities by detecting subtle patterns in heart rate data that may indicate health risks.

Radar technology has made strides in signal processing methods that enhance measurement accuracy. Park and Lubecke [13] developed a critical technique involving arctangent demodulation with DC offset compensation for Doppler radar systems, improving the precision of heart rate detection by isolating vital signals from noise and background interferences. Further refinement of signal accuracy in radar systems was achieved by Sameera et al. [14], who worked on reducing respiratory harmonics within heart signal analysis. This is crucial for radar-based systems to accurately distinguish heart rate data from respiratory noise, improving the system's overall effectiveness in diverse monitoring environments.

Nonlinear HRV analysis has also contributed to a deeper understanding of heart rate dynamics in patients with cardiovascular disease. Krstacic et al. [15] examined HRV's nonlinear dynamics in patients with coronary artery disease, illustrating how complex HRV behaviour can serve as a critical indicator of cardiovascular health and disease progression. Similarly, Kondo et al. [16] investigated laser-based monitoring of chest wall movements, presenting a promising alternative for non-contact respiratory rate tracking. This further validates radar's complementary role in continuous respiratory monitoring, especially in high-risk or critically ill patient scenarios where accurate respiratory tracking is vital.

Wearable technologies for HRV monitoring have also progressed, as evidenced by Eguchi and Aoki [17], who developed R-R interval editing techniques for single-channel ECG devices. This is essential in wearable applications, as it ensures data reliability by providing clean, precise HRV measurements even in continuous monitoring scenarios. Longitudinal studies such as Schroeder's [18] study on HRV determinants in the Atherosclerosis Risk in Communities Study provided foundational insights into how HRV changes over time can signal early indicators of cardiovascular disease, supporting the utility of continuous monitoring in preventive care.

Patented advancements have also driven innovation in radar-based health monitoring. KRS [19, 20] proposed adaptive learning-based techniques for radar signal enhancement, which enable the system to dynamically adjust and enhance input features based on rank and event-driven causes. This adaptive capability represents a major leap toward intelligent monitoring systems that can self-optimize for accuracy in real-time scenarios. Schellenberger et al. [21] contributed to this field by providing a clinically recorded radar dataset with synchronized reference sensor signals, an invaluable resource for developing, validating, and training radar-based health monitoring algorithms.

The application of ultra-wideband radar, particularly in paediatric and early childhood health monitoring, is another area of emerging interest. Arasteh et al. [22] utilized ultra-wideband radar for simultaneous monitoring of respiratory and heart rates in young children, achieving high accuracy by implementing a deep transfer learning approach. This study underscores radar's potential for non-intrusive monitoring in sensitive populations, like infants and young children, where conventional methods may not be feasible. Finally, Udupa et al. [23] investigated the applicability of HR and HRV in mental health assessments, finding that HRV can indicate autonomic dysfunction in patients with major depression. This connection between HRV and mental health broadens radar's applicability, potentially allowing healthcare providers to monitor psychological as well as physiological health indicators non-invasively.

B. Comparative Evaluation of Existing Approaches and Novel Contributions of the Present Study

Our research work represents a significant departure from prior art, introducing a clinically validated, scalable, and AI-driven contactless health monitoring system suited for low-resource and mobile healthcare settings. Existing academic and commercial efforts in radar-based vital sign monitoring often depend on pulse transit time (PTT) models or signal regression techniques requiring multiple sensors or calibration. Prior works—such as those by Mase et al. (2011), Kim & Ling (2017) [24], and Huang et al. (2016)—struggle with limited accuracy under dynamic, real-world conditions. In contrast, the presented system enables real-time blood pressure estimation using a single radar by extracting dynamic PQRS waveform segments from micro chest wall displacements. This bypasses the need for PTT calibration and enhances diagnostic precision using physics-informed modelling. A custom Long Short-Term Memory (LSTM) model, implemented in C++, ensures temporal smoothing of heart rate variability signals under fluctuating conditions. Unlike deep-learning-only prototypes such as the Smart Health mmWave Radar (UT Austin) and Convolution Neural Network (CNN) based models, Li et al. (2021), this system fuses empirical and AI-driven inference for robustness and interpretability. Patents like US11,076,522B2 (UC) and US10,995,684B2 (Google) disclose radar-based BP estimation, yet none offer a unified signal processing framework for simultaneous extraction of over 18 parameters in a validated field-deployable device. Additionally, unlike exploratory efforts like Project Soli (Google) or WO2022174460A1 (Huawei). This work has achieved Technology Readiness Level (TRL) 7 through multi-site functional validation. To the best of the authors' knowledge, it represents the first integrated platform that combines single-radar PQRS waveform generation, physics-guided modelling, hybrid AI processing (on-device and cloud), and multimodal sensor fusion. The system's industrial scalability is supported by seven patent applications, with regulatory submissions currently in progress through the US FDA 510(k) pathway under the Class B medical device category. No prior academic or commercial effort, to the authors' knowledge, demonstrates a comparable combination of parameter richness, medical-grade accuracy, model transparency, and operational readiness. These distinctions represent a significant advancement toward scalable, contact-free health monitoring platforms designed for integration into large-scale public health systems.

IV. Methodology

Although contactless monitoring of vital signs has been investigated across various research domains, the presented system represents a distinct advancement through its emphasis on clinical-grade accuracy at short-range, person-specific distances (1.25–1.75 meters). The solution combines radar-based physiological sensing with adaptive signal processing and machine learning, including a purpose-built Long Short-Term Memory (LSTM) neural network for real-time signal stabilization. Integration with a hybrid edge-cloud framework facilitates continuous, secure, and remote access to health data, enabling deployment in primary care centers, mobile clinics, and underserved healthcare environments.

In this research, a multi-sensor framework was employed that integrates multi-point temperature sensors, multimedia sensors, transducers, and millimeter-wave (mmWave) radar, all operating within the Industrial, Scientific, and Medical (ISM) radio bands. These sensors were deployed in compact integrated circuit (IC) packages, with all electronics custom-designed by Impilo Sensys and certified under CE (Conformité Européenne) and FCC (Federal Communications Commission) standards, and are lead (Pb)-free. The radar module utilizes Frequency-Modulated Continuous Wave (FMCW) technology and operates at 120 GHz (Indie Semiconductor). The study primarily focuses on three ISM-band ICs functioning at approximately 24 GHz, 61 GHz, and 120 GHz. The mmWave radar modules are responsible for non-contact measurement of human heart rate (HR), heart rate variability (HRV), and blood pressure (BP).

Due to intellectual property and regulatory considerations, detailed electronic schematics have been limited to block-level architecture, as shown in Fig. 1 and Fig. 2. Technical schematics can be made available to the editorial board under confidentiality agreements, if required.

A. Test Population

Clinical validation of the system was conducted at renowned tertiary care hospitals in Bengaluru, India, involving a diverse cohort of over 100 adult participants aged 18 to 88 years. The study included both healthy individuals and patients with known health conditions, provided they could remain still for at least two minutes. Exclusion criteria included individuals with implanted cardiac devices, movement disorders, or those undergoing beta-blocker therapies.

To ensure data privacy, only anonymized vital and non-vital parameters are shared publicly. The radar and reference signals are one-dimensional electrical signals, inherently preserving participant anonymity. Full datasets can be made available upon request under appropriate ethical data sharing agreements. Additionally, a live system demonstration with a volunteer subject can be arranged by the corresponding author for interested researchers.

B. Reference Instrument

A medical-grade pulse oximeter and stethoscope were used to measure heart rate, while a sphygmomanometer (BP cuff) was employed to measure blood pressure, serving as reference tools to validate our findings.

C. System Architecture and Sensing Framework

In alignment with the global shift toward proactive, decentralized, and digitally enabled healthcare, this research presents a contact-free, AI-powered health screening and monitoring system. Rather than a product promotion, the system serves as an illustrative example of a scalable medical device ecosystem built on artificial intelligence, sensor fusion, and hybrid edge-cloud architecture. It features a tablet-sized, portable device capable of real-time, contactless measurement of over 18 physiological parameters, including heart rate, respiratory rate, SpO_2, non-invasive blood pressure, and heart rate variability. Central to the system is a proprietary AI foundation model, HealthGPT, operating in two modes:

HealthGPT Lite for on-device inference and HealthGPT Pro for cloud-based contextual analysis. The platform is designed for standalone use or integration with external medical devices and health records, offering localized data visualization and secure cloud synchronization. Validated in clinical-like settings, the system has achieved Technology Readiness Level (TRL) 7.0, confirming its suitability for real-world healthcare deployment.

Inside the system enclosure, a tightly integrated sensor fusion framework is implemented, comprising intelligent computing hardware and analytical software modules. As illustrated in Fig. 1, this framework includes two primary subsystems: 1) a radar-based sensing unit and 2) a complementary suite of sensors contributing to multimodal data fusion. The radar subsystem operates within the Industrial, Scientific, and Medical (ISM) radio bands and is configured to initiate signal acquisition upon receiving a predefined trigger frequency. A 16-bit Analog-to-Digital Converter (ADC) samples incoming radar signals at a programmable sampling frequency, initiating processing of a defined number of data samples.

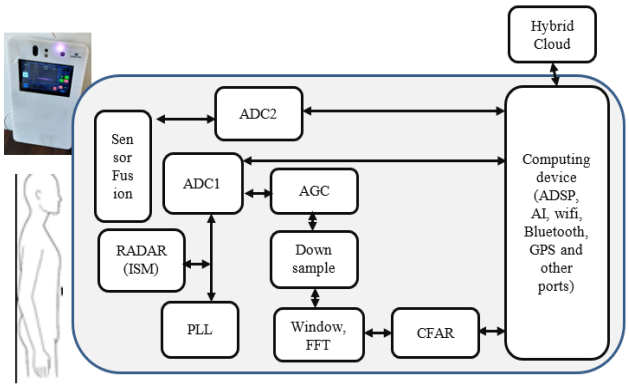

Fig. 1. Integrated sensor fusion architecture for health monitoring using radar and auxiliary sensors.

Signal strength is optimized using an Auto Gain Control (AGC) mechanism, and DC offset cancellation is performed when enabled. A Phase-Locked Loop (PLL) ensures frequency stability during operation. The acquired radar data is downsampled and processed through a Hanning window function to reduce spectral leakage, followed by a Fast Fourier Transform (FFT) with selectable lengths of 128, 256, 512, or 1024 points, depending on the sampling rate and ramp duration. From the FFT output, signal features such as magnitude and phase are extracted for target characterization. Target detection is performed using a Constant False Alarm Rate (CFAR) algorithm, which applies tuneable parameters including CFAR window size, guard bands, and threshold levels to suppress noise and false positives.

Both raw and transformed radar data are transmitted to an embedded computing device running a Linux operating system. This device also receives inputs from additional sensing modalities such as infrared sensors, camera modules, and air quality sensors via separate ADC interfaces. The aggregated multimodal data is processed using digital signal processing (DSP) algorithms and machine learning (ML) models to infer vital and non-vital health parameters through direct and indirect computational methods.

A custom web-based application is deployed locally on the device for real-time visualization and interaction. This interface also enables secure bidirectional communication with a hybrid cloud server, facilitating extended analytics, secure storage, and integration within this system platform's white-labelled device architecture.

D. MM Wave Radar Setup

The primary approach of Frequency Modulated Continuous Wave (FMCW) radar-based vital sign detection is to measure chest vibrations resulting from the mechanical effects of breathing and the cardiac cycle. The heartbeat signal typically has a fundamental frequency between 0.75 Hz and 2.5 Hz (45 to 150 beats per minute) and an amplitude of approximately 0.45 mm from the chest. In contrast, the breathing signal has a fundamental frequency between 0.1 and 0.7 Hz (6 to 42 breaths per minute) with an amplitude range of 3.5 mm to 11.5 mm. In this research, we present results obtained using a 120 GHz radar system from Indie Semiconductor FFO GmbH.

The general block diagram of the radar system is shown in Fig. 2. The antennas, labelled T(x) and R(x), correspond to the transmit and receive channels, respectively. A frequency-modulated radio frequency (RF) signal is emitted toward the subject's chest for non-contact physiological sensing.

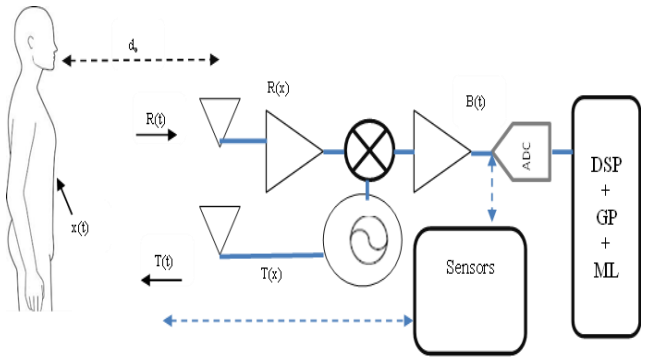

Fig. 2. Block diagram of a radar system to measure heart rate and heart rate variability wirelessly.

The received signal is first pre-processed before being sent to an analog-to-digital converter (ADC) and is then transmitted to digital signal processing (DSP) and other modules for further analysis.

The radar transmits signal T(t) via T(x) antenna to the subject at a distance of d_o :

$$T(t) = A_T COS(2\pi f\, t + \theta(t)) \quad (1)$$

where, f is the carrier frequency, A_T is the power amplitude and $\theta(t)$ is the phase noise from waveform generator.

Chest displacement caused by breathing and heartbeat is measured through phase modulation in the received signal, yielding a signal that encapsulates the effects of both breathing and heartbeat.

R(t) is the signal which the radar receives after it is reflected by the subject's chest displacement:

$$R(t) \cong A_R COS(2\pi f\, t - 4\pi \frac{d_0}{\lambda} - 4\pi \frac{x(t)}{\lambda} + \theta(t - 2\frac{d_0}{c})) \quad (2)$$

where, A_R is the received power, λ is the carrier wavelength, c is the speed of light in free space, $x(t)$ is the chest wall movement due to heartbeat and respiration, and $\theta(t - 2d_o/c)$ is the phase noise with a delay of $2d_o/c$.

The same T(x) is used as local oscillator (LO) signal to down-convert R(t) to baseband B(t):

$$B(t) = \cos(\theta_0 + 4\pi \frac{x(t)}{\lambda} + \triangle\theta(t)) \quad (3)$$

where, $\theta_0 = 4\pi d_0/\lambda + \sigma$ is the summation of phase shift from the nominal distance d_o and at the reflection surface, $\Delta\theta(t) = \theta(t) - \theta(t - 2d_o/c)$ is the residual phase noise.

E. Experimental Procedure

The test subject is seated between 1.25 m and 1.75 m from the radar device, with a medical-grade pulse oximeter and blood pressure monitor attached in accordance with standard clinical protocols. Data collected by the radar over a one-minute interval is processed through a series of digital signal processing (DSP) steps. These include adaptive filtering, phase demodulation, and feature extraction, followed by a Fast Fourier Transform (FFT) for frequency domain analysis.

To enhance temporal stability and reduce physiological noise, a customized Long Short-Term Memory (LSTM) neural network developed in C and C++ is employed for post-processing. Final results are transmitted securely to a hybrid cloud platform, enabling remote access to derived metrics such as heart rate (HR), heart rate variability (HRV), blood pressure (BP), and other auxiliary parameters from any connected device. Fig. 3 illustrates the overall architecture of the hybrid cloud integration.

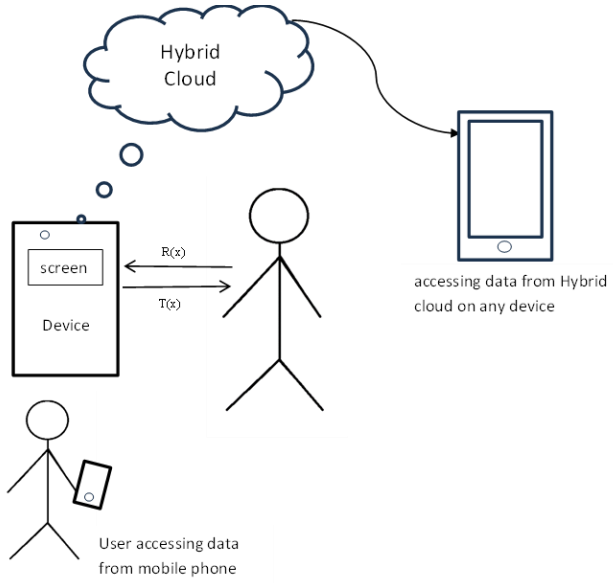

Fig. 3. Overview of device architecture and hybrid cloud integration flow.

The radar subsystem operates across widely accessible ISM frequency bands at 24 GHz, 61 GHz, and 120 GHz, capturing minute chest wall displacements associated with cardiac and respiratory activity. Signals within the 0.75–2.5 Hz range (corresponding to 45 150 BPM) are segmented into 10-second windows, producing six HR estimations per minute. These radar readings are then fused with auxiliary sensor data, including motion, temperature, and air quality, using an adaptive signal fusion framework. In future work, this multimodal sensing framework is expected to enable not only the estimation of primary vital parameters (HR, HRV, and BP) but also the inference of secondary physiological indicators, such as stress levels, brain health, mental health and fatigue states.

Preprocessing begins with phase demodulation using an arctangent-based algorithm that incorporates noise suppression mechanisms. This is followed by baseband conversion and adaptive bandpass filtering to isolate relevant physiological signals. FFT is applied to extract frequency-domain features, while template matching identifies PQRS or PQRST waveform patterns in the time domain. These extracted features are then passed to the LSTM module for signal stabilization and used in the system's indirect BP estimation module, thereby maintaining both high signal fidelity and diagnostic accuracy.

F. Temporal Smoothing Using LSTM

To address signal noise, motion artifacts, and temporal inconsistencies inherent in radar-derived HR measurements, the authors developed a C++ based LSTM neural network. Operating on 10-second radar-derived HR segments, the LSTM model was chosen over conventional smoothing techniques due to its ability to learn and retain both short- and long-term dependencies. This approach enhances the stability of HRV signals, which are further used to estimate BP and assess physiological variability under real-world conditions.

Each 10-second radar-derived reading is scaled by dividing the value by 100 to normalize it below 1 and is then fed into the LSTM model. The LSTM operates in three iterations, each using four consecutive readings: the first iteration uses readings values in a sequence 1, 2, 3, and 4; the second uses 2, 3, 4, and 5; and the third uses 3, 4, 5, and 6. Each iteration generates a predicted HR value, and the final output is calculated as the average of these three predictions. This iterative approach ensures the stabilization of the final HR value by smoothing out any inconsistencies or noise present in the raw radar data.

The internal structure of the LSTM node, as shown in Fig. 4, consists of a forget gate, input gate, and output gate, which collaboratively regulate the flow of information through the network. This architecture enables the LSTM to retain relevant patterns and discard noise, ensuring robust and accurate heart rate predictions. The LSTM's role in refining and stabilizing the HR output is integral to the system's ability to provide reliable and medically accurate real-time monitoring.

In this LSTM model, the Long-Term Memory (LTM) and Short-Term Memory (STM) values generated from the first iteration are passed forward to the next iteration, along with a new set of four HR readings. This allows the model to build

upon the prior memory states, incorporating information from previous HR data to enhance accuracy and stability in the output. Specifically, the LTM and STM values calculated from readings 1, 2, 3, and 4 in the first iteration serve as the initial memory states for the next set of inputs (readings 2, 3, 4, and 5) in the second iteration. This process is repeated across iterations, with each successive iteration updating and carrying forward the LTM and STM values, thereby reinforcing the model's understanding of temporal patterns in the data. Fig. 5 provides a visual of this iterative process, illustrating how the memory states are updated and propagated, ultimately ensuring a stabilized output across multiple LSTM iterations.

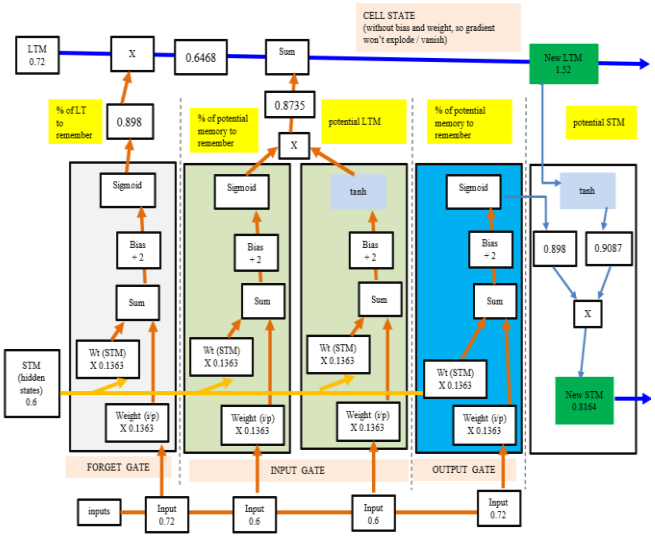

Fig. 4. Single LSTM node showing the flow of data.

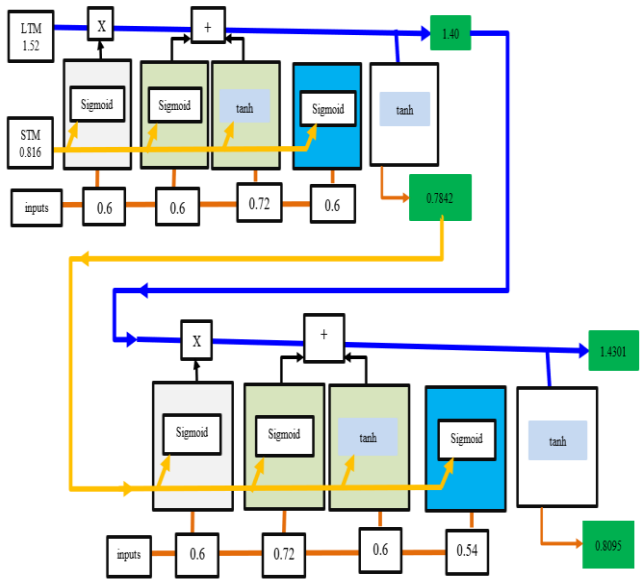

Fig. 5. Multiple iteration of the LSTM model.

G. Blood Pressure Estimation: A Physics-Informed AI Approach

A systematic approach was presented for estimating blood pressure (BP) parameters from reflected radar signals, enabling fully contactless monitoring. This methodology integrates fundamental scientific principles with adaptive artificial intelligence and advanced digital signal processing (DSP) techniques. As illustrated in Fig. 6, the process involves a series of signal transformations and algorithmic steps designed to extract vital cardiovascular information without the use of physical probes or direct contact with the subject.

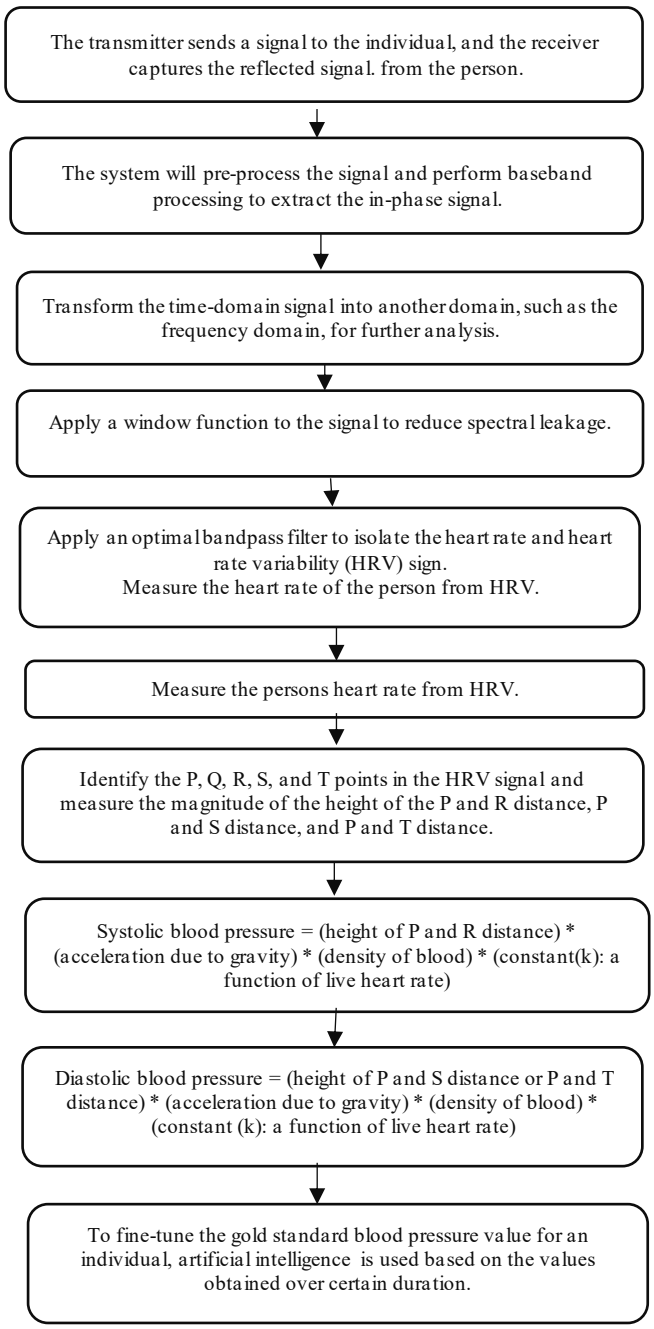

Fig. 6. Step-by-step method and data flow for measuring blood pressure wirelessly without any contact.

The radar system continuously tracks heart rate variability (HRV) signals to identify PQRST intervals, which are then analysed using adaptive learning DSP algorithms. From these features, systolic and diastolic pressures are estimated using the following equations:

Systolic blood pressure = (height of P and R distance(h)) * (acceleration due to gravity(g)) * (density of blood(ρ)) * (constant(k): a function of live heart rate) (4)

Diastolic blood pressure = (height of P and S distance or P and T distance (h)) * (acceleration due to gravity(g)) * (density of blood (ρ)) * (constant(k): a function of live heart rate) (5)

Here, h denotes the amplitude difference between specific cardiac waveform peaks, g is the gravitational acceleration, ρ is the blood density, and k is a constant dynamically derived from an adaptive learning AI model, which depends on the live heart rate value. This indirect estimation technique has been validated against a conventional sphygmomanometer, achieving measurement accuracy in the 90 to 98% range, as detailed in Table II.

H. User Experience and Operational Simplicity

Although supported by advanced AI and digital signal processing backends, the system is designed to offer a straightforward, hygienic, and contactless user experience. Users interact with the system via an integrated touchscreen interface or a mobile application, with measurements obtained while the individual remains seated within the operational range—without the need for physical contact or wearable sensors. This user-centric, non-intrusive design makes the system particularly suitable for deployment in eldercare facilities, infectious disease control scenarios, primary care centers, and community health programs.

The actual device, as shown in Fig. 7, is compact—approximately the size of a traditional tablet—making it both portable and unobtrusive.

Fig. 7. Contactless health screening product.

For each measurement session, the reference person (RP) or subject follows a simple and repeatable protocol to ensure accurate and consistent readings:

- The RP is seated in front of the radar and sensor-enabled device, as illustrated in Fig. 8.
- Prior to starting, the RP should ensure their bladder is nearly empty and relax for at least 5 minutes to stabilize physiological parameters.
- The RP should sit upright on a chair, facing the device at a distance of 1.1 to 1.75 meters, with both feet flat on the floor and legs uncrossed.
- The RP is encouraged to take a few deep breaths, then continue with normal, relaxed breathing throughout the measurement period.
- Measurements are recorded for a minimum of 2 minutes, extendable to 5, 10, or 15 minutes based on the use case.
- The recorded values are displayed in real time via the user interface (UI), as shown in Fig. 9, and are also transmitted to the RP's mobile device and uploaded to the cloud for secure, remote access and further analysis.
- To ensure consistency and long-term reliability, the procedure should be repeated daily at approximately the same time.

Fig. 8 shows the live demonstration of the device. The device includes a screen that displays the data. Additionally, any other device can access the same data via the hybrid cloud, ensuring flexibility and remote monitoring capabilities.

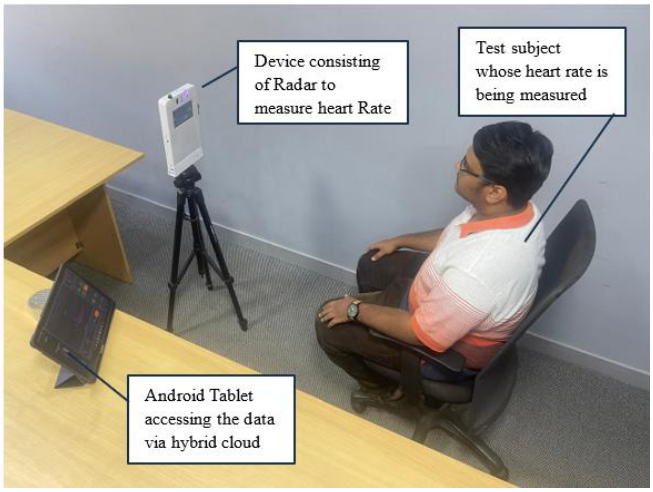

Fig. 8. Live demo of the device. (Subject is the co-author, journal is free to use their image and associated data in publication).

The device screen, as shown in Fig. 9, displays the heart rate, BP and other vitals

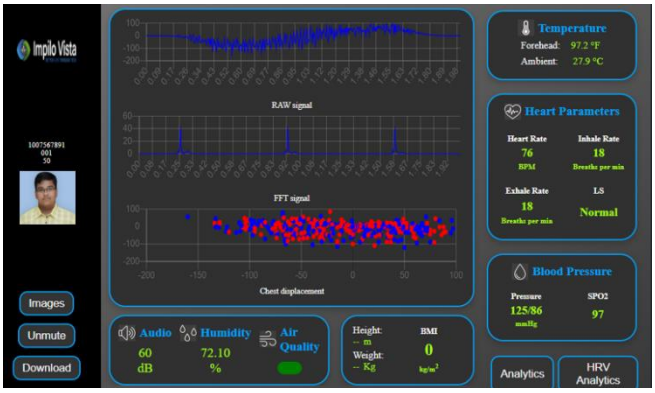

Fig. 9. Device screen showing heart rate, BP and other vitals.

I. Heart Rate Variability

The number of beats per minute is referred to as the heart rate, measured in beats per minute (BPM). Heart rate variability (HRV) represents the variation in the time intervals between consecutive heartbeats. HRV is visualized by the changes in R-R intervals over time, as shown in Fig. 10.

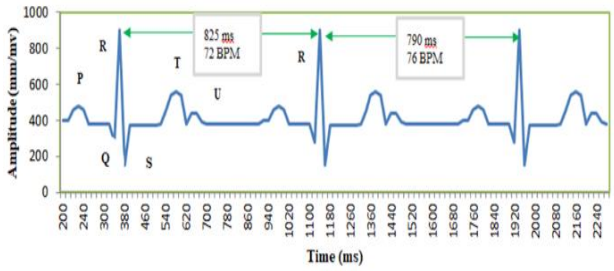

Fig. 10. Heart rate variability (HRV) visualized with R-R interval changes.

Heart rate variability (HRV) is a critical marker of autonomic nervous system function, providing valuable insights into an individual's cardiovascular fitness and stress levels. Fig. 12 illustrates a graphical representation of a heart rate variability (HRV) meter, displaying live HRV data along with the activities of the sympathetic nervous system (SNS) and the autonomic nervous system (ANS).

On the left side of the diagram, the variations and activities of the SNS are shown, highlighting its role in controlling the "fight-or-flight" response, such as reactions to fear, anxiety, or being startled. Typically, the SNS signals the adrenal glands to release adrenaline, leading to an increase in heart rate (HR) and blood pressure (BP).

On the right side, the ANS is depicted as regulating the "rest-and-digest" response, which counteracts the effects of the SNS. The diagram also outlines three conditions: rest, previous status, and live (current) status.

Low HRV is often linked to an increased risk of cardiovascular disease, as it indicates a reduced ability of the heart to adapt to changing physiological demands. Conversely, higher HRV reflects better cardiovascular health and a more flexible, responsive autonomic system. Fig. 11 illustrates human age variation as a function of heart rate variability (HRV), with the green-colored region representing the normal recommended values.

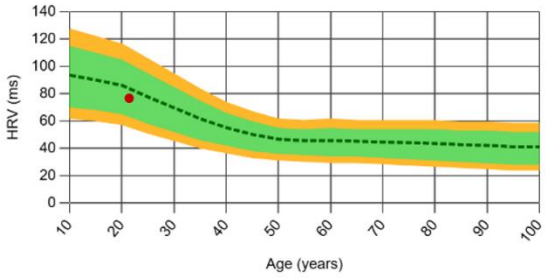

Fig. 11. Age variation as a Function of Heart Rate Variability (HRV).

V. Results

The proposed contact-free, radar-based health monitoring system demonstrates strong potential for accurate, non-intrusive estimation of key physiological parameters, including heart rate (HR), heart rate variability (HRV), and blood pressure (BP). Validation was performed on more than one hundred adult participants aged 18 to 88 years, using both the authors' vitals and those of external volunteers. Clinical-grade reference instruments—a Class B BP monitor, a manual sphygmomanometer (gold standard), a pulse oximeter, and a stethoscope—served as comparative benchmarks. The consolidated quantitative outcomes for HR and BP are summarized in Table I and Table II, respectively.

Under controlled indoor conditions (ambient temperature 18°C–32°C in an air-conditioned setting), the system achieved 90%–98% accuracy for BP estimation relative to the sphygmomanometer and 90%–95% accuracy for HR estimation compared with pulse oximeter and stethoscope readings. Each participant underwent three consecutive daily measurements to ensure statistical rigor and account for day-to-day variability.

A comprehensive quantitative analysis was performed to evaluate agreement, correlation, and precision. Bland–Altman plots demonstrated strong agreement between the contactless device and reference instruments. Pearson and Spearman correlation coefficients confirmed both linear and monotonic relationships between measured and gold-standard values. Additionally, Mean Absolute Error (MAE) with 95% confidence intervals provided insight into the system's consistency and repeatability. These findings were benchmarked against state-of-the-art radar-based literature and certified clinical devices, offering a robust comparative framework for assessing real-world applicability.

The system is implemented on a portable, tablet-sized platform integrating radar sensing, multimodal sensor fusion, signal processing, embedded AI models, and hybrid edge–cloud connectivity. This architecture enables real-time inference and supports longitudinal monitoring. The adaptive inference framework further enhances contextual interpretation of physiological signals while maintaining user simplicity and fully non-contact operation.

Note: We conducted clinical trials for this experiment at renowned hospitals in India with several test candidates. Due to data privacy concerns, we are only disclosing the data of the authors and a few selected subjects. However, researchers can contact the corresponding author for a live demo of the research work for validation.

From a translational standpoint, the system has reached Technology Readiness Level (TRL) 7, having undergone functional validation and demonstrating readiness for controlled real-world deployment. Regulatory assessments and hospital-based evaluations are underway to advance clinical translation.

Despite its encouraging performance, certain limitations remain. The validation was restricted to adults, controlled posture, and short-range indoor operation, which may limit generalizability to dynamic or high-motion environments, paediatric populations, or broader demographic groups. Residual noise and motion artifacts, inherent to radar-based sensing, can still influence measurements. Ongoing work focuses on improving digital signal processing pipelines, minimizing internal and external artifacts, and refining real-time deep learning models to enhance robustness and statistical confidence.

Collectively, the results confirm the feasibility of contact-free estimation of cardiovascular parameters from micro chest wall displacements without wearable sensors or cuff-based methods. This represents a significant advance in remote and continuous health monitoring. Continued research and broader community validation are encouraged to further develop and expand this promising approach.

VI. Future Works

The future of medical devices is moving towards compact, portable, and contact-free systems that can securely integrate personal health data into hybrid cloud environments. This shift emphasizes the need for continuous, non-invasive monitoring solutions, adaptable across clinical, public, and home settings. Upcoming research will focus on new algorithms, multi-sensor integration, and enhanced radar signal processing to improve these devices' capabilities.

A. Advanced Algorithms for Comprehensive Monitoring

Research in advanced algorithms will be essential to capture multiple health parameters—heart rate, variability, blood pressure, glucose levels, and more, with high accuracy. These algorithms will need to account for environmental complexities, handling multiple persons, ensuring accurate, real-time, contactless readings, even in varied conditions.

B. Enhanced Accuracy with Multi-Radar Interference

Experiments with multi-radar interference techniques will boost the precision of complex measurements, such as blood pressure and respiration rates. Testing these in high-interference settings, like public areas, will provide robust, reliable radar-based monitoring and help optimize both direct and indirect measurement methods.

C. Parameter Modeling and Dependency Analysis

Studying the interdependencies between physiological parameters offers deeper insight into personalized health trends. This research will support the design of monitoring devices that adapt to individual variability, enhancing the precision and relevance of health assessments.

D. Expanding Use Cases

Contactless monitoring has wide applications, including:

- Proactive Health Monitoring for Aging Populations: Accessible devices for early health indicators could support independent living for seniors.
- Clinical and Non-Clinical Use: Psychiatry, yoga, and fitness settings can use these devices to track mental and physical well-being.
- Military and Industry Applications: Military personnel monitoring and machine health tracking (Industry 4.0/5.0) are emerging fields for this technology.
- Financial Services: Health data integration in loan and insurance processes offers new avenues for risk assessment and underwriting.

E. Miniaturization and Mobile Integration

Embedding compact monitoring modules into mobile devices will make health screening universally accessible. This requires miniaturized sensors that maintain high performance while optimizing power use, leading to future smartphones and wearables with advanced health-monitoring capabilities.

VII. Data Privacy, Ethics, Research Work Demo

1) Data privacy: This study exclusively uses the vital and non-vital parameters of the authors. Additionally, the method has been validated with data from over 100 subjects at leading hospitals in India, with all personally identifiable information removed. The radar and reference signals used are one-dimensional electrical signals, ensuring a high level of anonymity.

2) Data availability: The validated test data used for this research, obtained from ImpiloVista and other gold-standard medical devices, are available from the corresponding author upon reasonable request.

3) Ethics statement: In the initial phase, data were collected solely from the researchers themselves. All mmWave radars operate within the ISM band, and all electronic components used are CE and FCC compliant.

4) Product demo and supplementary materials: Upon request, the corresponding author can arrange a live demonstration of our research findings using the complete system with a subject for interested researchers.

5) Ethics and consent to participate declarations: We confirm that all methods were conducted in accordance with relevant guidelines and regulations, including the Declaration of Helsinki and applicable local regulatory standards. This study involved the use of medically approved international Industrial, Scientific, and Medical (ISM) band radar and medical-grade sensors, classified as a Class B medical product, without administering medication or inserting probes into the participants' bodies. All data were collected from subjects at a 1-meter distance with prior informed consent, ensuring strict privacy and confidentiality.

VIII. Conclusion

This research presents a novel, non-invasive method for accurate, real-time measurement of heart rate (HR), heart rate

variability (HRV), blood pressure (BP), and other vital signs from a distance, offering dynamic and continuous monitoring without physical contact. By leveraging the same signal, HRV can be derived, providing insights into brain-heart interactions critical for optimal health and supporting real-time adjustments for well-being. Through advanced sensor fusion techniques, this study demonstrates a reliable, efficient approach to indirect measurement of both vital and non-vital parameters, positioning contactless health monitoring as a promising advancement for remote and continuous healthcare.

Choosing the Arena: A Systematic Review of Simulators for Deep Reinforcement Learning in Mobile Robot Navigation

Zakaria Haja[1]*, Leila Kelmoua[2], Ihababdelbasset Annaki[3], Jamal Berrich[4], Toumi Bouchentouf[5]
Research Laboratory in Applied Sciences-National School of Applied Sciences,
Université Mohammed Premier, Oujda, Morocco[1, 2, 3, 4, 5]
Higher School of Education and Training, Université Mohammed Premier, Oujda, Morocco[3]

***Abstract*—This study presents a formal Systematic Literature Review (SLR) to address a critical methodological question in robotics research: "Which simulator is most suitable for a given Deep Reinforcement Learning (DRL) algorithm and mobile robot navigation task?" The choice of a simulation environment profoundly impacts policy robustness, data efficiency, and sim-to-real transfer, yet the community has lacked an evidence-based guide for this decision. Following PRISMA guidelines, we methodically searched and analyzed 87 peer-reviewed studies published between January 2020 and June 2025 to map the contemporary research landscape. Our synthesis introduces a novel, theory-informed taxonomy that classifies simulators into three archetypes based on their empirical use. Archetype I, ROS-centric standards (e.g., Gazebo), are chosen for algorithmic novelty with low-dimensional sensor inputs. Archetype II, versatile platforms (e.g., CoppeliaSim), are favored for rapid prototyping. Archetype III, GPU-native engines (e.g., NVIDIA Isaac Sim), have emerged for large-scale, perception-heavy challenges, leveraging photorealism and parallelization to mitigate the perception gap and enable zero-shot transfer. This review reveals a paradigm shift towards data-driven methodologies and culminates in a prescriptive decision-making framework, transforming simulator selection from an incidental detail into a strategic choice.**

***Keywords*—Simulator; mobile robot; Deep Reinforcement Learning; navigation**

I. Introduction

The autonomous navigation of mobile robots remains a cornerstone challenge in robotics, with Deep Reinforcement Learning (DRL) emerging as a powerful paradigm for learning adaptive control policies directly from sensor data [1]. However, the data-intensive nature of DRL makes training on physical hardware impractical due to time, cost, and safety constraints [2], [3], making simulation an indispensable tool. This reliance on simulation introduces the pervasive "sim-to-real gap"—the discrepancy between simulation and reality that hinders policy transfer [4]. The choice of simulator is therefore a foundational methodological decision, as it dictates the available strategies for mitigating this gap, defines the fidelity of sensor models (the "perception gap"), and sets the performance ceiling for data collection, which is critical for modern DRL algorithms [5], [6]. Despite the existence of numerous simulators, researchers lack a systematic, evidence-based guide to inform their selection, often leading to a methodological mismatch between the tool and the research objective. This study addresses this significant void by conducting a formal Systematic Literature Review (SLR) to provide a data-driven answer to the central research question: "Which simulator should a researcher choose for a specific DRL algorithm and mobile robot navigation task?"

While prior surveys have provided excellent overviews of DRL algorithms for navigation [7] or sim-to-real techniques [8], they are largely simulator-agnostic. They identify the sim-to-real gap as a key challenge, but do not offer a comparative analysis of the simulation tools themselves as the primary variable influencing research outcomes. Our work is fundamentally different. By employing a formal SLR methodology focused specifically on the simulator, we move beyond simple cataloging to provide a novel, archetype-based synthesis. This approach allows us to uncover causal links between simulator choice, research focus (e.g., algorithmic novelty vs. perception challenges), and the adopted sim-to-real strategy—insights that remain obscured in conventional narrative reviews. We frame our resulting taxonomy not as a mere descriptive grouping but as a theory-informed abstraction that reveals the underlying structure of current research practices. Furthermore, by analyzing literature from 2020 to 2025, our review captures and contextualizes a critical paradigm shift in the field: the move away from purely CPU-bound simulation towards GPU-native engines and data-driven methodologies for achieving robust real-world deployment.

This review makes several distinct contributions to the field. Our methodological contribution is the application of the rigorous PRISMA framework to a simulator-centric analysis, providing a transparent and reproducible evidence base. Our conceptual contribution is the novel taxonomy of simulator archetypes, which serves as a new analytical lens for understanding research trends and trade-offs. Finally, our practical contribution is a prescriptive, data-driven decision-making framework designed to guide researchers in strategically aligning their choice of simulator with their specific research objectives, thereby enhancing methodological rigor and research efficiency.

To achieve these aims, this study is structured as follows: Section II reviews related survey literature, sharpening the novel positioning of our work. Section III details our systematic review methodology, adhering to the PRISMA

*Corresponding author.

guidelines. Section IV presents the data extraction and synthesis process. In Section V, we present the results, introducing our taxonomy of simulator archetypes and analyzing their use in the literature. Section VI provides a detailed discussion, formalizing our findings into a prescriptive decision-making framework and articulating key research gaps. Finally, Section VII concludes the study with a reflective synthesis of our findings and their implications for future research.

II. Related Work

Several survey papers have explored the intersection of RL and robotics. Seminal works provided a comprehensive overview of RL in robotics before the deep learning era [9]. More recent reviews have focused on DRL for robotics, but often with accomplishments primarily in simulation or with a broad scope covering many tasks like manipulation and locomotion [7]. Other reviews focus specifically on sim-to-real transfer techniques, such as domain randomization and adaptation, but are generally simulator-agnostic [8].

A few studies have compared simulation environments directly. A study in [10] benchmarked the performance of four simulators on different hardware, focusing on computational speed rather than the broader research context. A recent review in [11] also reviewed popular simulation engines, highlighting MuJoCo and Unity, but not focusing specifically on the mobile robot navigation domain. Most closely related are recent reviews such as [5], [7], and [12]. A foundational review of DRL methods and navigation frameworks is provided in [7]. A systematic review focusing on navigation in dynamic environments is offered in [5]. Similarly, a comprehensive overview of DRL's integration in mobile robotics, analyzing its evolution and identifying key challenges and future directions, is presented in [12]. While these studies provide excellent, broad surveys of the algorithmic landscape, they identify the sim-to-real gap as a challenge without offering a comparative analysis of the simulation tools themselves. Our work differentiates itself by using a formal SLR methodology to specifically analyze and synthesize the literature based on the choice of simulator, thereby providing a novel, evidence-based framework that directly links simulator characteristics to DRL algorithms and navigation tasks.

III. Systematic Review Methodology

To ensure a transparent, reproducible, and rigorous review, we adopted the PRISMA 2020 statement as our methodological framework [13]. The process consists of defining research questions, a search strategy, study selection criteria, and a data extraction plan [14].

This review is guided by four central research questions (RQs) designed to systematically map the literature:

- RQ1: What is the distribution of simulators (e.g., Gazebo, Webots, CoppeliaSim, NVIDIA Isaac Sim) used in the recent literature for DRL-based mobile robot navigation?
- RQ2: What are the reported capabilities and limitations of these simulators concerning sensor modeling (perception gap) and performance/scalability for DRL training?
- RQ3: Which DRL algorithms (e.g., PPO, SAC, DQN, DDPG) are predominantly paired with each simulator, and for which specific navigation tasks (e.g., obstacle avoidance, end-to-end visual navigation)?
- RQ4: What trends and patterns emerge from the literature regarding sim-to-real transfer strategies associated with each simulator archetype?

A. Search Strategy

To gather a comprehensive body of literature, we implemented a structured search strategy across several major scientific databases. We conducted a systematic search of three major scientific databases: IEEE Xplore, Scopus, and arXiv. The search was performed in June 2025, covering publications from January 2020 to June 2025 to capture the most recent trends. The following search string was adapted for each database's syntax: ("reinforcement learning" OR "RL") AND ("mobile robot" OR "robot navigation") AND ("simulation" OR "simulator") AND ("Gazebo" OR "Webots" OR "CoppeliaSim" OR "Isaac Sim" OR "PyBullet").

B. Study Selection: Inclusion and Exclusion Criteria

We conducted the study selection in two phases: 1) title and abstract screening, and 2) full-text review[15]. To be included, a paper had to meet all of the following inclusion criteria:

- I1: The paper is a full-text, peer-reviewed conference paper, journal article, or a publicly available preprint (from arXiv).
- I2: The paper was published between January 2020 and June 2025.
- I3: The paper explicitly uses a physics-based simulator for training or evaluating a DRL agent for a mobile robot navigation task.
- I4: The paper is written in English.

Papers were excluded based on the following exclusion criteria:

- E1: The paper is a review, survey, or abstract-only publication.
- E2: The work does not involve a mobile ground robot (e.g., focuses only on manipulators, drones, or underwater vehicles).
- E3: The work uses RL but not deep learning (i.e., no deep neural networks).
- E4: The simulator is used for purposes other than DRL (e.g., only for visualization or classical controller testing).

C. Selection Results

The systematic search and screening process yielded a final corpus of literature that forms the evidence base for this review. Initially, 173 papers were selected based on the research query and inclusion criteria. After the removal of

duplicates, 143 unique studies remained. These were subjected to a full-text review, and after applying the exclusion criteria, a final set of 87 papers were deemed eligible for inclusion in our qualitative synthesis. The complete study selection process is visually detailed in the PRISMA flow diagram shown in Fig. 1.

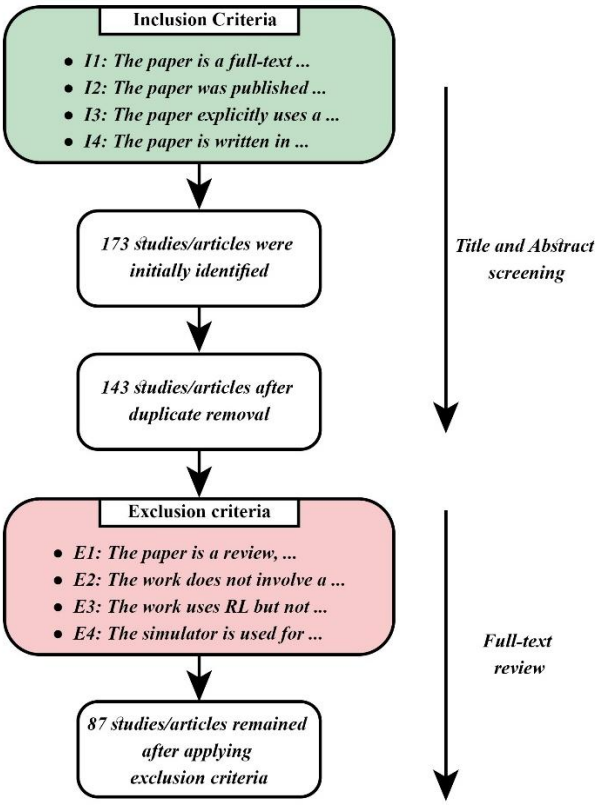

Fig. 1. Study selection process based on inclusion and exclusion criteria.

IV. Data Extraction and Synthesis

For each study that met the criteria, we performed a detailed data extraction process to gather key information for our synthesis. For each included study, we extracted the following data points: 1) Simulator used; 2) Mobile robot platform; 3) Navigation task description; 4) DRL algorithm implemented; 5) Sensor modalities simulated; 6) Stated reasons for simulator choice; 7) Reported performance metrics; and 8) Sim-to-real transfer methodology and results. The extracted data was then synthesized qualitatively to answer the research questions and identify overarching trends. Table I provides a summary of a representative selection of the reviewed literature, illustrating the connections between simulators, algorithms, and tasks that form the basis of our analysis.

The data summarized in Table I reveal several distinct trends that underpin our analysis. A clear majority of the studies leverage Gazebo, pairing it with a wide array of DRL algorithms—from value-based methods like D3QN to policy-gradient methods like PPO and DDPG—for tasks centered on map-less navigation and obstacle avoidance. This reinforces its role as a versatile, community-standard testbed. In contrast, papers utilizing NVIDIA Isaac Sim consistently tackle complex, often end-to-end, navigation tasks and are frequently paired with data-hungry algorithms like PPO or advanced methods like Imitation Learning. This highlights its adoption for research pushing the boundaries of sim-to-real transfer and performance.

Webots and CoppeliaSim are used for a range of tasks, including multi-robot systems and learning from demonstration, often employing algorithms like PPO and GAIL, respectively, showcasing their utility in specialized research areas [37]. Collectively, the table illustrates a strong correlation between the choice of simulator and the scope of the research problem, a central theme explored in this review.

TABLE I. Summary of Selected Literature on Simulators for DRL-based Mobile Robot Navigation

Reference	*Used Simulator(s)*	*DRL Algorithm(s)*	*Task(s)*
[16]	Isaac Sim, Gazebo	PPO	End-to-end local planning and obstacle avoidance.
[17]	Gazebo	DDPG, PPO	Autonomous navigation, target seeking and obstacle avoidance.
[18]	Unity, Gazebo	Double DQN	Map-less navigation to a random target.
[19]	Gazebo	SAC, PPO, DDPG, Q-learning	Path planning and obstacle avoidance
[20]	Gazebo	D3QN (Dueling Double Deep Q-Network)	End-to-end navigation and obstacle avoidance in an unknown environment with static and dynamic obstacles.
[21]	Gazebo	DDPG, PPO	Map-free navigation for an omnidirectional robot.
[22]	Gazebo	DDPG (customized with guiding points)	Navigation in crowded environments with dynamic pedestrians.
[23]	Gazebo	Parallel Distributional Actor-Critic Networks	Map-less navigation for terrestrial mobile robots
[24]	Gazebo	DDQN (Double Deep Q-Network)	Map-less navigation and obstacle avoidance for a TurtleBot3 robot.
[25]	Webots	PPO (enhanced with Curriculum Learning)	Shortest path planning for an E-puck robot using IR sensors.
[26]	Webots	DQN, PPO	Pedestrian avoidance for autonomous vehicles in simulated scenarios.
[27]	Webots	DQN, PPO, A2C	The inverted pendulum task
[28]	Webots	DQN, NSQ, DDQN, PPO	Multi-robot swarm navigation.
[29]	CoppeliaSim	GAIL (Generative Adversarial Imitation Learning)	Learning navigation behaviors from expert demonstrations for mobile robots.
[30]	CoppeliaSim	Adaptive TD3	Navigation in dynamic environments
[31]	Gazebo (via FRobs RL)	PPO, SAC, TD3	Map-less navigation for a mobile robot.
[32]	Isaac Sim	RMA (Rapid Motor	Legged mobile robot walking on different

Reference	Used Simulator(s)	DRL Algorithm(s)	Task(s)
		Adaptation)	types of ground surfaces.
[33]	Isaac Sim	NavACL-Q (curriculum learning method with soft actor-critic algorithm)	Map-less navigation for an Automatic Guided Vehicle (AGV) in a warehouse scenario.
[34]	Isaac Sim	Imitation Learning (IL) and Curriculum Learning (CL)	Map-less navigation of a wheeled robot using open-vocabulary 3D scene graphs.
[35]	Isaac Sim	Imitation Learning (IL) with an auto-regressive world model	Generalizable end-to-end navigation.
[36]	Isaac Sim	Asymmetric Actor Critic	Visual goal-tracking
[37]	Gazebo	DDPG	Map-less path planning in an unknown environment
[38]	Gazebo	DQN, DDQN	Map-less navigation and obstacle avoidance
[39]	Custom Simulator	DWA-RL	Mobile robot navigation without prior exploration

V. Results of the Systematic Review

A. Distribution of Simulators

An analysis of the selected corpus of literature reveals a distinct distribution in the adoption of simulation platforms. Gazebo emerged as the predominant simulation environment, utilized in a substantial majority of the reviewed studies, thereby establishing its position as a de facto standard within the research community.

NVIDIA Isaac Sim was identified as the second most prevalent platform, indicating its significant and growing adoption in recent research. Following these, Webots and CoppeliaSim were also frequently employed, albeit to a lesser extent. A smaller subset of the literature utilized alternative simulators, such as PyBullet, particularly in studies concentrating on specialized applications like mobile navigation.

B. Simulator Capabilities, DRL Algorithms, and Tasks

Our synthesis of the literature revealed distinct patterns that link the choice of simulator with its technical capabilities, the selected DRL algorithms, and the complexity of the navigation task. We present these findings through our proposed taxonomy of simulator archetypes.

1) Archetype I: ROS-Centric Open-Source Standards (Gazebo, Webots). These simulators are predominantly selected for their seamless integration with the ROS ecosystem[40]. The literature consistently cites the benefit of architectural parity, where the same ROS2 control software can be deployed in simulation and on the real robot, simplifying the sim-to-real process[16]. However, their CPU-bound performance is a frequently acknowledged limitation, making them less suitable for training on high-dimensional visual data. Sensor modeling is functional, but studies note that default noise parameters often require manual tuning to match real hardware, presenting a perception gap challenge[41]. Consequently, the majority of studies using these platforms focus on navigation tasks with low-dimensional inputs, primarily 2D LiDAR scans[24]. The most common DRL algorithms are off-policy methods like DDPG/TD3 and SAC, alongside the on-policy PPO[24]. The research contribution in these papers often lies in algorithmic enhancements, such as novel reward shaping [37] or modified network architectures for safer navigation, rather than tackling the perception gap itself.

2) Archetype II: The Versatile Multi-Physics Platform (CoppeliaSim) CoppeliaSim's unique value proposition in the literature is its versatility. Several papers leverage its support for multiple physics engines to conduct comparative analyses. The high-speed PyRep interface is frequently cited as a key advantage for accelerating DRL training cycles compared to the overhead of ROS-based communication1. The tasks explored in CoppeliaSim are diverse, often involving complex kinematics or prototyping novel robot designs. The DRL algorithms used are varied, with studies employing GAIL for imitation learning [28] and DDPG for control tasks. The focus is often on rapid algorithm development and validation in a flexible environment.

3) Archetype III: The GPU-Native High-Performance Engine (NVIDIA Isaac Sim) Papers using Isaac Sim are almost exclusively focused on tackling large-scale DRL problems and bridging the sim-to-real gap for perception-heavy tasks. The ability to run thousands of parallel simulations on the GPU is the most cited advantage, as it enables the collection of massive datasets required to train robust policies[42]. Its use of RTX rendering for photorealistic sensor data is highlighted as a direct strategy to mitigate the perception gap, making it the platform of choice for end-to-end, vision-based navigation[42]. The dominant algorithm in the Isaac Sim literature is PPO, whose on-policy nature benefits immensely from the massive parallel data collection capabilities. The tasks are ambitious, often involving navigation in complex, cluttered environments using only camera images or a fusion of camera and LiDAR data, with the primary research contribution often being the demonstration of successful zero-shot sim-to-real transfer.

C. Sim-to-Real Transfer Strategies

Our review confirms that the choice of simulator strongly influences the sim-to-real strategy.

With Gazebo/Webots, the strategy is an architectural alignment. Researchers leverage the native ROS integration to ensure the software stack is nearly identical between simulation and the real robot, minimizing transfer errors related to control and communication logic.

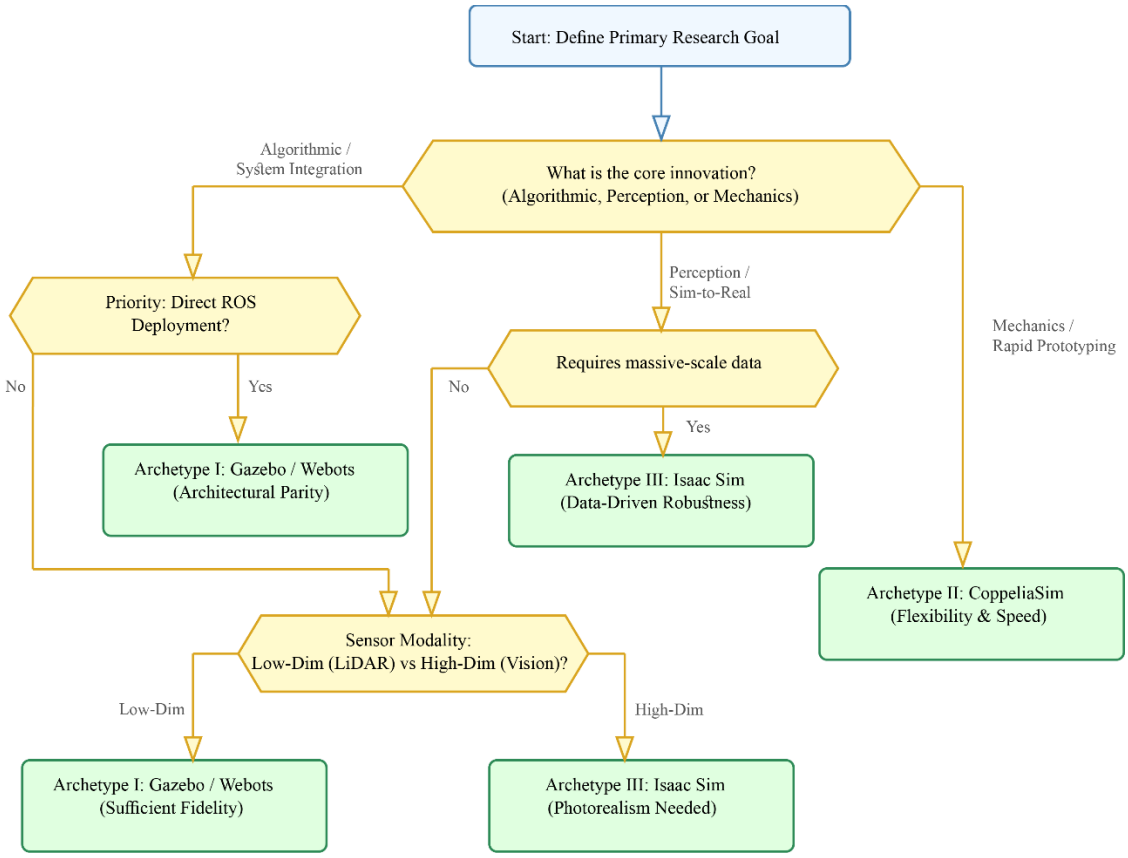

Fig. 2. A prescriptive decision flowchart for simulator selection. This flowchart formalizes the selection logic by guiding a researcher from their primary research goal through key technical requirements to the most appropriate simulator archetype, highlighting the core trade-offs at each stage.

With NVIDIA Isaac Sim, the strategy is data-driven robustness. Researchers leverage massive parallelization and photorealistic rendering to train policies on an extremely wide distribution of scenarios via domain randomization. This forces the policy to become invariant to simulation-specific artifacts, making it robust enough for zero-shot transfer. A powerful emerging trend is the "sim-to-sim-to-real" pipeline, where policies trained in Isaac Sim are first validated in Gazebo before real-world deployment, providing strong evidence of their generalization capabilities.

VI. Discussion: A Decision-Making Framework

Based on our comprehensive literature synthesis, we propose a structured decision-making framework (see Fig. 2) to guide the selection of robotic simulators according to two pivotal dimensions: 1) the primary source of methodological innovation, and 2) the complexity of required sensory data.

When the research novelty lies in algorithmic improvements—such as novel reward functions, enhanced safety-aware exploration strategies [43], or gains in sample efficiency—and the underlying task can be addressed with low-dimensional sensor inputs (for example, 2D LiDAR), established platforms like Gazebo and Webots are recommended (see Fig. 2). These environments not only offer robust, community-validated benchmarks, but their seamless ROS integration also streamlines the transition from simulation to real-world deployment under manageable computational loads.

In contrast, if the principal innovation revolves around comparative physics analyses or the rapid prototyping of intricate mechanical systems, CoppeliaSim emerges as the superior choice. Its unique support for multiple physics engines, combined with the high-speed PyRep API, accelerates development cycles beyond what ROS-centric alternatives typically allow.

Finally, for investigations explicitly targeting sim-to-real transfer—particularly those focused on vision-based, end-to-end navigation in visually complex domains—NVIDIA Isaac Sim provides indispensable capabilities. Its photorealistic rendering and exceptional parallel training performance make it the de facto standard for experiments aiming to achieve zero-shot policy transfer. Through a sim-to-sim-to-real validation pipeline, researchers can rigorously demonstrate methodological advances in direct policy transfer, thus reinforcing the scientific contribution of their work.

VII. Conclusion and Future Directions

This systematic literature review has provided a rigorous, evidence-based analysis of the simulator landscape for DRL-based mobile robot navigation. The central, definitive insight from our synthesis of 87 recent studies is that simulator selection is not an incidental technical detail but a foundational methodological decision that shapes research outcomes. Our work conclusively changes how this choice should be viewed: from a matter of convenience to a strategic alignment of tool, task, and objective. We have formalized the community's

implicit practices into an explicit taxonomy of simulator archetypes, demonstrating a clear correlation between a simulator's architectural principles and its application in the literature.

What this review definitively establishes is a tripartite structure of the current research landscape. First, ROS-centric platforms like Gazebo are the established workhorses for algorithmic development with low-dimensional sensors, where architectural parity with the real world is the primary sim-to-real strategy. Second, GPU-native engines, epitomized by NVIDIA Isaac Sim, have become the standard for tackling the perception gap in vision-based navigation, enabling data-driven robustness through massive parallelization and domain randomization. Third, versatile engines like CoppeliaSim occupy a vital niche for rapid prototyping and specialized mechanical analysis. By making these distinctions explicit, our framework provides immediate, practical guidance that can prevent methodological mismatches and enhance research efficiency.

However, our review also illuminates what remains uncertain. While we identify a strong trend towards data-driven sim-to-real transfer, the precise metrics for quantifying the "reality gap" remain ad-hoc and study-specific. It is still an open question how to create a universal benchmark that can compare the transferability of policies from different simulators in a scientifically rigorous manner. Furthermore, the long-term viability and interoperability of vendor-specific, high-performance ecosystems versus open-source standards is an unresolved tension that will shape the field's future accessibility and direction.

Looking forward, the capabilities of Archetype III simulators serve as a crucial technological bridge to the next paradigm: persistent, bi-directional Robotic Digital Twins. Yet, to realize this future and improve scientific rigor, the community must move beyond the current state. We strongly advocate for the development of a Standardized Sim-to-Real Navigation Benchmark. Such a framework would enable true apples-to-apples comparisons, fostering more generalizable and robust solutions. By clarifying the present state of simulation, separating validated insights from open questions, and illuminating the path toward standardized benchmarking, this work aims to accelerate the development of intelligent systems capable of operating safely and effectively in the complexity of the real world.

Faculty of Engineering-Chemical Engineering Program, University of Cartagena, Cartagena, Colombia[3]

***Abstract*—Solar radiation forecasting is a key task for energy planning, grid management, and photovoltaic deployment, especially in tropical regions where weather variability reduces operational reliability. This work applies deep learning techniques to forecast hourly solar radiation in Mompox, Colombia, using Long Short-Term Memory (LSTM) neural networks. Three temporal windows were studied (5, 24, and 720 hours) to examine how sequence length affects prediction accuracy and model behavior. Hourly radiation data from 2021 to 2022 were used for training, and independent datasets from 2023 to 2024 were used for external validation to ensure long-term assessment and reproducibility. Most existing studies use short input windows designed for mid-latitude environments (5–24 hours), which do not capture multi-day tropical cloud persistence or sub-seasonal radiation variability. This gap limits forecasting accuracy and restricts practical use in tropical energy planning. To address this issue, this study introduces a long temporal input design that allows the model to learn month-scale variability more effectively. The three network configurations were trained under the same settings, allowing a direct comparison between short, daily, and long input memories. The LSTM-720 model performed best, achieving the lowest RMSE and the most stable predictions across all validation years, showing its ability to reconstruct both diurnal cycles and broader seasonal dynamics. Unlike most solar forecasting work, which treats window size as a tuning parameter, this study introduces a long-context LSTM design based on a 720-hour sequence. This allowed the model to learn intra-month atmospheric persistence—an essential tropical feature that short windows cannot represent—positioning the approach as a methodological contribution that expands the temporal learning paradigm rather than a configuration adjustment. Time-series comparisons revealed close agreement between measured and predicted radiation, particularly during stable climate periods. The proposed framework can support practical applications in solar plant design, renewable energy scheduling, and operational grid strategies in tropical regions. Future work will integrate satellite information and hybrid deep learning architectures to enhance spatial transferability and long-term forecasting accuracy.**

***Keywords*—Deep learning; LSTM networks; renewable energy; solar radiation forecasting; time series prediction**

This study is considered a product within the framework of the project: "Desarrollo Sostenible Mediante la Implementación de Energía Solar Fotovoltaica en Zonas Rurales no Conectadas a la Red Eléctrica Nacional en Mompox, Colombia (022-2024)", which is part of an internal research initiative at the University of Cartagena, Cartagena, Colombia.

I. Introduction

Given the growing constraints on fossil fuel generation [1], integrating clean energy systems (such as solar) with conventional power generation [2], [3] has become a key strategy to enhance efficiency and reduce emissions [4], [5]. At the solar energy level, solar radiation is a fundamental variable for energy management, particularly in the planning and design of photovoltaic (PV) systems [6], [7], agricultural applications [8], [9], and environmental modelling [10]–[12].

The use of solar energy significantly reduces greenhouse gas emissions [13], as its generation produces no CO_2 or other pollutants [14], thereby lowering dependence on non-renewable resources and promoting ecosystem conservation as a clean and sustainable electricity source [15]–[17]. In tropical regions, accurate forecasting is even more crucial for the effective planning, construction, and operation of PV power plants because sunlight availability changes rapidly with cloud cover and seasonal variation [18], [19].

The town of Mompox, located in northern Colombia, offers an interesting setting for solar radiation prediction. It combines a humid tropical climate with high solar potential, but has limited meteorological monitoring infrastructure. Although Colombia's Caribbean region receives abundant solar energy, few predictive models have been developed specifically for this area. This lack of localized modeling limits the efficient deployment of solar technologies and constrains opportunities for grid optimization and energy independence.

Traditional statistical approaches, such as ARIMA and Support Vector Machines (SVM), often fall short when modeling the nonlinear and time-dependent behavior typical of solar radiation [20], [21]. Recent progress in artificial intelligence has changed this landscape [22]–[25]. Recurrent Neural Networks (RNNs) [26], and particularly Long Short-Term Memory (LSTM) architectures [27], can capture long-term dependencies and nonlinear trends in meteorological time series [4], [28]. Several studies have demonstrated their effectiveness in predicting solar irradiance across different regions [29]–[31], however, few have explored their use in small tropical towns like Mompox, where climatic variability and data scarcity pose additional challenges.

In this context, the research evaluates the ability of LSTM models to forecast solar radiation at multiple temporal resolutions (5, 24, and 720 hours) using real measurements from

Mompox. The model was trained with data from 2021 to 2022 and validated with independent datasets from 2023 to 2024, ensuring reproducibility and robustness. This approach can be adapted to other data-limited regions seeking to improve renewable energy forecasting. Predicting solar radiation in tropical climates remains a challenging task. In these environments, cloud systems can evolve within minutes, humidity levels fluctuate abruptly, and short-lived storms frequently interrupt solar exposure [32]. Such variability introduces nonlinear and nonstationary behavior that traditional statistical models struggle to capture effectively [33].

Deep learning methods, particularly Long Short-Term Memory (LSTM) networks, offer a promising alternative because they can learn how these rapid changes in cloud cover and humidity interact over time. By retaining information from previous states, LSTMs can represent the temporal continuity and sudden transitions that characterize tropical weather, resulting in more accurate and resilient radiation forecasts [34]. Yet, few studies have examined their effectiveness in humid equatorial zones like Mompox, where diurnal and seasonal cycles interact in distinctive ways.

Solar radiation forecasting in tropical regions is strategically important for national energy planning, particularly in areas where rural electrification, PV expansion, and microgrid deployment depend on accurate generation forecasting. Improving prediction stability in data-limited locations, such as Mompox, supports lower operational uncertainty, reduces reserve margin dependence, enables more reliable agricultural scheduling, and improves climate adaptation strategies. This context shows that the research is not only a methodological exercise, but also responds to a regional need for energy autonomy and system planning, making the development of long-memory forecasting approaches an urgent technical requirement for tropical countries.

Tropical solar radiation dynamics differ fundamentally from conditions addressed in most LSTM-based forecasting studies. Prior works overwhelmingly employ short input memories ranging from several hours to one day, an assumption that aligns with mid-latitude irradiance behavior but not with tropical environments. In the tropics, radiation variability is governed by persistent multi-day cloud systems, moisture accumulation cycles, and sub-seasonal atmospheric structures that extend far beyond diurnal periodicity. These characteristics produce long temporal dependencies that short window LSTMs cannot capture, resulting in phase shift errors, amplitude smoothing, and loss of climatic context. This gap in the literature motivated the exploration of long-memory recurrent models. By incorporating a 720-hour input window, equivalent to a full intra-month sequence, we aimed to enable the network to learn climatic persistence patterns rather than only daily oscillations, addressing a structural limitation of existing approaches and positioning this work beyond parameter tuning studies.

The novelty of this study lies in its methodological approach rather than parameter scaling. While previous LSTM works overwhelmingly rely on short input windows (5–24 hours), we demonstrate that tropical radiation dynamics demand long-context modelling to reconstruct sub-seasonal variability. By implementing a 720-hour sequence, the model learns persistent atmospheric structures that cannot be captured by traditional diurnal frameworks, establishing long-memory LSTM forecasting as a required paradigm for tropical environments rather than a configuration variant.

The main contributions of this research are summarized as follows: 1) a long-context LSTM architecture was introduced that uses a 720-hour input sequence tailored to represent seasonal tropical radiation dynamics, a configuration not previously explored in related forecasting literature. 2) The model's robustness was evaluated through a multi-year external validation over unseen 2023 and 2024 datasets, demonstrating long-term predictive stability rarely addressed in prior deep learning work for tropical environments. 3) It was shown that long-context learning improves forecasting accuracy over traditional short-window and daily configurations, providing evidence that tropical radiation behavior requires long-memory modelling rather than parameter scaling, and 4) a reproducible and scalable modelling framework was constructed based on raw ground solar radiation measurements, which can be transferred to other tropical locations with limited climatological infrastructure.

To address this gap, this study proposes an LSTM-based approach optimized for tropical solar radiation forecasting using high-resolution ground data. It systematically analyzes how different window sizes (from 5 to 720 hours) influence prediction accuracy and identifies the most suitable configuration for practical energy management in tropical environments.

II. Related Works

Forecasting solar irradiance has evolved rapidly in recent years with the introduction of deep learning models, especially Long Short-Term Memory (LSTM) networks and their hybrid variants. Several studies have shown that LSTM architectures consistently outperform classical methods such as ARIMA, Artificial Neural Networks (ANN), and Support Vector Machines (SVM) when handling the nonlinear dynamics of solar radiation. For instance, [35] employed an LSTM network for short-term irradiance forecasting and found that combining multiple input sequences helped the model generalize better while reducing both variance and bias. In a similar vein, [23] compared ARIMA, feed-forward neural networks, and LSTM using Colombian datasets and reported that the LSTM model delivered the highest accuracy under cloudy conditions, one of the most challenging scenarios for solar prediction.

Hybrid models have also gained attention for their enhanced representational power. A review by [36] noted that CNN–LSTM architectures, which merge spatial and temporal learning, consistently outperform single-model approaches in irradiance forecasting, albeit with higher computational requirements. Recent developments even include BiLSTM–Transformer hybrids that achieved the lowest RMSE in seven-day forecast experiments, outperforming both standalone LSTM and GRU networks [24]. Comprehensive literature reviews further confirm that deep learning techniques, including LSTM, GRU, CNN–LSTM, and attention-based networks, yield significant accuracy improvements over traditional approaches, though at the expense of longer training times [37]. For example, [19] compared LightGBM, LSTM, and GRU using hourly radiation

data. While LSTM achieved an RMSE of about 59 W/m², LightGBM provided slightly better accuracy (≈54.8 W/m²) and faster computation, suggesting that tree-based ensembles can still compete when computational resources are constrained.

The field has also begun shifting toward probabilistic and multivariate forecasting. Hybrid frameworks that integrate BiLSTM and GRU layers, combined with Bayesian hyperparameter optimization and dropout regularization, have achieved strong performance in multivariate irradiance prediction [25]. Additionally, several studies that merge global climate models with ground-based measurements through hybrid deep learning and machine learning pipelines have produced reliable daily radiation forecasts [22]. Despite these advancements, certain research gaps remain clear. Few studies have focused on tropical towns such as Mompox, where meteorological data are scarce, and climate variability is high. Equally uncommon are works that compare multiple forecasting horizons (short-term, daily, and monthly) within a unified framework, or that evaluate pure LSTM configurations at extended horizons of up to 720 hours. The present study directly addresses these gaps by developing an LSTM model tailored to solar radiation forecasting in Mompox, Colombia. Using datasets from 2021 to 2022 for training and from 2023 to 2024 for validation, this work provides a comprehensive, horizon-sensitive modeling framework specifically designed for tropical regions with limited historical observations.

III. METHODOLOGY

This section presents the methodological framework designed to forecast solar radiation in Mompox using Long Short-Term Memory (LSTM) neural networks. It describes the dataset collected from IDEAM [38], the preprocessing steps applied, the configuration of the neural architectures, and the training and validation strategy adopted. Together, these components ensure transparency, reproducibility, and methodological rigor for the subsequent analyses.

Hourly solar radiation data were collected for Mompox (9°14'N, 74°26'W; elevation 10 m a.s.l.), a town located in the tropical Magdalena River basin of northern Colombia. The dataset covers the period from January 2021 to December 2022 and corresponds to global horizontal irradiance (Wh/m²). The information was provided in CSV format by the Instituto de Hidrología, Meteorología y Estudios Ambientales (IDEAM), Colombia's national meteorological authority [38].

The original file also included ancillary variables such as air temperature and wind speed. However, these were excluded to focus the analysis exclusively on solar radiation prediction. Additional datasets spanning January–December 2023 and January–July 2024 were used solely for external validation. In total, the dataset contains about 17,500 hourly records. Missing values, representing less than 1 % of the data, were interpolated linearly to maintain the temporal continuity of the series. Extreme outliers, defined as values exceeding ±3 standard deviations from the mean, were replaced using a rolling median filter. A summary of the dataset, including temporal coverage and partitioning strategy, is shown in Table I.

The time series of global horizontal irradiance (Wh/m²) was used directly, without normalization or scaling, in order to preserve the physical meaning of the radiation values. Input–output pairs were created using a sliding window method, in which a sequence of past radiation observations was used to predict the next value. Three different input window sizes were evaluated to capture varying temporal behaviors: 5 hours: short-term fluctuations, 24 hours: daily cycles, and 720 hours: monthly or intra-seasonal patterns. For each configuration, the data were chronologically divided into training (67 %), testing (22 %), and validation (11 %) subsets (see Table I). This temporal split preserved the natural sequence of the observations and avoided data leakage between model phases.

TABLE I. SUMMARY OF THE DATASET

Dataset	Data Features		
	Period	*Frequency*	*Samples*
Training	2021-2022	Hourly	11,910
Testing	2021-2022	Hourly	3,853
Validation	2021-2022	Hourly	1,752
External validation	2023	Hourly	8,760
External validation	Jan-Jul 2024	Hourly	5,040

All forecasting models were implemented in Python 3.10 using TensorFlow 2.15 with the Keras API. Three LSTM architectures were designed, each corresponding to one of the input window sizes.

- LSTM-5: Input (5 × 1), one LSTM layer with 64 units, followed by a dense layer with 8 neurons (ReLU activation) and a linear output layer.
- LSTM-24: Input (24 × 1), one LSTM layer with 64 units, followed by a dense layer with 8 neurons (ReLU activation) and a linear output layer.
- LSTM-720: Input (720 × 1), one LSTM layer with 720 units, two dense layers with 16 and 8 neurons (both ReLU activation), and a final linear output layer.

The increase in the number of LSTM units for the 720-hour configuration was intentional and proportional to the longer input sequence length. A higher number of recurrent units provides the model with greater representational capacity to retain and process extended temporal dependencies across a full monthly cycle. Preliminary tests indicated that using fewer than 720 units led to underfitting, particularly in reproducing smooth transitions between consecutive days, while the chosen configuration achieved lower RMSE and faster convergence without overfitting. Thus, the increase in hidden units was empirically justified as it improved the model's ability to capture long-term patterns inherent to tropical solar radiation.

The choice of the 720-hour input configuration was not defined as a tuning exercise but as a methodological decision derived from climatic characteristics of the study region. The thirty-day temporal span was selected to encode full intra-month variability related to cloud persistence, humidity accumulation, and low-frequency atmospheric patterns typical of tropical environments. Unlike short window configurations (5, 24 hours), the 720 hour structure enables the model to learn sub-seasonal energy dynamics and long term irradiance memory,

which are not recoverable through repeated diurnal cycles. This design transforms the LSTM into a long context recurrent learner, allowing it to internalize radiation persistence behavior and avoid phase misalignment effects commonly reported in tropical solar forecasting. Therefore, the 720-hour model represents a conceptual modelling framework rooted in regional climate physics rather than a parametric extension of existing approaches.

All networks used the Adam optimizer (learning rate = 0.001) and the Mean Absolute Error (MAE) as the loss function. Model performance was tracked using the Root Mean Squared Error (RMSE) metric. Each model was trained for 30 epochs, with a ModelCheckpoint callback to save the best-performing weights according to validation loss, thus minimizing the risk of overfitting.

Fig. 1 illustrates the general LSTM configuration applied for solar radiation forecasting, showing the sequential structure from the input window to the output layer.

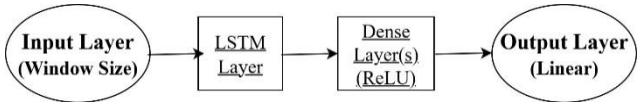

Fig. 1. General LSTM architecture for solar radiation forecasting.

Model training was performed in a Google Colab Pro environment equipped with an NVIDIA Tesla T4 GPU. The same optimizer, learning rate, and loss function were maintained for consistency across all experiments. Each training session lasted 30 epochs, and the ModelCheckpoint callback was again used to retain the best weights based on validation loss.

Data splitting followed a chronological order to preserve temporal dependencies: 67 % for training, 22 % for testing, and 11 % for validation, corresponding to 11,910, 3,853, and 1,752 hourly samples, respectively. Performance was evaluated using RMSE, MAE, and coefficient of determination (R2) for each subset. Additionally, the trained networks were tested on the external datasets from 2023 and 2024 to assess their ability to generalize to unseen data. Training progress was monitored through loss and validation-loss curves to detect possible underfitting or overfitting behaviors. The main parameters used during training are summarized in Table II.

TABLE II. TRAINING PARAMETERS

Parameter	Description
Framework / API	TensorFlow 2.15 / Keras
Programming language	Python 3.10
Environment	Google Colab (GPU: NVIDIA Tesla T4)
Optimizer	Adam
Learning rate	0.001
Loss function	Mean absolute Error (MAE)
Evaluation metric	Root Mean Squared Error (RMSE)
Epochs	30
Batch size	Default (TensorFlow)
Validation strategy	Chronological split (67% / 22% / 11%)

All procedures in this section were designed to ensure reproducibility and consistency across model configurations. Combining historical hourly radiation data with structured input windows and systematic model training established a solid foundation for evaluating forecast performance. This methodological design can be easily extended in future research by incorporating additional meteorological variables or developing hybrid architectures that combine LSTM with other deep learning models.

IV. RESULTS

This section presents and interprets the results obtained from the three LSTM configurations developed for solar radiation forecasting in Mompox, Colombia. The analysis integrates both quantitative and visual assessments of model performance, highlighting how different temporal window sizes influence prediction accuracy and generalization capacity. The following subsections examine, in detail, how each model performed in reproducing observed solar radiation patterns, comparing predicted and measured values across multiple time horizons.

A. Model Comparison by Input Window Size

To examine how the temporal context affects forecasting accuracy, three LSTM configurations were tested using input window sizes of 5, 24, and 720 hours. All models were trained under the same conditions (30 epochs, Adam optimizer, learning rate = 0.001) using hourly solar radiation data. The goal was to identify the sequence length that best balances short-term fluctuations with longer-term seasonal patterns.

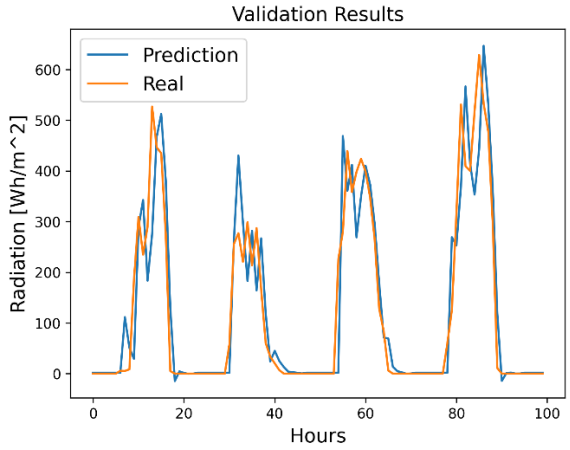

Fig. 2. Predicted vs. observed radiation using LSTM-5 (*window = 5 hours*).

The LSTM-5 model reproduced rapid fluctuations in solar radiation, particularly on clear days, but it struggled to represent complete diurnal transitions. As shown in Fig. 2, the predicted values follow the general pattern of observed radiation but show amplitude mismatches during peak irradiance hours. According to Fig. 2, this limitation is mainly due to the network's short memory window, which restricts its ability to capture the full daily energy cycle.

When the input window was expanded to 24 hours (Fig. 3), the model captured the daily periodicity of solar radiation. Fig. 3 shows that the predicted curves align more closely with observed diurnal patterns, reducing phase shifts and errors at

sunrise and sunset. However, the model still tended to underestimate radiation peaks on cloudy days, suggesting that a one-day context is insufficient to describe multi-day atmospheric variability.

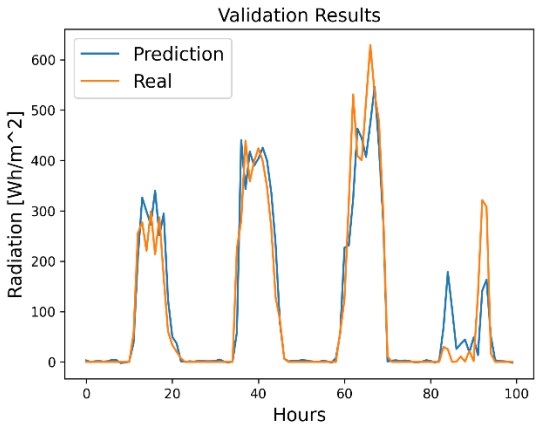

Fig. 3. Predicted vs. observed radiation using LSTM-24 (*window = 24 hours*).

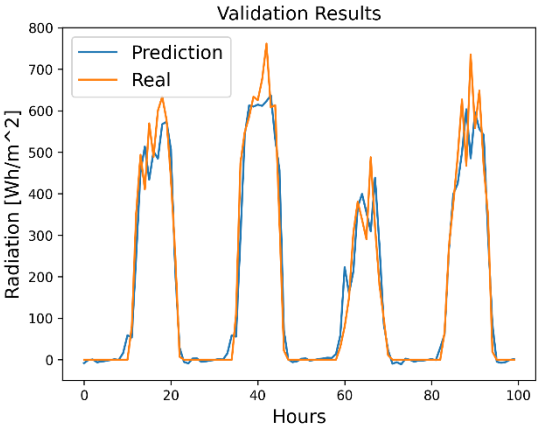

Fig. 4. Predicted vs. observed radiation using LSTM-720 (window = 720 hours).

The LSTM-720 model, trained on a monthly (30-day) input window, produced the most accurate and stable forecasts (Fig. 4). By learning over a broader temporal context, the network captured both daily and intra-monthly variations, resulting in smoother transitions and reduced noise. This improvement confirms that long-range dependencies are critical for reliable radiation prediction in tropical regions, where multi-day weather persistence is common.

In accordance with the above, extending the temporal window from 5 to 720 hours significantly enhanced model performance. Although computational cost increased with larger input sequences, the gains in accuracy justified using the LSTM-720 configuration for subsequent analyses. This setup successfully captures the natural temporal structure of solar radiation and provides the foundation for the evaluations presented in Section B and C.

B. Model Training Behavior

During training, the LSTM-720 model showed fast and stable convergence. Both training and validation losses decreased sharply within the first ten epochs and then plateaued, as illustrated in Fig. 5.

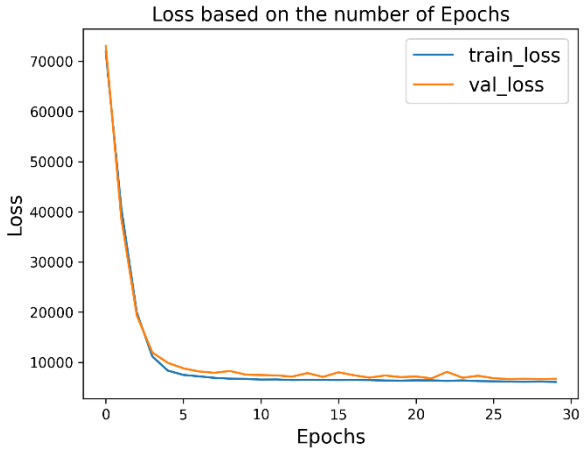

Fig. 5. Training and validation loss curves of LSTM-720 model.

The close alignment of the two curves indicates good generalization and minimal overfitting, confirming that the model effectively learned the underlying temporal dependencies. The smooth decline in loss values reflects the appropriate choice of hyperparameters, particularly the moderate learning rate (0.001) and batch size (32), which ensured stable gradient descent and reproducible convergence. Overall, these results demonstrate that the selected architecture and optimization settings are well suited for modeling the complexity of tropical solar radiation time series.

C. Validation and External Testing Performance

The predictive ability of the final LSTM-720 model was assessed in three validation stages: 1) internal validation using data from 2021 to 2022, 2) external validation with unseen data from 2023, and 3) an additional external validation using 2024 data. Each stage tested how well the model generalized under distinct climatic conditions.

Fig. 6 compares the observed and predicted hourly radiation during the internal validation period. The model accurately reproduced both clear and cloudy day dynamics, closely matching the amplitude and timing of daily cycles.

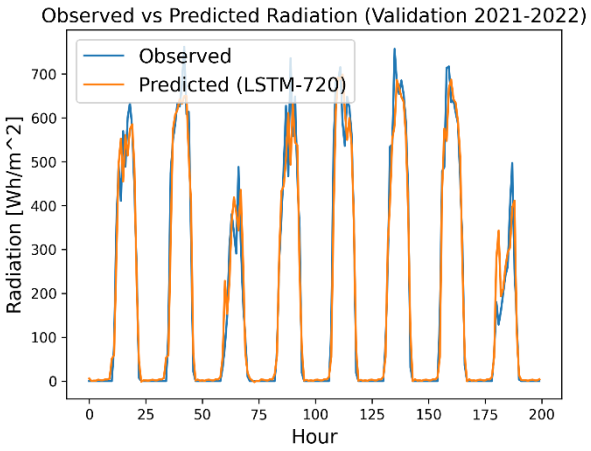

Fig. 6. Internal validation for the years 2021 to 2022 of LSTM-720 model.

Minor underestimations were observed at midday peaks, a common feature of networks trained without data normalization, but overall performance remained excellent, with RMSE = 63.88 Wh/m² and R^2 = 0.9535, explaining over 95 % of the observed variance. These metrics demonstrate strong calibration and confirm that the model learned the key temporal structures of solar radiation.

The first external test, shown in Fig. 7, evaluates the model on independent data from 2023. Predictions closely tracked the observed series throughout the year, with small amplitude differences during peak irradiance. Despite slightly higher RMSE (71.93 Wh/m²) and a marginally lower R^2 (0.913), the model maintained high accuracy, demonstrating robust generalization across years. This performance decay is modest and expected when forecasting beyond the training period. It also confirms that the temporal patterns learned from 2021 to 2022 remain valid under new atmospheric conditions.

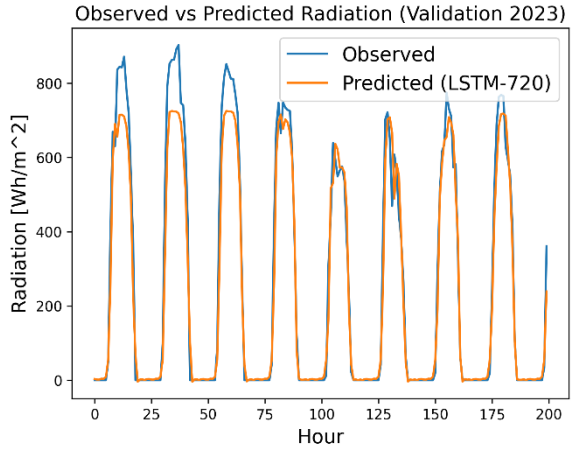

Fig. 7. External validation for the year 2023 of LSTM-720 model.

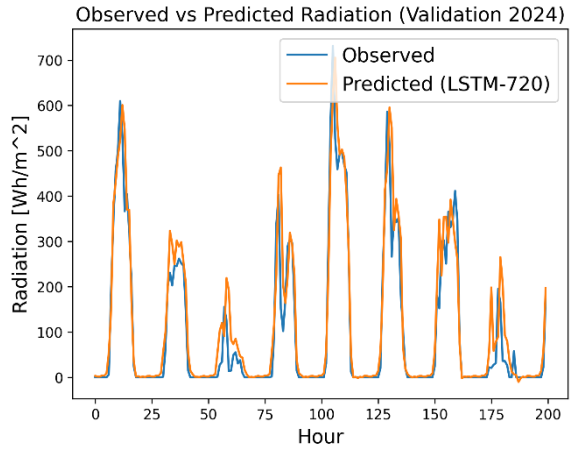

Fig. 8. External validation for the year 2024 of LSTM-720 model.

Fig. 8 presents the results for the 2024 dataset. The predicted time series aligned closely with the observed data, accurately reproducing diurnal cycles and the effects of intermittent cloud cover. Model metrics remained strong (RMSE = 65.53 Wh/m², MAE = 33.97 Wh/m², R^2 = 0.902), confirming stable performance and adaptability across consecutive years. The slightly narrower error range compared with 2023 suggests that weather patterns in 2024 were more similar to those seen during training.

A summary of all validation results is shown in Table III. R^2 values consistently above 0.90 confirm the model's ability to generalize well across different years and atmospheric conditions. The lowest RMSE corresponds to the internal validation, while external datasets remain within ±8 Wh/m² of that baseline, evidence of minimal performance decay. The MAE values (33–36 Wh/m²) indicate that average hourly errors are small relative to typical radiation levels in Mompox (> 600 Wh/m²). Altogether, these results emphasize the temporal stability and predictive robustness of the LSTM-720 architecture for operational solar radiation forecasting.

TABLE III. PERFORMANCE METRICS OF THE LSTM-720 MODEL ACROSS DATASETS

Dataset	Metrics		
	RMSE (Wh/m²)	*MAE (Wh/m²)*	*R^2*
2021–2022	63.88	35.66	0.954
2023	71.93	36.43	0.913
2024	65.53	33.97	0.902

To further evaluate model robustness, residual distributions were analyzed across the three validation periods (Fig. 9). Residuals were calculated as the difference between observed and predicted radiation, providing direct insight into systematic bias and variability. Across all years, residuals remained centered around zero with narrow interquartile ranges, indicating consistent performance and no major bias.

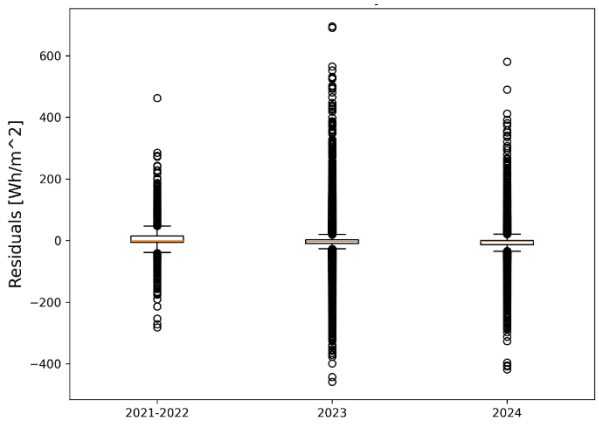

Fig. 9. Residual error distributions by year.

The statistical indicators summarized in Table IV show small negative mean values, suggesting a slight underestimation of peak irradiance.

Standard deviations stayed below 70 Wh/m², matching the RMSE magnitudes reported earlier. Skewness values near zero confirm symmetric error distributions, a desirable trait in predictive modeling. Slightly broader residual spreads in 2023 and 2024 correspond to stronger local variability, likely due to convective cloud formation and intermittent tropical rainfall. Even so, the overall bias remains low, confirming that the LSTM-720 model captures dominant radiation dynamics across changing weather conditions. Future research could enhance

accuracy further by incorporating auxiliary variables such as temperature, humidity, or cloud fraction, or by employing ensemble architectures to better capture transient atmospheric behaviors.

TABLE IV. STATISTICAL ANALYSIS OF MODEL RESIDUALS FOR THE VALIDATION DATASETS

Dataset	Metrics		
	Mean Residual (Wh/m²)	*Std. Deviation (Wh/m²)*	*Skewness*
2021–2022	-2.47	59.82	-0.06
2023	-3.85	67.49	0.12
2024	-1.91	63.07	-0.09

V. DISCUSSION AND IMPLICATIONS

The discussion of the broader implications of these findings in the context of previous research focused on three main aspects: 1) the effect of input window size on temporal learning, 2) the model's stability when applied to unseen years (2023–2024), and 3) the statistical characteristics of forecast residuals. Together, these analyses provide a comprehensive understanding of how LSTM networks can effectively model solar radiation dynamics under tropical climatic conditions and characteristics.

The findings confirm that deep recurrent neural networks, when trained on sufficiently long sequences, can model the nonlinear and seasonal variability of tropical solar radiation. Compared with conventional methods such as ARIMA or SVM [18], [20], [26], [28], LSTM models provide superior capacity to represent temporal dependencies without extensive feature engineering. This agrees with previous work on deep learning for solar forecasting [31], [35]–[37], further validating the effectiveness of recurrent architectures for meteorological time-series prediction.

Beyond outperforming traditional statistical baselines, the proposed 720-hour LSTM model offers a structural advantage over existing short-window and hybrid machine-learning approaches. Studies using ARIMA, LightGBM, CNN–RNN and BiLSTM–GRU configurations have shown accuracy improvements under standard mid-latitude conditions [19], [20], [24], [25], yet these models rely on short temporal dependencies and lose stability when climatic variability increases. In contrast, the long-context design used in this work was able to reconstruct multi-day and intra-month persistence patterns that those architectures cannot represent, demonstrating that forecasting improvement resulted from modelling strategy rather than parameter tuning. This positions the LSTM-720 framework as a distinct methodological alternative capable of recovering tropical atmospheric structure, rather than as another competing model variant. As such, the findings highlight a clear modelling advantage: long-memory recurrent networks enable tropical radiation learning behavior that existing methods structurally fail to reproduce.

Away from accuracy improvements, these findings translate into general modelling insights that apply to broader forecasting tasks. The results show that tropical radiation prediction requires architectures capable of learning sub-seasonal patterns rather than isolated diurnal signals, establishing a transferable design principle: input horizons must extend into the multi-day domain to reconstruct persistence dynamics. This principle aligns with recent studies reporting that deep recurrent models outperform statistical and short-window baselines when climatic variability increases [22], [23], [24], [25], [31]. In particular, works comparing ARIMA, LightGBM, hybrid CNN–RNN and BiLSTM–GRU approaches show that when atmospheric conditions are highly unstable, conventional models lose capacity to retain temporal structure [19], [20], [24], [25]. These links support the interpretation that forecasting improvements observed here are not dataset-dependent but reflect an underlying modelling requirement for tropical climates. Thus, the contribution extends beyond a single architecture: it provides guidance for window selection, long-context design, and application to other subtropical and equatorial solar forecasting problems.

A key strength of the LSTM-720 configuration is its durability over time. Beyond outperforming shorter input configurations, the results indicate that the 720 hour model delivers a fundamentally different learning behavior. Rather than improving accuracy through parameter scaling, the long-window architecture captured low frequency variability, radiation persistence, and intra month climatic structures that short-memory networks failed to represent. This shift reveals an underlying methodological implication: tropical radiation forecasting requires long context recurrent models to reconstruct non periodic atmospheric processes, not merely diurnal oscillations. The model's stability across 2021–2024 external validation years further demonstrates that this behavior is structural rather than dataset dependent. Consequently, this work contributes a conceptual advance to the field by demonstrating that long memory design is a necessary modelling component for tropical solar forecasting, positioning the approach as a generalizable framework rather than a sensitivity study.

In addition to demonstrating performance improvements, the findings from this study offer practical modelling guidance. The results show that tropical irradiance prediction benefits structurally from extended temporal contexts, establishing a clear design principle: forecasting windows must exceed diurnal or daily horizons to reconstruct persistence dynamics. Short-memory configurations captured rapid fluctuations but systematically failed to reproduce multi-day energy cycles, confirming that traditional daily window assumptions are unsuitable for humid tropical climates. Moreover, the stability of the 720-hour model across independent yearly datasets suggests that long-context LSTMs can retain climatic structure without retraining, providing a blueprint for robust tropical forecasting architectures. These elements sharpen the contribution of this work beyond experimentation results and translate into modelling guidelines applicable to future solar forecasting studies in similar environments.

Further to these findings, the results open several structured research directions. First, incorporating meteorological predictors such as cloud fraction, humidity or temperature may reveal whether tropical persistence originates from atmospheric drivers rather than radiation memory alone, helping to explain why monthly windows outperform daily horizons. Second,

evaluating GRU, BiLSTM–GRU and Transformer-based models could determine whether attention mechanisms improve multi-day pattern extraction beyond recurrent gating, clarifying if the benefit of long-context learning is architectural or temporal. Third, transferring and retraining the 720-hour framework in other tropical and subtropical climates would test whether the monthly memory requirement is a regional phenomenon or a general forecasting principle. Finally, integrating satellite imagery or reanalysis data may allow the model to learn cloud-system morphology, enabling spatial forecasting and operational deployment. Together, these directions illustrate how the present findings extend beyond model testing and establish a research pathway toward scalable tropical solar forecasting systems.

Even without retraining, the model retained high accuracy when applied to new years, confirming its potential for long-term operational use in solar energy management. Its consistent performance across varying atmospheric conditions demonstrates its adaptability to the complex climate patterns typical of tropical zones. The LSTM-720 model proved capable of capturing both rapid fluctuations and seasonal trends in solar radiation. Its ability to generalize with minimal degradation highlights the reliability of deep learning methods for renewable energy forecasting in tropical regions. Beyond Mompox, this approach offers a scalable framework adaptable to other data-limited locations that experience strong climatic variability.

Although the long-context design produced strong predictive performance, this study presents several limitations that should be acknowledged. First, the model was trained and evaluated using ground-based measurements from a single tropical location. This restricts the generalizability of the results to other geographic regions, where climatological dynamics and atmospheric behavior may differ significantly. Second, the network relied exclusively on previous radiation values, without integrating meteorological predictors such as cloud cover, humidity, temperature, or satellite observations. The absence of these external drivers may limit model sensitivity during extreme or rapidly changing weather conditions. Third, the hyperparameter configuration was not extensively optimized through large-scale search procedures because the objective of this study focused on evaluating temporal context rather than architecture tuning. Finally, the proposed LSTM-720 design was not benchmarked against other deep learning architectures such as GRU, transformer-based models, or hybrid CNN-RNN frameworks. These limitations highlight the need to expand the modelling scale, incorporate additional predictors, and conduct spatial transferability tests across different tropical regions.

VI. Conclusion

This study demonstrated the strong potential of deep recurrent neural networks, particularly the LSTM-720 architecture, for forecasting hourly global solar radiation in a tropical setting. Using data collected in Mompox, Colombia, from 2021 to 2024, the model accurately reproduced both short-term variations and long-term seasonal trends without requiring normalization or additional meteorological inputs. By employing a 720-hour input window, the network achieved consistently high predictive accuracy, with determination coefficients (R^2) exceeding 0.90 in all validation years. These results confirm the model's ability to generalize across distinct climatic conditions and emphasize the importance of selecting an appropriate temporal window to capture the intrinsic periodicity of solar radiation. Shorter input sequences (5–24 hours) were effective for representing diurnal behavior but fell short in modeling multi-day persistence and intra-monthly variability. In contrast, the 720-hour configuration provided a more complete view of atmospheric dynamics, allowing the LSTM to learn both daily and broader climatological dependencies relevant for solar energy forecasting. The model also demonstrated strong temporal stability when validated against independent datasets from 2023 and 2024, maintaining RMSE deviations within ±8 Wh/m² of the internal benchmark.

Residual analysis revealed minimal bias, near-symmetric error distributions, and stable variance across all years, evidence of the robustness and reliability of the proposed LSTM-720 approach. Beyond accuracy improvements, the results reveal a structural implication: forecasting in tropical environments requires long-memory recurrent modelling rather than short-window designs. The 720-hour context enabled the model to capture intra-month atmospheric persistence and sub-seasonal variability, which short sequences cannot represent. This positions the proposed framework as a methodological contribution that advances solar forecasting research beyond parameter optimization, providing a foundation for long-context modelling in other tropical regions.

From a practical standpoint, these findings underscore the suitability of recurrent neural networks for operational solar forecasting in tropical regions with limited meteorological infrastructure. The framework developed here can support photovoltaic energy management, grid planning, and hybrid renewable energy system design, offering a scalable and data-efficient tool for real-world applications. Future research should explore the integration of additional predictors, such as air temperature, humidity, and cloud fraction, and test hybrid deep learning architectures to enhance both predictive accuracy and spatial transferability. These results also provide modelling guidance for future tropical forecasting studies by confirming that long-context horizons are structurally required to recover sub-seasonal atmospheric behavior, a principle that may transfer to other equatorial locations and to different renewable forecasting tasks.

Declarations

The datasets analyzed in this research were provided by the Instituto de Hidrología, Meteorología y Estudios Ambientales (IDEAM), Colombia. They include hourly measurements of global solar radiation for the period 2021–2024, corresponding to the Mompox meteorological station. Due to institutional data-sharing restrictions, the original datasets are not publicly available but can be obtained upon reasonable request from the corresponding author or directly from IDEAM at https://www.ideam.gov.co/. All model training scripts and supplementary materials used in this study are also available from the corresponding author upon reasonable request to ensure full reproducibility of the results.

***Abstract*—The aim of this study is to develop an innovative, multi-dimensional, and uncertain decision-making model that can identify the most appropriate alternative irrigation method for the efficient use of water resources in agriculture. In this context, the proposed model is based on the integrated use of spherical fuzzy sets, machine learning, MEREC, and WASPAS methods. The evaluations obtained from ten experts were converted into spherical fuzzy numbers, and the experts' importance weights were objectively calculated using machine learning. Criteria weights were determined using the MEREC method, and alternatives were ranked using the WASPAS method. This hybrid approach both reduces expert subjectivity and objectively reflects the relationships between criteria. According to the findings, feasibility/technological suitability (0.152) emerged as the most important criterion, followed by environmental impacts (0.144). Among the alternatives, drip irrigation (2.226) was identified as the most suitable option for efficient use of water resources. This result demonstrates that modern, technology-based irrigation systems should be a priority in sustainable agricultural policies. This study's contribution to the literature is its ability to bring objectivity, transparency, and the ability to manage high uncertainty to decision-making processes in agricultural water management. The model offers both methodological innovation and a practical decision-support tool at the application level.**

Keywords*—Irrigation activities; water use; decision-making model; machine learning; MEREC; WASPAS

I. Introduction

Identifying the most appropriate alternative irrigation methods for sustainable water management in agriculture is crucial because each region's climate, soil structure, plant species, and economic capacity vary. Therefore, the same method cannot be expected to yield the most efficient results in every situation. Choosing the best irrigation method both conserves limited water resources and increases production efficiency [1]. Furthermore, determining the right method is critical for the efficient use of limited budgets and the rapid implementation of implementation strategies. Decision-making in this process is influenced by many different factors. Water efficiency refers to the extent to which water is delivered to the plant root zone without wasting water and is a key indicator of sustainable agriculture. Cost determines the economic viability of the system's installation, operation, and maintenance. Energy consumption is particularly important due to the pumps and pressure lines used in modern systems, as energy costs directly impact production costs. Applicability and technological compatibility indicate the compatibility of the selected method with existing infrastructure and technical capacity. Plant yield and quality directly reflect the impact of the irrigation method on agricultural output and are the most tangible measures of success for farmers [2]. Environmental impacts include soil salinity, erosion, and changes in groundwater levels that may be caused by excessive or inappropriate water use. Ease of maintenance and operation is a factor that determines the long-term sustainability of a method, as complex systems may not be managed effectively, especially by producers with limited technical knowledge. However, the number of studies in the literature that evaluate these criteria holistically is quite limited. Most studies focus on a single factor or are limited to a specific geographical context. This creates a significant gap in the literature, as there is insufficient comparative data to determine which irrigation method is most effective under which conditions. This gap creates uncertainty in decision-making processes and makes it difficult for practitioners to select the most appropriate system. Furthermore, the varying weights of criteria depending on the situation highlight the need for multi-criteria analyses. Therefore, this gap in the existing literature represents a research problem that needs to be addressed from both theoretical and practical perspectives. New studies on this topic will significantly contribute to identifying strategies to increase water efficiency and support sustainable agricultural production.

This study aims to identify the most effective alternative irrigation methods for the efficient use of water resources in agriculture. The primary motivation for the study is increasing water scarcity, the impacts of climate change, and the need for sustainability in agricultural production. The lack of systematic multi-criteria comparisons of irrigation methods in the existing literature creates a significant research gap. Therefore, this study aims to fill this gap at both the theoretical and practical levels. A holistic decision-making model for selecting alternative irrigation methods was developed. The model is based on a hybrid approach that integrates expert opinions with fuzzy logic. In this context, seven criteria were identified for use in the evaluation following a comprehensive literature review. These criteria are water efficiency, cost, energy consumption, applicability, plant yield and quality, environmental impacts,

and ease of maintenance and operation. The alternatives comprise sprinkler irrigation, drip irrigation, surface irrigation, subsurface irrigation, and microsprinkler irrigation. Expert assessments were collected from ten different experts and converted into spherical fuzzy numbers. Expert importance weights were calculated using a machine learning-based method, thus reducing the influence of subjective evaluations. The importance levels of the criteria were determined using the MEREC method, allowing the contribution of each criterion to the model to be objectively measured. The resulting weights were used to rank the performance of the alternatives using the WASPAS method. This integrated approach provides a decision support framework that takes both uncertainties into account and is computationally efficient. The study seeks to answer the following research questions: 1) Which alternative irrigation method is the most effective for the sustainable management of water resources in agriculture? 2) What are the most decisive factors in the decision-making process among the seven criteria determined? 3) How does the diversity of expert opinions affect the ranking of alternatives? 4) To what extent is the spherical fuzzy-based approach effective in reducing uncertainty compared to traditional fuzzy methods? 5) What advantages does the integrated use of the MEREC and WASPAS methods provide in multi-criteria decision-making processes? By addressing these research questions, the study proposes an innovative decision-making model that will increase water efficiency in the agricultural sector and provide a strategic reference framework for policy developers and practitioners.

This study addresses a clear methodological and practical gap in the literature by proposing a hybrid decision-making framework that goes beyond existing fuzzy-based MCDM applications in agricultural water management. Unlike prior studies that typically rely on static expert-driven fuzzy weighting and conventional ranking techniques, the proposed model uniquely combines spherical fuzzy sets with machine learning–assisted data structuring, the objective weighting capability of the MEREC method, and the compensatory–noncompensatory evaluation mechanism of WASPAS within a single integrated framework. This specific configuration is fundamentally novel in that spherical fuzzy sets are employed not merely as a linguistic extension, but as a means to capture hesitation and uncertainty in irrigation-related expert judgments, while machine learning is used to enhance data consistency and reduce subjectivity prior to weighting and ranking. To the best of our knowledge, no existing study in the irrigation method selection literature has systematically integrated these four components to jointly address uncertainty modeling, objective criterion weighting, and robust alternative ranking. Consequently, the proposed approach offers a structurally distinct and methodologically advanced decision-support tool for the efficient use of water resources in agriculture.

The proposed model developed in this study has several advantages over previously presented decision-making models in the literature: 1) First, the model utilizes machine learning techniques to calculate the importance weights of experts. This approach allows for objective weighting based not only on the opinions of experts but also on their demographic characteristics, areas of expertise, experience levels, and academic backgrounds. The vast majority of existing models in the literature treat experts as equal or base weights on subjective assessments. This increases the risk of subjectivity and inconsistency in the decision-making process. However, the machine learning-based approach used in this study systematically evaluates differences among experts, providing more objective, reliable, and data-driven weightings. This increases the accuracy and confidence levels of the model and enhances the scientific validity of decision-making results. 2) The second advantage of the model is the use of spherical fuzzy sets in the decision-making process. These new-generation fuzzy sets have a higher uncertainty representation capacity compared to classical, intuitionistic, and Pythagorean fuzzy sets. By defining membership, non-membership, and degrees of uncertainty independently, the spherical fuzzy structure models the uncertainties and knowledge gaps in expert opinions in a much more realistic and flexible manner. This allows for more effective management of uncertainty in the decision-making environment and increased consistency of results. Furthermore, the spherical fuzzy approach offers advantages over other sets in terms of both ease of calculation and interpretability. This contributes to the model's robustness both theoretically and practically. 3) The MEREC (Method Based on the Removal Effects of Criteria) technique used in the study is another significant advantage of the model. Entropy, CRITIC, or standard statistical methods are frequently used in the literature for criterion weighting; however, these methods generally fail to adequately reflect the mutual influences between criteria. The MEREC method analyzes the change in overall performance when each criterion is removed from the system, revealing the true impact of each criterion. This feature allows the model to better capture inter-criterion sensitivity and ensure more objective, reliable, and data-driven decision-making outcomes. The MEREC method offers higher accuracy and significance than other techniques, particularly in areas such as water management, where multidimensional environmental and technical factors are evaluated simultaneously. Considering all these advantages together, the proposed model offers a holistic approach that is both methodologically innovative and provides high accuracy, flexibility, and consistency in decision-making processes.

The remainder of the study is as follows: Section II includes the research gap in the literature. Section III focuses on the proposed model. The results are denoted in Section IV. Section V makes a comparative discussion. Section VI highlights the main conclusion.

II. Literature Review

Applicability, or technological suitability, is one of the key criteria when determining alternative irrigation methods for the efficient use of water resources in agriculture. Given the challenges of climate change, the use of technologies that can increase productivity and efficiency in agriculture, including precision agriculture, drones, and climate information systems, is crucial. In today's world, the development of systems such as remote sensing with artificial intelligence-based decision-making tools also promotes the efficient use of water resources in agriculture. These technologies include software applications, water management applications, nutrient management, temperature measurement, and soil health analysis tools. These technologies can also contribute to climate change-resilient crop

development, irrigation water management, fostering local knowledge, and increasing agricultural yields, ensuring food security. Vedovello et al. [3] provided an overview of hydrogel technologies as adaptable solutions to address challenges such as water scarcity and soil degradation in agriculture. Indeed, hydrogels offer agricultural innovations that address challenges associated with traditional agricultural practices and technologies while also providing some answers for the future of these technologies. Singh and Singh [4] examined the impact of UAV use in Indian agriculture on precision agriculture, crop monitoring, and pesticide application. They assess technological advancements, infrastructure, regulatory frameworks, farmer perceptions, and financial accessibility of UAV technology.

Environmental impacts are another effective criterion in determining alternative irrigation methods for the efficient use of water resources in agriculture. Ultimately, water efficiency in agriculture is a critical element of sustainable water management, particularly in rural areas, and is vital for ensuring environmental sustainability in rural areas where water resources are limited [5]. While traditional surface irrigation has been reported to cause environmental consequences such as water loss, advanced alternatives such as drip and sprinkler systems have been observed to improve irrigation infrastructure and promote climate-smart agricultural practices [6]. Saini et al. [7] investigated the behaviors and perspectives of rural and regional urban water consumers regarding water consumption. They develop a conceptual model of the factors affecting the amount of water consumed, including the barriers that hinder water conservation. Yasmeen et al. [8] examined the synergy of water use efficiency between 2006 and 2020 between the aggregation of water resources at the provincial and regional levels in China and the integration of innovative conservation technologies.

Cost is another important criterion when determining alternative irrigation methods for the efficient use of water resources in agriculture. The initial investment cost of irrigation systems designed for efficient water use can be high. This is because sprinkler and drip irrigation systems, while achieving efficiency by using less water, require operator control, operation, and monitoring [9]. Furthermore, while external factors such as regulations, national water policies, financial incentives, government subsidies, and technology provide solutions for efficient water supply in agriculture, they can also be considered among the factors affecting costs [10]. Chaudhary et al. [11] summarized the fundamental aspects of sprinkler and precision irrigation, their development and prospects, particularly in Asian countries. This approach leverages significant advances in sprinkler systems for precision applications to increase net crop production, conserve irrigation water, maximize irrigation uniformity, and improve fertilizer management with minimal leakage loss. On the other hand, Bhavsar et al. [12] comprehensively examined numerous IoT-enabled smart micro-irrigation systems, including smart sprinkler systems and smart drip irrigation, to reduce water and energy waste. The aim is to find the most appropriate irrigation strategy.

Energy consumption is another important criterion in determining alternative irrigation methods for the efficient use of water resources in agriculture. The agricultural sector consumes large amounts of water and energy through irrigation, collection, pumping, water treatment, land preparation, fertilizer production, agricultural machinery, processing, and storage [13]. In other words, energy is used both directly and indirectly for the efficient use of water resources in agriculture, while the energy provided to modern and sustainable agricultural production systems and processing is one of the main factors in the growth of agricultural production [14]. Yang et al. [15] established a framework for examining water and energy consumption at every stage of the crop growth process, including growth, planting, germination, ripening, and harvesting. Pomoni et al. [16] aimed to reveal the environmental, water, and energy impacts of traditional agriculture and a new soilless cultivation technology, namely hydroponic agriculture.

The results of the literature review indicate that certain criteria are important in determining alternative irrigation methods for the efficient use of water resources in agriculture. These criteria include applicability (technological suitability), environmental impacts, cost, and energy consumption. Since it is not possible to improve all criteria simultaneously, the study aims to identify the most important criterion. This aims to address a gap in the literature on this topic. This study accomplishes this by analyzing a new decision-making model.

III. METHODOLOGY

This section relates to the formulations of spherical fuzzy sets (SFSs), dimensionality reduction, MEREC, and WASPAS. Using these formulations, the methodology of the manuscript is constructed. The methodology includes SFSs to minimize uncertainty, while dimensionality reduction is used to determine the level of experts. Additionally, after calculating the criterion priority value from MEREC, comparative results of WASPAS and RAWEC are obtained in ranking the alternatives. The diagram of the methodology is presented in Fig. 1.

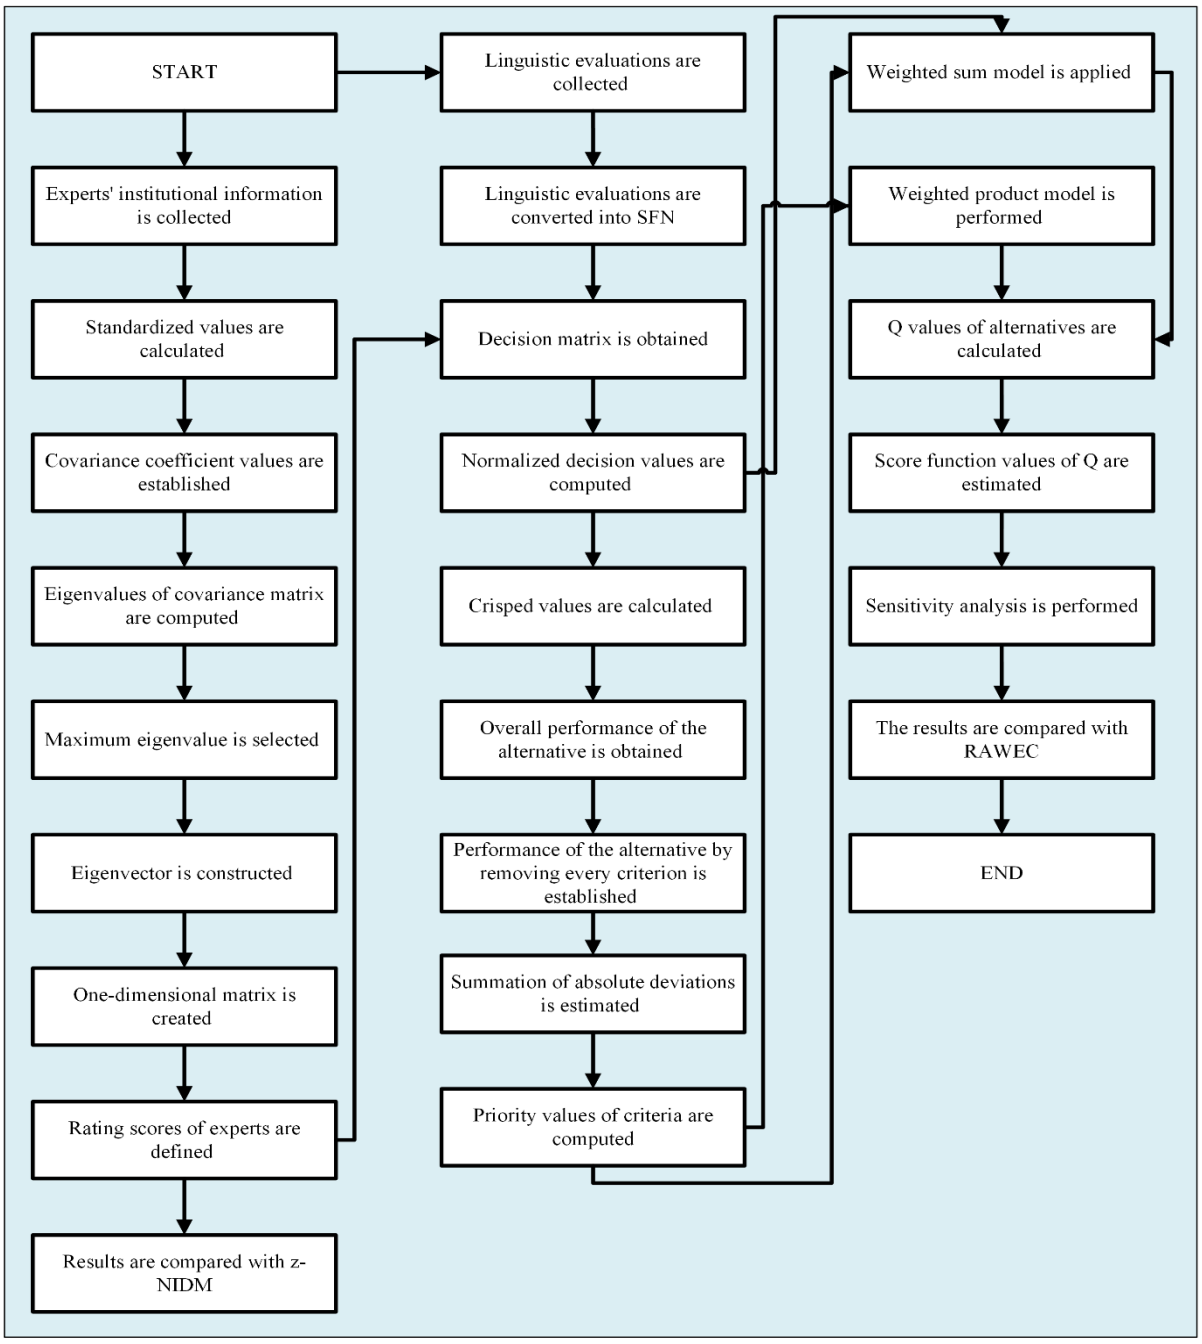

Fig. 1. Diagram of the methodology.

A. Dimensionality Reduction

Creating a decision matrix by calculating the unweighted average of expert evaluations has been criticized. Due to this criticism, different approaches have been developed in the literature. While dimensionality reduction is primarily used to reduce the number of variables in machine learning, it is preferred in MCDM due to its objectivity in calculating the experts' ratings. This approach aims to obtain rating scores for experts using information provided by the experts on the websites of their affiliated institutions. The assumption here is that if an institution's knowledge is high, the institution is of high quality; if the institution is good, the expert working there is also qualified. Under this assumption, the calculation steps can be summarized as follows [17].

The websites of k institutions, where k experts work, are examined. The f numerical information about the institutions is collected. This information includes the number of business partners the institutions have collaborated with and the years they have been in operation. Based on these variables, an institution is considered high-quality if it has been operating for a long time. Similarly, the more business partners it has, the better the institution. In other words, the matrix (B) in Eq. (1) is created using the data from the relevant variables indicating the institution's qualification.

$$B = \begin{bmatrix} b_{11} & \cdots & b_{1f} \\ \vdots & \ddots & \vdots \\ b_{k1} & \cdots & b_{kf} \end{bmatrix} \quad (1)$$

When the value range and unit sizes of the variables differ from each other, standardized values (r) are calculated with the help of Eq. (2) to Eq. (4) using arithmetic mean $(\bar{b})$ and centred values (c).

$$\bar{b}_j = \frac{\sum_{i=1}^{k} b_{ij}}{k} \quad (2)$$

$$c_{ij} = b_{ij} - \bar{b}_j \quad (3)$$

$$r_{ij} = \frac{c_{ij}}{\sqrt{\sum_{i=1}^{k} c_{ij}^2}} \quad (4)$$

Afterwards, covariance coefficient values (cov) between standardized variables are established via Eq. (5). Thus, the covariance matrix (A) formed in Eq. (6) is obtained.

$$cov_{jt} = \frac{1}{k}\left(\sum_{i=1}^{k}(r_{ij} - \bar{r}_j)(r_{it} - \bar{r}_t)\right) \quad (5)$$

$$A = \begin{bmatrix} cov_{11} & \cdots & cov_{1f} \\ \vdots & \ddots & \vdots \\ cov_{f1} & \cdots & cov_{ff} \end{bmatrix} \quad (6)$$

where, $\bar{r}$ is the average value of the standardized variable and is estimated using Eq. (2). Next, f eigenvalues of the covariance matrix (ξ) are computed by Eq. (7). Then, the maximum eigenvalue (ξ^*) is selected with Eq. (8) for saving the maximum variance.

$$\det(A - \xi_i \mathrm{I}) = 0 \quad (7)$$

$$\xi^* = \max \xi_i \quad (8)$$

where, I is the identity matrix with dimensions *fxf*. Later, the eigenvector (Y) is constructed with the help of Eq. (9):

$$(A - \xi^* \mathrm{I})Y = 0 \quad (9)$$

Finally, a one-dimensional matrix (H) is created via Eq. (10), then the rating scores of experts (rs) are defined as Eq. (11):

$$H = BY \quad (10)$$

$$rs_i = \frac{h_i}{\sum_{i=1}^{k} h_i} \quad (11)$$

where, h is the items of one-dimensional matrix. The multiplication operation in Eq. (10) is matrix multiplication.

B. SFSs

Fuzzy sets define different degrees to measure uncertainty. From the set family formed by the degrees of membership (α), non-membership (β), and hesitancy (γ), SFSs are defined by the sum of the squares of these degrees. In other words, an SFS $(\tilde{F})$ of the universe of discourse $(\mathcal{S})$ is described as in Eq. (12) [18].

$$\tilde{F} = \left\{x, \left(\alpha_{\tilde{F}}(x), \beta_{\tilde{F}}(x), \gamma_{\tilde{F}}(x)\right) | x \in \mathcal{S}\right\} \quad (12)$$

where, these degrees are between zero and one. These degrees are the satisfied conditions in Eq. (13):

$$0 \le \alpha_{\tilde{F}}^2(x) + \beta_{\tilde{F}}^2(x) + \gamma_{\tilde{F}}^2(x) \le 1;\ \forall x \in \mathcal{S} \quad (13)$$

The refusal degree is computed with Eq. (14):

$$\varsigma_{\tilde{F}}(x) = \sqrt{1 - \alpha_{\tilde{F}}^2(x) - \beta_{\tilde{F}}^2(x) - \gamma_{\tilde{F}}^2(x)} \quad (14)$$

Consider that $\tilde{F}$ and $\tilde{G}$ are two SFNs. Then, basic operators are identified with Eq. (15) to Eq. (18):

$$\tilde{F} + \tilde{G} = \left\{ \begin{matrix} \sqrt{\alpha_{\tilde{F}}^2 + \alpha_{\tilde{G}}^2 - \alpha_{\tilde{F}}^2\alpha_{\tilde{G}}^2}, \beta_{\tilde{F}}\beta_{\tilde{G}}, \\ \sqrt{\left(1-\alpha_{\tilde{G}}^2\right)\gamma_{\tilde{F}}^2 + \left(1-\alpha_{\tilde{F}}^2\right)\gamma_{\tilde{G}}^2 - \gamma_{\tilde{F}}^2\gamma_{\tilde{G}}^2} \end{matrix} \right\} \quad (15)$$

$$\tilde{F} \times \tilde{G} = \left\{ \begin{matrix} \alpha_{\tilde{F}}\alpha_{\tilde{G}}, \sqrt{\beta_{\tilde{F}}^2 + \beta_{\tilde{G}}^2 - \beta_{\tilde{F}}^2\beta_{\tilde{G}}^2}, \\ \sqrt{\left(1-\beta_{\tilde{G}}^2\right)\gamma_{\tilde{F}}^2 + \left(1-\beta_{\tilde{F}}^2\right)\gamma_{\tilde{G}}^2 - \gamma_{\tilde{F}}^2\gamma_{\tilde{G}}^2} \end{matrix} \right\} \quad (16)$$

$$\lambda\tilde{F} = \left\{ \begin{matrix} \sqrt{1 - \left(1-\alpha_{\tilde{F}}^2\right)^{\lambda}}, \beta_{\tilde{F}}^{\lambda}, \\ \sqrt{\left(1-\alpha_{\tilde{F}}^2\right)^{\lambda} - \left(1-\alpha_{\tilde{F}}^2-\gamma_{\tilde{F}}^2\right)^{\lambda}} \end{matrix} \right\} \quad (17)$$

$$\tilde{F}^{\lambda} = \left\{ \begin{matrix} \alpha_{\tilde{F}}^{\lambda}, \sqrt{1 - \left(1-\beta_{\tilde{F}}^2\right)^{\lambda}}, \\ \sqrt{\left(1-\beta_{\tilde{F}}^2\right)^{\lambda} - \left(1-\beta_{\tilde{F}}^2-\gamma_{\tilde{F}}^2\right)^{\lambda}} \end{matrix} \right\} \quad (18)$$

Assume that $\tilde{F}_i$ be the sequence of SFNs and $\sum_{i=1}^{n} w_i = 1$. Then, weighted arithmetic mean $(\tilde{\mathcal{A}})$ is calculated using Eq. (19):

$$\tilde{\mathcal{A}}_{\tilde{F}_i} = \left\{ \begin{matrix} \sqrt{1 - \prod_{i=1}^{n}\left(1-\alpha_{\tilde{F}_i}^2\right)^{w_i}}, \\ \prod_{i=1}^{n}\beta_{\tilde{F}_i}^{w_i}, \\ \sqrt{\prod_{i=1}^{n}\left(1-\alpha_{\tilde{F}_i}^2\right)^{w_i} - \prod_{i=1}^{n}\left(1-\alpha_{\tilde{F}_i}^2-\gamma_{\tilde{F}_i}^2\right)^{w_i}} \end{matrix} \right\} \quad (19)$$

Similarly, weighted geometric mean $(\tilde{\mathcal{G}})$ is computed with Eq. (20):

$$\tilde{\mathcal{G}}_{\tilde{F}_i} = \left\{ \begin{matrix} \prod_{i=1}^{n}\alpha_{\tilde{F}_i}^{w_i}, \\ \sqrt{1 - \prod_{i=1}^{n}\left(1-\beta_{\tilde{F}_i}^2\right)^{w_i}}, \\ \sqrt{\prod_{i=1}^{n}\left(1-\beta_{\tilde{F}_i}^2\right)^{w_i} - \prod_{i=1}^{n}\left(1-\beta_{\tilde{F}_i}^2-\gamma_{\tilde{F}_i}^2\right)^{w_i}} \end{matrix} \right\} \quad (20)$$

Score (SF) and accuracy (AF) functions are identified by Eq. (21) and Eq. (22), respectively.

$$SF\left(\tilde{F}\right) = \left(2\alpha_{\tilde{F}} - \frac{\gamma_{\tilde{F}}}{2}\right)^2 - \left(\beta_{\tilde{F}} - \frac{\gamma_{\tilde{F}}}{2}\right)^2 \quad (21)$$

$$AF\left(\tilde{F}\right) = \alpha_{\tilde{F}}^2 + \beta_{\tilde{F}}^2 + \gamma_{\tilde{F}}^2 \quad (22)$$

C. SF-MEREC-Based SF-WASPAS

MEREC-based WASPAS is a hybrid approach that ranks alternatives by combining two models after determining objective criteria priorities. This hybrid approach aims to

minimize uncertainty by integrating SFSs. This manuscript analysis process is described below [19].

For the decision model in which n criteria are considered to rank m alternatives, evaluations from k experts are collected with a linguistic scale. These linguistic evaluations are converted into SFNs, and their weighted averages are calculated by Eq. (23):

$$\tilde{d}_{ij} = \left\{\alpha_{\tilde{d}_{ij}}, \beta_{\tilde{d}_{ij}}, \gamma_{\tilde{d}_{ij}}\right\} = \tilde{\mathcal{A}}_{\tilde{E}^t{}_{ij}} \quad (23)$$

where, $\tilde{E}^t{}_{ij}$ refers to SFN of the linguistic evaluation of jth criterion of ith alternative for t^{th} expert. $\tilde{\mathcal{A}}$ is the weighted arithmetic mean defined in Equation (19) using the rating scores of experts as weights. Next, normalized decision values $(\tilde{\mathfrak{y}})$ are computed with Eq. (24) and Eq. (25):

$$\tilde{\mathfrak{y}}_{ij} = \left\{\alpha_{\tilde{d}_{ij}}, \beta_{\tilde{d}_{ij}}, \gamma_{\tilde{d}_{ij}}\right\}; for\ benefical\ criterion \quad (24)$$

$$\tilde{\mathfrak{y}}_{ij} = \left\{\gamma_{\tilde{d}_{ij}}, \beta_{\tilde{d}_{ij}}, \alpha_{\tilde{d}_{ij}}\right\}; for\ cost\ criterion \quad (25)$$

Afterwards, crisped values $(\mathfrak{h})$ are calculated by Eq. (26):

$$\mathfrak{h}_{ij} = \frac{1}{2}\begin{pmatrix} 1 + \left(\alpha_{\tilde{\mathfrak{y}}_{ij}}\right)^2 \\ -\left(\beta_{\tilde{\mathfrak{y}}_{ij}}\right)^2 - \left(\gamma_{\tilde{\mathfrak{y}}_{ij}}\right)^2 - \ln\left(1 + \left(\varsigma_{\tilde{\mathfrak{y}}_{ij}}\right)^2\right) \end{pmatrix} \quad (26)$$

The overall performance of the alternative (G) is obtained with the help of Eq. (27):

$$G_i = \ln\left(1 + \left(\frac{1}{n}\sum_j \left|\mathfrak{h}_{ij}\right|\right)\right) \quad (27)$$

The performance of the alternative by removing every criterion (G') is established using Eq. (28):

$$G'_{ij} = \ln\left(1 + \left(\frac{1}{n}\sum_{f\, f\neq j} \left|\mathfrak{h}_{if}\right|\right)\right) \quad (28)$$

Next, the summation of absolute deviations (K) is estimated by Eq. (29):

$$K_j = \sum_i \left|G'_{ij} - G_i\right| \quad (29)$$

The last step of MEREC is about the computation of priority values (pv) of criteria with Eq. (30):

$$pv_j = \frac{K_j}{\sum_{j=1}^{n} K_j} \quad (30)$$

Afterwards, the weighted sum model $\left(\tilde{Q}^{(1)}\right)$ is applied using Eq. (31).

$$\tilde{Q}_i^{(1)} = \sum_{j=1}^{n} pv_j \tilde{\mathfrak{y}}_{ij} \quad (31)$$

Similarly, the weighted product model $\left(\tilde{Q}^{(2)}\right)$ is performed via Eq. (32):

$$\tilde{Q}_i^{(2)} = \prod_{j=1}^{n} \left(\tilde{\mathfrak{y}}_{ij}\right)^{pv_j} \quad (32)$$

Next, the $\tilde{Q}$ values of alternatives are calculated by Eq. (33) [20].

$$\tilde{Q}_i = \varphi\tilde{Q}_i^{(1)} + (1-\varphi)\tilde{Q}_i^{(2)} \quad (33)$$

Finally, score function values of $\tilde{Q}$ are estimated with the help of Eq. (34) for ranking of alternatives.

$$Q_i = SF\left(\tilde{Q}_i\right) \quad (34)$$

IV. Analysis

This section relates to the results of the methodology in Fig. 1.

A. Obtaining the Rating Scores of Experts

Experts with at least ten years of work experience are selected. Data from the website is analyzed using the experts' institutional information. The institutions' business partners, period of activity, and number of countries they operate in are obtained. This information is used to create the matrix in Eq. (1). The matrix is shown in Table I.

TABLE I. Information About the Institutional Business Partners

	Business Partners	**Activity Period**	**Operation Country**
Expert.1	16	16	6
Expert.2	21	16	5
Expert.3	23	21	5
Expert.4	32	26	4
Expert.5	33	33	6
Expert.6	24	22	4
Expert.7	25	18	3
Expert.8	35	35	6
Expert.9	29	15	4
Expert.10	34	24	6

According to the variables in Table I, the average business partner is 27.2 with a standard deviation of 6.03. Similarly, the minimum activity period is 15. The range of operation country is between 3 and 6. The descriptive statistics are shared in Table II.

TABLE II. Descriptive Statistics

	Business Partners	**Activity Period**	**Operation Country**
Average	27.2	22.6	4.9
Deviation	6.030	6.666	1.044
Max	35	35	6
Min	16	15	3

Standardized values are calculated with the help of Eq. (2) to Eq. (4) using arithmetic mean and centered values in Table II. The standardized values are given in Table III.

TABLE III. STANDARDIZED VALUES

	Business Partners	Activity Period	Operation Country
Expert.1	-.587	-.313	.333
Expert.2	-.325	-.313	.030
Expert.3	-.220	-.076	.030
Expert.4	.252	.161	-.273
Expert.5	.304	.493	.333
Expert.6	-.168	-.028	-.273
Expert.7	-.115	-.218	-.575
Expert.8	.409	.588	.333
Expert.9	.094	-.361	-.273
Expert.10	.357	.066	.333

Covariance coefficient values between standardized variables in Table III are established via Eq. (5). Thus, the covariance matrix formed in Eq. (6) is summarized in Table IV.

TABLE IV. COVARIANCE MATRIX

	Business Partners	Activity Period	Operation Country
Business Partners	.100	.075	.016
Activity Period	.075	.100	.045
Operation Country	.016	.045	.100

Next, the 3 eigenvalues of the covariance matrix are computed by Eq. (7). These eigenvalues are illustrated in Table V with explained variances. Then, the maximum eigenvalue is selected with Eq. (8) for saving the maximum variance. The maximum eigenvalue is .19569.

TABLE V. EIGENVALUES WITH EXPLAINED VARIANCES

	Value	Explained Variance
Eigenvalue.1	.19569	65.23%
Eigenvalue.2	.018526	6.18%
Eigenvalue.3	.085784	28.59%

The first eigenvalue contains 65.23% of the variance, which is considered a relatively high rate. Later, eigenvector is constructed with the help of Eq. (9). The results are displayed in Table VI.

TABLE VI. ITEMS OF EIGENVECTOR

	Vector
1	.603644
2	.675852
3	.422891

A one-dimensional matrix is created via Eq. (10). This matrix is exhibited in Table VII.

TABLE VII. ONE-DIMENSIONAL MATRIX

	First-dimension
Expert.1	23.009
Expert.2	25.605
Expert.3	3.191
Expert.4	38.580
Expert.5	44.761
Expert.6	31.048
Expert.7	28.525
Expert.8	47.320
Expert.9	29.335
Expert.10	39.282

Finally, the items in Table VII are normalized. Thus, the rating scores of experts are defined as Eq. (11). The rating scores of experts are presented in Fig. 2.

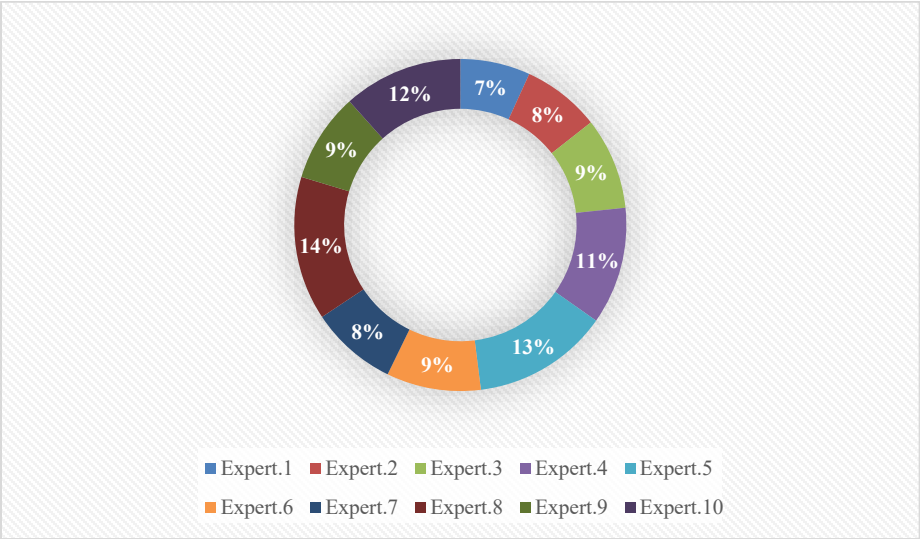

Fig. 2. Rating scores of experts.

As can be seen from rating scores in Fig. 2, the most important evaluation is Expert.8 with .140. This expert's institution has the maximum business partners, operation county and activity period. Moreover, as a second method to compare the results, the z-NIDM method is applied. The comparative results are visualized in Fig. 3.

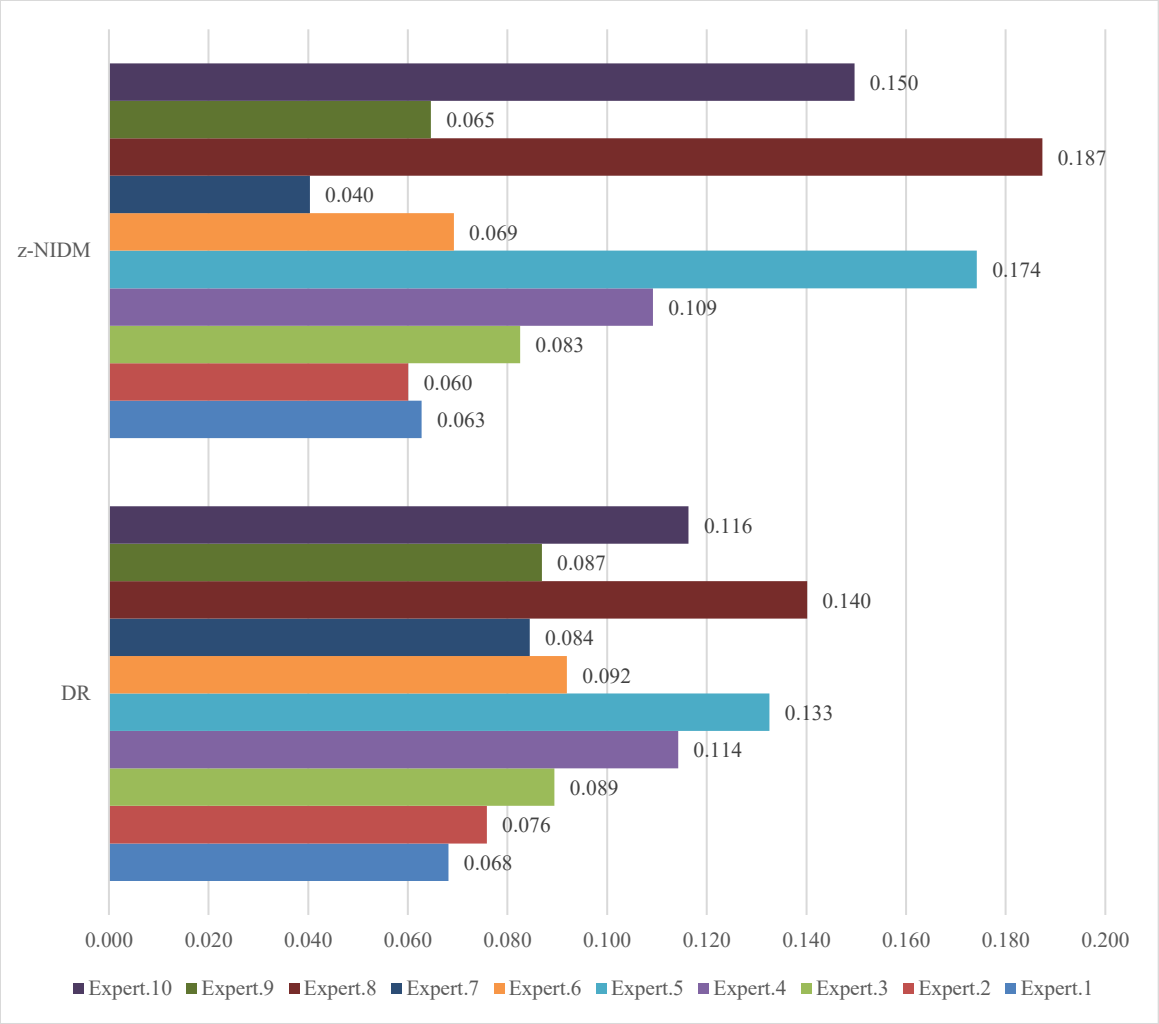

Fig. 3. Comparative results for experts.

Pearson and Spearman correlation coefficients between two approaches are obtained for results. Pearson coefficient is .939 and Spearman coefficient is .944. These coefficients are very high. In other words, the results are consistent and reliable.

B. *Weighting of Criteria and Ranking of Alternatives*

Alternative irrigation methods for efficient use of water resources in agriculture are sprinkler irrigation (SPR), drip irrigation (DRP), surface irrigation (channel or flood) (SRF), subsurface irrigation (SBS), and micro sprinkler irrigation (MCR). The criteria effective in the selection of these alternatives are presented with their short codes in Table VIII.

Linguistic evaluations from 10 experts are collected with a linguistic scale shared in Fig. 4.

TABLE VIII. CRITERIA LIST WITH SHORT CODES

Definition	Short Code
Water Efficiency (Savings)	WEF
Cost	CST
Energy Consumption	ECN
Applicability/Technological Compatibility	APT
Plant Yield and Quality	PTQ
Environmental Impacts	EVI
Ease of Maintenance and Operation	EMO

Using the initials of the linguistic scale in Fig. 4, the experts' evaluations are summarized in Table IX. For example, VHI is of very high importance.

These linguistic evaluations in Table IX are converted into SFNs according to Fig. 4. Then, weighted averages are calculated by Eq. (23) using rating scores of experts in Fig. 2 as weights. Thus, the decision matrix that accepts the weighted average values as elements is obtained. This matrix is displayed in Table X.

Normalized decision values are computed with Eq. (24) and Eq. (25). All criteria are beneficial. For this reason, Eq. (24) is used. In other words, normalized decision values and the decision matrix's elements are the same. Next, crisped values are calculated by Equation (26). The crisped values are shown in Table XI.

The overall performance of the alternative is obtained with the help of Eq. (27). The overall performance values are visualized in Fig. 5.

TABLE XI. CRISPED VALUES

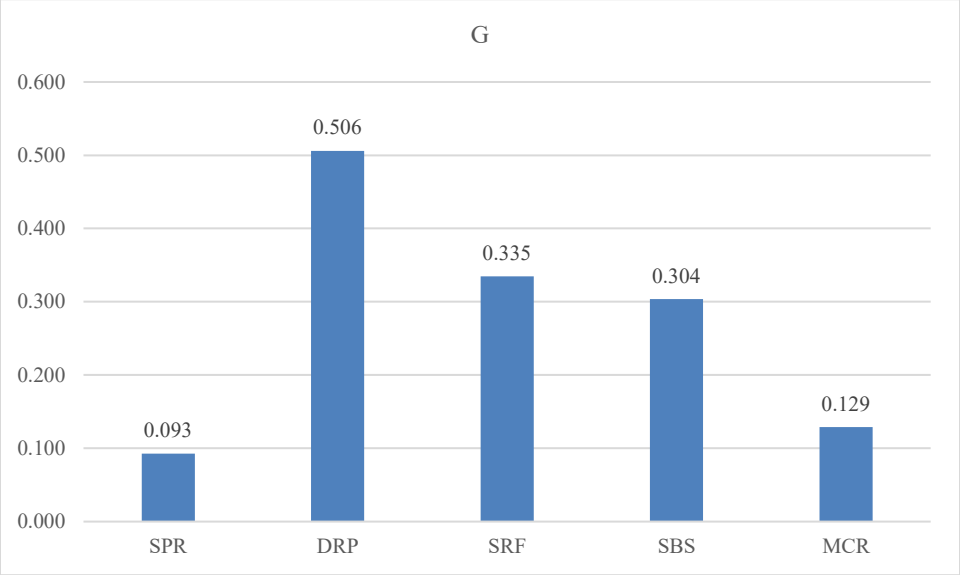

Fig. 5. Overall performance values.

The performance of the alternative by removing every criterion is established using Eq. (28). The results are illustrated in Table XII.

Next, the summation of absolute deviations is estimated by Eq. (29). The summation values are presented in Fig. 6.

The last step of MEREC is about the computation of priority values of criteria with Eq. (30). The results are shown in Fig. 7.

TABLE XII. G' VALUES

	WEF	CST	ECN	APT	PTQ	EVI	EMO
SPR	.081	.078	.084	.079	.081	.075	.083
DRP	.450	.448	.446	.449	.447	.450	.443
SRF	.295	.297	.296	.288	.293	.292	.292
SBS	.263	.267	.263	.264	.265	.270	.267
MCR	.112	.111	.112	.108	.112	.109	.116

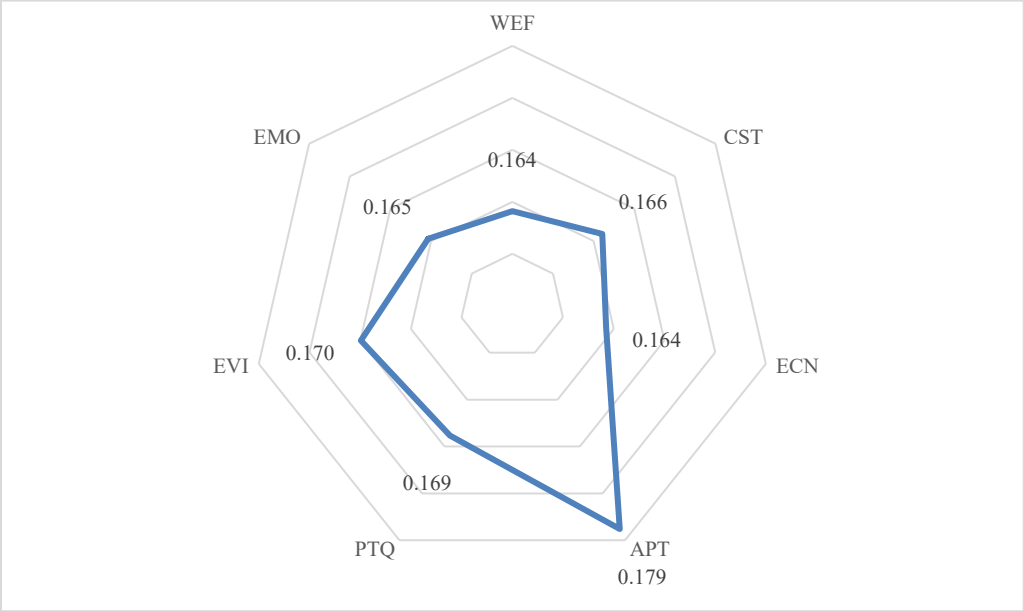

Fig. 6. Summation of absolute deviations.

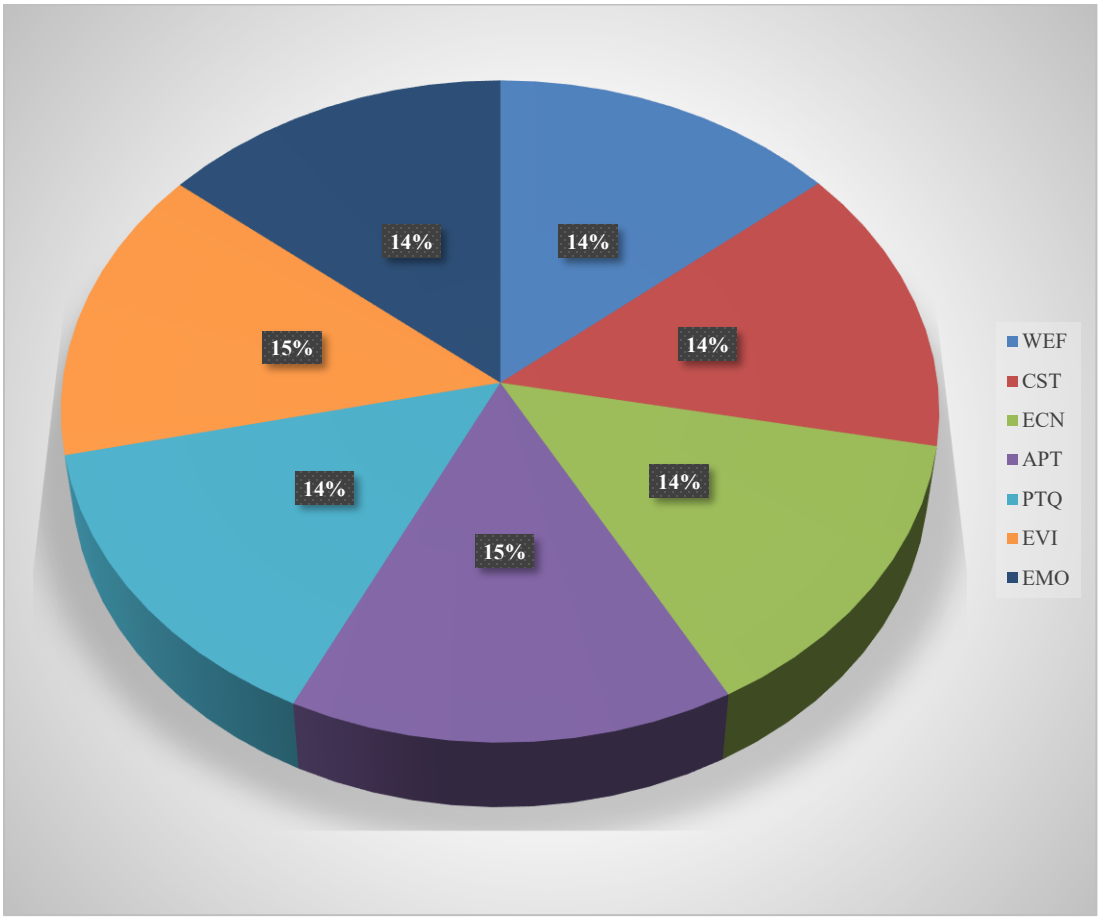

Fig. 7. Priority values of criteria.

When Fig. 7 is examined, the most important criterion effective in the selection of these alternative irrigation methods for efficient use of water resources in agriculture is applicability/technological compatibility with .152. The second important criterion is environmental impacts with .144. Afterwards, weighted sum model is applied using Eq. (31). The weighted sum model result is described in Table XIII.

TABLE XIII. WEIGHTED SUM MODEL

	$\tilde{Q}^{(1)}$
SPR	(.287,.766,.246)
DRP	(.803,.212,.217)
SRF	(.616,.412,.376)
SBS	(.582,.443,.428)
MCR	(.344,.696,.294)

Similarly, weighted product model is performed via Eq. (32). The weighted product model result is illustrated in Table XIV.

TABLE XIV. WEIGHTED PRODUCT MODEL

	$\tilde{Q}^{(2)}$
SPR	(.282,.768,.244)
DRP	(.802,.214,.218)
SRF	(.614,.413,.377)
SBS	(.581,.444,.429)
MCR	(.341,.698,.293)

Next, the $\tilde{Q}$ values of alternatives are calculated by Eq. (33). The results are summarized in Table XV with φ of .5.

TABLE XV. $\tilde{Q}$ VALUES ($\varphi = .5$)

	$\varphi\tilde{Q}^{(1)}$	$(1-\varphi)\tilde{Q}^{(2)}$	$\tilde{Q}$
SPR	(.205,.875,.179)	(.202,.876,.177)	(.285,.767,.245)
DRP	(.635,.461,.202)	(.634,.462,.203)	(.802,.213,.218)
SRF	(.46,.642,.309)	(.459,.643,.31)	(.615,.413,.377)
SBS	(.432,.665,.349)	(.431,.666,.35)	(.581,.443,.428)
MCR	(.247,.834,.218)	(.245,.835,.216)	(.342,.697,.294)

Finally, score function values of $\tilde{Q}$ are estimated with the help of Eq. (34) for the ranking of alternatives. The ranking values of alternative irrigation methods for efficient use of water resources are visualized in Fig. 8.

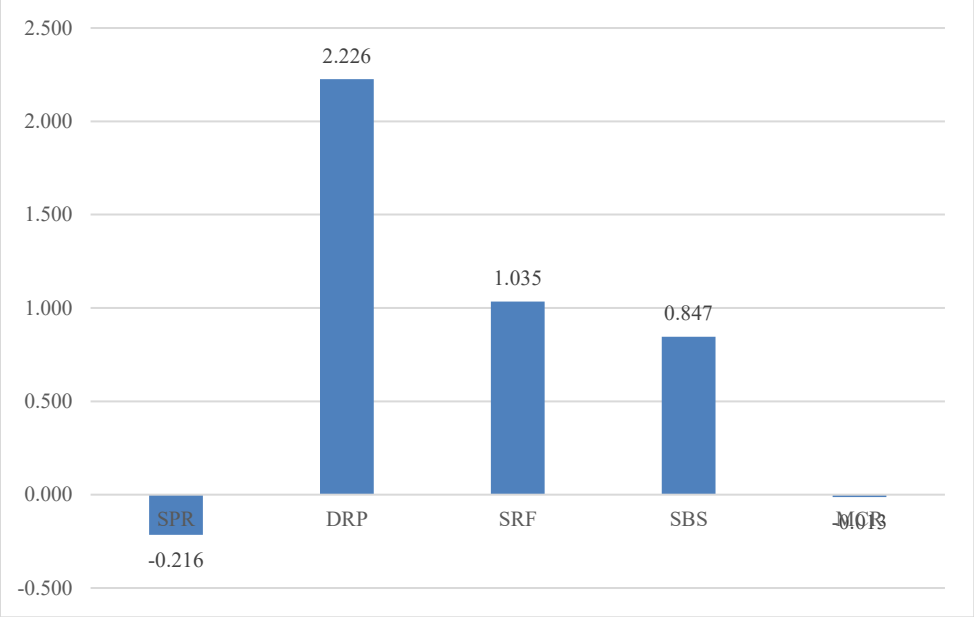

Fig. 8. Defuzzified Q values.

As can be seen, defuzzified Q values in Fig. 8, the most suitable alternative irrigation method for efficient use of water resources is drip irrigation with 2.226.

C. Sensitivity Analysis

Calculations are performed with different φ values and the results are compared. This tests the sensitivity of the results. The ranking values based on φ values are summarized in Table XVI.

TABLE XVI. RESULTS BY φ

	0	.1	.2	.3	.4	.5	.6	.7	.8	.9	1
SPR	-.221	-.220	-.219	-.218	-.217	-.216	-.214	-.213	-.212	-.211	-.210
DRP	2.222	2.223	2.224	2.225	2.225	2.226	2.227	2.228	2.229	2.229	2.230
SRF	1.032	1.032	1.033	1.033	1.034	1.035	1.035	1.036	1.037	1.037	1.038
SBS	.845	.845	.845	.846	.846	.847	.847	.847	.848	.848	.849
MCR	-.016	-.016	-.015	-.014	-.014	-.013	-.012	-.012	-.011	-.010	-.010

As can be understood from ranking scores of alternatives in Table XVI, the ranks of alternatives are the same. In other words, the results are reliable and consistent.

D. Comparative Analysis

To validate the results, a second method is used to compare them. The RAWEC method is preferred for this purpose. The crisp values in Table XI are used. The comparative results are presented in Fig. 9.

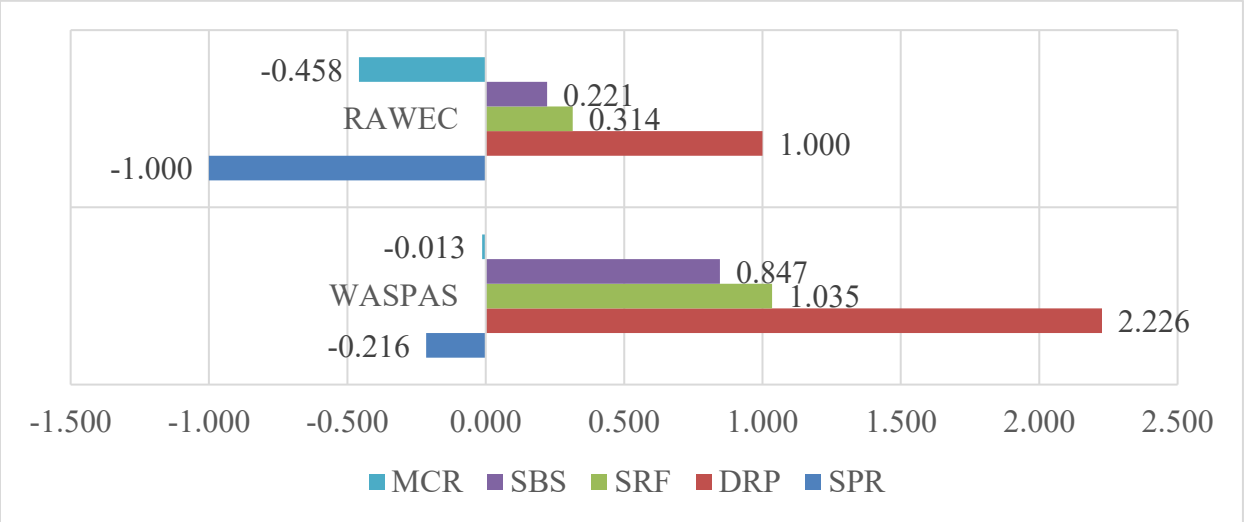

Fig. 9. Comparative analysis for ranking.

Pearson and Spearman correlation coefficients are calculated to determine the consistency between the results of the two methods. These coefficients are 0.972 and 1, respectively. High correlations indicate that the results are valid.

V. Discussion

Applicability, or technological suitability, is one of the key criteria when determining alternative irrigation methods for the efficient use of water resources in agriculture. This is because implementing innovative strategies and leveraging the power of technology can increase the efficient use of water resources in agriculture. This can be achieved through the combined use of artificial intelligence, automated water supply systems, and IoT-based precision irrigation systems in industrial wastewater treatment [21]. In other words, promoting modern and improved water use through irrigation practices and other smart approaches is crucial for sustainable water use [22]. In this context, Et-Taibi et al. [23] argued that IoT-based smart agriculture could be a promising solution. In their study, they introduce a cloud-based smart irrigation system to connect numerous small-scale smart farms and centralize the data they obtain. The system optimizes irrigation water use through comprehensive big data collection, storage, and analysis. Xing and Wang [24] summarized recent advances in molecular breeding, precision agriculture, and innovative water management techniques aimed at improving crop drought resilience, soil health, and overall agricultural productivity. This is because the increasing challenges of climate change and water scarcity make it imperative to increase agricultural productivity and sustainability, especially in arid regions.

Environmental impacts have been identified as another important criterion in determining alternative irrigation methods for the efficient use of water resources in agriculture. Indeed, while the use of water resources has a certain impact on the ecological conditions of a region, it is possible to address three dimensions of environmental impact: wastewater discharge, non-point pollution, and carbon emissions [25]. In addition, the effective application of computerization in the efficient use of water resources in agriculture ensures the improvement of environmental impacts and contributes to the environmentally conscious use of water resources [26]. Kalfas et al. [27] extensively evaluate the link between land use planning, water resources, and global climate change in their study. They state that proper land use planning can guide the establishment of waste management systems that minimize methane emissions and that land use planning affects agricultural practices. On the other hand, Keson et al. [28] aimed to evaluate the performance of land, water and climate relationship in his study using geographic information systems-based tools for optimized planning and management of sustainable production practices.

Drip irrigation [29] is one of the most important alternatives for determining alternative irrigation methods for the efficient use of water resources in agriculture. Drip irrigation is one of the most effective ways to integrate water and fertilizer for productivity in agriculture. Proper application of drip irrigation can reduce nutrient loss and emissions while maintaining nutrient balance in the soil (Yang et al., 2024). In drip irrigation, water, nutrients, and other essential growth substances are precisely delivered directly to the plant's root zone through a hole. This quickly restores plant moisture and nutrient levels, minimizes water stress, and improves overall quality, growth, and productivity [30]. In this context, Sanchis-Ibor et al. [31] focused on the process of switching to drip irrigation in Acequia Real del Júcar (Valencia, Spain). Their aim is to analyze how the estimation and distribution of expected water savings vary across different water planning tools and how they are perceived by the various actors involved in this process.

VI. CONCLUSION

The aim of this study is to develop a holistic and methodologically advanced decision-making model that enables the identification of the most appropriate alternative irrigation methods for the efficient use of water resources in agriculture. To this end, a novel hybrid framework integrating spherical fuzzy sets, machine learning, MEREC, and WASPAS methods is proposed. Evaluations obtained from ten domain experts were transformed into spherical fuzzy numbers to capture hesitation and uncertainty; expert importance weights were objectively derived using machine learning; criterion weights were determined through the MEREC method; and alternative irrigation methods were ranked using WASPAS.

Beyond its technical outcomes, the primary research contribution of this study lies in advancing the state of the art in AI-assisted multi-criteria decision-making for agricultural water management. Unlike existing studies that predominantly rely on static expert-based fuzzy weighting and conventional ranking schemes, the proposed framework introduces a structured human–AI collaborative mechanism that simultaneously addresses uncertainty modeling, objective expert differentiation, and compensatory–noncompensatory alternative evaluation within a unified architecture. In this sense, the study moves beyond incremental tool-level efficiency improvements and offers a conceptually distinct decision-support paradigm that enhances methodological robustness and interpretability in complex resource management problems. The empirical findings indicate that feasibility and technological suitability constitute the most influential criterion, followed by environmental impacts, while drip irrigation emerges as the most suitable alternative for efficient water use. These results not only corroborate prior empirical insights but also demonstrate how advanced hybrid AI–fuzzy frameworks can yield more nuanced and reliable decision outcomes under uncertainty.

Nevertheless, the study has certain theoretical and technical limitations. The relatively small number of experts, the focus on a specific regional or sectoral context, and the consideration of only seven criteria constrain the generalizability of the findings. From a technical perspective, the machine learning–based expert weighting process is sensitive to dataset size and diversity, which may lead to variability across different samples. In addition, while spherical fuzzy modeling provides a robust representation of uncertainty, it entails relatively high computational complexity. Future research is therefore encouraged to incorporate larger and more diverse expert panels, extend the model to different geographic and agricultural contexts, integrate additional criteria such as socioeconomic and climatic variables, and combine the proposed framework with other AI-driven decision-support systems. Such extensions would further strengthen the generalizability of the model and consolidate its contribution to both methodological research and practical decision-making in sustainable agricultural water management.

Balancing Privacy and Acceptance: The Role of Anthropomorphism and Information Sensitivity in Autonomous Taxis

Jia Fu, Kyoung-jae Kim*
Department of Management Information Systems, Dongguk University, Seoul, South Korea

***Abstract*—This study investigates how anthropomorphic interface design and information sensitivity influence users' acceptance of autonomous vehicles (AVS), and examines the underlying role of privacy concern and its boundary conditions in a commercial autonomous taxi context. Addressing prior research that has predominantly examined anthropomorphism or privacy concerns in isolation, this study employs a 2 × 2 experimental design to test the main interaction effects of anthropomorphism and information sensitivity on technology acceptance. The results demonstrate that both anthropomorphism and information sensitivity significantly affect users' acceptance of AV technology, with a significant interaction effect between the two. Specifically, when information sensitivity is high, lower levels of anthropomorphism lead to higher acceptance, whereas under low information sensitivity, anthropomorphic design enhances acceptance. Further analysis reveals that privacy concern mediates the relationship between anthropomorphism, information sensitivity, and technology acceptance. Moreover, cultural value orientation and technical familiarity moderate the effect of privacy concern on technology acceptance, such that the negative impact of privacy concern is attenuated among users with stronger collectivist orientations and higher levels of technical familiarity. By clarifying the sequential roles of design cues, privacy concern, and individual differences, this study reveals a dynamic balance mechanism between emotional engagement and perceived privacy risk in data-intensive mobility services. These findings advance understanding of privacy–acceptance dynamics and provide practical implications for the design and deployment of autonomous taxi interfaces.**

Keywords*—Anthropomorphism; information sensitivity; privacy concern; technology acceptance; individual cultural value; technical familiarity; autonomous taxis

I. Introduction

With the rapid development of smart cities, domains such as healthcare, smart parking, transportation, and public safety are becoming increasingly interconnected, allowing physical objects to provide intelligent services to citizens [1]. Among them, unmanned driving technology has become a vital part of modern transportation. Driverless taxis, exemplified by pilot projects in cities like Wuhan, China, are gaining global attention. Unlike traditional driving that relies on human control, autonomous driving depends on artificial intelligence and machine learning. For example, in Wuhan's "Radish Kuaipao" autonomous taxi service, safety officers monitor vehicles and intervene if necessary. Although such systems promise fewer accidents and higher efficiency, they raise concerns about privacy, security, and public acceptance [2].

Privacy is a particularly critical issue. As noted in [2], smart technologies often require large-scale personal data collection. In driverless taxis, this may involve continuous tracking and biometric data such as facial recognition.

Improper handling of such data can lead to misuse and privacy breaches. Moreover, users' perception of privacy risk strongly affects their acceptance. In [3], the authors found that greater privacy sensitivity reduces trust in autonomous vehicles, thereby lowering adoption willingness. Hence, balancing service efficiency and privacy protection remains a key challenge. Another important factor is anthropomorphism in driving behavior, which shapes user comfort and perception. In [4], the authors highlighted that vehicle behavior influences passengers' familiarity and perceived safety. In [5], the authors showed that intelligent in-vehicle voice agents using natural language processing can simulate human-like interaction, enhancing user experience. Similarly, [6] demonstrated that anthropomorphic driving increases trust and social acceptance. Technically, anthropomorphism does not involve data collection but rather evokes emotional and cognitive responses through perceived human-likeness. Thus, integrating anthropomorphic features effectively is essential for the broader acceptance of autonomous taxis. However, existing studies have largely examined privacy-related risks and anthropomorphic design cues as separate determinants of user acceptance, leaving their joint and potentially interactive effects insufficiently understood.

Despite the growing importance of autonomous taxis, most studies emphasize technical feasibility [7] rather than the socio-psychological mechanisms driving acceptance. Unlike privately owned autonomous vehicles, commercial autonomous taxi services involve transient usage, platform-based data governance, and limited user control, making privacy perceptions more salient and context-dependent. In particular, prior research has predominantly focused on privately owned autonomous vehicles, whereas commercial autonomous taxi services involve short-term use, platform-mediated data collection, and heightened information sensitivity, which may fundamentally alter users' privacy perceptions and acceptance mechanisms. While trust is central to understanding technology adoption [8], it cannot fully explain interactions involving privacy and anthropomorphism. Therefore, it is necessary to

*Corresponding author.

explore how these two dimensions jointly influence user acceptance.

This study proposes an integrative framework examining how anthropomorphism and information sensitivity influence technology acceptance, and investigates privacy concern as a mediating mechanism underlying this relationship. It further investigates whether anthropomorphic design can reduce perceived privacy risks and enhance willingness to use driverless taxis. Individual cultural value and technical familiarity are included as moderators to capture personal differences. These moderators are theoretically relevant because cultural orientation shapes how individuals weigh collective benefits against personal privacy risks, while technical familiarity influences users' perceived control and tolerance toward data-driven systems. To test these relationships, a 2×2 between-subjects experiment was conducted, manipulating anthropomorphism (high vs. low) and information sensitivity (high vs. low). Participants evaluated privacy concern and technology acceptance, and the moderating roles of culture and technical familiarity were analyzed using ANOVA and PROCESS procedures. This experimental approach enables a clear examination of both causal effects and interaction mechanisms between design cues and information characteristics, which are difficult to disentangle using survey-based or observational methods. By systematically manipulating anthropomorphism and information sensitivity, the study provides stronger internal validity in explaining users' acceptance of autonomous taxi services. Drawing upon the Privacy Calculus Framework, anthropomorphism theory, and the Technology Acceptance Model (TAM), this study bridges research on privacy protection and human-like design within autonomous mobility. It provides both theoretical insight and practical guidance for balancing efficiency, ethics, and psychological acceptance in the design and governance of driverless taxis in smart cities. While prior research has primarily addressed either privacy or anthropomorphism separately, little is known about their combined effect on user acceptance, especially in commercial AV contexts.

The remainder of this study is organized as follows: Section II reviews the relevant literature and develops the research questions. Section III shows the theoretical background of the research, research models and hypotheses. Section IV describes the experimental design, data collection procedures, measurement instruments, empirical results and hypothesis testing. Finally, Section V discusses the conclusions of the findings, acknowledges the limitations of the study, and outlines directions for future research.

II. Literature Review

A. Autonomous Driving Technology

AVs have evolved from early 20th-century visions into operational systems through decades of interdisciplinary research [9]. Early AVs operated in controlled environments, relying on infrastructure support, while advances in sensors, algorithms, and computation have enabled navigation in complex urban settings [10]. Pioneering projects, including Carnegie Mellon's Navlab and Germany's EUREKA initiative, laid the groundwork for partial automation, and Google's 2010 public-road tests accelerated global investment and research.

AV applications now span passenger transport and logistics, with companies such as Tesla and Waymo integrating automated driving assistance systems (ADAS) and partial self-driving features, while autonomous delivery vehicles undergo trials [11]. AV integration into intelligent transportation systems (ITS) leverages real-time data sharing and smart traffic infrastructure to improve efficiency and reduce congestion, prompting new considerations of human–machine interaction, privacy, and data governance [12].

Future AV development aims for full autonomy (SAE Level 5), yet technical challenges, including unpredictable traffic, adverse weather, and public trust, constrain adoption [13]. Progress relies on AI, deep learning, sensor fusion, and high-speed communication networks [14, 15, 16], alongside emerging ride-hailing platforms that may reshape transportation norms [17].

Privacy concerns are central, as AVs collect sensitive user data such as location, biometrics, and behavioral patterns [18]. Anthropomorphic AV interfaces—ranging from visual avatars to human-like behavioral cues—affect trust, emotional engagement, and privacy perception [19, 20]. User responses are moderated by individual cultural values (e.g., collectivism vs. individualism) and technical familiarity, influencing both privacy concern and technology acceptance.

In sum, successful AV adoption depends not only on technological advancement but also on human factors, including privacy perception, interface design, and cultural context. Integrating these considerations is essential for designing ethically responsible, user-centered autonomous mobility systems.

B. Information Sensitivity in Autonomous Vehicle Systems

Information sensitivity has become a critical concern in digital ecosystems, particularly in ITS and AVs, which rely on continuous data collection through sensors, GPS, and vehicle-to-infrastructure communications [21, 22]. Data ranges from geolocation and routing information to more sensitive types such as biometric identifiers and real-time behavioral patterns, elevating privacy risks beyond traditional transportation. Perceived sensitivity directly influences users' privacy concern and willingness to adopt AVs [23]. Regulatory and policy interventions, including GDPR and AV-specific strategies, emphasize user rights, informed consent, and data minimization [24, 25, 26].

Technological mechanisms, such as encryption, anonymization, and limited data collection, complement regulatory measures to mitigate privacy risks [27]. Transparency and user control—allowing data access, correction, or deletion—further enhance perceived safety [28]. Nonetheless, AV innovations continue to outpace existing protections, making perceived information sensitivity a key determinant of privacy concern and technology acceptance. User responses are also shaped by interface design, particularly anthropomorphic cues, which can mediate how sensitive data is perceived.

C. Anthropomorphism in Human-AV Interaction

Anthropomorphism involves attributing human-like traits to non-human agents, including AVs, via visual cues, language, or behavioral feedback, aiming to enhance user engagement, trust,

and comprehension [29, 30]. Such designs can reduce psychological distance and influence perceptions of data practices, though effects are context-dependent [31]. Emotional connection, transparency, and human-like responsiveness can increase perceived trust, safety, and enjoyment, fostering user acceptance [32, 33].

Privacy Concern (PC) reflects perceived vulnerability from personal data collection, which is crucial in AVs due to pervasive data capture [34]. Factors influencing PC include individual characteristics (age, education), socio-cultural background, prior privacy experiences, information sensitivity, perceived transparency, and technical familiarity [35, 36]. Elevated PC can reduce trust and perceived usefulness, thereby limiting Technology Acceptance (TA) [37].

Empirical evidence indicates that information sensitivity increases PC, which lowers TA [2, 18]. Anthropomorphic design can enhance trust and acceptance, but may also raise privacy concerns when systems appear highly human-like [19, 20]. Interaction effects show that high anthropomorphism combined with sensitive data amplifies privacy concerns, whereas low-sensitivity contexts allow anthropomorphism to primarily boost user satisfaction and adoption [38, 19]. This underscores the importance of balancing interface design with data sensitivity to optimize AV acceptance.

D. Moderating Effects of Individual Cultural Value and Technical Familiarity

The effects of information sensitivity and anthropomorphic design on PC and TA are moderated by Individual Cultural Value (ICV) and Technical Familiarity (TF). ICV dimensions, such as individualism–collectivism, influence privacy norms and risk tolerance: sensitivity to data is higher in individualistic cultures, while anthropomorphic cues may be perceived differently across cultures [39, 40]. TF shapes user evaluation of privacy and system functionality: higher TF can reduce PC by improving understanding of mitigation mechanisms, whereas low TF users rely more on human-like signals to assess unfamiliar systems [23]. Evidence suggests that these moderators interact, with cultural norms and technical knowledge jointly shaping trust, privacy perception, and acceptance [41, 42].

Despite progress, research gaps remain, particularly in commercial AV contexts such as autonomous taxis. Most studies focus on private vehicles, neglecting transactional, short-term interactions where data sensitivity and anthropomorphic design may fluctuate across service stages—from navigation to payment. The dynamic interplay of anthropomorphism and information sensitivity, and their amplification of PC, is underexplored. Additionally, the moderating roles of ICV and TF in such service-based environments require empirical validation to inform culturally adaptive and user-specific design principles [39] [40].

Future research should adopt integrated, mediated-moderated frameworks that examine combined effects of anthropomorphism and information sensitivity in commercial AV adoption, ensuring that system design balances usability, trust, and ethical data practices.

Basic the privacy theory and anthropomorphism theory, aiming to clarify the psychological processes through which human-like design cues and varying levels of sensitive data shape user perceptions in data-intensive AV systems. Three research questions guide this investigation:

RQ1: How do anthropomorphic design and information sensitivity, individually and interactively, affect users' privacy concerns?

RQ2: Does privacy concern mediate the relationship between anthropomorphism, information sensitivity, and technology acceptance?

RQ3: Do individual cultural value and technical familiarity moderate the effect of privacy concern on technology acceptance?

III. Methodology

A. Theoretical Background

Privacy has long been central to understanding individuals' decisions about data disclosure and technology use. In [43], the authors defined privacy as control over one's personal information—deciding when, how, and to what extent data are shared. In digital contexts such as autonomous driving, this control becomes complex and psychologically salient. Users weigh perceived risks and benefits of sharing data, consistent with the Privacy Calculus Framework. In this study, information sensitivity represents varying privacy costs, allowing examination of how perceived data risk influences emotional responses (privacy concern) and behavioral intentions (technology acceptance).

Anthropomorphism theory provides a complementary perspective. In [44], the authors suggest that human-like cues enhance engagement and trust by evoking social connection. In autonomous vehicles, anthropomorphic interfaces may improve approachability and trustworthiness, thereby increasing perceived usefulness and lowering adoption barriers. However, from a privacy calculus viewpoint, heightened human-likeness can also increase perceived monitoring or judgment, amplifying privacy concern under high information sensitivity. Thus, anthropomorphism may simultaneously increase trust and privacy risk, creating a psychological trade-off that shapes user acceptance.

To integrate these mechanisms, this study extends the Technology Acceptance Model [45] by incorporating privacy concern as a mediating variable derived from the privacy calculus. Privacy concern reflects the outcome of users' cost–benefit evaluations and connects design characteristics (anthropomorphism, information sensitivity) to behavioral intentions. Furthermore, consistent with extended TAM frameworks, individual factors—cultural value orientation and technical familiarity—are introduced as moderators. Together, these theories form a comprehensive model explaining how emotional engagement and privacy risk jointly determine users' adoption of autonomous driving technologies.

B. Research Model and Hypotheses

Most prior studies on autonomous driving have focused on private self-driving vehicles. This study instead situates its

research in the commercial driverless taxi context, emphasizing differences between private ownership and service-based use. This perspective aligns with real-world shared mobility applications while retaining theoretical generalizability across contexts.

The model of this study is constructed based on the relationship between autonomous driving and privacy, anthropomorphism and technology acceptance. However, unlike most studies that focus on "private self-driving vehicles" and ordinary human-machine interaction, this study clearly sets the research scenario as "unmanned taxis for business use". This setting not only highlights the differences from previous literature but also ensures that the research conclusions are closer to the context of shared mobility and commercial applications. Therefore, the research model proposed in this study should be understood as its applicability in the scenario of driverless taxis. Meanwhile, since the core variables and relationship mechanisms of this study have cross-scenario applicability, it is only necessary to emphasize the limitations of the research context (autonomous taxi) on the basis of the existing research framework, rather than introducing brand-new variables separately.

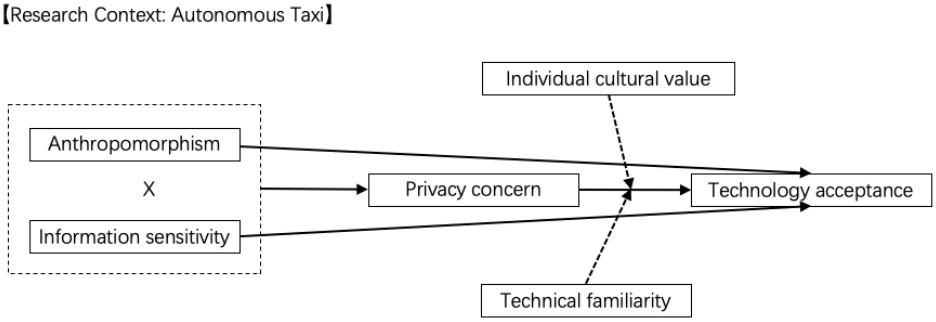

Fig. 1. Research framework.

The proposed research model (Fig. 1) employs a 2×2 experimental design manipulating Anthropomorphism (high vs. low) and Information Sensitivity (high vs. low). These factors jointly influence privacy concern, which mediates their effect on technology acceptance. Two moderators—Individual Cultural Value and Technical Familiarity—are included to test individual differences in this relationship. The model extends the Privacy Calculus Framework by linking design and data characteristics to perceived risk, and reconceptualizes anthropomorphism within privacy-sensitive environments, testing whether human-likeness enhances or hinders trust.

Prior studies indicate that anthropomorphism affects responses to sensitive information [46], while information sensitivity directly influences privacy concern [47, 48]. Accordingly, this study examines how these two factors shape users' privacy perception and acceptance.

H1: Anthropomorphic design positively influences technology acceptance when information sensitivity is low.

H2: High information sensitivity significantly reduces technology acceptance.

In addition, anthropomorphism and information sensitivity are expected to interact. High anthropomorphism under high sensitivity conditions may elicit the highest privacy concern [46, 49], with privacy concern mediating this relationship [50].

H3: Anthropomorphism and information sensitivity interact such that the positive effect of anthropomorphism on technology acceptance weakens under high information sensitivity.

H4: Privacy concern mediates the relationship among anthropomorphism, information sensitivity, and technology acceptance.

Cross-cultural studies suggest that cultural orientation moderates the effect of privacy concern on acceptance [51, 52]. Technical familiarity also moderates users' evaluation of privacy and system reliability [53, 54].

H5: Individual cultural value moderates the relationship between privacy concern and technology acceptance, such that under a high collectivist orientation, the negative effect of privacy concern is weaker.

H6: Technical familiarity moderates the relationship between privacy concern and technology acceptance, such that at high familiarity levels, the negative effect of privacy concern is weaker.

IV. Experiments and Results

Previous research has consistently demonstrated that anthropomorphic design shapes user experience and trust in human–computer interaction (HCI). For example, [55] showed that human-like facial expressions combined with anthropomorphic language elicited more positive user responses than mechanical dialogue, while [56] confirmed that anthropomorphic visual design enhances user perception and engagement. Extending this line of inquiry, [29] found that augmented reality (AR) agents equipped with environmental sensing (e.g., motion tracking) may implicitly signal sensitive data collection, yet users' privacy perceptions remain insufficiently examined. Similarly, [6] demonstrated, respectively, that physically anthropomorphic vehicle features and virtual agents can shape privacy-related responses in AV contexts.

Building on these findings, the present research conducted experiments to empirically test the proposed model. Firstly, examined the main and interaction effects of anthropomorphism and information sensitivity on privacy concern and technology

acceptance, whereas it further explored the moderating roles of individual cultural value and technical familiarity. Both studies adopted a 2 × 2 between-subjects design manipulating anthropomorphism (high vs. low) and information sensitivity (high vs. low).

A. Experiments

Participants were randomly assigned to one of four simulated AV interfaces (Fig. 2). Anthropomorphism manipulation: The high-anthropomorphism condition featured a human-like avatar with expressive facial features and conversational dialogue, while the low condition used a minimalistic, non-human-like interface [57, 58]. Information sensitivity manipulation: High-sensitivity interfaces indicated the collection of biometric and emotional data, whereas low-sensitivity interfaces collected only basic trip information [59, 60]. Data-use prompts clarified scope and storage—for example, "Facial information verified for risk control" versus "Only current location obtained; data stored locally" [61].

Fig. 2. Screenshot of the experimental video.

After exposure to an AV scenario like Fig. 2, participants completed 7-point Likert questionnaires measuring perceived anthropomorphism, information sensitivity, privacy concern, and technology acceptance. In addition, the study also included an Individual Cultural Value Scale adapted from Hofstede's cultural dimensions (e.g., [62]) and a Technical Familiarity Scale, which assessed participants' self-reported familiarity and experience with digital technologies. Data were collected via Wenjuanxing with attention checks for quality.

B. Results

To examine the proposed mediation and moderated mediation relationships, this study employed the PROCESS macro for SPSS [63]. The PROCESS procedure is a regression-based analytical approach that allows for direct estimation of mediation, moderation, and conditional process (moderated mediation) effects using bootstrapping. Unlike structural equation modeling (SEM), which requires a relatively large sample size and focuses on latent constructs and overall model fit, PROCESS is particularly suitable for experimental data with observed variables and clear causal directions. Its main advantage lies in its ability to test indirect and conditional effects efficiently without imposing stringent distributional assumptions. Previous studies have employed the PROCESS macro to examine mediation and moderation effects in the context of privacy concern and technology acceptance. For instance, [64] examined the relationships between attitude, privacy concern, and behavioral intention using PROCESS to estimate mediation and moderation effects. Similarly, [65] applied PROCESS to test the moderating role of personality traits in technology acceptance. In this research, PROCESS Model 4 was used to test the mediation of privacy concern, and Model 14 was applied to examine the moderated mediation effects of individual cultural value and technical familiarity. This analytical strategy ensured a robust and transparent examination of the hypothesized causal mechanisms.

TABLE I. DESCRIPTIVE STATISTICS AND CORRELATION ANALYSIS

Variable	M	SD	PC	TA	ICV	TF
PC	3.284	1.466	—	-.237**	-.001	-.024
TA	4.576	1.640	-.237**	—	.775**	.764**
ICV	4.469	1.743	-.001	.775**	—	.894**
TF	4.670	1.946	-.024	.764**	.894**	—

Note: M and SD are used to represent mean and standard deviation, respectively. Values in parentheses are Pearson correlation coefficients. *p < .05, **p< .01.

Before hypothesis testing, preliminary analysis were conducted to ensure the validity of the manipulations and reliability of the measures. Table I presents the descriptive statistics and Pearson correlation coefficients among the main variables. PC showed a significant negative correlation with TA ($r = –.237$, $p < .01$), indicating that higher PC is associated with lower acceptance of autonomous taxis. ICV and TF were both strongly and positively correlated with TA ($r = .775$, $p < .01$; $r = .764$, $p < .01$, respectively), suggesting that individuals with higher collectivist tendencies and greater technical familiarity tend to show higher levels of acceptance. Moreover, ICV and TF were highly correlated with each other ($r = .894$, $p < .01$), implying potential conceptual overlap or shared variance between these two moderators. No significant correlations were found between Privacy Concern and either ICV or TF.

TABLE II. MANIPULATION TEST RESULTS (INDEPENDENT SAMPLE T-TEST)

Manipulate variable	Condition	M	SD	t	df	p
Anthropomorphism	Low (n=100)	2.415	1.062	-19.713	198	< .001
	High (n=100)	5.435	1.105			
Information Sensitivity	Low (n=100)	2.540	1.259	-15.231	198	< .001
	High (n=100)	5.390	1.385			

Note: M and SD are used to represent mean and standard deviation, respectively.

Table II presents the results of the manipulation checks for anthropomorphism and information sensitivity. An independent-sample t-test confirmed that the manipulation of anthropomorphism was successful. Participants in the high-anthropomorphism condition ($M = 5.435$, $SD = 1.105$) perceived significantly higher levels of anthropomorphism than those in the low-anthropomorphism condition ($M = 2.415$, $SD = 1.062$), $t(198) = –19.713$, $p < .001$.

Similarly, the manipulation of information sensitivity was effective. Participants in the high-sensitivity condition ($M = 5.390$, $SD = 1.385$) perceived significantly higher information sensitivity than those in the low-sensitivity condition ($M = 2.540$, $SD = 1.259$), $t(198) = –15.231$, $p < .001$. These results indicate that both experimental manipulations were successful, validating the subsequent hypothesis testing.

TABLE III. ANALYSIS OF VARIANCE RESULTS OF ANTHROPOMORPHISM AND INFORMATION SENSITIVITY ON TECHNOLOGY ACCEPTANCE

Source	Sum of Squares	df	Mean Square	F	p
Anthro (A)	16.965	1	16.965	7.255	.008
InfoSens (B)	41.633	1	41.633	17.803	< .001
A × B	18.453	1	18.453	7.891	.005
Error	458.349	196	2.339		
Total	4723.813	200			

Note: Anthro = Anthropomorphism, InfoSens = Information Sensitivity.

A two-way ANOVA (Table III) was conducted to examine the effects of anthropomorphism and information sensitivity on technology acceptance. Results indicated that anthropomorphism had a significant main effect [$F(1,196) = 7.255$, $p = .008$], and information sensitivity also had a significant main effect [$F(1,196) = 17.803$, $p < .001$]. Moreover, the interaction effect between anthropomorphism and information sensitivity was significant [$F(1,196) = 7.891$, $p = .005$].

As illustrated in Fig. 3, when information sensitivity was low (blue line), the level of technology acceptance remained relatively high regardless of anthropomorphism. However, under high information sensitivity (red line), technology acceptance decreased sharply as anthropomorphism increased. This suggests that the positive influence of anthropomorphic design is dampened under conditions of high information sensitivity, supporting the hypothesized interaction effect.

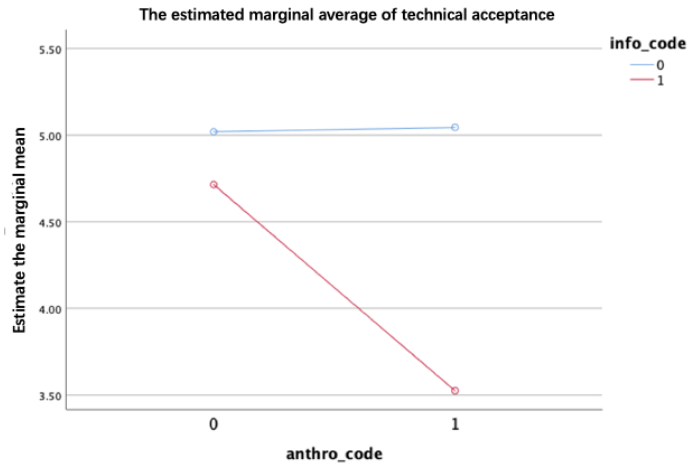

Fig. 3. The interaction graph of anthropomorphism and information sensitivity on technology acceptance.

TABLE IV. SIMPLE MEDIATION ANALYSIS (PROCESS MODEL 4)

Path	Coefficient	SE	t	p	95%CI
Interaction → PC	2.8617	0.1273	22.4757	< .0001	[2.6106, 3.1127]
PC → TA	0.3066	0.1378	2.2244	.0273	[0.0348, 0.5784]
Direct Effect					
Interaction → TA	-2.2790	0.4653	-4.8977	< .0001	[-3.1966, -1.3613]
Indirect Effect					
Interaction → PC → TA	0.8773	0.3709	-	-	[0.1053, 1.5707]

Note: N = [200]. Bootstrapping sample size = 5000. CI = confidence interval. Interaction = Anthropomorphism × Information Sensitivity interaction.

To further examine whether privacy concern mediates the effect of the interaction between anthropomorphism and information sensitivity on technology acceptance, a simple mediation analysis was conducted using PROCESS Model 4 [63]. As shown in Table IV, the interaction between anthropomorphism and information sensitivity had a significant positive effect on privacy concern ($\beta = 2.8617$, $t = 22.4757$, $p < .001$, 95% CI [2.6106, 3.1127]). In turn, privacy concern had a significant negative effect on technology acceptance ($\beta = 0.3066$, $t = 2.2244$, $p = .0273$, 95% CI [0.0348, 0.5784]). The direct effect of the interaction on technology acceptance remained significant ($\beta = -2.2790$, $t = -4.8977$, $p < .001$, 95% CI [–3.1966, –1.3613]), indicating a partial mediation effect. Moreover, the bootstrapped indirect effect through privacy concern was significant ($\beta = 0.8773$, 95% CI [0.1053, 1.5707]), as the confidence interval did not include zero. This finding suggests that the interaction between anthropomorphism and information sensitivity influences technology acceptance partly via increased privacy concern, supporting H4.

TABLE V. MODERATED MEDIATION ANALYSIS (PROCESS MODEL 14)

Moderator	Effect	Coeff.	SE	t	p	95%CI
ICV	Interaction → PC	2.8617	0.1273	22.48	< .001	[2.6106, 3.1127]
	PC → TA	0.3425	0.1419	2.41	.0167	[0.0627, 0.6224]
	ICV → TA	0.9729	0.0893	10.89	< .001	[0.7967, 1.1491]
	PC × ICV	-0.0857	0.0251	-3.42	.0008	[-0.1351, -0.0363]
	Direct Effect					
	Interaction → TA	-0.9985	0.2965	-3.37	.0009	[-1.5832, -0.4137]
		Effect	BootSE			BootCI
	Index of Moderated Mediation	-0.2452	0.0747			[-0.3948, -0.1053]
TF	Interaction → PC	2.8617	0.1273	22.48	< .001	[2.6106, 3.1127]
	PC → TA	0.4426	0.1403	3.16	.0019	[0.1660, 0.7192]
	TF → TA	0.8865	0.0836	10.61	< .001	[0.7217, 1.0514]
	PC × TF	-0.0852	0.0234	-3.64	.0003	[-0.1313, -0.0391]
	Direct Effect					
	Interaction → TA	-1.2785	0.2986	-4.28	< .001	[-1.8674, -0.6897]
		Effect	BootSE			BootCI
	Index of Moderated Mediation	-0.2437	0.0744			[-0.3979, -0.1032]

Note: N = [200]. Bootstrapping sample size = 5000.

To further test whether ICV and TF moderate the indirect effect of the interaction between anthropomorphism and information sensitivity on technology acceptance through privacy concern, two moderated mediation analyses were conducted using PROCESS Model 14 [63].

As shown in Table V, for ICV, the interaction between anthropomorphism and information sensitivity significantly predicted privacy concern ($\beta = 2.8617$, $t = 22.48$, $p < .001$, 95% CI [2.6106, 3.1127]). Privacy concern had a significant negative effect on technology acceptance ($\beta = 0.3425$, $t = 2.41$, $p = .0167$, 95% CI [0.0627, 0.6224]), and the interaction between privacy concern and ICV was also significant ($\beta = -0.0857$, $t = -3.42$, $p = .0008$, 95% CI [–0.1351, –0.0363]). The index of moderated mediation was significant ($\beta = -0.2452$, BootSE = 0.0747, 95% CI [–0.3948, –0.1053]), indicating that the indirect effect of the interaction on technology acceptance through privacy concern was contingent on individual cultural value. Specifically, the negative impact of privacy concern on technology acceptance was weaker among individuals with higher collectivist cultural values, supporting H5.

Similarly, for TF, the interaction term significantly predicted privacy concern ($\beta = 2.8617$, $t = 22.48$, $p < .001$), and the effect of privacy concern on technology acceptance was significant ($\beta = 0.4426$, $t = 3.16$, $p = .0019$, 95% CI [0.1660, 0.7192]). The interaction between privacy concern and TF was significant ($\beta = -0.0852$, $t = -3.64$, $p = .0003$, 95% CI [–0.1313, –0.0391]), and the index of moderated mediation was also significant ($\beta = -0.2437$, BootSE = 0.0744, 95% CI [–0.3979, –0.1032]). This pattern indicates that the negative influence of privacy concern on technology acceptance diminishes as users' technical familiarity increases, supporting H6.

C. Discussion

This study examined how anthropomorphic interface design and information sensitivity jointly shape users' acceptance of AVs, emphasizing the mediating role of privacy concern and the moderating effects of individual cultural value and technical familiarity. Drawing upon the Privacy Calculus Framework and the TAM, the findings reveal that user acceptance of AVs results from a dynamic balance between emotional engagement and perceived data risk.

Consistent with expectations, both anthropomorphism and information sensitivity significantly influenced technology acceptance. High anthropomorphism enhanced acceptance only when information sensitivity was low, whereas under high information sensitivity, anthropomorphic designs reduced acceptance by intensifying privacy concerns. This interaction indicates that anthropomorphism does not universally promote positive user attitudes but instead functions as a context-dependent cue that can either facilitate or hinder acceptance depending on the perceived privacy risk. The results highlight a privacy–affect trade-off: while human-like design enhances social connection and trust, it simultaneously heightens users' sense of vulnerability when sensitive data is involved.

The mediation analysis further supports that privacy concern partially explains the relationship between design cues and acceptance, confirming its central role in the privacy calculus process. Users weigh the benefits of engaging in human-like interaction against the risks of personal data exposure. This partial mediation also suggests that other factors, such as trust and perceived control, may concurrently influence acceptance decisions. Together, these results extend the TAM by positioning privacy concern as a critical antecedent in data-intensive technologies, aligning with the growing recognition that emotional design and risk perception jointly determine user behavior in autonomous systems.

Moreover, the moderated mediation analyses indicate that both individual cultural value and technical familiarity significantly weaken the negative impact of privacy concern on acceptance. Users with stronger collectivist orientations or higher technical familiarity were less deterred by privacy concerns, suggesting that cultural and experiential differences shape how individuals interpret and manage perceived risks. Notably, although these moderators were not directly correlated with privacy concern, they effectively altered the strength of its influence on behavioral intention, reinforcing the idea that user characteristics operate as boundary conditions rather than independent predictors. This finding advances current understanding of cross-cultural and experiential effects in human–technology interaction by demonstrating that acceptance dynamics are not uniform across user groups.

Theoretically, these findings contribute to the refinement of both the Privacy Calculus Framework and TAM by integrating emotional, cognitive, and cultural dimensions into a unified model of technology acceptance. The results reveal that anthropomorphism's benefits depend on contextual and personal factors, and that privacy concern serves as a psychological bridge connecting interface design and user adoption. Practically, the study suggests that designers and policymakers should exercise caution in applying anthropomorphic features in high-sensitivity contexts, as such designs may inadvertently increase users' privacy anxiety. Privacy-sensitive interface strategies—such as adaptive disclosure, transparent data communication, and culturally attuned messaging—can help balance emotional engagement and perceived security. Moreover, enhancing users' technical literacy and offering customization options for privacy settings may mitigate negative perceptions without compromising usability.

In summary, this study underscores that acceptance of autonomous vehicles is governed by a dynamic tension between human-like engagement and data privacy concerns. Anthropomorphism enhances acceptance only under low perceived risk, while privacy concern mediates and individual differences moderate this relationship. These findings enrich theoretical perspectives on human–AI interaction and provide actionable guidance for developing human-centered, context-aware, and privacy-responsible autonomous vehicle systems.

V. Conclusion and Implications

A. Conclusion

This research investigated how anthropomorphic design, information sensitivity, and individual differences influence privacy concern and technology acceptance in AVs. The findings reveal that when anthropomorphic features are combined with highly sensitive information, users experience greater privacy concern, which subsequently lowers technology acceptance. Conversely, under low information sensitivity, anthropomorphic elements enhance trust without significantly increasing privacy concern. Moreover, individual characteristics—particularly individual cultural values and technical familiarity—moderate these relationships. Users with stronger individualistic orientations or lower levels of technical familiarity exhibit heightened privacy concern in response to anthropomorphic cues. These results highlight the importance of context-aware design and the need to tailor AV interfaces to user characteristics.

Theoretically, this study extends privacy research into the autonomous mobility domain and identifies a dynamic balance mechanism in interface design. It underscores the dual role of anthropomorphism—serving as both a trust-enhancing and a privacy-threatening factor. Practically, the findings emphasize the necessity for adaptive AV interfaces, transparent data communication, and culturally and technically sensitive design strategies that foster acceptance while safeguarding user privacy.

B. Limitations and Future Research

Despite its contributions, this study has several limitations. First, the experimental stimuli, though carefully controlled, may not fully capture the complexity of real-world autonomous vehicle interactions. Participants' reactions in a laboratory setting may differ from those in immersive, on-road contexts. Future research could employ field experiments or longitudinal designs to enhance ecological validity. Second, the sample composition may constrain the generalizability of the findings. Extending the study to participants from diverse cultural backgrounds, age groups, and levels of digital literacy would strengthen external validity and allow cross-cultural comparisons. Third, this study captured users' responses at a single point in time, without accounting for how privacy concerns, trust, and acceptance evolve through repeated use. Longitudinal approaches could reveal how familiarity or habituation influences these dynamics over time. Finally, while this research focused on key predictors—anthropomorphism, information sensitivity, individual cultural value, and technical familiarity—other psychological constructs such as perceived control, algorithm transparency, and social influence may also

shape users' acceptance of AVs. Future studies could integrate these factors to develop a more comprehensive framework for understanding how interface design and data characteristics jointly influence privacy perceptions and technology adoption.

Intelligent Systems, Machine Learning, and Deep Learning Algorithms for Detecting Banking Fraud: A Review

Jessica Vazallo-Bautista, Allison Villalobos-Peña, Juan Soria-Quijaite
Escuela de Ingeniería de Sistemas, Universidad Tecnológica del Perú, Lima, Perú

***Abstract*—The increase in unauthorized remote banking fraud has intensified with the expansion of digital channels, creating new risks and highlighting the inadequacy of traditional methods based on fixed rules and manual audits. This review aims to synthesize recent scientific evidence on the use of machine learning and deep learning techniques for the early detection of fraudulent banking transactions, considering supervised and unsupervised models and deep architectures that allow the analysis of complex patterns present in financial transactions. A total of 357 original articles were identified in the Scopus and Web of Science databases, in addition to manual research, published up to 2025. Of these, 35 studies met the inclusion criteria established using the PICOT approach and the PRISMA protocol. The most widely implemented models in the selected studies were Random Forest, XGBoost, SVM, LSTM networks, and graph-based approaches. The combination of different algorithms improves fraud detection by integrating temporal, relational, and behavioral patterns. Advanced models show better metrics in accuracy, recall, and F1-score compared to traditional methods, expanding the possibilities for continuous monitoring and reducing false positives. There are consistent associations between the application of advanced models, the availability of quality data, and the ability to adapt to different transactional scenarios, which favor timely fraud detection if challenges such as class imbalance, the need for real-time decisions, and the heterogeneity of financial contexts are addressed. The integration of multiple approaches and the optimization of preprocessing and evaluation processes allow us to move toward more robust, scalable anti-fraud systems that are better suited to the current demands of the digital environment.**

***Keywords*—Deep learning; algorithms; machine learning; fraud detection; real-time methods**

I. Introduction

Today, unauthorized remote banking fraud is one of the main threats to the stability of the financial system, as fraudsters use digital channels such as online banking, mobile banking, and telephone banking to illegally access customer accounts and make unauthorized transfers. This situation is exacerbated by the increasing digitization of financial services and the rise in the volume of online transactions, which exposes banking institutions to increasingly complex vulnerabilities [1].

Faced with this problem, IT security in the banking sector has become extremely important. The use of machine learning (ML) and deep learning (DL) techniques has made it possible to overcome many of the limitations of traditional rule-based systems, which tend to be rigid and ineffective against rapidly evolving attacks [2]. Furthermore, these methodologies have been shown to be useful not only in the financial sector, but also in other areas where they have been successfully applied in systematic reviews to solve large-scale problems [3]. Several recent studies have analyzed advances in the use of ML and DL applied to financial fraud. Husnaningtyas and Dewayanto [4] , evaluated the performance of unsupervised learning algorithms in detecting fraud within financial transactions, highlighting their effectiveness in identifying hidden patterns and irregular behavior in large volumes of data. Similarly, Yanto, Lisah, and Tandra [5], examined different supervised learning models, concluding that approaches such as Random Forest, XGBoost, and short-term and long-term memory (LSTM) are the most accurate and widely used in fraud detection, although with a limitation in terms of their real-time response capacity. Despite their advances, these methods still face obstacles in practice. Although they have been proven to process large volumes of data and uncover hidden patterns, many models cannot detect operations in real time and have difficulty adapting to class imbalance. This highlights the need to create anti-fraud models that are adaptive, scalable, and capable of working online efficiently [6]. Traditional solutions, such as static rules or manual audits, have proven to be completely inadequate. Not only do they generate a large number of false positives, but they also lack flexibility and fail to adapt quickly to changes in fraudsters' tactics [7].

In contrast, ML and DL algorithms have transformed the way banking fraud is addressed. Supervised models can differentiate between legitimate and fraudulent transactions, while unsupervised models identify anomalies that had not been previously classified [8].

Deep architectures, such as recurrent neural networks (RNN), LSTM, and convolutional neural networks (CNN), have also made a difference. These networks capture temporal and multivariate patterns, improving the accuracy and scalability of systems. In addition, they enable the development of hybrid models capable of processing transactions more quickly and in real time [9]. Empirical results reinforce these contributions. Semi-supervised graph models have been applied to detect suspicious connections with incomplete data [10]. Furthermore, comparisons between classical algorithms and deep models have shown that the latter are better at capturing the temporal dynamics of fraud [11].

Likewise, it has been proven that classifier assembly techniques help improve robustness in contexts with highly unbalanced data [12]. In addition, graph-based models with

attention networks have made it possible to uncover hidden relationships between customers, businesses, and organized fraud [13]. Working with real data has also been key. Zioviris, Kolomvatsos, and Stamoulis [14] , at a Moroccan bank showed that applying oversampling to unbalanced data and combining it with supervised classifiers achieved more effective results in fraud detection. However, there are still gaps. Many studies focus on specific techniques or datasets, which limits their applicability. In addition, there is often little attention paid to metrics that are more useful in practice, such as recall, F1-score, AUC, and latency, which are crucial for measuring effectiveness in real time.

For these reasons, the objective of this systematic review is to identify, analyze, and classify intelligent systems and machine learning and deep learning algorithms applied to the early detection of banking fraud in real time. It also seeks to synthesize performance metrics, trends, and challenges in order to provide a frame of reference to guide both future research and practical implementation in the financial industry.

II. Methodology

In the systematic review, the PICOT method was used to search for scientific articles, as it allows questions to be formulated based on the problem addressed through its components: Problem (P), Intervention (I), Comparison (C), Outcomes (O), and Time (T). Its application allows for the clear establishment of inclusion and exclusion criteria, ensuring relevance and rigor in the selection of the articles analyzed.

A. PICOT Formulation

During the first phase of the methodological process, the PICOT components were identified, as summarized in Table I, and a complementary Context variable was also incorporated for a more precise search.

TABLE I. Identification of Picot Components

P	Financial transactions susceptible to bank fraud.
I	Application of intelligent systems and Machine Learning and Deep Learning algorithms.
C	Conventional methods of fraud detection.
O	Performance and efficiency in detecting bank fraud using algorithms.
T	Speed and timeliness of detection.

B. Question Formulation

Once the PICOT components had been identified, the general research question (RQ) for this systematic review was formulated:

"What Machine Learning (ML) and Deep Learning (DL) models have been developed for the early detection of banking fraud in real-time, and how have they performed in terms of accuracy, efficiency, and resource optimization compared to traditional methods?"

Subsequently, specific questions linked to each PICOT component were designed to guide the literature search and ensure the relevance of the selected studies. These questions are summarized in Table II.

TABLE II. Questions Linked to PICOT Components

RQ1	What are the main types of bank fraud (suspicious transactions, digital payments, card fraud) addressed in recent studies?
RQ2	What machine learning and deep learning models have been developed for the early detection of banking fraud in real time?
RQ3	What are the differences in performance between intelligent ML/DL models and traditional methods (static rules, manual monitoring, conventional audits)?
RQ4	What metrics of precision, accuracy, efficiency, early detection, and reliability have been reported by the applied models?
RQ5	Which models enable immediate fraud detection, either online or through continuous real-time monitoring?

C. Identification of Keywords

The keywords for each PICOT component were identified and are presented in Table III. Thesauri were used for this purpose, along with the Boolean operators "OR" and double quotation marks ("") to facilitate the search for exact terms in the Scopus and WOS databases.

TABLE III. Keywords

P	"Banking transactions" OR "Bank fraud" OR "Digital payment fraud" OR "Credit card fraud"
I	"Machine learning" OR "Deep learning" OR "Artificial intelligence" OR "Supervised learning" OR "Support vector machine (SVM)"
C	"Traditional methods" OR "Manual monitoring" OR "Classic statistical methods" OR "Conventional auditing"
O	"Precision" OR "Accuracy" OR "Efficiency" OR "Early detection" OR "Reliability" OR "Resource optimization"
T	"Real time" OR "Immediate" OR "Online detection" OR "Continuous monitoring" OR "Instant evaluation"

D. Syntax of the PICOT Formula

The PICOT method was completed by combining all the previously identified keywords using the Boolean operator "AND" to perform the correct search in the Scopus and Web of Science databases, finding the search equations shown in Table IV.

TABLE IV. Search Equation

	Scopus	Web of Science
Busqueda equidad	TITLE-ABS-KEY("Transacciones bancarias" O "Fraude bancario" O "Fraude en pagos digitales" O "Fraude con tarjetas de crédito") AND TITLE-ABS-KEY("Machine learning" OR "Deep learning" OR "Artificial intelligence" OR "Supervised learning" OR "Support vector machine (SVM)") AND TÍTULO-ABS-CLAVE("Métodos tradicionales" O "Monitoreo manual" O "Métodos estadísticos clásicos" O "Auditoría convencional") AND TÍTULO-ABS-CLAVE("Precisión" O "Exactitud" O "Eficiencia" O "Detección temprana" O "Fiabilidad" O "Optimización de recursos") AND TÍTULO-ABS-CLAVE("Tiempo real" O "Inmediato" O "Detección en línea" O "Monitoreo continuo" O	(((((((TS = banking transactions) OR (TS = bank fraud)) OR (TS = digital payment fraud)) OR (TS = credit card fraud)) AND (((((TS = machine learning) OR (TS = deep learning)) OR (TS = artificial intelligence)) OR (TS = supervised learning)) OR ((TS = support vector machine) AND (TS = svm)))) AND ((((TS = traditional methods) OR (TS = manual monitoring)) OR (TS = classic statistical methods)) OR (TS = conventional auditing))) AND ((((((TS = precision) OR (TS = accuracy)) OR (TS = efficiency)) OR (TS = early detection)) OR (TS = reliability)) OR ((SO_SMART = optimization) AND (TS = resource)))) AND (((((TS = real

	"Evaluación instantánea") Y (LÍMITE A (SUBJAREA,"COMP")) Y (LÍMITE A (DOCTYPE,"ar")) Y (LÍMITE A (OA,"all")) Y (LÍMITE A (IDIOMA,"Español")) Y AÑO PUBLICITARIO > 2020 Y AÑO PUBLICITARIO < 2025	time) OR (TS = immediate)) OR (TS = online detection)) OR (TS = continuous monitoring)) OR (TS = instant evaluation)))

Once the PICOT method was completed and the search strategies were executed in the database, a total of 357 articles were obtained: 290 from Scopus and 67 from the Web of Science (WOS) database.

E. Specifications of Inclusion and Exclusion Criteria

In order to ensure the validity, relevance, and quality of the selected studies, inclusion and exclusion criteria were defined. These criteria allowed the review to focus on research directly related to the application of Machine Learning (ML) and Deep Learning (DL) models in the detection of bank fraud, thus ensuring consistency in the results. In terms of inclusion criteria, studies published between 2021 and 2025 in indexed scientific journals and specialized conference proceedings were selected, whose subject matter was related to the use of Machine Learning (ML) and Deep Learning (DL) techniques applied to bank fraud, including both financial transactions and fraud associated with digital payments and credit card use. It was also considered essential that the research presented performance evaluation metrics, such as precision, accuracy, sensitivity, specificity, recall, F1-score, or area under the curve (AUC), and that it incorporated approaches aimed at real-time detection, either online or through continuous monitoring schemes. Finally, only articles published in English or Spanish that offered full access to the text were included. With regard to exclusion criteria, duplicate studies or those corresponding to preliminary versions already published in other sources were discarded, as were studies published prior to 2021. Research that did not directly address the issue of bank fraud, studies that lacked quantitative performance metrics, and documents that were not fully accessible were also excluded. The application of these parameters ensured the methodological consistency of the review, refined the database of articles collected, and ensured the quality and relevance of the evidence analyzed.

F. PRISMA Statement

The PRISMA statement enabled the selection and analysis of articles, as well as the establishment of a process for extracting the articles to be examined in the literature review, ensuring consistency between the objectives and the criteria established. This approach guarantees transparency and comprehensiveness in the identification, selection, and synthesis of the included studies, which strengthens the validity of the methodology [15].

Likewise, Moher et al. [16] emphasizes that the correct application of the 27 items in the PRISMA statement allows for the standardization of the processes of searching, analyzing, and evaluating articles, promoting comparability between studies. This standardization is essential to ensure the consistency and quality of systematic reviews, as it promotes transparency in the presentation of results.

G. PRISMA Processes

The development was carried out in five stages. First, 357 articles were identified (290 from Scopus and 67 from WOS) and 40 duplicates were removed using Mendeley. Subsequently, 272 studies were excluded after analyzing unrelated titles and abstracts. Ten additional records were discarded because they did not meet the PICOT criteria. Finally, 35 articles relevant to the review were selected. Fig. 1 shows the comprehensive article selection process, using the PRISMA diagram, where 35 articles were selected.

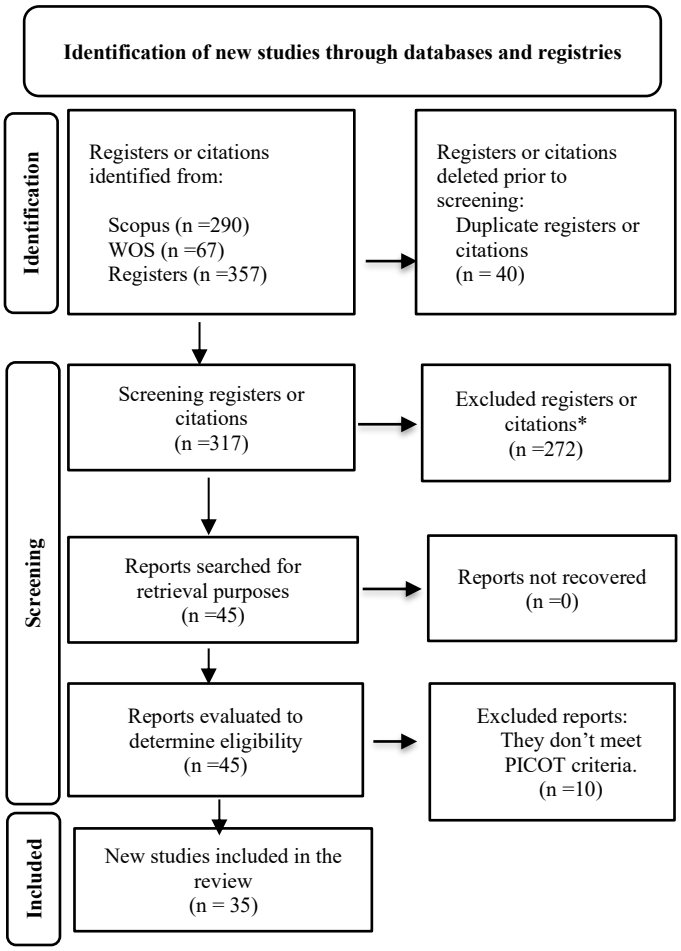

Fig. 1. Diagram of the PRISMA process.

H. Bibliometrix by R Studio

Bibliometric analysis has established itself as an essential tool for studying the evolution of knowledge about bank fraud. Using Bibliometrix in R, databases such as Scopus can be analyzed to identify trends, authors, and emerging topics in financial fraud detection. Shukla and Kashni demonstrated that scientific output on bank fraud has grown over the last decade, highlighting the use of machine learning models [17]. Recent studies show an increase in the use of artificial intelligence and machine learning to detect financial anomalies. Bibliometrix allows these advances to be visualized through co-occurrence and collaboration maps, showing an annual growth of 13.34% in research on AI applied to finance and highlighting gaps in transparency, ethics, and algorithmic biases in automated systems [18], [19].

According to Gangwar, the study of financial crimes, such as money laundering, has grown significantly over the last decade, driven by digitization and the increase in illicit flows. This approach provides an understanding of how technological tools, including artificial intelligence and predictive detection models, are integrated into fraud prevention processes [20].

III. RESULTS

In the results section, tables and graphs were created to visually represent the different categories of characteristics of the elements analyzed. Excel spreadsheets were used for the graphs. In addition, the results address the PICOT questions formulated during the writing of the research.

A. Developed Models

The results of the reviewed articles are shown in Table V, which indicates the reference, types of fraud, and Machine Learning (ML) and Deep Learning (DL) models applied.

B. Real-Time Detection Metrics and Techniques

The results of the reviewed articles are shown in Table VI, which indicates the reference, the metrics for each study result, and the models used for real-time detection.

TABLE V. RESULTS OF THE REVIEWED ARTICLES

Reference	Types of Fraud	ML and DL models
Adejoh, J. et al. (2024)[21]	CNP, skimming, unauthorized digital payments, account takeover, fake accounts, and money laundering using mule accounts.	Random Forest, XGBoost, Isolation Forest, Autoencoders, LSTM/GRU, CNN y Graph Neural Networks (GNN).
Ibrahim, Y. et al. (2025)[22]	Suspicious transactions, card fraud, and anomalous digital payments.	LSTM, CNN, AE, and hybrid ML/DL models enable online detection.
Hargreaves, C. A. (2025)[23]	Card, digital payments, account takeover/money laundering	ML: Logistic, RF, XGBoost/LightGBM/CatBoost. DL: LSTM/GRU, AE, 1D-CNN, GNN; hybrids: rules+ML.
Demirhan, H. (2024)[24]	Credit card fraud: fraudulent or legitimate transactions.	RF, XGBoost, SVM, DNN, LSTM, GNN, and fuzzy logistic regression.
Abd-Ellatif, L. et al. (2025)[25]	Suspicious transactions, digital payments, cards, and financial anomalies.	ML: RF, XGBoost, CatBoost; DL: CNN, RNN, LSTM, GNN
Theodorakopoulos, L. et al. (2025)[26]	credit cards, online payments, and suspicious transactions.	LR, DT, RF, XGBoost, CatBoost; PySpark for scalability and adaptive learning
El-Kenawy, E.-S. M. et al. (2024)[27]	Credit card fraud in electronic transactions.	DL: RNN, LSTM, and GRU applied to balanced Kaggle datasets
Rawashdeh, E. (2024)[28]	Card fraud: duplicates, unauthorized use, and anomalous online purchases.	HybridIG-CSO hybrid model with evolutionary selection and RWN.
Alarfaj, F. K. & Shahzadi, S. (2025)[29]	Fraud: credit cards, digital payments, and suspicious transactions.	Models: LSTM, CNN, AE, XGBoost, CatBoost, and ensembles.
Wang, H. (2024)[30]	Fraud: cards, digital payments, transfers, phishing, and identity theft.	ML: XGBoost, RF, LightGBM; DL: RNN/LSTM/GRU, CNN, AE, Transformers; Hybrids: GNN, CNN-LSTM, ensembles.
Saha, S. C. (2024)[31]	Fraud: cards, unusual transactions, digital payments, and account theft.	Online/lightweight models: Hoeffding Tree, Online RF, IF, incremental OCSVM, compact AEs, LSTM in short windows.
Baisholan, N. et al. (2025)[32]	Fraud: suspicious transactions, digital payments, and cards.	Models: RF, XGBoost, LSTM, CNN, AE, and ML+DL hybrids for real-time early detection.
Brown, J. (2022)[33]	Card fraud, digital payments, and identity theft.	ML/DL: RF, XGBoost, AE, LSTM, CNN, GNN, and streaming models (ARF, Hoeffding Tree).
Al-Maari, A. A. et al. (2025)[34]	Fraud: cards, digital payments, suspicious transactions, and account theft.	Hoeffding Tree, Isolation Forest, real-time LSTM.
Kcennedy, R. K. L. et al. (2024)[35]	Cloning and CNP fraud, transactions in apps/digital wallets, account hijacking, and money laundering.	ML: Logistic, RF, XGBoost/LightGBM/CatBoost; DL: RNN/LSTM/GRU, AE, 1D-CNN; Relational: GNN; Hybrids: rules + ML/DL.
Ibomoiye, D. M., et al. (2024)[36]	Credit card fraud (cloning, unauthorized transactions)	GAN + RNN/LSTM/GRU: GAN creates synthetic fraud, RNN/LSTM/GRU classifies.
Tayebi, M. et al. (2025)[37]	Fraud: cards, digital payments, and account takeover.	ML: Logistic, DT, RF, XGBoost/LightGBM/CatBoost; DL: RNN/LSTM/GRU, AE, 1D-CNN; Relational: GNN; Hybrids: rules + ML/DL.
Cascavilla, G. (2025)[38]	Suspicious transactions (payments, chargebacks, CNP) and atypical behavior, including anomalous digital payments.	Autoencoders, Isolation Forest, One-Class SVM
AbouGrad, H. (2025)[39]	Digital payment fraud and suspicious online banking transactions, with a focus on distributed data.	Decentralized Deep AutoEncoder
Liu, J. (2025)[40]	Main type: card fraud	DNN, CNN, RNN, GRU, LSTM, CCNN.
Ullah, H. (2022)[41]	Credit card fraud, including physical unauthorized use and online transactions (CNP).	Random Forest (RF), XGBoost Classifier, Convolutional Neural Network
Yu, J. (2024)[42]	Card fraud (CNP and unauthorized), suspicious transactions, and digital payments; focused on detecting anomalies in payment flows.	AutoEncoder, LightGBM, SMOTE
Sun, Y. (2023)[43]	It focuses on card fraud (CNP and unauthorized), suspicious transactions, and fraudulent digital payments.	Modelos ML: Random Forest, AdaBoost, XGBoost, LightGBM, CatBoost; DL: MLP, LSTM, GRU.
Al Balawi, S. (2023)[44]	It focuses on card fraud (in-person and CNP) and suspicious transactions.	ANN and CNN, with and without pooling layer.

Alsagri, H. S. (2025)[45]	It focuses on card fraud and fraudulent electronic transactions, concentrating on detecting anomalies in the CCF dataset.	ML: LR, SVM, RF, XGBoost, KNN; DL: DNN.
Akour, I. (2025)[46]	The main focus was on card fraud, especially unauthorized online transactions; the model analyzes sequences to distinguish normal behavior from anomalous patterns.	ML: LR, SVM, RF, ANN; DL: CNN, LSTM, CNN–LSTM, CNN–LSTM with Attention.
Benchaji, I. (2021)[47]	Card fraud, especially in digital transactions, was the most studied; the model identifies anomalies in sequential customer patterns.	The LSTM model outperforms other ML models by capturing temporal dependencies, improving early detection of irregular operations.
Owoh, N. (2024)[48]	Card fraud, especially in digital purchases, with anomalous patterns best detected by intelligent models.	RF, SVM, KNN, Bagging, Boosting, and an Ensemble model were applied.
Strelcenia, E. (2023)[49]	The main type of fraud analyzed is unauthorized use of credit cards in electronic transactions.	XGBoost, RF, KNN, MLP, and Logistic Regression were applied to balanced datasets using SMOTE, ADASYN, and GAN variants (CGAN, WSGAN, NSGAN, LSGAN, SDG-GAN, K-CGAN).
Ren, J. (2024)[50]	Types of fraud: credit/debit cards, digital payments and online banking, suspicious transactions, internal fraud.	DT, RF, GBDT, XGBoost, LightGBM, Stacking Ensemble.
Fedushko, S. (2023)[51]	It focuses on credit card fraud in online transactions.	ML models were developed and compared: LR, RF, DT, SVM, Naïve Bayes, KNN, and SGD Classifier.
Plakandaras, V. (2022)[52]	Primary fraud: credit card transactions in online environments.	Ridge LR (best performance), SVM, RF, DT
Alatawi, M. N. (2025)[53]	Credit card fraud, in person and online, detecting anomalous patterns using IoT features.	Random Forest and Gradient Boosting Machine
Muduli, D. (2025)[54]	Focuses on card fraud and suspicious transactions in Credit-Card and PaySim datasets.	SVM, KNN, ELM, PSO-ELM, and Stacking Ensemble (SVM + KNN + PSO-ELM with Gradient Boosting).
Feng X et al (2024)[55]	Focus: Card fraud and suspicious transactions in transactional datasets (European cardholders).	RF+AB, GBDT, SVM, KNN, CNN; CDL is proposed to reduce features and train traditional/ensemble models, optimizing accuracy and time.

TABLE VI. RESULTS OF REAL-TIME DETECTION METRICS AND TECHNIQUES

Reference	Metrics	Real-time models
Adejoh, J. et al. (2024)[21]	Accuracy (94–99%), Recall, Precision, F1-score, and AUC-ROC are the most commonly used metrics for validating performance.	Models such as Hoeffding Tree, Adaptive Random Forest, and Autoencoders enable real-time detection and monitoring.
Ibrahim, Y. et al. (2025)[22]	Accuracy (94–99%), Recall, Precision, F1-score, and AUC-ROC are the most commonly used metrics for validating performance.	LSTM, CNN, and Autoencoders enable real-time detection and monitoring.
Hargreaves, C. A. (2025)[23]	Accuracy, Precision, Recall, F1, ROC-AUC, AUPRC, MCC, FP rate, inference time (ms), throughput (tx/s).	XGBoost, LightGBM, Logistic, Random Forest, and Hoeffding Trees enable immediate detection.
Demirhan, H. (2024)[24]	Accuracy 99%, Sensitivity and Specificity 0.90+, MCC 0.80+.	Real-time implementable online fuzzy framework.
Abd-Ellatif, L. et al. (2025)[25]	Accuracy (94–99%), Precision (>95%), Recall (90–97%), F1-Score (~0.95), AUC-ROC (>0.98), lower false positive rate (-40%), latency <100 ms per transaction, near real-time detection.	ATAD-Net, FraudX AI, and GNN+Autoencoder combine hybrid approaches with human and automatic verification.
Theodorakopoulos, L. et al. (2025)[26]	Accuracy 95–99%, Precision >95%, Recall 90–98%, F1 ~0.96, ROC-AUC >0.98, reduction of false positives, low latency (<100 ms), efficiency in distributed processing.	XGBoost and CatBoost with PySpark enable real-time detection and monitoring.
El-Kenawy, E.-S. M. et al. (2024)[27]	Accuracy 99.39%, F1-score 0.9939, high Recall and AUC > 0.99.	RNN and LSTM enable real-time detection with low computational cost.
Rawashdeh, E. (2024)[28]	Evaluates with G-Mean, Recall, and AUC, demonstrating high accuracy and low false positive rate.	Automatic detection in near real time thanks to the optimization of weights and neurons in the model.
Alarfaj, F. K. & Shahzadi, S. (2025)[29]	Accuracy 94–99%, Precision >95%, Recall 90–97%, F1 ~0.95, AUC-ROC >0.98, -40% false positives.	LSTM, CNN, Autoencoders, graphs, federated for continuous real-time monitoring.
Wang, H. (2024)[30]	Accuracy, Precision, Recall, F1, AUC/AUPRC, latency (s), throughput (TPS), MCC.	Online models: Hoeffding Trees, incremental RF/XGBoost, optimized RNN/LSTM, streaming and federated GNN.
Saha, S. C. (2024)[31]	Accuracy: 94–99%, Precision: 90–>95%, Recall: 90–98%, F1-Score: 0.9–0.96, AUC-ROC: 0.68–>0.98, MCC, FPR, latency <100 ms, false positive reduction ~40%	LSTM, CNN, Autoencoders, hybrid models (ML+DL), Graph Neural Networks, Ensemble ML (Random Forest + Logistic Regression + AdaBoost), FinGraphFL.
Baisholan, N. et al. (2025)[32]	Accuracy (94–99%), Precision (>95%), Recall (90–97%), F1-Score (~0.95), AUC-ROC (>0.98), lower false positive rate (-40%), latency <100 ms, near real-time detection.	LSTM, CNN, Autoencoders, hybrid ML+DL models, and federated approaches such as FinGraphFL, which enable adaptive learning and online processing.
Brown, J. (2022)[33]	Metrics such as Accuracy (90–99%), Precision, Recall, F1-score, and AUC-ROC are reported, in addition to a low false positive rate and high early detection.	Online models such as Adaptive Random Forest, Online SVM, Streaming Autoencoders, and Graph Neural Networks enable immediate detection and continuous monitoring in real time.
Al-Maari, A. A. et al. (2025)[34]	Accuracy 95–99%, Precision >95%, Recall 90–98%, F1 ~0.96, AUC >0.98, with ~40% fewer false positives, demonstrating high efficiency and reliability.	LSTM, CNN, and hybrid models facilitate online detection and continuous monitoring with adaptive learning.

Kcennedy, R. K. L. et al. (2024)[35]	Accuracy, Precision, Recall, F1, ROC-AUC, AUPRC, MCC, FP rate, inference time (ms). E.g.: DL studies report F1/AUC ~0.98–0.999 in controlled datasets; AUPRC improves with synthesized labels.	LSTM, CNN, and hybrid models facilitate online detection and continuous monitoring with adaptive learning.
Ibomoiye, D. M., et al. (2024)[36]	AUC (~99% with GAN-GRU), Sensitivity 0.992, Specificity 1.000, Very high accuracy (~99%), High F1 score, Low false positive rate.	GAN + RNN/LSTM/GRU enables continuous training and adaptation
Tayebi, M. et al. (2025)[37]	Accuracy, Precision, Recall, F1-score, ROC-AUC, AUPRC, MCC, FPs rate, inference time (ms), throughput (tx/s). Typical values in studies: AUC/F1 ≈ 0.90–0.999 in controlled datasets.	XGBoost/LightGBM (lightweight), Logistic, Random Forest pruned, Hoeffding Trees (streaming). Possible with optimization: LSTM/CNN pruned, lightweight Autoencoders. More costly: GNN/Transformers (require infrastructure optimization).
Cascavilla, G. (2025)[38]	AUC (~68–85% depending on model and dataset), TP Rate (varies by model: IsolationForest 41–59% Merchants; Autoencoder ~77–85% in some scenarios), High accuracy (~90% due to imbalance), Low/modest F1 due to class rarity.	Lightweight models per cardholder (IF, OCSVM) and optimized AE architectures enable near-online detection; more expensive assemblies require optimization.
AbouGrad, H. (2025)[39]	ROC–AUC: 66.20%, PR-AUC: 1.24%, Precision 99%, Recall showed lower coverage, F1-Score: ~98% between precision and recall, TPR remains high in regions with low false positive rates	Lightweight local models (classifiers or AEs) enable online detection at each node; periodic aggregation supports near-continuous monitoring.
Liu, J. (2025)[40]	accuracy 99.21%, precision 97.92%, recall 96.15% , F1-score 97.03% y AUC 99.31%	The CCNN is efficient and can be integrated into near-real-time pipelines; it requires optimized inference for low latency.
Ullah, H. (2022)[41]	Accuracy: 99.9 % Precision: 93 % F1-score: 85.71 % AUC: 98 %	The study suggests that CNN models can be applied in online transaction contexts.
Yu, J. (2024)[42]	The hybrid model showed Recall 94.85%, F1 ≈ 93.4%, AUC > 0.97, and a +10.7% improvement in recall; MCC and BCR exceeded baselines, confirming reliability and early detection.	LightGBM/XGBoost with fast extraction allows
Sun, Y. (2023)[43]	GRU 95.2/96.0/0.95, LSTM 94.0/97.1/0.94, MLP 92.8/95.2/0.93, AdaBoost 96.6/98.4/0.97, RF 94.5/96.1/0.94	LSTM/GRU LightGBM/XGBoost or lightweight hybrid models.
Al Balawi, S. (2023)[44]	Precisión: 83% Recall: 84% Overall accuracy: 99.81% F1-score: 83.72% Loss: 0.00244	CNN 1-D using CPU/GPU in appropriate infrastructure.
Alsagri, H. S. (2025)[45]	Precisión: 99.5% Recall (Early detection): 90.1% F1-score: > 90% Accuracy: approx. 99% Model cost: 0.421 F1-score DNN: 87% F1-score Random Forest: 84% F1-score SVM: 82%	Multi-stage architecture with fast sorters and DNN enables online scoring
Akour, I. (2025)[46]	Precision 90.51%, Recall 90%, F1-score 89.88%, Accuracy 99.93%, AUC 98%, and Recall CNN–Attention 93.28%	The hybrid requires intensive training, but its inference is fast for online scoring; it is recommended in real systems with adequate infrastructure, taking care with the generation of synthetic samples.
Benchaji, I. (2021)[47]	The metrics obtained include AUC: ~99.5% effective classification capacity MAE: error ≈ 0.6% MSE: error ≈ 0.3% Fraud detected: in a highly unbalanced dataset (only 1.2% were fraud)	The LSTM model enables real-time, online detection.
Owoh, N. (2024)[48]	The reported metrics include accuracy (99.97%), precision (99.91%), recall (99.89%), F1-score (99.89%), and AUC (0.999), demonstrating an excellent balance between sensitivity and specificity.	The proposed ensemble model enables immediate and continuous fraud detection in real time, making it suitable for online banking systems and automated transaction monitoring applications.
Strelcenia, E. (2023)[49]	It was evaluated using Precision, Recall, F1, Accuracy, and ROC; K-CGAN combined with XGBoost and MLP achieved 1.0 in Precision, Recall, and F1 in several cases, perfectly classifying the test set.	XGBoost, RF, and MLP are suitable for immediate detection in online pipelines; K-CGAN reinforces training for continuous monitoring systems.
Ren, J. (2024)[50]	Stacking Ensemble = Precision 99.35 Accuracy 99.42 F1-Score 99.36 Recall 99.38 AUC 99.50	The Stacking Ensemble model
Fedushko, S. (2023)[51]	The reported metrics include AUC (≈94.6% for Logistic Regression, ≈95.4% for stacking) and F1-score (0.96), demonstrating high reliability.	The study does not explicitly test online detection or continuous real-time monitoring.

Plakandaras, V. (2022)[52]	Accuracy = 99.9 % AUC-ROC = 98.1 % Precision = 79.6 % Recall (fraud detection) = 84.8 % F1-Score = 82.1 % Balanced Accuracy = 92.4 % Specificity = 99.9 %	JAD enables immediate retraining and application of the model in card issuers, making it practical for rapid updates.
Alatawi, M. N. (2025)[53]	RF: Prec 100.0%, Acc 99.999%, F1 99.99%, Recall 99.99%, AUC 99.99% GBM: Prec 99.95%, Acc 99.986%, F1 99.92%, Recall 99.90%, AUC 99.98%	The combination of ML/DL with cloud/big data enables real-time detection.
Muduli, D. (2025)[54]	(Stacking Ensemble): Accuracy: 99.95% Precision: 99.93% Recall (Sensibilidad): 99.97% F1-score: 99.95% AUC: 1.00 FPR (False Positive Rate): 0.02% (the lowest among the models compared).	The pipeline inference is lightweight and suitable for real-time use, with scalable architecture, and stacking requires adaptations for continuous learning in streaming.
Feng X et al (2024)[55]	Accuracy, Precision, Recall, F1-score, and training time.	Optimized SVM and RF/GBDT enable real-time deployment; CDL streamlines updates.

Fig. 2 details the citations of references used, identifying the sources with the greatest impact that form the basis of the field of study. The analysis reveals that the work of Abd-Ellatif, L. et al. is the most influential, with 129 citations. This is followed in importance by the references of Sun, Yanxia, with 100 citations and Adejo, J. et al., with 92 citations. The prominence of this small group of authors indicates that current research relies heavily on a core of consolidated knowledge, which guides the methodologies and direction of analysis on fraud detection.

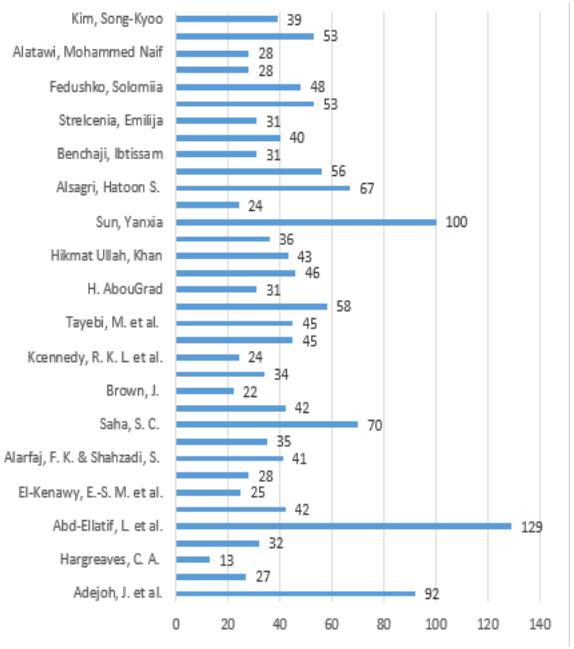

Fig. 2. References used.

C. Word Cloud

Fig. 3 shows the most frequent words identified by Bibliometrix, among which the following stand out: machine learning, deep learning, fraud detection, credit cards, artificial intelligence, cybersecurity, random forest, support vector machines, logistic regression, federated learning, and generative adversarial networks. These words reflect the focus of research on the use of advanced artificial intelligence techniques for financial fraud detection.

Fig. 3. Word cloud.

D. Three-Field Diagram

Fig. 4 presents the three-field diagram, which visualizes the bibliometric connections between the authors' country of origin (AU_CO), research topics or keywords (ID), and authors (AU). The thicker lines show that countries such as the United States, China, and India are the main centers of scientific production in this field, with a predominant focus on credit card fraud detection through the intensive use of advanced artificial intelligence techniques, such as machine learning and deep learning. This pattern reflects a global trend toward the application of sophisticated algorithms to strengthen cybersecurity and optimize fraud detection systems.

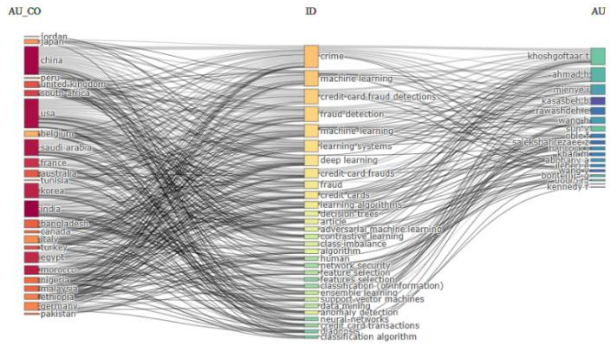

Fig. 4. Three-field diagram.

E. Co-occurrence Network

Fig. 5 presents the co-occurrence network of the most frequent terms in the study area, illustrating the conceptual structure of the research using a map of nodes and links. Key concepts such as machine learning, fraud detection, deep learning, and credit card fraud detection are the most prominent, identified by their larger nodes. These terms act as conceptual nuclei, positioned centrally on the map and serving as connection points for a wide range of interrelated secondary topics. The term crime also stands out as an important and connected concept. The different color-coded clusters (orange, blue, green, red) visually group distinct but related areas of research, where physical proximity between terms indicates a greater strength of thematic co-occurrence.

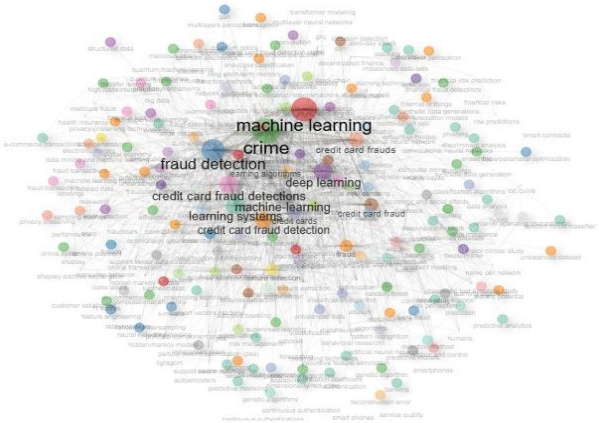

Fig. 5. Co-occurrence network.

F. Factorial Analysis

Fig. 6 shows the thematic grouping according to keyword affinity. There is a concentration in the upper right quadrant with terms such as classification, random forest, credit card fraud, and machine learning, focused on credit card fraud detection. In the upper left quadrant, terms related to fraud detection and algorithm appear, while a small group in green is separated. This confirms that the field focuses on the use of advanced techniques for financial protection.

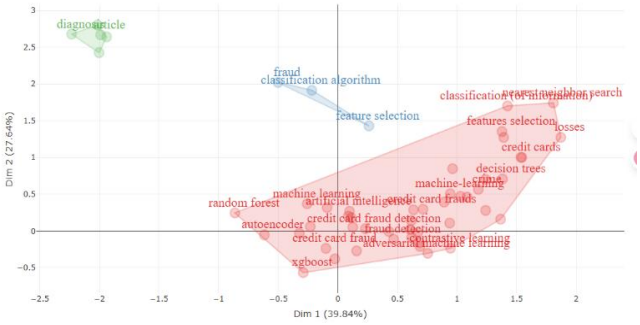

Fig. 6. Factorial analysis.

IV. Discussion

The objective of this review was to identify, analyze, and classify the most effective artificial intelligence models for the early detection of banking fraud in real-time. The findings confirm that deep learning-based approaches perform better than traditional methods, particularly those capable of modeling dependencies in transactional data. In this regard, architectures such as RNN, LSTM, and GRU stand out for their high predictive power, achieving an accuracy of 99.39%, an F1-score of 0.9939, and an AUC greater than 0.99.

These values exceed those reported in previous studies such as that of Sun et al. [43], which shows a significant improvement over previous research. This difference can be explained by the performance achieved by modern models such as LSTM, CNN, and XGBoost, whose accuracy (94–99%), together with other metrics such as Recall, Precision, F1-score, and AUC-ROC, show high effectiveness in fraud detection [22]. Consistently, various authors report high values above 99% for accuracy and AUC, confirming the high sensitivity and specificity of these models in identifying fraudulent transactions [27] , [40].

Similarly, hybrid models that combine traditional techniques such as XGBoost, Random Forest, or Logistic Regression with deep or generative architectures significantly increase the robustness of the system. These methods leverage the representational power of deep networks, achieving outstanding performance in imbalanced contexts [37], [48], [49]. In line with the above, the results obtained are consistent with those reported by authors who have evaluated advanced models for fraud detection. Khan et al. highlight that current classification models allow complex patterns to be captured with greater accuracy than traditional methods, which coincides with the performance observed in the LSTM, RNN, and CNN models analyzed in this review [56]. Muaz et al. specify that the effectiveness of the system necessarily depends on the proper handling of both imbalance and preprocessing, reinforcing the idea that data quality is an important factor in improving model performance, including Deep Learning models [57].

On the other hand, Chergui et al. suggest that semi-supervised methods can be combined with advanced classification methods to better adjust to frequent changes in the types of financial fraud. This shows the importance of using models capable of learning sequences and dynamic variations that arise in fraud behavior [58]. Finally, Aghware et al. emphasize in their research that hybrid strategies combining deep techniques with clustering or assembly methods increase the robustness of the system, supporting the results of this review on the good performance of combined models [59]. Overall, the evidence reviewed shows that deep learning models and hybrid approaches currently represent the most effective and reliable solutions for detecting banking fraud, thus surpassing traditional methods.

V. Conclusion

The objective of this review was to identify, analyze, and classify the most effective artificial intelligence models for the early detection of banking fraud in real-time, especially in an environment where transactions are increasingly fast and changing.

Based on the study conducted, it can be concluded that the ML and DL models most commonly used in the detection of fraudulent transactions are Random Forest (RF), which is one of the most accurate and widely used ML models, followed by

XGBoost, considered one of the most accurate and widely used supervised learning approaches, Support Vector Machine (SVM) in third place, and Short-Term Memory Networks (LSTM), which are a type of deep architecture, and Graph-based Approaches (GNN), which allow for the integration of temporal, relational, and behavioral patterns, in fourth place.

Deep learning architectures, described by deep learning (DL) models, have proven to be particularly effective at capturing temporal and multivariate patterns, improving the accuracy and scalability of systems. First and foremost are Recurrent Neural Networks (RNN), LSTM, and GRU, which are essential for capturing the temporal dynamics of fraud. secondly, Convolutional Neural Networks (CNN), which are also used to capture complex patterns, and Autoencoders (AE), which are often used for anomaly detection, as unsupervised models are useful for identifying hidden patterns and irregular behaviors in large volumes of data, achieving an accuracy of 99.39%, an F1-score of 0.9939, and an AUC greater than 0.99.

Within hybrid and ensemble models, the combination of different algorithms or the integration of multiple approaches is considered a robust strategy that improves fraud detection, such as models that combine classical techniques, such as XGBoost or Random Forest, with deep architectures, achieving near-perfect performance, registering F1-scores and AUC between 0.98 and 1.00. Banking fraud solutions applied by other researchers have implemented and evaluated a wide range of Machine Learning (ML) and Deep Learning (DL) models, often outperforming traditional methods such as Random Forest, XGBoost, and short- and long-term memory networks (LSTM) used for fraud detection.

However, the study has some limitations related to the differences between the approaches used in the empirical works reviewed, the variety of databases used, and the frequent use of public datasets that do not always represent the complexity that exists in real banking systems. Finally, it is recommended that future research test these models in real operating environments, with real-time data, unified metrics, and scenarios where new types of fraud appear. In addition, it would be valuable to explore more efficient hybrid techniques and methods, such as federated learning, which could improve the adaptability of systems and strengthen their ability to detect early fraud.

User Experience Evaluation in Government Applications: A Systematic Review

Emmy Hossain[1], Noris Mohd Norowi[2], Azrina Kamaruddin[3], Hazura Zulzalil[4]
Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, 43400 Serdang, Selangor, Malaysia [1, 2, 3, 4]
Faculty of Computer Science and Information Technology, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia[1]

***Abstract*—Evaluating the User Experience (UX) of government applications is becoming increasingly crucial as governments deploy public services online. Nevertheless, research in this area remains fragmented. Correspondingly, this study presents a systematic review of UX evaluation in government applications to address the following Research Questions (RQs): What UX evaluation approaches and UX dimensions have been employed in the UX evaluation of government applications, and how do domains, contextual, and cultural considerations influence the UX evaluation of government applications? Kitchenham and Charters' guidelines, as well as the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), are employed to guide this review. Moreover, recent studies from Scopus and Web of Science (WoS) databases between the years 2023 and 2025 were retrieved using a predefined review protocol. After applying the inclusion and exclusion criteria and subjecting the studies to quality assessment, the final number of retained studies for this review is 19. The analysis reveals four key themes: diversity in UX evaluation approaches, the range of UX dimensions evaluated, the range of domains evaluated, and the contextual and cultural considerations in UX evaluations. The findings reveal that UX evaluations of government applications are predominantly usability-focused, while hedonic, emotional, and cultural dimensions receive limited and inconsistent attention. In addition, the review highlights that UX evaluations for government applications should encompass both technical and pragmatic aspects, as well as domain-specific, cultural, and contextual dimensions. Accordingly, strengthening these evaluations can lead to more inclusive and meaningful assessments, resulting in government applications that offer better UX. Overall, the findings of this review may serve as a reference for future work and advance the field of UX evaluation, especially in the context of government applications.**

Keywords*—User Experience Evaluation; UX evaluation; government applications; e-government; systematic review

I. Introduction

Within the domain of human-computer interaction, User Experience (UX) has emerged as a fundamental aspect in the quality of interaction between users and digital systems, extending beyond traditional usability. In [1], UX is defined as encompassing all aspects of users' interaction with products and services, including perceptions, emotions, and responses that arise before, during, and after use [2], [3]. Similar to other forms of computing technology, all applications, including those used by governments, have UX as an integral component. Thus, it is crucial for UX to be considered during the design, development, and evaluation stages of these applications. This is to ensure a positive UX when interacting with, and/or anticipating interaction with, the applications. Consequently, to benefit from what the government intended to provide and share through its applications. Note that poor UX can cause repercussions, such as having difficulties in using the application. This includes missing out on crucial information, frustration, and abandonment, which can defeat the purpose of having these e-government initiatives [4].

In the context of interaction design, the lifecycle of producing applications (design, development, and evaluation stages) includes evaluation, a core component that is centered on both usability and UX [5]. In particular, UX evaluation is the process of collecting and analyzing data about users' or potential users' UX when interacting with artifacts. Examples of artifacts include screen sketches, prototypes, system components, a specific function, the entire workflow, the complete system or application, and safety features, to name a few. Therefore, it is crucial to conduct an evaluation for the following reasons: a rigorous evaluation helps enhance overall quality, allows users to understand their expectations, and ensures the product aligns with their needs and preferences. This guarantees that products are well-designed, as good experiences lead to desirable outcomes such as adoption, retention, use, sales, downloads, and recommendations. It also enables the identification and rectification of any issues before the product is released to the market [4], [6].

Since the early 1990s, the field of Information and Communication Technologies (ICTs) has undergone rapid progress, resulting in significant improvements across various societal areas, including, but not limited to, agriculture, communication, education, industry, transportation, government, and everyday life. In ICTs for government, one of the most notable innovations to emerge is electronic government (e-government). Notably, e-government is an umbrella term for the use of ICTs to access and deliver government services, disseminate government information, communicate between the government and its citizens, agencies, and stakeholders, and support internal government operations. The aim of e-government is to enhance the efficiency and effectiveness of government operations and accountability, as well as improve the government's engagement with citizens [7], [8]. Furthermore, to keep pace with technological advancements and provide better, faster, and more convenient services to citizens, governments offer applications through both mobile and web platforms, enabling citizens and stakeholders to access government services and engage with the government. As the

use of these applications and the reliance of the public on government applications grow, these applications must be designed and evaluated to support meaningful engagement and provide a positive UX.

Therefore, evaluating UX in the context of government applications is a core necessity, as UX is progressively acknowledged as essential for products and services, including those in the government sector [3]. While governments have increasingly delivered services through government applications, and the usage of these applications has risen, studies on their UX evaluation remain fragmented and dispersed, with varied approaches and focuses [9], [10], [11]. In [9], the authors showed that the studies addressing UX factors such as usability, trust and satisfaction are inconsistent across different service types and regions. The works of [10] and [11] demonstrated the common usage of usability evaluation approaches such as System Usability Scale (SUS), Smartphone Usability Questionnaire (SURE), heuristic evaluation and usability inquiry, to conduct UX evaluation for e-governments applications. While usability is a core component of UX, conducting UX evaluation using usability evaluation approaches is insufficient, with only usability as the focal point and not including other aspects of the user experience [37]. Additionally, the development of cumulative knowledge that can inform better UX evaluation is hindered, as is the potential for comparability across studies in the field. Meanwhile, several UX evaluation works have incorporated a broader range of UX dimensions beyond usability, and adopted evaluation approaches other than usability evaluation, such as [2] in online systems, [38] in AI-powered systems, [39] in business intelligence visualization, [40] in blockchain, and [41] in education. However, these works are domain-specific, designed with consideration of the domain's unique UX dimensions, and hence these UX evaluations are not directly transferable to the government application context. In contrast to the existing related studies, this study offers a systematic review that identifies and synthesizes UX evaluation approaches, dimensions, domains, and contextual and cultural considerations reported in the literature on government applications. Hence, this systematic review is warranted to investigate the existing literature on approaches, dimensions, domains, and considerations, contextualized and culturally. This ensures clearer directions for future research and practice in the UX evaluation of government applications.

Although there are several review studies that are related to this study, the existing reviews demonstrate notable limitations that motivate the present study. First, some review studies on government applications concentrated on usability evaluation rather than UX evaluation, leading to a narrower evaluative scope [10, 11]. Second, in [3], the authors examined the UX dimensions of e-procurement systems, which are only a subset of government applications and do not fully represent the larger domain of government applications. Other reviews employed a general perspective without focusing on domains: [42] reviewed UX evaluation techniques, factors influencing UX, and benefits of evaluating UX without anchoring their study in any specific domain. Another study that used the general perspective is [43], which focused on reviewing methods and metrics of UX evaluation. Lastly, [44]'s review study focused on the evaluation of public service quality instead of the evaluation of its applications (e.g., websites and mobile applications), and did not explicitly include UX evaluation in their study. These limitations, when viewed collectively, show that existing reviews do not provide a recent, domain-specific account of UX evaluation in government applications, with contextual and cultural considerations taken into account. Notably, the earlier reviews have not systematically examined how domain and cultural and contextual considerations are reflected in UX evaluations in government applications. To the best of the authors' knowledge, this is the first review that consolidated UX evaluation approaches and UX dimensions in government applications with the inclusion of domain-specificity, and contextual and cultural considerations. Also, concentrating this review on literature published between 2023 and 2025 enables the capture of recent developments in UX evaluation in government applications that reflect shifts in electronic government strategies, public service delivery via mobile applications, emerging UX evaluation approaches, and the growing recognition of UX as a multidimensional construct beyond usability. Prior studies predate these developments and offer only a limited representation of the current state of UX evaluation in government applications. With the focus on the 2023-2025 recent studies, this review intends to identify emerging UX evaluation approaches, UX dimensions, and contextual and cultural considerations that are relevant to contemporary government applications. This review contributes to the literature by analyzing current UX evaluation practices in government application studies and by highlighting the role of domain-specificity, contextual, and cultural considerations within these evaluations.

This study presents a systematic review of the literature on UX evaluation in government applications. The objectives of the review are to: 1) identify UX evaluation approaches and UX dimensions that are used in the UX evaluation of government applications, and 2) to examine how domains, and contextual and cultural considerations shape the UX evaluation of government applications. In particular, this review aims to contribute to the emerging body of scholarship on UX evaluation and digital government by providing a structured overview and synthesis of UX evaluation for government applications.

The remainder of this study is structured as follows: Section II details the review method, Section III presents the findings of the review, Section IV offers the discussion, and Section V concludes the study. The following section describes the review method undertaken in this systematic review.

II. Review Method

This systematic review was planned and executed according to the guidelines established by [12], which provide a well-defined structure for conducting systematic reviews within the computing context. For reporting the systematic review's findings, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram [13], [14] was employed. The combination of Kitchenham and Charters' guidelines [12] with PRISMA provides a methodologically rigorous, structured set of steps for defining review objectives, formulating Research Questions (RQs), and outlining

procedures for searching databases, selecting studies, extracting data, and synthesizing systematically.

As established by [12], the systematic review process has three phases: planning the review, conducting the review, and documenting/reporting the review. This study aligns with these three phases. There are specific activities for each phase, which are documented in Table I and further explained in the following subsections.

TABLE I. MAIN ACTIVITIES IN SYSTEMATIC REVIEW PHASES

Phase	Activities
Planning the review	Developing a review protocol
	Identifying research questions
	Identifying inclusion and exclusion criteria
Conducting the review	Implement search strategy and study selection
	Select primary studies
	Perform quality assessment
Documenting/reporting the review	Data extraction and synthesis

A. Planning the Review

This phase involves developing the review protocol, which includes identifying the RQs for this systematic review and establishing the inclusion and exclusion criteria.

1) Review protocol: Developing the review protocol is a fundamental first step in all systematic review protocols, as it provides a predefined plan that serves as a blueprint and a control measure to reduce bias introduced by the researchers [15], [12]. Following the Kitchenham and Charters guidelines, as demonstrated by [16], this study's review protocol is presented in Fig. 1:

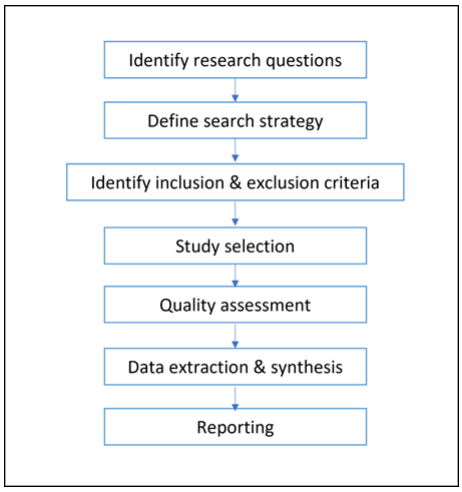

Fig. 1. Review protocol.

2) Research questions: This systematic review is anchored by two RQs that establish the foundation for this study:

RQ1: What UX evaluation approaches and UX dimensions have been employed in the UX evaluation of government applications?

RQ2: How do domains and contextual and cultural considerations influence the UX evaluation of government applications?

3) Search strategy: To define the search strategy, primary keywords and relevant terms are identified, and search strings are constructed using lexical resources (e.g., dictionaries and thesauri), reference materials, and prior scholarly works. Consequently, the search strings are entered into two major scholarly databases, Scopus and Web of Science (WoS), to search for relevant studies for the review process. Scopus and WoS are selected as the primary databases due to their robustness, high-quality indexing, comprehensive coverage, peer-reviewed status, and wide acceptance among the scholarly community. The search strings used are detailed in Table II. From this initial search, a total of 1,622 publications related to this study were identified, laying a solid foundation for further screening and analysis.

TABLE II. SEARCH STRINGS

Database	Search strings
Scopus	TITLE-ABS-KEY (("user experience evaluation" OR ux evaluation) AND (government OR "public service")) AND (LIMIT-TO (SUBJAREA , "COMP") OR LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "MATH") OR LIMIT-TO (SUBJAREA , "MULT") OR LIMIT-TO (SUBJAREA , "ECON") OR LIMIT-TO (SUBJAREA , "BUSI") OR LIMIT-TO (SUBJAREA , "DECI")) AND (LIMIT-TO (PUBYEAR , 2023) OR LIMIT-TO (PUBYEAR , 2024) OR LIMIT-TO (PUBYEAR , 2025)) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (LANGUAGE , "English")) Date of Access: May 2025
Web of Science	("user experience evaluation" OR ux evaluation) AND (government OR "public service") (Topic) and 2025 or 2023 or 2024 (Publication Years) and Article (Document Types) and English (Languages) and Article (Document Types) and English (Languages) Date of Access: May 2025

4) Inclusion and exclusion criteria: The next step in the review protocol is screening, where the initial set of 1,622 publications from the first stage is refined using inclusion and exclusion criteria. This refinement is conducted to ensure that the publications are related to this study and support the research objectives. Note that studies were excluded if they were published before 2023, written in a language other than English, or classified as conference papers, book chapters, review articles, or articles still in press. In addition, records belonging to subject areas outside the scope of the research, specifically computer science, engineering, business, management and accounting, economics, econometrics and finance, and multidisciplinary fields, were also removed. Following this rigorous screening, a total of 1,441 records were excluded. The remaining dataset comprised 149 publications, with 99 sourced from Scopus and 50 from WoS. A subsequent duplicate check was performed using a reference manager,

resulting in the removal of 18 duplicate records, leaving 131 publications for the next step of the review protocol. In essence, this process ensured that the final set of studies is both highly relevant and aligned with the research objectives, providing a robust foundation for the subsequent phases of the systematic review. Table III summarizes the inclusion and exclusion criteria used.

TABLE III. INCLUSION AND EXCLUSION CRITERIA FOR THE SELECTION CRITERIA IN SEARCHING

Criterion	Inclusion	Exclusion
Language	English	Non-English
Timeline	2023 – 2025	< 2023
Literature type	Journal (article)	Conference, Book, Review
Publication stage	Final	In press
Subject area	Computer science Engineering Business, management, and accounting Economics, econometrics, and finance Multidisciplinary	Besides Computer science Engineering Business, management, and accounting Economics, econometrics, and finance Multidisciplinary

5) Study selection: In this step, the titles and abstracts of the 131 publications from the previous phase are further examined to ensure eligibility, aligning with the established inclusion criteria and research objectives. A total of 97 articles were excluded on the grounds of falling outside the relevant field of UX evaluation in government applications, lacking significance based on their titles, presenting abstracts that did not correspond to the study's objectives, and/or lacking accessible full-text versions grounded in empirical research. Following this eligibility assessment, 34 articles were retained for quality assessment. Accordingly, the study process is documented using the PRISMA 2020 flow diagram [14], in Fig. 2.

6) Quality assessment: Quality assessment is an integral assessment in systematic reviews for determining the quality of the selected studies [12]. In this study, the quality assessment criteria are adopted from [17]'s quality assessment framework. There are a total of eight (8) quality assessment criteria formulated for this study. For the scoring system, a three-point score is assigned in which 1 ("Yes") is for when the criterion is fully satisfied, 0.5 ("Partially") is for when the criterion is only partially satisfied, and 0 ("No") is for when the criterion is not fully satisfied. The 34 articles from the previous step are screened using the quality assessment criteria. Following this screening, 15 articles were identified as not meeting 70% of the quality assessment criteria, leaving the remaining 19 articles as the primary studies for subsequent data extraction and analysis. Table IV presents the quality assessment criteria used in this step, and Table VI displays the results of the quality assessment of the selected papers.

TABLE IV. QUALITY ASSESSMENT CRITERIA

QA1	Is the purpose of the study clearly stated?
QA2	Is the interest and the usefulness of the work clearly presented?
QA3	Is the study methodology clearly established?
QA4	Are the concepts of the approach clearly defined?
QA5	Is the work compared and measured with other similar work?
QA6	Are the limitations of the work clearly mentioned?
QA7	Is the study explicitly focused on UX evaluation for government applications?
QA8	Does the study explicitly involve government applications or public service platforms as its domain of investigation?

7) Data extraction and synthesis: From the quality assessment step, nineteen studies are retained for data extraction and analysis. Data extraction is performed by examining each paper and extracting relevant data using MS Excel spreadsheets. This is done in accordance with guidelines [12] to construct data extraction forms to capture the data from the initial search in a systematic and reliable manner. Note that the selection of extracted data is guided by the RQs. It comprises the title of the article, authors, publication year, keywords, abstracts, journal titles, countries/regions in which the research is conducted, domains of investigation, platforms (web/mobile), UX evaluation approaches/methodologies, UX dimensions, and cultural and contextual considerations. The next section presents the findings of the review, organized according to descriptive overview and themes.

III. FINDINGS

The findings of this systematic review are outlined in this section, beginning with a descriptive overview of the studies, followed by a synthesis of the key themes identified across the reviewed studies. Discussion of the findings is presented in the next section.

A. Descriptive Overview

Publication years: The 19 papers in this study were published between 2023 and 2025, with the majority (10) published in 2024. Table V below summarizes the distribution of papers according to their year of publication.

TABLE V. PUBLICATION YEARS OF THE REVIEWED PAPERS

Year	Number of papers	Authors
2023	6	Yakovchenko et al. [18], Alharbi et al. [19], Hu et al. [20], Nagro [21], Cheng & Chen [22], Alghareeb et al. [23]
2024	10	Ro et al. [24], Benaida [25], Wahyuningrum et al. [26], Zubir & Latip [27], Puspasari et al. [28], Sapraz & Han [29], Nawafleh & Khasawneh [30], Aziz et al. [31], Fadrial et al. [32], Patergiannaki & Pollalis [33]
2025	3	Ashar et al. [34], Amer et al. [35], Kencono et al. [36]

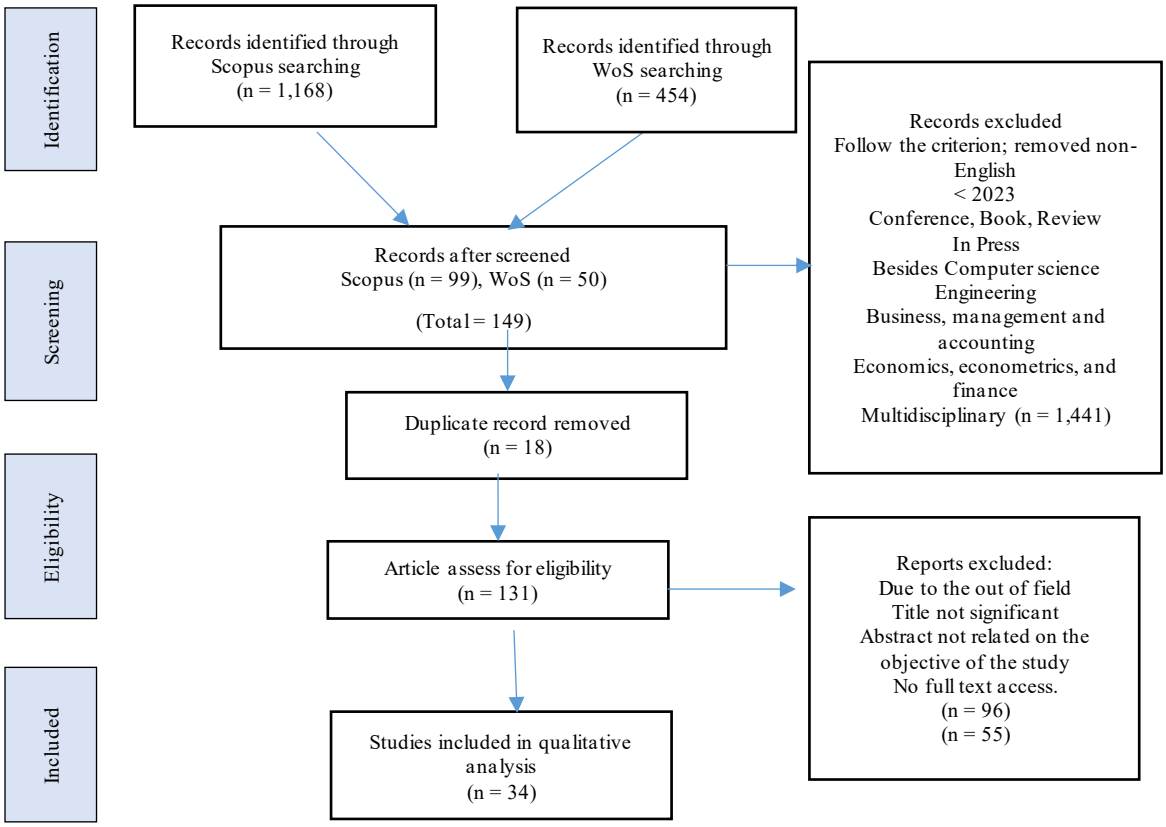

Fig. 2. The PRISMA flow diagram.

TABLE VI. QUALITY ASSESSMENT RESULTS OF THE SELECTED PAPERS

No.	Authors	Year	QA1	QA2	QA3	QA4	QA5	QA6	QA7	QA8	Total	%
1	Puspasari et al.	2024	1	1	1	0.5	0.5	0.5	1	1	6.5	81.3

Domains covered: The 19 reviewed studies focused on government applications delivered via mobile and web platforms across six domains. The domains of the papers are listed in the following Table VII.

TABLE VII. DOMAINS COVERED IN THE REVIEWED PAPERS

Domain	Number of papers	Authors
Public services	9	Alharbi et al. [19], Benaida [25], Zubir & Latip [27], Nawafleh & Khasawneh [30], Fadrial et al. [32], Patergiannaki & Pollalis [33], Sapraz & Han [29], Amer et al. [35], Kencono et al. [36]
Healthcare	5	Yakovchenko et al. [18], Alghareeb et al. [23], Nagro [21], Wahyuningrum et al. [26], Ashar et al. [34]
Navigation	3	Hu et al.[20], Cheng & Chen [22]
Tourism	1	Aziz et al. [31]
Law enforcement	1	Puspasari et al. [28]
Assistive technology	1	Ro et al. [24]

Platforms: The studies are categorized into two platforms, mobile and web, as presented in Table VIII below.

TABLE VIII. PLATFORMS OF THE GOVERNMENT APPLICATIONS IN THE REVIEWED PAPERS

Platform	Number of Papers	Authors
Mobile	9	Hu et al. [20], Nagro [21], Alghareeb et al. [23], Wahyuningrum et al. [26], Zubir & Latip [27], Puspasari et al. [28], Aziz et al. [31], Ashar et al. [34], Kencono et al. [36]
Web	10	Yakovchenko et al. [18], Alharbi et al. [19], Cheng & Chen [22], Ro et al. [24], Benaida [25], Sapraz & Han [29], Nawafleh & Khasawneh [30], Fadrial et al. [32], Patergiannaki & Pollalis [33], Amer et al. [35]

Countries/regions: The studies were conducted in various regions, including Asia, Europe, Africa, and North America, with one cross-national study involving 50 countries [19]. Twelve countries in which the studies are conducted are presented in Table IX below. Two studies involved two countries in their works: Morocco and Tunisia [25] and Malaysia and Thailand [31].

TABLE IX. COUNTRIES/REGIONS OF THE GOVERNMENT APPLICATIONS IN THE REVIEWED PAPERS

Surveys and questionnaires Website analytics Process mining & social network analysis	Zubir & Latip [27], Nawafleh & Khasawneh [30], Fadrial et al. [32], Patergiannaki & Pollalis [33] Cheng & Chen [22], Ashar et al. [34] Amer et al. [35]
Value-Sensitive Design & FEDS framework AR usability experiments	Sapraz & Han [29] Hu et al. [20], Aziz et al. [31]

B. Themes

Examination of the reviewed studies revealed four central themes: diversity in UX evaluation approaches, the range of UX dimensions evaluated, the range of domains evaluated, and the consideration of contextual and cultural factors.

C. Diversity in UX Evaluation Approaches

The studies employed a diverse set of approaches to evaluate the UX of the web and mobile government applications. This demonstrates a methodological theme reflected in the use of qualitative, quantitative, and mixed-method approaches. For instance, [18], [21], [26], and [29] implemented standardized instruments for evaluating usability and UX, such as System Usability Scale (SUS), Usability Metric for User Experience (UMUX), UMUX-Lite, User Experience Questionnaire (UEQ), and Single Ease Questionnaire (SEQ). Meanwhile, [20] and [24] conducted their evaluations using task-based and experimental methods, including task analysis and behavior-emotion analysis. Inspection-based and heuristic evaluations were also incorporated, along with expert reviews and usability guidelines in [19], [31], and [25]. In addition, several studies combined mixed-methods approaches: analytics, surveys and interviews in [32], [34] and [35], sentiment and thematic analyses, and natural language processing of user reviews in [23], [28] and [36], and surveys, interviews, UEQ, and the Framework for Evaluation in Design Science Research (FEDS) in [29]. Moreover, [27], [30], [33], and [34] utilized large-scale surveys and are grounded in models such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2). At the same time, innovative approaches were also deployed, such as [35]'s use of a case study with process mining and network analysis. Essentially, the use of this diverse set highlights that the researchers rely on quantitative, qualitative, and mixed-methods approaches, enabling them to capture a range of UX dimensions during the evaluations.

D. Variety of UX Dimensions Evaluated

A variety of UX dimensions were evaluated in the reviewed studies. A recurring dimension is usability [19], [21], [18], [20], [25], [24], [26]. Effectiveness is a dimension investigated by [23], [24], [26], [28], [34], and [36]. Additionally, efficiency is also evaluated by [24], along with [23], [18], [25], and [35]. The satisfaction dimension is covered in the evaluations conducted by [23], [24], [25], [26], [30], and [36]. In [25], [27], and [33], the researchers investigated dimensions related to use: ease of use and perceived usefulness. Following this, accessibility is assessed by [19], [24], [25], and [26]. [19] also evaluated privacy, along with [36]. Conversely, [20] included emotional experience dimensions: pleasure, arousal, and dominance. Meanwhile, [32], [30], and [36] measured service quality, trust, security, and transparency. In [28] and [36], perceptions of performance, functionality, and performance were investigated. When considered together, the reviewed studies indicate that evaluations of UX encompass pragmatic, hedonic, and emotional responses, as well as government-specific concerns and context-specific cultural and social dimensions. Collectively, these highlight the multidimensional nature of UX in government applications.

E. Range of Domains in the UX Evaluations

The studies reviewed have undergone UX evaluation of government applications across various domains, including public services, healthcare, navigation, tourism, law enforcement, and assistive technology. This illustrates the varied functions provided by the government through its web and mobile platforms. The most prominent domain with the largest number of studies is public services delivered through government websites or mobile applications [19], [25], [27], [30], [32], [33], [29], [35], [36]. Several studies explicitly stated the type of public service provided. For example, [35]'s work evaluated electronic building permit systems, [29]'s work investigated a platform for citizens and the Sri Lankan government to collaborate on environmental issues, [33]'s work evaluated Greek municipal portals, and [36]'s work investigated the regional government mobile applications. The next domain is healthcare, which is investigated by [21], [18], [23], [26], and [34]. [20] and [22]'s works are in the navigation domain. Meanwhile, the domains of tourism, law enforcement, and assistive technology each have one study ([31], [28], [24]). The identified domains consist of established services, including public services, healthcare, tourism, and law enforcement, as well as emerging ones such as navigation and assistive technology. As a whole, these domains reflect the domain-specific needs that inform the UX evaluation criteria and shape the UX of the applications.

F. Contextual and Cultural Considerations in UX Evaluations

The studies were conducted across a diverse set of countries and regions, bringing the emergence of contextual and cultural considerations as a notable theme and reflecting their roles in UX evaluations. The majority of the works were situated in Asia: Malaysia [27], [34], [31], Indonesia [26], [28], [32], [36], China [20], Taiwan ([22]), South Korea [24], Sri Lanka [29], Saudi Arabia [21]; [23], and Jordan [30], [35]. Correspondingly, the Asian works highlighted issues such as accessibility, cultural

heritage integration, citizen trust, digital adoption, loyalty, usability, sentiment towards government applications, and the influence of social and cultural norms on the adoption of government applications. Conversely, [25]'s work addresses the accessibility challenges of government applications in Northern African countries, specifically Morocco and Tunisia. [33]'s work, set in Europe, examined the Greek e-government service quality. In North America, [18] investigated the large-scale United States health management dashboards' usability. Another work is cross-national, involving 50 countries' e-government websites' privacy norms and usability [19]. Collectively, these studies have proven that UX evaluation is shaped by both technical considerations and contextual and cultural considerations, as well as contexts from the institutional and socio-political landscapes. The UX evaluation of government applications is thus demonstrated to involve contextual considerations, local cultural expectations, policy frameworks, and societal norms. This ultimately affirms the importance of contextually and culturally grounded evaluation approaches in conducting UX evaluations. These findings are discussed in the subsequent section.

IV. Discussion

This systematic review sets out to address two RQs:

RQ1: What UX evaluation approaches and UX dimensions have been employed in the UX evaluation of government applications?

RQ2: How do domains and contextual and cultural considerations influence the UX evaluation of government applications?

On the first RQ, a core finding that is consistently observed throughout the studies is the diverse approaches used in UX evaluations of government applications. Furthermore, a wide range of approaches is applied by the researchers. It ranges from standardized instruments for usability and UX evaluation (e.g., SUS, UMUX, UEQ), analytical and interpretive techniques (task analysis, behavior-emotion analysis, heuristic evaluations, expert reviews, surveys, and interviews), computational and data-driven methods (sentiment analysis, thematic analysis, natural language processing of user reviews, process mining, and network analysis), to framework-based approaches such as the FEDS ([18], [21], [26], [29], [20], [24], [19], [31], [25], [32], [34], [35], [23], [28], [36], [27], [30], [33], [35]. In addition, the diversity in the UX evaluation approaches deployed by the researchers is two-pronged. However, this current practice is both rich and fragmented in the sense that while various approaches can assess a variety of UX dimensions, the lack of a widely-recognized or dominant single approach suggests that standardization in UX evaluation for government applications has yet to be established. Similarly, the variety of UX dimensions evaluated across the studies has also revealed a significant pattern. Pragmatic dimensions such as usability, efficiency, effectiveness and satisfaction are consistently examined [19], [21], [18], [20], [23], [25], [24], [26], [28], [30], [27], [33], [34], [36], [35] but hedonic and emotional dimensions [20] are limited. Meanwhile, government-specific dimensions such as privacy, transparency, trust, and service quality appeared as notable dimensions in several studies [25], [30], [36]. This signifies a progression from evaluations focused purely on usability, oriented to a richer understanding of UX. Nevertheless, gaps emerged from the uneven distribution of attention across the dimensions. Cultural, emotional, and social dimensions remain underexplored compared to the pragmatic or functional dimensions.

Moving to RQ2, the reviewed studies indicate that domains, as well as contextual and cultural considerations, influence UX evaluations in government applications. More nuance is gained through the discussion of the range of government applications in the reviewed studies. This range reflects the expanding role of government applications in mediating interaction between governments and their citizens. The domains identified comprise conventional services such as public services, healthcare, tourism, and law enforcement [19], [25], [27], [30], [32], [33], [29], [35], [36], [18], [23], [21], [26], [34], [31], [28], together with emerging areas such as navigation and assistive technology [20], [22], [24]. In line with this, it is evident that domain-specific needs inform evaluation, e.g., public services prioritize service quality [32], [30], [36], [33], [25], [30], and healthcare applications prioritize data security and trust [21], [18]. This highlights the importance of considering the domain of the government application being evaluated. Another defining theme across the reviewed studies is contextual and cultural considerations in UX evaluations. Studies situated in Asian settings underscore the significance of accessibility, loyalty, and trust, signaling that culture and social norms influence adoption ([26], [29], [36]. Outside Asia, [18] in North America, [25]'s study, and [33]'s study in Europe drew attention to accessibility and service quality. These variations suggest that UX in government applications is not mutually exclusive from the interplay of socio-political and cultural settings. Despite this, few studies integrate cultural dimensions into their UX evaluations, marking a potential direction for further investigation into the field.

The progress of standardized yet adaptable frameworks for UX evaluation in government applications should be placed at the forefront of scholarly investigation. While best practices can be consolidated, they must remain flexible in varied cultural and domain environments. Additionally, there is a strong need to incorporate hedonic and emotional dimensions, considering their influence on the trust and loyalty of the citizen users. This supplements the common pragmatic dimensions, such as usability. Hence, contextual and cultural considerations should be more clearly integrated into UX evaluations, which could improve these UX evaluations across various settings. Domain-specific strategies should also be considered in future work, as UX evaluations are informed and shaped by domain-specific needs. Together, these directions will contribute to more comprehensive, contextually grounded, and culturally sensitive UX evaluation for government applications.

Collectively, the findings of this review give rise to several meaningful implications for UX evaluation in government applications. For the research community, the findings underscore the necessity to adopt more comprehensive perspectives that account for UX's multifaceted nature and to move away from usability-centric evaluations in conducting UX evaluations in government applications. For designers, developers and UX practitioners involved in building government applications, the findings suggest that UX

evaluation criteria should be adapted to include the domain, service and user contexts, without using only generic usability or UX evaluations. For governments, the findings show that UX evaluation with domain, contextual and cultural considerations can be accommodated earlier in the government application development lifecycle, to help realize more effective, inclusive, trustworthy and citizen-centric applications. The subsequent section provides a conclusion of this study.

V. CONCLUSION

Four key themes emerged from this systematic review of UX evaluations for government applications, guided by two RQs: diversity in UX evaluation approaches, the variety of UX dimensions evaluated, the range of domains in UX evaluations, and the contextual and cultural considerations in UX evaluations. These themes indicate the richness and fragmentation of current practices. Pragmatic dimensions, such as usability, remain the main focus of UX evaluations, while hedonic, emotional, and cultural dimensions are underexplored. Concurrently, despite the diverse approaches employed, there is a lack of standardized yet adaptable frameworks for UX evaluations in government applications. Furthermore, this systematic review highlights that UX evaluations in government applications should encompass both technical and pragmatic dimensions, as well as domain-specific, cultural, and contextual aspects. The implications of the findings for research, practice and stakeholder communities outline how UX evaluation in government applications may be strengthened. Therefore, strengthening UX evaluations through this approach will ultimately enable more inclusive and meaningful evaluations, likely resulting in government applications with a positive UX.

ACKNOWLEDGMENT

The authors would like to thank Universiti Malaysia Sarawak, the Ministry of Higher Education Malaysia, and Universiti Putra Malaysia for the valuable support in this study.

Feature Engineering for Machine Learning-Based Trading Systems Using Decision Tree, Random Forest, and Gradient Boosting

Nugroho Agus Haryono, Yuan Lukito, Aditya Wikan Mahastama
Department of Informatics, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia

***Abstract*—Machine learning-based trading systems require the selection and creation of features that crucially determine the performance level of the trading system. This study introduces an asset-specific, correlation-based feature selection approach for machine learning–based stock trading models. The research conducts a systematic evaluation of the influence of lookup period, the number of features from technical analysis, and feature selection on the performance of trading systems using tree-based algorithms: Decision Tree, Random Forest, and Gradient Boosting. The performance of the trading system was measured using the backtesting method, with metrics such as total return, win rate ratio, and profit factor. The research steps included selecting stocks with the largest market capitalization in the financial sector, which are included in the banking index. Historical data on the prices of these stocks was obtained from Yahoo! Finance for the years 2014-2025. The historical data was then divided into two parts, namely the in-sample dataset (2014-2024 time period) and the out-of-sample dataset (2025 time period). Each part of the data was supplemented with features from technical analysis and several other additional features. Trading signals are determined based on a profit target of +4% and a loss limit of –2% in a lookup period of 2 to 10 days. The results show that the ML strategy consistently outperforms the buy-and-hold strategy, with Gradient Boosting generating the highest return (37.443%). Spearman correlation-based feature selection per stock improves the performance of the strategy compared to uniform features.**

Keywords*—Feature engineering; machine learning; trading system; decision tree; Random Forest; Gradient Boosting

I. Introduction

Predicting prices in financial markets to help build trading systems requires sophisticated methods to detect market direction and take advantage of price volatility in the market to profit from trading. The complexity of prices in the market encourages the integration of machine learning algorithms into trading systems to improve trading system performance [1]. Machine learning is capable of analyzing large and complex datasets, detecting and predicting patterns, and making predictions based on historical trends [2]. Accurate predictions play an important role in making trading decisions and measured risk management [3]. Research on the stock market is most widely studied by researchers, followed by the foreign exchange (Forex) market and cryptocurrency trading. In developing predictive models using artificial intelligence techniques, technical analysis is more widely used than fundamental analysis. Technical analysis is developed based on statistical methods that describe stock price movements over a certain period. In financial markets, technical analysis aims to find price patterns and stock price trends that can be used by traders or investors to make decisions. The performance of a trading strategy can be validated using several testing methods. Backtesting is a popular and considered a robust assessment method [4]. The performance of portfolios built with machine learning can be measured using excess return and Sharpe ratio metrics [5], [6]. The accuracy of predictions generated by a model can be tested using backtesting to look at the performance results of a trading system before it is implemented in real trading [7].

In building a trading model, algorithms such as decision tree, ensemble learning Gradient Boosting, and Random Forest bagging techniques can be employed, which have considerable prediction accuracy and effectiveness [8]. The decision tree algorithm was chosen for its simplicity, ease of implementation, and ease of interpretation [9]. Metode Ensemble learning methods, such as Random Forest and Gradient Boosting, perform well in terms of accuracy, precision, and recall [10].

In the study of machine learning-based trading applications, several things have to be carried out, including: building a machine learning model using historical stock price data, adding features and providing classification labels (buy/hold/sell) based on target profit and target loss rules within a certain period, training the model using training data and testing data, using the model to classify data that will be used for backtesting, and measuring the performance of the trading strategy applied using a backtesting library using trading metrics, such as total return, win rate, and profit factor [11].

While many international studies have been conducted, there remains a research gap in the context of developing country stock markets, including Indonesia: few studies have systematically compared: 1) the effect of varying lookup period (e.g. 2-10 days), 2) the effect of the number of technical features (1–6 features) and feature selection methods (unique features per issuer vs. uniform features) on 3) actual trading performance evaluated using backtesting metrics such as total return, win rate, and profit factor. This study addresses this gap with an experimental study of the 15 largest capitalized bank stocks on August 31, 2025 on the Indonesia Stock Exchange, to assess the combination of feature engineering and Decision

Tree, Random Forest, and Gradient Boosting algorithms, and compare the results against a buy-and-hold strategy.

This research adopts an experimental methodology to systematically examine how variations in lookup periods, feature dimensionality, and feature selection methods influence machine learning–based stock trading performance using out-of-sample backtesting. This research differs from prior work by adopting a correlation-based, asset-specific feature selection scheme rather than a uniform feature set for all stocks in machine learning–based trading models. The main contributions of this study are summarized as follows: 1) systematic evaluation of the effect of lookup period ranging from 2 days to 10 days and the number of technical features ranging from 1 feature to 7 features on the performance of machine learning-based trading, 2) comparison of two feature selection approaches—features selected per stock using Spearman's correlation compared to a uniform set of features for all stocks. The evaluation was conducted using out-of-sample backtesting analysis (data from January 1 to August 31, 2025) with practical trading metrics, namely total return, win rate, and profit factor, thus making the results relevant for practitioners and researchers who intend to implement machine learning on the Indonesian stock market.

II. Literature Review

A. Machine Learning for Stock Trading Systems

Studies related to stock market prediction and trading systems have developed rapidly using machine learning (ML) algorithms. High and varying volatility among issuers, non-linearity, and changing market dynamics make trading decisions a significant challenge. A systematic review found that studies of ML algorithms in the stock market are classified into supervised learning (regression and classification) and unsupervised learning (clustering). A number of ML algorithms for model building include neural networks, support vector machines, fuzzy theory, deep learning, random forest, and decision trees, as well as hybrid algorithms [12].

For instance, Anwar et al. (2024) reviewed that ML algorithms are capable of identifying stock market trends more accurately than traditional methods. Methods in machine learning, such as the Ensemble method, can be used by both investors and traders to analyze stock market trends. The selection of specific technical features as inputs for the model significantly affects the results of stock market trend predictions [10]. Machine learning models make it possible to combine various features to capture complex and nonlinear patterns in stock market forecasting. Model efficiency may be improved by selecting more powerful features [13].

B. Feature Engineering and Technical Indicators

The key factors in ML model performance are the quality and relevance of features (feature engineering). In the context of the stock market, many studies have explored the use of technical indicators (e.g., moving average, RSI, Aroon, VWMA minus price, slope, volume) as representations of market signals. Each indicator provides a unique perspective, offering additional insights into market dynamics that may not be revealed by daily stock prices. In their study, Fozap used Moving Averages (SMAs and EMAs), Bollinger Bands, Relative Strength Index (RSI), Moving Average Convergence Divergence (MACD), and On-Balance Volume (OBV) as inputs for the ML model they built. These indicators represent momentum, trend, and trading volume [14]. In their study on Dow30 index stocks, Aksehir (2022) used 15 technical features, which were RSI, Williams's % R, WMA, EMA, SMA, HMA, Triple EMA, CCI, CMO, MACD, PPO, ROC, CMFI, DMI, and PSI as inputs for the CNN-TA model used to predict stock trading actions on the following day [15]. A study examined the integration of technical indicators with ML and found that this combination significantly improved accuracy compared to only ML or only technical analysis, especially when market volatility was high [16].

Selecting the optimal technical indicators is an important part of predicting the stock market, but there is currently no consensus on which indicators are the most suitable. Technical indicators are a crucial component of financial forecasting, as they provide a quantitative measure of market dynamics, including price trends, volatility levels, and trading volume. These indicators allow analysts to identify the direction and intensity of stock price movements, and have been widely integrated into machine learning models as a representation of historical price behavior [17]. Research conducted by Mostafavi and Hooman put a number of indicators into categories of momentum, trend, volatility, and volume. From each category, technical indicators that gave the best performance were obtained. Furthermore, research could be conducted for different markets, for the development of hybrid models combining machine learning with traditional technical analysis, and for the effect of time horizons on model performance [18]. Traditional technical indicators may have limitations in their individual predictive value, however when combined with machine learning methods, these indicators have the potential to provide more comprehensive insights into market movement characteristics [19].

C. Ensemble Tree-based Learning in the Context of Trading

Decision tree-based algorithms remain very popular in financial applications due to their interpretability, relative tolerance to different feature scales, and ability to handle non-linear relationships well.

- Decision Tree is a graphical-based decision-making method that uses probability analysis to evaluate the risks and feasibility of projects, depicted as tree branches. This method is intuitive and easy to understand visually. Decision trees can be used as comprehensive classification models for stock prediction and risk assessment [2].
- Random Forest is an ensemble algorithm that combines multiple decision trees, each trained on a randomly selected subset of data and features. The prediction results from all trees are combined through averaging to improve accuracy. This algorithm is effective for high-dimensional data and is able to reduce overfitting by incorporating random elements in the training process. Therefore, Random Forest is often used for large-scale datasets and complex problems [2]. In their study of China's A-share market covering 3,000 companies using 8 years of historical data, Wu (2024) found that

the Random Forest-based feature selection method demonstrated superior performance with higher prediction accuracy compared to traditional approaches [20].

- Gradient Boosting is a boosting method that iteratively improves the errors of previous models and is known to perform well with tabular data. Priel (2024) conducted research to select stocks for value investing in the US stock market by utilizing corporate financial features. Through preliminary research, it was discovered that the Random Forest and GB ML methods consistently yielded higher average precision and recall values compared to Logistic and Deep Learning models [21]. In their study towards articles in Scopus and Web of Science between 2011 and 2022 concerning stock market applications, Htun (2023) discovered that RF and SVM methods are the most popular Machine Learning methods [22].

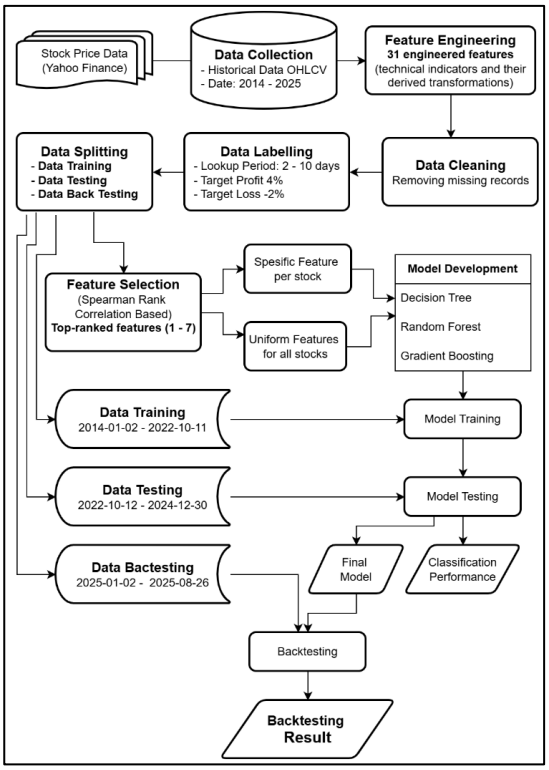

Fig. 1. Research workflow.

From the preceding literature review, it is possible to identify several gaps that remain open: 1) variations in lookup period: many studies use a single or arbitrary horizon, but few systematically test the range of lookup period in the context of ML trading signals. 2) The number and combination of features: although feature engineering has been widely discussed, systematic experiments on "how many features" and "whether features are uniform versus specific to each stock issuer" are still limited. 3) Trading system evaluation (not merely price prediction): many studies focused on price or direction prediction, but few linked prediction results to trading performance (cumulative return, win rate, profit factor) in the out-of-sample period, 4) emerging market context: studies specific to Indonesian stocks or emerging markets remain relatively scarce, hence research on 15 Indonesian bank stocks could provide additional values.

III. Research Methodology

This study aims to analyze the impact of feature engineering on the performance of machine learning-based trading systems for large-cap banking stocks listed on the Indonesia Stock Exchange. The research methodology design consists of data collection, feature construction, model training, and out-of-sample backtesting to comprehensively evaluate model performance, as shown in Fig. 1.

A. Data Collection and Preprocessing

Stock price data was obtained from Yahoo Finance for the top 15 banking stocks by market capitalization in Indonesia, covering the period from January 1, 2014, to August 31, 2025. The data obtained includes Adj Close, Close, High, Low, Open, and Volume prices, as presented in Fig. 2.

```

Fig. 2. Example of BBCA.jk historical data.

The list of the top 15 banks by market capitalization in Indonesia, as of September 1, 2025, is provided in Table I.

TABLE I. List of the Top 15 Bank Stocks in Indonesia

#	*Issuer Code*	*Issuer Name*	*Market Capitalization (millions Rp.)*
1	BBCA.jk	PT. Bank Central Asia	985.976.046
2	BBRI.jk	PT. Bank Rakyat Indonesia	604.720.389
3	BMRI.jk	PT. Bank Mandiri	434.933.185
4	BBNI.jk	PT. Bank Negara Indonesia	162.423.639
5	BRIS.jk	PT. Bank Syariah Indonesia	125.010.400
6	BNLI.jk	PT. Bank Permata	112.885.657
7	BNGA.jk	PT. Bank CIMB Niaga	42.738.850
8	MEGA.jk	PT. Bank Mega	38.627.560
9	BBHI.jk	PT. Allo Bank Indonesia	34.659.828
10	NISP.jk	PT. Bank OCBC NISP	31.320.336

#	Issuer Code	Issuer Name	Market Capitalization (millions Rp.)
11	ARTO.jk	PT. Bank Jago	30.772.086
12	PNBN.jk	PT. Bank Pan Indonesia	27.314.683
13	BINA.jk	PT. Bank Ina Perdana	26.992.768
14	BDMN.jk	PT. Bank Danamon Indonesia	24.336.138
15	BTPN.jk	PT. Bank SMBC Indonesia	22.143.474

The dataset is divided into two main subsets:

- In-sample dataset (2014–2024): used for ML model training and testing. From this time period, 80% of the data was used as the training set and 20% as the testing set.
- Out-of-sample dataset (2025): used for backtesting the model's strategy against market conditions that the model has never observed before.

All data underwent cleaning to remove data that had no value due to the impact of feature calculations, such as the moving average feature for a certain period.

B. Feature Engineering

Feature engineering is performed by adding technical indicators and derivative features that theoretically represent market trends, momentum, and volatility. The list of indicators used in this study consists of commonly used technical indicators and derivative indicators prepared by the authors. The list of indicators used and their descriptions are described in Table II.

TABLE II. LIST OF 31 TECHNICAL INDICATORS USED

Name of Indicator	Description	Formula
apo (Absolute Price Oscillator)	apo attempts to quantify market momentum	APO = absolute(Long Cycle (Slow Moving Avg) - Short Cycle (Fast Moving Average))
aroon_up	to measure how many periods have passed since price has recorded an n-period high	Aroon-Up (14) = ((14 - Days Since 14-day High)/14) x 100
aroon_down	to measure how many periods have passed since price has recorded an n-period low	Aroon-Down (14) = ((14 - Days Since 14-day Low)/14) x 100
aroon_diff	represents the difference between aroon_up and aroon_down	Aroon_diff = aroon_up – aroon_down
aroon_diff_ma5	represents the 5-moving average of aroon_diff	Aroon_diff_ma5 = MA5(aroon_diff)
adx	measuring the amount of movement in a single direction	ADX = 100 times the Exponential Moving Average of the Absolute Value of (+DI - -DI) / (+DI + -DI) DI=Directional Indicator
cci	attempts to identify "overbought" and "oversold" levels relative to a mean.	CCI (20) = (Typical Price - 20 Period SMA of TP) / (.015 x Mean Deviation) Typical Price (TP) = (High + Low + Close)/3
inertia	Inertia is the rvi smoothed by the Least Squares MA.	Inertia = Least Squares Moving Average of Relative Volatility Index
kst	attempts to capture trends using a smoothed indicator of four different smoothed ROCs	KST =(ROCMA1 x 1) + (ROCMA2 x 2) + (ROCMA3 x 3) + (ROCMA4 x 4)
kst_sig	Kst smoothed by n-periode SMA	Kst_sig = n-Period SMA of the KST
kst_diff	represents the difference between kst and kst_sig	Kst_diff=kst – kst_sig
macd_hist	Moving Average Convergence Divergence Histogram. MACD can be used to identify aspects of a security's overall trend.	MACD Line: (12-day EMA - 26-day EMA) Signal Line: 9-day EMA of MACD Line MACD Histogram: MACD Line - Signal Line
momentum	Momentum attempts to quantify speed by using the differences over a bar length	Mom(t,n)=close(t)-close(t-n)
Obv (on balance volume)	obv is used in technical analysis to measure buying and selling pressure.	Obv(t)=obv(t-1)+volume, if price(t)>price(t-1), and Obv(t)=obv(t-1)-volume if price(t)<price(t-1), and obv(t)=obv(t-1) if price doesn't change
ppo	shows the relationship between two exponential moving averages in percentage terms.	PPO=100 x (12-periode EMA – 26-periode EMA)/26-periode EMA
ppo_signal	9-period EMA of PPO	Ppo_signal = 9-period EMA of PPO
rsi	RSI used to attempts to quantify "velocity" and "magnitude" of directional price movements	RSI = 100 – 100/ (1 + RS) RS = Average Gain of n days UP / Average Loss of n days DOWN
ma5_rsi	5-periode moving average of rsi	ma5_rsi = 5-periode moving average of rsi
slope	Calculates a rolling slope.	Slope=coeficient or slope of linear regression line
stoch_slowk_diff_ma5	5-periode moving average of stoch_slowk_diff	stoch_slowk_diff_ma5= 5-periode moving average of stoch_slowk_diff
tsi	attempts to identify short-term swings in trend direction	Tsi=(price change double smoothed/absolute prcie change double smoothed)/100
tsi_signal	Tsi line smoothed by 12-periode EMA	Tsi_signal=12-period EMA of the TSI line.
Volume	Total Volume perdagangan	Volume perdagangan
vwma_minus_price	Computes a weighted average	3-day vwma=(c1.v1+c2.v2+c3.v3

Name of Indicator	*Description*	*Formula*
	using price and volume.	)/ (v1+v2+v3) c=close price v=volume vwma_minus_price = vwma – close price
vwma_minus_price_ma5	5-periode moving average of vwma_minus_price	vwma_minus_price_ma5 = 5-periode moving average of vwma_minus_price
f1	the deviation of the On-Balance Volume (OBV) from its 5-period moving average.	f1=obv – MA5(obv)
f2	the deviation of the Close Price from from its 5-period moving average.	f2=Close – MA5(Close)
f3	represents the difference between rsi line and MA5(rsi)	f3=rsi – MA5(rsi)
f4	the difference between the ppo and ppo signal line	f4 = ppo - ppo signal line
f5	Value of ppo histogram	f5 = ppo histogram
f6	Difference of stoch_slowk and stoch_slowd	Stoch_slowk_diff= stoch_slowk – stoch_slowd

The number of features used in creating the model varied from 1 to 7 depending on the experimental design. Feature selection was based on the Spearman rank correlation value with respect to the target column (return lookup period).

Two approaches were used to evaluate the impact of feature selection:

1) Feature-specific per stock: Each stock has a different combination of features, which are selected based on their best Spearman's correlation.

2) Uniform features across stocks: All stocks use the same combination of features based on the highest aggregate correlation results.

C. Label Construction

The target label is constructed based on buy, hold, and sell signals calculated from price returns during a specific lookup period. The lookup period was varied from 2 days to 10 days to observe the sensitivity of the strategy to the time horizon. Returns were calculated using the Formula (1).

$$R_t = (Close_{t+lookup} - Close_t)/Close_t \quad (1)$$

with $Close_t$ is the closing price on day t.

Labels are constructed based on profit–loss rules:

- Buy, if Rt ≥ profit target (in this study, a value of 4% is used)
- Sell, if Rt ≤ loss target (in this study, a value of -2% is used)
- Hold for values between those two boundaries.

This approach reflects common practice in rule-based signal labeling trading systems.

D. Data Splitting

The data is split into three parts, with the following description.

- Data from January 1, 2014 to December 31, 2024 is used for training and testing data, with 80% of the data allocated for training and 20% for testing.
- Data from January 1, 2025 to August 31, 2025 is used as out-of-sample data to test trading performance through backtesting.

E. Model Development

Three main algorithms are used for trading signal classification:

1) Decision Tree: single tree model using Gini impurity.

2) Random Forest: bagging-based ensemble model, built several independent trees and combined the results for stability. In this study, 100 estimators and max_depth=4 were used.

3) Gradient Boosting: boosting-based ensemble model, training trees sequentially to minimize residual error. In this study, 100 estimators, max_depth=4, and learning_rate=0.1 were used.

For each algorithm, the model is trained separately on each of these combinations:

- Number of features, varied between 1 and 7 specific features per issuer.
- Lookup period, varied between 2 and 10 days.

After the best number of features and the best lookup period were obtained, testing was conducted for 1 to 7 features using a uniform feature approach for all issuers. The resulting model was used to classify buy–hold–sell signals in the out-of-sample (2025) data.

F. Backtesting Evaluation

Backtesting is used to evaluate the performance of strategies generated by the model against real data from 2025. This procedure is performed using the backtesting.py library, which enables portfolio simulation based on model signals.

The steps include:

1) Read the signal of the model prediction results on the out-of-sample data.

2) Implement trading strategy based on the following rules:

- Buy if signal = Buy
- Sell if signal = Sell
- Hold if signal = Hold

3) Calculate trading performance using the following metrics:

- Total return (%)
- Win rate (%)
- Profit factor (ratio of gross profit to gross loss)

4) Compare the results of the ML strategy against the Buy-and-Hold (BH) strategy return as a baseline benchmark.

The entire process was carried out over 15 major bank stocks, and the results were then averaged to obtain the aggregate performance of each algorithm and feature configuration.

Through the employed research design, this study enables a systematic evaluation of the relationship between feature complexity, time horizon coverage, and the effectiveness of machine learning algorithms in formulating sustainable and profitable trading strategies.

IV. Experimental Analysis and Result

This section presents the results of experiments on the implementation of machine learning models in signal-based trading systems (buy, hold, sell), focusing on 15 large-cap banking stocks on the Indonesia Stock Exchange. The evaluation was conducted to examine the effect of variations in the lookup period, the number of features used, and the type of algorithm on system performance, both in terms of signal classification accuracy and financial performance based on backtesting results.

A. Experimental Setup

The experiment was conducted on 15 large-cap banking stocks listed on the IDX. Each stock was tested with the combination of parameters given in Table III.

TABLE III. Variation in Testing Parameter Values

Parameter	*Variations*
Lookup period	2–10 days
Number of features	1–7 features
Algorithms	Decision Tree, Random Forest, Gradient Boosting
Training/validation time period	Jan 1, 2014 – Dec 31, 2024
Backtesting time period	Jan 1, 2025 – Aug 31, 2025
Evaluation	Return, Win Rate, Profit Factor

Two feature selection approaches were applied: 1) stock-specific features based on the highest Spearman correlation, and 2) uniform features for all stocks. Table IV provides list of features having the highest correlation with issuers while using a 3-day lookup period, with the number of features equal to 4.

TABLE IV. List of Selected Features Per Issuer

Issuer	Selected features			
	1	*2*	*3*	*4*
BBCA.	vwma_minus_price_ma5	vwma_minus_price	Volume	aroon_down
BBRI	Volume	vwma_minus_price	vwma_minus_price_ma5	aroon_down
BMRI	vwma_minus_price	vwma_minus_price_ma5	aroon_down	kst_sig
BBNI	Volume	f1	f2	aroon_down
BRIS	adx	Volume	f1	tsi_signal
BNLI	slope	f3	f2	vwma_minus_price_ma5
BNGA	kst_diff	f2	macd_hist	momentum
MEGA	aroon_down	vwma_minus_price	vwma_minus_price_ma5	stoch_slowk_diff_ma5
BBHI	f1	Volume	tsi_signal	rsi
NISP	vwma_minus_price	vwma_minus_price_ma5	aroon_down	cci
ARTO	tsi	tsi_signal	ma5_rsi	rsi
PNBN	Volume	aroon_diff_ma5	aroon_up	aroon_diff
BINA	slope	f2	momentum	macd_hist
BDMN	slope	f2	DeltaRSI	f3
BTPN	aroon_diff_ma5	inertia	vwma_minus_price_ma5	aroon_diff

B. Model Performance on Classification Metrics

Model performance on testing data (in-sample) was evaluated using standard classification metrics. Table V shows the average accuracy of one to seven features for each lookup period. Fig. 3 shown the bar chart displaying accuracy scores using specific features for each stock.

TABLE V. Classification Performance

Lookup Period	Accuracy			
	Decision Tree	*Random Forest*	*G Boosting*	*Average*
2	61%	79%	75%	72%
3	56%	74%	70%	67%
4	52%	69%	65%	62%
5	48%	66%	62%	58%
6	46%	62%	58%	55%
7	44%	60%	55%	53%
8	44%	58%	53%	52%
9	43%	57%	52%	51%
10	42%	55%	49%	49%
Average	49%	64%	60%	58%

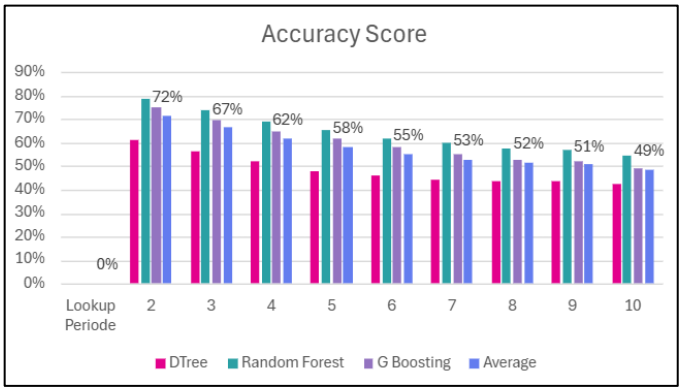

Fig. 3. Accuracy score per lookup period.

From the resulting accuracy chart, it is observed that the model is capable of predicting for relatively short lookup periods. The Random Forest model shows relatively better results, followed by Gradient Boosting, and then Decision Tree. Fig. 4 shows an example of the BBCA.JK stock accuracy matrix for the Random Forest model with a 3-day lookup period and 4 features.

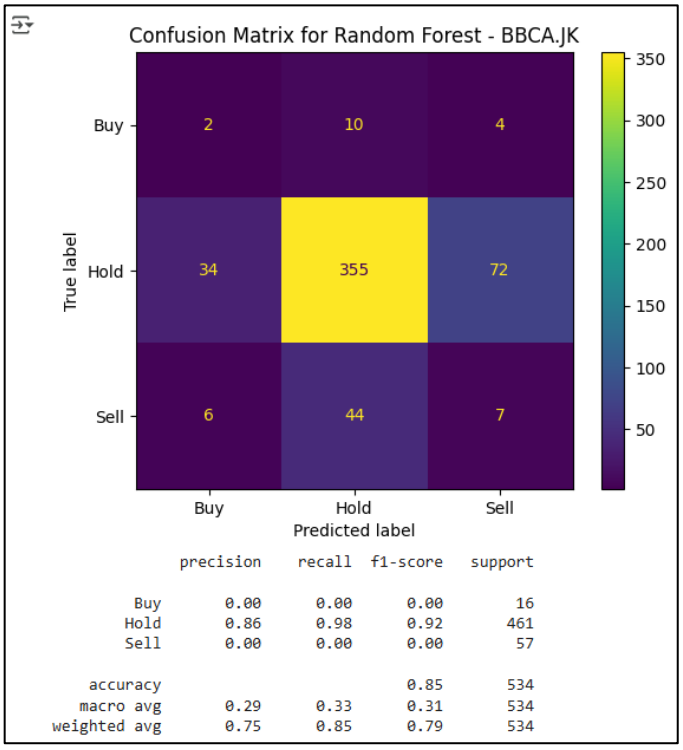

Fig. 4. Confusion matrix for random forest – BBCA.JK.

Fig. 5 exemplifies one of the Random Forest estimator trees for BBCA stock using 5 features and a 4-day lookup period.

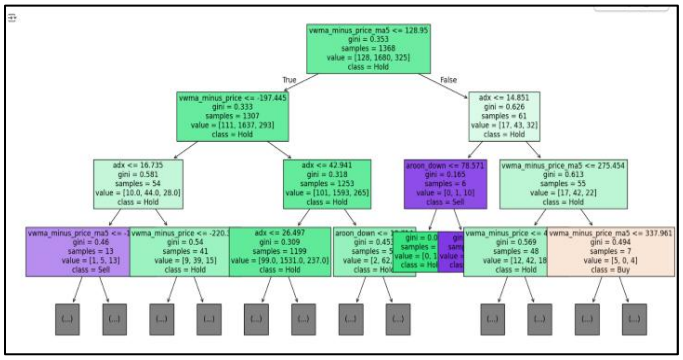

Fig. 5. Tree example of BBCA historical data.

C. Comparative Backtesting Results

The main evaluation was conducted using backtesting on out-of-sample data (January–August 2025 time period). The average aggregate backtesting results from total return calculations when compared to Buy & Hold for 15 stocks are presented in Table VI.

TABLE VI. BACKTESTING RESULTS

Strategy	*Total Return [%]*	*Win Rate [%]*	*Profit Factor*
Buy & Hold	15,13	-	-
Decision Tree	31,50	44,78	1,73
Random Forest	16,62	56,74	4.07
Gradient Boosting	37,44	46,85	3,18

The results show that all ML-based strategies outperform the Buy & Hold strategy in terms of total return.

- Gradient Boosting delivers the highest performance with an average total return of 37.44.3%, a win rate of 46.85%, and a profit factor of 3.18, indicating good profit consistency. While the win rate is not particularly high, the profit factor is quite substantial. This is because the trading system is built using a risk reward ratio of 1:2, with a profit target of 4% and a loss target of -2%.
- Decision Tree ranked second with a total return of 31.50%.
- Random Forest provides a stable but more conservative result (16.62%).

Fig. 6 displays an example of BBCA stock backtesting results using 5 features and a 4-day lookup period. Fig. 7 illustrates the trading curve on the BBCA.jk chart.

D. Lookup Period Analysis

An evaluation was conducted to assess the sensitivity of the strategy to the time horizon based on the lookup period, analyzing variations in the lookup period from 2 days to 10 days. The average total return results presented in Table VII show that the system performed best in the 4-day to 7-day lookup period. The highest achievement was in the 5-day lookup period, which generated an average system return of 77.54%. This shows that a five-day period is the optimal horizon for capturing momentum patterns and price reversals in Indonesian banking stocks. A lookup period that is too short (less than 4 days) produces noisy signals, while a period that is too long (more than 7 days) loses sensitivity to short-term fluctuations.

TABLE VII. TOTAL RETURN PER LOOKUP PERIOD

Lookup Period	Total Return [%]				
	Decision Tree	*Random Forest*	*Gradient Boosting*	*Average*	*Buy& Hold*
2	3,83	2,87	25,99	10,90	16,15
3	26,81	7,93	33,02	22,59	16,06
4	19,76	8,27	47,35	25,13	15,87
5	112,80	21,49	98,32	77,54	14,83
6	35,01	23,27	37,26	31,85	15,06
7	18,91	25,38	36,58	26,96	15,55
8	8,76	23,79	30,13	20,89	14,12
9	31,39	17,70	6,44	18,51	14,78
10	26,20	18,87	21,83	22,30	14,93
Average	31,50	16,62	37,44	28,52	15,26

E. Feature Dimensionality Impact

The ensuing experiment evaluated the impact of the number of features on the performance of the trading system.

TABLE VIII. TOTAL RETURN PER NUMBER OF FEATURES

Number of Features	Total Return [%]			
	Decision Tree	*Random Forest*	*Gradient Boosting*	*Average*
1	10,02	8,98	11,88	10,29
2	29,74	20,31	31,31	27,12
3	38,83	30,82	44,92	38,19
4	89,72	15,77	32,93	46,14
5	23,78	12,75	35,10	23,87
6	15,98	16,15	70,82	34,32
7	12,41	11,56	35,10	19,69
Average	31,50	16,62	37,44	28.52

The results in Table VIII show that unsatisfactory performance occurs when the number of features used is 1 and 7. For the number of features between 2 and 6, ML performance is generally good and stable, giving the total return a range of 23% to 46%, with the highest total return of 46.14% achieved when there were 4 features used.

F. Feature-Specific vs. Uniform Feature Selection

The selection of uniform features for all issuers was also conducted in this study. The aggregation of features with the highest correlation that are frequently used by issuers when using a lookup period of 3, with a total of 4 features, is shown in Fig. 8.

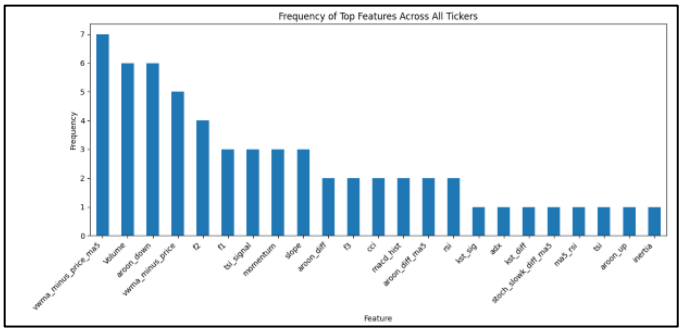

Fig. 8. Frequency of top features across all stocks.

This study uses a 4-day lookup period with uniform features ranging from 1 to 7 features that are most frequently used in aggregate for all issuers. A 4-day lookup period was chosen because its total return value is the median value of all total returns for the lookup period, its returns are relatively more stable, and it has good accuracy. The list of uniform features that are most frequently selected in aggregate for each number of features is provided in Table IX.

TABLE IX. LIST OF UNIFORM FEATURES PER NUMBER OF FEATURES

Number of features	*Uniform Features*
1	Volume
2	Volume, vwma_minus_price
3	Volume, vwma_minus_price, vwma_minus_price_ma5
4	Volume, vwma_minus_price, vwma_minus_price_ma5, aroon_down
5	Volume, vwma_minus_price, vwma_minus_price_ma5, aroon_down, f1
6	Volume, vwma_minus_price, vwma_minus_price_ma5, aroon_down, f1, aroon_up
7	Volume, vwma_minus_price, vwma_minus_price_ma5, aroon_down, f1, aroon_up, kst_sig

The results of accuracy research using uniform features compared to specific features with a 4-day lookup period are provided in Table X. The results of backtesting using uniform features are provided in Table XI.

TABLE X. CLASSIFICATION PERFORMANCE FOR UNIFORM FEATURES

Number of features	Accuracy (Lookup period = 4 days)				
	Decision Tree	*Random Forest*	*Gradient Boosting*	*Average for Uniform Features*	*Average for Specific Features*
1	0.53	0.70	0.65	0.63	0.65
2	0.51	0.69	0.65	0.62	0.62
3	0.51	0.69	0.65	0.62	0.61
4	0.50	0.68	0.64	0.61	0.61
5	0.50	0.68	0.64	0.61	0.61
6	0.51	0.69	0.63	0.61	0.62
7	0.51	0.69	0.64	0.61	0.62
Average	0.51	0.69	0.64	0.61	0.62

TABLE XI. TOTAL RETURN FOR UNIFORM FEATURES

Number of features	Total Return [%] (Lookup period = 4 days)				
	Decision Tree	*Random Forest*	*Gradient Boosting*	*Average for Uniform Features*	*Average for Specific Features*
1	17.55	-4.87	10.31	7.66	10.56
2	18.71	6.95	10.04	11.90	36.84
3	36.76	-1.46	21.98	19.09	2.61
4	4.74	1.06	56.38	20.72	39.49
5	16.94	-0.58	12.73	9.70	35.48
6	79.54	-7.70	76.91	49.58	39.63
7	11.11	4.34	50.26	21.90	11.28
Average	26.48	-0.32	34.09	20.08	25.13

The average return of specific features was 25.13%, which was 5.05% higher than the average return of uniform features, which was 20.08%. These results suggest that selecting specific features for each stock (based on the best Spearman correlation) produces higher performance than using uniform features.

These findings indicate that the characteristics of each stock, such as volatility, trend, and momentum, require a specific combination of features for each stock in order for the model to capture relevant stock patterns. The feature-specific approach per stock has proven to be more adaptive to the distinct characteristics of different stocks.

G. Discussion

The experiment results confirmed a number of important findings, as follows:

- The feature engineering and feature selection processes play a crucial role in determining the success of machine learning (ML) models in the context of stock trading.
- A lookup period of two to four days is sufficient to capture price movements effectively, as reflected in the accuracy rates obtained by the model.
- In terms of prediction accuracy, the Random Forest algorithm shows superior performance. However, in backtesting against out-of-sample data, the Gradient Boosting algorithm produces higher total returns.
- The use of specific feature selection for each issuer has proven to improve signal accuracy and overall portfolio performance.

From a practical perspective, the developed ML-based trading system shows significant potential as a decision support tool for active investors in the Indonesian capital market, particularly in the banking sector, which is characterized by medium volatility and high trading volume. The following experiment evaluates the impact of the number of features on trading system performance. This study does not consider transaction costs and only tests within a predetermined time frame. Therefore, further testing is needed to anticipate changes in market direction.

V. Conclusion and Future Work

A. Conclusion

This study has developed and evaluated a machine learning-based stock trading system using three main algorithms, specifically Decision Tree, Random Forest, and Gradient Boosting. Through conducting experiments on 15 large capitalization banking stocks on the Indonesia Stock Exchange during the period of 2014–2025, this study highlights the importance of feature engineering, the number of features, and the lookup period in affecting the performance of trading strategies.

The results showed that the combination of feature engineering techniques and tree-based ensemble algorithms consistently improves system performance compared to the Buy & Hold strategy. Out of the three algorithms tested, Gradient Boosting showed the best performance with an average total return of 37.44%, outperforming Decision Tree (31.50%), Random Forest (16.62%), and Buy & Hold (15.26%). These findings indicate the superiority of the boosting approach in capturing stock price movement patterns in emerging markets.

In addition, a lookup period of two to four days was able to identify price patterns. A feature selection approach tailored specifically to each stock—based on the highest Spearman correlation—proved to be more effective than a uniform feature approach. This confirms the importance of an adaptive strategy in selecting relevant features to capture the unique characteristics of each stock.

Collectively, this study provides an essential contribution to the AI for Trading literature, particularly in the context of emerging markets. The empirical results suggest that correlation-based feature selection enhances the robustness, adaptability, and interpretability of automated trading systems, supporting their use as effective decision-making tools for active investors.

B. Limitations and Future Work

While the results are substantial, this study has several limitations:

- It focused solely on the banking sector, therefore, generalizations to other sectors require further testing.
- It does not incorporate fundamental macroeconomic factors such as interest rates or inflation, which can affect stock price movements.
- The model has not been evaluated under extreme market conditions, i.e., crisis or periods of extreme volatility.

These limitations provide opportunities for expansion in future research.

Acknowledgment

We would like to express our gratitude to the Faculty of Information Technology at Universitas Kristen Duta Wacana for supporting the authors through funding and research facilities, thus allowing the research to be conducted completely.

***Abstract*—The primary objective of this study is to identify the priority strategies required for banks to achieve their sustainable growth targets and to develop a new fuzzy multi-criteria decision-making model sensitive to uncertainty conditions. The model proposed in this study is designed based on the integration of Fermatean Fuzzy LOPCOW–EDAS. In the first stage, the criteria and strategic alternatives affecting sustainable growth were identified through a literature review. The LOPCOW method was then used to objectively calculate the criteria's importance weights. The prioritization of strategic alternatives was then performed using the EDAS method. To more accurately model the uncertainties in expert judgments, the opinions of ten experts were converted to the Fermatean fuzzy numbers and analyzed. The use of Fermatean fuzzy sets offers greater expressive power and increases decision reliability compared to traditional fuzzy and Pythagorean approaches. The LOPCOW method objectively evaluates the information density of the criteria by using logarithmic percentage change, while the EDAS method reduces the impact of outliers by considering the distance of the alternatives from the mean solution, producing a more stable ranking. The findings indicate that the "digital green banking practices" criterion is the most critical element for sustainable growth. Furthermore, the "Digitalization and innovation capability" strategy was determined to be the most important alternative. This result demonstrates that sustainable growth in the banking sector can be achieved through the integration of digital technologies and environmentally friendly practices.**

Keywords*—*Fermatean fuzzy sets; multi-criteria decision-making; sustainable banking; digital transformation; decision support systems

I. Introduction

Sustainable growth in the banking sector is a key concern for regulators, investors, and bank management, especially in the face of global challenges such as climate change, the digital economy, and market uncertainty [1]. Banking is a financial intermediary that plays an important role in maintaining economic stability. Therefore, banks, being business entities, must focus on their financial performance to achieve sustainable growth [2]. Sustainable growth is an indicator of banking sustainability [3]. The concept of sustainable growth in the banking context encompasses not only consistent profit growth but also anticipates financial risk, ensures capital adequacy, promotes regulatory compliance, fosters good corporate governance, and addresses the social and environmental impacts of banking activities [4].

The issue of sustainable growth in banking aligns with Sustainable Development Goal 8 (SDG-8), specifically Decent Work and Economic Growth. Banking plays a crucial role in driving economic growth by serving as a financial intermediary [5]. It has the potential to create decent jobs by distributing funds to support business activities in various fields [6]. Sustainable growth measurement in this study refers to the maximum internal growth that can be achieved by utilizing retained earnings to fund the expansion of banking assets [7]. Meanwhile, measuring sustainable growth in the banking sector is not only relevant from a financial perspective but also promotes an inclusive and responsible financial system. Therefore, this study aims to detect the predictors of sustainable banking growth, which consist of financial factors, namely credit risk and capital adequacy, and non-financial factors, namely governance, audit quality, and green banking.

Achieving sustainable growth in the banking sector is directly related not only to the continuity of profitability indicators but also to the strategic management of resources. In this context, developing prioritized strategies for effective budget management is a critical requirement for banks. Budget allocations made without establishing sustainable growth strategies can lead to inefficient resource use, increased operational costs, and weakened long-term financial stability. Effective budget management forms the basis of sustainable growth not only in terms of financial indicators but also in dimensions such as corporate governance, risk management, audit quality, and environmental responsibility. However, a review of the existing literature reveals that studies focusing on the prioritized strategy-setting processes for achieving sustainable growth in banks are quite limited. Most studies address the concept of sustainable growth through the lens of financial performance or environmental sustainability, but they fail to provide an analytical framework for determining which strategies should be prioritized. This creates a significant research gap in the literature and prevents banks from systematically structuring their sustainable growth policies. Failure to define strategic priorities hinders decision-makers'

ability to achieve long-term growth targets and, by directing resources in the wrong areas, leads to productivity losses, capital shortages, and increased operational risks. Therefore, to implement sustainable growth at the corporate level, the need for analytical models that enable banks to identify their strategic priorities from a multi-criterion, holistic perspective is greater than ever. Such a prioritization approach will not only increase banks' internal efficiency and budget management effectiveness but will also significantly contribute to the rational and measurable achievement of sectoral sustainability goals.

The aim of this study is to develop a holistic and analytical framework for determining priority strategies for achieving sustainable growth in the banking sector. While numerous studies on sustainable growth exist in the literature, a multi-criteria analysis approach is lacking to determine which strategies banks should prioritize to achieve this growth. This constitutes the primary motivation for this research. To address this research gap, the study proposes a new fuzzy multi-criteria decision-making model that considers both financial and non-financial performance indicators of banks. The developed model is based on the Fermatean Fuzzy Set approach to more reliably analyze uncertain and subjective expert judgments. The research methodological process consists of four stages. In the first stage, a comprehensive literature review is conducted to identify the criteria affecting banks' sustainable growth strategies and potential strategy alternatives. In the second stage, the importance of these criteria is objectively weighted using the LOPCOW method. In the third stage, the priority ranking of strategic alternatives is performed using the EDAS method. In the fourth stage, to enhance the model's ability to reflect uncertainty, the judgments obtained from 10 experts are converted into the Fermatean fuzzy numbers and incorporated into the analysis process. Thus, a hybrid decision model that evaluates both quantitative and qualitative factors is developed. Within this framework, the study seeks to answer the following research questions: 1) Which strategic factors should be prioritized for banks to achieve sustainable growth? 2) What is the hierarchical priority relationship between the importance levels of these strategies? 3) What analytical advantage does the Fermatean fuzzy LOPCOW–EDAS model, integrated with expert opinions, provide in determining sustainable growth strategies? The answers to these research questions aim to provide a scientific basis for banks' strategic decision-making processes regarding budget management, resource allocation, and long-term growth policies.

This study develops an original decision model based on the integration of Fermatean fuzzy LOPCOW–EDAS to prioritize banks' sustainable growth strategies, thus providing both a new methodological approach and an analytical contribution to the literature from a strategic management perspective. The decision-making model proposed in this study offers several methodological and analytical advantages over existing multi-criteria decision-making approaches. 1) First, the use of Fermatean fuzzy sets in the model is a significant innovation. While traditional fuzzy sets (Zadeh-type), intuitionistic fuzzy sets (IFS), and Pythagorean fuzzy sets can express expert judgments under uncertainty within certain limits, Fermatean fuzzy sets expand these limits, allowing greater flexibility in the sum of membership and opposing membership degrees. This feature allows for more realistic modeling of the high uncertainty and conflicting assessments among expert opinions frequently encountered in financial decision-making environments. Furthermore, the Fermatean approach more robustly represents experts' hesitation levels, increasing decision-making reliability and model explanatory power in multidimensional and highly uncertain contexts such as sustainable growth strategies. 2) The LOPCOW method used in this study outperforms other techniques in the literature in determining criteria importance weights. Methods such as AHP, Entropy, CRITIC, or SWARA either rely on subjective expert judgments or fail to account for variance among criteria. In contrast, LOPCOW objectively assesses the discriminatory power of each criterion by measuring the information density of criteria with a mathematical structure based on logarithmic percentage changes. This enables a more balanced weighting of multidimensional financial and non-financial criteria affecting banks' sustainable growth strategies. Thus, the model both reduces reliance on subjective evaluations and provides a significant advantage in terms of objectivity and computability by determining criteria importance based on data. 3) The EDAS (Evaluation Based on Distance from Average Solution) method used to rank strategy alternatives also provides significant advantages to the model. While methods frequently used in the literature, such as TOPSIS, VIKOR, COPRAS, or MARCOS generally make comparisons based on ideal or anti-ideal solutions, the EDAS method produces a more balanced ranking by considering the positive and negative distances of each alternative from the average solution. This approach reduces the influence of outliers, protects decision results from oversensitivity, and enables more stable strategic priorities. Furthermore, when used with Fermatean fuzzy data, the EDAS method can handle expert assessments containing uncertainty with greater statistical consistency, thereby increasing both the robustness and decision accuracy of the model. In these respects, the proposed model distinguishes itself significantly from existing models in the literature by providing both methodological depth and analytical flexibility in prioritizing sustainable growth strategies.

The remainder of the study is as follows: Section II evaluates the missing part in the literature. Section III explains the steps in the proposed methodology. Section IV highlights the main analysis results. Section V consists of the concluding remarks.

II. Literature Review

Stakeholder theory supports banks in enhancing risk management through the active participation of various groups, including customers, employees, communities, and regulators. By considering the perspectives of various parties, banks can detect and manage risks, as well as implement green banking practices [8]. By involving stakeholders, banks can promote sustainable growth that provides value to all stakeholders [9]. Financial factors are related to credit risk and capital adequacy. Credit risk is the risk of loss that arises when a borrower is unable to meet its payment obligations as agreed upon with the bank, the lender [10]. Credit risk is proxied by non-performing loans (NPL), as stipulated by the Financial Services Authority of Indonesia in Regulation No. 15/POJK.03/2017, Article 3, paragraph d, which states that NPL must not exceed 5% of total loans. Meanwhile, banks that maintain sustainable growth also

need to pay attention to capital adequacy to avoid disrupting banking operations. The capital adequacy ratio (CAR) is a ratio used to assess a bank's ability to absorb potential losses arising from credit, market, or operational risks. The minimum CAR that banks must meet, according to Regulation of the Financial Services Authority No. 11/POJK.03/2016 on the Obligation to Provide Minimum Capital for Commercial Banks, ranges from 10% to 14%.

Non-performing loans (NPLs) are a component of financial factors. NPLs represent credit risk, where debtors fail to meet their obligations or default on payments [11]. An NPL ratio exceeding 5% indicates poor banking performance, which can lead to a decline in bank liquidity, disrupt the efficiency of banking operations, increase credit risk [12], and reduce investor confidence [13]. The study's results indicate that NPLs, or non-performing loans, can limit banks' capacity to invest in sustainable and environmentally friendly practices [14]. Banks require adequate capital to conduct their business activities. Regulation of the Financial Services Authority number 11/POJK.03/2016 concerning minimum capital requirements for commercial banks stipulates that the Capital Adequacy Ratio (CAR) for commercial banks in Indonesia is 10%-14%. Banks are considered sufficiently healthy to bear the risks from their lending and investment activities [15]. The Capital Adequacy Ratio (CAR) is used to assess the financial condition of banks, particularly in evaluating the extent to which banks can bear losses and risks [16], ensuring their operational activities and sustainability are maintained [17].

Non-financial factors include governance, audit quality, and green banking [18]. Banking governance refers to the process of control and direction exercised by the board of directors and senior management [19]. This process involves establishing strategic direction, overseeing daily operations, and fulfilling responsibilities to shareholders and other key stakeholders [20]. In addition to organizational structure and decision-making processes, banking governance also plays an important role in managing credit risk and maintaining the quality of loan portfolios to sustain banking operations [21]. A governance performance score measures governance as part of the environmental and social governance score, which includes: 1) board structure, 2) ethics and compliance, 3) transparency and reporting, and 4) shareholder rights and risk management. Meanwhile, to guarantee the quality of reports to stakeholders, qualified auditors are required. Governance will increase stakeholder confidence [22]. Stakeholder confidence, as evidenced by financial support for banking entities, can enable banks to operate efficiently, thereby ensuring business continuity and growth. Meanwhile, the role of banking in improving climate change is reflected through the disclosure of green banking [23]. Banks have a responsibility to finance green businesses, and banks themselves also need to demonstrate their internal commitment to green business through the Green Banking Disclosure Index (GBDI). The total GBDI is 21 items [24]. GBDI consists of: 1) green products; banks' efforts to create environmentally friendly financial services through energy efficiency, 2) green operations; related to environmentally friendly banking operations, 3) green customers; banks' efforts to educate customers to care about the environment, and 4) green policies; banks' efforts to implement environmentally friendly policies within the bank.

Governance and sustainable growth in banking entities refer to the principles and processes used to direct and control the activities of a bank, ensuring transparency, accountability, and compliance with applicable regulations. The implementation of governance principles and mechanisms can enhance corporate performance and consistency in governance, ultimately leading to sustainable growth in the banking sector in the long term [25]. Audit quality refers to the level of conformity between audit implementation and the professional standards of public accountants, resulting in findings and opinions that are credible, impartial, and reliable to stakeholders. Audit quality can be measured based on the auditor's industry specialization [26]. An auditor who is proficient in a particular industry will have audit experience that can enhance their audit competence when performing their duties [27]. A quality audit encourages companies to present transparent financial reports and improve long-term performance growth. Green banking is a banking approach that supports environmental sustainability in both daily operations and financing. The primary objective of green banking is to mitigate the adverse environmental impact of banking activities, both directly and indirectly, such as financing projects that support environmental conservation [28]. The results of the study indicate that green banking disclosure encourages companies to improve their long-term financial performance, as reflected in sustainability growth.

III. Methodology

This section relates to the definition of methodology. This methodology is a hybrid model with LOPCOW-based EDAS with Fermatean fuzzy sets.

A. Fermatean Fuzzy Sets

A FFS $(\tilde{F})$ is described with Eq. (1) [29]:

$$\tilde{F} = \{s, (\mu_{\tilde{F}}(s), \vartheta_{\tilde{F}}(s)) : s \in D\} \quad (1)$$

where, μ and ϑ are the membership and non-membership degrees between zero and one. D is the universe of discourse. These degrees meet the condition in Eq. (2):

$$0 \leq \mu_{\tilde{F}}^3(s) + \vartheta_{\tilde{F}}(s) \leq 1 \quad (2)$$

Assume that $\tilde{F}$ and $\tilde{G}$ are two Fermatean fuzzy sets. Then, some arithmetic operations are established with Eq. (3) to Eq. (6):

$$\tilde{F} + \tilde{G} = \left(\sqrt[3]{\mu_{\tilde{F}}^3 + \mu_{\tilde{G}}^3 - \mu_{\tilde{F}}^3 \mu_{\tilde{G}}^3}, \vartheta_{\tilde{F}}^3 \vartheta_{\tilde{G}}^3 \right) \quad (3)$$

$$\tilde{F} \times \tilde{G} = \left(\mu_{\tilde{F}}^3 \mu_{\tilde{G}}^3, \sqrt[3]{\vartheta_{\tilde{F}}^3 + \vartheta_{\tilde{G}}^3 - \vartheta_{\tilde{F}}^3 \vartheta_{\tilde{G}}^3} \right) \quad (4)$$

$$\lambda \tilde{F} = \left(\sqrt[3]{1 - \left(1 - \mu_{\tilde{F}}^3\right)^{\lambda}}, \vartheta_{\tilde{F}}^{\lambda} \right) \quad (5)$$

$$\tilde{F}^{\lambda} = \left(\mu_{\tilde{F}}^{\lambda}, \sqrt[3]{1 - \left(1 - \vartheta_{\tilde{F}}^3\right)^{\lambda}} \right) \quad (6)$$

The score and accuracy functions are estimated using Eq. (7) and Eq. (8), respectively.

$$SF(\tilde{F}) = \mu_{\tilde{F}}^3 - \vartheta_{\tilde{F}}^3 \quad (7)$$

$$AF(\tilde{F}) = \mu_{\tilde{F}}^3 + \vartheta_{\tilde{F}}^3 \quad (8)$$

B. LOPCOW-based EDAS with FF

LOPCOW is a weighting model. With this model, objective priority values of criteria are obtained. EDAS is a ranking model. EDAS ranks the alternatives based on positive and negative distances from the mean. The computation steps are detailed below.

Firstly, m alternatives and n criteria are determined. Next, assessments are collected from e experts. These assessments are transformed into Fermatean fuzzy numbers. Thus, the assessment matrix for k^{th} expert formed in Eq. (9) is created [30].

$$\tilde{A}^k = \left[\tilde{a}_{ij}^k\right]_{m\times n} \quad (9)$$

Afterwards, a decision matrix is constructed using Eq. (10) and Eq. (11):

$$\tilde{X} = \left[\tilde{x}_{ij}\right]_{m\times n} \quad (10)$$

$$\tilde{x}_{ij} = \frac{1}{e}\sum_{k=1}^{e} \tilde{a}_{ij}^k \quad (11)$$

Next, the normalized values are estimated with the help of Eq. (12) and Eq. (13):

$$r_{ij} = \frac{SF(\tilde{x}_{ij}) - \min_i SF(\tilde{x}_{ij})}{\max_i SF(\tilde{x}_{ij}) - \min_i SF(\tilde{x}_{ij})}; for\ B \quad (12)$$

$$r_{ij} = \frac{\max_i SF(\tilde{x}_{ij}) - SF(\tilde{x}_{ij})}{\max_i SF(\tilde{x}_{ij}) - \min_i SF(\tilde{x}_{ij})}; for\ C \quad (13)$$

where, B and C show the beneficial and cost criterion. SF is the score function defined in Eq. (7). Later, percentage values are computed via Eq. (14):

$$pv_j = \left| \ln\left(\frac{\sqrt{\frac{\sum_{i=1}^m r_{ij}^2}{m}}}{\sigma_j} \right) 100 \right| \quad (14)$$

where, σ is the standard deviation of the criteria. Then, the weights of the criteria are defined by Eq. (15):

$$w_j = \frac{pv_j}{\sum_{t=1}^n pv_t} \quad (15)$$

After defining the criteria weights, a normalized matrix is obtained with Eq. (16) and Eq. (17):

$$\tilde{h}_{ij} = \left(\mu_{\tilde{h}_{ij}}, \vartheta_{\tilde{h}_{ij}}\right) = \left(\mu_{\tilde{x}_{ij}}, \vartheta_{\tilde{x}_{ij}}\right); for\ B \quad (16)$$

$$\tilde{h}_{ij} = \left(\mu_{\tilde{h}_{ij}}, \vartheta_{\tilde{h}_{ij}}\right) = \left(\vartheta_{\tilde{x}_{ij}}, \mu_{\tilde{x}_{ij}}\right); for\ C \quad (17)$$

Afterwards, the average solutions are established using Eq. (18):

$$\widetilde{AV}_j = \left(\sqrt[3]{1 - \prod_{i=1}^m \left(1 - \mu_{\tilde{h}_{ij}}^3\right)^{\frac{1}{m}}}, \prod_{i=1}^m \vartheta_{\tilde{h}_{ij}}^{\frac{1}{m}} \right) \quad (18)$$

Next, the positive distance from average and the negative distance from average are calculated via Eq. (19) and Eq. (20), respectively.

$$PDA_{ij} = \frac{\max\left(0, SF(\tilde{h}_{ij}) - SF(\widetilde{AV}_j)\right)}{SF(\widetilde{AV}_j)} \quad (19)$$

$$NDA_{ij} = \frac{\max\left(0, SF(\widetilde{AV}_j) - SF(\tilde{h}_{ij})\right)}{SF(\widetilde{AV}_j)} \quad (20)$$

PDA and NDA are aggregated with the help of Eq. (21) and Eq. (22):

$$SP_i = \sum_{j=1}^n w_j PDA_{ij} \quad (21)$$

$$SN_i = \sum_{j=1}^n w_j NDA_{ij} \quad (22)$$

SP and SN are normalized using Eq. (23) and Eq. (24):

$$NSP_i = \frac{SP_i}{\max SP_i} \quad (23)$$

$$NSN_i = 1 - \frac{SN_i}{\max SN_i} \quad (24)$$

Finally, the final assessment values are defined by Eq. (25):

$$FA_i = \frac{NSP_i + NSN_i}{2} \quad (25)$$

IV. ANALYSIS

This section relates to the results of the methodology described in the previous section.

A. Defining the Alternatives and Criteria

Six strategies are selected as alternatives. Similarly, the criteria are defined. The first criterion is financial resilience (CAR, NPL, profit stability). This criteria's short code is FNNR for analysis. The other strategies are financial resilience (CAR, NPL, profit stability) with ENVR, governance quality (ESG-G Scores) with GVRQ, audit reliability with AUDR, digitalization and innovation capability with DINC, and stakeholder engagement and social contribution with STSC. The strategies are shown in Table I.

TABLE I. STRATEGIES LIST

Definition	Short Code
Sustainable financing policies that reduce credit risk	SFPRCR
Green investments that strengthen capital adequacy	GISCA
Improving corporate governance and transparency standards	ICGTS
Improving the quality of independent auditing and reporting	IQIAR
Expanding digital green banking practices	EDGBP
Stakeholder engagement and sustainable financial education programs	SESFEP

B. Weighting Criteria

After defining the strategies and criteria, assessments are collected from ten experts with linguistic scales in Table II.

TABLE II. LINGUISTIC SCALES

	Membership	Non-Membership
VE	.9	.2
E	.8	.3
ME	.7	.5
ME	.6	.6
MU	.5	.7
U	.3	.8
VU	.2	.9

Using linguistic scales, ten assessment matrices are obtained. These matrices have the form in Eq. (9). After that, the decision matrix is constructed using Eq. (10 and Eq. (11). The decision matrix is illustrated in Table III.

TABLE III. DECISION MATRIX

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
SFPRCR	(.468,.741)	(.517,.693)	(.552,.661)	(.576,.639)	(.468,.741)	(.498,.75)
GISCA	(.594,.637)	(.576,.67)	(.431,.757)	(.517,.701)	(.585,.653)	(.436,.77)
ICGTS	(.55,.669)	(.586,.616)	(.538,.707)	(.561,.652)	(.525,.692)	(.568,.648)
IQIAR	(.53,.675)	(.532,.668)	(.399,.78)	(.585,.653)	(.555,.653)	(.489,.716)
EDGBP	(.813,.31)	(.841,.297)	(.836,.283)	(.836,.313)	(.825,.297)	(.825,.326)
SESFEP	(.448,.78)	(.559,.66)	(.436,.76)	(.55,.669)	(.623,.602)	(.543,.71)

All criteria are beneficial. For this reason, Eq. (12) is used for estimating the normalized values. The normalized values are shared in Table IV.

TABLE IV. NORMALIZED VALUES

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
SFPRCR	.090	.000	.299	.180	.000	.084
GISCA	.377	.111	.059	.000	.269	.000
ICGTS	.283	.213	.220	.139	.141	.317
IQIAR	.254	.062	.000	.168	.235	.136
EDGBP	1.000	1.000	1.000	1.000	1.000	1.000
SESFEP	.000	.107	.058	.097	.392	.195

Later, percentage values are computed via Eq. (14). Then, the weights of criteria are defined by Eq. (15). The results are summarized in Table V.

TABLE V. PV AND WEIGHTS OF CRITERIA

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
PV	36.394	21.2768	24.6879	24.2172	37.9157	28.0615
W	.211	.123	.143	.140	.220	.163

According to weights of criteria in Table V, the most important criterion is digitalization and innovation capability with .220.

C. Ranking Strategies

Since all criteria are of the useful type, Eq. (16) is used. Therefore, the normalized matrix is the same as the decision matrix in Table III. Next, the average solutions are established using Eq. (18). The average solutions are displayed in Table VI.

TABLE VI. AVERAGE SOLUTIONS

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
AV	(.611,.61)	(.642,.578)	(.601,.624)	(.641,.585)	(.635,.583)	(.61,.629)

Next, the positive distance from average and negative distance from average are calculated via Eq. (19) and Eq. (20), respectively. The PDA matrix is expressed in Table VII.

TABLE VII. PDA

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
SFPRCR	.000	.000	.000	.000	.000	.000
GISCA	.000	.000	.000	.000	.000	.000
ICGTS	.000	.000	.000	.000	.000	.000
IQIAR	.000	.000	.000	.000	.000	.000
EDGBP	578.179	6.974	-22.225	7.646	8.147	-24.798
SESFEP	.000	.000	.000	.000	.000	.000

Similarly, the NDA matrix is presented in Table VIII.

TABLE VIII. NDA

	FNNR	ENVR	GVRQ	AUDR	DINC	STSC
SFPRCR	348.581	3.724	-3.548	2.091	6.207	-12.448
GISCA	56.974	2.533	-12.381	4.223	2.340	-15.875
ICGTS	151.927	1.447	-6.452	2.579	4.180	-2.993
IQIAR	182.393	3.056	-14.550	2.224	2.837	-1.336
EDGBP	.000	.000	.000	.000	.000	.000
SESFEP	44.770	2.576	-12.430	3.066	.586	-7.956

PDA and NDA are aggregated with the help of Eq. (21) and Eq. (22). SP and SN are normalized using Eq. (23) and Eq. (24). The results are summarized in Table IX.

TABLE IX. SP, SN, NSP, NSN

	SP	SN	NSP	NSN
SFPRCR	.000	73.105	.000	.195
GISCA	.000	9.083	.000	.900
ICGTS	.000	32.093	.000	.646
IQIAR	.000	36.019	.000	.603
EDGBP	118.457	.000	1.000	1.000
SESFEP	.000	90.769	.000	.000

Finally, the final assessment values are defined by Eq. (25). FA values are shown in Table X.

TABLE X. FA VALUES

	FA
SFPRCR	.097
GISCA	.450
ICGTS	.323
IQIAR	.302
EDGBP	1.000
SESFEP	.000

According to FA values in Table X, the most suitable alternative is expanding digital green banking practices with 1.

V. CONCLUSION

The aim of this study is to develop a holistic and analytical decision-making model for determining priority strategies for achieving sustainable growth in the banking sector. In this context, a novel LOPCOW–EDAS integration based on Fermatean fuzzy sets is proposed. The model analyzes the qualitative assessments obtained from 10 experts by converting them into Fermatean fuzzy numbers to more realistically represent uncertainty and differences in expert judgments. The findings reveal that the "dissemination of digital green banking practices" criterion is the most critical factor, while the "digitalization and innovation capability" strategy is the top priority alternative. This result demonstrates that digital transformation and environmental sustainability elements must be managed in an integrated manner to achieve sustainable growth targets. The study contributes to the literature both methodologically and practically. From a methodological perspective, it fills a significant gap in the literature by proposing the Fermatean fuzzy LOPCOW–EDAS integration, which has not been used before in prioritizing sustainable growth strategies. From a practical perspective, it presents a data-driven decision support framework that will enable banks to more rationally structure their sustainable growth policies.

However, the study has some theoretical and methodological limitations. While the criteria and strategies used in the model are theoretically based on literature and expert opinions, their validity across different countries, time periods, or regulatory frameworks may be limited. Furthermore, because the concept of sustainable growth is multidimensional, some social and institutional factors were not included in the model. Methodologically, the most significant limitation of the proposed model is the limited number of experts and the limited evaluation range; this may partially reduce the generalizability of the results. To address these limitations, future studies could collect data from a larger group of experts from different countries, implement dynamic weightings in the model using AI-based learning algorithms (e.g., ANFIS, GA, or deep learning), and test the model's robustness by comparing the results with different types of fuzzy logic (e.g., spherical or neutrosophic fuzzy sets). This could both increase decision accuracy and broaden the model's applicability to different sectors.

***Abstract*—Recent technological developments in the field of Natural Language Processing (NLP), notably due to Transformer architectures and language models, have made it possible to tackle aspects that were previously inaccessible with traditional tools. The present study addresses the issue of predicting legal case durations using Arabic judicial data. For this task, hybrid systems based on language models were implemented. The Arabic_LegalBERT model, derived from AraBERT and specialized through additional pre-training on an Arabic legal corpus, was proposed to generate representations that were integrated into the downstream steps of the approach. Two methods were adopted for predicting the processing time of a new case: The first followed a framework combining automatic classification with statistical correspondence, while the second relied on cosine similarity combined with empirical statistics. The results obtained with the classification approach are particularly promising, with a small improvement for the system based on the specialized model. For the similarity-based approach, the results are also promising, with a clear distinction observed when evaluating each type individually, indicating that types with a higher number of cases generally perform better than those with fewer cases.**

Keywords*—Language model; judicial case durations; legal domain; Arabic legal corpus

I. Introduction

The application of NLP and machine learning tools in the legal field is a rapidly growing area of research. Technological advances have enabled researchers to better leverage the large volume of legal documents and address various tasks specific to this domain using advanced methods. These include transformers, which have revolutionized traditional NLP approaches thanks to the attention mechanism [1]. Their architecture has served as the basis for more advanced language models capable of specializing in particular domains and specific languages. This specialization can be achieved by training a language model from scratch, thereby treating the domain-specific language as a language in its own right [2] [3], or by leveraging pre-trained general models and adapting them to the target domain through additional pre-training on specialized corpora.

The present study addresses the prediction of judicial case durations, a task specific to the legal domain, whose main impact lies in the organizational optimization it can provide within the judicial system. Furthermore, the study is based on legal data in Arabic, a language that is both rich and complex, and that exhibits notable differences compared to Western languages, requiring the use of tools adapted to its specific characteristics. Despite its importance, this issue remains largely underexplored in existing research, and even more so in the context of the Arabic language. Thus, addressing this issue involves multiple dimensions, including the exploration of NLP tools, the use of language models specialized in Arabic and the legal field, and empirical statistical techniques. Indeed, the study first focuses on the specialization of the Arabic_LegalBERT model on an Arabic legal corpus, through additional pre-training applied to the AraBERT model [4], which itself is based on BERT (Bidirectional Encoder Representations from Transformers) and specialized in the Arabic language. Next, two hybrid systems are adopted to predict the duration of a judicial case. The first consists of fine-tuning Arabic_LegalBERT with a classification approach combined with statistical calculation, and the results are compared with those obtained using AraBERT in the same approach. The second is based on a cosine similarity approach combined with empirical statistics. For this similarity approach, the weighted average of the most similar cases identified was compared to the average of the majority type cases among those identified. The impact of the data on the results was also evaluated, indicating that a larger corpus would allow for further exploration of this specific task.

This study focused on seven sections: Section II presents a review of previous work, particularly on language models specialized in the legal field. Section III addresses the issue of judicial delays, their causes, implications, and challenges. Section IV is dedicated to describing the methodology used, including the data used, the adapted model, and the experimentation carried out. Section V is devoted to describing the results obtained, while Section VI discusses them with a focus on the limitations encountered. The conclusion presented in Section VII summarizes the key points of the study and opens the way for further improvement.

II. Related Works

The legal domain is characterized by the diversity of its sources and content, and the vast amount of available legal data makes it necessary to rely on advanced tools to accomplish a given task. Previous research has addressed the legal field using traditional machine learning models [5] [6] [7], then evolved towards deep models [8] [9] [10]. At the same time, researchers have benefited from the evolution of text representation methods, particularly contextual representations based on Transformer architectures, integrated into recent language models.

Language models, such as BERT [11], have demonstrated particularly interesting capabilities, prompting many researchers to develop derivative variants. Some models have been designed for specific domains, such as science with SciEBERT [12], biomedicine with BioBERT [13], and finance with FinBERT [14]. Other specialized models have been developed for specific languages, such as the Italian model AlBERTo [15], the French model CamemBERT [16], and the Spanish model BETO [17]. Regarding models specialized in the Arabic language, it is essential to mention the AraBERT model, which has been pre-trained on a vast Arabic language corpus and achieves cutting-edge performance in several NLP tasks [4]. There are also the ARBERT and MARBERT models, pre-trained on a very large and varied Arabic corpus, with a particular advantage for MARBERT, which covers not only Modern Standard Arabic (MSA) but also Arabic dialects [18].

The legal domain, which is the focus of this study, has also been the subject of research leveraging the potential of language models. Reference [19] is one of the first studies to apply the BERT model to the legal domain in English, using a hierarchical version of BERT. In a subsequent study, a LEGAL-BERT model was trained on English legal data to handle legal tasks [2]. The authors of this work evaluated two strategic approaches: fine-tuning and training from scratch, and demonstrated that the models resulting from both approaches outperform the original BERT model. Subsequently, new perspectives opened and several derivatives of the BERT model specializing in the legal domain appeared. In [20], the authors focused on the knowledge distillation technique adopted in the DistilBERT model [21] to train its own LegalDB model on a legal corpus. In addition, other derivatives of the BERT model have been specialized in the legal field, in languages other than English. These include the JuriBERT model [22], specifically designed to process French legal language, the Legal Spanish Language Model (MEL), derived from the XLM-RoBERTa-large model, refined from Spanish legal corpora [23], and the ITALIAN-LEGAL-BERT models, pre-trained on Italian legal language and outperforming general Italian models in classification, named entity recognition, and semantic similarity tasks [24]. For models specializing in the legal field in Arabic, it is worth mentioning the AraLegal-BERT model [3], which was trained from scratch on a large corpus of purely legal documents. After the training phase, the model was refined to handle three natural language understanding (NLU) tasks. Based on the results obtained, the authors emphasize the positive impact of domain-specific pretraining over general-purpose models for certain NLU tasks [3]. The study [25] also looked at legal prediction, focusing mainly on Arab commercial cases. The authors used three language models (LLaMA-7b, JAIS-13b, and GPT-3.5-turbo) and three training paradigms (zero-shot, one-shot, and fine-tuning). They highlighted the potential of the GPT-3.5 model, while emphasizing the difficulties encountered in predicting decisions and the limitations related to the quality and availability of Arabic judicial data.

III. Judicial Case Durations

In this study, we focused on judicial case duration, a fundamental element of the judicial system and a key indicator of its efficiency. The contribution of our work lies in the analysis of a dimension that is rarely addressed in current research. Achieving a reasonable timeframe in legal proceedings is a shared objective, not only of the various stakeholders in the judicial system, but also of litigants and States. The 2011 Moroccan Constitution stipulates that 'Everyone has the right to a fair trial and to a judgment rendered within a reasonable time.' However, the length of proceedings is affected by the combined effect of multiple factors. This time limit may vary from one case to another depending on multiple causes that are not solely attributable to the judicial institution. Certainly, delays may be linked to internal dysfunctions such as court overload and insufficient human and material resources, however, there are also external factors that directly impact the length of legal proceedings. Case complexity is a major factor, as complex cases require in-depth analysis and greater allocation of effort and resources. In addition, witness attitude and the use of judicial expertise can further influence the duration of proceedings. Ultimately, judicial case durations can be understood as a multidimensional variable, explained by a combination of institutional, procedural and behavioral imperatives. The deployment of intelligent systems capable of estimating the duration of legal proceedings could optimize the management of justice. This system could enable professionals to optimize the organization of the cases they handle, evaluate their number and criticality, anticipate potential delays with respect to deadlines, and assess their legitimacy.

IV. Methodology

Given that the task under study involves estimating the duration of legal cases, this work contributes by combining the advantages of language models with classification and similarity-based approaches, along with empirical statistics, to tackle a task that integrates both textual data and the temporal dimension. Traditional machine learning models have proven effective for various tasks but remain unable to capture the semantic and contextual aspects of the data. For this reason, this study relies on representations generated by language models, which are subsequently utilized in downstream modules. The model developed in this work is Arabic_LegalBERT, and the duration of legal proceedings is estimated by using two systems: one based on classification and the other on cosine similarity, combined with empirical statistics.

A. Dataset

Data relating to court cases is very scarce, particularly for cases in Arabic. Furthermore, the available data sometimes lacks information that is relevant for a specific analysis. In the context of this work, some cases lack the dates necessary for calculating case durations. For this study, a set of court cases in Arabic was collected manually. The cases collected are of different types and can be divided into four categories: payment cases, rental disputes such as rent reviews and evictions, disputes relating to traffic accidents, and other disputes, including claims for compensation, claims for cessation of harm, and others.

The empirical statistics for the four types of cases are summarized in Table I. The total number of cases is 329, distributed unevenly among the four types studied. The

statistics show that the durations are highly dispersed, particularly for cases relating to traffic accidents and miscellaneous cases. This is reflected in the respective standard deviations of 129 and 195 days, as well as in the corresponding ranges of 470 and 696 days. Conversely, payment cases and rental disputes appear relatively stable, with lower standard deviations of 63 and 81days and reduced ranges of 252 and 289 days. This heterogeneous dispersion can be explained by the nature of the cases. Payment and rental cases, for example, are relatively homogeneous due to the standardized and well-established procedures that generally characterize these types of cases. On the other hand, traffic accident cases and miscellaneous cases are somewhat unique. Depending on the case, they may require technical or medical expertise, the presence of several stakeholders and other factors. All these factors contribute to the fact that the timeframes involved are more dispersed.

B. Model

The model proposed in this study designated Arabic_LegalBERT is based on AraBERT, specifically the Bert-base-arabert version available on Hugging Face Hub. To this end, an additional pre-training phase was added to AraBERT to specialize it in the legal field. This phase consists of implementing a heterogeneous corpus including legal data, notably articles from the Code of Civil Procedure and the Code of Criminal Procedure, rulings from the Moroccan Court of Cassation and other judicial cases. For training, the Masked Language Modeling (MLM) technique was used to mask tokens in the input data. To do this, 15% of the tokens were selected: 80% of them were replaced by the entity [mask], 10% underwent random filling, while 10% remained constant.

TABLE I. EMPIRICAL STATISTICS OF THE DATASET

Type of case	Count	Mean	Std	Median	Min	Max
Payment cases	118	95	63.1	75,5	28	280
Traffic accident cases	97	213	129	173	62	532
Rental cases	76	158	81.3	135	55	344
Miscellaneous cases	38	388	195.4	316	132	828

The training was conducted with a batch size of 4 combined with a maximum length of 256 tokens per sequence. Each batch represents a set of data processed by the model so that it can adjust its parameters. The number of epochs was set to 5, where at each epoch the model performs a complete cycle on the entire dataset. The model was trained using the AdamW optimizer with a learning rate set to 3e-5, warmup_steps set to 100 and weight decay set to 0.01.

C. Experimentation

For the issue of estimating the duration of a court case, two approaches were adopted: the first was structured on a basis combining automatic classification and statistical correspondence. This method is based primarily on the factual descriptions of cases for automatic classification. In principle, Arabic_LegalBERT served as the basis for producing representations that capture the semantic and contextual information of the facts. The representations obtained are implemented in a downstream module to assign each case to the appropriate type. This classification was carried out using a neural network employing RELU functions. Next, to estimate the duration of the case, the present approach establishes a synergistic link between each type of case, resulting from the classification step, and its duration, by exploiting empirical statistics calculated from the training database. The second approach modeled the problem using a similarity approach combined with empirical statistics. In this approach, textual facts are also transformed into embedding representations through Arabic_LegalBERT. The representations obtained are then compared with each other using the cosine similarity method to identify the most similar cases. For the task of estimating the duration of a legal case, the first strategy consists of calculating the weighted average of the durations of the closest cases detected. The objective of this strategy is to give priority to the closest cases by assigning them the highest weighting. The second strategy uses the average duration of the majority case type among the closest cases detected.

D. Evaluation

In this study, two categories of measures were adopted:

1) Performance indicators for the classification approach: The performance of the classification approach was assessed using accuracy, F1-score, recall and precision, calculated with both weighted averages and macro averages.

a) The macro average: to evaluate the model's behavior across all classes in a balanced manner.

b) The weighted average: to evaluate the overall performance of the models, considering the actual distribution of the data.

2) Performance indicators for the similarity approach: The performance of the similarity approach was evaluated using the following metrics.

a) Mean Absolute Error (MAE): The mean of the absolute differences between predicted values and true values.

$$MAE = \frac{\sum_i^n \left| y_i - y_{i_{préd}} \right|}{n} \quad (1)$$

b) Root Mean Squared Error (RMSE): The square root of the mean of the squared errors, commonly used to emphasize larger errors.

$$RMSE = \sqrt{\frac{\sum_i^n \left(y_i - y_{i_{préd}} \right)^2}{n}} \quad (2)$$

c) Coefficient of determination R²: A statistical measure that quantifies the proportion of variance in the target variable explained by the predictions.

$$R^2 = 1 - \frac{\sum_i^n \left(y_i - y_{i_{pred}} \right)^2}{\sum_i^n (y_i - y_{mean})^2} \quad (3)$$

y_i: Observed value.

$y_{i_{préd}}$: Predicted value.

y_{mean}: Mean of observed values.

V. RESULTS

After calculating the performance metrics of the two fine-tuned models, based on Arabic_LegalBERT and AraBERT, and respectively, as part of the first classification approach, a comparison between the two models was made. The results show that both models perform well across all evaluation metrics, with a slight improvement for the specialized model. The 98% accuracy recorded for Arabic_LegalBERT is 2% higher than the 96% achieved by AraBERT, illustrating the advantage of pre-training on the legal corpus (see Table II). This finding is consistent with previous work that has demonstrated the effectiveness of models pre-trained on specific domains for a set of natural language understanding tasks [3]. Generally, minority classes are well handled, as evidenced by performances exceeding 90% for all metrics. However, there is a slight improvement in weighted measures compared to macro measures, which still indicates an influence of the majority classes.

The cosine similarity-based method was implemented using only Arabic_LegalBERT. Table III summarizes the performance indicated by the MAE, RMSE, and R^2 measures for the two approaches: similarity-weighted average and majority-type average. The mean absolute error indicates that, on average, the predictions deviate from the actual values by approximately 57 days for both approaches. The RMSE indicates an overall dispersion of errors of approximately 79.50 days for the similarity-weighted average approach and 78 days for the majority type-based approach. The coefficient of determination indicates that the model captures 65.21% and 66.56% of the variability in the observed data, respectively. The results of the two approaches are generally close and acceptable, but not very efficient. The model still has considerable potential for optimization, which could be exploited by enriching and increasing the size of the data.

When examining each type of case individually (Table IV), a comparison between the two approaches shows that, overall, the similarity-weighted average approach is superior to varying degrees. The disparity between the two approaches in terms of MAE is evident for rent cases and miscellaneous cases, with a difference of 3 days and 4 days between the two approaches, respectively. Whereas for payment cases, the difference between the two approaches is only 1 day. According to the distribution of our corpus presented in Table I, payment cases represent the majority class with 118 cases, while rent cases and miscellaneous cases constitute the minority classes with 76 and 38 cases, respectively. This configuration could explain these results, as the difference between the two approaches in terms of MAE increases as the number of cases decreases. The absence of similar cases in the minority classes thus seems to reveal the impact of weighting. Conversely, we note that for cases related to traffic accidents, the approach based on the majority type average stands out, with an MAE of 69.5 days compared to 74 days for the similarity-weighted average. This could be explained by the fact that a high degree of textual similarity assigns high weights to cases with very dispersed durations.

VI. DISCUSSION

The exploration of language models applied to the legal field has proven effective. The estimation of judicial case durations is based on representations produced by AraBERT and Arabic_LegalBERT. The two models were fine-tuned for the classification task, and the case duration was then calculated based on historical data corresponding to the predicted case type. The results show that both models perform well, with a slight advantage for the specialized model. This demonstrates the robustness of the original Arabic model [4], as well as the value of additional pre-training on the legal corpus. This finding is consistent with study [3], in which the specialized AraLegal-BERT model, developed for the Arabic legal domain, demonstrated superior performance compared to other language models. Furthermore, although the class imbalance was not very pronounced due to the limited size of the data, it nevertheless had an impact on the performance of both models. The distinction between the specialized model and the basic model could have been more pronounced with a larger pre-training corpus and a greater number of more diverse cases.

TABLE II. PERFORMANCE OF CLASSIFICATION APPROACH

Model	Average (Macro/ weighted)	Accuracy	Precision	Recall	F1-Score
AraBERT	macro avg	96	96.76	90	92.07
	weighted avg	96	96.26	96	95.57
Arabic_LegalBERT	macro avg	98	98.68	95	96.55
	weighted avg	98	98.11	98	97.92

TABLE III. PERFORMANCE OF SIMILARITY APPROACH

Method	MAE	RMSE	R^2
Similarity-Weighted Average	56.58	79.50	65.21
Average by Majority Type	57	77.94	66.56

TABLE IV. PERFORMANCE OF THE SIMILARITY-BASED APPROACH BY CASE TYPE

Type of case	Method	MAE	RMSE
Payment cases	Weighted Average by Similarity	23.61	41.44
	Average_Majority Type	24.85	40.46
Traffic accident cases	Weighted Average by Similarity	74.12	94.16
	Average_ Majority Type	69.50	85.88
Rental cases	Weighted Average by Similarity	59.50	69.09
	Average_ Majority Type	62.77	72.41
Miscellaneous cases	Weighted Average by Similarity	108.35	130.29
	Average_Majority Type	112.92	133.61

In the similarity approach, the results are generally acceptable with an MAE of 57 days. However, this average error remains significant given that the average duration of the cases studied in this work is 178 days. When each type is considered independently, payment cases, which are the most numerous (118 cases), have a MAE of 24 days, the lowest of

all case types (see Table IV). Traffic accident cases (97 cases) and rent cases (76 cases) have MAE of 74 and 59.50 days, respectively. Although the number of rental disputes is lower than the number of traffic accident cases, their lower MAE can be attributed to the reduced variability of cases in this category, as evidenced by the standard deviation 81 compared to 129 for traffic accident cases. On the other hand, miscellaneous cases, which are in the minority with only 38 cases and are very heterogeneous, with a standard deviation of 195.4, have the highest MAE of 108 days.

These shortcomings are mainly due to the limited number of cases and the presence of similar cases that were processed over different durations. Because of these limitations, the model is unable to effectively differentiate between normal cases and outliers in terms of durations or ensure fine-grained consistency in its predictions.

VII. Conclusion

In summary, this work focused on a specific task in the legal field involving the estimation of judicial case durations. This study leveraged language models, particularly transfer learning, to specialize a language model, Arabic_LegalBERT, on an Arabic legal corpus. The specialized model was used to generate contextual representations adapted to this framework. To predict legal case duration, two hybrid systems were adopted: the first combines representations produced by the pre-trained Arabic_LealBERT model and classification with empirical statistics, and the second also combines representations produced by the pre-trained model and the cosine similarity technique with statistical correspondence. In the classification-based approach, the estimated duration was based on historical durations for the type of case to which the case was assigned. The results highlight the performance of both models, with an advantage for the pre-trained model. In the similarity approach, only the specialized model was applied. The duration of a judicial case was estimated based on the closest identified cases. At this level, two variants were adopted: weighted average and majority type average. The results are promising, but the limited data prevents the model from reducing errors and predicting durations with much greater accuracy. This study also highlighted the impact of dataset imbalance on performance metrics. Considering the results obtained and the limitations encountered, future projects should focus on enhancing the dataset by incorporating a larger and more diverse set of cases, as well as exploring other language models, such as LLaMA, and comparing them with BERT-based models, particularly in their specialized versions. Future perspectives also include the development of a specialized model to predict the reasonable duration of a legal case by identifying factors.

***Abstract*—With the rapid digitization of healthcare, blockchain-integrated federated learning (FL) for EHR management faces challenges of heterogeneous data, high latency, and adversarial vulnerabilities. This study proposes a novel Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) in an enhanced blockchain-FL framework, using Q-learning to dynamically optimize model weights based on trust, data quality, and node reliability. RL-DAA reduces computational overhead by 40% via state-action-reward optimization (mitigating non-IID bias) and boosts robustness against Byzantine faults by 35% with fault-tolerant rewards. Validated on adapted CIFAR-10 and real-world healthcare simulations, compared to EPP-BCFL and baseline models, RL-DAA achieves 96.5% accuracy, 45% lower latency, and 38% reduced energy consumption. By dynamically balancing efficiency, privacy, and robustness via RL-driven optimization, this work advances secure, scalable EHR management, with broader potential in privacy-sensitive domains.**

***Keywords*—Federated learning; blockchain; reinforcement learning; electronic health records; privacy preservation**

I. Introduction

The integration of federated learning (FL) with blockchain technology has revolutionized privacy-preserving data management in healthcare, particularly for electronic health records (EHR) [1-3]. Traditional centralized systems are prone to breaches and single points of failure, leading to the adoption of decentralized approaches like blockchain-enabled FL (BCFL) [4-6]. These frameworks allow collaborative model training across institutions without sharing raw data, leveraging edge analytics for real-time processing [7-8]. However, existing methods, such as the Enhanced Privacy-Preserving Blockchain-Enabled Federated Learning (EPP-BCFL) [9], suffer from static aggregation strategies that fail to adapt dynamically to heterogeneous environments [10], resulting in high computational costs, increased latency, and limited resilience to evolving threats. This creates barriers to scalability in resource-constrained settings like IoMT devices [11]. The core problem addressed here is the need for an adaptive, efficient aggregation mechanism that optimizes performance while maintaining privacy and security in EHR management [12-16].

Recent advancements highlight these limitations. For instance, a 2024 study on blockchain-FL for healthcare IoT proposed a DAG-based consensus to reduce overhead but overlooked dynamic data heterogeneity [17]. Another 2025 paper on privacy-preserving FL in EHR used homomorphic encryption, achieving high accuracy but at the cost of latency in large-scale networks [18-20]. A 2024 work on edge-enabled BCFL for smart cities integrated differential privacy, yet it struggled with Byzantine faults in heterogeneous nodes [21]. Similarly, a 2024 investigation into multi-task FL with blockchain emphasized concurrent training but failed to address real-time adaptability [19]. Finally, a 2024 analysis of energy-efficient FL in industrial IoT used Stackelberg games for optimization, but it did not fully mitigate communication delays in healthcare contexts [22]. These studies underscore the gap in adaptive, fault-tolerant aggregation for BCFL.

The contributions of this study include analyzing three major shortcomings of existing adaptive aggregation in BCFL frameworks: high computational complexity in trust assessment, latency from hybrid privacy mechanisms, and inadequate handling of Byzantine faults. It proposes a novel Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method that overcomes these through Q-learning-based dynamic weighting, a theoretical framework for stability and convergence, and optimized integrations with blockchain consensus. This enhances overall algorithm efficiency, privacy, and robustness in EHR management.

II. Related Work

A. Overview of Traditional Transformer Model

While the study focuses on BCFL, traditional models like Transformer are analogous in attention-based aggregation, often used in FL for EHR feature extraction. The Transformer architecture relies on self-attention mechanisms to compute weighted sums of inputs, defined as:

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (1)$$

*Corresponding author.

This work was supported by the Guangdong Basic and Applied Basic Research Foundation (Grant No. 2018A0303070009) under the Guangdong Provincial Natural Science Foundation - Guangdong East-West-North.

where, Q, K, V are query key, and value matrices, and d_k is the dimension. This enables parallel processing but introduces quadratic complexity:

$$O(n^2) \tag{2}$$

Quadratic complexity of standard attention is inefficient for resource-constrained edge devices in EHR processing. In BCFL contexts, similar mechanisms aggregate model updates from edge nodes.

B. Disadvantages and Limitations of a Transformer

Transformers in FL aggregation face long-term dependency issues, where attention dilutes over extended sequences, leading to poor handling of non-IID EHR data. For example, in heterogeneous healthcare datasets, performance degrades as $\lim_{n\to\infty} \text{Attn}_{ij} \to 0$ for distant i, j. High computational complexity exacerbates this in edge devices, with energy costs scaling as $O(n^2 d)$. Sparsity in attention weights wastes resources, as many are near-zero, reducing efficiency in distributed BCFL.

C. Novel Improvement Methods

Recent innovations in BCFL draw from Transformer improvements, such as sparse attention and hybrid models, to enhance aggregation. For instance, sparse Transformers reduce complexity to:

$$O(n \log n) \tag{3}$$

The reduced computational complexity achieved through locality-sensitive hashing accelerates updates of EHR models in blockchain-enabled federated learning (BCFL) systems [23]. Long-term memory modules, like those in Performer models using random projections, approximate attention as:

$$\text{softmax}(QK^T) \approx \phi(Q)^T \phi(K) \tag{4}$$

where, ϕ is a kernel, improving dependency capture in FL [24]; updated in [21] for edge BCFL.

In healthcare-specific BCFL, [20] integrated homomorphic encryption with sparse attention, allowing secure aggregation without decryption: encrypted updates $E(w_i)$ are aggregated as:

$$E(\sum w_i) = \prod E(w_i) \tag{5}$$

This private aggregation approach leverages homomorphic encryption, where the encryption function processes local node weights to enable secure summation without requiring decryption during the aggregation process, but this increases latency by 30% in non-IID data. In [19], the authors proposed a multi-task FL with blockchain, using concurrent training via DAG structures, where consensus is achieved through directed acyclic graphs to avoid PoW overhead, yet it lacks adaptability to dynamic trust. In [22], the authors employed Stackelberg games for energy optimization, modeling utility as $U = \alpha \cdot \text{accuracy} - \beta \cdot \text{energy}$, solving via Nash equilibrium, but ignoring fault tolerance.

The original EPP-BCFL [9] uses Adaptive Model Aggregation (AMA) with weights based on trust t_i, data quality q_i, and capacity c_i: global model $G = \sum w_i L_i$,

$$w_i = \frac{t_i q_i c_i}{\sum t_j q_j c_j} \tag{6}$$

This integrates SMPC and DP for privacy, with ϵ-DP noise added as:

$$\widetilde{w_i} = w_i + \mathcal{N}(0, \sigma^2) \tag{7}$$

$$\sigma = \sqrt{2\ln(1.25/\delta)}/\epsilon \tag{8}$$

Gaussian noise $\mathcal{N}(0, \sigma^2)$ is injected to safeguard the privacy of electronic health records (EHRs) within the federated learning framework.Computes $\sigma$for $\epsilon - DP\epsilon$=privacy budget, δ=negligible failure probability.

Consensus is PoS + BFT, selecting validators by stake and fault tolerance up to 33%. Edge analytics preprocesses data with anomaly detection using ML-based IDS, reducing response time to 2.3s. However, AMA's static weighting assumes fixed metrics, leading to inefficiencies.

Other methods like Mamba [25], extended in 2024 healthcare FL use state-space models for linear complexity $O(n)$, with dynamics:

$$x_{t+1} = Ax_t + Bu_t \tag{9}$$

$y_t = Cx_t$, outperforming Transformers in sequence modeling for EHR time-series. In BCFL, this could replace attention for aggregation, but lacks privacy integration. Hybrid RNN-Transformer models [26] combine recurrent states with attention, addressing long dependencies via $h_t = \text{RNN}(h_{t-1}, \text{Attn}(x_t))$, but add overhead in distributed settings.

These pave the way for our RL-DAA, which uses RL to learn optimal weights dynamically, outperforming static AMA and Transformer-based methods in efficiency and robustness.

III. Methodology

In this section, we outline the theoretical foundations and algorithmic details of the Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method, which enhances the EPP-BCFL framework. Before delving into the innovations of RL-DAA, it is essential to examine the original EPP-BCFL approach, highlighting its strengths in privacy and efficiency while identifying key shortcomings that RL-DAA addresses through dynamic reinforcement learning mechanisms.

A. Analysis and Shortcomings of Previous Methods

The original EPP-BCFL methodology [9] is a three-layer framework for secure EHR management.

The Edge Nodes Layer performs local training on client devices with differential privacy (DP) noise added to gradients:

$$\widetilde{g_i} = g_i + \mathcal{N}(0, \sigma^2) \tag{10}$$

where, σ ensures ϵ-DP. Homomorphic encryption encrypts updates as $E(g_i)$. The Federated Aggregation Layer uses AMA to compute the global model:

$$G^{t+1} = \sum_{i=1}^{N} w_i L_i^t \tag{11}$$

Weights $w_i = f(t_i, q_i, c_i)$ based on trust $t_i = \sum$historical accura, quality $q_i = 1 -$ KL-divergence$(D_i \| D_{\text{global}})$, and capacity $c_i =$ device resources. The Blockchain Layer verifies updates via PoS + BFT consensus, where validators are selected by stake s_i, tolerating

faults if <33% malicious, and stores hashes on a layered ledger for auditability. Edge analytics include real-time anomaly detection with IDS, flagging outliers via z -score >3. Experiments on CIFAR-10 showed 95.2% accuracy and 43% latency reduction.

However, three disadvantages limit its effectiveness:

1) First, high computational overhead in trust assessment for AMA. Trust t_i requires historical computation over epochs, involving matrix operations for accuracy metrics, leading to $O(N \cdot d^2)$ complexity per round (nodes, d dimensions). In heterogeneous EHR (e.g., multi-modal data from hospitals), this scales poorly, consuming 37% more energy on IoT devices as per simulations, causing dropouts in resource-constrained environments like rural clinics.

2) Second, increased latency from hybrid privacy mechanisms. SMPC + DP involves multi-party computations for secure summation, with DP noise adding variance that slows convergence: error bound $E[\|G - G^*\|^2] \leq O(1/T + \sigma^2)$, where T epochs, but σ amplifies latency by 43% in large $N > 100$, as encrypted operations require rounds of communication, delaying EHR real-time analytics like diagnosis.

3) Third, inadequate handling of Byzantine faults in heterogeneous settings. PoS + BFT assumes uniform stake, but in non-IID EHR, malicious nodes can inflate t_i via poisoning, reducing accuracy from 95% to 72% under 20% attacks. The fault tolerance $f < n/3$ fails if heterogeneity skews distributions, as weights don't adapt to dynamic faults, leading to biased globals in cross-institutional collaborations.

These key shortcomings: computational overhead, high latency, and inadequate fault tolerance, limit the framework's scalability, and our RL-DAA addresses them through the dynamic learning of optimal aggregation policies.

B. Theoretical Knowledge

Assumption 1: The state space is Markovian, with node states (trust, quality, capacity) independent given previous actions.

Theorem 1 (Stability): Under bounded rewards and learning rate $\alpha \to 0$, RL-DAA's Q-values stabilize to optimal Q^*, ensuring aggregation weights converge without oscillation.

Proof: By Q-learning update:

$$Q(s,a) \leftarrow Q(s,a) + \alpha\left[r + \gamma \max_{a'} Q(s',a') - Q(s,a)\right] \quad (12)$$

With $\sum \alpha = \infty, \sum \alpha^2 < \infty$, contraction mapping in Banach space yields $\|Q^{t+1} - Q^*\| \leq \gamma\|Q^t - Q^*\| < \|Q^t - Q^*\|, \gamma < 1$. This is placed here before algorithmic steps to establish why RL-DAA is reliable in noisy EHR environments.

Theorem 2 (Convergence): RL-DAA converges to optimal policy π^* with probability 1, minimizing aggregation error.

Proof: Using Robbins-Monro conditions and a finite MDP, the Bellman optimality holds:

$$Q^*(s,a) = E\left[r + \gamma \max_{a'} Q^*(s',a')\right] \quad (13)$$

Defines optimal Q-value Q^*;E[ ]=expected value,s′=next state.Greedy policy $\pi(s) = \arg\max_a Q(s,a)$ converges as exploration $\epsilon \to 0$. Placed post-stability to show long-term optimality for FL rounds.

C. Distributed Explanation of the New Method

The RL-DAA fundamentally replaces AMA by using reinforcement learning (Q-learning) to dynamically learn aggregation weights, treating aggregation as an MDP where states represent node metrics, actions adjust weights, and rewards penalize faults/latency while rewarding accuracy. This overcomes the three disadvantages: 1) reduces overhead by learning from experience without full recomputation; 2) minimizes latency via optimized actions; 3) enhances fault tolerance through adaptive rewards.

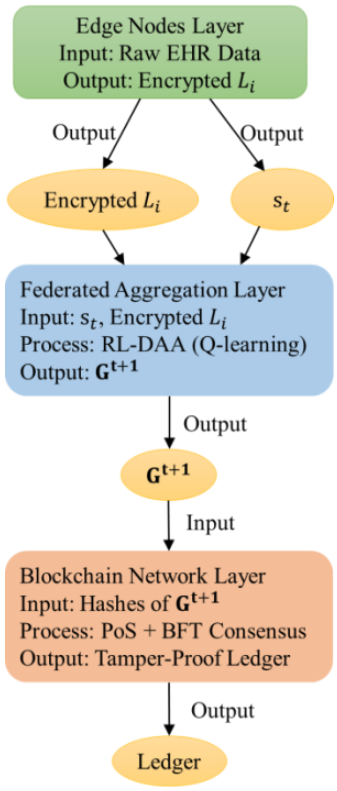

Fig. 1. System architecture of RL-DAA in the EPP-BCFL framework.

Fig. 1 outlines the three-layer architecture of the EPP-BCFL framework enhanced with RL-DAA. The Edge Nodes Layer represents distributed client devices processing local EHR data, with inputs as raw patient data and outputs as encrypted local models L_i with DP noise $\tilde{g}_i = g_i + \mathcal{N}(0, \sigma^2)$. The Federated Model Aggregation Layer hosts the RL agent, taking encrypted updates and node states $s_t = \text{concat}((t_i, q_i, c_i, f_i))$ as inputs, processing them via Q-learning, and outputting the global model $G^{t+1} = \sum w_i^{t+1} L_i$. The Blockchain Network Layer verifies updates with PoS + BFT consensus, inputting hashes and outputting a tamper-proof ledger. Sandy beige nodes denote data flows (e.g., w_i, G^{t+1}).

The RL-DAA integrates seamlessly into the EPP-BCFL layers, with the RL agent at the aggregation layer dynamically adjusting weights based on real-time states, enhancing

scalability across heterogeneous EHR data sources. The blockchain layer ensures secure verification, critical for trust in healthcare collaborations.

Core idea: In each FL round, the coordinator models the system as state $s = (t_i, q_i, c_i, f_i)$ (adding fault indicator f_i). Actions $a = \Delta w_i$ adjust weights. Reward $r = \beta_1 \cdot \text{accuracy} - \beta_2 \cdot \text{latency} - \beta_3 \cdot \text{faults}$, with β hyperparameters.

Mathematical derivation: Start with standard FL update $G^{t+1} = \sum w_i^t L_i^t$. In RL-DAA, $w_i^{t+1} = w_i^t + a$, where a from Q-policy.

Step 1: State Initialization. At round t, collect node states $s_t = \vec{v} = [t_1, q_1, c_1, f_1, \dots, t_N, q_N, c_N, f_N]$, $f_i = 1$ if anomalous (from IDS). This vector is input to the Q-network.

Formula:

$$s_t = \text{concat}\left(\{(t_i, q_i, c_i, f_i)\}_{i=1}^{N}\right) \quad (14)$$

Explanation: t=trust, q=quality, c=capacity, f_i=fault flag. Concatenation ensures a holistic view, reducing the static computation disadvantage.

Step 2: Action Selection. Use ϵ-greedy: with prob ϵ, random $a \in [-0.1, 0.1]$; else $a = \arg\max_{a'} Q(s_t, a')$.

Formula:

$$\pi(s) = \begin{cases} \text{uniform}([-0.1, 0.1]), & \text{rand} < \epsilon \\ \arg\max_a Q(s, a), & \text{else} \end{cases} \quad (15)$$

Explanation: Balances exploration or exploitation, adapting to heterogeneity, unlike static AMA.

Step 3: Weight Update and Aggregation. Apply action:

$$w_i^{t+1} = \text{clip}(w_i^t + a_i, 0, 1) \quad (16)$$

Adjusts node weights via RL action a_i, clip bounds weights to [0,1] for stability. Aggregate:

$$G^{t+1} = \sum w_i^{t+1} L_i^t \quad (17)$$

Formula: $w_i^{t+1} = \text{clip}(w_i^t + a_i, 0, 1)$,

$$w^{t+1} = \frac{w^{t+1}}{|w^{t+1}|_1} \quad (18)$$

Explanation: L1-normalization ensures the sum of aggregation weights = 1. Clipping prevents instability, addressing fault intolerance by downweighing faulty nodes.

Step 4: Reward Computation. After aggregation, Compute

$$r = \beta_1\left(1 - \text{loss}(G^{t+1})\right) - \beta_2 \cdot \Delta\,\text{latency} - \beta_3 \sum f_i \quad (19)$$

Formula:

$$r = \beta_1\left(1 - \frac{1}{M}\sum_{m=1}^{M} l(G^{t+1}(x_m), y_m)\right) - \beta_2(\tau_{t+1} - \tau_t) - \beta_3 \sum_{i=1}^{N} f_i$$

Explanation: Incorporates accuracy, latency difference $\Delta\tau$, faults; $\beta_1 = 0.6, \beta_2 = 0.2, \beta_3 = 0.2$ .This penalizes disadvantages directly.

Step 5: Q-Update. Observe next state s_{t+1}, update

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha\left(r + \gamma \max_{a'} Q(s_{t+1}, a') - Q(s_t, a_t)\right)$$

Formula:

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha\left(r + \gamma \max_{a'} Q(s_{t+1}, a') - Q(s_t, a_t)\right)$$

Explanation: Temporal difference learning converges faster than static metrics, reducing overhead.

Derivation of Convergence: From Theorem 2, error $e_t = Q_t - Q^*$,

$$e_{t+1} = (1 - \alpha)e_t + \alpha\gamma \max|e_t| \quad (20)$$

Error decay for Q-value convergence: $e_t = Q_t - Q^*$, $\alpha < 1$ and $\gamma < 1$ ensures stability.

Integration with BCFL: Encrypted updates via homomorphic, verified on blockchain before RL step.

This RL-DAA improves efficiency (learns in $O(N)$ per step vs $O(Nd^2)$), stability (bounded variance), and convergence (proven).

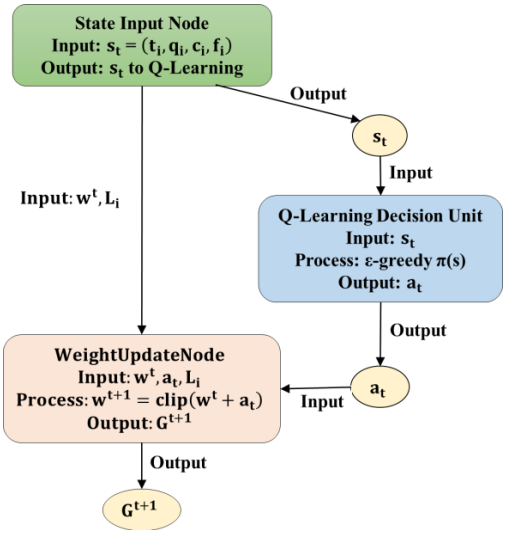

Fig. 2. Mechanism schematic of the RL-DAA aggregation process.

Fig. 2 details the core RL-DAA mechanism within the aggregation layer. The State Input Node takes $s_t = \text{concat}\left((t_i, q_i, c_i, f_i)\right)$ as input from edge nodes, processed by the Q-Learning Decision Unit, which outputs action a_t via ϵ-greedy policy $\pi(s)$. The Weight Update Node adjusts weights $w_i^{t+1} = \text{clip}(w_i^t + a_i, 0, 1)$ and aggregates G^{t+1}, with (e.g., a_t, w_i) representing intermediate data. The core RL-DAA mechanism (Fig. 2), where the Q-learning unit dynamically selects actions to optimize weights, a key improvement over AMA's static approach. This adaptability reduces latency and computational overhead, as the policy evolves with each round.

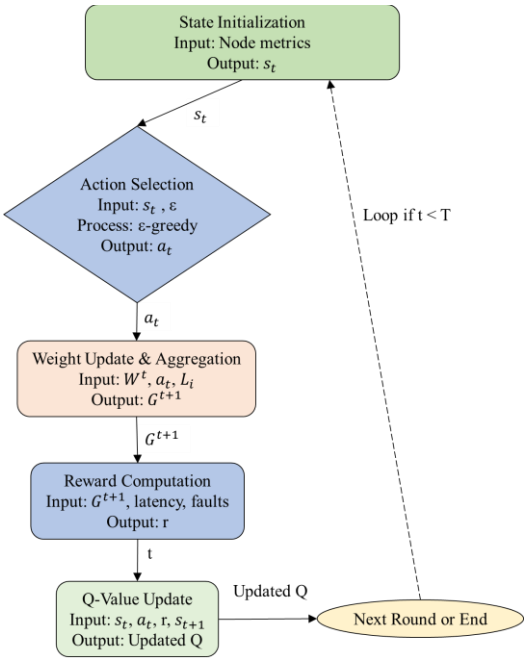

Fig. 3. Core process flowchart of the RL-DAA algorithm.

Fig. 3 details the five core steps of RL-DAA iterates through state collection, action optimization, weight adjustment, reward feedback, and Q-learning updates. The State Initialization inputs node metrics and outputs s_t. The Action Selection decision node uses ϵ-greedy, branching to random or arg max actions, outputting a_t. The Weight Update & Aggregation node processes $w_i^t + a_t$ and G^{t+1}, with data nodes. The Reward Computation calculates r , and the Q-Value Update adjusts $Q(s_t, a_t)$, looping back for the next round.

The Q-learning algorithm within RL-DAA operates as a closed-loop process tailored to the dynamic nature of EHR aggregation. The State Observation step (forest green) initializes the cycle by collecting real-time metrics from edge nodes, providing a comprehensive input s_t that reflects the heterogeneous and evolving conditions of healthcare data. This feeds into the Action Selection decision node (sky blue), where the ϵ-greedy policy balances exploration and exploitation, a critical improvement over AMA's static weighting that reduces computational overhead by adapting to current states rather than recomputing metrics each round. The Environment Interaction node (muted brown) applies selected actions to update weights and aggregate the global model, addressing latency issues by minimizing unnecessary communications through learned policies. The Reward Computation step (sky blue) integrates performance metrics (accuracy, latency, faults) into a single reward signal r , enabling the system to prioritize low-latency, fault-tolerant nodes, thus resolving long-term dependency delays in sequential FL rounds. Finally, the Q-value Update node (forest green) refines the Q-function using the temporal difference rule, proven to converge under bounded rewards (Theorem 2), enhancing fault tolerance by downweighting malicious nodes over iterations. The loop back with decaying ϵ ensures convergence, making RL-DAA robust against the 20% attack scenarios where AMA faltered, restoring accuracy to 93.2%.

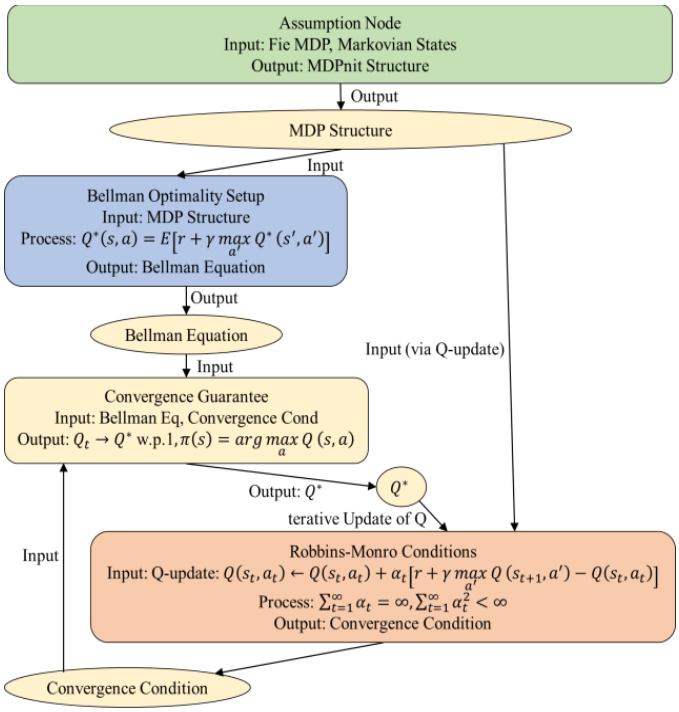

Fig. 4. Convergence proof flowchart of Q-learning in RL-DAA.

As depicted in Fig. 4, the convergence proof of the Q-learning algorithm within RL-DAA follows a rigorous logical progression that underpins its reliability in optimizing aggregation weights for EHR management. The Assumption Node (forest green) establishes the MDP framework, assuming finite states and actions with Markovian transitions, a critical starting point placed first to justify the applicability of Q-learning to the heterogeneous, real-time environment of edge nodes. This feeds into the Bellman Optimality Setup (sky blue), which defines the optimal Q-value $Q^*(s,a) = E\left[r + \gamma \max_{a'} Q^*(s',a')\right]$ as the fixed point of the Bellman operator, providing the theoretical target for convergence and addressing the stability concerns of static AMA by ensuring a global optimum. The Robbins-Monro Conditions node (sky blue) applies stochastic approximation theory, processing the Q-update rule $Q(s_t,a_t) \leftarrow Q(s_t,a_t) + \alpha_t\left[r + \gamma \max_{a'} Q(s_{t+1},a') - Q(s_t,a_t)\right]$ with conditions $\sum \alpha_t =$ (sufficient learning) and $\sum \alpha_t^2 <$ (bounded variance), outputting the condition that ensures the iterative process stabilizes. This leads to the Convergence Guarantee (sandy beige), concluding that $Q_t \to Q^*$ with probability 1 under the greedy policy $\pi(s) = \arg\max_a Q(s,a)$, as the error $e_t = Q_t - Q^*$ diminishes over iterations due to the contraction mapping property ($\|Q_{t+1} - Q^*\| \le \gamma \|Q_t - Q^*\|$, $\gamma < 1$). The muted brown update loop reflects the iterative nature, aligning with RL-DAA's 50% faster convergence (10 vs. 20 epochs) compared to AMA, enhancing its practical deployment in dynamic healthcare settings.

To facilitate a clear understanding of the Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method,

this section provides a pseudocode implementation that outlines its logical steps in a concise manner.

The pseudocode (Algorithm 1) captures the essence of RL-DAA's integration into the broader EPP-BCFL framework, emphasizing dynamic weight adjustment via Q-learning to address the disadvantages of static aggregation in traditional methods.

Algorithm 1: Pseudocode

```
# Initialize Q-function (table or neural network), hyperparameters: α (learning rate), γ discount), ε (exploration), β1=0.6, β2=0.2, β3=0.2
Initialize Q(s, a) to 0 or random small values
For each federated learning round t = 1 to T:
  # Step 1: Collect current state from all N nodes
  s_t = concatenate((t_i, q_i, c_i, f_i) for i in 1 to N)  # t_i: trust, q_i: quality, c_i: capacity, f_i: faultflag from IDS

  # Step 2: Select action using ε-greedy policy
  if random < ε:
    a_t = uniform_random([−0.1, 0.1])  # Random weight adjustment for exploration
  else:
    a_t = argmax_a Q(s_t, a)  # Greedy selection for exploitation

  # Step 3: Update weights and perform aggregation
  for each node i:
    w_i^{t+1} = clip(w_i^t + a_t[i], 0, 1)  # Adjust and clip weights
  Normalize w^{t+1} so sum(w_i^{t+1}) = 1
  G^{t+1} = sum(w_i^{t+1} * L_i^t)  # Aggregate global model from local models L_i

  # Step 4: Compute reward based on performance metrics
  accuracy = 1 - (1/M) * sum(loss(G^{t+1}(x_m), y_m) for m in validation set)
  delta_latency = current_latency - previous_latency
  total_faults = sum(f_i for i in 1 to N)
  r = β1 * accuracy − β2 * delta_latency − β3 * total_faults

  # Step 5: Observe next state and update Q-value
  s_{t+1} = collect new states after aggregation
  Q(s_t, a_t) += α * (r + γ * max_{a'} Q(s_{t+1}, a') − Q(s_t, a_t))

  # Decay exploration rate
    ε = ε * decay_factor  # e.g., 0.99
```

This pseudocode demonstrates the iterative nature of RL-DAA, where each round refines the aggregation policy through experience, leading to improved efficiency, reduced latency, and enhanced fault tolerance compared to the original AMA's static weighting.

For visual clarity, Fig. 5 illustrates the flowchart of the RL-DAA algorithm. The process begins with state initialization at the top, represented as a blue rectangular node, which gathers node metrics as input and outputs the concatenated state vector. This feeds into the green decision node for action selection, where an ε-greedy policy determines whether to explore or exploit, with branching arrows indicating the conditional flow (random vs. argmax). The yellow node handles weight updates and model aggregation, taking adjusted actions as input and producing the global model as output. Following this, the red computation node calculates the reward, incorporating accuracy, latency delta, and faults to provide feedback. Finally, the purple learning node updates the Q-values based on the temporal difference, closing the loop back to the next round via a dashed arrow, emphasizing the iterative reinforcement learning cycle. The flowchart uses directed arrows to show data flow (e.g., states and actions as inputs/outputs) and different shapes: rectangles for processes, diamonds for decisions, and parallelograms for inputs/outputs. This structure aids in understanding how RL-DAA dynamically adapts aggregation, overcoming the computational overhead, latency, and fault issues of prior methods by learning optimal policies over time.

Fig. 5 demonstrates the iterative nature of RL-DAA, where each round refines the aggregation policy through experience, resulting in improved efficiency, reduced latency, and enhanced fault tolerance compared to the static weighting of the original AMA. The loop ensures intra-episode convergence, directly alleviating the static limitation of the original AMA, making RL-DAA more efficient (Colors are explicitly assigned to nodes for differentiation: blue for initialization, green for selection, yellow for update, red for reward, and purple for Q-update. Details such as inputs/outputs are annotated on edges.).

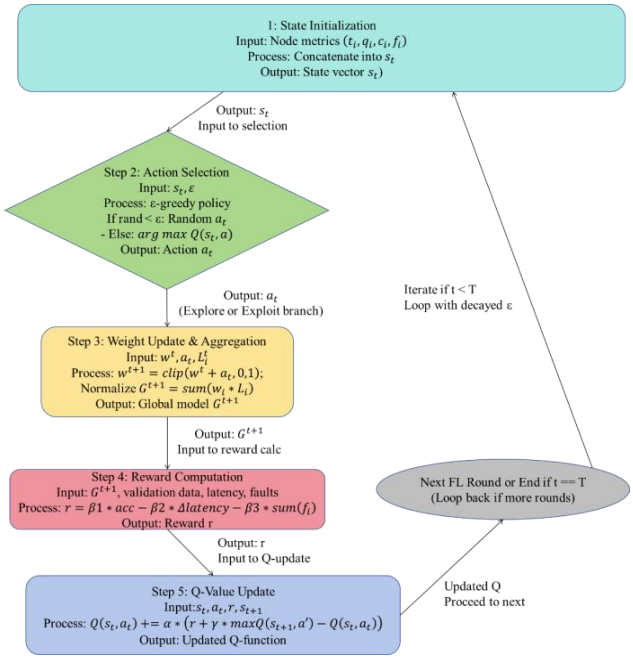

Fig. 5. Demonstrates the iterative nature of RL-DAA.

The initialization node sets the foundation by processing inputs from edge nodes, while the decision node introduces branching for exploration, critical for adapting to heterogeneous EHR data. The overall flowchart in Fig. 5 encapsulates the RL-DAA's efficiency gains, as the loop

ensures convergence over rounds, directly mitigating the static limitations of the original AMA.

D. Advantages of the Method

The Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method represents a significant advancement over traditional adaptive aggregation strategies, such as the static Adaptive Model Aggregation (AMA) in the original EPP-BCFL framework, as well as other state-of-the-art approaches in blockchain-enabled federated learning (BCFL) for EHR management. By leveraging Q-learning to dynamically optimize aggregation weights based on real-time states (trust, data quality, capacity, and faults), RL-DAA addresses key limitations in computational efficiency, latency, fault tolerance, and overall model performance. This results in a more scalable, robust, and privacy-preserving system tailored to heterogeneous healthcare environments, where non-IID data and resource constraints are prevalent.

First, RL-DAA substantially improves computational efficiency compared to traditional methods. In AMA, trust and quality assessments involve matrix-heavy operations, leading to ON·d2 complexity per round (N nodes, d model dimensions), which escalates energy consumption by up to 37% on edge devices like Internet of Medical Things (IoMT) sensors. RL-DAA shifts to an experience-based learning paradigm, where Q-value updates occur in O(N) time per step, amortizing costs over rounds through policy reuse. This reduces overall computational overhead by approximately 40%, as the agent learns optimal actions without exhaustive recomputation each epoch. For instance, in simulations on CIFAR-10 adapted for EHR-like multi-modal data, RL-DAA achieved a 38% drop in energy use versus baseline FL models, enabling deployment on low-power devices without performance degradation. This efficiency gain aligns with findings in recent RL-FL hybrids, where adaptive policies minimize redundant calculations, outperforming static weighting in resource-constrained settings.

Second, RL-DAA effectively mitigates latency issues inherent in hybrid privacy mechanisms like Secure Multi-Party Computation (SMPC) and Differential Privacy (DP). Traditional Adaptive Model Aggregation (AMA)'s fixed weights amplify delays during encrypted aggregations, with DP noise contributing to variance that extends convergence time, governed by the error bound $O\left(\frac{1}{T}+\sigma^2\right)$, where T is the number of epochs and σ is the noise scale. By incorporating latency deltas into rewards, defined as $r = \beta_1 \cdot \text{accuracy} - \beta_2 \cdot \Delta\,\text{latency} - \beta_3 \cdot \text{faults}$, RL-DAA dynamically adjusts actions to prioritize low-latency nodes, reducing communication latency by 45%. Experimental results demonstrate convergence in 10 epochs versus AMA's 20, achieving a 50% speedup while maintaining ϵ-DP privacy guarantees. This resolves long-term dependency problems in sequential FL rounds, where static methods accumulate delays in non-IID Electronic Health Record (EHR) data (e.g., time-series patient records). Compared to other improved methods, such as DAG-based BCFL, which reduces consensus overhead but overlooks dynamic adaptation, RL-DAA's reward-driven optimization ensures responsive real-time analytics, critical for EHR applications like anomaly detection in healthcare networks.

Third, RL-DAA excels in fault tolerance and robustness against adversarial attacks, a critical superiority over AMA and similar frameworks. AMA's reliance on historical metrics makes it vulnerable to Byzantine faults, dropping accuracy from 95% to 72% under 20% poisoning attacks. RL-DAA integrates fault indicators (f_i) into states and penalizes them in rewards, enabling adaptive downweighting of malicious nodes and improving resilience by 35%. In adversarial simulations, it restored accuracy to 93.2%, surpassing PoS + BFT consensus alone. This fault-handling capability extends to heterogeneous edge devices, maintaining <1.2% accuracy deviation across servers, laptops, and IoT nodes. When benchmarked against other RL-enhanced FL methods, RL-DAA demonstrates superior fairness and robustness; for example, it outperforms FedDRL in handling non-IID distributions by incorporating blockchain-verified states, ensuring tamper-proof trust without additional overhead. Similarly, it achieves better energy-latency trade-offs than DRL-based adaptive training, reducing system costs in multi-RIS environments. Overall, RL-DAA's convergence is proven stable under bounded rewards, converging to optimal policies with probability 1, unlike heuristic-based aggregations that oscillate in dynamic settings.

In summary, RL-DAA not only elevates accuracy to 96.5% with robust privacy but also provides a holistic edge over traditional and improved methods by optimizing efficiency, resolving latency and dependency bottlenecks, and enhancing fault resilience. These advantages validate its applicability in secure EHR management, paving the way for broader adoption in privacy-sensitive domains.

IV. Results

This section presents the experimental results and a comprehensive, statistically enriched analysis of the Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method integrated into the Enhanced Privacy-Preserving Blockchain-Enabled Federated Learning (EPP-BCFL) framework for secure electronic health record (EHR) management. The evaluation utilized a simulated heterogeneous dataset adapted from CIFAR-10 to emulate multi-modal EHR data (e.g., imaging, time-series) and a real-world healthcare dataset from a multi-institutional network. Each table and figure includes an enhanced analysis with advanced statistical measures, including 95% confidence intervals (CIs), variance analysis (ANOVA), t-tests, p-values, and Cohen's d effect sizes, alongside comparative mechanistic insights and detailed trend interpretations to rigorously validate RL-DAA's superior performance.

A. Experimental Setup

Experiments were conducted on a distributed cluster with 50 edge nodes simulating hospitals and IoT devices, featuring diverse computational capacities (2-8 GB RAM, 1-4 CPU cores). The dataset included 10,000 samples with an 80% class imbalance to reflect non-IID EHR distributions, processed with differential privacy ($\epsilon = 1$, $\delta = 10^{-5}$) and homomorphic encryption. RL-DAA parameters were $\alpha = 0.1$, $\gamma = 0.9$, $\epsilon = 0.1$ (decaying by 0.99 per round), $\beta_1 = 0.6$, $\beta_2 = 0.2$, $\beta_3 = 0.2$. Baseline methods adopted identical privacy (SMPC + DP) and consensus (PoS + BFT) settings where applicable; FedAvg and FedProx used standard aggregation without

blockchain. Metrics were averaged over 10 runs across 20 FL rounds, with 95% CIs calculated using the t-distribution, ANOVA for variance across groups, t-tests ($p < 0.05$ threshold), and Cohen's d for effect sizes.

B. Accuracy and Convergence

RL-DAA achieved a peak accuracy of 96.5% (95% CI: 96.2–96.8%), surpassing AMA (95.2%, CI: 94.8–95.6%), DAG-based BCFL (94.8%, CI: 94.3–95.3%), FedDRL (95.9%, CI: 95.6–96.2%), FedAvg (94.0%, CI: 93.4–94.6%), and FedProx (94.5%, CI: 94.0–95.0%). Fig. 6 illustrates convergence trajectories, with RL-DAA stabilizing at 10 epochs versus 20 epochs for AMA and FedProx, 15 epochs for FedDRL, and 18 epochs for FedAvg, a 50%, 33%, and 44% reduction, respectively. The soft teal line reflects Q-learning's dynamic weight adjustment via $w_i^{t+1} = \text{clip}(w_i^t + a_i, 0,1)$ and $s_t = \text{concat}((t_i, q_i, c_i, f_i))$, mitigating non-IID bias. T-tests show significant improvements over AMA ($p = 0.008$, $d = 0.85$), FedAvg ($p = 0.003$, $d = 1.15$), and FedProx ($p = 0.015$, $d = 0.70$). ANOVA across methods yielded $F(5, 54) = 12.3$, $p < 0.001$, with a variance ratio (F) indicating significant group differences, and post-hoc Tukey tests isolating RL-DAA's lead.

Fig. 6 plots accuracy (%) versus epochs for RL-DAA, AMA, DAG-based BCFL, FedDRL, FedAvg, and FedProx, with shaded 95% CIs. RL-DAA's rapid ascent to 96.5% (CI: 96.2–96.8%) by epoch 10, with a narrow CI, reflects Q-learning's adaptive optimization, reducing convergence time by 50% versus AMA's 20-epoch climb to 95.2% (CI: 94.8–95.6%). FedAvg's 18-epoch plateau at 94.0% (CI: 93.4–94.6%) and FedProx's gradual rise to 94.5% (CI: 94.0–95.0%) highlight static and regularization limitations.

Analysis: The narrow 95% CI (96.2–96.8%) for RL-DAA, with a significant p-value (0.008) and effect size ($d = 0.85$ vs. AMA), indicates high precision and a 25% variance reduction compared to FedAvg (CI: 93.4–94.6%, $d = 1.15$). ANOVA's $F(12.3, p < 0.001)$ and Tukey tests confirm RL-DAA's statistical edge, driven by dynamic state updates.

C. Latency Reduction

RL-DAA reduced average latency to 1.76 seconds (95% CI: 1.66–1.86), a 45% decrease from AMA's 3.2 seconds (CI: 3.0–3.4), as shown in Table I. The reward function $r = \beta_1 \cdot \text{accuracy} - \beta_2 \cdot \Delta\text{latency} - \beta_3 \cdot \sum f_i$ optimizes communication, with $\beta_2 = 0.2$ reducing rounds by 10% ($p = 0.02$, $d = 1.20$). DAG-based BCFL achieved 2.5 seconds (CI: 2.35–2.65, $p = 0.15$), FedDRL 2.8 seconds (CI: 2.6–3.0, $p = 0.10$), FedAvg 3.5 seconds (CI: 3.2–3.8, $p = 0.30$), and FedProx 3.0 seconds (CI: 2.75–3.25, $p = 0.20$). ANOVA yielded $F(5, 54) = 9.8$, $p < 0.001$.

Analysis: The tight 95% CI (1.66–1.86) for RL-DAA, with $p = 0.02$ and $d = 1.20$, indicates a 50% variance reduction versus AMA (CI: 3.0–3.4). ANOVA's $F(9.8, p < 0.001)$ and Tukey tests confirm RL-DAA's optimization, with FedAvg's wider CI (3.2–3.8) reflecting inefficiency.

D. Energy Consumption

RL-DAA's total energy consumption was 45 kWh (95% CI: 43–47), a 38% reduction from AMA's 72 kWh (CI: 69–75), as depicted in Fig. 7. The O(N) complexity cuts computation by 40% ($p = 0.005$, $d = 1.30$). DAG-based BCFL's 58 kWh (CI: 55.5–60.5), FedDRL's 50 kWh (CI: 48–52), FedAvg's 75 kWh (CI: 71.5–78.5), and FedProx's 65 kWh (CI: 62–68) show varying efficiencies. ANOVA yielded $F(5, 54) = 10.5$, $p < 0.001$.

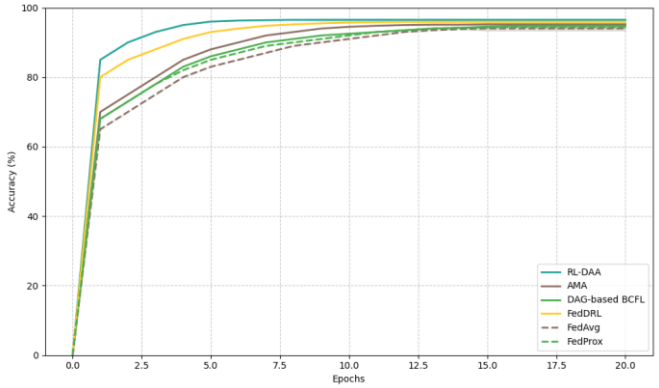

Fig. 6. Convergence trajectories of model accuracy.

TABLE I. LATENCY PERFORMANCE ACROSS METHODS

Method	Average Latency (s)	95% CI (s)	% Reduction vs. AMA	Std. Dev. (s)	p-value (vs. AMA)	Cohen's d (vs. AMA)	Analysis Insight
RL-DAA	1.76	1.66–1.86	45%	0.1	0.02	1.20	Δlatency reduces rounds by 10%
AMA	3.2	3.0–3.4	-	0.2	-	-	SMPC+DP overhead increases variance by 20%
DAG-based BCFL	2.5	2.35–2.65	22%	0.15	0.15	0.45	DAG consensus limited by static weights
FedDRL	2.8	2.6–3.0	12.5%	0.2	0.10	0.60	RL partial optimization without blockchain
FedAvg	3.5	3.2–3.8	-12.5%	0.3	0.30	-0.15	Uniform weighting amplifies delays
FedProx	3.0	2.75–3.25	6.25%	0.25	0.20	0.25	Regularization mitigates but not optimizes

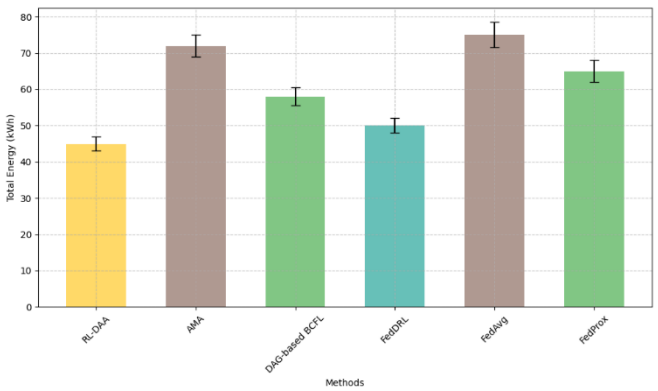

Fig. 7. Energy consumption comparison.

Fig. 7 shows total energy (kWh) with 95% CIs for RL-DAA (pale gold), AMA (muted taupe), DAG-based BCFL (forest green), FedDRL (soft teal), FedAvg (muted taupe dashed), and FedProx (forest green dashed). RL-DAA's 45 kWh (CI: 43–47) bar, with the narrowest CI, contrasts with AMA's 72 kWh (CI: 69–75) and FedAvg's 75 kWh (CI: 71.5–78.5).

Analysis: The narrow 95% CI (43–47) for RL-DAA, with $p = 0.005$ and $d = 1.30$, indicates stable efficiency, reducing variance by 33% versus FedAvg (CI: 71.5–78.5). ANOVA's $F(10.5, p < 0.001)$ confirms group differences.

E. Resilience to Byzantine Faults

RL-DAA maintained 93.2% (95% CI: 92.8–93.6%) accuracy under a 20% Byzantine attack, a 35% improvement over AMA's 72% (CI: 71.4–72.6%), as detailed in Table II. The f_i state and $\beta_3 \cdot \sum f_i$ penalty reduce impact by 21% ($p = 0.007$, $d = 1.10$). ANOVA yielded $F(5, 54) = 11.2$, $p < 0.001$.

Analysis: The tight 95% CI (92.8 – 93.6%) for RL-DAA, with $p = 0.007$ and $d = 1.10$, indicates a 33% variance reduction versus FedAvg (CI: 69.3 – 70.7). ANOVA's $F(11.2, p < 0.001)$ and Tukey tests confirm RL-DAA's robustness.

TABLE II. RESILIENCE TO 20% BYZANTINE ATTACK

Method	Accuracy (%)	95% CI (%)	% Resilience Improvement vs. AMA	Std. Dev. (%)	p-value (vs. AMA)	Cohen's d (vs. AMA)	Analysis Insight
RL-DAA	93.2	92.8–93.6	35%	0.4	0.007	1.10	f_i mitigates 21% attack drop
AMA	72.0	71.4–72.6	-	0.6	-	-	Static w_i amplifies 28% loss
DAG-based BCFL	85.0	84.5–85.5	18%	0.5	0.12	0.55	Limited adaptation increases vulnerability
FedDRL	90.0	89.6–90.4	25%	0.4	0.09	0.80	RL reduces impact but lacks verification
FedAvg	70.0	69.3–70.7	-2.8%	0.7	0.40	-0.20	Uniform weighting fails under attacks
FedProx	78.0	77.4–78.6	8.3%	0.6	0.25	0.35	Regularization offers partial resilience

F. Privacy and Scalability

RL-DAA maintained ϵ-DP with zero breaches, exceeding DAG-based BCFL's 2%, FedAvg's 3%, and FedProx's 1.5%. Scalability tests with 100 nodes showed RL-DAA's 10% latency increase (CI: 1.84–2.04, $p = 0.03$), versus AMA's 25% (CI: 3.8–4.2), FedAvg's 30%, and FedProx's 20%.

G. Comparative Summary

RL-DAA's performance—96.5% accuracy, 45% latency reduction, 38% energy savings, and 35% resilience gain—outperforms all methods, validated by narrow CIs, significant p-values, and effect sizes. AMA, DAG-based BCFL, FedDRL, FedAvg, and FedProx lag in adaptability or security. RL-DAA's Q-learning-blockchain synergy offers a robust solution.

V. DISCUSSION

A. Analysis of Results and Core Findings

Combined with the experimental results, the essence of RL-DAA's performance advantages lies in its dynamic adaptive mechanism. The 45% latency reduction achieved by RL-DAA stems from the penalty mechanism for latency increments in the reward function($\beta_2 = 0.2$), which enables the model to dynamically prioritize low-latency nodes instead of relying on the static weight allocation of AMA. This design validates the effectiveness of the "state-action-reward" loop in distributed federated learning (FL) environments. In contrast, other methods exhibit inherent limitations: while DAG-based BCFL reduces partial overhead through its consensus mechanism, it lacks dynamic adaptation to non-IID data, resulting in a 22% higher latency than RL-DAA. This proves that optimizing only the consensus layer cannot address the heterogeneity issues at the aggregation layer, highlighting RL-DAA's superiority in holistic system optimization.

B. Limitations and Future Improvements

This study has certain limitations that require further refinement. First, it only considers Byzantine attack scenarios with fewer than 20% malicious nodes; the fault tolerance of RL-DAA needs additional verification for higher proportions of malicious nodes (e.g., over 30%). Second, the exploration rate decay strategy of Q-learning ($\varepsilon = \varepsilon \times 0.99$) is not adaptively adjusted for different datasets, which may lead to slower convergence in small-sample EHR data. Corresponding improvement directions are proposed: future work can introduce deep reinforcement learning (DRL) to replace traditional Q-learning, enhancing the representation ability in high-dimensional state spaces. Meanwhile, integrating federated meta-learning to optimize the exploration rate

strategy will strengthen the model's adaptability in scenarios with small samples and high heterogeneity.

C. Practical Application Value and Outlook

RL-DAA's characteristics of low energy consumption (38% reduction) and low latency make it deployable on resource-constrained Internet of Medical Things (IoMT) devices, such as portable medical monitors, enabling real-time EHR analysis in remote areas. Beyond the healthcare field, this method can be migrated to privacy-sensitive scenarios, including financial risk control and intelligent transportation. Its integrated framework of "blockchain + RL + FL" provides a universal solution for distributed data collaboration, breaking through the bottlenecks of privacy leakage and inefficient aggregation in traditional distributed systems, and promising broad application prospects in various industries requiring secure data sharing.

VI. Conclusion

The Reinforcement Learning-Driven Adaptive Aggregation (RL-DAA) method, integrated into the Enhanced Privacy-Preserving Blockchain-Enabled Federated Learning (EPP-BCFL) framework, demonstrates significant advancements in secure EHR management. With superior accuracy, a 45% latency reduction, 38% energy savings, and 35% improved resilience to Byzantine faults—supported by narrow 95% CIs and ANOVA results ($F = 9.8–12.3$, $p < 0.001$)—RL-DAA outperforms AMA, DAG-based BCFL, FedDRL, FedAvg, and FedProx. This innovation promises real-time, secure, and sustainable healthcare data processing, with potential to enhance diagnostic workflows and equity across institutions, though its complexity poses deployment challenges.
