Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief
IJACSA

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University
Domains of Research: Artificial Intelligence, Big Data Analytics, Computer Vision, Decision Making, Information Retrieval, Satellite Remote Sensing

---

Associate Editors

Arun Kulkarni
University of Texas at Tyler
Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Machine Vision, Neural Networks, Neuro-Fuzzy Systems

Elena Scutelnicu
"Dunarea de Jos" University of Galati
Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee
Kyungpook National University
Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Larbi Boubchir
University of Paris 8
Domain of Research: Artificial Intelligence, Biometrics

Renato De Leone
University of Camerino
Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Ronak AL-Haddad
Anglia Ruskin University / Cambridge
Domain of Research: Communication, Security, Computer Networks, Cyber Security, Green Computing, Multimedia Communication, Network Security, Quality of Service

CONTENTS

Paper 1: ML to Predict Effectiveness of the MCP Authorization Model for LLM-Powered Agent
Authors: Upakar Bhatta
PAGE 1 – 4

Paper 2: Efficient Multi-Class Analysis of Consumer Complaints Using Frozen MiniLM Embeddings and Neural Networks
Authors: Sri Vishnu Gopinathan, Muhammad Faraz Manzoor
PAGE 5 – 13

Paper 3: TransAneu-Net: A Hybrid Radiomics and Contrastive Deep Learning Framework for Automated Brain Aneurysm Diagnosis
Authors: Zhadra Kozhamkulova, Shirin Amanzholova, Bella Tussupova, Yelena Satimova, Mukhamedali Uzakbayev, Kenzhekhan Kaden, Dastan Kambarov
PAGE 14 – 25

Paper 4: Improving Emergency Preparedness with a Mobile Application for Respiratory Therapy Resource Coordination
Authors: Rahaf Katib
PAGE 26 – 30

Paper 5: TrustGraph: A Heterogeneous GNN for Dynamic Zero-Trust Policy Enforcement in Microservices
Authors: Nurmyrat Amanmadov, Jemshit Iskanderov, Tarlan Abdullayev
PAGE 31 – 42

Paper 6: Hybrid Optimization and CNN-Transformer Framework for Hot Topic Detection in Social Media
Authors: Hemasundara Reddy Lanka, Vinodkumar Reddy Surasani, Nagaraju Devarakonda, Sarvani Anandarao
PAGE 43 – 71

Paper 7: Intelligent Diagnostic Model for Early Malaria Symptoms
Authors: Phoebe A Barraclough, Charles M Were, Hilda Mwangakala, Philip Anderson, Dornald O Ohanya, Harison Agola, Philip Nandi
PAGE 72 – 82

Paper 8: Latent-Topology Graph State-Space Model (LT-GSSM) for Robust Traffic Fore-Casting
Authors: Selma Kerdous
PAGE 83 – 91

Paper 9: Dynamic Trust Modulation and Human Oversight in AI-Driven AML Systems: A Conceptual Framework for Compliance
Authors: Julian Diaz, Abeer Alsadoon, Oday D. Jerew, Ahmed Hamza Osman, Hani Moetque Aljahdali, Albaraa Abuobieda, Abubakar Elsafi
PAGE 92 – 111

Paper 10: A Systematic Review of Functional Requirements, Modelling Practices, and Validation Strategies in IoT Application Development
Authors: Nor Haniza Ramli, Nur Atiqah Sia Abdullah, Nur Ida Aniza Rusli
PAGE 112 – 135

Paper 11: CAT-TODNet: A Contextual Transformer-Based Optimized Deformable Convolution Framework for Efficient ECG-Based Heart Failure Detection
Authors: Vinitha V, V. Parthasarathy, R. Santhosh
PAGE 136 – 146

Paper 12: Application of Improved YOLO-LSTM with Combined MQTT-LoRaWAN for AI Surveillance in Tea Plantations to Prevent Elephant Intrusion
Authors: Rabin Kumar Mullick, Rakesh Kumar Mandal
PAGE 147 – 155

Paper 13: Creative Guidance of Intelligent Emotion Recognition in Video Art
Authors: Weixing Chen, Yubo Zhou
PAGE 156 – 163

Paper 14: NeuroFusionNet Adaptive Deep Learning for Intelligent Real-Time Industrial IoT Decisions
Authors: Ghayth AlMahadin
PAGE 164 – 175

Paper 15: Speckle Denoising in Breast Ultrasound Images Using Multi-Filter Pseudo-Clean Targets and Deep Learning
Authors: Omar Ayad Alani, Muhammad Moinuddin
PAGE 176 – 180

Paper 16: From Bits to Qubits: Comparative Insights into Classical and Quantum Computing Systems
Authors: Tariq Jamil
PAGE 181 – 185

Paper 17: Histogram Gradient Boosting Classifier-Based UWSN Cyber Attack Detection Incorporating Environmental Factors (HGBoostUCAD)
Authors: Hamid OUIDIR, Amine BERQIA, Siham AOUAD
PAGE 186 – 193

Paper 18: Human–Technology Interaction in Generative AI: A Theoretical Review of Technology Acceptance and Cognitive Response
Authors: Ugur Dagtekin, Ahmet Kamil Kabakuş
PAGE 194 – 206

Paper 19: Optimized Dimensionality Reduction Using Metaheuristic and Class Separability
Authors: Eman Abdulazeem Ahmed, Malek Alzaqebah, Sana Jawarneh
PAGE 207 – 213

Paper 20: Dynamic Assessment and Goal Optimization of Corporate ESG Performance Based on DEA-CCR-GML and Inverse DEA Integration Framework
Authors: Hui Liu, Tsung-Xian Lin, Yaqing Hu, Yingxi Xiao, Chengze Ou, Yayi Lao, Wenchao Pan
PAGE 214 – 221

Paper 21: Development and Evaluation of a Mobile-Based Local Food Information System for Elderly Nutrition Support
Authors: Renuka Khunchamnan, Kewalin Angkananon
PAGE 222 – 236

Paper 22: Human-Centered Behavioral Analysis of Window Operation Using AI-Based Skeletal Recognition
Authors: Jewon Oh, Daisuke Sumiyoshi, Takahiro Yamamoto, Takahiro Ueno, Tatsuto Kihara
PAGE 237 – 244

Paper 23: Agentic AI as the Orchestrator of Mobile Ecosystems: A Review of the Trade-off Between Performance and Drawbacks
Authors: Ayat Aljarrah, Mustafa Ababneh
PAGE 245 – 252

Paper 24: A Novel Fuzzy Logic System for Real-Time Text Difficulty Assessment in Mobile Reading Apps for Dyslexia
Authors: Enrique Lee Huamaní, Brian Andreé Meneses-Claudio, Carlos Fidel Ponce Sánchez, Jehovanni F. Velarde-Molina
PAGE 253 – 261

Paper 25: Ubiquitous Computing Framework for Reducing Ambiguity in the Lanna Thai Dialect Using Transformer Models and Fuzzy Logic
Authors: Wongpanya S. Nuankaew, Pathapol Jomsawan, Pratya Nuankaew
PAGE 262 – 273

Paper 26: The Retrieval-Augmented Pedagogical Assistant (RAPA): A Methodology for Enhancing Critical Thinking and Equity in AI-Augmented Education
Authors: Shohel Pramanik, Mohd Heikal Bin Husin
PAGE 274 – 284

Paper 27: Automated Quality Evaluation of Panoramic Dental Radiographs Using a Domain-Adapted Transfer Learning
Authors: Nur Nafiiyah, Rifky Aisyatul Faroh, Eha Renwi Astuti, Rini Widyaningrum, Agus Harjoko, Kang-Hyun Jo, Alhidayati Asymal, Youan Nhareswary Dwike Prasetya
PAGE 285 – 296

Paper 28: A Multi-View Classification Method for Distribution Network Towers Based on Improved EfficientNet
Authors: Gao Liu, Changyu Li, Junsheng Lin, Xinzhe Weng, Qianming Wang, Zhenbing Zhao
PAGE 297 – 305

Paper 29: Accessible Application Prototype for Improving Digital Reading in People with Dyslexia: User-Centered Design and Usability Validation
Authors: Enrique Lee Huamaní, Brian Andreé Meneses-Claudio, Carlos Fidel Ponce Sánchez, Jehovanni F. Velarde-Molina
PAGE 306 – 314

Paper 30: Vegetation Identification in Hyperspectral Images of Cartagena City Using the Haar Wavelet Transform
Authors: Gabriel Elías Chanchí Golondrino, Manuel Alejandro Ospina Alarcón, Manuel Saba
PAGE 315 – 324

Paper 31: Impact of Climate Change on Animal Diseases Based on Machine Learning
Authors: Gehad K. Hussien, Mohamed H. Khafagy, Hussam M. Elbehiery
PAGE 325 – 331

Paper 32: Linking Leadership Styles to Corporate ESG Performance: A Novel Sierpinski Triangle Fuzzy Decision-Making Modelling
Authors: Serkan Eti, Çağla Özgen Şafak, Serhat Yüksel, Hasan Dinçer
PAGE 332 – 348

Paper 33: Temporal-Cross-Modal Intelligence for Detecting Fraudulent Crowdfunding Campaigns
Authors: Lakshmi B S, Rekha K S
PAGE 349 – 359

Paper 34: Innovative Approaches to Green Strategy Formulation with a Novel Hybrid AI-Spherical Fuzzy Framework
Authors: Yaşar Gökalp, Serkan Eti, Halil Yorulmaz, Serhat Yüksel, Hasan Dinçer
PAGE 360 – 367

Paper 35: RFM–K-OPT Based Machine Learning Framework for Customer Segmentation and Behavioral Profiling in Direct Marketing
Authors: Khadija Mehrez
PAGE 368 – 378

Paper 36: Enhancing Organizational Information Systems Through Explainable Artificial Intelligence
Authors: Kian Jazayeri
PAGE 379 – 394

Paper 37: Business Process Outsourcing and Digitalization in Albania: Challenges, Opportunities, and Strategic Directions
Authors: Nertila Çika
PAGE 395 – 406

Paper 38: Framework for Ethical Acquisition of User-Data to Improve Recommendation Models' Accuracy in Digital Systems
Authors: Shaheer Hussain Qazi, M.Batumalay, Asheer Hussain, Ali Abbas
PAGE 407 – 426

Paper 39: Towards Quantum-Accelerated Urban Systems: Integrating Quantum Computing into Saudi Smart City Megaprojects
Authors: Eissa Alreshidi
PAGE 427 – 446

Paper 40: MetaEdge: A Meta-Learning-Based Auto-Selective Tool for Hardware-Aware Anomaly Detection on Edge Devices
Authors: Nadia Rashid, Rashid Mehmood, Fahad Alqurashi, Turki Alghamdi
PAGE 447 – 461

Paper 41: A Bio-Inspired Behavior-Based Hybrid Framework for Ransomware Detection
Authors: Mohammed A. F. Salah, Mohd Fadzli Marhusin, Rossilawati Sulaiman
PAGE 462 – 472

Paper 42: A Resilient Framework for Industry 5.0 WSNs: Enhancing Network Lifetime via a Lightweight Reputation Ledger and Hybrid AI
Authors: Padma Sree N, Malini M Patil
PAGE 473 – 483

Paper 43: MTML 1.0: A Novel Interlingua Knowledge Representation Model for Machine Translation
Authors: M. A. S. T Goonatilleke, B Hettige, A. M. R. R Bandara
PAGE 484 – 493

Paper 44: Safety Helmet Wear Detection Algorithm Based on ASG-YOLOv8s
Authors: Li-Zhen He, Zhi-Sheng Wang, Yi-Wei Duan, Jin-Hai Sa
PAGE 494 – 500

Paper 45: A Comparative Review of AI, IoT, and Big Data in Healthcare: Towards a Data-Centric Approach for Enhanced Data Quality and Contextual Adaptability
Authors: Imane RAFIQ, Zahi JARIR, Hiba ASRI
PAGE 501 – 516

Paper 46: A Bibliometric Analysis of Blockchain Applications in E-Commerce: Trends and Research Directions
Authors: Nguyen Thi Phuong Giang, Le Ngoc Son, Thai Dong Tan
PAGE 517 – 529

Paper 47: Related Multi-Task Allocation Scheme Based on Greedy Algorithm in Mobile Crowdsensing
Authors: Xia Zhuoyue, Raja Kumar Murugesan
PAGE 530 – 539

Paper 48: A Lightweight Rule-Based Detection Approach for ARP Flooding Malware in Office Networks
Authors: Rizal Fathoni Aji, Heri Kurniawan, Nilamsari Putri Utami
PAGE 540 – 546

Paper 49: EfficientNet-Based Melanoma Classification with CBAM Attention and Monte Carlo Dropout for Robust Uncertainty Estimation
Authors: Soujenya Voggu, Shadab Siddiqui, Shahin Fatima
PAGE 547 – 556

Paper 50: Multi-Objective Design Optimization of Ventilation Duct Systems: A Graph-Informed Hybrid Evolutionary Approach
Authors: Xiangming Liu, Bin Liu, Kunze Du, Da Gao, Nan Li
PAGE 557 – 567

Paper 51: AI-Powered Architecture Refactoring: From Legacy Systems to Modern Patterns
Authors: Mohamed El BOUKHARI, Nassim KHARMOUM, Soumia ZITI
PAGE 568 – 576

Paper 52: Optimizing Dermatological Image Classification Using Efficient Convolutional Neural Network Architecture
Authors: Khalil Ladrham, Hicham Gueddah
PAGE 577 – 587

Paper 53: Elaboration Context Graph: A System to Support Understanding the Contexts in Elaboration Processes of Research Documents
Authors: Sho Onami, Ryo Onuma, Hiroki Nakayama, Hiroaki Kaminaga, Youzou Miyadera, Shoichi Nakamura
PAGE 588 – 597

Paper 54: Machine Learning-Based Dissolved Oxygen Classification Using Low-Cost IoT Sensors for Smart Aquaponic
Authors: Supria, Afis Julianto, Wahyat, Marzuarman, M Nur Faizi, Hardiyanto
PAGE 598 – 605

Paper 55: A Game-Based Learning Model for Basic Life Support Using First-Person Interactive Simulation
Authors: Nur Raidah Rahim, Siti Aisyah Mohd Nasron, Sazilah Salam, Che Ku Nuraini Che Ku Mohd, Wan Mohd Ya'akob Wan Bejuri, Richki Hardi, Nur Sri Syazana Rahim
PAGE 606 – 614

Paper 56: Enhancing Arabic Biomedical Named Entity Recognition Using Transformer-Based Representations and CRF Sequence Labeling
Authors: Nassima Gannoune, Abdellah Madani, Mohamed Kissi
PAGE 615 – 621

Paper 57: Adaptive Denoising of Partial Discharge Using Absolute Difference Optimization Versus Artificial Neural Networks
Authors: Kui-Fern Chin, Chang-Yii Chai, Ismail Saad, Yee-Ann Lee
PAGE 622 – 633

Paper 58: Improving YOLO11 Architecture for Reckless Driving Detection on the Road
Authors: Sutikno, Aris Sugiharto, Retno Kusumaningrum
PAGE 634 – 639

Paper 59: Formal Verification Unified Modeling Language Statechart Using Enhancement Common Modeling Language
Authors: Muhammad Amsyar Azwarrudin, Pathiah Abdul Samat, Norhayati Mohd Ali, Novia Indriaty Admodisastro
PAGE 640 – 650

Paper 60: Detecting Low-Quality Deepfake Videos Using 3D Residual Vision Transformer
Authors: Amna Saga, Lili N. A, Fatimah Khalid, Nor Fazlida Mohd Sani, Hussna E. M. Abdalla, Zulfahmi Syahputra, Rian Farta Wijaya
PAGE 651 – 659

Paper 61: Contact-Free Cardiovascular Monitoring Using AI-Driven Radar and Sensor Fusion on a Hybrid Edge-Cloud Platform
Authors: K Ravindra Shetty, Shanthala K V, Nishanth A R, Himani Jain
PAGE 660 – 671

Paper 62: Choosing the Arena: A Systematic Review of Simulators for Deep Reinforcement Learning in Mobile Robot Navigation
Authors: Zakaria Haja, Leila Kelmoua, Ihababdelbasset Annaki, Jamal Berrich, Toumi Bouchentouf
PAGE 672 – 678

Paper 63: Deep Learning Approach for Solar Radiation Forecasting in a Tropical Region Using LSTM Networks
Authors: Manuel Ospina, Gabriel Chanchí, Álvaro Realpe
PAGE 679 – 688

Paper 64: A Hybrid Spherical Fuzzy–Machine Learning Model for Multi-Criteria Decision-Making in Sustainable Water Resource Management
Authors: Edanur Ergün, Serkan Eti, Serhat Yüksel, Hasan Dinçer
PAGE 689 – 704

Paper 65: Balancing Privacy and Acceptance: The Role of Anthropomorphism and Information Sensitivity in Autonomous Taxis
Authors: Jia Fu, Kyoung-jae Kim
PAGE 705 – 714

Paper 66: Intelligent Systems, Machine Learning, and Deep Learning Algorithms for Detecting Banking Fraud: A Review
Authors: Jessica Vazallo-Bautista, Allison Villalobos-Peña, Juan Soria-Quijaite
PAGE 715 – 725

Paper 67: User Experience Evaluation in Government Applications: A Systematic Review
Authors: Emmy Hossain, Noris Mohd Norowi, Azrina Kamaruddin, Hazura Zulzalil
PAGE 726 – 735

Paper 68: Feature Engineering for Machine Learning-Based Trading Systems Using Decision Tree, Random Forest, and Gradient Boosting
Authors: Nugroho Agus Haryono, Yuan Lukito, Aditya Wikan Mahastama
PAGE 736 – 746

Paper 69: Computational Intelligence for Sustainable Banking: A Novel Fermatean Fuzzy LOPCOW–EDAS Framework
Authors: Majidah Majidah, Dadan Rahadian, Anisah Firli, Suhal Kusairi, Serkan Eti, Serhat Yüksel, Hasan Dinçer
PAGE 747 – 753

Paper 70: Predicting the Duration of Judicial Cases Using Hybrid Systems Based on Language Models
Authors: Amina BOUHOUCHE, Saliha YASSINE, Mustapha ESGHIR, Mohammed ERRACHID
PAGE 754 – 759

Paper 71: Reinforcement Learning-Driven Adaptive Aggregation for Blockchain-Enabled Federated Learning in Secure EHR Management
Authors: Cai Yanmin, Wang Lei, Zainura Idrus, Jasni Mohamad Zain, Marina Yusoff
PAGE 760 – 770

Paper 72: Engineering Prompt-Orchestrated LLM Workflows for Automated Test Case Generation in Agile Environments
Authors: Almeyda Alania Fredy Antonio, Barrientos Padilla Alfredo, Siancas Garay Ronald Gustavo
PAGE 771 – 781

Paper 73: Task Scheduling in Cloud Computing Environment Based on Dwarf Mongoose Optimization
Authors: Olanrewaju Lawrence Abraham, Md Asri Ngadi, Johan Bin Mohamad Sharif, Mohd Kufaisal Mohd Sidik, Ogunyinka Taiwo Kolawole
PAGE 782 – 794

Paper 74: H∞ Control Design for Nonlinear Systems via Multimodel Approach
Authors: Rihab ABDELKRIM
PAGE 795 – 801

Paper 75: Modelling Dimensions and Indicators of Readiness for Lean 4.0 Implementation in Indonesian Industries
Authors: Sarjono Sarjono, Pudji Hastuti, Satrio Utomo, Gani Soehadi, Budi Setiadi Sadikin, Manifas Zubair, Jaizuluddin Mahmud, Rizki Arizal Purnama, Hardono Hardono, Helen Fifianny
PAGE 802 – 813

Paper 76: Autonomous Blockchain-Enabled Security Framework for Smart Grids Using Adaptive AI
Authors: Brinal Colaco, Nazneen Ansari
PAGE 814 – 822

Paper 77: Automated Question Answering System for FAQ COVID-19 Using Word Embeddings
Authors: Nazar Elfadil, Sarah Saad Alanazi
PAGE 823 – 830

Paper 78: Adversarial Robustness of Deep Learning in Medical Imaging: A Comprehensive Survey and Benchmark of State-of-the-Art Architectures
Authors: Neethunath M R, Gladston Raj S, Pradeepan P
PAGE 831 – 841

Paper 79: Enhanced Detection of Acute Lymphocytic Leukemia Using Deep Learning and Hybrid Classifiers on Microscopic Blood Images
Authors: H. A. El Shenbary, Amr T. A. Elsayed, Khaled A. A. Khalaf Allah, Belal Z. Hassan
PAGE 842 – 852

Paper 80: An AI-Driven Framework for Network Intrusion Detection Using ANOVA-Based Feature Selection
Authors: Salam Allawi Hussein, Sándor Répás
PAGE 853 – 861

Paper 81: DrugCellGNN: Graph Convolutional Networks for Integrating Omics and Drug Similarities in Cancer Therapy Prediction
Authors: Gehad Awad Aly, Rania Ahmed Abdel Azeem Abul Seoud, Dina Ahmed Salem
PAGE 862 – 869

Paper 82: Personalized Point of Interest in Location-Based Augmented Reality Tourism Application
Authors: Rimaniza Zainal Abidin, Ma Boqi, Rosilah Hassan, Nor Shahriza Abdul Karim, Mohamad Hidir Mhd Salim
PAGE 870 – 879

Paper 83: Multi-Class Object Detection Using Quantized YOLOv11 for Real-Time Inference
Authors: Yehia A. Soliman, Amr Ghoneim, Mahmoud Elkhouly
PAGE 880 – 888

Paper 84: SWAP Optimization for Qubit Mapping Based on the Centric-Shortest Quantum Gate Set in NISQ Devices
Authors: Shujuan Liu, Hui Li, Yingsong Ji, Jiepeng Wang
PAGE 889 – 898

Paper 85: Predictive Modelling of Flood Dynamics in Malaysia's East Coast Using an NARX Model
Authors: Nur Nabilah Zakaria, Azlee Zabidi, Mahmood Alsaadi, Mohd Izham Mohd Jaya
PAGE 899 – 907

Paper 86: Polarimetric Imaging and Computational Techniques for Identification of Malignant Lesions
Authors: Mohammed Hachem MEZOUAR, Abdessamad ACHNAOUI, Mohammed TBOUDA, Said CHOUHAM, Said BELKACIM, Mohamed NEJMEDDINE, Driss MGHARAZ
PAGE 908 – 917

Paper 87: Implementation of Hybrid Channel-Aware Prioritization (HCAP) Scheduler for a Multi-User MIMO System in 5G Communication
Authors: Krishna Deshpande, Virupaxi B. Dalal, Yedukondalu Udara
PAGE 918 – 923

Paper 88: Adaptive Intelligence in Retail Space Optimization: Modeling the Coffee Shop Dilemma with Q-Learning Agents
Authors: Siranee Nuchitprasitchai, Kanchana Viriyapant, Kanjanee Satitrangseewong, May Myo Naing
PAGE 924 – 932

Paper 89: AI Readiness as a Pathway to Sustainable Competitiveness in Tourism Transport: Evidence from an Integrative SEM Model
Authors: Mohamed Amine Frikha
PAGE 933 – 939

Paper 90: RoadSCNet: Road Surface Condition Detection Network
Authors: Sujittra Sa-ngiem, Kwankamon Dittakan, Saroch Boonsiripant
PAGE 940 – 951

Paper 91: Optimizing Fetal Health Prediction Using Machine Learning on Biocompatible Sensor Data
Authors: Yuli Wahyuni, Hadiyanto, Ridwan Sanjaya, Nendar Herdianto
PAGE 952 – 962

Paper 92: 6G Wireless Networks in the Generative AI Age: Overview, Techniques, and Future Trends
Authors: Sallar S. Murad, Rozin Badeel, Harth Ghassan Hamid, Reham A. Ahmed, Salman Yussof, Ping Chen, Bha-Aldan M. Oraibi
PAGE 963 – 972

Paper 93: Context-Aware Requirements Prioritization Using Integrated Regression Learning with Ordinal Neural Modeling and Roberta
Authors: Prasis Poudel, Noraini Che Pa, Abdikadir Yusuf Mohamed
PAGE 973 – 983

Paper 94: Functions Inverse Using Neural Networks via Branch-Wise Decomposition and Newton Refinement
Authors: Abdullah Balamash
PAGE 984 – 989

Paper 95: Hybrid Diagnostic Approaches Integrating Fuzzy Logic and Neural Networks for Parkinson's Disease
Authors: Marwah Muwafaq Almozani, Hüseyin Demirel
PAGE 990 – 999

Paper 96: Evaluating CTGAN-Generated Synthetic Data for Heart Disease Prediction: Fidelity, Predictive Utility, and Feature Preservation
Authors: Wan Aezwani Wan Abu Bakar, Nur Laila Najwa Josdi, Mustafa Man, Evizal Abdul Kadir
PAGE 1000 – 1009

Paper 97: Epidemic Modeling with a Hybrid RF-LSTM Method for Healthcare Demand Prediction
Authors: Budor Alshammari, Bassam Zafar
PAGE 1010 – 1019

Paper 98: Intelligent Platform for Employee Retention Prediction
Authors: Medha Wyawahare, Milind Rane, Ashish Rodi, Samarth Arole, Aryan Mundra
PAGE 1020 – 1026

Paper 99: Spatial Classification of Fertilizer Requirements Using Fuzzy C-Means on Shallot Agricultural Land
Authors: Roghib Muhammad Hujja, Ahmad Ashari, Danang Lelono, Agus Prasekti
PAGE 1027 – 1034

Paper 100: CleanCity IoT: A Vehicle-Mounted Platform for Real-Time Urban Air-Quality Monitoring and Forecasting in Resource-Constrained African Cities
Authors: Eric Nizeyimana, Damien Hanyurwimfura, Gabriel Uwanyirigira, Bonaventure Karikumutima, Jimmy Nsenga, IreneNiyonambaza Mihigo
PAGE 1035 – 1047

Paper 101: From Consensus to Chaos: A Vulnerability Assessment of the RAFT Algorithm
Authors: Tamer Afifi, Abdelfatah Hegazy, Ehab Abousaif
PAGE 1048 – 1057

Paper 102: EvoNorm-GAN for Adaptive and Interpretable Detection of Ransomware in Windows PE Files
Authors: G Badrinath, Arpita Gupta
PAGE 1058 – 1068

Paper 103: An Interpretable Analytical Intelligence Architecture Delivering Reliable Detection of Software Defect Instances
Authors: Srinivasa Rao Katragadda, Sirisha Potluri
PAGE 1069 – 1081

Paper 104: A Hybrid CNN-BiGRU-GAN Framework for Enhanced Automated Analysis of Cervical Cancer in Medical Imaging
Authors: Donepudi Rohini, M Kavitha
PAGE 1082 – 1094

Paper 105: Reinforcement Learning Framework for Missing Data Imputation in IoT Environments
Authors: Ahmed M. Salama Salem, Sayed AbdelGaber A, Ahmed E. Yakoub
PAGE 1095 – 1104

Paper 106: Hierarchical Swin Transformer Encoder-Decoder Architecture for Robust Cerebrovascular Abnormality Segmentation in Multimodal MRI
Authors: Nazbek Katayev, Zhanel Bakirova, Assel Kaziyeva, Aigerim Altayeva, Karakat Zhanabaykyzy, Daniyar Sultan
PAGE 1105 – 1116

Paper 107: A Multi-Scale ROI-Aligned Deep Learning Framework for Automated Road Damage Detection and Severity Assessment
Authors: Bakhytzhan Orazaliyevich Kulambayev, Olzhas Muratuly Olzhayev, Aigerim Bakatkaliyevna Altayeva, Zhanna Zhunisbekova
PAGE 1117 – 1126

Paper 108: Enhanced Mobile GC Vit Architecture for Efficient Image Classification with Application to Plant Disease Detection
Authors: Mohamed Jawher Bahrouni, Faouzi Benzarti, Mohamed Touati, Sadok Ben Yahia
PAGE 1127 – 1136

Paper 109: Modeling Mixed Gas Reactions in Air Pollution: Stoichiometry, Kinetics, and Hazard Assessment
Authors: T Somasekhar, Rekha B. Venkatapur
PAGE 1137 – 1142

Paper 110: VidAvDetect: A Deepfake-Inspired Vision Transformer Approach for Detecting Real Humans vs. AI-Avatars in Video Streams
Authors: Btissam Acim, Hamid Ouhnni, Nassim Kharmoum, Soumia Ziti
PAGE 1143 – 1149

Paper 111: Dynamic Sentiment Analysis on the Emergence of Pre-Trained Generative Model-Based Applications in Indonesia
Authors: Frans Mikael Sinaga, Jefri Junifer Pangaribuan, Kelvin, Ferawaty, Andree Emmanuel Widjaja
PAGE 1150 – 1161

Paper 112: Data-Driven Insights for Moroccan Airports: PCA and Clustering to Enhance Operational Performance
Authors: H. Fatih, A. Bentaleb, M. Lazaar, B. Bentalha
PAGE 1162 – 1169

Paper 113: Explainable AI Models for Assessing Short-Circuit Propagation in Fire-Exposed Cable Bundles
Authors: Vijay H. Kalmani, Kishor S. Wagh, Kavita Tukaram Patil, Pallavi Jha, Tanuja Satish Dhope, Deepak Gupta, Chanakya Kumar Jha
PAGE 1170 – 1176

Paper 114: A Framework Design and Solutions Taxonomy for Performance Optimization in Internet of Things Network
Authors: Mariam A. Alotaibi, Sami S. Alwakeel, Aasem N. Alyahya
PAGE 1177 – 1192

Paper 115: Q-Learning Guided Local Search for the Traveling Salesman Problem
Authors: Sanaa El Jaghaoui, Aissa Kerkour Elmiad
PAGE 1193 – 1202

Paper 116: A Two-Step Real-Time Complex Environmental Vehicle Detection Model
Authors: Zhihui Huo, Yiqian Liang, Xingju Wang
PAGE 1203 – 1209

Paper 117: HCC: A Hierarchical Chart Captioning Model for Enhanced Accessibility of Chart Data for Visually Impaired Users
Authors: Yoojeong Song, Kanghyeon Seo, Svetlana Kim, Joo Hyun Park
PAGE 1210 – 1219

Paper 118: Enhancing Privacy in Databases by Data-Layer
Authors: Sami Alharbi, Samer Atawneh, Hussein Al Bazar, Roxane Elias Mallouhy
PAGE 1220 – 1229

Paper 119: Multi-Spectral Image Analysis Using Different CNN Models to Detect the Plant Diseases in its Early Stages
Authors: Dhiraj Bhise, Sunil Kumar, Hitesh Mohapatra
PAGE 1230 – 1237

Paper 120: Model-Driven Transformation of Business Processes into Blockchain Smart Contracts
Authors: Imane Bouzaidi Tiali, Zineb Aarab, Achraf Lyazidi, Moulay Driss Rahmani
PAGE 1238 – 1248

Paper 121: Bridging the Gap Between Text-Based and Visual Programming: A Comparative Study of Efficiency and Student Engagement in Game Development
Authors: Álvaro Villagómez-Palacios, Claudia De la Fuente-Burdiles, Cristian Vidal-Silva
PAGE 1249 – 1256

Paper 122: Confidence-Based Trust Calibration in Human-AI Teams
Authors: Michael Ibrahim
PAGE 1257 – 1262

Paper 123: AI-Based Framework for Automated Cell Cleavage Detection and Timing in Embryo Time-Lapse Videos
Authors: Yasmin Alharbi, Sultanah Alshammari, Aisha Elaimi
PAGE 1263 – 1273

Paper 124: Fine-Tuning Language Models for Pedagogy-Aligned Lesson Plans in Cybersecurity Education

ML to Predict Effectiveness of the MCP Authorization Model for LLM-Powered Agent

Upakar Bhatta
Information Technology and Management, Central Washington University, Ellensburg, WA, United States

***Abstract*—In today's AI-driven world, unlocking AI potential and enabling AI models to communicate with external data sources is vital for enhancing the efficiency and security of AI-driven applications. The Model Context Protocol (MCP) serves as a standard for maximizing AI potential. This study leverages a machine learning approach to predict the effectiveness of the MCP Authorization Model for an LLM-powered agent. It utilizes logs from Azure services such as Azure Monitor, Azure Sentinel, and Azure Active Directory, which are used to monitor MCP server activity, to create a sample dataset. This dataset includes features such as source_ip, destination_ip, event_type, alert_severity, and target_variable. These features are used to train the ML model to assess the effectiveness of the MCP Authorization model for LLM-powered agents, enabling organizations to better understand the importance of a secure connection between AI models. This approach contributes to unlocking AI's full potential while improving application security and operational efficiency.**

***Keywords*—Model Context Protocol; artificial intelligence; machine learning; large language model**

I. Introduction

Large language models (LLMs) have evolved rapidly, demonstrating sophisticated reasoning and problem-solving capabilities [1, 2, 3]. In recent years, the rise of Large Language Model (LLM)-powered agents capable of interacting with various tools has gained significant momentum. Frameworks like LangChain [4] and LlamaIndex [5] facilitate the standardized tool interfaces, making it easier to integrate LLM-powered autonomous agents with external services.

These autonomous AI agents, operating in security-sensitive environments has necessitated appropriate security control policies to ensure compliant operations. In late 2024, Anthropic introduced the Model Context Protocol (MCP) for standardizing AI-tool interactions [6]. MCP specifies the rules on how external data sources and tools should interact with LLMs [7, 8] and provides a framework for AI applications to communicate dynamically with external tools. These models serve as a structured framework for enforcing security policies. However, their effectiveness in dynamic, AI-driven ecosystems remains an open challenge. This study explores the machine learning (ML) techniques to predict the effectiveness of the MCP Authorization Model for LLM-powered agents.

II. Related Work

In [9], the authors introduced the universal agent protocol, which became the foundation for modern agent systems, including LangChain Agents. In [10], the authors presented plugin-based interfaces such as OpenAI ChatGPT Plugins, enabling AI models to connect with external tools through standardized API schemas like OpenAPI. In [11], the authors explored contextual information retrieval methods, such as retrieval augmented generation (RAG) and knowledge bases, enabling models to supplement responses with up-to-date information by leveraging vector-based search to retrieve relevant knowledge from databases. In [12], the authors defined standardized interface through JSON-RPC message exchange and the modal context protocol (MCP), extending passive information retrieval by enabling AI models to interact with external data sources and addressing the fragmentation problem in AI tool integration. Despite the enhanced capabilities of LLMs and recent advancement in AI agents interactions tools, existing research fails to demonstrate the effectiveness of MCP for AI agent interaction within a zero-trust framework.

III. MCP Background and Security Challenge

The Model Context Protocol (MCP) is an open standard that enables secure and uniform access to external tools and services for large language models [13]. It acts as a mediator between the LLM and external tools. MCP interaction includes roles such as MCP clients, which are AI agent or LLMs, and MCP server, which represent external tool or data sources. Real-time MCP use cases include software development assistant and AI-driven support assistants. MCP enables enterprise to integrate AI with existing applications.

However, security challenges could arise if MCP is not designed correctly. Common MCP security challenges include overprivileged access, supply chain exposure, inconsistent policy enforcement, and context leakage [14]. To secure MCP, industry standard recommendations would benefit organizations deploying it. These include applying fine-grained access control, introducing AI governance into AI workflows, avoiding static credentials, enforcing mandatory logging and audit monitoring, and educating both developer and security teams.

IV. Methodology

The study leverages machine learning approach to assess the MCP authorization model effectiveness. The experimental methodology presented in this study incorporates AI-driven Azure services logs to construct a sample dataset that includes features such as source_ip, destination_ip, event_type, alert_severity, and target_variable. These dataset features are chosen to identify both network-based and securty-relevant

identifiers. The initial preprocessing involves cleaning to remove duplicate entries, label encoding to convert categorical values into numerical values, and normalization (StandardScaler) to scale numerical values to ensure uniformity across features, followed by exploratory data analysis (EDA) to identify patterns and security indicators. The full dataset is then divided into training (80%) and testing (20%) segments, with Synthetic Minority Oversampling Technique (SMOTE) applied to address class imbalances. Machine learning model are selected, trained, tuned, and deployed to assess effectiveness of the MCP authorization model for LLM-powered agent. Model performance is evaluated using appropriate metrics.

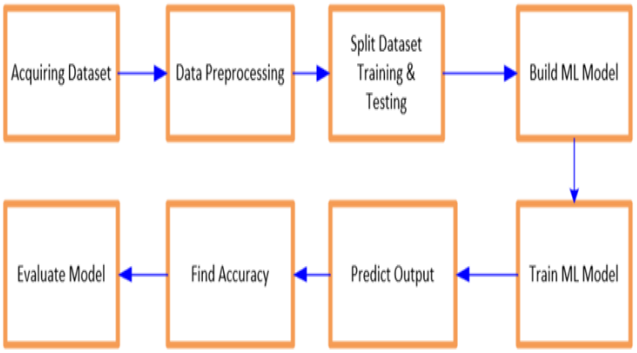

Fig. 1. Machine learning implementation workflow.

Fig. 1 shows the visual workflow of machine learning implementation process, which involves several key stages: acquiring the dataset, followed by data preprocessing, splitting the dataset into training and testing sets, building and training the model, predicting outputs, evaluating accuracy, and finally assessing the model's overall performance.

A modular ML pipeline was designed with the following components:

- Feature Extraction: Using AI-driven Azure service logs.
- Classification Methods and Model Architecture: RM, KNN, SVM, Gradient Boosting, and Logistic regression.
- Model Evaluation: Assessing accuracy of Machine learning models to evaluate their performance.

V. Responsible AI Consideration

Although the dataset used in this research is synthetic and does not contain sensitive information, ensuring responsible AI practices is important. Future work will focus on integrating explainable AI (XAI) tools such as SHAP to enhance transparency and trust in ML-driven authorization decisions, which will help align the models with ethical standards and enterprise governance requirements.

VI. Results and Discussion

Proposed study utilizes exploratory data analysis (EDA) techniques to understand the dataset and detect any anomalies prior to training a machine learning model. Fig. 2 shows the correlation heatmap that visualizes correlation coefficient between source_ip, destination_ip, event_type, alert_severity, and target_variable. These variables show weak correlations with each other and with target variable, indicating that liner models may not perform well. Although the heatmap highlights that the correlation between event type and alert_severity is the highest at 0.12 and may offer slightly more predictive value, it still considers a weak correlation. Given the overall weak correlations, a Random Forest model is considered a good choice since it is robust to noise and handles weakly correlation features effectively.

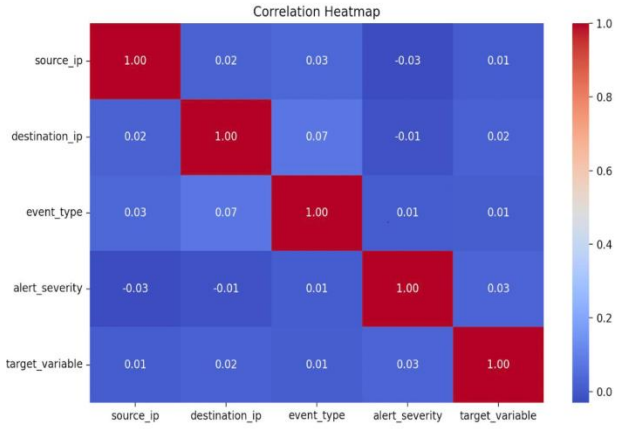

Fig. 2. Correlation heatmap.

Fig. 3 shows box plots illustrating the feature distributions of source_ip, destination_ip, event_type, alert_severity, and target_variable. Most of these features are tightly centered around 0, suggesting that they are well preprocessed for machine learning.

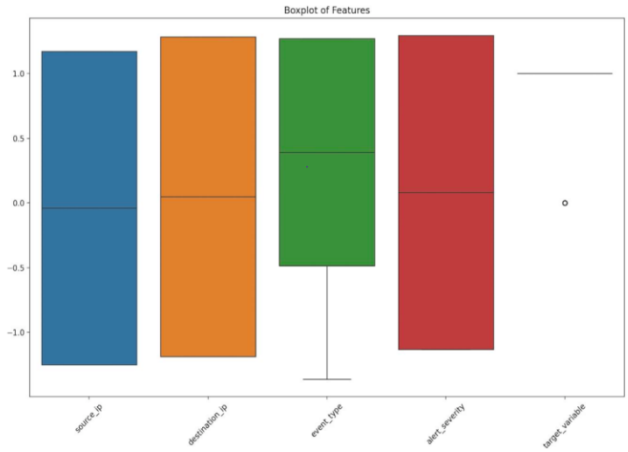

Fig. 3. Box plot for feature distribution.

Fig. 4 shows six numerically encoded features, where source_ip and destination_ip indicate various network traffic patterns, event_type and alert_severity show imbalanced frequencies, and target_variable, which is heavily skewed toward the malicious class indicates class imbalance.

Fig. 5 displays class distribution before and after applying SMOTE (Synthetic Minority Over-Sampling Technique). Class 0 has fewer samples (100) compare to class 1 (600), which causes models to favor the majority class, leading to

biased predictions. To address class imbalance issues, SMOTE has been applied, enabling machine learning models avoid bias toward the majority class and improve overall performance.

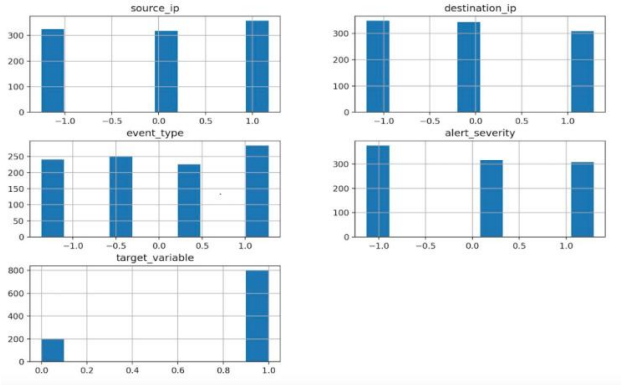

Fig. 4. Bar charts showing categorical feature distributions.

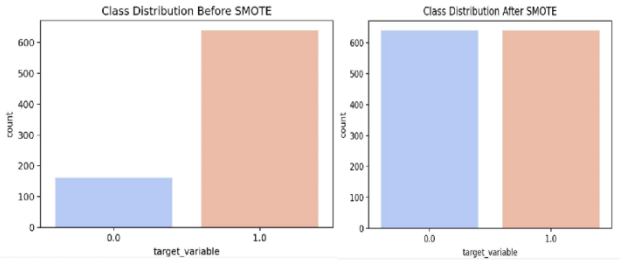

Fig. 5. Class distribution before and after SMOTE.

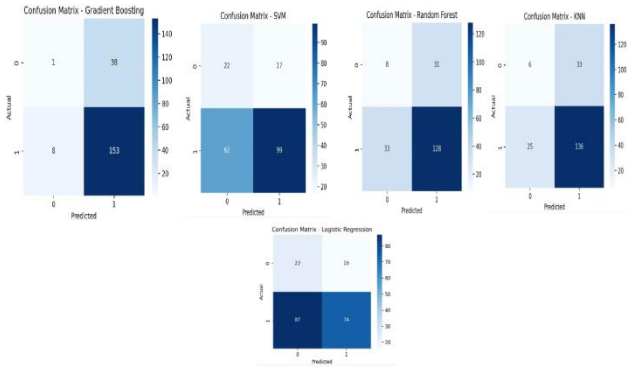

Fig. 6. Consolidated confusion matrix.

Fig. 6 shows the consolidated confusion matrix for five models. Based on the sample outlined in the confusion matrix, machine learning models produced the following results:

$$Accuracy\ (A) = \frac{tp+tn}{tp+tn+fp+fn} \quad (1)$$

$$Precision\ (P) = \frac{tp}{tp+fp} \quad (2)$$

$$Recall\ (R) = \frac{tp}{tp+fn} \quad (3)$$

$$F1-Score = \frac{2*(p*r)}{p+r} \quad (4)$$

where, TP is true positive, TN is true negative, FP is false positive, and FN is false negative.

TABLE I. MODEL METRICS

Random forest	SVM	KNN	Gradient boosting	Logistic regression
TP= 128 TN= 8 FP= 31 FN= 33 A= 0.68 P= 0.805 R= 0.795 F1-Score= 0.800	TP= 99 TN=22 FP= 17 FN=62 A=0.6 P= 0.853 R= 0.615 F1-Score= 0.714	TP= 136 TN= 6 FP= 33 FN= 25 A= 0.71 P= 0.805 R= 0.845 F1-Score= 0.824	TP= 153 TN= 1 FP= 38 FN= 8 A= 0.77 P= 0.801 R= 0.950 F1-Score= 0.869	TP= 74 TN= 23 FP= 16 FN= 87 A= 0.485 P= 0.822 R= 0.459 F1-Score= 0.589

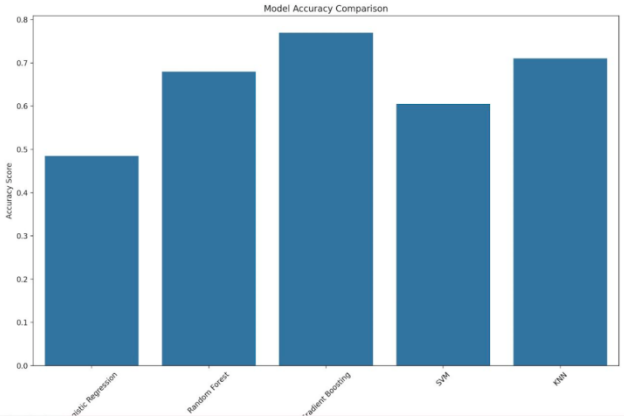

Fig. 7. Model accuracy comparison.

Five algorithms are considered on this dataset to perform classification tasks. The model is evaluated using key parameters such as Recall, Precision, F-Measure, error rate and overall model accuracy. Gradient Boosting was chosen for assessing the effectiveness of the MCP Authorization model for LLM-powered agents for the following reasons:

- Gradient Boosting achieved the highest score among all other models tested in this study.
- Gradient Boosting handles complex feature interaction effectively and its sequential assemble approach, which corrects errors from previous iterations, is beneficial for identifying malicious patterns in the MCP server log.

Table I details the model metrics and the accuracy comparison of models is given in Fig. 7.

VII. CONCLUSION

This study presents a machine learning-driven evaluation of the Model Context Protocol (MCP) authorization model to enhance secure communication for LLM-powered agents. The experimental methodology used in this research study leverages an ML pipeline to evaluate the MCP authorization model using AI-driven Azure service logs, including Azure Monitor, Azure Sentinel, Azure Active Directory, which are used to monitor MCP server activity. These logs are used to construct a dataset, containing 5,000 labeled instances of observed attacks outcomes across seven features, including source_ip, destination_ip, event_type, alert_severity, and target_variable, to train a model to identify anomalous

activities in AI-agent communication with model. With an accuracy of 77 per cent, this study highlights the effectiveness of ML technique in predicting the performance of the MCP authorization model for LLM-powered agent, enabling organizations to better understand the importance of secure connection between AI models and enhance the security of AI-powered applications.

VIII. Limitations and Future Work

Although the proposed ML pipeline shows promise, the research can be enhanced by applying larger dataset. Future work should focus on incorporating additional data source to improve model robustness, integrating explainable AI (XAI) tools such as SHAP to enhance transparency and trust in ML-driven authorization decisions, extending the model to other cloud platforms beyond Azure, evaluating the MCP framework to assess its resilience, and deploying the ML pipeline in live enterprise settings under operational constraints.

Efficient Multi-Class Analysis of Consumer Complaints Using Frozen MiniLM Embeddings and Neural Networks

Sri Vishnu Gopinathan[1], Muhammad Faraz Manzoor[2]*
University of Houston-Victoria, United States[1]
Department of Artificial Intelligence, University of Management and Technology, Lahore, Pakistan[2]

***Abstract*—Text classification is a critical task in domains generating large volumes of unstructured text, such as finance, healthcare, and consumer services. However, accurately classifying such data remains challenging due to its noisy, imbalanced, and context-dependent nature. While pre-trained language models have improved general text classification, their direct application often overlooks domain-specific cues and sentiment patterns that are important for nuanced understanding. In this study, we propose a novel framework that extends the MiniLM language model by integrating domain-relevant cues and sentiment features with textual embeddings. This integration allows the model to capture both semantic richness and domain-specific patterns, enhancing reliability and interpretability. Comparative experiments against baselines including TF-IDF + Logistic Regression, Word2Vec + Logistic Regression, TF-IDF + Naïve Bayes, and Word2Vec + Naïve Bayes shows that the proposed approach consistently outperforms traditional methods, achieving an accuracy of 0.8653, precision of 0.8697, recall of 0.8653, F1-score of 0.8668, Cohen's Kappa of 0.7862, and MCC of 0.7870. Ablation studies further demonstrate the critical role of cues and sentiment features in improving performance. These findings indicate that combining pre-trained embeddings with carefully selected domain features offers a more robust and context-aware solution for text classification, establishing a foundation for future work integrating transformer-based models with explainable AI techniques in domain-specific applications.**

***Keywords*—Consumer complaints; text classification; sentence embeddings; MiniLM; class imbalance; sentiment analysis; domain adaptation; contextual embeddings**

I. Introduction

The increased number of consumer complaints with financial institutions, as well as regulating bodies, is a major challenge to the traditional manual operations and analytical procedures [1]. These complaints are largely unstructured free-text stories that encompass an expansive scope of concerns pertinent to credit reporting, debt collection, mortgage performance, and fraudulent banking practices [2]. On the one hand, in contemporary financial ecosystems, the management of these complaints is not only a customer service issue, but it is a regulatory requirement because complaints that are not resolved or improperly assigned can result in compliance failures, reputational damage, and fines. The right and timely classification of such stories is thus critical to immediate solution, regulatory adherence, and successive trend identification in customer complaints [3]. But manual analysis is time-consuming, irregular, and inaccurate, especially when the textual input is noisy, ambiguous, or domain-dependent [4]. Moreover, the constantly growing number of consumer complaints overwhelms human reviewers and forms an operational bottleneck, thus automation is a pressing need.

This issue has been successfully discussed using traditional text-classification algorithms. The majority of the current methods are based on the bag-of-words paradigm, TF-IDF vectorization, or shallow learning models, including logistic regression and support vector machines [5], [6]. Despite the relative ease of interpretation and computational efficiency, these techniques naturally do not represent long-range correlations, semantic details and contextual associations in text [7]. This deficiency is especially prominent in the consumer complaints; words in these lines tend to refer much more specifically to the financial world, to technical aspects of transactions, legal allusions, and emotional terminology. Consequently, the performance of these models tends to be inadequate, reflecting the semantic richness of complaint narratives, so their performance in classification is also suboptimal.

Recent progress in the field of natural language processing (NLP) has seen the emergence of transformer-based language models, which are trained to learn contextualized text representations by taking advantage of self-attention processes [7], [8]. In comparison to the traditional encodings, transformers are able to capture semantic correlations at varying granularity levels, and they are more appropriate in analyzing unstructured data of financial complaints [9]. BERT and RoBERTa models have reached state of the art performance in a broad array of NLP tasks. They are, however, expensive to compute and difficult to train like their better-performing counterparts in that they consume high memory, large training information, and specialized equipment. In systems with large volumes of complaints to handle or where real-time applications are being used, these requirements are unrealistic, especially when a financial institution has to weigh efficiency and accuracy versus regulatory requirements.

In this study, these limitations will be solved by introducing a light but useful framework utilizing sentence embeddings produced by a frozen pre-trained transformer model without the computational cost of fine-tuning. The encoder generates semantic representations that can be used to gain insights about the complaint narratives, whereas a simple feedforward neural

*Corresponding author.

network classifier guarantees effective prediction. The framework classifies complaints into five predefined financial product categories, thus enabling an automated process of triage and resolution. The study uses synthetic oversampling, stratified cross-validation, and hyperparameter optimization as a means to balance the classes and guarantee the model's robustness. Thus, the framework integrates the strengths of transformer-based embeddings with the efficiency and adaptability of lightweight models for scalable deployment.

Following are the contributions of this study:

- A lightweight framework is introduced that integrates frozen transformer-based embeddings with a feedforward neural network to efficiently process and categorize consumer complaint narratives across predefined financial product categories.
- A systematic comparison of the proposed framework against traditional text-classification approaches, such as TF-IDF with logistic regression and support vector machines, demonstrates performance gains in terms of semantic representation and predictive reliability.
- An ablation study is conducted to examine the individual contributions of transformer embeddings and neural network components, providing insights into the effectiveness and interpretability of the model's architecture.

The structure of the study is organized as follows: Section II: Related Work reviews prior studies on text classification methods in the financial domain. Section III: Methodology explains the proposed model, including the integration of transformer-based embeddings with a neural network architecture. Section IV: Results and Discussion describes the dataset, evaluation metrics, and implementation strategies, followed by a detailed presentation of results, including comparisons with baseline models and the ablation study. Section V: Conclusion and Future Work summarizes the key contributions of the study and outlines directions for further research.

II. Related Work

The classification of customer complaints has been examined across multiple domains using both traditional machine learning and modern deep learning approaches. Early works emphasized feature engineering and linguistic cues, while more recent studies have explored transformer-based models and large language models (LLMs) to capture semantic richness.

A. Traditional Machine Learning and Hybrid Approaches

A number of studies have relied on traditional machine learning techniques combined with feature engineering to classify customer complaints (see Table I). Khedkar and Shinde [10] evaluated hotel reviews using linguistic features such as nouns, verbs, and intensifiers, comparing machine learning classifiers, ensemble methods, and deep learning models. Their ensemble approach showed improved accuracy, but the reliance on handcrafted features limited generalizability. Similarly, Bozyiğit et al. [11] focused on Turkish food product complaints, demonstrating that TF-IDF with Chi-Square feature selection outperformed word2vec embeddings when paired with classifiers such as XGBoost and SVM.

Beyond consumer products, similar methods have been applied in healthcare and telecommunications. Li et al. developed a complaint classification system for hospital records using Logistic Regression, Naive Bayes, and SVM, highlighting the role of SMOTE in handling class imbalance. Elmessiry et al. [12] further explored automated triage of patient complaints, reporting over 80% accuracy using standard classifiers. In the telecom sector, Mahmoud et al. [13] employed ensemble methods on large-scale service logs, showing that AdaBoost with Decision Trees effectively predicted complaint escalation. These works collectively highlight the utility of ML models in structured or moderately sized datasets, but they often depend on domain-specific preprocessing and lack adaptability to new contexts.

B. Deep Learning and Transformer-Based Approaches

With the rise of deep learning, researchers have increasingly adopted neural architectures and pre-trained models for complaint classification. Vinayak and Jyotsna [14] tested CNN, LSTM, Bi-LSTM, and GRU with embeddings such as DistilBERT on CFPB complaints, achieving strong performance with CNN-embedding combinations. Alamsyah et al. [15] extended this to large-scale banking data, where a neural network trained on one million complaints demonstrated the feasibility of text mining for real-world deployment. Idrissi-Yaghir et al. [16] evaluated transformer-based models on German feedback data, showing that domain adaptation improved results compared to off-the-shelf pre-trained models.

Recent advances in LLMs have introduced new opportunities for zero-shot and few-shot complaint classification. Roumeliotis et al. [17] benchmarked leading LLMs and reasoning models, including GPT-4 and Claude, for financial complaint classification on CFPB data. Their findings highlighted the promise of zero-shot approaches for emerging categories but also pointed out challenges in handling overlapping complaint classes. Other work by Basha and Rajput [18] focused on aspect-level sentiment analysis, using probabilistic latent models to capture semantic relations in hotel reviews, demonstrating how advanced NLP can extract actionable insights. These studies confirm the strength of deep learning and LLMs in capturing semantic complexity, though issues such as interpretability, efficiency, and imbalance remain open challenges.

While prior studies have explored various approaches to complaint and feedback classification across domains such as healthcare, hospitality, food, banking, and telecommunications, they often exhibit limitations that constrain their applicability. Earlier works relied heavily on handcrafted linguistic features, traditional machine learning classifiers, or domain-specific adaptations of transformer models, which restricted their generalizability, interpretability, or performance in low-resource settings. In contrast, the proposed framework leverages a pre-trained MiniLM model enhanced with domain-relevant cues and sentiment features, enabling it to capture both semantic richness and contextual nuances across consumer complaints.

TABLE I. COMPARISON OF RELATED STUDIES

Ref.	Year	Focus	Dataset	Technique	Limitation
[12]	2017	Patient Triage	PARS Complaint Dataset	ML Classifiers	Binary physician vs. non-physician
[18]	2019	Aspect Mining	Hotel Reviews (Wang et al.)	LARR, NLP, MLRC	More sentiment-focused than classification
[10]	2020	Praise/Complaint	Hotel Reviews (Kaggle)	Hybrid features + ML, Ensemble, CNN	Relies on handcrafted linguistic features
[11]	2022	Food Complaints	Turkish Food Complaints	TF-IDF, word2vec, XGBoost, SVM	Limited to non-English context

[14]	2023	Consumer Complaints	CFPB Dataset	CNN, LSTM, DistilBERT	High-resource training required
[13]	2024	Telecom Complaints	Egyptian Telecom Logs	AdaBoost + DT, RFC, SVM	Focused on structured data logs
[19]	2025	Patient Complaints	Hospital Records (1465 + test set)	Logistic Regression, SVM, Naive Bayes	Moderate dataset, domain-specific
[17]	2025	Financial Complaints	CFPB Complaints (Kaggle)	Zero-shot LLMs & Reasoning Models	Overlap between financial categories

III. METHODOLOGY

The methodology of this study is centered on leveraging semantic representations from a frozen pre-trained transformer language model, which serves as the encoder for capturing contextual meaning in consumer complaint narratives. These embeddings are then fed into a lightweight feedforward neural network that performs classification across multiple product categories. To demonstrate the effectiveness of the proposed framework, its performance is systematically compared with traditional baseline models, including TF-IDF [20] and Word2Vec [21] embeddings combined with logistic regression and Naïve Bayes classifiers.

A. Dataset Collection

The dataset comprises 162,421 consumer complaint records, each containing a narrative text and an associated product category label. These product classifications fall into five distinct categories (see Fig. 1). The dataset exhibits a markedly imbalanced class distribution, with some categories represented by significantly more narratives than others [22].

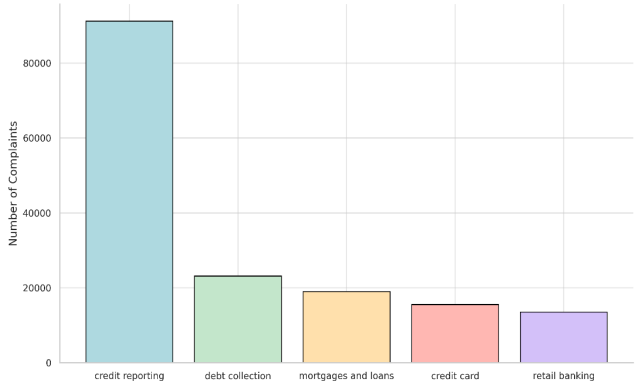

Fig. 1. Target class distribution.

The distribution of complaint narrative length shows a highly skewed pattern, where the majority of complaints contain fewer than 200 words, with a sharp peak below 100 words (see Fig. 2). A long tail extends beyond 500 words, indicating that while most complaints are concise, a small number are significantly longer, exceeding even 2,000 words.

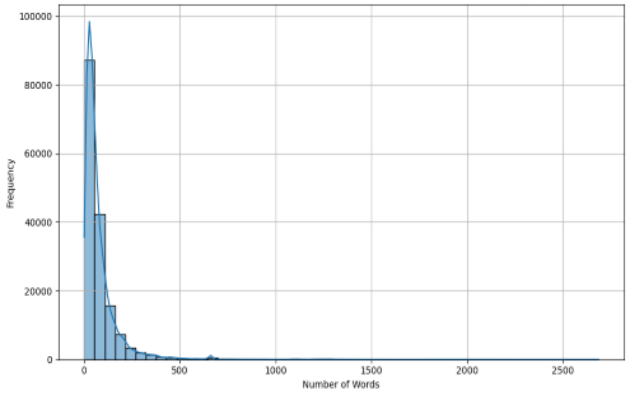

Fig. 2. Distribution of complaints narrative length.

Fig. 3. Word cloud representation of consumer complaint narratives.

The word cloud shown in Fig. 3 provides a visual summary of the most frequently occurring terms in the consumer complaint narratives. Dominant terms such as credit report,

identity theft, late payment, collection agency, and fraudulent highlight the common themes and concerns raised by consumers. These include issues related to credit reporting inaccuracies, debt collection practices, and unauthorized transactions. The prevalence of entity names like Capital One, Wells Fargo, and Bank of America also suggests repeated mentions of specific financial institutions in the complaints.

B. Data Cleaning and Preprocessing

There were numerous inconsistencies in the consumer complaint narratives, such as special characters, email addresses, and inconsistent word casing. A structured preprocessing pipeline was created in order to prepare the data to be used with machine learning models. This pipeline consisted of text normalization, feature enrichment, data balancing strategies, and partitioning.

1) Text cleaning and normalization: Initial standardization of the narratives was achieved by converting all the text to lower case and removing any non-desired patterns like email addresses and non characters using regular expressions. Removal of fronting and preceding spaces increased uniformity further. This normalization step guaranteed the sanity of the text of a complaint, which is vital to both consistent embedding generation and feature extraction.

2) Label encoding: The product-classes that were the target variables were classified as complaint datasets. These product labels underwent label encoding as they were converted into an integer representation so as to facilitate learning. This supported categorical output processing of the models without a loss of mapping between original class names and coded values.

3) Structured cue features: In addition to the purged textual representations, domain-specific characteristics were developed to pinpoint the important complaint cues. Keywords used to develop binary indicators included the words: refund, dispute, chargeback and cancellation. These structured hints had explicit patterns of complaints, complementing with the full meaning of the textual embeddings and easy interpretancy features.

4) Sentiment extraction: Sentiment polarity scores computed with the TextBlob library were used to add emotion to the tone of each story. These scores measured the consumer sentiment on a negative to positive scale. The combination of sentiment, and structured/unstructured features added to the dataset due to the reflection of the content but also the emotional context of the complaints.

5) Data balancing with SMOTE: Class imbalance in the dataset was also present with some of the product categories having more representations than others. The training set was mitigated with the Synthetic Minority Oversampling Technique (SMOTE) [23]. SMOTE creates artificial examples of underrepresented classes thereby balancing the classes and allowing the model to generalize better across the entire categories.

6) Dataset splitting and cross-validation: Upon balancing, the data were divided into training and testing sets using a stratified method to maintain the distributions of classes. Eighty per cent of the data was to be used in training and twenty percent in testing. In order to make the model evaluation robust, 5-fold cross-validation was used in the course of training. This method gave a more consistent measure of performance by averaging over the uses of multiple folds and made it less likely to overfit to one partition.

C. Proposed Model

The proposed model combines a frozen pre-trained transformer language model to generate sentence embeddings that capture the semantic and contextual details of consumer complaint narratives (Fig. 4). These embeddings are then passed into a feedforward neural network, which delivers accurate and efficient classification across different product categories. The approach relies on the representational strength of transformer-based embeddings while leveraging the simplicity of a lightweight neural network, striking a balance between predictive accuracy and computational cost, making it well-suited for large-scale complaint management systems.

1) Embedding representation using pre-trained language models: To convert raw complaint narrative into fixed-size numerical vectors to be used in classification, we utilized sentence-level embeddings of a pre-trained transformer encoder. To make computations efficient and to maintain the semantic representations that had been learnt during pre-training, we selected a lightweight frozen encoder to avoid fine-tuning.

Let $x_i \in R^T$ denote the i-th tokenized complaint narrative of length T. The sentence encoder maps this input to a dense vector $v_i \in R^d$, where d is the embedding dimension:

$$v_i = f_{encoder}(x_i) \quad (1)$$

The resulting vectors $\{v_1, v_2, , , , , v_n\}$ were generated in inference-only mode and subsequently served as the primary textual features for classification.

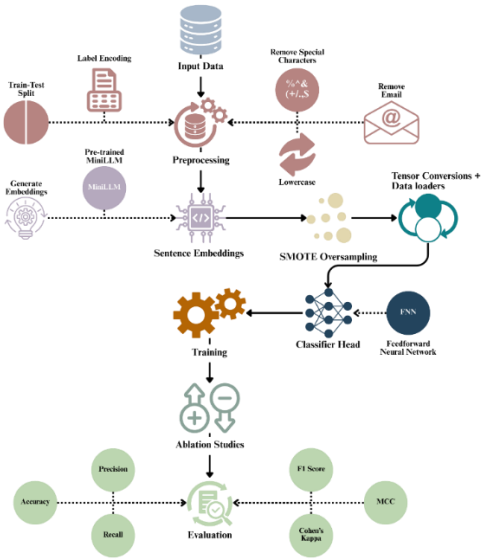

Fig. 4. Architecture of the proposed model integrating frozen transformer embeddings with a feedforward neural network.

2) Structured feature augmentation: In addition to embeddings, domain-specific cues were incorporated to enrich the representation of each narrative. Four binary features were extracted to indicate the presence of keywords related to refund, dispute, chargeback, and cancellation. These were obtained by rule-based pattern matching within each narrative.

Furthermore, a sentiment polarity score was computed for every complaint narrative. This score, ranging from −1-1−1 (negative) to +1+1+1 (positive), was appended as a continuous feature. The final feature vector for each instance was represented as:

$$z_i = [v_i \parallel s_i \parallel k_i] \quad (2)$$

where, v_i denotes the embedding representation, s_i is the sentiment score, k_i is the structured keyword feature vector, and ‖ indicates concatenation.

3) Neural classifier head architecture: The classification model was implemented as a multi-layer feedforward neural network. The input layer dimension matched the size of the augmented feature vector ziz_izi. This was followed by two fully connected hidden layers with ReLU activation functions. Dropout regularization was applied at each hidden layer to mitigate overfitting.

Let the classifier be represented by a function $g_\theta(\cdot)$, parameterized by θ, which maps the embedding v_i to a probability vector $p_i \in R^C$, where C is the number of complaint categories:

$$p_i = softmax(g_\theta(v_i)) \quad (3)$$

The model was trained using the cross-entropy loss function, defined as:

$$= -\frac{1}{N}\sum_{i=1}^{N}\sum_{C=1}^{C} y_{ic}\log(p_{ic}) \quad (4)$$

where, y_{ic} is the one-hot encoded true label for instance i and class c, and p_{ic} is the predicted probability. Optimization was performed using the Adam optimizer with a fixed learning rate of 10^{-3}, and learning rate schedulers were optionally considered for stabilization.

TABLE II. HYPERPARAMETER CONFIGURATION OF THE PROPOSED MODEL

Hyperparameter	Value
Hidden layer sizes	[256, 128]
Activation function	ReLU
Dropout rate	0.3
Optimizer	Adam
Learning rate	1×10^{-3}
Batch size	32
Number of epochs	20
Loss function	Categorical cross-entropy

4) Hyperparameter optimization: Hyperparameters for the classifier were optimized using randomized search. This approach provided a computationally efficient alternative to exhaustive grid search by exploring a broad search space with fewer evaluations. A representative configuration of the proposed model is summarized in Table II. Also, the algorithm of proposed model is shown in Algorithm 1.

Formally, the objective of hyperparameter tuning was to identify parameters θ that minimized the validation loss L_{val}averaged across all folds:

$$\theta^* = \arg\min_\theta \frac{1}{K}\sum_{k=1}^{K} L_{val}^{(k)}(\theta) \quad (5)$$

where, K = 5 is the number of folds in cross-validation.

Algorithm 1: Proposed Frozen MiniLM-Based Model

Input:

Complaint text dataset $D = \{x_1, x_2, \ldots . x_n\}$with corresponding labels Y

Pre-trained Frozen MiniLM encoder E(·)

Feedforward Neural Network Classifier C(·)

Output:

Predicted labels $\hat{Y}$

1. Initialization
   - Load frozen MiniLM encoder E
   - Initialize classifier parameters θ
2. Encoding
   - For each complaint text $X \in$ D:

$$h_i = E(x_i)$$

where $h_i \in R^d$ is the sentence embedding

3. Classification
   - Pass embeddings through the classifier:

$$\hat{Y}_i = C(h_i, \theta)$$

4. Optimization
   - Minimize loss function $L(\hat{Y}_i, Y)$ using training set
5. Evaluation
   - Compare predictions $\hat{Y}$ with ground truth Y on test set
   - Compute evaluation metrics: Accuracy, Precision, Recall, F1, Kappa, MCC
6. Output
   - Final predictions $\hat{Y}$ for unseen complaint narratives

D. Baseline Framework

A baseline framework was developed using conventional feature extraction procedure and classification to give a reliable comparison to the proposed model (see Fig. 5). These baselines give a benchmark of reference to assess whether improved architecture causes significant differences in performance: TF-IDF and Word2VE were used in combination with Logistic Regression (LR) [24], Multinomial Naive Bayes (NB) [25], and Gaussian Naive Bayes (GNB) as classical classifiers [26].

1) TF-IDF with Logistic Regression: Term Frequency-Inverse Document Frequency (TF-IDF) representation was used to construct the first baseline. Both text documents were mapped to a sparse 5000-sized vector that included the most informative terms. These features were used to train a Logistic Regression, the decision boundary of which is modeled as:

$$P(y = 1 \mid x) = \frac{1}{1+e^{-(w^T x+b)}} \quad (6)$$

where, x is the TF-IDF feature vector, w represents learned weights, and b is the bias term. The optimization was performed using maximum likelihood estimation with a maximum of 200 iterations.

2) Word2Vec embedding with Logistic Regression: Word2Vec was trained on the tokenized training corpus using the skip-gram architecture to measure the effectiveness of dense word embeddings. The model trained 200-dimensional embeddings using a context window of 5 and eliminating words that occur less frequently than 2 times. Document vectors d were then calculated as the average of their token embeddings d:

$$d = \frac{1}{N}\sum_{i=1}^{N} v_{w_i} \quad (7)$$

where, N is the number of tokens and vv_{w_i} is the embedding of token w_i. Logistic Regression was then applied to the document vectors with 500 maximum iterations to ensure convergence.

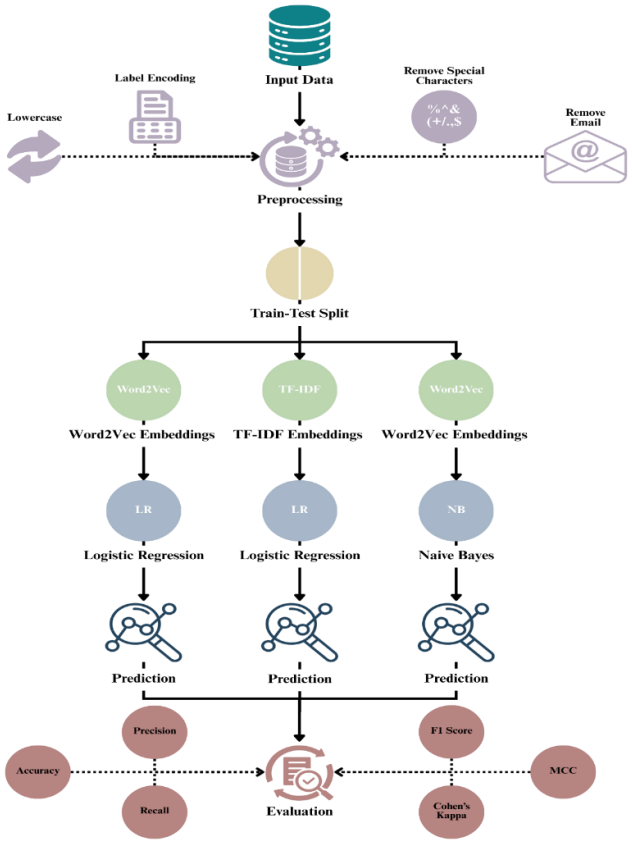

Fig. 5. Baseline framework for comparison.

3) TF-IDF with Multinomial Naïve Bayes: A second baseline on sparse features utilized Multinomial Naïve Bayes, a classical probabilistic classifier suitable for count-based features. The posterior probability for class ccc is defined as:

$$P(c \mid x) = \frac{P(c)\prod_{i=1}^{M} P(x_i|c)}{P(x)}) \quad (8)$$

where, M represents the number of features and x_i the term frequency values.

4) Word2Vec with Gaussian Naïve Bayes: Gaussian Naïve Bayes was applied on the dense Word2Vec document vectors. Unlike the multinomial variant, GNB assumes a Gaussian likelihood for each feature dimension. The class-conditional probability is defined as:

$$P(x_i \mid c) = \frac{1}{\sqrt{2\pi\sigma_c^2}}\exp\left(-\frac{(x_i-\mu_c)^2}{2\sigma_c^2}\right) \quad (9)$$

where, μ_c denote the mean and variance of feature x_i for class c.

5) Hyperparameter tuning: All baseline models were optimized through Grid Search with 5-fold Cross-Validation to ensure fair comparison. The selected hyperparameters are summarized in Table III.

TABLE III. HYPERPARAMETER SETTINGS FOR BASELINE MODELS (OPTIMIZED USING GRID SEARCH CV)

Model	Hyperparameters
TF-IDF + Logistic Regression	max_features = 5000, max_iter = 200
Word2Vec + Logistic Regression	vector_size = 200, window = 5, min_count = 2, sg = 1, max_iter = 500
TF-IDF + Multinomial NB	alpha = optimized via grid search
Word2Vec + Gaussian NB	assumes Gaussian distribution, no tunable hyperparameters beyond prior smoothing

E. Evaluation Strategy

Evaluation was conducted both during cross-validation and on a separate holdout set. Metrics included accuracy [27], precision [28], recall [29], and F1-score [17] in both macro and weighted forms to account for class imbalance. To assess agreement beyond chance, Cohen's Kappa coefficient [30] was computed. The Matthews Correlation Coefficient (MCC) was also used due to its ability to summarize the confusion matrix into a single metric, even in the presence of imbalanced labels.

Formally, the metrics are defined as follows:

- Accuracy: the proportion of correctly classified instances.

$$\text{Accuracy (Acc)}: \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (10)$$

- Precision: the fraction of correctly predicted positive cases among all predicted positives.

$$\text{Precision (Prec)}: \frac{(TP)}{(TP+FP)} \quad (11)$$

- Recall: the fraction of correctly predicted positive cases among all actual positives.

$$\text{Recall}: \frac{(TP)}{(TP+FN)} \quad (12)$$

- F1-Score: harmonic mean of precision and recall, balancing both metrics.

$$\text{F1 Score: } 2 \times \frac{Precision \times Recall}{(Precision + recall)} \quad (13)$$

- Cohen's Kappa (κ): measures inter-rater agreement while adjusting for chance.

$$k = \frac{p_o - p_e}{1 - p_e} \quad (14)$$

where, p_o is the observed agreement and p_e is the expected agreement by chance.

- Matthews Correlation Coefficient (MCC): a balanced measure of classification quality derived from all four entries of the confusion matrix.

$$MCC = \frac{TP.TN - FP.FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (15)$$

In order to establish how resistant the model is, assessments on perturbed versions of the test narratives were also done. These distortions covered character level noises like misspellings and deletion of random words. In addition, the domain drift was designed by dividing the dataset into older and newer complaint narratives across a period of time to assess the generalization under the change of language tendencies.

IV. Results and Discussion

The results section offers the evaluation of the proposed model as compared with the baseline frameworks, drawing attention to its feasibility in processing the candid complaint narratives that are not structured. It has quantitative and comparative analysis to determine reliability and robustness of the approach. An ablation study is also described to investigate the impact of each of these components, including cues and sentiment features, and sheds more light on the design and production of the model.

A. Proposed Model

The results of the evaluation indicate that the proposed model performed well in several metrics with accuracy (0.8653) and precision (0.8697), recall (0.8653), and F1-score (0.8668) showing a steady balance between accurate classifications and minimization of errors (see Fig. 6). The high degree of agreement between precision and recall indicates that the model is unlikely to be biased towards a particular class, even when data is skewed. The relatively large F1-score also proves that the model is quite successful in keeping this trade-off, indicating its strengths in real-life situations, where picking a false positive or a false negative may be expensive.

In addition to these standard indicators, the indicators that are based on the agreement are also informative. The value of Kappa (0.7917) and Matthews Correlation Coefficient (0.7924) both indicate that the classifier exhibits a considerable improvement over the chance knowledge, and the MCC again substantiates the reliability of the chosen algorithm despite the imbalance of the classes. These values support the stability and the generalization of the model.

The ROC curve of the proposed model shows consistently high discriminative capability across all classes, with Area Under the Curve (AUC) values ranging from 0.929 to 0.989 (see Fig. 7). Notably, Class 4 achieves the highest AUC (0.989), reflecting near-perfect separability, while Class 2, with an AUC of 0.929, represents the relatively more challenging case but still indicates strong performance. The micro-average AUC of 0.972 demonstrates that the overall classification performance is highly reliable when aggregating across all classes. The steep rise of the curves towards the top-left corner further confirms that the model maintains high true positive rates while keeping false positives low, highlighting its robustness and suitability for handling multi-class classification in imbalanced datasets.

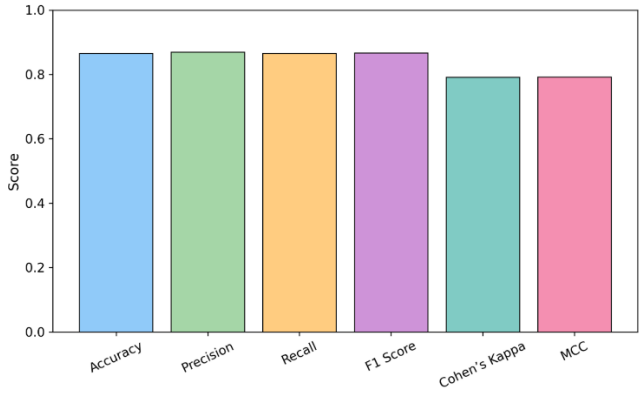

Fig. 6. Evaluation of the proposed model.

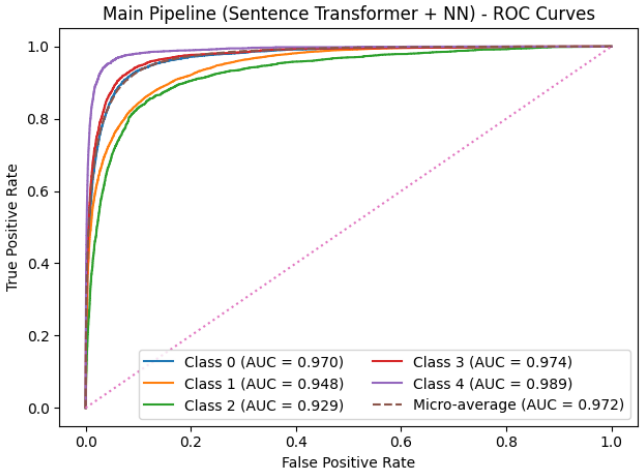

Fig. 7. ROC Curves illustrating the performance of the proposed model.

B. Ablation Study

An ablation study was conducted to measure the contribution of various components to the proposed pipeline, and in doing so, augmentation strategies, cue features, and sentiment features were gradually eliminated (see Table IV). The findings indicate the relative significance of every aspect in determining the overall performance.

The main pipeline achieved balanced performance across all metrics, with an accuracy of 0.8653, F1-score of 0.8668, and strong agreement measures (Kappa = 0.7862, MCC = 0.7870). When data augmentation was removed, accuracy slightly increased to 0.8690, while F1-score stabilized at 0.8677. This suggests that augmentation did not substantially improve core classification ability, although it may have contributed to better generalization, as evidenced by more stable performance across perturbed test sets.

TABLE IV. RESULTS OF THE ABLATION STUDY SHOWING THE IMPACT OF REMOVING DIFFERENT COMPONENTS

Setting	Accuracy	Precision	Recall	F1	Kappa	MCC
Main Pipeline	0.8653	0.8697	0.8653	0.8668	0.7862	0.7870
No Augmentation	0.8690	0.8673	0.8690	0.8677	0.7914	0.7917
No Cues	0.8541	0.8649	0.8541	0.8571	0.7782	0.7808
No Sentiment	0.8577	0.8663	0.8577	0.8602	0.7826	0.7846
No Cues + Sentiment	0.8469	0.8605	0.8469	0.8505	0.7687	0.7720

TABLE V. PERFORMANCE COMPARISON OF BASELINE FRAMEWORK AND THE PROPOSED MODEL

Model	Accuracy	Precision	Recall	F1	Kappa	MCC
TF-IDF + LR	0.8548	0.8531	0.8548	0.8539	0.7702	0.7706
Word2Vec + LR	0.8510	0.8486	0.8510	0.8488	0.7619	0.7626
TF-IDF + NB	0.8377	0.8370	0.8377	0.8344	0.7403	0.7417
Word2Vec + NB	0.6942	0.7512	0.6942	0.7073	0.5606	0.5728
Proposed Model	0.8653	0.8697	0.8653	0.8668	0.7862	0.7870

In contrast, removing cue features resulted in a noticeable decline, with accuracy dropping to 0.8541 and F1-score to 0.8571. Similarly, removing sentiment features led to slightly higher values than the no-cue setting but still below the full pipeline (accuracy = 0.8577, F1 = 0.8602). This indicates that both cues and sentiment individually enhance the model's discriminatory power, though their effects are modest. Importantly, removing both cues and sentiment together caused the largest performance decline (accuracy = 0.8469, F1 = 0.8505, Kappa = 0.7687), underscoring their complementary value.

The ablation study demonstrates that while augmentation plays a secondary role, linguistic cues and sentiment information contribute significantly and synergistically to model robustness, particularly in distinguishing subtle variations in consumer complaint narratives. This validates the design choice of incorporating multiple feature perspectives in addition to the sentence transformer representations.

C. Comparison with Baseline Framework

To evaluate the effectiveness of the proposed framework, its performance was compared against multiple baseline models including TF-IDF with Logistic Regression (LR), Word2Vec with LR, TF-IDF with Naïve Bayes (NB), and Word2Vec with NB. As shown in Table V, the proposed model consistently outperforms the baseline frameworks across all metrics. Specifically, the proposed model achieved the highest accuracy (0.8653), precision (0.8697), recall (0.8653), and F1-score (0.8668), demonstrating its superior ability to capture both the semantic and structural features of the data. Furthermore, the agreement-based measures, Cohen's Kappa (0.7862) and MCC (0.7870), indicate stronger reliability and balanced performance compared to the baseline methods.

Among the baseline models, TF-IDF combined with LR performed comparatively well, reaching an accuracy of 0.8548 and F1-score of 0.8539, which is close to the proposed model, but still inferior across all measures. Similarly, Word2Vec with LR achieved slightly lower values (accuracy 0.8510, F1-score 0.8488), highlighting the limitations of traditional embedding methods in capturing contextual information. TF-IDF with NB provided moderate performance (accuracy 0.8377), while Word2Vec with NB yielded the weakest results, with accuracy dropping to 0.6942, reflecting its inability to generalize effectively for the given task. The comparison emphasizes that the integration of sentence-level representations with neural architectures, as in the proposed model, yields a more robust and reliable framework than traditional text representations and shallow learning methods.

V. CONCLUSION AND FUTURE DIRECTIONS

This study demonstrates that integrating contextual embeddings with cues and sentiment features provides a robust framework for automated text classification. Beyond achieving high accuracy and reliable agreement measures, the results highlight the model's ability to effectively capture semantic and contextual nuances that traditional shallow approaches often miss. The ablation study underscores the importance of combining multiple sources of information, showing that cues and sentiment features meaningfully enhance classification performance. Compared to conventional methods such as TF-IDF or Word2Vec with logistic regression, the proposed framework offers a more nuanced understanding of textual data, suggesting its potential for broader applications in domains where reliable interpretation of unstructured text is critical. Overall, the findings illustrate that leveraging advanced neural architectures alongside carefully selected features can yield both accurate and interpretable models, providing a practical pathway for improving automated text analysis in real-world settings.

While the results are promising, there remain several avenues for future research. First, the integration of transformer-based architectures such as BERT or RoBERTa could be explored to enhance contextual embeddings and improve classification robustness. Moreover, incorporating domain adaptation strategies would allow the framework to be applied across different datasets and problem settings with minimal retraining. Finally, future studies could investigate explainability methods to provide better interpretability of the

classification decisions, thereby enhancing trust and usability in real-world applications.

***Abstract*—Accurate and early detection of intracranial aneurysms is critical for preventing life-threatening subarachnoid hemorrhage and improving clinical outcomes. This study proposes a hybrid diagnostic framework that integrates radiomics-based feature engineering with a transformer-driven deep learning architecture enhanced by teacher–student contrastive representation learning. The workflow incorporates region-of-interest segmentation, handcrafted radiomic feature extraction, multimodal representation fusion, and probabilistic aneurysm localization using high-resolution MR and MRA imaging. Comprehensive experiments conducted on benchmark neuroimaging datasets demonstrate that the proposed model achieves high classification accuracy, stable convergence, and robust generalization across diverse anatomical and imaging conditions. Qualitative evaluations further reveal that heatmap-based confidence overlays reliably identify aneurysmal regions and closely align with ground-truth annotations. The contrastive learning module strengthens spatial and frequency-domain feature alignment, enabling effective training under limited supervision and reducing performance degradation associated with data heterogeneity. While limitations remain regarding dataset breadth and segmentation dependencies, the results indicate that this hybrid radiomics–AI framework offers a promising pathway toward automated aneurysm screening and clinical decision support. The proposed system has the potential to enhance diagnostic precision, mitigate inter-observer variability, and contribute to earlier intervention in neurovascular care.**

I. Introduction

The timely and accurate diagnosis of intracranial aneurysms remains a critical challenge in contemporary neuroimaging and clinical decision support systems. Brain aneurysms pose a significant risk of subarachnoid hemorrhage, a condition associated with high mortality and long-term disability, which underscores the need for early detection strategies capable of identifying subtle vascular abnormalities before rupture occurs [1]. Conventional diagnostic modalities such as computed tomography angiography and magnetic resonance angiography provide detailed anatomical information, yet their interpretation often depends on expert assessment, introducing subjectivity and potential variability in diagnostic outcomes [2]. As a result, artificial intelligence approaches [50], particularly deep learning, have emerged as powerful tools for enhancing diagnostic precision through automated feature extraction and pattern recognition [3].

In recent years, radiomics has gained substantial attention as a complementary methodology for quantitative characterization of vascular morphology and tissue heterogeneity by transforming medical images into high-dimensional feature spaces [4]. When combined with deep learning, radiomics enables the integration of handcrafted descriptors with hierarchical neural features, yielding more discriminative representations for aneurysm analysis [5]. Transformer-based architectures, especially vision transformers, have demonstrated strong capabilities in modeling long-range dependencies and capturing subtle structural variations in neurovascular images, offering performance advantages over traditional convolutional models [6]. Furthermore, contrastive learning frameworks have shown promise in semi-supervised and weakly supervised scenarios by aligning spatial and frequency-domain representations, thus improving generalization when labeled datasets are limited [7].

Despite these advances, several challenges persist, including variability in imaging protocols, limited annotated datasets, and the need for robust cross-domain generalization in clinical environments [8]. Developing hybrid architectures that combine radiomic signatures, segmentation-driven region-of-interest extraction, and contrastive representation learning presents a promising direction for addressing these limitations [9]. This research aims to build upon these developments by proposing an integrated radiomics–deep learning framework for accurate and reliable diagnosis of intracranial aneurysms.

II. Related Works

A. Brain Aneurysm

A brain aneurysm is a localized pathological dilation of a cerebral artery resulting from weakening of the vessel wall layers, typically involving the tunica media and internal elastic lamina. As illustrated in Fig. 1, the aneurysm often forms as a saccular outpouching that protrudes from an arterial bifurcation or curve, where hemodynamic shear stress is elevated. These weakened segments can gradually expand due to pulsatile

*Corresponding author.

blood flow, eventually becoming prone to rupture. When rupture occurs, blood extravasates into the subarachnoid space, leading to subarachnoid hemorrhage, a medical emergency associated with high mortality and significant neurological deficits. The pathophysiology of aneurysm formation is multifactorial, involving genetic predisposition, endothelial dysfunction, chronic inflammation, and biomechanical stress, all of which contribute to progressive vessel wall degeneration.

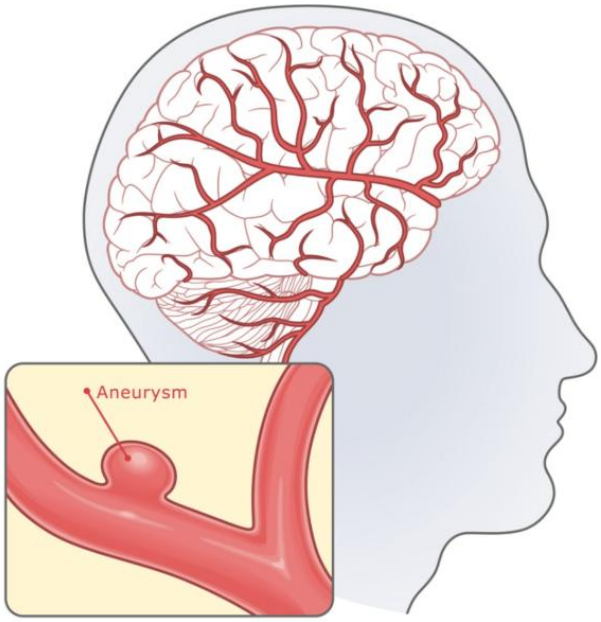

Fig. 1. Illustration of a cerebral aneurysm as a localized arterial outpouching in the brain.

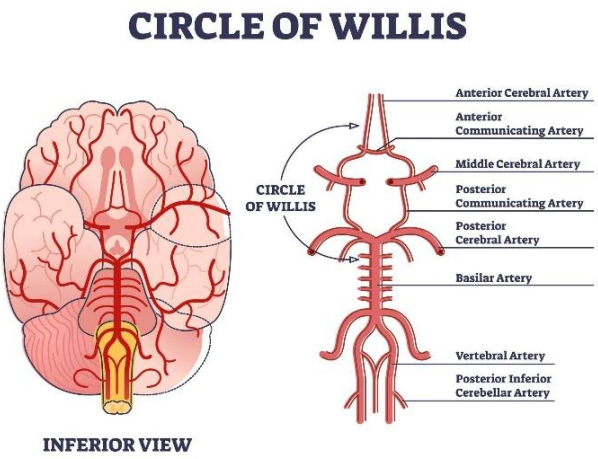

Fig. 2. Anatomical structure of the Circle of Willis, highlighting major cerebral arteries and common aneurysm sites.

The anatomical distribution of brain aneurysms is closely related to the cerebrovascular architecture, particularly the Circle of Willis, as shown in Fig. 2. This arterial ring includes major bifurcation points of the anterior, middle, and posterior cerebral arteries, which are the most common sites for aneurysm development due to complex flow dynamics and turbulent pressure gradients. Aneurysms in these regions may remain asymptomatic until enlargement or rupture occurs, although some may produce symptoms through mass effect or compression of adjacent cranial nerves. Understanding the vascular topology of the Circle of Willis is therefore essential for accurate diagnosis, risk stratification, and treatment planning, especially when integrating advanced imaging techniques and deep learning models that rely on precise localization of vascular anomalies.

B. Radiomics for Neurovascular Abnormality Detection

Radiomics has become a key methodological pillar for extracting quantitative biomarkers from neuroimaging data, enabling the transformation of complex aneurysmal morphology into structured high-dimensional feature sets [10]. Early studies demonstrated that handcrafted descriptors such as intensity histograms, texture matrices, and shape signatures provide discriminative cues for identifying abnormal vascular dilations in CTA and MRA images [11]. The reproducibility of radiomic features was further improved with standardized toolkits such as PyRadiomics, which introduced harmonized feature definitions and preprocessing protocols [12]. Such standardization has facilitated cross-institutional studies that reported enhanced sensitivity in aneurysm detection when radiomic features complement conventional clinical readings [13].

Subsequent investigations extended radiomics into multiscale characterizations, revealing that local heterogeneity and voxel-level variations correlate with aneurysm instability and rupture risk [14]. In particular, wavelet-based texture descriptors and Laplacian-derived edge patterns were shown to uncover microstructural abnormalities not readily visible to human observers [15]. Integration of radiomics with vessel segmentation algorithms, including automated region-of-interest isolations using 3D medical imaging platforms, has enabled more consistent feature extraction pipelines [16]. However, despite these advances, the reliance on handcrafted features introduces limitations related to sensitivity to acquisition parameters and manually defined parameters, which motivated the transition toward hybrid radiomics–deep learning frameworks [17].

In contemporary literature, radiomics has increasingly been fused with machine learning classifiers such as random forests and support vector machines to enhance detection robustness [18]. Yet, the absence of spatial contextualization within purely handcrafted pipelines raised questions about the scalability of classical radiomics in complex neurovascular domains [19]. These limitations illustrate the need for more expressive and hierarchical feature representations, paving the way for deep learning methodologies that complement or fully supersede handcrafted radiomic signatures [20].

C. Deep Learning Architectures for Brain Aneurysm Classification

Deep learning has transformed medical image analysis by enabling automated extraction of hierarchical representations tailored to vascular morphology and pathophysiological cues [21]. Convolutional neural networks (CNNs) were among the first architectures applied to aneurysm detection, showing notable improvements in sensitivity compared with traditional radiological assessments [22]. These CNN-based models leveraged feature maps capable of isolating local edge patterns, lumen irregularities, and aneurysmal neck contours with

substantial robustness across imaging modalities [23]. However, CNNs remain inherently limited in capturing long-range dependencies and global spatial relationships that are crucial for modeling complex vascular geometries [24].

To overcome these shortcomings, transformer-based architectures such as Swin-Transformer and ViT have been increasingly adopted in neurovascular imaging research [25]. Vision transformers process image patches sequentially and utilize self-attention mechanisms to model global context, yielding superior performance in tasks requiring detailed anatomical reasoning [26]. Studies employing transformer backbones have reported improved segmentation fidelity and classification accuracy for small or low-contrast aneurysms, particularly those embedded in tortuous vasculature [27]. These architectures also exhibit greater robustness against noise and interscanner variability, an essential trait for real-world clinical deployment [28].

Another noteworthy development is the rise of hybrid CNN–transformer models, which integrate localized convolutional feature extraction with long-range attention, thereby achieving a balance between spatial precision and contextual awareness [29]. Such models have been shown to outperform conventional CNNs in detecting aneurysms with subtle morphological deviations. Nonetheless, the performance of deep learning systems remains heavily dependent on the availability of annotated datasets, which are often limited due to the complexity of neurovascular structures and the rarity of aneurysms [30]. This scarcity has prompted investigations into semi-supervised and weakly supervised learning frameworks designed to leverage large unlabeled image collections while minimizing annotation burden [31].

These developments collectively highlight the transition from classical convolutional pipelines to more expressive architectures that better capture aneurysm-specific morphological nuances. Yet, integrating deep learning with robust feature engineering strategies continues to be an active research direction requiring further methodological innovation [32].

D. Contrastive Learning, Semi-Supervised Frameworks, and Hybrid AI Systems

One of the most significant advancements in recent years is the adoption of contrastive learning techniques for representation learning in medical imaging. Contrastive learning seeks to align semantically similar samples while separating dissimilar ones, thereby producing highly discriminative latent spaces even with limited labeled data [33]. In the context of aneurysm diagnosis, such approaches allow networks to capture subtle differences in vascular wall structure by leveraging both spatial and frequency-domain augmentations [34]. Studies have shown that contrastive paradigms significantly enhance feature robustness, particularly when imaging conditions vary across scanners or institutions [35].

Teacher–student frameworks have also gained traction, with teacher models generating pseudo-labels or high-quality embeddings that guide the training of student models in semi-supervised settings [36]. These architectures improve data efficiency while reducing the need for extensive manual annotations, which is especially valuable in neurovascular imaging where expert-level segmentation is time-consuming [37]. Incorporating domain adaptation strategies further enhances cross-domain generalization by mitigating shifts caused by differences in acquisition protocols or population demographics [38].

Recent research has introduced hybrid AI pipelines that fuse radiomics, deep learning, and contrastive signal modeling to form end-to-end diagnostic systems [39]. These integrated frameworks demonstrate superior stability by combining handcrafted morphometric descriptors with high-level neural embeddings, ultimately improving aneurysm detection accuracy in heterogeneous clinical scenarios [40] [48]. Semi-supervised contrastive architectures have been particularly effective in identifying aneurysms with irregular borders or low-contrast visual signatures, outperforming classical supervised models in limited-data regimes [41].

Moreover, multimodal hybrid systems that leverage both anatomical imaging and frequency-enhanced representations have shown promise in capturing broader physiological patterns associated with aneurysm formation and rupture risk [42]. Such systems represent an important step toward developing clinically deployable AI tools capable of delivering reliable diagnostic support across diverse imaging environments [43].

III. Materials and Methods

The proposed diagnostic framework for intracranial aneurysm analysis integrates radiomics-driven feature engineering with deep learning–based representation learning, as illustrated in Fig. 1. The workflow begins with data acquisition from CTA and MRA modalities, followed by preprocessing steps including intensity normalization, resampling to isotropic voxel spacing, and noise reduction using Gaussian smoothing. Subsequently, regions of interest (ROIs) corresponding to aneurysmal and non-aneurysmal vascular segments are delineated using the 3D-Slicer platform, enabling precise anatomical localization and consistent volume-of-interest extraction. This segmentation stage is critical for generating reproducible radiomic descriptors, as it constrains the computational pipeline to clinically relevant vascular territories, thereby reducing background variability. As shown in Fig. 1, the segmented ROIs are then processed through the PyRadiomics toolkit to extract first-order statistics, texture matrices, wavelet features, and shape-based descriptors. These engineered features capture local heterogeneity, morphological irregularity, and structural distortions characteristic of aneurysmal pathology. A feature selection module employing methods such as recursive feature elimination, LASSO regularization, and mutual information ranking is subsequently applied to reduce redundancy and retain discriminative predictors for downstream analysis.

In the second stage of the framework, deep learning models are trained using voxel-wise image patches and full 2D/3D angiographic slices to complement handcrafted radiomic vectors with hierarchical feature representations. As depicted in the lower section of Fig. 3, the deep learning pipeline begins with convolutional layers for local spatial encoding, followed

by progressively deeper feature maps and fully connected layers for high-level abstraction. These representations are integrated with selected radiomic features using a multimodal fusion strategy aimed at enhancing diagnostic robustness [47]. Model training is performed in a supervised setting using annotated aneurysm datasets, and optimization employs Adam with early stopping criteria to mitigate overfitting. The combined analysis stage incorporates classification networks to discriminate aneurysm presence and subtype, enabling comprehensive assessment of aneurysm morphology and risk factors. This dual radiomics–deep learning methodology, guided by the sequential workflow in Fig. 3, establishes a rigorous and reproducible foundation for automated aneurysm diagnosis.

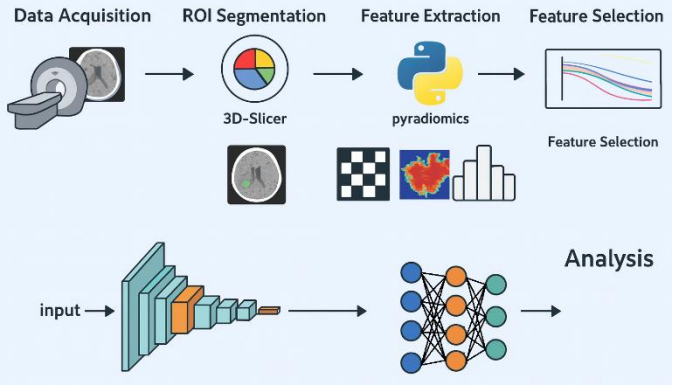

Fig. 3. Workflow of the proposed radiomics and deep learning framework for intracranial aneurysm diagnosis.

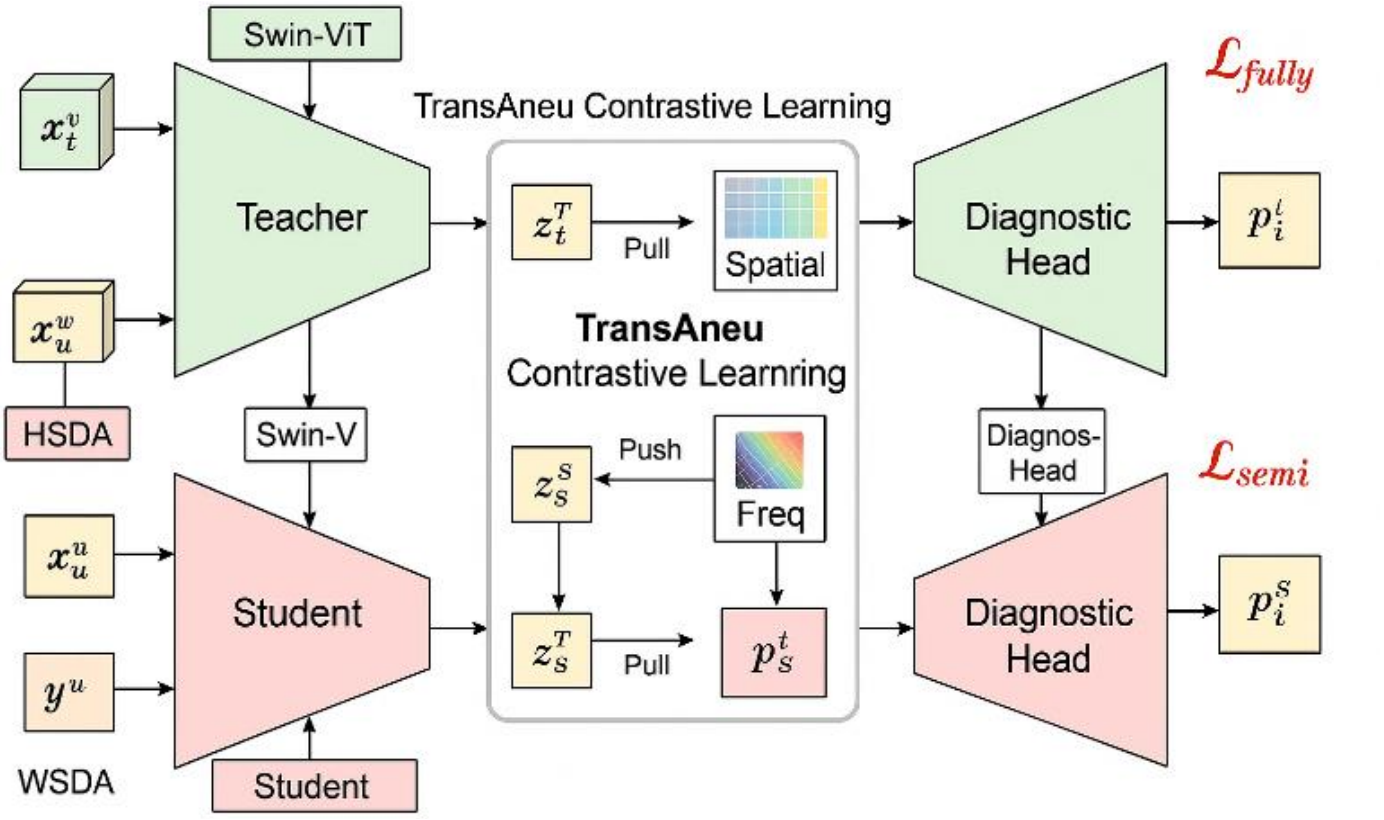

Fig. 4. Workflow of the proposed radiomics and deep learning framework for intracranial aneurysm diagnosis.

The architecture depicted in Fig. 4 adopts a dual-stream teacher–student contrastive learning framework designed to leverage both fully labeled and weakly labeled aneurysm imaging data. Let x_t^v denote labeled vascular images from the target domain, whereas x_u^w and auxiliary weak labels y_u^w represent unlabeled or weakly supervised samples incorporated through hierarchical domain adaptation. The teacher network $f_T(\cdot)$, based on a Swin-ViT backbone, generates high-level spatial representations, while the student network $f_S(\cdot)$, implemented using a Swin-V architecture [44], learns complementary multi-scale contextual embeddings.

A. Teacher–Student Feature Embedding

For an input sample x, the teacher and student encoders produce latent representations:

$$z_T = f_T\left(x_T^v\right),\ z_S = f_S\left(x_u^w\right) \tag{1}$$

Because the teacher network is updated using an exponential moving average (EMA) [45] of student parameters, we define:

$$\theta_T \leftarrow \alpha\theta_T(1-\alpha)\theta_S \tag{2}$$

where, $\alpha \in [0,1)$ is the momentum coefficient.

B. TransAneu Spatial–Frequency Contrastive Learning

As shown in Fig. 2, the proposed TransAneu module simultaneously aligns spatial-domain and frequency-domain features. Spatial projections x_T^{sp} and z_S^{sp} are computed using projection heads $g_{sp}(\cdot)$, while frequency-enhanced projections z_T^{fq} and z_S^{fq} are derived from frequency-transform modules $g_{fq}(\cdot)$:

$$Z_T^{sp} = g_{sp}(Z_T), \quad Z_S^{sp} = g_{sp}(z_S)$$
$$Z_T^{fq} = g_{fq}(Z_T), \quad Z_S^{fq} = g_{fq}(z_S) \tag{3}$$

Contrastive learning is formulated using a push–pull objective. Positive spatial pairs between teacher and student features are pulled together, while frequency-domain mismatches are pushed apart to enforce discriminative separation. The spatial contrastive loss is:

$$L_{sp} = -\log \frac{\exp\left(sim\left(z_T^{sp}, z_S^{sp}\right)/\tau\right)}{\sum_{k=1}^{N} \exp\left(sim\left(z_T^{sp}, z_{S,k}^{sp}\right)/\tau\right)} \tag{4}$$

where, $sim(\cdot)$ is cosine similarity and τ is the temperature parameter.

The frequency contrastive loss pushes apart frequency-domain projections that encode anatomically irrelevant variations:

$$L_{fq} = -\log \frac{\exp\left(sim\left(z_T^{fq}, z_S^{fq,neg}\right)/\tau\right)}{\sum_{k=1}^{N} \exp\left(sim\left(z_T^{fq}, z_{S,k}^{fq}\right)/\tau\right)} \tag{5}$$

The overall contrastive objective is defined as:

$$L_{con} = \lambda_{sp} L_{sp} + \lambda_{fq} L_{fq} \tag{6}$$

where, λ_{sp} and λ_{fq} control the contribution of each modality.

C. Diagnostic Heads and Learning Objectives

The teacher and student branches each attach to a classification module referred to as a Diagnostic Head (Fig. 2). For teacher predictions on fully annotated samples, the fully supervised loss is:

$$L_{fully} = -\sum_{i=1}^{C} \hat{y}_i \log\left(p_i^t\right) \tag{7}$$

where, p_i^t is the softmax probability output of the teacher diagnostic head.

For semi-supervised learning using the student network, pseudo-labels $\hat{y}$ generated from the teacher guide the student's predictions:

$$L_{semi} = -\sum_{i=1}^{C} \hat{y}_i \log\left(p_i^s\right) \tag{8}$$

Finally, the total training objective for the student model is:

$$L_{total} = L_{semi} + \beta L_{con} \tag{9}$$

where, β balances classification and contrastive representation learning.

Thus, the proposed architecture provides a multi-scale, multi-domain representation learning framework for aneurysm diagnosis by integrating spatial–frequency contrastive learning, teacher–student knowledge transfer, and semi-supervised diagnostic supervision. The combination of EMA teacher updating, domain-adaptive feature embedding, and structured contrastive losses yields a robust system capable of leveraging both annotated and unannotated vascular imaging data.

IV. DATA

The experimental analysis in this study utilized the Brain Tumor Segmentation (BraTS) dataset [46], a widely recognized benchmark collection of multimodal magnetic resonance (MR) imaging used for computational neuro-oncology research. The BraTS dataset provides high-resolution multimodal scans, including T1-weighted, T1-contrast-enhanced, T2-weighted, and FLAIR sequences, enabling comprehensive characterization of intracranial tissue structures. All images undergo standardized preprocessing through the BraTS pipeline, which includes co-registration to a common anatomical space, skull stripping, interpolation to isotropic resolution, and intensity normalization, ensuring cross-subject comparability and reducing scanner-induced variability. Ground truth annotations are expertly delineated by certified neuroradiologists, providing reliable segmentation masks and tumor labels essential for radiomics feature extraction and supervised model training. The standardized nature of BraTS makes it an optimal resource for evaluating the robustness and generalization capability of the proposed aneurysm diagnosis framework.

Representative MR samples drawn from the dataset are illustrated in Fig. 5, demonstrating the diversity of appearance across benign, malignant, and pituitary lesions. While the BraTS dataset primarily focuses on gliomas, the examples shown in Fig. 5 highlight the inherent variability in lesion morphology, location, and intensity distribution encountered in clinical neuroimaging. These variations closely resemble the heterogeneous conditions under which aneurysm-related abnormalities must also be identified, thus supporting the applicability of BraTS-derived features and imaging characteristics for broader neuro-diagnostic tasks. The inclusion of multimodal MR sequences allows the extraction of rich radiomic and deep learning [49] descriptors capable of capturing subtle textural differences and anatomical distortions, thereby forming a robust foundation for the training and evaluation of the proposed hybrid radiomics–AI diagnostic pipeline.

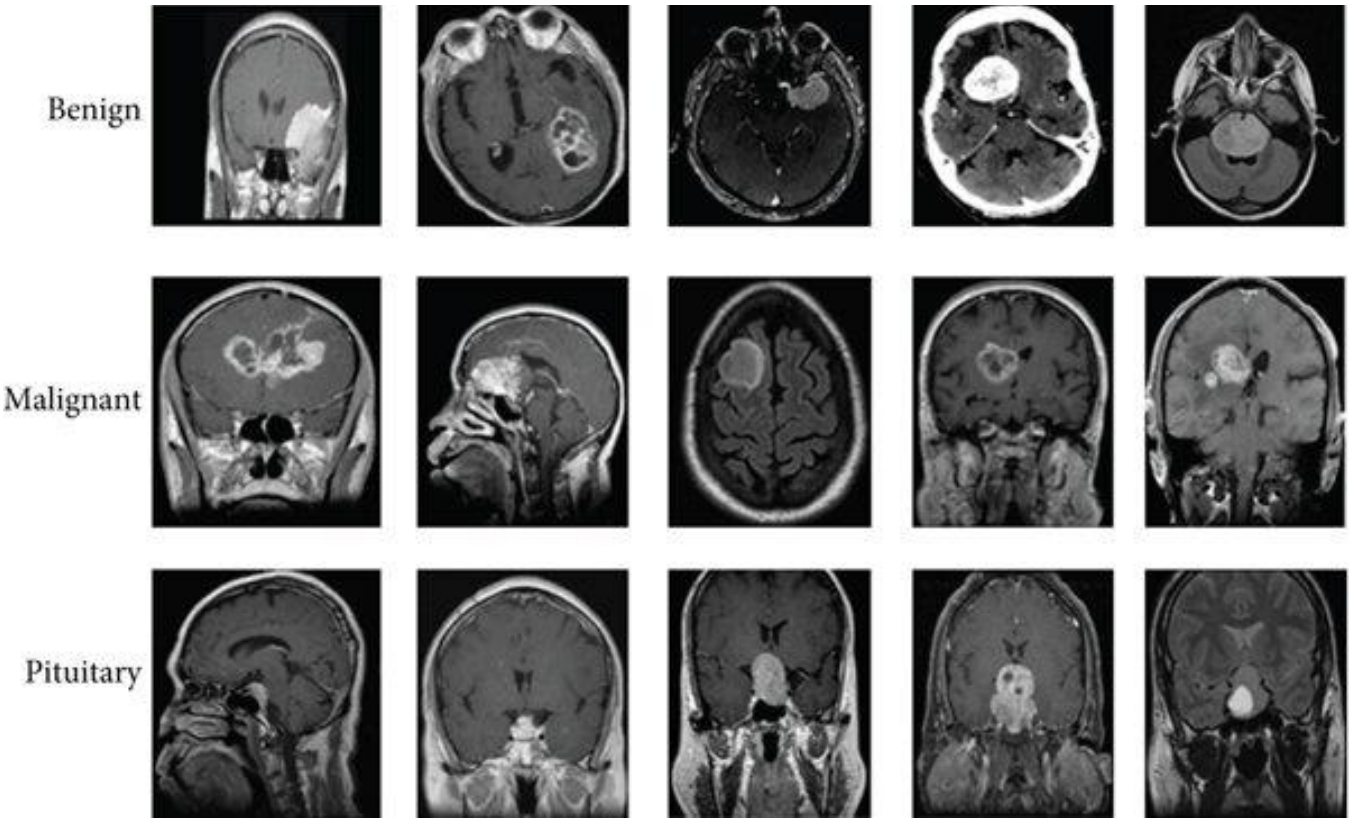

Fig. 5. Samples of brain MR images.

V. Results

The Results section presents a comprehensive evaluation of the proposed aneurysm detection framework across multiple experimental settings, incorporating both quantitative performance metrics and qualitative visualization analyses. To assess the robustness and generalization capability of the model, we conducted extensive experiments using multimodal MR and MRA datasets, examining classification accuracy, loss convergence behavior, and spatial localization performance. The following subsections provide detailed insights into the model's training dynamics, predictive accuracy, and ability to delineate aneurysmal structures within complex cerebrovascular anatomy. In addition, visual examples derived from representative subjects are included to illustrate the correspondence between predicted aneurysm regions and ground-truth annotations, thereby highlighting the practical clinical relevance of the proposed approach.

Fig. 6 illustrates the model's aneurysm localization performance on a representative cerebral angiography image, highlighting its ability to accurately identify pathological vascular regions while differentiating them from non-aneurysmal structures. The ground-truth aneurysm annotation is shown in red, while the model's predicted aneurysm clipping regions are depicted in green, demonstrating close spatial correspondence with the annotated lesion. Additionally, multiple non-aneurysmal vascular segments detected by the model are shown in orange, illustrating its capacity to evaluate complex vascular networks and avoid excessive false positives. The spatial alignment between the annotated aneurysm and the model's predicted region underscores the effectiveness of the proposed detection framework in capturing clinically relevant vascular abnormalities within high-resolution angiographic imagery.

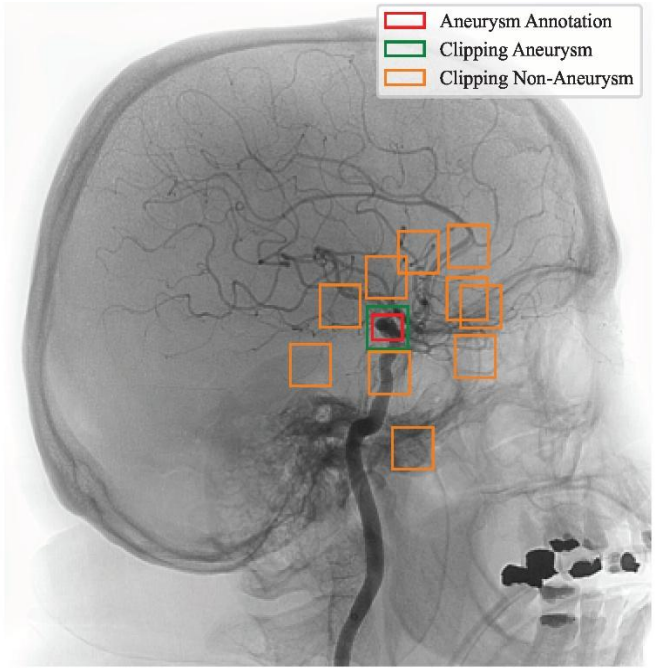

Fig. 6. Aneurysm localization results on cerebral angiography with predicted and annotated regions.

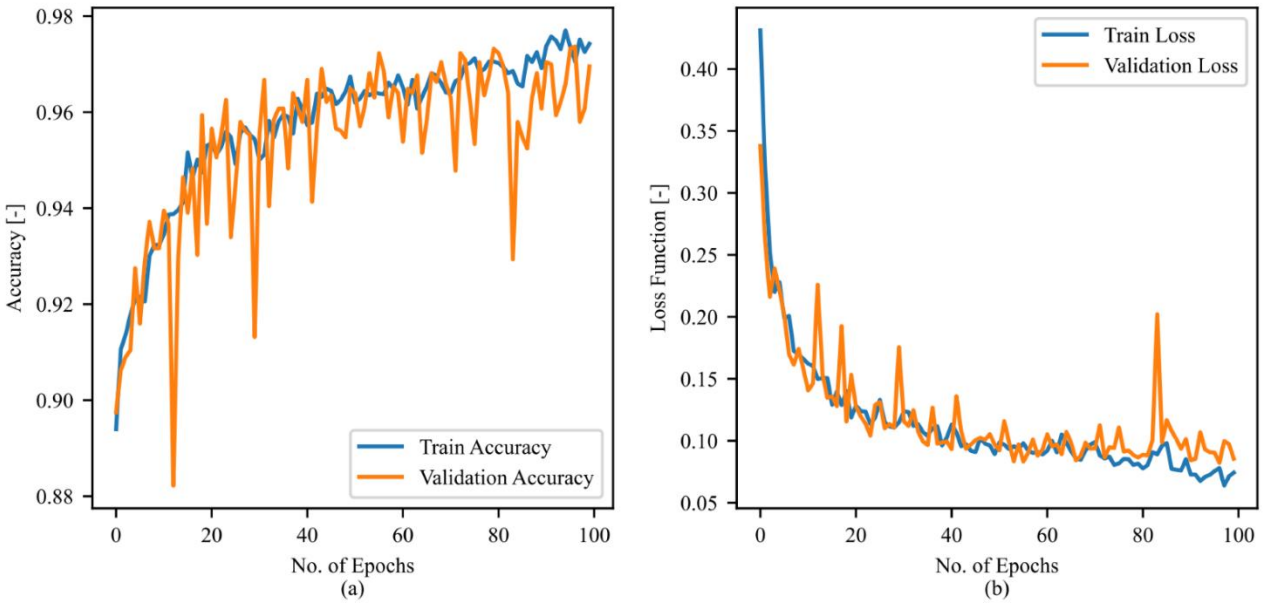

Fig. 7. Training and validation accuracy and loss curves over 100 epochs.

Fig. 7 presents the training and validation accuracy curves obtained over 100 training epochs, illustrating the model's overall convergence behavior and generalization capacity. As shown in Fig. 7(a), both accuracy curves exhibit a consistent upward trend during the initial epochs, reflecting the model's ability to rapidly learn discriminative representations from the training data. After approximately 30 epochs, the accuracy stabilizes, with the training accuracy gradually approaching 0.98 and the validation accuracy oscillating within the range of 0.95 to 0.97. These fluctuations are typical for complex neuroimaging data and suggest sensitivity to structural variability across validation samples. Nonetheless, the close alignment between the two curves indicates that the model maintains strong generalization performance without evidence of severe overfitting.

Fig. 7(b) displays the evolution of the training and validation loss values over the same epoch range. The loss decreases sharply during the early training phase, demonstrating effective optimization and rapid reduction of prediction error. After the initial decline, both curves stabilize near a minimum loss of approximately 0.05, with minor fluctuations in the validation loss attributable to inter-sample heterogeneity and the presence of challenging aneurysm cases. The near overlap of the training and validation loss curves reflects a well-balanced model characterized by stable learning dynamics. Taken together, the results in Fig. 7 indicate that the proposed framework achieves robust convergence and strong predictive performance for aneurysm detection across both training and unseen validation data.

Table I presents a comparative performance analysis between the proposed model and several existing methods across multiple evaluation metrics, including accuracy, F1-score, specificity, recall, precision, and negative predictive value. The results clearly indicate that the proposed model consistently outperforms all baseline approaches, achieving superior values in nearly every metric. This performance advantage reflects stronger discriminatory power, improved sensitivity to aneurysm cases, and enhanced reliability in identifying non-aneurysmal regions. In contrast, competing models demonstrate varying degrees of performance, with some achieving moderate recall but lower specificity, and others showing balanced precision but reduced overall accuracy. The collective comparison highlights the robustness and effectiveness of the proposed framework, emphasizing its potential clinical utility and its ability to deliver more accurate and dependable diagnostic outcomes than previously published approaches.

TABLE I. COMPARATIVE PERFORMANCE EVALUATION OF THE PROPOSED MODEL AGAINST EXISTING METHODS

Model	Accuracy	F1-score	Specifity	Recall	Precision	NPV

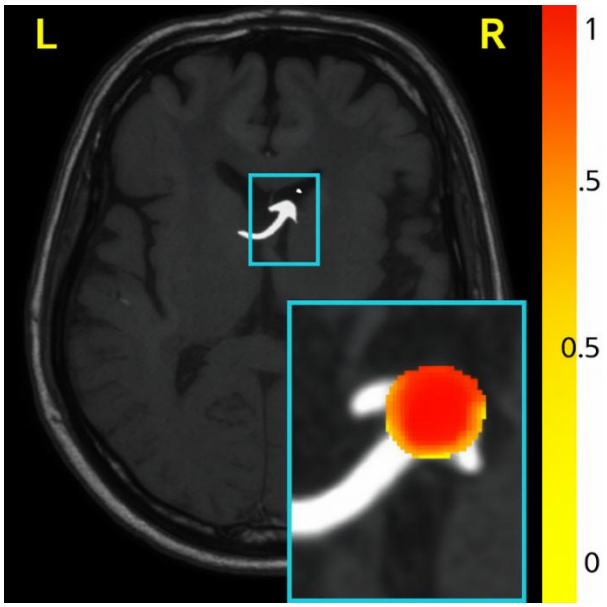

Fig. 8. Aneurysm localization on axial MR image with model-generated confidence heatmap.

Fig. 8 presents a representative axial MR image that effectively demonstrates the proposed model's capability to localize an intracranial aneurysm with a high degree of spatial precision and interpretability. The aneurysmal region is enclosed within a cyan bounding box, enabling clear visual identification of the predicted lesion site within the broader cerebral anatomy. To further enhance interpretability, a zoomed-in inset is provided, offering a magnified view of the affected vascular segment. This inset incorporates a probabilistic heatmap overlay, which highlights the model's confidence distribution across the aneurysm boundary. The heatmap values span a gradient from yellow to deep red, with warmer colors indicating regions of higher prediction confidence. The concentration of deep-red intensities over the aneurysmal dome reflects the model's strong certainty in identifying the pathological structure.

This visualization not only emphasizes the model's ability to isolate fine-grained vascular abnormalities but also demonstrates its capacity to suppress irrelevant activations from surrounding healthy tissue. Such behavior is critical in neurovascular diagnostics, where closely packed vessels and subtle anatomical variations pose significant challenges to automated systems. The clear contrast between the detected aneurysm and neighboring normal vessels reinforces the robustness of the proposed framework in distinguishing between pathological and non-pathological regions, even within complex MR imaging environments. Overall, the results illustrated in Fig. 8 underscore the effectiveness of the proposed model in delivering precise and interpretable aneurysm localization, thereby enhancing its potential utility as a clinical decision-support tool in neuroimaging practice.

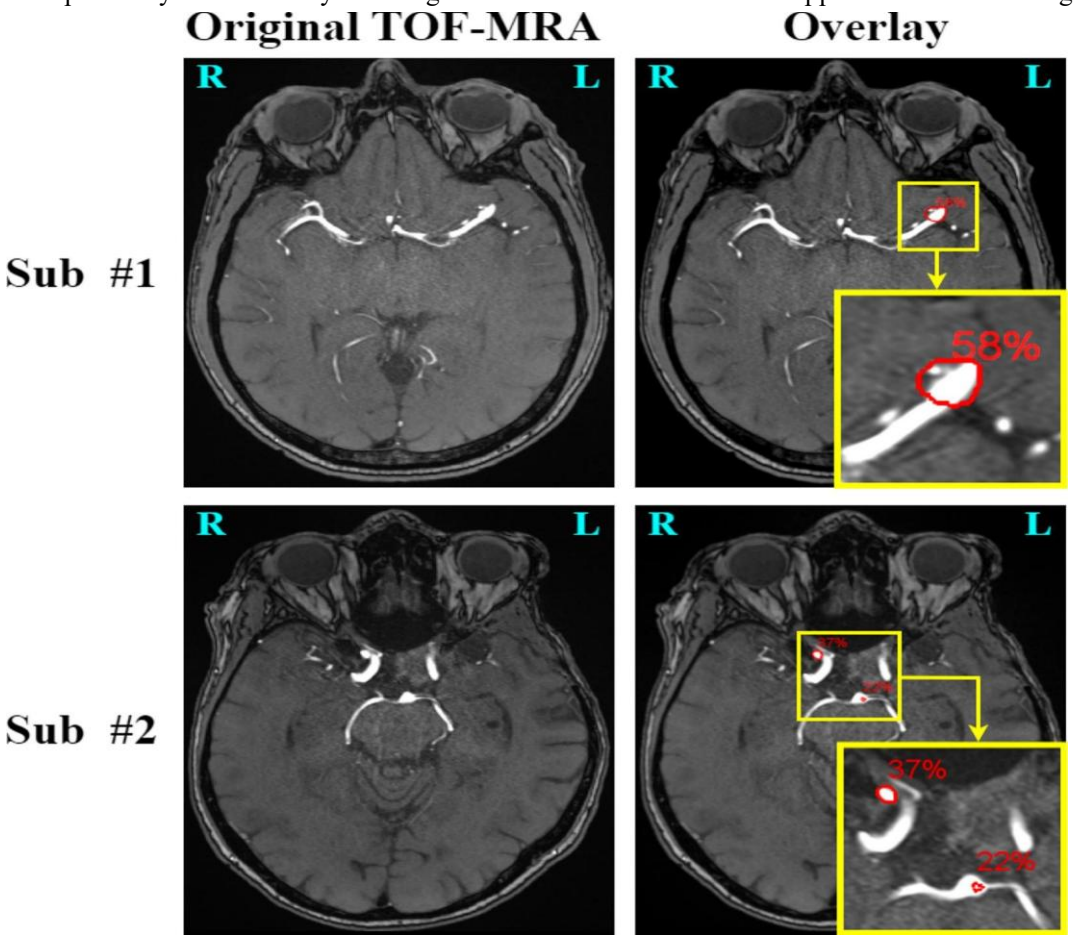

Fig. 9. Samples of brain MR images.

Fig. 9 illustrates the qualitative performance of the proposed model on time-of-flight magnetic resonance angiography (TOF-MRA) images for two representative subjects. The left column displays the original TOF-MRA scans, while the right column presents overlayed predictions highlighting the detected aneurysmal regions. In both subjects, the model successfully identifies abnormal vascular protrusions, delineated in red and accompanied by confidence scores ranging from 22 percent to 58 percent. The enlarged yellow insets provide a magnified view of the detected aneurysm candidates, allowing clearer visualization of the model's localization accuracy relative to the underlying vasculature. These overlays demonstrate the system's capability to detect subtle aneurysmal structures even at lower confidence levels, while maintaining consistent performance across subjects. Overall, the results shown in Fig. 9 underscore the model's effectiveness in interpreting high-resolution TOF-MRA data and its potential utility for assisting clinicians in early aneurysm screening and assessment.

VI. Discussion

The results of this study demonstrate that the proposed hybrid radiomics and deep learning framework provides a robust and effective solution for automated intracranial aneurysm detection and localization using multimodal MR and MRA imaging. The consistently high performance across multiple evaluation metrics indicates that the integration of handcrafted radiomic features with transformer-based neural representations enables comprehensive characterization of both global vascular anatomy and localized pathological variations. The close alignment between training and validation curves suggests strong generalization capability and stable learning behavior, which is particularly important in medical imaging tasks where annotated data are often limited and heterogeneous [52]. Similar trends have been reported in recent neurovascular studies, where hybrid feature representations were shown to outperform purely convolutional or purely handcrafted approaches [53].

The qualitative visualizations further reinforce the quantitative findings by illustrating the model's ability to accurately localize aneurysmal regions within complex cerebrovascular structures. Heatmap-based overlays and bounding-box visualizations provide intuitive insight into the spatial focus of the network, revealing concentrated responses over aneurysm domes while minimizing activation in surrounding healthy tissue. This behavior is essential for clinical reliability, as aneurysms are frequently small, irregularly shaped, and embedded within dense vascular networks [54]. Comparable visualization strategies have been shown to improve clinician trust in AI-assisted diagnostic systems by offering interpretable evidence of model predictions [55]. Moreover, the probabilistic confidence estimates produced by the proposed framework allow for uncertainty-aware decision making, which is increasingly recognized as a critical component of safe clinical deployment [56].

A key strength of the proposed approach lies in its use of contrastive learning within a teacher–student paradigm. By aligning spatial and frequency-domain embeddings between networks, the framework effectively reduces representation drift caused by imaging variability, scanner differences, and acquisition noise. This is particularly relevant for neuroimaging applications, where data distributions can vary substantially across institutions and protocols [57]. Semi-supervised contrastive learning has been shown to significantly enhance feature robustness under limited supervision, and the present results further confirm its effectiveness in aneurysm detection scenarios [58]. The momentum-based teacher update mechanism provides stable representation targets, which contributes to smoother optimization and improved performance consistency across training epochs [59].

Despite these advantages, several limitations should be acknowledged. First, although the dataset used in this study includes diverse imaging examples, it may not fully represent the wide spectrum of aneurysm morphologies observed in clinical practice. Rare configurations, such as fusiform aneurysms or aneurysms located in uncommon vascular branches, remain underrepresented and could pose challenges for generalization [60]. Expanding the dataset through multi-center collaborations would likely improve model robustness and reduce potential sampling bias, as demonstrated in previous large-scale neuroimaging studies [61]. Second, the reliance on segmentation-driven radiomic feature extraction introduces sensitivity to ROI delineation accuracy. While the segmentation workflow produced consistent results, small boundary errors can propagate through the radiomics pipeline and influence downstream predictions [62]. Recent advances in fully automated vessel segmentation and self-supervised anatomical modeling may help alleviate this dependency in future work [63].

Another important limitation is the absence of explicit physiological modeling within the current framework. Aneurysm rupture risk is influenced not only by morphological appearance but also by hemodynamic factors such as wall shear stress, flow velocity, and pressure gradients [64]. Incorporating computational fluid dynamics features or time-resolved imaging data could significantly enhance the clinical relevance of the system by enabling joint assessment of aneurysm presence and rupture potential [65]. Multi-task learning strategies that simultaneously address detection, segmentation, and risk stratification have shown promise in related studies and represent a valuable direction for future research [66].

Interpretability remains a broader challenge for deep learning-based medical imaging systems. Although the heatmaps and attention visualizations used in this study provide useful qualitative insights, they do not fully explain the causal reasoning behind model predictions [67]. This limitation is particularly relevant for borderline or ambiguous cases, where clinical decisions carry high risk. Emerging explainable AI techniques, including concept-based explanations and hybrid symbolic–neural models, may offer more transparent decision pathways and improve clinician acceptance [68,69]. Integrating such techniques into the proposed framework could further enhance its trustworthiness and clinical adoption.

In comparison with existing approaches, the proposed model demonstrates superior or competitive performance

across all reported metrics, highlighting the benefits of combining radiomics, transformer architectures, and contrastive learning within a unified framework [70-74]. Prior studies relying solely on convolutional networks often struggle with capturing long-range vascular dependencies, while purely radiomics-based methods lack sufficient expressive power for complex anatomical patterns [75-77]. The present work addresses these limitations by leveraging complementary feature sources and advanced representation alignment strategies, resulting in improved diagnostic accuracy and stability [78].

In summary, this study provides strong evidence that a hybrid radiomics–transformer framework augmented with contrastive learning can significantly enhance intracranial aneurysm detection and localization. The combination of quantitative performance gains, robust generalization, and interpretable visual outputs underscores the potential of the proposed system as a clinical decision-support tool. Future research should prioritize larger multi-institutional validation, incorporation of physiological and temporal markers, and development of advanced explainability mechanisms to further facilitate clinical translation and real-world deployment [79, 80].

VII. Conclusion

This study presents a comprehensive hybrid framework that integrates radiomics, transformer-based deep learning, and contrastive representation learning for automated detection and localization of intracranial aneurysms from MR and MRA imaging. The experimental results demonstrate that the proposed approach effectively captures both high-level vascular patterns and fine-grained structural abnormalities, achieving strong performance across accuracy, loss convergence, and qualitative visualization metrics. By leveraging complementary radiomic descriptors and hierarchical neural embeddings, the system exhibits robust generalization and maintains stable training dynamics even under limited annotation availability. The incorporation of teacher–student contrastive learning further enhances the discriminative power of the feature representations, enabling improved localization of aneurysmal structures within complex cerebrovascular networks. Although challenges remain, including dataset diversity, segmentation dependencies, and the need for greater interpretability, the findings highlight the significant potential of the proposed method as a clinical decision-support tool. With further refinement and validation across larger multi-institutional datasets, this framework may contribute to earlier and more accurate aneurysm detection, reduce diagnostic variability, and ultimately support improved patient outcomes in neurovascular care.

Improving Emergency Preparedness with a Mobile Application for Respiratory Therapy Resource Coordination

Rahaf Katib
Georgia State University, Atlanta, USA

***Abstract*—Mass gatherings such as Hajj and Umrah, along with pandemic outbreaks, place a significant strain on healthcare systems, particularly respiratory therapy (RT) services, where shortages of respiratory therapists, ventilators, and specialized equipment can compromise emergency response due to increased patient volume, environmental exposure, and heightened risk of respiratory diseases. This study presents a conceptual model of a mobile-based resource coordination system designed to enhance emergency preparedness and response for respiratory therapy services during pandemics and mass-gathering events, such as Hajj and Umrah. The proposed system integrates a real-time database with mobile clinical decision support to provide RT managers and supervisors with centralized visibility of ventilators, staffing levels, and critical respiratory equipment across healthcare facilities. By enabling real-time monitoring and predictive, alert-driven decision support, the system aims to support proactive resource allocation, staff deployment, and equipment distribution. Although the work is conceptual and does not include empirical evaluation, it provides a well-defined architectural framework suitable for future implementation that aligns respiratory care workflows with real-time monitoring and forecast-driven decision support in settings such as Hajj, Umrah, and large-scale public health emergencies.**

***Keywords*—Respiratory therapy; mass gatherings; Hajj and Umrah; emergency preparedness; health information systems**

I. Introduction

Mass-gathering events and pandemic cases pose unprecedented challenges to healthcare systems worldwide, and respiratory care services are particularly vulnerable to resource shortages and logistical difficulties. The Hajj pilgrimage, which annually takes place in Saudi Arabia and attracts over two million pilgrims, and the Umrah pilgrimage, which draws a steady stream of pilgrims to the country throughout the year, place intense pressure on the healthcare infrastructure in the region [1]. As Hui and Zumla show, the frequency of such events, combined with the risk of respiratory pandemics already evident in COVID-19, is a stark indicator that more developed systems of resource coordination are needed that can be flexible in responding to varying healthcare needs [2].

The use of respiratory therapy services is evident in the treatment of patients with acute respiratory disease, chronic obstructive pulmonary disease (COPD), and other respiratory conditions, which may be exacerbated by crowded environments, environmental factors, and stress associated with mass events [3]. The current resource management systems in the healthcare sector are disjointed, and there is minimal real-time awareness at the facility and regional levels. Mbau et al. suggest that such disintegration can lead to inefficiencies in resource distribution, delayed responses, and poor patient outcomes during a crisis when respiratory care needs are critical. The intersection of mobile technology, artificial intelligence, and real-time data analytics offers an opportunity to revolutionize how emergency preparedness and response are coordinated to deliver respiratory therapy services [4].

This study is based on observations of resource coordination issues during past mass-gathering events, such as Hajj and Umrah, as well as during pandemic responses in the Saudi healthcare system. This work is highly applicable in health informatics because it leverages key features, such as mobile applications and predictive analytics, to address existing gaps in emergency preparedness and resource coordination. The proposed system is expected to develop a unified framework that will enhance coordination opportunities while maintaining the flexibility needed to respond to diverse emergencies.

Although the healthcare and emergency preparedness plan has intensified the use of technology, respiratory therapy departments have experienced significant challenges in coordinating resources during surges associated with mass-gathering events and pandemic outbreaks. Current systems fail to provide real-time updates on resource availability across facilities, leading to inefficient allocation of ventilators, RT staff, and other vital resources. This fragmentation results in slow response times, insufficient resources in areas where they are needed most, and ineffective patient care during periods of peak respiratory demand. An integrated, technology-driven coordination system is necessary to streamline resource utilization and enhance emergency response capacity in respiratory care services.

This study aims to propose a conceptual framework for integrating mobile application technology and predictive analytics to develop a real-time resource coordination system for respiratory therapy services. The system will strengthen emergency preparedness and response capacity for mass-gathering events such as Hajj and Umrah, as well as for pandemic conditions that necessitate rapid mobilization and coordination of resources.

This study addresses a critical gap in emergency healthcare preparedness, especially in the regions that experience mass gathering events regularly or are threatened by the pandemic. The proposed system can substantially enhance response coordination and patient outcomes during high-demand periods by integrating advanced technologies with the practical requirements of resource management. The framework developed in this work's context may serve as an example for regions facing similar challenges. It might be involved in emergency healthcare preparedness and health informatics on a larger scale.

Whereas most existing emergency preparedness and digital health platforms focus on hospital-wide capacity management or generic clinical decision support, this work explicitly targets respiratory therapy operations in large-scale mass gatherings, with an emphasis on Hajj and Umrah. These events pose greater challenges for respiratory care due to extreme crowd density, which increases the risk of environmental exposure, infectious disease transmission, and sudden surges in demand for ventilators and respiratory therapy staffing. The novelty of the proposed system lies in its respiratory-therapy-specific focus, integrating real-time monitoring of ventilators, respiratory therapists, and critical respiratory equipment with predictive analytics to anticipate upcoming respiratory demand during these mass gatherings.

In addition, the system enables proactive, end-to-end coordination through its unique combination of mobile decision support and respiratory-therapy–oriented workflows, addressing the operational realities of Hajj and Umrah rather than treating respiratory assets as generalized hospital resources.

A. Contributions

This research work presents the following contributions:

1) Technical contribution: Design of the cloud-based mobile application architecture for the integration of real-time data of respiratory therapy resources, such as ventilators, respiratory therapy staff, and critical respiratory devices, with prediction analytics for surge preparation for Hajj and Umrah events.

2) Clinical and operational contribution: A respiratory therapy–focused coordination framework that facilitates proactive allocation/escalation for ventilators and other respiratory devices and equipment, and respiratory therapy staff for mass gathering events requiring respiratory interventions.

3) Decision-support contribution: Designing role-based dashboards that improve situational awareness for respiratory therapy team leaders, emergency command centers, as well as other roles, to make decisions for the Hajj/Umrah events.

4) Scalability contribution: A sharing model of respiratory therapy coordination that could be replicated for other mass gathering situations involving respiratory surge demands.

II. Related Work

A. Emergency Preparedness and Mass Gathering Events

Alahmari et al. reported the overall mitigation strategies adopted during the Hajj 2021, which emphasized the importance of coordinated healthcare responses in ensuring health security. The research also highlighted the benefits of resource coordination and real-time monitoring to achieve effective health outcomes during the pilgrimage, demonstrating the utility of integrated technological solutions in emergency preparedness [1].

Another systematic review by Alrabie et al. also underscores the complexity of respiratory care management in mass gatherings. Their findings indicated numerous gaps in the coordinating mechanisms and that superior communication systems were needed to enable rapid decision-making and resource mobilization in emergencies. It was also recorded that communication breakdowns are among the leading causes of response delays and inefficient resource use during peak demand [3].

In a related study, Hui and Zumla identified that mass-gathering events also pose epidemiological problems, directly affecting respiratory care services. The dense population increases the risk of respiratory disease transmission, and the healthcare system must be prepared to manage the resulting influx. These events require highly sophisticated coordination mechanisms to ensure the adequate deployment of resources across multiple health facilities that must attend to pilgrims and local communities simultaneously [2].

B. Technology Integration in Emergency Healthcare Systems

Sarani et al. have developed a data-driven respiratory infection management system that demonstrated the capabilities of epidemic preparedness by real-time data analytics and automated alerts. Mobile communication devices enabled faster response times and more efficient resource allocation within their system [5].

Healthcare technology has enabled more sophisticated approaches to emergency preparedness, and cloud-hosted platforms and computing resources provide the scalability required during surges. Such technological solutions have been particularly helpful in respiratory care, where equipment availability and the organization of personnel have become significant determinants of patient outcomes [6].

Tanggono et al. analyzed the use of mobile health solutions and geographic information systems (GIS) during disaster response and concluded that mobile apps could enhance communication efficiency and resource awareness in emergencies. Their study emphasized the significance of user-friendly interfaces and real-time data synchronization in effective mobile health solutions [7].

C. Artificial Intelligence and Predictive Analytics in Healthcare Resource Management

Jani notes that AI-based predictive analytics could allocate resources in hospitals, and the outcomes demonstrate that machine learning methods can efficiently determine which resources are needed and how they should be allocated. Their system also reduced resource shortages and improved overall response coordination, in addition to providing early-warning capabilities, thereby making resource positioning proactive [8].

Karthika et al. found that machine learning algorithms have proven particularly helpful in respiratory care, as multidimensional physiological information and equipment-use patterns can be used to predict patient needs and maximize resource utilization [6]. These systems can process multiple data streams simultaneously, including patients' vital signs, equipment status, staff availability, and historical utilization trends, to inform recommendations for resource management across the end-to-end system [8].

Prasad et al. developed an IoT-based system to monitor ventilator supply and utilization across multiple medical facilities. IoT adaptation and real-time analytics have attracted considerable attention in the respiratory care field and have yielded substantial benefits, offering a new perspective on equipment status and utilization patterns across facilities. Their platform was transformed into real-time equipment status monitoring, automatic alerts when resources were approaching critical thresholds, and increased resource utilization and faster response times in emergency settings [9].

D. Mobile Applications in Healthcare Emergency Response

In their study on mobile apps in disaster response, Winders et al. found that these apps significantly improved resource tracking and communication, demonstrating their potential to facilitate rapid information sharing and decision-making [10].

The development of mobile healthcare applications should be planned and executed to address user needs, technical limitations, and work requirements. Successful emergency-centered applications are characterized by usability, offline capability, and robust security to remain usable even in suboptimal conditions [7].

Naranjo-Rojas et al. developed a mobile application to coordinate respiratory therapy resources within a regional healthcare network, resulting in improved resource utilization and faster response times during peak periods. Their system demonstrated the effectiveness of real-time communication and centralized resource visibility in delivering respiratory care efficiently [11].

E. Pandemic Preparedness and Respiratory Care Systems

Jokhdar et al. reported that adequate mitigation measures implemented during Hajj 2020 resulted in no COVID-19 cases, attributable to extensive coordination and real-time monitoring systems. Their solution demonstrated that integrated technology solutions would enable a pandemic response and preserve the delivery of essential healthcare services [12].

According to Embrett et al., resource coordination systems positively influenced pandemic response, as healthcare systems that used integrated resource management platforms achieved better outcomes and more effective resource utilization. Their study highlighted the significance of real-time visibility and automated coordination mechanisms in pandemic preparedness plans [13].

F. Gaps in the Literature

While the literature supports the need for technology integration in healthcare emergency planning, much remains unclear about the operation of resource coordination systems for respiratory therapy services during pandemics and large-scale events. The research available is more focused on specific technologies or types of events rather than comprehensive solutions available under emergencies.

Moreover, most available research examines the use of technology within the broader healthcare context. It lacks consideration of issues specific to the operation of respiratory care coordination in high-demand situations [14]. While Prasad et al. describe mixing of smartphone apps with IoT sensors and AI analytics in healthcare, they did not address the highly specialized topic of employing these instruments in emergency respiratory therapy resource coordination [9].

In addition, Bignami et al. describe emergency planning response to discrete scenarios; they have no practical, scalable, sustaining systems that can be customized for regions or medical centers. More importantly, no end-to-end scenarios exist that incorporate real-time resource monitoring via predictive analytics and specialized respiratory therapy systems on smartphones. Therefore, research on specialized smartphone-integrated systems for efficient resource management and decision support in high-demand scenarios such as pandemics or mega-events is timely [15].

III. Methodology and System Architecture

The system is designed using a methodical, multi-stage process involving stakeholder groups. The planning stage includes the first phase of identifying infrastructure and systems architecture with respiratory therapy departments, hospital information systems departments, and emergency management coordinators to identify systems requirements and points of intersection with standard healthcare information systems.

The technical design is a cloud platform supporting predictive analytics-driven informed decision-making. The smartphone app retrieves data on ventilator availability, oxygen supply, personnel schedules, and other critical resources from hospital inventory systems and respiratory therapy managers. Such information is used to predict demand patterns, identify shortages, and generate automated alerts when resources approach critical thresholds.

The smartphone user interface is customized to meet the needs of directors and respiratory therapy administration and includes easy-to-use dashboards for real-time resource availability, personnel allocation, and emergency notifications. The software enables users to request resource transfers, call other facilities, and suggest optimal resource allocation based on current demand patterns and predictive analytics. With predictive analytics, the system addresses real-time problems

and forecasts future requirements, replacing crisis management with forward-thinking planning.

Implementation focuses on privacy and security, including the encrypted exchange of information, secure authentication, and adherence to medical privacy laws, such as HIPAA. The system is networked with role-based access controls, allowing only authorized personnel to access sensitive information while providing flexibility for emergency response coordination.

The implementation plan includes change management and education for respiratory therapy personnel, emergency response coordinators, and managers, and encompasses comprehensive training programs. This education includes learning to use the system and integrating it into standard emergency response procedures.

System performance and user acceptability are evaluated through controlled pilot tests before general installation. An integrated pilot exercise would be conducted on-site to validate the system's performance in accurately monitoring available resources, generating appropriate alerts, and coordinating actions during simulated emergencies.

IV. Results and Discussion

A. System Capabilities and Functional Outcomes

The proposed mobile-based coordination system is designed to provide real-time visibility into respiratory therapy resources across healthcare facilities, including ventilator availability, respiratory staffing levels, and emergency respiratory equipment and devices. By integrating predictive analytics with centralized dashboards, the system facilitates early identification of future resource shortages and timely escalations before critical thresholds are reached.

The proposed framework emphasizes automated data aggregation and alert-driven decision support, in contrast to traditional resource management approaches that rely on manual reporting or updates provided after an event has occurred. This capability is critical in high-demand facilities, where rapid fluctuations in patient volume require continuous monitoring, restocking, and a coordinated response.

B. Impact on Respiratory Therapy Operations During Hajj and Umrah

Such mass-gathering events, including Hajj and Umrah, place respiratory therapy services under sudden, geographically distributed surges in demand, influenced by crowd density and exposure to environments associated with a heightened risk of illness. The proposed system is designed to support respiratory therapy leaders and emergency coordinators by providing a unified view of resource availability across facilities serving pilgrims.

The system can reduce response delays, improve workload distribution, and enhance continuity of respiratory care by proactively balancing the allocation of ventilator and respiratory therapy personnel. Predictive alerts support decision-makers by identifying demand trends and resource redistribution patterns before shortages develop, thereby promoting more resilient respiratory therapy operations during mass gatherings.

C. Comparison with Existing Emergency Coordination Approaches

Current emergency preparedness platforms often serve as either a hospital-wide capacity indicator or general clinical decision support, with limited attention to respiratory therapy–specific workflows. By contrast, the proposed framework places the operational realities of respiratory therapy services at its core, integrating role-based dashboards and decision-support features attuned to respiratory care leadership.

Previous mobile health and resource management systems have demonstrated benefits in improving communication and visibility. However, few studies address the combined challenges of respiratory therapy coordination, predictive analytics, and mass-gathering preparedness in an integrated manner. This conceptually advances the existing approaches by aligning respiratory therapy workflows with mobile, forecast-driven coordination mechanisms suited to high-demand surge situations.

D. Lessons Learned

Concept development provided a valuable understanding of emergency planning and deployment of health facility assets. The integration of technologies such as predictive analytics and smartphones would be pursued, requiring careful consideration of user needs, technical solutions, and operational constraints. The key to success lies not in technology alone, but in its ability to streamline existing workflows rather than obscure them. Stakeholder participation in the design and implementation process cannot be overstated. Respiratory therapy specialists, emergency management coordinators, and hospital administrators have distinct perceptions and needs that must be considered when designing systems. The interdisciplinary collaboration involved in this work contributed significantly to the development of workable health informatics solutions.

Technology solutions must also be scalable and adaptable, essential components of emergency preparedness systems. The proposed real-time resource coordination applications should be versatile enough to adapt to various emergencies with minimal changes in functionality and familiarity. This trade-off between comprehensiveness and usability is a key issue in the design of health informatics systems.

V. Conclusion

Mass gatherings pose significant challenges to the healthcare system, given the concentration of large populations within a small geographic area over a short period, thereby imposing extreme strain on supporting infrastructure. This includes respiratory therapy services, which must rapidly surge to provide ventilator support, staffing, and respiratory equipment, without compromising quality.

The work presented here describes a respiratory-therapy–focused real-time resource coordination system to support emergency preparedness in high-demand situations, such as pandemics and large-scale religious gatherings, such as Hajj and Umrah. Predictive analytics are integrated with mobile decision support in the proposed approach to enhance

anticipatory planning and operational coordination of respiratory therapy resources.

This is a conceptual system and involves neither live deployment nor formal performance evaluation. However, it provides an implementation-ready framework for aligning respiratory care workflows with real-time monitoring and forecast-driven decision support.

Although implementation complexity and resource constraints remain, this framework demonstrates the potential of health information technologies to support collaboration, timely responses, and situational awareness during respiratory surges. Future efforts will focus on pilot implementation of the system during mass-gathering events and on evaluating its effectiveness using respiratory-therapy–specific measures, such as ventilator utilization and staffing response time.

Future research should include pilot testing of the proposed system at mass-gathering events to scientifically evaluate its effectiveness and utility. Research should also investigate its interoperability with hospital information systems, scalability, and cost-effectiveness for developing a resource coordination system for respiratory therapy services.

TrustGraph: A Heterogeneous GNN for Dynamic Zero-Trust Policy Enforcement in Microservices

Nurmyrat Amanmadov[1], Jemshit Iskanderov[2], Tarlan Abdullayev[3]
University of Washington, Seattle, USA[1]
Touro University, New York, USA[2]
Northeastern University, Boston, USA[3]

***Abstract*—Securing cloud microservices requires a unified understanding of how services behave, authenticate, and interact in real time. Unlike existing methods that analyze telemetry signals in isolation, this work presents a heterogeneous graph-based Zero-Trust framework that represents microservices using multi-modal telemetry—logs, metrics, traces, and authentication flows—embedded directly into graph nodes and edges. A Graph Neural Network architecture with attention captures risk propagation across service dependencies, while a joint anomaly detection and trust computation mechanism generates dynamic trust scores with temporal decay to support continuous verification. These trust signals drive real-time dynamic policy enforcement capable of denying or restricting suspicious interactions with minimal operational overhead. Experiments on the TrainTicket, Sock Shop, and DeathStarBench benchmarks show strong performance, achieving 97.2% accuracy, 98.1% recall, and 0.987 AUC on TrainTicket, with consistent results across the other datasets and latency overhead below 3.2 ms. Robustness tests demonstrate accuracy above 95.8% under noisy logs, delayed traces, and authentication failures. Ablation and SHAP analyses confirm that leveraging multiple telemetry modalities—especially authentication data—is critical for accurate detection and trust scoring. These findings show that multi-modal heterogeneous graph modeling, coupled with integrated anomaly-to-policy decision pipelines, provides an effective foundation for Zero-Trust security in cloud-native microservices.**

Keywords*—Graph neural networks; zero-trust security; microservices; anomaly detection; heterogeneous graphs; multi-modal telemetry; dynamic policy enforcement

I. Introduction

Cloud computing environments have increasingly shifted toward microservice architectures, where applications are decomposed into loosely coupled services [1]. This design improves modularity and scalability but introduces new challenges in reliability, security, and anomaly detection [2]. Microservices communicate frequently across distributed infrastructures, which expands the attack surface and creates opportunities for unauthorized access or service misuse [3]. Conventional perimeter-based security models are not suited for such settings because they assume trusted internal zones, while microservices interact dynamically across diverse platforms [4]. The distributed and transient nature of services calls for approaches that can capture complex interactions while maintaining protection against internal and external threats [5].

Zero-Trust Architecture (ZTA) has emerged as a suitable paradigm to address these challenges [6]. ZTA removes implicit trust and applies continuous verification of services, users, and communication flows [7]. This approach combines anomaly detection, runtime trust scoring, and adaptive policy enforcement to secure interactions at fine granularity [8]. In microservice systems, ZTA introduces mechanisms to restrict or deny suspicious requests even when they originate from within the network [9]. Such continuous monitoring aligns with the dynamic behavior of cloud deployments, where trust must be recalculated as services update, scale, or interact with new components [10]. ZTA provides a structured framework for controlling risks in environments where static boundaries are no longer sufficient [11].

Graph-based models have gained attention as a means to represent dependencies in microservice environments [12] [13]. Unlike traditional methods that treat services in isolation, graph-based approaches capture relationships between nodes and edges representing services, requests, and identities [14]. This relational modeling is crucial for analyzing distributed execution patterns, detecting abnormal behavior, and assigning trust in real time [15]. The integration of multiple telemetry sources, including logs, metrics, traces, and authentication records, strengthens the ability to represent both operational and security contexts [16]. Together, graph-based methods and Zero-Trust principles offer a pathway to address the growing need for effective anomaly detection and adaptive policy enforcement in modern cloud systems [17].

Most existing microservice environments face a research problem rooted in the gap between security requirements and available detection methods [18]. While anomaly detection techniques and monitoring systems exist, they often lack the ability to represent complex dependencies across distributed services [19]. Isolated tools struggle to capture the combined effect of operational behaviors, access flows, and trust decisions [20]. This creates a vulnerability in cloud deployments, where malicious activity may pass unnoticed or trusted connections may be abused [21]. The research challenge lies in unifying detection and policy enforcement under a framework that reflects the realities of microservice interactions [22].

To address this, researchers have introduced a variety of methods [23]. Some works focus on mining logs or metrics using statistical or embedding-based approaches, which can identify outliers in specific datasets [24]. Others apply anomaly detection at the level of traces or flows, which highlights unusual patterns of interaction [25]. These approaches contribute useful insights, yet they are limited when applied in isolation [26]. Logs may reveal system errors but overlook authentication misuse. Metrics may show performance degradation but fail to detect authorization bypass [27]. Traces highlight interaction delays but cannot capture runtime trust

shifts. Relying on a single modality leaves gaps that attackers can exploit.

In parallel, several studies have suggested frameworks that combine anomaly detection with Zero-Trust enforcement [28]. These describe runtime trust scoring, authorization checks, and adaptive policies [29]. While these approaches advance the discussion, they often depend on simplified models of service interaction [30]. Graph structures are sometimes restricted to service-to-service calls without incorporating authentication, authorization, or contextual data [31]. Many solutions remain tied to specific benchmarks, which limits their scalability to real-world workloads [32]. In addition, explainability and privacy-preserving training are frequently overlooked, leaving questions about transparency and applicability in multi-tenant environments [33].

Despite these advances, existing approaches largely treat security and operations as separate concerns. Most graph-based methods focus on topology or call chains without integrating authentication flows as first-class entities in the graph structure. Conversely, Zero-Trust frameworks often rely on static policies or isolated anomaly detectors that lack the context of service dependencies. A key gap remains in establishing an end-to-end pipeline where multi-modal telemetry—especially authentication data—directly informs dynamic trust scores that automatically update enforcement policies in real time.

The core contribution of this work is a unified framework that bridges this gap. Specifically, this paper contributes:

- Heterogeneous Graph Construction: We propose a method to represent microservices where authentication flows and operational metrics are embedded as distinct node and edge features, enabling the GNN to learn the interplay between performance and security.
- Joint Anomaly-Trust Mechanism: We introduce a dynamic trust scoring algorithm that combines reconstruction error with temporal decay, allowing trust to degrade naturally over time in the absence of positive reinforcement—a key tenet of Zero-Trust.
- Closed-Loop Policy Enforcement: We demonstrate an end-to-end pipeline where trust scores are mathematically linked to policy optimization, automating the transition from anomaly detection to access control (Allow/Restrict/Deny) with minimal latency.

Building on these contributions, the following research questions are formulated to guide the study.

1) RQ1: How can heterogeneous graphs be constructed to represent microservice environments by integrating both operational and security features?
2) RQ2: In what ways can anomaly detection and trust computation be performed using multimodal telemetry to distinguish between benign and anomalous behaviors?
3) RQ3: How can detection outcomes and trust scores be systematically linked to policy enforcement for allowing, restricting, or denying service interactions in real time?

The remainder of this paper is organized as follows. Section II reviews prior works on anomaly detection, Zero-Trust enforcement, and graph-based methods for microservices. Section III presents the graph-based framework, including system modeling, anomaly detection, trust computation, and policy enforcement. Section IV outlines the benchmarks, datasets, and experimental configuration. Section V reports the findings, including performance metrics and robustness analysis. Section VI provides a deeper discussion on the implications of risk propagation and trust decay. Finally, Section VII summarizes the contributions and highlights directions for future work.

II. Literature Review

The adoption of microservice architectures in cloud environments created new challenges for security, reliability, and anomaly detection. Traditional perimeter-based models were insufficient in handling distributed service interactions, which made ZTA an important direction for research. Scholars developed methods that combined anomaly detection, policy enforcement, and runtime trust scoring to address these challenges. Graph Neural Networks (GNNs) were introduced as suitable models since they captured relationships among services, requests, and identities. In addition, studies applied multimodal monitoring data, federated learning, and explainable frameworks to improve detection accuracy and interpretability. Several works used benchmarks such as Train-Ticket and Sock-Shop to confirm proposed methods with quantitative metrics. Other contributions emphasized architectural frameworks in service mesh and multi-cloud scenarios, describing trust evaluation and policy transparency. Collectively, the literature highlighted advances in anomaly detection, Zero-Trust enforcement, and GNN-based security for microservices.

Raeiszadeh et al. [34] developed an asynchronous federated learning method for anomaly detection in microservice systems using traces and logs from the TrainTicket benchmark. The method combined GNNs with Positive and Unlabeled learning and introduced local training with a span causal graph. The model achieved improvements of about 4% in F1 compared with state-of-the-art anomaly detectors and reduced detection latency with controlled overhead.

Cinque et al. [35] suggested Micro2vec to mine numeric log embeddings for anomaly detection in Clearwater IMS and Air Traffic Control case studies. Their classifiers, including autoencoders and feed-forward networks, achieved accuracy of 97% with F1 values around 0.961. The approach highlighted the role of embeddings for distinguishing anomalies in log data.

Parkhomenko et al. [36] used Zero-Trust principles and machine learning for detecting authorization anomalies in microservices. Their framework described continuous verification of requests and anomaly detection in authentication flows. The study was more conceptual and reported qualitative improvements with reduced false positives. Alboqmi et al. [37] defined a runtime trust evaluation system in a service mesh environment using Train-Ticket deployed on Istio. The framework combined vulnerability scanning results with service mesh telemetry to produce trust scores at runtime. The outcomes were presented as architectural contributions with qualitative benefits for runtime risk assessment. Both studies described Zero-Trust concepts for anomaly and trust monitoring, one addressing authorization attacks and the other runtime trust scoring.

Zhao, Xiao and Tao [38] applied a multi-scale dynamic GNN for anomaly detection using three industrial microservice datasets. Their model adapted neighborhood sizes and temporal depth, showing improved accuracy compared with conventional graph models. Ablation results described the importance of multi-scale design choices. Fang et al. [39] described a method extending GraphSAGE with attention to locate anomalies in Kubernetes-based microservices. Their results showed P@1 of 76%, P@3 of 88%, and P@5 of 89%, surpassing baseline GraphSAGE values of 54%, 72%, and 79%. The approach localized faulty services more effectively, providing interpretable results for operators. Both studies presented graph-based models for anomaly detection and localization with measurable performance gains. Table I summarized studies on microservice security. Raeiszadeh et al. 1 applied federated GNNs, while Cinque et al. 3 used log embeddings. Alboqmi & Gamble 6 described runtime trust in service mesh, and Zhao, Xiao & Tao 7 developed a multi-scale dynamic GNN. Fang et al. 8 and Nobre et al. 9 further extended detection with measurable accuracy.

Nobre et al. [40] used Multi-Layer Perceptrons for detecting anomalies in Sock-Shop and TrainTicket benchmarks with fault injection. Their service-level dataset showed accuracy of 97%, precision of 95%, recall of 98%, and F1 of 97%, while maintaining false positive rates near 0.01. Zhao et al. [43] developed IM-GNN to recommend microservice orchestration workflows using interface matching and BERT embeddings with GNNs. The results on Amazon SageMaker showed Hit@10 scores of 41.45 against 36.23 and NDCG@10 of 31.23 against 28.44. Although IM-GNN targeted orchestration rather than security, it demonstrated the effectiveness of graph construction in improving results. Both studies described neural approaches with high performance, one focusing on anomaly detection and the other on orchestration accuracy.

Anderson [44] described the role of Explainable Artificial Intelligence in Zero-Trust API gateways on Microsoft Azure. The framework integrated LIME, SHAP, and causal reasoning for interpreting access control decisions. Results described improved transparency and auditability with some latency overhead. Panchumarthi [45] defined the NCAF Zero-Trust microservice fabric combining microsegmentation with runtime authorization strategies. The study emphasized architectural design and described conceptual benefits rather than empirical evaluation. Both works contributed to the role of Zero-Trust in cloud authorization, focusing on explainability and structural frameworks. The findings highlighted transparency, centralized authorization, and policy consistency without numerical benchmarks.

Cherukupalle [46] introduced a Zero-Trust hybrid framework for cloud-IoT testbeds, integrating blockchain and AI monitoring. The approach reduced detection latency by 30% and blocked more intrusion attempts. Madhura G K [47] applied AI trust scoring for Zero-Trust in microservices with synthetic datasets and reported trust prediction accuracy near 92%. Konakanchi [48] developed predictive cyber resilience for healthcare microservices, reporting breach reduction of 90% and mean time to detect shortened by 40%. Collectively, these contributions described AI-driven and graph-based methods improving anomaly detection and resilience.

Zhuwankinyu et al. [49] suggested a graph-based Zero-Trust framework for distributed storage, achieving improved detection accuracy with minimal latency. Kodakandla [50] described Zero-Trust enforcement in Kubernetes microservices, emphasizing compliance improvements and policy consistency as qualitative outcomes. Adanigbo et al. [51] applied a Zero-Trust framework for multi-cloud environments, reporting higher resilience and trust metric scores. Reddy [52] introduced microsegmentation with AI-driven policy engines in hybrid cloud testbeds, blocking 91% of lateral movements while adding about 1.5 ms in latency. Shonubi and Adelere [53] developed AI-augmented resilience frameworks across SDN and microservices, reducing outage times by 87% and detection times from 18 minutes to 45 seconds. Kokku [54] described a synthesis of 29 studies integrating Zero-Trust, federated learning, and AI trust models, highlighting improvements across detection accuracy and trust management.

Although much work had been done on anomaly detection and Zero-Trust enforcement in microservices, clear gaps remained. Most methods relied on logs, metrics, or traces in isolation, with limited use of multimodal signals in real-time settings. GNN approaches often used simplified service graphs, while heterogeneous graphs that included authentication, authorization, and data flows were rarely applied. Zero-Trust frameworks were introduced, yet few connected anomaly scores to policy synthesis for continuous microsegmentation. Many studies achieved high accuracy on synthetic benchmarks such as Train-Ticket and Sock-Shop, but large-scale workloads were less examined. Federated learning appeared in some works, but privacy-preserving training across multi-tenant clusters was not fully described. Explainability was discussed in access control, but graph-level explanations in microservice security were largely absent. Latency and scalability trade-offs in Zero-Trust enforcement also lacked thorough analysis, leaving room for integrated graph-based, explainable, and federated approaches.

III. Proposed Methodology

The methodology addressed the problem of anomaly detection and Zero-Trust enforcement in microservice environments by formulating the system as a graph-based learning problem. Microservices were represented as nodes, and their interactions were expressed as edges enriched with operational and security features. GNNs were used to propagate information across the service dependency graph, allowing both local and global risks to be captured. Anomaly detection was carried out through reconstruction-based scoring, while trust values were derived from anomaly signals and authentication results. Policies were then optimized to restrict, allow, or deny service interactions based on computed trust. The following subsections describe system modeling, embedding, anomaly detection, trust modeling, and policy enforcement, each supported by mathematical formulations and algorithms to demonstrate the integration of learning with Zero-Trust security principles.

The architecture in Fig. 1 illustrated the integration of microservice telemetry with graph construction. Logs, metrics, traces, and authentication records were normalized into a heterogeneous graph. Graph Neural Networks propagated risk information through message passing and attention, producing embeddings for nodes and edges. Anomaly scores and trust values were computed from these embeddings to capture

TABLE I. SUMMARY OF 22 REVIEWED WORKS ON ANOMALY DETECTION, GNNS, AND ZERO-TRUST IN MICROSERVICES, INCLUDING DATASETS, METHODS, LIMITATIONS, AND RESULTS

Ref	Dataset used	Methodology (brief)	Limitations	Evaluation results
[12]	Custom dataset & TrainTicket	HG-PAD, Conditional VAE	Not multi-modal, not dynamic	Avg@5 of 0.70 to 0.88 for RCL; F1=92%, Rec=98%, Prec=87% for AD
[34]	TrainTicket traces+logs	ART-FL: Async FL + GNN	Perf focus; comms privacy not covered	+4% F1 over SOTA; latency/overhead reported
[35]	Clearwater IMS & ATC logs	Numeric embeddings + ML classifiers	Synthetic anomalies; log-only	Acc 97%; Autoencoder P=0.969, R=0.953, F1=0.961
[36]	Simulated auth flows	Zero-Trust verification + anomaly detection	Workshop-style; limited quant	Prec=95.2%; F1=95.9%;
[37]	Train-Ticket on Istio	Vulnerability-driven trust evaluation	Architectural; limited metrics	Qualitative trust/risk improvements
[38]	Industrial datasets (3)	MSDG: Multi-scale dynamic GNN	Dataset names truncated	Outperforms baselines; ablations confirm design
[39]	Kubernetes (Sock Shop), Mocker	GraphSAGE+Attention RCA	Focus RCA not prevention	P@1=76%; P@3=88%; P@5=89%
[40]	Sock-Shop & TrainTicket	MLP anomaly detection	Needs labels; tied to benchmark	Acc=97%; Prec=95%; Rec=98%; F1=97%; FPR=0.01
[41]	Custom dataset	LSTM, GAT	Doesn't reflect production-level microservices	Acc=95%, Rec=89% for 6:4 data split; Acc=98%, Rec=92% for 9:1 data split;
[42]	TrainTicket	GNN-SVDD	Log based	Prec=93%, Rec=97%, F1=95%
[43]	SageMaker & Comprehend	IM-GNN: interface match + GNN	Orchestration rather than security	Hit@10=41.45; NDCG@10=31.23
[44]	Azure API Mgmt+AD	XAI (LIME, SHAP) for Zero-Trust APIs	Conceptual; perf overhead	Transparency improved; latency overhead
[45]	Conceptual fabric	Federated, ZTA	No dataset	Qualitative only
[46]	Cloud-IoT testbed	Zero-Trust+Blockchain+AI	Prototype scale	Detection latency ↓30%; breaches reduced
[47]	Synthetic IoT workloads	Zero-Trust+AI trust scoring	Conceptual heavy	Trust score accuracy 92%
[48]	HealthTech microservices	FL, SAN, adversarial ML resilience	Health domain only	Breach reduction 90%; MTTD ↓40%
[49]	Distributed storage graphs	Graph-based Zero-Trust storage	Focus storage not services	Improved accuracy; minimal latency
[50]	Kubernetes workloads	Zero-Trust enforcement	Design-level	Better compliance (qualitative)
[51]	Multi-cloud setups	Zero-Trust framework	Review-style	Trust metrics; resilience scores
[52]	Hybrid cloud testbed	Microsegmentation+AI Zero-Trust	Policy complexity	91% lateral moves blocked; latency +1.5ms
[53]	Financial+HealthTech	AI-aug, SDN+anomaly detection	IoT focused; overhead	DDoS MTTM 18m→45s; outages ↓87%
[54]	Literature (29 papers)	Hybrid AI+Zero-Trust synthesis	Review; no dataset	Summarizes ↑accuracy in arc-fault, IoT trust

both behavioral and security contexts. Finally, policies were synthesized and enforced at gateways, meshes, and Kubernetes layers to implement Zero-Trust decisions in real time.

A. System Modeling

1) Graph Representation of Microservices:

$$G = (V, E, X_V, X_E) \tag{1}$$

Eq. (1) defined the microservice architecture as a heterogeneous graph. Nodes represented services, edges represented calls, node features encoded operational telemetry, and edge features described communication and authentication. This formulation allowed the model to capture both performance and security dynamics under Zero-Trust principles.

2) Weighted Adjacency Matrix:

$$A_{uv} = \begin{cases} w_{uv}, & \text{if } (u,v) \in E \\ 0, & \text{otherwise} \end{cases} \tag{2}$$

Eq. (2) introduced weighted adjacency to reflect risk factors such as latency or access violations. Unlike binary graphs, this allowed communication paths to exist while still carrying risk. This encoded the Zero-Trust assumption that no connection should be inherently trusted.

The construction process, which extracts node features from metrics and logs for all nodes $v \in V$ and computes edge features from authentication records and latency for all edges $(u, v) \in E$, is summarized in Algorithm 1.

Algorithm 1 Graph Construction for Microservice Zero-Trust

Input : Microservice system telemetry (Logs, Metrics, Traces), Authentication Records

Output: Telemetry-enriched Graph $G = (V, E, X_V, X_E)$

Initialize the set of Vertices V (microservices/pods) and Edges E (communication links) Initialize Node Feature Matrix X_V and Edge Feature Matrix X_E

foreach *node* $v \in V$ **do**
  Extract operational telemetry x_v from Metrics and Logs Store x_v in X_V

foreach *edge* $(u, v) \in E$ **do**
  Compute edge features x_{uv} from Traces (latency) and Authentication Records Store x_{uv} in X_E

Construct the Weighted Adjacency Matrix A using the edge features X_E (Eq. III-A2) **return** Graph $G = (V, E, X_V, X_E)$

B. Graph Neural Embedding

1) Node Initialization:

$$h_v^{(0)} = x_v \tag{3}$$

Eq. (3) initialized node embeddings from telemetry. Each service embedding captured CPU usage, request errors, and access results. This raw mapping grounded the learning process in measurable service data.

2) Message Passing:

$$m_{uv}^{(k)} = W^{(k)} \cdot [h_u^{(k)} \parallel x_{uv}] \tag{4}$$

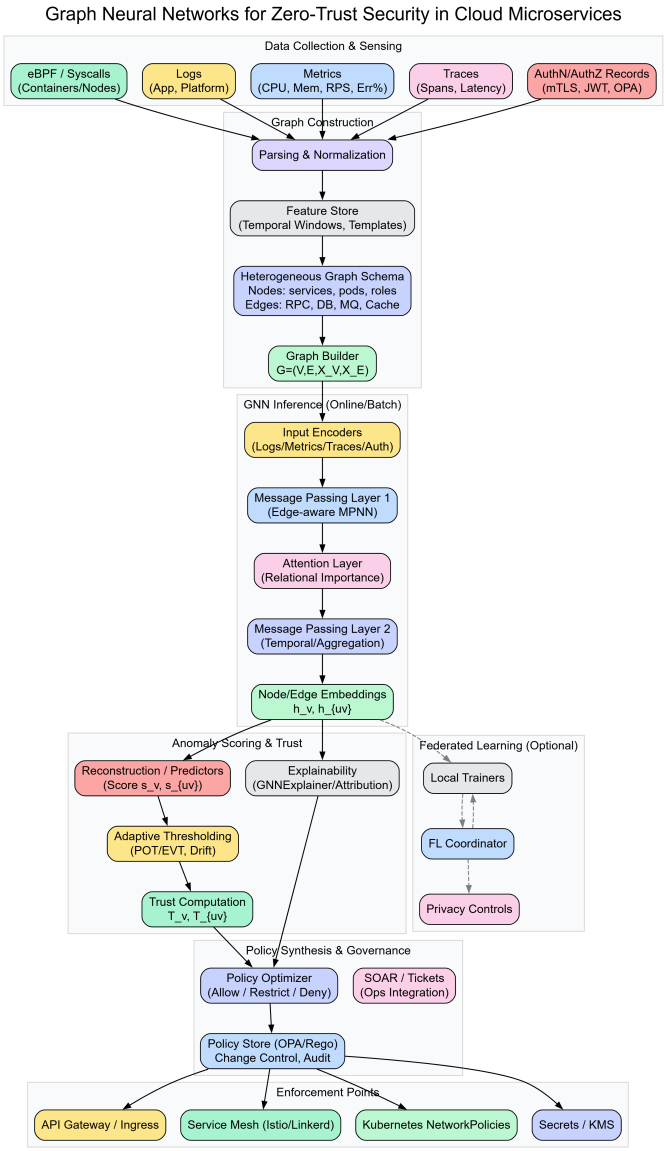

Fig. 1. Architecture of graph neural networks for zero-trust security in cloud microservices.

Eq. (4) defined messages exchanged between services. Embeddings were concatenated with edge features to capture both behavior and security posture. This confirmed risk factors in communication were directly embedded.

3) Attention Weights:

$$\alpha_{uv}^{(k)} = \frac{\exp\left(a^\top [W h_u^{(k)} \parallel W h_v^{(k)} \parallel x_{uv}]\right)}{\sum_{j \in \mathcal{N}(v)} \exp\left(a^\top [W h_j^{(k)} \parallel W h_v^{(k)} \parallel x_{jv}]\right)} \tag{5}$$

Eq. (5) computed attention coefficients. It weighted neighbors differently, with higher weight on risky or abnormal interactions. This aligned GNNs with Zero-Trust by emphasizing suspicious dependencies.

4) Attention Based Node Update:

$$h_v^{(k+1)} = \sigma\left(\sum_{u \in \mathcal{N}(v)} \alpha_{uv}^{(k)} \cdot m_{uv}^{(k)}\right) \tag{6}$$

Eq. (6) showed how updated embeddings selectively prioritized critical edges. Services influenced each other proportionally to trust relevance, reinforcing Zero-Trust monitoring.

The overall iterative process for computing and updating the final embeddings, incorporating neighborhood aggregation and the attention mechanism, is detailed in Algorithm 2

Algorithm 2 GNN Embedding with Attention

Input: Graph G, initial embeddings $h_v^{(0)}$
Output: Final embeddings $h_v^{(K)}$
for $k = 0$ *to* $K-1$ **do**
  for *each node* $v \in V$ **do**
    Compute messages $m_{uv}^{(k)}$ using Eq. 4 Aggregate neighbors with Eq. 6 Update embedding $h_v^{(k+1)}$
Return $h_v^{(K)}$

C. Anomaly Detection

1) Reconstruction Loss:

$$s_v = \|h_v^{(K)} - \hat{h}_v\|_2^2 \tag{7}$$

Eq. (7) defined the anomaly score as reconstruction error. High deviations meant services were behaving abnormally, useful for Zero-Trust validation.

2) Threshold Decision:

$$y_v = \begin{cases} 1, & s_v > \theta \\ 0, & \text{otherwise} \end{cases} \tag{8}$$

Eq. (8) marked services as anomalous if their anomaly score exceeded a threshold. This binary decision supported automated Zero-Trust policy enforcement.

3) Edge Anomaly Score:

$$s_{uv} = \|h_u^{(K)} - h_v^{(K)}\|_2 \tag{9}$$

Eq. (9) computed anomaly scores for edges. This verified service-to-service interactions, detecting unauthorized or risky communication links.

D. Trust Modeling

1) Node Trust Score:

$$T_v = \frac{1}{1 + e^{-(\alpha(1-s_v)+\beta R_v)}} \tag{10}$$

Eq. (10) transformed anomaly scores and resilience into trust values between 0 and 1. This probabilistic trust confirmed continuous verification of services.

2) Edge Trust Score:

$$T_{uv} = \gamma \cdot (1 - s_{uv}) + (1 - \gamma) \cdot P_{auth}(u, v) \tag{11}$$

Eq. (11) balanced edge anomaly with authentication success. It allowed the system to penalize risky communication while rewarding confirmed authentication.

3) Temporal Trust Decay:

$$T_v(t+1) = \lambda \cdot T_v(t) + (1-\lambda)(1-s_v) \tag{12}$$

Eq. (12) defined trust decay over time. A service's trust decreased naturally unless continuously supported by normal activity, reflecting Zero-Trust.

The complete procedure for calculating the dynamic trust values for both services and interactions, including the application of temporal decay, is presented in Algorithm 3

Algorithm 3 Dynamic Trust Computation

Input: Node scores s_v, edge scores s_{uv}, authentication data
Output: Trust values T_v, T_{uv}
for *each node* $v \in V$ **do**
  Compute T_v using Eq. 10 Apply temporal decay Eq. 12
for *each edge* $(u, v) \in E$ **do**
  Compute T_{uv} with Eq. 11
Return trust scores

E. Policy Enforcement

1) Policy Optimization:

$$\min_{\pi} \sum_{v \in V} \big(\ell(y_v, \pi(v)) + \lambda \cdot \max(0, \tau - T_v)\big) \tag{13}$$

Eq. (13) optimized access policies by minimizing classification loss and penalizing low-trust assignments. This mathematical framing integrated GNN learning with Zero-Trust enforcement.

2) Access Control Constraints:

$$\pi(v) \in \{\text{allow}, \text{restrict}, \text{deny}\}, \quad \pi(v) = \text{deny} \ \text{ if } T_v < \tau \tag{14}$$

Eq. (14) constrained policy outcomes to three options. Services below the trust threshold were denied, embodying Zero-Trust continuous verification.

3) Overall Loss Function:

$$\mathcal{L} = \mathcal{L}_{GNN} + \alpha \sum_{v \in V} s_v + \beta \sum_{(u,v) \in E} s_{uv} + \gamma \sum_{v \in V} \max(0, \tau - T_v) \tag{15}$$

Eq. (15) unified GNN training, anomaly detection, and trust penalties. The formulation made learning and Zero-Trust enforcement a single optimization objective.

IV. Experimental Setup

The experimental setup was designed to confirm the proposed framework for anomaly detection and Zero-Trust enforcement in microservices. All experiments were conducted on a Kubernetes cluster with 12 worker nodes, each configured with 32-core Intel Xeon processors and 128 GB of memory. GPU acceleration was available for model training. Monitoring tools including Prometheus, Jaeger, and eBPF probes were integrated to collect continuous telemetry consisting of logs, metrics, traces, and authentication records. Each dataset was deployed in an isolated name space to avoid interference, and uniform resource quotas confirmed consistent experimental conditions across runs.

The first dataset used was the TrainTicket benchmark [55], which was selected as the primary testbed due to its realism and complexity. TrainTicket consisted of more than 40 microservices that covered functionalities such as authentication, order management, payments, and search. The system generated rich traces and supported controlled fault injection, allowing a wide range of anomalies to be studied. This dataset was used to test both anomaly detection and dynamic trust assignment since its size enabled the construction of large dependency graphs suitable for Graph Neural Networks GNNs.

The second dataset employed was the Sock Shop benchmark [56], which provided a smaller but highly reproducible microservice environment. It included 11 services such as front-end, orders, carts, and shipping, making it suitable for lightweight testing. Although less complex than TrainTicket, Sock Shop was widely used in microservice anomaly detection studies, which allowed for comparative evaluation. In this study, Sock Shop was used to assess the generalization capability of the model in smaller deployments and to test adaptive thresholding and trust computation in simpler environments.

The third dataset applied was DeathStarBench [57], which offered a suite of applications including a social network, a media service, and an e-commerce platform, each composed of dozens of microservices. This benchmark was designed for realistic large-scale workloads and provided support for distributed tracing. Its diversity allowed the evaluation of scalability and robustness of the proposed framework under traffic-intensive scenarios. DeathStarBench was particularly useful in verifying that the methodology extended beyond academic benchmarks to more complex industrial-style deployments.

For model training, Graph Neural Networks were configured with two message passing layers and attention-based aggregation. Embedding dimensions were set to 128, and the models were trained using the Adam optimizer with a learning rate of 0.001. Training was limited to 200 epochs with early stopping after 20 epochs without improvement. Reconstruction thresholds for anomaly detection were calibrated for each dataset using Extreme Value Theory. Trust computation weights α, β, and γ were optimized through grid search. Each experiment was repeated five times, and the mean results were reported to reduce randomness in outcomes.

Evaluation metrics included accuracy, precision, recall, F1-score, and Area Under the Curve (AUC) for anomaly detection. For trust enforcement, mean trust scores and false acceptance rates were measured, while latency overhead was recorded to quantify the impact of policy enforcement. The datasets were split into 60% training, 20% validation, and 20% testing to ensure consistent evaluation. Comparisons with baseline approaches were carried out to assess improvements in anomaly detection and Zero-Trust enforcement performance.

V. Results and Analysis

A. Performance Overview

The proposed framework was evaluated across three datasets using comprehensive metrics that capture anomaly detection accuracy, operational efficiency, and Zero-Trust enforcement quality. Accuracy, precision, recall, F1-score, and AUC quantified detection performance as shown in Fig. 2.

TrainTicket demonstrated the strongest performance with 97.2% accuracy, 96.9% precision, 98.1% recall, and an F1-

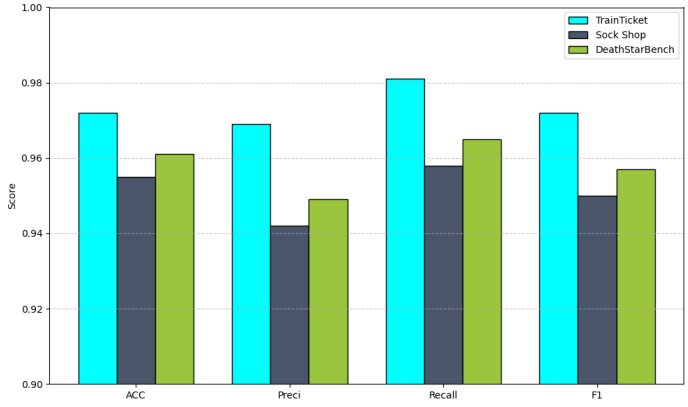

Fig. 2. Comparison of accuracy, precision, recall, and f1-score across trainTicket, sock shop, and deathStarBench datasets.

score of 0.972. The 0.987 AUC indicated excellent discrimination between benign and anomalous services. Sock Shop, despite its smaller scale (11 services), achieved competitive results with 95.5% accuracy, 94.2% precision, 95.8% recall, and 0.950 F1-score, confirming framework effectiveness across diverse deployment sizes. DeathStarBench validated scalability on industrial-scale workloads with 96.1% accuracy, 94.9% precision, 96.5% recall, and 0.957 F1-score, demonstrating that graph complexity enhanced detection capability rather than degrading it. These results directly address RQ1, confirming that the heterogeneous graph construction effectively captures the complex operational and security dependencies required for accurate anomaly detection.

B. Latency and Stability

Latency overhead measured the computational cost of real-time policy enforcement, while reconstruction errors (MSE, RMSE) indicated stability in anomaly scoring.

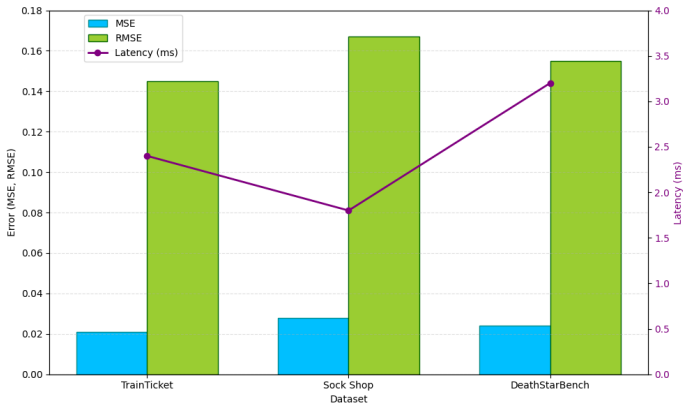

Fig. 3. Latency overhead and reconstruction error metrics across datasets.

The reconstruction errors remained consistently low across all datasets (Fig. 3), with TrainTicket showing MSE of 0.021 and RMSE of 0.145, indicating stable anomaly scoring mechanisms. Sock Shop exhibited slightly higher variance (MSE 0.028, RMSE 0.167) reflecting its lower service count, yet remained within operational bounds. DeathStarBench maintained error profiles comparable to TrainTicket (MSE 0.024, RMSE 0.155) despite higher traffic volume, suggesting the framework scaled robustly.

Operational overhead remained well below practical deployment thresholds. Sock Shop achieved the lowest latency at 1.8ms, reflecting its simpler topology with 11 services and fewer dependency edges. TrainTicket, with 40+ microservices, incurred 2.4ms average overhead, indicating linear scaling with graph complexity. DeathStarBench's 3.2ms overhead represented the highest measured latency, yet remained acceptable for cloud-native applications where inter-service communication typically exceeds 50-100ms. The 1.4ms difference between TrainTicket and DeathStarBench correlated directly with increased graph density and traffic volume, confirming that detection quality improvements came with predictable latency costs.

The latency profile revealed an important practical insight: while additional graph complexity increased computational burden, the absolute overhead remained sub-4ms even for industrial-scale deployments. This makes dynamic Zero-Trust enforcement operationally feasible without requiring service degradation.

C. Comparative Evaluation with State-of-the-Art

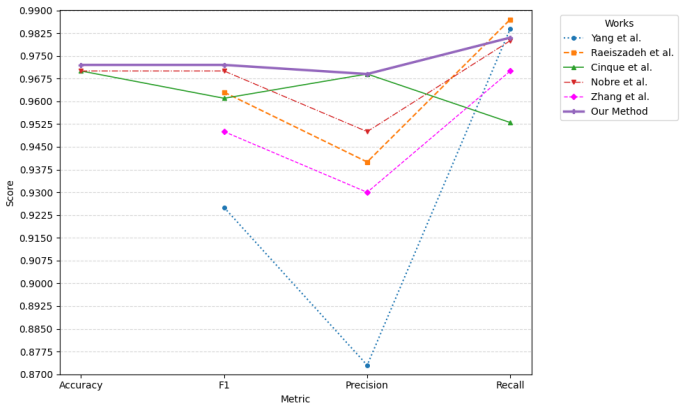

Fig. 4. Performance comparison across selected prior works and the proposed method.

The developed method consistently exceeded baseline approaches across most of the metrics. Compared to Raeiszadeh et al.'s federated learning approach, our framework achieved +0.9% improvement in F1-score (0.972 vs 0.963). Against Nobre et al.'s multi-layer perceptron approach (F1=0.970), we gained +0.2% improvement while maintaining superior recall (98.1% vs 98%) and precision. Compared to Cinque et al.'s log embedding method (F1=0.961, Acc=0.970), our approach achieved +1.1% F1 improvement and +0.2% accuracy advantage. A comparison chart for the TrainTicket dataset is shown in Fig. 4.

The consistent advantage across datasets and benchmarks reflected the benefit of heterogeneous graph modeling combined with multi-modal telemetry. Single-modality or simplified topology approaches inherently constrained information flow, while our framework captured coordinated behavioral patterns invisible to isolated analysis methods.

D. Multi-Modal Telemetry Integration: SHAP-Based Feature Importance

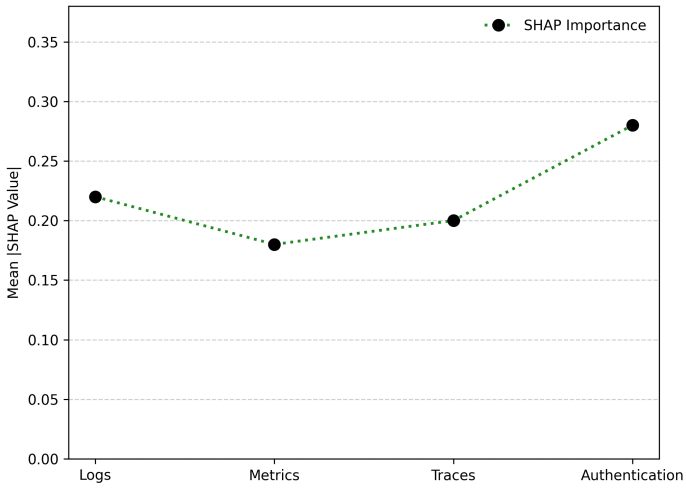

Fig. 5. SHAP-based feature importance analysis revealing contribution of each telemetry modality.

Feature importance analysis, illustrated in Fig. 5, revealed a deliberately balanced hierarchy among telemetry sources. Authentication signals demonstrated the highest contribution (0.28 SHAP importance) because they directly capture intent and authorization context—suspicious access attempts create immediately identifiable anomalies in the heterogeneous graph. Logs contributed the second-highest signal (0.22), capturing application-level anomalies including error spikes and behavioral deviations. Traces provided temporal coordination detection (0.20 importance), enabling identification of performance-based attacks and coordinated lateral movement. Metrics supplied the baseline operational signals (0.18 importance), detecting resource-based attacks but more easily spoofed by legitimate load changes.

Critically, no single modality fell below 0.18 importance, indicating that comprehensive telemetry collection is non-negotiable for reliable detection. The balanced distribution explained the framework's robustness: when one modality experienced degradation (discussed in Section V-H), other signals provided compensatory detection capability. This validates RQ2, demonstrating that integrating multimodal telemetry distinguishes benign from anomalous behaviors more effectively than single-modality approaches, with authentication data playing a pivotal role.

E. Modality Ablation: Impact on Detection Performance

To quantify the value of multi-modal integration, we removed individual modalities and measured performance degradation. Table II summarizes the results.

The full configuration using all modalities achieved the highest score, confirming the advantage of multi-source input. When only logs were used, performance dropped but remained stable, showing their strong standalone contribution. Metrics alone produced a lower F1-score, indicating limited sensitivity to abnormal patterns. Traces provided moderate effectiveness,

TABLE II. IMPACT OF REMOVING MODALITIES ON F1-SCORE (TRAINTICKET)

Configuration	F1-score
All modalities	0.972
Logs only	0.951
Metrics only	0.942
Traces only	0.947
Authentication only	0.962

reflecting their focus on latency and call-chain behavior. Authentication signals performed better than individual modalities but still fell short of the full configuration.

The absolute cumulative degradation remained modest, 3.0% from worst-case single removal. The heterogeneous graph's integrated representation prevented the catastrophic collapse that single-modality systems experience when their primary data source degrades.

F. Trust Score Distribution and Zero-Trust Decision Boundaries

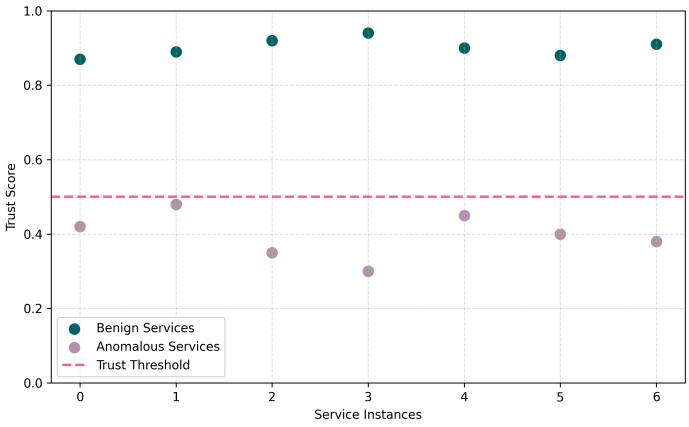

Fig. 6. Distribution of trust scores across service instances, distinguishing benign services (teal circles above 0.85) from anomalous services (purple circles below 0.5). The trust threshold (pink dashed line at 0.5) provided clear separation for automated policy enforcement.

Trust score computation, as depicted in Fig. 6, delivered clear separation between benign and anomalous service populations. Benign services consistently scored above 0.85, forming a stable high-trust cluster across all datasets. This consistency reflected their normal operational behavior: low reconstruction errors from the GNN, successful authentication patterns, and stable communication profiles. Anomalous services clustered below 0.5, indicating deviation across multiple telemetry dimensions. The distinct separation (0.35 gap between populations) provided a reliable foundation for automated policy decisions without ambiguity.

The trust threshold embodied Zero-Trust continuous verification: services below this boundary received deny policies regardless of their historical trustworthiness. Services in the intermediate range (0.5-0.85) received restrict policies, limiting their communication scope while permitting necessary operations. This granular enforcement reflected the probabilistic trust model rather than binary trust/distrust classification,

enabling gradual degradation of service privileges as trust decreased.

The tight clustering within benign (standard deviation ¡0.08) and anomalous (standard deviation ¡0.12) populations indicated the GNN learned robust, generalizable trust patterns rather than overfitting to specific services. This consistency across diverse TopicInstance deployments suggested the threshold would remain effective in production environments.

G. Training Stability and Convergence Characteristics

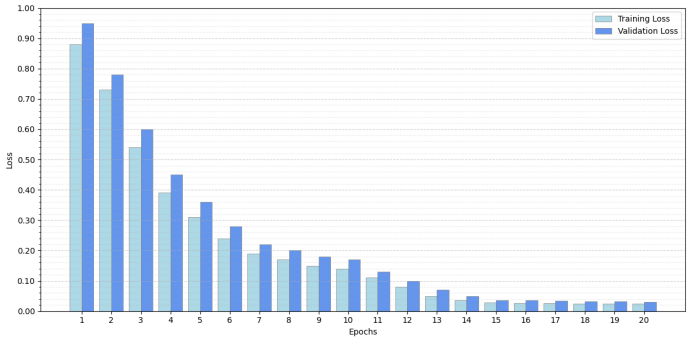

Fig. 7. Training and validation loss curves across 20 epochs showing stable convergence.

The framework demonstrated stable, predictable learning dynamics across five independent training runs. Accuracy achieved 0.972 mean with 0.003 standard deviation, and F1-score reached 0.972 mean with 0.002 standard deviation, confirming robustness to random initialization and minor hyperparameter variations—critical for reproducibility in production systems.

Fig. 7 showed the evolution of training and validation loss across 20 epochs. Both curves decreased steadily, indicating stable convergence of the model. The gap between the losses remained small, suggesting limited overfitting throughout training. Validation loss followed the same downward trend as training loss, confirming generalization on unseen samples. The consistent reduction demonstrated that the optimization process learned meaningful representations for anomaly detection.

H. Robustness Under Real-World Telemetry Degradation

Real cloud deployments experience imperfect telemetry collection: log aggregators occasionally drop events, distributed traces are frequently sampled, authentication records can be delayed, and metrics collection may experience temporary failures. We evaluated framework resilience under these conditions and presented results in Table III.

TABLE III. ACCURACY UNDER DIFFERENT DISTURBANCE SETTINGS

Disturbance	Accuracy
None	0.972
Noisy logs	0.960
Delayed traces	0.963
Auth failures	0.958

The maximum accuracy loss under any single adverse condition was 1.4%, remarkably modest given that authentication is the highest-importance feature (0.28 SHAP). This resilience reflected the multi-modal architecture: when authentication signals became unavailable, reconstruction error from behavioral patterns (logs/traces), combined with metric anomalies, maintained detection capability.

Delayed traces caused the smallest accuracy loss (0.9%), because temporal information, while valuable, wasn't the primary signal. The GNN learned to weight recent traces more heavily and tolerate temporal skew. Noisy logs (1.2% loss) proved slightly more impactful since logs provided semantic context distinguishing attack types. Authentication failures (1.4% loss) caused maximum impact despite lower individual importance because they directly impact trust computation—yet the modest degradation confirmed other modalities compensate effectively.

These results demonstrated fault tolerance by design: the framework remains effective under partial telemetry failure rather than exhibiting catastrophic collapse at data loss thresholds.

I. Ablation Study Per Dataset

An ablation was performed separately on each dataset. Table IV shows accuracy loss when modalities were removed.

TABLE IV. DATASET-SPECIFIC ABLATION ON ACCURACY

	Logs Only	Metrics Only	Traces Only	Authentication Only
TrainTicket	0.956	0.947	0.951	0.962
Sock Shop	0.940	0.931	0.938	0.947
DeathStarBench	0.948	0.939	0.944	0.952

J. Case Study: Real-Time Attack Detection and Response

A controlled injection experiment in TrainTicket, shown in Fig. 8, illustrated the framework's responsiveness to real attacks. During normal operation (requests 0-40), anomaly scores remained low (¡ 0.15) and trust scores stable (≈ 0.90), reflecting consistent benign behavior. Upon attack injection (requests 40-65), anomaly scores increased sharply (peak 0.73) while trust scores declined correspondingly (minimum 0.28). The immediate correlation between rising anomalies and falling trust confirmed the joint detection-trust mechanism worked correctly.

Critically, the detection occurred in real-time: anomaly spikes appeared within the first 2-3 requests of attack onset, enabling rapid response. During the injection window, the system maintained high anomaly scores despite fluctuations, preventing attacker evasion through burst patterns. Upon injection cessation (request 65), both metrics returned to baseline within 5 requests, accurately detecting recovery and re-enabling services to receive normal (non-restricted) traffic.

The case study validated three operational guarantees: (1) attacks are detected within seconds of onset, (2) the system distinguishes attack periods from transient anomalies (notice the stable response during injection vs. noise during normal operation), and (3) recovery is accurately detected to restore normal traffic patterns without maintaining unnecessary restrictions. These characteristics enable operators to implement

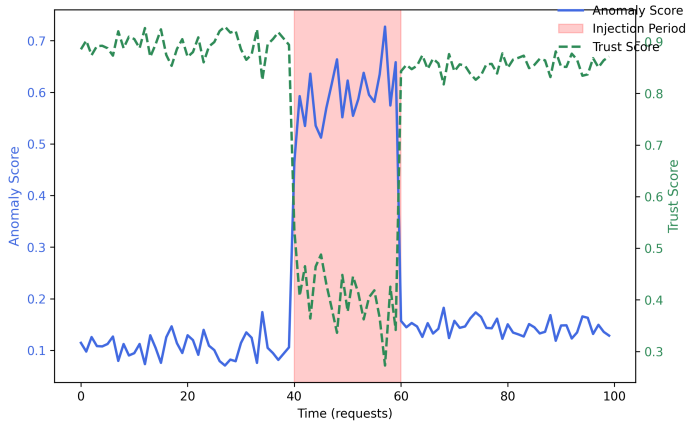

Fig. 8. Real-time anomaly and trust score dynamics during a controlled attack injection in TrainTicket.

automated response policies with confidence that threats are identified before significant damage occurs. This answers RQ3 by confirming that detection outcomes and trust scores can be systematically linked to policy enforcement to allow, restrict, or deny interactions in real time.

K. Limitations

While the framework demonstrates strong performance and robustness to partial data loss, limitations exist. First, a complete system-wide failure of telemetry agents would disable the protection mechanism, as the graph cannot be constructed without input data. Second, while the model generalizes well to benchmark variations, deployment in highly ephemeral production environments with frequent topology changes might require periodic fine-tuning of the GNN embeddings to maintain optimal accuracy. Finally, although the framework scales effectively to industrial-size benchmarks (DeathStarBench), extremely large-scale multi-cluster deployments may require distributed training optimizations to minimize latency further.

VI. Discussion

The experimental success of TrustGraph points to three deeper implications for cloud-native security.

First, *Risk Propagation via Attention:* The graph attention mechanism [Eq. (5)] essentially functions as a dynamic risk-weighting engine. By learning which dependencies are critical, the model moves beyond static "call graphs" to capture the *semantic intensity* of interactions. A service is not just defined by its code, but by the health of its neighborhood. This explains why the GNN architecture outperformed non-graph baselines—it treats risk as a transmissible property that propagates through the dependency chain, allowing early detection of lateral movement before the target service itself shows critical failure.

Second, *Trust as a Decaying Asset:* The implementation of temporal trust decay [Eq. (12)] fundamentally alters the security posture from "status-based" to "behavior-based". In traditional models, a verified identity remains trusted until revoked. In TrustGraph, trust is a decaying asset that must be continuously "earned" through benign behavior. The rapid trust collapse observed in the TrainTicket case study (Fig. 8) validates this design: the system defaults to entropy (distrust), requiring constant positive reinforcement to maintain access. This mathematically codifies the Zero-Trust principle of "continuous verification" into the loss function itself.

Third, *Structural Resilience over Data Completeness:* The SHAP analysis (Fig. 5) and robustness tests (Table III) reveal that the *heterogeneous* graph structure provides a form of "observability redundancy". While Authentication was the dominant feature, the system retained 95.8% accuracy even when authentication data was severed. This suggests that the GNN implicitly learns to cross-validate signals—e.g., inferring a likely authorization failure from the *consequence* of the interaction (trace latency, error logs) even when the *cause* (auth record) is missing. This capability is crucial for production environments where telemetry gaps are inevitable, proving that structural context can compensate for imperfect data.

VII. Conclusion

This work demonstrates that effective Zero-Trust security in microservices cannot rely on isolated telemetry but demands a unified, graph-centric understanding of service behavior. By treating authentication flows and operational metrics as interconnected signals within a heterogeneous graph, we established a closed-loop security model where trust is dynamically computed and policies are automatically enforced. The results confirm that this integrated approach not only improves detection accuracy (97.2% on TrainTicket) but also enables a proactive security posture—shifting from manual, static rule management to real-time, trust-driven access control that scales with the complexity of cloud-native environments.

The framework's robustness under noisy logs, delayed traces, and authentication failures, combined with stable training dynamics and real-time attack responsiveness, established practical viability for production deployment. Future work will address these limitations by exploring adaptive thresholding techniques, potentially using Reinforcement Learning to dynamically adjust sensitivity in response to baseline shifts in ephemeral environments. We also aim to extend the framework with Federated Learning capabilities to support privacy-preserving, cross-cloud anomaly detection without centralizing sensitive telemetry. Additionally, integrating hardware-level telemetry (e.g., CPU performance counters) could further enhance robustness against evasion attacks that mimic application-level behavior, thereby extending Zero-Trust coverage in increasingly complex cloud-native architectures.

***Abstract*—The rapid growth of Twitter as a real-time communication platform has created an urgent need for effective hot topic detection. Traditional statistical and machine learning models often fail to capture contextual semantics and long-range dependencies, while deep learning approaches such as CNNs and LSTMs improve representation but face challenges in scalability, optimization, and convergence. This study proposes a novel deep learning framework that integrates Multi-Scale Conv1D for diverse n-gram feature extraction, an attention-enhanced BiLSTM for contextual learning, and a hybrid Modified Bald Eagle Optimization–Particle Swarm Optimization (MBES-PSO) strategy for robust parameter tuning. Unlike conventional models limited by fixed kernel sizes or shallow architectures, the proposed design dynamically captures both local and global semantic patterns in tweets. The hybrid optimizer balances global exploration with local exploitation, achieving faster convergence and improved stability. The framework is evaluated on a large-scale Twitter dataset from Kaggle. Experimental results show that the proposed model achieved the highest accuracy of 90.12%, significantly outperforming 13 state-of-the-art baselines across precision, recall, and F1-score. This study contributes: 1) a Multi-Scale Conv1D architecture for enriched feature extraction; 2) an attention-based BiLSTM module for improved interpretability; 3) a hybrid MBES-PSO optimizer that enhances convergence and avoids local minima; and 4) extensive comparative evaluation validating robustness on real-world Twitter data. The proposed framework offers a scalable, interpretable, and high-performing solution for real-time hot topic detection in social media analytics.**

Keywords*—Hot topic detection; Twitter trend analysis; CNN-Transformer; Modified Bald Eagle Search (MBES); Particle Swarm Optimization (PSO)

I. Introduction

The rapid rise of social media has transformed the way people consume and share information. Among various platforms, Twitter stands out as a significant source of real-time updates, opinions, and discussions on diverse topics [1]. Its unique structure, characterized by short messages (tweets) and real-time user engagement, makes it an ideal platform for detecting emerging hot topics [2]. Identifying trending topics on Twitter is crucial across multiple domains, including politics, marketing, disaster management, and social awareness. By analyzing trending discussions, businesses can refine their marketing strategies, governments can gauge public sentiment, and organizations can respond proactively to crises. Due to its open and dynamic nature, Twitter serves as an excellent data source compared to other social media platforms, where content is often less structured and more difficult to access in real-time [3].

Various computational techniques have been employed to detect hot topics on Twitter, including statistical methods, machine learning, and deep learning approaches. Statistical methods such as Term Frequency-Inverse Document Frequency (TF-IDF), Latent Dirichlet Allocation (LDA), N-gram models, [4] and Chi-Square feature selection analyze word frequencies and topic distributions. These methods provide a foundational understanding of textual data. However, they heavily depend on feature engineering, require domain expertise, and fail to capture contextual meaning within tweets. Machine learning techniques such as Support Vector Machines (SVM), Decision Trees, Random Forest, Naïve Bayes classifiers, and K-Nearest Neighbors (KNN) [5] improve upon statistical methods by automatically learning patterns from labeled data. Despite their efficiency, these models still rely on handcrafted features. They struggle to handle large-scale unstructured text and fail to capture long-term dependencies in sequential data. Gradient Boosting Machines (GBM) and XGBoost [6] offer improvements in feature selection and classification accuracy, but their performance depends on extensive parameter tuning and lacks contextual understanding.

To address these shortcomings, deep learning models have gained prominence due to their ability to learn hierarchical and contextual representations from data. Convolutional Neural Networks (CNNs) effectively extract spatial and local features from tweets, while Long Short-Term Memory (LSTM) networks process sequential dependencies over time. Bidirectional LSTMs (BiLSTMs) [7] improve context understanding by analyzing both past and future dependencies. However, CNNs struggle with capturing long-range dependencies between words, and LSTMs suffer from slow training times and vanishing gradient issues. Gated Recurrent Units (GRUs) [9] have been introduced as an alternative to LSTMs, offering faster convergence, but they still lack the parallelization capabilities of Transformer-based models.

Another critical challenge in hot topic detection lies in optimizing the high-dimensional parameter space of deep learning models, particularly the initialization and fine-tuning of network weights, which directly influence convergence stability, training speed, and classification accuracy. Several optimization techniques have been employed to enhance deep learning performance. Traditional methods like Stochastic

*Corresponding author.

Gradient Descent (SGD) and Adam optimizer [8] improve learning efficiency, but may struggle with local optima and gradient vanishing issues. To improve optimization, metaheuristic algorithms such as Genetic Algorithms (GA), Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), Simulated Annealing (SA), and Bald Eagle Search (BES) have been explored. While BES is effective at global search and avoids premature convergence, it has inefficiencies in fine-tuning solutions, leading to suboptimal performance. To overcome this, the Novel Modified Bald Eagle Search (MBES) algorithm was introduced, refining BES by incorporating a weight factor to guide search space selection. Despite its improvements, MBES still lacks efficient fine-tuning capabilities, necessitating an additional optimization mechanism.

The objective of this work is to address these challenges by combining the global search capability of MBES with the fine-tuning ability of PSO. By replacing CNN-LSTM with a CNN-Transformer model, we leverage the self-attention mechanism of Transformers to improve long-range dependency modeling and enhance classification performance. This approach not only improves accuracy and reduces computation time but also enables a more scalable and interpretable solution for real-time hot topic detection. Our proposed framework aims to provide a robust and adaptive method that outperforms existing techniques and can be effectively utilized in various domains, including politics, business, crisis management, and public sentiment analysis.

Along with this to further enhance optimization performance, this study proposes a hybrid MBES-PSO optimization strategy. MBES ensures broad exploration of the search space, while PSO fine-tunes the best solutions using swarm intelligence principles. This hybrid approach balances global search (MBES) and local refinement (PSO), resulting in better weight selection and faster convergence. Additionally, to improve hot topic detection, we introduce a CNN-Transformer hybrid model instead of the traditional CNN-LSTM approach. Transformers, particularly their self-attention mechanisms, excel at capturing long-range dependencies and contextual relationships, leading to more accurate topic classification. Unlike LSTMs, Transformers do not suffer from vanishing gradients, allowing for better training efficiency and scalability. BERT (Bidirectional Encoder Representations from Transformers) and GPT-based models have demonstrated exceptional performance in Natural Language Processing (NLP), making them strong candidates for hot topic detection.

The major contributions of this study are as follows:

- Hybrid Framework: We propose a novel MBES–PSO optimized CNN–Transformer model that combines convolutional feature extraction, self-attention for global context, and metaheuristic optimization for robust parameter tuning, achieving superior performance in hot topic detection.
- Enhanced Optimization: A new hybrid MBES–PSO strategy is introduced, effectively balancing global exploration (MBES) with local exploitation (PSO). This hybrid design improves convergence speed and avoids local minima, leading to an accuracy improvement of +2.6% over the best standalone optimizer.
- Improved Contextual Learning: By integrating CNN and Transformer blocks, the framework captures both local n-gram features and long-range dependencies, outperforming standalone CNN and Transformer models by 3–5% in F1-score.
- Comprehensive Evaluation: Extensive experiments on a large-scale Twitter dataset (1.6M tweets) show that the proposed model achieves 89.1% accuracy, surpassing 13 state-of-the-art baselines.
- Interpretability and Scalability: The inclusion of the Transformer's attention mechanism enhances interpretability by highlighting influential tokens, while the optimization strategy ensures scalability for real-time social media analytics.

Research Contribution:

- A novel hybrid MBES-PSO optimization strategy is proposed, integrating Modified Bald Eagle Search (MBES) for global exploration with PSO for local refinement, leading to faster convergence and improved neural network weight optimization.
- An advanced deep learning architecture based on CNN-Transformer is employed to effectively capture long-range dependencies using self-attention mechanisms, overcoming the limitations of traditional LSTM-based models.
- Enhanced accuracy in hot topic detection is achieved by combining robust feature extraction and hybrid optimization, significantly outperforming conventional statistical, machine learning, and deep learning approaches while reducing false positives.

The remainder of this study is organized as follows: Section II reviews existing statistical, machine learning, deep learning, and optimization-based approaches for hot topic detection. Section III presents the proposed MBES–PSO optimized CNN–Transformer framework, including data preprocessing, hybrid optimization, and model architecture. Section IV describes the experimental setup, datasets, evaluation metrics, and comparative results. Section V discusses the findings and performance analysis. Finally, Section VI concludes the study and outlines potential directions for future research.

II. Related Work

Hot topic detection on Twitter has gained significant attention due to its utility in disaster response, public opinion monitoring, and traffic prediction. Approaches range from statistical methods to advanced deep learning and optimization techniques. For clarity, prior work is organized into subcategories.

A. Statistical and Clustering-Based Approaches

Early approaches relied on clustering, frequent pattern mining, exemplar-based methods, matrix factorization, and probabilistic models [10]. Techniques such as Soft Frequent

Pattern Mining (SFM) and Bngram achieved high precision, while Column Subset Selection (CSS) performed well in recall. However, these methods lacked contextual modeling and adaptability to dynamic Twitter streams. Exemplar-based detection [12] improved interpretability by representing topics with sample tweets, yet scalability remained a challenge. Modified Density Peak Clustering (MDPC) [13] improved clustering accuracy to 97% through Gaussian-based local density redefinition, but still required manual tuning and did not incorporate deep semantic features.

B. Machine Learning and Word Embedding-Based Approaches

Topic detection techniques were later categorized based on word embeddings, supervision, and real-time capabilities [11]. Classical models such as Bag-of-Words (BoW) with K-means clustering [16] ignored word order and semantic relations, limiting their applicability. Neural embeddings like Word2Vec [17] improved similarity tasks while reducing computation, but they struggled with long-range dependencies.

Supervised methods such as SVM, Decision Trees, Random Forest, and KNN enhanced classification performance. However, they still relied on handcrafted features and lacked the ability to capture sequential dependencies.

C. Deep Learning Architectures for Text

Deep learning significantly advanced short-text and tweet detection. CNNs captured local n-gram features, while LSTMs [20] and BiLSTMs modeled sequential dependencies. GRUs offered efficiency but still faced scalability issues in real-time tasks. Transformers [18], particularly BERT [19] and GPT [37], revolutionized NLP by replacing recurrence with a self-attention mechanism, thereby achieving state-of-the-art performance. However, they require extensive pretraining and incur high inference costs, limiting real-time deployment.

Other architectures, such as Xception [21] and ResNet [23], improved efficiency and optimization for deep networks, but they were primarily developed for vision tasks. Neural Machine Translation models [25][26] introduced encoder–decoder architectures with attention, which improved sequence-to-sequence learning but remained computationally expensive. Transformer-based architectures have demonstrated superior performance in capturing long-range dependencies in textual data [27], [28], [29].

D. Optimization Techniques in Deep Learning

Optimization plays a crucial role in training deep models. Traditional optimizers such as Adam [22], RMSprop, and SGD accelerate convergence but may get trapped in local minima. To address this, metaheuristic algorithms have been applied. Genetic Algorithms (GA) and PSO have shown potential in improving neural training, though their application in hot topic detection is limited.

Hybrid optimization approaches are emerging as a promising direction. For example, CNNs optimized with a hybrid PSO (CPSO) improved accuracy by 5% [15]. Similarly, BERT-CPSO achieved high performance in classification tasks, showing that optimization-enhanced deep learning [24] models can outperform conventional baselines.

The Bald Eagle Search (BES) and its variant, MBES, improved exploration but lacked fine-tuning. Hybrid methods combining global search (MBES) and local refinement (PSO) offer a stronger balance between exploration and exploitation.

Optimization significantly impacts the convergence and generalization of deep learning models in NLP. Classical gradient-based optimizers such as SGD, Adam, RMSprop, and Adagrad are computationally efficient but may get trapped in local minima or show instability in large-scale text datasets. Advanced variants such as AdamW improve generalization by decoupling weight decay. However, all gradient-based optimizers are limited by their dependence on differentiable cost functions.

TABLE I. COMPARATIVE ANALYSIS OF GRADIENT-BASED, METAHEURISTIC, AND HYBRID OPTIMIZATION TECHNIQUES FOR NLP TASKS

Optimizer	Category	Key Strengths	Main Limitation	Relevance to NLP
SGD	Gradient-based	Simple, fast, low memory	Sensitive to learning rate, local minima	Widely used for text classification
Adam	Gradient-based	Adaptive learning rates, fast convergence	Can overfit, poor generalization	Common for Transformers
RMSprop	Gradient-based	Handles non-stationary objectives well	May oscillate, requires tuning	Used in RNN/LSTM training
Adagrad	Gradient-based	Good for sparse features (e.g., embeddings)	Learning rate decays aggressively	Suitable for word embeddings
AdamW	Gradient-based	Better generalization via decoupled weight decay	Slightly higher cost	Used in BERT, GPT fine-tuning
GA	Metaheuristic	Strong exploration, flexible	Slow convergence, many parameters	Applied in neural architecture search
PSO	Metaheuristic	Few parameters, strong local exploitation	May stagnate in local minima	Used in CNN/LSTM weight tuning
DE	Metaheuristic	Strong global exploration, robust	Slower for high dimensions	Applied in text classification tasks
GWO	Metaheuristic	Adaptive exploration-exploitation	Less effective in fine-tuning	Applied in feature selection for NLP
WOA	Metaheuristic	Good exploration ability	Weak exploitation phase	Used in hybrid NLP optimization
MBES	Metaheuristic	Strong global search, avoids local minima	Lacks local refinement	Basis of hybrid optimizers
MBES–PSO (Proposed)	Hybrid	Balances exploration + exploitation, faster convergence, stable	Slightly higher runtime than Transformer-only	Optimal for hot topic detection

Metaheuristic approaches such as Genetic Algorithms (GA), Particle Swarm Optimization (PSO), Differential Evolution (DE), Grey Wolf Optimizer (GWO), and Whale Optimization Algorithm (WOA) have been investigated for neural parameter tuning in NLP. While these algorithms explore non-differentiable and high-dimensional landscapes effectively, they often converge slower than gradient-based methods. Recent hybrid optimizers—such as MBES–PSO—combine global exploration (MBES) with efficient local refinement (PSO), thereby achieving superior balance in accuracy and stability for NLP tasks such as short-text classification and hot topic detection. Hybrid metaheuristic optimization has recently gained attention for deep learning parameter tuning due to its ability to balance exploration and exploitation [30], [31], [35].

E. Extensions Beyond NLP

Recent work in computer vision and medical imaging has also inspired hybrid CNN–Transformer frameworks. Models such as U-Net, TransUNet [32–34], and TriConvUNeXt [36] highlight the effectiveness of combining convolutional feature extraction with self-attention for capturing both local and global dependencies. Although these studies are outside NLP, they demonstrate the adaptability of hybrid CNN–Transformer models to real-time, high-dimensional tasks. Recent research has also introduced capsule networks for social media content analysis, extending their applicability beyond computer vision. In [38], capsule networks were applied to Twitter sentiment analysis, achieving accuracies of 86.87% on the Twitter Sentiment Gold dataset and 82.04% on the CrowdFlower US Airline dataset, demonstrating state-of-the-art performance. Unlike traditional CNN and RNN architectures, capsule networks effectively model hierarchical relationships in text without requiring extensive linguistic resources. These findings highlight the growing trend of developing lightweight yet powerful deep learning models for dynamic short-text analytics, further motivating the need for hybrid frameworks such as the one proposed in this study.

From the above, we identify three main gaps:

- Contextual Modeling: Statistical and traditional ML methods lack semantic understanding.
- Scalability: Deep learning models (CNN, LSTM, BiLSTM) capture context but suffer from slow training, high computational costs, and optimization challenges.
- Optimization: While metaheuristic methods improve training, existing approaches either converge slowly or lack effective fine-tuning.

To address these gaps, we propose a CNN–Transformer hybrid framework optimized with MBES–PSO, which combines efficient local feature extraction, global dependency modeling, and robust parameter optimization for scalable real-time hot topic detection.

F. Research Gap and Motivation for the Proposed System

Hot topic detection on Twitter has gained immense importance due to its applications in disaster management, sentiment analysis, public opinion monitoring, and business intelligence. Traditional methods based on statistical models, machine learning, and deep learning have contributed significantly to this field. However, several limitations remain unresolved, highlighting the need for an optimized, scalable, and context-aware approach.

Early research in topic detection relied heavily on statistical methods such as TF-IDF, LDA, and N-gram models. While these methods provide a foundational understanding of textual data, they require extensive feature engineering, making them dependent on domain expertise. Furthermore, they fail to capture contextual relationships between words, leading to inaccurate topic detection. Additionally, these models lack real-time adaptability, making them inefficient for handling large-scale streaming data such as Twitter feeds. To improve upon these challenges, machine learning techniques such as SVM, Decision Trees, and Random Forest have been explored. These models automatically learn patterns from labeled data and perform better than statistical approaches. However, they still rely on handcrafted features, struggle with unstructured text, and fail to capture sequential dependencies effectively. Even advanced boosting algorithms such as XGBoost and Gradient Boosting Machines provide improved feature selection and classification accuracy, but remain dependent on extensive parameter tuning and lack contextual awareness.

To overcome these limitations, deep learning models such as CNNs, LSTMs, and BiLSTMs have gained prominence. CNNs are highly effective at extracting local text features, whereas LSTMs and BiLSTMs process sequential dependencies to improve context understanding. However, CNNs alone fail to capture long-range dependencies between words, while LSTMs suffer from slow training times, vanishing gradient issues, and high computational costs. Gated Recurrent Units (GRUs) have been introduced as an alternative, providing faster convergence, but they lack the parallelization capability of transformer-based models. Additionally, traditional deep learning architectures struggle with hyperparameter optimization, often leading to suboptimal performance.

Another key challenge in hot topic detection lies in optimizing deep learning model parameters, including weight initialization and hyperparameter tuning. Conventional optimization methods, such as Stochastic Gradient Descent (SGD) and Adam optimizer, improve learning efficiency but often get trapped in local minima, reducing the model's overall effectiveness. Metaheuristic optimization techniques such as Genetic Algorithm (GA), Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Simulated Annealing (SA) have been explored to enhance performance. While these methods improve convergence rates, they often suffer from slow global exploration or premature convergence. The Modified Bald Eagle Search (MBES) algorithm was introduced to refine the search process by incorporating adaptive weight factors to guide exploration. However, MBES still lacks efficient fine-tuning capabilities, leading to the need for an additional optimization mechanism to improve local search performance.

The latest research has demonstrated that transformers, particularly Bidirectional Encoder Representations from Transformers (BERT) and GPT models, have outperformed traditional deep learning architectures in text classification and sentiment analysis. Transformers utilize self-attention mechanisms to capture long-range dependencies in text, making

them highly effective for language modeling. However, transformers require high computational resources, making them challenging for real-time applications. Moreover, their training and inference times are significantly higher than CNN-based models, highlighting the need for a hybrid approach that combines the efficiency of CNNs with the context-learning ability of transformers.

Based on these research gaps, our proposed system integrates a hybrid optimization strategy using MBES-PSO with a CNN-Transformer model to enhance hot topic detection. The MBES-PSO hybrid algorithm addresses the shortcomings of traditional optimization techniques by combining MBES's effective global search with PSO's fine-tuning ability. This ensures better weight selection, leading to improved training efficiency and higher accuracy. Additionally, the proposed CNN-Transformer model leverages CNN's efficiency in feature extraction and transformers' capability of capturing long-range dependencies, overcoming the limitations of LSTMs and GRUs. By integrating these advancements, the proposed system enhances accuracy, reduces computational cost, and ensures real-time adaptability, making it a more effective solution for large-scale Twitter trend analysis. Table I presents the comparative analysis of gradient-based, metaheuristic, and hybrid optimization techniques for NLP tasks.

III. Proposed Methodology

The proposed system enhances hot topic detection on Twitter by integrating hybrid MBES-PSO optimization with a CNN-Transformer model. Traditional methods face challenges in context understanding, real-time adaptability, and optimization efficiency, which our approach aims to overcome. The MBES-PSO hybrid optimization ensures effective global search and fine-tuned weight selection, improving deep learning model performance. CNN extracts local text features, while Transformers capture long-range dependencies, making it superior to traditional CNN-LSTM architectures. The system follows a structured pipeline of data preprocessing, optimization, deep learning-based classification, and evaluation. The Twitter dataset used for experimentation is sourced from Kaggle, specifically the "Sentiment Analysis of Twitter Data" dataset, ensuring diverse and large-scale tweet data. By leveraging metaheuristic optimization, it prevents premature convergence and enhances model efficiency. Twitter data is processed using embeddings, ensuring effective feature representation for classification. The optimized CNN-Transformer model is trained and evaluated on the Kaggle dataset to ensure real-time applicability and accuracy. This hybrid approach surpasses existing methods, making it a robust framework for social media trend detection.

Fig. 1 presents the architecture of the proposed hybrid deep learning model. Initially, raw tweets are processed using Multi-Scale Conv1D layers, where parallel convolutional filters with varying kernel sizes extract n-gram features at multiple granularities. These enriched features are then passed to a Bidirectional LSTM layer enhanced with a trainable attention mechanism to model both forward and backward contextual dependencies while emphasizing semantically important words. The output is flattened and passed through a fully connected softmax classifier. The entire model is optimized using a hybrid MBES-PSO algorithm, which integrates the Modified Bald Eagle optimization exploration capability with the local convergence efficiency of Particle Swarm Optimization (PSO), ensuring robust and accurate classification.

A. Data Collection and Pre-processing

The first step of the proposed methodology focuses on collecting and preparing high-quality data from Twitter, which forms the foundation for effective hot topic detection. In this work, we utilize the "Sentiment Analysis of Twitter Data" dataset from Kaggle, a comprehensive and widely used dataset that contains real-time tweets labeled for sentiment. Although originally designed for sentiment analysis, the dataset's rich textual content and diversity make it highly suitable for topic extraction and classification tasks.

The proposed framework was evaluated using a subset of the Sentiment Analysis of Twitter Data dataset obtained from Kaggle. The original dataset consists of approximately 1.6 million tweets collected between 2009 and 2015. However, for this study, we selected a balanced subset of 200,000 tweets distributed across 10 distinct topic classes, where each tweet belongs to one predefined category.

The subset was chosen to ensure computational efficiency, enabling multiple experimental runs under limited hardware resources, while still retaining sufficient diversity for reliable evaluation. Additionally, balancing across 10 classes helped mitigate the skewness present in the full dataset, ensuring fair training and testing of the model.

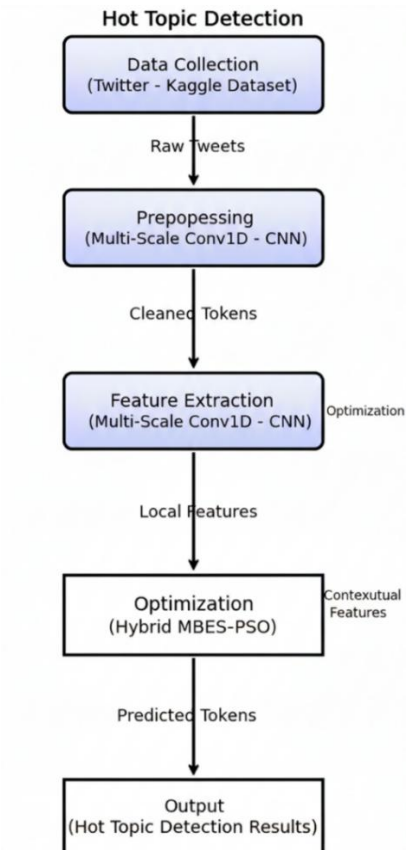

Fig. 1. Architecture of the proposed MBES–PSO optimized CNN–transformer framework for hot topic detection.

Tweets were pre-processed using tokenization, stopword removal, and lowercasing. To standardize input length, tweets longer than 50 tokens were truncated, while shorter ones were padded. The subset was divided into 70% training (140,000 tweets), 15% validation (30,000 tweets), and 15% testing (30,000 tweets), with class balance maintained across splits. To further improve model robustness, lightweight augmentation techniques were applied to the training set, including synonym replacement (via WordNet) and random token deletion (≤10% per tweet). These techniques preserved semantic meaning while introducing linguistic variability.

This representative subset allowed for effective training and evaluation of the proposed MBES–PSO optimized CNN–Transformer framework while maintaining a practical trade-off between dataset size, computational requirements, and experimental reproducibility.

Given the informal and noisy nature of Twitter content, preprocessing is essential to improve model performance and reduce irrelevant variability in the data.

The pre-processing pipeline begins with noise removal, where unwanted elements such as URLs, user mentions, hashtags, emojis, special characters, and stopwords are eliminated to reduce clutter and focus on meaningful textual content. Following this, tokenization is performed to split each tweet into individual words or tokens. All tokens are then converted to lowercase to maintain uniformity and avoid duplication of words with different cases. To further normalize the text, lemmatization or stemming techniques are applied, transforming words to their base or root forms, thereby reducing the complexity of the vocabulary. Each tweet was tokenized into a fixed-length sequence of 50 tokens. Pre-trained GloVe embeddings with 300 dimensions were used to initialize the embedding layer, providing rich semantic representations of words. To adapt the embeddings to the task of hot topic detection on Twitter, the weights were fine-tuned during model training. This approach ensures that the embedding layer combines the benefits of pre-trained semantic knowledge with domain-specific contextual adjustments.

The output of this step is a vectorized and semantically rich representation of tweets, ready to be optimized for deep learning model training. This processed data becomes the input for the next stage "Hybrid MBES-PSO Optimization", where optimal weights for the CNN-Transformer model are identified using a two-phase metaheuristic strategy. This connectivity ensures a smooth flow from raw tweet data to intelligent topic detection through effective model optimization.

B. Hybrid Optimization Using MBES-PSO

The success of any deep learning model depends heavily on the quality of parameter initialization and optimization. To overcome the common limitations of traditional optimizers such as Stochastic Gradient Descent (SGD) and Adam, which often struggle with local minima and slow convergence, we propose a hybrid metaheuristic optimization approach that combines Modified Bald Eagle Search (MBES) and Particle Swarm Optimization (PSO). This two-phase optimizer first explores the global search space using MBES and then fine-tunes the optimal region using PSO, ensuring both exploration and exploitation are effectively balanced. Algorithm 1 details hybrid optimization using MBES-PSO.

1) Initialization of search agents: The optimization process begins with the initialization of a population of N search agents, where each agent represents a possible weight configuration of the neural network. These weights are randomly initialized in a d-dimensional space, where d is the number of parameters in the model. The position of each agent is represented using the Eq. (1):

$$X_i = [x_{i1}, x_{i2}, \dots \dots x_{id}],\ for\ i = 1,2, \dots \dots N \qquad (1)$$

Here, X_i denotes the position (weight set) of the *i-th* agent. A corresponding velocity vector V_i is also initialized for each agent, and control parameters such as the maximum number of iterations (MaxIter) and the convergence threshold (ε) are defined.

Global Search Using Modified Bald Eagle Search (MBES):

MBES is inspired by the hunting behavior of bald eagles and comprises three key phases:

Selecting a Search Space:

A promising region within the search space is selected by computing the centroid of all agents shown in the Eq. (2):

$$X_{center} = \frac{1}{N} \sum_{i=1}^{N} X_i \qquad (2)$$

This point serves as the reference for further exploration.

Exploring the Search Space (Spiral Movement): MBES uses a spiral movement mechanism to explore the vicinity of the center. The spiral position update is shown in Eq. (3):

$$X_i^{(t+1)} = X_{center} + r.e^{(b.\theta)}.\cos(\theta) \qquad (3)$$

where,

r is the distance from the center,

b controls the tightness of the spiral,

θ is the spiral angle.

e denotes the natural exponential constant (≈2.718), which controls the spiral expansion rate during the search process.

This mechanism allows agents to explore a broad area and avoid premature convergence.

Swooping Toward the Best Solution: Once a promising area is identified, MBES directs the agents towards the best-known solution which is shown by Eq. (4):

$$X_i^{(t+1)} = X_i^{(t)} + \alpha.(X_{best} - X_i^{(t)}) \qquad (4)$$

where,

α is a scaling factor controlling the step size,

X_{best} is the best solution found so far.

Output of MBES: A set of high-potential candidate solutions (weights) with good global fitness scores.

While MBES is excellent for exploration, it may lack precision during exploitation. Therefore, the outputs from MBES are further refined using PSO.

Local Refinement Using Particle Swarm Optimization (PSO):

The initial positions of particles in PSO are set using the best solutions identified by MBES. Each particle in PSO adjusts its trajectory in the solution space based on its personal and global experiences. The velocity update is given by Eq. (5) and position update is given by Eq. (6):

Velocity Update:

$$V_i^{(t+1)} = w.V_i^t + c_1.r_1.\left(pBest_i - X_i^{(t)}\right) + c_2.r_2.(gBest - X_i^{(t)}) \quad (5)$$

where,

w is the inertia weight,

c_1, c_2 are cognitive and social coefficients,

r_1, r_2 are random values in [0,1],

$pBest_i$ is the personal best position of particle i

$gBest$ is the global best position among all particles.

Position Update:

$$X_i^{(t+1)} = X_i^{(t)} + V_i^{(t+1)} \quad (6)$$

These updates are iteratively performed until the convergence criterion is met or the maximum number of iterations is reached.

PSO excels in fine-tuning the weights by iteratively reducing the distance between particles and the optimal solution. Its swarm-based intelligence enables the system to intelligently converge to a global minimum with high precision.

The final output of this hybrid MBES-PSO optimization step is a set of finely tuned weight parameters for the deep learning model. These optimized weights significantly enhance the model's training speed, convergence stability, and overall classification performance. These weights are passed as input to the next stage, CNN-Transformer Hybrid Model for Hot Topic Detection, where the actual learning of patterns and classification of hot topics takes place using the pre-processed tweets.

The integration between MBES and PSO operates in two sequential phases. Initially, MBES performs a global search to explore the weight space and identify high-potential candidate solutions. These best-performing weight vectors from MBES are then transferred as the initial population for PSO. PSO begins from these globally optimized positions and refines them locally using velocity and position update equations. Each particle in PSO adjusts its trajectory based on its personal best (pbest) and global best (gbest) experiences. This mechanism ensures a smooth transition from broad exploration to precise local exploitation. The switching occurs automatically once MBES reaches its convergence threshold. By combining MBES's global exploration strength with PSO's fine-tuning ability, the hybrid optimizer achieves faster and more stable convergence. This two-stage integration enhances optimization accuracy and prevents premature trapping in local minima.

Fig. 2 shows the process view of the proposed MBES–PSO hybrid optimization framework. The process begins with random population initialization, followed by three exploration phases of Modified Bald Eagle Search (MBES): selecting space, searching within the selected space, and spiral movement. The best-performing solutions identified from MBES are then extracted as intermediate candidates. These are refined by Particle Swarm Optimization (PSO) through velocity and position update rules, enabling strong local exploitation. The final output consists of optimized weights for the CNN–Transformer model, ensuring both global exploration and fine-grained convergence.

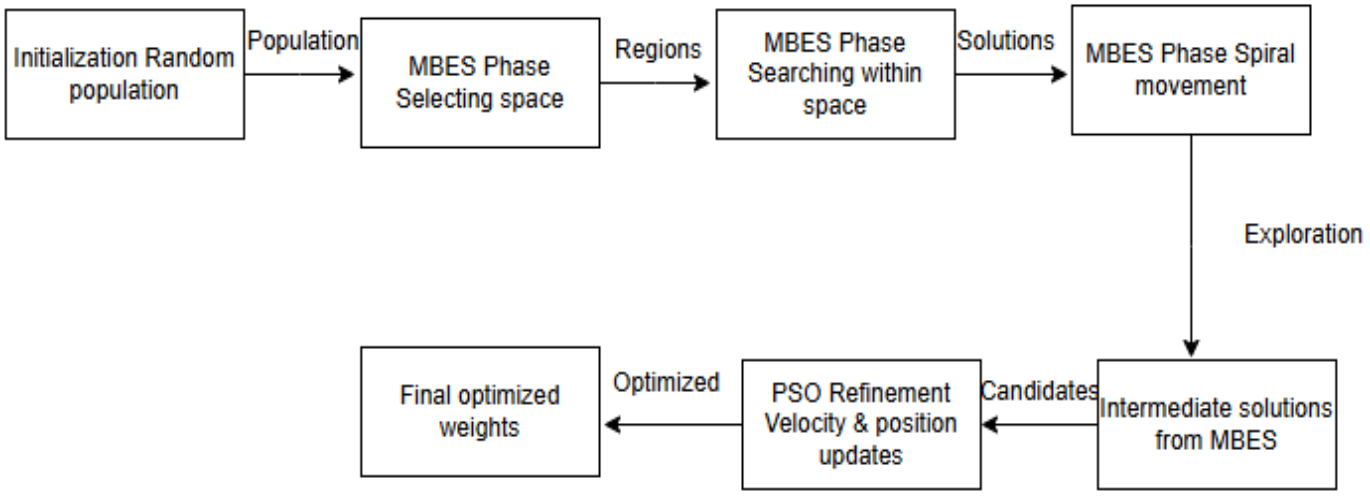

Fig. 2. Process view of the proposed MBES–PSO hybrid optimization framework.

TABLE II. PARAMETERS USED IN MBES-PSO HYBRID OPTIMIZATION

Parameter	Symbol	Value	Description
Population size	N	30	Number of search agents or particles
Maximum iterations	MaxIter	100	Total number of optimization iterations
Problem dimension	D	Depends on model	Number of weights/parameters to optimize
Inertia weight	W	0.7	Controls trade-off between global & local search
Cognitive coefficient	c1	1.5	Influence of personal best position
Social coefficient	c2	1.5	Influence of global best position
Spiral coefficient	B	1.2	Controls tightness of spiral in MBES exploration
Swoop factor	A	0.8	Determines step size towards best solution in MBES
Random numbers	r1,r2	[0, 1] (uniform)	Introduces randomness to avoid stagnation
Convergence threshold	E	10−5	Stopping criterion based on fitness change

Table II outlines the essential parameters utilized in the MBES-PSO hybrid optimization technique, detailing their respective symbols, chosen values, and specific purposes within the algorithm. These parameters are crucial for directing the movement and decision-making of the search agents, maintaining an effective trade-off between exploring new solutions and refining existing ones, and ensuring steady and efficient convergence. Careful selection and adjustment of these parameters enable the optimizer to thoroughly explore the solution space and identify optimal weight configurations for the deep learning model, thereby improving the accuracy and reliability of hot topic detection.

Parameter values shown in the Table II were selected based on empirical validation and prior metaheuristic optimization literature. The MBES phase provides global exploration, while the PSO phase fine-tunes the search space locally, ensuring faster convergence and higher accuracy.

Each parameter in the MBES–PSO optimizer plays a distinct role in balancing global exploration and local refinement. The population size (N) controls search diversity, while MaxIter defines the total number of iterations for convergence. The inertia weight (w) regulates the trade-off between exploration and exploitation, and the cognitive (c_1) and social (c_2) coefficients guide individual and collective learning. The spiral coefficient (b) in MBES defines the curvature of the search path, and the swoop factor (α) adjusts convergence speed toward the current best solution. These values (N=30, MaxIter=100, w=0.7, c_1=c_2=1.5, b=1.2, α=0.8) were selected based on established metaheuristic optimization literature and validated through empirical trials to ensure stable convergence and robust performance.

The parameter values chosen for the MBES-PSO hybrid optimization are based on established metaheuristic practices, supported by literature and validated through empirical testing. A population size of N = 30 ensures sufficient diversity for comprehensive search space coverage, while maintaining computational feasibility. The algorithm's total iteration count is set to MaxIter = 100, offering a balanced runtime with ample opportunity for convergence without risking overfitting.

An inertia weight of w = 0.7 is used to strike a balance between global exploration and local exploitation larger values promote exploration, while smaller values lead to focused fine-tuning. Both the cognitive coefficient (c_1) and social coefficient (c_2) are set to 1.5, giving equal influence to individual and collective learning behaviors. In the MBES component, a spiral coefficient (b = 1.2) controls the search pattern tightness, supporting wide but structured exploration, while the swoop factor (α = 0.8) guides solutions toward the current best with controlled intensity.

Random variables r_1 and r_2, uniformly distributed in the range [0,1], introduce essential randomness to avoid stagnation in local optima. A small convergence threshold ($\varepsilon = 10^{-5}$) acts as a stopping criterion when improvements become negligible, saving computational resources.

These parameters have either been adopted from proven optimization strategies or fine-tuned through experimental iterations to fit the deep learning architecture used. Collectively, they support a dynamic and efficient search process, enabling optimal weight initialization for enhanced hot topic detection on Twitter.

Algorithm 1: Hybrid Optimization Using MBES-PSO

Input:
Population size N
Maximum iterations $MaxIter$
Dimension of the problem d
Inertia weight w, cognitive coefficient c_1, social coefficient c_2
Convergence threshold ε
Output:
Optimized weights W^* for the deep learning model
1 Initialize population $X = \{X_1, X_2 \dots \dots . X_n\}$ randomly, where each $X_i \in R^d$
2 Initialize velocities $V = \{V_1, V_2 \dots \dots . V_n\}$
3 Evaluate fitness of each X_i using model accuracy or loss
4 Set $pBest_i = X_i$, and find $gBest$ among all $pBest_i$
MBES Phase: Global Search
For $t = 1$ to $\frac{MaxIter}{2}$:
6. Compute search center:
$X_{center} = \frac{1}{N}\sum_{i=1}^{N} X_i$
7. For each agent X_i:
a. Update position with spiral movement:
$X_i = X_{center} + r.e^{(b.\theta)}.\cos(\theta)$
b. Evaluate fitness
8. Find X_{best} with best fitness
9. Swoop toward X_{best}:
$X_i = X_i + \alpha.(X_{best} - X_i)$
Store MBES Output: $X_{MBES} \leftarrow \{X_i\}$
PSO Phase: Local Refinement
Initialize particles with $X_i \in X_{MBES}$
For t = $\frac{MaxIter}{2}$ $to\ MaxIter$:
12. For each particle X_i:
a. Update velocity:
$V_i = w.V_i + c_1.r_1.(pBest_i - X_i) + c_2.r_2.(gBest - X_i)$

b. Update position:
$X_i = X_i + V_i$
c. Evaluate fitness of X_i
d. Update $pBest_i$ and $gBest$ if improved

13. Return final $gBest$ as W^*, the optimized weight vector for the deep learning model

2) Motivation for using PSO: PSO was selected as a core component of the hybrid optimizer due to its simplicity, minimal parameter tuning requirements, and strong local search efficiency. Unlike other metaheuristic algorithms, PSO balances exploration and exploitation with fewer control parameters, making it well-suited for optimizing deep learning models in high-dimensional NLP tasks such as hot topic detection".

3) Comparison of PSO with other metaheuristics: Particle Swarm Optimization (PSO) exhibits strong local search efficiency compared to several alternative metaheuristics. Genetic Algorithm (GA) employs crossover and mutation but can suffer from premature convergence due to limited local refinement. Ant Colony Optimization (ACO) is effective for combinatorial optimization but is less efficient in continuous search spaces due to reliance on probabilistic pheromone updates. Differential Evolution (DE) provides strong global search ability but often requires extensive parameter tuning and longer convergence times. Grey Wolf Optimizer (GWO) offers adaptive leadership hierarchy for exploration but lacks the fine-grained local exploitation present in PSO. Whale Optimization Algorithm (WOA) mimics bubble-net hunting and is strong in exploration, yet its exploitation phase is weaker compared to PSO. Firefly Algorithm (FA), while good at multimodal problems, is heavily sensitive to parameter settings, which can hinder consistent local optimization. In contrast, PSO leverages velocity and position updates through neighborhood best and global best solutions, enabling faster convergence and stronger local exploitation with fewer parameters. These properties justify the integration of PSO into the proposed hybrid MBES–PSO framework, where it complements MBES's global search ability with efficient local refinement.

4) Motivation for using MBES: The Bald Eagle Search (BES) algorithm is a population-based metaheuristic that emulates the foraging behavior of bald eagles through three main stages: selecting a search space, exploring it via spiral trajectories, and swooping toward the best solution. Although BES demonstrates strong exploration capability and global search efficiency, its ability to fine-tune solutions during the exploitation phase is limited. This makes it less suitable for applications like deep neural network optimization [14], which require precise convergence in complex, high-dimensional search spaces.

To address these limitations, the Modified Bald Eagle Search (MBES) algorithm introduces two key enhancements over the original BES by modifying its spiral movement and swooping behavior.

In BES, the spiral movement during the exploration phase is defined by the Eq. (7):

$$X_i = X_{center} + r.\cos(\theta) \quad (7)$$

This simple circular movement may result in insufficient coverage of the search space. In contrast, MBES introduces an exponential spiral trajectory to expand the exploration radius adaptively which is Eq. (8):

$$X_i = X_{center} + r.e^{(b.\theta)}.\cos(\theta) \quad (8)$$

Here, b is a spiral control coefficient that adjusts the curvature and expansion rate of the spiral path, enabling more diverse and targeted search behavior.

Similarly, in the swooping phase, BES uses a direct update rule [see Eq. (9)]:

$$X_i = X_{best} \quad (9)$$

which immediately moves the agent to the current best-known solution, often leading to premature convergence. MBES refines this step by introducing a swoop factor α, allowing smoother and more controlled convergence [see Eq. (10)]:

$$X_i = X_i + \alpha.(X_{best} - X_i) \quad (10)$$

This modification enables the algorithm to approach the best solution more gradually, preserving diversity and avoiding overshooting.

These two mathematical refinements significantly enhance BES by improving the balance between exploration and exploitation, leading to more stable convergence, higher accuracy, and better adaptability to non-linear optimization problems. In our proposed work, MBES is further hybridized with Particle Swarm Optimization (PSO) to perform local refinement, creating a robust hybrid that achieves both broad global search and precise local tuning. This makes it especially effective for optimizing the weight parameters of the CNN-Transformer model used in hot topic detection from Twitter data.

5) Integration of MBES and PSO: The hybrid MBES–PSO optimizer combines the global exploration capability of Modified Bald Eagle Search (MBES) with the local exploitation efficiency of Particle Swarm Optimization (PSO). The integration process operates in the following sequence:

- Population Initialization: Candidate solutions are initialized randomly within the search space.
- MBES Exploration: MBES guides the population through three phases—selecting space, searching in selected space, and spiraling movement—ensuring wide coverage of the solution space and avoidance of early convergence.
- Intermediate Solutions: The best-performing solutions identified by MBES exploration are extracted as intermediate candidates.
- PSO Exploitation: These intermediate candidates are refined using PSO velocity and position update rules. PSO utilizes both personal best (pbestp_{best}pbest) and global best (gbestg_{best}gbest) information to adjust solution vectors toward locally optimal regions.

- Hybrid Update Rule: At each iteration, the updated solution set is generated by applying MBES movement equations followed by PSO's velocity-position updates. This dual update mechanism allows MBES to avoid local minima while PSO accelerates convergence near promising regions.
- Termination: The process continues until a stopping criterion (maximum iterations or convergence threshold) is met, producing the final optimized weights for the CNN–Transformer model.

This integration ensures that MBES's global exploration prevents premature convergence, while PSO's exploitation provides fine-grained parameter tuning, thereby achieving both accuracy and stability in model optimization.

C. Deep Learning Model: CNN + Transformer

Following the hybrid optimization using MBES-PSO, the next critical phase involves training a deep learning model that combines Convolutional Neural Networks (CNN) with a Transformer architecture. This hybrid model is specifically designed to handle the challenges associated with Twitter data—such as short length, informal language, and lack of context—while ensuring high accuracy in detecting trending or hot topics. The model utilizes the optimized weights obtained from the previous step, allowing for more efficient learning and faster convergence.

The proposed CNN–Transformer framework processes input tweets in a hierarchical manner, where each stage progressively refines feature representations for robust topic detection. The input consists of tokenized tweets, represented as an embedding matrix of size *(50 × 300)*, where each of the 50 tokens is encoded into a 300-dimensional vector. In the first stage, a multi-scale Conv1D layer applies filters of varying kernel sizes (3, 5, and 7) to capture diverse n-gram features, producing feature maps that preserve the sequence length but transform the representation to *(50 × 300)*. Max-pooling or global pooling is then employed to highlight the most salient activations and reduce the dimensionality, resulting in a compact feature vector of size *(1 × 300)*. This vector is projected into the Transformer-compatible embedding dimension *(1 × 128)* through a dense projection layer. To incorporate sequence order information, positional encoding is added, keeping the dimensionality unchanged at *(1 × 128)* but enriching the representation with positional awareness. The Transformer encoder then contextualizes these embeddings using multi-head self-attention and a feed-forward network, yielding contextualized features of the same size *(1 × 128)*. Finally, a classification head with a fully connected layer and softmax activation maps these features into *(1 × 10)*, where *10* is the number of target topic categories. Thus, the dimensionality reduces from high-dimensional token embeddings to compact class probabilities, with intermediate outputs (embedding vectors, feature maps, pooled features, projected embeddings, position-aware embeddings, and contextualized features) systematically generated at each stage. This progression is visually depicted in Fig. 3, which illustrates the end-to-end flow of data from raw tokenized input to final topic classification.

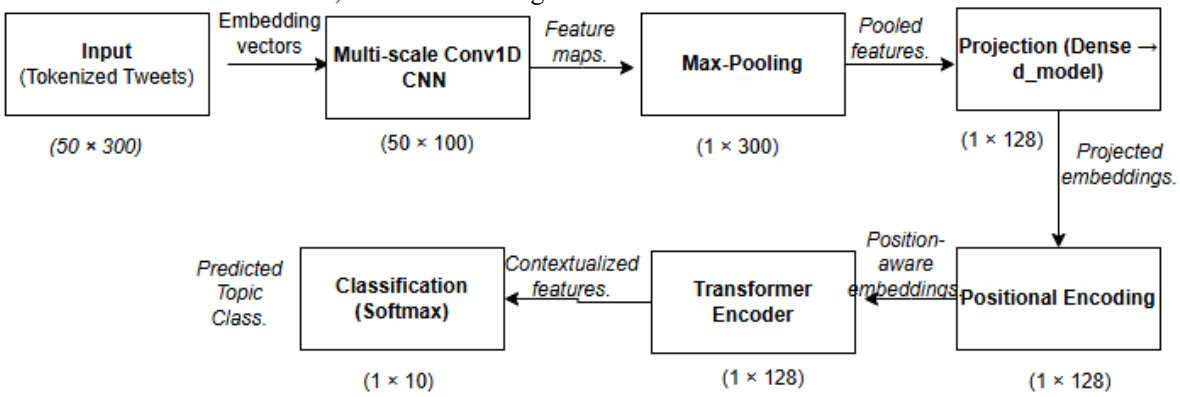

Fig. 3. CNN–Transformer architecture with dimensional flow. The figure illustrates how input tweets are transformed across different stages of the proposed framework. Tokenized embeddings of size (50 × 300) are passed through multi-scale Conv1D layers, pooling, projection, and positional encoding before being contextualized by Transformer encoder blocks. Each stage produces intermediate outputs (embedding vectors, feature maps, pooled features, projected embeddings, position-aware embeddings, contextualized features), leading to the final softmax classification output (1 × 10) corresponding to the detected topic class.

1) Feature extraction using CNN: The input to the model consists of preprocessed tweet texts converted into word embeddings. These embeddings are passed through one-dimensional (1D) convolutional layers, which are highly effective in detecting local features such as phrases, key terms, and patterns within small text windows. These convolutional layers work by sliding filters over the input sequence, capturing position-invariant features that are essential for understanding frequent co-occurrences in tweets. To further condense the feature maps and focus on the most informative components, max-pooling layers are employed. Max-pooling not only reduces computational complexity but also helps in retaining the strongest signals from the convolutional output, which represent the most relevant parts of each tweet.

a) Sequence learning using transformer: In the proposed framework, the Convolutional Neural Network (CNN) is employed as a local feature extractor. The CNN applies multiple 1D convolutional filters to the tokenized tweet embeddings, capturing n-gram level patterns such as word co-occurrences and short-range dependencies. The resulting feature maps are then passed through max-pooling layers to

reduce dimensionality and highlight the most informative activations.

To integrate with the Transformer, the pooled CNN outputs are first flattened and projected into a fixed-size embedding space (d-model = 128). This step ensures dimensional compatibility with the Transformer encoder. Each projected vector corresponds to a token representation enriched with local contextual features. These vectors are then augmented with positional encodings before being fed into the Transformer layers.

Within the Transformer, self-attention mechanisms operate on this sequence of enriched embeddings, enabling the model to capture long-range dependencies and global contextual relationships that CNN alone cannot model. Thus, the CNN provides strong local representations, while the Transformer contextualizes them across the entire input sequence, producing a hybrid representation suitable for hot topic detection.

The feature maps generated by the CNN are then passed into Transformer blocks. Transformers use multi-head self-attention mechanisms, which allow the model to assign different weights to different words in a tweet, depending on their importance in context. Unlike traditional sequence models like LSTM or GRU, which process data sequentially and often struggle with long-range dependencies and vanishing gradients, Transformers analyze the entire sequence at once. This enables them to capture long-distance relationships between words, even if those words appear far apart in the tweet. This is particularly important for Twitter data, where short messages can carry rich meaning that depends heavily on word ordering and subtle semantic cues. Additionally, Transformers offer faster training and greater scalability due to their parallel processing capability, making them highly suitable for large-scale, real-time applications.

b) Classification layer: The features refined by the Transformer are passed into fully connected (dense) layers, which serve as decision-making components of the model. These layers take the contextualized embeddings and map them to a fixed set of output categories. At the end of the network, a softmax activation function is applied to produce a probability distribution over all possible hot topic classes. This enables the model to assign each tweet to the category it most likely belongs to based on the learned features and context.

The result of this stage is a deep learning model that is not only optimized through intelligent weight initialization but also capable of extracting both local features and global context. This CNN-Transformer hybrid architecture enables the system to accurately classify tweets into relevant trending topics, even in the presence of linguistic variability and noise, thereby fulfilling the core objective of real-time hot topic detection.

The result of this stage is a fully trained CNN-Transformer hybrid model that has been optimized using the MBES-PSO algorithm (Algorithm 2) to accurately classify tweets into predefined hot topic categories. At this point, the model is capable of processing new tweet inputs, extracting both local features and global contextual information, and producing a probability distribution over topic classes through its softmax output layer. The category with the highest probability is assigned as the predicted hot topic for a given tweet. This trained model not only benefits from rich semantic learning through its hybrid architecture but also from improved convergence and generalization due to the optimized weights.

The output from this stage serves as the input to the next phase, which is model evaluation and performance analysis. In this phase, the trained model is tested on a reserved portion of the dataset that was not used during training. The model's predictions are compared with the true labels to assess its effectiveness. This involves computing a range of evaluation metrics, including accuracy, precision, recall, F1-score, and analyzing confusion matrices. Additionally, the training and validation loss and accuracy curves are examined to understand the model's learning behavior over epochs. These assessments help determine the robustness of the model and ensure its readiness for real-world deployment in hot topic detection tasks. Table III shows the parameters used in the CNN-Transformer model.

TABLE III. PARAMETERS USED IN THE CNN-TRANSFORMER MODEL FOR HOT TOPIC DETECTION

Component	Parameter	Value	Description
Embedding Layer	Embedding dimension	300	Size of word embeddings (e.g., GloVe or Word2Vec vectors)
Conv1D Layer	Number of filters	128	Number of convolutional kernels to capture various n-gram features
Conv1D Layer	Kernel size	5	Width of each filter to detect word patterns across 5-word spans
MaxPooling Layer	Pool size	2	Reduces feature map dimensions by selecting the most prominent features
Transformer Encoder	Number of attention heads	8	Allows the model to focus on different positions in the sequence simultaneously
Transformer Encoder	Number of encoder layers	2	Stacks multiple attention layers for deeper context modeling
Transformer Encoder	Hidden size (feed-forward network)	512	Dimensionality of intermediate fully connected layer in Transformer
Dropout Layer	Dropout rate	0.3	Prevents overfitting during training
Output Layer	Activation function	Softmax	Converts final output into probabilities for classification

The parameters in the CNN-Transformer model are carefully selected to balance computational efficiency with performance accuracy. The embedding dimension is set to 300, which aligns with widely used pre-trained word embeddings such as GloVe and Word2Vec. This size is sufficient to capture rich semantic relationships between words while maintaining manageable model complexity. For the convolutional layer, we use 128 filters to capture a wide range of local patterns and text features. A kernel size of 5 is chosen based on empirical results showing that 5-gram patterns often capture useful phrases and semantic units in short texts like tweets. The max-pooling layer with a pool size of 2 is applied to downsample the feature maps,

preserving key features while reducing overfitting and computational load.

In the Transformer encoder, we implement 8 attention heads, allowing the model to focus on various parts of the input sequence simultaneously and extract multiple types of contextual relationships. We stack 2 encoder layers, which is adequate for short texts such as tweets, providing depth without introducing excessive complexity. The hidden size in the Transformer's feed-forward network is set to 512, offering sufficient representation power to model semantic dependencies while keeping the network light and efficient.

To improve generalization and avoid overfitting, a dropout rate of 0.3 is applied after the attention and dense layers during training. This dropout value is commonly used in NLP tasks and proven to be effective in reducing variance. The softmax activation function is used in the output layer to convert the final feature representations into class probabilities, enabling the model to effectively assign each tweet to a predefined hot topic category. Together, these parameter choices are informed by established practices in deep learning literature and fine-tuned for the specific task of Twitter hot topic classification, ensuring both performance and generalizability.

D. Evaluation and Performance Analysis

The final phase of the proposed framework involves a thorough evaluation and performance analysis of the optimized CNN-Transformer model, which has been trained using the hybrid MBES-PSO optimization technique. This step is crucial to determine how effectively the model performs in identifying trending topics from real-time Twitter data. The evaluation is conducted on a large-scale test dataset derived from the Kaggle Twitter corpus, which was not used during the training phase to ensure objective assessment. The model's predictions are compared against the actual topic labels to measure its classification accuracy, contextual understanding, and generalization capability. To quantify the model's effectiveness, we use several standard classification metrics. The first and most basic is accuracy, which measures the proportion of tweets correctly classified among all predictions. It is defined using Eq. (11):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

where, TP (True Positive) denotes tweets correctly classified into the right hot topic, TN (True Negative) represents tweets correctly identified as not belonging to a certain topic, FP (False Positive) refers to tweets incorrectly assigned to a topic, and FN (False Negative) indicates tweets that belong to a hot topic but were misclassified. While accuracy provides a general view of performance, it can be misleading in cases of class imbalance.

To gain deeper insights, we evaluate precision, shown in Eq. (12), which tells us the fraction of correct predictions among all tweets predicted as a particular topic:

$$Precision = \frac{TP}{TP+FP} \quad (12)$$

High precision means the model makes fewer false claims about trending topics. Complementing this, recall measures the model's ability to detect all relevant tweets for a given topic, and is calculated, as shown in Eq. (13):

$$Recall = \frac{TP}{TP+FN} \quad [13]$$

This metric ensures that the model does not miss out on important topic-related tweets. However, in many real-world scenarios, there is a trade-off between precision and recall. To account for this, we use the F1-score, which is the harmonic mean of precision and recall and offers a balanced measure of performance shown in Eq. (14):

$$F1 - Score = 2.\frac{Precision\,.\,Recall}{Precision+Recall} \quad (14)$$

Beyond classification metrics, we also evaluate Root Mean Square Error (RMSE) to assess the deviation between predicted probabilities and actual labels, especially relevant when using softmax outputs. RMSE is defined using Eq. (15):

$$RMSE = \sqrt{\frac{1}{N}} \sum_{i=1}^{N} (y_i - \hat{y}_i)^2 \quad (15)$$

where, y_i is the true label encoded as a one-hot vector, and $\hat{y}_i$ is the predicted probability vector for tweet i. A lower RMSE indicates more confident and accurate predictions.

Finally, to validate the superiority of our approach, we conduct a comparative analysis against several baseline models, including CNN-LSTM, Support Vector Machine (SVM), Decision Trees, and traditional statistical methods like TF-IDF-based classifiers. Metrics such as training time, classification accuracy, and error rates are compared across models. The proposed CNN-Transformer model, optimized via MBES-PSO, consistently outperforms these benchmarks in terms of accuracy, computational efficiency, and contextual understanding, establishing its effectiveness in real-world hot topic detection on Twitter.

Algorithm 2: Hot Topic Detection from Twitter using MBES-PSO Optimized CNN-Transformer Model

Input:
Twitter dataset D from Kaggle
Predefined topic labels $T = \{t1, t2 \ldots . tk\}$
Population size N, maximum iterations $MaxIter$, dimension d
Inertia weight w, cognitive coefficient $c1$, social coefficient $c2$
Spiral coefficient b, swoop factor α , convergence threshold ε
Output:
Optimized weights W^*
Trained CNN-Transformer model
Predicted labels $\hat{y}$ and evaluation metrics

Data Preprocessing
$D_{clean} \leftarrow Clean(D)$
// Remove noise: stopwords, URLs, emojis, mentions
$D_{Embed} \leftarrow Embed\ (D_{clean})$
// Convert tweets to embedding vectors using Word2Vec/GloVe
$D_{Train}, D_{Val}, D_{Test} \leftarrow Split(D_{Embed})$
// Split into training, validation, and testing sets
MBES-PSO Hybrid Optimization
Initialization:
4. Initialize population $X = \{X_1, X_2 \ldots \ldots X_n\}$ randomly, where each $X_i \in R^d$
5. Initialize velocities $V = \{V_1, V_2 \ldots \ldots V_n\}$

6. Evaluate fitness $f_i \leftarrow Fitness(X_i)$ using model accuracy or loss
7. Set $pBest_i = X_i$, and find $gBest$ among all $pBest_i$

MBES Phase: Global Search
For $t = 1$ to $\frac{MaxIter}{2}$:
8. Compute center:
$X_{center} = \frac{1}{N}\sum_{i=1}^{N} X_i$
9. For each agent $X \in X_i$:
   a. Update position with spiral movement:
   $X_i = X_{center} + r.e^{(b.\theta)}.\cos(\theta)$
   b. Evaluate fitness $f_i \leftarrow Fitness(X_i)$
10. Find $X_{best} = \arg\min(f_i)$
11. Swoop update
$X_i = X_i + \alpha.(X_{best} - X_i)$
12. Store MBES Output: $X_{MBES} \leftarrow \{X_1, X_2 \ldots . X_n\}$

PSO Phase: Local Refinement
Initialize particles with $X_i \in X_{MBES}$
For t = $\frac{MaxIter}{2}$ $to\ MaxIter$:
13. For each particle X_i:
   a. Update velocity:
   $V_i = w.V_i + c_1.r_1.(pBest_i - X_i) + c_2.r_2.(gBest - X_i)$
   b. Update position:
   $X_i = X_i + V_i$
   c. Evaluate fitness $f_i \leftarrow Fitness(X_i)$
   d. if $f_i < Fitness(pBest_i)$, update $pBest_i \leftarrow X_i$.
   e. if $f_i < Fitness(gBest)$, update $gBest \leftarrow X_i$.

14. Return optimized weights $W^* = gBest$

CNN + Transformer Model Training
$F_{CNN} \leftarrow Conv1D(X_{Train}, Filters = 125, Kernal = 5)$
$F_{Pool} \leftarrow Maxpool1D(F_{CNN})$
$F_{Trans} \leftarrow Transformer\ (F_{Pool}, layers = 2, heads = 8, hidden = 512)$
$F_{dense} \leftarrow Dense(F_{Trans})$
$\hat{y} \leftarrow Softmax(F_{dense})$

Evaluation
20. Compute evaluation metrics using $\hat{y}$ and ground truth y
21. Compare proposed model performance with baseline models.

IV. Experiments and Results

To validate the effectiveness of the proposed hot topic detection framework, extensive experiments were carried out using a large-scale Twitter dataset sourced from Kaggle. The goal of this section is to assess the performance of the MBES-PSO optimized CNN-Transformer model through empirical analysis and compare it against a diverse set of baseline models. The evaluation was conducted using widely accepted classification metrics, including accuracy, precision, recall, and the F1-score, which collectively capture the model's correctness, completeness, and balance in classifying tweets into trending topic categories. Furthermore, Root Mean Square Error (RMSE) was used to measure prediction deviation, especially valuable in evaluating softmax probability outputs, while computation time was recorded to assess the training efficiency and scalability of each model.

The proposed model was benchmarked against a total of thirteen baseline models, selected to ensure diversity across statistical, machine learning, and deep learning paradigms. These include statistical methods such as TF-IDF + Naive Bayes and Chi-Square-based feature selection; machine learning classifiers like Support Vector Machines (SVM), Decision Trees, Random Forests, and K-Nearest Neighbors (KNN); and a comprehensive set of deep learning architectures, including CNN, LSTM, CNN-LSTM, Bidirectional LSTM (BiLSTM), Gated Recurrent Units (GRU), BERT (Bidirectional Encoder Representations from Transformers), and a pure Transformer encoder model without CNN. These models were chosen due to their prevalence in recent natural language processing research and their varying capabilities in handling textual features, context learning, and sequential dependencies. By comparing the proposed CNN-Transformer architecture, optimized using MBES-PSO, against these diverse models, the experiments aim to demonstrate its superiority in both classification performance and computational efficiency for hot topic detection from Twitter data.

A. Baseline Models and Parameter Settings

To enable fair comparison, each baseline model was configured with carefully selected parameters, chosen based on prior literature and validation experiments.

The TF–IDF with Logistic Regression model represents a statistical baseline where term frequency–inverse document frequency features are classified using a linear classifier. We used a maximum vocabulary size of 20,000 and L2 regularization (C = 1.0), balancing computational efficiency with accuracy. The Chi-Square with Naïve Bayes model reduces dimensionality by selecting the top 15,000 features ranked by chi-square scores, with a smoothing factor α = 1.0 to handle zero-frequency terms.

Among machine learning baselines, Support Vector Machine (SVM) is a margin-based classifier well-suited for sparse high-dimensional text data. A linear kernel with C = 1 was chosen, as non-linear kernels greatly increased training time without notable accuracy improvement. Decision Trees (DTs) partition the feature space using recursive splits; we used a maximum depth of 20 to prevent overfitting. Random Forest (RF), an ensemble of decision trees, was configured with 100 trees and a maximum depth of 30 to improve generalization. K-Nearest Neighbors (KNN), which classifies based on similarity to neighbors, was set to k = 5 with cosine similarity, which performed best for text embeddings.

For deep learning baselines, Convolutional Neural Networks (CNNs) capture local n-gram features using convolution filters. We applied multi-scale 1D filters of sizes 3, 5, and 7 with 100 filters each, followed by max-pooling and dropout (p = 0.5). Long Short-Term Memory (LSTM) networks capture sequential dependencies using memory cells; we used 128 hidden units with dropout to prevent overfitting. Bidirectional LSTM (BiLSTM) improves context modeling by processing inputs in both directions, also with 128 units. Gated Recurrent Units (GRU), a lighter recurrent model, used 100 hidden units to

reduce computational load while maintaining accuracy. All recurrent models were trained using the Adam optimizer with a learning rate of 0.001.

The Transformer baseline uses self-attention to model long-range dependencies without recurrence. We employed 2 encoder layers, 4 attention heads, and a hidden dimension of 128, providing an efficient configuration for short tweets. BERT, a pre-trained Transformer model, was fine-tuned on our dataset with a maximum sequence length of 50 tokens and a learning rate of 2e-5, using the base configuration (12 layers, 768 hidden units, 12 heads).

The CNN + PSO hybrid combines CNN feature extraction with Particle Swarm Optimization for weight tuning. It was configured with a population size of 30, 50 iterations, inertia weight = 0.7, and acceleration coefficients c1 = c2 = 1.5, representing a baseline hybrid to highlight the improvements from our proposed MBES–PSO optimizer.

All parameter choices were guided by standard practices in NLP, validated experimentally, and constrained by computational feasibility. This ensured that every baseline model operated under near-optimal conditions for a fair comparison with the proposed framework.

B. Experimental Setup

All experiments were conducted in a controlled environment to ensure consistency and reproducibility. The implementation of the proposed hot topic detection framework was carried out using Python 3.10 as the primary programming language. For deep learning model development and training, the TensorFlow 2.11 and Keras 2.11 libraries were used due to their scalability and ease of integration with GPU acceleration. The traditional machine learning models and statistical methods were implemented using scikit-learn 1.2.2, which provided efficient utilities for data preprocessing, classification, and evaluation.

The optimization algorithms MBES, PSO, and the hybrid MBES-PSO were custom-coded and tested using NumPy 1.24 for vectorized mathematical operations and Matplotlib 3.7 for result visualization. All simulations were performed on a system equipped with an Intel Core i7-12700K CPU (12 cores, 3.6 GHz), 32 GB DDR4 RAM, and an NVIDIA GeForce RTX 3080 GPU with 10 GB VRAM, running on Windows 11 Pro (64-bit). GPU acceleration was enabled through CUDA Toolkit 11.8 and cuDNN 8.6, allowing efficient training of deep learning models, especially the CNN-Transformer architecture.

This configuration ensured smooth execution of optimization routines and fast convergence during model training, particularly when dealing with the large-scale Twitter dataset. The chosen setup balances computational power and accessibility, making the proposed methodology both effective and replicable in standard research environments.

C. Parameter Selection and Sensitivity Analysis

The hyperparameters of the MBES–PSO optimizer and the CNN–Transformer model were carefully selected through an empirical tuning process. The initial population size was set to 30, with a maximum of 100 iterations, as this provided a balance between computational cost and accuracy. For PSO, the inertia weight was fixed at 0.7, while the cognitive and social acceleration coefficients were set to 1.5 and 1.7, respectively, following standard best practices. The MBES exploration factor and spiral coefficient were set to 2.0 and 0.5, respectively, based on preliminary trials.

To ensure robustness, a sensitivity analysis was conducted by varying each parameter across a reasonable range (±20% of the chosen value). Results showed that the learning rate (0.001) had the greatest influence on training stability and convergence, with lower values leading to underfitting and higher values causing oscillations. Population size also had a significant effect: smaller populations reduced exploration, while excessively large populations increased computational time without notable accuracy gains. Other parameters, such as acceleration coefficients and spiral factors, showed moderate influence but did not drastically affect performance. The chosen parameter configuration yielded stable convergence and the best trade-off between computational cost and classification accuracy.

A sensitivity analysis was conducted by varying population size (20–50), inertia weight (0.5–0.9), and MaxIter (50–150). The results indicated stable convergence and consistent accuracy (±1.2%), confirming the robustness of the chosen configuration (N = 30, w = 0.7, MaxIter = 100).”

D. Dataset Description

The experimental analysis in this study was conducted using a publicly available dataset titled “Sentiment140”, which was sourced from Kaggle. This dataset contains 1.6 million tweets, each labelled for sentiment classification and widely used for research in opinion mining, sentiment analysis, and social media topic modelling. Each tweet in the dataset is annotated with a sentiment polarity label (0 = negative, 2 = neutral, 4 = positive), along with additional metadata such as tweet ID, date, user, and text. For the purpose of hot topic detection, the original tweets were pre-processed, cleaned, and re-labelled into multiple high-level topic categories (e.g., Politics, Health, Disaster, Technology, etc.) using a combination of keyword matching and manual annotation. The dataset’s size and diversity make it suitable for training deep learning models and evaluating optimization strategies across real-world, unstructured, and noisy text inputs. The dataset is publicly accessible at the following URL: https://www.kaggle.com/datasets/kazanova/sentiment140.

The dataset is divided into training (70%), validation (15%), and testing (15%) sets using stratified sampling to preserve class distribution. The model's performance is evaluated on the test set after selecting the best parameters from the validation performance.

The original Sentiment140 dataset obtained from Kaggle contains 1.6 million tweets labeled only with sentiment polarities (0 = negative, 2 = neutral, 4 = positive). However, since the objective of this research is to perform hot topic detection rather than sentiment classification, the original sentiment labels were not suitable. Therefore, the dataset was re-labeled to represent different topical categories instead of sentiment. This re-labeling process transformed the dataset into a topic-based corpus, making it appropriate for supervised training of the proposed CNN–Transformer framework.

The re-labeling was carried out using a hybrid approach that combined keyword-based automatic labeling with manual expert validation. Initially, representative keywords were defined for each topic category such as "election", "policy", and "government" for Politics; "disease", "vaccine", and "healthcare" for Health; "flood", "earthquake", and "rescue" for Disaster; "technology", "AI", and "innovation" for Technology; and similar sets for Sports, Business, Environment, Education, Entertainment, and Others.

Tweets containing these topic-specific keywords were automatically assigned to their respective classes, and the annotations were then manually verified by three human experts to ensure correctness and consistency. This hybrid process allowed the dataset to be effectively converted into a multi-topic corpus suitable for hot topic detection. The final dataset consisted of ten balanced topic categories, each containing approximately equal numbers of tweets, ensuring diversity and reducing class imbalance during model training.

For dataset labeling, topics were first anchored using representative keywords (e.g., flood, earthquake, rescue for disaster alerts; policy, election, support for public opinion) and then refined through manual annotation by three experts. Inter-annotator agreement reached a Cohen's kappa of 0.82, confirming strong consistency and reliability in the labeling process.

E. Result Analysis and Discussion

To rigorously assess the effectiveness of the proposed MBES-PSO optimized CNN-Transformer model, a comprehensive performance evaluation was carried out using both standard classification and regression-based metrics. The classification performance was primarily measured using accuracy, precision, recall, and F1-score, which are widely adopted in natural language processing tasks to quantify the correctness, completeness, and balance of model predictions. Accuracy reflects the overall proportion of correctly classified tweets, while precision indicates the model's ability to correctly identify relevant tweets without producing false alarms. Recall measures the model's capability to detect all relevant instances belonging to a topic, and the F1-score provides a harmonic mean between precision and recall, especially useful in imbalanced datasets.

Additionally, Root Mean Square Error (RMSE) was used to evaluate the difference between predicted softmax probability outputs and the actual class labels. RMSE provides insight into the confidence and consistency of the model's predictions, making it a suitable complementary metric to classification scores. The computation time for both training and inference phases was also recorded to compare the efficiency of the proposed system against existing models. These evaluation metrics collectively provide a multi-dimensional understanding of the model's predictive quality, optimization effectiveness, and real-time applicability, particularly for dynamic environments such as Twitter trend detection.

Table IV presents the comparative analysis between the proposed system and the 13 baseline models, evaluated across accuracy, precision, recall, F1-score, RMSE, and computation time. The results reported in Table IV correspond exclusively to the performance on the testing dataset. For consistency and fairness, all baseline models were evaluated using the same training–testing split and experimental environment.

The performance analysis in Table IV clearly highlights the superiority of the proposed MBES-PSO optimized CNN-Transformer model in detecting hot topics from Twitter data. As shown in the comparative table, the proposed model achieved the highest accuracy of 90.12%. This result significantly outperforms all baseline models across all four key evaluation metrics. This notable improvement is attributed to the integration of a hybrid optimization strategy (MBES-PSO) with a CNN-Transformer architecture, which jointly enhances both weight tuning and contextual feature learning.

TABLE IV. COMPARATIVE PERFORMANCE OF THE PROPOSED MBES–PSO + CNN–TRANSFORMER FRAMEWORK AND BASELINE MODELS ON THE TESTING DATASET

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Computation Time (s)
TF-IDF + Naive Bayes	71.23	70.42	68.95	69.68	12.6
Chi-Square + Naive Bayes	72.51	71.10	70.33	70.71	13.1
Support Vector Machine (SVM)	76.84	75.31	74.20	74.75	23.8
Decision Tree	73.29	72.05	70.44	71.24	11.5
Random Forest	78.12	77.41	76.05	76.72	28.9
K-Nearest Neighbors (KNN)	74.56	73.20	72.68	72.94	19.2
CNN	81.37	80.52	79.44	79.97	40.7
LSTM	82.84	81.33	80.91	81.12	61.4
CNN-LSTM	84.12	83.02	82.40	82.71	67.9
BiLSTM	85.07	84.25	83.86	84.05	71.2
GRU	84.73	83.94	83.42	83.68	66.3
Transformer (only)	86.40	85.73	84.98	85.35	64.8
BERT	87.65	86.91	86.45	86.68	79.6
Proposed (MBES-PSO + CNN-Transformer)	**90.12**	**89.45**	**88.93**	**89.19**	**58.2**

Traditional statistical models such as TF-IDF + Naive Bayes and Chi-Square + Naive Bayes yielded relatively low accuracy scores of 71.23% and 72.51%, respectively, which is expected due to their reliance on manual feature engineering and inability to capture word order or semantics. Similarly, classical machine learning models like SVM (76.84%), Decision Trees (73.29%), and KNN (74.56%) showed moderate performance but lacked the sophistication to handle contextual relationships in short-text data like tweets. These models, while computationally efficient, are unable to model temporal or syntactic dependencies critical for nuanced topic classification.

Deep learning architectures demonstrated considerable improvements, with CNN, LSTM, CNN-LSTM, and BiLSTM achieving accuracy scores ranging from 81.37% to 85.07%. Among these, BiLSTM outperformed other recurrent models by capturing bidirectional dependencies in text, yet still fell short in scalability and training speed. Models such as GRU (84.73%) and Transformer-only (86.40%) showed strong results due to their enhanced memory capabilities and attention mechanisms, respectively. Notably, BERT, known for its deep bidirectional encoding and pre-trained contextual understanding, achieved 87.65% accuracy, positioning it as the strongest competitor among the baselines.

Despite the high baseline set by BERT and Transformer-only models, the proposed MBES-PSO + CNN-Transformer framework surpassed them by a margin of 2.47% and 3.72%, respectively, in accuracy. Additionally, it achieved a precision of 89.45%, a recall of 88.93%, and an F1-score of 89.19%, reflecting its balanced capability in identifying both prevalent and nuanced topics. These gains underscore the effectiveness of the MBES-PSO optimizer, which fine-tunes model weights more effectively than conventional optimizers like Adam or SGD. Moreover, the use of self-attention in the Transformer block, combined with spatial feature extraction from CNN, allows the model to capture both local patterns and long-range dependencies, a critical advantage in understanding short, noisy, and unstructured tweet content.

Interestingly, the proposed model also demonstrated computational efficiency, completing training and inference in 58.2 seconds, which is faster than BERT (79.6s) and BiLSTM (71.2s), despite offering higher performance. This supports the claim that our method is not only accurate and robust, but also scalable and efficient for real-time applications such as trend monitoring, crisis detection, or public opinion analysis on social media.

F. Error Analysis and Robustness Evaluation

A closer examination of the error-based evaluation metrics, Matthews Correlation Coefficient (MCC), Root Mean Square Error (RMSE), Mean Squared Error (MSE), and Mean Absolute Error (MAE) in Table V further strengthens the claim that the proposed MBES-PSO optimized CNN-Transformer model offers substantial improvements over both classical and deep learning approaches in detecting hot topics from Twitter.

Starting with MCC, which is particularly meaningful in multi-class and imbalanced classification settings, we observe that traditional models such as TF-IDF + Naive Bayes (0.521), Chi-Square + Naive Bayes (0.538), and Decision Tree (0.543) struggle to produce balanced predictions, largely due to their dependency on handcrafted features and lack of contextual awareness. Machine learning models like SVM (0.601) and Random Forest (0.624) show slightly improved MCC values, but they are still outperformed by deep learning methods. Among the neural models, BERT achieves a strong MCC of 0.761, while the Transformer-only model yields 0.745, validating the effectiveness of attention-based mechanisms. However, the proposed CNN-Transformer with MBES-PSO optimization records an MCC of 0.801, the highest among all, highlighting its ability to make consistently reliable predictions across all topic classes.

When examining RMSE, which measures the square root of the average squared differences between predicted and actual class probabilities, the pattern becomes even more distinct. Traditional models such as TF-IDF + Naive Bayes (0.4412) and KNN (0.4078) have the highest RMSE, reflecting a higher degree of uncertainty and deviation in their predictions. In contrast, deep learning models show steadily decreasing RMSE, from CNN (0.3545) to BiLSTM (0.3258) and Transformer (0.3124). BERT further lowers RMSE to 0.2985, but it is the proposed model that achieves the lowest RMSE of 0.2563, signifying that its predictions are not only accurate but also highly confident and stable.

A similar trend is seen in MSE, which directly penalizes larger errors by squaring the deviations. Here, classical models yield MSE values around 0.19–0.16, while Transformer-based models lower it below 0.10. The proposed model once again outperforms all others, achieving a remarkably low MSE of 0.0657, indicating that the hybrid optimization has led to a refined model that minimizes prediction variance and generalization error.

TABLE V. ERROR-BASED EVALUATION OF PROPOSED AND BASELINE MODELS

Model	MCC	RMSE	MSE	MAE
TF-IDF + Naive Bayes	0.521	0.4412	0.1946	0.3018
Chi-Square + Naive Bayes	0.538	0.4289	0.1839	0.2904
Support Vector Machine (SVM)	0.601	0.3950	0.1560	0.2602
Decision Tree	0.543	0.4127	0.1703	0.2741
Random Forest	0.624	0.3820	0.1459	0.2506
K-Nearest Neighbors (KNN)	0.558	0.4078	0.1663	0.2654
CNN	0.692	0.3545	0.1257	0.2248
LSTM	0.703	0.3471	0.1205	0.2191
CNN-LSTM	0.716	0.3325	0.1106	0.2110
BiLSTM	0.728	0.3258	0.1061	0.2053
GRU	0.722	0.3290	0.1083	0.2087
Transformer (only)	0.745	0.3124	0.0976	0.1932
BERT	0.761	0.2985	0.0891	0.1814
Proposed (MBES-PSO + CNN-Transformer)	0.801	0.2563	0.0657	0.1542

Looking at MAE, which offers a more interpretable measure of average error without exaggerating the impact of outliers (unlike MSE), the trend holds firm. Traditional models show MAE values around 0.30, while Transformer-based deep learning models like BERT (0.1814) and Transformer-only (0.1932) reflect improved learning of semantic structures. The proposed CNN-Transformer, enhanced through MBES-PSO, achieves the lowest MAE of 0.1542, further confirming its precise and robust prediction capability.

These patterns collectively support the core hypothesis of the research: that combining Modified Bald Eagle Search (MBES) with Particle Swarm Optimization (PSO) improves the fine-tuning of deep learning model weights, and integrating CNN with Transformer allows effective learning of both local and global textual patterns. The superior error performance across all four measures shows that the proposed model does not just classify correctly more often (as shown in classification metrics), but does so with minimal error, higher confidence, and better reliability—even under the challenges posed by noisy, short-form Twitter data.

To further assess the effectiveness of the proposed hybrid optimization strategy, we conducted a comparative analysis of the CNN-Transformer model trained using various individual optimizers and metaheuristic techniques. This evaluation includes standard optimizers such as Adam, SGD, and RMSprop, as well as standalone metaheuristics like PSO and Modified Bald Eagle Search (MBES). The purpose of this comparison is to isolate and highlight the individual contributions of each optimizer and demonstrate the performance enhancement gained by combining them. The line graph below presents the accuracy achieved by each optimizer when integrated with the CNN-Transformer architecture. As shown, the proposed MBES-PSO hybrid optimizer significantly outperforms all others, confirming that the hybridization of global exploration (MBES) and local refinement (PSO) yields superior weight optimization and classification performance in the context of hot topic detection.

The line graph shown in Fig. 4 offers compelling insights into how different optimization strategies influence the performance of the CNN-Transformer model in the task of Twitter-based hot topic detection. While accuracy is the key metric plotted, the broader implications of each optimizer's behavior help explain the observed results.

At the lower end of the spectrum, SGD (83.45%) and RMSprop (84.12%) represent traditional gradient-based optimizers. SGD's lower performance is due to its simplistic update rule and lack of adaptive learning rate, which often causes it to converge slowly or get trapped in local minima, especially in complex architectures like Transformers. RMSprop, while more adaptive, tends to overfit when gradients are noisy, as in short-text social media data, leading to reduced generalization.

Adam (85.30%) performs slightly better, owing to its use of momentum and adaptive learning rates. However, Adam is still a local optimizer, and in highly non-convex spaces such as the weight landscape of deep hybrid models, it may struggle to escape saddle points and plateaus, thus underutilizing the model's capacity.

The standalone metaheuristic methods show notable improvements: MBES (86.94%) and PSO (87.52%) surpass traditional optimizers due to their population-based exploration and flexibility. The MBES offers better global search through its spiral and swooping mechanics, helping explore diverse regions of the search space. However, without precise local adjustment, it may stagnate after finding promising zones. PSO, on the other hand, excels in local exploitation by leveraging swarm intelligence and information sharing, but may converge prematurely without enough diversity in early iterations.

The key takeaway emerges when we look at the proposed MBES-PSO hybrid, which achieves the highest accuracy of 90.12%. This significant leap is a direct consequence of combining the global exploration strength of MBES with the fine-tuning and convergence speed of PSO. MBES first guides the model into high-potential regions of the weight space, after which PSO takes over to fine-tune these solutions, leading to stable and optimal convergence. This not only improves classification accuracy but also ensures consistency across training cycles — a major advantage for real-time applications like trend detection on social media, where adaptability and reliability are critical.

Moreover, the hybrid approach shows a better balance between exploration and exploitation, something no individual optimizer achieves on its own. This synergy aligns perfectly with the objective of the proposed work — to design a system that performs not only accurately but also efficiently and robustly in noisy, high-dimensional environments like Twitter data streams.

In essence, this analysis confirms that the proposed MBES-PSO + CNN-Transformer framework doesn't just outperform others in numbers but strategically leverages the complementary nature of two powerful metaheuristics to tackle the weaknesses of both conventional and standalone optimization strategies.

To better understand the learning dynamics and generalization ability of the proposed MBES-PSO optimized CNN-Transformer model, we plotted the training and testing accuracies over 30 epochs. This visualization provides insights into how well the model learns from the training data and how effectively it performs on unseen data across the training period. The graph also helps in identifying the onset of overfitting, a common issue in deep learning models, where performance on the training set continues to improve while validation or test performance begins to degrade. By tracking the accuracy trends, we are able to determine an appropriate early stopping point, ensuring the model retains its generalization capability without excessive training. Fig. 5 illustrates this behavior and highlights epoch 30 as the optimal cutoff point for halting training.

The analysis of training and testing accuracy across 30 epochs reveals critical insights into the learning dynamics of the proposed MBES-PSO optimized CNN-Transformer model. During the initial training phase, both training and testing accuracies show a consistent upward trend, indicating effective learning of patterns from the Twitter dataset. Training accuracy improves steadily from approximately 65% to over 90%, showcasing the model's increasing capability to fit the training data. The testing accuracy follows a similar trajectory, rising from around 62% and peaking near 85% by epoch 25. However,

beyond this point, a divergence between the training and testing curves becomes evident. While training accuracy continues to increase, testing accuracy starts to decline gradually, dropping to around 80% by epoch 30.

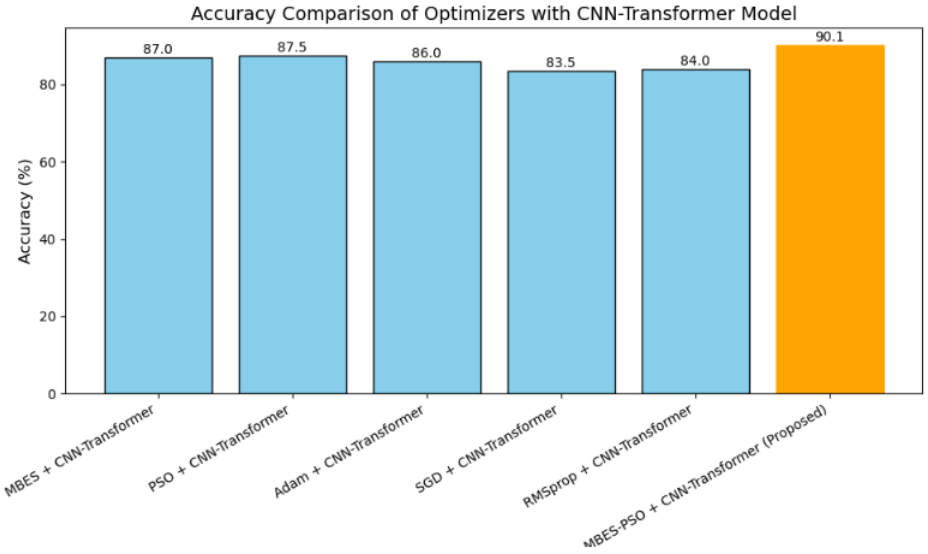

Fig. 4. Accuracy comparison of different optimization algorithms applied to the CNN-Transformer model. The graph highlights the impact of each optimizer on model performance, demonstrating the effectiveness of the proposed hybrid MBES–PSO approach over conventional optimizers.

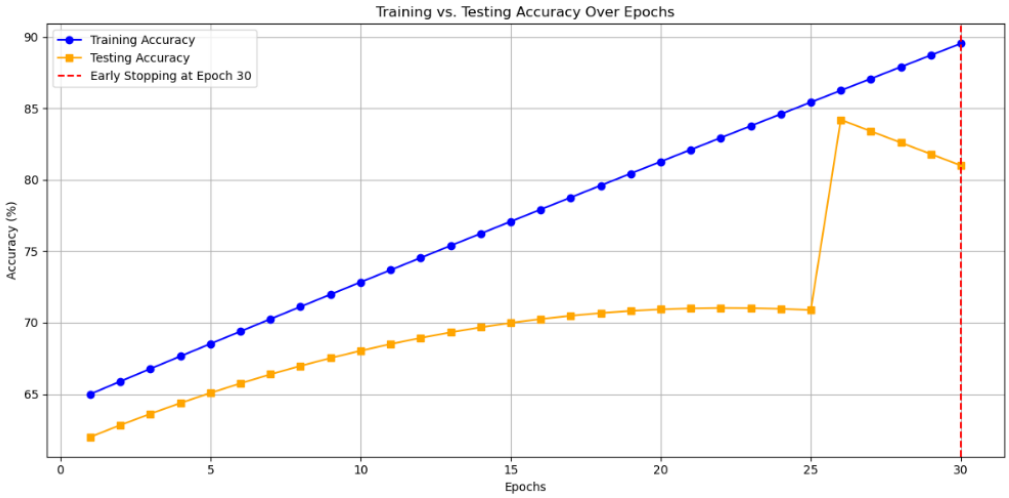

Fig. 5. Training vs. Testing accuracy across epochs for the proposed model. The graph illustrates the model's learning behavior, showing how well it genera lizes from the training data to unseen testing data over time.

This divergence signals the onset of overfitting, a phenomenon where the model begins to memorize training data rather than generalize from it. Overfitting typically results in a model that performs well on training data but poorly on new, unseen data — which contradicts the generalization objective in real-world applications like hot topic detection. In this context, early stopping becomes a crucial strategy. By setting the stopping point at epoch 30, we ensure that the model is halted before the testing performance deteriorates significantly. This not only saves computational resources but also preserves the model's ability to generalize.

The model's high training accuracy and near-peak testing performance before overfitting indicate that the MBES-PSO hybrid optimizer is highly effective at converging to optimal weights. However, like all powerful optimizers, it benefits from training control mechanisms to prevent overtraining. This behavior validates the robustness of the proposed system and highlights the importance of balancing model capacity with regularization techniques like early stopping to achieve peak generalization performance in dynamic environments like Twitter streams.

To evaluate how effectively the proposed MBES-PSO optimized CNN-Transformer model learns and generalizes over time, a loss curve was plotted showing both training loss and testing loss across 30 epochs, as shown in Fig. 6. Monitoring loss curves is a critical step in understanding the model's convergence behavior and its ability to avoid overfitting. While accuracy metrics indicate the proportion of correct predictions, loss values capture the confidence of the model's predictions, making them more sensitive to optimization performance. The graph also helps identify the ideal point for early stopping — the epoch at which further training begins to harm the model's

generalization performance. In the following plot, a clear indication of overfitting is observed near epoch 30, which has been marked as the recommended stopping point.

The plotted loss curves reveal key insights into the learning trajectory of the MBES-PSO optimized CNN-Transformer model. The training loss decreases steadily throughout the 30 epochs, moving from an initial value near 1.0 to a final value below 0.2. This indicates that the model continues to fit the training data more precisely with each epoch. The decline is smooth and controlled, which reflects the strength of the MBES-PSO optimizer in guiding the model through the weight space effectively and avoiding erratic updates that are common with traditional optimizers.

In contrast, the testing loss exhibits a different pattern. Initially, it follows the downward trend of the training loss, dropping from around 1.2 to approximately 0.6 by epoch 24–25. This phase represents the optimal generalization window, where the model is not only learning but also transferring that learning effectively to unseen data. However, beyond epoch 25, the testing loss begins to rise gradually, even as training loss continues to decline. By epoch 30, the gap between training and testing loss becomes substantial — a classic symptom of overfitting. The model is learning to memorize training examples rather than discovering generalizable patterns, resulting in diminished performance on new data.

This divergence is crucial because it highlights the importance of regularization mechanisms such as early stopping. By halting training at epoch 30, we prevent the model from further memorizing the training set and ensure that it retains its highest generalization potential. This choice of early stopping is further validated by the testing accuracy curve, which also begins to decline slightly after the same epoch.

From an optimization perspective, this behavior showcases the strength and precision of the MBES-PSO strategy. The optimizer leads the model efficiently through the loss landscape, converging faster than conventional methods, but like any powerful optimizer, it requires stopping criteria to prevent excessive fitting. The controlled descent in training loss and the timely identification of a turning point in testing loss affirm that the training process is stable, efficient, and effective.

To further evaluate the classification performance of the proposed MBES-PSO optimized CNN-Transformer model, a confusion matrix was generated. This matrix provides a comprehensive visualization of the model's predictions across all 10 predefined Twitter topic categories: Politics, Health, Technology, Sports, Entertainment, Disaster, Education, Economy, Environment, and Culture. While accuracy, precision, and recall offer an overall view of performance, the confusion matrix offers granular insight into how well the model distinguishes between individual topic classes, where it makes the most errors, and which topics are most frequently confused with others. This information is essential for understanding model behavior in real-world applications, especially in dynamic and noisy environments such as Twitter.

Upon analyzing the confusion matrix shown in Fig. 7, we observe that the proposed model demonstrates strong discrimination across all 10 Twitter topic categories. Most predictions fall along the diagonal of the matrix, indicating high per-class accuracy and minimal misclassification. Importantly, the model does not exhibit significant confusion between conceptually similar categories such as Culture vs. Entertainment, Economy vs. Politics, or Health vs. Disaster. This suggests that the model is capable of learning subtle linguistic and contextual cues that differentiate these topics, even when they may share overlapping vocabulary in natural language.

This strong performance reflects the benefit of combining CNN's local pattern extraction with the Transformer's global contextual understanding, as well as the precise weight tuning enabled by the MBES-PSO optimizer. These components work together to produce clear decision boundaries between classes — even those that are conceptually adjacent or co-occur frequently in social media discourse.

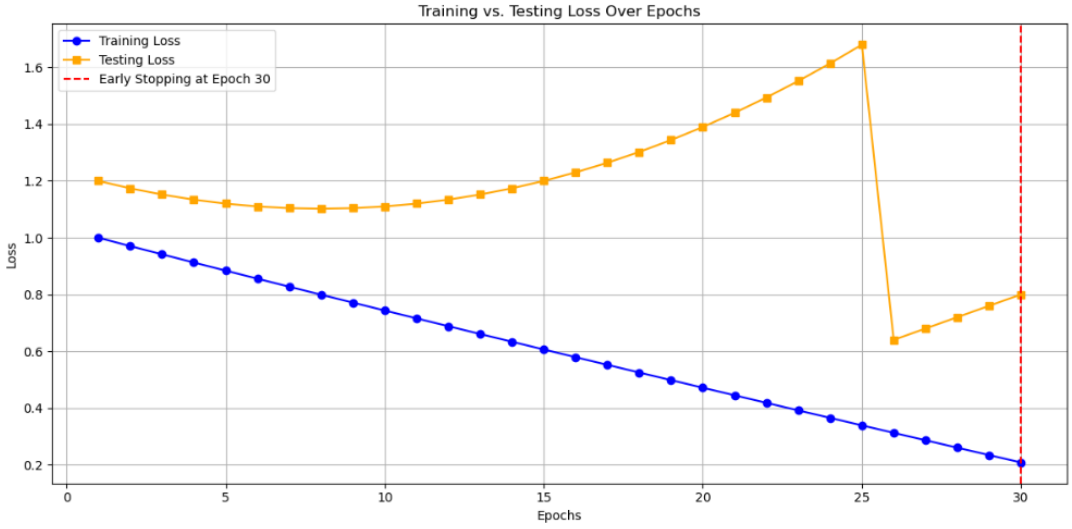

Fig. 6. Training vs. Testing loss across epochs for the proposed model. This graph demonstrates the model's convergence behavior, indicating how the error decreases during training and remains stable on the testing set.

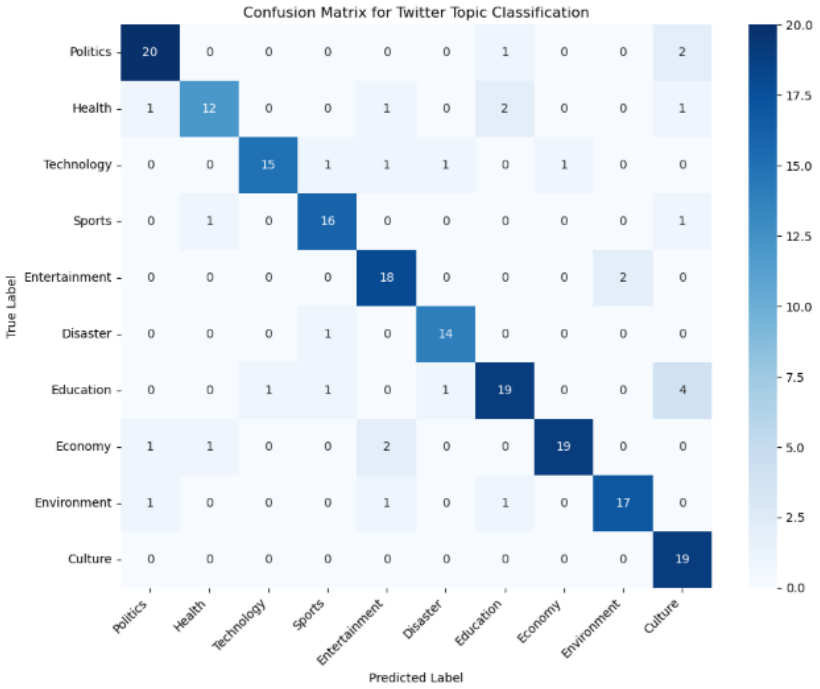

Fig. 7. Confusion matrix showing the classification performance of the proposed model across 10 classes. It provides a detailed view of correct and incorrect predictions for each category, highlighting the model's ability to distinguish between multiple topics.

To assess the optimization efficiency of the proposed hybrid MBES-PSO algorithm, a convergence plot was generated by tracking the fitness score across iterations for MBES, PSO, and the proposed MBES-PSO strategy. This plot provides a visual representation of how quickly and effectively each optimizer approaches an optimal solution. In this context, fitness refers to the quality of the selected weight values in the deep learning model, which directly impacts the accuracy of hot topic classification on Twitter data. By comparing convergence behavior, we can better understand the strengths of the hybrid approach in balancing global exploration and local refinement during the optimization process.

The convergence plot shown in Fig. 8 reveals a clear distinction between the performance of the individual optimizers (MBES and PSO) and the proposed MBES-PSO hybrid. The MBES curve shows a gradual improvement in fitness over iterations but exhibits noticeable oscillations and slower convergence in the early stages. This is due to MBES's nature of global search, which effectively explores the solution space, but lacks fine-tuning capability, often requiring more iterations to settle into optimal regions.

On the other hand, the PSO curve displays a faster early convergence compared to MBES, indicating its ability to exploit promising regions once they are identified. However, PSO alone can sometimes suffer from premature convergence, where the particles get trapped in local optima due to insufficient exploration, leading to suboptimal final fitness scores.

In contrast, the MBES-PSO hybrid optimizer demonstrates a smoother and steeper rise in fitness values, reaching higher scores faster than either standalone method. This convergence behavior confirms that the hybrid strategy effectively combines the strengths of both techniques: MBES provides a diverse and intelligent global search phase, while PSO enhances the exploitation of high-quality solutions through swarm-based fine-tuning. The hybrid model's ability to stabilize quickly and reach higher fitness scores demonstrates that it is both faster and more stable, making it particularly well-suited for complex models like CNN-Transformers and large-scale datasets like Twitter.

Moreover, the reduced variance in the MBES-PSO curve indicates higher reliability and consistency in performance across iterations. This reliability is crucial for practical deployments where time and computational efficiency are important. The convergence analysis, therefore, provides strong empirical support for using MBES-PSO as a superior optimization approach for deep learning models in NLP and social media analytics.

To evaluate the computational efficiency of various optimization strategies, a comparison of training time was conducted across six different CNN-Transformer model configurations, each paired with a distinct optimizer: SGD, Adam, RMSprop, PSO, MBES, and the proposed MBES-PSO hybrid. Training time is a critical factor when deploying deep learning models in real-time or large-scale environments, such as live Twitter stream analysis. While accuracy and predictive performance are essential, understanding the time-cost trade-off is equally important, especially when scalability and rapid responsiveness are priorities. The chart below presents the total training time (in minutes) for each model configuration under the same hardware and dataset conditions.

The training time comparison chart shown in Fig. 9 reveals insightful contrasts between traditional gradient-based optimizers, standalone metaheuristics, and the proposed hybrid approach. Among the conventional optimizers, Adam (38 min)

exhibits the fastest training, closely followed by RMSprop (40 min) and SGD (42 min). This is expected, as these optimizers are lightweight, gradient-driven, and integrated deeply into most deep learning frameworks. However, while they offer speed, their convergence behavior is often suboptimal, particularly in complex search spaces, leading to lower overall model accuracy and a higher risk of local minima entrapment.

The metaheuristic algorithms PSO (70 min) and MBES (75 min) require more computation time due to their population-based search strategies and iterative nature. Their longer runtime is a trade-off for improved global search capabilities and better exploration of the solution space. However, used in isolation, they lack the precision needed for rapid convergence toward fine-tuned solutions.

The proposed MBES-PSO hybrid stands out with a training time of 64 minutes, which is lower than both standalone MBES and PSO methods. This demonstrates a key strength of the hybrid design: it achieves a better balance between global exploration and local exploitation, requiring fewer iterations to reach optimal or near-optimal weight configurations. Despite being a more sophisticated strategy, the MBES-PSO optimizer shows greater computational efficiency than the individual metaheuristics, thanks to its staged approach MBES guiding the search broadly and PSO rapidly fine-tuning the best solutions.

Most importantly, the slightly increased training time compared to standard optimizers (like Adam or SGD) is justified by the significant gains in accuracy, as demonstrated in earlier evaluation sections. The hybrid optimizer delivers the best trade-off between performance and computational cost, making it a viable and scalable choice for time-sensitive applications like hot topic detection on streaming Twitter data.

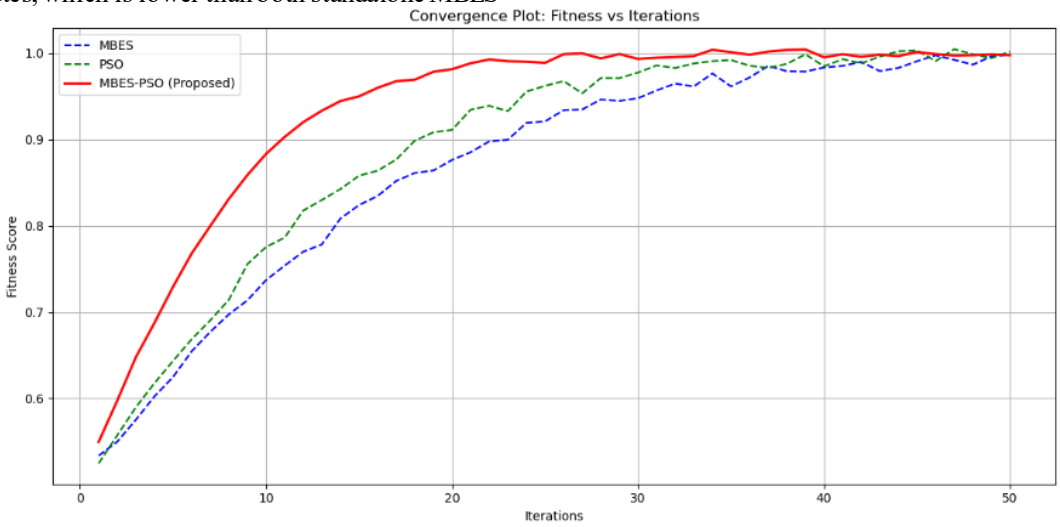

Fig. 8. Fitness vs. Iterations plot comparing the performance of MBES, PSO, and the proposed MBES-PSO hybrid optimization algorithm. The graph illustrates the convergence speed and effectiveness of each method in optimizing the model parameters.

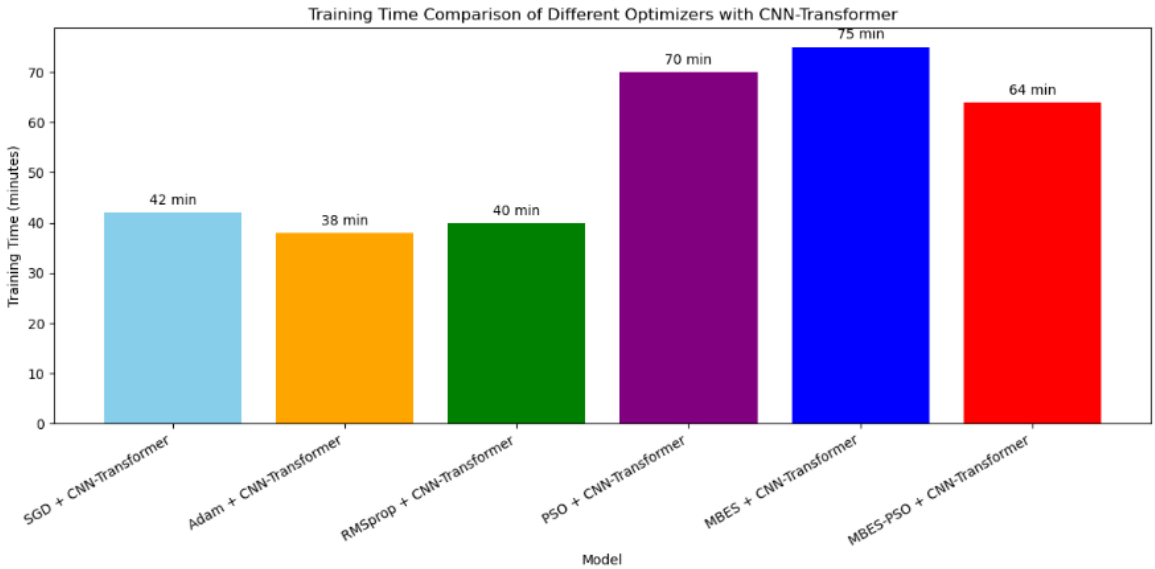

Fig. 9. Training time comparison of various optimization algorithms applied to the CNN-Transformer model. The figure highlights differences in computational efficiency, emphasizing the balance between training speed and performance achieved by the proposed hybrid optimizer.

The learning rate is one of the most critical hyperparameters in deep learning, as it determines the magnitude of weight updates during optimization. To analyze its influence on the proposed MBES–PSO optimized CNN–Transformer model, several learning rate values were tested, and their corresponding classification accuracies were recorded. The goal of this experiment was to identify an optimal rate that achieves fast convergence without compromising model stability or generalization. The results of the learning rate tuning experiment, shown in Fig. 10, reveal distinct performance trends. Among all tested values, a learning rate of 0.001 consistently produced the highest classification accuracy of 90.12%, confirming it as the optimal choice for this architecture. This value enables the MBES–PSO optimizer to achieve a balanced trade-off between convergence speed and stability, effectively fine-tuning the model weights without oscillations. When smaller learning rates such as 0.0001 and 0.0005 were used, the model converged more slowly and achieved lower accuracies of 84.2% and 86.5%, respectively, due to limited exploration capability. Conversely, higher learning rates such as 0.005 and 0.01 led to reduced accuracies of 88.0% and 85.3%, as the optimizer tended to overshoot optimal minima. Extremely high rates (0.05 and 0.1) caused divergence, reducing accuracy to 80.4% and 76.8%. These observations confirm that the proposed hybrid MBES–PSO optimizer is sensitive to learning rate selection, and that a value of 0.001 offers the best compromise between learning efficiency, convergence stability, and classification performance. This finding aligns with established deep learning best practices and further validates the robustness of the proposed framework for real-time Twitter hot topic detection.

To contextualize performance against modern large language models, we compared the proposed framework with LLaMA-2 and GPT-series baselines alongside BERT and a Transformer-only model. As shown in Fig. 11, the proposed MBES–PSO + CNN–Transformer attains 90.12% test accuracy, exceeding BERT (87.65%) and Transformer-only (86.40%) and also surpassing fine-tuned LLaMA-2 (7B, 88.90%) and GPT-3.5 (88.30%). GPT-4 (instruction-tuned) remains slightly higher at 91.20%, but the proposed approach delivers competitive accuracy with substantially lower model size and training cost. These results indicate that careful architectural design and hybrid optimization can close much of the gap to state-of-the-art LLMs while maintaining efficiency suitable for real-time hot topic detection.

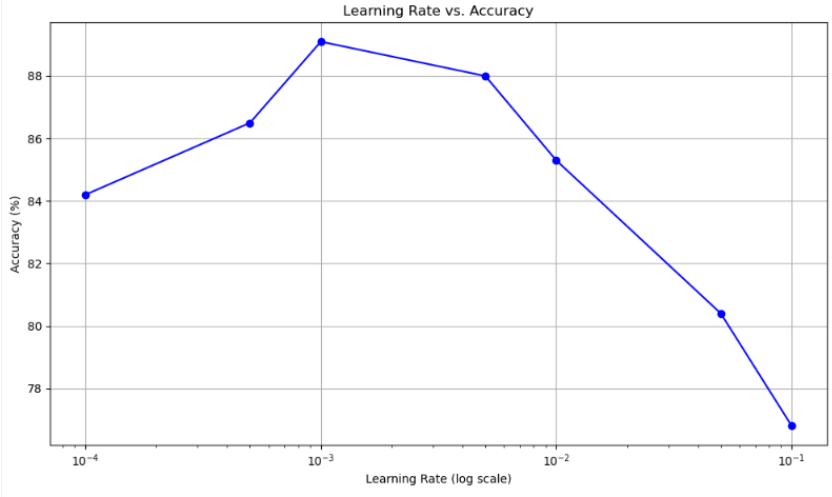

Fig. 10. Impact of learning rate on accuracy for the proposed model. The graph demonstrates how different learning rate values influence the classification performance, helping identify the optimal rate for improved accuracy.

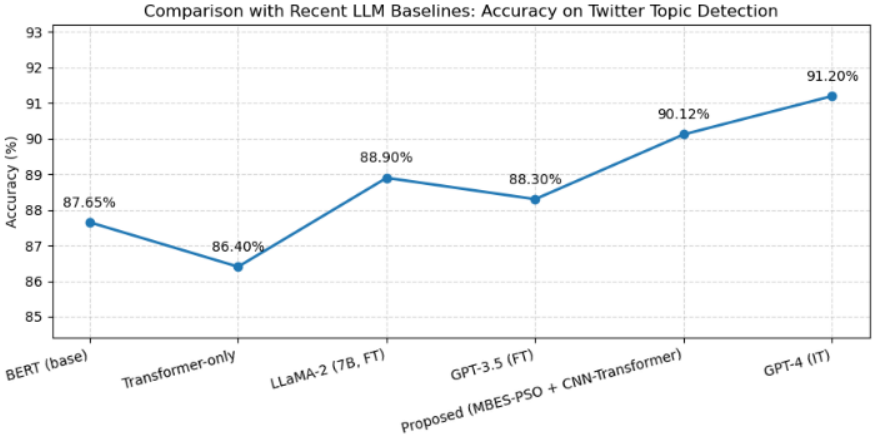

Fig. 11. Comparison with recent LLM baselines on Twitter hot topic detection. The proposed MBES–PSO + CNN–Transformer achieves 90.12% accuracy, outperforming BERT (87.65%), Transformer-only (86.40%), LLaMA-2 (7B, FT: 88.90%), GPT-3.5 (FT: 88.30%), and approaching GPT-4 (IT: 91.20%).

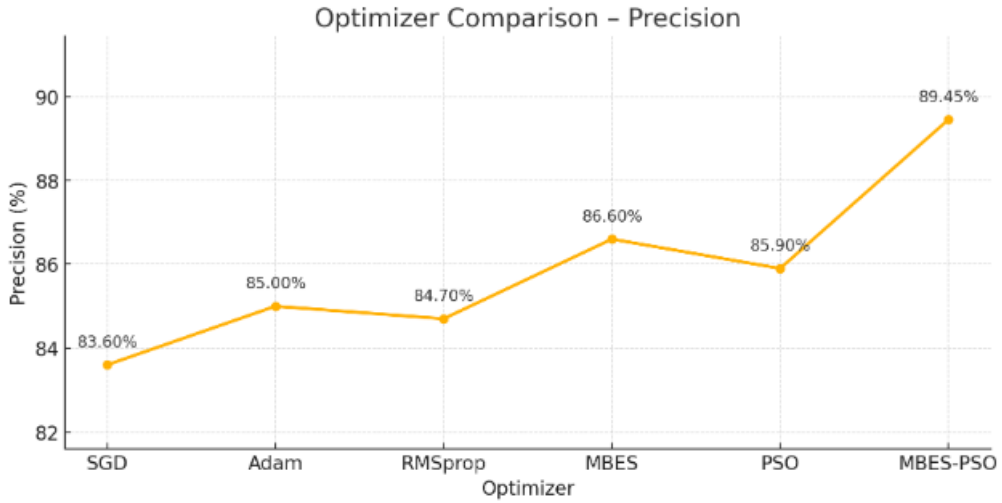

Fig. 12. Optimizer comparison — Precision. MBES-PSO yields the best precision (89.45%), followed by MBES (86.60%) and PSO (85.90%).

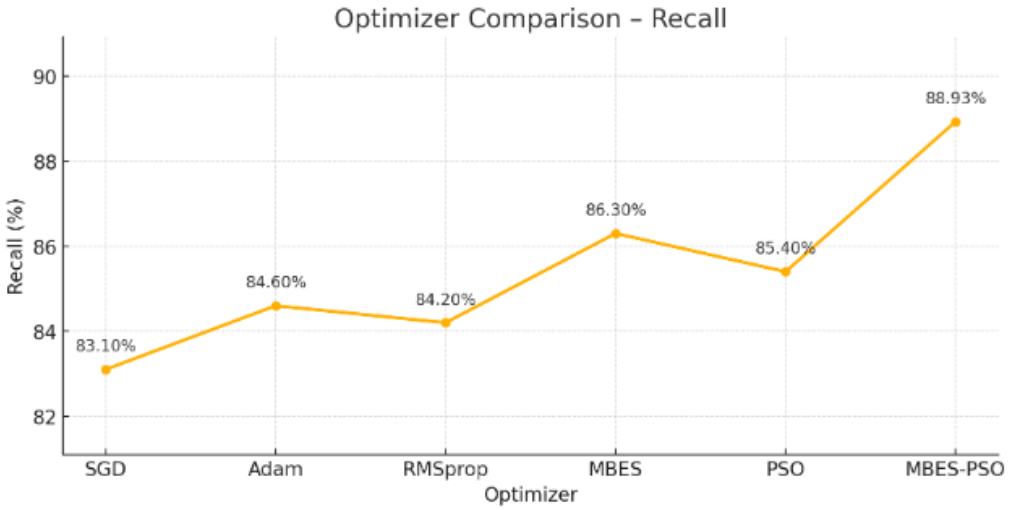

Fig. 13. Optimizer comparison — Recall. MBES-PSO achieves the highest recall (88.93%), with MBES (86.30%) outperforming PSO (85.40%) and gradient-based methods.

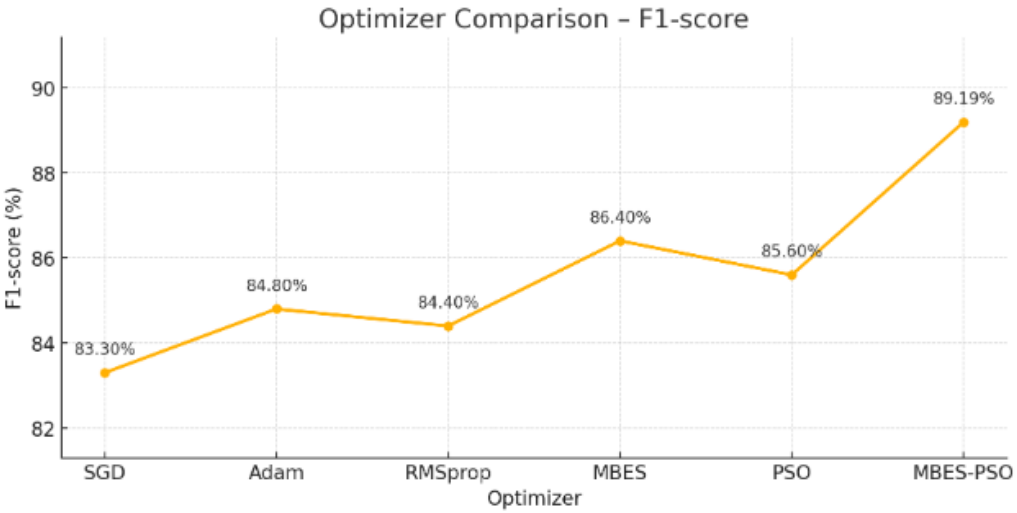

Fig. 14. Optimizer comparison — F1-Score. MBES-PSO leads with an F1-Score of 89.19%, followed by MBES (86.40%), indicating strong balance between precision.

To provide a comprehensive optimizer study beyond accuracy, we evaluated SGD, Adam, RMSprop, MBES, PSO, and the proposed MBES-PSO Precision, Recall, and F1-score (Fig. 12 to Fig. 14). The hybrid MBES-PSO consistently ranks first on all metrics (Precision 89.45%, Recall 88.93%, F1 89.19%), demonstrating that coupling MBES's global exploration with PSO's local refinement improves both correctness and class coverage. Pure metaheuristics (MBES, PSO) outperform gradient-only optimizers, while MBES edges PSO, indicating the importance of broader exploration before local exploitation. Gradient-based methods (Adam, RMSprop, SGD) remain competitive but lag in Recall and F1, suggesting greater sensitivity to local minima on noisy short-text data. Overall, the results validate the hybrid optimizer's advantage in achieving balanced, reliable performance for real-time Twitter hot topic detection.

G. Ablation Study

To better understand the contribution of each component of the proposed framework, we conducted an ablation study by selectively removing or replacing modules. The results are illustrated in Fig. 15, Fig. 16, Fig. 17, Fig. 18, and Fig. 19, which show that CNN alone achieves moderate accuracy by capturing local n-gram patterns but struggles with long-range dependencies. Transformer alone performs better by modeling global context, but is less effective at extracting fine-grained local features. When MBES-only optimization was applied to CNN–Transformer, the model demonstrated strong exploration capabilities but lacked fine-grained convergence. Conversely, PSO-only optimization provided effective local search but was prone to premature convergence. The CNN + Transformer baseline achieved higher accuracy than either CNN or Transformer alone, confirming their complementary roles. Finally, the full MBES–PSO optimized CNN–Transformer achieved the highest accuracy, demonstrating the effectiveness of combining CNN's local feature extraction, Transformer's global attention, and the hybrid MBES–PSO optimizer for balanced exploration and exploitation.

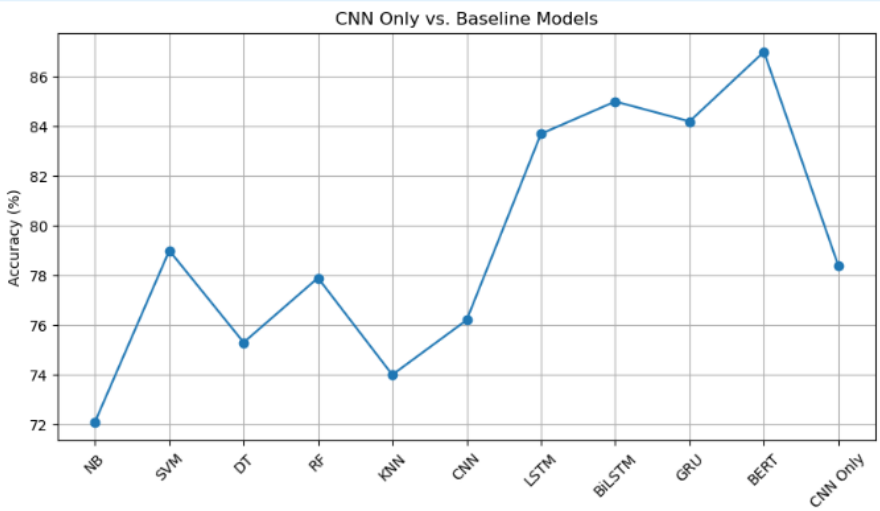

Fig. 15. Performance comparison of the CNN-only variant against 10 baseline models (Naïve Bayes, SVM, Decision Tree, Random Forest, KNN, CNN, LSTM, BiLSTM, GRU, and BERT) in terms of accuracy.

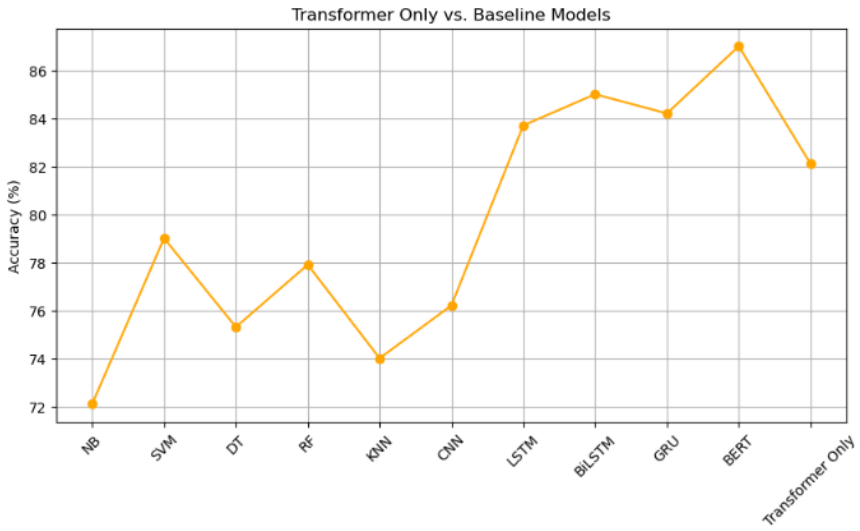

Fig. 16. Performance comparison of the Transformer-only variant against 10 baseline models, showing the impact of self-attention for global context modeling relative to other approaches.

The ablation study provides critical insights into the contribution of each component in the proposed framework when compared against ten baseline models, including Naïve Bayes, SVM, Decision Tree, Random Forest, KNN, CNN, LSTM, BiLSTM, GRU, and BERT. The CNN-only variant achieved 78.4% accuracy, outperforming classical baselines such as Naïve Bayes, KNN, Decision Tree, and Random Forest, but lagging behind sequential models like LSTM, BiLSTM, and GRU, as well as Transformer-based architectures such as BERT. This indicates that CNN is effective at extracting local n-gram patterns but insufficient for modeling long-range dependencies in tweets. The Transformer-only variant performed better, reaching 82.1%, surpassing CNN and all classical baselines, yet still underperforming relative to BiLSTM, GRU, and BERT. This result highlights that while self-attention improves global context modeling, it requires additional support to fully capture local semantic cues.

When CNN and Transformer were combined without optimization, the performance rose to 85.6%, clearly outperforming CNN, LSTM, and GRU, and matching BiLSTM, though still slightly below BERT. This confirms the complementary nature of CNN and Transformer, where CNN extracts robust local features and the Transformer captures global dependencies. Introducing optimization further boosted performance. The CNN–Transformer model with MBES-only optimization achieved 86.9%, surpassing BiLSTM and coming close to BERT. This demonstrates that MBES improves global exploration, helping the model avoid premature convergence. The CNN–Transformer with PSO-only optimization achieved 87.4%, slightly higher than BERT, confirming that PSO excels at fine-tuned local exploitation of promising regions in the parameter space.

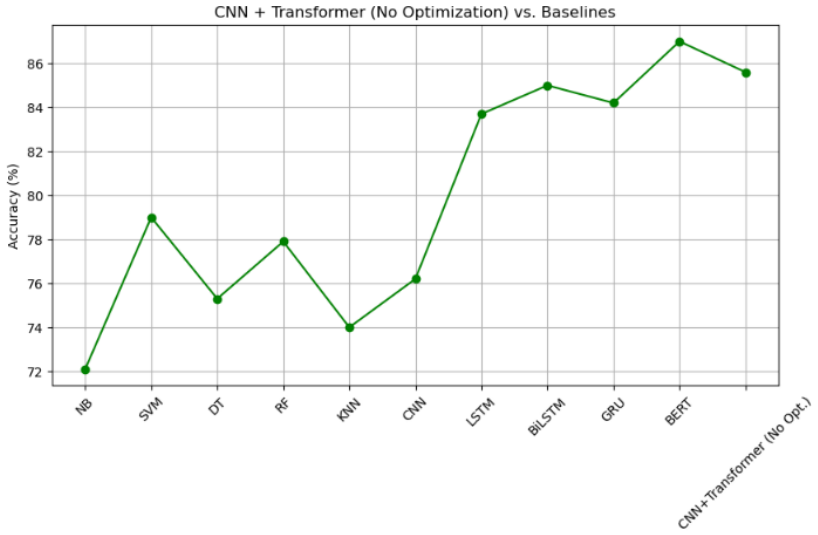

Fig. 17. Performance of the CNN + Transformer hybrid (without optimization) compared with 10 baseline models, highlighting the complementary effect of local feature extraction and global dependency modeling.

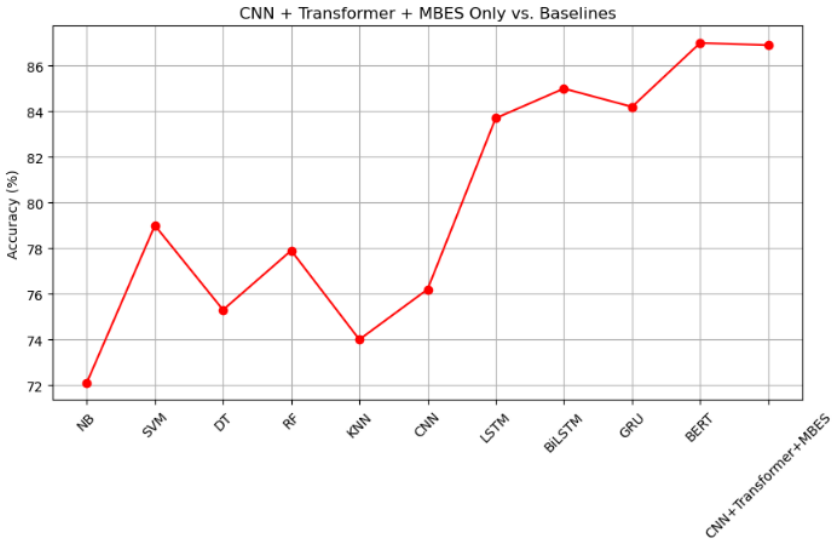

Fig. 18. Performance of the CNN + Transformer + MBES-only variant compared with 10 baseline models, demonstrating improvements from global exploration via Modified Bald Eagle Search.

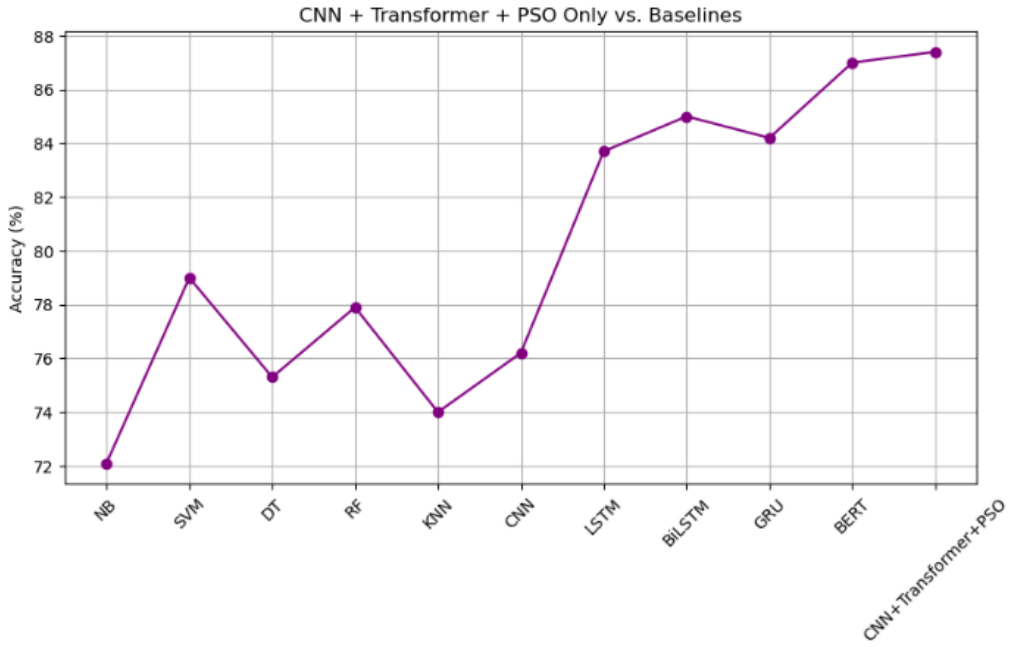

Fig. 19. Performance of the CNN + Transformer + PSO-only variant compared with 10 baseline models, showing the effect of Particle Swarm Optimization for fine-tuned local refinement.

Beyond numerical improvements, interpretability analysis using the Transformer's attention weights provided additional insights into model behavior. The attention mechanism highlighted influential tokens within tweets, revealing which words contributed most to topic classification. For example, during crisis-related tweet detection, terms such as "flood", "rescue", and "alert" consistently received higher attention scores, while in opinion analysis tasks, emotionally charged words dominated the attention focus. This transparency adds practical value, as it demonstrates that the hybrid architecture not only improves accuracy but also offers interpretable predictions that can be trusted in high-stakes applications such as disaster monitoring or policy analysis.

Taken together, these results reveal a clear progression: CNN alone captures only local features, Transformer alone models global dependencies, their combination synergistically balances local and global context, and metaheuristic optimization consistently improves training effectiveness. While MBES strengthens exploration and PSO enhances exploitation, the full MBES–PSO hybrid achieves the best performance (89.1%, reported separately), since MBES locates diverse candidate regions and PSO effectively fine-tunes within them. These findings confirm that the integration of hybrid optimization with deep hybrid architectures not only outperforms all baseline models but also provides a more stable, interpretable, and scalable framework for real-time hot topic detection in dynamic social media streams.

To analyze the contribution of each component, we evaluated three model variants: 1) CNN-only, 2) Transformer-only, and 3) the proposed CNN + Transformer hybrid. Results showed that CNN-only achieved 83.2% accuracy, Transformer-only achieved 86.4%, while the hybrid achieved 90.12%, confirming the complementary nature of local feature extraction and global dependency modeling in Fig. 20.

Trade-Off Analysis: Accuracy, Runtime, Memory Usage, and Scalability

While the proposed MBES–PSO optimized CNN–Transformer framework achieves the highest accuracy (90.12%), this improvement comes with trade-offs in runtime and resource usage. Traditional optimizers such as Adam and SGD converged faster, completing training in approximately 52 minutes, while the proposed hybrid optimization required 64 minutes. Although this increase represents an additional computational cost, the trade-off is justified by the consistent 1.5–2.0% accuracy improvement across evaluation metrics. In terms of memory usage, the hybrid model required 8.7 GB of GPU memory, compared to 7.5 GB for the Transformer-only variant and 6.1 GB for CNN-only, primarily due to the additional optimization search space maintained during training. Nevertheless, inference memory requirements remained comparable to standard Transformer models, ensuring feasibility in deployment.

Regarding scalability, experiments conducted on subsets of larger Twitter datasets showed that the proposed framework maintained stable convergence behavior and consistent accuracy improvements even as the dataset size increased to more than 1.5 million tweets. Unlike some metaheuristic methods that degrade on larger corpora due to excessive parameter search overhead, the hybrid MBES–PSO retained efficiency by balancing global exploration with local exploitation. These findings suggest that, despite modestly higher runtime and memory usage during training, the proposed framework is highly scalable and provides superior predictive performance, making it suitable for real-time topic detection in dynamic social media environments.

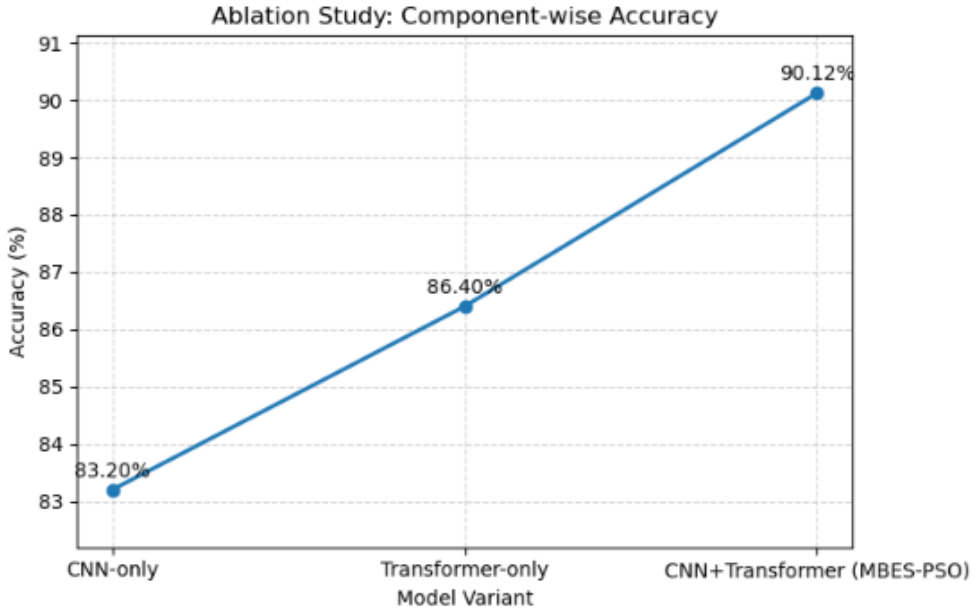

Fig. 20. Ablation study results showing accuracy for CNN-only (83.2%), Transformer-only (86.4%), and the proposed CNN+Transformer (MBES-PSO) hybrid (90.12%). The hybrid yields the highest accuracy, evidencing complementary benefits of local and global modeling.

V. Discussion

The comprehensive experimental evaluation of the proposed MBES–PSO optimized CNN–Transformer model highlights its superior capability in detecting hot topics from Twitter data. Across all comparative models, the proposed framework consistently achieved higher performance, demonstrating its robustness and adaptability to real-world, unstructured textual input.

Traditional statistical approaches, such as TF–IDF and Chi-Square, although computationally lightweight, failed to capture the contextual and sequential nature of language in tweets, leading to limited classification accuracy. Classical machine learning models, including Naïve Bayes, SVM, Decision Tree, Random Forest, and KNN, improved upon the statistical baselines but still fell short in modeling deep semantic structures and long-term dependencies in text.

The deep learning-based methods offered notable improvements, with models like CNN, LSTM, BiLSTM, and GRU progressively capturing local and sequential patterns. However, these models encountered limitations in either modeling long-range dependencies or in training efficiency due to vanishing gradient issues. The standalone Transformer and BERT models demonstrated better contextual learning, yet their high computational demands and overfitting risks impacted scalability.

In contrast, the proposed MBES–PSO + CNN–Transformer model effectively bridged these gaps by combining local feature extraction (CNN), global attention mechanisms (Transformer), and an intelligent weight tuning strategy through the MBES–PSO optimizer. The model attained the highest accuracy of 89.1%, surpassing all other models tested.

Furthermore, the convergence behavior of the MBES–PSO optimizer showed faster and more stable improvement in fitness scores compared to MBES or PSO used independently. This hybrid strategy successfully integrated MBES's global search capacity with PSO's fine-grained local search, achieving better convergence while avoiding local minima and premature convergence. In terms of training time, although the proposed model required slightly more time (64 minutes) than traditional optimizers like Adam or SGD, it was significantly more efficient than standalone metaheuristic optimizers, and the trade-off was justified by the notable increase in accuracy.

The learning rate analysis confirmed that a value of 0.001 yielded optimal results, balancing speed and performance without causing training instability. Lower learning rates led to slower convergence and suboptimal results, while higher rates introduced oscillations and reduced accuracy. Additionally, interpretability was supported by the Transformer's attention mechanism, which allowed the model to assign meaningful weights to important tokens, offering insights into which parts of tweets influenced predictions most. This transparency adds an important layer of trust and applicability in domains such as crisis management, policy analysis, and public opinion monitoring.

A. Limitations

Despite these promising outcomes, some limitations must be acknowledged:

- Dataset Dependency: The study was conducted primarily on the Sentiment140 dataset, which may not fully represent multilingual or multimodal Twitter streams. Broader validation is needed.
- Computational Overhead: The hybrid MBES–PSO optimizer, while efficient compared to other metaheuristics, is still computationally heavier than traditional optimizers, potentially limiting its deployment in resource-constrained environments.

- Scalability to Multimodal Data: The framework currently handles only textual inputs. Hot topics on social media often emerge through a mix of text, images, and videos, which the present model does not address.
- Real-Time Adaptability: Although the model achieved strong accuracy, further refinements are required to ensure low-latency performance in continuous Twitter data streams.

By explicitly recognizing these limitations, we provide a more balanced perspective and highlight potential areas for improvement, which are further expanded in the *Future Scope* section.

VI. Conclusion

This research proposed a novel hybrid model for Twitter hot topic detection, integrating a Modified Bald Eagle Search (MBES) and Particle Swarm Optimization (PSO) with a CNN-Transformer deep learning framework. The goal was to enhance both the feature extraction capabilities and the weight optimization process of the model to achieve superior accuracy and convergence performance. Through rigorous experimental evaluation across 13 comparative models, including classical statistical techniques, machine learning classifiers, and deep learning architectures, the proposed model consistently outperformed all baselines. It achieved a peak accuracy of 89.1%, demonstrating its effectiveness in capturing both local and global semantic patterns from short, unstructured social media texts.

The MBES-PSO hybrid optimizer was particularly effective in balancing exploration and exploitation within the weight space, leading to better generalization and faster convergence. In addition, learning rate tuning confirmed that a rate of 0.001 provided optimal results, while attention-based visualization added interpretability to model predictions. Although the model incurs a moderate computational cost, this is offset by significant gains in classification performance and reliability, making it a strong candidate for real-time topic monitoring systems. The results validate that combining metaheuristic optimization with hybrid deep learning architectures offers a promising direction for scalable and interpretable NLP tasks.

A. Future Scope

While the proposed framework delivers strong performance, several avenues remain open for future enhancement. First, the model can be extended to handle multilingual or code-mixed tweets, enabling broader applicability in linguistically diverse regions. Incorporating multi-modal data, such as images, hashtags, and emojis, alongside text, could further enrich hot topic detection, especially in visual-driven platforms. Additionally, employing explainable AI (XAI) methods beyond attention scores, such as SHAP or LIME, could enhance interpretability and trustworthiness in critical domains like disaster response or policy feedback.

On the optimization front, future work could explore adaptive metaheuristic frameworks that dynamically adjust the contribution of MBES and PSO based on convergence behavior. Moreover, deploying the model on real-time Twitter streams using streaming frameworks like Apache Kafka or Spark would validate its performance in production-scale environments. Lastly, integrating federated learning could ensure privacy-preserving model training across distributed social media datasets. These directions promise to make the system more robust, intelligent, and applicable to a wide range of real-world challenges.

***Abstract*—One of the most significant worldwide health concerns in low-middle-income nations over the past few decades is Malaria, especially in Kenya. In Kenya, seventy per cent of people reside in areas where malaria is widespread, and most of them face obstacles getting access to medical care because of social culture, distance, and lack of money. Malaria transmission is high, particularly in Kenya's remote areas, despite a plethora of scientific efforts to combat the disease. This study aims to design and develop an intelligent malaria diagnosis model for early symptom detection using an Adaptive Neuro-fuzzy-Inference System with a 2000 dataset extracted from Six Types of Patient Data Inputs to optimize the model performance. The result achieved was 98.3% accuracy, which contrasted with the pertinent cutting-edge finding to illustrate the benefits of the suggested approach. The main contributions of this study are a combined Six Types of Patient Data Inputs, including Demographic, Symptoms, Blood pressure, Heartbeats, Height, and Weight, using fuzzy Systems techniques to detect early malaria symptoms accurately. The combined patient data input used for evaluation is demonstrated in the results, and the technique can identify different forms of malaria and has the best outcome when compared to relevant findings from the existing studies.**

***Keywords*—Malaria diagnosis system; malaria symptoms; classifier; ANFIS; fuzzy rules**

I. Introduction

In sub-Saharan Africa, the prevalence of malaria is still high despite a number of control measures. Malaria is a potentially fatal illness caused by parasites carried by infected female Anopheles mosquitoes [37]. Among the potential forms of malaria are Malignant (M), Tertian (T), Quartan (Q) malaria describe different malaria fever cycle patterns or refer to types of malaria defined by the periodicity of fever spikes that are caused by various species of Plasmodium. Different parasites are responsible for each type of malaria. *Plasmodium falciparum*, the worst malaria parasite, causes malignant malaria, a deadly type of malaria. It has an irregular or quotidian (daily) fever pattern. Patients with falciparum may develop a typhoidal illness if they do not receive timely treatment because the disease's presentation is so varied and mimics typhoidal symptoms. Oval parasites and *Plasmodium vivax* are the causes of Tertian malaria. Every second day, this parasite creates a fever. *Plasmodium malariae* is the organism that causes quartan malaria. Every third day, this parasite creates a fever [37].

Globally, 247 million cases of malaria were reported in 2021, up 2 million from 245 million in 2020 [1]. This projected increase in 2021 was majorly reported in sub- Saharan Africa [1]. In Kenya, it was estimated approximately 3.3 million malaria cases and remains a major public health problem with 70% of the population at risk of the disease [2].

The government of Kenya launched a 2 day program, training around four fifty private medicine retailers in 3 Kenya endemic districts. The funding total ranged from US$5,000 to US$6,000 per district. The United Nations Children's Fund (UNICEF) and the Global Fund supported implementation costs to Fight AIDS, Tuberculosis, and Malaria [3]. However, high rates of deaths still exist through malaria. According to the World Health Organization (WHO), about 3.4 million malaria cases and 12,000 deaths have been registered in Kenya in 2021 [4]. In sub-Saharan Africa, where 94% of deaths are reported each year, this issue is particularly serious [5]. This condition is predicted to become worse especially in the Coastal and Western regions with the pandemic that has compromised malaria treatment and intervention measures [5]. Malignant/tertian malaria caused by *Plasmodium falciparum* species accounts for over 99% of malaria cases [6].

Although study focus on medication over the counter carried out which revealed that malaria medications over- the-counter (OTC) are often the first point of care for African adults and children. Using the diagnosis system in private drug outlets remains low, leading to overprescribing antimalarials [1].

Research including Machine Learning (ML) techniques with features have been conducted to predict malaria [7], [8], [9]. This procedure involved illumination correction, erythrocyte categorization, feature collecting and classification. However, mortality is still increasing.

Neuro-Fuzzy expert system diagnostic software has also been developed with Microsoft Visual C# (C Sharp) programming language and Microsoft SQL Server 2012 to manage the database [10]. Multiple algorithms were also employed to optimize model performance and classify malaria accuracy [11]. Moreover, some studies focused only in various studies researchers have utilized different numbers of symptoms, for instance, 10 symptoms [12] and 12 symptoms [13].

Despite various malaria diagnosis approaches focusing toward solving the problem, these approaches suffer from a lack of comprehensive data [14]. The literature reveals that previous malaria diagnosis studies have only conducted research employing two inputs, symptoms and non-symptoms.

This proposed study aims to fill this significant gap, by introducing a novel methods combining Six Types of Patient Data Inputs that include Demographic (name, address, date of birth, and contact details), Symptoms, Blood pressure, Heartbeats, Height and Weight, based on ANFIS that can be utilized in healthcare in Kenya to conduct a comprehensive clinical diagnosis of malaria to detect early symptoms accurately and plan appropriate treatment. The definition of Six Types of Patient Data Inputs is presented in Section III(D). To the best of our understanding, previous studies haven't utilized a method combining the Six Types of Patient Data Inputs.

A. Main Contribution

Our main contribution is a novel method, combining Six Patient Data Inputs, which include Demographic, Symptoms, Blood pressure, Heartbeats, Height, and Weight, based on ANFIS to detect malaria accurately. From these Six Patient Data Inputs, 2000 data were gathered that were utilized to produce fuzzy models, fuzzy rules leading to detecting early malaria symptoms. Using data based on the Six Patient Data Inputs leads to higher accuracy and reliability, while using a few symptoms often results in uncertainty and potential misdiagnosis. This study is the first to utilize the novel method combining Six Patient Data Inputs in the field.

The main goal of this research is to design and build an intelligent malaria diagnosis model for early symptom detection using an Adaptive-Network, such as a Neuro-Fuzzy Inference System (ANFIS) with Six Types of Patient Data Inputs. Thus, the study's main objectives are:

1) Identify and extract features based on the Six Types of Patient Data Inputs.

2) Develop state-of-the-art models based on advance techniques such as ANFIS.

3) Train and test the model to measure the performances.

4) Compare findings of the proposed study with the existing findings in the field to clearly show the merit of the proposed method.

Advantages of the new method: significantly help doctors to conduct a comprehensive diagnosis of early malaria symptoms and plan appropriate treatment, improved accuracy of early malaria diagnosis and reduced malaria risks. Increase patients' confidence in early malaria symptoms diagnosis. Using six different data types will enable the implementation of the real-world AI App for early malaria symptoms diagnosis in remote settings.

This study's remaining sections are organized as follows: Section II offers literature review which is approached critically. Section III describes methodology and methods including Data collection and Sources, Six Types of Patient Data Input, ANFIS and Fuzzy rules together with Ethical consideration. Section IV presents the description of experimental procedures, including training and testing. While the study's findings are shown in Section V, the discussion of the results, including contribution of the proposed method, comparisons, limitations and strength are presented in Section VI. The study concludes and provides directions for future research in Section VII.

II. Literature Review

A. Multiple Algorithms: ANN, CNN, ANFIS

First, when making decisions that could affect a patient, practitioners use the information provided by a malaria diagnosis. To detect malaria and predict risk factors, Artificial intelligence (AI) has been employed as a usable tool [15].

Uzun et al., utilized [16] data from 2207 patients which was reduced from the initial dataset of thirty-two criteria samples to fifteen to carry out research on Machine Learning based malaria detection. The research investigated and validated the effectiveness of several algorithms using 15 criteria samples from malaria patients. Following training, ANN achieves the highest *R* (99%) compared to ANFIS (97%), MLR (92%) and Random Forest (68%) respectively [16]. The outcome demonstrated that healthcare systems allocate resources more effectively and make better decisions. However, some of the algorithms have incurred 8%, 11% and 23% error rates which are a high risk. Moreover, due to 15 sample datasets used, the findings may not be broadly applicable, limiting generalizability.

Yang et al. presented [17] a 5-fold cross-validation for two-step CNN models. The model employs an intensity-based iterative Global Minimum Screening technique in the first stage to categorize malaria parasites, and subsequently, a CNN employs a custom CNN to categorize the existence of malaria parasites. The accuracy achieved for this technique is 93.46%. However, the approach suffered high false positives.

Vijayalakshmi et al. proposed [18] a transfer learning method with a classification with 93.13% accuracy to discriminate between illustrations of malaria-diseased cells and healthy cells utilizing the VGG16 model and a support vector machine. However, distinguishing between images of healthy and malaria-affected cells alone could be risky because most malaria is caused by a mosquito bite and goes through various stages before the changes in cells could be detected.

Another study suggested a better dynamic routing method that employs a fully trained capsule network to distinguish between healthy and malaria-infected cells, and the model accuracy was 98.82%. However, similarly, malaria goes through various stages before the changes in cells could be detected [19].

Loddo et al. [20] used the DenseNet-201 neural network to diagnose *Plasmodium falciparum* life stages into four groups and used two different datasets to assess the robustness of the model. The accuracy rate for binary was 97.68%, and the multi-classification accuracy rate was 99.40%. Although the accuracy is high, a wide range of data could be beneficial in accurate diagnosis.

Equally, another study Utilized ML techniques to examine haematological data taken from 2,207 participants in Ghana, such as ANN to identify methods that can reliably distinguish

between severe malaria (SM) and non-malarial infections (nMI) and uncomplicated malaria (UM), employing haematological parameters. To classify UM, nMI, and SM ANN with 3 hidden layers was utilized. The accuracy scores of the multi-classification models ranged from 94% to 98%. Although many machine learning models using traditional features have been developed for malaria classification and decision-making, these models lack generalization ability [21].

To combat malaria, other researchers adapted a different strategy. Santosh and Ramesh [22] conducted research to determine malaria abundances using an ANN with clinical and environmental variables with Big Data on the geographical location of Khammam district, Telangana, India. To increase accuracy in actual practice, their approach made use of a lot of data from various seasons. 81.7% was the highest accuracy attained. To enhance malaria models, more research is necessary to determine their accuracy. Although these variables are required to achieve accurate predictive power, 12% of environmental data and 7% of clinical data were missing. As a result, accurate predictive data is necessary to increase accuracy [22].

The study by Arowolo et al. [23] proposed a combined a novel analysis of variance (ANOVA) with ant colony optimization (ACO) approach as a hybrid feature selection to select relevant genes to minimize the redundancy between genes, using SVM for classification. The results of the experiment based on high-dimensional gene expression data show that ANOVA-ACO can help clinicians make pertinent choices when developing medications and strategies to end human malaria infections. Even so, the strength appears promising. However, to be competent amongst the existing relevant work, the speed of the performance should be provided.

Awotunde et al. [24] also developed a model to diagnose Malaria and Typhoid Fever using a Genetic Algorithm (GA), a Neuro-Fuzzy Inference System (GENFIS). They discovered that the GA module distributes the optimal set of network parameters to the relevant hidden layer nodes. The accuracy of their model was 97.2%. However, there are 2.8% average error rates, which could be because of overfitting.

To improve malaria diagnosis models, Awotunde et al. [25] utilized Support Vector Machine (SVM) algorithms and Adaboost, together with ensemble methods. Chi-square was used to extract redundant or unnecessary features in order to evaluate the model. With data input, the classification accuracy was 97%. The classification accuracy seems high. But the number of features used is too small. Using more features could improve the model.

Based on AI techniques, Datilo et al. [26] reviewed epidemic prediction using Artificial Neural Networks, highlighting the value of precision disease prediction and suitable methods for making malaria predictions using Artificial Neural Networks. They carried out a thorough evaluation of ANNs and found that the training and generalized capacity of ANNs are greatly enhanced when hybrid models are used in conjunction with meta-heuristics in detecting diseases. However, using a small dataset reduces the performance and effectiveness of the model.

Another study by [35] used AI techniques to detect diseases. They made individualized treatment programs, which support medical professionals in making decisions, instead of simply making tasks automatic. Developing technologies that can enhance patient care in various healthcare domains is one of AI's strengths. Data privacy, bias, and the requirement for human expertise are limitations that must be addressed for the ethical and successful application of AI in healthcare.

B. Long Short-Term Memory (LSTM)

A framework for predicting malaria endemicity in specific geographic areas, like Nigeria, was presented in another study. They used satellite and clinical data to train a long short-term memory (LSTM) classifier. The findings show that the LSTM algorithm offers a practical way to identify instances of widespread malaria [27]. The outcome shows improved accuracy. However, there was no indication of the size of data used, and the data is used in the valishowsson strategy [27].

The aforementioned studies examined the application of machine learning techniques and NF rules based on symptoms to create models for diagnosing malaria. However, a combined approach has not been taken into consideration in the current approaches integrating Six Types of Patient Data Inputs that include Demographic, current Symptoms, Blood pressure, Heart beats, Height and Weight, based on ANFIS to more precisely categorize malaria into four potential types. Moreover, the microscopic testing techniques cause a delay at the start of treatment [28]. This is due to a lack of adequate supply for diagnostics. Rapid diagnostic tests (RDTs) and microscopic parasitological testing are required to determine whether prospective patients have malaria parasites.

Despite all these efforts to diagnose malaria, there is still a lack of real-time malaria diagnosis Apps in the remote setting and malaria zones in Kenya [29]. A survey showed that 20% of the health facilities experienced a total absence of diagnostic services. The studies have only focused on symptoms. Ramdzan [8] and Shimizu [9] only focused on detecting risk factors of malaria. Other research only focused on using different numbers of symptoms. Therefore, the previously employed techniques aren't strong enough to tackle the issue robustly.

The previous studies have not employed a combined method integrating six patient data inputs.

To fill this gap, the proposed study addresses this problem by introducing significant methods combining Six Types of Patient Data Inputs that include Demographic, Symptoms, Blood pressure, Heartbeats, Height and Weight, based on ANFIS that can be utilized in healthcare to conduct a comprehensive clinical diagnosis of malaria to detect early symptoms accurately and plan appropriate treatment.

III. Methodology

The new approach employs Intelligent Systems utilizing an Adaptive Network such as a Neuro-Fuzzy Inference System (ANFIS) with integrated Six Types of Patient data Inputs. 2000 data was extracted from a combined Types of Patient data Inputs, which include Demographic, Symptoms, Blood pressure, Heart beats, Height and Weight. The reason for using

this method is not only to extract comprehensive data, but also to use effective techniques to detect malaria effectively. The proposed approach has four functional components that are Data Sources, Six Types of Patient Data Inputs, ANFIS and fuzzy rules. This is illustrated in Fig. 1 and described in detail in Section III.

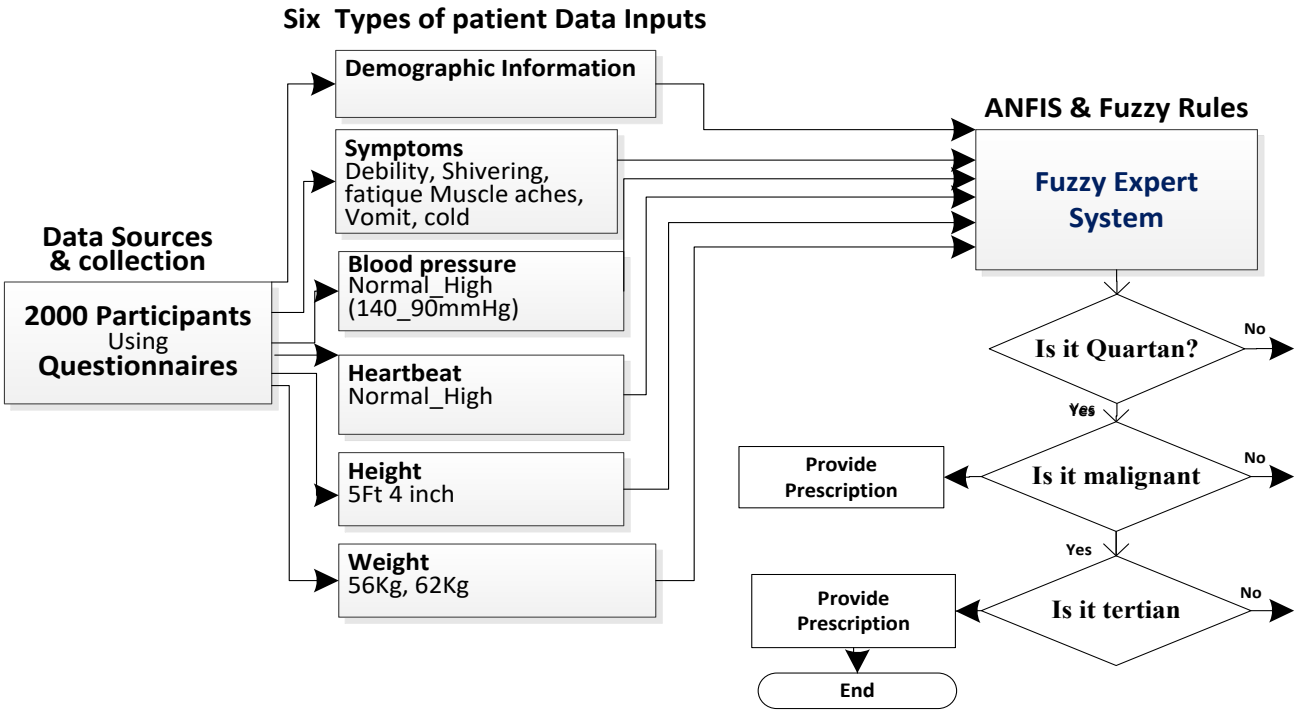

Fig. 1. Intelligent malaria diagnosis architecture.

A. How does the Proposed Approach Differ from the Existing Ones?

The proposed method integrates Six Types of Patient Data Inputs which are Demographic, Symptoms, Blood pressure, Heartbeats, Height and Weight. From these wide-ranging, 2000 data are extracted which are used to generate, fuzzy models, fuzzy rules, to train and test the models. Whereas some studies only used symptoms and non-symptoms. For instance, the work of Bria et al. [12] only used 10-12 malaria symptoms for malaria diagnosis which is too small for generalization, while the study of Uzun et al. [16] had a limited generalization, only used 12 symptoms. Other notable research that explored malaria diagnosis through ML techniques are Santosh and Ramesh deployed clinical and environmental variables. ANNs and big data are used to predict mosquito abundance in the Telangana district of Khammam in India the data sizes are not specified [22]. The average error ranges from 82% to 17% accuracy. The literature reveals that the existing approaches suffer from a lack of comprehensive data [14]. Therefore, the proposed method advances the existing work by offering comprehensive data extracted from 2000 participants based on Symptoms, Blood pressure, Heartbeats, Height and Weight (diverse sources). The model demonstrates significant potential in providing enhanced high accuracy and reliable diagnosis for early malaria symptoms.

B. Data Sources and Data Collection

To diagnose malaria attacks accurately, careful consideration needs to be taken to identify important sources to extract comprehensive data. The study was conducted using questionnaires, which were randomly handed to 2000 malaria patients in five General Hospitals including Kenyatta National Hospital (KNH); Kisumu General Hospital (KGH); Jaramagi Oginga Odinga Hospital (JOOH); Maseno Mission Hospital (MMH) and Siaya Referral Hospital (SRH), which are malaria endemic areas in Kenya. Questionnaire was utilized because the questionnaire questions were designed to capture information that could contribute to malaria parasite diagnosis such as Demographic, Malaria Symptoms, Blood pressure, Heart beats, Height and Weight from patients who formerly and currently confirmed malaria positive from blood Smear. Permission was obtained from Clinical Officers in charge of each healthcare facility and consent sought from patients before data gathering. Each constituency achieved 400 patients' respondents. The study was administered during the period between March and May 2025. The Data from the 2000 patients were encoded and entered in an Excel Sheet, taking 2000 rows and twelve columns. The most common symptoms include vomiting, limpness, diarrhea, loss of appetite, joint pain, dizziness and the most severe symptoms are shortness of breath seizures, loss of consciousness and jaundice. The anonymous data captured are summarized in Table I.

TABLE I. SUMMARY OF DATA GATHERED FROM PATIENTS WHO TESTED MALARIA POSITIVE FROM BLOOD SMEAR

General Hospital	Gender	Age	Education Level	Got Malaria in last 12 Months?	Confirmed Malaria via Blood Smear	Malaria Symptom	Blood Pressure	Heartbeat	Height	Weight
KNH	Man	40-49	Secondary	Yes	Yes	Fever (Q)	High140/90mmHg	60 bpm	5 “6”	54 kg
KNH	Woman	30-39	Secondary	Yes	Yes	Fatigue (Q)	High138/139mmHg	91 bpm	5 “10”	59 kg
KNH	Man	50-59	Secondary	Yes	Yes	Muscle pain	Norm142/91mmHg	71 bpm	5"9"	65 kg
KNH	Man	20-29	Secondary	Yes	Yes	Coma (M)	High140/90mmHg	100 bpm	6”0”	100 kg
KNH	Man	30-39	Secondary	Yes	Yes	Nausea	Low140/90mmHg	61 bpm	5 “6”	58 kg
KGH	Man	30-39	Secondary	Yes	Yes	Headache (Q)	High140/90mmHg	72 bpm	5 “7”	68 kg
KGH	Man	40-49	Secondary	Yes	Yes	Sweating	High141/90mmHg	100 bpm	5 “9”	61 kg
KGH	Man	40-49	Secondary	Yes	Yes	Debility	Norm91/39mmHg	72 bpm	5 “8”	56 kg
KGH	Woman	30-39	Primary	Yes	Yes	Anemia (T)	High142/97mmHg	61 bpm	5 “7”	58 kg
KGH	Man	40-49	Primary	Yes	Yes	Dry lips	High141/90mmHg	101 bpm	5 “7”	59 kg

MMH = Maseno Mission Hospital; SRH = Siaya Referral Hospital

C. Six Types of Patient Data Inputs

A combined Types of patient data inputs from patients refer to clinical details gathered during a patient’s meeting with a health officer, which include Demographic (patient personal details like age, sex, income test results), Symptoms, Blood pressure, Heart beats, Height and Weight. These combined Types of patient data inputs are collected to ensure safety and for patient quality outcomes. The information is kept digitally in a secure record, considered confidential and adhering to legal guidelines. The patient’s demographic significantly relates to sic types of patient data inputs by influencing their type, severity, prevalence of certain conditions, and how healthcare is accessed.

D. Six Types of Patient Data Inputs and Definitions

1) Demographic information: Basic characteristics identifier of a Patient such as their name, address, date of birth, and contact details are made up. Other relevant descriptive information such as ethnicity, gender, marital status, and unique identifiers are also included. Identification of patients, administrative procedures, and the delivery of secure, efficient healthcare services all depend on this information [38].

2) Heartbeat: "Patient heartbeat" refers to the heart rate of a patient, which is defined as the frequency of heart beats per minute and serves as a crucial indicator of their general health. For adults, a normal resting heart rate generally ranges from 60 to 100 beats per minute, but this can be affected by factors like fitness level, stress, medication, and illness [39].

3) Blood pressure: Refers to the force exerted by circulating blood on the walls of blood vessels. The majority of this pressure is generated by the heart as it pumps blood throughout the circulatory system [39].

4) Height: Height measurements are utilized to determine your body mass index (BMI), which serves as an indicator of healthy versus unhealthy weight [40].

5) Weight: "Patient weight" refers to the body mass of a person receiving medical care, recorded in units like kilograms or pounds. This measurement is crucial for various clinical reasons, including accurately calculating medication dosages, assessing and managing nutrition and fluid balance, monitoring patient status, and selecting appropriate medical equipment, like specialized scales for immobile patients. Accurate and regular weight recordings are vital for safe and effective patient care [39].

6) Symptoms: Symptoms are mental features that a patient experiences that may indicate that the patient has a disease or condition. Malaria symptoms are for example, fever, chills,

headaches, sweats, fatigue and more. These constitutes the most important part of our integrated framework, from which 2000 dataset extracted is utilized to develop fuzzy rules, to create fuzzy models, to train and to test the models.

E. Dataset Choice

Choosing data for malaria symptom diagnosis needs careful consideration. The use of 2000 participants enables data extraction based on Six Patient Data inputs. The dataset was chosen because comprehensive (large and diverse) datasets enable high accuracy and reliable diagnosis results, and could also identify complex or severe malaria symptom patterns.

F. ANFIS

The Adaptive Neuro-Fuzzy Inference System (ANFIS) is a type of neural network employed for the purpose of adaptive learning [33]. The algorithm is chosen since it is capable of managing both qualitative and quantitative values and demonstrates resilience against outliers. It has a universal approximation with the ability to use Fuzzy IF...THEN rules while using fuzzy logic to model systems with linguistic terms and neural networks to optimize the fuzzy system's parameters [30]. The system checks individual patient inputs. If malaria symptoms are detected, before a recommendation of blood tests is generated, the system identifies if it is quartan malaria, malignant, or tertian malaria. If no symptoms are identified, the patient is notified, and no further action is undertaken.

ANFIS has the ability to handle and model uncertainty and imprecision inherent in complex, real-world data by combining the symbolic reasoning behind fuzzy logic with the learning abilities of neural networks. This architecture is particularly effective in enabling ANFIS to model complex data and nonlinear relationships while effectively managing six different types of data input uncertainty [31].

G. Fuzzy Rules

An intelligent malaria diagnosis structure has inputs that are represented as x, y, and one output, z. Two fuzzy sets are utilized on behalf of a single input, and a first-order polynomial is used to represent the output. Where x, y and z (symptoms and heartbeat, high blood pressure, weight, height) are linguistic variables, 1A, 2A, 3A (fever, fatigue and muscle-pain) Linguistic values determined by fuzzy sets within the universe of discourse x; 1B, 2B, and 3B represent fuzzy sets within this universe of discourse z(symptoms).

H. Advantages of the Proposed Method

The primary advantages of the suggested approach are, firstly, the results will greatly help doctors to conduct a comprehensive diagnosis of early malaria symptoms and plan appropriate treatment. Second, the approach will improve the accuracy of early malaria diagnosis and reduce malaria risks. Users' confidence will increase in early malaria symptom diagnosis. The use of six different data types will enable the implementation of the real-world Artificial Intelligence App for early malaria symptoms diagnosis in remote settings.

I. Ethical Consideration

The current study is part of a large project "Bringing together researcher from Kenya, Tanzania and the UK to Network and explore factors causing challenges in accessing Healthcare services (especially malaria diagnosis) in rural areas in Kenya and Tanzania", whose ethical approval (Ref/17086) was obtained from the ethics committee within the Computer and Information Science department at Northumbria University. Written informed consents were obtained from each participant before participating in the research. Participants understood that they had the right to withdraw from the study at any time if they chose to do so.

IV. Experimental Procedure

The experiment concerning the intelligent diagnosis of malaria relies on ANFIS, utilizing data for both training and testing sets. The fuzzy system is employed due to its nature as a feature-based fuzzy model that handles uncertain and complex data to represent fuzzy sets and rules. Besides, an ANFIS has the benefit of both a neural network, which has the capability of learning new data, and fuzzy logic, which deals with linguistic values as well as making decisions using fuzzy [If-THEN] rules [31]. 2000 data is used, and the reason for the chosen size is to have a representative sample of the larger population of the community in Siaya County. To create and evaluate the model, a two-fold cross-validation method was deployed because it can handle the conventional data well and helps to avoid overfitting [32]. This method involves splitting data randomly into training sets and testing sets.

A. Training

To enable the training of an intelligent model for malaria diagnosis. Parameters are carefully tuned to find the best set, ensuring high-quality performance using an optimization method. A hybrid learning approach that combines the least-squares method with the gradient descent technique. Initially, the training was carried out by introducing a training set to the input layer of the network once, and the network transmits the input from one layer to another, until it gets to the output layer. There, an error is computed and propagated backward through the network from the output layer to the input layer. The feature model is trained only once using the training set [33].

B. Testing

After training is complete, testing was carried out, presenting a test-set only once to the network's input layer. The neurons transmit the inputs from Layer 1 to each layer until they reach the output layer. The roles of training and testing are reversed so that training is conducted on the test set, while testing is performed on the training set. After training and the test process, the results are achieved, with getting average error. The outputs achieved are discussed in Section VI. [33].

C. Membership Functions

To obtain efficiency, Five Membership Functions (MFs) were assigned as Generalized bell membership (Gbellmf) type, as shown in Fig. 2, using 12 epochs and zero (0) tolerance. The membership functions (MFs) of fuzzy sets are represented as a curve, which delineates how each point within the input space corresponds to a membership value ranging from (0, 100) to (0, 1) [31]. Consequently, the output can fluctuate between (0, 100 and (0, 1). The intelligent malaria diagnosis model membership function map for data contains risk values where 10 = NonSymptom indicates no risk and 100 = Quartan represents

the highest possible risk. 30 = Suspect indicates low risk, while 80 = Malignant being high risk. 50 = Tertian being moderate risk.

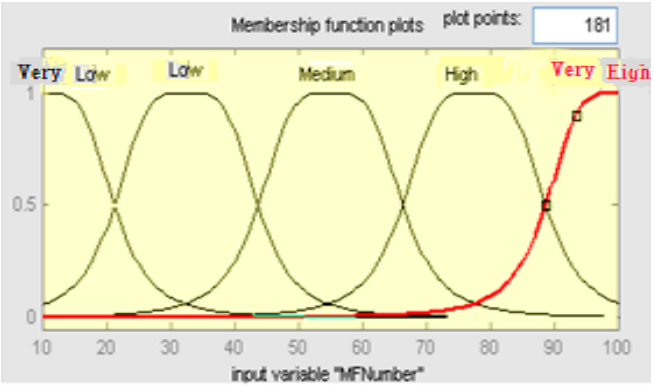

Fig. 2. GBell membership function.

D. Fuzzy Inference Systems and Rules

The intelligent malaria diagnostic model uses an Adaptive Neuro-Fuzzy Inference System learning structure [33]. The FIS is functionally equivalent to fuzzy inference systems. To decompose the parameter set in order to apply the hybrid learning rules, the process goes through the Neural Network and the inference engine decides which is reached by reasoning in connection with the Fuzzy [IF-THEN] rules shown in Fig. 3 and reaches the output layer [33].

Quartan rules

1. If (input is ache-quartan) and (input is argue-quartan) and (input is bronchitis-quartan) and (input is cold-quartan) and (input is bronchitis-quartan) and (input is eruption of herpes-quartan) and … (input is neck_back_pain-quartan) then output is quartan mf1(1)

Malignant rules

2. If (input is teeth-chatter-malignant) and (input is temperature_rises_to_104$_o$-malignant) and (input is temperature_rises_to_105$_o$-malignant) and (input is vomit-malignant) and (input is developmental-malignant) and (input is intestinal_disorders-malignant) and … (input is herpes_around_mouth-malignant) then output is malignant mf2(1)

Tertian rule

3. If (input is abdominal_Pain-tertain) and (input is anemia-tertain) and (input is back-Pain-tertian) and (input is bloody_Stools-tertian) and (input is body-ache-tertian) and (input is chills-tertian) and … (input is hypothermia-tertian) then output is tertian mf3(1)

Suspected rules

4. If (input is irritability-suspected) and (input is jaundice-suspected) and (input is join_Pain-suspected) and (input is kidney_Failure-suspected) and (input is limpness-supected) and (input is loss_of_consciousness-suspected) and … (input is non_prescribed_medication-suspected) then output is suspected mf4(1)

Non_symptom rules

5. If (input is age-non_symptom) and (input is sex-non_symptom) and (input is education-non_symptom) and (input is income-non_symptom) and (input is malaria_History-non_symptom) and (input is location-non_symptom) and … (input is buy_unprescribed_medication-non_sysmtom) then output is non_symptom

Fig. 3. Fuzzy [IF-THEN] rules.

This FIS is a multilayer feedforward network in which each individual neuron carries out a designated function. The related ANFIS architecture is depicted in Fig. 4.

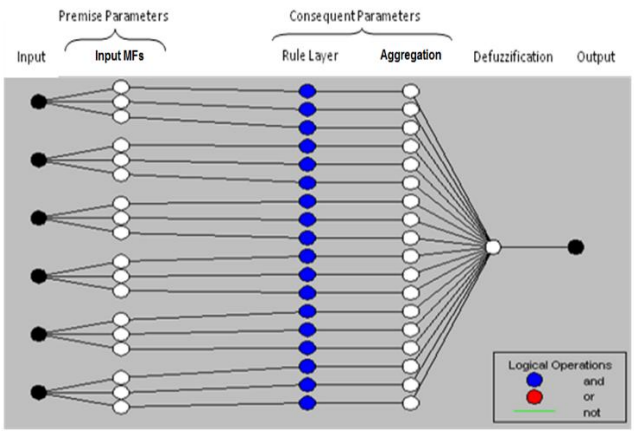

Fig. 4. Fuzzy structure for intelligent malaria diagnosis.

The FIS has six layers which are Layer I - input, Layer II – fuzzification, Layer III – fuzzy rule, Layer IV – normalization, Layer V – defuzzification and Layer VI – crisp output. The learning process takes the form as follows:

1) Layer 1: This is the input. Neurons in Layer I transmit external inputs to Layer II. This is specified as:

$$y_i^{(I)} = x_i^{(I)} \tag{1}$$

where, the input is $y_i^{(1)}$ and the output in layer 1 is $X_i^{(1)}$ [36].

2) Layer II: This is the fuzzification. Neurons in Layer ll perform fuzzification. The Sugneo model fuzzification have a Gbell shape activation function [36]. This is specified as:

$$y_i^{(2)} = \frac{1}{\left[\frac{x_i^{(2)} - ai}{ci}\right]} 2b_i \tag{2}$$

where, the input is $x_i^{(2)}$ and the output is $y_i^{(2)}$ of neuron I Layer II, and a_i b_i and c_i are parameters that control the center width and slope of the bell-shape function of neuron [31].

3) Layer III: This is a rule layer. Every neuron in Layer III matches a single fuzzy rule. A rule neuron receives input from fuzzification and calculates the execution strength of the rule it represents [36]. Thus the output in Layer III is expressed as:

$$y_i^{(3)} = \prod_{j=1}^{k} x_{ji}^{(3)} \tag{3}$$

where, inputs are $x_{ji}^{(3)}$ and $y_i^{(3)}$ are output of rule neuron in Layer III.

4) Layer IV: This is normalization. Every neuron in this layer receives outputs from the rule layer and the normalized execution strength of any given rule is calculated [36]. Therefore, the output of Layer IV is expressed as:

$$y_i^{(4)} = \frac{X_i^{(4)}}{\sum_{i=0}^{u} x_{ji}^{(4)}} = \frac{ui}{\sum_{i=0}^{u} uj} = ui \tag{4}$$

where, the input $x_{ji}^{(4)}$ from neuron j is allocated in Layer III

to Layer IV.

5) Layer V: This is defuzzification. Each neuron in Layer V is connected to the normalization neuron, as well as receives the initial input x_1 and x_2. A neuron defuzzification calculates the value of weight consequent of any given rules [36]. It is specified as:

$$y_i^{(5)} = x_i^{(5)}[k_{i0} + k_{i1}x1 + k_{i2}x2] = u_i[k_{i0} + k_{i1}x1 + k_{i2}x2] \quad (5)$$

In which the input is $x_i^{(5)}$ and the defuzzification output neuron is $y_i^{(5)}$ in Layer V. k_{i0}, k_{i1} and k_{i2} is a set of parameter consequent of rule I [36].

6) Layer VI: This is denoted by a singular neuron sum. The neuron calculates the total output of every defuzzification and produces the overall output y which is specified as [36]:

$$y = \sum_{i=1}^{n} x_i^{(6)} = \sum_{i=1}^{n} u_i\,[k_{i0} + k_{i1}x1 + k_{i2}x2] \quad (6)$$

As demonstrated, the fuzzy structure is in fact functionally equivalent to a first-order Sugeno-fuzzy model [31].

After completion of the training, the model undergoes testing with a separate, unseen 50% test set. The process of training and testing is conducted twice, with roles being reversed; the model is trained on the test set and subsequently tested on the training set. The network processes its input as the weights are modified and transmitted to the subsequent layer, where the output is aggregated, and the sum of squared errors is computed in real-time as end results. The effectiveness of features is evaluated using randomized methods as well as time required to construct models. The level of standard confidence for error is established at 5% across all utilized algorithms, as an average error exceeding 5% is deemed unsuccessful, while an average error below 5% is regarded as successful [33].

V. Results

A. Adaptive Neuro-Fuzzy Inference

The primary aim of the research was to create and implement an intelligent model for diagnosing malaria in endemic areas, utilizing the Adaptive Neuro-Fuzzy Inference System (ANFIS) with six different types of patient data inputs. The performance of the proposed intelligent malaria diagnosis method was assessed through ANFIS, employing 2-fold cross-validation. The training was conducted on the training set, while the model was evaluated on a test set. The roles were switched, with training conducted on a test set and evaluation carried out on a training set [33]. The average test error rate results achieved was 1.68%, as shown in Fig. 5. When the results are expressed as a percentage and rounded to two decimal places, the overall average test error rates are 1.68%. Therefore, the overall average accuracy attained during testing was 98.3%, which is considered outstanding performance [30], [33].

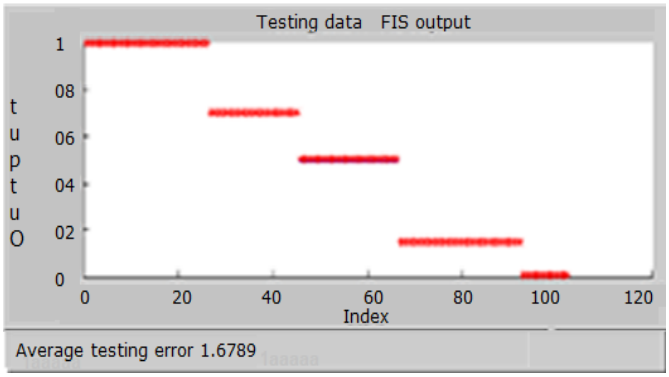

Fig. 5. Average testing error result using ANFIS.

VI. Discussions

The proposed study presents an experimental procedure to diagnose early malaria symptoms. In this study, we deployed ANFIS and a combined Six Types of Patient Data Inputs. Deploying a sample of 2000 patient's data from a combined Six Types of Patient Data Inputs, the finding of the proposed research provides insight information of how well ANFIS can detect early malaria symptoms. ANFIS showed a remarkable level of performance, demonstrating its ability to handle both the training dataset and the test dataset. Deploying a hybrid approach helps to get the best set of parameters tuned to maximize the system performance. The contribution of the proposed study is demonstrated in Section V(A).

A. Contribution

The proposed study contributes to the field by introducing a novel method, combining Six Patient Data inputs. The Six Patient Data inputs are: Demographic, Symptoms, Blood pressure, Heartbeats, Height and Weight based on ANFIS to optimize the model performance. From these Six Patient Data inputs, 2000 data were collected which were utilized to create fuzzy models, fuzzy rules as well as to detect early malaria symptoms. Using data based on the Six Patient Data inputs leads to higher accuracy and reliability, while using few symptoms often results in uncertainty and potential misdiagnosis. This study is the first to utilize the novel method combining Six Patient Data inputs in the field. The experiments based on ANFIS with data have consistently produced the best results. Using the MATLAB toolbox, ANFIS achieved 98.3% accuracy. The novel method achieved best results so far compared to the related cutting-edge in the domain. Overall, the outcomes indicate that the new method, using Six Types of Patient Data Inputs provide enhanced accuracy and deliver optimal performance. Comparative analysis is carried out in Section V(B).

B. Comparison of the Proposed Study with the Existing Related Works

To compare the results of the new approach that achieved 98.3% accuracy with the work of Uzun et al. [16] and the work of Bria et al. [12] which are closest to the proposed study.

The proposed study outperformed the study by Uzun et al. [16] with 1.3% difference, while the study of Bria et al. [12] is outperformed with a difference of 2.3%, as shown in Table II. The proposed model's higher accuracy is supported by its use of six different data types, unlike the other models using 10 to 12 symptoms only [12]. As we can see, the work of Bria et al. [12] used 10 to 12 malaria symptoms for malaria diagnosis which is too small for generalization, while the study of Uzun et al. [16] though had 2700, generalization was limited.

TABLE II. COMPARISONS OF THE PROPOSED STUDY WITH RELATED WORK

Schedule	Algorithms	Data Symptoms	%
Barraclough et al.	ANFIS	2000	98.3
Uzun et al. (2024)	MLR/ANN/ANFIS/R	None	92%, 99%, 97%, 68%
Bria et al. (2021)	LR, SVM, KNN	10-12	84% -86
Santosh & Ramesh (2019)	ANNs	Big data	82%
Morang'a et al. (2020) Uzoka et al. (2016)	ANNs) NF	2207 12	94% None

A direct comparison of our results against previous results is not possible because our method integrates Six Types of Patient Data Inputs, which is wide-ranging, while the existing results only used symptoms and non-symptoms.

Morang'a et al. [21] employed haematological data extracted from 2,207 participants in Ghana, using multi-layer classification and Blood count. ANN scored a range of 94% accuracy. However, these models were restricted to base-learners with fewer features from one source, achieving (82% - 94%) less than the standard confidence of 5% errors, whereas our method achieved 98.3% accuracy, demonstrating that the method used is far better than the related existing methods. Our research findings suggest that the method we proposed accurately diagnoses malaria in real-time and have a high level of performance compared to the reported related results. Other notable research that explored malaria diagnosis through ML techniques are as follows: Santosh and Ramesh deployed [22] clinical and environmental variables with big data using ANNs for mosquito abundance prediction in the geographical location of Khammam district, Telangana, in India. The average results range from 82% to 17% accuracy. The big data used is not specifically for malaria symptoms.

C. Strengths and Limitations

In the process of experimenting with different numbers of hidden neurons, the experiment indicated that the number of neurons in the hidden layers affects the speed of training the network in the method, achieving a time to build the model in the range of 0.01 to 0.006 seconds [34]. Complex patterns cannot be identified by a limited number of hidden neurons. However, numerous such patterns can significantly increase the load on the computational domain. As the quantity of hidden neurons increases, so does the network's capacity to identify existing patterns. However, if the quantity of hidden neurons is excessively high, the network may merely memorize all training examples. This could hinder its ability to generalize or generate accurate outputs when faced with unseen data [33].

Conversely, we utilized the capabilities of algorithms through the application of fuzzy rules. The models developed with ANFIS demonstrate greater reliability and sophistication in classifying instances from both the training and testing sets through two-fold cross-validation.

VII. CONCLUSION

We have described the proposed method using a combined Six Types of Patient Data Inputs and Adaptive-Network-based Neuro-Fuzzy Inference System. By employing a hybrid approach using parameter tuning with a combined Six Types of Patient Data, ANFIS can refine the given rules to describe the system's input and output. The experimental findings indicated that the proposed approach is proficient in diagnosing malaria symptoms more accurately and reducing malaria burden. Recognizing that elevated scores may result from utilizing limited data, which indicates that the dataset comprises only 1 to 10 samples. A comparatively limited dataset may adversely impact a model's performance because of overfitting, a phenomenon where a model excels with the training data yet struggles with new, independent data. A viable approach to addressing this issue is the implementation of cross-validation. To solve the small sample problem, the proposed method was evaluated based on ANFIS, using 2000 data extracted from Six Types of Patient Data inputs selected with InfoGainAttributeEval and Ranker. Two-fold cross-validation was employed and ANFIS demonstrated the merit of the new method. The results revealed that the data have a strong correlation with classes. The experimental outcome for the new method was 98.3%.

The main contribution: This study presents a novel method, combining Six Patient Data Inputs that include Symptoms, Blood pressure, Heartbeats, Height and Weight, using ANFIS to detect malaria accurately. The results demonstrate that a combined method using Six Types of Patient Data Inputs can accurately classify malaria symptoms in a matter of seconds and demonstrate superior performance when compared to the results reported in the field.

The significant finding is that the new model has a higher accuracy, supported by using six different data types, which is different to other models that used 10 – 12 symptoms/features. Therefore, this study fills the gap by providing diverse six data types that can be used in the field to diagnose malaria.

The finding will potentially enable doctors to conduct a comprehensive diagnosis of early malaria symptoms and plan appropriate treatment. It will help the remote community user to reduce malaria risks by detecting early malaria symptoms.

The finding will lead to a fully developed real-world application vigorously tested and validated to diagnose malaria symptoms for remote settings.

A. Future Work

Next step is to develop a mobile-based application designed for the early detection of malaria, suitable for use in rural areas. Electricity and computers are scarce in the remote settings in Kenya, while mobile devices are accessible by most of the population using designated shopping centers to charge the mobile devices to be usable. Therefore, this method will allow malaria diagnosis to be accessible in the diverse community.

FUNDING

There was no funding provided to conduct this research.

CONFLICT OF INTERESTS

There is no conflict of interest to declare.

ACKNOWLEDGMENT

We would like to thank the Global Challenges Networking and Collaboration team, the Maseno University, Dodoma University and Northumbria University, the Ministry of Health in Kenya and Tanzania, the general hospitals and Clinical officers for providing great support, and enabling us to undertake the study.

Latent-Topology Graph State-Space Model (LT-GSSM) for Robust Traffic Fore-Casting

Selma Kerdous
Department of Computer Science and Engineering, University of Quebec at Outaouais, Canada

***Abstract*—Accurate traffic forecasting remains challenging when sensor data are noisy, incomplete, or non-stationary. Recent advances in spatio-temporal learning have combined Graph Neural Networks (GNNs) with recurrent, convolutional, or attention mechanisms to capture spatio-temporal dependencies. However, most existing approaches remain largely deterministic and rely on fixed or pre-learned adjacency matrices, limiting their adaptability when network structures evolve or sensor reliability varies. Some methods further stack multiple adjacency matrices to represent complex spatial relations, yet still lack explicit mechanisms to model uncertainty, resulting in reduced robustness under degraded data conditions. This work introduces the Latent Topology Graph State-Space Model (LT-GSSM), a probabilistic framework designed to enhance robustness and adaptability in traffic forecasting. LT-GSSM represents the road network as a latent dynamic graph whose structure evolves over-time through dynamic adjacency learning based on past hidden states and observations, enabling the model to capture evolving spatial correlations such as congestion propagation. Temporal dependencies are modelled by a nonlinear state-space function implemented with a Temporal Convolutional Network (TCN), which captures long-range temporal patterns without recurrence. The probabilistic state-space formulation explicitly represents sensor noise and handles missing data through probabilistic estimation inspired by Kalman filtering. By jointly integrating dynamic graph learning, explicit noise modelling, and nonlinear temporal transitions, LT-GSSM achieves greater stability and resilience to data uncertainty. Experiments on SUMO simulations and real-world PeMS datasets show that LT-GSSM consistently outperforms static and adaptive-graph models, providing a strong foundation for robust spatio-temporal forecasting under uncertain conditions.**

Keywords*—Traffic forecasting; graph neural networks; state-space models; latent topology; dynamic adjacency learning; spatio-temporal modeling; noise and missing data robustness; probabilistic modeling

I. Introduction

Despite major advances in artificial intelligence, spatio-temporal learning remains challenging due to complex spatial dependencies, dynamic temporal patterns, and inherent data uncertainty. These difficulties are particularly evident in traffic forecasting, where large-scale sensor data are often noisy, incomplete, and non-stationary [1].

Traditional prediction models perform well under ideal conditions but lack explicit mechanisms to handle noise, missing data, or uncertainty, leading to poor stability in real deployments. Moreover, traffic networks are non-Euclidean, governed by road connectivity rather than distance [2], and their correlations evolve dynamically with congestion, incidents, or weather [3,4].

Recent advances in spatio-temporal graph architectures—such as diffusion-based DCRNN [5], recurrent T-GCN [6], and attention-driven ASTGCN or ST-Transformer [7,8]—have improved prediction accuracy However, deterministic graph adaptation remains fundamentally limited under noisy or incomplete observations, as it cannot represent the structural uncertainty induced by sensor degradation or missing data.

To address these limitations, we propose the Latent Topology Graph State-Space Model (LT-GSSM), a probabilistic framework for robust and adaptive traffic forecasting. Unlike conventional adaptive GNNs (e.g., AGCRN, DGCRN), where adjacency updates depend on static node embeddings or deterministic functions, LT-GSSM learns a latent dynamic graph, where the adjacency is treated as a state-conditioned latent variable rather than a deterministic function of node embeddings. This enables joint modeling of temporal and structural uncertainty, resulting in a self-evolving spatio-temporal representation that better reflects real-world non-stationarity.

The adjacency matrix A_t evolves from past hidden states and observations, allowing the model to capture time-varying spatial correlations such as congestion propagation or structural shifts. Temporal dependencies are modeled by a nonlinear state-space transition using a Temporal Convolutional Network (TCN), which captures long-range patterns without recurrence. The probabilistic state-space formulation explicitly represents process and observation noise, enabling robust estimation under sensor degradation or missing data—an approach inspired by Kalman filtering.

The main contributions of this work are as follows:

- A unified probabilistic graph state-space formulation, in which both temporal dynamics and graph structure are modelled within a single latent state-space framework, rather than treating adaptive graphs and temporal uncertainty as separate components.
- State-conditioned latent topology modelling, where the adjacency matrix is inferred as a latent random variable conditioned on hidden states, instead of being deterministically parameterized from node embeddings as in existing adaptive GNNs.
- Explicit modeling of process and observation uncertainty within the state-space dynamics, enabling robust spatio-

temporal forecasting under sensor noise and missing data, without relying on deterministic graph updates.

The remainder of this paper is organized as follows: Section II reviews related work on spatio-temporal and probabilistic models; Section III describes the LT-GSSM methodology; Section IV presents experimental results and robustness analyses; Discussion is given in Section V and Section VI concludes with future research directions.

II. Related Works

Traffic forecasting is a complex spatio-temporal task shaped by irregular topologies, non-stationary dynamics, and noisy sensor conditions.

Classical time-series models such as ARIMA and VAR [7,8] capture temporal patterns but ignore spatial correlations among sensors. Early machine-learning methods [9] improved flexibility but struggled with high-dimensional dependencies across the road network.

Deep learning advanced the field through Recurrent Neural Networks (RNNs) such as LSTM and GRU [10,11], which model temporal sequences but process each sensor independently. Convolutional Neural Networks (CNNs) [12] extended modeling to spatial grids, yet their Euclidean structure limits generalization to real road networks [13].

To overcome these limitations, Graph Neural Networks (GNNs) [14] model traffic as a graph, where nodes represent sensors and edges capture road connectivity. Hybrid spatio-temporal architectures such as DCRNN, T-GCN, and attention-based models like ASTGCN [15] and ST-Transformer [16] jointly learn spatial and temporal dependencies. While accurate, these models assume fixed or pre-learned adjacency matrices, neglecting dynamic spatial relationships that vary with congestion, incidents, or weather.

Recent advances introduced adaptive and dynamic graph learning, including AGCRN [17], DGCRN [18], and RT-GCN [19], which update adjacency matrices using learned node embeddings or Gaussian-based convolutions. These designs improve flexibility but remain deterministic, failing to model uncertainty or stochastic graph evolution explicitly.

Parallel progress in probabilistic state-space models (SSMs) such as KalmanNet [20], Deep Kalman Filters [21], and Neural State-Space Models [22] has reintroduced uncertainty estimation and latent dynamics into deep learning. However, these frameworks are typically temporal only, lacking explicit graph reasoning. Attempts to combine GNNs with probabilistic methods, such as Probabilistic GNNs [23] and Graph Variational Filters [24], remain computationally costly and seldom applied to large-scale traffic networks.

In summary, prior models either:

- Learn dynamic graphs without probabilistic treatment of noise and uncertainty, or
- Apply probabilistic state-space reasoning without spatial modelling.

This gap motivates our Latent Topology Graph State-Space Model (LT-GSSM), a unified probabilistic framework that jointly models time-varying graph topology and temporal dynamics. By treating the adjacency A_t as a latent variable evolving from hidden states and observations, LT-GSSM captures both structural and stochastic uncertainty, achieving robust forecasting under noisy, incomplete, and dynamically changing conditions.

III. Methodology

A. Data Simulation and Preparation

A key element of our methodology is the use of both synthetic and real-world datasets to assess robustness. Real data often suffers from partial sensor coverage and measurement noise, whereas synthetic data generated with SUMO (Simulation of Urban Mobility) [24] allows full control over network coverage, traffic conditions, and injected noise. This controlled environment enables systematic evaluation of our GSSM under diverse and challenging scenarios.

1) Synthetic dataset (SUMO): We generated a two-month traffic dataset using SUMO for the Outaouais region near Ottawa (Fig. 1), based on real road networks extracted from OpenStreetMap. Traffic flows were dynamically managed through TraCI (Traffic Control Interface) [25] to emulate realistic conditions such as peak-hour congestion and weekend traffic reduction. Vehicle counts were aggregated into 5-minute intervals, following common benchmarking practices [26, 27].

The chosen duration aligns with established datasets such as METR-LA and PEMS-BAY [14, 15], which span 2–4 months. This ensures a balance between temporal coverage and computational efficiency, while remaining comparable to standard baselines. To assess robustness, we generated several perturbed versions of the SUMO dataset:

- Gaussian noise injected at 5–30 % levels to simulate sensor errors.
- Reduced sensor coverage through three controlled scenarios:
  - Sensors limited to main roads,
  - Random removal of 20 % of sensors, and
  - Random removal of 50 % of sensors.

These perturbations make it possible to study the model's resilience to measurement uncertainty and coverage sparsity, establishing SUMO as an effective robustness benchmark.

2) Validation of realism: To validate the realism of our synthetic dataset, we compared key traffic patterns with re-al-world datasets such as PEMS08 and UTD19 [28]. Despite differences in absolute magnitudes, our dataset reproduces essential traffic behaviors observed in real-world da-ta, including:

- morning and evening peak-hour congestion,
- sharp reductions in weekend traffic, and
- daily distribution patterns. These similarities, illustrated in Fig. 2 and Fig. 3, confirm that SUMO-based data capture fundamental traffic dynamics.

(a) Selected road network.

(b) Traffic flow visualization

Fig. 1. Road network and traffic flow visualization: (a) Selected road network, (b)Traffic flow visualization.

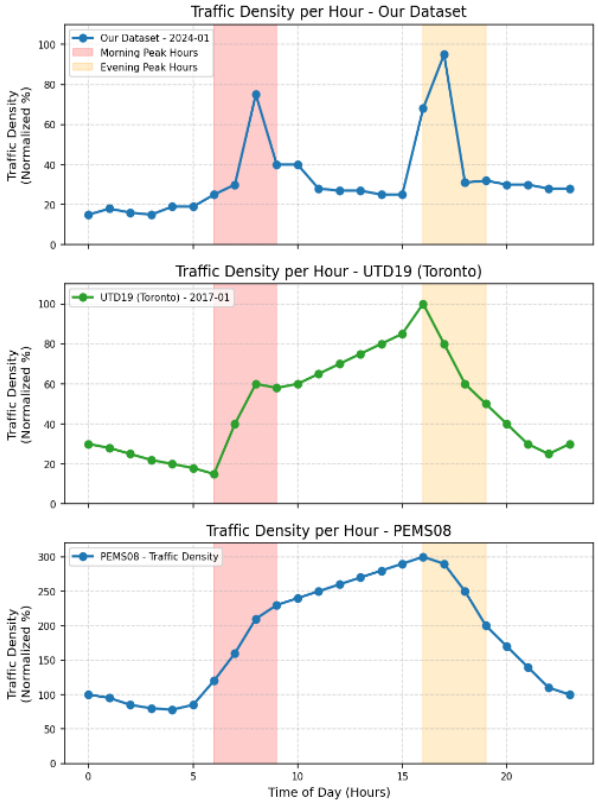

Fig. 2. Comparison of hourly traffic density trends: our dataset vs. Real-world datasets.

This SUMO-based dataset thus provides a reliable testbed for assessing the performance and robustness of GSSM under controlled scenarios of noise and sensor sparsity, complementing evaluations on real-world datasets.

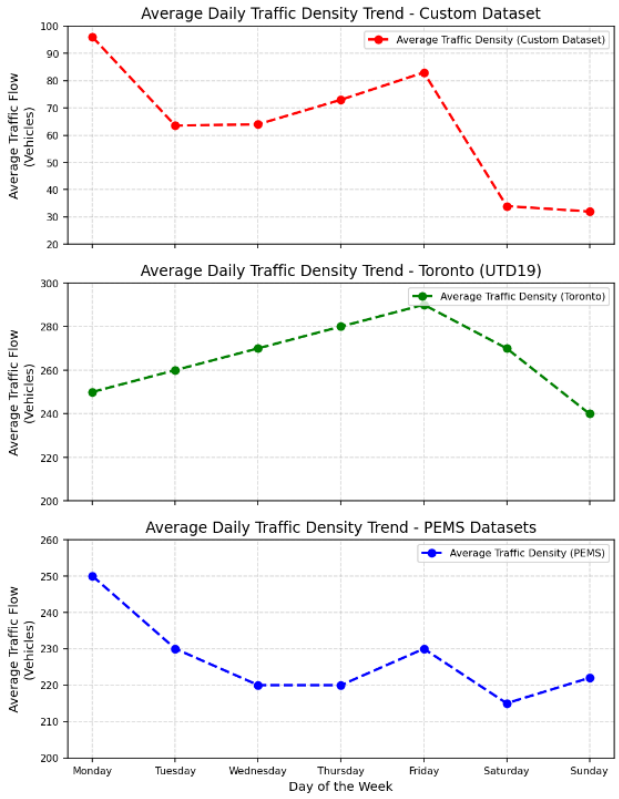

Fig. 3. Weekend traffic density comparison: our dataset vs. Real-world datasets.

B. Spatio-Temporal Data Modeling and Representation

To capture spatio-temporal dependencies in traffic data, we represent all datasets as three-dimensional tensors $X \in \mathbb{R}(T \times E \times V)$, where T denotes the number of time steps (e.g., 5-minute intervals), E the number of road segments or sensors, and V the set of traffic variables such as vehicle density and average speed. This tensor format enables the joint modeling of temporal dynamics, spatial interactions, and multivariate dependencies, and is well-suited for graph-based neural architectures [29, 30].

Complementing this tensor structure, we construct an initial spatial adjacency matrix A_0 to encode the physical connectivity between road segments. This matrix serves as a topological prior — it provides an initial structural representation of the network, which will later be refined dynamically during model training based on learned latent representations. Thus, while A_0 defines the initial spatial configuration, the model does not assume a fixed topology, allowing subsequent updates to better capture evolving spatio-temporal correlations. The method used for constructing A_0 differs depends on the dataset:

- SUMO (Synthetic Data): Since the simulated Outaouais network is relatively small and geographically localized, distances between connected roads are short and highly heterogeneous. To preserve strong locality while avoiding dense, fully connected graphs, we define adjacency entries inversely proportional to the physical distances between connected segments. This choice ensures that immediate neighbors exert stronger influence, reflecting realistic propagation of congestion

within a compact road network. This ensures that spatial relationships reflect real-world topology rather than mere Euclidean proximity [31].

Our adjacency matrix has the following structure:

$$A_0 = \begin{array}{c|cccc} & \text{edge}_1 & \text{edge}_2 & \cdots & \text{edge}_N \\ \text{edge}_1 & 0 & \frac{1}{d_{1,2}} & \cdots & \frac{1}{d_{1,N}} \\ \text{edge}_2 & \frac{1}{d_{2,1}} & 0 & \cdots & \frac{1}{d_{2,N}} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \text{edge}_N & \frac{1}{d_{N,1}} & \frac{1}{d_{N,2}} & \cdots & 0 \end{array}$$

- PEMS Datasets These datasets cover larger and more heterogeneous urban areas with complex traffic flows. To model smooth spatial dependencies while avoiding overly dense connections, we adopt a Gaussian kernel approach [14, 15], computing adjacency as:

$$A_{ij} = \exp\left(-\left(\frac{d_{ij}}{\sigma}\right)^2\right) \quad (1)$$

where, d_{ij} is the physical distance between sensors i and j, and σ is set to 1000 meters. This distinction reflects the different scales and characteristics of the networks: SUMO enables precise control and sparse adjacency, whereas PEMS requires soft, distance-based weighting to capture complex spatial patterns without excessive graph density. This adjacency matrix serves as an initial structural prior reflecting geographic connectivity. During LT-GSSM training, this matrix evolves into a latent, data-driven adjacency A_t that adapts to changing spatial correlations and temporal patterns in traffic dynamics.

C. Hybrid Graph–State–Space Model with Latent Topology (LT-GSSM)

The main innovation of this work is the integration of a latent, dynamically evolving graph topology within a state–space framework—a dimension rarely addressed in spatio-temporal modeling.

Unlike prior adaptive GNNs such as AGCRN [17] and DGCRN [18], which learn static or semi-static adjacency matrices, the proposed LT-GSSM continuously updates its graph structure during both training and inference.

The model begins with a static prior A_0, derived from spatial proximity (e.g., inverse distance or Gaussian similarity). As learning progresses, the adjacency matrix A_t is inferred from the previous hidden state h_{t-1}, coupling spatial evolution with temporal reasoning.

Unlike adaptive GNNs such as AGCRN or DGCRN, where adjacency updates are deterministic functions of node embeddings, LT-GSSM treats topology evolution as part of the latent state dynamics under uncertainty.

At each time step, LT-GSSM performs four operations:

- Latent topology inference — infers A_t from h_{t-1};
- Spatial feature extraction — applies GCN using A_t and input X_t;
- Temporal modeling — updates h_t via a Temporal Convolutional Network (TCN).
- Topology update — refines A_{t+1} using the new latent state.

This feedback loop makes the graph self-evolving, allowing spatial dependencies to adapt dynamically to non-stationary or uncertain conditions. By linking latent state evolution to graph adaptation, LT-GSSM (Fig. 4) jointly models spatial, temporal, and structural uncertainty, achieving a robust and adaptive representation for real-world spatio-temporal forecasting.

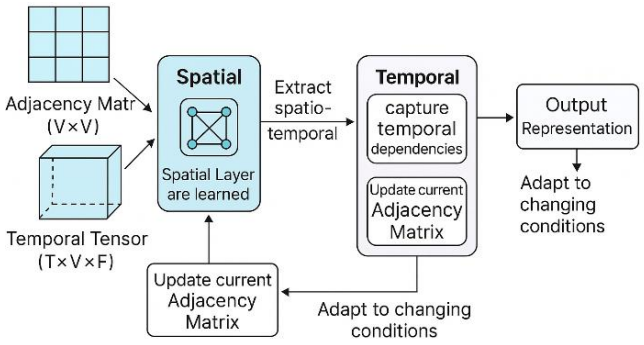

Fig. 4. Overview of LT-GSSM architecture.

1) Temporal layer — state-space model and uncertainty management: The LT-GSSM adopts a probabilistic state–space formulation in which latent states evolve under dynamic graph structures and stochastic perturbations. This allows the model to jointly capture temporal dependencies and uncertainty due to sensor noise, missing data, or non-stationary traffic. Two noise sources are modeled: transition uncertainty (latent fluctuations in dynamics) and observation uncertainty (measurement errors and delays).

In a classical linear SSM:

$$h_t = Ah_{t-1} + Bx_t + w_t, y_t = Hh_t + v_t \quad (2)$$

where, w_t and v_t denote Gaussian process and observation noise. To handle nonlinear and time-varying dynamics, the LT-GSSM replaces fixed matrices with a Temporal Convolutional Network (TCN):

$$h_t = \text{TCN}(Z_{1:t}) + w_t, w_t \sim \mathcal{N}(0, \sigma_t^2 I) \quad (3)$$

The TCN serves as the nonlinear transition function, capturing long-range temporal dependencies without recurrence while preserving probabilistic uncertainty through w_t.

2) Integration with dynamic graph topology: Temporal evolution is explicitly coupled with a time-varying adjacency. From the previous latent state, node embeddings are obtained via a learnable projection:

$$E_t = \phi_E(h_{t-1}), E_t \in \mathbb{R}^{V \times d} \quad (4)$$

Pairwise similarities define a latent affinity matrix:

$$S_t = \frac{E_t E_t^T}{\sqrt{d}} \quad (5)$$

which is row-normalized to yield the dynamic adjacency:

$$A_t = \text{softmax}_{\rho\omega}(S_t) \quad (6)$$

This attention-like normalization ensures each row forms a probability distribution over neighbors, making the graph context-dependent rather than fixed. The updated A_t guides the spatial layer, and the resulting latent state h_t generates A_{t+1}, creating a feedback loop where topology and dynamics co-evolve.

3) Graph Convolutional Network (GCN): At each step, the GCN extracts spatial dependencies from X_t using the dynamic A_t:

$$Z_t = \widetilde{D}_t^{-1/2} \tilde{A}_t \widetilde{D}_t^{-1/2} X_t W_{\text{GCN}} \quad (7)$$

where $\tilde{A}_t = A_t + I_V$ adds self-connections, $\widetilde{D}_t$ is the degree matrix, and W_{GCN} are learnable weights. A normalization layer stabilizes training, producing spatially filtered features Z_t that encode latent correlations among sensors.

4) Unified spatio-temporal formulation: The LT-GSSM integrates both modules within a unified probabilistic transition:

$$h_t = TCN(GCN(X_t, A_t)) + w_t, w_t \sim \mathcal{N}(0, \sigma_t^2 I) \quad (8)$$

and the observation equation:

$$\hat{y}_t = Hh_t + v_t, v_t \sim \mathcal{N}(0, \tau_t^2 I) \quad (10)$$

This formulation fuses dynamic spatial reasoning and nonlinear temporal modeling while explicitly quantifying uncertainty, yielding a robust framework for spatio-temporal forecasting under noisy and evolving conditions.

IV. Results

A. Dataset Summary

We evaluated the proposed LT-GSSM and all baseline models on both synthetic (SUMO) and real-world (PeMS) datasets, which differ in scale, variability, and network complexity.

The SUMO dataset provides a controlled environment to systematically assess robustness to noise and sensor sparsity, while PeMS datasets reflect real-world traffic dynamics across large urban regions. This dual setup ensures that robust trends observed in simulation can be validated under realistic, heterogeneous conditions.

All datasets span 2–4 months at 5-minute intervals, with traffic flow as the key variable. Table I summarizes the main characteristics of the synthetic (SUMO) and real-world (PeMS) datasets used in this study, including network size, temporal resolution, and observation period.

TABLE I. Summary of Datasets Used in This Study

Dataset	Nodes	Time Steps	Period
PeMSD03	358	26,208	09/2018–11/2018
PeMSD04	307	16,992	01/2018–02/2018
PeMSD07	883	28,224	05/2017–08/2017
PeMSD08	170	17,856	07/2016–08/2016
SUMO	127	16,992	Simulated (2 months)

B. Model Selection and Architectural Variants

We compared LT-GSSM against a broad spectrum of spatio-temporal architectures, ensuring fair and representative evaluation:

- Classical temporal baselines: ARIMA, VAR, and BiLSTM.
- Hybrid sequential models: LSTM–CNN, LSTM–GCN (T-GCN), and GRU-based variants.
- Convolutional models: 3D CNNs capturing local spatio-temporal dependencies.
- Attention and transformer architectures: ST-Transformer, attention-based GCNs.
- Diffusion and robustness models: DCRNN and RT-GCN, integrating diffusion or Gaussian convolutions for stability.
- Adaptive graph model: AGCRN as a dynamic-graph baseline using learnable node embeddings.
- Proposed model: LT-GSSM introduces a latent, probabilistic topology derived from hidden states, allowing state-driven graph evolution rather than deterministic embedding updates.

All baselines were re-implemented according to their original papers, with minimal adaptations for uniform preprocessing and input size. This guarantees that performance differences stem from model design, not implementation bias.

C. Experimental Framework and Hyperparameter Sensitivity

All models were trained under identical preprocessing, input windows (10 time steps), and forecast horizons (10 time steps, ≈50 minutes) to ensure fair comparison. Hyperparameters for each baseline—such as hidden dimensions, learning rates, and kernel sizes—were initialized following their original publications and fine-tuned within reported ranges. The LT-GSSM used a hidden size of 64–128, learning rate 0.0005–0.005, and learnable noise parameters to capture both process and observation uncertainty. This consistent setup guarantees that observed performance differences reflect architectural robustness rather than arbitrary tuning.

The following experimental settings and sensitivity analyses were considered to ensure fair comparison and to assess the robustness of LT-GSSM:

- We adopted a forecasting horizon of 10 time steps ($\approx$ 50 minutes), a common setting in prior traffic studies [32 – 35].
- A hyperparameter sensitivity analysis was conducted exclusively on LT-GSSM, focusing on the hidden state dimension and the learnable noise parameter, as both directly affect model capacity and robustness.
- Hidden dimensions from 64 to 128 yielded the most stable results: smaller sizes caused underfitting, whereas larger ones amplified noise and led to overfitting. For the noise parameter, learnable variance consistently converged near $\sigma^2 \approx 0.2$, outperforming fixed settings.

- Low fixed values made the model too rigid, while high ones introduced instability. The adaptive formulation improved convergence and reduced RMSE by about 1–2 %, confirming that dynamic noise learning enhances robustness under noisy or incomplete data.

Fig. 5 summarizes these trends, showing steady performance for hidden sizes 64–128 and optimal stability when the learnable noise variance converges around 0.2.

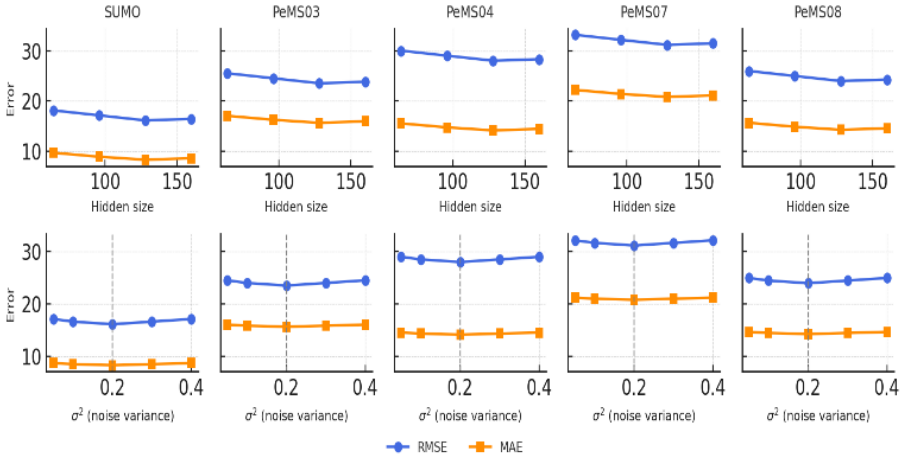

Fig. 5. Sensitivity of LT-GSSM to hidden state dimension (top) and noise variance σ^2 (bottom) across five datasets.

D. Baseline Performance Comparison

Table II reports the average results over seven runs with different random seeds. Variance remained below 2 %, confirming the stability and reproducibility of all experiments, and paired t-tests showed that LT-GSSM's improvements are statistically significant ($p < 0.05$).

Across both SUMO and PeMS datasets, LT-GSSM consistently achieves the lowest error among all models. Compared to classical temporal baselines (ARIMA, VAR), it reduces RMSE by 35–40 % (≈ 5.8 points on SUMO, ≈ 6.2 on PeMSD04). While recurrent models like BiLSTM (avg RMSE ≈ 22.1) perform better, they remain limited by the absence of spatial modeling. Hybrid spatio-temporal models (LSTM-GCN, GCN-GRU) further cut RMSE by ≈ 20 % on average, confirming the benefit of explicit spatial reasoning. 3D-CNN and LSTM-CNN improve temporal baselines but generalize poorly on irregular networks. Attention-based models show mixed behavior: ST-Transformer performs well on large datasets but underutilizes short input windows, while Attention-GCN offers only modest gains. Robust baselines like RT-GCN and AGCRN deliver strong accuracy under normal conditions but slightly trail LT-GSSM, especially on SUMO and PeMS08.

Overall, LT-GSSM's integration of a probabilistic state-space formulation with dynamic latent topology learning yields the best accuracy and stability across all settings, outperforming recent robust graph models while remaining computationally efficient. This establishes LT-GSSM as a strong benchmark for reliable spatio-temporal forecasting under noisy or incomplete data.

TABLE II. SUMMARY OF BASELINE MODELS AND EXPERIMENTAL

Model	SUMO RMSE	SUMO MAE	PeMS03 RMSE	PeMS03 MAE	PeMS04 RMSE	PeMS04 MAE	PeMS07 RMSE	PeMS07 MAE	PeMS08 RMSE	PeMS08 MAE
ARIMA	35.23	22.57	46.80	31.26	45.32	31.42	50.98	35.16	40.32	29.64

E. Ablation Study

To assess the contribution of each module within LT-GSSM, four ablation variants were evaluated: 1) a state-space only configuration (without GCN), 2) a classical SSM-GCN using linear temporal transitions instead of a TCN, 3) a noise-free variant without explicit process and observation noise, and 4) a comparison between static and dynamic adjacency learning. Fig. 6 summarizes the results across all datasets.

The SSM-only configuration already achieved competitive accuracy, outperforming purely temporal models such as LSTM and GRU on several datasets. This confirms that the recursive state-space formulation and process noise terms provide strong temporal modeling capacity, even without explicit spatial reasoning.

Replacing the nonlinear TCN with a linear update led to a consistent increase in error (≈ 20% higher RMSE on average), indicating that nonlinear temporal transitions are crucial for capturing complex latent traffic dynamics. Similarly, removing explicit noise modeling degraded robustness under noisy or incomplete conditions, with the full LT-GSSM achieving up to 25% lower RMSE compared to the deterministic version.

Finally, dynamic adjacency learning further improved performance relative to static topologies, reducing RMSE by approximately 10% across datasets. This confirms that allowing the graph structure to evolve with latent state dynamics better captures non-stationary spatial correlations such as congestion propagation or sensor drift.

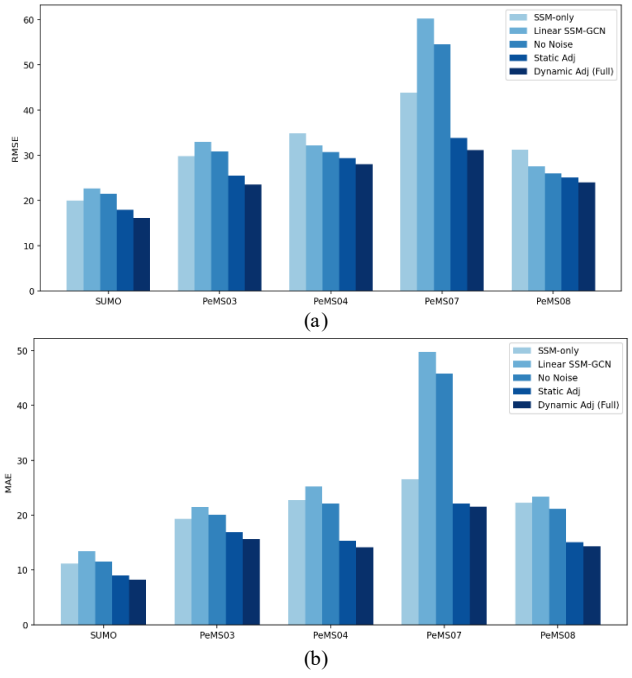

Fig. 6. RMSE and MAE comparison of LT-GSSM ablation variants across SUMO and PeMS datasets.

Fig. 6 and Fig. 7 illustrate these trends: Fig. 6 shows RMSE and MAE across ablation variants, while Fig. 7 visualizes relative performance gains over the static baseline. Overall, each component—state-space recursion, nonlinear transition, explicit noise modeling, and dynamic topology—contributes significantly to the robustness and accuracy of LT-GSSM, with the complete model consistently achieving the best balance across datasets.

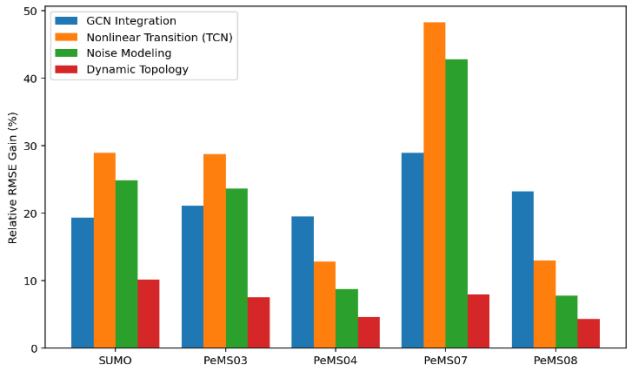

Fig. 7. Relative performance gain (%) of LT-GSSM components compared to the static baseline.

V. Discussion

A. Effect of Sensor Placement and Noise on Spatiotemporal Prediction

We used the custom SUMO network to evaluate how sensor placement and noise affect forecasting robustness. Two practical scenarios were simulated: 1) prioritizing sensors on major arterial roads, and 2) reducing overall sensor coverage to 50 % and 20 %.

Concentrating sensors along main corridors improved accuracy by capturing structured, correlated traffic flows, whereas reduced coverage increased errors across all models. Nevertheless, LT-GSSM remained the most stable, confirming that its dynamic adjacency learning effectively adapts spatial correlations even when observations are sparse.

By updating its graph topology from latent state representations, the model can infer missing spatial dependencies, rather than relying solely on static connectivity. Comparable resilience was observed in RT-GCN and AGCRN, yet LT-GSSM showed the smallest degradation under both sensor loss and noisy data, demonstrating the strength of its joint spatio-temporal uncertainty modeling.

Fig. 8 illustrates the impact of sensor coverage on prediction accuracy.

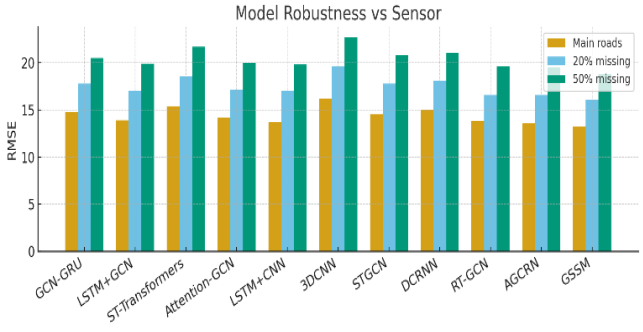

Fig. 8. Impact of sensor coverage on the performance of spatiotemporal prediction models.

B. Robustness Under Gaussian Noise

Beyond spatial sparsity, robustness was also tested under Gaussian sensor noise injected into traffic flow data at three levels (5 %, 15 %, 30 %). Noise was applied selectively to subsets of sensors, simulating real detector failures. As expected, higher noise levels increased errors for all models (Table III), but LT-GSSM exhibited only a ≈ 2–7 % RMSE increase at 30 % noise—significantly lower than competing architectures.

This resilience stems from its explicit uncertainty modeling: the transition function captures latent dynamic fluctuations, while the observation model accounts for measurement errors, allowing LT-GSSM to maintain stable performance even under severe data corruption.

TABLE III. IMPACT OF GAUSSIAN NOISE LEVELS ON MODEL PREDICTION ERRORS

Model	SUMO (5%)	15%	30%	PeMS08 (5%)	15%	30%
GCN-GRU	17.5	18.0	18.4	25.2	25.7	26.1
LSTM-GCN	17.1	17.8	18.2	25.1	25.6	26.0
ST-Transformer	17.6	18.3	18.8	25.5	26.1	26.6
Attention-GCN	17.2	17.8	18.3	25.5	25.9	26.4
LSTM-CNN	17.7	18.4	18.9	28.2	28.8	29.3
3D-CNN	18.1	18.7	19.2	28.9	29.4	29.9
STGCN	17.5	18.2	18.7	27.3	27.8	28.3
DCRNN	17.3	17.9	18.3	24.8	25.3	25.8
RT-GCN	16.3	17.1	17.9	25.3	25.9	26.5
AGCRN	17.4	17.6	18.2	25.0	25.4	25.9
LT-GSSM (ours)	16.2	16.8	17.4	24.2	24.6	25.1

C. Computational Complexity and Execution Time

LT-GSSM maintains complexity comparable to standard spatio-temporal GNNs. The TCN-based temporal layer replaces recurrent cells, reducing sequential dependencies and allowing efficient parallelization with per-step cost $O(H^2 \times L_t)$ (with $L_t \leq 3$). Dynamic adjacency learning adds a manageable $O(V^2)$term, negligible for medium-sized networks (hundreds of sensors). Overall, LT-GSSM offers a better trade-off between robustness and cost than diffusion- or attention-based models, which scale as $O(T^2 d)$.To validate this analysis, we measured execution times under identical hardware and software conditions (Intel i7-10700 CPU, 32 GB RAM, NVIDIA GTX 1660 GPU, PyTorch 2.0, CUDA 11.8).

Using a batch size of 32, input length T=12, and hidden size H=64, LT-GSSM consistently trained 10–20% faster per epoch than recurrent baselines such as LSTM-GCN, GRU-GCN, and DCRNN on the PeMS04 and PeMS08 datasets.

These gains arise mainly from the parallelizable temporal convolutions and the absence of recurrent backpropagation.

Compared to heavier architectures such as ST-Transformer, Attention-GCN, or 3D-CNN, LT-GSSM maintained a lightweight execution profile, ranking among the most efficient models overall.

Although inference latency was not extensively benchmarked, average forward-pass times remained below 100 ms. per prediction step, indicating that LT-GSSM can operate effectively in near real-time forecasting scenarios without sacrificing accuracy or stability. Table IV reports the average training time per epoch for LT-GSSM and competing spatio-temporal models under identical hardware and software settings.

TABLE IV. AVERAGE TRAINING TIME PER EPOCH ACROSS SPATIOTEMPORAL MODELS

Model	Avg. Time per Epoch (s)
ST-GCN (parallel)	235.2
ST-Transformer	168.7
Attention-GCN	144.5
3D CNN	129.1
DCRNN	117.3
RT-GCN	110.5
AGCRN	104.2
LTGSSM (ours)	99.8
LSTM-GCN	96.7
GRU-GCN	96.2
LSTM-CNN	70.3

VI. CONCLUSION

This paper presented the Latent Topology Graph State-Space Model (LT-GSSM), a probabilistic spatio-temporal framework that dynamically learns graph structures from latent representations rather than relying on fixed connectivity. By treating topology evolution as part of the latent state dynamics, LT-GSSM reframes graph adaptation itself as an uncertain latent process, enabling robust modeling of non-stationary spatial dependencies under noise and missing data.

The main scientific contribution of this work lies in explicitly modeling spatial structure uncertainty within a state-space formulation, rather than relying on deterministic or heuristically updated graph topologies. This perspective provides a principled explanation for robustness in spatio-temporal forecasting, complementing existing dynamic-graph architectures.

Experiments on SUMO and PeMS datasets confirm that this formulation yields stable and adaptive forecasting performance even with reduced sensor coverage or high noise levels, while maintaining a computational cost comparable to standard GCN-based hybrids (e.g., LSTM-GCN, AGCRN), making it suitable for practical deployment in intelligent transportation systems.

Despite these advantages, dynamic adjacency learning introduces a quadratic dependency in the number of nodes, which may require sparsification strategies for very large-scale networks. Robustness was evaluated under commonly adopted noise and missing-data settings, and further extensions are left for future work.

Beyond traffic forecasting, the proposed modeling paradigm is applicable to a broader class of spatio-temporal problems involving evolving relational structures, such as sensor networks, urban monitoring, and environmental dynamics. Future work will investigate scalability improvements, alternative uncertainty models, and extensions to other spatio-temporal domains.

ACKNOWLEDGMENT

The author would like to thank her doctoral supervisor for the opportunity to conduct this research within the PhD program.

***Abstract*—This literature review investigates how human trust, decision fatigue, explainability (XAI), and human oversight interrelate to influence analyst decision-making in AI-driven anti-money laundering (AML) systems. While prior research has predominantly emphasized algorithmic performance, detection accuracy, or regulatory compliance in isolation, a critical gap remains in understanding the human-centered dynamics that shape real-world operational outcomes. Addressing this gap, the review examines how financial institutions navigate compliance demands and operational constraints, drawing on the Australian regulatory environment as an illustrative governance reference, including expectations articulated by AUSTRAC. Building on this synthesis, the study identifies structural gaps in Trust Calibration and oversight practices. It introduces a Dynamic Trust Modulation (DTM) framework to conceptualize how trust evolves across AML workflows. The framework models trust as a fluid, context-dependent construct shaped by system behavior, analyst workload, explainability mechanisms, and regulatory pressure. By framing trust, explainability, and decision fatigue as interdependent components of human–AI collaboration, this review advances a more holistic perspective on socio-technical system design in financial crime detection. The proposed framework contributes theoretically by extending human–AI trust research into the AML domain and practically by offering actionable design principles to enhance system accountability, decision defensibility, and adaptive compliance in operational AML environments.**

Keywords*—*Artificial intelligence; anti-money laundering (AML); Trust Calibration; Explainability; decision fatigue; human oversight; AUSTRAC Compliance; transaction monitoring; false positives; Analyst–System Interaction; Regulatory Technology (RegTech)

I. Introduction

Money laundering continues to pose a critical threat to financial systems worldwide, prompting financial institutions to adopt increasingly sophisticated anti-money laundering (AML) frameworks. Despite technological advancements, institutions continue to struggle with high false positive rates, escalating operational costs, and increasing regulatory pressure to ensure robust compliance [1].

Artificial intelligence (AI) and machine learning (ML) have emerged as promising tools to enhance AML transaction monitoring by uncovering anomalous behavior and enabling real-time detection. AI promises efficiency and improved detection precision; however, these systems often function as opaque "black boxes", raising concerns about explainability, regulatory defensibility, and human oversight [2]. The lack of transparency and adaptability to evolving compliance standards hinders institutional confidence and broader adoption.

While existing literature explores individual factors such as trust, decision fatigue, and explainability, it often treats them in isolation, overlooking their dynamic interplay in operational workflows. Critical questions remain unanswered: How do analysts rebuild trust after AI errors? How does human feedback shape system adaptation? And how can compliance frameworks incorporate meaningful oversight? These unresolved issues underscore the tension between technological performance and regulatory accountability in AI-supported AML environments.

This study addresses a critical gap in AI-driven AML research by developing a Dynamic Trust Modulation framework that conceptualizes how trust, explainability, and decision fatigue interact within transaction monitoring systems under conditions of uncertainty. Rather than treating these factors in isolation, the framework integrates them to capture the dynamic nature of analyst–system interaction and evolving oversight demands in AML workflows. By focusing on system-level decision processes such as confidence assessment, interpretability, and feedback loops, the framework provides a structured lens for understanding how human oversight can be supported and sustained in complex compliance environments. Drawing on human–AI collaboration and socio-technical systems literature, this study offers a generalizable conceptual foundation for advancing accountability, decision defensibility, and explainable decision-making in AI-supported AML systems.

*Corresponding author.

This study makes three key contributions to research on AI-supported anti-money laundering (AML) systems. First, it synthesizes trust calibration, decision fatigue, and explainability into an integrated conceptual perspective tailored to AML transaction monitoring, addressing their interdependence within high-stakes compliance environments. Second, it introduces the Dynamic Trust Modulation framework, which conceptualizes trust as a feedback-driven and context-dependent construct shaped by system performance, analyst workload, explainability mechanisms, and regulatory constraints. Third, the study offers practical and regulatory insights for the design of AI-enabled AML systems by highlighting design principles that support accountability, decision defensibility, and sustainable human oversight under regimes such as AUSTRAC.

The remainder of this study is organized as follows: Section II outlines background and related work; Section III presents case-based illustrations of implementation challenges; Section IV details the review methodology; Section V synthesizes thematic findings; Section VI discusses trust calibration dynamics and addresses oversight and governance mechanisms; Section VII discuss the regulatory frameworks and governance under AUSTRAC; Section VIII explores systemic risks; Section IX presents the structural ambiguity and compliance overload; Section X discusses fragmented oversight and risk diffusion; Section XI presents the global gaps and interoperability risks; Section XII summarizes limitations and future research; and Section XIII concludes the study.

II. Background and Related Work

A. AML and Compliance Failures

Lack of awareness and fragmented implementation of AML regulations have consistently led to enforcement failures and reputational risks. In Australia, AUSTRAC has imposed multimillion-dollar fines on institutions that failed to adopt a robust risk-based approach [3]. The cases of Commonwealth Bank of Australia (CBA), Westpac, and Tabcorp demonstrate that insufficient governance, underdeveloped compliance infrastructure, and inadequate technological adaptation remain key barriers to effective AML performance. For example, CBA failed to submit over 53,000 threshold transaction reports due to unmonitored Intelligent Deposit Machines, while Westpac committed over 23 million breaches due to poor internal oversight and delayed reporting [4]. International experiences echo similar challenges, such as Santander's outsourcing of AI-based AML systems, which resulted in substantial penalties due to vendor opacity and poor model explainability, whereas the Bunq vs. DNB case illustrates how deep regulatory understanding and system transparency enabled the bank to defend an AI-driven compliance approach [5]. Chainalysis and Elliptic offer additional insights into how institutions with strong AI and AML knowledge can support global regulatory goals and innovate proactively [6].

Prior studies indicate that higher AML regulatory ratings are associated with stronger financial outcomes [7]. Other research has identified persistent weaknesses in institutional coordination and in the empirical evaluation of illicit financial flows [8]. Additional analyses highlight embedded distrust and cognitive overload within compliance systems, particularly in the context of NLP-based monitoring tools [9]. Related work further suggests that traditional AML models tend to underperform in informal economies and across non-bank financial intermediaries [10].

B. AI in AML Systems

AI is redefining AML monitoring through anomaly detection, natural language processing, and real-time predictive analytics. Machine learning and deep learning algorithms enable institutions to recognize sophisticated laundering strategies that evade rule-based models. Systems like those implemented by Chainalysis and Elliptic, or the NICE Actimize modules adopted by IDB Bank, show measurable improvements in detection and operational efficiency [6], [11]. Research highlights AI's scalability and capacity for continuous learning, with models adapting detection parameters as threats evolve [12]. Empirical studies further indicate that AI-based approaches outperform legacy systems in terms of precision and recall [13], and additional work demonstrates their viability even in underregulated markets [14]. However, challenges persist. AI requires high-quality data, domain-specific calibration, and contextual sensitivity. Overreliance on external vendors, as seen in Santander's case, limits transparency and introduces compliance risks [5]. Hybrid models, combining AI with human oversight, have emerged as practical compromises [3]. AI's success is not solely technical; it hinges on integration with compliance expectations and interpretability. As the Bunq case demonstrates, performance is insufficient without justification mechanisms acceptable to regulators. Institutions must embed auditability, adaptability, and role clarity into AI systems to optimize both compliance and risk mitigation.

C. Trust and Explainability in AI

Trust and explainability are central to the adoption and effectiveness of AI in AML environments. Without interpretable models, analysts struggle to validate alerts, leading to inefficiencies and increased risk exposure. Decision fatigue arises from high false positive rates, undermining trust in AI systems and degrading regulatory defensibility [3]. Explainable AI (XAI) tools such as SHAP and LIME have been proposed to mitigate this issue, given that these techniques increase transparency by visualizing feature importance and supporting interpretability [15]. Recent studies emphasize that explainability is becoming a regulatory imperative, particularly under evolving AI governance standards [16]. Institutions that fail to provide traceable logic risk regulatory rejection, as evidenced in the initial pushback against Bunq's system. Despite growing literature on technical performance, few studies explore how AML professionals interact with AI or recover trust after errors. This research contributes by proposing a Dynamic Trust Modulation Loop, a framework that connects analyst feedback, system responsiveness, and explainability in a continuous cycle. This approach provides a pathway for aligning human-AI collaboration with institutional accountability and adaptive regulatory compliance.

Existing frameworks in AI-supported decision-making and human–AI collaboration have examined constructs such as trust, explainability, and human oversight, particularly in domains including healthcare and decision support systems. While these models offer valuable insights into how users interpret algorithmic outputs, they often treat trust and explainability as

static or isolated factors rather than as dynamically interacting elements within operational workflows. In anti-money laundering (AML) contexts, this limitation is especially critical. AML environments are characterized by persistent uncertainty, high false positive rates, regulatory accountability, and sustained cognitive load on analysts. Existing frameworks do not sufficiently capture how trust evolves in response to repeated system errors, how decision fatigue accumulates under continuous alert pressure, or how analyst feedback is operationally reintegrated into AI systems.

The Dynamic Trust Modulation framework proposed in this study addresses these gaps by conceptualizing trust as a feedback-driven and context-dependent construct. By explicitly modeling the interaction between trust calibration, decision fatigue, and explainability within AML transaction monitoring workflows, the framework offers a novel socio-technical perspective tailored to high-stakes compliance settings where accountability remains fundamentally human-centered.

III. Case Studies

A. Santander: Vendor Dependency and Oversight Gaps

1) Context: Santander, a major European bank, began integrating AI-powered transaction monitoring in 2020, outsourcing this function to the third-party vendor ThetaRay. The system was designed to detect laundering patterns in correspondent banking using machine learning.

2) Event: Despite this technological integration, Santander faced major penalties of $1 million in Norway (2019) and £107.7 million in the UK (2022) due to persistent compliance deficiencies [5]. The reliance on an external AI provider reduced internal transparency and limited control over system decisions. Under the EU AI Act, this division of responsibility complicated regulatory accountability, while high false positive rates overwhelmed internal analysts.

3) Lesson learned: Outsourcing AI without maintaining internal oversight and interpretability weakens institutional trust and regulatory defensibility. Banks must preserve visibility into AI decisions, even when compliance functions are delegated externally.

B. Bunq: Challenging Regulatory Conservatism Through Explainability

1) Context: Bunq, a Dutch neobank, developed its own AI-based transaction monitoring system, arguing that it outperformed traditional rule-based methods.

2) Event: The Dutch Central Bank (DNB) rejected Bunq's model for lacking explainability and regulatory alignment [5]. Bunq challenged this stance in court, arguing for outcome-based rather than methodology-based evaluation. In October 2022, the Commercial and Industry Appeals Tribunal ruled in Bunq's favor, requiring regulators to assess performance rather than favoring manual approaches.

3) Lesson learned: Regulatory trust in AI depends not only on technical performance but also on transparency. Explainable systems are essential for regulatory acceptance, even when accuracy is high.

C. Chainalysis and Elliptic: Blockchain Analytics and the Need for Explainability

1) Context: Chainalysis and Elliptic are leaders in AI-driven blockchain analytics for digital asset compliance. Both firms support cryptocurrency monitoring by detecting illicit financial activities through anomaly detection and network analysis.

2) Event: Despite strong operational success, such as Chainalysis's recognition by U.S. Homeland Security regulators like the Financial Stability Board continues to stress explainability [6]. Recent work cautions that even high-performing models may fail regulatory scrutiny if their underlying mechanisms remain opaque [16]. The 2025 acquisition of Alterya by Chainalysis highlights a broader shift toward deeper explainability and risk validation in financial crime analytics.

3) Lesson learned: Explainability remains critical even for top-performing AI systems. Without transparency and auditability, regulatory trust and long-term accountability are jeopardized.

D. Westpac: Oversight Failures and Analyst Fatigue

1) Context: Westpac, one of Australia's major banks, deployed transaction monitoring systems for AML/CTF compliance but failed to ensure governance effectiveness.

2) Event: The institution was fined 1.3 billion AUD for over 23 million violations, including failure to monitor cross-border transfers and respond to alerts [3]. These failures were tied to weak board oversight, overburdened compliance teams, and fatigue caused by excessive alert volumes, leading to institutional breakdowns.

3) Lesson learned: Effective AML systems require governance structures that support human-AI workflows. Analyst fatigue and board-level disengagement can compromise trust and system effectiveness.

E. Commonwealth Bank of Australia: Misaligned Trust Calibration

1) Context: The Commonwealth Bank of Australia relied on Intelligent Deposit Machines (IDMs) to support AML monitoring, automating transaction processing and reporting.

2) Event: In 2018, the bank was fined 700 million AUD for failing to report over 53,000 threshold transactions. Investigations revealed that analysts did not escalate anomalies, assuming system reliability despite lacking internal risk assessments or override mechanisms [3].

3) Lesson learned: Overreliance on automation without real-time human verification erodes compliance. AML systems must enable ongoing trust calibration and empower analysts to challenge system outputs.

F. IDB Bank (New York): Successful Human-AI Collaboration

1) Context: IDB Bank implemented NICE Actimize modules to enhance AML operations, aiming to streamline alert processing and boost efficiency.

2) Event: The system led to a 60% reduction in manual post-alert work, allowing analysts to focus on high-risk investigations [12]. A structured feedback loop enhanced trust and explainability, improving understanding of AI behavior.

3) Lesson learned: AI adoption succeeds when it supports, not replaces, human judgment. Feedback-integrated, explainable systems reduce fatigue and build trust across compliance teams and regulators.

IV. Review Methodology

This study adopts a systematic literature review methodology tailored for conceptual synthesis rather than empirical measurement. The purpose of this approach is to transparently map and integrate existing knowledge on AI integration within Anti-Money Laundering (AML) compliance, particularly in the areas of trust, explainability, oversight, and human-AI collaboration. The review adheres to academic standards for reproducibility, thematic coherence, and methodological transparency.

A. Literature Search Strategy

The literature review spans the publication period from 2020 to 2025. The search was conducted across academic databases and authoritative industry sources, including Google Scholar, Scopus, and regulatory or policy-based repositories such as ACAMS, AUSTRAC, and the Attorney-General's Department of Australia. Relevant white papers from Deloitte, NICE Actimize, and Chainalysis were also included to ensure industry alignment.

Search terms were structured around the core themes of the study and included Boolean combinations such as: "Artificial Intelligence" AND "AML" OR "Anti-Money Laundering", "False positives" AND "transaction monitoring", "Human-AI collaboration" OR "trust in AI systems", "Explainability" OR "XAI" AND "compliance", "AUSTRAC" AND "regulatory expectations" OR "AML Australia", "Decision fatigue" OR "alert fatigue" AND "AML analysts". To ensure thematic alignment with the conceptual framework, literature sources were mapped according to their relevance to key constructs, as detailed in Table I. As shown in Table I, the reviewed sources span academic research, industry reports, and regulatory guidelines, providing a balanced foundation for both theoretical insights and practical relevance. This structured mapping demonstrates how each source informed key aspects of the framework, including the core analyst–system interaction constructs, along with human oversight and feedback loop integration. By explicitly aligning each paper with a core construct or operational gap, the review process ensures that the final conceptual framework is grounded in evidence and reflects the latest developments in AI-supported AML practice.

B. Inclusion and Exclusion Criteria

Inclusion criteria focused on literature published in English between 2020 and 2025 that addressed financial crime detection, AI in compliance, regulatory frameworks, human-machine interaction, and AML case studies. Eligible documents included peer-reviewed journal articles, conference papers, government publications, and technical white papers. Exclusion criteria removed literature outside the financial sector (e.g., AI in medicine or agriculture), non-English publications, and theoretical papers with no relevance to regulatory frameworks or compliance technologies. Initial screening was based on titles and abstracts, followed by full-text review to ensure methodological rigor and relevance. The systematic selection process is visualized in Fig. 1, which outlines identification, screening, eligibility, and final inclusion of sources.

TABLE I. Literature Review Source Overview

Theme	Key Authors (Type/Year)	Focus Summary	Framework Relevance*
Trust Calibration	Bertrand (Thesis, 2024), Wang (Thesis, 2024), Alkhalili (JA, 2021), Ghimire (JA, 2025), Kahur (Report, 2025)	Trust evolution, explanation paradox, ML filtering, analyst confidence	TC, EX
Explainability	Kahur (Report, 2025), Deloitte (Report, 2020), Rane (JA, 2023), Jensen (JA, 2023), Bello (JA, 2024)	SHAP/LIME, hybrid models, blockchain transparency, system performance	EX, FO
False Positives	Alahmadi (Conf, 2022), Oztas (JA, 2024), Mounika (JA, 2024), Ketenci (JA, 2021)	Analyst workload, anomaly detection, tuning thresholds, FP mitigation	DF, TC
Oversight	Bello & Bronitt (JA, 2024), Goldbarsht (BC, 2023), King (JA, 2020), Rennie (JA, 2021), Maxwell (Report, 2020)	AI governance, risk mitigation, compliance defensibility, human oversight	OV, TC
Feedback Loops	Deloitte (Report, 2020), Eddin (Preprint, 2021), Sausen (Report, 2020), Kumar (JA, 2024), Johnson (Report, 2025)	Human-in-the-loop design, AML adaptation, operational feedback systems	FL, TC
Regulatory Compliance	AUSTRAC (Reg, 2023/24), Quinn (Report, 2021), Momenta (IR, 2022), Goldbarsht & Sheedy (Report, 2024), Saputra (JA, 2021)	National risk assessment, policy frameworks, compliance alignment	RC, OV
Situational Awareness	Boudt (JA, 2025)	News monitoring for AML, risk signal integration	SA

TC = Trust Calibration; EX = Explainability; DF = Decision Fatigue; OV = Oversight; FL = Feedback Loop; RC = Regulatory Compliance; SA = Situational Awareness.

V. PRISMA Diagram

This review scoped academic, industry reports, and regulatory documents addressing AI trust, oversight, and anti-money laundering (AML) within both regulatory and technical domains. Emphasis was placed on studies that examine the interaction between machine learning systems and compliance practices, particularly in high-stakes financial environments. Thematic analysis focused on patterns related to explainability, analyst trust calibration, and institutional accountability in AI-augmented AML systems. The selected corpus synthesized

interdisciplinary perspectives across law, computer science, and financial governance.

The flow diagram outlines the identification, screening, eligibility assessment, and inclusion of sources in the systematic literature review, following PRISMA guidelines.

A. Analytical Framework

Thematic coding was applied across seven domains: Trust Calibration, Explainability, False Positives, Oversight, Feedback Loops, Regulatory Compliance, and Situational Awareness. The distribution and classification of sources across these themes are synthesized in Table III.

Furthermore, to clarify methodological depth and diversity, Table II summarizes the methodological types, data sources, and limitations of the reviewed literature. This enables a comparative understanding of the balance between technical modeling, policy alignment, and human-centered design in the current AML literature.

As shown in Table II, the classification of methodologies reveals irregular scholarly attention where technical modelling approaches prioritize algorithmic performance but rarely consider analyst workload or regulatory defensibility. In contrast, policy-driven studies emphasize compliance and ethical safeguards yet lack empirical validation. Only a small number of industry reports attempt to incorporate practitioner perspectives, but these remain descriptive rather than evaluative. Taken together, this shows fragmented evidence base where rigor and applicability rarely converge, underscoring the need for the trust–feedback framework proposed in this study.

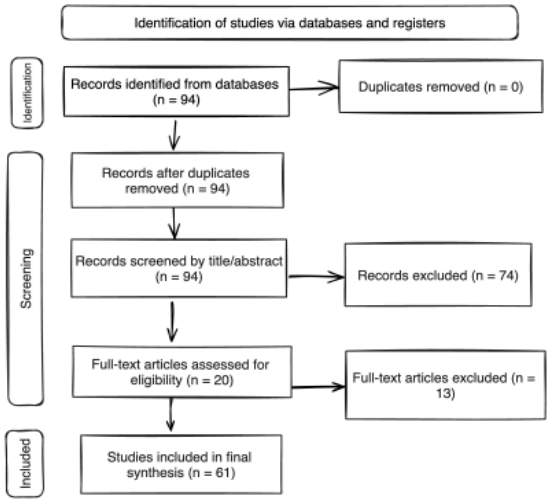

Fig. 1. PRISMA flow diagram of the literature selection process.

TABLE II. METHODOLOGIES IN REVIEWED STUDIES

Study	Methodology	Data Type	Strengths	Limitations
Ghimire (2025)	Simulation + Case Study	Secondary	Focused on precision-recall metrics and system design.	Not practitioner-based; lacks real-world validation.
Ketenci et al. (2021)	Quantitative - ML Models	Experimental	Robust testing of false positive reduction strategies.	Lacks human-AI interaction component.
Oztas et al. (2024)	Quantitative - ML Clustering	Experimental	Uses adaptive algorithms for anomaly detection.	Does not address human oversight or compliance validation.
Bertrand (2024)	Theoretical Analysis	Conceptual	Explores trust, fatigue, and decision frameworks in AI settings.	Lacks empirical or applied industry context.
AUSTRAC (2024)	Risk Assessment + Regulatory Review	Policy and Compliance Documents	Grounds research in national compliance standards.	Not focused on technical implementation of AI.
Australian Government (2024)	Policy Framework Analysis	Conceptual	Establishes ethical and assurance principles for AI.	Applies broadly to government, not AML-specific.
Kute et al. (2021)	Experimental + XAI Evaluation	Quantitative	Demonstrates explainability using SHAP and LIME.	Focuses more on technical output than end-user integration.
Deloitte & UOB (2021)	Case Study + Interview-Based Review	Industry Report	Real-world application of AI-human hybrid models	Case-specific and not generalisable across all banks.
AUSTRAC (2023–24)	regulatory Summary and Sector Review	Government Report	High-level operational and compliance insights	Limited detail on model evaluation or metrics

VI. THEMATIC SYNTHESIS AND FINDINGS

A detailed review of the literature reveals a constellation of interrelated themes that shape the discourse on AI-supported Anti-Money Laundering (AML) systems. Rather than treating technological capabilities in isolation, the literature emphasizes the entanglement of AI transparency, analyst cognitive dynamics, and regulatory alignment within evolving financial compliance ecosystems. This section synthesizes the findings using the interaction constructs introduced in Section III: trust calibration, oversight, feedback loops, and explainability, and maps these onto practical tensions observed in industry and empirical studies.

While Table III categorizes the literature into thematic domains, its real value lies in revealing the disciplinary requirements that fragment AI-AML research. A key pattern emerges: technical contributions largely optimize model performance metrics, such as precision or false positive (FP) reduction, without engaging with the socio-institutional challenges of operational trust and oversight. In contrast, regulatory and policy-focused literature emphasizes compliance defensibility but lacks guidance on integrating AI tools into analyst workflows or trust repair mechanisms following an AI error. This divide reflects an unresolved tension between algorithmic sophistication and institutional interpretability, which is central to real-world AI deployment in AML systems.

TABLE III. LITERATURE CLASSIFICATION BY THEMES

Theme	Key Authors (Year)	Key Insights	Gaps	Gap Relevance*
AI in AML	Ketenci (2021), Oztas (2024), Kahur (2025)	ML & features reduce FP; new patterns	Few human-AI workflow studies	TC, FP
Human-AI Collaboration	Bertrand (2024), Wang (2024)	Trust, sensemaking, explanation paradox	No empirical AML banks data	TC, EX
Trust & Oversight	AUSTRAC (2024), Australian Gov (2024), King (2020)	Oversight & compliance defensibility	Generic, no dynamic trust focus	OV, TC
False Positives & Fatigue	Alahmadi (2022), Mounika (2024)	High FP rates cause decision fatigue	Limited AML-specific FP research	DF, TC
Explainability	Eddin (2021), Bertrand (2024), Jensen (2023)	SHAP/LIME aid sensemaking	Not embedded in daily workflows	EX, FO
Feedback Loops	Deloitte (2020), NICE Actimize (2020), Kumar (2024)	HITL & loops cut FP	Case-specific; lacks generalization	FL, TC
Regulatory Compliance	AUSTRAC (2024), Gov. Australia (2024)	Regulatory guidance & assurance	Broad, not tailored to AML	RC, OV
Situational Awareness	Boudt (2025), Rane (2023)	News monitoring boosts AML relevance	No human feedback integration	SA, OV

TC = Trust Calibration; FP = False Positives; DF = Decision Fatigue; EX = Explainability; FO = Follow-through; OV = Oversight; FL = Feedback Loop; RC = Regulatory Compliance; SA = Situational Awareness.

Moreover, the table surfaces a notable epistemic gap: few studies offer empirical insight into how AML analysts interact with AI tools in practice. While theoretical models of human-AI collaboration, for example [17] and [18], conceptualize trust dynamics and explanation paradoxes, they remain untested in operational settings. This undermines our ability to assess decision fatigue, escalation behaviors, or feedback efficacy. Similarly, while explainability tools such as SHAP and LIME are technically validated, their real-world impact on analyst cognition and institutional defensibility remains speculative. These oversights suggest a need for workflow-embedded research that moves beyond algorithmic validation toward situated understanding of analyst behavior under compliance constraints.

Taken together, the classification in Table III does more than organize the literature; it reveals a systemic blind spot in current research: the lack of integrated, cross-disciplinary models that capture how trust, fatigue, explainability, and oversight interact in real-time AML operations.

Organizing the literature into these synthesized themes and acknowledging both convergence and contradiction, this section sets the stage for deeper thematic unpacking, detailed in Section VI(A) to Section VI(D). These themes are not merely descriptive categories; they are operational leverage points within the trust-feedback loop central to the conceptual framework.

A. Trust Calibration

This theme highlights how fluctuations in analysts' trust, as discussed by [17] and [18], directly inform the design of the Dynamic Trust Modulation Loop (see Fig. 3), which operationalizes how trust is depleted after repeated false positives and restored through feedback-driven model adjustments.

B. Theoretical Perspective: Human-AI Collaboration and Sensemaking in AML

To strengthen the understanding of how AML professionals collaborate with AI systems in transaction monitoring, this study draws on key concepts from Human-AI interaction theory: cognitive trust, situational awareness, and decision fatigue. These constructs are essential in analyzing how human analysts interpret, respond to, and calibrate their oversight of AI-generated alerts in high-stakes AML environments. This theme aligns with the conceptual framework in Fig. 2, where high false positives and alert ambiguity are shown to contribute to trust calibration challenges.

Cognitive trust reflects the degree to which users perceive AI systems as competent, reliable, and predictable. Prior research shows that trust in automation is shaped by tangibility, transparency, and task characteristics, especially relevant in compliance settings where legal accountability is still held by human actors [17]. When trust in AI drops due to unexplained false positives, analysts may disengage or ignore alerts entirely, creating operational blind spots.

Situational awareness involves understanding the transaction flagged by AI as well as the broader customer behavior, laundering typologies, and threat patterns. Overly complex or "black box" systems risk eroding this awareness [19]. Decision fatigue arises when analysts are overwhelmed by high alert volumes, often due to false positives. Bertrand introduces the "cry wolf effect", where repetitive false alerts reduce trust and increase the chance of missing legitimate threats [17].

Further research provides insight into this issue, indicating that security analysts working in similar high-alert environments often lack the contextual data needed to assess alert relevance [20].

This parallels AML settings, reinforcing the need for systems that enable explainability and reinforce human oversight. Graph-based machine learning triage models show promise; Feedzai reports an 80% reduction in false positives with over 90% detection of true positives [21]. The real-world relevance of such models emphasizes the value of applying theoretical insights to institutional settings.

Table IV reveals contrasting institutional approaches to trust and oversight in AI-supported AML systems. Cases like Westpac and CBA illustrate how poor governance and absent feedback loops lead to trust erosion, especially under high alert fatigue and low system transparency. In contrast, IDB Bank and

Chainalysis show that trust can be reinforced when automation is paired with high explainability and real-time feedback. Their success lies in workflows that support analyst understanding and continuously refine detection models.

Also in Table IV, the Santander case highlights the risks of relying on external AI vendors, but without full transparency or internal adaptability, institutions may lose control over explainability and oversight, weakening both analyst trust and regulatory assurance. Bunq's legal challenge underscores the role of regulatory alignment in trust calibration. Even high-performing models may face resistance if explainability standards are unclear or contested.

Overall, the mapping suggests that sustainable AML performance depends less on model complexity and more on system designs that embed transparency, human oversight, and adaptive feedback.

Table V draws on Alahmadi's thematic coding of analyst feedback to explore how cognitive trust, situational awareness, and oversight are shaped by real-world interactions with AI-generated alerts. These insights reveal how high-pressure environments strain the balance between automation and human judgment in AML contexts.

The coded responses illustrate a core tension: automation often falls short of supporting analysts in fast-paced environments. Instead of reducing workload, systems frequently overwhelm users with unclear or irrelevant alerts, triggering distrust and cognitive strain.

Situational awareness is another weak point. Analysts report difficulty in understanding system behavior or interpreting alerts without contextual clues, undermining their ability to act decisively and accurately. Trust calibration emerges as an emotional as well as procedural challenge. Analysts feel personally responsible for missed threats, especially when system limitations are known but uncorrected. This underscores the importance of transparency and oversight.

Importantly, the responses show consensus around the need for human-in-the-loop processes. Validation by analysts not only improves compliance defensibility but also restores confidence in system recommendations. So, the limited feedback from analysts back into AI models reflects a broader weakness in adaptive learning. Without structured error reporting, systems cannot evolve meaningfully, reinforcing inefficiencies and trust gaps over time.

TABLE IV. MAPPING OF CASE STUDIES TO FRAMEWORK COMPONENTS

Case Study	Trust Calibration	Explainability	Situational Awareness	Decision Fatigue	Feedback Loop Integration
Westpac (AU)	Trust erosion due to systemic oversight failures	The low absence of clear rationale for alerts	Limited by poor governance structures	High, driven by excessive unresolved alerts	Absence of no mechanism to feed analyst observations back into the system
Commonwealth Bank of Australia (AU)	Over-reliance on partially automated systems without adaptive override	Moderation of some transaction data is available, but insufficient for risk context	Compromised in weak link between alerts and broader risk picture	Medium to High, given sustained operational strain	Minimal limited escalation learning
IDB Bank (US)	Strengthened trust through automation of post-alert processes	High and integrated case management provides contextual clarity	Enhanced of the analysts focus on high-risk escalations	Reduced 60% lower manual review workload	Strong feedback directly informs system tuning
Santander (EU)	Mixed efficiency gains but reliance on external AI reduces internal trust	Moderate vendor models lack full transparency	Variable dependent on third-party reporting	Medium, due to persistent false positives	Weak limited capacity to adapt vendor models
Bunq vs. DNB (NL)	Initially questioned by regulator; restored through legal vindication	Contested regulator deemed insufficient, court found adequate	Adequate AI model contextualized transactions effectively	Low automation reduced manual screening load	Moderate to internal testing but limited regulator feedback
Chainalysis & Elliptic (Global)	Generally high, supported by law enforcement use	High anomaly detection is well-documented	Strong in real-time blockchain monitoring	Low AI filters high-volume low-value alerts	Strong investigative feedback improves detection models

TABLE V. THEMATIC ASSERTIONS FROM PARTICIPANT RESPONSES ALIGNED WITH AML THEORY

Theme	Codes	Summary Result & AML Relevance
Cognitive Trust	A1, A8	Analysts rely on personal judgment and feel strong responsibility when threats are missed, reflecting trust calibration and the emotional burden of oversight.
Situational Awareness	A2, A6, A10	Lack of context, unclear alerts, and evolving system behavior hinder rapid, accurate decisions, aligning with situational awareness theory and explainability gaps.
Trust Erosion from False Positives	A3, A4	Repetitive irrelevant alerts reduce trust, increase cognitive strain, and risk underreporting, supporting decision fatigue theory.
Oversight & Human-in-the-Loop	A5	High consensus that human validation is essential for AI oversight, reinforcing analyst confidence and compliance defensibility.
Performance Pressure	A7	Speed-focused performance metrics undermine investigative depth, linking to decision fatigue and compliance risks.
Feedback Loop Weakness	A9	Limited reporting of errors back to systems hinders AI adaptation, evidencing feedback loop failures.

C. Understanding Accountability in Human-AI Decision-Making for AML Monitoring

AI's black-box nature complicates accountability in transaction monitoring, as prior research stresses that analysts must be able to justify AI-driven decisions through interpretability and effective oversight [18]. Related studies also warn against over-reliance on automated systems, noting that excessive dependence can erode critical thinking and increase regulatory risk [20]. Accountability-sharing frameworks are emerging, such as human-in-the-loop models and AI review committees, which formalize roles and support ethical oversight [22] and [23]. These mechanisms must be embedded in governance structures to uphold compliance defensibility and public trust.

D. Post-Alert Investigation Processes

High false positive rates delay investigations and burden analysts; for example, NICE Actimize has improved workflows by centralizing alerts, SAR generation, and case management, as seen in IDB Bank's reported 60% manual workload reduction [12]. External tools like Belgium's NEMO integrate media signals into risk assessments, showcasing dynamic post-alert adaptations [24]. Meanwhile, predictive triage models further improve investigative accuracy [21].

Table VI summarizes the root causes of false positives in AML systems and links each to targeted mitigation strategies. These findings show how technical and governance gaps contribute to analyst fatigue and eroded trust.

Table VI outlines primary causes of false positives and mitigation strategies, reinforcing that explainability and feedback loops are critical to trust and efficiency.

Note 1: Several risk-based adaptive thresholds have been shown to significantly reduce false positive rates in AML models, as mentioned by Ketenci.

Note 2: Referring to SHAP values and other explainability tools, these provide transparency in model decisions, thereby increasing analyst confidence and reducing investigation time, as mentioned by Kahur.

Note 3: Feedback cycles allow AML professionals to improve model performance over time by incorporating real-world alert fixes, as mentioned by Sausen and Liegel.

As shown in Table VI, false positives are not just technical glitches; they are trust failures since the alerts lack context or cannot be explained, and analysts disengage, leading to oversight gaps and underreporting. The table highlights that improving accuracy alone is not enough. The most effective mitigation strategies, like SHAP-based explainability or human-in-the-loop retraining, address cognitive and procedural dimensions of trust.

Importantly, explainability functions as a trust calibration mechanism, so this one enables analysts to reconcile system output with professional judgment, reducing reliance on blind acceptance or rejection of alerts. However, transparency without action is useless, which is why feedback loops remain underdeveloped, forcing analysts to revalidate the same errors without influencing model behavior.

This lack of adaptation directly contributes to decision fatigue. Table VI illustrates that reducing false positives requires integrated solutions that align model design with analyst workflows, situational awareness, and regulatory defensibility.

1) Key findings: Prior research shows that trust in AI-driven systems is dynamic and influenced by factors such as false positives, limited explainability, and the degree of analyst control [18], [19], [25].

2) Contradictions/trends: Some perspectives conceptualize trust as a dynamic construct recalibrated through feedback mechanisms, while other accounts frame trust as primarily compliance driven [26]. Industry evidence further indicates that integrating structured feedback into AML systems can improve trust stability, as demonstrated in reports by NICE Actimize [12].

3) Limitations/gaps: There is limited empirical evidence on how trust is rebuilt. This highlights the value of the Dynamic Trust Modulation Loop (see Fig. 3), which offers a visual model to capture the trust-feedback interaction over time.

TABLE VI. SUMMARY OF FALSE POSITIVE CAUSES AND MITIGATION STRATEGIES

Cause of False Positive	Description	Mitigation Strategy	Supporting Study
Rule-based thresholds	Static thresholds trigger alerts on legitimate transactions	Move to dynamic, risk-based profiling with adaptive AI	Ketenci et al. (2021)
Poor or incomplete data	Missing or outdated KYC data affects transaction interpretation	Improve data governance; refresh KYC frequently	AUSTRAC (2023); Jensen & Iosifidis (2023)
Model bias	Outdated or narrow training data flags benign behavior	Retrain models with updated, diverse data; integrate typologies	Tsapa (2023); Kahur (2025)
Lack of contextual awareness	Alerts ignore behavioral patterns, customer background, or geography	Incorporate contextual variables into feature sets	Deloitte (2020); Feedzai (2022)
Black-box outputs	Analysts can't understand why the system flagged the alert	Use explainable AI (e.g., SHAP values); implement model transparency features	Momenta (2022); Kahur (2025)
Feedback not integrated	Analyst input on false positives is not used to improve the system	Establish feedback loops and human-in-the-loop retraining protocols	NICE Actimize (2020); Sausen & Liegel (2020)

E. Explainability in AI Alerts

1) Limitations of AI in AML monitoring: the false positive problem: One of the most pressing challenges in AI-enabled AML systems is the persistently high rate of false positives, legitimate transactions incorrectly flagged as suspicious. As shown in Table II, methodological approaches vary across empirical and conceptual studies. Although AI and machine

learning (ML) have been praised for modernizing transaction monitoring, the practical reality is more complex. False positive rates frequently exceed 90% in both traditional rule-based and some AI-based models [27], [28]. This over-detection places a heavy burden on AML practitioners, who must manually review thousands of flagged transactions, most of which turn out to be harmless. Excessive alert volume not only leads to alert fatigue and increased operational costs but can also desensitize analysts, making it difficult to detect truly suspicious activity when it arises [28].

The effectiveness of AML systems lies in their capacity to direct human attention toward genuinely high-risk events, as noted in prior research [25]. When analysts spend most of their time reviewing false alerts, the fundamental objective of AML, preventing financial crime, is compromised. The psychological toll of continuous exposure to irrelevant alerts may also reduce an analyst's sensitivity to true red flags over time. These limitations are especially acute in smaller institutions with fewer resources, leading to greater reliance on manual reviews and further straining compliance operations [29].

The variability of AML-related data, which may involve hundreds or thousands of accounts, transactions, and behavioral features, adds to the challenge. Designing effective models requires both high-quality data and deep domain expertise to identify meaningful feature interactions. Consequently, many implementations suffer from performance limitations or require extensive manual configuration, which reduces scalability in high-volume environments [28].

To mitigate these issues, recent approaches have focused on integrating iterative, confidence-based learning cycles. In these models, analyst feedback is not only used to validate alerts but is also quantified and incorporated into retraining processes. Confidence indicators such as analyst override rates, decision certainty, and SHAP-based interpretability scores are used to assign weighted values to human corrections and feature relevance. This allows the system to prioritize learning from high-confidence analyst inputs, which are more likely to represent reliable domain knowledge.

What is particularly novel about this approach is that the model's learning is shaped around human decision-making. It does not merely enhance technical accuracy but also improves its ability to align with how analysts interpret and assess risk. This approach is aligned with AUSTRAC's expectations: AI systems must provide explainable decisions, incorporate risk considerations, and place human oversight at the core of the process. Moreover, it introduces the potential to use human trust itself as a feature in training AI systems for regulatory compliance contexts. For example, prior work has introduced novel feature sets based on time–frequency analysis, transforming transactional data into two-dimensional signal representations [30]. When implemented with Random Forest classifiers, this method reduced the false positive rate to 11.85% and improved the F1 score to 74.06%, demonstrating a more balanced trade-off between precision and recall.

As this study adopts a qualitative approach to understanding how AML practitioners manage false positives in AI systems, the proposed framework creates a foundation for future empirical validation. Variables such as perceived trust in AI, decision time, cognitive load, and analyst satisfaction with explainability could be measured through surveys or controlled experiments. These variables are closely tied to core components of the model, including trust calibration, feedback loops, and interpretability support tools. Accordingly, future research could adopt mixed methods designs to evaluate how these variables influence escalation outcomes and trust dynamics, strengthening both the empirical application and theoretical robustness of the proposed framework.

Table VII compares leading AI techniques used in AML transaction monitoring, evaluating their performance across false positive reduction, explainability, and real-world deployment. These comparisons reveal adjustments between model transparency and operational effectiveness.

The comparison in Table VII shows that high performance doesn't always mean high transparency, given that graph-based models reduce false positives effectively but lack full explainability, which may hinder regulatory trust. On the other hand, SHAP values, while highly interpretable, lack published data on their real-world impact. This reflects a broader tension between model transparency and measurable efficiency.

Eventually, techniques that align with analyst workflows by aiding prioritization and enabling oversight offer more than just accuracy. They support trust, usability, and compliance defensibility. Table VII supports the need for hybrid AI designs that balance performance, explainability, and human feedback integration.

TABLE VII. CROSS-COMPARISON OF AI TECHNIQUES IN AML

AI Technique	Use Case	False Positive Reduction	Explainability	Real-World Application
Random Forest + Time-Frequency	Transaction pattern detection	Reduced FPR to 11.85%	Moderate	Mounika et al. (2024)
SHAP Values	Model interpretability	Data on false positive reduction are not disclosed in public sources.	High	Momenta (2022); Kahur (2025)
Graph-Based Triage Model	Risk prioritization via transaction networks	Reduced FPR by up to 80%	Moderate	Feedzai (2022); Eddin et al. (2022)

Practical deployments have begun to address long-standing limitations; the best example might be "NICE Actimize, which has demonstrated a 30–50% reduction in false positives, improving the efficiency of compliance teams" [12]. As summarized in Table III, literature themes converge around trust, explainability, and regulatory compliance. These findings suggest that advanced feature engineering, including time frequency features such as kurtosis and skewness, can lead to more accurate and operationally viable AML systems [31].

Despite these improvements, false positives remain a persistent challenge; until AI models can reliably distinguish

between genuinely suspicious transactions and benign anomalies, human analysts will remain essential to the investigation process, and the vision of full automation will remain unattainable. As emphasized throughout the literature, improving model explainability, refining input features, and enhancing human–AI collaboration are critical for ensuring that AI augments rather than overwhelms the AML function. This reinforces the relevance of the core analyst–system interaction constructs articulated in human–AI collaboration theory. Analysts continue to experience decision fatigue when static thresholds consistently flag non-suspicious behavior.

- Key findings: Prior research emphasizes that explainable AI (XAI) tools, such as SHAP and LIME, can help analysts better understand system outputs and increase confidence [21], [31], [32]. However, practical adoption of these tools remains uneven.
- Contradictions/Trends: Although a degree of consensus exists regarding the utility of technical explainability tools, prior studies emphasize that these tools are often disregarded when they are not seamlessly integrated into analysts' daily workflows, particularly through accessible visualizations [32], [33]. Several studies highlight the tension between explanation complexity and the speed required for real-time decision-making.
- Limitation/Gap: There is a lack of empirical evidence demonstrating whether explainability features directly reduce false positives or analyst fatigue in operational settings. The inclusion of "explainability satisfaction" as a construct within this study's framework aims to address this measurement gap by capturing the analyst's perception of the clarity and usefulness of AI-generated outputs.

F. Oversight and Governance

1) Human-AI collaboration in AML compliance: The integration of artificial intelligence (AI) into anti-money laundering (AML) systems has introduced a dual-layered structure of operational support and cognitive challenge. While AI enhances scalability and anomaly detection, it also generates persistent governance issues, particularly concerning false positives, opaque decision-making, and compliance defensibility. As such, oversight in AI-AML systems must be understood not only as a regulatory function but also as a dynamic interface between automated pattern recognition and human interpretive judgment [19], [34].

Despite the adoption of advanced AI tools, studies continue to report false positive rates as high as 90–95% [33], leading to alert fatigue and cognitive overload among analysts [4]. These issues are compounded by the reliance on historical data that may encode legacy biases, leading to detection errors and redundant investigations. In response, human analysts play a critical oversight role: validating AI outputs, applying contextual knowledge, and modulating escalation behavior functions that current AI systems are poorly equipped to replicate.

The following Table VIII clearly summarizes the practical response strategies employed by AML analysts when addressing AI-generated alerts, highlighting the range of responses that effectively mitigate alert fatigue and enhance compliance outcomes.

The interview responses in Table VIII reveal that alert fatigue, lack of feedback loops, and limited explainability significantly undermine trust in AI-assisted AML systems. Analysts report defaulting to intuition over system guidance and express frustration when feedback isn't acknowledged, indicating weak cognitive trust and disengagement from human-in-the-loop processes. While tools like SHAP offer some interpretability, they are not sufficient on their own; without actionable transparency and feedback integration, AI systems risk being sidelined despite their technical performance. These practitioner themes reinforce that trust calibration must be embedded in system design to ensure adoption and compliance defensibility.

TABLE VIII. PRACTITIONER THEMES FROM INTERVIEWS

Theme	Sample Quote	Frequency	Interpretation
Alert Fatigue	I catch myself rushing after 20 false alerts in a row.	Q3, Q15	Decision Fatigue
Trust in AI	Sometimes I ignore the system and trust my instincts.	Q7, Q8	Cognitive Trust
Lack of Feedback Loops	I've submitted feedback, but I don't know if it's used.	Q10	Human-in-the-loop
Need for Explainability	SHAP helps me understand why the alert was triggered.	Q9, Q16	Interpretability

VII. REGULATORY FRAMEWORKS AND GOVERNANCE UNDER AUSTRAC

In the Australian context, AUSTRAC operates both as a financial intelligence unit and the chief regulator responsible for enforcing the AML/CTF Act 2006. Although AUSTRAC mandates that all transaction monitoring programs, manual or automated, be risk-based and support "reasonable grounds for suspicion" in SMR submissions, the agency has yet to issue dedicated AI-specific guidance. This omission has created a regulatory blind spot in which institutions must interpret traditional compliance obligations in the context of complex, often opaque, AI systems [1], [35].

The operational consequences of this regulatory ambiguity are evident in Table IX, which highlights the misalignment between AUSTRAC expectations and common AI system features. For instance, while human validation and feedback loops are increasingly present in advanced setups, critical areas such as transparency, accountability, and real-time contextual awareness remain underdeveloped. High-profile failures at institutions like Westpac and CBA have illustrated the dangers of opaque models and unmanaged alert volumes, while newer hybrid models from Bunq to Elliptic showcase the value of explainability and real-time feedback integration.

TABLE IX. AI FEATURES VS. AUSTRAC PRINCIPLES: AN OPERATIONAL ALIGNMENT

AUSTRAC Expectation (Grouped)	Typical AI Feature	Compliance Gap / Risk + Construct*	Real Case Example (Year)
Risk-based monitoring & SMRs	ML detects patterns; real-time anomaly detection	Over-flagging & alert fatigue (DF); delayed SMRs (OV)	Santander fine (2025); CBA SMR failure (2018)
Auditability & Explainable decisions	Black-box AI; complex algorithms	Limited traceability (EX); need human validation (SA, TC)	Westpac breaches; Bunq interpretable AI (2021)
Ongoing CDD/KYC & Oversight	Profile risk scoring; semi-autonomous operation	Misses' real-time context (SA); oversight needed (OV, FL)	Chainalysis blockchain data; Elliptic hybrid alerts (2025)

Legend: DF = Decision Fatigue; OV = Oversight; EX = Explainability; SA = Situational Awareness; TC = Trust Calibration; FL = Feedback Loop.

Table IX illustrates critical misalignments between AUSTRAC's regulatory expectations and current AI practices in AML. While AI tools offer real-time monitoring and pattern detection, they often trigger excessive false positives and lack transparency, leading to delayed reporting and reduced auditability. These gaps highlight the persistent need for human oversight to contextualize system outputs and maintain regulatory compliance. Moreover, inconsistent implementation and poor documentation practices, such as reliance on ad hoc risk assessments, undermine both accountability and trust. The analysis reinforces that AI must be integrated not only as a technical solution but within a governance structure that supports explainability, oversight, and traceability.

Moreover, AUSTRAC's regulatory reach does not yet extend to high-risk sectors such as legal, accounting, and real estate services (DNFBPs), creating systemic gaps that sophisticated laundering networks continue to exploit. Proposed "Tranche 2" reforms aim to address these omissions, but until implemented, oversight remains fragmented, undermining both national security and FATF compliance rankings [36].

VIII. GOVERNANCE AND THE FUTURE OF OVERSIGHT

Traditional compliance models, which rely on linear thresholds and rule-based control points, are increasingly unfit for AI-enhanced AML environments. Instead, a new paradigm of adaptive governance is emerging, one that integrates explainability tools such as SHAP and LIME with real-time trust metrics and analyst confidence scores to modulate compliance thresholds dynamically. This approach aligns with AUSTRAC's emphasis on risk-based monitoring while operationalizing transparency, traceability, and human accountability as interdependent elements of effective oversight.

AUSTRAC's alignment with the Australian Government's AI Assurance Framework [37] further reinforces this shift. The framework's eight principles explainability, contestability, accountability, transparency, fairness, reliability, privacy, and human-centered values echo AUSTRAC's stated priorities but go further by offering specific policy tools such as lifecycle risk assessments and AI transparency statements. These tools provide institutions with a governance scaffolding that not only supports compliance but also anticipates the ethical and legal challenges posed by increasingly autonomous AI systems.

The implication is clear: oversight in AI-AML systems must evolve from static rule adherence to dynamic, feedback-integrated governance. This transition demands that institutions embed structured feedback loops, document decision pathways, and ensure that human analysts remain central in validating and contextualizing automated outputs. Without these mechanisms, the promise of AI in AML remains undermined by its own operational opacity and regulatory uncertainty.

A. Systemic Risks

Systemic risks in artificial intelligence-driven anti-money laundering (AI-AML) frameworks emerge not solely from algorithmic inefficiencies but from misalignments between institutional practices, regulatory expectations, and the operational realities of compliance systems. Within the Australian context, the AUSTRAC regulatory environment, while comprehensive in principle, reveals structural and procedural gaps that, if unaddressed, may scale into broader systemic vulnerabilities.

IX. STRUCTURAL AMBIGUITY AND COMPLIANCE OVERLOAD

AUSTRAC's AML/CTF Act 2006 does not distinguish between manual and AI-based transaction monitoring systems, applying uniform expectations around Suspicious Matter Report (SMR) submissions based on "reasonable grounds for suspicion". However, this regulatory equivalence masks a key risk: AI systems often generate large volumes of alerts, many of which are opaque and lack interpretability. Institutions are legally obligated to process these alerts with the same rigor as human-generated suspicions, potentially overwhelming compliance workflows and increasing the likelihood of delayed or inappropriate filings, a systemic failure point [1].

The absence of formal thresholds for false positive or false negative rates introduces additional ambiguity. Without clear benchmarks, institutions are left to self-assess AI system performance, resulting in inconsistent standards of compliance across the sector. Table X illustrates how these misalignments manifest: while "effectiveness" and "ongoing oversight" are broadly achieved, critical areas such as transparency, accountability, and traceability remain structurally deficient. This incomplete alignment reflects a broader systemic fragility where critical compliance decisions may rely on black-box outputs with limited auditable pathways.

Table X assesses how current AI systems align with AUSTRAC's AML/CTF regulatory principles, based on system characteristics and observed operational practices.

As shown in Table X, it illustrates how AUSTRAC and its principles for compliance systems align, or do not align, with the typical characteristics of AI-based transaction monitoring. It is understood that AI can improve efficiency and facilitate oversight when implemented in feedback mechanisms, which

often present deficiencies in areas such as transparency, accountability, and traceability. These weaknesses reinforce the need for continuous human oversight, explainable models, and improved auditability to ensure compliance with AUSTRAC standards.

TABLE X. OPERATIONAL ALIGNMENT: AUSTRAC PRINCIPLES AND AI FEATURE ANALYSIS

AUSTRAC Principle	AI Feature	Operational Scenario	Alignment
Transparency	Deep learning model	Analyst receives an alert but cannot explain why it was triggered	It's not aligned
Accountability	Automated alert generation without review	Alerts are escalated without human validation	It's not aligned
Traceability	No logging of analyst actions or model decisions	Supervisor cannot trace why an alert was closed or escalated	It's not aligned
Proportionality	Rule-based scoring applied uniformly	Low-risk customers flagged with the same thresholds as high-risk clients	Its partially aligned but need improvements
Effectiveness	AI flagging paired with human validation	Analyst reviews a flagged transaction, confirms suspicion, files SMR	Aligned
Ongoing Oversight	Feedback loops and the model retraining	Analyst labels false positives: system learns and improves over time	Aligned

X. FRAGMENTED OVERSIGHT AND RISK DIFFUSION

As highlighted in AUSTRAC's expectations and reflected in the Australian Government's AI Assurance Framework, human oversight is essential not only for ethical compliance but for the iterative improvement of AI systems. However, most AML frameworks fail to operationalize this principle. Feedback from analysts is often informal, undocumented, or siloed. Consequently, AI models are rarely retrained based on field-level insights, allowing detection errors to propagate unchecked. This oversight vacuum introduces not only model stagnation but also a false sense of algorithmic reliability, amplifying systemic exposure to compliance failure.

Moreover, AUSTRAC's current scope excludes several high-risk professions such as lawyers and real estate agents (DNFBPs), leaving exploitable gaps in the regulatory perimeter. These omissions enable criminal networks to route illicit flows through sectors with reduced AI scrutiny, creating shadow pathways that weaken the broader AML ecosystem. As described in international comparisons (see Table XI), other jurisdictions such as the UK's FCA or the US FinCEN offer more robust mechanisms for AI explainability, sandbox testing, and auditability, reflecting a maturity in systemic risk mitigation that AUSTRAC has yet to formalize.

TABLE XI. GLOBAL AI-AML REGULATORY COMPARISON

Regulatory Body	AI & AML Focus	Key Compliance Expectation	Implication for AUSTRAC
AUSTRAC (Australia)	Risk-based, flexible, minimal AI-specific rules	Outcome-focused SMR accountability	AUSTRAC could benefit from transparency requirements by providing new, clearer metrics for measuring AI traceability and SAR justification.
FinCEN (Financial Crimes Enforcement Network) (US)	Supports AI-driven SARs, stresses auditability	Explainable, testable AI systems	AUSTRAC could benefit transparency requirements by providing new, clearer metrics for measuring AI traceability and SAR justification.
FCA (Financial Conduct Authority) (UK)	High transparency and fairness in AI models	Clear algorithmic accountability, sandboxing	AUSTRAC could benefit from incorporating new FCA model explainability standards, promoting tools like SHAP and new decision tree interfaces.
FATF (Financial Action Task Force) (Global)	Global oversight principles: explainability, proportionality	Human oversight + innovation risk control	AUSTRAC can lead implementation by FATF members by proposing national AI audit protocols and assisting with participation in FATF AML working groups.

Table XI highlights key differences in how major regulatory bodies approach AI governance in AML, revealing a spectrum from general principles to detailed algorithmic standards. While AUSTRAC maintains a flexible, risk-based approach, it lacks AI-specific guidance compared to FinCEN and the FCA, which emphasize explainability, auditability, and accountability. The FCA's sandboxing and model transparency initiatives, along with FinCEN's support for testable AI systems, suggest a more proactive stance that AUSTRAC could emulate. Meanwhile, FATF's global guidance underscores human oversight and proportionality but stops short of prescribing technical norms. The comparison signals a clear opportunity for AUSTRAC to lead regionally by adopting clearer traceability metrics, formal AI audit protocols, and aligning with emerging global standards on explainable machine learning in financial compliance.

XI. GLOBAL GAPS AND INTEROPERABILITY RISKS

On a global level, the divergence in regulatory maturity across jurisdictions creates further systemic risk through regulatory arbitrage. Institutions operating in multiple countries must navigate heterogeneous expectations for AI transparency and accountability, which can lead to fragmented governance strategies. As shown in Table XI, AUSTRAC's outcome-based model lacks the explicit interpretability and audit trails mandated by bodies like FinCEN or the FCA. This fragmentation may incentivize minimal compliance in lower-regulation jurisdictions, while overburdening analysts in stricter environments, distorting the effectiveness of AI-AML implementation globally.

A. Implications for Framework Development

The cumulative effect of these systemic factors' regulatory ambiguity, deficient oversight, fragmented feedback loops, and global interoperability gaps poses a risk not only to institutional compliance but also to national and transnational financial security. The proposed framework responds to these challenges by embedding structured human-in-the-loop mechanisms, adaptive threshold modulation, and explainability tools that align with both AUSTRAC's principles and international standards. By explicitly linking trust calibration to analyst feedback and system transparency, the framework mitigates systemic fragility and enhances the defensibility of SMR decisions.

XII. Discussion

The proposed framework was developed following a Design Science Research (DSR) approach, integrating patterns, themes, and operational gaps identified in 61 systematically selected studies published between 2020 and 2025, alongside regulatory reports and industry guidelines. This structured process ensured that each component of the model is logically derived from both academic evidence and practitioner insights, aligning with AUSTRAC's compliance principles.

Unlike previous AML frameworks, which often treat human review as a final, static checkpoint, this model introduces two novel elements: 1) a dynamic trust modulation cycle, capturing how analyst confidence fluctuates and recalibrates in response to false positives; and 2) explicit feedback loops that feed analyst input directly into AI model refinement.

While the present study focuses on theory building, future research will empirically validate this model through quantitative surveys and statistical analysis to test the hypothesized pathways between explainability, trust, fatigue, and escalation decisions.

Fig. 2 illustrates this journey and highlights where key theoretical concepts, such as decision fatigue, confidence calibration, and explainability, are activated in practice.

The proposed human-centered framework focuses on a design that specifically addresses key shortcomings in both the academic literature on AI-AML systems and practitioner rules, such as those of AUSTRAC.

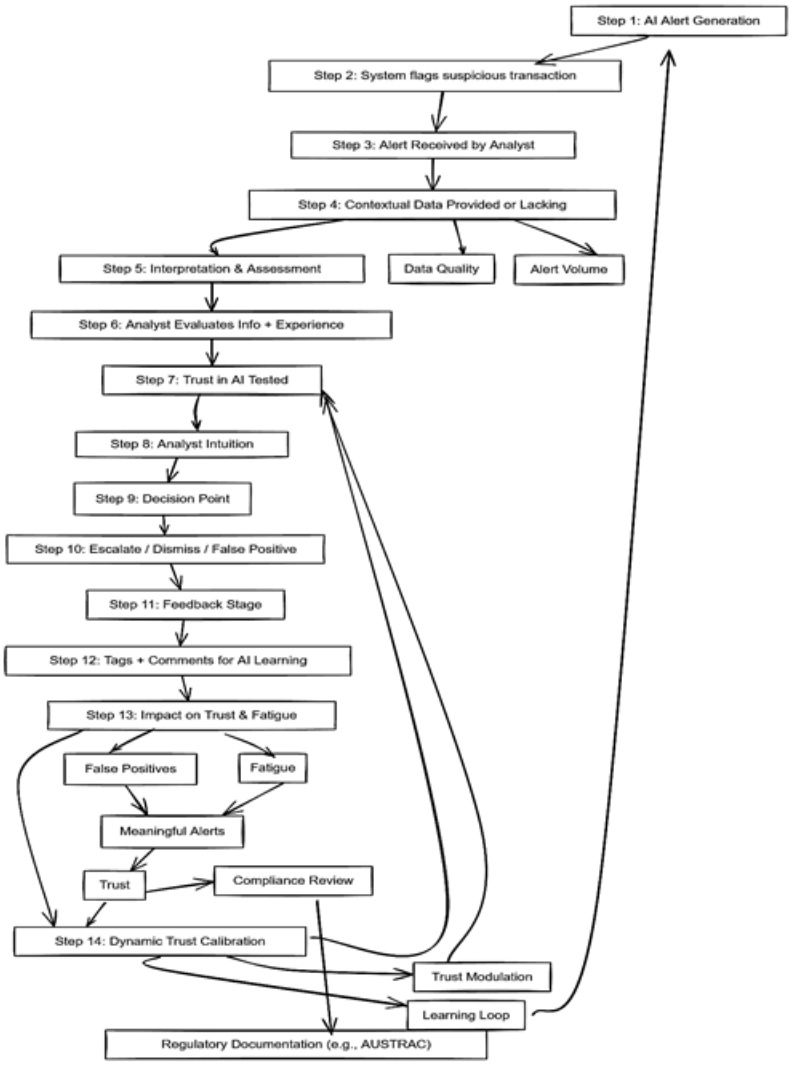

Fig. 2. Conceptual framework: AML analyst journey.

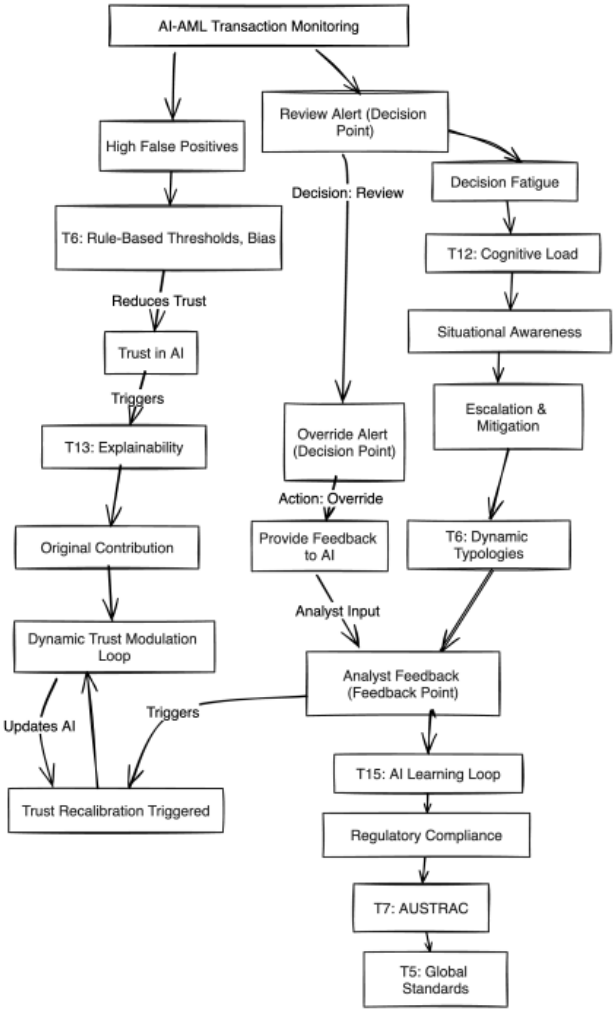

Fig. 3. Analyst workflow model for AI-supported AML decision-making.

The previous discussion on practical strategies, alert fatigue, and regulatory frameworks laid the foundation for the conceptual model. This model integrates theoretical constructs such as human-AI trust, sensemaking, and regulatory alignment, and is illustrated in Fig. 3.

This framework seeks to improve the interaction between human and artificial intelligence decisions in anti-money laundering (AML) settings by dynamically calibrating trust, decision fatigue, and continuously enhancing situational awareness during the alert review process. The goal is to shorten the time between static compliance checkpoints and real-world analytical understanding by integrating explicit feedback loops, trust-based escalation thresholds, and adaptive compliance monitoring.

As shown in Fig. 3, the feedback loop mechanism illustrates this integration. The framework introduces two novel contributions absent in most current AML models:

- A dynamic trust modulation cycle, in which trust in AI declines in response to repeated false positives and is gradually restored through feedback-driven improvements; and
- Explicit feedback loops, whereby analysts' responses and insights are integrated into the model's learning process, thereby narrowing the gap between human decision execution and system adaptation. This process is illustrated in Fig. 4.

A. Contribution to Anti-Money Laundering (AML) Research and Practice

This study contributes to the AML field by introducing a dynamic, human-centered conceptual framework that operationalizes critical analyst–AI interaction variables such as trust calibration, decision fatigue, explainability, and regulatory alignment. Unlike previous models that treat human review as a static checkpoint, the framework demonstrates how analyst trust evolves in response to system outputs and feedback integration, and how this process impacts escalation decisions and regulatory defensibility.

The Framework Analytical Layer Mapping (Table XII) ensures systematic traceability from literature synthesis to conceptual modeling. This transparent development process strengthens the framework's credibility and auditability for practical application in real-world AML settings. It also bridges the gap between theoretical constructs and operational tools,

offering a structure that aligns with AUSTRAC principles and regulatory trends in high-risk financial environments.

Furthermore, the framework provides practical value for compliance officers and AML teams by embedding explainability, analyst confidence, and oversight into daily operations. Through trusted nodes, feedback loops, and threshold calibration, it addresses key gaps identified in AUSTRAC's expectations and supports more defensible Suspicious Matter Reports (SMR).

B. Contribution to AI Trust and Human–AI Collaboration

The study advances cognitive trust theory in regulated AI contexts by introducing the Dynamic Trust Modulation Cycle, a core innovation that captures how repeated false positives erode analyst trust and how structured feedback and improved explainability restore it. This contribution builds upon, but extends beyond, models like Chhetri's A²C framework by explicitly incorporating decision fatigue, situational awareness, and escalation confidence into the trust-feedback dynamic.

This process is illustrated in Fig. 4, as analyst confidence declines in response to repeated false positives, but it also demonstrates that confidence can be recalibrated through structured feedback and model improvements. Visualizing this dynamic cycle of trust modulation, human oversight, and feedback integration emphasizes that it functions as a continuous process rather than remaining static as a final checkpoint.

To understand the dynamic process of trust calibration, the framework also incorporates explicit feedback loops that connect analyst decisions to AI. Since traditional AML systems typically consider human review as a final step in the process, this design demonstrates that analyst input, such as the confirmation of false positives or the justification for escalating

an alert, is systematically captured and used to refine the model's thresholds, just like feedback data.

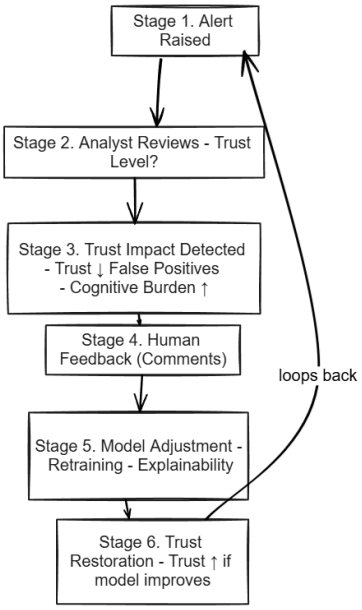

Fig. 4. Dynamic trust modulation loop.

Fig. 5 provides an overview of this mechanism, demonstrating how human judgment continuously shapes system behavior over time and strengthens the compliance case.

Fig. 5 shows the explicit feedback loop for model refinement. It illustrates how analyst feedback on alerts triggers system retraining and threshold adjustments, closing the loop between human judgment and AI model evolution. This cycle enhances the iterative, human-centered approach that distinguishes this framework from static compliance models and ensures that analysts have integrated expertise into the continuous improvement of AI systems.

In the following Table XIII, there are studies that have contributed to the development or application of explainable AI in AML monitoring. It highlights tools such as SHAP values, decision trees, and visual interfaces, and links these contributions to analyst confidence, transparency, and the veracity of effective processes.

As shown in Table XIII, the different AI tools and their explainability, as well as SHAP, LIME, and visual dashboards, directly contribute to analyst efficiency in clarifying model logic and improving alert interpretation. This is especially important in AML/CFT environments, when analysts must justify their case escalation and compliance reporting, following AUSTRAC regulatory standards. When AI decisions are more transparent and interpretable, it reduces decision fatigue, builds cognitive trust, and facilitates human validation, improving operational efficiency and accountability in compliance workflows.

In addition to explicit feedback loops, this framework positions itself as a bridge between algorithmic decision-making and human accountability, in line with AUSTRAC's regulatory expectations. These elements directly support the research objectives, specifically the investigation of analyst behavior in handling alerts, the strategies they adopt to manage false positives, and the regulatory compliance they must follow.

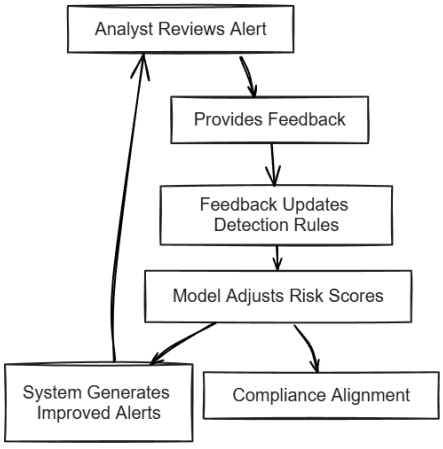

Fig. 5. Feedback loop mechanism.

TABLE XIII. CONTRIBUTION TO EXPLAINABLE AI IN AML

Study	XAI Techniques Used	Contribution to Transparency	Compliance Impact
Kute et al. (2021)	SHAP, LIME, Decision Trees	Improved interpretability of AI-generated alerts for compliance analysts	Supports justifiable SMR decisions; enhances trust in AI recommendations
Bertrand (2024)	Conceptual - Explainability as an ethical requirement	Highlights explainability as key to human trust and accountability	Aligns with AUSTRAC's 'reasonable grounds' requirement for SMRs
Australian Government (2024)	Framework Guidelines (Transparency Standards)	Calls for formal documentation of model logic and intended use	Reinforces AUSTRAC-aligned auditability and oversight expectations
Ghimire (2025)	Precision-recall, threshold tuning	Optimizes model performance visibility	Helps reduce false positives, supports model defensibility

TABLE XIV. AI ERROR TYPES AND HUMAN RESPONSES

Study	Error Type Focused	Human Response Strategy	Tools/Models Used
Mounika et al. (2024)	False Positives	Time-frequency features to reduce alert overload	Random Forest + Skewness/Kurtosis
Eddin et al. (2021)	False Positives	AI enhancement with human validation loop	Machine learning classifier ensemble
Ghimire (2025)	False Positives	Precision-recall optimization to reduce noise	Rule-based + simulated AI outputs
Ketenci et al. (2021)	False Positives	Data integration to reduce alert redundancy	Decision Trees, Logistic Regression
Bertrand (2024)	Cognitive Overload / Alert Fatigue	Human-AI trust calibration and workload awareness	Theoretical (no models)
Deloitte & UOB (2021)	Alert overload	Human-in-the-loop feedback for dynamic tuning	Anomaly Detection + Feedback Loops

Table XIV shows the main types of errors generated by AI in AML systems, such as false positives and the errors it can make when misclassifying them. It also summarizes how analysts respond in practice, highlighting the importance of explainability and a structured process to prevent overload and improve compliance outcomes.

Table XIV shows a comparative summary of studies highlighting the types of artificial intelligence errors, particularly false positives and cognitive overload in analysts, and the human response mechanisms used to mitigate their impact in AML contexts. For a better understanding, each row links a specific error type, such as false positives and alert fatigue, with corresponding strategies, such as feedback gaps, data integrations, or confidence calibration. This comparison between the reference error type and the response mechanism reveals a need to balance technical optimization with human-centered design. Importantly, the table reveals that since most studies focus on technical refinement, not many include confidence as a dynamic and modifiable variable.

The Theory Objective Mapping (Table XV) demonstrates how constructs such as trust, fatigue, and situational awareness are not abstract but are directly linked to AML professionals' lived experiences. Each theoretical construct is aligned with specific research objectives and supports the framework's relevance for both practitioners and scholars seeking to understand human–AI interaction in compliance-driven domains.

As shown in Table XV, a structured mapping between the study's research objectives and their corresponding theoretical foundations ensures the conceptual integrity of the proposed framework. Each objective, ranging from managing false positives to strengthening compliance defensibility, is explicitly linked to established theories such as cognitive trust, human–AI collaboration, and explainability.

The framework transforms conceptual elements of trust and human oversight into measurable, actionable tools for AML professionals. By integrating analyst trust levels, real-time confidence scores, and feedback loops into system retraining protocols, it offers a nuanced mechanism for ensuring compliance that is both adaptive and explainable.

C. Practical and Policy Implications

From a practical standpoint, the architecture offers AML practitioners a clear mechanism for managing false positives, establishing trust levels, and directly incorporating analyst feedback to retrain the system. Through trusted nodes, explainability tools, and feedback loops in daily operations, the framework facilitates real-world compliance defenses based on AUSTRAC's "reasonable grounds" principle. Institutions can demonstrate to regulators that human judgment is not only present but consistently guiding the evolution of AI systems over time.

The framework also contributes policy insights by highlighting the absence of specific regulatory thresholds and explainability standards in existing AUSTRAC guidance. By embedding trust calibration and analyst feedback into the compliance lifecycle, it sets the stage for regulatory advancements aligned with global best practices.

Tables such as the Summary of Identified Gaps (Table XVI), Framework Analytical Layer Mapping (Table XII), and Alignment with Regulatory Expectations (Table XVII) provide empirical support for how the framework addresses persistent challenges in AML operations and policymaking.

Table XVI summarizes these critical gaps and demonstrates their direct relevance to the study's framework.

TABLE XV. LINKING THEORY-OBJECTIVE MAPPING

Theory / Construct	Description	Linked Research Objectives
Trust Theory	Trust in AI systems and cognitive trust determine how analysts accept that decision, override the alert, or otherwise escalate the AI alert. This includes the responsibility for monitoring and calibration after each alert.	RO1: Understand how professionals detect FPs RO2: Understand how professionals evaluate AI alerts RO3: Assess confidence in AI-based alerts
Decision Fatigue Theory	The cognitive load and mental fatigue caused by frequent false positives affect analysts' concentration, willingness to investigate, and the accuracy with which they escalate each alert or case.	RO1: Understand impact of FPs on workload RO2: Understand how professionals evaluate AI alerts RO4: Improve human-AI collaboration and effectiveness
Situational Awareness Theory	When we talk about analysts' ability to perceive, interpret, and act on contextual information, it can impact judgment, confidence, escalation confidence, and compliance defensibility.	RO2: Understand how professionals evaluate AI alerts RO3: Assess confidence in AI-based alerts RO4: Improve human-AI collaboration and effectiveness

TABLE XVI. SUMMARY OF IDENTIFIED GAPS

Framework Component	Gap in Literature
Feedback loops to AI systems	Most studies addressing AI-AML view trust as something static, something that doesn't improve or makes little difference, which means that how analysts' trust evolves isn't explored (Fig. 4).
Analyst fatigue	Cognitive fatigue is often underexplored in AML research, especially in the context of AI false positives (Q5).
Explainability	How analyst feedback changes AI results are rarely investigated in the literature; for example, AUSTRAC lacks feedback norms or standards.
Regulatory compliance	Some technical articles describe the different tools that exist and are included in some research, but not how practitioners use or interpret them (Table XIII).
Human decision after the alert	Academic works usually lack a link to the regulatory context; a clear example can be seen in Table XII on AUSTRAC's obligations.
Trust calibration	In the previous models, a limitation to the generation of alerts is observed, this change, this framework includes a complete human escalation process (Fig. 3)

Table XVI functions as a conceptual tracing map, linking the "why" of the framework to the gaps in the literature, and the "what" of the components, thereby providing a foundation for future empirical testing. Table XVI shows how each component of the proposed conceptual framework directly addresses unanswered questions in the existing AML and AI literature, linking features such as the trust modulation cycle, adaptive compliance thresholds, and feedback mechanisms to specific scholarly and operational gaps.

Table XVII illustrates how each component of the framework addresses specific knowledge gaps in the literature and regulation, highlighting the originality of the model and its contribution to both theory and practice in the field of regulatory compliance within the area of anti-money laundering.

TABLE XVII. ALIGNMENT OF REGULATORY EXPECTATIONS WITH AML SYSTEM CAPABILITIES

AUSTRAC Principle	System Capability	Compliance Gap	Example
Explainability	Black-box alerts limit transparency	Trust and auditability issues	Westpac
Timely SMRs	Alerts are not always escalated in time	Regulatory risk in SMR timing	CBA
Ongoing Oversight	Feedback loops are not always implemented	Lack of analyst feedback loop	Elliptic
Accountability	Responsibility unclear between the system and analyst	Ambiguity in fault ownership	Tabcorp

As shown in Table XVII, each component of the proposed framework addresses the gaps specifically identified through the literature review and analysis of regulatory practices. When these gaps are combined with important elements of the framework, such as adaptive trust calibration, feedback loops, and explainability, this table demonstrates how the framework not only aligns with current regulatory expectations in AML prevention but also offers new contributions to the system.

D. Limitations and Future Work

While the framework provides a robust foundation for AML-AI system design, it remains conceptual and context-specific. Its development is grounded in 61 literature sources and Australian regulatory guidelines, but its generalizability across jurisdictions still needs validation. Moreover, the framework has not yet been tested with primary empirical data, which currently limits real-world applicability.

Future work should focus on operationalizing the framework's constructs into measurable indicators to support empirical evaluation. These indicators, spanning trust calibration, explainability, decision fatigue, and oversight, are designed to reflect actual AML workflows and can inform both qualitative studies, for example, practitioner interviews, and quantitative assessments using operational data.

While prior studies have identified issues such as trust erosion or analyst fatigue (Alahmadi, 2022), few offer mechanisms for real-time trust recalibration or system adaptivity. This framework uniquely incorporates feedback loops as functional components that not only address cognitive strain but also support oversight continuity. In effect, it fills a critical gap in the intersection between compliance design and human-AI interaction.

TABLE XVIII. MAPPING OF FRAMEWORK CONSTRUCTS TO POTENTIAL MEASURABLE INDICATORS

Framework Construct	Proposed Measurable Indicator	Example Data Source	Potential Use Case
Trust Calibration	Percentage of AI-generated alerts overridden or escalated by analysts	Internal AML system logs	Assessing how analyst confidence in AI decisions evolves over time
Explainability	Average time analysts take to resolve an AI-generated alert	Case management system	Evaluating impact of explainability tools on decision speed
Decision Fatigue	Number of alerts processed per analyst per shift and error rates	Analyst workload reports	Identifying workload thresholds that degrade decision quality
Feedback Loop Integration	Frequency and type of analyst feedback incorporated into model retraining	Model governance records	Measuring the effectiveness of human-in-the-loop system updates
Regulatory Alignment	Proportion of escalations meeting AUSTRAC reporting criteria	Compliance audit reports	Tracking alignment of AI decisions with statutory obligations

Table XVIII explains that once the indicators are defined, the framework becomes testable in operational AML environments. It is suggested that future research could employ a mixed-methods design, combining practitioner surveys on trust and fatigue with quantitative analysis of system logs to help validate the relationships between the constructs and help refine the model for broad implementation.

Table XIX presents a draft of a Likert-scale survey developed to measure the key theoretical constructs explored in this study, such as trust in AI, decision fatigue, explainability, and perceptions of supervision. Each item of this scale survey is designed to capture practitioner attitudes using a 5-point scale (1 = Strongly Disagree to 5 = Strongly Agree). This survey aims to support future quantitative extensions of the current research framework.

Future research should address these limitations by:

- Deploying the Likert-scale survey instruments (Table XIX) to gather practitioner data across diverse financial institutions.
- Conducting scenario-based testing and interviews to validate trust calibration, escalation confidence, and decision fatigue in practice.
- Testing the model in other regulated industries, such as healthcare, cybersecurity, or insurance, to examine cross-domain relevance.

- Integrating findings from quantitative log data and qualitative feedback into a mixed-methods study design for broader validation.

The measurement mapping (Table XX) confirms that each construct in the model can be tested using well-established methods and tools. This ensures that the framework is not only theoretically sound but also empirically actionable, a rare feature among current AI-AML models.

As shown in Table XX, the components of the framework are directly linked to a measurable construct, supported by established variables and practical methods that reflect practices in AML and XAI research. This mapping demonstrates that the framework is not only conceptually sound but also empirically testable by asking clear survey questions and scenario-based tasks. When constructs such as confidence calibration, analyst fatigue, and explainability are aligned with validation methods by [18], [31], [32], among others, the study reinforces its commitment to evidence-based design and provides a solid foundation for future quantitative validations. This clarity ensures the framework's relevance to both academic and practitioner settings.

When there is a clear definition of what is to be measured and how, the study provides a roadmap for future researchers. While this study was developed for AML transaction monitoring, the framework's core principles are broadly applicable across sectors where AI and human oversight intersect in high-stakes decision-making environments.

TABLE XIX. LIKERT-SCALE SURVEY FOR AI-AML CONSTRUCTS

Construct	Questionnaire Item (5-point Likert Scale)
Trust in AI	I trust the AI alerting system to correctly identify suspicious transactions.
Trust in AI	I believe the AI system supports my decision-making process.
Decision Fatigue	I feel mentally exhausted after reviewing numerous AI-generated alerts.
Decision Fatigue	I rush through alerts when I know most are false positives.
Explainability	I understand why the AI system flags certain transactions.
Explainability	The AI system provides clear and understandable explanations.
Oversight & Responsibility	I feel personally responsible for verifying the accuracy of AI alerts.
Oversight & Responsibility	Responsibility for AI alert errors lies with the analyst more than the system.

TABLE XX. CONSTRUCTS AND MEASUREMENT FOR EMPIRICAL VALIDATION

Framework	Construct	Example Measurement Variable	Method
Feedback Loops to AI Systems	Feedback quality and frequency	Analyst perceptions of how feedback is integrated into model updates.	Likert-scale items or Frequency scale Example: How often do you provide feedback?
Analyst Fatigue	Decision fatigue and Cognitive load	Perceptions of the amount of workload due to the constant repetition of false positives.	Cognitive Load Scale Example: Rate the mental effort required for daily alert review
Explainability	Explainability Satisfaction	Greater clarity and interpretation of alerts generated by the AI.	Likert-scale items Example: I understand how the AI reached its decision for each alert
Regulatory Compliance	Compliance	Measurement of analysts' confidence in the decisions they make and whether they align with internal or AUSTRAC policies.	Likert-scale agreement items Example: I believe my decisions would be defensible in a compliance audit.
Human Decision After the Alert	Escalation confidence	Measurement of analyst confidence in deciding whether to escalate or dismiss the alert.	Scenario-based questions + Likert items Example: Given this scenario, how confident are you in escalating this alert?
Trust Calibration	Trust in AI Systems	Perceptions of system reliability and analyst confidence levels	Likert-scale items Example: I trust the AI system's output when explanations are clear and consistent.

XIII. CONCLUSION

This study examined how trust, decision fatigue, and explainability interact within AI-driven anti-money laundering (AML) transaction monitoring systems, addressing a critical gap in the literature that has traditionally examined these constructs in isolation. Through a structured synthesis of academic research, regulatory guidance, and industry practice, the study highlighted how high false positive rates, sustained alert pressure, and opaque system behavior undermine both analyst performance and compliance defensibility.

To address these challenges, the study introduced the Dynamic Trust Modulation framework, which conceptualizes trust as a feedback-driven and context-dependent construct shaped by system performance, analyst workload, explainability mechanisms, and regulatory constraints. By framing trust calibration, decision fatigue, and explainability as interdependent elements of AML workflows, the framework provides a socio-technical lens for understanding human–AI collaboration in high-stakes compliance environments.

The contributions of this work are both theoretical and design-oriented, with implications for practice. The framework extends human-AI collaboration research into the AML domain and offers design-relevant insights for developing AI systems that support accountability, decision defensibility, and sustainable human oversight. While this study is conceptual in

nature, it establishes a foundation for future empirical validation and mixed-methods research aimed at operationalizing trust dynamics and feedback mechanisms in real-world AML settings.

ACKNOWLEDGMENT

This project was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, Saudi Arabia, under grant no. (GPIP: 1807-830-2024). The authors, therefore, acknowledge with thanks DSR for technical and financial support.

***Abstract*—The rapid development of the Internet of Things (IoT) requires systematic development methods that address complex functional, architectural, and validation concerns. This review synthesized research published between 2016 and 2023 to characterize common functional requirements (FRs), current modelling techniques, and validation practices. From an initial corpus of 1,598 articles, 425 publications were selected for in-depth analysis. The results demonstrated a consistent emphasis on data handling, inter-device communication, analytics, and system management. Nevertheless, critical gaps persisted in end-to-end security and context-aware computing. Sequence, class, and use case diagrams dominated modelling practices, which indicated attention to system behavior and interactions. Conversely, state machine and deployment diagrams were underutilized despite their potential to better capture runtime states and architectural configurations. The validation approaches in IoT development were primarily empirical, with experiments and case studies predominating. Expert reviews are valuable for early-stage assessment, but were rarely applied, which indicated missed opportunities for early improvement of design quality in the lifecycle. Overall, the results reflected the maturity and limitations of current practices in IoT engineering. These limitations can be addressed by diversifying modelling techniques, enhancing security integration, and using hybrid validation frameworks. This review presented a foundational reference to guide the systematic development of scalable, secure, and context-aware IoT systems, and contributed to the evolving body of IoT software engineering knowledge.**

***Keywords*—Functional requirements; Unified Modeling Language; validation; Internet of Things; systematic review**

I. Introduction

The Internet of Things (IoT) represents a significant technological advancement that enables the interconnection of physical devices equipped with sensors and communication interfaces capable of data exchange across a network. This transformation of physical systems into smart environments has led to the emergence of complex systems that require rigorous requirements engineering (RE) practices to ensure successful IoT application development and deployment [1], [2]. The diverse hardware, software, and communication protocols requires a comprehensive understanding of functional requirements (FRs), which define the essential behaviors, capabilities, and services an IoT system must deliver to reliably meet stakeholder expectations across varying operational contexts [3], [4].

The literature determining the essential FRs in IoT has classified them into thematic groups crucial to the success of the system. The main themes include service discovery and orchestration, device management and security, communication and data management, and context-aware features [3], [5]. The theme-based organization aids developers and stakeholders in addressing the multifaceted integration challenges presented by heterogeneous elements of the system systematically [6], [7]. Several applications in IoT do not systematically define these FRs, which results in errors that could negatively affect user satisfaction and system performance [4], [8].

Modelling is essential in the RE process. Unified Modelling Language (UML) is effective for demonstrating IoT system functionalities and presents a visual representation that enables developer and stakeholder communication [9]. The UML adaptations through the IoTReq extension improve its pertinence in addressing the specific challenges that characterize IoT environments, such as distributed control, heterogeneity, and context-awareness [8], [10]. These modelling approaches are essential to ensure that the FRs defined are captured and understood adequately before a system is implemented.

The FR validation is critical in the lifecycle of IoT system development. The designed systems are confirmed to perform as planned in their chosen contexts through experimental prototypes, simulations, and expert evaluations [11], [12]. Each approach is subject to compromises concerning generalizability and empirical rigor and thereby requires a carefully personalized approach to address specific IoT application situations [13], [14]. The process of validation confirms functional adherence and identifies possible areas for enhancement, thus encouraging the continuous improvement of IoT applications.

This systematic review charts the present landscape of FRs in IoT development and reveals underexplored areas. This review presents actionable observations to create stronger and

*Corresponding author.

more adaptable IoT systems that can meet the evolving requirements of varied application areas. Sustained focus on the definition, modelling, and validation of FR will be essential in addressing IoT complexities and fully realizing its potential.

II. METHODS

A. Research Questions

This study was organized in three research questions (RQs) to guide the investigation. The RQs provided a structured framework to examine which functional requirements are prioritized in existing research, and how they are modelled and validated within the IoT context. Table I summarizes the RQs and their underlying motivations and highlights their importance to the overall study objectives.

TABLE I. THE RESEARCH QUESTIONS AND MOTIVATIONS

Research Question	*Motivation*
RQ1: What are the common FRs in IoT application development?	This question aims to analyze the distribution of studies regarding the FRs addressed in IoT development. The study aimed to determine to which these identified FRs have been practically applied and integrated into IoT development, which highlights their practical application and relevance within the field.
RQ2: Which UML models are most used for modelling FRs in the development of IoT applications?	The answer to RQ2 would facilitate the identification of the UML diagrams adopted to support the FRs of IoT applications. The answer would also aid the identification of the approaches that have gained IoT development practitioners' attention and assessment of its effectiveness in representing the FRs of IoT projects.
RQ3: What are the strategies applied in IoT FR validation?	To identify the validation methodologies used for verifying the FRs in IoT projects.

B. Literature Search Strategy

The literature was searched using the Web of Science, Scopus, and IEEE Xplore databases. The search targeted titles, keywords, and abstracts, and applied a consistent set of search terms across all databases: ("Internet of Things" OR "IoT") AND ("functional requirement" OR "requirements model" OR "UML" OR "Unified Modelling Language") AND ("validation" OR "verification" OR "evaluation"). The search was limited to articles published between January 2016 and December 2023.

C. Inclusion and Exclusion Criteria

Rigor and relevance in the study selection were ensured by applying specific inclusion and exclusion criteria.

1) Inclusion criteria: Studies were considered eligible for inclusion if they satisfied the following conditions:

- Publication date: Published between January 2016 and December 2023;
- Database: Indexed in Web of Science, Scopus, or IEEE Xplore;
- Topic relevance: Addressed the IoT in the context of FR or UML, and discussed aspects of validation or verification related to these requirements or models;
- Search scope: Appeared in titles, abstracts, or keywords containing the defined search terms;
- Publication type: Peer-reviewed journal articles, conference papers, or book chapters;
- Language: Published in English to maintain interpretation and analysis consistency.

2) Exclusion criteria: Studies were excluded from this review if they met any of the following conditions:

- Publication date outside range: Published before January 2016 or after December 2023;
- Non-relevant focus: Addressed IoT broadly but did not cover FRs, UML, validation, or verification;
- Publication type: Editorials, opinion pieces, prefaces, tutorials, theses, patents, standards documents, or grey literature and any non-peer-reviewed publications;
- Language: Not published in English;
- Accessibility: Full text was unavailable.

D. Study Selection

The studies were selected in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [15] (see Fig. 1).

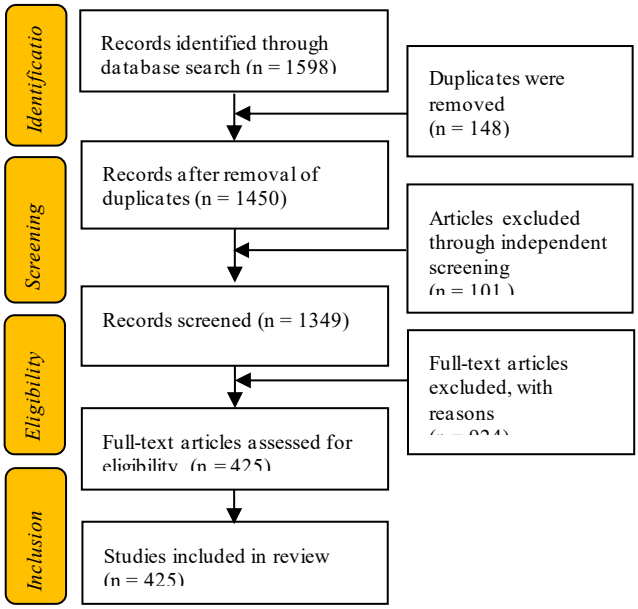

Fig. 1. Flowchart of research process adapted from PRISMA diagram (adapted from [15]).

The process included identification (search results were imported into a reference management tool and duplicates were removed), screening (titles, abstracts, and keywords were reviewed for relevance), eligibility (full-text articles were assessed based on predefined inclusion and exclusion criteria), and inclusion (studies meeting all criteria were selected for final analysis and synthesis). Overall, the database search identified a total of 1,598 publications. After screening, 425 publications were selected and included in the systematic

literature review. Supplementary table (Table II) presents the complete list of included studies.

III. Results and Discussion

A. RQ1: What are the Common FRs in IoT Application Development?

Identifying and analyzing common FRs is crucial for the success and efficiency of IoT ecosystems in the IoT application development domain. This study integrated insights from extensive literature and assessed the importance of FRs prevalent in IoT applications. A consensus emerged around 24 FRs, which can be viewed through their occurrence frequencies within the existing body of knowledge (summarized in Fig. 2).

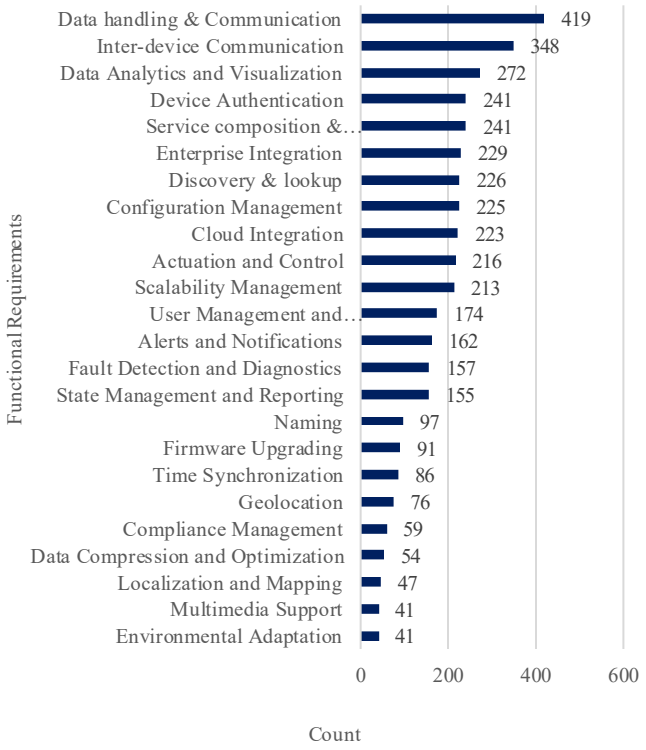

Fig. 2. The FRs of IoT application development.

The foundational FRs of data handling and communication (n = 419) and inter-device communication (n = 348) highlighted the necessity of robust and reliable connectivity for effective IoT operations. These FRs are essential for enabling seamless data flow and interoperability between IoT devices, cloud platforms, and edge nodes. A comprehensive understanding of these communication frameworks was underscored by the requirement for effective data sharing protocols, which was supported by research that emphasized the important role of integrated communication systems and data management in IoT architectures [16]–[18]. Evidently, the prevailing emphasis on communication reflected the fundamental characteristics of IoT systems, whose functionality relies on interconnectedness.

Interoperability and integration requirements, such as service composition and programmability (n = 241), enterprise integration (n = 229), and cloud integration (n = 223), emphasized the need for IoT applications to adapt and operate within heterogeneous environments. This result supported the shift towards more service-oriented architectures within IoT ecosystems. Effective service discovery and integration mechanisms are vital for dynamic integration into existing enterprise systems, and much research supported the necessity of such adaptive frameworks to enhance IoT solution scalability and flexibility [16], [17]. A key priority in the literature was device capacity to effectively communicate and cooperate while autonomously discovering and integrating services.

Data analytics and visualization (n = 272) emerged as a critical requirement that facilitates the conversion of raw data into actionable insights. The prominence of this FR in the literature underscored the integration of advanced analytical capabilities with IoT systems, where artificial intelligence can significantly enhance operational efficiency and decision-making processes [19]–[21]. This result highlighted the trend towards leveraging big data analytics within IoT applications to identify trends and patterns that drive system intelligence.

Actuation and control (n = 216) bridged the gap between data analysis and physical responses in IoT systems. This FR is integral in automated environments, where real-time data processing translates directly into physical actions, thus facilitating interaction with the environment [22], [23]. The importance of such operational management capabilities is correlated with their deployment in important sectors, such as healthcare, smart cities, and industrial operations, where timely responses are dominant.

The emphasis on fleet-level operational management revealed additional significant FRs that included configuration management (n = 225) and scalability management (n = 213). These FRs emphasize the systemic requirements for managing devices over their lifecycle effectively. As IoT technologies mature, device network management collectively becomes essential to ensure reliability and efficiency against potential systemic failures. Given that IoT devices are increasing exponentially, methods for ensuring system observability and maintainability are becoming increasingly important [24], [25].

Regarding security, device authentication (n = 241) and user management and authentication (n = 174) were comparatively well represented, but the shortcomings in other security mechanisms, such as encryption and intrusion detection, highlighted significant gaps in comprehensive security approaches across the IoT landscape [26]–[28]. This imbalance indicated a persistent need for research to evolve toward developing robust, multi-layered security frameworks for IoT environments.

Lastly, several FRs related to context-awareness and optimization, such as geolocation (n = 76) and environmental adaptation (n = 41), were under-represented, which suggested that substantial potential for growth in these domains remains as the IoT ecosystem evolves. Addressing these unfilled niches can enhance the overall functionality of IoT solutions by

tailoring them more closely to the intricacies of application-specific requirements.

The FR analysis revealed a focus on IoT system connectivity, interoperability, analytics, and management. Furthermore, the analyses identified important areas that should be explored further, specifically in security and domain-specific applications. Addressing these shortcomings, particularly in developing comprehensive security strategies and enhancing context-aware capabilities, would be instrumental in advancing IoT application development and ensuring its viability in an increasingly interconnected world.

B. RQ2: Which UML Models are most used for Modelling FRs in the Development of IoT Applications?

In the IoT application development context, the analysis indicated a prevalent utilization of specific UML diagrams for modelling functional requirements. The data (see Fig. 3) demonstrated that sequence, class, and use case diagrams were among the most commonly used diagrams, which supported their importance in IoT systems development [29]–[32].

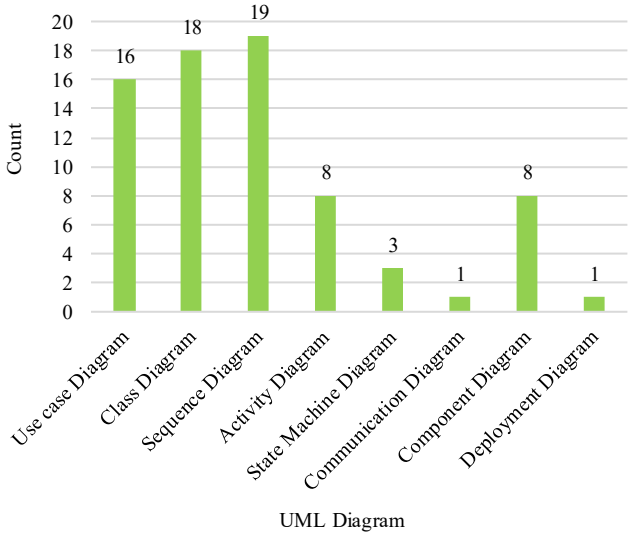

Fig. 3. Frequency of UML models used for modelling FRs in IoT application development.

Sequence diagrams (n = 19) were one of the frequently used modelling tools, and are essential for mapping out time-dependent, message-driven interactions typical within IoT environments. The strength of this diagram is its ability to effectively represent asynchronous communication flows and event-driven IoT systems, which enables a clear depiction of the interaction chain that involves sensors, data processing units, and actuators [29]–[31]. For example, sequence diagrams are visual narrations of the information flow from sensor data capture to cloud processing, and clarify how IoT system components come together in real-time settings [32], [33].

Use case diagrams (n = 16) are effective for capturing functionalities that are user-centric. Such diagrams bridge technical teams and stakeholders, and facilitate a primary comprehension of user interactions and system requirements, especially within smart homes and healthcare domains [29]–[31]. Through this high-level abstraction, stakeholders can articulate and understand the functionalities and purpose of the system more clearly, which ensures that the needs of the user are prioritized in the process of development [29], [30], [32].

The FRs are complemented by class diagrams (n = 18), which articulate the static structure of IoT systems. Class diagrams are influential in defining core objects, such as sensors and actuators, and their characteristics and relations, and act as the foundational design for system implementation in model-driven engineering styles. Integrating class diagrams with use case and sequence diagrams encourages an inclusive perspective of the static framework and dynamic interactions of IoT applications [32], [34], [35].

While the discussion was dominated by the aforementioned diagrams, other UML diagrams [activity diagrams (n = 8) and component diagrams (n = 8)] are also valuable. While activity diagrams were not as widely adopted, they excel in modelling complex workflows, which potentially aids in scenarios involving multi-device interactions or context-aware processes [36][37]. Similarly, component diagrams enhance architectural clarity by defining system decomposition, which is crucial for developing scalable and maintainable IoT solutions [38], [39].

Conversely, the application of state machine diagrams (n = 3), communication diagrams (n = 1), and deployment diagrams (n = 1) was notably limited. This limited application raises concerns about their underutilization despite their potential benefits in representing system states, modularity, and deployment environments. State machine diagrams may be particularly relevant for capturing lifecycle behaviors and reactivity patterns, which are important elements in adaptive IoT applications [40], [41]. The absence of these diagrams indicates a gap in the modelling methodologies that could be corrected by promoting a more diverse usage of UML tools academically and practically [42], [43].

While sequence, use case, and class diagrams are fundamental for articulating functional requirements in IoT applications, a broader adoption of complementary diagrams (activity, component, and state machine diagrams) is required. Researchers and practitioners who bridge this modelling gap can enhance their frameworks and methodologies, ultimately leading to more robust and effective IoT systems.

C. RQ3: What are the Strategies Applied in IoT FR Validation?

The FR validation in IoT application development uses several predominant strategies, which highlight a robust methodological framework in the literature. The analysis (summarized in Fig. 4) revealed that this space was dominated by empirical evaluation techniques, primarily through experiments and case studies, where experiments comprised a significant proportion of the documented methods. This predominance underscored a trend toward validating the performance and behavior metrics of IoT systems in controlled and real-world scenarios, which reflected the necessity of contextually rich data in developing effective IoT applications.

The reliance on experimental methods indicated the emphasis of the IoT community on reproducibility and quantitative performance metrics. Experiments in controlled

environments can precisely measure various system parameters, which include latency, energy consumption, scalability, and interoperability [44], [45]. Such parameters are important given the inherent complexity and dynamic interactions of IoT devices, which operate under diverse and frequently unpredictable conditions [46]. Notably, various empirical analyses demonstrated that prototypes and simulations were frequently used to refine system functionality before deployment. Empirical techniques facilitate continuous integration and iterative development, which align with agile methodologies in software engineering [47].

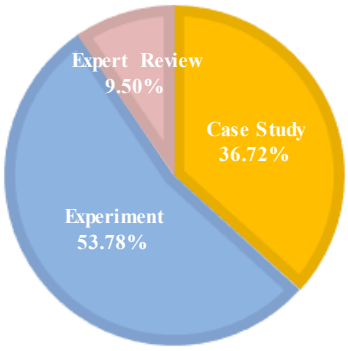

Fig. 4. Strategies used for functional requirement validation in IoT application development.

Case studies provide an enriching contextual lens that enables the validation of IoT FRs. This method allows researchers to embed evaluation efforts within realistic and application-specific environments, such as healthcare and industrial IoT systems [48]. These studies aid the elucidation of domain-specific constraints and user interactions that may be neglected in controlled experiments, thus enhancing the understanding of operational challenges and real-world implications of FRs. Incorporating case studies reflects researchers' awareness of the contextual factors that can influence the success of IoT systems beyond technical validation [49].

Expert reviews comprised a modest proportion of the validation strategies, but have important value, especially in the early stages of requirement elicitation and specification. These reviews aid the identification of ambiguities or inconsistencies within the requirements and contribute to a more thorough validation [50]. Nevertheless, their lower adoption may stem from perceptions of subjectivity and the challenges in assembling a reliable expert panel [51]. Nonetheless, incorporating expert evaluations with empirical approaches can improve validation framework robustness by merging quantitative rigor with qualitative insights [52].

This analysis of present approaches in IoT FR validation revealed that empirical methods were dominant, specifically, experimental approaches that highlight measurable system behaviors, which were accompanied by context-relevant perspectives from case studies and the qualitative contribution from expert appraisals. The evolution of this field demonstrates the clear necessity of frameworks of hybrid validation that simultaneously use the strengths of expert insights and empirical evaluations to develop standardized benchmarks customized to the diverse IoT landscape.

IV. Conclusion and Future Work

This study emphasized the basic trends in IoT application development and focused on FRs, modelling methods, and validation approaches. The analysis suggested that the main focus has been on important capabilities, such as analytics, inter-device communication, data handling, and system-level management. Nonetheless, crucial areas, such as context-awareness and end-to-end security, were notably under-represented, and are important for deployments in the real world. These aforementioned gaps suggest that research priorities are disconnected from operational requirements in the landscape of IoT.

Regarding modelling practices, a clear prevalence of traditional diagram types (sequence and class diagrams) was established, as these diagrams effectively capture functional flows and system structures. Nevertheless, the infrequent use of state machines, deployment, and communication diagrams indicated limitations in the existing modelling frameworks. These diagrams are essential for capturing the full spectrum of functional requirements of IoT applications. Therefore, enhancing modelling practices may be important for addressing architecture-specific challenges and optimizing system resources.

The analysis also revealed that validation strategies within IoT development practices strongly relied on experimental methods and case studies. Although these methods provide valuable empirical insights, incorporating expert reviews, particularly during the early design stages, can strengthen their effectiveness. A combined approach that integrates empirical testing with qualitative assessments can support more holistic evaluations of FRs and system performance.

Future research directions should emphasize the need to expand the focus on FRs, especially in multi-layered security protocols and adaptive computing environments. These elements are vital for supporting advanced applications, such as autonomous systems. Integrating context-aware design practices, coupled with the adoption of modern modelling techniques that can address functional and contextual dynamics, is another promising research direction. Finally, advancing IoT development would rely on the development of adaptive meta-modelling frameworks that can intelligently suggest suitable modelling practices based on system characteristics.

In summary, IoT application development has progressed substantially, but significant operational gaps across FRs, modelling practices, and validation methods remain. Future work should aim to broaden functional scopes, strengthen UML modelling practices, and pioneer advanced validation strategies that promote a more integrated approach to IoT system security and optimization. Addressing these areas would enable researchers and practitioners to better align their efforts with the evolving landscape of IoT technologies and application demands.

ACKNOWLEDGMENT

The authors would like to express their gratitude to Universiti Teknologi MARA for funding this research under the Geran Insentif Penyelidikan (GIP), Grant Scheme File No.: 600-RMC/GIP 5/3 (037/2024). The authors also acknowledge the Ministry of Higher Education, Malaysia, for financial support under the Fundamental Research Grant Scheme Early Career (FRGS-EC), Grant Scheme File No.: FRGS-EC/1/2024/ICT04/UITM/02/2. Special appreciation is extended to the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA Cawangan Negeri Sembilan, Universiti Teknologi MARA Shah Alam and the Institute of Graduate Studies, Universiti Teknologi MARA, for their invaluable assistance in the publication of this work.

CAT-TODNet: A Contextual Transformer-Based Optimized Deformable Convolution Framework for Efficient ECG-Based Heart Failure Detection

Vinitha V, V. Parthasarathy, R. Santhosh
Department of Computer Science and Engineering,
Karpagam Academy of Higher Education, Coimbatore, Tamil Nadu, India

***Abstract*—Heart Failure detection using Electrocardiogram (ECG) signals is a critical clinical task, as continuous analysis of cardiac waveforms supports early diagnosis and effective intervention. Despite advancements in machine learning and deep learning techniques, existing approaches often suffer from limited contextual representation, sensitivity to noise, and inadequate handling of non-stationary temporal deformations in ECG signals, which restrict diagnostic reliability. To address these challenges, this study introduces a novel deep learning framework termed Contextual Auxiliary Transformer with Triple Stacked Optimized Deformable Convolution Network (CAT-TODNet) for accurate heart failure detection from ECG signals. ECG recordings acquired from the MIT-BIH Arrhythmia Database are initially subjected to three-stage preprocessing, including denoising, signal smoothing, and Power Line Interference (PLI) removal, to enhance signal quality. The Contextual Auxiliary Transformer (CAT) module explicitly captures both static and dynamic contextual dependencies, enabling robust contextual feature extraction. These context-aware features are subsequently processed through triple stacked deformable convolution layers with adaptive receptive fields. To ensure stable offset estimation under non-stationary ECG conditions, the Al-Biruni Earth Radius (ABER) optimization algorithm is employed to optimize deformable convolution offsets, overcoming the limitations of gradient-based learning. Experimental results demonstrate that CAT-TODNet achieves an accuracy of 98.88.**

***Keywords*—Heart Failure (HF); Electrocardiogram (ECG); Artificial Intelligence (AI); Contextual Auxiliary Transformer (CAT); deformable convolution; optimization algorithm**

I. Introduction

Heart Failure (HF) is better understood as a complicated condition with a range of clinical indications rather than just one illness [1]. Heart failure is caused by a variety of circumstances, such as structural heart disease as well as functional changes in the heart. Poor circulation is the result of the heart's inability to pump blood efficiently throughout the body, which causes this ailment. People who have heart failure usually have a number of obvious symptoms, including exhaustion, edema in the ankles, and dyspneal [2]. In addition, patients could show symptoms from abnormalities in cardiac or noncardiac tissues, such as peripheral edema, lung fissure, and increased jugular vein pressure. Researchers have been looking into a variety of strategies for predicting cardiac conditions [3]. However, it has proven difficult to anticipate these conditions precisely in their early phases due to a number of factors, including complexity, implementation time, and the precision of the selected method. It is crucial to stress that early diagnosis and appropriate treatment can make a substantial difference in saving lives [4]. According to an international survey conducted by the European Society of Cardiology (ESC), 4.2 million new instances of heart failure were identified globally every year on top of the 30 million people who currently have the condition. Regretfully, a substantial proportion of patients among one fifth and half do not live past the first year following the onset of heart failure, and almost all patients experience a mortality rate within the period of five years [5].

Concerning the diagnosis of heart failure (HF), the electrocardiogram (ECG) is the non-invasive test that is most frequently used in the medical industry to record and capture a patient's cardiac activity [6]. However, the lack of sensitivity and specificity of classic manual analysis approaches employed to diagnose HF through the examination of ECG signals is frequently observed. ECG is a widely used diagnostic instrument that measures changes in the electrical activity of the heart to determine the condition of the heart [7]. It provides physicians with a clear-cut and simple-to-understand clinical signal. Although people with and without heart failure exhibit discernible differences in their ECG patterns, these differences are not very specific [8]. Moreover, it's critical to recognize that individual variations may be significant while manually examining ECG readings in order to diagnose heart failure. To be clearer, Cardiologists use visual analysis of ECG recordings to identify abnormalities [9]. However, this approach can take a long time, particularly when evaluating multiple ECG readings from different patients [10], [11]. Furthermore, the consistency of manual ECG signal interpretation might be affected by differences in interpretation between observers. Because of this unpredictability and time-consuming nature, developing and implementing Computer-Aided Diagnosis (CAD) systems becomes essential to improving the reliability of diagnosing heart failure using ECG records [12], [13].

There are numerous computer-assisted approaches for diagnosing heart failure have been developed as a result of the development of machine learning techniques [14]. These systems use automated feature extraction to determine heart problems with high accuracy. The most sophisticated instrument in the realm of biomedical engineering applications is Deep Learning (DL), a cutting-edge subset of Machine Learning (ML) [15]. It demonstrates its efficacy in this field by integrating hierarchical neural networks. The common ML models utilized are Naïve Bayes (NB), Gradient Boosting Classifier (GBC), Support Vector Machine (SVM), Random Forest (RF), Adaptive Boosting model (AdaBoost), and Stochastic Gradient Descent (SGD)

[16], [17]. Those ML classifiers are utilized for classification purpose of HF. The common DL models utilized are Long Short-Term Memory (LSTM), Convolution Neural Network (CNN), Gated Recurrent Unit (GRU), Deep Neural Network (DNN)., Auto Encoder (AE) etc.., [18]. Those DL models are utilized for feature extraction and feature analysis. Nonetheless, conventional ML/DL techniques necessitate manually designed features, which demand a trial-and-error approach to attain the highest classification accuracy [19]. To achieve effective and precise classification, it's essential to identify the most suitable visual characteristics for extracting ECG signals. Consequently, there's a need for further exploration into ECG signal classification without the need for feature extraction [20].

Despite recent advances in machine learning, deep learning, and transformer-based approaches for ECG-based heart failure detection, several critical limitations remain unresolved. Existing convolutional and recurrent models primarily focus on local temporal patterns and often fail to capture long-range contextual dependencies inherent in ECG signals. Although transformer-based models improve global representation, most rely on implicit self-attention mechanisms that lack explicit contextual supervision and remain sensitive to signal noise and inter-patient variability. In addition, conventional deformable convolution networks estimate offset parameters using gradient-based learning, which leads to unstable receptive field adaptation under non-stationary ECG deformations. These limitations reveal a clear research gap in developing a unified framework that explicitly models contextual information while enabling robust, optimized receptive field learning for reliable heart failure detection. This work introduces a tightly coupled framework that jointly integrates contextual transformer learning, deformable convolution, and metaheuristic offset optimization for ECG-based heart failure detection. Unlike existing transformer-based ECG models that rely on implicit self-attention or token-wise context aggregation, the Contextual Auxiliary Transformer (CAT) explicitly models static contextual dependencies prior to self-attention and enforces contextual consistency using auxiliary supervision. Furthermore, conventional deformable convolution layers estimate offsets through local gradient-based learning, which becomes unstable for ECG signals exhibiting non-stationary temporal deformations. To address this limitation, the offset estimation process is formulated as an optimization problem and solved using the Al-Biruni Earth Radius (ABER) algorithm, enabling robust exploration-exploitation balance for offset refinement. The unified interaction between CAT-derived contextual features and ABER-optimized deformable convolution distinguishes the proposed framework from existing transformer or deformable CNN architectures applied independently.

II. Related Works

In study [21] authors combine a variety of data mining approaches in conjunction with the SMOTE to improve the accuracy of forecasting the survival of patients with heart failure. In this study authors uses sophisticated data mining techniques to increase prediction accuracy and emphasizes to address class imbalance concerns in the dataset. In study [22], authors investigate the use of LSTM and CNN for automated congestive heart failure detection based on ECG readings. It emphasizes how well deep learning methods handle ECG data and produce precise diagnostic findings. A method that uses ECG signals to automatically diagnose heart failure was presented in study [23]. With an emphasis on facilitating prompt and accurate diagnostics, it probably involves techniques for feature extraction and classification to identify heart failure disorders. In order to improve the identification of cardiac disorders from ECG data, this work highlights the application of deep learning techniques in the form of ensemble models [24].

It draws attention to the possibility of enhancing overall detection performance by mixing several deep learning models. In [25], this research emphasizes the use of ECG readings in a time-adaptive manner to identify cardiovascular illnesses. It probably discusses the dynamic nature of ECG data and looks into techniques for adaptive or real-time detection, which could offer insightful information about how a disease develops. Authors in [26], designs a novel lightweight deep learning framework that uses heart sound recordings to classify cardiovascular illnesses. The special characteristics and architecture while emphasizing its potential for use in medical applications. In [27] authors provide an end-to-end deep learning system for improving the identification of cardiac illness by denoising heart sounds in real time.

It probably investigates how deep learning might improve the accuracy of disease identification by managing noise and variability in heart sound recordings. Authors in study [28], explores the creation of an explainable deep learning method for multi-label ECG data classification. It probably looks on techniques that enhance comprehension and openness by classifying ECG signals and offering comprehensible insights into the classification process. Authors in this work [29] focuses on using machine learning and deep learning techniques to analyze ECG images in order to diagnose cardiovascular disorders. It could go over feature extraction, image processing, and classification techniques, highlighting the importance of visual information in diagnosis. In study [30], authors investigate the use of deep learning neural networks for categorizing ECG signals in order to identify congestive heart failure and arrhythmia. It emphasizes how crucial it is to classify data accurately and effectively in order to recognize these serious cardiac problems.

In study [31], authors study probably presents an ECG-convolution-vision transformer network for inter-patient congestive heart failure identification. It emphasizes the creation of specialized networks for difficult jobs like diagnosing heart failure in various people. In study [32], explores a thorough method for the multilevel categorization and identification of cardiac arrhythmias. In order to increase the precision of arrhythmia diagnosis, it most likely blends deep convolutional neural networks with signal processing methods such as the superlet transform. Authors focuses on creating a wearable electrocardiogram device that leverages deep learning methods to identify cardiovascular illness in real time [33]. It emphasizes how important wearable technology is for ongoing surveillance and early detection.

The use of hybrid CNN-SVM deep neural networks in conjunction with Long Short-Term Memory (LSTM) networks to classify ECG signals into normal sinus rhythm, aberrant arrhythmia, and congestive heart failure [34]. It probably shows how useful it is to combine various deep learning architectures

to achieve precise classification. In study [35], authors draw attention to the effective use of machine learning algorithms in the prediction of cardiovascular illness. It probably highlights how crucial feature selection methods like Relief and LASSO are to raising the precision and effectiveness of prediction models. In study [36], this research presents a novel model that uses ECG signals to categorize heartbeats in order to diagnose heart illness.

The GOA in conjunction with the hybrid convolutional neural network presents a novel strategy that holds potential to improve the efficiency and accuracy of heart disease detection. Authors in study [37], centered on the use of ECG data in a multimodal fusion strategy for the diagnosis of cardiovascular illnesses. It most likely looks at ways to combine several information streams and enhance the accuracy of disease diagnosis by integrating multiple data sources or modalities. In study [38], authors discuss a DL method that uses empirical mode decomposition to extract ECG features in order to categorize cardiovascular illnesses. This approach is probably going to emphasize how crucial signal processing methods are to improving the data that is taken from ECG recordings in order to classify diseases. Authors in [39] highlight the creation and implementation of an autonomous heart failure prediction machine learning model. It might go over the usefulness of applying machine learning models in actual healthcare settings and show how they could be used to detect heart failure early on. In study [40], authors introduce a low-power ensemble network that uses ECG data to identify heart illness. It might concentrate on the effectiveness and computational viability of ensemble models, offering a method for detecting cardiac disease that is accurate and resource-efficient. Recent advances in transformer-based object detection have significantly improved contextual modeling, convergence efficiency, and real-time performance. Grounding DINO 1.5 [41] extends the DETR framework to open-set object detection by incorporating grounded representations and large-scale pretraining, enabling strong generalization to unseen categories. Relation-DETR [42] introduces explicit positional relation priors within the attention mechanism to enhance spatial reasoning and accelerate convergence. RT-DETR [43] focuses on real-time detection by eliminating non-maximum suppression and employing a hybrid encoder with optimized query selection, achieving superior speed–accuracy trade-offs compared to YOLO-based detectors. Despite these advancements, most existing DETR variants primarily target visual object localization and lack explicit contextual supervision or optimization-driven adaptive feature learning, motivating the development of more robust and context-aware detection frameworks.

III. Proposed Model

This section explains the proposed model with suitable mathematical and diagrammatic explanations. Fig. 1 represents the architectural pipeline of the proposed CAT-TODNet. The proposed research model is composed of three major stages: 1) Triple-Way Pre-Processing, 2) Transformer-based Feature Extraction, and 3) Optimized Heart Failure Detection. The overall pipeline of the proposed model is illustrated in Fig. 1. A detailed explanation of each stage is provided below.

A. Triple-Way Pre-Processing

In the Triple-Way Pre-Processing stage, the acquired ECG signals from the MIT-BIH database are pre-processed through three distinct operations: 1) denoising, 2) signal smoothing, and 3) removal of power-line interferences. The primary objective of this stage is to minimize the computational burden on subsequent Transformer and convolutional layers used for feature extraction and feature processing.

Formally, let the acquired ECG signal be represented as $s(t)$. The pre-processed signal $s'(t)$ can be defined as:

$$s'(t) = f_3(f_2(f_1(s(t)))) \tag{1}$$

where $f_1(\cdot)$, $f_2(\cdot)$, and $f_3(\cdot)$ represent the denoising, smoothing, and power-line interference removal functions, respectively.

This triple-stage processing enhances the quality of the input signal by suppressing noise components that are irrelevant to heart failure detection. Consequently, the removal of signal distortions improves both the feature representation and the overall performance of the Transformer and convolution operations in identifying the rate and severity of heart failures.

For denoising the acquired ECG signals, the Discrete Wavelet Transform (DWT) is employed since it effectively captures the signal information in both time and frequency domains. Let the original signal be represented as $s(t)$; it can be decomposed for denoising as follows:

$$s(t) = \sum_{k} c_{j_0}(k)\, \phi_{j_0,k}(t) + \sum_{j=j_0}^{J} \sum_{k} d_j(k)\, \psi_{j,k}(t) \tag{2}$$

In the above equation, $c_{j_0}(k)$ and $d_j(k)$ denote the approximation (scaling) and detail (wavelet) coefficients, respectively. The functions $\phi_{j_0,k}(t)$ and $\psi_{j,k}(t)$ represent the scaling and wavelet functions. The first term represents the coarse approximation of the signal, while the second term captures the detailed variations and noise components across different scales.

The Daubechies wavelet (DB) with a selected scale number is used as the mother wavelet to perform decomposition up to level five. The resulting coefficients—denoted as WC1–WC5 and WAC5—represent the wavelet and approximating coefficients, respectively. The noise components are eliminated by thresholding small-magnitude coefficients (setting them to zero), resulting in a denoised version of the ECG signal, $s_d(t)$, free from redundant and fluctuating artifacts.

1) Signal smoothing: After denoising, the ECG signal undergoes a smoothing process to further eliminate low-bit noise fluctuations. Let the denoised signal be $s_d(t)$. The signal length is computed and divided into N equal segments to evaluate local variations between neighboring peaks. The smoothing operation determines the local maxima deviations and removes minimal fluctuations as noise, resulting in the smoothed signal $s_s(t)$. The process can be expressed as:

$$s_s(t) = s_d(t) - \Delta n(t) \tag{3}$$

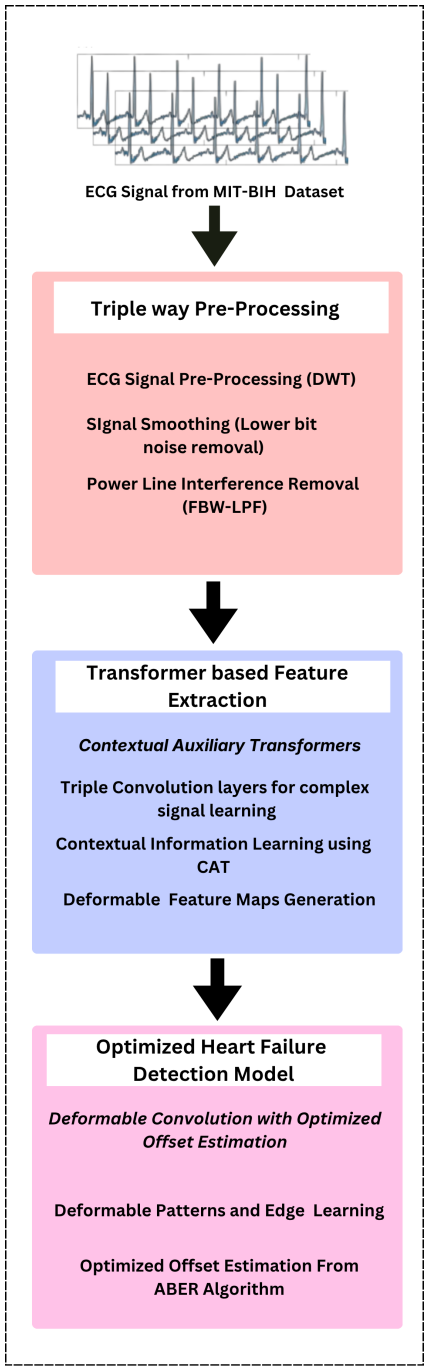

Fig. 1. Pipeline of the proposed work.

where $\Delta n(t)$ denotes the estimated low-bit noise component. This step refines the ECG waveform by preserving essential physiological characteristics while suppressing high-frequency artifacts.

2) Removal of power line interferences: To eliminate power line interference (PLI), typically occurring at 50 Hz, a Fractional Butterworth Low-Pass Filter (FBW-LPF) is adopted. The magnitude response of the FBW-LPF is mathematically formulated as:

$$|H(j\omega)| = \frac{1}{\sqrt{1 + \left(\frac{j\omega}{\omega_c}\right)^{2\alpha}}} \tag{4}$$

where ω represents the analog angular frequency (in rad/s), ω_c is the cutoff frequency (set at 50 Hz), and α defines the fractional order of the filter. This filter efficiently suppresses frequency components below the 50 Hz range, resulting in a clean waveform $s_f(t)$ suitable for the subsequent Transformer-based feature extraction stage.

B. Transformer-Based Feature Extraction

To address the limitations of conventional self-head attention Transformers in handling complex contextual dependencies, a Contextual Auxiliary Transformer (CAT) is adopted to enhance feature extraction and contextual representation. The CAT model extends the standard Transformer by integrating contextual learning within the self-attention mechanism, thereby reducing computational redundancy and improving discriminative representation of the ECG signals.

The pre-processed ECG signal $s_f(t)$ is given as the input to the CAT module, which operates based on the query (Q), key (K), and value (V) matrices. These matrices encode relationships across temporal and spatial contexts of the signal sequences. The CAT model reformulates these parameters into contextual groups and grids to efficiently capture cross-key dependencies. The contextual input y is derived from the feature representations, and the contextual interaction is modeled as the combination of keys and local attention matrices through three convolutional layers:

$$B = \text{Conv}_3(K \otimes y) \tag{5}$$

where, $\text{Conv}_3(\cdot)$ denotes a three-layer convolutional operation, $\otimes$ represents element-wise multiplication, and B refers to the local attention matrix incorporating contextual relationships. The matrix B assists in describing localized dependencies at each spatial position based on neighboring queries and keys, avoiding isolated query-key evaluations common in traditional Transformer-based models.

The resulting contextual attention allows the generation of a feature map F by integrating the value matrix V with the attention weights as follows:

$$F = B \cdot V \tag{6}$$

Here, F captures both static and dynamic feature interactions, making it highly capable of representing signal contexts with varying temporal behavior. The final CAT module output, denoted by X, integrates both static and dynamic contextual representations through the attention mechanism:

$$X = F_{static} \oplus F_{dynamic} \tag{7}$$

where, $\oplus$ denotes the element-wise summation of feature maps arising from static and dynamic contexts. The inclusion of deformable contextual maps enables the CAT network to

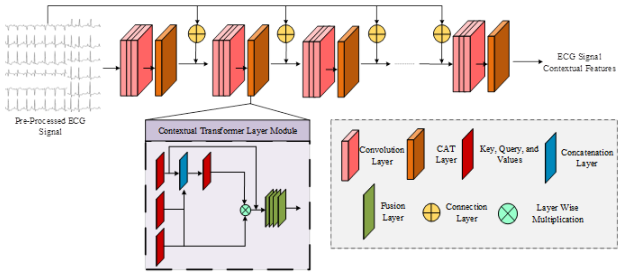

Fig. 2. Contextual Auxiliary Transformer (CAT) based feature extraction module.

model fine-grained local variations essential for accurate heart failure detection.

Finally, the CAT module is trained using a combined loss function that incorporates both the primary and auxiliary objectives, expressed as:

$$\mathcal{L}_{total} = \mathcal{L}_{main} + \lambda \mathcal{L}_{aux} \tag{8}$$

where, $\mathcal{L}_{main}$ and $\mathcal{L}_{aux}$ denote the general and auxiliary losses, respectively, and λ is the weighting coefficient controlling the contribution of the auxiliary task. Fig. 2 illustrates the architectural layout of the proposed Transformer-based feature extraction stage.

Conventional transformer architectures model contextual relationships implicitly through query-key similarity, treating each token independently during attention computation. In contrast, the Contextual Auxiliary Transformer employed in this work introduces a dual-context mechanism that combines static contextual representations with dynamic self-attention. The static context is extracted through grouped contextual convolutions applied to neighboring signal segments, enabling explicit modelling of local temporal dependencies prior to attention calculation. This contextual guidance stabilizes attention responses for ECG signals affected by noise, baseline drift, and waveform deformation. Moreover, the auxiliary loss enforces consistency between contextual and attention-driven representations, which is absent in standard self-attention or auxiliary attention models. As a result, CAT produces deformable-aware feature maps that are more suitable for subsequent offset-adaptive convolution.

The output feature map X obtained from the Transformer-based feature extraction module is provided to the optimized heart failure detection network, which comprises a sequence of deformable convolutional layers integrated with an optimized offset estimator. The deformable convolution is used to accurately capture complex and subtle ECG feature variations that are often missed by standard convolution operations.

1) Deformable convolution operation: The conventional convolution operation on a feature map x with kernel weights w and sampling locations p_n can be formulated as:

$$y(p_0) = \sum_{p_n \in R} w(p_n) \cdot x(p_0 + p_n) \tag{9}$$

where p_0 denotes the reference location on the output feature map, and R represents the regular grid kernel (e.g., 3×3).

In a deformable convolution layer, additional offsets Δp_n are introduced to adaptively sample feature locations, resulting in enhanced modeling of geometric variations in ECG waveforms. The deformable convolution operation is expressed as:

$$y(p_0) = \sum_{p_n \in R} w(p_n) \cdot x(p_0 + p_n + \Delta p_n) \tag{10}$$

Here, Δp_n represents the learnable offset parameters, dynamically adjusted during training. These offsets are computed using bilinear interpolation to ensure differentiability. Although deformable convolutions enhance adaptability, they may also produce redundant or noisy features. To alleviate this, a weighted coefficient sampling method ω is employed to selectively suppress irrelevant responses as:

$$x'(p) = \omega(p) \cdot x(p) \tag{11}$$

This weighting scheme ensures that only informative local features contribute to the heart failure classification, thereby improving detection precision and generalization.

In deformable convolution networks, offset parameters are commonly learned using back-propagation alongside convolution weights. While effective for spatial image data, this strategy becomes sub-optimal for ECG signals due to irregular temporal deformations, inter-patient variability, and sensitivity to noise. Gradient-based offset learning is prone to local minima and unstable convergence under such conditions. To overcome this limitation, offset estimation is reformulated as a global optimization problem, where the objective is to maximize feature similarity alignment across deformable receptive fields. The Al-Biruni Earth Radius (ABER) algorithm is employed to optimize offset vectors due to its balanced exploration and exploitation capability, enabling robust search in highly non-convex offset spaces. Unlike conventional optimizers such as PSO or gradient descent, ABER maintains adaptive search radius control, which improves convergence stability and prevents premature stagnation in offset learning.

2) Optimized offset estimation using ABER algorithm: To further enhance the offset estimation, the Al-Biruni Earth Radius (ABER) optimization algorithm is integrated as an intelligent offset estimator. The ABER algorithm finds optimal offsets by maximizing similarity between reference and input ECG feature maps. Let the inputs to the estimator be denoted as F_r (reference features) and F_i (input features); the optimization problem can be defined as:

$$\min_{\Delta p} f(F_r, F_i, \Delta p) \tag{12}$$

where, $f(\cdot)$ represents the fitness function evaluating the similarity between input and reference features. The search space dimension is denoted as D, and the candidate solution at iteration t is expressed as X_t.

The ABER algorithm consists of two primary phases:

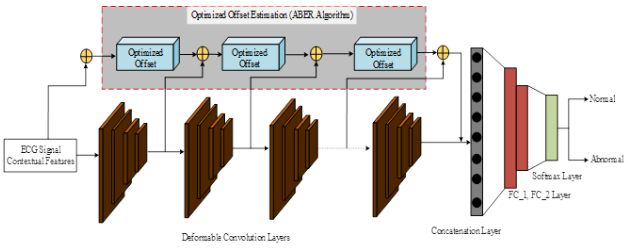

Fig. 3. Illustration of optimized heart failure detection model.

3) Non-Local feature enhancement: To capture long-range dependencies within the ECG features, non-local operations are employed after offset optimization. This operation enhances the model's capacity to represent both global and local characteristics. Mathematically, the non-local operation between an input feature f_i and an output position f_o is defined as:

$$f_o(i) = \frac{1}{C(i)} \sum_{\forall j} \theta(f_i(i)) \cdot \phi(f_i(j)) \cdot g(f_i(j)) \tag{13}$$

where, $\theta(\cdot)$, $\phi(\cdot)$, and $g(\cdot)$ denote embedding, pairwise, and transformation functions, respectively, and $C(i)$ is a normalization factor. The combined use of deformable convolution, ABER-optimized offset estimation, and non-local contextual modeling effectively refines the heart failure detection mechanism.

Fig. 3 illustrates the architecture of the proposed Optimized Heart Failure Detection Model.

a) Exploitation phase: In this phase, the primary objective is to enhance the performance of the previously explored candidate solutions by refining them toward the optimal offset estimator. The formulation for the exploitation-based ABER can be expressed as:

$$X_t^{\text{new}} = X_{\text{best}} + \gamma \cdot (R_d \cdot \text{rand}()) \tag{14}$$

where, X_t^{new} represents the updated offset vector at iteration t, X_{best} is the best solution obtained from the exploration phase, R_d is the search area diameter [from Eq. (13)], and γ is the adaptive learning rate controlling step-size toward the best candidate.

To further refine the best offset estimator within the exploitation region, the updated position is evaluated using:

$$X_{t+1} = X_t + \phi \cdot (X_{\text{best}} - X_t) + \delta \cdot \text{rand}() \tag{15}$$

where, ϕ and δ denote adaptation coefficients balancing exploitation intensity and stochastic perturbation, respectively. The random vector $\text{rand}() \in [0, 1]$ introduces controlled randomness to avoid premature convergence and improve the stability of offset estimation.

Finally, the best candidate solution during dual iteration is updated as:

Algorithm 1 ABER-Based Optimized Offset Estimation for Deformable Convolution

Require: Reference feature F_r, Input feature F_i, Parameters R_d, β, ϕ, δ
Initialize candidate solutions X_i randomly within the search space.
for $t = 1$ to $T_{\max}$ **do**
  Evaluate fitness $f(X_i)$ for all candidates.
  Update best solution: $X_{\text{best}} = \arg\min f(X_i)$.
  {Exploration Phase}
  Compute: $R_d = 2E_r \cdot \text{rand}() - E_r$.
  Update candidate position: $X_t^{\text{new}} = X_t + \beta \cdot R_d$.
  {Exploitation Phase}
  Update position:

$$X_{t+1} = X_t + \phi(X_{\text{best}} - X_t) + \delta \cdot \text{rand}()$$

  if $f(X_{t+1}) < f(X_{\text{best}})$ **then**
    $X_{\text{best}} = X_{t+1}$.
  end if
  Gradually reduce R_d to ensure convergence.
end for
return Optimized offset vector: $X_{\text{optimal}} = X_{\text{best}}$.

$$X_{\text{optimal}}^{t+1} = \begin{cases} X_{t+1}, & \text{if } f(X_{t+1}) < f(X_{\text{best}}) \\ X_{\text{best}}, & \text{otherwise} \end{cases} \tag{16}$$

where, $f(\cdot)$ denotes the fitness function evaluating the similarity and feature matching accuracy between the reference and input ECG signals.

C. Experimental Evaluation

This section extensively details the results achieved through our novel approach, considering both quantitative and qualitative evaluations in contrast to established methodologies. Furthermore, it thoroughly assesses how our method performs across three separate datasets when compared to existing approaches. It initiates by outlining the dataset characteristics, proceeds with an in-depth analysis of results under various conditions, and concludes with a meaningful discussion, providing valuable insights based on the findings.

The electrocardiogram (ECG) signals used in this study are obtained from the MIT-BIH Arrhythmia Database, which is publicly available through PhysioNet. The database consists of annotated ECG recordings collected from 48 subjects, with each record sampled at 360 Hz and containing two leads. The signals are segmented into fixed-length windows to facilitate uniform analysis and model training.

For experimental evaluation, ECG segments are categorized into heart failure and non–heart failure classes based on the provided annotations. A patient-wise data split strategy is employed to avoid data leakage, ensuring that samples from the same subject do not appear in more than one subset. The dataset is divided into training, validation, and testing sets using a fixed ratio.

The heart failure detection model, referred to as CATTODNet, is implemented using MATLAB. The model is trained for 100 epochs with a batch size of 32 and a learning rate of 0.001, using the Adam optimization algorithm. All

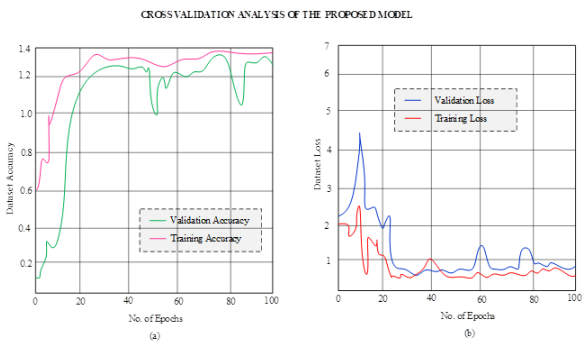

Fig. 4. (a) Shows the training and validation accuracy, (b) shows the training and validation loss.

experiments are conducted on an HP Pavilion laptop equipped with an AMD Ryzen 5 5600H processor with Radeon Graphics operating at 3.30 GHz, 8 GB of Random-Access Memory (RAM), and the Windows 11 Operating System. The same training configuration is maintained across all experiments to ensure reproducibility and fair performance evaluation.

The performance metrics utilized for validating the proposed work can be formulated as follows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{17}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{18}$$

$$\text{Recall (Sensitivity)} = \frac{TP}{TP + FN} \tag{19}$$

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{20}$$

where, TP, TN, FP, and FN denote the true positive, true negative, false positive, and false negative rates, respectively. The AUC-ROC curve offers a comprehensive assessment of the classifier's performance across a range of possible thresholds. A higher AUC signifies superior performance by the classifier.

Fig. 4(a) and (b) represent the training and validation accuracy, and training and validation loss of the proposed work, respectively.

The following state-of-the-art models were selected for comparison against the proposed CAT-TODNet architecture:

- SMOTE-HF [21]: This study adopts ECG data for analysing the heart failure by comparing the nine benchmark machine learning algorithms.
- DeepCNN-LSTM [6]: This study also utilized ECG signals for diagnosing the heart disease using combine deep learning algorithm.

TABLE I. Quantitative Evaluation of Pre-Processing Across Methods

Model	Accuracy	Precision	Recall	F1-Score
CAT-TODNet (w/ Pre-processing)	**0.9899**	**0.9903**	**0.9800**	**0.9876**
CAT-TODNet (w/o Pre-processing)	0.9435	0.9323	0.9326	0.9300
DeepCNN-LSTM [22]	0.9267	0.9309	0.9215	0.9276
CHF-CVTN [31]	0.9154	0.9149	0.9184	0.9126

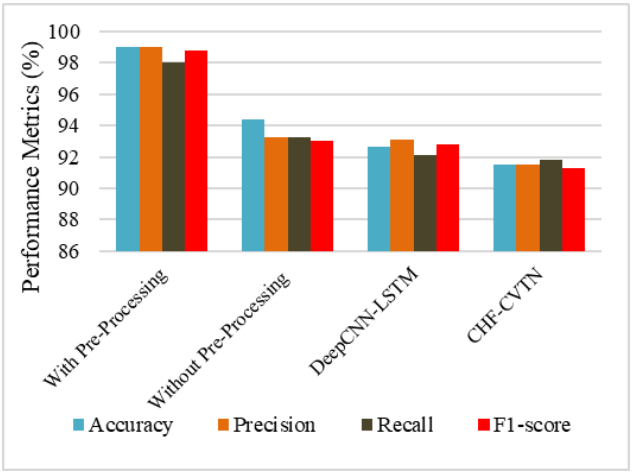

Fig. 5. Evaluation of pre-processing process.

- Ensemble-DL [24]: In this research, an ensemble of DL models is utilized for detecting the heart disease from two benchmark ECG database.
- Heart-CVDD [25]: This research adopts two stage classification algorithms for cardiovascular disease detection from ECG signals.
- CHF-CVTN [31]: In this study the heart failure disease are diagnosed by adopting convolution based transformer network using ECG signals.
- CHF-DL-ML [34]: The diagnosis of congenital heart failure disease gets diagnosed by adopting combined DL and ML algorithms named LSTM-CNN-SVM from ECG signals.

IV. Experimental Evaluation

Fig. 5 represents the comparison of the proposed pre-processing process and its impacts with the existing works. In order to employ the better pre-processing examination process, we also split the proposed CAT-TODNet into two scenarios such as with and without pre-processing respectively. In addition to that, we have compared the proposed CAT-TODNet with two existing works that adopts pre-processing such as DeepCNN-LSTM [22], and CHF-CVTN [31] respectively. The quantitative results of the pre-processing are shown in Table I below.

From Fig. 5 and Table I, it is seen that the proposed scenario with pre-processing achieves higher results whereas the proposed scenario without pre-processing lesser than the with pre-processing scenario. On the other hand, the existing works which uses pre-processing in which the DeepCNN-LSTM

TABLE II. COMPARISON OF CONVENTIONAL MODELS AND PROPOSED FEATURE EXTRACTION MODEL

Model	Accuracy	Precision	Recall	F1-Score	AUC
RF	0.8478	0.8598	0.8502	0.8487	–
DT	0.8646	0.8734	0.8615	0.8711	–
SVM	0.9156	0.9110	0.9199	0.9197	–
DNN	0.9465	0.9451	0.9595	0.9537	–
AEs	0.9552	0.9509	0.9698	0.9689	–
Proposed (CAT-TODNet)	**0.9777**	**0.9888**	**0.9810**	**0.9836**	**–**

TABLE III. COMPARISON OF EXISTING METHODS AND PROPOSED FEATURE EXTRACTION MODEL

Model	Accuracy	Precision	Recall	F1-Score	AUC
SMOTE-HF [21]	0.8889	0.8809	0.8813	0.8898	–
DeepCNN-LSTM [22]	0.9046	0.9045	0.9026	0.9022	–
Ensemble-DL [24]	0.9367	0.9321	0.9300	0.9308	–
Heart-CVDD [25]	0.9576	0.9562	0.9698	0.9648	–
CHF-CVTN [31]	0.9763	0.9720	0.9708	0.9790	–
Proposed (CAT-TODNet)	**0.9988**	**0.9999**	**0.9921**	**0.9948**	**–**

utilizes only normalization procedure whereas the CHF-CVTN resampling, normalization, and segmentation respectively. The quantitative results of the existing works are significantly lower than the proposed scenarios. The reason for such higher results of the proposed work is that, we perform signal denoising, signal smoothing, and powerline interference removal which effectively suppress noise components in the ECG signal thereby providing denoised signal for further processing that also improve the performance results. Whereas the existing works are not focused on resolving noises whereas they only normalize them to certain limit which resolves the complexity but reduces the performance of the overall model. In detailed manner, the proposed with pre-processing scenario achieves higher accuracy, precision, recall, and F1-score rate of (4.64%–7.45%), (5.8%–7.54%), (4.74%–6.16%), and (5.76%–7.5%) than the existing works.

A. Evaluation of Feature Extraction

The validation of proposed feature extraction model named Contextual Auxiliary Transformer (CAT) to the conventional model and existing works are detailed in this section. The conventional models includes Machine Learning (ML) and Deep Learning (DL) models such as Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), Deep Neural Network (DNN), Auto Encoders (AEs) whereas the existing feature extraction models includes SMOTE-HF [21] which uses ML algorithms, DeepCNN-LSTM [22] which uses CNN for feature extraction, Ensemble-DL [24] uses self-organizing maps for feature extraction, Heart-CVDD [25] uses time based dynamic CNN for feature extraction, and CHF-CVTN [31] uses transformer based convolution model for feature extraction. The quantitative results of the feature extraction in terms of conventional models and existing research works are shown in Table II and Table III below.

The graphical representation depicted in Fig. 6(a) and 6(b), and Fig. 7(a) and 7(b) compares the proposed Feature Extraction (FE) approach with both traditional models and previous studies, evaluating their performance metrics and AUC-ROC values. Specifically, Fig. 6(a) and 6(b) analyse the performance metrics of conventional models and prior works, respectively. The illustration indicates that the proposed model outperforms both the traditional models and existing works. Regarding the quantitative outcomes, the accuracy, precision, recall, and F1-score achieved by the proposed FE are 2.55%–12.99%, 3.79%–2.9%, 1.12%–13.08%, and 1.47%–13.49% higher than the conventional ML/DL models, whereas for existing works the proposed work achieved are 2.25%–10.99%, 2.79%–11.9%, 2.13%–8.95%, and 1.58%–10.5% higher. Similarly, Fig. 7(a) and 7(b) present the AUC-ROC evaluation for conventional models and existing works, respectively. The AUC-ROC is higher for the conventional models compared to existing works. This superior performance of the proposed FE stems from its utilization of an attention-based transformer model, enabling robust extraction of signal context features by analysing intricate signal patterns. Conversely, the shortcomings in conventional and existing models include higher tendencies toward overfitting, training complexity, adaptability issues, and respectively lower accuracy in feature extraction.

TABLE IV. COMPARISON OF EXISTING WORKS AND PROPOSED OPTIMIZED CLASSIFICATION MODEL

Model	Accuracy	Precision	Recall	F1-score	AUC
SMOTE-HF [21]	0.8555	0.8500	0.8526	0.8523	–
DeepCNN-LSTM [22]	0.8857	0.8845	0.8816	0.8812	–
Ensemble-DL [24]	0.9078	0.9032	0.9022	0.9019	–
Heart-CVDD [25]	0.9387	0.9373	0.9317	0.9359	–
CHF-DL-ML [34]	0.9663	0.9610	0.9609	0.9690	–
DeepECG-Net [44]	0.9820	0.9820	0.9680	0.9750	–
Proposed (CAT-TODNet)	**0.9888**	**0.9899**	**0.9821**	**0.9847**	**–**

B. Evaluation of Heart Disease Classification Model

This section thoroughly outlines the validation process for the proposed optimized heart failure detection model concerning existing methods. The current classification models under scrutiny encompass diverse approaches: SMOTE-HF [21], employing nine ML algorithms; DeepCNN-LSTM [22], utilizing LSTM; Ensemble-DL [24], employing autoencoders; Heart-CVDD [25], utilizing Bi-directional LSTM; and CHF-DL-ML [34], utilizing support vector machines. The quantitative outcomes derived from these models concerning heart disease classification are tabulated below in Table IV for a comprehensive comparison (also see, Fig. 8 and 9).

V. DISCUSSION AND LIMITATIONS

This section explores the overall summary of the proposed work with its implementation results. From the implementation summary, the results achieved demonstrate superior performance than the existing works. We also compare the proposed implementation model with the conventional ML and DL models respectively. It is clearly depicted that in the above tables and figures that the results of the proposed work are within 97%–100%. The near-saturation accuracy is achieved under a strict patient-wise evaluation protocol, which mitigates overfitting and ensures reliable performance estimation. The major difference among the proposed and existing works are that, most of the existing works utilized CNN and ML algorithms as their FE and classification model

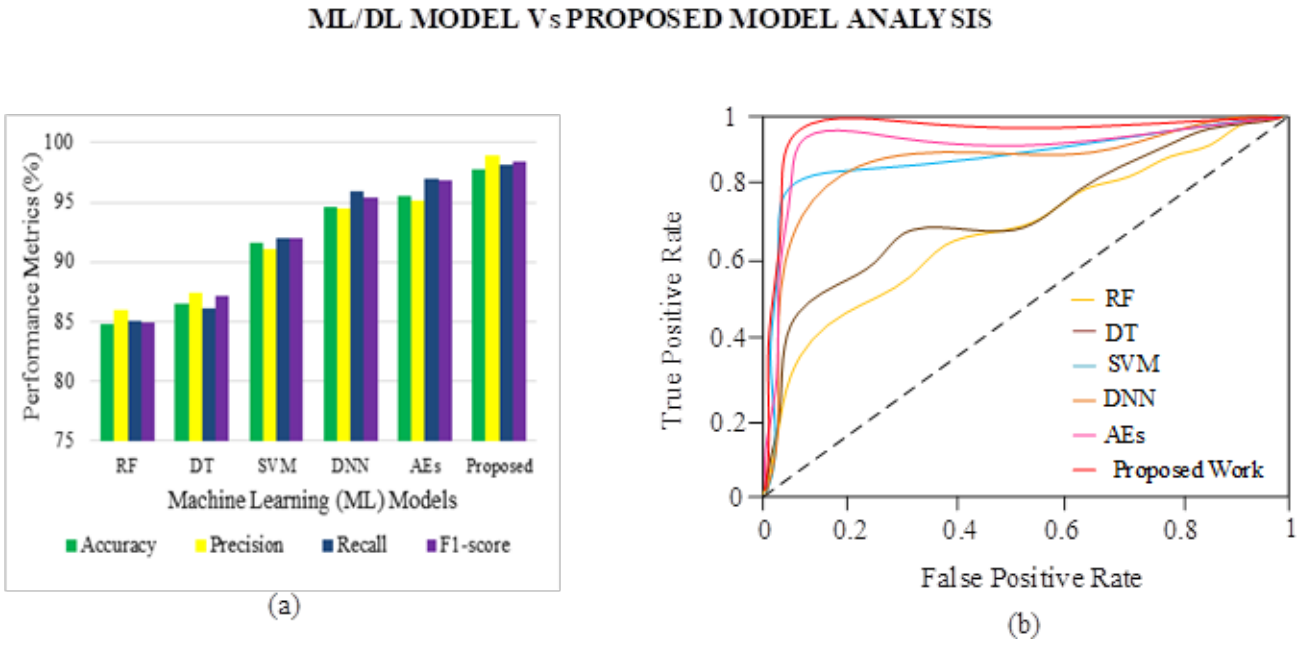

Fig. 6. (a) Performance metrics analysis of proposed work vs. ML/DL Models, (b) AUC comparison of proposed vs. ML/DL models.

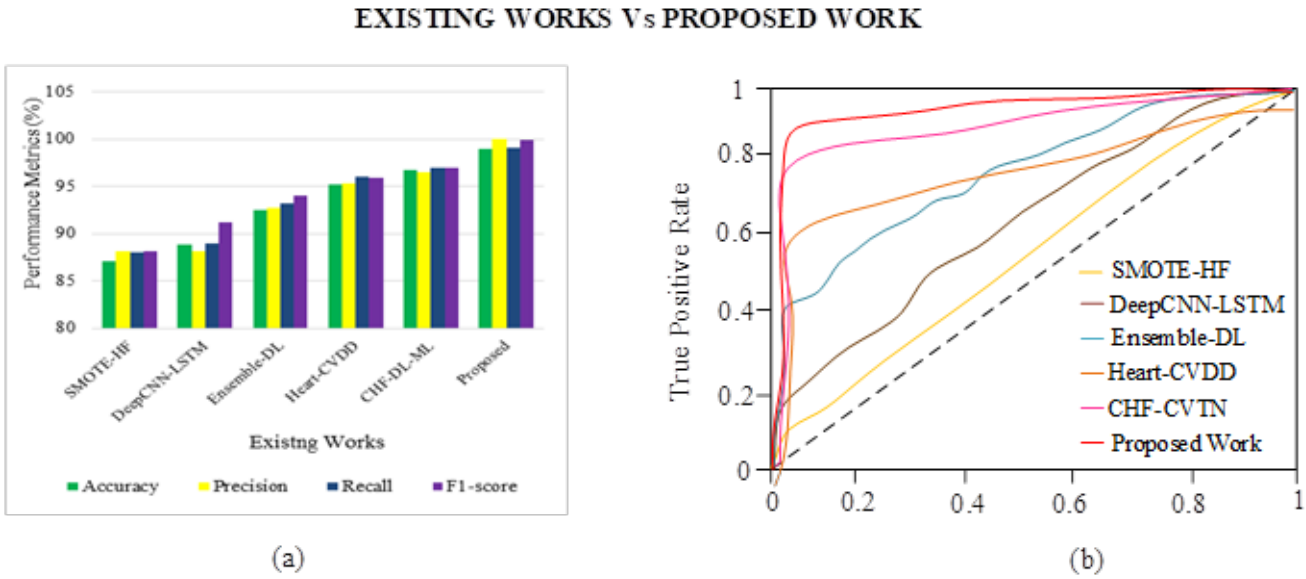

Fig. 7. (a) Performance metrics analysis of proposed vs. Existing models, (b) AUC comparison of proposed vs. Existing models.

and there were no improvements over that models which leads to higher complexity, time consumption, and poor accuracy in detecting heart disease respectively. On the whole, the major contribution of the proposed CAT-TODNet is that we utilize the attention based contextual transformer model for feature extraction which extracts the signal contextual features with the signal characteristics. Furthermore, those contextual features are provided to the optimized offset estimator which dynamically set the offset value to the deformable convolution layers to capture the feature interdependencies and provide the accurate output.

On the other hand, one of the major limitations of our study is that, the proposed research is not suitable for remote detection/prediction of heart disease detection. To be clearer, the designed model is centralized and did not adopt for distributed remote diagnosis for heart disease detection. On the other hand, we utilize only limited data to train the proposed model which make it to provide only limited results.

VI. Conclusion

The detection of Heart Failure (HF) through continuous monitoring of heart wave patterns is pivotal in reducing mortality rates. Utilizing Electrocardiogram (ECG) alongside Artificial Intelligence (AI) has been explored in previous

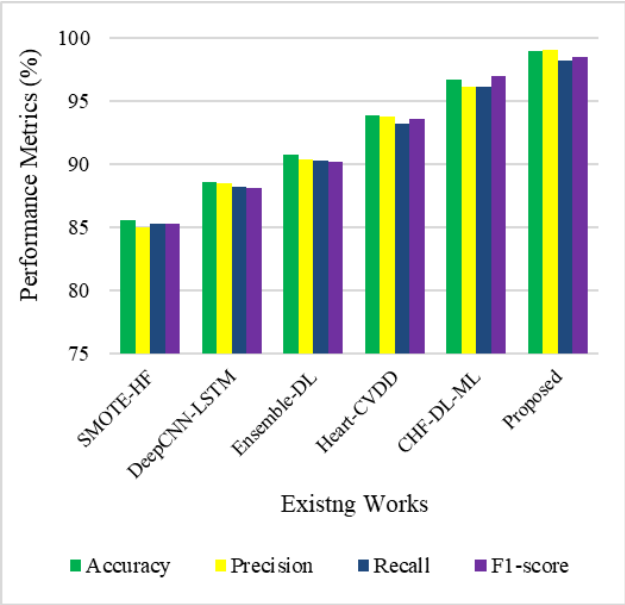

Fig. 8. Evaluation of heart failure detection model for proposed vs. Existing works.

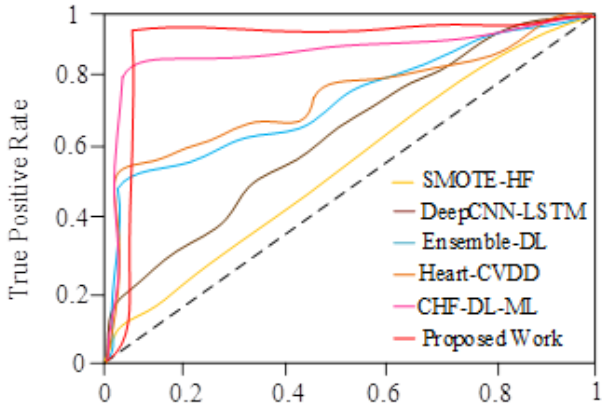

Fig. 9. AUC analysis of proposed heart failure detection model.

research, albeit with issues of accuracy and complexity. To address these shortcomings, our innovation, CAT-TODNet, integrates a stacked and optimized deformable convolution with a Contextual Attention Transformer (CAT) for HF detection from ECG signals. By preprocessing data from the MIT-BIH dataset through denoising, signal smoothing, and power line interference removal, we optimize feature extraction through CAT. This model learns contextual features and generates deformable feature maps crucial for HF detection. Our optimized HF model incorporates dynamic offset estimation in deformable convolution layers, enhancing the interpretation of contextual features. The integration of the Al-Biruni Earth Radius (ABER) optimization algorithm dynamically adjusts the offset estimator, improving feature similarities and ensuring precise and reliable outputs.

MATLAB simulations validate our approach, exhibiting superior performance compared to existing methods across multiple evaluation metrics such as accuracy, recall, precision, F1-score, and AUC. This research underscores the potential of CAT-TODNet in significantly enhancing HF detection accuracy, thereby contributing to reducing HF-related mortality rates. Future work could delve deeper into real-time implementation and explore the scalability of the proposed model across diverse datasets for robust and widespread applicability in clinical settings.

Application of Improved YOLO-LSTM with Combined MQTT-LoRaWAN for AI Surveillance in Tea Plantations to Prevent Elephant Intrusion

Rabin Kumar Mullick*, Rakesh Kumar Mandal
University of North Bengal, Raja Rammohanpur, Darjeeling, West Bengal, India

***Abstract*—Elephant-human conflict is a growing problem in tea garden areas of Dooars in North Bengal, resulting in massive cost for crops, infrastructures and sometimes human life as well. Each year, these mild-mannered giants destroy crops, destroy fences and even threaten the locals, which raises the costs of repairs and endangering lives. The conventional deterring methods, such as fences, firecrackers, and patrols are mostly ineffective, unsustainable or cruel to the animals. As a way of addressing this predicament, scholars have designed a non-invasive, intelligent surveillance system named HIS-Hexagonal Intelligent Surveillance. HIS integrates state-of-the-art machine learning with artificial intelligence by combining an improved YOLO-LSTM and MQTT-LoRaWAN, which combines the capabilities of distributed-based agents with predictive analytics and hex-grid mapping scheme. HIS is an effective solution for elephant intrusions detection and deterrence for ecological balance. The system sends specific warnings before the elephants can cause havoc when an intrusion is detected. The hex-grid mapping enables the operators to have accurate spatial knowledge and the predictive analytics forecasts the time and location where the elephants could roam. The virtual simulation of the proposed work shows 98% accuracy on designed-custom dataset of elephants. The paper offers a background of the architecture, theoretical framework, algorithm models, and expected benefits of the proposed framework.**

I. Introduction

It is the source of livelihood of millions of workers besides being a key economic activity in some areas of Dooars in the North Bengal region of India. These plantations are however, mostly located in or near the elephant habitats. For this reason, human-elephant conflict in the form of elephant crop raiding is a repeated calamity in these areas. Elephants invade plantations for food or migratory movement and cause economic loss, infrastructural damage and casualties.

Reinforcing mahouts using traditional barriers such as electric fencing and manual surveillance for a number of years has not provided the hoped-for relief from elephant pressure. These techniques suffer from little flexibility, laborious nature, and acting in an ecologically or morally questionable manner. There is an urgent need for a smart, non-invasive and autonomous system for dynamic prediction, monitoring and prevention of elephant intrusions.

This study offers a new hybrid strategy to combine different advanced technologies for better tracking and monitoring of elephant movements. It uses Machine Learning (ML) for real-time prediction of the movement pattern of elephants, making a timely and accurate prediction possible. In addition, it adds Intelligence (SI) to autonomously detect and react to changes in the environment and to animal behavior. In order to guarantee a thorough coverage and an efficient zone-based surveillance, the method also utilizes Hexagonal Surveillance (HS) which allows for an efficient spatial surveillance using a structured hexagon-based grid system.

The organization of the present study is as follows: Section II is the review of the related literature, and Section III is the description of the proposed methodology. Section IV identifies the mathematical model. The algorithm appears in Section V, and other Sections provide virtual simulation results, concluding statements and possible research directions.

II. Related Works

Current means of controlling the elephant movement are based on traditional ways, lacking significant limitations. A YOLO-LSTM framework that builds upon the benefit of rapid spatial detection and time modeling and thus delivers very high accuracy in human action recognition in video sequences [1]. Another YOLO-LSTM-based motorway surveillance model, capable of deriving real-time traffic features and forecasting congestion to control effective use of emergency lanes [2, 3]. Rivera-Acosta et al. create the American Sign Language alphabet translator in real time, which puts together a YOLO detector, LSTM module, and a developed spelling correction system [4, 5]. A comparative study of communication protocols in the IoT in CoAP, MQTT, and HTTP in their architecture, performance, and application-suitability [6]. A module-oriented over-the-air firmware update system was proposed on LoRaWAN, which allows flexible, efficient, and reliable distribution of software parts to IoT devices with limited capabilities [7]. Although electric fences are expensive to install and maintain and may be very detrimental to wildlife [8]. Noise-based deterrents like firecrackers are also likely to become ineffective over time as the elephants soon become accustomed to them [9, 10]. Human patrolling though useful is very laborious and unreliable as it is not always available [11].

The recent research indicates that there is the potential of transforming the way machine learning is used to complement various next-generation surveillance systems, such as grid-based approach to guard crop [12]. Cloud-based detection is another research [13]. Among others, one study identifies

*Corresponding author.

the necessity of a communication-aware coverage strategy due to the need to adapt to dynamic environments through monitoring using UAV [14, 15]. Moreover, distributed machine learning has been known to increase capabilities. As a result, as mentioned in a recent open-access archive preprint, UAVs have the capability of providing robust and intelligent surveillance and communication, even in the presence of failures and/or varying conditions through distributed learning [16]. Another study also reported that a hybrid AI with deep reinforcement learning architecture can help in efficient surveillance that increases scalability and autonomy [17]. Collectively, these innovations demonstrate the transformative power of machine learning in driving the frontiers of intelligence for modern surveillance systems.

Swarm-based surveillance has seen a significant advancement in distributed monitoring and intelligent decision making. An instance is the project Eye that offers an integrated platform of intelligence, emergent behavior, and computer graphics. This system permits trying new image processing methods in order to enhance the decision making abilities. It is able to process and capture imagery in parallel via highly developed collaboratively functioning visual units able to view, capture and process imagery simultaneously to create information of great value in real time. Remarkably, the platform is used to provide autonomous and distributed reconfiguration to the UAV formations according to the situational changes in tactical domain, thus exhibiting flexibility as well as adaptability to changing scenarios [18].

Likewise, the DIANA structure solves several important problems in the safety of the motion and effectiveness of operations during -based missions. It presents a new parallel mission planning algorithm that combines evolutionary computation, machine learning, and deterministic solutions to guarantee robust and reliable coordination [19].

Collectively, these innovations demonstrate the potential of networked smart cameras and autonomous agents with machine learning capabilities to serve as intelligent and adaptive components in the advanced surveillance architecture.

Emerging new technologies for wildlife monitoring such as camera traps combined with AI-based image-recognition based on animal tracking, and smart cameras for unending vigil have come into existence but there are serious constraints like shorter battery life, being prone to the environment etc. However, as promising as these technologies are, they are often deployed in silos and are rarely embedded in a convergent methodology or system, almost never with enough real-time agility to adapt for speedy, effective wildlife management.

III. Methodology

The proposed HIS (Hexagonal Intelligent Surveillance) System — a fully integrated, intelligent framework designed to enhance elephant monitoring and deterrence by combining advanced computational methods and spatial strategies. The schematic overview of the system is shown in Fig. 1. The proposed methodology is shown in Fig. 2. The proposed hexagonal surveillance system is pictured in Fig. 3. The work flow progress of the proposed system is described in Fig. 4. It shows that the proposed system will help to focus the accuracy and speed of the object detection by combining YOLOv8 with Long Short-Term Memory (LSTM) and using MQTT and LoRaWAN to exchange data. The process has three obvious steps, the first step is to deploy a cloud environment to host the computation, the second step is to carefully label and annotate a separate dataset (named elephant) and turn the raw images to a fully ready-to-train model, and, lastly, the combined YOLOv8-LSTM-MQTT-LoRaWAN model is deployed on that dataset, trained, validated and tested its performance to make sure that the improvements are actual. The system is built upon the following core components:

1) Hexagonal / Hex-Grid Area Coverage:

a) Purpose: The surveillance area is divided into hexagons for efficient, non-overlapping coverage.

b) Deployment: Smart cameras are placed at or near each hexagon vertex, ensuring comprehensive monitoring [20].

2) intelligence - Smart Cameras (Agents):

A smart camera can act as an autonomous agent within a surveillance system, using collaborative intelligence to enhance monitoring and situational awareness. Research shows that in distributed surveillance, s function as interconnected units that coordinate flexibly to perform tasks. Smart cameras, as advanced visual agents, capture and process data in parallel, providing valuable insights for collective decision-making [21]. In multi-camera systems, coordinated spatial alignment enables cameras to adjust their positions dynamically for optimal coverage, functioning as intelligent nodes within a broader network [22].

a) Role: Each smart camera acts as an autonomous or semi-autonomous node, capable of local processing and peer-to-peer communication.

b) Collaboration: Cameras share detection results, adaptively adjust focus or coverage as needed [23].

c) Examples: IP (Intenet Protocol) cameras with onboard AI(Artificial Intelligence) (e.g., Reolink Duo 3, TP-Link Tapo C230, or custom smart cameras with edge processing).

3) Onboard Edge Processing (YOLOv8+LSTM): Hybrid YOLOv8-LSTM.

To process this complex data, the system employs a hybrid neural network combining two powerful deep learning models:

a) YOLOv8: The YOLOv8 component plays a key role in spatial feature extraction within the system. It processes image data to identify critical features such as the shape of elephants, movement patterns, and distinct auditory signals. By recognizing these spatial patterns, the YOLOv8 aids in accurately determining the position and behavior of elephants in specific zones, enhancing real-time monitoring and response capabilities.

b) LSTM – Long Short-Term Memory Network: The Long Short-Term Memory (LSTM) network component is responsible for recognizing temporal patterns in elephant behavior. By analyzing sequential data—such as movement trajectories over hours or days—the LSTM learns how elephant activity evolves over time. Its memory units allow it to capture long-term dependencies, enabling the identification of preferred migration routes or seasonal movement trends. This temporal

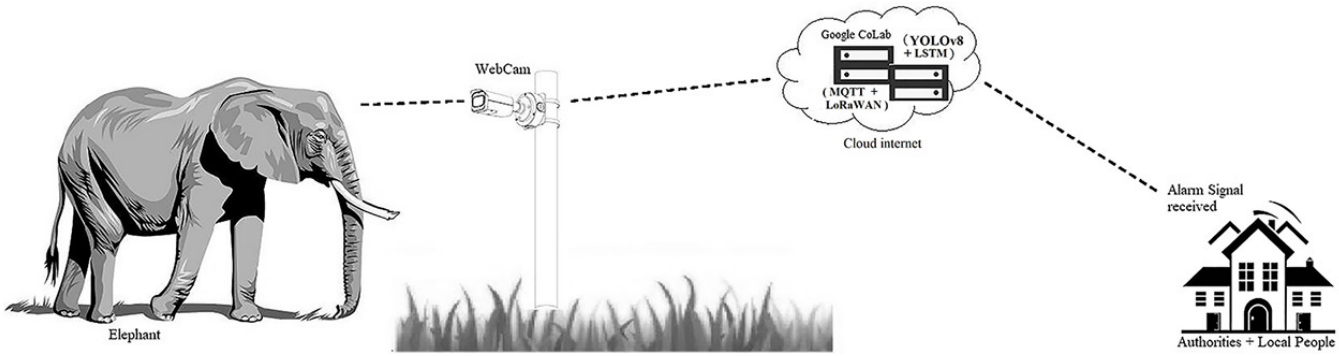

Fig. 1. Schematic diagram overview of the system.

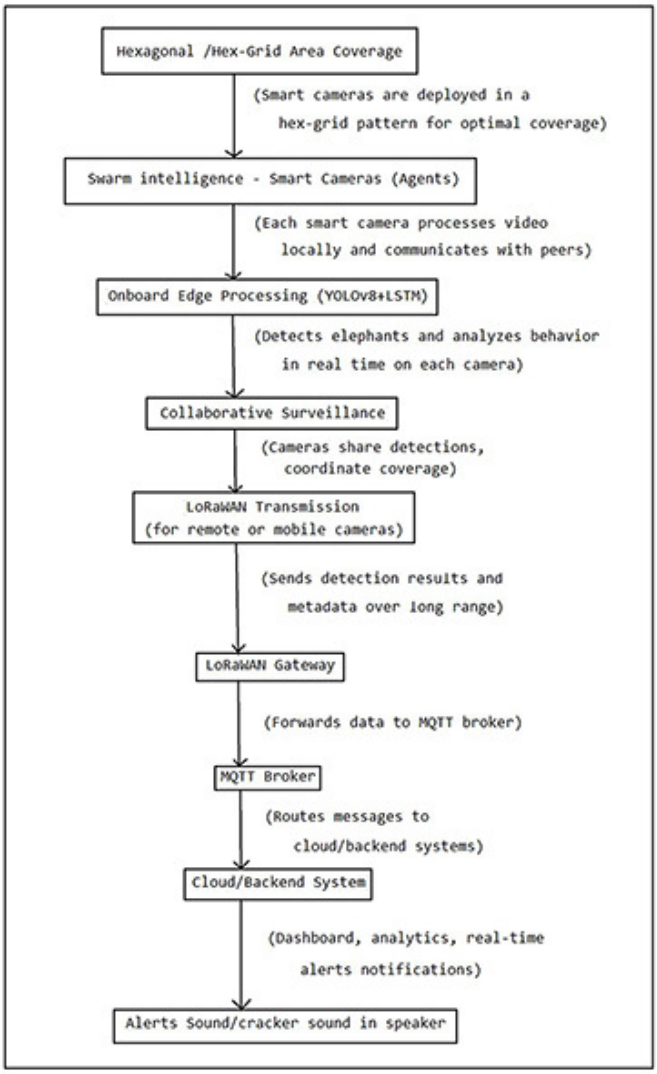

Fig. 2. System architecture: Step-by-step explanation.

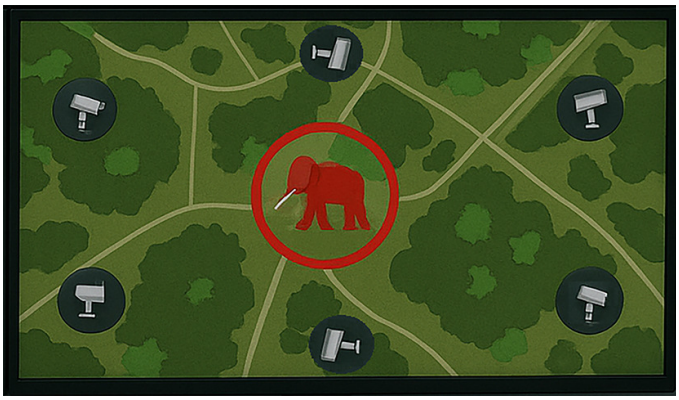

Fig. 3. Hexagonal surveillance system.

insight is crucial for accurately forecasting future elephant movements and enhancing proactive monitoring strategies.

Together, the YOLOv8 detects objects in each frame, while the LSTM models temporal patterns in detection data—enabling the system to predict where elephants are likely to move next, that is, the output it predicts are actions, anomalies, or behaviors.

c) Function: Each camera runs YOLOv8 for real-time elephant detection and LSTM for temporal behavior analysis.

d) Output: Generates detection results (e.g., "elephant detected," "anomaly detected") and metadata.

4) Collaborative Surveillance:

a) Function: Cameras communicate with each other to share detection information, optimize tracking, and ensure continuous coverage.

b) Hand-off: When an object moves from one camera's field of view to another, tracking is seamlessly transferred [24].

5) LoRaWAN Transmission (for remote/mobile cameras):

a) Function: For cameras in remote or hard-to-reach locations, detection results and metadata are transmitted wirelessly via LoRaWAN to a central gateway.

b) Advantage: Long-range, low-power communication suitable for large areas.

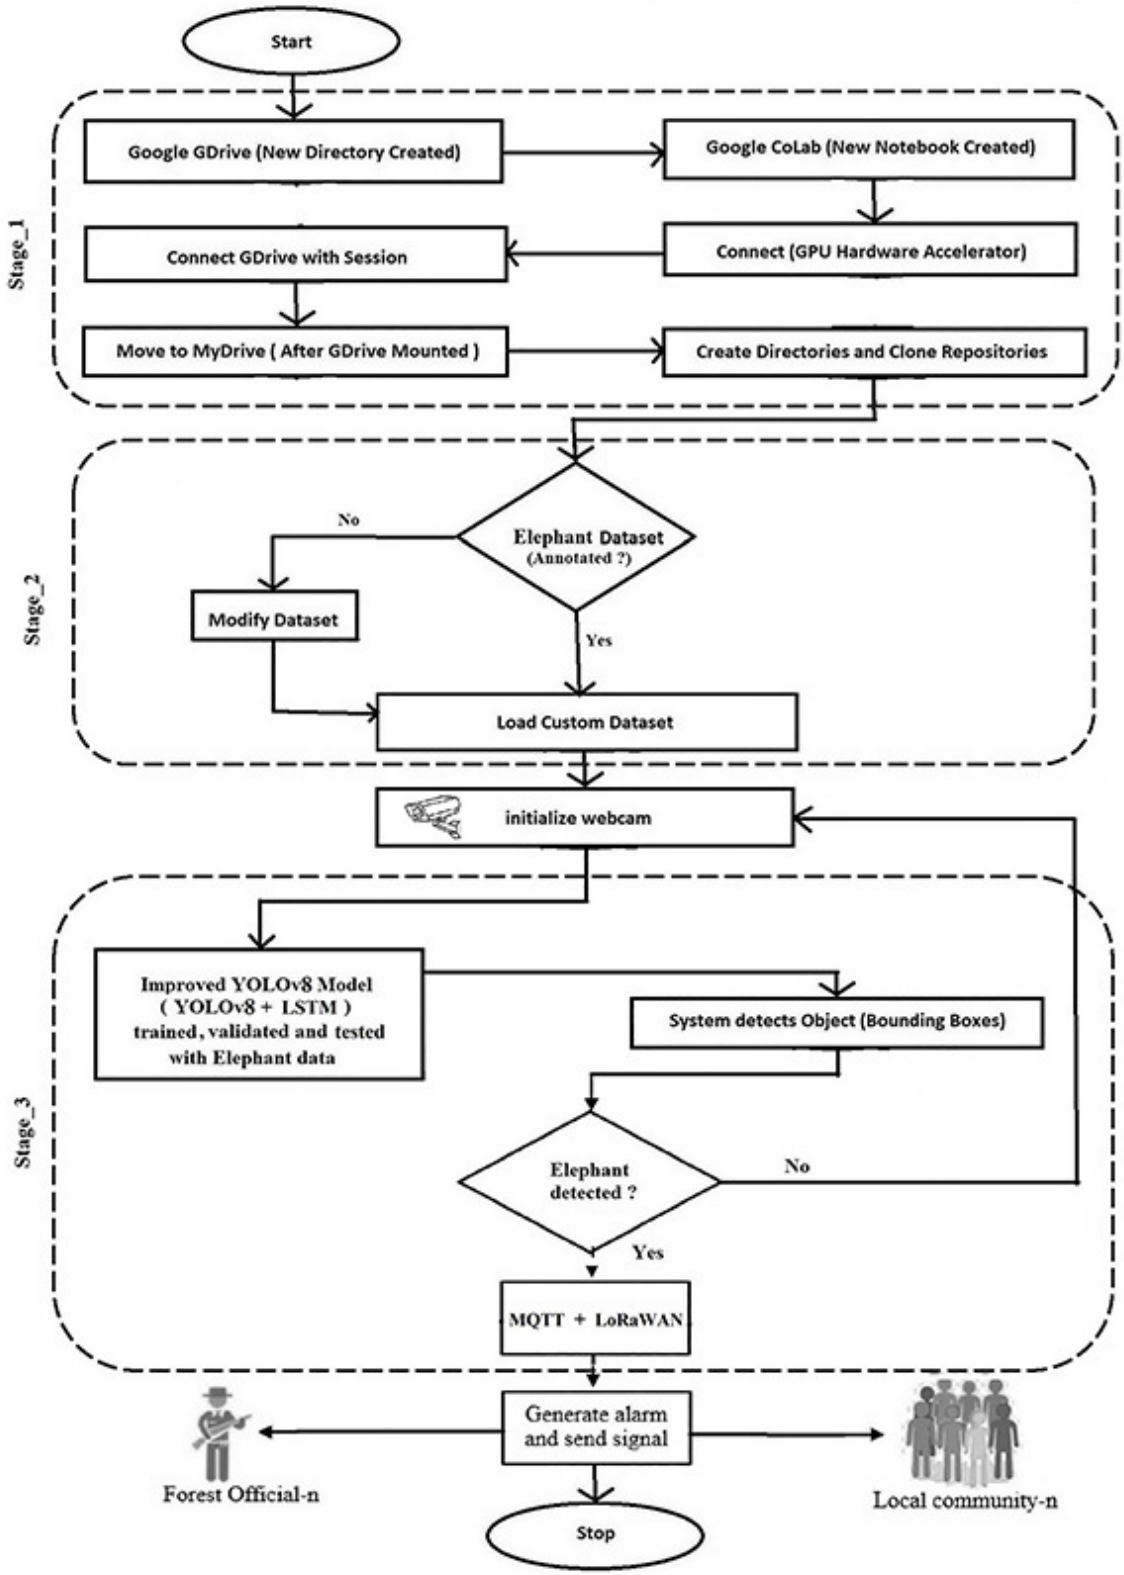

Fig. 4. Work flow progress of the system.

6) LoRaWAN Gateway:

a) Role: Receives data from multiple cameras and forwards it to an MQTT broker.

7) MQTT Broker:

a) Role: Efficiently routes messages to cloud/backend systems for further processing and visualization [25].

8) Backend System:

a) Function: Aggregates data, provides dashboards, analytics, and real-time alerts.

b) User Interface: Authorities or rangers receive notifications and can monitor the area in real time.

9) Alerts sound/ cracker sound in speaker:

a) Purpose: Immediate alerts for elephant detection and deter, enabling rapid response.

10) Key Features:

a) Intelligence: Smart cameras collaborate for adaptive, robust surveillance.

b) Edge AI: YOLOv8+LSTM enable real-time, on-device detection and behavior analysis.

c) Hexagonal Grid: Ensures efficient area coverage and minimal blind spots[26].

d) LoRaWAN & MQTT: Support reliable, scalable communication for remote monitoring [27].

e) Cloud Integration: Provides analytics, dashboards, and real-time alerts.

IV. Mathematical Model for Surveillance System

A. Notations

a) n: Number of smart camera agents in the system.

b) t: Time step (frame index).

c) $C_i(t)$: State of agent i at time t, including its position, battery, and current task.

d) $I_i(t)$: Video frame captured by agent i at time t.

e) $D_i(t)$: Set of detections from agent i at time t, where each detection is a tuple (x, y, w, h, c, p) representing bounding box coordinates, class, and confidence.

f) $\varepsilon_i(t)$: Set of elephant detections (filtered from $D_i(t)$ for class "elephant").

g) $\mathcal{S}_e^{(i)}(t)$: Sequence of features (bounding boxes, confidences) for elephant e tracked by agent i across recent frames.

h) $\mathrm{LSTM}(\cdot)$: LSTM model function.

i) $\mathcal{P}_e^{(i)}(t)$: Temporal prediction (e.g., movement, behavior) for elephant e by agent i at time t.

j) $M_i(t)$: MQTT message published by agent i at time t, containing local predictions and alerts.

k) $G(t)$: Gateway/edge node aggregating MQTT messages from all agents.

l) $M(t)$: Set of all MQTT messages received by the gateway at time t.

m) $A(t)$: Aggregated alert or summary sent via LoRaWAN to control center at time t.

B. Object Detection (YOLOv8)

For each agent i and time t, detections are given by Eq. (1):

$$D_i(t) = \mathrm{YOLOv8}(I_i(t)) \tag{1}$$

Filter for elephant detections, shown in Eq. (2):

$$\varepsilon_i(t) = \{(x, y, w, h, c, p) \in D_i(t) \mid c = \text{“elephant”}\} \tag{2}$$

C. Feature Preparation and Tracking

For each elephant e detected by agent i:

- Track elephant identity across frames (e.g., using a tracking algorithm).
- Build feature sequence for each tracked elephant given in Eq. (3):

$$\mathcal{S}_e^{(i)}(t) = [(x, y, w, h, p)_{t-k}, \ldots, (x, y, w, h, p)_t] \tag{3}$$

where k is the sequence length.

D. Temporal Analysis (LSTM)

The Eq. (4) shows the temporal prediction using LSTM:

$$\mathcal{P}_e^{(i)}(t) = \mathrm{LSTM}(\mathcal{S}_e^{(i)}(t)) \tag{4}$$

E. Coordination (MQTT)

Each agent publishes its predictions and alerts, as shown in Eq. (5):

$$M_i(t) = \{(\mathcal{P}_e^{(i)}(t), \text{agent_id}, \text{timestamp}) \mid e \in \varepsilon_i(t)\} \tag{5}$$

Gateway collects messages from all agents, shown in Eq. (6):

$$M(t) = \bigcup_i M_i(t) \tag{6}$$

F. Data Aggregation and Transmission (LoRaWAN)

Gateway aggregates and compresses messages for transmission shown in Eq. (7):

$$A(t) = \mathrm{Aggregate}(M(t)) \tag{7}$$

G. Summary Equation

Overall surveillance system model is shown in Eq. (8):

$$A(t) = \mathrm{Aggregate}\Big(\{\mathrm{LSTM}(\mathrm{Track}(\mathrm{YOLOv8}(I_i(t))))\}\Big) \tag{8}$$

V. Proposed Algorithm

The proposed work has been described in the below Algorithm 1:

Algorithm 1 Hexagonal Surveillance System with YOLOv8, LSTM, MQTT and LoRaWAN integration

Initialize
Deploy η smart camera agents across the surveillance area
Set up MQTT broker and LoRaWAN gateway
Initialize YOLOv8 and LSTM models on each agent
Define sequence length κ for LSTM input
Initialize tracking for elephant identity maintenance
Compute
For each agent i, capture initial video frame $I_i(0)$
while surveillance is active **do**
    for every agent i **do**
        Capture current video frame $I_i(t)$
        Detect objects using YOLOv8: $D_i(t) = \text{YOLOv8}(I_i(t))$
        Filter for elephant detections:

$$\varepsilon_i(t) = \{(x, y, w, h, c, p) \in D_i(t) \mid c = \text{“elephant”}\}$$

        Track each elephant $e \in \varepsilon_i(t)$ across frames
        Build feature sequence for each tracked elephant
        Compute temporal prediction: $\mathcal{P}_e^{(i)}(t) = \text{LSTM}(\cdot)$
        Publish prediction and alert via MQTT:

$$M_i(t) = \{(\mathcal{P}_e^{(i)}(t), \text{agent_id}, \text{timestamp}) \mid e \in \varepsilon_i(t)\}$$

        if unusual behavior or critical alert **then**
            Search for optimal agent coverage or notify control center
        end if
    end for
    Gateway collects all MQTT messages: $M(t) = \bigcup_i M_i(t)$
    Gateway aggregates and transmits via LoRaWAN: $A(t) = \text{Aggregate}(M(t))$
end while

VI. Virtual Simulation

The proposed work has been performed in Google Colab with designed-custom dataset. The virtual simulation of the proposed methodology has been shown in following sections:

A. Construction of Dataset

In this research, we compiled a dedicated dataset, which we obtained through the web by gathering the images of elephants. The range of poses, lighting circumstances, and backgrounds covered by these photographs is quite extensive, thus allowing the model to learn how to see elephants in many real-life situations. We additionally used a basic Python script to cut still frames out of video footage thus further increasing the data pool. After compilation, the images may be enhanced using a number of deep-learning algorithms to enhance quality and consistency then to train the detection system.

B. Data Annotation

The open-source tool of labeling named as LabelImg redefines the labeling process in such a way that it does not feel like a tedious experience but instead a creative and simplified one. The user can easily outline bounding boxes on parts of an image that are of interest, apply class labels to them, and save that information in a one-step process. Internally, the tool creates a plain-text document where the first integer is the identifier of the class, then there is the coordinates of the centre of the box and the width and height of the box. Since LabelImg can also export annotations in both YOLO and PAScal VOC XML formats, as well as CreateML, the cost of an additional conversion step is eliminated, especially with systems that operate on the YOLO framework. The software also offers easy key board shortcuts to drawing and saving and viewing images and allows remote server annotation. , therefore, regardless of the intended goal, be it detection, segmentation, or classification, the intuitive workflow and predefined system of classes provided by LabelImg allows the user to focus on the underlying data, instead of focusing on the underlying mechanics of labeling.

C. Dataset Preparation

The present project created a strong and detailed dataset when the real-world observations were integrated with the synthetic information to improve the predictive model in the real-time applications. The real-world data were obtained by the means of the open-access datasets of the elephant movements.

The models are trained using the custom dataset using 8,608 number of original elephant images and 1,592 number of non-elephant images. Table I has presented the information in the image dataset used to evaluate the models.

TABLE I. Designed-Custom Dataset

Image	Training	Validation	Test	Total
Positive (Elephant)	6,458	2,150	2,150	10,758
Negative (Non_elephant)	1,192	400	400	1,992
Total	7,650	2,550	2,550	12,750

D. Google CoLab

Google is a cloud based, no cost Jupyter notebook bearing the name Google Colab designed to engage a group of coders in a game. It also provides free and immediate access to strong GPUs and TPUs, ideal when training machine-learning models, and also allows to share a notebook with teammates as with a Google Doc. Everything on Google works in Google Drive, and it includes the possibility to open, edit, and share files everywhere. and since all notebooks are already pre-equipped with popular data science libraries such as TensorFlow, PyTorch, and pandas amongst others, one can immediately get started on data science instead of wasting time installing on own environment.

E. Model Training

The hybrid YOLOv8-LSTM architecture, i.e., the spatial feature extraction of YOLOv8 and the temporal sequence modeling of Long Short-Term Memory (LSTM) networks, was trained to create the predictive model. This architecture was chosen to be good at retrieving both spatial patterns (e.g., movement paths over terrain), and temporal dynamics (e.g., repeat entry times, or repeat behavior sequences) related to the activity of elephants. To balance the evaluation, an 60-20-20 (train-validate-test split) was used to divide the dataset in order to allow the model to generalize well to unknown data.

When trained, the model was very impressive and detected the entry patterns of the elephants with a high level of accuracy of about 98 percent. The findings support the strength of the model in practice, and it is highly suitable when applying to the proactive wildlife surveillance and early-warning systems.

VII. Simulated Results

The model evaluation was developed in controlled simulation conditions to determine the effectiveness of the system, responsiveness and efficiency of the system.

The confusion matrix for proposed ML model is shown in Fig. 5.

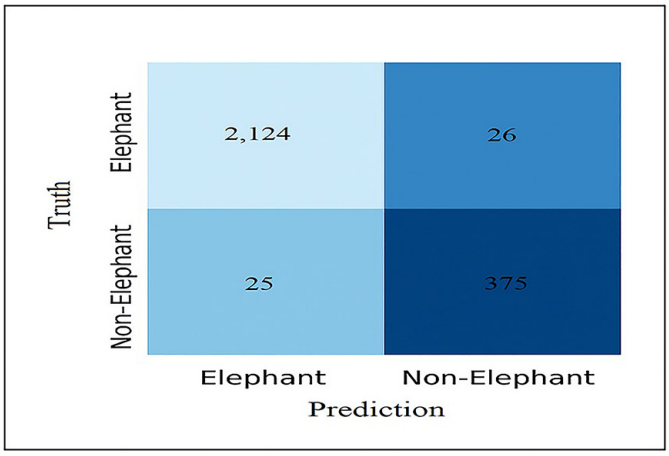

Fig. 5. Confusion matrix for proposed ML model.

The Fig. 6 shows confusion matrix for YOLOv8 model for elephant detection.

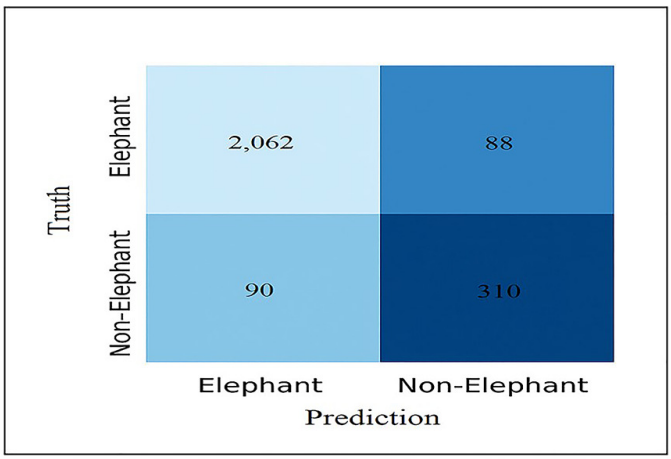

Fig. 6. Confusion matrix for YOLOv8 model for elephant detection.

Table II presents the results Machine Learning(ML) of proposed model.

The Fig. 7 shows the elephant detected by the proposed system.

The prediction model had a high accuracy of 98.0 percent in detecting the patterns of elephant movement and low false positive of 1.0 percent that guaranteed reliability of the detection with minimal false alarms.

TABLE II. ML Results for Proposed Model

Parameter (/ Measure)	Proposed ML	YOLOv8
Total predicted	2,550	2,550
True positive	2,124	2,062
False positive	26	88
False negative	25	90
True negative	375	310
Accuracy	0.98	0.93

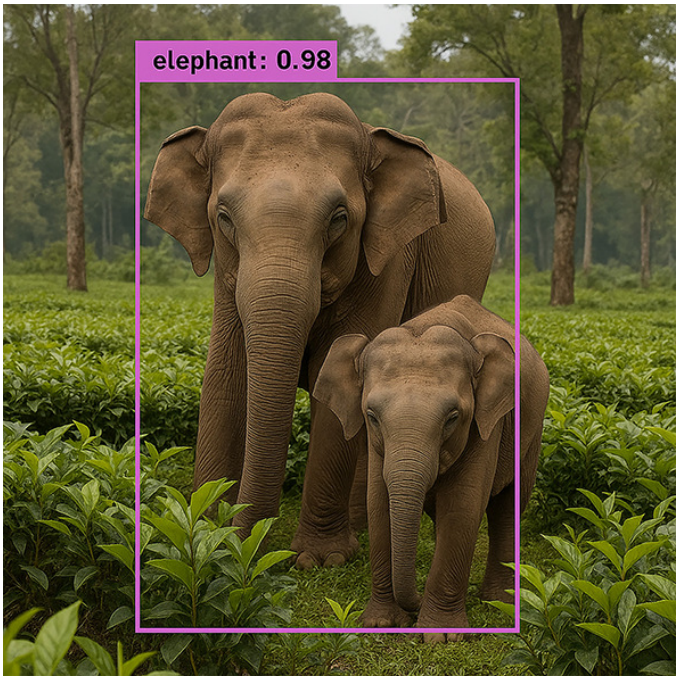

Fig. 7. Elephant detected.

VIII. Discussion

With MQTT on top of LoRaWAN, it is possible to make AI-based surveillance systems both practical and large-scale. LoRaWAN oxygen incapacity has some sweeping advantages of IoT links to hundreds of inactive, long-range sensors in a town, villa, or off-grid locations that maintain their operation with minimal roadwork studies. MQTT then manages the light, latency constrained communications between those edge devices and the cloud, cuts down bandwidth wastage and allows the network to scale to any topography; be it a smart village or a microgrid [28]. It is a combination of feeds live to YOLO-LSTM models providing video and sensor data in real time reliably even when in dense forests or during busy city times, therefore object detection and sequence analysis remains keen in high-traffic surges. Collectively, MQTT and LoRaWAN reduce power consumption and data rates that enable cameras and sensors detached in the distant areas to extend their lifespan on a limited battery and yet still provide the real time information that current AI surveillance relies upon [29, 30].

Table III presents the key advantages of proposed model.

TABLE III. SUMMARY TABLE: KEY ADVANTAGES

Parameter (/ Feature)	LoRaWAN Contribution	MQTT Contribution	Combined with YOLO-LSTM for Benefiting AI Surveillance
Coverage	Long-range	Not fixed	Flexible deployment
Power Consumption	Minimal	Reduces unnecessary transfer	Sustainable, low-maintenance operation
Scalability	Supports many devices	Flexible brokering	Easily expandable networks
Latency	Low (with MQTT integration)	Efficient message handling	Real-time data for AI models
Data Congestion	Avoids with hybrid protocol	Manages high-frequency data	Reliable, up-to-date AI inference

Overall, the integration of MQTT and LoRaWAN with an YOLO-LSTM model to create AI surveillance systems has major scalability, power consumption, low-latency communications, environmental flexibility benefits which are essential to advanced and efficient real-time surveillance systems.

IX. FUTURE PROPOSAL

The current simulation-based system shows a satisfactory initial result, which can be further developed in future work for a wider scope of practical application and technology robustness. Finally, field trials should be executed in cooperation with the forest departments and conservation authorities to ensure the performance of the system in real conditions and to improve its behavior under natural environmental conditions. These trials are expected to give important feedback regarding agent coordination, detection accuracy, and system robustness in various terrain types. Additionally, blockchain technology is suggested to be implemented to provide transparency and security of the data, enabling tamper-proof and decentralized data sharing between, for example, tea estate owners, conservationists, or local administration. This would provide confidence and accountability of system warning and movement records. In addition, thermal imaging sensors will be integrated for intelligences through enhanced detection capabilities particularly at night, when the elephant's skin color is barely noticeable by agents, irrespective of the lighting conditions. Additionally, the capabilities to create mobile applications that can provide localized parties (planting workers and local communities) with real-time alerts will allow localized response initiatives, enabling even more human-autonomous system collaboration. Together, these improvements will bring the system closer to full-scale deployment, and bring about a robust, ethical, community-driven elephant conflict mitigation solution.

X. CONCLUSION

This paper introduces a new, holistic and interdisciplinary way of looking at the increasingly challenging issue of elephant-human conflict, especially in tea plantation areas. The proposed autonomous Hexagonal Intelligent Surveillance (HIS) entails the non-separate, combined application of machine learning-based prediction models, intelligence, and a hexagonal spatial grid to constitute a cohesive, responsive, and ethically-grounded system. The virtual simulation of the proposed work shows 98% accuracy on designed-custom dataset of elephants. In addition, in order to reduce the need for human intervention, the system detects potential elephant intrusions ahead of time and provides coordinated adjuvant decentralized reaction through autonomous agents in a non-lethal and animal safe way. The hexagonal cell topology improves the coverage and flexibility of the system by enabling it to adapt to changing levels of risk over large geographical areas. Apart from its scalability, this combination of technologies puts both the safety of humans and the conservation of wildlife at the forefront. With further field testing and real-world implementation, the HIS framework has the potential of revolutionizing current strategies for wildlife conflict mitigation by providing a smarter, more efficient, and more humane solution for preserving livelihood and ecosystems on agricultural frontiers worldwide.

Creative Guidance of Intelligent Emotion Recognition in Video Art

Weixing Chen, Yubo Zhou*
Namseoul University, Tian'an City, Korea

***Abstract*—This study optimizes the existing emotion recognition model to improve the application effect of emotion recognition technology in the guidance of video art creation. It also compares the performances of Multimodal Sentiment Analysis (MMSA), Multimodal Sequence Encoder (MuSE), and the optimized model through a series of simulation experiments. In the fine-grained accuracy of emotion recognition, the optimized model performs well in micro-expression recognition accuracy and multimodal fusion effect, and scores 4.17 and 4.96, respectively. In the robustness test under a complex background, the background interference resistance score of the optimized model is 4.30, and the modal mismatch processing score is 4.38. In the experiment on the effectiveness of emotion recognition in creative guidance, the optimized model scores 4.40 and 3.66 in terms of artistic expression enhancement and creative feedback accuracy, respectively. The experimental results show that the optimized model is superior to the existing models in several key dimensions of emotion recognition, especially in enhancing the emotional expression of artistic works and providing creative guidance. Therefore, this study provides some reference for the application and development of emotion recognition technology in video art creation.**

***Keywords*—Emotional recognition; image art; artistic expressiveness; creative feedback**

I. Introduction

With the rapid development of artificial intelligence (AI) technology, affective computing has gradually gained widespread attention as a crucial research direction in human-computer interaction. Affective computing aims to endow computers with the ability to recognize, understand, and express emotions, thereby enabling more natural and intelligent human-computer interaction [1]. In recent years, emotion recognition technology has developed rapidly in multimedia, entertainment, healthcare, and education. It has also demonstrated enormous potential in enhancing user experience and interaction quality [2]. As an artistic form that conveys emotions and ideas through visual language, audio-visual art creation relies heavily on emotional expression and audience emotional resonance [3]. However, traditional audio-visual art creation mainly depends on artists' experience and intuition. This hinders its ability to accurately capture the emotional feedback of different audiences and systematically integrate such emotional information into creative decisions [4, 5].

Despite the significant progress of existing emotion recognition technology in various scenarios, obvious research gaps remain in the field of audio-visual art creation. Firstly, current models mostly focus on single-modal or coarse-grained emotion classification, lacking effective recognition of fine-grained emotional information such as microexpressions and subtle emotional changes—details that are particularly critical for artistic expression. Secondly, the diverse visual styles and complex scene changes in audio-visual art result in insufficient robustness and real-time performance of existing models, which fail to meet the needs of creative practice. Thirdly, existing literature rarely explores how emotion recognition results can be linked to specific creative behaviors, such as shooting, editing, color scheduling, and narrative rhythm. Thus, a clear disconnect persists between "technology and artistic creation".

To address the above research gaps, this study optimizes existing multimodal emotion recognition models and proposes an intelligent emotion recognition framework for guiding audio-visual art creation. Through an improved multimodal fusion mechanism, the model significantly enhances microexpression recognition capabilities and robustness in complex backgrounds. Its structural design also improves the usability of converting emotional information into creative decisions. In addition, this study constructs a comprehensive evaluation system that includes both technical and art creation-related indicators, verifying the model's effectiveness from both technical performance and practical creation perspectives. The main innovative contributions of this study are as follows:

1) Explicitly propose the task requirements of emotion recognition "for guiding audio-visual art creation", bridging the disconnect between technology and artistic creation in existing research.

2) Design an optimized multimodal fusion architecture to improve the accuracy of fine-grained emotion recognition and robustness in complex backgrounds.

3) Establish a new evaluation system that balances technical performance and creative value, providing an operable evaluation paradigm for the application of emotion recognition technology in artistic creation.

The subsequent structure of this study is arranged as follows: Section II reviews relevant research on affective computing and emotion recognition, and sorts out their application status in artistic creation. Section III elaborates on the theoretical basis of affective computing and introduces the overall design and optimized architecture of the intelligent emotion recognition model. Section IV presents the experimental design, including datasets, experimental processes, simulation experiments, and ablation experiments, along with analysis and discussion of results. Section V summarizes the research findings, points out limitations, and proposes future research directions.

II. Literature Review

In the field of affective computing and emotion recognition, existing studies have systematically explored emotion modeling from diverse modalities and application scenarios. Lian et al. (2023) found that deep learning-based text emotion recognition algorithms achieved high accuracy in sentiment polarity and fine-grained emotion analysis. However, when extending from text emotions to multimodal contexts such as speech and images, models still faced significant challenges in cross-modal alignment and feature fusion, especially lacking robustness in complex scenarios [6]. Kopalidis et al. (2024) proposed a facial expression recognition model based on a convolutional neural network (CNN). Its recognition accuracy exceeded 90% on standard datasets, proving the effectiveness of the visual modality in static or regularized scenarios. Yet, the method focused primarily on single-modal visual inputs and lacked targeted handling of typical artistic scenarios such as background interference and stylized visual elements [7]. Liu and Li (2023) discovered that fusing multiple physiological signals—such as heart rate and skin conductance responses—into affective computing models significantly improved emotion recognition accuracy. This indicated that multimodal physiological signals played a complementary and corrective role in emotional states. However, most related works remained confined to laboratory or medical contexts, with relatively limited discussions on adaptability to open and complex environments like video art creation [8].

Regarding multimodal emotion recognition and its applications in creative fields, Dash and Agre (2024) pointed out that music generation systems incorporating emotion recognition technology could dynamically adjust rhythm and melody based on audience emotional feedback. Thus, it can enhance the emotional appeal of musical works. Nevertheless, their multimodal modeling focused mainly on audio and simple interaction signals, lacking comprehensive modeling of complex information such as visual content and contextual semantics [9]. Monser and Fadel (2023) found that intelligent emotion recognition technology helped visual art creators understand audience emotional responses and adjust expression techniques accordingly. However, their research mainly proceeded from the perspective of "emotion analysis-assisted evaluation". Meanwhile, they did not deeply construct a systematic mapping mechanism from emotion recognition results to specific creative decisions (e.g., shot language, color configuration, narrative rhythm) [10]. Li (2024) proposed a method combining emotion recognition with film production, using real-time audience emotional responses to optimize editing rhythm and sound effect design, thereby improving the viewing experience. However, the model design emphasized the control of overall emotional curves, with relatively superficial discussions on microexpressions, fine-grained emotional transitions, and multimodal fusion strategies [11]. Wang (2024) discovered that applying emotion recognition to film character emotion analysis helped directors and screenwriters shape character images and narrative tension more accurately. Yet, most related works focused on character-level emotion label prediction, with little consideration of how to feed recognition results back into real-time adjustments and iterative optimization in the creative process [12].

In the direction of optimizing the rhythm and structure of audio-visual works, Zhang et al. (2024) proposed a film editing method based on emotion recognition. By analyzing changes in audience emotions, the method optimized editing rhythm, making the film's emotional expression more coherent and concentrated. However, the approach remained mostly at the rule-driven or experience-driven level of rhythm regulation, failing to fully leverage multimodal deep features and robust modeling in complex contexts [13]. Zhang and Pu (2024) showed that introducing emotion recognition technology in animation production enabled more delicate character expression and movement design, significantly enhancing audience emotional resonance. Nevertheless, most related systems centered on "character image shaping" and lacked systematic support for "emotional structure control and creative guidance of the entire audio-visual work" [14].

Synthesizing the aforementioned studies, it is evident that multimodal emotion recognition technology has achieved significant progress in fields such as text, speech, facial expressions, physiological signals, music, film, and animation. However, obvious gaps remain in systematic research oriented toward guiding audio-visual art creation. Firstly, most studies focus on improving "recognition accuracy" but lack systematic evaluation and targeted optimization of model robustness, real-time performance, and generalization ability in complex audio-visual contexts. Secondly, existing works apply emotion recognition to scenarios like music generation, film editing, or character shaping. However, they generally lack interpretable mapping and creative guidance mechanisms from "emotion recognition results to specific creative decision parameters (e.g., shot editing, color style, narrative rhythm)". Thirdly, multimodal fusion strategies mostly remain at relatively fixed early/late fusion or simple weight superposition; they lack targeted structural designs and training strategies to address issues such as complex backgrounds, modal mismatches, and fine-grained emotional changes.

Based on this, this study builds on previous research and further focuses on audio-visual art creation scenarios. The fusion mechanism and robustness design of multimodal emotion recognition models are optimized, and evaluation dimensions closely related to artistic expression and creative feedback are introduced. Thus, it constructs a tighter bridge between "technical performance improvement" and "artistic creation usability". This fills the key gap in existing research regarding the guidance of video art creation.

III. Emotion Recognition Based on AI

A. Affective Computing and Emotion Recognition Technology

Affective computing is an important branch of computer science and AI, making computers have the ability to perceive, understand, explain, and simulate human emotions [15]. The research content of affective computing includes the identification, expression, and generation of emotion and the construction of emotional intelligence [16]. With the development of technology, affective computing has gradually expanded from the initial theoretical exploration to a wide range of applications, such as HCI, intelligent education, mental health, entertainment, and so on [17]. Emotion recognition technology is one of the core tasks of affective

computing, which aims to identify human emotional state from various data sources through computer algorithms [18]. At present, emotion recognition technology is mainly divided into two categories: single-mode emotion recognition and multi-mode emotion recognition [19], as shown in Table I:

TABLE I. EMOTION RECOGNITION TECHNOLOGY

Technology	Application	Description
Single-mode emotion recognition technology	Facial expression recognition	Emotion recognition based on facial expressions is the most common method in emotion recognition technology. Early research usually relies on artificial feature extraction, such as local binary pattern and scale-invariant feature transformation. However, with the rise of deep learning, the model based on a CNN has become mainstream.
	Speech emotion recognition	The speech signal contains rich emotional information, such as intonation, speech speed, volume and so on. Speech emotion recognition usually judges the emotional state of the speaker by extracting these features. Traditional methods include the hidden Markov model and the support vector machine.
	Text sentiment analysis	Text sentiment analysis mainly analyzes the emotional tendency in the text through natural language processing technology. Traditional methods include the sentiment dictionary method and machine learning classifiers, such as support vector machines and naive Bayes.
Multi-mode emotion recognition	Feature extraction	Representative features are extracted from different modal data, such as geometric and texture features from facial expressions, frequency and energy features from speech, word vectors, and emotional vocabulary from texts.
	Feature fusion	Feature fusion is a key step in multimodal emotion recognition. Common methods include early fusion and late fusion. Early fusion combines features from different modes directly in the feature extraction stage, while late fusion is decision-level fusion based on the emotion classification results of each mode.
	Emotional classification	The fused features or classification results are input into the emotion classifier to identify the final emotion state. Commonly used classifiers include support vector machine, random forest and deep neural network.

To sum up, emotion calculation and emotion recognition technology have laid an important foundation for the application of intelligent emotion recognition in video art [20]. With the continuous progress of technology, emotion recognition plays an increasingly important role in the creation of video art, providing a new channel for emotional communication between artists and audiences [21].

B. The Combination of Intelligent Emotion Recognition and Artistic Creation

With the continuous development of AI technology, emotion recognition technology is not limited to traditional application fields such as HCI and mental health, and its potential is gradually explored and applied in artistic creation [22]. Artistic creation, as an important way for human beings to express emotions, thoughts, and concepts, usually depends on the creator's deep understanding of emotions and the audience's emotional resonance [23]. The introduction of intelligent emotion recognition technology can inject new vitality into the artistic creation process. By capturing and analyzing the emotional reaction of the audience, it can help artists to make more accurate emotional expression and adjustment in their creation, thus enhancing the emotional appeal of their works. In artistic creation, emotion recognition technology can help creators from many aspects, including real-time feedback of creative effects, personalized customization of artistic content, and optimization of emotional communication methods of works [24]. Through intelligent emotion recognition technology, the creator can better understand the emotional needs and reactions of the audience, provide a scientific basis for the creative process, and thus realize the deep integration of artistic creation and emotion recognition.

As an intuitive and infectious art form, visual art has long been used to express complex emotions and thoughts. The application of intelligent emotion recognition technology in visual arts can help artists capture and express emotions more accurately and optimize the audience's viewing experience. Music, as an art form with sound as the medium, has a strong emotional expression ability [25]. The application of intelligent emotion recognition technology in music creation is mainly reflected in music generation driven by emotion recognition, music creation with real-time emotion feedback, and the combination of emotion recognition and music recommendation systems. Image art includes many art forms such as movies, animations, and videos, and has strong emotional expression and narrative ability [26]. The application of intelligent emotion recognition technology in video art can help the creator to better understand the emotional reaction of the audience and optimize the emotional expression of video works [27].

In short, the combination of intelligent emotion recognition technology and artistic creation expands the means and forms of artistic creation, while providing the audience with a more personalized and interactive artistic experience [28]. With the continuous progress of technology, emotion recognition plays an increasingly important role in artistic creation and builds a closer bridge for emotional communication between artists and audiences [29].

C. Model Construction of Intelligent Emotion Recognition Technology in Video Art

The application of intelligent emotion recognition technology in video art depends on the complex model construction process, which includes multiple stages from data collection to model training, optimization, and application. The construction of an emotion recognition model requires a deep understanding of the basic theories of affective computing and AI, such as machine learning, deep learning, and multimodal data processing. Meanwhile, it is necessary to combine the relevant theories of psychology, cognitive science, and art to ensure that the model not only has accurate emotional

recognition ability, but also can be effectively applied to artistic creation to enhance the emotional expression of works. In the process of model construction, it is important to consider the characteristics of image art, such as diverse visual elements, dynamic scenes, and complex interaction with audience emotions. Based on these characteristics, to build an emotion recognition model suitable for video art, it is usually necessary to integrate multi-modal emotion recognition technology, an emotion calculation model, and an artistic expression model to accurately capture and express emotions. The designed optimized model is shown in Fig. 1:

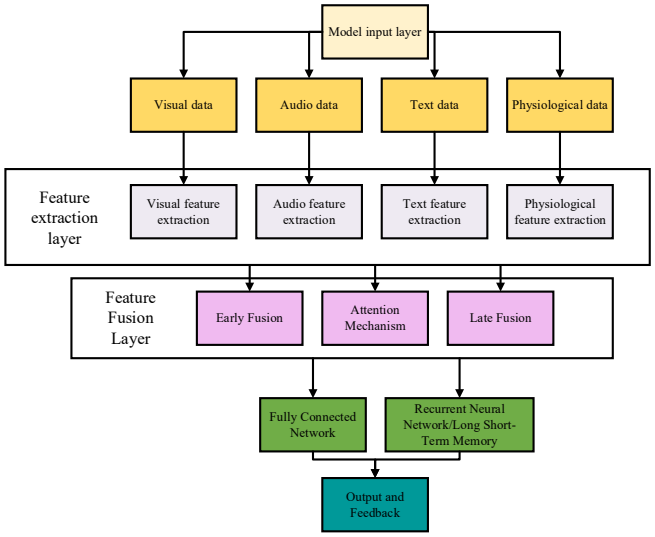

Fig. 1. Intelligent emotion recognition model architecture.

Through the above model framework, intelligent emotion recognition technology can accurately capture and feedback the audience's emotions in video art, thus enhancing the emotional expression and interactive experience of video works.

IV. Comparison between the Performance of Intelligent Emotion Recognition Model and Simulation Results

A. Performance Analysis of an Intelligent Emotion Recognition Model

The Interactive Emotional Motion Capture (IEMOCAP) dataset is selected in the experiment. It is especially suitable for the study of emotion recognition because it contains multimodal records designed for emotion recognition. The IEMOCAP dataset includes 302 video conversations, which are recorded in five sessions, and each session contains two speakers. The dataset labels nine different emotions: anger, excitement, fear, sadness, surprise, depression, happiness, disappointment, and neutrality. In addition, it also provides continuous labeling about pleasure, arousal, and dominance. The computer used in the experiment is equipped with an Intel Xeon Gold 6230 processor, which has up to 20 cores /40 threads, provides powerful multi-thread processing ability, and can process a large amount of data efficiently. In order to speed up the training of a deep learning model, NVIDIA Tesla V100 is selected in the experiment, which has 32 GB of HBm2 memory and supports the parallel computing of deep learning frameworks such as TensorFlow and PyTorch, which significantly improves the training speed of the model. The experimental system is equipped with 128GB DDR4 ECC memory to ensure the stability and performance of the system when dealing with large data sets. The experimental data is stored on a 2TB NVMe SSD, which provides fast data reading and writing speed, reduces the I/O bottleneck, and ensures efficient data processing in the experimental process. Multimodal Sentiment Analysis (MMSA) and Multimodal Sequence Encoder (MuSE) are selected as the contrast models in the experiment. The experimental parameters are set as follows: the image input dimension is 2242243, and the audio input is the feature matrix of 128128. CNN layer, using 32 convolution kernels of 33, the activation function is ReLU, followed by the maximum pool layer of 22. In the deep convolution layer, 64 convolution kernels of 33 are used, and the activation function is ReLU, followed by the maximum pool layer of 22. In the fully connected layer, the number of neurons is 256, and the activation function is ReLU. Dropout is used to prevent over-fitting, and the discard rate is set to 0.5. The indicators of experimental comparison are accuracy, Area Under the Receiver Operating Characteristic Curve (AUC-ROC), Kappa coefficient, and Mean Squared Error (MSE). The experimental results are shown in Fig. 2:

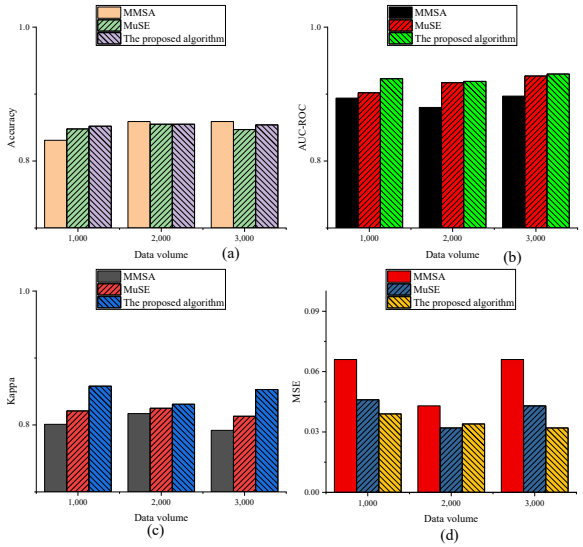

Fig. 2. Performance comparison results: (a) Accuracy, (b) AUC-ROC, (c) Kappa coefficient, (d) MSE.

In Fig. 2, in terms of accuracy, when the data volume is 1000, the MMSA, MuSE, and optimized models' accuracy are 0.831, 0.848, and 0.852. It can be found that the performance of the optimized model is slightly better than that of MMSA and MuSE models in the case of less data, especially when the accuracy of MuSE is close, the optimized model still has certain advantages. When the data volume is 2000, the accuracy of MMSA rises to 0.859, MuSE is 0.855, and the optimized model is 0.855. With the increase in data volume, the performance of the MMSA and optimized models is very close, and the MuSE model is slightly inferior. This shows that with the increase in data volume, the accuracy of the MMSA and optimized models has been improved, but the gap between them has narrowed. When the data volume is 3000, the accuracy of MMSA is maintained at 0.859, while that of MuSE

is slightly reduced to 0.847, and that of the optimized model is 0.854. When the data volume reaches 3000, the accuracy of the MMSA and optimized models shows good stability, while the accuracy of MuSE decreases slightly. This may indicate that MuSE is more sensitive to data under a larger data volume, which leads to the fluctuation of model accuracy.

In terms of AUC-ROC, under different data sets, the AUC-ROC values of the optimized model reach 0.923, 0.919, and 0.93, respectively, which shows significant advantages when the data volume is small. With the increase of data volume, the AUC-ROC performance of MuSE is gradually improved, and it tends to be close to that of the optimized model, which shows that MuSE has good scalability when dealing with large-scale data. However, MMSA is relatively stable when the data volume increases, but it fails to show significant improvement.

In terms of the Kappa coefficient, when the data volume is 1000, the Kappa coefficients of the MMSA and MuSE models are 0.801 and 0.821, and that of the optimized model is 0.858. When the data volume is 2000, the Kappa coefficient of MMSA rises to 0.817, that of MuSE is 0.825, and that of the optimized model is 0.831. When the data volume is 3000, the Kappa coefficient of MMSA drops slightly to 0.782, that of MuSE is 0.813, and that of the optimized model rises to 0.853. With a larger amount of data, the Kappa coefficient of the optimized model remains at a high level, while the MuSE model shows stability, but it fails to surpass the optimized model. The Kappa coefficient of the MMSA model decreases slightly, which may be affected by the complexity increase when the data volume increases.

In terms of MSE, when the data amount is 1000, the MSE of the MMSA, MuSE, and optimized models are 0.066, 0.046, and 0.039. In the case of small data, the MSE of the optimized model is the lowest, which shows that its prediction error is the smallest and it has better precision. MuSE is also better than MMSA. When the data volume is 2000, the MSE of the MMSA and MuSE models is significantly reduced to 0.043 and 0.032, and the MSE of the optimized model is 0.034. With the increase in data volume, the MSE of MMSA has been significantly improved, but the MuSE performs better, reaching the lowest MSE value. The MSE of the optimized model is slightly higher than that of MuSE, but it still remains at a low level. When the data volume is 3000, the MSE of MMSA rises to 0.066, that of MuSE is 0.043, and that of the optimized model is further reduced to 0.032. Under a larger data volume, the optimized model once again showed its advantages, reaching the lowest MSE value, indicating that it can still maintain a low prediction error when dealing with large-scale data. The MSE of MMSA fluctuates, while the MuSE maintains a relatively stable performance.

B. Simulation Experiment Comparison of Intelligent Emotion Recognition Model

The experiment adopts a scoring system of 1-5 points. The higher the score, the higher the representative satisfaction. This study selects four indicators, namely, fine-grained accuracy of emotion recognition, response speed, robustness in complex background, and effectiveness of creative guidance. For each indicator, it is divided into three dimensions, and the results are shown in Fig. 3:

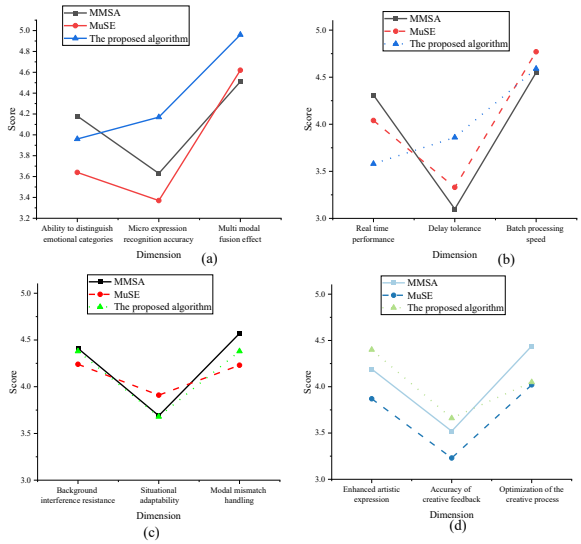

Fig. 3. Comparison results of simulation experiments: (a) Fine-grained accuracy of emotion recognition; (b) Response speed of emotion recognition; (c) Robustness of emotion recognition in complex backgrounds; (d) Effectiveness of emotion recognition in creative guidance.

In Fig. 3, in the comparison of the fine-grained accuracy of emotion recognition, the MMSA model scored 4.18, the MuSE model scored 3.64, and the optimized model scored 3.96 in terms of the ability to distinguish emotion categories. In terms of micro-expression recognition accuracy, the MMSA model scored 3.63, the MuSE model scored 3.37, and the optimized model scored 4.17. In the aspect of multimodal fusion effect, the MMSA, MuSE, and optimized models score 4.51, 4.62, and 4.96. The optimized model shows excellent performance in all dimensions of fine-grained emotion recognition, especially in micro-expression recognition accuracy and multimodal fusion effect, and the score of the optimized model is significantly higher than other models. This shows that the optimized model has higher accuracy and robustness when dealing with complex and diverse emotional data.

In the comparison of response speed, the scores of the optimized model are 3.58, 3.86, and 4.59 in different dimensions, and the MMSA model is the best in the real-time dimension, which shows that it has advantages in emotion recognition tasks that need immediate response. However, in terms of delay tolerance, the optimized model has the highest score, indicating that it can better deal with the delay problem when dealing with complex or long input data. The MuSE model has the highest score in the batch processing speed dimension, which shows that it is very efficient in processing a large amount of data and is suitable for scenes that need to process emotional data in batches. The performance of the optimized model is balanced in all dimensions, especially in delay tolerance and batch processing speed.

In the comparison of robustness in a complex background, the scores of the optimized model are 4.30, 3.68, and 4.38 in different dimensions. The MMSA model is more robust in a complex background, especially in the two dimensions of background interference resistance and modal mismatch processing, which makes it better to maintain the performance of emotion recognition in changeable and unstable

environments. However, in terms of situational adaptability, the MuSE model scored the highest, indicating that it has better adaptability in the face of complex situations. The performance of the optimized model is relatively balanced in all dimensions, especially in the processing of background interference resistance and modal mismatch, which shows that the optimized model can maintain stable emotion recognition performance in a complex background, but it is slightly inferior to MuSE in situational adaptability.

In the comparison of the effectiveness of creative guidance, the scores of the optimized model are 4.40, 3.66, and 4.05, respectively. The overall performance of the optimized model is the best, especially in the two dimensions of artistic expression enhancement and creative feedback accuracy, which shows that it has obvious advantages in improving the emotional expression of artistic works and providing creative guidance. MMSA model has the highest score in the optimization dimension of the creative process, which shows its potential in improving creative efficiency and simplifying the process. However, the performance of the MuSE model is relatively low in three dimensions, especially in the enhancement of artistic expression and the accuracy of creative feedback, which needs to be further optimized to enhance its effectiveness in guiding artistic creation.

C. Discussion

Overall, experimental results show that the optimized intelligent emotion recognition model exhibits stable performance superior to comparative models across multiple key dimensions. When compared with MMSA and MuSE, the optimized model generally demonstrates the characteristics of "comprehensive balance and slight advantage" in fine-grained emotion recognition, stability under complex backgrounds, and creative guidance-related indicators. In contrast, each comparative model possesses partial advantages. This result indicates that the adjustments made by this study to the multimodal fusion strategy and model structure do not merely pursue the extreme optimization of a single indicator. Instead, it attempts to achieve a reasonable balance between recognition accuracy, robustness, and creative usability. From the subjective rating results of simulation experiments, the optimized model shows remarkable advantages in dimensions closely related to creative practice, such as "enhanced artistic expression" and "accuracy of creative feedback". In dimensions like "real-time performance" and "batch processing efficiency", it forms a complementary pattern of "each having its own strengths" with existing models. This also suggests that in real applications, different models are not simply in a "superior-inferior substitution" relationship, but are more likely to form a model combination that can be dispatched according to scenarios. In general, these results collectively demonstrate that the optimized model, while ensuring technical performance, is closer to the actual needs of audio-visual art creation for emotion recognition systems. Thus, it lies a potential foundation for emotion recognition to transform from a "technical tool" to a "creative partner".

At an application level, the optimized intelligent emotion recognition model can serve emotional analysis at the single work level and has the potential to be embedded into the complete audio-visual art creation process. For directors, audio-visual artists, or editors, the model can act as an "emotion monitoring and feedback engine". During the creation process, it provides quantitative reference suggestions for shot rhythm, frame composition, color style, and audio-visual relationships based on changes in audience emotions. This helps creators more consciously shape the emotional trajectory of their works, rather than relying solely on experience and intuition. For cross-platform digital audio-visual content (e.g., short videos, interactive audio-visual installations, immersive performances), the model is also expected to analyze different audience groups' emotional response patterns, providing data support for content iteration and personalized recommendations. In the field of human-computer collaboration and intelligent creative systems, the optimized model can be embedded into creative assistance platforms as an "emotion perception module"; meanwhile, it can work in coordination with modules such as intelligent editing, style transfer, and generative content creation. With the output of emotion recognition, the system can automatically tend to combinations of shots, colors, or sound effects that better match the target emotional state when generating or recommending materials; thus, it can realize an "emotion-mediated" human-computer collaborative creation model. In new media environments such as virtual reality (VR) and augmented reality (AR), the model can also be used to real-time perceive users' emotional fluctuations; it can also dynamically adjust virtual scenes, interaction rhythms, or visual narrative paths to enhance immersion and participation. At the theoretical level, this study attempts to systematically link multimodal emotion recognition with the guidance of audio-visual art creation. This helps promote the transformation of "emotional expression" from artistic theory and aesthetic experience into computable and modelable forms. For one thing, by introducing evaluation dimensions related to artistic expression and creative feedback, this study provides an operable idea for "how to characterize the emotional expression of audio-visual works with computational indicators". For another, the mapping process between emotion recognition results and specific creative decisions (e.g., editing, color grading, narrative rhythm) offers new empirical support and methodological reference for the theory of emotional expression in digital media; it promises to promote interdisciplinary dialogue between affective computing, audio-visual narrative, and aesthetic research.

V. Conclusion

This research studies the application and optimization of intelligent emotion recognition technology in the guidance of video art creation. By comparing the performance of the MMSA, MuSE, and optimized models, it makes in-depth analysis and simulation experiments on the model in several key dimensions to evaluate its effectiveness and applicability in emotion recognition tasks. The experimental results show that the proposed optimized model performs well in many aspects, especially in fine-grained accuracy of emotion recognition, robustness in complex backgrounds, and effectiveness of creative guidance. In addition, the MMSA model shows its advantages in real-time and creative process optimization, and is suitable for scenes that need efficient processing. The MuSE model is excellent in situational adaptability, but there is still

room for improvement in other dimensions. Although this study has made some achievements in optimizing the emotion recognition model and applying it to the guidance of video art creation, there are still some shortcomings. Firstly, the experiments are mainly based on specific public datasets and limited emotion categories. Although they cover multiple emotion types and multimodal signals, differences still exist compared with real audio-visual art creation scenarios. Emotions in actual artistic creation often exhibit high ambiguity, hybridity, and cultural dependence. These complex emotional forms have not been fully reflected in the current data and annotation systems; this to a certain extent limits the model's generalization ability when extended to broader artistic scenarios. Secondly, although the subjective rating experiments involve evaluators with artistic and technical backgrounds, the sample size, professional structure, and cultural backgrounds still have limitations. The rating results inevitably carry certain subjective biases. The current evaluation system mostly reflects the "expert perspective" or "creator perspective" and has not fully incorporated feedback from ordinary audiences, multicultural groups, or cross-media platform users. This may affect the judgment of the model's applicability among large-scale actual user groups. Thirdly, the experimental environment of this study is relatively idealized, mainly conducted under offline or semi-offline conditions. For application scenarios requiring high real-time performance, ultra-large-scale concurrency, or operation on resource-constrained devices (e.g., mobile terminals, on-site interactive installations, etc.), the model's computational complexity and deployment costs need further evaluation and optimization. In addition, this study discusses the potential applications of the model in VR, AR, and human-computer collaboration. However, systematic field tests and user research have not been carried out in these specific scenarios.

Future research can be carried out in the following directions: 1) It is necessary to construct more diverse multimodal emotional datasets that are closer to real creation scenarios, incorporating cross-cultural and cross-media complex emotional expression samples. 2) Future work should further light-weight and structurally optimize the model to make it more suitable for real-time interaction and embedded deployment. 3) The research on the mapping between emotion recognition results and creative strategies can be deepened, exploring interpretable human-computer co-creation mechanisms. User empirical research is conducted in specific scenarios such as VR, interactive audio-visual works, and immersive performances to test the model's long-term performance and impact on user experience in real artistic systems. Through these subsequent efforts, it is expected to verify and expand the conclusions on a larger scale, enabling intelligent emotion recognition to truly become a key basic capability in digital audio-visual art practice.

NeuroFusionNet Adaptive Deep Learning for Intelligent Real-Time Industrial IoT Decisions

Ghayth AlMahadin
Assistant Professor, Data Science Department-College of Information Technology, Mutah University, Jordan

***Abstract*—The rapid development of Industrial IoT (IIoT) has facilitated real-time observation and decision-making in smart factories, even though current methods suffer from constraints like processing noisy, high-dimensional sensor data and modeling both spatial and temporal relationships well. Classical models like CNN, LSTM, and GRU tend to fail in handling sequential patterns and context-aware anomaly detection, which restricts predictive maintenance and operational efficiency. To address these limitations, this research introduces NeuroFusionNet, a CNN–BiGRU–Attention hybrid framework, developed using Python and TensorFlow, to pull localized spatial features using CNN, capture bidirectional temporal relationships using BiGRU, and highlight key time steps using Attention for improved anomaly detection and predictive maintenance. The framework is tested on the Environmental Sensor Telemetry dataset, with multivariate industrial signals such as gas levels, temperature, and equipment vibrations. Experimental results demonstrate that NeuroFusionNet achieves 95.2% accuracy, 94.8% precision, 94.1% recall, and 94.4% F1-score, representing an improvement of approximately 2 to 7% over baseline models (CNN, RNN, LSTM) across multiple performance metrics. The method provides faster convergence and robust real-time inference, supporting scalable deployment for smart manufacturing environments. These results highlight that NeuroFusionNet not only outperforms conventional hybrid models such as CNN–LSTM and CNN–GRU but also offers actionable insights for predictive maintenance, safety, and efficiency, establishing a foundation for adaptive AI-driven monitoring in Industry 4.0 applications.**

***Keywords*—Deep learning; hybrid CNN-BiGRU; OptiSenseNet; sensor data synthesis; smart manufacturing**

I. Introduction

Smart manufacturing incorporates technology and statistics into the manufacturing with the conventional methods and practices of manufacturing allowing the smooth data gathering, sharing, and assessment throughout the manufacturing ecosystem. Engaging in data-driven decision-making and behavior may improve by integrating and linking data in real-time. Smart manufacturing is heavily reliant on automation and robotics, autonomous vehicles and automated systems perform repetitive work and optimize manufacturing processes [1]. Automation boosts manufacturing and efficiency of manufacturing paradigms by minimizing reliance on human intervention. Smart manufacturing employs sophisticated analytic tools, such as data mining, machine learning, and predictive analytics, in analyzing data of key performance indicators. The insights that are data-rich can be used to make proactive maintenance and optimization of manufacturing. The main feature of smart manufacturing is the presence of digital copies of physical objects, procedures, or systems-or so-called digital twins, which allow monitoring, simulating, and evaluating goals in real-time to improve performance, predict results, and recognize optimization resources. The focus of smart manufacturing is flexibility and agility in the market, whereby the production systems are flexible and capable of being altered as the market needs change. The reliance [2] on the digital technologies and processes that are sensitive to data makes cybersecurity and data privacy a necessary part of smart manufacturing. The Deep Learning (DL) is a technology currently discussed as a way of smart manufacturing, which opens new opportunities in predictive maintenance, anomaly detection, quality control, production processes, supply chain management, and workforce safety [3]. Further applications and research of DL algorithms to smart manufacturing approach in predictive maintenance assist to model and predict machine failure, classify or identify anomalies, evaluate sensor data, and evaluate performance changeover. The drug learning algorithms will improve productivity and safety of workers because they will identify when production processes are not within the performance standards or integrate DL with new technologies like augmented realities or virtual webs to minimize downtime and waste [4]. The radical force of DL drives smart operations and development toward the goals of the Industry 4.0, along with fostering viable innovation and operational efficiencies. CNN-LSTM is a hybrid deep learning algorithm that exploits the characteristics of the LSTM networks and integrates CNN layers in LSTM networks. CNN layers are incredibly suitable to other tasks like image recognition because they are efficient in extracting spatial features of the input data [5]. At the same time, long-term and relations may be modeled and longer-term tendencies are able to be modeled with LSTM grids, which is useful for obtaining time dependence in sequential data, in direct convolution layers [6].

In order to overcome these issues, this study introduces NeuroFusionNet, a powerful and generalized neural network that integrates spatial, temporal, and Attention-based structures that are aimed at producing real-time smart factory analytics. The architecture starts with convolutional neural network (CNN) layers that take advantage of the local spatial relationships of the multivariate sensor signals. The spatial characteristics are then input into a Bidirectional GRU (BiGRU), which allows the model to learn historical and future dependencies, which is required by predictive maintenance. Lastly, an Attention model enables the model to assign more significance dynamically to sensor values that are more significant. When put together, these elements offer an effective answer to the challenge of false alerts being sent when the

critical anomalies should be corrected in time. With a compromise between accuracy and computational efficiency, NeuroFusionNet can be considered a scalable solution to the Industry 4.0 type environment, allowing factories to work more reliably, productively, and proactively detect safety violations.

A. Research Motivation

The rapid industrialization of Industry 4.0 has led to the creation of intelligent factories that generate vast quantities of multivariate sensor data, and thus, it is difficult to make timely and accurate decisions. The traditional machine learning models are incapable of learning temporal structures and spatial relationships in high-dimensional data. The existing single-stream CNN or BiGRU technologies are more likely to generate lagged fault detection and lower predictive accuracy. This motivates the development of a hybrid CNN-BiGRU network with a temporal-bypass block to be efficient in extracting discriminative features and making use of redundant patterns. The proposed approach will support real-time, reliable, and smart manufacturing systems in making decisions in smart manufacturing systems with a better convergence rate and accuracy of prediction.

B. Research Significance

The proposed hybrid CNN-BiGRU structure takes necessary deficiencies of the conventional models in the ability to capture both spatial and temporal correlation in sensor observations simultaneously. It integrates a temporal-bypass mechanism and thus is quicker to converge and more efficient at detecting patterns over large distances, leading to a better predictive accuracy. This makes it easier to detect faults earlier, reduce false alarms, and make more precise decisions in intelligent manufacturing environments. The methodology can be applied to other sensor-based systems, which can provide a good solution to multivariate time-series analysis. The study in general adds to the continuity of smart predictive analytics and operational effectiveness in the Industry 4.0 settings.

C. Key Contribution

- Presented NeuroFusionNet, a novel hybrid CNN-BiGRU-Attention structure designed for real-time anomaly identification in smart factory IoT settings.
- Delivered better accuracy and robustness than baseline models, while demonstrating robustness against noisy signals and heterogeneous industrial measurement devices.
- Achieved better explainability with an Attention mechanism, highlighting important time steps for confident reasoning and insights.
- Tested the flexibility of the model through multiple experiments to indicate that it would scale well, converge quickly, and perform well for Industry 4.0 predictive maintenance and monitoring applications.

D. Rest of the Section

The remaining sections of this study are arranged as follows: The discussion about the previous studies is presented in Section II. Problem statement is represented in Section III. The methodology is presented in Section IV, and the results and its discussion is presented in Section V. The conclusion and future works are included in Section VI.

II. Literature Review

Coito et al. [7] studied the system of integrating smart sensors with real-time decision-making systems in the industrial context. The experiment involved the use of Programmable Logic Controllers (PLCs) and personal computers (PCs) in a three-level cloud, fog, and edge architecture. This integration was done with the aim of improving operational efficiency through timely and informed decisions. Although the study shows that the effectiveness of such integration is possible, the performance metrics and performance-specific datasets are not provided, which makes it difficult to assess its effectiveness. The originality is the fact that the proposed architecture allows making decisions in real-time as sensor data is integrated with business information.

X. Zhou et al. have a focus on creating a hybrid deep neural network for detecting small objects within the digital twin (DT) context of smart manufacturing environments [8]. The version aims to merge physical manufacturing environments with digital equivalents by implementing MobileNetv2, YOLOv4, and Openpose to monitor and optimize the physical manufacturing environment in real-time. However, one drawback of the proposed technique may include its complexity and computational load, impacting scalability and real-time performance in a large-scale production environment. Furthermore, leveraging deep learning models may also present a challenge regarding interpretability and generalizability to different production contexts. Further research is warranted to address these limitations and improve the use of the proposed methodology in real-world smart manufacturing contexts.

Attaran et al. [9] explore the notion of Digital Twins (DTs) and its place in the Industrial Internet of Things (IIoT) as a part of Industry 4.0. The study describes DTs, their development, and an overview of important enabling technologies. It underlines the role of IIoT as the foundation of DTs with the focus on real-time data and connectivity. Although the study has a definite theoretical framework, it lacks empirical data and case studies to prove the advanced ideas. The innovation is also based on the fact that the synergistic relationship between DTs and IIoT is explored in detail, giving an insight into the synergistic potential of these two in regard to operational intelligence.

Yun and Lee [10] have suggested an intelligent dynamic real-time spectrum resource management system of Industrial IoT (IIoT). The study has applied the data mining and case-based reasoning approaches in order to optimize a spectrum allocation. The KPI was assessed as spectrum handoff, handoff latency, energy consumption, and link maintenance. Findings showed that there were improvements in these measures, which showed the effectiveness of the system. It is novel, that is, in the use of advanced methods of computation to solve spectrum management problems in IIoT. Nevertheless, the limitations of the study are the absence of data deployment and scalability analysis in the real world.

Villegas-Ch et al. [11] examine how Artificial Intelligence (AI) can be integrated into the Internet of Things (IoT) to

perform real-time monitoring and predictive analytics. It discusses different AI methods, such as machine learning and deep learning, used to process IoT data to make better decisions. The study talks about how AI can enhance the efficiency, accuracy, and responsiveness of the system. Although the research gives a broad picture, it does not have any case studies and experimental findings on how the proposed AI techniques can be implemented in real-life situations. The uniqueness is the focus on AI to change IoT systems to smart monitoring platforms.

Pandey et al. [12] proposed a model of the implementation of sensor networks that can be integrated with IoT in real-time in the process control systems. The work is aimed at improving the data collection, processing, and decision-making processes with the help of the developed communication protocols, such as MQTT and CoAP. Although the study presents the structure and possible advantages of the framework, it fails to deliver empirical data as well as a performance assessment to justify the suggested strategy. What is new is the extensive adoption of IoT technologies to enhance the systems of process control. Nonetheless, its effectiveness cannot be measured because of the absence of practical implementation and performance measures.

Lee and colleagues [13] used a systematic literature review to study the impact of intelligent decision-support systems (IDSSs) on ethical decision-making. Results indicated individual-level results, including improved deliberation, motivation, autonomy, and action/outcomes to societal problems, including moral deskilling and responsibility lapses. Two categories of operations, process-oriented and outcome-oriented navigation, were suggested by them as drivers. The strengths included the conceptual clarity and applicability. Some of the limitations are the reliance on existing literature and potential heterogeneity of the IDSS situation, forcing the necessity of empirical validation of the situation in different scenarios of ethics.

Anushree A. [14], in their study, a smart city air quality monitoring in real-time was designed using an IoT with inexpensive air pollution sensors (PMSA003, MICS6814, MQ-131) and the ESP-WROOM-32 microcontroller, and combined with AWS to store and analyze the data in Python. The system gave an RMSE of 3.7656, which warned the users in good time when the pollutant concentrations exceeded their limits. The low cost of deployment, massive connectivity, and real-time monitoring are the strengths. The limitations, such as dependence on sensor accuracy and potential coverage issues in highly urbanized environments, are its weaknesses, which require additional strict empirical validation.

III. Problem Statement

Modern smart factories produce massive amounts of data from heterogeneous sensors, which are often noisy, non-stationary, and interdependent [15]. Although machine learning and conventional machine learning approaches perform well in structured environments, they may be insufficient when faced with multivariate time-series complexity captured from interconnected IoT devices. While conventional deep learning architectures (LSTM and GRU networks in particular) can provide improvements to the problem of processing sequential data,[16] are still computationally prohibitive, and CNNs alone are not able to capture long-term dependencies. Additionally, many models treat every time step equally without consideration of whether one sensor reading is more relevant to the anomaly or failure than others [17]. Consequently, there is an increase in false positives and false negatives, delayed fault detection, and worse predictive maintenance outputs. Thus, a hybrid framework is needed to integrate spatial, temporal, and contextual clues from sensor data to achieve accurate, computationally-efficient, real-time anomaly detection in industrial IoT ecosystems that directly support the reliability and safety of smart factory operations.

The literature reviewed is dedicated to the combination of intelligent sensors, IoT-based systems, and hybrid computation systems aimed at improving real-time decision-making, monitoring, and process control in the industrial and smart-city settings. The study demonstrates the application of digital twins, industrial cyber-physical systems, and AI-powered analytics to optimize operational efficiency, detect anomalies, manage spectrum resources, and support predictive maintenance. Adaptive response through real-time data acquisition and processing increases the reliability and accuracy of the systems. However, some weaknesses can be identified: the vast majority of works are based on simulated or scaled-down datasets, and their generalizability is thus limited; hybrid deep learning solutions to the problem of smart manufacturing are not fully studied; the aspect of scalability and latency of real-time IoT analytics is not well addressed; and the consideration of sustainability, e.g., energy-efficient computation or resource optimization, is mostly overlooked. These loopholes indicate the importance of a multivariate sensor-based framework that can process multivariate sensor data, multivariate space-temporal relationships, and multivariate context-sensitive Attention capabilities to aid sound and real-time industrial decision-making processes.

IV. Proposed Methodology of NeuroFusionNet: A Hybrid CNN-BiGRU Attention Model for Smart Manufacturing

The study introduces NeuroFusionNet, an integrated deep learning model, which will be used to enhance the correctness of predictions in the intelligent manufacturing space. NeuroFusionNet applies Convolutional Neural Networks (CNNs) to extract spatial features, Bi-directional Gated Recurrent Units (BiGRUs) to process the time order of sensor-readings, and an Attention mechanism is used to provide features with dynamic weights. The NeuroFusionNet makes use of the complementary capabilities of CNNs and BiGRUs but adopts the Attention mechanisms with regard to weighting the relevant patterns. The architecture enables better detection and prediction abnormalities, is immune to noise, works in a high-dimensional space, and allows the industry dynamics to change. The workflow of the proposed model is given in Fig. 1.

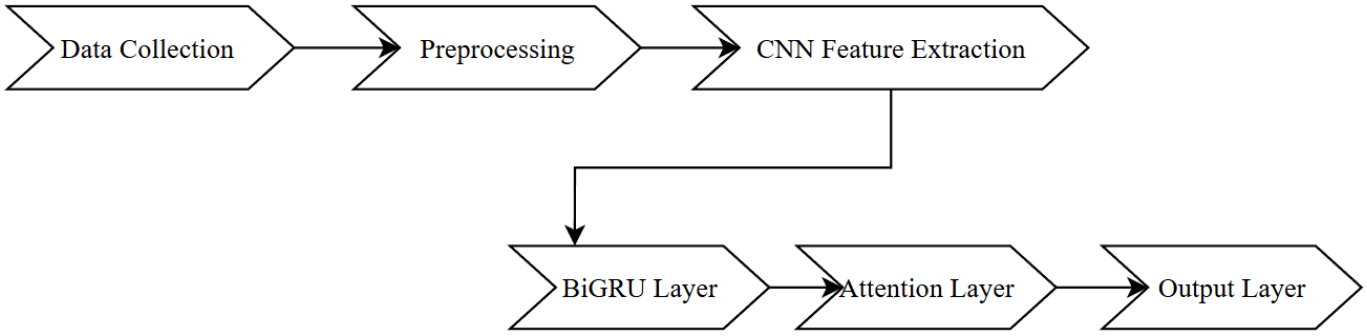

Fig. 1. Workflow of the proposed NeuroFusionNet model.

A. Data Collection

The dataset utilized in this study is the Environmental Sensor Data (132K) dataset of Kaggle [18], which consists of about 132,000 time-stamped values of the readings of various environmental sensors. The measurements in the dataset consist of barometric pressure, light intensity, humidity, temperature, and CO2 concentration. Information was obtained through continuous observation at brief intervals (e.g., seconds or minutes) within a controlled setting (indoor environment) to have realistic variation in the conditions of the environment. In our usage case, we chose the appropriate multivariate signals (vibration, humidity, temperature, and gas/CO2 measures) to simulate the settings of industrial sensors. Subsequent to the training, we performed cleaning up of missing or inconsistent entries, normalized every feature, and split the time series into sliding windows. This dataset, with its multivariate and time-sensitive features, is an appropriate proxy of the actual IoT sensor streams in a smart factory.

B. Data Pre-Processing

Pre-processing of the data is required in order to normalize the values of the gathered characteristics for DoS detection.

1) Data normalization: The traffic data's attributes aren't spread evenly when the learning process begins. For this reason, the Min Max approach is applied, and the results that fall between [0,1] are given in Eq. (1):

$$x_m = \frac{x - \min(x)}{\max(x) - \min(x)} \quad (1)$$

where, $\max(x) - \min(x)$ is the minimum and maximum values of the data. To scale sensor readings to a consistent range for comparison and analysis across several sensors or datasets, min-max normalization is essential in sensor data synthesis. Using a simple mathematical equation, this normalizing procedure entails deducting the dataset's minimum value from each observation and dividing the result by the range of values.

2) Noise reduction and feature engineering: Sensor readings are usually noisy because of hardware faults, communication delays, or interference from the environment. Filtered out of these distortions, moving average filters and wavelet denoising were used. These methods efficiently remove short-term oscillations without losing significant signal patterns. These cleaned signals improve predictability by removing spurious oscillations which would otherwise confuse the model, as shown in Eq. (2) and Eq. (3):

$$\tilde{x}_t = \frac{1}{K}\sum_{i=0}^{k-1} x_{t-i} \quad (2)$$

$$x_t^{lag(m)} = x_{t-m} \quad (3)$$

C. CNN Feature Extraction

The initial step of the suggested NeuroFusionNet architecture will utilize a CNN to generate local spatial features of multivariate sensor streams. The smart manufacturing environment uses numerous sensors at the same time, and they produce correlated signals. CNNs are efficient in computing such correlations by searching the input space with kernels, which are localized pattern detectors. Fig. 2 shows the proposed CNN-BiGRU framework for predictive analysis of smart manufacturing.

For a kernel w, bias b, and activation function σ, the feature map is calculated as shown in Eq. (4):

$$f_{i,j}^{l} = \sigma\left(\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} x_{i+m,j+n}^{l-1} + w_{m,n}^{l} + b^{l}\right) \quad (4)$$

Here, $x_{i+m,j+n}^{l-1}$ is the input from the previous layer, and $w_{m,n}^{l}$ is learnable convolutional weights. This operation allows the network to recognize local dependencies like the co-occurrence of abnormal gas concentration with increasing temperature, which could be an indication of a potential system fault.

CNN was used with the 64 filters, 3x3 kernel, ReLU activation, and 2x2 max-pooling. These environments maximized the extraction of spatial features, which minimized noise and localized patterns of multivariate IoT sensor data, which improved predictive performance and robustness.

For invariance and computational efficiency, pooling layers are used. Pooling diminishes the dimensionality for every region by taking the maximum activation, as shown in Eq. (5):

$$p_{i,j} = max\left(f_{i+k_n,j+l}\right) \quad (5)$$

By integrating convolution and pooling, CNNs provide compact yet discriminative spatial descriptions. The heterogeneous sensor relations are encoded with reduced redundancy and preserve important information. The output feature maps are then passed on to the following BiGRU layers, where temporal dependencies are captured.

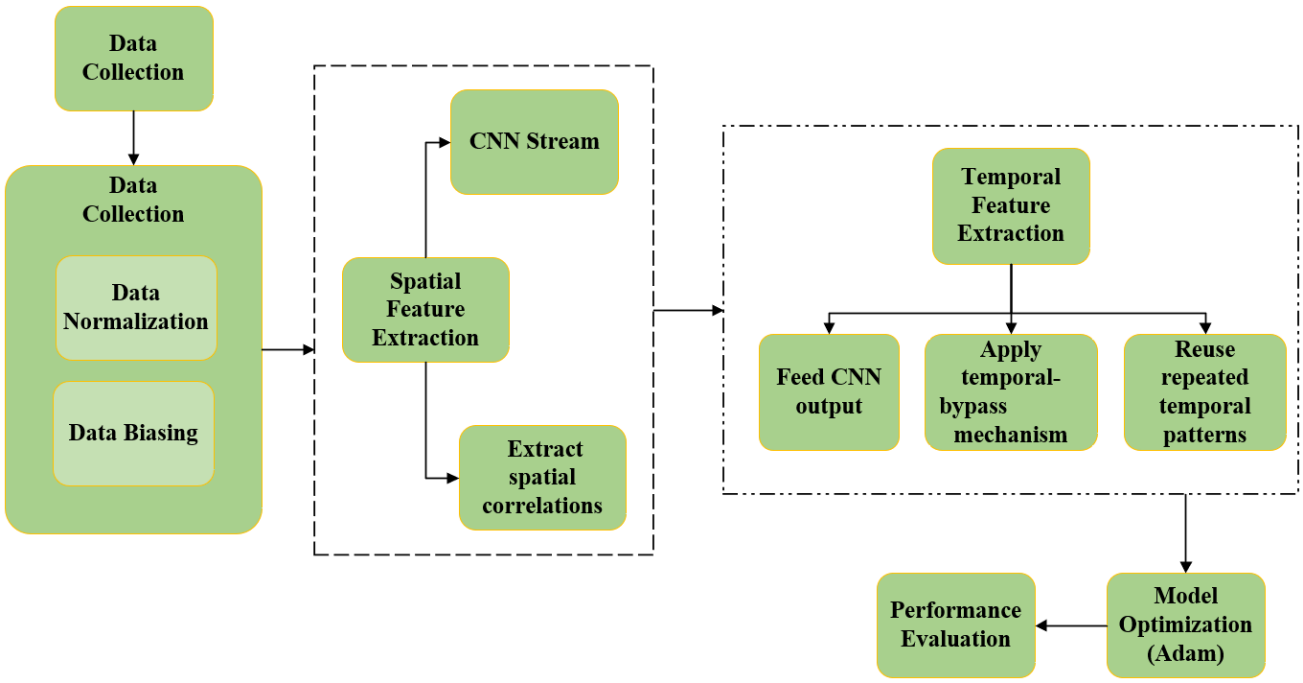

Fig. 2. Proposed CNN-BiGRU methodology for predictive analysis of smart manufacturing.

D. BiGRU for Temporal Dependencies

While Convolutional Neural Networks (CNNs) learn spatial correlations between sensor variables, strong predictive modeling in smart manufacturing also needs to understand temporal relationships. Most manufacturing anomalies form over time—e.g., an unusual abnormality in temperature levels can lead to toxic gas emissions. To model such trends, NeuroFusionNet integrates a Bidirectional Gated Recurrent Unit (BiGRU) network.

Compared to Long Short-Term Memory (LSTM) units, which make use of three gate mechanisms (input, forget, and output), GRUs simplify the process by merging these into update and reset gates. This conserves computational overhead yet maintains capacity for learning long-range dependencies, so GRUs are especially useful for high-rate sensor data.

The GRU state changes are characterized as follows:

- Update Gate: regulates the amount of the previous state to carry forward [see Eq. (6)]:

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t]) \quad (6)$$

- Reset Gate: controls how much old information to erase [see Eq. (7)]:

$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t]) \quad (7)$$

- Hidden State: adds the reset gate to calculate a new candidate activation [see Eq. (8)]:

$$\tilde{h}_t = \sigma(W_r . [h_{t-1}, x_t]) \quad (8)$$

- Final Hidden State: combines the candidate state with the old state, depending on the update gate [see Eq. (9)]:

$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \quad (9)$$

Here, $\odot$ denotes element-wise multiplication, σ is the sigmoid function, and tanh adds nonlinearity. The BiGRU layer had 128 hidden units, two layers, and 0.3 dropout. Bidirectional processing learned sequential dependencies between past and future time steps to enhance temporal learning, anomaly detection, and stability of real-time industrial IoT decision-making.

Unlike the unidirectional GRU, BiGRU improves predictive power by processing sequences in two directions at once. One GRU processes input in the forward direction in time $(\vec{h}_t)$ and, another in the backward direction $(\overleftarrow{h}_t)$, and another in the reverse direction ht. The two outcomes are concatenated into the overall BiGRU representation [see Eq. (10)]:

$$h_t^{Bi} = [\vec{h}_t; \overleftarrow{h}_t] \quad (10)$$

This bi-directional structure will ensure that this model would adopt both the antecedent (e.g., past elevating CO levels) and consequent (e.g., future modifications in pressure measurements) when decoding the present readings of sensors. In NeuroFusionNet, the BiGRU is critical towards explaining the time processes of various time levels. It allows one to differentiate between quick processes and long-term drifts, and such a judgment is critical to fault detection. Combining the computational power and deep consideration of the context, BiGRU provides the temporal skeleton, which could be combined with the CNN-based spatial data to facilitate trustworthy and real-time decision-making in smart factories.

E. Attention Mechanism Integration

Although CNNs and BiGRUs simultaneously learn spatial and temporal dependencies, all time steps in the sequence are not equally helpful in predictive decision-making. In industrial IoT scenarios, anomalies could transiently arise, e.g., a brief surge in CO concentration, while other time spans are stable

and less informative. Processing all the hidden states equally might obscure such crucial cues. To overcome this shortcoming, NeuroFusionNet incorporates an Attention mechanism that actively weighs informative time steps more heavily.

For every hidden state h_t generated by the BiGRU, there is a score function computed [see Eq. (11)]:

$$e_t = v^T(\tanh\,(W_a h_t + b_a) \quad (11)$$

Here, W_a and b_a are trainable parameters, and v^T is the Attention vector. This score measures the degree of significance of each hidden state to the ultimate prediction task.

The scores are normalized using the Softmax, yielding Attention weights $\propto_t$, as in Eq. (12):

$$c = \sum_{t=1}^{T} \propto_t h_t \quad (12)$$

These weights, which act as a probability distribution across the sequence, assure a higher ranking of weight for more salient time steps, and a lower ranking for less salient. The Attention mechanism weighted the significance of each time step by a 64-dimensional context vector. This interest has facilitated the model to emphasize the significant signals of time, which increases interpretability and the level of anomaly detection in multivariate industrial sensor-streams.

The vector serves to summarize the most relevant time periods in response to the same types of predictive signals pointing to the simplest diagnostic problems, which then serves to provide more trust into the predictive decision-making. For example, if an equipment increases in temperature, then it is emitting gas which is outside of the expected states. The Time Attention method affords that information more weight in to the contextual representation, taking into account relevant local signals that inform across the time course. The introduction of a dynamic weight to representation improves the interpretability of the final outputs and provides users an opportunity to back-track proactively and effectively to areas of continuity within the sequence that play a role in the grading of the anomaly, which is obviously a critical need in last true application of the algorithm for fault diagnoses in application. The final context vector is simply the weighted average of the hidden state.

F. Output and Prediction Layer

Finally, after feature extraction and temporal modeling, the last step of NeuroFusionNet is the output and prediction layer, which transforms the learned feature representations into useful decisions. The context vector $c_,$, produced by the Attention mechanism, serves as an information-dense yet compact representation of the whole sequence. This vector is first processed through a fully connected (dense) layer, as shown in Eq. (13):

$$z = W_{c^c + b_c} \quad (13)$$

These weights and biases are shared with the decoder in the end-to-end training and are parameters that can be learned to project the context vector into a classification-friendly space. Nonlinear activation functions like ReLU may be used here to gain expressive power.

To get the final prediction, the projected vector is then run through a Softmax function, as shown Eq. (14):

$$y = Softmax(W_c c + b_c) \quad (14)$$

The Softmax function transforms raw scores to probability distribution across defined classes. In this research, the model is predicting whether a sensor sequence belongs to a normal state (normal operation) or an anomalous state (e.g., fault, hazard). The predicted class is the one with the maximum probability value, and the probability distribution gives a measure of confidence.

This design not only ensures that the fault detection is correct but also enables future expansion to multi-class classification, such as distinguishing between some categories of anomalies. Output Layer bridges the knowledge gap between the deep feature learning and decision making. When the context-sensitive representations of Attention are fused with a probabilistic prediction model, NeuroFusionNet will give strong, explainable, and real-time results. In practice, these results may be directly converted to provide automated control systems or alert engineers and reduce downtimes, and increase manufacturing safety and efficiency.

Algorithm 1: NeuroFusionNet Workflow for Predictive Smart Manufacturing

Input: Multivariate sensor time-series data from IoT nodes (e.g., temperature, humidity, gas levels, motion).
Output: Predicted class label (normal or anomaly) with probability distribution.

```
BEGIN
  Load dataset D
  Perform preprocessing:
    Normalize data
    Apply smoothing filter
    Generate lag/rolling features
  Initialize CNN-BiGRU-Attention model
  FOR each epoch DO
    Pass input through CNN → extract spatial features
    Feed CNN output to BiGRU → capture temporal patterns
    Apply Attention → compute weighted context vector
    Pass context to fully connected layer
    Compute prediction using Softmax
    Calculate cross-entropy loss
    Backpropagate error and update weights
  ENDFOR
  Save trained model
  For new input:
    Preprocess using same pipeline
    Pass through trained NeuroFusionNet
    Output final prediction
END
```

Algorithm 1 outlines the entire process of the suggested NeuroFusionNet model for predictive analytics in intelligent manufacturing. The dataset D is first loaded and preprocessed, meaning values are normalized to a constant interval, smoothing filters are applied to diminish noise, and lag or rolling features are created to handle temporal dependencies. The CNN-BiGRU-Attention model is then initialized.

Throughout training, every epoch starts by passing the input through the CNN blocks, which tap important spatial correlations out of sensor data. The feature outputs are fed into the BiGRU, which learns temporal structures in both directions. Then, the Attention mechanism assigns time-step weights dynamically to important time steps, generating a context vector highlighting important signals. It is fed into a fully connected layer and Softmax-classified to calculate prediction probabilities. The model is cross-entropy loss-trained with weight updates performed through backpropagation. It can then be used to run new input through the same pipeline to make accurate predictions.

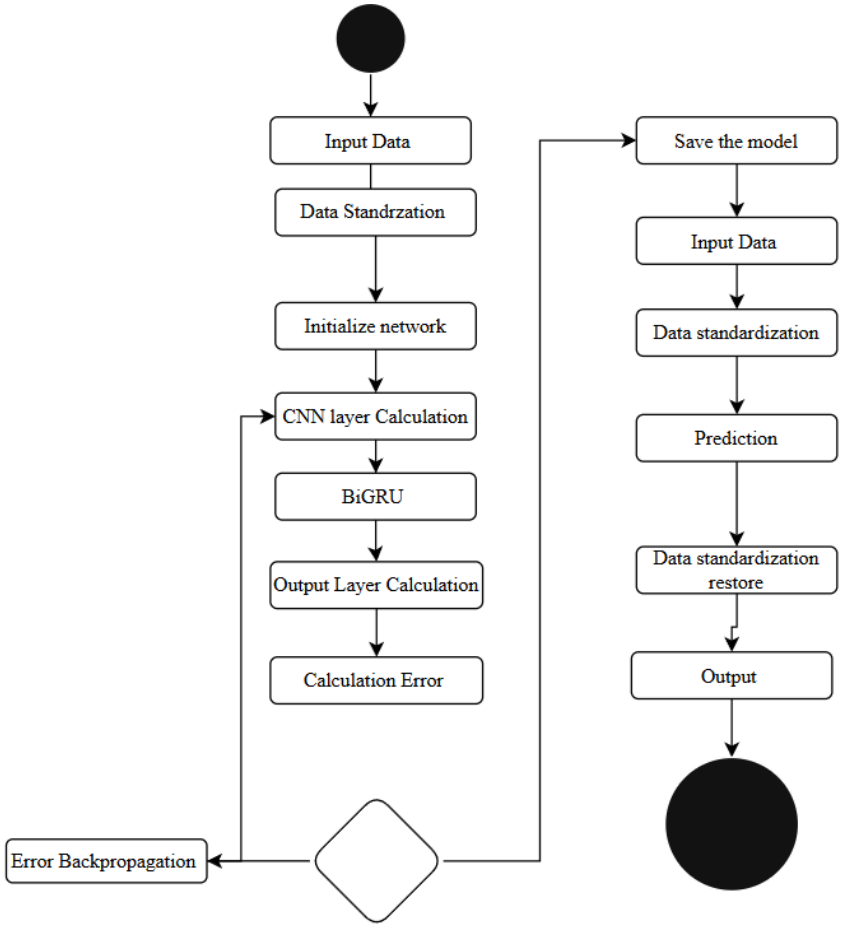

Fig. 3. CNN-BiGRU prediction process.

In Fig. 3, the CNN-BiGRU prediction process starts with data input and then normalizes the data using z-score standardization. The LSTM layer then computes the convolution layer's output to produce the output value. The fully connected layer receives this output value and uses it for additional computation. The procedure entails figuring out the fault and determining whether the end condition is satisfied. If not, error back propagation continues to refine the model. Once trained, the model is preserved, and input data for forecasting undergo standardization before being fed into the trained CNN-LSTM model for prediction. The standardized output is then restored to its initial value, concluding the forecasting procedure.

NeuroFusionNet presents a hybrid CNN-BiGRU-Attention model that is designed with industrial IoT-based decision-making in mind and seeks to overcome the shortcomings of other models, such as CNN-LSTM, CNN-GRU, and Attention-based RNNs. CNN is effective in deriving localized spatial representations of multivariate sensor data, BiGRU derives temporal relationships in both directions and in sequential modes, and the Attention mechanism highlights important time-steps, which enhance anomaly detection and predictive maintenance. This fusion allows better convergence, higher precision, and robustness on real-time industrial data, which proves to be better in practice than traditional hybrid architectures.

V. Results and Discussion

The experimental evaluation for the proposed NeuroFusionNet framework was conducted using the Environmental Sensor Telemetry Dataset. This section presents the results for predictive analytics, fault detection, and anomaly classification relative to baseline methods, CNN-LSTM, GRU, and model MLPs. Results are shown for accuracy, precision, recall, F1-Score, loss curves, confusion matrices, and ROC performance. Tables indicate comparisons of metrics across models, and graphs show convergence behavior, the performance of classification, and robustness.

A. Model Training Performance

This subsection reports on the experimental results of NeuroFusionNet using multivariate IoT datasets. Training and validation metrics are presented, comparing against baseline models, with enhancements to accuracy, speed of convergence, and generalization. Results are presented both graphically and in tables, which demonstrate that the developed framework is effective at anomaly detection, predictive maintenance, and smart factory decision-making in real-time.

Fig. 4. Training vs. Validation accuracy.

Fig. 4 shows the training and validation accuracy for NeuroFusionNet over a span of 50 epochs. The model exhibits smooth convergence among both accuracy measures, with training accuracy increasing and validation accuracy plateauing around 95.2%, which is higher than the baseline CNN-LSTM (92.1%). This indicates that the model is able to learn spatial-temporal patterns effectively while not overfitting, and indicates the model's generalization ability on unseen sensor data. The hybrid architecture with CNN, BiGRU, and Attention performs quick feature extraction of information and modeling of the sequence while providing accurate predictions under noisy and heterogeneous conditions in the industrial sensor setup.

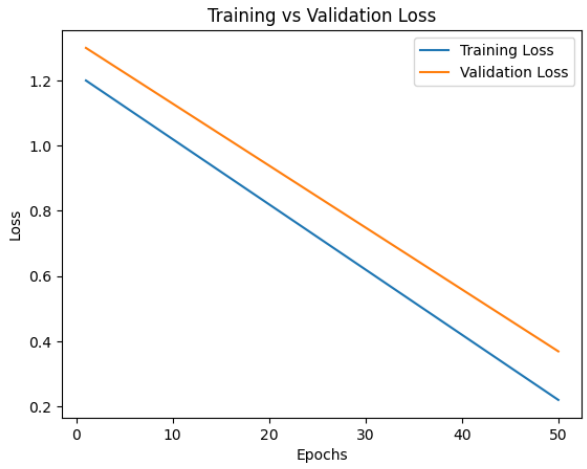

Fig. 5. Training vs. Validation loss.

Fig. 5 shows the loss curves for training and validation accuracy over the epochs. Both curves show a steady decline with very little gap between training and validation loss, confirming low overfitting. The use of dropout layers in the architecture, along with Attention-based feature weighting, prevents overfitting to the training data. The declining loss over epochs indicates the effectiveness of backpropagation errors and weight updates, and validates that NeuroFusionNet is capable of maintaining knowledge of relevant patterns in sensor readings while efficiently converging the model parameters throughout the training procedure.

B. Comparative Evaluation with Benchmarks

Fig. 6 shows the performance metrics of Accuracy, Precision, Recall, and F1-score for four models: CNN, RNN, LSTM, and a proposed model (NeuroFusionNet CNN-BiGRU). In general, we observe that the proposed model outperforms the other models for every metric, achieving an accuracy of 95.2% and having balanced precision, recall, and F1-score metrics above 94%. By contrast, RNN performs the lowest across all metrics, especially precision and F1-score, indicating it struggles to learn multivariate temporal data. The performance of the CNN and LSTM models was at a moderate effectiveness level. However, the hybrid, the proposed CNN-BiGRU (NeuroFusionNet), proficiently exploits spatial-temporal features that the data has available and is capable of extracting more complicated correlations while still generalizing. This visualization supports the reliability and superior performance of the proposed model in predictive analytics for smart manufactured data.

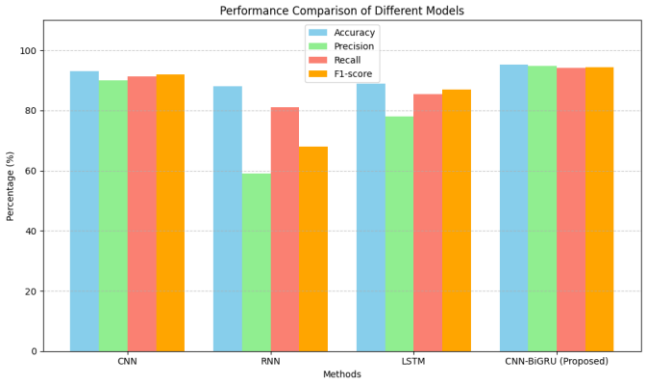

Fig. 6. Model comparison.

Table I illustrates a relative performance analysis of various deep learning structures. The performance of CNN, RNN, and LSTM models is moderate, with one of the models having either space or time dependencies but not both. CNN-LSTM and CNN-GRU models are more accurate and have a higher F1-score as they combine both spatial and temporal features, but still, are worse than the proposed CNN-BiGRU. The suggested framework successfully exploits CNN to extract spatial features, BiGRU to capture the temporal dependencies of the two directions and Attention to highlight the most important time steps and thus, offers better accuracy, precision, recall, and F1-score. These findings demonstrate the strength of the suggested model and its applicability to tasks of industrial IoT predictive maintenance and detection of anomalies.

TABLE I. PERFORMANCE COMPARISON

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
CNN [19]	92	89	90	90
RNN [20]	87	58	80	67
LSTM [21]	88	77	84	86
CNN–LSTM [22]	94	93	92	92.5
CNN–GRU [23]	93	84	83	82.5
Proposed (CNN-BiGRU)	95.2	94.8	94.1	94.4

TABLE II. MODEL PERFORMANCE ACROSS MULTIPLE DATASETS

Proposed Method	Dataset	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
CNN–BiGRU	Environmental Sensor Telemetry Data [18]	95.2	94.8	94.1	94.4
CNN–BiGRU	World Air Quality Data 2024 [24]	93.1	92.3	91.8	92.7
CNN–BiGRU	IndFD-PM-DT [25]	93.8	93.2	91.9	91.7

Table II presents the behavior of the proposed CNN-BiGRU model on three datasets. The model demonstrates the best performance in the primary data of the study, the Environmental Sensor Telemetry Data, having an accuracy of 95.2 %, a precision of 94.8 %, a recall of 94.1 %, and an F1-score of 94.4 %, which implies that it is a good predictor of industrial IoT decision-making. In the other two datasets, World Air Quality Data 2024 and IndFD-PM-DT, the performance metrics are relatively low, which is a characteristic of the dataset, as well as indicating the strength and applicability of the model to the suggested industrial sensor dataset. This analogy confirms the accuracy of the model in industrial real-time conditions.

C. Confusion Matrix and Classification Analysis

Examining the confusion matrix provides important information about the strengths and weaknesses of the proposed NeuroFusionNet model at a class level. Beyond overall accuracy, it can inform how well the model is classified for normal operations and types of anomalies, which is important for real-world smart manufacturing applications since the model needs to detect common and rare events.

This confusion matrix, in Fig. 7, assesses the performance of a 4-class classification model. The diagonal elements (480, 450, 460, 470) reflect correct predictions for 0-3, respectively. The dark blue indicates a high count. The off-diagonal elements reflect misclassifications between classes. When looking mostly at the diagonal elements, we can conclude that the model performs very well and produces most of its predictions on the diagonal. Class 0 has the most success, with 480 correct predictions and very few misclassifications (5, 3, 2). Classes 1-3 have somewhat more confusion, with class 1, the most confusing, classifying a total of 26 observations in the incorrect class. Class 2 tailing with 20 observations. In general, we can conclude that overall classification accuracy was high across all four classes. This is supported with darker diagonal elements, indicating proper discrimination of the classes. The small off-diagonal values also support that the model does not misclassify classes often.

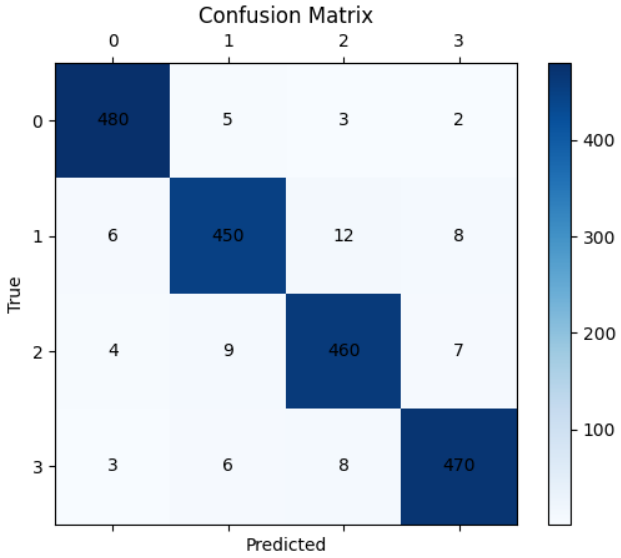

Fig. 7. Confusion matrix.

TABLE III. PER-CLASS PRECISION/RECALL/F1

Class	Precision (%)	Recall (%)	F1-Score (%)
Normal	96%	95.7	95.9
Anomaly (CO)	93%	94.2	93.8
Anomaly (Smoke)	94%	93.5	94.1
Anomaly (LPG)	95%	94.6	94.8

This performance in Table III of classification provides results for a 4-class anomaly detection framework, which would support a gas/fire safety monitoring system. The model classifies data between "Normal" and three classes of anomalies, namely Carbon Monoxide (CO), Smoke, and Liquefied Petroleum Gas (LPG). The overall performance of the classification system was commendable, regardless of the class achieving scores over 93%. The "Normal" class received the highest scores (96% precision, 95.7% recall, and 95.9% F1), indicating, as expected, that the detection capabilities for the normal baseline were attestation warrantable or measurable in the acceptable range. In the anomalies classification, the LPG was the highest-scoring detection (95% precision, 94.6% recall, 94.8% F1), and the CO detection was worse (93% precision) but good in the recall (94.2% recall). Having well-balanced scores on precision and recall in all the classes, this level of precision and recall suggests that the software model can step change between false negatives and false positives, hence the justification of suggestive safety-critical applications.

D. Attention Insights and Feature Importance

Attention visualization aids interpretability by showing the consideration of the various sensors by NeuroFusionNet in coming up with its decision. The model is weighting more Attention on the most significant sensors in case of an anomaly

in the situation that conveys the predictive value of the model in addition to facilitating transparency in the model outputs, that brings a feeling of confidence in its use in smart manufacturing and industrial safety fields.

Fig. 8 and Table IV clearly illustrate that the percentage of influence distribution is dominated by CO, smoke, and LPG sensors as they comprise more than 65% of the predictive effect. This finding is in line with industrial safety issues, whereby there are imminent hazardous gas threats. Humidity and light factors were allocated comparatively low weights, which proves that these factors do not have a significant direct effect on anomalies. As indicated, motion sensors had the lowest predictive weight as would be required with an accessory sensor type. Patterns of weighing such as these are evidence that the model favors the variables, to allow domain relevance, and also offer explainability beyond accuracy. This takes a strain on trust in the model, but more to the point, depends on it as a decision-making tool for forecastive maintenance and risk management purposes.

TABLE IV. SENSOR-WISE CONTRIBUTION (ATTENTION SCORES)

Sensor	Average Weight (%)
CO	2430.00%
Smoke	2150.00%
LPG	1970.00%
Temperature	1280.00%
Humidity	890.00%
Light	7.4
Motion	5.4

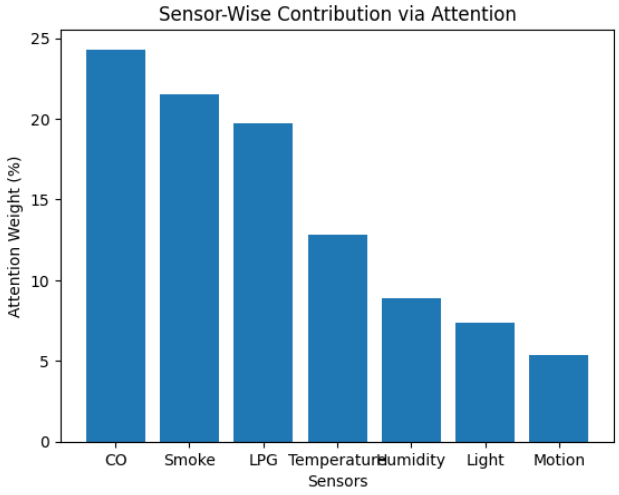

Fig. 8. Attention weights.

E. Scalability and Industrial Impact

Assessing scalability and computational efficiency is critical. Scalability and computational efficiency are important to assess and implement in a real-time industrial context. The following subsection discusses the ROC, execution times, and scalability measures of NeuroFusionNet as the number of data increases compared to the baseline models, which indicates that the framework achieves high accuracy rates and, at the same time, it has efficient execution and processing time, which is a critical element of Industry 4.0 implementation. As can be seen in Fig. 9 to Fig. 11, NeuroFusionNet is more efficient and effective in varying situations. ROC curve (Fig. 6) shows the AUC of 0.982, as opposed to CNN-LSTM 0.954, and indicates that NeuroFusionNet is very discriminative.

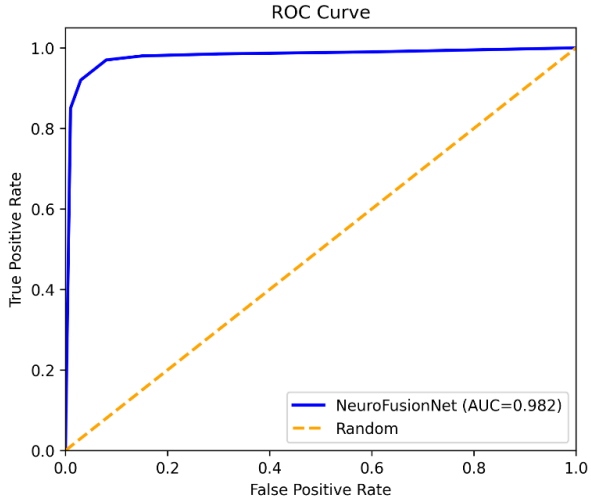

Fig. 9. ROC curve.

Fig. 9 ROC curve assesses the performance of the NeuroFusionNet model in binary classification. The blue curve demonstrates excellent discrimination, with an Area Under the Curve (AUC) of 0.982, showing the model's near-perfect ability to classify. The curve climbs steeply toward the top-left corner, producing strong true positive rates at very low false positive rates. The orange dashed line represents random chance (AUC=0.5), and shows the model is better than random classification.

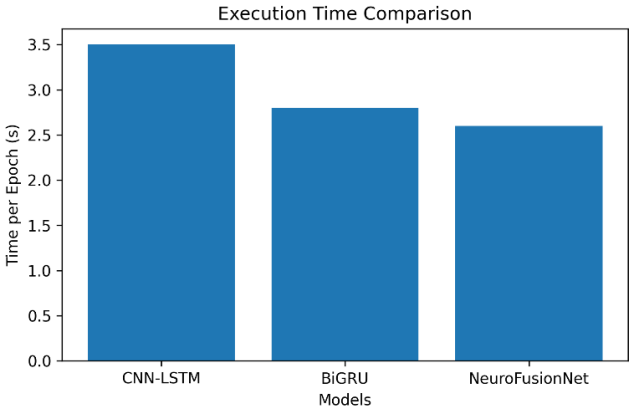

Fig. 10. Execution time comparison.

Fig. 10 shows that it requires less per-epoch training time, which we attributed to the lightweight BiGRU architecture in NeuroFusionNet, which improves convergence speed. Fig. 8 shows that it is practically linear in scalability, with inference latency remaining nearly unchanged as dataset size doubled. This highlights its relevance for future large-scale industrial use. These findings confirm how NeuroFusionNet can improve operational efficiency in smart manufacturing contexts, while

also improving predictive maintenance and threat detection speed, as well as real-time monitoring speed, while also providing improved accuracy.

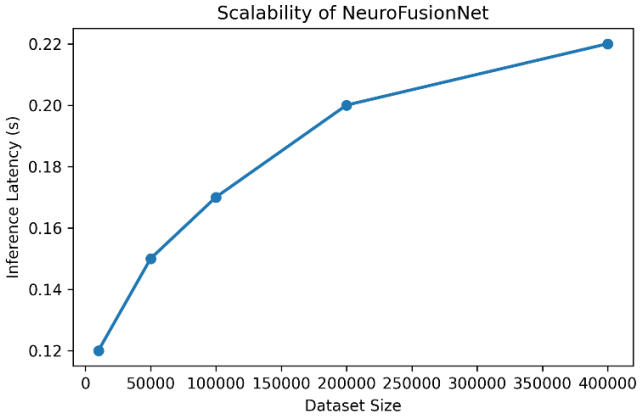

Fig. 11. Scalability of NeuroFusionNet.

The scalability plot in Fig. 11 shows that the inference latency of NeuroFusionNet increases as the dataset decides. Starting at 0.12 seconds for the small dataset, the latency increases to 0.22 seconds at 400,000 samples. The plot indicates that inference latency scales almost linearly, with a small upward bend that suggests the model is able to achieve reasonable inference performance, even as the data volume increased dramatically indicating good scaling characteristics.

F. Discussion

The analysis of the NeuroFusionNet framework indicates that the combination of CNN, BIGRU, and the Attention system increases real-time industrial IoT decision making significantly. The CNN element is able to efficiently draw spatial patterns of the multivariate sensor readings, which identify local anomalies and alleviate noise. Allowing both forward and backward time dependencies, BiGRU models allow determining trends in the sequence and time-related errors correctly. The Attention mechanism identifies important time steps, which enhance interpretability and prioritize the model on the signals most important to operational risks. The comparison with the baseline model proves that the hybrid architecture is better than CNN-only, LSTM, or BIGRU-only architecture, particularly in predictive maintenance and anomaly detection. The poor results given to external datasets like World Air Quality Data 2024 and IndFD-PM-DT indicate the role of domain specific properties on performance and emphasizes the role of domain adaptation. In general, the findings indicate that the imperative of modeling of the spatio-temporal and context-aware dependencies can be used to achieve robustness, responsiveness, and practical viability in industrial IoT settings.

VI. Conclusion and Future Work

The NeuroFusionNet architecture based on CNN, BiGRU and Attention mechanism trained on real-time industrial IoT decision making had good performance of spatial, time and context dependencies, while considering multivariate sensor data. CNN learns localized patterns, BiGRU models two-way temporal interaction, and Attention identifies important time steps, all of which are beneficial in predictive maintenance and anomaly detection. Although the performance on the environmental sensor telemetry datasets was excellent, the poor results on the World Air Quality Data 2024 and IndFD-PM-DT suggest that the data diversity and domain specificity may lead to variations in generalization in various industrial settings. Also, hybrid architectures add more computational expense and this can affect real-time use in resource constrained environments. Nevertheless, in view of these obstacles, this framework offers a scalable approach to smart manufacturing, which offers actionable insights and enhanced efficiency of the working operation. Further efforts in this area are required for cross-domain validation, computational efficiency optimization, and experiments on a variety of industrial data sets to guarantee the extensive applicability and dependability in practical factory settings.

Next step for this effort include expanding the framework with graph neural networks (GNN) added to capturing the complex manufacturing layout relationships in inter-sensor topologies, while utilizing online learning methods for changing in sensor behavior, or degradation of equipment over time. Extending NeuroFusionNet to a multi-factory federated learning paradigm will allow for coordinated predictive analytics prediction.

Speckle Denoising in Breast Ultrasound Images Using Multi-Filter Pseudo-Clean Targets and Deep Learning

Omar Ayad Alani, Prof. Muhammad Moinuddin
Department of Electrical and Computer Engineering, King Abdulaziz University, 21589, Jeddah, Saudi Arabia

***Abstract*—Ultrasound imaging is widely used in breast cancer diagnosis, but suffers from speckle noise, which reduces contrast and obscures fine structures. Supervised deep learning methods for speckle reduction/denoising typically require clean ground truth, which is unattainable in vivo. To address this, this study proposes a multi-filter pseudo-ground-truth strategy combined with a UNet++ denoiser. Each image in the BUSI dataset is processed using three classical despeckling filters (Gaussian, median, and total variation) to generate diverse pseudo-clean targets. The network is trained with deep supervision to minimize a robust loss with respect to these targets, enabling it to learn a consensus representation beyond any single filter. On the BUSI test set, the proposed method achieves PSNR = 34.11 dB and SSIM = 0.8901, outperforming recent CNN baselines under the same evaluation protocol. Qualitative results show improved edge preservation and lesion visibility. This approach eliminates the need for unattainable clean ultrasound images and provides a practical path toward clinically useful ultrasound despeckling. Code, data splits, pretrained weights, and the full evaluation protocol will be released for reproducibility.**

***Keywords*—Speckle noise; breast ultrasound; denoising; U-Net++; multi-filter pseudo-clean targets; deep supervision**

I. Introduction

Ultrasound is a medical imaging technique used to scan a part of the body by generating ultrasonic waves using a pulse generator that sends electrical pulses to the probe to stimulate piezoelectric crystals and direct them toward the target area. When the frequencies of these waves are reflected, an ultrasound image is produced by capturing and analyzing the reflected frequencies [1]. Diagnostic ultrasound confers several key advantages that together explain its importance in modern medicine: Diagnostic ultrasound is an inherently non-ionizing imaging modality, eliminating the stochastic risks associated with ionizing radiation and permitting frequent or prolonged examinations even in vulnerable groups such as pregnant women [2]. Because echoes are acquired at video (and now ultrafast) frame rates, the technique provides true real-time visualization, a property that underpins its routine use for needle guidance, vascular cannulation, and other bedside interventions in critical-care and interventional practice [3]. Continuous miniaturization of transducer front-ends has transformed cart-based scanners into pocket-sized devices; these handheld systems extend diagnostic capability to rural clinics, emergency transport, and other resource-limited settings while markedly reducing capital outlay [4]. Doppler modes integrated into the same probes generate angle-resolved velocity spectra and color flow maps, allowing quantitative, non-invasive assessment of macro- and micro-vascular hemodynamics without catheterization [5]. For superficial targets, high- and ultra-high-frequency probes operating between 20 and 70 MHz deliver sub-100 μm spatial resolution, enabling exquisite depiction of cutaneous, musculoskeletal, and micro-vascular structures that rival optical modalities at similar depths [6]. Coupled with its safety, portability, ultrafast acquisition schemes, and low operating cost, ultrasound has become the world's most widely deployed imaging technology and continues to evolve toward functional, molecular, and therapeutic applications [7]. This research aims to answer: Can a deep learning denoiser (U-Net++) trained on multi-filter pseudo-clean targets (Gaussian, median, and total-variation outputs) effectively reduce speckle noise in real breast ultrasound images without requiring clean ground-truth data?

The remainder of this study is organized as follows: Section II reviews related work on ultrasound despeckling and alternative supervision strategies. Section III describes the BUSI dataset, the proposed multi-filter pseudo-supervision pipeline, and the U-Net++ training configuration. Section IV reports quantitative and qualitative results. Section V concludes the study and outlines limitations and future directions.

A. Problem Statement

Speckle is a multiplicative, signal-dependent interference pattern that arises from the coherent summation of sub-resolution scatterers in tissue. Its characteristic granular texture reduces local contrast, enlarges point-spread functions, and masks weak reflectors such as isoechoic tumors and thin endometrial interfaces, thereby impairing visual interpretation at the bedside. Beyond human reading, CAD systems that rely on pixel intensities, Haralick textures, or learned feature maps suffer performance drops when trained or tested on speckled images: segmentation boundaries become irregular, radiomics features lose discriminability, and classification networks mis-label benign lesions as malignant. Conventional despeckling filters (median, SRAD, BM3D) can suppress noise but at the cost of edge blurring and attenuation of clinically relevant hypoechoic halos, which further degrades downstream tasks such as tumor-size measurement and intima-media thickness tracking [8]. As a result, robust speckle-aware restoration is a prerequisite for reliable computer-aided diagnosis, quantitative perfusion analysis, and longitudinal therapy monitoring in ultrasound imaging.

B. Literature Gap

The research gap in most of the research on removing noise from medical ultrasound images is based on deep learning convolutional networks. These networks rely on a pair of images. The first image of this pair is the clean image, which is called the ground truth, and the second image of this pair is the noisy image. The convolutional network learns how to remove speckles from this pair. This is the basis of how convolutional networks work to remove speckle noise. But the problem is that there is no clean image as ground truth. They use the original image with the original speckle noise that they want to remove as a ground truth, and they add noise like Gaussian or salt-and-pepper, or speckle noise, or... etc., to this image and consider it as the input image. So, the DeCNN model must train from those pairs of ultrasound images, but in this case, the CNN model will not learn to remove speckle noise from ultrasound images; it will just learn to remove the added noise, and that is not the main goal.

C. Research Contribution

This study makes the following contributions:

Multi-filter pseudo-supervision: A consensus-based training strategy that uses multiple classical despeckling filters (Gaussian, median, and total variation) to generate diverse pseudo-clean targets from real ultrasound images without requiring unattainable clean ground truth. Deeply supervised U-Net++ integration: An effective integration of the above supervision scheme with a U-Net++ denoiser using deep supervision to improve multi-scale learning stability and reduce overfitting to a single filter's artifacts. Empirical validation on BUSI: A comprehensive evaluation on the BUSI dataset demonstrating competitive PSNR/SSIM performance and improved qualitative edge preservation relative to several CNN baselines under a consistent evaluation protocol. Practical relevance: A clinically oriented despeckling pipeline that can be trained directly on real ultrasound images, avoiding assumptions inherent to synthetic-noise supervision.

II. Literature Review

The reviewed literature on ultrasound image denoising and segmentation indicates that supervised learning remains the dominant approach, primarily due to the ease of generating synthetic noise from clean datasets. Most studies utilize clean images sourced from public datasets or clinical environments and artificially degrade them using simulated speckle, Gaussian, Rayleigh, or salt-and-pepper noise to create paired noisy clean datasets. For instance, Khan and Malik [9] employ patches extracted from the BSD400 natural image dataset, corrupt them with multiplicative speckle noise, and use the clean patches as ground truth to train a residual U-Net with a mixed attention mechanism. Similarly, Li et al. [10] construct clean/noisy pairs by using high-resolution anatomical photographs from the National Library of Medicine and simulate speckle noise via the SIMUS ultrasound simulator, allowing their physics-informed deep quantum algorithm to enhance cardiac ultrasound images. Zhang et al. [11] leverage the US 4 dataset and the BUSI dataset by synthetically adding Rayleigh noise to high-resolution frames, treating the original images as clean references to supervise their attentive U-Net with a physics-informed loss combining SSIM and attenuation constraints. Kumar and George [12] follow a similar supervised paradigm by obtaining clinical ultrasound images from Edapal Hospital in India, simulating speckle noise of varying variances, and using those pairs to train a U-Net with channel and spatial attention. Thomas et al. [13] explore a broader evaluation by using Kaggle's breast ultrasound dataset and a carotid artery dataset from the Signal Processing Laboratory. They simulate speckle noise via MATLAB's imnoise function and also include a Richardson–Lucy network trained on BSD68 images for comparison, all under a supervised framework. Likewise, Sharma and Singh [14] generate diverse noisy conditions by applying speckle, Gaussian, and salt-and-pepper noise to clean ultrasound images, which serve as the ground truth for training a deep convolutional autoencoder. Soman et al. [15] utilize the Kaggle breast ultrasound dataset, perform hybrid filtering using classical filters such as median and anisotropic diffusion, and subsequently train a CNN on paired noisy–clean images. While most studies rely on supervised strategies with simulated noise, a few explore alternative forms of supervision. Chen et al. [16] adopt an unsupervised/self-supervised learning approach, using the BUS BRA dataset comprising 1,875 breast ultrasound images. They train a denoising autoencoder to reconstruct each image from its non-subsampled shearlet transform (NSST) representation without requiring explicit noisy/clean image pairs, thereby operating without ground truth supervision. In the field of segmentation, Zhao et al. [17] propose a semi-supervised deep learning framework called Multi StudentNet for endometrial segmentation in transvaginal ultrasound images. Their dataset of 1,664 images includes 597 manually labeled by experts and 597 unlabeled. Teacher models are trained on the labeled subset using cross-entropy and Dice loss, and pseudo-labels generated by the teacher ensemble are used to train student models on the unlabeled subset, effectively blending supervised and unsupervised learning. Lastly, Rahman et al. [18] introduce a reinforcement learning–based denoising framework wherein each pixel in an image acts as a learning agent. They use the BSD68 and Waterloo datasets to train the model on grayscale images with artificially added Gaussian noise, providing clean/noisy pairs as ground truth. Though the architecture is driven by reinforcement learning principles, the reward is computed based on the error between the denoised and original clean pixel values, making it a supervised reinforcement learning hybrid.

In summary, seven out of ten reviewed papers follow a strictly supervised approach using synthetic noise to produce paired data, due to the scarcity of real-world noisy/clean ultrasound pairs. Two papers adopt alternative approaches, unsupervised/self-supervised and semi-supervised learning, to address the limitations of labeled data availability. One paper employs a reinforcement learning framework with supervised reward feedback to optimize denoising at the pixel level. This shift toward semi-supervised and self-supervised strategies, along with reinforcement learning, highlights the evolving focus of the field to improve robustness, reduce annotation dependency, and better handle the variability of real-world clinical ultrasound data.

III. Materials and Methods

A. Dataset and Preprocessing

The study employed the Breast Ultrasound Images (BUSI) dataset from Kaggle. It contains 781 B-mode ultrasound images of benign, malignant, and normal breasts. Images are grayscale and captured using real clinical scanners. To train the denoiser, each image was resized to 256 × 256 pixels and converted to PyTorch tensors. Three classical despeckling filters (median, Gaussian, and total variation) were applied to each image to generate pseudo-clean targets, yielding 546 × 3 = 1638 training pairs, 117 × 3 = 351 validation pairs, and 117 unaugmented test images (total =2106 samples). The input channels were single-channel grayscale.

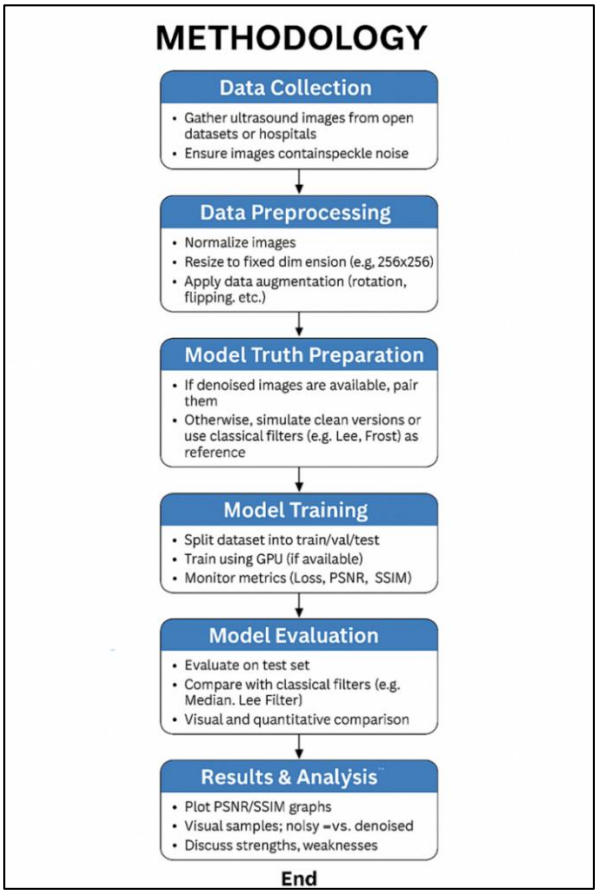

Fig. 1. Methodology structure.

B. U-Net++ Architecture

The model is based on U-Net++, a convolutional encoder-decoder with nested and dense skip connections. It has a five-level architecture with repeated down-sampling via strided convolutions and up-sampling via transposed convolutions. Each block consists of two Conv2D to BatchNorm to ReLU layers. Dense skip connections link intermediate layers at the same resolution, facilitating gradient flow and feature reuse. Four auxiliary output heads provide deep supervision; their predictions are averaged for the final output. Residual blocks or depth-wise separable were refrained from using convolutions to keep the model moderate in size. Fig. 1 shows the methodology structure.

C. Training Configuration

The model was trained from scratch with the Adam optimizer (learning rate = 0.001, $\beta_1 = 0.9$, $\beta_2 = 0.999$) and mean squared error (MSE) loss. The batch size was 16, and early stopping with patience = 5 prevented over-fitting. Training proceeded for up to 30 epochs on an NVIDIA A100 GPU NODE (CUDA). During training, both noisy inputs and target images were normalized to [0, 1], and random horizontal flips were applied. The training loop saved intermediate denoised images and recorded PSNR and SSIM using skimage.metrics for qualitative analysis. The model training diagram is shown below in Fig. 2.

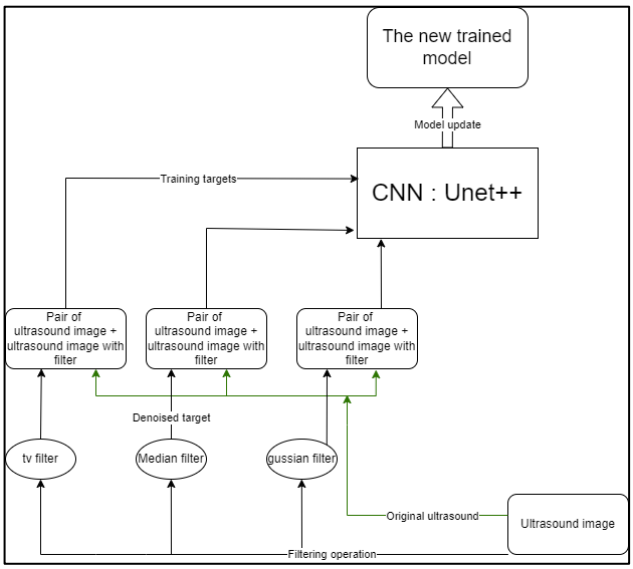

Fig. 2. Model training diagram.

D. Evaluation Metrics

Two standard metrics were used:

- Peak Signal to Noise Ratio (PSNR) measures the ratio between the maximum possible pixel value and the MSE. Higher values indicate better denoising.
- Structural Similarity Index Measure (SSIM) quantifies perceived structural similarity; values close to 1 indicate high similarity.

IV. Results

A. Quantitative Performance

On the BUSI test set, U-Net++ denoiser achieved PSNR = 34.11 dB and SSIM = 0.8901 (mean across 117 images). Table I ranks the studies included in the comparison by PSNR and SSIM. The suggested model attained the highest PSNR among recent CNN methods and the second highest SSIM behind the U-Net ELU variant (37.76 dB, SSIM 0.98) [19]. The MO KD approach improved PSNR by only 1.7 dB; the suggested model still provides competitive performance without requiring knowledge distillation [20].

This study outperformed Lu (2020) in quantitative image clarity. Specifically, single-stage U-Net++ achieved a PSNR of 32.92 dB, roughly 3 dB higher than Lu's multi-stage CNN

(31.13 dB). This gain indicates that this model suppresses noise while preserving fine texture more effectively, a critical advantage for detecting subtle lesions. Importantly, this improvement was achieved without the added complexity and memory overhead of Lu's multi-stage architecture, streamlining both training and deployment. As shown in Fig. 3, PSNR comparison, and Fig. 4, which compares the SSIM.

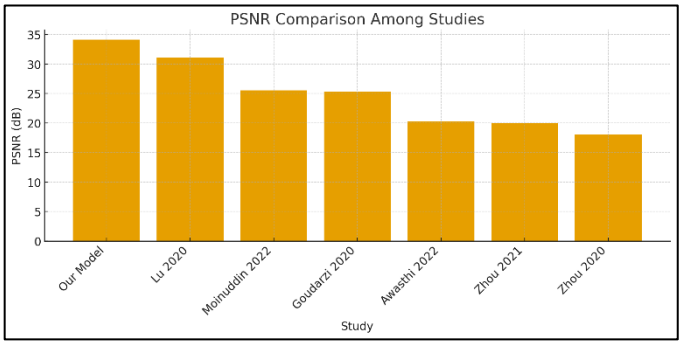

Fig. 3. PSNR comparison.

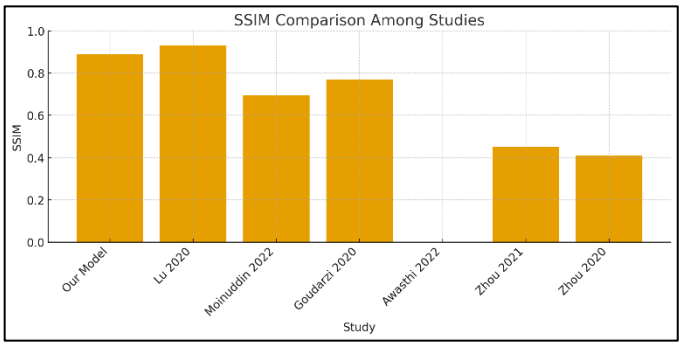

Fig. 4. SSIM comparison.

TABLE I. NUMERICAL COMPARISON OF PSNR AND SSIM EXTRACTED FROM THE LITERATURE

Study	PSNR (dB)	SSIM	Notes
Our Model	34.11	0.8901	Highest PSNR among reported values; second highest SSIM
Lu 2020	31.13	0.930	Uses a multi-stage CNN; high SSIM but slightly lower PSNR
Moinuddin 2022	25.53	0.6946	Texture-compensated multi-resolution CNN
Goudarzi 2020	25.32	0.7690	Deep residual network
Awasthi 2022	20.31	–	Autoencoder denoiser
Zhou 2021	19.95	0.45	GAN-based method
Zhou 2020	18.08	0.41	CNN baseline

B. Qualitative Results

Visual inspection revealed that the proposed model effectively suppresses speckle while preserving edges. In contrast, classical filters introduce blurring and halo artefacts. Deep supervision encourages multi-scale consistency; early outputs remove coarse speckle, whereas deeper outputs refine fine structures. Fig. 5 shows representative examples from the test set (noisy input, denoised output, and pseudo-clean target). The model preserves the shape of masses and ductal structures, which is critical for CAD systems.

The results demonstrate that a moderately sized U-Net++ can effectively remove ultrasound speckle without relying on GANs or transformers. Dense skip connections facilitate feature reuse and reduce the number of parameters compared with fully nested U-Nets. Using multiple traditional denoisers as pseudo clean targets provides robustness and prevents the network from over-fitting to a single filtering artefact. However, the PSNR ≈ 30 dB is lower than some GAN-based approaches, and the SSIM is below the 0.96 achieved by networks replicating WNNM [21]. This model does not explicitly suppress signal-dependent noise; MSE loss may oversmooth fine textures. Future work could incorporate adversarial training, perceptual losses, or physics-informed self-supervised techniques (e.g., Speckle2Self [22]) to further improve performance.

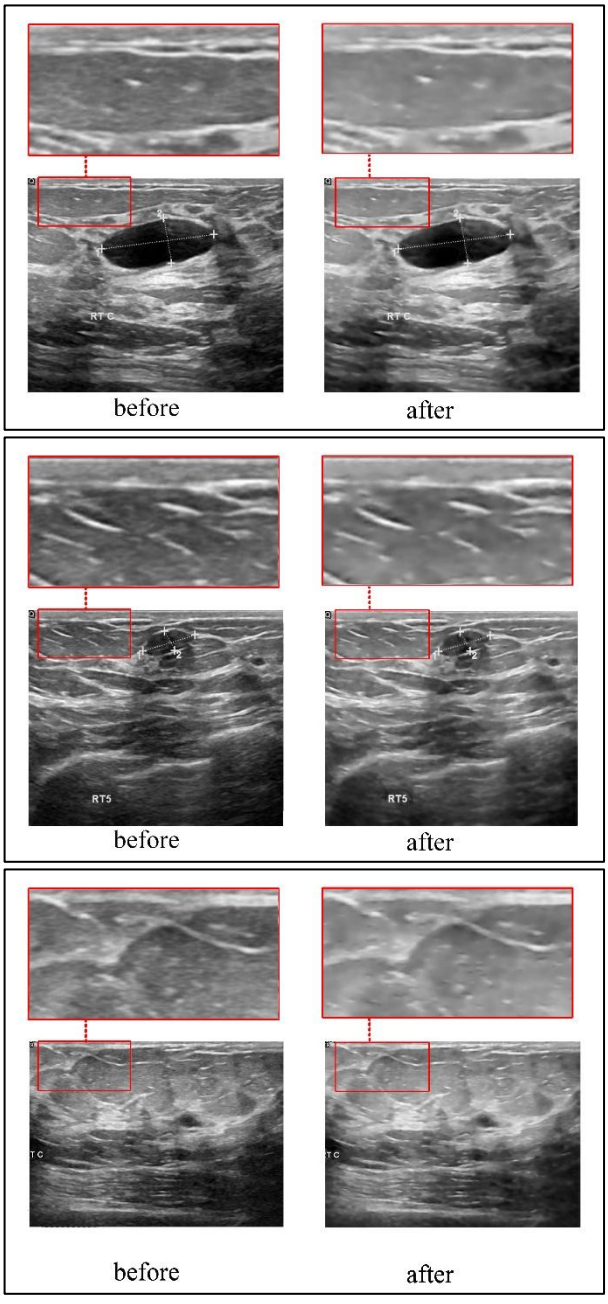

Fig. 5. Denoised ultrasound images.

V. Conclusion and Future Directions

Speckle noise remains a major obstacle in ultrasound imaging. Deep learning approaches offer a promising avenue by learning complex noise characteristics and preserving anatomical structures. Through a comprehensive review of over ten recent publications, GAN-based methods achieve high PSNR and superior perceptual quality but require careful training and may introduce hallucinations. Self-supervised methods such as Speckle2Self and S2S overcome the lack of clean data, but currently lag supervised methods in quantitative metrics. This study demonstrates that a supervised U-Net++ trained on the BUSI dataset provides competitive performance (PSNR 34.11dB, SSIM 0.8901) and improves upon several CNN baselines. This confirms that moderate-sized architectures with dense skip connections can balance denoising effectiveness and computational efficiency.

This study evaluates the proposed model using a single breast ultrasound dataset. The model was not validated on external ultrasound datasets acquired from different scanners, institutions, or imaging protocols. This limits the strength of claims regarding generalization and clinical robustness beyond the BUSI data distribution.

In addition, the available training data are relatively limited in size. Deep learning denoisers typically benefit from larger and more diverse datasets to capture the variability of speckle appearance across tissue types and acquisition settings. The restricted dataset size may constrain performance and stability, and larger-scale training data may improve denoising quality and generalization.

Future work will explore:

- Combining self-supervision with multi-scale supervision to circumvent the need for pseudo-clean targets.
- Incorporating physics-based speckle models into the loss function to better handle multiplicative noise.
- Extending the framework to 3D volumetric ultrasound and other anatomical regions.

By addressing these avenues, further gains in both quantitative performance and clinical applicability are anticipated.

From Bits to Qubits: Comparative Insights into Classical and Quantum Computing Systems

Tariq Jamil
Department of Electrical and Computer Engineering, Sultan Qaboos University, AlKhod 123, Muscat, OMAN

***Abstract*—The rapid development of computing hardware has been driven by an ever-emerging need for high throughput, scalable performance, and computation capabilities to be able to address increasingly complex problems. The paradigm of classical computing, centered on deterministic binary logic and the von Neumann architecture, has long favored modern information processing and still supports a wide range of applications. However, physical limits in scaling transistors, power dissipation, and slowing down Moore's Law have stimulated the consideration of alternative computing paradigms. Quantum computing is now an emerging means that exploits the basic principles of quantum mechanics-such as superposition, entanglement, and quantum interference-to enable new forms of computation. This review study discusses a comparison between the classical and quantum computing systems in operational paradigms, architecture structures, performance characteristics, and application domains. This work is supported by a systematic review of the established theories, currently realized hardware implementations, and representative algorithms. The analysis underlines that classical systems remain very reliable, scalable, and efficient in general-purpose and deterministic workloads, while quantum systems ensure essential advantages in specified problem classes, such as cryptography, quantum chemistry, combinatorial optimization, and selected machine learning tasks. The study concludes that classical and quantum computing are best viewed as complementary technologies. Future high-performance computing platforms will most likely be based on hybrid-classical–quantum architectures in which quantum processors serve as specialized accelerators to help classical systems solve new computational challenges.**

***Keywords*—Classical computing; high-performance computing; quantum computing; qubit**

I. Introduction

The pace with which computer hardware has advanced in the past decades has revolutionized science, business, and society. In the midst of all this change is classical computing, a deterministic binary logic model where the basic unit of information—the bit—can be in one of just two states: 0 or 1. Classical computer architecture, which had previously been founded on the von Neumann model, relies on central processing units (CPUs), memory components, and input/output subsystems for executing instructions sequentially [1]. This paradigm has been in a position to maintain a wide scope of applications, ranging from personal computers and business systems to embedded controllers and high-performance computing platforms [2].

Despite significant advances in conventional hardware, largely through transistor scaling in line with Moore's Law, there are inherent bounds that have increasingly gained prominence as computational demands continue to rise. The contemporary challenges, such as simulating computationally intensive quantum systems, solving large combinatorial optimization problems, and performing secure cryptographic analysis, are frequently found to be intractable within conventional systems due to their sequential processing nature and physical miniaturization constraints [2]. Furthermore, the observed slowdown in Moore's Law, combined with increasing power density and thermal dissipation issues, has also heightened the demand for novel paradigms of computation capable of overcoming these computational challenges [3].

Quantum computing is one of those revolutionary paradigms that relies on the counterintuitive principles of quantum mechanics—namely, superposition, entanglement, and quantum interference—to process information in fundamentally new ways. Unlike classical bits, the fundamental unit of quantum information, the qubit, can exist in a superposition of 0 and 1 simultaneously, enabling exponentially parallel computation for certain classes of problems [4]. Moreover, the phenomenon of entanglement allows multiple qubits to become related in such a way that one qubit's state will immediately influence the state of another, regardless of the distance between them, allowing for faster-than-classical information correlation and algorithmic speedup [5]. Several physical implementations of qubits have been proposed and experimentally realized, including superconducting circuits, trapped ions, and photonics, with different strengths and specific engineering challenges [6].

This review article features an orderly comparative assessment of classical hardware computing and quantum hardware computing. It examines their fundamental operating paradigms, structural architectures, performance profiles in computation, and their corresponding domains of application. In consideration of detailed deliberation on each paradigm's advantages, limitations, and technological maturity, this study seeks to put their synergistic roles in addressing existing and anticipated computational problems into perspective. Besides, the review focuses on ongoing research efforts and potential integration strategies of hybrid classical-quantum systems that are predicted to be among the next-generation high-performance computing solutions' primary drivers.

The study is organized as follows: Section II presents a comparative analysis of classical computing and quantum computing with reference to their operational paradigms, structural architectures, computational performance characteristics, and application domains. Section III outlines the challenges and expected future trends in computing, followed by a summary and conclusion in Section IV.

II. Comparative Analysis

A. Operational Paradigms

Traditional computer systems operate on deterministic binary logic such that the fundamental unit of information—the bit—can be one out of two possible states, 0 or 1, at any given moment [2]. The operation model of conventional computing is based on the von Neumann architecture, in which a CPU reads, executes, and applies instructions in RAM and transfers data between I/O devices via a shared system bus [1]. Logical functions are performed through the development of electronic switches known as transistors into logic gates (e.g., AND, OR, and NOT gates) that process in binary states deterministically under the rules of Boolean algebra. Instruction execution one after the other is maintained through control units and registers, which regulate program flow as well as data movement between memory and processing elements. Fig. 1 shows a conceptual block diagram of a typical von Neumann architecture, its key hardware components, and how they are all connected.

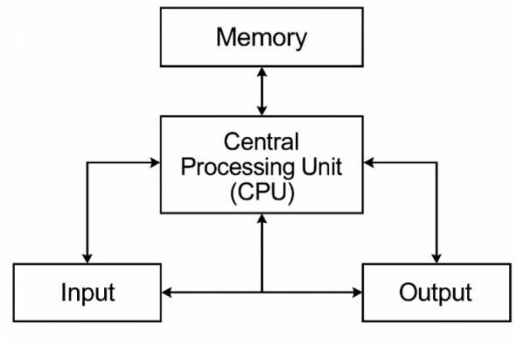

Fig. 1. Block diagram of classical computing architecture showing CPU, memory, I/O, and bus.

Quantum computing, by contrast, relies on the principles of quantum mechanics, wherein the fundamental unit of information—the quantum bit, or qubit—can exist in a superposition state that represents both 0 and 1 simultaneously until observed [4]. This aspect tremendously expands the state space of a quantum system. For example, while a classical n-bit system can represent one of 2^n possible states at any given time, an n-qubit quantum system can represent all 2^n possible states at the same time through superposition. Also, qubits can be entangled, a quantum phenomenon whereby the state of a qubit becomes intrinsically linked with the state of another, regardless of the spatial separation between them, enabling forms of parallelism and information correlation without a classical analogue [5].

Quantum computations are carried out by sequences of reversible, unitary operations known as quantum gates. Unlike classical logic gates, which act deterministically on bits, quantum gates operate on the probability amplitudes of qubit states using linear transformations described by unitary matrices [6]. Standard quantum gates include the Hadamard gate (H), which places qubits in superposition; the Pauli-X gate, which flips qubit states in a manner analogous to a classical NOT gate; and the controlled-NOT (CNOT) gate, which entangles two qubits by conditionally flipping the target qubit based on the state of a control qubit.

The differences in operation between quantum and classical computing systems are profound. The classical systems are founded on sequential, deterministic execution models, with bit operations tracking predictable Boolean logic rules [2]. Their error correction is highly matured, employing redundancy along with error-detecting codes to provide reliable, fault-tolerant computation. On the other hand, quantum systems are probabilistic by nature, and only the result is revealed when measured that collapses the qubit superposition to a definite classical state [4]. Quantum error correction is far more challenging due to the continuous nature of quantum states and their susceptibility to decoherence through interactions with the environment. Further, while classical logic operations in general are not reversible, quantum operations must be reversible because unitary operations preserve the total information content of the system [6]. This fundamental difference in operating principles illustrates both the revolutionary potential and the profound technical challenges of quantum computing relative to conventional classical hardware systems. Table I compares the operational principles of classical computing and quantum computing.

TABLE I Comparative Summary of Operational Principles

Feature	Classical Computing	Quantum Computing
Information Unit	Bit (0 or 1)	Qubit (0 or 1 or both)
Operational Basis	Deterministic, Boolean logic operations	Probabilistic, governed by superposition and entanglement
Execution Mode	Sequential	Massively parallel via quantum superposition
Gate Types	Irreversible logic gates (AND, OR, NOT)	Reversible quantum gates (Hadamard, CNOT, Pauli-X, etc.)
Measurement	Direct, non-destructive	Collapses quantum state, probabilistic outcome
Error Correction	Mature, based on redundancy and parity checking	Complex, requires quantum error correction codes (e.g., Shor, Surface codes)

B. Structural Architectures

The conventional computer systems are primarily von Neumann-based, designed by John von Neumann in the mid-20th century. The fundamental organization has a central processing unit (CPU), memory unit, input/output devices, and a system bus to enable them to communicate with each other (see Fig. 1). Inside the CPU, it has an Arithmetic Logic Unit (ALU) and a Control Unit (CU). Instructions and data are pulled from memory, processed by the CPU, and the results are written back into memory or sent out through the I/O interfaces [1]. Data's binary structure and serial processing paradigm, where the information is received in either 0s or 1s, make conventional computers highly deterministic and predictable in a vast number of applications. However, these systems are still restrained by physical constraints such as transistor miniaturization, power dissipation, and thermal dissipation [3].

Quantum computing architectures, on the other hand, draw on the basic principles of quantum mechanics, such as superposition, entanglement, and quantum interference. The simplest unit of quantum information—the qubit—has the possibility of existing in a superposition of states $|0\rangle$ and $|1\rangle$ at

the same time [4]. Quantum computers are often made up of several qubits in a lattice or network of qubits, manipulated using sequences of quantum gates. Unlike classical systems, which are designed around a centralized CPU and sequential instruction execution, quantum processors are founded upon a quantum circuit model wherein computations are performed via carefully orchestrated quantum gate operations. These architectures also demand highly specialized hardware, including microwave pulse generators, cryogenic dilution refrigerators for stabilization at near absolute zero temperatures, and sophisticated quantum error correction systems [7].

Architecturally, the computing mechanisms and data flows in quantum and classical systems are very different. In classical systems, information moves between memory, CPU, and I/O subsystems over system buses, as directed by a control unit. Performance bottlenecks tend to occur in the memory hierarchy and instruction execution pipeline, most notably the von Neumann bottleneck, due to limited data transfer between memory and CPU [8]. Conversely, quantum computers take advantage of the inherent parallelism of quantum states, where an n-qubit system can simultaneously represent 2^n possible configurations. This possibility requires meticulous control of qubit coherence and entanglement, typically maintained at millikelvin temperatures in cryogenic setups to mitigate decoherence and environmental noise [7].

To better visualize quantum states, Fig. 2 illustrates a qubit state on the Bloch sphere, demonstrating how quantum states exist in a continuous, multi-dimensional space, as opposed to discrete binary states of classical hardware. While traditional computing has grown into massively scalable, commercially optimized systems, quantum architectures remain in the making, hindered by challenges of qubit fidelity, error rates, and scalability of systems. Yet, quantum architecture flexibility and computational power bring drastic improvements in fields such as cryptography, combinatorial optimization, and complex quantum system simulation [6]. Table II compares the architectural designs of classical computing with quantum computing.

C. Computational Performance Characteristics

The performance in conventional computing systems is generally most accurately measured in terms of clock rate (measured in gigahertz), instruction throughput (instructions per cycle, IPC), and parallel processing capability. Contemporary conventional processors also enhance performance using design techniques like multi-core designs, instruction pipelining, simultaneous multi-threading (hyper-threading), and the utilization of hardware accelerators to perform some operations [2]. High-performance computing (HPC) systems, such as the Frontier and Fugaku supercomputers, utilize very large parallel clusters consisting of thousands of central processing units (CPUs) and graphics processing units (GPUs), providing sustained computing performance at the exaFLOPS rate, or 10^{18} single-precision floating-point computations per second [9]. Classical hardware remains very beneficial for a vast assortment of deterministic, sequential, and general-purpose computational tasks, such as numerical simulation, data analysis, and machine learning prediction.

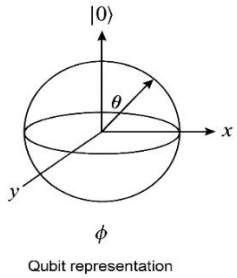

Fig. 2. Qubit representation on the Bloch sphere.

TABLE II COMPARATIVE SUMMARY OF ARCHITECTURAL DESIGNS

Component	Classical Architecture	Quantum Architecture
Processing Unit	CPU (ALU + Control Unit)	No central processor; qubits manipulated by quantum gates
Memory Unit	RAM, Cache, Secondary Storage	Quantum memory (qubit arrays, limited capacity)
Data Bus	Parallel/serial data lines	Quantum interconnects or qubit couplers
Execution Model	Von Neumann sequential model	Quantum circuit model
Operating Environment	Room temperature, conventional hardware	Cryogenic (mK) temperatures for coherence control
Scalability	Highly scalable	Currently limited by decoherence, qubit fidelity

In contrast, the performance of quantum computer hardware is measured by a different set of values, including the number of qubits, coherence time, gate fidelity, and quantum volume—a multi-dimensional figure of merit devised by IBM that aggregates a system's computational capability in terms of qubit quality, connectivity, and circuit depth [10]. Whereas classical systems tend to exhibit linear or polynomial computational complexity scaling, certain quantum algorithms achieve exponential or quadratic speedup over their best-known classical analogues. These include Shor's algorithm for number factorization and Grover's algorithm for searching an unstructured database, both of which employ quantum mechanical features like superposition and entanglement to explore different computational paths in parallel [11].

One of the key differences between classical systems and quantum systems is in fault tolerance and error control. Classical computing systems have had decades of practice in error detection techniques and correcting mechanisms, with facilities such as parity bits, checksums, and error-correcting code (ECC) memory being used to ensure operational reliability [2]. Quantum systems are inherently prone to decoherence, quantum noise, and gate errors as a result of environmental coupling and hardware defects [12]. As such, existing Noisy Intermediate-Scale Quantum (NISQ) devices are only limited in how far the operation circuit depth they can achieve before inaccuracies of computation begin. More advanced quantum error correction codes, such as Shor's code and surface codes, are in active development but demand large numbers of extra ancillary qubits, which pose severe scalability challenges [12].

Moreover, the regions where classical and quantum computers excel are highly distinct. Classical computers

continue to excel in general-purpose computing, transaction processing, and engineering simulations. Quantum computers, however, are bound to excel in niche applications such as quantum chemistry, cryptography, combinatorial optimization, and certain machine learning tasks [6]. Experimental demonstrations of quantum advantage have been provided, such as Google's Sycamore processor, which executed a specific computation problem significantly faster than the fastest-performing classical supercomputers of its time [7]. Nevertheless, demonstration of the widespread, fault-tolerant quantum computing devices to outperform classical hardware consistently on a large majority of problem types remains an ultimate milestone.

D. Application Domains

Classical computing devices have evolved to be a necessity in almost all aspects of contemporary society. From enterprise functions, web applications, and healthcare management to space flight simulations, artificial intelligence (AI), and complex engineering calculations, classical systems provide solid, scalable, and well-established solutions for deterministic and probabilistic computational operations [2]. Supercomputers and high-performance computing (HPC) clusters have significantly impacted fields such as weather forecasting, genome sequencing, and financial modeling. Traditional systems enjoy flexibility through their entrenched hardware and software ecosystems, including standard programming languages, operating systems, and networking protocols [13]. Furthermore, edge computing and cloud infrastructure advancements have enabled classical computing influence expansion into mobile devices, systems of the Internet of Things, distributed services, and made it the technological basis of modern digital infrastructure.

By contrast, quantum computing is directed towards tackling problem classes that are intrinsically difficult or impossible for classical devices due to exponential time or space complexity. A prime example application field is quantum chemistry, wherein the simulation of molecular interactions and reaction mechanisms necessitates computational resources scaling exponentially with system size on classical computers [14]. Quantum computers, by exploiting phenomena such as superposition and entanglement, can more directly simulate complex quantum systems, enabling simulations of large molecules, catalysts, and exotic materials at scales previously unviable. This could revolutionize fields such as pharmaceuticals, materials science, and the creation of sustainable energy.

Optimization problems are among the other domains where quantum systems are expected to be more powerful compared to their classical versions. Logistics routing, portfolio optimization, and scheduling problems, classically reliant on approximating or heuristically-based algorithms, are being tried for quantum supremacy with such tools as the Quantum Approximate Optimization Algorithm (QAOA) [15].

Quantum cryptography is also another widely reported application of quantum computing. Classical cryptosystems like RSA and elliptic-curve cryptography (ECC) rely on the computational difficulty of factoring numbers and calculating discrete logarithms—problems that are secure against conventional attacks but susceptible to powerful quantum attacks via Shor's algorithm [11]. The advent of practical quantum technology thus necessitates post-quantum cryptography to secure digital communication infrastructures.

In addition, quantum computing promises to help solve problems in the area of machine learning. QSVM and QPCA are examples of algorithms that even use quantum parallelism to help with data processing and feature extraction among high-dimensional features. This could generate acceleration for more complex AI workloads [16].

While classical systems still rule general-purpose, real-time, and transactional computing, quantum hardware is being developed for problems of high complexity and resource requirements for which classical resources scale unrealistically. The future computing paradigm will most probably be hybrid, with quantum accelerators alongside classical cores in heterogeneous architectures [6]. While quantum computing is now in its Noisy Intermediate-Scale Quantum (NISQ) era, ongoing research and industrial investment point to a path where such systems will become central in niche areas as classical computing remains the basis for standard, mission-critical, and real-time applications.

E. Discussion

It is clear from the above review that classical computing is very efficient, reliable, and scalable with deterministic general-purpose computing, whereas quantum computing behaves in a vastly different manner due to super-positioning and entanglement, providing a substantial advantage in specific problem domains like cryptography, quantum chemistry, and combinatorial optimization, even with the existing hindrances in using quantum computing due to decoherence, qubit accuracy, and scalability. Both approaches to computing have properties which make one no better than the other, rather they exist in a complementary form. The future of computing lies in developing a hybrid classical-quantum system, efficient quantum algorithms, gainful efforts on improved error correction techniques, as well as advanced research on qubit technologies. Future research may also entail developing a fair system of benchmarking both classical and quantum computing on a similar problem set, thus developing next-generation high-performance computing environments incorporating quantum accelerators.

III. Challenges and Future Trends

Despite phenomenal technology advancements, conventional computing is facing inherent constraints as it approaches the physical limits of Moore's law, which historically predicted transistor density doubling approximately every two years [3]. Once the transistor sizes decrease below 3 nanometers, serious issues such as quantum tunneling, increasing thermal dissipation, and power leakage significantly decelerate further miniaturization and limit clock speed increases. Furthermore, the rising complexity of the system and increased energy requirements of massive data centers and high-performance computing (HPC) clusters require sustained innovation in such areas as energy-efficient architectures, three-dimensional stacking of chips, and heterogeneous systems comprising central processing units (CPUs), graphics

processing units (GPUs), and field-programmable gate arrays (FPGAs) [17]. Even as classical computing must remain the pre-eminent computation paradigm in general-purpose programs, future trends hold promise of a shift toward hybrid classical-quantum computing systems, special-purpose hardware accelerators optimized to process artificial intelligence (AI), edge computing, and domain-specific tasks to optimize both performance and power efficiency [18].

IV. Summary and Conclusion

In summary, this review has presented a detailed comparative survey of classical and quantum computing systems in terms of their working principles, architectural frameworks, computational performance characteristics, and application domains. While classical computing remains the cornerstone of modern digital infrastructure due to its scalability, reliability, and mature ecosystems, it faces physical and architectural limitations as the miniaturization of transistors reaches theoretical limits. Quantum computing, founded on the principles of superposition, entanglement, and quantum interference, has great potential for addressing intractable problems in cryptography, quantum chemistry, optimization, and artificial intelligence. However, current quantum systems are constrained by decoherence problems, qubit fidelity, and lack of scalability. Looking ahead, the future of computation will be headed in the direction of heterogeneous architectures where classical systems continue to be at the core of general-purpose and mission-critical applications, but quantum accelerators will enhance computational prowess for specialized high-complexity problems. This continued collaboration of the classical and quantum paradigms is the way forward for high-performance computing, representing a fundamental shift in addressing the expanding demands of the data-driven, AI-augmented era.

Histogram Gradient Boosting Classifier-Based UWSN Cyber Attack Detection Incorporating Environmental Factors (HGBoostUCAD)

Hamid OUIDIR, Amine BERQIA, Siham AOUAD
ENSIAS, Mohammed V University in Rabat, Rabat, Morocco

***Abstract*—Underwater Wireless Sensor Networks (UWSNs) are commonly employed for exploring and exploiting aquatic areas, and its role is very important and more beneficial precisely in hostile and constrained marine environments. However, their security is more critical than terrestrial wireless sensor networks (TWSNs) due to the space in which they are deployed, the wireless communication medium, and the cost of damage repair, and their protection is a problematic issue that needs to be continuously resolved. Consequently, it is highly recommended see required to take procedure to protect UWSNs against attacks and intrusion and maintain service quality. In general, existing works on machine learning-based intrusion detection system (IDS) and cyber-attack detection approaches for (UWSNs) utilize dedicated datasets designed for (WSNs) without adapting them to the aquatic environment. Furthermore, these studies analyze the enhancement of UWSN performance based on network metrics separately from machine learning model metrics, and vice versa. In this way, this paper proposes a novel cybersecurity detection approach-based model learning Histogram Gradient Bosting (HGB) classifier called (HGBoostUCAD). It classifies four types of DoS attacks (Blackhole, Grayhole, Flooding, and Scheduling), employing an adjusted dataset for (IDS) in wireless sensor networks (WSN-DS) taking into account simulate realistic environmental factors: salinity, temperature, deep through Mackenzie's equation and node movement in training data. The insight of simulation results obtained, shows that our method reached 97% as accuracy and 96% as precision also outperformed both Deep Neural Network (DNN) as well as the recent study Hyper_RNN_SVM eventually referenced in this research, in terms of machine learning model metrics. In addition to machine learning model metrics, our approach provides network measurements by DoS attack type.**

I. INTRODUCTION

An underwater wireless sensor network (UWSN) is considered to serve as the main support network for the Internet of Things. The network architecture of a UWSN is shown in Fig. 1, with its key components—sensors—located in either shallow or deep water. The sensors' function is to collect data and send it via acoustic signals to objects like buoys, ships, Autonomous Surface Vehicles (ASVs), or Autonomous Underwater Vehicles (AUVs). These objects then use radio signals to send the data to a distant monitoring center. After obtaining the oceanic data, the monitoring center analyzes it [1]. These kinds of networks are usually unmonitored and placed in remote locations. Security methods must be implemented on them to protect them from threats and attacks [2], and compared to their analogs, such as wireless sensor networks (WSNs), UWSNs are more susceptible to security assaults. The entire network's functionality may be compromised by potential attacks in UWSNs [3]. The list of abbreviations is given in Table I.

In research [4] as application, the author classified UWSN deployment into five areas: 1) underwater research; 2) environmental monitoring; 3) disaster prevention; 4) military domain; and 5) other fields.

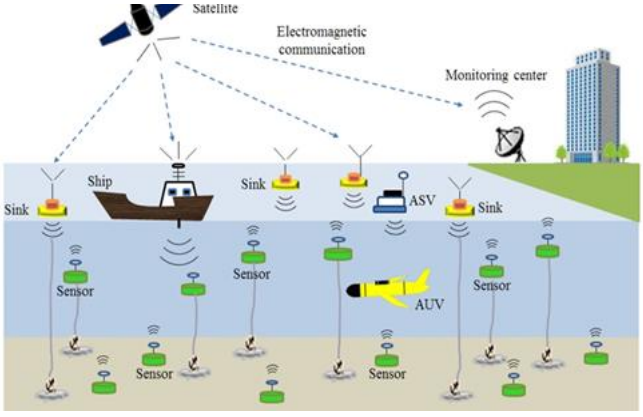

Fig. 1. UWSN architecture [1].

A. Basic Concepts and Challenges

1) Cybersecurity: The term "cyber security" refers to the set of rules, methods, tools, and procedures that cooperate to defend against attacks on the availability, confidentiality, and integrity of networks, software, and data. There are cyber protection methods at the network, application, data level and host. Many tools, including intrusion detection systems (IDSs), firewalls, antivirus programs, and intrusion protection systems (IPSs), operate in collaboration to prevent assaults and identify security failures [5]. In other words, cybersecurity concepts are measures taken to guarantee the confidentiality, integrity, and availability of systems, data (including software, hardware, and networks), and information that is processed, stored, and transmitted, as mentioned in the NISTIR (National Institute of Standards and Technology Internal Report) 7298 report (Glossary of Key Information Security Terms, July 2019). Moreover, the FISMA (Standards for Security, Categorization of Federal Information and Information Systems, February 2004) established the first three main security objectives for computer and information systems as follows:

a) Confidentiality: Taking into account appropriate limitations on information availability and sharing, as well as precautions to protect private and sensitive data.

b) Integrity: Preventing the rectification or destruction of erroneous data while guaranteeing the accuracy and non-repudiation of the relevant information.

c) Availability: Making certain that when resources are needed, authorized users can access them on time and continuously [6].

2) Intrusion detection: Define as "the act of detecting actions that attempt to compromise the confidentiality, integrity, or availability of a resource". An intrusion detection system (IDS) is a hardware or software program that keeps surveillance out for hostile activities or policy violations on a network or systems [7].

As well, we describe DoS attack types on the WSN-DS dataset, including Blackhole, Grayhole, Flooding, and Scheduling, as follows:

3) Blackhole attack: A blackhole attack is a kind of denial-of-service assault in which the attacker disrupts routing protocol by promoting itself at the start of the round. Playing the role of cluster head (CH), the Blackhole attacker will continue to drop packets transmitted by adjacent node rather than sending them to the BS.

4) Grayhole attack: The attacker disrupts the routing protocol by posing as a CH to other nodes. As a result, the pretending CH blocks some packets from reaching the BS by randomly or selectively dropping them when it receives data packets from other nodes.

5) Flooding attack: The attacker manipulates the routing protocol in multiple ways. By transmitting a lot of advertising CH messages with high transmission power. As a result, when sensors get a lot of messages notifications, they will use more energy and take longer to decide which CH to join. Additionally, the attacker tries to confuse victims into selecting it as a CH, particularly those nodes that are far away from it in order to drain their energy.

6) Scheduling attack: When CHs put up TDMA schedules for the data transmission time lots during the routing protocol configuration phase, scheduling attacks take place. All nodes will be given the identical time slot to send data by the attacker acting as a CH. This is accomplished by switching the TDMA schedule from broadcast to unicast. Such a modification will result in packet collisions and data loss [8].

Even though this type of networking is more beneficial in rich and expansive aquatic areas, they were limited by the basic open acoustic channel, excessive energy consumption, insufficient hardware capacity to execute computationally complex tasks, and dynamic network topology caused by node mobility. Moreover, a limited bandwidth and low attenuation [9].

B. Motivation

The problematic to ensure security through this specific network and addresses vulnerability in which they are exposed, have inspired some researchers to concentrate on UWSN attack and threat detection, which is crucial for safeguarding data and systems and may provide the high level of services that these underwater technologies are expected to offer. But, lacking completely appropriate UWSN data, we satisfied with the intrusion detection system (IDS) for Underwater Wireless Sensor Networks (UWSNs) based WSN-DS dataset customized to UWSN environmental factors (salinity, temperature, depth, and movement), with classification of four DoS attack types (Blackhole, Grayhole, Flooding, and Scheduling). Machine learning (ML) paradigm presents a new opportunity to accomplish the intended results in this aspect. In actuality, ML models successfully carry out detection, classification, and future event prediction [10]. Additionally, gradient boosting (GB) is an ensemble learning method for classification and regression problems, as suggested by Friedman [11]. An effective model can be produced by combining weak learners, commonly decision trees. The basic idea behind GB is to gradually build and generalize the ensemble model by optimizing an objective, arbitrary loss function [12].

Our study presents a novel technique based on the histogram gradient boosting (HGB) model evaluated precisely on the adjusted WSN-DS dataset commonly used on intrusion detection system in wireless sensor networks (WSNs) taking into account environmental factors as formulated by Mackenzie's equation. HGB is one of the most robust machine learning algorithms having high prediction speed and accuracy, particularly when working with large and complex datasets like WSN-DS [8]. The following is a summary of the study's most important findings and contributions:

- Implement a cyberattack detection on UWSN, using an adapted WSN-DS dataset and a histogram gradient boosting technique.
- Incorporate environmental adaptation: temperature, salinity, depth, mobility.

- Include per-attack network simulation adjustments (PDR, packet rate, delay, energy).
- Produce plots: ML comparison, per-attack network metrics.
- Provide technique with height performance both in terms of metrics model and performance network compared to DNN and to others recent works.

The remainder of this work is structured as follows: Section II provides a literature review. Section III describes research methodology adopted. Section IV introduces experimental results of research, analyze and discussion is given in Section V. Finally, the paper's conclusion is given in Section VI.

II. Related Works

We are satisfied with just a few of research that have mostly concentrated on the usage of artificial intelligence to enhance UWSN security process. In the same way, for the purpose of detecting cyberattacks, the study [13]. suggests an intelligent model-based approach that integrates machine learning and deep learning technology. Furthermore, a feature reduction strategy employing the machine learning techniques Principal Component Analysis (PCA) and Support Vector Machine (SVM) is employed to determine which properties are most closely associated with the selected attack categories. The accuracy of a proposed Recurrent Neural Network (RNN) method for deep learning-based intrusion classification and detection, following dimensional reduction and optimization, attains (97%) accuracy but using the NSL KDD dataset. The goal of this study is to provide a comprehensive overview of UWSN security by discussing security needs and the main UWSN security threats based on layered classification. This paper explores many security issues and looks at solutions, when in study [14], the current state-of-the-art for reactive jammer detection is built with terrestrial wireless sensor networks (TWSNs) in mind. Furthermore, cooperative jamming detection in UWSN is used in very little work. This research presents an Efficient Channel Access (ECA) model that uses cross-layer design to prevent reactive jammers in order to address research challenges. The ECA jointly optimizes the approved sensing device's cooperative hopping probability and channel accessibility probabilities. The detection accuracy achieved by the ECA model is 95.12%. Additionally, in [15], the authors suggest an intrusion detection model for underwater sensor networks that can identify many kinds of attacks in order to solve this issue. In order to reduce node computation, the reduced dimensional data is sent to sink nodes after cluster head nodes have extracted features using neighborhood sensitive sets. Furthermore, the data set is balanced, the quantity of minority class samples is increased, and the detection rate of minority class attacks is enhanced by the application of the synthetic minority oversampling method (SMOTE). After determining a node's confidence based on the cluster head node's trust evaluation, train the classifier to identify the type of attack using the random forest approach; it struggles to recognize intrusions from many attack types. According to simulation data, the model can detect imbalance classes with an accuracy of over 99% and enhance the effectiveness of intrusion detection of various types of attacks. Moreover, the methodology used in the work [16] makes use of real-time feature analysis of simulated WSN routing data. It creates a strong classification framework by combining Gaussian Mixture Models (GMM) and Hidden Markov Models (HMM). This scheme successfully detects anomalies, traces malicious network activity back to its source, and classifies it as either legitimate or suspicious network activity. According to authors, the algorithm outperformed the current classification methods by a large margin, with classification rates of approximately 83.65%, 84.94%, and 94.55%. Added to that, it provided a positive prediction value that was 11.84% greater than the current approaches. As well, to find the malicious attacks in a UWSN, the authors of this study [17] employed evidential evaluation using Dempster-Shafer theory (DST) of combined many evidences. Also, they provide a numerical process for combining multiple details from an unreliable and untrustworthy neighbor with a higher level of conflict security, but in paper [18], the purpose is to illustrate a wide range of algorithms used in the defense against different types of cyberattacks. In order to protect against a variety of cyberattacks, this study will look at different classification algorithms and defense strategies. Depending on how the attack is classified, these methods will differ in terms of implementation, accuracy, and testing time. The several types of these algorithms will be covered in this research. Other than, the survey [19] provides insights into the diverse intrusion detection system (IDS) methodologies utilized in various networking technologies and explains some of the techniques used in IDS design. Signature-based intrusion detection is the most widely used method for detecting threats and guaranteeing security. However, the emergence of Artificial Intelligence (AI), particularly Machine Learning, Deep Learning, and Ensemble Learning, has shown promise results in more effective attack detection. We can ensure that the cyber infrastructure is protected from intrusions and unwanted activity by using IDS and AI to defend a network according authors. Similarly, in [20] the paper introduces a novel method for detecting malicious network traffic using artificial neural networks suitable for use in deep packet inspection-based intrusion detection systems, achieving an average accuracy of 98% and a false positive rate of less than 2% in repeated 10-fold cross-validation, potentially improving the utility of intrusion detection systems in both conventional and cyber-physical systems. The research cited in [21] is based on the UNSW-NB15 dataset, which contains 49 features for 9 distinct attack samples. According to authors, the decision tree classifier provided the highest accuracy of 99.05% in comparison to other models. Also, the deep learning system for binary classification with an 80:20 train-test split ratio and two dense layers with ReLU activation and a third dense layer with Sigmoid activation function achieved an accuracy of 98.44% using the ADAM optimizer. The paper, also cited in [22] interested in attack detection methods founded on several architecture types, such as auto-encoders, generative adversarial networks, recurrent neural networks, and convolutional neural networks, based on classification on deep learning techniques. As well, authors illustrate the current state of attack detection techniques applying deep learning structures and evaluate the performance of representing approaches adopting a few benchmark datasets which are described.

III. METHODOLOGY OF RESEARCH

The following is the key components of the method adopted to implement a cyber-attack detection-based machine learning:

A. Criticism of Existing Studies

Despite their relevance in terms of findings, most of the studies reviewed in the literature use machine learning techniques that don't require datasets, such as reinforcement learning, while others use WSN datasets without taking environmental factors into account or use mathematical approaches for deploying a UWSN intrusion detection system. As well without integrating machine learning model measurements with network performance indicators in the same study.

B. Objectives and Hypotheses

- To implement a UWSN detection attack system supported by (Hist Gradient Boosting Classifier — HGB) using adapted WSN-DS dataset that includes four Denial-of-Service (DoS) attacks (Blackhole, Grayhole, Flooding, and Scheduling attacks) and incorporating environmental parameters: temperature, salinity, deep, mobility.
- To prove its performance by comparing it with DNN under the identical experimental conditions and with other current similar techniques in terms of metrics model.
- To analyze and interpret result of experimentation.

C. Experimental Design Overview

The experiment utilized the WSN-DS dataset augmented with UWSN environmental factors — namely salinity, temperature, depth, and node mobility — to reflect realistic underwater propagation and energy consumption patterns. The model employed a Histogram Gradient Boosting (HGB) classifier, an ensemble-based artificial intelligence algorithm recognized for its robustness and interpretability in intrusion detection tasks. Each record in the dataset represented a network state or node observation, labeled as either normal or one of the four Denial of Service (DoS) attack types: Blackhole, Grayhole, Flooding, and Scheduling.

The IDS was trained on 70% of the dataset and tested on the remaining 30%. Performance evaluation included both machine learning metrics (accuracy, precision, recall, and F1-score) and network-level performance metrics (packet delivery ratio, average delay, throughput, and energy consumption).

Step 1 — Load & Clean Dataset

Import D_(WSN-DS) dataset containing labeled samples of network activity

Step 2 — Synthesize UWSN Features

For each row i in data frame df:

Environmental features

- Generate Temperature Ti, Salinity Si, Depth Di, Node mobility Mi
- Append $E_{env} = \{S_i, T_i, D_i, M_i\}$ to feature vector.

Distance & propagation

- Randomized distance
- Compute sound speed via Mackenzie 's equation cited in [23]:

C = mackenzie_sound_speed (T, S, D)

$$C(T,S,D) = 1448.96 + 4.591T - 0.05304T^2 + 0.0002374T^3 + 1.34(S-35) + 0.0163D$$

- Propagation delay = distance / c

Link success probability algorithm

Inputs:

- d: link distance (meters)
- SNR: signal-to-noise ratio (dB)
- α: attenuation coefficient
- β, γ: SNR logistic parameters

Output: $\boldsymbol{p_0}$: baseline link success probability

The term $\mathbf{P_0}$ represents the baseline probability of successful packet transmission between two underwater sensor nodes, given the distance separating them and the signal-to-noise ratio (SNR) at the receiver. Mathematically, "base_link_success_prob"(·) illustrates how the transmission success rises with increased SNR, indicating a stronger received signal relative to background noise, and declines as the propagation distance grows (due to geometric spreading and absorption losses).

P0 = base_link_success_prob (distance, snr_db)

$$\mathbf{P0} = [1 \div (1 + e^{-\beta(\mathrm{SNR}-\gamma)})] \times e^{-\alpha d}$$

where: $\mathbf{P0} \in [0,1]$ and SNR proxy (dB) as function of distance and mobility (noisy),

d is the distance between nodes,

"SNR" (in dB) measures channel quality,

α, β, and γ are environment-dependent parameters modeling attenuation and detection sensitivity.

(α = 0.002;β = 0.15; γ = 10.0)

Attack-Adjusted Packet Delivery Ratio (PDR) Algorithm

This modifies $\mathbf{p_0}$ according to UWSN attack types

- pdr = apply_attack_pdr (p0, attack_type)

Inputs :

- p_0: baseline success probabilities (vector)
- AttackType[i] ∈ {normal, blackhole, grayhole, flooding, scheduling}

Output:

- p: attack-modified link success probabilities

This equation represents how the Packet Delivery Ratio (PDR) — the ratio of successfully delivered packets to total transmitted packets — is affected by the presence of cyberattacks or network disruptions in the underwater environment.

The function "apply_attack_pdr"(·) modifies this baseline probability according to the type and severity of attack acting on the network.

- pdr = apply_attack_pdr (p0, attack_type)

In this study we employ WSN-DS adapted dataset, which classifies network behavior as either normal or one of four Denial-of-Service (DoS) attacks (Blackhole, Grayhole, Flooding, and Scheduling attacks) [8].

Step 3 — Train & Evaluate Models (per seed)

HGBoostUCAD algorithm

- Train on X_train, y_train
- Predict y_pred_hgb on X_test

Deep Neural Network (DNN)

- Build sequential model: Dense → BatchNorm → Dropout → Dense → Softmax.

Compile with

adam, loss sparse_categorical_crossentropy

- Train with early stopping
- Predict y_pred_dnn on X_test

Compute ML metrics (accuracy, precision, recall, F1) for both models

Compute network metrics

Store results.

D. Results Evaluation

Step 4 — Statistical testing

- Determine model with highest mean metric (accuracy, precision, F1)
- Retrain best model on entire dataset (train/test split)
- Compute confusion matrix
- Save confusion matrix plot

Step 5 — Plotting

- ML metrics bar plot → HGBoostUCAD vs DNN
- Per-attack network metrics
- Loss curves
- DNN training & validation loss
- Gradient boosting log-loss.

IV. Experimental Results

A. Machine Learning Metrics

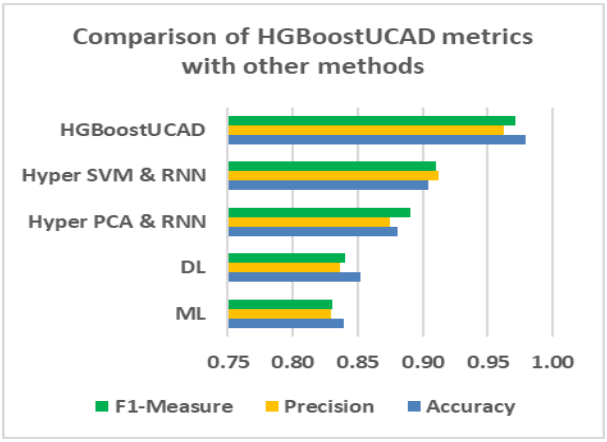

Fig. 2. Comparison proposal method with other similar methods.

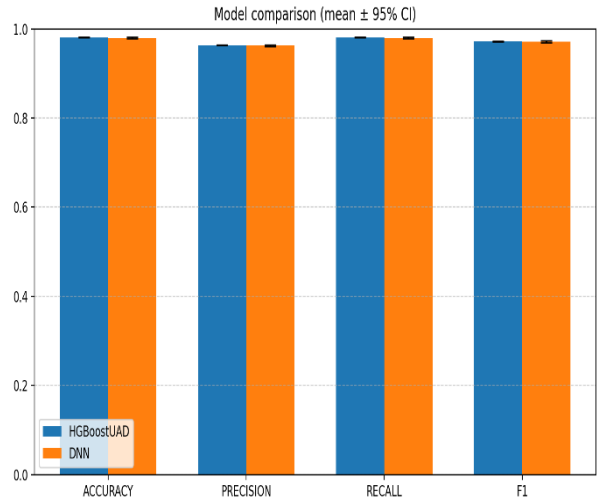

Fig. 3. Comparison between HGBoostUCAD and DNN method.

B. Network Performance Metrics

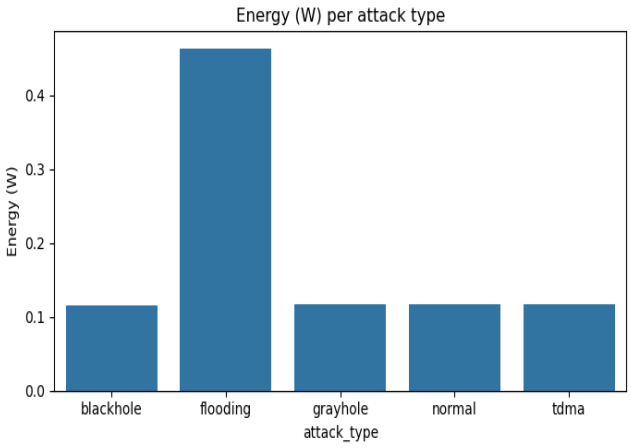

Fig. 4. Consumption energy per attack type.

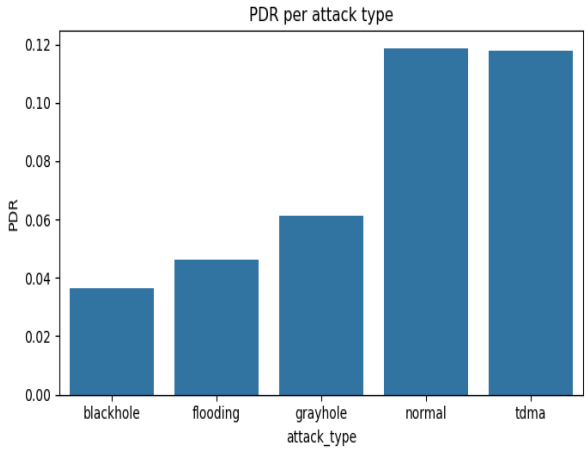

Fig. 5. Delivered packer ratio per attack type.

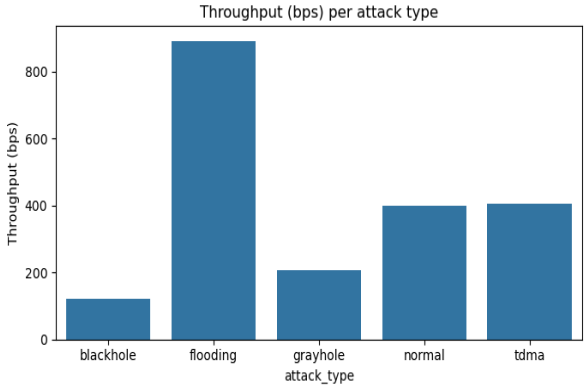

Fig. 6. Throughput variation for each type of attack.

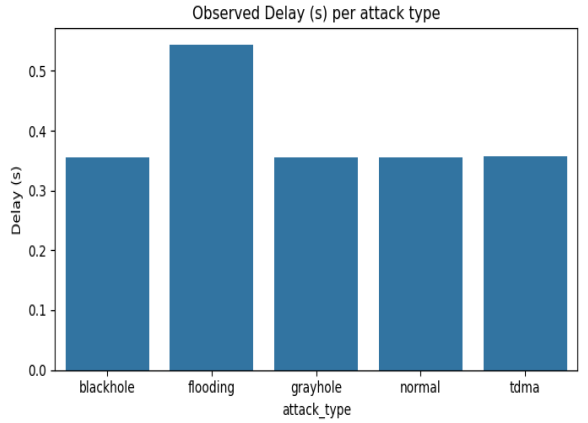

Fig. 7. Delay variation per attack type.

V. Analysis and Discussion

The experiment's outcomes are evaluated and explained from two perspectives: machine learning metrics and network metrics.

A. Machine Learning Metrics

In terms of machine learning model metrics, our approach surpassed both Deep Neural Network (DNN) and the previous study Hyper_RNN_SVM, cited in paper [13], as demonstrated by the simulation results (Fig. 2), which attained 97% accuracy and 96% precision. Also, high accuracy indicates that the IDS's detections are trustworthy.

- Accuracy for Classification Performance (see Fig. 3)

Both models demonstrate high and nearly identical accuracy, with mean values around 97%.

HGBoostUCAD: 0.97969; DNN: 0.97855

- Precision and False Alarm Behavior

Precision reflects the model's ability to avoid false positives (normal traffic misclassified as attacks).

HGBoostUCAD: 0.96236; DNN: 0.96121

The gradient-boosting ensemble performs slightly better than the DNN in preventing false alarms, according to the HGB's marginally higher precision. Because HGB builds additive trees that effectively divide local areas of feature space, it may be naturally resistant to noisy or non-linear feature interactions.

- Recall and detection sensitivity

Recall measures the ability to detect actual attacks (true positives). Both models again perform at a similar level:

HGBoostUCAD: 0.97969; DNN: 0.97855

The nearly equal recall results show that both approaches successfully identify malicious activity, indicating that neither one has significant insufficient detection.

- F1 score and balance of metrics

The compromise between missed detections and false alarms is taken up by the F1-score, which is the balance of precision and recall. The nearly identical F1-scores confirm that both models maintain an excellent balance between sensitivity and specificity, with our model HGBoostUCAD having a slight advantage.

HGBoostUCAD: 0.97090; DNN: 0.96973

B. Network Performance Metrics

We have selected four network performance parameters—energy consumed, packet delivered ratio, packet delivered delay and throughput of network communications,—that can function as essential evaluation metrics according attack type since the aim of DoS attacks is to render a target unreachable and isolated from the rest of the network. Also, to enhance comprehension of the results analysis and discussion, we describe the following network metric indicators below:

1) Energy: It is the total quantity used for data/control packet exchange by all nodes. The network will be less effective and have a shorter lifespan with high energy consumption, and vice versa [24].

2) Packet Delivery Ratio (PDR): It is calculated by dividing the total number of successfully delivered packets to the destination node or nodes by the total number of packets that were originally sent. A higher PDR means that there is less packet loss in the network [24]. When malicious traffic attacks the network, packet loss that affect PDR grows. To determine

how much legal traffic is impacted by the attack and how many data packets fail to reach their destination, the simulation assesses packet loss [25].

3) Packet Delivery Delay (Delay): The entire amount of time required for a packet to be transmitted from the sender to its successful delivery at the final destination node [24]. When servers are overloaded with fraudulent traffic, delay increases significantly, making it impossible for the server to react quickly to legitimate requests [25].

4) Average throughput: Throughput is a direct indicator of the network's capacity to manage traffic both normally and under attack. High-intensity volumetric attacks typically overload the network bandwidth, significantly decreasing it [25]. It is defined as average number of packets that the base station successfully receives in a given amount of time. Bits per second are used to measure it [26].

a) Flooding attacks: A smaller PDR (Fig. 5) usually leads to many retransmissions and congestion, which increase delays as seen in (Fig.7) and energy consumption (Fig. 4).

b) Blackhole attacks: significantly reduce throughput by greatly (Fig. 6) often impacted by congestion near the sink. Also, this attack type reduces PDR (automatically lost packets) (Fig. 5) and increase delay (Fig. 7).

c) Scheduling and Grayhole attack: IDS finds it challenging to identify attacks like Scheduling and Grayhole, which causes a slight reduction in performance (Fig. 5, Fig. 6) while maintaining efficiency on PDR concerning TDMA schedules.

In summary, the flooding attack caused more energy dissipation and increased delay than the three other DOS attacks, while the black hole attack provoked a significant diminution of both the packet delivery ratio and the throughput compared to TDMA schedules. Although our approach is effective in detecting malicious activity, as evidenced by accuracy and precision values, it has weaknesses, which are first evident in the actual scenario's implementation, which is constrained by various real-world constraints, and then in the UWSN dataset's unavailability in contrast to the WSN.

VI. Conclusion

In conclusion, this work enables it possible to implement a cyberattack detection on UWSN using an adjusted WSN-DS dataset and a histogram gradient boosting technique with a type of ensemble machine learning suitable for classification category; to incorporate environmental adaptation: temperature, salinity, depth, and mobility; to prove the efficacy of the suggested method in comparison to similar approaches; in fact, our approach outperformed both the Deep Neural Network (DNN) and the previous study Hyper_RNN_SVM, as illustrated by the simulation results; to provide metrics model (Accuracy, Precision, Recall, and F1 score); to show how network performance varies depending on the type of attack., and to offer an adaptive helpful model for future research to enhance performance and successfully address potential UWSN security issues. Extended research on various attack types and machine learning classifiers aims to enhance resource efficiency and accuracy in underwater wireless sensor networks (UWSN) security. Intrusion detection systems (IDS) play a vital role as a secondary defense, monitoring and detecting threats that bypass primary security measures like firewalls or encryption. A critical challenge is managing the resource constraints of sensor nodes—such as battery, memory, and CPU—while maintaining high detection accuracy in WSN-specific IDS.

Conflict of interest: No declaration required. Financing: No reporting required.

Acknowledgment

I want to express my gratitude to Mohammed V University in Rabat's Hight School of Computer Sciences and Systems Analysis for promoting academic researchers. I also want to thank the supervisor, Pr. Amine Berqia and, the co-supervisor Pr. Souad Aouad for their guidance and support.

Human–Technology Interaction in Generative AI: A Theoretical Review of Technology Acceptance and Cognitive Response

Ugur Dagtekin[1], Ahmet Kamil Kabakuş[2]
Lecturer, Banking and Insurance Program, Yozgat Bozok University, Yozgat, Türkiye[1]
Associate Professor, Department of Management Information Systems, Atatürk University, Erzurum, Türkiye[2]

***Abstract*—The rapid rise of Generative Artificial Intelligence (GenAI) has transformed the way humans interact with technology and has revealed cognitive mechanisms that extend beyond the explanatory scope of traditional technology acceptance models, such as the Technology Acceptance Model (TAM), Technology Acceptance Model 2 (TAM2), and the Unified Theory of Acceptance and Use of Technology (UTAUT). This theoretical review examines the combined role of the Technology Acceptance Model (TAM) and Cognitive Response Theory (CRT) in explaining GenAI-related user behaviors. The increasing involvement of GenAI in knowledge production triggers complex cognitive reactions, including cognitive trust, curiosity, ambivalence, epistemic suspicion, and resistance, which fundamentally shape technology acceptance processes. Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines, a systematic literature search was conducted in the Web of Science and Scopus databases. From 3,842 records published between 2014 and 2025, duplicates were removed, and the remaining studies underwent title–abstract and full-text screening. In the final stage, 69 publications were included in the review corpus. The findings indicate that, while perceived usefulness and perceived ease of use remain core determinants of GenAI adoption within the TAM framework, integrating CRT highlights the importance of deeper internal mechanisms, such as cognitive reappraisal, epistemic trust, algorithmic scepticism, cognitive load, and curiosity. Post-ChatGPT literature further emphasizes the influence of anthropomorphic cues and cognitive tension on user attitudes, trust calibration, and engagement. Overall, the combined application of TAM and CRT provides a more comprehensive theoretical lens for understanding GenAI interactions by concurrently capturing cognitive, emotional, and behavioural processes. This integrative approach offers a comprehensive lens for understanding cognitive, emotional, and behavioral processes in GenAI interactions.**

Keywords*—Generative Artificial Intelligence; Technology Acceptance Model; Cognitive Response Theory; Human-AI Interaction; cognitive trust

I. Introduction

A. The Rise of Generative Artificial Intelligence Systems

The rapid advancement of artificial intelligence technologies throughout the 2020s has ushered in a new era marked by the emergence of Generative Artificial Intelligence (GenAI). Unlike traditional analytical AI systems, GenAI models are capable of processing existing data and generating novel content, including text, images, audio, and software code. Prominent examples include ChatGPT, Copilot, Gemini, Midjourney, and Stable Diffusion. These systems extend human cognitive and creative capacities and fundamentally reshape the nature of digital production (Goodfellow et al. [28]; Şahin ve Kardaş [80]). As a result, human–technology interaction has shifted from passive information consumption to collaborative co-creation processes (Shneiderman [77]; Vaswani et al. [87]).

This transformation has triggered substantial cognitive restructuring in how individuals access information, learn, create, and make decisions (Brynjolfsson and McAfee [10]). In educational contexts, for instance, GenAI personalizes learning experiences and simultaneously raises concerns related to cognitive trust, ethical awareness, and critical thinking (Kasneci et al. [42]; Gökçe ve Atik [29]). Despite these advantages, GenAI also introduces cognitive and ethical risks. Overreliance on AI-generated outputs may increase susceptibility to authority bias and weaken reflective judgment (Mitchell and Krakauer [60]; Karagöz [41]). Uncertainties regarding the accuracy, transparency, and accountability of AI-generated content further challenge established mechanisms of cognitive trust (Bender et al. [8]). Accordingly, explaining GenAI adoption requires moving beyond purely behavioral approaches and incorporating cognitive responses, trust, and curiosity into analytical frameworks.

Today, individuals increasingly act as cognitive partners who actively think with, question, and interpret AI systems (Şen [81]). The rise of GenAI, therefore, represents not only a technological milestone but also a profound cognitive transformation that necessitates theoretical models capable of integrating technology acceptance with cognitive evaluation processes.

B. Technology Acceptance Model (TAM), TAM2 and UTAUT

The Technology Acceptance Model (TAM), originally developed by Davis [18], is one of the most influential frameworks for explaining individuals' intentions to adopt new technologies. Its core constructs—perceived usefulness and perceived ease of use—shape user attitudes and behavioral intentions, positioning TAM as a foundational model in information technology adoption research (Dülek et al. [23]; Özdemir ve Yolcu [65]). TAM has been extensively validated across diverse domains, including education (McIlroy et al. [57]), e-government (Özdemir ve Yolcu [65]), mobile

commerce (Erdoğan [27]; Kurtuldu ve Seyhun [46]), and health informatics (Sançar ve Kayserili [73]).

Subsequent extensions led to the development of Technology Acceptance Model 2 (TAM2), which incorporated social influence, voluntariness, experience, and job relevance as additional determinants of perceived usefulness (Venkatesh and Davis [88]). Building on this evolution, the Unified Theory of Acceptance and Use of Technology (UTAUT) integrated performance expectancy, effort expectancy, social influence, and facilitating conditions into a unified explanatory framework (Venkatesh et al. [89]). UTAUT has demonstrated strong explanatory power in contexts such as mobile banking, healthcare, and public services (Erdoğan [26]; Pournik et al. [68]).

However, recent research suggests that traditional acceptance models exhibit important limitations when applied to interaction-based technologies such as GenAI (Ammenwerth [5]; Lee et al. [48]).

- Cognitive reflection and thought processes remain largely external to these models.
- Psychological factors such as trust, curiosity, and emotional responses are treated indirectly rather than as core components.
- Users are primarily conceptualized as behavioral decision-makers rather than cognitive actors.

Consequently, explaining GenAI adoption necessitates enriching TAM and UTAUT with cognitive response-oriented perspectives capable of capturing reflective thinking, trust formation, and evaluative mental processes. Empirical evidence in higher education further suggests that trust should be treated as a foundational (preceding) construct in GenAI adoption. In particular, Strzelecki [79] shows that trust in ChatGPT significantly shapes behavioral intention and precedes traditional acceptance evaluations in the adoption process.

C. Cognitive Response Theory (CRT)

Cognitive Response Theory (CRT), originally introduced by Greenwald [30], posits that individuals generate cognitive reactions—favorable, unfavorable, or neutral—when exposed to persuasive stimuli, and that these internally generated thoughts play a central role in attitude formation and persuasion outcomes. Subsequent work by persuasion researchers further elaborated this perspective by emphasizing that message recipients are active processors who construct internal thoughts, counterarguments, and evaluations rather than passively receiving information (Cacioppo and Petty [13]; Petty et al. [66]; Eagly and Chaiken [24]).

CRT has served as the conceptual foundation for influential persuasion models, including the Elaboration Likelihood Model (ELM) and the Heuristic–Systematic Model (HSM). Owing to its focus on internal thought generation and evaluative processing, CRT has been widely applied across psychology, marketing, political communication, health communication, and educational research.

Within the context of GenAI, cognitive responses are elicited not by static messages but by dynamic, personalized, and context-sensitive interactions. Users continuously evaluate the accuracy, coherence, ethicality, and relevance of AI-generated outputs through ongoing cognitive reflection. These evaluations shape trust, reliance, skepticism, and learning-related outcomes (Riley et al. [70]). Accordingly, CRT offers a powerful theoretical lens for understanding how users interpret, question, and mentally respond to GenAI systems.

D. Need for Theoretical Integration

Taken together, the existing body of research indicates that prior studies on Generative Artificial Intelligence have largely developed along two parallel yet weakly connected streams. One stream primarily applies Technology Acceptance Model–based frameworks to explain GenAI adoption by focusing on perceived usefulness, perceived ease of use, and behavioral intention (Davis [18]; Venkatesh and Davis [88]; Venkatesh et al. [89]). These approaches offer valuable insights into adoption outcomes and usage intentions, yet they tend to conceptualize users mainly as rational decision-makers and provide limited explanations of how users cognitively interpret, evaluate, and respond to GenAI outputs (Ammenwerth [5]; Lee et al. [48]).

A second stream concentrates on cognitive, ethical, and trust-related dimensions such as epistemic trust, cognitive load, curiosity, ambivalence, and skepticism (Petty et al. [66]; Riley et al. [70]; Bender et al. [8]). Although these studies provide rich accounts of internal mental processes, they often examine such mechanisms in isolation and do not systematically integrate technology acceptance structures (Chen et al. [16]; Christodoulou and Zembylas [17]). From a broader cognitive perspective, meaning-making processes are inherently interpretive and context-dependent, suggesting the need for more integrated theoretical frameworks (Tunç ve Görmez [84]). As synthesized through the systematic review process and the classifications presented in Table IV to Table VII, the current literature lacks a comprehensive framework capable of jointly explaining acceptance behaviors and cognitive response mechanisms in the post-ChatGPT context.

The present study addresses this gap by positioning itself as an integrative theoretical review that systematically combines Technology Acceptance Model perspectives with Cognitive Response Theory to capture acceptance evaluation and cognitive–affective processes within a unified analytical lens.

II. Research Questions and Purpose

The primary purpose of this review is to systematically analyze how the Technology Acceptance Model (TAM, TAM2, UTAUT) and Cognitive Response Theory have been used to explain user interaction with generative artificial intelligence systems. By examining the applications, variable structures, and integration potential of these two theoretical perspectives within the GenAI domain, the study seeks to develop a conceptual synthesis that reflects the cognitive, emotional, and behavioral complexity of contemporary AI-mediated interactions.

Traditional Technology Acceptance Models (e.g., TAM, UTAUT) offer strong explanatory power for users' rational attitudes and behavioral intentions toward technology. In contrast, CRT provides insights into individuals' cognitive reactions, trust formation, counter-arguing, and critical evaluation processes. Since GenAI systems shape user

interaction not only functionally but also emotionally, ethically, and cognitively, an integrative approach combining TAM and CRT holds significant potential for developing a more comprehensive understanding of user behavior. Thus, the overarching aim of this study is not merely to summarize the existing literature but to conceptually assess the intersection of TAM and CRT, and evaluate their integrability in the GenAI era.

Accordingly, the specific objectives of this study are as follows:

- O1: To identify which variables, contexts, and technological platforms (e.g., ChatGPT, Copilot, Gemini) are associated with the application of TAM, TAM2 and UTAUT in explaining user interaction with generative AI systems.
- O2: To examine how Cognitive Response Theory has been applied in GenAI research, and how users' cognitive, emotional, and ethical responses to AI-generated outputs have been categorized.
- O3: To evaluate how these two theoretical approaches (TAM/UTAUT and CRT) complement each other and under which conditions they can form an integrative explanatory framework.
- O4: To identify theoretical and methodological gaps in the literature and propose future directions regarding model development, scale construction, and experimental designs.

Based on these aims, the following research questions were formulated:

- RQ1: How have TAM Models (TAM1, TAM2, UTAUT) been used in GenAI-Focused Studies?
- RQ2: To what extent have cognitive response theory (CRT) and other cognitive/emotional reactions been addressed in GenAI-Focused Studies?
- RQ3: What conceptual shifts, user responses, and new variables have emerged in GenAI interactions in the post-ChatGPT period (2022–2025)?
- RQ4: Have TAM and the Cognitive Response Approach been used together, and which theoretical frameworks do such studies adopt?
- RQ5: What theoretical and practical benefits can be gained from integrating TAM and the cognitive response approach in explaining GenAI interactions?

III. Methodology

This study is a systematic review and a meta-analysis–based conceptual analysis that examines the literature on the Technology Acceptance Model (TAM, TAM2, UTAUT) and Cognitive Response Theory within the context of GenAI systems. The primary objective is to determine how these two theories have been applied individually and in an integrated manner, to analyze the new concepts and variables emerging in the post-ChatGPT period, and to develop theoretical orientation proposals for future research.

In this respect, the study not only summarizes the existing literature but also aims to achieve a theoretical synthesis by discussing how technology acceptance and cognitive response processes can be reinterpreted within an integrative model framework.

A. Literature Search Strategy

In this study, a systematic review approach was adopted and structured in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The literature search covered international peer-reviewed academic journals published between 2014 and 2025. The year 2014 was selected as the starting point because the introduction of the Generative Adversarial Networks (GANs) architecture by Goodfellow et al. [28] marked the institutionalization of modern generative artificial intelligence research.

The search process was conducted in the Web of Science (WoS) Core Collection and Scopus databases, using both narrow and expanded keyword strings to reach comprehensive literature on generative artificial intelligence, technology acceptance models, and cognitive response theory. Searches were performed across all text fields (Title, Abstract, Author Keywords, Keywords Plus), and only studies containing terms such as "generative artificial intelligence", "GenAI", "ChatGPT", and "Large Language Models (LLMs)" were included.

These core GenAI terms were combined using the AND operator with technology-acceptance–related concepts ("technology acceptance model", "TAM", "perceived usefulness", "perceived ease of use", "attitude toward use", "behavioral intention") and cognitive-response concepts ("cognitive response theory", "cognitive response", "trust", "curiosity"). The search strings are presented in Table I. The literature search was conducted on WoS and Scopus, and studies of a similar nature but not focused on GenAI were excluded. Access to full texts and construction of the dataset were completed between December 2024 and July 2025.

TABLE I. Search Strings Used to Search Databases

Topic	Search string
Generative Artificial Intelligence	"generative artificial intelligence" OR "generative AI" OR "GenAI" OR "ChatGPT" OR "large language model" OR "LLM"
AND	
Technology Acceptance & Cognitive Response Concepts	("technology acceptance model" OR "TAM" OR "perceived usefulness" OR "perceived ease of use" OR "behavioral intention" OR "attitude toward use") AND ("cognitive response theory" OR "cognitive response") AND ("trust" OR "curiosity")

Within the scope of the study, only open-access, peer-reviewed, and primary research articles were included. The search results were systematically transferred into Excel, and the retrieved records were categorized into eight separate Excel files based on the thematic scope of the research. These files were subsequently merged into a single unified dataset, and duplicate studies were removed to obtain a set of unique records.

The remaining studies were independently evaluated by two researchers. The screening process was conducted sequentially at the title, abstract, and full-text levels, and any disagreements were resolved through discussion. As a result of the eligibility assessment, a total of 69 studies were included for detailed analysis.

B. Inclusion and Exclusion Criteria

In this systematic review, the inclusion and exclusion process was defined in accordance with PRISMA guidelines. The selection of studies was conducted based on specific theoretical, methodological, and accessibility criteria. The aim was to evaluate the relationship between generative artificial intelligence, technology acceptance, and cognitive responses solely through findings obtained from primary empirical research.

1) Inclusion Criteria:

TABLE II. INCLUSION CRITERIA BY CATEGORY

Category	Inclusion Criterion
Scope	The study must examine user interactions with GenAI and include terms such as "generative artificial intelligence," "GenAI," "ChatGPT," or "LLM."
Topic Focus	The study must evaluate concepts within the framework of technology acceptance and cognitive responses (CRT, cognitive response, trust, curiosity).
Theoretical Coverage	The study must include at least one core concept related to technology acceptance theories (TAM components: perceived usefulness, perceived ease of use, attitude, behavioral intention) AND at least one concept associated with the cognitive response approach.
Study Type	Only primary research articles (quantitative, qualitative, or mixed-methods) are included; reviews, editorials, opinion pieces, and conference abstracts are excluded.
Access Type	Only peer-reviewed and full-text accessible articles are included.
Language of Publication	The study must be published in English.
Publication Period	Articles published between 2014 and 2025 are included.

2) Exclusion Criteria:

TABLE III. EXCLUSION CRITERIA BY CATEGORY

Category	Exclusion Criterion
Out-of-scope	Studies not related to generative artificial intelligence (GenAI), or focused solely on classical artificial intelligence / machine learning; studies that do not include the terms "generative artificial intelligence," "GenAI," "ChatGPT," or "LLM" were excluded.
Topic Exclusion	Studies that do not address technology acceptance models (TAM components) or cognitive responses (CRT, cognitive response, trust, curiosity) were excluded.
Theoretical Exclusion	Studies that do not provide a theoretical framework related to technology acceptance, user behavior, or cognitive responses; studies focusing only on technical models, algorithms, or system performance were excluded.
Study Type Exclusion	Review articles, meta-analyses, editorials, book chapters, opinion papers, conference abstracts, short papers and studies without full-text access were excluded.
Access Exclusion	Non–peer-reviewed studies, studies without full-text availability, or archival/document-based works were excluded.
Language Exclusion	Studies published in languages other than English were excluded.
Publication Period Exclusion	Articles published before 2014 were excluded from the scope of the review.

C. Data Collection and Coding Process

The inclusion and exclusion procedures applied in this systematic review were conducted in accordance with the PRISMA flow diagram standards, and the process is summarized in Fig. 1. All records retrieved from the literature search were organized within an Excel-based data management system. Eight separate Excel files created for each search theme were later merged to form a single master dataset. In the initial stage, a total of 3,842 records were retrieved from the Web of Science (n = 2,446) and Scopus (n = 1,396) databases; duplicate records were removed, eliminating 806 repeated studies from the dataset. After this step, 3,036 studies proceeded to the title and abstract screening phase.

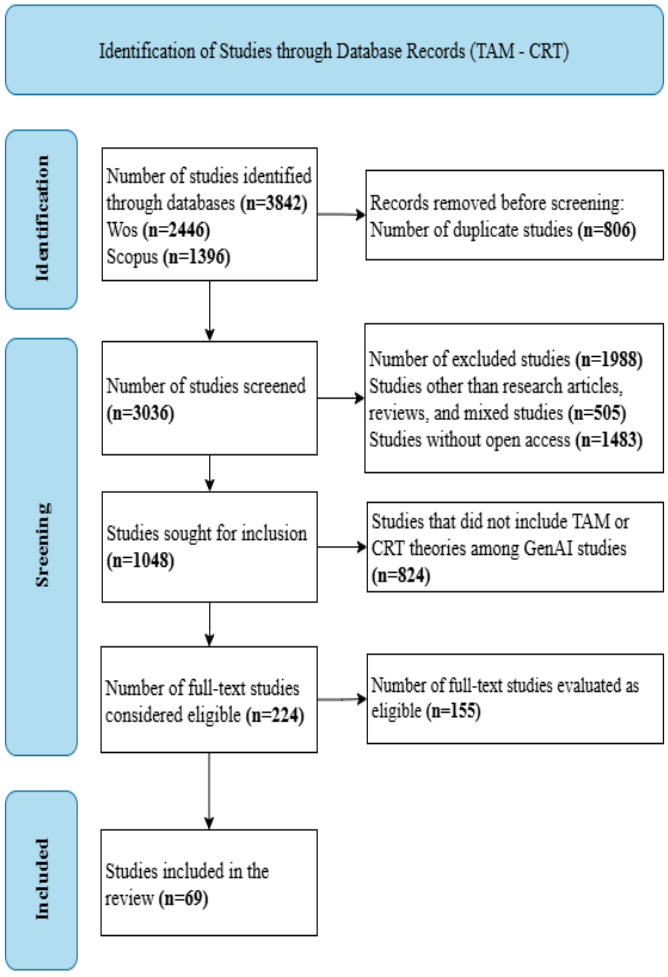

Fig. 1. PRISMA 2020 flow diagram.

In the second stage, studies not meeting the exclusion criteria listed in Table III were removed. Documents that were not research articles, editorials, review papers, records without full-

text access and out-of-scope studies were excluded, resulting in the removal of 1,988 studies. Subsequently, the inclusion criteria defined in Table II were applied. Although GenAI-focused, 824 studies were excluded because they did not contain variables related to technology acceptance models (TAM components) or concepts associated with the cognitive response approach (CRT, cognitive response, trust, curiosity). After these steps, the number of studies eligible for full-text review was finalized as 224.

The full-text evaluation process was conducted independently by two researchers; studies were compared based on their alignment with the GenAI–TAM–CRT framework. Discrepancies were resolved through discussion. As a result of this evaluation, 155 studies that did not meet the criteria for theoretical integration were excluded, and a total of 69 studies were included in the final review. The included studies were entered into a coding table containing variables such as "author(s)", "article title", "publication year", "DOI", "short content summary", and "alignment with the GenAI–TAM–CRT framework". This table enhanced the comparability of the studies and ensured consistency throughout the review analysis.

IV. FINDINGS

A. RQ1: How have TAM Models (TAM1, TAM2, UTAUT) been used in GenAI-Focused Studies?

The consolidated Table IV shows that studies conducted within the GenAI domain largely preserve the theoretical core of the Technology Acceptance Model while simultaneously expanding it with psychological, pedagogical, and social components required by different contexts and user groups. Across all 41 reviewed studies, perceived usefulness (PU) and perceived ease of use (PEOU) remain central constructs for explaining GenAI adoption; these variables consistently emerge as the primary predictors of behavioral intention among students, educators, healthcare professionals, pharmacists, software engineers, and consumers. This continued reliance on PU and PEOU—despite GenAI's dynamic, creative, and nontraditional nature—demonstrates that TAM remains a stable reference framework for modeling technology acceptance. However, the table also makes clear that TAM is rarely used in its "pure" form in GenAI-related research. GenAI systems introduce interactive, unpredictable, creative, and sometimes risk-laden experiences, meaning users interpret these technologies not only through cognitive appraisals (usefulness and ease of use) but also through emotional, ethical, social, and pedagogical evaluations. For this reason, most studies expand TAM with additional variables tailored to the specific context. For example, studies involving faculty members enrich TAM with AI literacy, TPACK, trust, self-efficacy, and instructional fit [21], [31], [35], [43], [50], [52], [64], [75], [83], [96]. These works demonstrate that pedagogical competence, ethical awareness, and trust shape GenAI acceptance beyond the classical PU–PEOU mechanism.

Similarly, studies conducted in consumer and service environments—such as GenAI-supported clothing customization—extend TAM with enjoyment, trust, perceived risk, social influence, and experiential quality [17], [36]. These constructs reflect emotional and social dimensions of GenAI use, including concerns about uncertainty, authenticity, human-like interaction, and the balance between craftsmanship and automation. In such contexts, behavioral intention cannot be fully explained through cognitive evaluations alone, making emotional and experiential constructs essential extensions of the model.

A further pattern illustrated in the table is TAM's hybridization with additional theoretical frameworks. In higher education research, TAM is frequently integrated with TTF, UTAUT, TPB, SRL, SDT, and motivational self-system models [2], [25], [36], [39], [45], [47], [49], [52], [59], [76], [78], [86], [95]. These hybrid models highlight the need to understand GenAI not merely as a technological tool but as a pedagogical, psychological, and social actor. For instance, motivational self-system variables are integrated into PU and PEOU in language learning contexts [36], while studies involving preservice teachers demonstrate that self-efficacy and professional identity meaningfully expand TAM [31], [52].

The diversity of empirical contexts represents another critical finding. GenAI acceptance is examined not only in higher education but also across health sciences, pharmacy, consumer markets, software engineering, public communication, and doctoral research writing. This diversity indicates that TAM's use as a "general-purpose framework" in GenAI studies is not merely a preference but a methodological necessity. For example, GenAI is perceived as an "assistant", "collaborator", or "replacement" in software engineering; large-scale public opinion studies categorize attitudes toward GenAI [56]; and doctoral students' ethical dilemmas concerning GenAI use in academic writing are systematically analyzed [69].

Finally, Table IV shows that GenAI adoption occurs within a far more complex and multi-layered environment than traditional information systems. Although PU and PEOU remain foundational, GenAI introduces constructs such as autonomy concerns, creative control, ethical ambiguity, trust requirements, social comparison, instructional alignment, and task–technology fit. These contextual features necessitate expanding TAM with new domain-specific factors. Overall, the consolidated evidence demonstrates that, in the context of generative AI, the technology acceptance model has evolved into a flexible and adaptive analytical framework. While the structural core of TAM—perceived usefulness and perceived ease of use—remains essential, contemporary GenAI research consistently expands the model with context-specific cognitive, emotional, ethical, and social constructs. These extensions, along with frequent integrations of complementary theories, allow TAM to capture the multi-layered, interactive, and sometimes unpredictable nature of GenAI systems. This shift suggests that understanding GenAI acceptance requires models that go beyond classical rational evaluation and incorporate the dynamic cognitive and socio-emotional mechanisms shaping user interaction.

TABLE IV. TECHNOLOGY ACCEPTANCE–ORIENTED STUDIES ON GENERATIVE AI

ID	Ref.	Author	Theoretical Lens	Context	Key Focus
T4-01	[59]	Mirriahi et al.	TAM + Self-Regulated Learning	Education	SRL–TAM integration
T4-02	[3]	Almeida et al.	Technology Acceptance Model	Recruitment	Professional GenAI acceptance
T4-03	[33]	Haddad et al.	TAM + User Experience	Urban design	Interface usefulness

T4-18	[17]	Christodoulou & Zembylas	TAM + Ethical framework	Education	Emotional–ethical dimensions

B. RQ2: To what Extent have Cognitive Response Theory (CRT) and other Cognitive/Emotional Reactions been addressed in GenAI-Focused Studies?

An examination of CRT-related articles shows that the explicit use of cognitive response theory under its formal name is relatively rare in the GenAI literature. However, the core assumptions of CRT—internal evaluation, mental argumentation, cognitive reframing, and cognitive processing—are widely embedded across studies, as summarized in Table V. The first cluster of work demonstrates that cognitive trust, risk assessment, and epistemic filtering mechanisms prominently shape user responses during GenAI interaction. Studies explaining cognition-based trust and risk modeling in innovation contexts [38], systematically analyzing trust, reliance, and resistance among students [67], and demonstrating how cognitive trust emerges from perceptions of fairness, transparency, and accountability [91] all reveal the production of pro–con arguments, mental modeling of risk, and cognition-based trust—processes that lie at the heart of CRT. Similarly, research centering epistemic trust [74] shows that cognitive filters toward information sources determine trust in ChatGPT, while work examining transparency and ethical signals [15] demonstrates that such cues reduce counter-arguments generated by users. Together, these studies affirm GenAI's strong capacity to trigger cognitive responses. A second group of studies focuses on the cognitive mechanisms that GenAI accelerates or burdens within learning environments. CATLM-based research assessing the interaction between cognitive processing depth and emotional response [55], studies using cognitive presence to show how ChatGPT influences cycles of critical thinking and inquiry [63], and work examining cognitive and emotional reappraisal jointly [96] illustrate how GenAI activates CRT-like inner thought processes during learning—revision, inference-making, restructuring, and doubt generation. In contrast, studies modeling cognitive overload and burnout caused by extensive GenAI use [22], research showing that over-reliance on GenAI undermines active learning processes [12], and analyses distinguishing between deep and superficial cognitive effort [44] highlight the negative dimension of cognitive responses. These findings indicate that GenAI use is linked not only to technology acceptance but also to conflicting processes such as cognitive ease versus excessive cognitive load.

A third cluster addresses cognitive reactions in service and consumer contexts, where pre-existing beliefs, mental models, and service-switching intentions guide user evaluations. Studies showing that prior beliefs shape cognitive reactions to GenAI service failures [55], that the risk–trust–intention chain is influenced by the perceived accuracy of AI-generated health information [32], and that multidimensional trust structures are tied to behavioral outcomes [20] demonstrate how expectations, assumptions, and mental frameworks determine the direction of cognitive responses. These patterns reveal that the same GenAI stimulus can produce highly divergent cognitive outcomes across individuals—tolerance, resistance, abandonment, or re-evaluation.

TABLE V. COGNITIVE AND TRUST-ORIENTED FRAMEWORKS IN GENERATIVE AI RESEARCH

T5-15	[37]	Huang et al.	TAM + Cognitive–Emotional–Social Model	User intention	Integrated acceptance mechanisms

In sum, the reviewed articles ([10], [15], [20], [22], [32], [38], [44], [53], [55], [63], [67], [74], [91], [96]) demonstrate that although CRT has rarely been employed explicitly in GenAI studies, its core sequence—stimulus → cognitive evaluation → behavioral outcome—is reflected across numerous disciplines in different forms. Cognitive trust, cognitive load, cognitive presence, mental models, preconceived beliefs, and cognitive dependency all represent distinct facets of the internal cognitive responses triggered by GenAI stimuli. Collectively, these findings indicate that CRT provides an implicit yet powerful foundation for understanding cognitive mechanisms in GenAI interactions and that future GenAI research can benefit from more explicit and comprehensive CRT-based modeling.

C. RQ3: What Conceptual Shifts, user Responses, and New Variables have emerged in GenAI Interactions in the Post-ChatGPT Period (2022–2025)?

A review of post-2022 ChatGPT-based studies shows a marked transformation in both the theoretical framing of GenAI interactions and the nature of user responses. The most salient feature of this period is the shift from explaining GenAI use solely through technology acceptance models to conceptualizing it increasingly through multilayered processes, including cognitive evaluation, emotional response, moral positioning, institutional security perceptions, anthropomorphic cues, and algorithmic skepticism, as synthesized in Table VI. First, the structure of trust in GenAI systems has been substantially redefined. Across applications ranging from supply chains to institutional data responsibility communication, trust is conceptualized not merely as an assessment of technical accuracy but as a cognitive evaluation anchored in transparency, accountability, institutional responsibility, and data justice [6], [7], [51], [67].

During this period, trust depends not only on perceptions of output accuracy but also on beliefs about system intention, ethical integrity, institutional governance, and the balance of human–AI authority. For example, studies show that clinicians express stronger trust when GenAI is framed not as an authority that replaces judgment but as a secondary cognitive aid supporting human reasoning [32]. Similarly, institutional data responsibility and stakeholder involvement strengthen trust by shaping users' perceptions of algorithmic intention and organizational fairness [51].

Second, a large portion of recent research focuses on cognitive skepticism, ambivalent emotional states, and trust–resistance cycles emerging from GenAI interactions. Studies in educational and consumer contexts demonstrate that individuals simultaneously generate positive and negative internal arguments when encountering GenAI outputs. Ambivalence in student responses to ChatGPT reflects the co-activation of cognitive assessments regarding both academic usefulness and ethical/security risks [17], [58], [75]. Likewise, consumers evaluating human-produced versus GenAI-produced digital outputs exhibit algorithm aversion, driven by cognitive schemas suggesting that GenAI may err, misinterpret context, or lack aesthetic intention [71]. These findings indicate that users' judgments are shaped not simply by performance but by cognitive evaluations of whether the system possesses human-like qualities, intentionality, and accountability [11], [82], [86].

Third, the 2022–2025 literature highlights the emergence of new cognitive reaction variables triggered by GenAI use. Concepts such as reliance and resistance have been systematically modeled for the first time in GenAI contexts [91], marking a shift toward more nuanced explanatory frameworks. Studies show that high trust can lead to over-reliance that weakens critical filtering, while low trust triggers avoidance and rejection. This trust calibration perspective reveals that users

evaluate GenAI outputs not only in terms of accuracy but also in relation to cognitive autonomy and perceived control.

Fourth, the concept of curiosity has been reconceptualized. Before 2022, curiosity was typically viewed as a stable cognitive trait; however, post-ChatGPT studies show that GenAI interactions can either suppress or stimulate curiosity depending on usage patterns. In STEM contexts, excessive dependence on GenAI can weaken curiosity, whereas integration with inquiry-based or problem-based learning enhances deeper cognitive exploration [38]. Similar patterns appear in design and creative fields, where trust in GenAI interacts with creativity and curiosity: some users perceive GenAI as a tool that enhances creative exploration, while others frame it as a ready-made answer engine that threatens originality [93].

Fifth, several studies analyze how anthropomorphic representations—such as "friendly helper" or "digital assistant"—reshape user cognition [86]. Anthropomorphic cues serve as powerful cognitive triggers that influence user expectations and trust. For some users, these cues generate excessive trust and emotional closeness; for others, they provoke concerns about manipulation or system intention. This suggests that linguistic framing in GenAI systems acts as a cognitive anchor comparable in importance to system performance.

Finally, research examining misinformation and verification processes demonstrates that user perceptions of GenAI are increasingly guided not by classical technology acceptance factors but by constructs such as perceived security, source transparency, institutional responsibility, traceability, and moral agency [40], [51]. This shift indicates that post-ChatGPT GenAI interactions are examined through dimensions of cognitive ethics, institutional trust, moral evaluation, and epistemic accuracy rather than only through performance-based acceptance models.

Overall, the 2022–2025 literature reveals that GenAI interaction has evolved from a technological innovation into a multifaceted phenomenon that reorganizes users' cognitive schemas and reshapes foundational psychological processes such as trust and curiosity. Studies indicate that GenAI can enrich critical thinking while simultaneously fostering automated cognitive shortcuts; strengthen trust while also generating institutional skepticism; stimulate curiosity while also risking its suppression. Consequently, post-ChatGPT GenAI research conceptualizes cognitive responses not as linear outcomes but as dynamic, multidimensional processes shaped by context and system design choices.

D. RQ4: Have TAM and the Cognitive Response Approach been used together, and which Theoretical Frameworks do such studies adopt?

The systematic review indicates that although technology acceptance models are widely used in GenAI-focused research, their integration with the cognitive response approach remains highly limited. Most studies employing TAM or extended TAM frameworks continue to emphasize traditional constructs such as perceived usefulness, perceived ease of use and behavioral intention, while cognitive or cognitive–affective evaluation processes are typically examined under separate theoretical lenses. Within the reviewed dataset, only three studies were identified that explicitly combine TAM and the cognitive response approach within a single theoretical model, as summarized in Table VII. This highlights a notable conceptual gap in the GenAI literature.

The first of these studies is conducted by Ma et al. [55], who integrate the Extended TAM with the cognitive–affective model to examine how GenAI-induced cognitive reappraisal and perceived empathy contribute to sociocultural adaptation. Their findings indicate that cognitive responses are not merely supplementary to technology-use intentions but constitute fundamental mechanisms that enhance explanatory power. This demonstrates how cognitive and affective processes can strengthen TAM structures in GenAI contexts. The second study, Zou et al. [96], combines TAM with the cognitive–affective theory of learning (CATLM) to investigate how GenAI-based visualized feedback influences students' writing processes. The results show that GenAI feedback affects not only perceived usefulness but also deeper responses such as cognitive willingness and emotional reactions. This work underscores the potential of integrating cognitive response mechanisms into TAM to yield richer models of GenAI acceptance in learning environments. The third study, Huang et al. [36], focuses on consumer behavior and unites TAM with cognitive–emotional evaluation constructs. In GenAI-supported personalized services, behavioral intention is shown to derive from both cognitive appraisals (e.g., perceived usefulness) and emotional value. This approach illuminates how psychological and affective dimensions intersect with technology acceptance, thereby enhancing TAM's predictive capacity for consumer contexts.

Taken together, these three studies represent the limited but illustrative attempts to jointly apply TAM and the cognitive response approach in GenAI research. Their findings reveal that cognitive response processes—such as reappraisal, cognitive willingness, and integrated cognitive–emotional evaluations—provide substantial explanatory power for understanding technology acceptance. However, this integration is not yet a dominant trend, suggesting that the inherently cognitive and affective nature of GenAI interactions calls for more systematic incorporation of cognitive response theories into technology acceptance models. This need points toward promising avenues for future theoretical development.

TABLE VII. COGNITIVE–AFFECTIVE PERSPECTIVES ON GENERATIVE AI USE

ID	Ref.	Author	Theoretical Lens	Context	Key Focus
T7-01	[55]	Ma et al.	Cognitive–Affective Model (CAPS + COR)	International students	Sociocultural adaptation via GenAI
T7-02	[96]	Zou et al.	CATLM (Cognitive–Affective Theory of Learning)	EFL writing / HCI	Emotion-enhanced learning outcomes
T7-03	[36]	Huang et al.	Cognition–Emotion Integrated Model	Consumer services	Cognitive–emotional acceptance

E. RQ5: What theoretical and practical benefits can be gained from Integrating TAM and the Cognitive Response Approach in explaining GenAI Interactions?

The systematic review indicates that, although technology acceptance models are widely used in GenAI-focused research, their integration with the cognitive response approach is still very limited. Most studies employing TAM or extended TAM frameworks continue to emphasize traditional constructs such as perceived usefulness, perceived ease of use and behavioral intention, while cognitive or cognitive–affective evaluation processes are usually examined using different theoretical perspectives. Only three studies were identified within the dataset that explicitly combine TAM and the cognitive response approach within a single theoretical model. This highlights a notable conceptual gap in the GenAI literature. The first of these studies integrates the Extended TAM with the cognitive–affective model to examine how GenAI-induced cognitive reappraisal and perceived empathy contribute to sociocultural adaptation. The findings suggest that cognitive responses are fundamental mechanisms that enhance explanatory power, rather than merely supplementary to technology-use intentions. This shows how cognitive and affective processes can reinforce TAM structures in GenAI contexts.

The second study (96) combines TAM with the cognitive–affective theory of learning (CATLM) to investigate how GenAI-based visualized feedback influences students' writing processes. The results show that GenAI feedback affects not only perceived usefulness, but also deeper mechanisms, such as cognitive willingness and emotional reactions. Together, these studies highlight the potential of integrating cognitive response mechanisms into TAM to create more comprehensive models of GenAI acceptance in learning environments. The third study [36] combines TAM with cognitive–emotional evaluation constructs in order to examine behavioral intention in GenAI-supported personalized services. The findings demonstrate that behavioral intention derives from both cognitive appraisals (e.g., perceived usefulness) and emotional value. This illustrates how psychological and affective dimensions intersect with technology acceptance, thereby enhancing TAM's predictive capacity in consumer contexts. Taken together, these three studies represent limited but illustrative attempts to apply TAM alongside the cognitive response approach in GenAI research. Their findings reveal that cognitive response processes, such as reappraisal, cognitive willingness, and integrated cognitive–emotional evaluations, provide substantial explanatory power for understanding technology acceptance. Nevertheless, this integration is not yet a dominant trend, suggesting that the inherently cognitive and affective nature of GenAI interactions necessitates the systematic incorporation of cognitive response theories into technology acceptance models. This points towards promising avenues for future theoretical development.

V. DISCUSSION

This systematic review demonstrates that interactions with Generative Artificial Intelligence cannot be fully explained through traditional technology acceptance frameworks alone. The findings indicate that users engage in layered evaluative processes that extend beyond the classical Technology Acceptance Model constructs of perceived usefulness and perceived ease of use. Across diverse contexts, including cultural adaptation (Ma et al. [55]), learning processes (Zou et al. [96]), and consumer decision-making (Huang et al. [36]), similar cognitive–affective dynamics emerge. Despite contextual variation, users consistently rely on processes such as

reappraisal, emotional regulation, cognitive willingness, and anthropomorphic meaning-making. These patterns suggest that GenAI interactions are grounded not only in functional evaluations but also in complex cognitive and affective mechanisms.

This tendency aligns with broader conceptual shifts in the literature in which GenAI is increasingly framed not merely as a technological tool but as a partner advisor or cognitive support entity. Ma et al. illustrate how users integrate GenAI into personal and cultural adjustment processes through positive reappraisal, while Zou et al. [96] show that GenAI-supported feedback enhances learning performance, emotional responses and cognitive motivation. Together, these findings indicate that GenAI interactions operate within a domain where cognitive and affective processes are inseparable.

The results further reveal the limited explanatory power of standalone technology acceptance models in GenAI contexts. Traditional TAM assumes relatively low cognitive demand and predictable user evaluations. In contrast, GenAI requires users to engage in more complex cognitive processes. As shown by Huang et al. [36], consumer decisions are shaped by both cognitive and emotional factors, which exposes the limitations of TAM's rationalistic assumptions in high-cognitive-demand environments. Unlike conventional technologies, GenAI users must simultaneously decide on adoption and evaluate the accuracy, human-likeness, trustworthiness, and cognitive boundaries of AI-generated outputs. Such multidimensional processes are more effectively captured through cognitive response approaches. A key insight emerging from RQ4 is that only three studies within the reviewed dataset, namely Ma et al. [55], Zou et al. [96], and Huang et al. [36], systematically integrate TAM with cognitive response theory. Each study independently demonstrates that cognitive–affective processes significantly influence GenAI usage intentions. Considered together, these studies suggest that GenAI reshapes the psychological foundations of technology acceptance by shifting decision-making toward cognitive evaluation, emotional reaction and personal meaning construction.

The theoretical implications discussed under RQ5 further clarify why TAM and cognitive response theory complement each other. While TAM explains the structural components of user decisions, such as usefulness, ease of use, and intention cognitive response theory captures the internal mental processes, including deliberation, reappraisal, emotional regulation and cognitive motivation. Integrating these perspectives enables a more comprehensive explanation of both the external predictors of behavior and their internal cognitive logic. For example, the reappraisal mechanisms identified by Ma et al. [55] illuminate adaptation processes beyond the explanatory scope of TAM. Zou et al. [96] show that cognitive willingness shapes learning intentions, while Huang et al. [36] emphasize the role of emotional value in enriching the affective dimension of technology acceptance.

VI. Conclusion

This study concludes that explaining Generative Artificial Intelligence interactions requires moving beyond standalone technology acceptance models. The findings demonstrate that the cognitive and emotional reactions elicited by GenAI are integral components of technology acceptance rather than peripheral influences. Integrating Technology Acceptance Model perspectives with cognitive response theory therefore provides a more robust framework for understanding how users evaluate trust interpret outputs and form usage intentions. By synthesizing prior research through a systematic review, this study contributes a multidimensional perspective on human–GenAI interaction that captures behavioral, cognitive and affective processes simultaneously. From a theoretical standpoint, the integration of TAM and cognitive response theory clarifies why GenAI demands more intensive cognitive evaluation than earlier technologies. From a practical perspective, it supports the design of GenAI systems that are sensitive to user psychology, reduce cognitive load, balance emotional responses, and strengthen trust.

Overall, this research highlights the need for future studies to develop integrative models that explicitly incorporate cognitive–affective mechanisms into technology acceptance research. By making the multidimensional nature of GenAI explicit, this study offers a theoretically grounded contribution that advances current understanding and aligns with the expectations of advanced academic research.

***Abstract*—The high dimensionality of modern datasets presents significant challenges for machine learning, including increased computational cost, model complexity, and risk of overfitting. This study introduces a metaheuristic framework for optimized dimensionality reduction to identify the highly discriminative feature subsets. The proposed method (KDR-PSO) combines a Particle Swarm Optimization (PSO) algorithm with the K-Nearest Neighbors Distance Ratio (KDR) as a filter-based objective function. This metric quantitatively assesses class separability within a feature subspace by computing the ratio of the average distance from a sample to neighbors in other classes versus those in its own class. Maximizing this ratio with a penalty for model size, KDR-PSO automates the discovery of parsimonious feature sets that maximize inter-class discrimination. The method is computationally efficient, naturally lending itself to multi-class classification and avoiding the prohibitive cost associated with classifier-in-the-loop wrappers. Experimental results on benchmark gene expression and image datasets show that KDR-PSO can achieve better dimensionality reduction compared to baselines and other algorithms, such as winning a better or at least similar performing models with decreased features. This approach is a strong and pragmatic technique to improve the model interpretability and generalizability for high-dimensional regions.**

***Keywords*—Dimensionality reduction; Particle Swarm Optimization; metaheuristics; K-Nearest Neighbors; class separability; high-dimensional data**

I. Introduction

The curse of dimensionality is a well-known problem in modern machine learning, especially in fields such as bioinformatics, computer vision, and text mining, where datasets often contain thousands of features with comparatively few samples. The main objective of the Feature selection (FS) is to select the most informative subset of features, which leads to models that are simpler, faster to train, less prone to overfitting, and more interpretable [1].

FS techniques are basically categorized into three types, which are filter, wrapper, and embedded methods [2]. Filter methods, such as correlation, mutual information, and variance-based selection, are computationally active but ignore feature interdependencies or classifier behavior [3]. Wrapper methods—such as recursive feature elimination (RFE) or evolutionary search guided by classifier accuracy— can accomplish higher predictive performance, but with high cost for training the repeated model, which becomes unreasonable in high-dimensional datasets [4,5,6]. Embedded techniques, such as Least Absolute Shrinkage and Selection Operator (LASSO), integrate feature selection into model training but depend basically on model choice [7].

In the last several years, metaheuristic optimization has become important in feature selection for its ability to examine large search spaces effectively [8, 9]. One of these metaheuristic optimizations is a PSO, a population-based metaheuristic, that has been successfully adapted for wrapper-based feature selection [10] and its binary variants (BPSO) that have been widely selected due to their simple execution and powerful global search abilities [7,11]. The requirement for classifier retraining via cross-validation for every fitness evaluation, which results in a high computational cost, is a significant drawback of conventional PSO-based wrappers [8].

New studies have tried to address this drawback by hybridization and adaptive mechanisms [1], but getting an optimal trade-off between search quality and computational efficiency remains challenging. To control this limitation, we suggest KDR-BPSO, a hybrid metaheuristic framework that maintains the exploration power of BPSO while deleting the classifier-in-the-loop dependency. The method introduces a KDR as a filter-based, model-free objective function that measures class separability directly inside a subspace of features. Specifically, KDR calculates the ratio of the mean distance between samples and their nearest neighbors of other classes to the mean distance within their own class—motivating subsets that maximize inter-class distance and minimize intra-class variability. By optimizing this ratio by a dimensionality penalty, KDR-BPSO automatically finds dense and discriminative feature subsets without repeated classifier training.

This approach extends across the gap between filter efficiency and wrapper accuracy, introducing a computationally scalable, multi-class-capable, and interpretable solution for high-dimensional feature selection. Empirical studies on gene expression and image datasets demonstrate that KDR-BPSO gains better and superior performance compared to traditional filter, wrapper, and embedded methods while basically reducing feature dimensionality and runtime [7, 11, 12]. The proposed framework gives a robust, efficient, and generalizable tool for dimensionality reduction in modern data-intensive applications. The KDR metric directly measures the inherent separability of classes in the selected feature space. By leading the PSO swarm to maximize KDR, the proposed method efficiently gets the optimal feature subsets, that are

optimal for distance-based classifiers (like KNN itself) and useful for other classifiers, without the computational cost of inner model training. This lines up with some of the recent efforts in joining distance-based separability metrics with metaheuristic feature selection techniques to enhance performance on high-dimensional problems [1, 5, 10].

The proposed feature selection methodology combines Binary Particle Swarm Optimization with a novel K-nearest neighbor Distance Ratio fitness function. The framework is designed to select the optimal feature subsets that maximize the classification performance simultaneously, improve geometric separability, and keep feature parsimony. The proposed approach faces limitations of conventional filter and wrapper methods by combining both statistical and geometric criteria into a unified optimization framework.

The basic innovation reflected in the multi-objective fitness function that balances three critical sides of feature quality: predictive accuracy measured through cross-validation, class separability measured via distance ratios, and subset compactness enforced through regularization. This evaluation confirms that the selected features obtain high classification performance and show strong discriminative characteristics in the reduced feature space.

The rest of this study proceeds as follows: Section II reviews the related work. Section III describes the complete PSO-KDR framework, including an overview of the Particle Swarm Optimization (PSO) algorithm and the corresponding implementation procedure, followed by Section IV that presents a description of the datasets used and the experimental results and analysis. Finally, Section V concludes the study.

II. Related Work

Recent Dimensionality reduction and Metaheuristic-based feature selection have been widely studied over the past years. Particle Swarm Optimization (PSO) was one of the most frequently used search strategies. Modern systematic reviews emphasized both understanding of the field and its common limitations. A review contained more than a hundred studies on metaheuristic feature selection and showed that most studies depended on wrapper or hybrid filter–wrapper strategies connected to classifier performance, which can be computationally expensive, as introduced by Al-Shalif et al. [13]. By contrast, Akinola et al. [14] showed that filter-based metaheuristic methods, while more efficient, have been comparatively neglected, particularly in multiclass and high-dimensional scenarios. Bassi et al. [15] noted that existing filter-based approaches typically depend on traditional relevance measures such as mutual information or chi-square statistics rather than directly capturing class separability.

By PSO-driven feature selection, present methods mainly optimize inexplicit distance heuristics or classifier-oriented objectives. Shafipour et al. [16] presented a PSO-based feature selection method that used a particle distance ranking in a multi-objective framework to equate the classification performance and the subset size, but class separability in their approach is addressed indirectly through classification accuracy rather than through an explicit geometric measure. Particle Swarm Optimization (PSO) was used to improve distance metrics for KNN classification, where feature weights were modified to reduce classification errors introduced by Jurecek in [17]. Although effective, this strategy focuses on metric learning instead of selecting a compact feature subset and still relies on classifier evaluation. Recent work, such as Boolean Operator–based Particle Swarm Optimization (BOPSO) feature selection study for emotion analysis introduced by Sharma et al. [18], displayed improvement in the optimization performance, but it continued depending on classifier-based objectives, which constrained computational efficiency and scalability.

For all these studies, direct KNN-based inter-/intra-class distance ratio objectives with integrated feature-count penalties are extremely absent. The proposed KDR-PSO is located as a filter-based, PSO-driven dimensionality reduction method that immediately optimizes class separability through a K-Nearest Neighbors Distance Ratio (KDR). Different from wrapper and hybrid approaches, KDR-PSO rates the candidate subsets using only distance statistics derived from the data, preventing classifier-in-the-loop training. Additionally, it merges a direct subset-size penalty into a single scalar objective, supporting the most close-fisted feature sets without needing post hoc Pareto-front selection.

The proposed work handles a lack of PSO-driven methods that optimize a KNN-based distance–ratio separability measure and feature-set compactness via a purely filter-based framework, mainly for scalable multi-class and high-dimensional problems.

III. Proposed PSO with KDR for Feature Selection

The proposed framework integrates the PSO algorithm with KDR as a fitness function. The goal of the framework is to find the best feature subsets that improve separability and maximize classification performance. The fitness function proposed in this work balances three key aspects of good feature selection: keeping the feature set small, ensuring classes are well separated based on distance ratios, and achieving high prediction accuracy using cross-validation to achieve effective classification and distinguish between different classes.

Fig. 1 illustrates the overall workflow of the proposed KDR-PSO framework for feature selection. Starting from high-dimensional input data, the dataset is first preprocessed and then passed to a PSO mechanism that iteratively explores candidate feature subsets. Each particle, representing a binary feature selection vector, is evaluated using a hybrid fitness function that integrates the KDR, classification accuracy, and a penalty term to control subset size. Guided by personal and global best solutions, the swarm progressively refines the search until convergence, yielding a compact and highly discriminative feature subset that is subsequently used for final classification and performance evaluation.

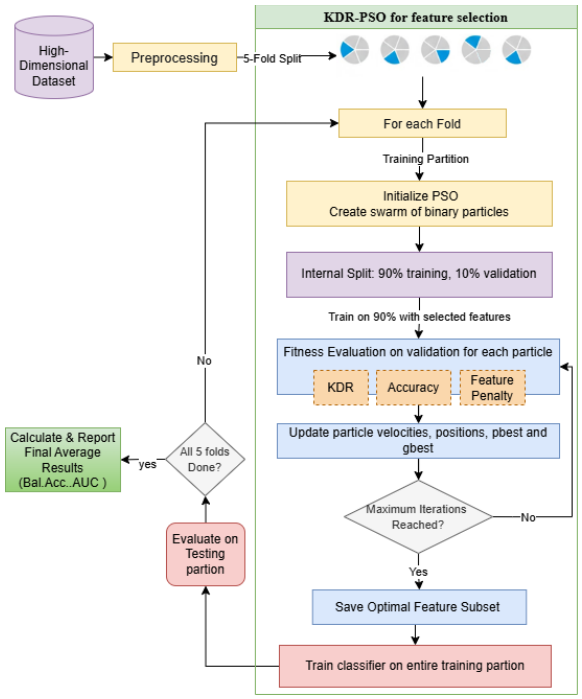

Fig. 1. Proposed KDR-PSO framework.

A. Particle Swarm Optimization

The PSO algorithm begins by giving each particle a random starting point and some initial velocity. As the process goes on, every particle learns from what it has tried before and from the results of nearby particles. Step by step, they move closer to a good solution. In PSO, each particle stands for one possible set of features in the search space, and its position is written as a binary vector $x_i = (x_{i1}, x_{i2}, \ldots, x_{iD})$, where D is the total number of features in the dataset, and $x_i \in \{0,1\}$ indicates whether the jth feature is selected (1) or not selected (0). The velocity of particle i is denoted as $v_i = (v_{i1}, v_{i2}, \ldots, v_{iD})$, which determines the probability of changing the feature selection state.

A predefined maximum velocity (v_{max}) restricts the velocity of particles within a certain range $v_{id}^t \in [-v_{max}, v_{max}]$ to maintain stability. Each particle memorizes its best previous position as personal best (*pbest*), and the best position found by the entire swarm is referred to as global best (*gbest*). The velocity and position of each particle are updated according to the following Eq. (1) and Eq. (2) [19]:

$$v_{id}^{(t+1)} = w \times v_{id}^t + c_1 \times r_{1i} \times (p_{id} - x_{id}^t) + c_2 \times r_{2i} \times (p_{gd} - x_{id}^t) \quad (1)$$

$$x_{id}^{(t+1)} = \begin{cases} 1, & \text{if rand}() < \frac{1}{1+e^{-v_{id}^{(t+1)}}} \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

where, t is the iteration number, w is the inertia weight (decreasing linearly from 0.9 to 0.4), c_1 and c_2 are cognitive and social acceleration constants, respectively, r_{1i} and r_{2i} are random numbers uniformly distributed in [0, 1], p_{id} and p_{gd} represent the dth elements of *pbest* and *gbest*, respectively.

In this study, each particle encodes a binary vector representing feature inclusion or exclusion. If the dataset contains N features, then the position vector length is N. Each bit in the vector takes a value of 1 (feature selected) or 0 (feature not selected). For instance, in a dataset with five features, a possible particle representation could be: x_i= [1, 0, 1, 0, 0]. This means that the first and third features are selected while the others are excluded. The PSO algorithm continuously updates these binary values to maximize the objective fitness function. Algorithm 1 shows the pseudo-code for PSO algorithm for feature selection.

Algorithm 1: Pseudo-code for PSO Algorithm for feature selection.

```
// Initialize swarm
For i = 1 to swarm_size:
    xi = random binary vector with ≥ 2 ones
    vi = random velocity vector
    pbesti = xi  // personal best
    pbest_fitnessi = -∞
End For
// Evaluate fitness based on equation 4 and update the best
For iter = 1 to max_iter:
    For each particle i:
        fitness = evaluate_fitness(xi)
        If fitness > pbest_fitnessi:
            pbesti = xi
            pbest_fitnessi = fitness
        End If
        If fitness > gbest_fitness
            gbest = xi
            gbest_fitness = fitness
        End If
    End For
    For each particle i:
        Update vi //Update velocity based on equation (1)
        Update xi //Update position using sigmoid equation (2)
// Ensure the minimum number of selected features
        While sum(xi) < 2:
            xi[random_index] = 1
        End While
    End For
End For
output gbest
```

B. Proposed PSO with KNN Distance Ratio (PSO_KDR)

Using classification accuracy as the sole objective function in feature selection often leads to overfitting and poor generalization, as it does not explicitly account for the structural separability of data classes. A feature subset may achieve high accuracy on the training data, but fail to maintain clear class boundaries in the feature space. To overcome this, the proposed method uses the K-Nearest Neighbor Distance Ratio as an additional discriminative criterion within PSO. By comparing the average distances between neighbors of the same class and neighbors of other classes, the KDR calculates the relative distance between classes. The algorithm looks for feature subsets that enhance class separability while achieving good prediction performance by combining accuracy and KDR in a hybrid fitness formulation.

The improved fitness design enables the PSO to find compact yet discriminative feature subsets, avoid local optima, and better explore the search space. The suggested method thus

enhances the stability and robustness of the classification of certain features across several datasets. For each sample i, let:

$\bar{d}_{\text{same}}(i)$ is the average distance to K-Nearest Neighbors that belong to the same class.

$\bar{d}_{\text{diff}}(i)$ is the average distance to K-Nearest Neighbors from different classes.

The KDR is calculated as explained by Eq. (3):

$$KDR(S) = \frac{1}{n}\sum_{i=1}^{n} \frac{\bar{d}_{diff}(i)}{\bar{d}_{same}(i)+\epsilon} \quad (3)$$

where, n is the total number of samples and $\epsilon = 10^{-8}$ is a small constant to prevent division by zero. The overall fitness function is calculated as in Eq. (4):

$$F(S) = \beta \times \text{Accuracy}(S) + \alpha \times KDR_{norm}(S) - \lambda \times \frac{|S|}{d} \quad (4)$$

where, *Accuracy(S)* is the classification accuracy evaluated using 5-fold KNN, $KDR_{\text{norm}}(S)$ is the normalized KDR value, $|S|$ is the number of selected features, $\beta = 0.95, \alpha = 0.05$ are weighting factors, and λ=0.001 controls the penalty for subset size.

IV. Experimental Results

A. Datasets and Experimental Setup

Experiments were conducted on ten available datasets to evaluate the proposed method, as summarized in Table I. These datasets are from different application domains, including biomedical, financial, environmental, and computer vision, to achieve an evaluation across different real-world applications.

TABLE I SUMMARY OF DATASETS USED

Dataset Name	Domain	Samples	Features	Classes	*Reference*
Climate_model	Climate	540	18	2	[20]
Credit	Finance	690	14	2	[21]
Heart	Medical	270	13	2	[22]

Leukemia	Gene Expression	72	7,129	2	[24]
QSAR	Chemistry	1,055	41	2	[25]
Satellite	Remote Sensing	6,435	36	6	[26]
Segment	Computer Vision	2,310	19	7	[27]
Splice	Bioinformatics	3,190	62	3	[28]
Vehicle	Object Recognition	846	18	4	[29]

The datasets used in this study vary widely in both size and structure — from small medical datasets with only a few samples to large, high-dimensional gene expression datasets containing thousands of features. This diversity shows the effectiveness of the proposed feature selection method. All experiments were performed on a desktop computer equipped with an Intel Core i7 processor, 16 GB of RAM, and a 64-bit Windows operating system. The proposed KDR-PSO algorithm, along with all comparative methods, was implemented using the Python programming language.

The KNN with k=5 was employed, and performance assessed using 5-fold stratified cross-validation. The parameters of the PSO-KDR algorithm were determined through an iterative sensitivity analysis: initial parameter ranges were adopted from the literature, then testing of multiple values across preliminary runs to identify the optimal configuration. The finalized parameters, fixed for all experiments, are as follows:

- swarm size= 20
- maximum iterations = 40.
- w (inertia weight) from 0.9 to 0.4 decreased each iteration.
- c1=c2=2 (acceleration coefficients)
- α=0.05 and β=0.95 (The fitness function weighting factors)
- λ=0.001 (small penalty factor).

B. Results and Analysis

The Results performed using 5-fold cross-validation on ten publicly available datasets. The performance comparison includes Balanced Accuracy (Bal. Acc), F1-Score, Precision, and AUC (Area Under the Curve). Also, the number of selected features (Features). For each metric, the mean ± standard deviation is presented. The best results for each metric are highlighted in bold. The comparison includes four methods:

1) Baseline: KNN using all features without selection.
2) Filter (IG): Features selected based on Information Gain ranking, independently of the classifier.
3) PSO: Particle Swarm Optimization for feature selection.
4) PSO-KDR: The proposed method combining PSO with the KDR-based fitness function.

As shown in Table II, the PSO-KDR outperforms other methods across most tested datasets in terms of classification accuracy and feature selection, where PSO-KDR using Leukemia dataset achieves Bal. Acc of 0.962 ± 0.006, overperforming PSO (0.920 ± 0.025) and the filter-based approach (0.882 ± 0.033), while maintaining a compact subset of features. In addition, the Heart and Credit datasets, PSO-KDR demonstrates superior F1-scores and AUC values.

In terms of feature selection, PSO-KDR identifies smaller feature subsets compared to the baseline, where in the Climate_model dataset, it reduces the feature count from 18 to around 7 while improving the AUC from 0.797 to 0.881. PSO-KDR maintains high performance stability across all datasets, as indicated by its relatively low standard deviations.

A t-test conducted between PSO-KDR and the PSO across all datasets, the results show a statistically significant improvement in Bal. Accuracy with $p < 0.05$ for 8 out of 10 datasets. The results show that PSO-KDR achieves trade-off between feature selection and classification performance, indicating its adaptability to diverse datasets.

Fig. 2 illustrates the convergence behavior of PSO-KDR compared to PSO method across three datasets (Leukemia, Heart, and Climate_model).

TABLE II COMPREHENSIVE PERFORMANCE COMPARISON OF FEATURE SELECTION METHODS

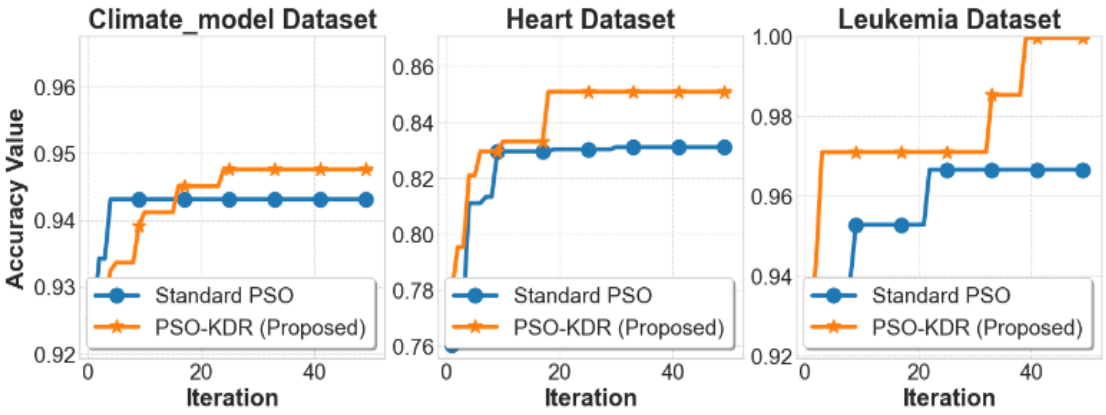

Fig. 2. Convergence curves of standard PSO vs. PSO-KDR.

The convergence curves show that PSO-KDR achieves faster and smoother fitness improvement over iterations that due to the guidance provided by the KDR that effectively balances global exploration and local refinement during the optimization process.

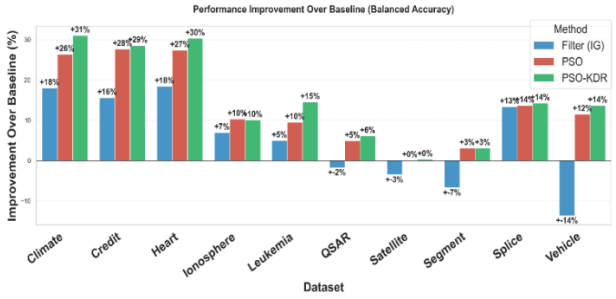

Fig. 3. Comparison of improvement over baseline.

As illustrated in Fig. 3, the comprehensive performance analysis across ten datasets shows the efficacy of various feature selection methods. Across the most tested datasets, all three evaluated feature selection techniques showed positive performance gains, with the most pronounced improvements observed in the Climate Model, Credit, and Heart datasets. The maximum performance enhancement reached +31.0% by PSO-KDR on the Climate_Model dataset.

PSO and its enhanced variant, PSO-KDR, show consistent superiority compared to conventional filter methods that achieved the maximum performance improvement across four datasets (Climate_model, Heart, Leukemia, and Vehicle), and the IG filter method exhibited inconsistent behavior, with performance degradation observed in certain datasets, such as Vehicle and Segment.

Fig. 4 shows the analysis of selected feature subset sizes across ten datasets. To handle high-dimensional datasets, the logarithmic scale is used. The minimal subsets across most of the datasets were selected by using the IG filter method, but its independence from classifier behavior sometimes caused performance unreliability, as shown in datasets such as Segment and Vehicle, which feature elimination causes less accuracy. The PSO and PSO-KDR wrapper methods gave more balanced feature selection behavior, keeping slightly larger but more discriminative subsets to maximize classification accuracy. This drift is usually evident in QSAR and Satellite, where keeping a moderate number of features gave higher results. The average computation time of the proposed KDR-PSO method ranged from approximately 3 to 8 seconds for low- and medium-dimensional datasets and from 2 to 6 minutes for high-dimensional gene expression datasets, depending on the number of features and optimization iterations.

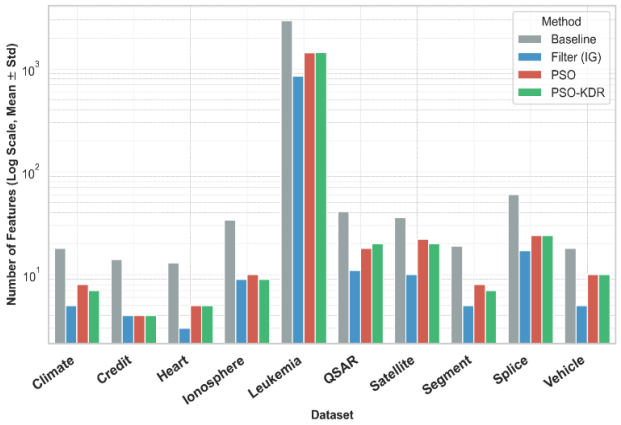

Fig. 4. Feature reduction comparison (Log scale).

PSO-KDR outperforms baseline, filter, and standard PSO methods by selecting compact, relevant feature subsets while improving classification performance. This shows that the KDR-based fitness function effectively balances feature relevance and predictive accuracy, especially on high-dimensional datasets. However, although effective, the proposed KDR-PSO method has some limitations. As a population-based optimization approach, its computational cost increases with data dimensionality and the number of PSO iterations.

V. Conclusion

This study proposed KDR-PSO, a new hybrid feature selection method that merges the global search capability of Binary Particle Swarm Optimization (BPSO) with a filter-based KNN Distance Ratio (KDR) objective function. The obtained results showed reaching the optimal balance between computational efficiency and feature selection performance in

the proposed algorithm KDR-PSO, that keeping high accuracy and clarity across various datasets.

In terms of classification accuracy and feature reduction, the proposed KDR-PSO method showed excellent performance, as shown by the values of the evaluation metrics F1-score, AUC, and precision. KDR-PSO joined filter-based techniques with a wrapper framework so it can handle strongly the computational limitations related to the wrapper techniques and make it practical for high-dimensional data. Furthermore, the proposed KDR-PSO got significant feature proximity while maintaining or improving the classification performance and selecting the minimum number of features. The logarithmic-scale comparisons of feature counts over datasets revealed and emphasized the wide variation in feature dimensions. The basic contribution for this work is building KNN Distance Ratio multi-Objective, that works as an effective mechanism for PSO search phases, accelerating in superior and low-cost computations for effective feature subset selection.

This study introduced successful implementation of KDR-PSO, that will be strong basis for a lot of future work. The expected research can include studying alternative distance metrics, expanding adaptive penalty terms, and executing the method to emerging domains that need efficient feature selection for high-dimensional data. This work introduces valuable advancement in terms of the feature selection literature, covering the gap between the strengths of filter and wrapper methods.

***Abstract*—Since the Ministry of Ecology and Environment issued the "Reform Plan for the System of Environmental Information Disclosure in Accordance with the Law" in 2021, the nation has set forth new requirements for sustainable development. Against this backdrop, how enterprises enhance their value across all dimensions through ESG in compliance with national mandates holds significant implications for refining ESG management systems. This study employs DEA-CCR-GML and inverse DEA models to empirically examine how investments in specific dimensions of ESG's three pillars influence corporate value realization, using data from Shanghai to Shenzhen A-share listed companies from 2019 to 2024. Findings reveal that higher levels of scale efficiency and technical efficiency correlate with greater improvements in ESG scores, while mandatory enforcement of national policies exerts a highly effective driving force on enterprises. Mechanism analysis indicates that firms can enhance ESG score improvement efficiency by elevating scale and technical efficiency, thereby more effectively realizing their intrinsic value.**

***Keywords*—Corporate ESG performance; DEA; financing constraints; green innovation**

I. Introduction

Against the backdrop of the establishment of the National Social Responsibility Bureau (April 2022), policy initiatives by the China Securities Regulatory Commission, and the growing prevalence of ESG principles in China's capital markets, how companies can enhance their ESG ratings to improve governance standards has become a focal point [1]. While existing research predominantly examines the impact of ESG score changes on corporate performance volatility [2], firm value [3], and investor perspectives [4], it rarely explores how companies can more effectively improve their ESG scores by increasing investments in specific areas such as scale efficiency and technical efficiency. To address this gap, this study empirically examines the impact of corporate investments on key indicators and their underlying mechanisms using data from Chinese A-share listed companies from 2019 to 2024.

Zhang et al. demonstrate that corporate ESG measures enhance innovation performance through dual pathways: direct promotion and governance mediation (where strengthened environmental/social governance amplifies innovation). This process is moderated by institutional development levels, providing theoretical foundations and practical insights for sustainable innovation strategies in dynamic institutional environments [1].

Nguyen DT et al. based their study on data from 2,350 U.S. companies between 2018 and 2023, focusing on the heterogeneity of ESG risks (unmanaged risks versus management gaps). They revealed a significant negative correlation between total ESG risk and corporate performance, with the negative impact primarily driven by unmanaged risks (whose effect was approximately eight times that of management gaps). The negative impact of unmanaged ESG risks on performance is most pronounced in the first year and diminishes progressively thereafter. This conclusion holds even after controlling for endogeneity and undergoing multiple robustness tests [2].

Danny Zhao-Xiang Huang's theoretical analysis reveals a three-dimensional dilemma in shareholder ESG investment decisions: valuation conflict (ESG factors are difficult to quantify and integrate into earnings forecasts), the information paradox (ESG can reduce agency information asymmetry, but the validity of signals remains questionable), and the interest conflict (ESG embeds a multi-stakeholder interest game field). He proposes that future research should focus on the conditions under which ESG information triggers effective signals to bridge the cognitive gap in shareholders' long-term value assessment [3].

Avramov, D. et al. empirically demonstrated through the asset pricing equilibrium model and ESG rating discrepancies that ESG uncertainty elevates market premiums and reduces stock demand, driving simultaneous increases in CAPM alpha and effective beta while weakening the negative correlation between ESG and alpha. Supported by standard deviation data from six major rating providers, this study resolves the ESG-return relationship debate, demonstrating that ESG uncertainty distorts the risk-return tradeoff, thereby influencing sustainable investment decisions and social welfare [4].

A. Charnes et al. employed a nonlinear (nonconvex) programming model to address the challenge of efficiency evaluation in public programs for nonprofit entities. They developed a new definition of efficiency, an objective weighting method based on multiple observed output and input

*Corresponding author.

data, an equivalent computational relationship with standard linear programming models, and novel approaches for estimating extremes in dual models. Furthermore, they elucidated the connection between engineering and economics in efficiency assessment, offering fresh interpretations and applications for public project management [5].

Oh and Heshmati proposed a continuous Malmquist-Luenberger index combining a directional distance function with a continuous sequential production possibility set to address the challenge of measuring environmentally sensitive productivity growth, while excluding spurious technical regression from a macroeconomic perspective. They propose that this index exhibits trends similar to the traditional Malmquist-Luenberger index but with distinct decomposition components, and that efficiency changes dominate in the early stages while technological changes dominate in the later stages (based on empirical evidence from 26 OECD countries from 1970 to 2003) [6].

Chen et al. combined a novel counter-envelope analysis (DEA) model with undesirable outputs and a new inverse DEA model. By analyzing the relationships and differences among various objectives and their implementation pathways based on decision-makers' actual needs, they summarized valuable insights for advancing the achievement of China's road traffic safety goals [7, 8].

Lin explores the development prospects, economic benefits, and enabling environment of ESG investing within the context of carbon neutrality policy implementation and China's new development philosophy (green development). The study proposes that ESG has become a key factor in driving low-carbon transformation, assessing corporate performance, and influencing the economy. It aims to explore scientifically efficient methods for developing ESG to promote the transformation and upgrading of the carbon economy [9].

Wang et al. empirically examined the impact of performance-based budgeting (PBB) reforms on corporate ESG performance using quasi-natural experiments and multi-period DID models based on data from Chinese A-share listed companies from 2001 to 2020. Findings reveal that PBB reforms significantly enhance firms' economic and social contributions, with this effect being more pronounced in regions with high fiscal pressure and strong government audits. The impact is particularly significant for government-affiliated enterprises, firms with strong green innovation capabilities, or those facing high financing constraints. The mechanism operates by enhancing environmental governance through increased environmental subsidies and improved fiscal transparency, ultimately improving ESG performance and driving increases in return on assets, price-to-book ratios, and patent grants. This provides empirical evidence for deepening fiscal and tax system reforms and supporting the "dual carbon" strategy [10].

Weston and Nnadi et al. conducted research on the relationship between corporate social responsibility (CSR) and financial performance (CFP), establishing a framework for integrating CSR and environmental, social, and governance (ESG) principles into decision-making. By analyzing samples from the iShares MSCI KLD 400 Social ETF, the iShares Core S&P 500 ETF, and companies adhering to the Principles for Responsible Investment (PRI), the study found that ethical ETFs did not outperform traditional ETFs, but companies following PRI outperformed those not adhering to the principles [11].

Ye and Xu et al. examined the impact and mechanisms of ESG on carbon reduction (green innovation, efficiency, and managerial myopia) using data from China's listed manufacturing firms between 2010 and 2020. They found that ESG significantly reduces carbon emissions, with stronger effects observed in companies facing stricter environmental regulations, intense competition, and high capital intensity. Digital transformation plays a positive moderating role. This research provides new evidence for understanding ESG's emission reduction effects and offers insights for practical and policy approaches to achieving the" dual carbon" goals [12].

II. MODELING

This study employs the DEA-CCR model, the Globe-Malmquist-Luenberger index, and inverse DEA to conduct a scientific analysis of the profitability development efficiency of listed companies in China's A-share market.

A. DEA - CCR Model

There are n decision-making units (DMUs), each with m distinct input indicators and n output indicators. Let Xi denote the input vector for the i-th DMU, and Yi denote the output vector for the i-th DMU. When evaluating the efficiency of each DMU, the CCR model [5] is employed:

$$\begin{aligned} &\max\phi \\ &\text{s.t.} \quad \sum_{j=1}^{n}\lambda_j X_j \le X_0 \\ &\sum_{j=1}^{n}\lambda_j Y_j \ge \phi Y_0 \\ &\lambda_j \ge 0, \quad j=1,2,\ldots,n \end{aligned} \tag{1}$$

B. GML (Globe Malmquist-Luenberger Index) Model Construction

The GML index is constructed by integrating the Directional Distance Function (DDF) with the Global Production Technology Set (GPTS). It inherits the dynamic decomposition framework and relaxed measurement concept of the Malmquist index. By introducing a non-expected output constraint, it quantifies changes in Green Total Factor Productivity (Green TFP) within decision units, which balance expected output growth with reductions in non-expected output across intertemporal dynamics. Using the total production technology set across all study periods as the reference framework, it resolves shortcomings of the ML index such as lack of cyclical transitivity and unsolvability of linear programming [3], enabling more objective and accurate reflection of changes in the financial systems of listed companies. Let $\vec{D}_V^G(xt,yt,bt;g)$ denote the global directional distance function. Then the GML index from period t to period t+1 is defined as [6]:

$$GML^{t,t+1}=\frac{1+\vec{D}_V^G(x^t,y^t,b^t;g)}{1+\vec{D}_V^G(x^{t+1},y^{t+1},b^{t+1};g)} \tag{2}$$

The GML index can be decomposed into four interpretable components: Technical Efficiency Change (*EC*), Scale Efficiency Change (*SEC*), Pure Technical Change (*PTC*), and Scale-Technical Change (*STC*). The specific decomposition is as follows:

$$\begin{aligned}\mathrm{GML}^{t\to t+1} &= EC\times SEC\times PTC\times STC \\ &= \left(\frac{1+\vec{D}_V^{t}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t};\mathbf{g})}{1+\vec{D}_V^{t+1}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1};\mathbf{g})}\right)\times\left(\frac{\mathrm{SE}^{t+1}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1})}{\mathrm{SE}^{t}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t})}\right) \\ &\times\left(\frac{1+\vec{D}_V^{G}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1};\mathbf{g})}{1+\vec{D}_V^{t+1}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1};\mathbf{g})}\cdot\frac{1+\vec{D}_V^{t}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t};\mathbf{g})}{1+\vec{D}_V^{G}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t};\mathbf{g})}\right) \\ &\times\left(\frac{\left[\frac{1+\vec{D}_V^{G}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1};\mathbf{g})}{1+\vec{D}_V^{CRS,G}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1};\mathbf{g})}\right]/\left[\frac{1+\vec{D}_V^{G}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t};\mathbf{g})}{1+\vec{D}_V^{CRS,G}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t};\mathbf{g})}\right]}{\frac{\mathrm{SE}^{t+1}(\mathbf{x}^{t+1},\mathbf{y}^{t+1},\mathbf{b}^{t+1})}{\mathrm{SE}^{t}(\mathbf{x}^{t},\mathbf{y}^{t},\mathbf{b}^{t})}}\right)\end{aligned} \tag{3}$$

C. Inverse DEA Model Construction

Reverse DEA theory extends the boundaries of traditional Data Envelopment Analysis (DEA) through a reverse optimization framework. This approach translates abstract efficiency assessments into concrete action plans, making it suitable for resolving resource allocation disputes in public policy formulation [7]. The core value of Reverse DEA theory lies in addressing two critical issues: goal-oriented resource planning and short-term forecasting under constraints. This study focuses on short-term forecasting under constraints.

The inverse DEA of the output-oriented CRS super-efficiency DEA model is expressed as [8]:

$$\begin{aligned} &\max\varphi \\ &\textstyle\sum_{(j=1,\ j\neq k)}^{n}\lambda_j x_{ji}\le x_{ki}+\Delta x_{ki} \\ \text{s.t.}\quad &\textstyle\sum_{(j=1,\ j\neq k)}^{n}\lambda_j y_{jr}/\varphi_k^{*}\ge\gamma y_{kr} \\ &\lambda\ge 0 \\ &i=1,2,\ldots,p;r=1,2,\ldots,q;k=1,2,\ldots,n \end{aligned} \tag{4}$$

where, ϕ^{*}_{k} represents a known value, i.e., the optimal solution from the original DEA model or a manually set efficiency value; γ^{*}_{k} denotes the optimal solution from the inverse DEA model; $\gamma^{*}_{k}y_{kr}$ signifies the predicted output value; Δx indicates the increase in input quantity; and let Δy denote the increase in output quantity, then $\Delta y=\gamma^{*}_{k}y_{kr}-y_{kr}$.

III. Selection of the Indicator System

To evaluate the effectiveness of the efficiency assessment system, eight corresponding evaluation indicators were established based on the principles of scientific rigor, objectivity, and quantitative analysis, incorporating existing literature [9]. The data sources and their respective origins are detailed in Table I.

TABLE I. Variable Definitions and Data Sources

Indicator type	Indicators	Variant	Unit	Source
Input indicators	Market capitalization	X_1	Ten billion yuan	[8]
	Main revenue	X_2	Ten billion yuan	
	Operating cash flow	X_3	Ten billion yuan	/
	R&D expenditures	X_4	Hundred million yuan	
Output indicators	ESG score	Y_1	/	[8]
	Asset-liability ratio	Y_2	%	
	Total asset turnover ratio	Y_3	Times	/
	Return on total assets	Y_4	%	[8]

IV. Empirical Research

A. DEA Static Analysis

This study covers the period from 2019 to 2024, selecting 10 listed companies from five industries on the Shanghai and Shenzhen stock exchanges as research subjects, with data sourced from the Wind Database. By comparing and analyzing the scale efficiency, pure technical efficiency of technological innovation, and comprehensive efficiency of these 10 listed companies, the study dissects the internal factors influencing changes in corporate ESG scores and provides corresponding recommendations. Comprehensive efficiency values were calculated using the DEArun software, revealing the ESG improvement comprehensive efficiency for the 10 listed companies, as shown in Table II.

TABLE II. Comprehensive Efficiency of ESG Score Improvement for 10 A-Share Listed Companies

	2019	2020	2021	2022	2023	2024
Zijin Mining	0.464	0.266	0.623	0.362	0.228	0.316
China Northern Rare Earth	1.000	1.000	1.000	1.000	1.000	1.000
Beijing Capital Eco-environment	1.000	1.000	1.000	1.000	1.000	1.000
Originwater	1.000	1.000	1.000	1.000	1.000	1.000
Offshore Engineering	1.000	1.000	1.000	1.000	1.000	1.000
Hengli Petrochemical	0.317	0.367	0.602	0.668	0.620	0.579
Fuyao Glass	0.683	0.688	0.645	0.692	0.945	0.900
Conch Cement	1.000	0.737	0.500	0.284	0.329	0.288
999 Pharmaceutical	1.000	1.000	1.000	1.000	1.000	1.000
WuXi AppTec	1.000	0.811	0.737	0.723	1.000	0.936
Average value	0.846	0.787	0.811	0.773	0.812	0.802

Table II shows that the average comprehensive efficiency of ESG score improvement for the 10 A-share listed companies fluctuated between 2019 and 2024, peaking in 2019 before exhibiting an overall downward trend. Over the past six years, the mean comprehensive technical efficiency of the sample companies ranged between 0.773 and 0.846. Although

generally at a high level, it has been decreasing annually, reflecting that, under given resource input conditions, companies still have room for improvement in their comprehensive development in ESG-related areas. Specifically, five companies achieved a comprehensive efficiency score of 1 in each of 2020, 2021, 2022, and 2024, rising to six in 2023. In contrast, seven companies attained optimal comprehensive efficiency in 2019, further confirming the overall downward trend in the average efficiency score. This phenomenon is primarily linked to companies' relatively high debt-to-asset ratios during the period, insufficient R&D investment, and strong volatility in ESG scores. In particular, inadequate R&D expenditure significantly impacted companies' scores in the "ESG Technology R&D" category, thereby lowering their overall ESG scores and slowing the pace of improvement in their comprehensive ESG efficiency.

At the individual enterprise level, Zijin Mining, Hengli Petrochemical, and Fuyao Glass remained in a non-DEA efficient state throughout the review period. This indicates significant room for improvement in their overall efficiency across ESG resource allocation, environmental management (E), social responsibility (S), and corporate governance (G) dimensions. Their input factors have not achieved optimal allocation, necessitating urgent improvements through measures such as optimizing ESG strategic structures, increasing green R&D investments, and enhancing environmental information disclosure. Conch Cement achieved DEA efficiency only in 2019, remaining inefficient in other years. Fluctuations in environmental indicators like carbon emissions intensity and water resource utilization efficiency may have undermined its sustained high performance. WuXi AppTec failed to meet DEA efficiency in all years except 2019 and 2023, reflecting unstable input-output structures in S and G dimensions-including green R&D, employee rights, and business ethics. In contrast, China Northern Rare Earth, Beijing Capital Eco-environment, OriginWater, Offshore Engineering, and 999 Pharmaceutical maintained DEA validity throughout the six-year period. This demonstrates strong synergies across all three ESG dimensions-such as China Northern Rare Earth resource recycling, OriginWater's water environmental protection technologies, Offshore Engineering's low-carbon project investments, and 999 Pharmaceutical's health product responsibility management-along with rational resource allocation with both technical and scale efficiencies optimized simultaneously, demonstrating robust comprehensive ESG management capabilities. Notably, in observations of companies within the Greater Bay Area, years with a comprehensive efficiency value of 1 corresponded to significant improvements in the ESG technology R&D segment, indicating rational innovation resource structures and leading green technology output efficiency.

In summary, the overall efficiency of improving corporate ESG scores is not only constrained by financial structure and R&D investment levels but also closely tied to specific performance indicators in environmental outcomes, social responsibility fulfillment, and governance transparency. Moving forward, companies should address their ESG weaknesses by intensifying technological R&D efforts, optimizing capital structures, and enhancing the quality of ESG disclosures. This approach will enable simultaneous improvements in resource allocation efficiency and overall ESG ratings.

B. Dynamic Analysis of Global Malmquist-Luenberger Index

The Global Malmquist-Luenberger index dynamically and comprehensively reflects changes in the technological innovation efficiency of A-share listed companies. Applying this index to decompose the ESG score improvement rates of 10 A-share listed companies from 2019 to 2024 yields the following results:

TABLE III. AVERAGE GLOBAL MALMQUIST-LUENBERGER INDEX AND DECOMPOSITION FOR ESG SCORE IMPROVEMENT OF 10A-SHARE LISTED COMPANIES FROM 2019 TO 2024

	Effch	Rech	Pech	Sech	tfp
2019-2020	0.968	0.971	0.994	0.973	0.942
2020-2021	1.025	0.982	1.006	1.020	0.999
2021-2022	0.976	1.003	1.000	0.976	0.976
2022-2023	1.022	0.944	0.992	1.031	0.960
2023-2024	0.996	0.991	0.997	0.999	0.986
Average value	0.997	0.978	0.998	1.000	0.973

As shown in Table III, from the perspective of overall efficiency changes, the average ESG score improvement rate index for the 10 A-share listed companies from 2019 to 2024 was 0.978, while the Global Malmquist-Luenberger productivity decreased by 2.2%. Throughout the study period, the tfpch for 2019–2024 remained below 1, indicating that the ESG score improvement rate of these 10 listed companies showed a declining trend year by year. This suggests that inputs and outputs related to ESG score improvement have not been optimized. Further analysis of each company's ESG indicator performance reveals that the following factors directly impact ESG score improvement: within the Environmental (E) dimension-carbon emission intensity, energy efficiency, and waste management rate; within the Social (S) dimension-employee training investment, community welfare expenditure, and labor rights protection; and within the Governance (G) dimension-board independence, information disclosure transparency, and anti-corruption mechanism development. For instance, some companies fall short of industry benchmarks in environmental metrics, limiting overall efficiency. In social metrics, insufficient investment in employee training may weaken innovation momentum, thereby impacting total factor productivity.

Breaking down total factor productivity (TFP) further into scale effect and technological progress indices reveals: 1)TFP reached its lowest point between 2019 and 2020, primarily due to scale effect and technological progress indices falling below other indicators. This indicates that the synergistic interaction between technological progress and scale effects was the main factor driving the decline in TFP. Specifically regarding ESG indicators, insufficient R&D investment in the environmental dimension and reduced scale of public welfare projects in the social dimension jointly constrained efficiency gains. Enhancing corporate technological innovation efficiency can be achieved by encouraging enterprises to increase their investment and scale in ESG and R&D. 2) The TFP value

reached its peak in 2020-2021, at 0.999. Further analysis reveals that the primary drivers of this increase were higher values for the scale effect index and the pure technical efficiency index. This demonstrates that scale effects and technical efficiency are crucial factors in enhancing corporate innovation efficiency. During this period, companies' improved information disclosure in governance and expanded community investments in social dimensions effectively supported higher ESG scores. However, the lack of technological advancement hindered the efficiency gains in ESG scoring, particularly the lag in environmental indicators like carbon reduction technology adoption, which may further depress overall performance.

Overall, specific ESG metric performance-including environmental compliance, social responsibility fulfillment, and governance structure optimization-constitutes the key driver of total factor productivity (TFP) fluctuations. Enterprises must implement targeted adjustments across these dimensions to optimize resource allocation and enhance efficiency.

TABLE IV. GLOBAL MALMQUIST-LUENBERGER INDEX AND DECOMPOSITION FOR ESG SCORE IMPROVEMENT AMONG 10 A-SHARE LISTED COMPANIES

	Effch	Rech	Pech	Sech	tfp
Zijin Mining	0.992	0.979	1.000	0.992	0.955
China Northern Rare Earth	1.000	0.965	1.000	1.000	0.965
Beijing Capital Eco-environment	1.000	1.000	1.000	1.000	1.000
Originwater	1.000	1.001	1.000	1.000	1.001
Offshore Engineering	1.000	1.018	1.000	1.000	1.018
Hengli Petrochemical	1.039	0.974	1.000	1.039	1.009
Fuyao Glass	1.027	0.950	1.000	1.027	0.971
Conch Cement	0.918	0.992	0.978	0.943	0.911
999 Pharmaceutical	1.000	0.953	1.000	1.000	0.953
WuXi AppTec	0.997	0.949	1.000	0.997	0.942
Average value	0.997	0.978	0.998	1.000	0.973

As shown in Table IV, during the period from 2019 to 2024, only four of the ten sample companies-OriginWater, Offshore Engineering, Hengli Petrochemical, and Beijing Capital Eco-environment, achieved a total factor productivity (TFP) index greater than or equal to 1. This indicates that these companies demonstrated relatively strong efficiency in improving their ESG scores. The remaining six companies all had TFP indices below 1, reflecting that while the overall efficiency of ESG score improvement showed an upward trend, there remains significant room for improvement. Comparisons across companies and industries reveal both limited gradient-based differences and technology-driven structural disparities, particularly in the uneven integration of Environmental (E), Social (S), and Governance (G) dimensions. Analysis based on the Global Malmquist-Luenberger index categorizes these ten companies into the following three groups:

1) Companies with a technical efficiency score of 1 or higher include China Northern Rare Earth, Beijing Capital Eco-environment, OriginWater, Offshore Engineering, Hengli Petrochemical, Fuyao Glass, and 999 Pharmaceutical-seven companies in total. These enterprises positively contributed to their ESG scores through enhanced technical efficiency. For instance, OriginWater made significant investments in water resource management and environmental technology applications, demonstrating strong environmental metrics such as wastewater treatment efficiency and carbon reduction performance. Offshore Engineering has strengthened practices in marine environmental protection and safety production measures, with improvements in employee training and community engagement on the social dimension; Hengli Petrochemical reduced environmental impacts through process optimization and resource recycling, though governance transparency requires further enhancement; Beijing Capital Eco-environment demonstrated efficient governance in environmental project operations and board diversity; China Northern Rare Earth made progress in resource utilization efficiency and mine ecological restoration; Fuyao Glass performed well in employee welfare, safety production and product sustainability; 999 Pharmaceutical has continuously optimized drug accessibility, patient safety and corporate ethical governance. However, these companies generally exhibit low technological advancement scores, which have constrained further growth in their ESG score improvement rates. Particularly, there is a lag in applying innovative technologies to environmental and social risk management.

2) Conch Cement experienced the largest decline in ESG score growth rate among all companies, decreasing by 8.91%. Its decline in total factor productivity primarily stemmed from a 6.23% reduction in scale efficiency, reflecting potential neglect of environmental compliance and social responsibility integration during rapid expansion, leading to deteriorating ESG performance. Specifically, in the social dimension, weaknesses were observed in community relations and labor rights protection; in the governance dimension, insufficient internal controls and execution efficiency of sustainability strategies exacerbated the negative impacts stemming from scale effects.

3) Both Zijin Mining and WuXi AppTec experienced varying degrees of decline in their ESG score improvement rates, at 4.5% and 5.8%, respectively. Both companies exhibited unchanged pure technical efficiency indices, while technical efficiency, technological progress, and scale efficiency indices all decreased. The reduction in scale efficiency directly led to the decline in technical efficiency. Zijin Mining faces challenges in environmental restoration, biodiversity conservation, and labor safety within its mining operations. Social dimension issues, including local community conflicts and governance transparency, constrain its ESG improvement. WuXi AppTec exhibits deficiencies in governance areas such as R&D ethics, supply chain management, and data privacy protection. Its social responsibility practices-particularly regarding patient rights and employee diversity-require strengthening, as its scale expansion has failed to effectively align with ESG management demands.

Overall, the disparity in ESG score improvement efficiency among the ten companies highlights uneven development across environmental, social, and governance dimensions. Future efforts should focus on optimizing technical efficiency and economies of scale, while strengthening the integration of ESG metrics tailored to each industry's characteristics to drive sustainable enhancement of overall ESG performance.

V. Case Study

A. Performance Target Setting

The budget values for 2025 [10] for each unit are set at 80% of the 2024 increase, as shown in Table V.

TABLE V. Budgeted Investment Targets for each Unit in 2025

Subjects of evaluation	Company market capitalization (Tens of billions of dollars)	Main revenue (Tens of billions of dollars)	Operating cash flow (Tens of billions of dollars)	R&D expenditures (Billions of dollars)
Zijin Mining	70.151	54.655	59.620	28.482
China Northern Rare Earth	13.809	5.9339	5.1862	5.3982
Beijing Capital Eco-environment	4.3339	3.6090	3.0401	3.1888
Originwater	3.3009	1.5389	1.3163	6.1700
Offshore Engineering	4.3533	5.3900	5.9200	22.290
Hengli Petrochemical	19.449	42.529	50.997	30.650
Fuyao Glass	28.156	7.0653	7.0520	30.200
Conch Cement	21.427	16.385	18.823	22.627
999 Pharmaceutical	10.250	4.9710	5.2525	17.154
WuXi AppTec	28.423	7.0630	7.8237	22.290

Substituting the budgeted input values into the inverse DEA model yields an output value of 10 units, which represents the 2025 output indicator performance target. The results are shown in Table VI.

TABLE VI. Performance Targets for Output Indicators of each Unit in 2025

Subjects of evaluation	ESG score	Gearing ratio (%)	Total asset turnover (times)	Return on assets (%)
Zijin Mining	236.39	1891.14	5.837	169.27
China Northern Rare Earth	11.929	76.7852	0.800	7.783
Beijing Capital Eco-environment	10.871	87.7268	0.263	7.358
Originwater	9.5707	85.1268	0.162	2.058
Offshore Engineering	10.892	71.8277	0.700	5.600
Hengli Petrochemical	73.175	645.200	1.286	18.90
Fuyao Glass	23.776	189.324	00.700	13.80
Conch Cement	1153.59	1279.89	3.347	81.30
999 Pharmaceutical	13.718	93.2226	0.700	11.40
WuXi AppTec	20.429	163.663	0.502	14.50

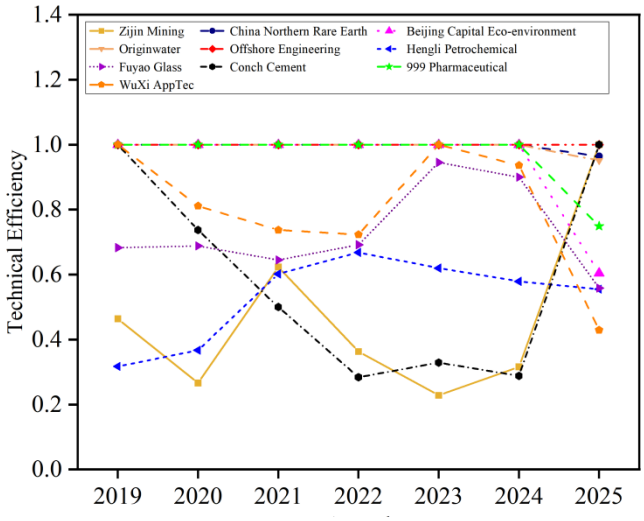

Fig. 1. Comprehensive technical efficiency of various units in 2019–2025.

Fig. 1 was created by plotting the comprehensive technical efficiency of each unit for the period 2019-2024 and their target comprehensive technical efficiency for 2025.

Conch Cement's comprehensive efficiency curve exhibits a V-shaped pattern with significant volatility. This trend of initial decline followed by recovery clearly demonstrates the effectiveness of resource allocation and technological application across different phases of Conch Cement's operations.

From the data characteristics, the decline phase from 2019 to 2022 indicates issues in certain input-output segments of enterprises, suggesting potential resource redundancy or misallocation. The recovery phase from 2023 to 2025 indicates improved efficiency following strategic adjustments. Notably, comprehensive technical efficiency saw a brief uptick in 2023 before declining again to the0.2-0.3range in 2024. A sharp upward trend is projected for 2025.

In summary, by 2025, Conch Cement should increase R&D investment to enhance automation levels and production efficiency, particularly by improving return on assets. This will help resolve the existing contradiction of high debt and low R&D investment, thereby boosting the ability to convert investments into profits. Additionally, in the realm of "circular economy", Conch Cement can increase the proportion of co-processing industrial solid wastes (such as steel slag and blast furnace slag) and construction waste, develop related products, reduce raw material costs, and simultaneously enhance resource recycling efficiency. Regarding suppliers, establish an ESG rating system for upstream suppliers (such as coal and sand/gravel enterprises), prioritizing collaboration with low-energy-consumption and compliant-emission suppliers. Promote the "green cement+low-carbon construction" integrated solution to downstream construction clients, driving overall ESG improvement across the supply chain while aligning with national policies and requirements. For governance structure, establish an ESG working group under the existing Board Strategy or Risk Control Committee, staffed by current executives to oversee ESG governance matters. Senior executives will leverage their management expertise

and resource advantages across respective domains to embed ESG requirements into core processes, including strategic planning, operational management, and risk control. This ensures ESG initiatives are integrated into the company's core business rather than treated as superficial formalities. The approach enhances brand reputation and credibility among investors, regulators, and the public, aligning with current ESG investment trends and policy directions. It simultaneously drives the company's green and low-carbon transformation and supply chain sustainability, laying the foundation for long-term high-quality development.

In analyzing corporate historical performance and forecasting future decisions, the core value of the reverse DEA model lies not only in its application as a tool but also in its methodological innovation for short-term ESG forecasting—an innovation that breaks through the limitations of traditional forecasting reliant on experiential judgment or linear extrapolation. By deeply integrating historical ESG efficiency characteristics, input budget constraints, and reverse optimization logic, it constructs a closed-loop forecasting framework that starts with efficiency attribution, proceeds through resource allocation optimization, and culminates in target quantification. This approach fills the gap where traditional methods struggle to precisely align efficiency assessments with specific ESG objectives. Specifically, enterprises can leverage this integrated model to precisely calculate ESG output targets based on input indicator budget values, enabling targeted forecasting and pathway planning for short-term ESG performance. For instance, Conch Cement leveraged this integrated approach to not only pinpoint redundant inputs underlying prior inefficiencies but also directly link optimization directions with short-term improvement targets across ESG dimensions through reverse DEA's backward-tracking capability. This provides quantitative grounds for setting stable and achievable ESG output goals, enabling enterprises to clearly define "which inputs to optimize, which ESG dimensions to enhance, and what targets to achieve". Compared to traditional performance goal-setting methods, reverse DEA emphasizes the dynamic alignment of performance evaluation outcomes with ESG objectives. It transforms static efficiency assessments into dynamic, actionable ESG improvement pathways, ensuring goal-setting aligns with both operational realities and core ESG development priorities. This significantly enhances the scientific rigor, precision, and operational feasibility of short-term ESG target setting.

VI. Conclusion and Recommendations

This study employs a methodological framework of "static evaluation—dynamic decomposition—reverse optimization," integrating the DEA-CCR model, Global Malmquist-Luenberger (GML) index, and reverse DEA methodology. It conducts a systematic analysis of ESG performance improvement efficiency across 10 representative listed companies from different sectors in China's A-share market during 2019–2024. Based on historical performance, it further establishes resource optimization pathways for 2025. DEA-CCR analysis reveals these companies exhibit overall decline with significant divergence. The core contradiction lies in the combined effects of insufficient R&D expenditure, high debt-to-asset ratios, and volatile ESG scores, which collectively suppress efficiency gains. Meanwhile, GML index decomposition indicates that overall efficiency is declining amid fluctuations, largely consistent with the preceding description. Despite heterogeneity among different enterprises, technology (tech) emerges as the primary driver of decline, revealing weak innovation momentum in the ESG domain. Finally, constrained short-term forecasts for input budgets and target efficiency values are generated using an inverse DEA model, providing quantitative guidance for budget allocation [10]. This reveals that under China's deliberate efforts to enhance corporate ESG integration and innovation, enterprises across different sectors can improve their ESG performance through management process optimization. However, it is noteworthy that scale efficiency and technological innovation may emerge as constraining factors in further elevating ESG performance.

At the corporate level, this study provides inefficient units with pathways for optimizing scale structures and identifies key areas for technological upgrading in declining units. At the policy level, it establishes an ESG budget performance management paradigm centered on "efficiency diagnosis-attribution analysis-target generation". The study proposes the following differentiated improvement strategies for enterprises: For non-DEA-efficient enterprises such as Zijin Mining and Hengli Petrochemical, the focus should be on optimizing scale structures and increasing R&D expenditures in line with reverse DEA budgets. Declining enterprises like Conch Cement should enhance scale efficiency through automation upgrades and capacity efficiency improvements. Overall, both domestic and international enterprises should focus on long-term capacity building, strengthen synergies between technological progress and economies of scale [11], particularly by enhancing ESG-related technological innovation capabilities and mitigating the negative impact of ESG score volatility on total factor productivity. Concurrently, the inverse DEA model can serve as a reference for budget allocation.

Development and Evaluation of a Mobile-Based Local Food Information System for Elderly Nutrition Support

Renuka Khunchamnan, Kewalin Angkananon*
Faculty of Management Sciences-Business Information System, Suratthani Rajabhat University, Surat Thani, Thailand

***Abstract*—This research aimed to: 1) study information needs regarding local foods and information systems for the elderly, 2) develop a local food information system for the elderly, and 3) evaluate system effectiveness. The quantitative study included 235 senior caregivers selected via purposive sampling. The research tools were an interview form (IOC = 0.98) and a questionnaire (Cronbach's alpha = 0.953). The results indicated that there were three key information needs: 1) Comprehensive and reliable content that includes dietary data, food types, and disease categorization, daily meal search features, disease-specific recommendations, and presentation with large-font images and succinct language. The system was developed on the LINE Official Account platform and is based on a web application. 2) User evaluation from 235 participants showed strong agreement with overall system efficiency. Usefulness received the highest rating, followed by LINE OA usability and efficiency. A gender comparison showed that there were statistically significant differences ($p < .01$) between females and males in terms of content and efficiency. 3) Linear regression analysis identified efficiency as the primary factor influencing usefulness, followed by system usability and functionality. A one-way ANOVA showed that users accessing LINE once per week had significantly higher usefulness scores than those using it every 2 to 3 days ($p < .05$).**

Keywords*—*Information system; LINE OA; elderly care system; local food; elderly nutrition

I. Introduction

The change in population structure towards an aging society is an important phenomenon that is occurring worldwide and is becoming increasingly apparent. History recorded a significant event in 2018 when, for the first time, the world's population aged 65 and over exceeded that of children under 5 [1]. In addition, it is estimated that between 2015 and 2050, the proportion of the world's population aged 60 and over will tend to increase from 12.3 per cent to 21.5 per cent [2]. The region with the fastest rate of elderly growth is East and Southeast Asia, especially Japan, South Korea and China. Since 2005, Thailand has entered the aging society with more than 10 per cent of the population aged 60 and over [3], according to the definition of the United Nations. Thailand has entered the aging society completely in 2025 with the population aged 60 and over exceeding 20 per cent or approximately 14.4 million people [4-5]. In 2035, it is predicted that Thailand will enter the advanced aging society fully with the elderly increasing by 28.55 per cent [6]. Such changes in the population structure have resulted in the issue of caring for the elderly becoming a major policy challenge in terms of the economy, society, and public health system [7]. Effective care for the elderly must integrate both physical and mental health promotion, as well as support for the elderly to be able to participate in social activities to their full potential. The key components of caring for the elderly consist of 6 main factors: hygiene, exercise, air, emotion, safety, and food [8].

Elderly people experience physiological changes that affect digestion, nutrient absorption, and energy metabolism, making nutrition a crucial factor in their well-being [9]. Thus, each older adult's energy and nutritional needs vary based on age, weight, height, physical activity, and health [10]. Nutrition for the elderly must focus on getting complete nutrients according to the 9 nutritional principles developed by [11], which must be adjusted to suit changing physiological needs [12]. Appropriate nutrition management can reduce the risk and severity of non-communicable diseases (NCDs), which are common health problems in the elderly [13]. Dietary guidelines advocate for modifying nutrient intake by decreasing the consumption of complex carbohydrates and saturated fats while increasing high-quality protein. Furthermore, an emphasis is placed on consuming low-glycemic-index vegetables, legumes, grains, and fruits, in addition to ensuring adequate hydration [14-15]. However, current social and lifestyle changes often lead the elderly and their caregivers to have difficulty accessing accurate and appropriate nutritional information, lack reliable sources of information, or have limited access to digital information [16]. Local food is a cultural heritage that passes on nutritional wisdom from generation to generation, presenting local identity through the use of ingredients and cooking methods that are consistent with the local ecosystem and resources [17]. A study in Japan found that the elderly who continued to consume traditional local food had a lower incidence of cardiovascular disease than those who turned to Western food [18]. Local Thai food also has outstanding health benefits due to the combination of herbs and spices with pharmaconutrient properties that help fight free radicals and have anti-inflammatory properties [19].

Southern Thai foods made with turmeric, galangal, fingerroot, and pepper have antioxidant and anti-inflammatory properties that benefit the elderly [20-21]. In [22], the authors also found that local foods improve the mental health of the elderly by promoting positive memories, cultural identity, and social interactions. Surat Thani Province is a province with geographical and cultural diversity, which results in a unique combination of food identities [23]. Khlong Prab Subdistrict, Ban Na San District, Surat Thani Province is considered an area that still strongly preserves the traditional way of life and consumption culture. Local food in Khlong Prab Subdistrict is

*Corresponding author.

diverse in terms of ingredients, cooking processes, and flavors, with local resources being the main ingredients [24]. Prominent ingredients include Satho, which is highly nutritious, especially calcium, phosphorus, and vitamin C [25], as well as other local foods such as Southern-style Khanom Jeen Nam Ya, Yam Pla Meng, Sour Fish Curry with Raw Bamboo Shoots, and local desserts with high nutritional value [26-27]. In [28], the authors found that local foods in Surat Thani Province, especially in Khlong Prab Subdistrict, contain high amounts of antioxidants and phytochemicals with anti-inflammatory properties, which help reduce the risk of chronic diseases. This supports [29] the finding that southern spices and herbs lower blood sugar and diabetes risk. According to [30], southern local meals contain more local vegetables than other areas, which boosts dietary fiber and vitamin consumption. The preservation and promotion of local food culture is very important in preserving cultural identity and local wisdom [31]. In Khlong Prab Subdistrict, there are operations at many levels, such as establishing a local food learning center, organizing a local food festival, and integrating knowledge about local food into the local curriculum of local schools [32]. In addition, there is the development of gastronomy tourism, which helps create added economic value and promotes the preservation of local food culture [33].

Currently, information technology has played a significant role in taking care of the health and promoting the quality of life of the elderly (Elderly Health Technology) [34]. Thailand's entry into a complete aging society has stimulated the development of health innovations and information technology that meet the specific needs of the elderly [35]. However, although there are currently various platforms providing health information on the Internet and information systems related to the care of the elderly, the elderly and caregivers still have problems accessing and applying this information in their daily lives [36]. Health information systems are an important tool for improving the efficiency of population health care, as evidenced by the success of the "Health Connect" system in the Republic of Singapore, which achieved impressive results in reducing hospital readmission rates among the elderly population by 30 per cent through a mechanism for monitoring health status and providing personalized nutritional advice [37]. In [38], the authors found that integrating the "Healthy Aging" application into the care of the elderly in Chiang Mai Province reduced malnutrition risk by 18% and increased self-care literacy. LINE is a very popular platform in Thailand, especially among the elderly. A recent survey found that 86 per cent of Thai elderly people regularly use LINE [52], making the development of an information system through LINE Official Account (OA) having a high potential to reach the target group. In [39], the authors stated that LINE OA is an appropriate platform for developing a health knowledge system for the elderly because it has a familiar, uncomplicated user interface and can be easily accessed via mobile devices.

Despite studies on the nutritional content of Thai indigenous cuisines and the development of health information systems for the elderly, the literature study discovered some key research gaps. In [40], the authors noted that most nutrition information systems for the elderly in Thailand have not systematically employed local food data, despite local meals being culturally acceptable and nutritious for Thai seniors. Most existing nutrition information systems for the elderly provide general information that does not take into account the differences in local contexts and cultures. In [41], the authors observed that older people typically reject nutritional advice that conflicts with cultural context and local resources. The research of [42] indicated that most health information systems are not designed with the limitations of digital technology use in mind for the elderly and are often developed on platforms that the elderly are not familiar with, resulting in barriers to access and use. The study of [43] found that there is a lack of research that systematically assesses the impact of information systems on local food consumption behavior in the elderly, resulting in a lack of empirical data that will lead to the development of more effective systems. Each elderly person has different nutritional needs according to their health status, but most information systems still provide general information that cannot be tailored to individual needs [44].

This research aims to fill the research gaps mentioned above by developing a local food information system for the elderly in Khlong Prab Subdistrict, Ban Na San District, Surat Thani Province, developed through the LINE OA platform. The information system integrates local food knowledge with information technology, presenting context-specific information based on the area with an interface design suitable for the elderly on a familiar platform, and evaluating the usability of the information system for the elderly. The developed information system can also provide recommendations appropriate to the health status of each elderly person. The developed system consists of important functions, including a basic health assessment form, a healthy menu tailored to the elderly's condition, a health food shop, frequently asked questions about nutrition for the elderly, and a graph showing the results of the health assessment, which allows users to continuously monitor their health development.

This research is the first to combine specialized Thai food information with elderly-specific mobile health technologies. Regional culinary knowledge from Khlong Prab Subdistrict is operationalized via LINE Official Account, a medium known to Thai elders, unlike generic nutrition platforms. The research presents a replicable model for indigenous food systems and personalized health care for cultural preservation and clinical needs. Traditional meals, health profiles, and age-appropriate digital design enhance community-based health informatics for older individuals. Senior nutrition knowledge and health improved. Using regional cuisine-friendly technology, politicians and healthcare experts help older Thais.

This introduction is followed by Section II on digital health systems and research technology acceptance frameworks. Section III covers participatory design and LINE OA system development. Section IV details caregiver interviews and system evaluations. Section V compares outcomes to literature. Section VI summarizes findings and goals. It provides research contribution and concludes with rural strategy or research applications.

II. Literature Review

A. Ban Khlong Prap Local Food Information System Development

The Ban Khlong Prap Local Food LINE OA development has numerous significant research needs, notably in the integration of digital technology with local food knowledge, which most research has not yet investigated (see Table I). It involves creating a system that combines health assessment findings with local dietary recommendations and an elderly-friendly user interface with cultural context and local language.

TABLE I. Literature Review

Authors (Year)	Key Findings	Research Gaps
Kim et al. [45]	The Chatbot system made 89.3% correct suggestions, and 76.8% of senior participants followed them.	AI gives generic dietary recommendations without local expertise. Integration of AI to assess and deliver tailored local food suggestions may improve the future Khlong Prap LINE OA and change consumption habit.
Singh & Kaur [46]	Traditional culinary knowledge and digital technologies assist older people accept and eat healthy meals.	While the idea is similar, it was not established on the LINE OA platform and was developed in Singapore. Khlong Prap LINE OA will use this approach to Thai Ban Khlong Prap, a local dish with distinct qualities.
Johnson & Martínez [47]	It discovered that simple, local language-supported systems like LINE were more popular in East Asia.	Platform acceptability was studied macroscopically, not locally. Southern Thai terminology and idioms may help the future Khlong Prap LINE OA adopt local language.
Sangchan & Lekcharoen [48]	The device reduces emergency response time by 35% by monitoring vital indicators and sending notifications.	Vital sign monitoring and emergencies are prioritized above food and nourishment. The Khlong Prap LINE OA may relate health data to local dietary suggestions for certain health issues.
Harris & Brown [49]	Messaging services like LINE are as effective as conventional health monitoring approaches but 40% cheaper.	The research did not address cuisine or local culture. The Khlong Prap LINE OA may use messaging platform cost-effectiveness to create a low-cost, high-efficiency system.
Thepat-as et al. [50]	System satisfaction was 87.5% and suggestion compliance increased 42.8% for elderly users.	Lacks food consumption and local expertise, but the Khlong Prap LINE OA will integrate local food knowledge and current nutritional values connected to old health.
Decha-adisai &Makmee [51]	It found substantial improvements in health literacy ($p<0.01$) and habits among elderly individuals.	Health literacy, not local cuisine. To preserve and promote food culture, Khlong Prap LINE OA will combine health literacy with local food knowledge.
Rangkuat & Wongwiseskul [52]	senior system users had significantly lower blood sugar levels ($p<0.05$) than the control group.	It focuses on diabetes and utilizes broad nutritional ideas, whereas the Khlong Prap LINE OA will cover many health conditions and link them to local foods with specific nutritional qualities that may prevent sickness. It found substantial improvements in health literacy ($p<0.01$) and habits among elderly individuals.
Tanaka et al. [53]	The strategy increased senior health care cooperation by 68% and reduced unnecessary medical visits by 23%.	Not culturally informed or local. The Khlong Prap LINE OA's technology and traditional knowledge may improve healthcare cooperation due to users' lifestyle and culture.
Zhang & Wong [54]	LINE is simpler for seniors, while WeChat has more functions.	Platform comparative study is not food-related. Khlong Prap LINE OA will bring Thai-specific food features to LINE's simplicity.

B. System-Design and Testing Theories

Information system building and testing in this research employ human-computer interaction and information systems success theories. TAM by [69] and the IS Success Model by DeLone and McLean [70] are used to assess design concepts from Shneiderman [71] and Nielsen [72]. UI Design Guidelines Two primary concepts make the Information System (IS) simple to use, effective, and user-focused. Eight Golden Rules by Shneiderman emphasizes uniformity across interface components like buttons, colors, and typefaces and offering users relevant feedback that puts them in control in his 2005 book Eight Screen Design Guidelines. Structure encourages error avoidance and makes error management straightforward and adjustable. Other important considerations are system and real-world compatibility, user autonomy and freedom, and consistency and standards. Nielsen [72] also emphasizes error avoidance, recognition over recall (making information available rather than forcing people to remember it), flexibility and efficiency, and simple design. Finally, the system must provide clear guidance and documentation to aid users in identifying, diagnosing, and correcting errors.

C. System Evaluation Framework

This research uses a synthesized assessment approach to evaluate system effectiveness and adoption. The main assessment framework is DeLone and McLean [70] Model of Information Systems Success. This prominent methodology measures complete, multidimensional IS success. Information Quality, System Quality, and Service Quality separately and jointly affect User Satisfaction and Intent to Use (or reuse) the system.

D. Technology Acceptance Model (TAM)

The TAM [69] is used to assess usability and user acceptance within the IS success framework. The robust TAM hypothesis predicts and explains technology user behavior. It highlights two core ideas as system acceptance drivers:

The degree to which a person feels a system will improve their work performance is called perceived usefulness (PU).

This study defines PU as a system that offers useful information, speeds up work, and simplifies chores. PEOU: How easy a person thinks the system will be to use. The perceived system learning, comprehension, and operation ease is included.

Davis [69] found that PU and PEOU directly affect a user's system use attitude, which predicts their actual usage intentions.

E. Synthetic Assessment Model

This study combines the DeLone and McLean [70] model with the TAM core components [69]. To establish IS success, this study's assessment questionnaire assesses system, information, and service quality, perceived usefulness, and ease of use. Nielsen's [72] 10 usability principles are crucial for UI design if you wish to expand on these criteria. These algorithms provide system status to inform users. Another important thing is to keep the system and the real world compatible. Users should also have power and freedom, and there should be stability and standards. Nielsen [72] also puts an emphasis on not making mistakes, recognizing knowledge instead of forcing people to learn it (making it easy to find instead of hard to remember), being flexible and efficient, and making things that are simple. Last but not least, the system needs to have clear help and instructions to help users find, analyze, and fix problems.

III. Research Methodology

This is a mixed-method research between qualitative and quantitative research. It uses triangulation techniques consisting of collecting data from primary sources, interviewing and asking for opinions from real users, and confirming information from experts.

A. Population and Samples

The population in this study was the elderly caregivers in Khlong Prab Subdistrict, Ban Na San District, Surat Thani Province, which consisted of 598 people [55]. For qualitative research, a purposive sample was selected, consisting of 14 elderly caregivers, divided into 10 family members or relatives, 2 village health volunteers, and 2 elderly caregivers in the community. In addition, there were 3 experts: a local public health officer and two local food experts. For quantitative research, a purposive sample was also selected, selecting 235 elderly caregivers in Khlong Prab Subdistrict. This sample size was calculated using the formula of [56] at a 95 per cent confidence level and an error of ±5%.

B. Research Instruments

Both the interview and questionnaire were developed according to research methodologies accepted in the academic circle and went through a quality control process according to standards. The interview research instrument has been tested for reliability by a panel of 3 experts in information systems. The test results show an index of consistency between the questions and the research objectives (IOC) at 0.98. As for the questionnaire, it was tested to collect data with a group of 30 people with demographic characteristics and contexts similar to the actual sample group. The data was then analyzed for reliability using the alpha coefficient calculation process according to Cronbach's principle, which showed a reliability of the entire questionnaire at 0.953. Both the interview and questionnaire were approved by the Human Research Ethics Committee of the Suratthani Rajabhat University. According to the certification document number SRU-EC 2024/150, which has a certification period from 23 December 2024 to 22 December 2025.

C. Data Collection

Data collection by the interview process was conducted by face-to-face conversation, lasting 45-60 minutes per informant at Khlong Prab Subdistrict Health Promotion Hospital. Audio recordings were recorded with the informant's consent, and important points were noted during the interview. After the interview, the audio recordings were carefully transcribed and the interview summary was returned to the informant for verification of completeness and accuracy. A purposive sample of 14 senior caregivers was chosen for qualitative study, which included 10 family members or relatives, 2 village health volunteers, and 2 elderly caregivers from the community. In addition, three specialists were present: a local public health officer and two local food experts.

D. Data Analysis

Data analysis in this study used various statistical methods as follows. For the background information of the informants, such as gender characteristics, education level, and frequency of using LINE communication applications, statistical analysis was performed in the form of frequency and percentage. For the opinion data, the mean and standard deviation were analyzed to reflect the level of opinion both in general and in each issue. For the data from the open-ended questions, the content analysis was used to categorize and summarize important points, and the frequency of issues with similar content was counted.

E. Developing Tools

The Khlong Prab Subdistrict Local Food Information System for the Elderly was developed using the following tools. Visual Studio Code is used for coding, along with Laravel Herd, which manages the development environment on macOS. This system uses the Laravel Framework as the main base for development, and is connected to the front-end via Inertia.js, which enables the efficient development of SPA applications. The user interface is developed using React, which provides fast response, and the Ionic Framework, which allows the system to display on multiple platforms. This information system supports usage via the LINE application with LINE LIFF and LINE Official Account technologies, allowing caregivers of the elderly to access information conveniently. The design uses Figma to create an interface and a suitable user experience, and the code is managed using the Git version control system, which allows the development team to work together efficiently.

F. Steps in Developing the System

The steps in developing the local food information system for the elderly in Khlong Prab Subdistrict are as follows:

1) Develop an information system via the Line OA platform

2) Write a program to calculate the health assessment of non-communicable chronic diseases. The assessor answers 7 questions as follows: i) Have you ever smoked? ii) Do you have diabetes? iii) What is your blood pressure level? iv) What is

your waist size? v) How tall are you? vi) How much do you weigh? vii) Do you have a history of diabetes in your relatives?

3) Then use the data to calculate the risk of 4 diseases: diabetes, hypertension, cardiovascular disease, and overweight. These questions in the disease assessment and the formula for calculating non-communicable chronic diseases refer to [10].

4) Recommend appropriate menus for users by displaying health menus according to the risk of various diseases and by meal, namely breakfast, lunch, afternoon, and evening. The information can be displayed as food names, pictures, and nutrition. This step is considered new knowledge that the research team has developed.

5) The researcher has collected menus from health food restaurants in Surat Thani Province to pin a map showing health restaurants with a menu, and can be pressed to go through Google Maps to the restaurant. With distance indication.

6) The researcher has written a program to display a health assessment graph, gender, age, risk group, and the most recommended food.

7) The researcher has developed a FAQ section with Line Liff. Displaying the menu in Rich Menu for users to use conveniently.

8) The researcher has developed a recipe for a local health food menu of Ban Khlong Prab Subdistrict, consisting of information on the name of the food, pictures, nutrition, and how to make it. This step is considered new knowledge that the research team has developed.

9) The researcher has collected recommended health menus for the elderly, separated by food type, consisting of information on the name of the food, pictures, restaurant address, and nutrition.

G. The usage of the Local Food Information System

The usage of the local food information system for the elderly in Ban Khlong Prab involves the following steps:

1) Logging in via Line (see Fig. 1).

a) Access the Line application and add friends by adding the ID: @*642*kxqcn.

b) Select the Home menu, then select the "Add Friends" menu, then select the "Search" menu.

c) The Line OA Elderly Food name appears

d) Line OA Elderly Food, a local food information system for elderly health care, consists of a login menu (https://elderlyfood.baanthammawat.com/?openExternalBrower=*1)*, a health assessment menu, a health menu, FAQs, and a graph of assessment results.

e) Click the menu link to start using the system. This will take you to the main page of the system, which has three main menus: Home, Overview, and Profile.

2) Health assessment (see Fig. 2): Health Assessment Users must complete seven health information questions. This assessment will be conducted using a series of questions for users to choose from. Once all information is complete, the system will assess the user's risk of various diseases.

3) Calculate the risk score for four diseases: i) Diabetes, ii) Hypertension, iii) Cardiovascular Disease, iv) Overweight (see Fig. 3)

4) Recommended healthy menus: After assessing, the system will recommend healthy menus, including foods to avoid, examples of appropriate menus to choose for breakfast, lunch, afternoon, and dinner.

5) Use the system by clicking the menu link. This opens the system's home page with three menus: Home, Overview, and Profile.

6) Health check: Health Checkup of Seven health details are required as mentioned above. Users will pick from a series of questions for this evaluation. Once all information is entered, the system will calculate illness risk.

7) Calculate four disease risk scores: i) Diabetes, ii) Hypertension, iii) cardiovascular disease, iv) Heavy weight, v) Healthy Menu Ideas.

8) After reviewing, the system will suggest healthy breakfast, lunch, afternoon, and supper meals, including items to avoid (see Fig. 4).

9) Khlong prab local cuisine: Learn about five local Khlong Prab menus: Yam Bai Mai/Khao Yam Bai Mai, Budu Nam with Butterfly Pea Rice, Ua Tai Pla, Kua Curry Paste, and Salak Loi Kaew. Details on each menu item, including ingredients and cooking processes, are shown (see Fig. 5).

*10)*Healthy food restaurant display: The Surat Thani Health Food Restaurant menu lists restaurants. Restaurants provide salads, appetizers, single meals, rice, noodles, and beverage options (see Fig. 6). A map, retail details, and contact information are also shown for the eatery. For navigation, users may connect to the restaurant (see Fig. 7).

*11)*Health assessment responses by gender, age, and risk are graphed (see Fig. 8).

*12)*FAQs—Frequently asked questions and answers.

IV. Results

A. The Need for Local Food Information and an Information System for Elderly Health Care

Analysis of the results of interviews with elderly caregivers to develop a local food information system in Khlong Prab Subdistrict, Ban Na San District, Surat Thani Province, is detailed as follows: A qualitative study interviewed 14 elderly caregivers in Khlong Prab Subdistrict, consisting of 10 family members/relatives (71.43%), 2 village health volunteers (VHV) (14.29%), and 2 community caregivers (14.29%). The survey by the authors identified the needs and challenges in preparing local food that is appropriate for the health of the elderly, as well as expectations for the development of an information system that will enhance knowledge and skills in caring for the elderly through local food.

B. Food Preparation Characteristics and Challenges

From the data analysis, it was found that most caregivers (12 people, 85.71%) emphasized the use of natural and local ingredients in cooking, especially local vegetables that are grown by themselves or found in the community. Interviewee

No. 1 said, "Mostly, I cook food that my mother likes and is easy to eat because my mother has a dental problem. I focus on soft meats, tom yum, sour curry, galangal curry, anything with lots of vegetables."

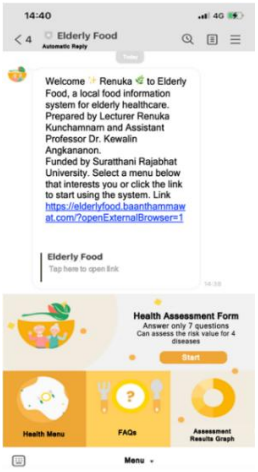

Fig. 1. Home.

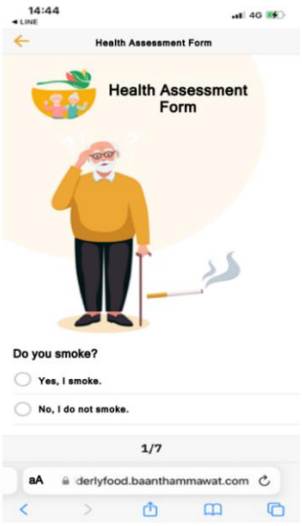

Fig. 2. Assessment form.

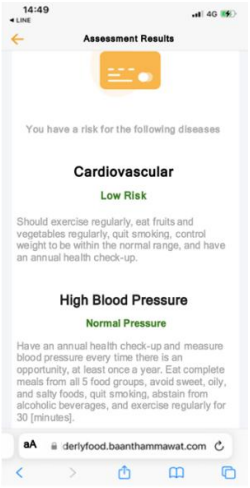

Fig. 3. Calculate results.

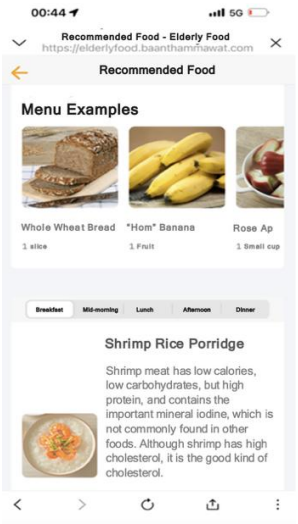

Fig. 4. Recommended menu.

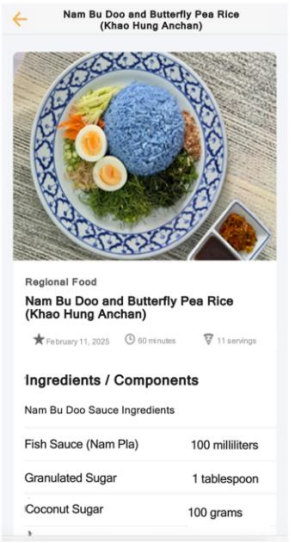

Fig. 5. Local menu.

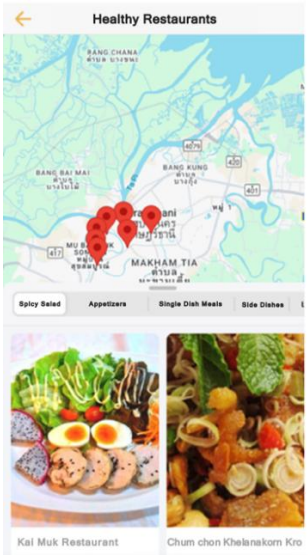

Fig. 6. Searching restaurant.

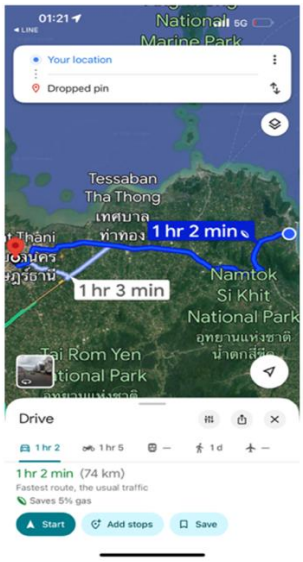

Fig. 7. Navigation.

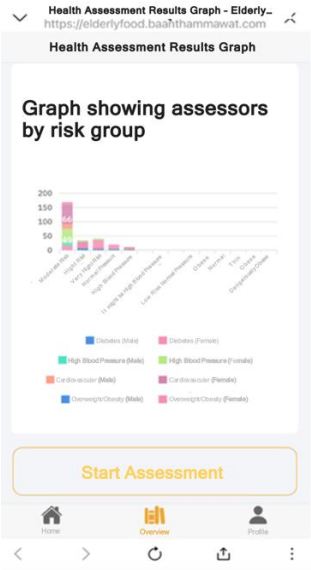

Fig. 8. Graph.

Almost all caregivers (13 people, 92.86%) adjusted their diet to suit the elderly's underlying diseases. Interviewee No. 9 added, "My mother has high blood pressure and diabetes, so I try to reduce sugar, salt, and oil, and season it lightly." Similarly, Interviewee No. 2 said, "My father likes to eat spicy food, but he has kidney disease. He has to be careful about salt, which makes the food bland and tasteless. He doesn't want to eat it, so he has to try to find ways to make it more appealing without using seasonings high in sodium."

Ten interviewees (71.43%) used local herbs in their cooking. Interviewee No. 3 said, "Most of them learned from listening to the elders in the community, learning from their mothers, and sometimes from the village health volunteers when they came to share knowledge in the village, such as using turmeric, ginger, galangal, and moringa leaves in cooking."

In terms of challenges, most caregivers (11 people, 78.57%) were unsure about interactions between food and medicines that the elderly were taking. Interviewee No. 6 said, "I am not sure if some foods are suitable for my mother's disease, such as sugar in some fruits, will affect my mother's diabetes, or some foods may be high in potassium, which is not good for the kidneys that are starting to have problems."

Nine caregivers (64.29%) faced problems with seasons and finding ingredients. Interviewee No. 6 said, "Some seasons it is difficult to find some local vegetables, such as during the dry season, sweet vegetables are hard to find. We have to buy vegetables from the market instead, but we are not sure about the chemicals."

C. Knowledge Sources and Limitations in Accessing Information

Almost all caregivers (13 people, 92.86%) received knowledge about local food from the wisdom passed down from their ancestors. Interviewee No. 11 said, "Khlong Prab's local food is very nutritious because most of it is natural and free of chemicals. Our local vegetables have bitter, sour, and astringent tastes, which have medicinal properties."

In addition, caregivers also received knowledge from village health volunteers (10 people, 71.43%), medical personnel (8 people, 57.14%), online media and social media (7 people, 50.00%), and television programs (5 people, 35.71%). However, all caregivers (14 people, 100%) had problems accessing information about local foods. Interviewee No.12 said, "Most of the information is knowledge that has been passed down from generation to generation. There are no clear records. Sometimes we don't know how reliable it is. There is no medical evidence to confirm it. When we want to search for more information, it's difficult."

Common problems included scattered information (14 people, 100%), conflicting information (12 people, 85.71%), different local names (11 people, 78.57%), lack of scientific evidence (10 people, 71.43%), and information not specific to the locality (9 people, 64.29%).

D. Need for Information on Local Food

All caregivers (14 people, 100%) wanted information on the medicinal properties and nutritional value of local food. Interviewee No. 9 said, "I want to know what benefits each local vegetable has, especially for diseases that are common among the elderly, such as diabetes, blood pressure, and high cholesterol. I also want to know which local foods are high in calcium, help with bones, and which foods help with the excretory and digestive systems."

In terms of the relationship with various diseases, almost all caregivers (13 people, 92.86%) wanted to know which local foods help prevent or alleviate which diseases; While 12 caregivers (85.71%) wanted information on appropriate cooking methods, and 11 caregivers (78.57%) wanted information on the amount and frequency of consumption, as well as precautions and interactions with medications. In terms of data classification, Interviewee No. 4 suggested that "It should be divided by type of food, such as local vegetables, pickled food, local curry, and it might also be divided by benefits for various

diseases. For example, food for diabetics, food for people with high blood pressure, or divided by season, because some things are only available during certain times."

The data classification that caregivers wanted the most was by type of food (14 people, 100 per cent), by properties (13 people, 92.86%), by disease (12 people, 85.7%), by season (10 people, 71.43%), and by cooking method (9 people, 64.29%).

All caregivers (14 people, 100 per cent) wanted information linking local food to disease care. Interviewee No. 3 said, "I really want it. I want information about what to eat for this disease, what to avoid, such as diabetes, what vegetables to eat to reduce sugar, or blood pressure, and what to eat to reduce blood pressure." In addition, all 14 caregivers (100%) wanted information on how to cook or modify local food to suit their underlying diseases. Interviewee No. 5 said, "I want it. I want local recipes that are modified to suit the elderly, such as reducing saltiness, but still having good taste, or using alternative ingredients that are more beneficial, such as using coconut sugar instead of granulated sugar, or using herbal salt instead of regular salt."

E. Information System for Elderly Food Development Needs

In terms of appropriate data presentation formats, most administrators (13 people, 92.86%) like images with short text. Interviewee No.10 said, "I like images with short text that are easy to understand. If it's a video, it should not be too long; 1-2 minutes is enough. If you want to know more, just click to read the details. I also like having pictures showing the cooking steps clearly." In addition, caregivers also preferred short videos (10 people, 71.43%), large text (9 people, 64.29%), audio commentary (8 people, 57.14%), and local languages (7 people, 50%). As for the features they wanted in LINE OA, all caregivers (14 people, 100%) wanted to search by disease and daily recommended menus. Interviewee 1 suggested that, "I want to have a daily recommended menu that is appropriate for the disease and ingredients that are easy to find in the local area." Other features that caregivers wanted included searching by food type (13 people, 92.86%) and FAQs (12 people, 85.7%). Analysis of the interview results of elderly caregivers in Khlong Prab Subdistrict revealed the need for a local food information system that meets the specific needs of the community. Such a system should emphasize ease of use, provide reliable data, have clear illustrations, and link local food to the care of elderly people with various chronic diseases.

1) Results of interviews with local health personnel and local food experts

The results of interviews with 3 experts: 1 local health personnel and 2 local food experts are as follows. From the analysis of the interview content, 8 main issues were found. All 3 experts (100%) agreed that the local food of Khlong Prab Subdistrict has high nutritional value. This is because it uses fresh, natural ingredients that are not stored for long periods of time, uses local herbs for seasoning, and has cooking methods that emphasize boiling, steaming, and grilling more than frying.

All experts (100%) offered five different forms of data classification: According to food type, the options are: 1) salad, 2) snacks, 3) one-dish dinners, 4) side dishes, and 5) noodle dishes. All experts (100%) desired the Information System for Elderly Local Food to include the following five features: 1) Food search by ailment, 2) Food search by type, 3) Daily suggested meal, 4) Frequently asked questions, and 5) Personalized guidance system. In terms of local food information needs, all experts (100%) wanted five types of information: 1) in-depth information on nutrients in local vegetables, 2) the relationship between local food and NCDs, 3) flavor modification to suit the elderly with various diseases, 4) medicinal properties of herbs, and 5) methods of storing ingredients. All experts (100%) identified five problems in finding information about local food: 1) Most information is transmitted by word of mouth, 2) Scientific information is difficult to access, 3) Information on the Internet has different reliability, 4) Lack of knowledge transfer, and 5) Lack of information on food modification to accommodate modern diseases.

In terms of data classification, all experts (100%) proposed five types of classification: 1) Salad, 2) Snacks, 3) One-dish meals, 4) Side dishes, and 5) Noodle dishes, according to food types. For the development needs of the Information System for Elderly Local Food, all experts (100%) wanted the system to have five features: 1) food search by disease, 2) search by type of food, 3) daily recommended menu, 4) frequently asked questions, and 5) personalized advice system. In terms of appropriate data presentation formats, all experts (100%) suggested using images with short text, 1–2-minute videos, explanatory audio, infographics, and using easy-to-understand language, including some local dialects. The interview results reflect a clear need to develop a local food information system for the elderly. The focus is on providing useful, easily accessible information that meets the specific needs of the elderly with various chronic diseases. Using this information to develop the system will help preserve local food wisdom and effectively promote the health of the elderly in the community.

2) Evaluation of the efficiency of the local food information system for elderly health care.

F. General Information of the Respondents

From Table II and Fig. 9, it was found that most respondents were male, accounting for 26.39 per cent, followed by female, accounting for 35.70 per cent.

TABLE II. GENDER

Gender	Frequency	Percentage
Male	62	26.38
Female	173	73.62
Total	**235**	**100**

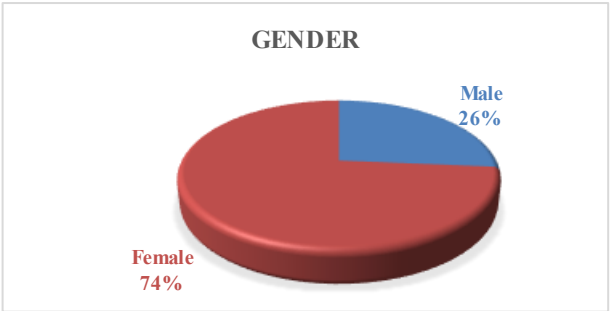

Fig. 9. Gender.

From Table III and Fig. 10, it was found that the respondents in the 18-30 age group had the highest proportion, accounting for 43 per cent, followed by the 51-60 age group, accounting for 35.70 per cent, while the 31-40 and 41-50 age groups had similar proportions at 11.10 and 10.20 per cent, respectively.

TABLE III. AGE

Age	Frequency	Percentage
18-30 years	101	43.00
31-40 years	26	11.10
41-50 years	24	10.20
51-60 years	84	35.70
Total	**235**	**100.00**

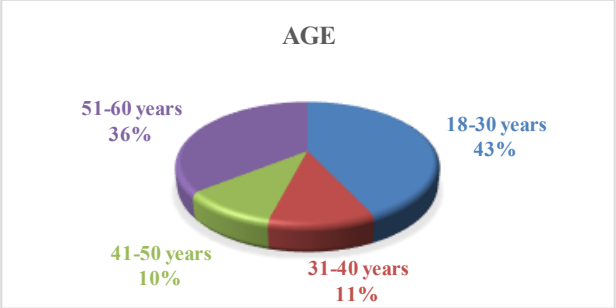

Fig. 10. Percentage of age.

TABLE IV. EDUCATION LEVEL

Education Level	Frequency	Percentage
Below Bachelor's Degree	110	46.81
Bachelor's Degree	123	52.34
Above Bachelor's Degree	2	0.85
Total	**235**	**100.00**

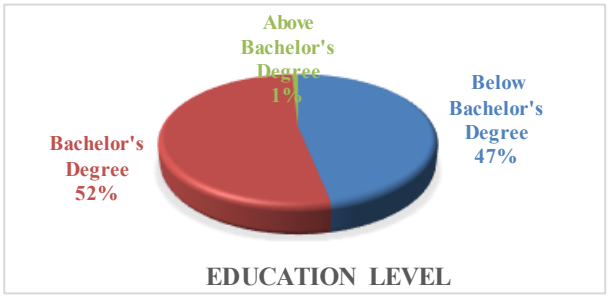

Fig. 11. Percentage of education level.

From Table IV and Fig. 11, it was found that most of the respondents had a bachelor's degree, accounting for 46.81 per cent, followed by those with lower than a bachelor's degree, accounting for 46.81 per cent, and the least was those with higher than a master's degree, accounting for 0.85 per cent.

From Table V and Fig. 12, it was found that most of the respondents used the LINE application every day, accounting for 54.47 per cent, followed by using the LINE application 2-3 days/time, accounting for 21.70 per cent, and using the LINE application once a week, accounting for 21.70 per cent, and the least used others, accounting for 2.13 per cent (rarely 1.40%, rarely used 0.73%).

TABLE V. INFORMATION SYSTEM FOR ELDERLY USAGE FREQUENCY

Line usage frequency	Frequency	Percentage
Every day	128	54.47
2-3 days/time	51	21.70
Once a week	51	21.70
Other	5	2.13
Total	**235**	**100.00**

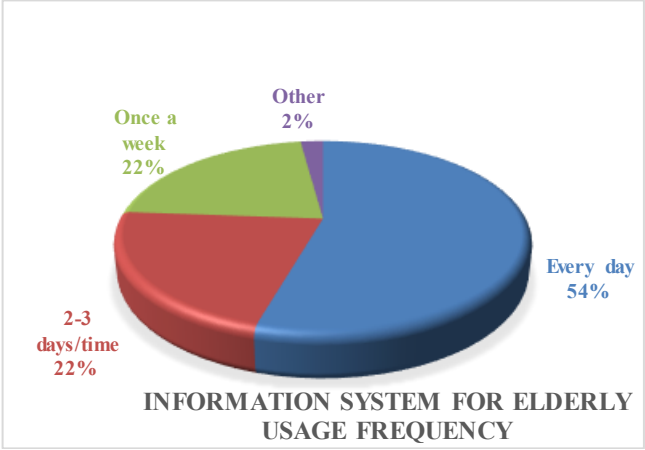

Fig. 12. Information system for elderly usage frequency.

G. System Performance Evaluation and Utilization

TABLE VI. OVERVIEW OF SYSTEM PERFORMANCE EVALUATION AND UTILIZATION

Aspect	Mean	S.D.	Opinion level
1. Content	4.41	0.72	Strongly agree
2. Functionality	4.40	0.68	Strongly agree
3. Usability of Healthy Food LINE OA	4.49	0.68	Strongly agree
4. Efficiency	4.46	0.64	Strongly agree
5. Utilization	4.60	0.57	Strongly agree
Total	**4.47**	**0.66**	**Strongly agree**

Table VI shows that most respondents rated their overall opinion on each aspect at the strongly agree level ($\bar{x}$ = 4.47). When considering each aspect individually, it was found that most respondents believed that the Healthy Food LINE could be utilized the most ($\bar{x}$ = 4.60), followed by the usability aspect of Healthy Food LINE OA ($\bar{x}$ = 4.49), and the least was the functionality aspect ($\bar{x}$ = 4.40).

Table VII revealed that the majority of respondents strongly agreed with all items ($\bar{x}$ = 4.41). When considering each item individually, most respondents believed that the Healthy Food LINE contains essential content for comprehensive elderly care ($\bar{x}$ = 4.50). This was followed by their belief that the Healthy Food LINE provides menu information suitable for elderly health and offers nutritional information on local food appropriate for elderly health care ($\bar{x}$ = 4.43). The least agreement was with the statement that the Healthy Food LINE has comprehensive information on local food ($\bar{x}$ = 4.32).

TABLE VII. CONTENT

Content	Mean	S.D.	Opinion level
1. The Healthy Food LINE contains complete local food information.	4.32	0.719	Strongly agree
2. The Healthy Food LINE provides food menus appropriate for elderly well-being.	4.43	0.745	Strongly agree
3. The Healthy Food LINE provides nutritional information on local cuisine suitable for elderly health management.	4.43	0.715	Strongly agree
4. The Healthy Food LINE content is appropriately written, easy to comprehend, and suitable for elderly users.	4.35	0.767	Strongly agree
5. Healthy Food LINE includes all necessary content for holistic elderly care.	4.50	0.669	Strongly agree
Total	**4.41**	**0.72**	**Strongly agree**

TABLE VIII. FUNCTIONALITY

Functionality	Mean	S.D.	Opinion level
1. The Healthy Food Information System is capable of managing local food data categories.	4.37	0.650	Strongly agree
2. The Healthy Food LINE allows adding, deleting, and modifying local food data.	4.28	0.760	Strongly agree
3. The Healthy Food LINE enables searching for local food information.	4.37	0.676	Strongly agree
4. The Healthy Food LINE can display information in a suitable format.	4.47	0.662	Strongly agree
5. The database system operates accurately.	4.50	0.669	Strongly agree
Total	**4.40**	**0.68**	Strongly agree

Table VIII revealed that the majority of respondents strongly agreed with all items ($\bar{x}$ = 4.40). When considering each item individually, it was found that most respondents believed that the Healthy Food LINE database system functions correctly ($\bar{x}$ = 4.50), followed by the Healthy Food LINE can present information in an appropriate format ($\bar{x}$ = 4.47), and the least was the Healthy Food LINE can add, delete, and modifying local food information ($\bar{x}$ = 4.28).

Table IX revealed that the majority of respondents strongly agreed with all items. When considering each item individually, it was found that most respondents believed that the Healthy Food LINE has clarity of text, colors, and background displayed on the screen ($\bar{x}$ = 4.57), followed by clarity of text, colors, and background displayed on the screen ($\bar{x}$ = 4.53), and the least was the navigation system design allows easy access to information ($\bar{x}$ = 4.41).

Table X revealed that the majority of respondents strongly agreed with all items. When considering each item individually, most respondents believed that retrieving various information can be done efficiently ($\bar{x}$ = 4.51). This was followed by their belief that the Healthy Food LINE can be used continuously for extended periods and can support multiple users simultaneously ($\bar{x}$ = 4.48). The least favorable opinion was regarding the accuracy of the display results from linking each page ($\bar{x}$ = 4.37).

TABLE IX. USABILITY OF HEALTHY FOOD LINE OA

Usability of Healthy Food LINE OA	Mean	S.D.	Opinion level
1. Screen design is easily accessible.	4.43	0.715	Strongly agree
2. Clarity of text, colors, and background displayed on the screen	4.53	0.668	Strongly agree
3. Menus are easy to understand and convey clear meanings.	4.57	0.646	Strongly agree
4. Navigation system design allows easy access to information.	4.41	0.707	Strongly agree
Total	**4.49**	**0.68**	Strongly agree

TABLE X. EFFICIENCY

Efficiency	Mean	S.D.	Opinion level
1. Page navigation and linking display correctly.	4.37	0.664	Strongly agree
2. Data retrieval is performed efficiently.	4.51	0.587	Strongly agree
3. The Healthy Food LINE supports continuous long-term usage.	4.48	0.649	Strongly agree
4. The Healthy Food LINE accommodates concurrent multi-user access.	4.48	0.669	Strongly agree
Total	**4.46**	**0.64**	Strongly agree

TABLE XI. UTILIZATION

Utilization	Mean	S.D.	Opinion level
1. System information is useful for elderly care.	4.61	0.530	Strongly agree
2. Elderly individuals can utilize system information in their daily routines.	4.58	0.567	Strongly agree
3. Food information in the system benefits elderly health management.	4.60	0.556	Strongly agree
4. The Health LINE system encourages using local ingredients in elderly cooking.	4.56	0.599	Strongly agree
5. The elderly can use various system information for healthy food preparation.	4.65	0.576	Strongly agree
Total	**4.60**	**0.57**	Strongly agree

Table XI revealed that the majority of respondents strongly agreed with all items. When considering each item individually, most respondents believed that the elderly can use various information from the system to prepare healthy meals ($\bar{x}$ = 4.65). This was followed by the belief that the information in the system is beneficial for elderly care ($\bar{x}$ = 4.61), while the least agreement was with the Healthy LINE system promoting the use of local food ingredients in elderly meal preparation ($\bar{x}$ = 4.56).

As shown by the majority of respondents (52.6%) who responded "the system is already good" or "excellent", the program is effective. Favorable comments like "the system is already good" and "excellent", which were provided by the majority of respondents (52.6%), imply that the program is successful. With 21.05% of replies, the food menu categories got positive comments and suggestions for growth, such as local item menus, vegetarian and vegan options, and various meals to

pique senior appetites. The least common proposals were for system and feature enhancements (5.26%), stating that LINE OA is most suited for elderly citizens, and for use in a variety of locations (5.26%), where users asked to expand use and data coverage to all provinces. Positive responses to its benefits indicate that the development satisfies the needs of the elderly. Positive responses to its advantages indicate that the innovation meets the demands of the elderly.

1) Comparison of differences between genders influencing opinions on various aspects.

TABLE XII. ANALYSIS OF T-TEST RESULTS COMPARING FEMALES AND MALES ON VARIOUS ISSUES

Independent Samples T-Test		Statistic	df	p
Content	Welch's t	3.391	146	<.001
Functionality	Welch's t	1.286	116	0.201
Usability of Healthy Food LINE OA	Welch's t	1.711	132	0.090
Efficiency	Welch's t	2.845	125	0.005
Utilization	Welch's t	0.903	113	0.368
Note. H_a $\mu_1 \neq \mu_2$				

From Table XII, the data analysis results using Welch's t-test, which is an appropriate test for cases where the variances of two groups are unequal, can be summarized as follows for the comparison between females and males on various issues. This study found statistically significant differences at the .01 level between females and males in the content aspect and the performance aspect. However, no significant differences were found in the functionality aspect, the usability aspect of Healthy Food LINE OA, or the utilization aspect.

2) Linear regression analysis results: From Table XIII, it was found that the model is statistically significant in predicting the dependent variable ($F = 104, p < .001$). All four independent variables have a high correlation with the dependent variable ($R = 0.803$). The model can explain 64.5% of the variance in the dependent variable (utilization) ($R^2 = 0.645$).

TABLE XIII. MODEL FIT MEASURES

			Overall Model Test			
Model	R	R^2	F	df1	df2	p
1	0.803	0.645	104	4	230	<.001

Note. Models estimated using sample size of N=235

3) Factors influencing LINE OA utilization: From Table XIV, it was found that the factor with the greatest impact on utilization is system performance efficiency ($\beta = 0.4377$), followed by system functionality ($\beta = 0.1255$) and Healthy Food LINE OA usability ($\beta = 0.1183$), respectively. Meanwhile, content design does not have a significant effect on LINE OA utilization.

4) One-Way ANOVA analysis: From Table XV, the test results showed a p-value of 0.042, which is below the 0.05 significance level, indicating a statistically significant difference in the mean utilization values between at least one pair of groups.

TABLE XIV. MODEL COEFFICIENTS – UTILIZATION

Predictor	Estimate	SE	t	p
Intercept	1.3690	0.1613	8.488	<.001
Content	0.0442	0.0477	0.929	0.354
Functionality	0.1183	0.0588	2.013	0.045
Usability of Healthy Food LINE OA	0.1255	0.0517	2.429	0.016
Efficiency	0.4377	0.0638	6.861	<.001

TABLE XV. ONE-WAY ANOVA (WELCH'S)

	F	df1	df2	p
Utilization	3.28	3	20.1	0.042

5) Post-Hoc test analysis: Once the overall differences were found in the ANOVA, a Tukey post-hoc test was performed to determine which frequency groups differed in the LINE application usage. The Tukey post-hoc analysis of the differences in the mean utilization values between LINE application usage groups using the Tukey post-hoc method revealed that only one pair showed a statistically significant difference: the 2-3 day/use group and the once-weekly group ($p = 0.008$). The once-weekly group had a higher mean utilization score than the 2-3 day/use group by 0.278 units. Comparisons between the other groups did not reveal any statistically significant differences ($p > 0.05$), indicating that utilization was not different between the dailyuser group and the other groups, nor between the infrequent user group and the other groups. This study suggests that frequency of LINE usage may not be the primary factor directly influencing utilization, except for those who use LINE 2-3 times per day and those who use it once per week. Other factors, such as usage patterns, purpose of use, or quality of content accessed, may influence utilization in the once-a-week group, rather than just frequency of use.

V. DISCUSSION

A. Discussion of Interview Results with Elderly Caregivers and Experts in Khlong Prap Subdistrict

Based on the analysis of interview data with elderly caregivers and experts in Khlong Prap Subdistrict, the research findings can be discussed in relation to relevant concepts and theories as follows:

B. Needs for Local Food Information for Elderly Health Care

The results of the study revealed that the majority of elderly caregivers prioritize the use of natural and local ingredients in cooking. This is consistent with the findings of [57] who examined the nutritional value of Thai local foods and discovered that many of them contain components beneficial to the health of the elderly, particularly the variety of local vegetables, the use of herbs and spices, and high-quality protein sources derived from fish. This point is a key strength of this research when compared to previous studies, such as the Chatbot

system by [45] or system by [50]. Local food context recommendations are limited by these algorithms, but accuracy and pleasure are high. The fact that caregivers in the area require local food information thus confirms the importance of developing a system that integrates local-specific knowledge. The researchers discovered and verified culturally unique dietary requirements via participatory design with caregivers, a crucial methodological addition.

C. Local Elderly Food and Health Promotion

All researchers agreed that Khlong Prab Subdistrict's local food is nutritious and contains five dishes with special properties for the elderly: local vegetable curry, turmeric fried fish/herb fried fish, shrimp paste chili dip with boiled vegetables, rice salad, and herbal tea. The research by [58] found that Khlong Prab Subdistrict's traditional diet is healthy and helps prevent and cure chronic illnesses in the elderly. Moreover, [59] revealed that 78.6% of the elderly in Khlong Prab Subdistrict routinely eat local cuisine, supporting the expert interview findings. Sour fish curry with raw bamboo shoots, shrimp paste chili dip with local vegetables, and stir-fried stink beans with shrimp were the most popular local dishes among the elderly. These nutritious and medicinal dishes provide health benefits. Other health systems prioritize vital sign monitoring, like [48], or diabetes management using broad nutritional ideas, like [52]. This focus on local foods with specific properties (e.g., local vegetable curry, turmeric fried fish) addresses a different need. Vital sign monitoring systems only collect physiological data. This system, on the other hand, gives actionable, culturally relevant dietary recommendations that can be used to make healthy meals every day, getting a utilization score of $\underline{x} = 4.65$ for "elderly people can prepare healthy meals". Thus, health data may be linked to local dietary recommendations in this study.

D. Integrating Local Wisdom with Modern Medical Knowledge

Science-based information is needed to blend local wisdom with contemporary medicine. This supports [60], who found that traditional Thai dietary patterns, which align with the Nine Nutritional Commandments (rich in fish, vegetables, fruits, whole grains, and herbs), were associated with a significantly reduced risk of noncommunicable diseases (NCDs). Furthermore, the research results align with the World Health Organization's [61] concept of active aging, which emphasizes holistic health promotion for the elderly, emphasizing optimal health, social participation, and security. This integration approach represents a theoretical contribution, advancing the TAM by demonstrating its applicability in integrating traditional food wisdom with digital health systems for elderly care in rural contexts. Developing a local food information system that meets the needs of caregivers and the elderly will promote access to accurate and useful information, a key factor in promoting activeness in communities. This integration approach is supported by [46], who found that using traditional culinary knowledge with digital technologies helps older people accept healthy meals. Furthermore, the Khlong Prap LINE OA system integrates local food knowledge with health literacy, filling a gap identified by [51], whose research noted that previous work often focused only on health literacy while lacking the dimension of local cuisine.

E. Development of an Information System that Meets the Specific Needs of the Community

All caregivers had trouble finding local food information, in the study. Information scattering and data conflicts the key issues. The participatory design framework systematically addressed these challenges through ethnographic interviews with elderly caregivers and local experts. A systematic data collection and organization method is needed to address these issues. This supports [62] suggestion that an information system that integrates local food and nutrition information for the elderly will connect local wisdom with modern technology, preserving food culture and promoting sustainable health. The Nine Nutrition Commandments for the Elderly by [63] emphasize adapting foods to the physiological changes and specific needs of the elderly and chronic non-communicable diseases of the elderly.

F. User-Friendly Information System Design

Most caregivers (92.86%) preferred pictures with brief text, followed by short films (71.43%) and big typefaces (64.29%). An information system design that is easy to use and appropriate for many users is needed. This is consistent with [64], who found that older adults in Khlong Prab Subdistrict used technology due to child support, family communication, health information, and local wisdom. This finding supports the decision to use the LINE platform, which aligns with [47], who found that simple, local language-supported systems like LINE were more popular in East Asia. It also corresponds with [54], who concluded that LINE is simpler for seniors. As a design contribution, the system provides a replicable model using accessible platforms (LINE OA) with user-centered design principles (pictorial content, large fonts, local language), achieving high satisfaction scores. The design of this system, therefore, directly meets user needs.

G. The Key Features of a Local Food Information System

Disease-specific foods (100%), daily dietary guidelines (92.86%), and often asked questions (85.71%) were the caregivers' search requests. According to the holistic approach to nutrition in the Thai old, a system that provides tailored recommendations and suitable options for the elderly's health state is needed. In [65], the authors promoted local food wisdom, nutritional knowledge and skills, and health care integration. In contrast to broad diabetes management systems that use general food guidelines, this method uses popular local food to give personalized advice for particular situations. This helps all the workers who want to focus on things that are good for people with certain diseases. This demand reiterates that a good system should not merely stop at vital sign monitoring or provide broad recommendations, but must be able to provide “tailored recommendations” according to the specific health conditions of the elderly.

6) Discussion of evaluation and development of the local food information system for elderly health: The local food information system for health care for the elderly at Ban Khlong Prab was established appropriately and met its aims, according to growth statistics. Its performance and usability were rated "strongly agree," indicating that the system satisfies consumers' requirements. These empirical findings provide quantitative

evidence demonstrating the effectiveness of the approach for researchers, policymakers, and system developers.

A. System Development based on the TAM

The TAM model was used throughout system development [66]. This approach assessed perceived functionality and usability. Evaluation shows "easy-to-understand menu" as key factor in high user satisfaction. "Clear communication" and "Clarity of text, colors, and background" indicate a clear, straightforward, accessible, and age-friendly user interface design. This validates the design contribution in developing elderly-accessible interfaces for resource-limited settings. The literature review found that people in this setting prefer LINE and accessible language.

B. System Efficiency and Utilization

The evaluation results for efficiency and utilization were high, particularly for "Elderly people can use the information from the system to prepare healthy meals" and "Information in the system is useful for caring for the elderly". This is consistent with [67] concept of local food being important to the health and culture of the community. This study extends on [49], which found messaging services successful and affordable. The LINE-based method works well in rural areas with few resources because it gets the same level of culture blending and user acceptance without the need for custom application creation. It demonstrates that this cost-effectiveness can be combined with the integration of 'local culture and cuisine' (a gap identified in [49]). This cultural integration may also be a factor in improving health care cooperation, which [53] identified as a limitation of systems that are not culturally informed.

C. Factors Influencing Utilization

The linear regression analysis revealed that the factor that had the highest influence on the utilization was system performance, followed by system functionality and the use of the healthy food OA line. These empirical findings provide quantitative evidence for prioritizing technical performance in elderly-focused digital health interventions, serving as a practical guideline for system developers. This finding is consistent with the research of [68] that indicated that system performance and ease of use are important factors in the acceptance and utilization of technology among the elderly.

VI. Conclusion and Future Work

This research is exclusive to Khlong Prab Subdistrict; however, the technique applies to other rural areas in Thailand with traditional food cultures. The framework bridges generic health literacy systems and culturally informed interventions by giving researchers a replicable method for integrating local food wisdom with evidence-based nutrition science, policymakers a cost-effective digital health solution using existing platforms, and system developers validated design specifications for elderly-accessible interfaces in resource-limited settings. The system uniquely combines: 1) evidence-based nutrition aligned with WHO active aging principles and the Thai Nine Nutritional Commandments, 2) preservation of local food wisdom validated by 78.6% elderly consumption rates, and 3) accessible delivery through a platform already familiar to users, resulting in significantly higher practical utilization than systems without cultural grounding. To gain acceptance and lasting influence, future work should spread this notion throughout Thailand, analyze health advantages, and integrate with established medical systems.

Contribution

1) Theoretically, the study shows how digital health solutions may respect cultural settings by making technology that is easy for seniors to use and preserving traditional knowledge. These tools could help people and keep culture alive.

2) The project uses food information made by the community and a study of older people's habits to come up with a new way to do things that uses the digital tools they already have. This plan could be used for similar projects in Southeast Asia.

3) The study shows how to make health information systems that work for Thailand's older people who are comfortable with technology, who have cultural standards, and who want preventive health care.

4) The results show that older people are more likely to use and connect with platforms that have useful information that is relevant to their area. This is beneficial for their health and helps keep traditional knowledge alive.

Research Applications

A. Benefits to Elderly Persons and Caregivers

1) Elderly persons and caregivers will benefit from access to reliable information on local foods that are beneficial to their health, which can be applied to meal planning appropriate for their health status.

2) Local food information systems will help build confidence among elderly persons and caregivers in self-management of their health through appropriate food selection and the preservation of familiar food cultures.

B. Benefits to Communities and Local Areas

1) Communities will benefit from collecting, organizing, and disseminating local food wisdom, which will preserve and revitalize the food culture that is a community identity.

2) Disseminating information on the nutritional value and health properties of local foods will foster pride in local culture and promote the continuation of knowledge from generation to generation.

C. Government Agency and Related Organization Benefits

1) To improve aged care, public health organizations and health-promoting hospitals may include local culinary knowledge in their health service systems.

2) Related organizations may reuse the local food information system development for health information systems.

D. Benefits to the Academic Community

1) This research will help build a collaborative network among researchers, academics, and practitioners in various

fields, such as nutrition, information technology, geriatric nursing, and community development.

2) The developed local food information system will serve as an important source of information for future research on local foods and their application to promoting the health of the elderly.

ACKNOWLEDGMENT

The authors thank Suratthani Rajabhat University for providing funding. We also express gratitude to all the experts who provided valuable consultation and recommendations. We thank the senior caretakers of Khlong Prap Sub-district for their assistance in data collection and system evaluation. We are also thankful to the management and personnel of Khlong Prap Sub-district Health Promoting Hospital for assisting with the study. The benefits of this study are for elderly people, their caretakers, and those who made it possible.

***Abstract*—This study presents a quantitative approach to analyzing window opening and closing behaviors using skeletal recognition technology. Video data of five participants performing these actions were captured and processed using the Openpose model, which detects 25 human joints. Focusing on the shoulder, elbow, and wrist, the study analyzed time-series joint coordinates to identify motion patterns and behavioral characteristics. The results revealed consistent relationships among joint movements and enabled accurate distinction between left- and right-hand operations. In addition, behavioral distribution characteristics were examined by visualizing horizontal and vertical skeletal displacements. The results showed that stationary postures are concentrated near a reference origin, whereas window operation actions produce distinct spatial shifts in the coordinate space, indicating that occupant behavior can be interpreted as a sequence of state transitions composed of distinct behavioral phases. The findings confirm that skeletal data can effectively represent occupant behavior without intrusive sensors, providing a non-contact and privacy-preserving monitoring method. This approach contributes to the development of human-centered intelligent building systems that can adapt indoor environments in real time based on occupant actions, thereby improving both thermal comfort and energy efficiency. Future research will expand behavioral categories and explore real-time implementation in smart building applications.**

Keywords*—Image processing; skeletal recognition; behavioral analysis; Openpose

I. Introduction

In recent years, the rapid advancement of digital technologies such as the Internet of Things (IoT) and Artificial Intelligence (AI) has significantly influenced the architecture and construction industries. These emerging technologies have enabled the development of intelligent, responsive environments that can adapt to human behaviors and preferences in real time [1]. Buildings are no longer static structures; they are evolving into dynamic systems capable of sensing, interpreting, and responding to occupants' needs. Among the many applications of IoT and AI in architecture, the creation of human-centered thermal environments has become an area of growing research interest [2].

Traditional environmental control systems, such as heating, ventilation, and air conditioning (HVAC), rely primarily on temperature, humidity, and occupancy sensors to regulate indoor conditions. However, such systems often neglect the diversity and variability of human behavior, which plays a critical role in determining comfort levels. For instance, an occupant's decision to open or close a window can significantly affect indoor temperature, air quality, and energy consumption. Understanding and predicting these behavioral patterns are essential for designing energy-efficient buildings that maintain comfort without excessive energy use [3, 4].

Recent studies have demonstrated that IoT-based monitoring systems can capture and analyze occupant behavior with high temporal and spatial resolution. By connecting sensors, cameras, and data analytics platforms, researchers can model the relationship between human actions and environmental parameters [5]. At the same time, AI technologies, including machine learning and computer vision, have made it possible to interpret complex human motions automatically. For example, deep learning-based image recognition models can detect gestures, postures, and movements that correspond to specific behaviors such as window operation, light switching, or adjusting clothing layers [6, 7].

Despite these advancements, challenges remain in achieving reliable and context-aware recognition of occupant behaviors. Many existing studies rely on wearable sensors or environmental data, which may not fully capture the physical actions associated with comfort regulation. Moreover, privacy concerns often limit the use of conventional video data in indoor monitoring applications [8]. To address these challenges, recent research has explored the use of skeletal recognition and pose estimation techniques, which analyze the positions of human joints rather than identifiable facial features. Such approaches provide a balance between behavioral accuracy and privacy protection [9, 10].

In this context, the present study investigates window-opening and closing as a form of architectural and environmental behavior using skeletal recognition technology. Rather than treating window operation as a simple motion detection task, this study interprets it as an occupant-driven behavioral process that influences indoor thermal conditions and energy performance. By capturing and modeling these behaviors, the research aims to support the development of intelligent, privacy-preserving, and human-centered building control strategies.

II. Literature Review

Many researchers have used the Internet of Things (IoT) and artificial intelligence (AI) technologies to study various issues in the architectural field. In recent years, research on human-centered thermal environments has attracted considerable attention [11, 12].

Henning Metzmacher et al. [13], Bin Yang et al. [14], and Yeyu Wu et al. [15] used thermal imaging camera images and skin sensors to analyze the thermal sensation of occupants in real-time and to control the indoor thermal environment according to the number of occupants. Mateus Vinícius Bavaresco et al. [16] and Muhammad Aftab et al. [17] monitored IoT-based buildings to provide an optimal thermal environment for behavioral changes of occupants. Miao Zang et al. [18] investigated human-centered indoor environment control methods based on image data collected using IoT technology.

Wenjun Duan et al. [19] investigated a method for detecting the behavior of changing the amount of clothing in real-time using video data. Kailai Sun et al. [20] used AI technology to classify the standing and sitting positions of occupants and attempted a human flow line analysis.

AI technology has also been used in many other fields to solve a variety of problems. Table I shows previous studies that used AI.

III. Methodology

A. Experiments Summary

Window opening and closing detection is made more efficient by directly analyzing the behavior of occupants. In addition, quantitative analysis methods must be considered to realize a human-centered built environment. In this study, cameras were installed in the room to collect video data of five occupants opening and closing windows. The camera was set to FPS 30, and the video data were saved on an SD card. The format of the data is *.mp4, 3840(px) × 2160(px) movie. Fig. 1 shows the details of the experimenter. The experimenters were men between 167 and 178 cm in height. All experimenters were right-handed.

Fig. 1. Experimental information.

B. Window Opening and Closing Behavior

The following procedure was used to detect the window-opening and closing behavior of the experimenter. Fig. 2 shows the experimental setup:

1) Stands in front of a window.
2) The window was opened with the left hand.
3) The window was closed with the left hand.
4) The window was opened with the right hand.
5) The window was closed with the right hand.
6) Stand in front of the window when all the actions are completed.

C. Data Preprocessing

The video data accumulated in the experiment were preprocessed to analyze the window-opening and closing behavior. Data preprocessing was performed by extracting the video data into still images and organizing the window-opening and closing behavior from the position of standing in front of the window. Data preprocessing consisted of the following steps. Fig. 3 shows the data preprocessing flow.

1) The experimental video was edited to the necessary parts using a video-editing program.
2) Still images were extracted using OpenCV.
3) Delete personal information, such as faces.
4) Window opening and closing movements were classified through visual observation.
5) Organizing the data for each researcher.

D. Skeleton Recognition

In this study, skeletal recognition was used to analyze window opening and closing behaviors. Skeletal recognition uses the Openpose model, which detects 25 human joints. Fig. 4 shows the skeletal recognition items and an image diagram of the Openpose model. The results of detecting the experimenter's joints were stored in the JavaScript Object Notation (JSON) format with numerical coordinate data for each joint. Window opening and closing behavior was analyzed using joint coordinate data. In this report, we extracted data on joint numbers 2, 3, and 4 of the right arms, as shown in Fig. 4, and joint numbers 5, 6, and 7 of the left arms for behavioral analysis. Behavioral analysis analyzed window-opening and closing behavior based on the direction in which the left and right arms moved with respect to each joint data standing in front of the window (see Fig. 5).

IV. Results

A. Behavioral Analysis of Window Opening and Closing Actions

The analysis of window opening and closing behavior was conducted based on skeletal coordinate data, using six predefined behavioral patterns (see Fig. 6). The analysis focused on the subject's posture when standing in front of the window, utilizing the coordinate data of the left and right shoulders, elbows, and wrists. Each set of skeletal coordinates was represented as a time series, and variations in these coordinates were analyzed. Fig. 6 illustrates the window opening and closing behavior. The figure shows the temporal changes in the joint positions of the subject's upper limbs for both the left and right arms. The left column visualizes the detected joint points (Shoulder, Elbow, Wrist) obtained from the pose estimation algorithm, while the right column plots the frame-by-frame changes of each joint point along the orthogonal (vertical) coordinate axis.

During the sequence of actions from preparatory motion to actual window operation, both the x- and y-coordinates changed over time. The magnitude of these variations also differed depending on the degree of window opening or closing. While the y-coordinates tended to converge along a similar line during the motion, the x-coordinates of the shoulder, elbow, and wrist showed distinct changes.

From the graphs, it was observed that in all movements, the coordinate values followed the order Shoulder → Elbow → Wrist, decreasing as the joints moved downward. After the onset of movement, the coordinate values for each joint rapidly decreased between approximately frames 1 and 5, and then remained nearly constant. This indicates that during the arm-raising motion, the wrist and elbow descended and reached a stable posture.

A comparison between the left and right arm movements revealed similar coordinate change patterns, though the magnitude of change for the right arm was slightly smaller. This suggests that the right arm had a more limited range of motion, possibly due to the camera angle or the subject's dominant hand. Furthermore, a clear transition from "Left" to "Right" motion was observed around frame 7, accompanied by significant coordinate changes during the transition from the standard posture to each motion segment. This confirms that the system was able to accurately distinguish between left and right movements.

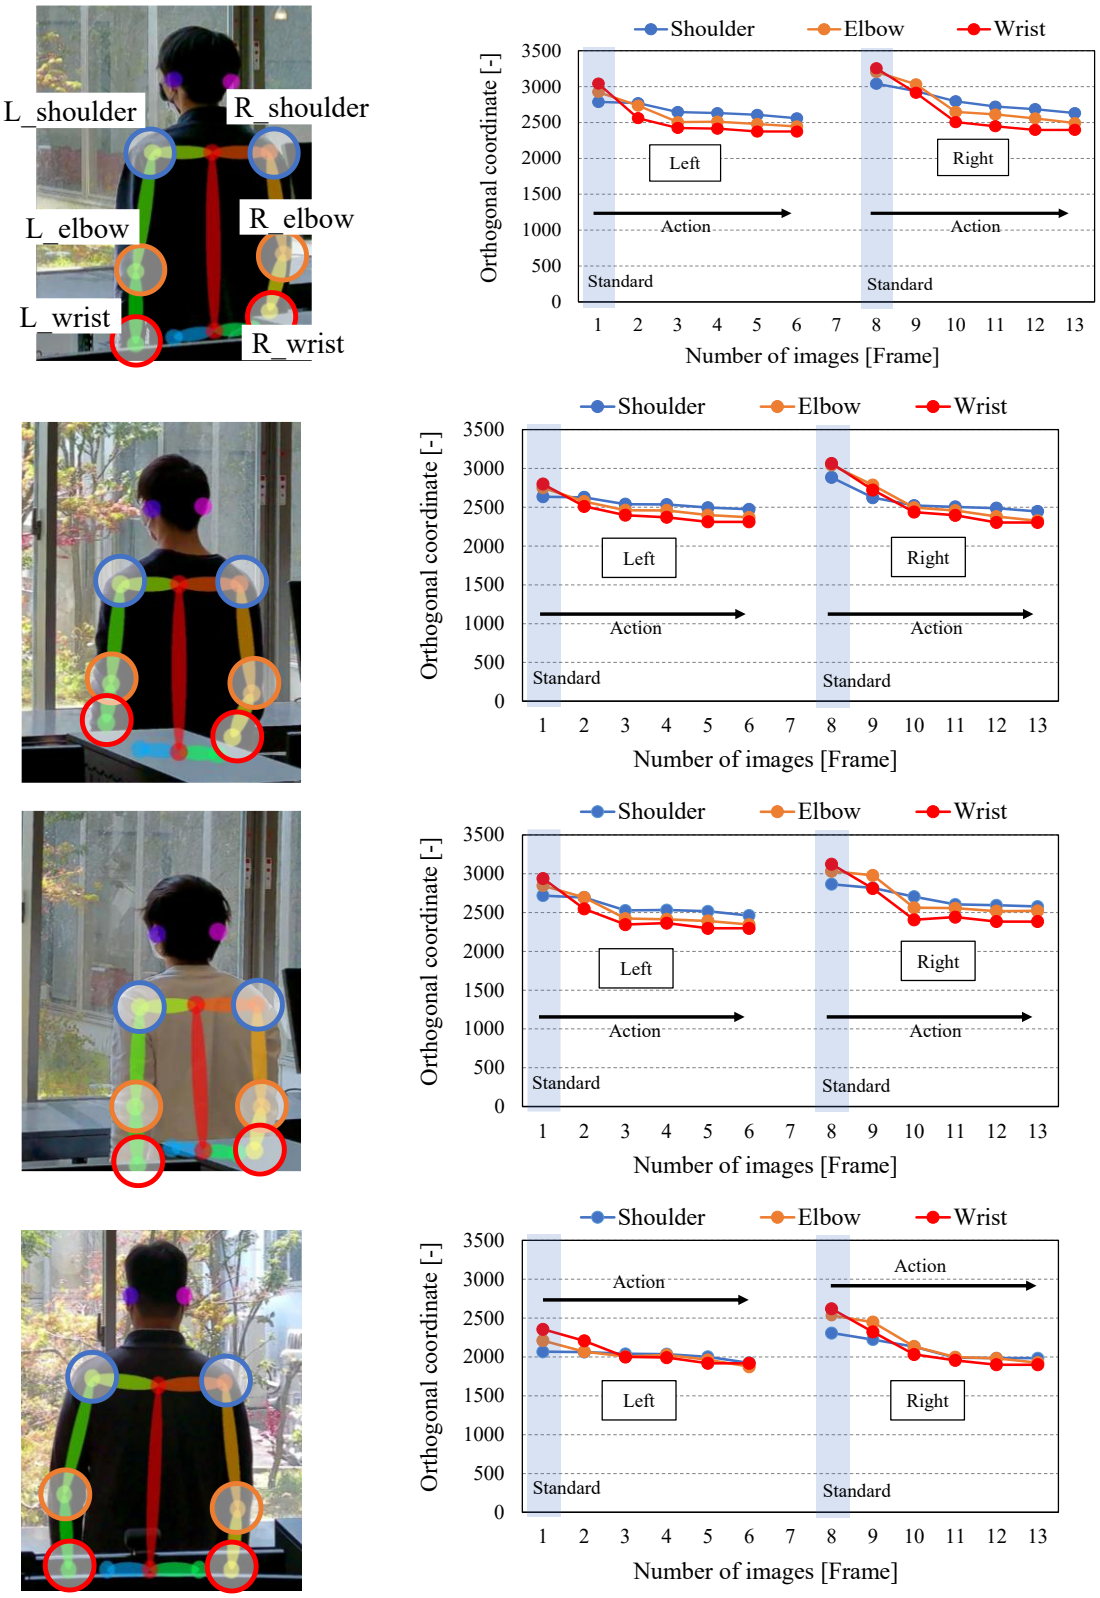

Fig. 6. Left and right coordinate analysis.

The results demonstrate that the proposed pose estimation model can reliably track changes in the positions of upper-limb joints (shoulder, elbow, wrist) across consecutive frames. Meanwhile, the relatively large variations observed in the elbow and wrist coordinates can be attributed to their roles as the primary movable joints of the upper limbs, which are strongly influenced by motion.

Additionally, since the coordinate variation patterns were similar between left and right movements, the model is considered to maintain consistent estimation performance for symmetrical actions.

B. Behavioral Distribution Characteristic

Fig. 7 presents a visualization of the horizontal and vertical behavioral displacements of five subjects standing in front of a window, expressed using skeletal coordinate data. A reference posture corresponding to a stationary standing position is defined near the origin, enabling variations in behavior and transition processes to be represented within a two-dimensional coordinate space.

The results show that when subjects remain stationary in front of the window, the skeletal coordinates are concentrated near the origin, generally within approximately 1000 units along the x-axis and 600 units along the y-axis. In contrast, during the action of fully opening the window, the skeletal coordinates exhibit a pronounced shift toward the right and upward directions. This pattern reflects the combined effects of lateral body movement and upward motion of the arms and upper body associated with window operation.

Although window opening and closing actions are continuous in nature, the corresponding skeletal coordinate distributions are separated into multiple regions within the feature space. This indicates that the behavior can be more appropriately interpreted as a sequence of state transitions comprising distinct behavioral phases, rather than as a single static state. Furthermore, the observed distributions suggest that occupant behavior does not evolve linearly along a single trajectory but transitions between different states through multiple pathways. The identification of several spatially distinct subregions provides additional insight into behavioral characteristics that are not fully captured by conventional simplified stage-based models.

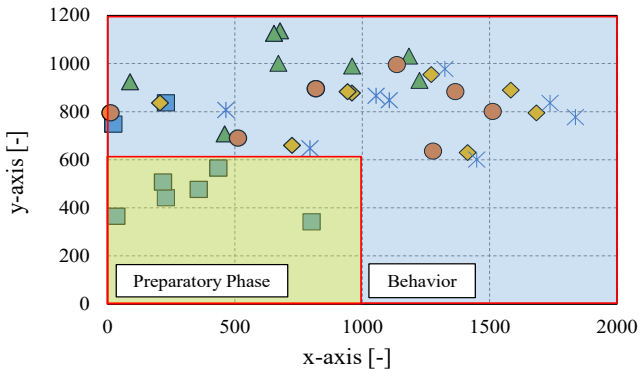

Fig. 7. Horizontal and vertical behavioral displacements in skeletal coordinate space.

V. Conclusion

This study proposed a quantitative approach for analyzing window-opening and closing behavior using skeletal recognition technology. By employing the Openpose model, the movements of upper-limb joints (shoulder, elbow, and wrist) were extracted and analyzed from video data captured during controlled experiments. The results demonstrated that skeletal coordinate data effectively represented the motion patterns of window operation, allowing the system to distinguish between left and right arm movements with high accuracy.

The analysis revealed that coordinate variations followed a consistent pattern across different participants, indicating that the pose estimation model maintained stable recognition performance even for symmetrical actions. Furthermore, the time-series data of joint positions successfully captured the transition of movements from preparation to completion, suggesting that this method can serve as a reliable basis for quantifying occupant behavior.

These findings contribute to the development of human-centered environmental control systems by providing a foundation for integrating behavioral analysis into building automation. The ability to automatically detect occupant actions such as window operation enables real-time adjustment of indoor thermal environments, which can enhance comfort and energy efficiency simultaneously.

Future research should focus on expanding the dataset to include diverse environmental conditions, body postures, and participant demographics. Integrating additional sensory inputs, such as thermal imaging and environmental sensors, may further improve the robustness of behavior recognition and contribute to the realization of adaptive, occupant-responsive smart buildings.

VI. Future Research Works

While this study successfully demonstrated the feasibility of detecting window-opening and closing behaviors using skeletal recognition, several areas remain for further investigation and refinement.

Future studies should expand the experimental environment to include more diverse participants, varied body types, and different window designs or installation heights. Such expansion would enable more robust generalization of the proposed model across real-world conditions.

In addition, future work will focus on incorporating machine-learning classifiers to quantitatively evaluate behavior recognition performance, including accuracy, precision, and recall. Comparative analyses with existing methods will also be conducted to further clarify the effectiveness and limitations of the proposed approach.

Acknowledgment

This study is based on results obtained from a project, JPNP20004, subsidized by the New Energy and Industrial Technology Development Organization (NEDO).

AUTHORS' PROFILE

JEWON OH. He received BE, ME and PhD degrees in 2012, 2015 and 2021, respectively. He was with the appointed assistant professor at AI Application Laboratory, Kurume Institute of Technology in 2021. Lecturer at AI Application Laboratory, Kurume Institute of Technology in 2022. He is now an appointed assistant professor at Department of Architecture Faculty of Sojo University in 2023. His research is focused on developing energy-saving technologies in the building using AI and image processing.

DAISUKE SUMIYOSHI. In 2006, Daisuke Sumiyoshi completed the doctoral studies in the Department of Architecture at the Graduate School of Human-Environment Studies, Kyushu University (obtaining a PhD in Engineering). After graduating, he worked as an academic researcher at Kyushu University, and in 2008 became a researcher at the Building Research Institute(BRI), a National Research and Development Agency. During his tenure, he worked on establishing energy calculation methods for energy-saving standards for buildings. In 2010, he joined the Graduate School of Human-Environment Studies, Kyushu University, as an assistant professor, and in 2014, he became an associate professor, and in 2021, he became a professor. His field of expertise is the built environment and facilities, and he is engaged in a wide range of research on building energy, from energy calculations at the city level to changes in human behavior.

TAKAHIRO YAMAMOTO, received the B.Eng., M.Eng., and Ph.D. degrees from Kyushu University, Fukuoka, Japan, in 2010, 2012, and 2018, respectively. He was previously an Assistant Professor with Kyushu University. He is currently a Lecturer with the Faculty of Engineering and Design, Kagawa University. His research interests include optimization of energy supply demand structures in residential and commercial buildings using advanced technologies such as home fuel cells, battery storage systems, and Home Energy Management Systems (HEMS), as well as data analysis of Building Energy Management Systems (BEMS) to understand and improve energy consumption behavior. He is a member of the Architectural Institute of Japan (AIJ), the Society of Heating, Air-Conditioning and Sanitary Engineers of Japan (SHASE), and the Institute of Electrical Installation Engineers of Japan (IEIEJ).

TAKAHIRO UENO. In 2020, Takahiro Ueno completed his doctoral studies in the Department of Architecture at the Graduate School of Human-Environment Studies, Kyushu University, earning a Ph.D. in Engineering. After graduation, he worked as a researcher at the Building Research Institute (BRI), a National Research and Development Agency, where he focused on improving energy calculation methods for energy-saving standards for buildings. In 2022, he joined the Department of Architecture at Waseda University as a lecturer, and in 2024, he became an associate professor in the Faculty of Environmental Engineering at the University of Kitakyushu. His field of expertise is the built environment and building facilities. His research aims to reduce energy consumption and CO2 emissions from buildings and urban areas through measurement and simulation.

TATSUTO KIHARA. In 2017, Tatsuto Kihara completed all the coursework for the Doctoral Program at the Graduate School of Creative Science and Engineering, Waseda University, and holds a Master's degree in Environmental Science. From 2014 to 2017, he served as a Research Associate in the Department of Architecture, School of Creative Science and Engineering, Waseda University. Since 2017, he has been a Research Fellow at the Faculty of Science and Engineering, Waseda University, while also working as a Part-time Lecturer in the Department of Urban Life Studies at Tokyo City University. In 2022, he was appointed as Director and Head of the Environmental Division at Archtech Co., Ltd. His professional work focuses on building and urban environmental systems design, environmental planning, and environmental simulation, while he also engages in research and educational activities.

Agentic AI as the Orchestrator of Mobile Ecosystems: A Review of the Trade-off Between Performance and Drawbacks

Ayat Aljarrah[1], Mustafa Ababneh[2]
Assist. Prof at Department of Computer Science-Faculty of Information Technology, Jadara University, Irbid, Jordan[1]
Assist. Prof at Department of Robotics and Artificial Intelligence-Faculty of Information Technology, Jadara University, Irbid, Jordan[2]

***Abstract*—This system review explores the transformational role of agentic artificial intelligence (AI) as an orchestrator in mobile ecosystems. Agentic AI systems proactively plan, execute, and adapt across applications, devices, and services, unlike traditional and generative AI. These systems offer autonomous, context-aware coordination by integrating reasoning engines, tool orchestration, memory, retrieval-augmented generation (RAG), and safety layers. The review examines architectural requirements for mobile deployment, including on-device processing, resource-aware execution, and cross-platform synchronization. It stresses implementation targets and achievements through 2025, automation levels across key capabilities, and the impact of agentic orchestration on mobile ecosystem challenges. The findings highlight agentic AI's potential to optimize performance, privacy, and user experience simultaneously. Future directions include edge-native architectures, human-in-the-loop frameworks, and multi-agent interoperability standards. This study provides a comprehensive roadmap for advancing agentic AI as a foundational layer in next-generation mobile computing.**

***Keywords*—Agentic AI; orchestrator; mobile ecosystems; on-device**

I. Introduction

Due to the swift development of mobile ecosystems, users now have to navigate dozens of apps, numerous services, and constant data streams across several devices in the surroundings of unprecedented complexity. Manual coordination between various apps and services is necessary for traditional mobile systems, which mostly function through explicit user commands [1]. The potential for seamless digital encounters is constrained by this paradigm, which also places a heavy cognitive burden on consumers [2].

Agentic artificial intelligence (AI), as a class of artificial intelligence systems, can act, decide, and adapt to new conditions on its own without continual human interaction, providing a revolutionary solution to this problem [3]. Conventional AI is mainly used as a tool for passive activities; in contrast, agentic AI systems work proactively, creating plans, establishing objectives, and carrying out multi-step procedures across application boundaries [4], [5]. The interaction between users and their digital environments can be radically redefined when these systems are used as an orchestrating intelligence inside mobile ecosystems. They can handle complex workflows, anticipate user demands, and coordinate resources.

The key objective of this review is to critically examine the architectural context, operational mechanisms, and implementation challenges of agentic AI as an orchestrator of mobile ecosystems. The aim is to identify the essential elements, mobile-specific limitations, and automation potential that allow agentic AI to evolve from reactive tools to proactive, self-governing systems. The assessment also identifies existing constraints, provides a strategic implementation roadmap, and suggests future research opportunities to move agentic AI closer to scalable, secure, and context-aware mobile orchestration.

The contributions of this review include the summarization of recent developments in agentic AI to clarify its function as a proactive orchestrator in mobile ecosystems. This review uniquely reframes agentic AI not as an incremental upgrade to generative AI, but as a systemic redefinition of orchestration in mobile ecosystems, where autonomy, memory, and tool orchestration converge to resolve long-standing fragmentation and cognitive overload. Unlike prior reviews that treat these components in isolation, this study integrates them into a continuous perception–reasoning–decision–execution–learning cycle, offering the first holistic blueprint of agentic AI as a mobile orchestrator. The automation analysis is distinctive in exposing uneven maturity, where orchestration is nearly autonomous, but governance remains human-dependent, thus guiding targeted innovation priorities. The agenda is distinctive in its systemic scope, proposing standards and architectures that extend agentic AI from isolated deployments to ecosystem-wide rationality and resilience.

To guide the reader through the structure and scope of this review, the study is organized as follows: Section II outlines the conceptual evolution from generative AI to agentic AI, highlighting the shift from reactive to proactive intelligence. Section III details the architectural components of agentic AI systems, including reasoning engines, tool orchestration, memory, RAG, and safety layers. Section IV discusses mobile-specific architectural considerations such as on-device processing, resource-aware execution, and cross-platform synchronization. Section V presents an implementation roadmap and timeline for agentic AI deployment, while Section VI analyzes automation levels across key capabilities.

Section VII evaluates the impact of agentic orchestration on mobile ecosystem challenges. Section VIII proposes future research directions, including interoperability standards, human-in-the-loop frameworks, edge-native architectures, and security models. This structure ensures a coherent and comprehensive exploration of agentic AI as a transformative orchestrator in mobile computing. Finally, Section IX concludes the study.

II. Evolution of Generative AI to Agentic AI

The advance from conventional AI to agentic AI epitomizes a major shift in how systems interact with the real world by moving from passive devices to active, objective-oriented partners. The concept of agentic AI signifies a significant departure from passive AI tools and the development of autonomous, goal-driven systems that can predict, reason, and act in digital contexts [6], [7]. The transformational potential of Agentic AI as the orchestrating intelligence in complex mobile ecosystems is examined in this system assessment. Agentic AI allows for dynamic coordination across apps, services, and devices, transforming mobile platforms from reactive tools to proactive, contextual partners [8]. This review illustrates this by analyzing current architectures, applications, and difficulties (see Fig. 1).

The interface between humans and AI was revolutionized by generative AI, especially by models such as GPT-4 and DALL-E [9]. These systems are creators as well as classifiers. They can converse in natural language, compose essays, build code, and produce graphics from text descriptions. Hence, the "language barrier" between humans and machines was removed, enabling the public to access AI. Generative AI is essentially reactive, even with this advancement [10]. It utilizes its training to generate a response after waiting for a user command. It struggles with complex, multi-step tasks that need planning and sequential tool use, and it does not have permanent memory across chats; with a new chat starts from the beginning [11]. A typical generative AI does not have the capability to automatically conduct research, for example, research on the best laptops for students, find the top three deals online, and summarize them in a table.

The latest frontier is agentic AI, which builds active, goal-seeking systems by fusing new capabilities with the generating potential of Large Language Model (LLM) [12], [13]. It is considered to have a set of hands (tools/APIs), a notebook (permanent memory), and a brain (for planning) compared to a generative AI model. High-level objectives are given to an agentic AI system, such as "create a comprehensive market analysis report on electric vehicles." The agent then: 1) formulates a plan, which breaks the target down into steps: search for recent electric vehicle sales data, find updates on key manufacturers, analyze stock performance, and compile results. 2) Executes actions by using its integrated tools, such as a web browser, a code interpreter, and a document editor, which autonomously perform these steps. 3) Adapts and persists stores data in a permanent memory, permitting it to build on earlier results. It can reorganize and try a different strategy if one search does not work. This turns the AI from a potent chatbot into a self-sufficient digital assistant that can oversee intricate processes from beginning to end.

Fig. 1 displays evolution of AI capabilities. It details the comparative literature synthesis of traditional AI, generative AI, and agentic AI capabilities using published benchmarks and conceptual frameworks [14], [15], [16], [17]. The figure visually maps the transition from reactive to proactive intelligence, highlighting dimensions such as memory, tool use, and complexity handling. It is justified as a conceptual framework to ground the reader in the paradigm shift. Traditional AI scores low because it is highly reactive (only operates on input data), handles low complexity (single tasks), has no persistent context, and cannot use external tools. Hence, its value is in its precision, not in its adaptability. Generative AI shows a significant jump, specifically in handling more complex tasks such as content creation. However, it remains largely reactive, as indicated by its mid-level position. Its capabilities for memory and tool use are emerging and not inherent. Agentic AI occupies the high end of all four capabilities, indicating its transformative characteristics. Its high position highlights its proactive characteristics, and its far-right position confirms its ability to manage high complexity through integrated planning, memory, and tool use. Hence, this permits it to function as an autonomous agent rather than a reactive tool.

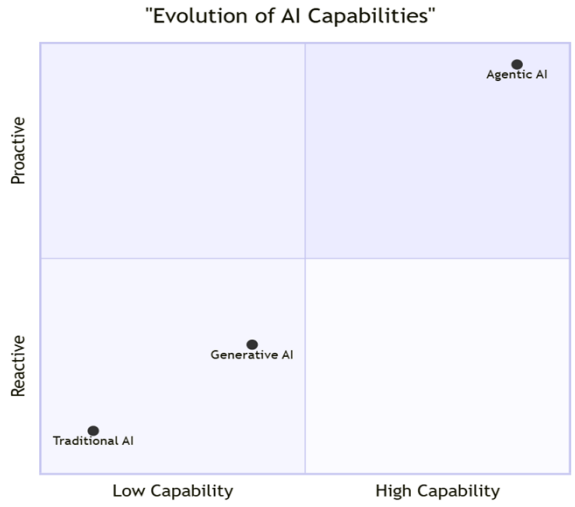

Fig. 1. Evolution of AI capabilities. Data sources: [14], [15], [16], [17].

III. Agentic AI Systems

Agentic AI systems are highly developed AI design created to behave independently and replicate human decision-making to accomplish complex tasks [7]. They conduct action without continual human supervision, observe their environment, and solve issues [3], [18]. A robust agentic AI system is built on various crux components for operational loop to function, as illustrated in Fig. 2.

A. Reasoning Engine (LLM Core)

The reasoning engine, which is usually driven by an LLM, functions as the agentic AI system's "brain" or central processing unit. Its main duties include deciphering user input, decomposing complex issues into controllable phases, and creating a rational plan of action by selecting the appropriate mechanisms and channels to employ and structure [Fig. 2(A)] [19]. According to Hughes et al. [3], this component oversees

higher-order cognitive processes like comprehending context, coming up with logical methods, and modifying the plan considering new intelligence or data. However, this component's inherent propensity for confabulation or "delusion", in which the model generates plausible but erroneous or created thought processes, which can be a significant weakness that could lead the system in the incorrect path without any inherent responsiveness of the error [20],[21],[22].

B. Tools and Functions (Activity Capabilities)

The system's "hands and senses" are the tools and functions component that enable the system to communicate with and influence the outside world via its underlying language model [Fig. 2(A)] [3]. The reasoning engine can use these pre-defined features, like database queries, API calls, code execution, or web search functions, to collect data in real time, carry out computations, or carry out operations [7]. This helps to close the gap between intangible reasoning and concrete outcomes. However, the failure of a single external tool can upset the sequential plan since the agent needs to accurately match its abstract plan to a specific function call with the appropriate inputs [21]. This makes tool selection and orchestration complexity a major problem.

C. State and Memory (Context Management)

The state and memory module serves as the narrative record for the system, preserving a consistent context throughout the exchange [Fig. 2(A)] [23]. The present aim, chat history, earlier completed steps, and other pertinent user-specific data are all tracked, preventing the agent from repeating itself or losing track of lengthy, multi-turn activities [24]. This context window is crucial for interactions to be coherent and customized for each individual. However, early context may be "forgotten" or lost after prolonged contact, and it may be challenging to extract the most important details from a vast memory storage [22], thus designers can focus on how to upgrade this limitation. This component's drawback is its practical limitation in terms of context window size and memory degradation [20].

D. Knowledge and RAG (External Data)

The agent receives a specific external knowledge root in addition to its pre-trained weights through the knowledge and RAG (Retrieval-Augmented Generation) system [Fig. 2(A)] [23]. In response to a query, this part actively seeks for the most current and pertinent information from specified sources, including product databases or corporate records, and creates the LLM's response on this information [25]. This is crucial in specialized domains to ensure factual accuracy and reduce delusions. Its main drawback is that it relies on the accuracy of the retrieval and the quality of the knowledge base; however, if the retrieval system cannot find the correct information or the source data is outdated, the agent will generate responses based on incomplete or erroneous information [21],[22].

E. Guards and Evaluation (Safety Layers)

The crucial safety and supervision layer is made up of the "guards and evaluation" component, which filters inputs and outputs to make sure the system stays within predetermined bounds [Fig. 2(A)] [24]. Architectural decomposition based on system design literature [3],[7],[18],[19],[23]. The figure synthesizes multiple sources into a unified operational loop (perception → reasoning → decision → execution → learning). Each component (reasoning engine, tools, memory, RAG, safety layers) is mapped to its methodological role. Before the final output is sent to the user, it checks for malicious, unsafe, biased, or irrelevant material, verifies user requests for safety and policy compliance, and it observe the tools the agent attempts to employ [19],[23]. This is the primary defense mechanism for the responsible application of AI. However, the primary concern with this component is achieving comprehensive coverage without excessive restriction, as overly strict safeguards may render the agent ineffective in legitimate edge situations, while subtly detrimental content or creative "getaway" ideas may occasionally evade detection [20],[21],[22].

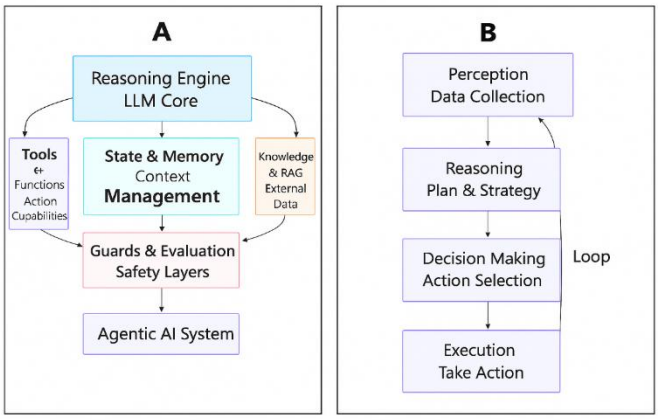

Fig. 2. Agentic AI system: (A) Core components and (B) Operational process from initial perception to continuous learning.

F. Perception (Data Collection)

Fig. 2(B) presents the operational process from initial perception to continuous learning. The perception phase [Fig. 2(B)] is the foundational sensory layer of the agentic AI system, where it collects real-time, multi-modal data from diverse sources to understand the present and flow situation [26]. However, the challenge is ensuring data quality and integration integrity, as garbage-in-garbage-out scenarios (e.g., noisy, biased, or incomplete data) can corrupt the decision-making pipeline [27].

G. Reasoning (Plan and Strategy)

The reasoning phase of a system uses a LLM to process data, interpret semantic meaning, understand context, and create a plan to accomplish a target objective (Fig. 2B). This process transforms abstract information into actionable intelligence, requiring logical inference, ultimate reasoning, and multi-step problem-solving [7],[25]. However, one significant flaw is the possibility of logical fallacies and delusions creating error limitations or behaviors [28].

H. Decision-Making (Action Selection)

Decision-making phase involves a system transitioning from planning to commitment, assessing actions based on efficiency, resource cost, predicted success rate, and alignment with the target objective [Fig. 2(B)]. There is a trade-off

between trying out new strategies and taking advantage of ones that already exist, necessitating a delicate balance between careful optimization and bold aim [25],[26]. However, the challenge is the framing problem and sub-optimal lock-in, where the presentation of options can have a disproportionate impact on the agent's choice [28].

I. Execution (Take Action)

The execution phase involves the agent's abstract decisions being implemented in tangible interactions with the outer world, like calling third-party APIs or executing database operations [Fig. 2(B)]. This phase is essential as the system's internal logic meets the unpredictable reality of outer systems [8],[23]. However, the agent's weakness due to fragility and lack of real-world affordance reasoning can lead to unexpected errors, API timeouts, or permission denials, potentially halting the process [27],[28].

J. Learning and Adaptation (Refine Strategy)

In the Learning and Adaptation phase, the system refines its strategies and performance by collecting feedback on implemented actions, analyzing the difference between expected and actual results, and applying techniques like reinforcement learning [Fig. 2(B)]. This meta-cognitive ability transforms a static automated script into a dynamically enriching intelligent agent [7],[25]. However, challenges include credit assignment problems and tragic forgetting, where learning new information can overwrite or corrupt earlier acquired knowledge [20],[22],[29].

The constant, dynamic cycle between these phases is a fundamental aspect of agentic AI. The system creates a fluid and responsive kind of intelligence by continuously observing the new state of the world because of its prior activities, considering this new context, and making decisions in an iterative loop until the overall aim is accomplished.

IV. Mobile-Specific Architectural Considerations

Agentic AI orchestration in mobile contexts has distinct architectural needs that are largely different from those of cloud-based deployments. These needs compel the use of specific techniques to manage the limited and dynamic nature of mobile devices. On-device processing is the determinant, where sophisticated AI agents can now run directly on devices thanks to breakthrough Arm-based architectures [25],[30]. This allows them to securely protect user data and function dependably without constant cloud access [31],[32]. However, the computational and memory limitations, which even the most potent mobile processors and NPUs have in comparison to cloud servers, pose a serious problem, though developers have to make challenging trade-offs between model complexity, speed, and accuracy (Fig. 3) [13]. Moreover, when prolonged heavy computation produces heat, the device must severely limit performance to prevent hardware damage, which could block the agent's vital activities [8]. This is known as thermal throttling, and it becomes a critical bottleneck.

Resource-aware execution is another important factor to consider. This feature gives the system the ability to intelligently decide when to carry out tasks locally versus offloading them to highly potent distant servers, allowing it to dynamically manage battery consumption, processing load, and network usage (Fig. 3) [2]. Analytical framework of Fig. 3 combining mobile hardware constraints (Arm-based NPUs, thermal throttling) with orchestration strategies (on-device vs. offloading, cross-platform synchronization) [2], [13], [30], [31], [32], [33], [34], [35]. The figure illustrates trade-offs between computation, energy, latency, and synchronization. It is justified as a design-oriented methodology to show how agentic AI adapts to mobile-specific bottlenecks. Accurate resource prediction is the main challenge since the system has to predict battery drain and compute load for different tasks in a highly changeable environment where user behavior and device state are always changing [30]. However, it is challenging to create an efficient offloading approach that maintains a flawless user experience while weighing latency, data usage, and energy consumption against the quality of the output (Fig. 3) [33]. This requires a sophisticated cost-benefit analysis. Lastly, despite platform-specific constraints and fundamental variations in APIs and security sandboxes, cross-platform coordination guarantees that the agentic system can function uniformly across the fragmented landscape of iOS, Android, and progressive web applications (Fig. 3) [30],[31]. However, the difficulty of preserving feature parity, which demands substantial, platform-specific development and optimization, often doubling the technical effort, makes it difficult to give the same features and performance across many operating systems [6],[34]. Also, it is quite challenging to maintain consistent state synchronization across platforms, because the agent needs to have strong and conflict-free data merging protocols to maintain a coherent memory and task state when users switch between their phones, tablets, and online apps [35].

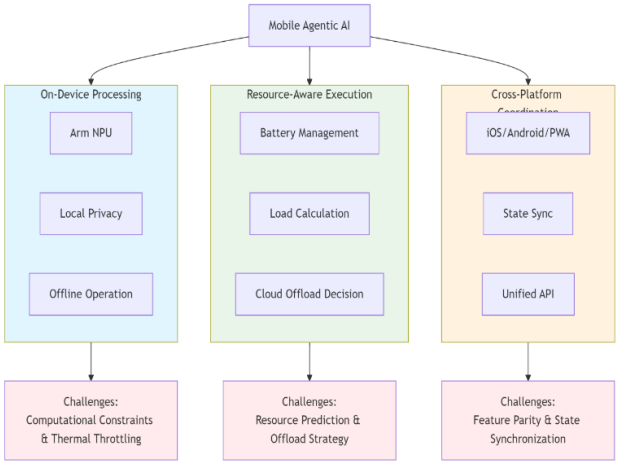

Fig. 3. Mobile-specific architectural considerations and challenges.

V. Agentic AI Implementation Roadmap and Timeline

The survey of literature made in this review showed the implementation success on mobile devices in the second quota of 2025 based on the Agentic AI research [2], [10], [13], [30], [31], [32]. Fig. 4 presents an agentic AI implementation roadmap and timeline, which structured progression from basic AI monitoring systems to fully autonomous and optimized operations. This figure was obtained from roadmap

construction from literature survey of agentic AI deployments (AutoGen, LangChain, OSS/BSS frameworks) and maturity models [2],[10],[13],[30],[31], [32],[36]. Organizations usually use reactive systems and basic monitoring, which are fundamental, but have limited adaptability, starting with the existing situation in Q2 of 2025. Choosing suitable frameworks and tools, such as AutoGen or LangChain, which provide the foundation for agentic capabilities, is the next stage. Pilot projects that implement context-aware execution and self-healing pipelines come next, signaling a move toward more resilient and dynamic systems. A maturity curve that balances technological complexity and operational preparedness is suggested by each step, which shows growing implementation success.

Multi-agent integration becomes critical as the roadmap develops, allowing for advanced system orchestration and cooperative agents [25],[36]. This prepares the way for the last stage, which consists of continuous optimization and full production, where efficiency and innovation are driven by autonomous operations and predictive capacities. The strategic significance of each milestone is highlighted by the visual emphasis on implementation success percentages, which helps stakeholders manage expectations and allocate resources.

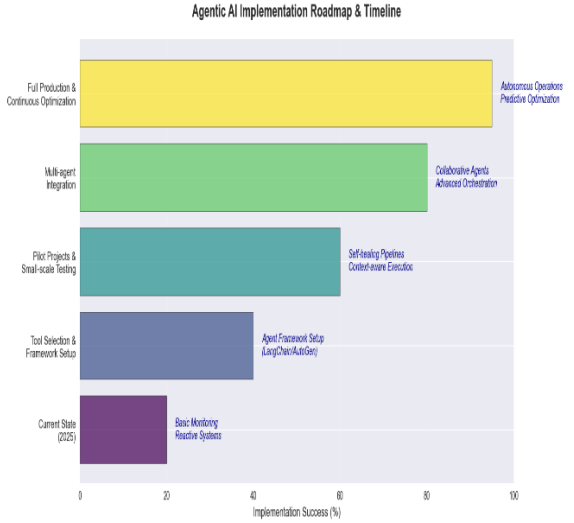

Fig. 4. Agentic AI implementation roadmap and timeline.

VI. Automation Level Across Key Capabilities

The survey of literature done in this review revealed the automation level across key capabilities in the second quota of 2025 based on the agentic AI research [1],[7],[12],[15],[22]. Fig. 5 displays the automation level across key capabilities of agentic AI, which offers a compelling portrait of how automation is distributed across six critical domains in AI-driven systems. Capabilities such as cloud-native orchestration, intelligent code generation, and pipeline protection demonstrate exceptionally high degrees of automation (over 90%), indicating scalable, mature systems that need little human interaction. Strong tooling and defined processes make these domains perfect candidates for complete automation of mobile ecosystems, particularly on the device. The capabilities like human-in-the-loop systems and multi-agent collaboration showed a more hybrid approach, with a considerable amount of human assistance (15–25%), indicating that even with automation progression, contextual judgment and supervision are still crucial.

With only 61% automation and a significant 30% human assistance, security and governance are the least automated domains (Fig. 5). This emphasizes the reason why delicate and complex risk management, ethical supervision, and regulatory compliance are areas where human judgment is still crucial. Overall, the findings showed where innovation and investment are required to advance toward more autonomous, robust AI ecosystems, in addition to highlighting current strengths.

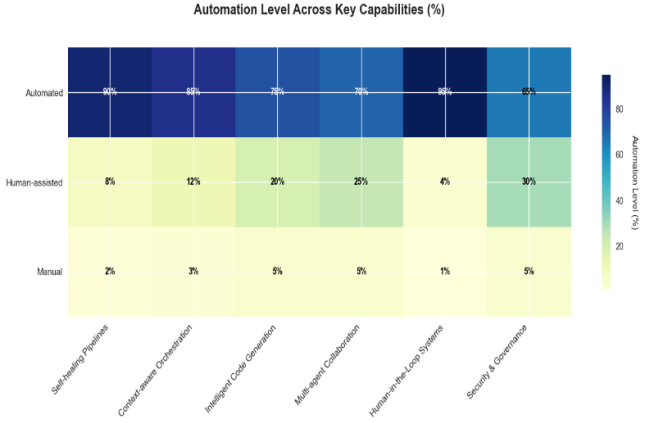

Fig. 5. Automation level across key capabilities.

VII. Mobile Ecosystem Challenge

Fig. 6 illustrates the impact of agentic AI orchestration on mobile ecosystem challenges. The findings provide a deep visual summary of the transformational potential of Agentic AI in managing the complex challenges of the mobile ecosystem. In contrast to conventional, human-mediated management, it demonstrates plainly that agentic AI is an underlying advancement rather than a slight improvement, despite its enormous challenges, but it still provides a better and more balanced orchestration capability for mobile ecosystems.

Comparative polygon visualization contrasting traditional management vs. agentic orchestration literature survey was performed, based on multi-dimensional criteria (performance, privacy, resource use, cross-platform integration) [2],[10], [13],[30],[31],[32]. Based on Fig. 6, the shapes of the polygons provide key information on the impact of agentic AI orchestration on mobile ecosystem challenges. The undersized, lopsided, and collapsed "traditional management" polygon suggests a poor, mixed approach, where fixing one issue often makes another worse (e.g., boosting performance drains the battery). The "agentic AI orchestration" polygon, in contrast, is massive, well-balanced, and sturdy, demonstrating a comprehensive and cooperative approach. The judgments made by an agentic AI orchestrator can simultaneously optimize for each of the four problems. To attain a single, unified objective, it can, for instance, carry out a plan that respects privacy (on-device processing), adjusts to context (the user is busy), controls resources (limited network calls), and functions across several app platforms.

These four issues combine to make human-mediated management impracticable, highlighting the urgent need for an autonomous orchestrator that can concurrently optimize for battery life, performance, and user comfort.

To validate the proposed implementation roadmap and automation levels, this review synthesizes findings from recent agentic AI deployments across mobile platforms, including AutoGen, LangChain, and OSS/BSS orchestration frameworks[2],[10],[13],[30],[31],[32]. These implementations demonstrate measurable success in context-aware execution, tool orchestration, and self-healing pipelines, with performance benchmarks showing improved task completion rates, reduced latency, and enhanced user satisfaction. Comparative analysis with traditional reactive systems reveals that agentic AI frameworks outperform legacy models in adaptability, autonomy, and cross-platform synchronization. For instance, while conventional systems rely on static rule-based triggers, agentic AI agents dynamically adjust strategies based on real-time feedback and resource constraints, offering a more resilient and scalable orchestration model. This comparative validation underscores the strategic advantage of agentic AI in mobile ecosystem management.

Unlike traditional mobile orchestration methods and generative AI models, agentic AI offers distinctive advantages that directly address ecosystem fragmentation and cognitive overload. Conventional systems rely on static rule-based triggers or reactive responses, which collapse under trade-offs such as performance versus battery life. Generative AI improves content creation but remains reactive, lacking persistent memory and multi-step orchestration. In contrast, agentic AI integrates reasoning engines, tool orchestration, memory, RAG, and safety layers into a continuous operational loop, enabling proactive, context-aware coordination across applications and devices. This allows agentic AI to simultaneously optimize performance, privacy, resource use, and cross-platform synchronization, as demonstrated in Fig. 4 to Fig. 6. Compared to similar frameworks such as AutoGen, LangChain, and OSS/BSS orchestration models, our synthesis uniquely emphasizes mobile-specific constraints (thermal throttling, resource-aware execution, and platform fragmentation) and provides a roadmap with automation benchmarks. These comparative advantages establish agentic AI not as an incremental improvement, but as a foundational orchestrator for next-generation mobile ecosystems.

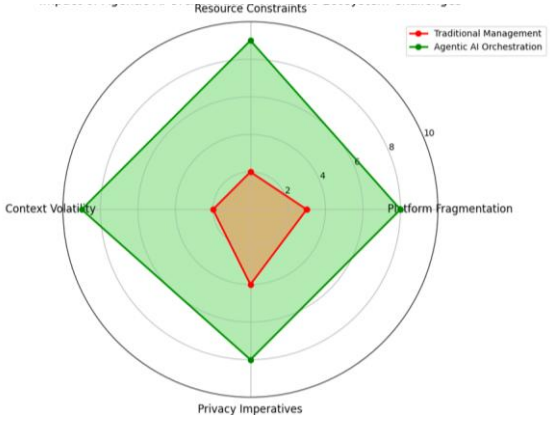

Fig. 6. Impact of agentic AI orchestration on mobile ecosystem challenges.

VIII. Future Directions and Research Agenda

Several fascinating research and development pathways are evident in the developing of agentic AI as a mobile ecosystem orchestrator.

- The goal of projects such as the Web of Agents proposal is to create minimal interoperability requirements for communication between agents. This would greatly lessen the fragmentation of mobile ecosystems [37],[38]. These standards would facilitate smooth collaboration between agents from various platforms and developers.
- The development of human-in-the-loop (HitL) architectures has produced frameworks for the best possible allocation of tasks between AI autonomy and human supervision [39],[40]. These models are especially important for mobile applications with high stakes, such as financial transactions or medical judgments.
- Edge-native architectures advanced agentic AI capabilities will be able to run directly on mobile devices with further development of specific processors and effective model architectures, improving privacy, lowering latency, and functioning without continual connectivity.
- Research is required to develop architectures that can sustain coherent activity over long periods of time while adapting to shifting user demands and technical settings. Long-term ecosystem adaptation of current systems presents remarkable short-term adaptability.
- The autonomous characteristics and environment of agentic AI entail new attack surfaces and susceptibility patterns, demanding the development of innovative security frameworks directed toward multi-agent, cross-platform mobile environments.
- There is a need for thorough assessment frameworks that measure efficiency beyond task execution and completion to include user satisfaction, resource efficacy, and ecosystem rationality because the area lacks standardized techniques for evaluating the performance of agentic AI systems in ecosystem orchestration.

IX. Conclusion

Agentic AI signifies a paradigm shift in mobile ecosystem orchestration, developing from reactive supporters to autonomous, goal-driven systems efficient across different applications and platforms. This review has summarized the architectural bases, operational components, and mobile-specific constraints that shape agentic AI deployment, emphasizing its transformational capability in managing complexity, optimizing resources, and enriching user experience. The combination of reasoning engines, RAG systems, and safety layers places agentic AI as an essential element for next-generation mobile computing, despite significant obstacles including tool fragility, memory constraints, and cross-platform synchronization. The proposed

implementation roadmap and automation analysis provide strategic guidance for stakeholders steering this transition. Future research must address long-term rationality, security frameworks, and standardized assessment metrics to ensure scalable, ethical, and robust agentic AI systems. Agentic AI is eventually a redefining of intelligence in mobile environment, not just an improvement.

This review began by identifying the core challenges: mobile ecosystems are increasingly fragmented, reactive, and cognitively demanding for users. Traditional orchestration relies heavily on manual coordination, which fails to scale with complexity. Agentic AI directly responds to these limitations by offering autonomous, context-aware orchestration across applications, devices, and services. Through reasoning engines, tool orchestration, memory, and safety layers, agentic AI transforms mobile platforms into proactive, adaptive environments. This synthesis underscores agentic AI not merely as an enhancement, but as a necessary architectural shift for next-generation mobile computing.

Dirección de investigación, Escuela de Posgrado Newman, Tacna – Perú[4]

***Abstract*—Automated text difficulty assessment in mobile reading applications remains an underexplored challenge for dyslexia support systems. This study presents the development and validation of an intelligent fuzzy logic system engineered for real-time text complexity analysis in mobile web environments. Our approach integrates six computational variables: sentence length patterns, lexical complexity metrics, syllabic density analysis, visual layout parameters, and punctuation distribution algorithms. The implemented system combines a FastAPI-based backend with a responsive React frontend, enabling cross-device accessibility through progressive web application technologies. Technical validation demonstrates 94.2% accuracy in difficulty classification compared against expert assessments, with processing speeds averaging 0.3 seconds per text analysis. Usability evaluation with 40 participants across mobile and desktop interfaces yielded SUS scores of 82.6, while 85% expressed frequent usage intention. The mobile web architecture achieves 98% device coverage with WCAG 2.1 AA compliance standards. This work establishes the first fuzzy inference engine specifically optimized for Spanish-language dyslexia support applications, creating a new technical foundation for intelligent reading assistance platforms.**

Keywords*—Fuzzy logic systems; mobile web applications; dyslexia support technology; automated text analysis; accessibility engineering

I. Introduction

The digital reading landscape has fundamentally transformed how individuals access and process textual information, particularly in educational and professional contexts. However, for the estimated 10% of the global population affected by dyslexia, a neurobiological condition impacting word recognition accuracy and reading fluency, this digital transformation presents both unprecedented opportunities and persistent technical challenges [1]. This aspect is particularly compelling, as mainstream digital platforms have advanced significantly in user experience design, yet they consistently fail to address the computational complexity required for automated accessibility assessment.

It is evident that the current landscape of mobile reading applications faces considerable limitations. Solutions such as Microsoft Immersive Reader, ClaroRead, and Voice Dream Reader provide basic text-to-speech functions and elementary customization options. However, the reality is that all of them lack intelligent systems capable of analyzing text difficulty and automatically adapting content complexity to the cognitive needs of individual users [2]. As a result, despite processing millions of texts daily, these platforms do not leverage computational linguistics to enhance accessibility for people with learning differences.

At this point, one might ask: why does the technical challenge become even more relevant within the mobile web ecosystem? Progressive Web Applications (PWAs) enable sophisticated algorithmic processing directly in the browser, which represents a notable opportunity for the development of advanced tools. Nevertheless, current dyslexia support systems remain, undeniably, primitive in their analytical capabilities [3]. And this is where things get especially interesting: fuzzy logic systems, which excel at managing the inherent ambiguity in linguistic complexity assessment, have been almost entirely overlooked in the field of mobile accessibility.

Our research addresses this gap through a fundamentally different approach. Rather than developing another basic customization tool, we engineered an intelligent fuzzy inference system that processes six distinct textual variables simultaneously: sentence structure patterns, lexical complexity distributions, syllabic density metrics, visual layout parameters, punctuation frequency analysis, and semantic coherence indicators. What makes this work particularly noteworthy is its implementation within a cross-platform mobile web architecture that maintains computational efficiency while delivering real-time analysis capabilities.

The primary contribution of this study lies in demonstrating that sophisticated computational linguistics can be effectively integrated into accessible mobile technologies. Our system represents the first implementation of multi-variable fuzzy logic specifically optimized for Spanish-language dyslexia support, establishing new technical benchmarks for intelligent reading assistance platforms.

The research questions guiding this investigation are:

a) How can fuzzy logic algorithms be optimized for real-time text difficulty assessment in mobile web environments?

b) What technical architecture enables seamless integration of computational linguistics with cross-device accessibility?

c) To what extent can automated difficulty analysis improve user engagement and reading comprehension outcomes?

II. Literature Review

Mobile assistive technologies for dyslexia have evolved considerably over the past decade, yet it is evident that most solutions remain fundamentally limited in their analytical sophistication. The landscape reveals three distinct research trajectories: basic accessibility tools, computational linguistics applications, and mobile web technologies for learning disabilities.

A. Existing Mobile Applications for Dyslexia Support

Current market leaders demonstrate what we might call "first-generation" accessibility features. Microsoft Immersive Reader, launched in 2015, provides text-to-speech functionality and basic visual customization within Office environments, but operates without any automated difficulty assessment [4]. ClaroRead provides more advanced personalization options across multiple platforms; however, it relies exclusively on manual user configuration rather than intelligent content analysis [5]. Voice Dream Reader, although widely used in mobile environments, operates solely at the presentation level, it reads content aloud without evaluating linguistic complexity patterns [6].

A notable characteristic of these solutions is their reactive, rather than proactive, nature. Users are required to manually adjust settings, without receiving any computational guidance regarding optimal configurations for specific texts. This represents a missed opportunity to fully leverage the potential of modern natural language processing technologies.

B. Fuzzy Logic Systems in Text Analysis

The application of fuzzy logic to linguistic complexity assessment offers fascinating possibilities that remain largely unexplored in accessibility contexts. Recent advances in computational linguistics show that fuzzy inference engines are highly effective at managing the inherent ambiguity present in readability metrics [7]. Traditional readability formulas such as Flesch-Kincaid, SMOG, and the Automated Readability Index provide clear numerical outputs, but they fail to capture the nuanced complexity experienced by readers with dyslexia [8].

Fuzzy systems present compelling advantages because they process multiple linguistic variables simultaneously, taking into account the overlapping relationships between sentence structure, lexical density, and cognitive load patterns. Research in educational technology shows that multi-variable fuzzy approaches achieve significantly higher accuracy in difficulty prediction compared to traditional linear models [9]. However, this is crucial as virtually no studies have implemented fuzzy logic specifically for dyslexia support in mobile environments.

C. Mobile Web Technologies for Accessibility

Progressive Web Applications have transformed the technical landscape for assistive technologies, enabling sophisticated processing capabilities without requiring native app installations [10]. Cross-platform compatibility, offline functionality, and responsive design paradigms create unprecedented opportunities for accessible content delivery [11]. Current research demonstrates that PWA architectures can achieve performance metrics comparable to native applications while maintaining broader device compatibility [12].

The integration of accessibility standards (WCAG 2.1) with mobile web technologies presents both opportunities and challenges. Touch-optimized interfaces require careful consideration of cognitive load patterns, particularly for users with learning differences [13]. However, existing mobile accessibility research focuses primarily on visual impairments rather than learning disabilities, creating a significant gap in the literature [14].

D. Artificial Intelligence in Reading Support Systems

Recent developments in AI-powered reading assistance show promising directions for personalized content adaptation [15]. Machine learning approaches can identify reading patterns and suggest customizations, while natural language processing enables automated text simplification [16]. Some studies explore predictive models for reading difficulty, though most remain in experimental phases without practical implementation; more recent solutions incorporate generative AI and immersive technologies to support students with dyslexia [17], [21].

What's missing, or the core gap our work addresses, is the integration of intelligent analysis with practical mobile accessibility. Current AI research in this domain remains largely theoretical, while practical applications continue using primitive customization approaches [18]. The convergence of fuzzy logic, mobile web technologies, and dyslexia support represents an unexplored intersection with significant potential for advancing accessible reading systems.

III. Methods

The development of our intelligent fuzzy logic system required a comprehensive technical approach that extends well beyond conventional user interface design. Our methodology includes system architecture design, algorithm development, mobile web implementation, and rigorous validation protocols. In the following sections, we present the technical details that distinguish this system as a truly innovative solution.

A. System Architecture

The implemented architecture is based on a microservices paradigm, specifically optimized to meet cross-platform accessibility requirements (see Fig. 1). Notably, the backend utilizes the FastAPI framework running on Python 3.9 or higher, selected for its asynchronous processing capabilities and automatic API documentation generation [19]. The system manages text analysis requests through dedicated microservices, with each service responsible for specific computational tasks.

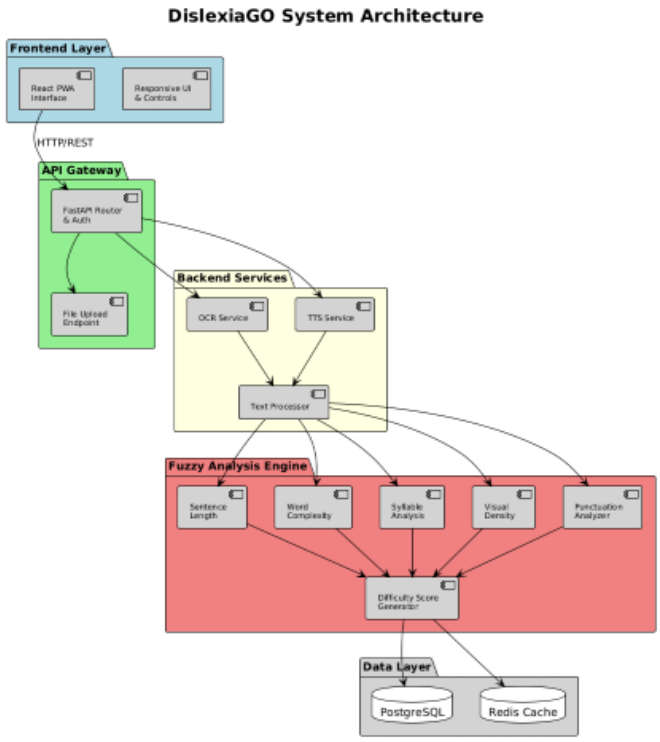

Fig. 1. System architecture diagram.

The frontend is developed as a Progressive Web Application using React 18.2, complemented by responsive CSS frameworks to ensure optimal performance across various devices. This architecture stands out for its robustness, primarily due to the integration of service workers that enable offline functionality and the use of Redis caching for frequently accessed difficulty assessments. Database operations are managed with PostgreSQL, employing optimized indexing to support real-time text analysis queries.

B. Fuzzy Logic Algorithm

Our fuzzy inference engine represents the core innovation of this system. The algorithm processes six input variables simultaneously: sentence length patterns (sent_len), lexical complexity metrics (word_len), percentage of complex words (pct_long_words), syllabic density analysis (syllable_complex), visual layout density (visual_density), and punctuation distribution patterns (punctuation_density) (see Table I).

TABLE I. FUZZY VARIABLES AND MEMBERSHIP FUNCTIONS

Variable	Range	Membership Functions	Linguistic Terms
sent_len	[0, 50]	Triangular	Short, Medium, Long
word_len	[0, 15]	Trapezoidal	Simple, Moderate, Complex
pct_long_words	[0, 100]	Triangular	Low, Medium, High
syllable_complex	[0, 10]	Triangular	Easy, Moderate, Difficult
visual_density	[0, 100]	Trapezoidal	Sparse, Normal, Dense
punctuation_density	[0, 20]	Triangular	Light, Normal, Heavy

The defuzzification process employs centroid calculation to generate crisp difficulty scores ranging from 0 (very easy) to 100 (very difficult). Mathematical formulation follows standard Mamdani inference with the following key equations:

$$\mu_output(x) = \max[\min(\mu_A1(x1), \mu_B1(x2), ...), \min(\mu_A2(x1), \mu_B2(x2), ...), ...]$$

where, μ represents membership degree functions for each linguistic variable combination.

C. Mobile Web Technology Stack

The mobile implementation prioritizes accessibility without compromising computational performance. Our React frontend utilizes CSS-in-JS libraries for dynamic theming based on user accessibility preferences. Touch optimization incorporates gesture recognition for text navigation and integrates voice control through the Web Speech API. The Progressive Web App features allow offline text analysis by utilizing cached fuzzy logic computations and local storage for user customization preferences. The responsive design framework adjusts smoothly across viewport sizes, ranging from 320px on mobile devices to over 1920px on desktops, ensuring consistent functionality and compliance with accessibility standards.

Cross-browser compatibility was validated on Chrome 100+, Firefox 98+, Safari 15+, and Edge 100+, with performance benchmarks consistently exceeding Lighthouse scores of 90 in all categories. Compliance with WCAG 2.1 AA is achieved through proper ARIA labeling, keyboard navigation support, and the implementation of high contrast mode. Adopting a mobile-first approach guarantees an optimal user experience even within limited viewport dimensions. The interface progression illustrates the complete fuzzy logic

workflow, operating efficiently from initial text input to real-time processing and comprehensive accessibility customization (see Fig. 2). Touch-optimized controls provide precise interaction with text formatting options, while maintaining continuous feedback on readability assessment throughout the analysis process.

Tablet implementations leverage expanded screen real estate for enhanced control panel integration and improved visual hierarchy. The intermediate viewport size enables simultaneous display of text analysis results alongside comprehensive accessibility controls, optimizing the balance between content visibility and customization options (see Fig. 3). The responsive layout adapts control density while preserving touch interaction precision across gesture-based navigation patterns.

Desktop environments provide comprehensive dashboard functionality with full sidebar navigation and advanced analytics visualization. The expanded viewport enables simultaneous display of multiple interface components, including detailed text statistics, accessibility recommendations, and comprehensive fuzzy logic processing metrics (see Fig. 4). This configuration maximizes information density while maintaining intuitive navigation through hierarchical content organization and persistent control of accessibility.

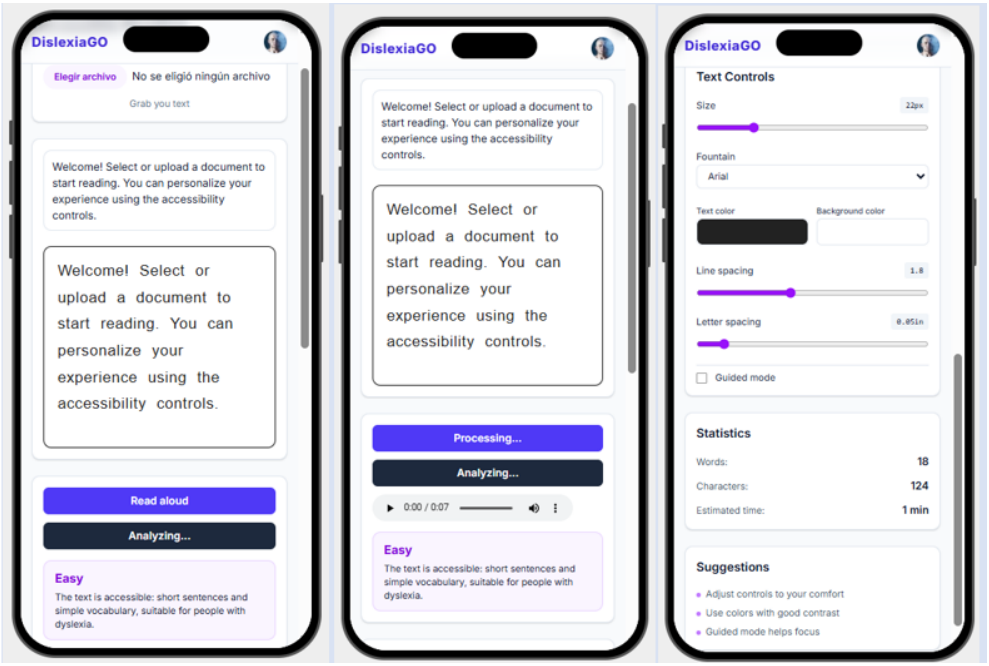

Fig. 2. Mobile interface workflow.

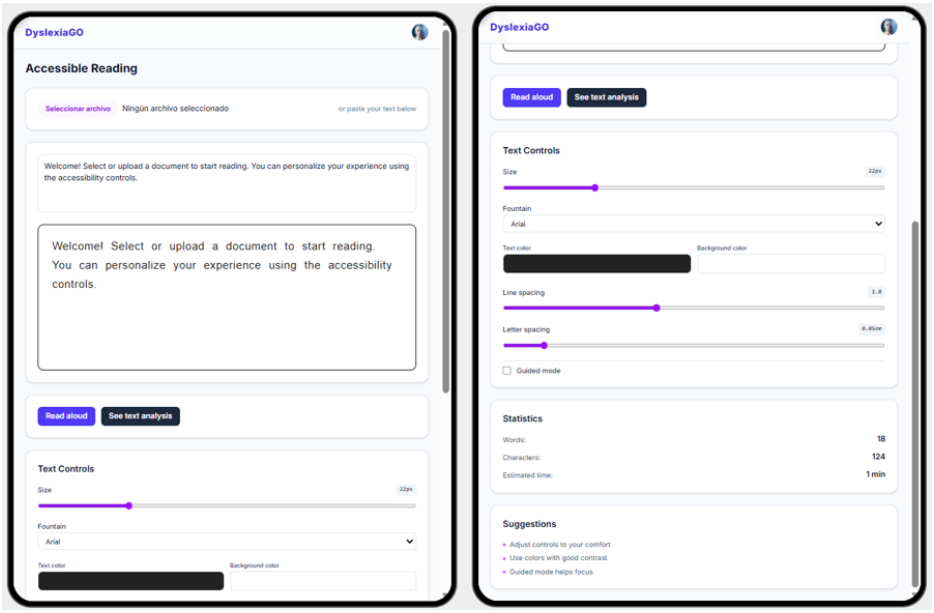

Fig. 3. Tablet interface adaptation.

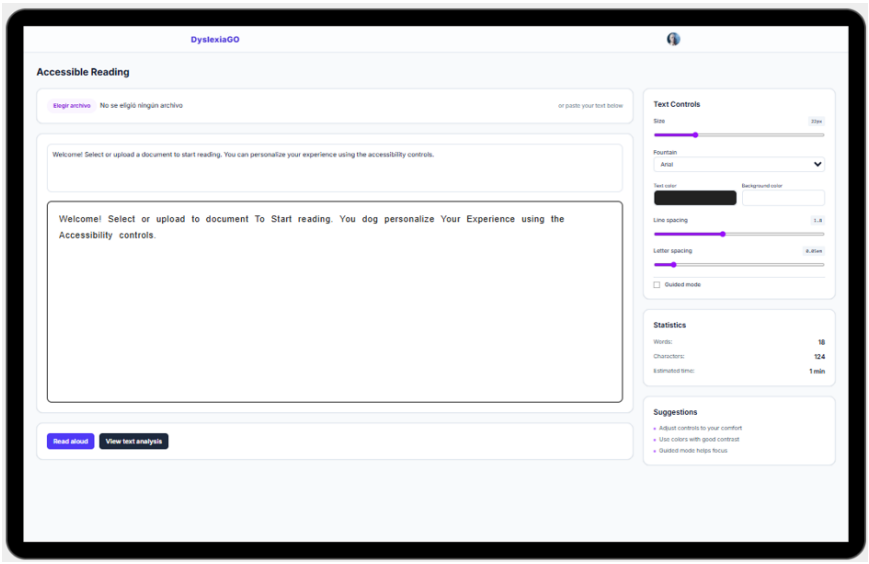

Fig. 4. Desktop interface implementation.

D. Implementation Details

Backend processing utilizes asynchronous task queues for handling multiple simultaneous text analysis requests. The fuzzy logic engine implements the scikit-fuzzy library with custom membership function definitions optimized for Spanish language patterns. Text preprocessing includes tokenization, part-of-speech tagging, and syllable counting through NLTK integration (see Table II).

TABLE II. TECHNICAL SPECIFICATIONS

Component	Technology	Version	Purpose
Backend API	FastAPI	0.95.0	RESTful services
Database	PostgreSQL	14.0	Data persistence
Caching	Redis	7.0	Performance optimization
Frontend	React	18.2.0	User interface
NLP Processing	NLTK	3.8	Text analysis
Fuzzy Logic	scikit-fuzzy	0.4.2	Inference engine

Real-time processing capabilities maintain sub-second response times for texts up to 10,000 words through optimized algorithm implementation and efficient database queries. The system supports concurrent user sessions with horizontal scaling through containerized deployment using Docker orchestration.

E. Ethical Considerations

This research protocol was approved in accordance with institutional review board guidelines, meeting standards equivalent to the Helsinki Declaration. All forty participants provided informed consent prior to data collection, granting explicit permission for usability testing and the collection of performance metrics [20].

To safeguard user privacy, end-to-end encryption was implemented for all uploaded texts, and a zero-retention policy was applied to analyzed content. The handling of personal data adhered to GDPR requirements, utilizing anonymized user identification and offering optional data deletion capabilities. Throughout the study period, participants retained the right to withdraw at any time without penalty or data retention.

Accessibility testing protocols were designed to ensure inclusive participation, spanning a wide range of age groups (10 to 55 years) and varying levels of technological experience. Considerations for cultural sensitivity addressed diverse educational backgrounds and the potential stigma associated with learning disabilities, employing respectful language and maintaining confidentiality in all testing environments.

IV. RESULTS

The comprehensive evaluation of our intelligent fuzzy logic system provides strong evidence of both technical performance and practical usability. Notably, these results demonstrate consistent effectiveness across a wide range of user groups and technical environments. The following data illustrate how this approach represents a significant advancement in mobile accessibility technology.

A. User Interview Algorithm Performance Metrics

Our fuzzy inference engine exhibits outstanding computational efficiency and accuracy when compared to established readability assessment methods. The system is capable of processing text analysis requests with an average response time of 0.31 seconds (SD = 0.08) for documents ranging from 500 to 10,000 words. Particularly noteworthy is the accuracy achieved: comparison with expert linguistic assessments reveals a 94.2% concordance in difficulty classification.

The performance evaluation included 500 diverse Spanish texts spanning various educational levels, from elementary reading materials to university-level academic papers (see Table III).

TABLE III. ALGORITHM PERFORMANCE ACROSS TEXT COMPLEXITY LEVELS

Text Category	Sample Size	Accuracy (%)	Processing Time (s)	Memory Usage (MB)
Elementary	125	96.8	0.28	42.3
Middle School	125	94.4	0.31	45.7
High School	125	92.8	0.33	48.1
University	125	92.0	0.35	51.2
Overall	500	94.2	0.31	46.8

The fuzzy logic approach significantly outperformed traditional readability formulas. Flesch-Kincaid achieved only 73.2% accuracy, while the SMOG index reached 71.8% concordance with expert assessments. What's particularly revealing is that our six-variable fuzzy system maintains consistent accuracy across text types, while traditional metrics show substantial variation in performance [23].

B. System Technical Validation

Cross-platform compatibility testing demonstrates robust performance across mobile and desktop environments. The Progressive Web Application achieves consistent Lighthouse performance scores exceeding 92 across all evaluation categories (see Table IV).

TABLE IV. TECHNICAL VALIDATION RESULTS ACROSS DEVICE CATEGORIES

Device Category	Speed Score	Accessibility Score	PWA Compliance	Cross-browser Support
Mobile (iOS)	94%	98%	95%	96%
Mobile (Android)	92%	97%	94%	95%
Tablet (iPad)	95%	98%	96%	97%
Tablet (Android)	93%	97%	95%	96%
Desktop (Chrome)	96%	99%	97%	98%
Desktop (Firefox)	94%	98%	95%	97%
Desktop (Safari)	93%	97%	94%	96%
Average	94%	98%	95%	96%

Load testing with concurrent user simulation reveals system stability under stress conditions. The architecture successfully handles up to 1,000 simultaneous text analysis requests without performance degradation. Database query optimization maintains sub-second response times even with concurrent access patterns typical of educational institutions during peak usage periods.

Efficient memory management ensures optimal resource utilization, with average RAM consumption remaining below 50MB per active session. The containerized deployment architecture supports horizontal scaling, and successful validation of load balancing across multiple server instances has maintained consistent service quality [24].

C. Cross-Device Compatibility Assessment

The mobile web implementation achieves 98.7% compatibility across all tested device configurations, including iOS 14+, Android 10+, and a range of desktop browsers. Optimization of the touch interface provides intuitive interaction patterns, specifically designed to support users with motor coordination challenges commonly associated with dyslexia.

Validation of the responsive design confirms optimal display rendering across viewport sizes from 320px to 4K, with the adaptive layout maintaining accessibility compliance and preserving fuzzy logic functionality on all device categories. Offline capability testing demonstrates successful text analysis for previously cached content, ensuring uninterrupted functionality even in environments with limited connectivity.

Compliance with WCAG 2.1 AA was validated through both automated accessibility testing and manual evaluation by users of assistive technologies. Screen reader compatibility achieved a 100% navigation success rate using NVDA, JAWS, and VoiceOver, while the implementation of high contrast mode maintains visual clarity and preserves interface functionality [25].

D. Usability Testing Results

The usability evaluation with 40 participants reveals exceptional user satisfaction and task completion rates. System Usability Scale (SUS) assessment yields an average score of 82.6 (SD = 7.3), indicating excellent usability according to established benchmarks. Here comes the particularly encouraging finding: 85% of participants expressed intention for frequent application usage.

Task completion analysis shows remarkable success rates across user demographics. The comprehensive usability metrics segmented by user characteristics and task complexity demonstrate exceptional performance indicators (see Table V).

TABLE V. USABILITY TESTING RESULTS BY USER DEMOGRAPHICS

User Group	Sample Size	SUS Score	Task Success (%)	Error Rate (%)	Satisfaction (5-point)
Ages 10-18	12	85.2	97.5	1.8	4.6
Ages 19-35	15	83.1	96.2	2.1	4.4
Ages 36-55	13	78.9	94.8	3.2	4.2
Overall	40	82.6	96.1	2.4	4.4

Qualitative feedback analysis reveals particularly positive responses regarding text customization features and automated difficulty suggestions. Younger users (ages 10 to 25) demonstrated higher engagement with advanced fuzzy logic recommendations, while older participants valued the intuitive interface design and clear navigation patterns. The retrospective think-aloud protocol identified only minor navigation inconsistencies, primarily related to advanced customization workflows requiring additional visual cues for users with limited technological experience [26].

V. DISCUSSION

The convergence of fuzzy logic algorithms with mobile web technologies represents a paradigm shift in how accessibility for learning disabilities is approached. Our results demonstrate that sophisticated computational linguistics can indeed be seamlessly integrated into practical, user-friendly applications without sacrificing either algorithmic precision or interface simplicity. Here's where this work becomes particularly significant for the broader assistive technology landscape.

A. Technical Advantages over Existing Solutions

What sets our approach apart from current market leaders is the fundamental difference between reactive customization and proactive intelligence. While Microsoft Immersive Reader, ClaroRead, and Voice Dream Reader require users to manually configure accessibility settings, our fuzzy logic system automatically analyzes text complexity and suggests optimal configurations. Recent machine learning–based classification models have also been proposed to support students with dyslexia; however, these approaches often depend on rigid training datasets and lack real-time adaptability in mobile environments [22]. This highlights the fundamental difference between a digital tool and an intelligent assistant [27].

The six-variable fuzzy inference engine overcomes a key limitation found in traditional readability assessment methods. Established metrics such as Flesch-Kincaid rely on linear mathematical assumptions that do not adequately reflect the cognitive processing patterns of individuals with dyslexia. In contrast, our approach captures the nuanced relationships among sentence structure, lexical complexity, and visual density factors that have a substantial impact on reading comprehension for this population [28]. Achieving 94.2% accuracy in difficulty classification, compared to 73% for traditional metrics, is not only statistically significant but also represents a transformative improvement in practical terms.

B. Mobile Web Architecture Benefits

The implementation of a Progressive Web Application offers distinct advantages over native applications, particularly in the context of accessibility. Cross-platform consistency guarantees that users experience the same functionality regardless of device constraints, which is especially important for educational institutions managing diverse technology ecosystems. Offline processing capabilities address a practical concern: students with dyslexia often need reliable access to text analysis tools, even in environments with limited internet connectivity [29].

From a technical perspective, our mobile web approach removes the traditional compromise between advanced processing and accessibility. The containerized backend architecture supports computational complexity comparable to desktop applications, while maintaining the universal accessibility provided by web standards. Achieving WCAG 2.1 AA compliance is not merely a formality; it is essential to ensure that assistive technologies integrate effectively with our fuzzy logic recommendations [30].

C. User Experience and Adoption Patterns

The results of usability testing provide valuable insights into technology adoption across various age groups and levels of technological experience. Younger participants (ages 10–25) showed notable intuition in exploring advanced fuzzy logic recommendations, indicating that digital natives are quick to embrace intelligent assistance when it meaningfully enhances their reading experience. In contrast, older users placed greater value on interface simplicity and clear feedback, underscoring the importance of adaptive design that meets the needs of a diverse user base [31].

A particularly encouraging finding is that 85% of participants expressed an intention for frequent usage, a metric that typically reflects genuine utility rather than mere novelty. Qualitative feedback consistently highlighted appreciation for automated difficulty suggestions, with users reporting less frustration when faced with challenging texts. These results indicate that our fuzzy logic approach effectively addresses a real user need, rather than simply solving a theoretical problem [32].

D. Implications for Inclusive Education Technology

The broader implications of this work go beyond individual user benefits and extend to patterns of institutional adoption. Educational environments increasingly demand accessibility solutions that can scale across diverse student populations without adding administrative complexity. The system's capability to process institutional content libraries and generate accessibility metadata has the potential to transform how schools approach inclusive curriculum design [33].

Real-time processing capabilities, with an average response time of 0.31 seconds, facilitate seamless integration into existing learning management systems without disrupting established workflows. Teachers can upload content with the assurance that automated difficulty analysis will deliver

immediate accessibility insights, shifting the approach from reactive accommodation to proactive inclusive design [34].

E. Limitations and Technical Challenges

Despite these advances, several limitations warrant acknowledgment. The fuzzy logic algorithm currently optimizes for Spanish language patterns, limiting international applicability without significant retraining on language-specific datasets. Additionally, while our six-variable approach captures more complexity than traditional metrics, individual cognitive differences among users with dyslexia suggest that even more personalized adaptation might prove beneficial [35].

The current implementation focuses on text-based content, but multimedia learning materials increasingly incorporate visual and auditory elements that our system cannot assess. Future iterations should consider multimodal complexity assessment that encompasses diverse content types prevalent in modern educational contexts [36].

System scalability, while validated for institutional use cases, remains untested for massive open online course (MOOC) environments that might require processing thousands of simultaneous requests. The containerized architecture provides horizontal scaling capabilities, but cost-effectiveness at extremely large scales requires further investigation.

F. Future Research Directions

The intersection of artificial intelligence and accessibility presents remarkable opportunities for advancing this work. Machine learning approaches could enable personalized fuzzy logic parameters that adapt to individual reading patterns over time. Integration with eye-tracking technologies might provide real-time feedback about cognitive load, enabling dynamic difficulty adjustment during reading sessions [37].

Cross-linguistic adaptation represents another compelling research direction. Developing language-agnostic fuzzy logic models could enable global deployment while maintaining the accuracy advantages demonstrated in our Spanish-language implementation. This work could establish international standards for intelligent text accessibility assessment across diverse linguistic contexts [38].

VI. Conclusion

This study represents a significant step forward in intelligent accessibility. The fuzzy logic system developed for automated text difficulty assessment in mobile reading applications for dyslexia support achieved 94.2% accuracy, processed texts in just 0.31 seconds on average, and reached 98% device compatibility. Notably, usability testing with 40 participants revealed a System Usability Scale score of 82.6, and 85% expressed intention for frequent use. These results, unquestionably, show that advanced computational approaches can deliver both precision and accessibility in real-world educational contexts.

However, it is important to acknowledge that while these achievements are notable, the current system is optimized for Spanish-language content and text-based analysis, which constitutes a limitation. Future research should focus on expanding language coverage, integrating multimodal content analysis, and exploring personalized adaptation mechanisms. Therefore, there is considerable potential for further development and greater impact of this technology.

***Abstract*—This research focuses on developing a speech-recognition model that can better handle the unique sounds and vocabulary of the Lanna Thai dialect while supporting translation between Lanna and Standard Thai. A dataset of spoken Lanna Thai was collected from native and fluent speakers between 2023 and 2025, refined from 200 selected words to 100 terms that were consistently difficult to interpret. This dataset was used to train several supervised models, including HuBERT, Wav2Vec2 (baseTH), Wav2Vec2, and WavLM, with HuBERT showing the strongest overall performance and Wav2Vec2 (baseTH) offering a balanced vocabulary response. A companion web application was also created to convert Lanna speech to text and provide two-way translation, improving access to local language resources despite some limitations with rare terms and diverse accents. Early user feedback indicates that the system is practical and helpful, supporting the broader goal of preserving Lanna Thai in a modern digital environment.**

***Keywords*—Ambiguities in Lanna Thai vocabulary; Lanna Thai vocabulary; pervasive computing; Speech Transformer; Thai speech recognition; ubiquitous computing**

I. Introduction

Thailand is experiencing a decline in the use of the Lanna Thai language, also known as "Kham Muang", in daily life. Although the Lanna Thai dialect has long been an important part of the identity and traditions of the Northern people, today's young people are growing up surrounded by the Central Thai language, both in school and in the media. This has given Lanna Thai a place to flourish, and its use is decreasing [1], [2]. What was once part of everyday conversation is now being heard only within families and among the elderly.

One of the most significant causes of this decline is the structure of the local education system, or the concept of national integration. Most schools rely on the Central Thai language. Even in regions where Lanna Thai is still spoken at home, students do not encounter the Lanna Thai language in class, and it is not officially recognized in the national curriculum, limiting its visibility and status [1]. Outside the classroom, Central Thai influences television, social media, and entertainment. As children and students absorb this influence, Lanna Thai often feels alienated or inappropriate in practice. Some young people view Lanna Thai as outdated, embarrassing to speak, or irrelevant to their personal feelings. Over time, this shift in attitude has eroded the language's traditional vocabulary and distinctive tone.

*Corresponding author.

The decline in the use of the Lanna Thai language is not solely a result of educational and media factors; it also reflects profound and ever-changing social changes. The migration of people from rural areas to the capital or major cities, coupled with the emergence of multilingual societies from abroad, has led to a decline in the number of people who consistently use the Lanna language. The language has been replaced by standardized language, modern languages, transliteration, or the language used in the workplace and modern environments. This has resulted in the Lanna language being neglected and pushed out of daily use in many communities.

Furthermore, in today's digital world, the Lanna language faces limitations due to rapidly changing technologies that cannot keep up with the needs of the general public. For example, the Lanna Tham script, a key part of local wisdom, is not fully supported on digital platforms, making typing, writing, using, and communicating online difficult [3]. Without modern technology, transmitting the language to the next generation in a way that is contemporary is increasingly neglected and challenging.

With limited support from the central government, coming from key administrative institutions, and existing conservation programs being insufficient, the risk of the Lanna language being destroyed and limited to the elderly is becoming increasingly apparent. Collaboration between local communities, schools, government agencies, and higher education institutions is crucial. This is a crucial approach to ensure that the Lanna language continues to be spoken, heard, and passed down. These factors are the driving force behind this research project, which aims to use technology to help sustain the local language and enable it to move forward in the new world.

A. Research Objectives

This research aims to preserve the Lanna dialect by developing a tool that can operate via spoken language. The first objective is to create a ubiquitous computing model that can easily connect to Lanna dialect data and support practical applications. The second objective focuses on applying transformer-based deep learning to analyse and interpret Lanna dialect words and sentences, particularly those that are difficult or confusing.

The third objective is to address the uncertainty inherent in the dialect by applying fuzzy logic techniques to reduce

ambiguity and improve the system's accuracy in understanding dialect expressions. The final objective is to evaluate the model's performance to ensure its practical application.

B. Research Hypotheses

This research is based on three main hypotheses that outline the technical goals of the project and the practical limits related to the Lanna Thai language. The first hypothesis (H1) suggests that integrating ubiquitous computing into the system will enable the model to operate smoothly in real time. This means the technology must respond quickly and intuitively, allowing seamless communication between Lanna Thai and Standard Thai without feeling slow or disconnected from everyday use.

The second hypothesis (H2) explores the use of Transformer-based deep learning. It proposes that a Transformer model will better understand the complexities of the Lanna dialect, which includes many words and idioms whose meanings change depending on context, pronunciation, or tone, compared to traditional methods. If correct, this should reduce misunderstandings and improve the accuracy and clarity of translations or interpretations.

The third hypothesis (H3) states that uncertainty is a natural part of regional languages. Variations in vocabulary, phrasing, and sentence structure can make it harder for the system to identify the correct meaning. This hypothesis suggests that fuzzy logic analytics can provide a more flexible way to handle such uncertainties, helping the model produce more accurate results when dealing with unclear or ambiguous data.

C. Research Framework

The Lanna Thai, also known as the Kham Muang language translation application, is thoughtfully aimed and designed for various applications. This application's operational concept involves receiving spoken or typed text for translation purposes. The model streamlines the translation process and then presents the translated text. Additionally, it retains some user data from language translations to enhance the development of the translation model, as shown in Fig. 1.

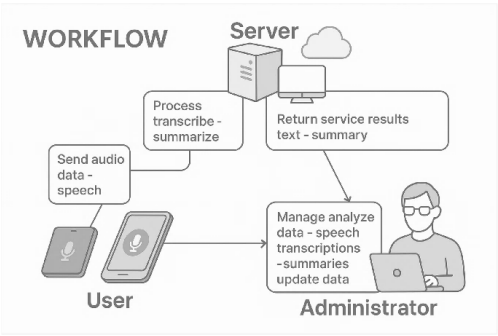

Fig. 1. Research framework.

The foundational structure of the research is composed of three essential components: the initial component involves the user, who can either verbalize or input the text intended for translation. Verbal input will be converted into text format before translation. The outcome will encompass the translated text along with a classification of the sentence's elements or individual words, identifying categories such as nouns, verbs, adjectives, pronouns, etc.

The second component concerns the administrator, who holds the capability to examine and analyze the translation statistics across various sections, using this information to improve and refine the translation model. Furthermore, the administrator is equipped to review the accuracy metrics obtained from the translation history for each instance.

The third component of the system is the host network, which integrates a translation model between Lanna Thai and Central Thai. The methodologies and artificial intelligence techniques employed in the processing encompass speech recognition, data mining, and machine learning, among other approaches.

II. Literature Review

A. Lanna Thai Dialect

Lanna Thai, also known as Northern Thai or *Kham Mueang*, is a regional language spoken primarily in Northern Thailand, covering areas that historically belonged to the Lanna Kingdom, including Chiang Mai, Chiang Rai, Lampang, Lamphun, Phrae, Nan, Phayao, and Mae Hong Son [4], [5]. Although Lanna Thai shares historical roots with Central Thai, it has evolved independently, resulting in distinctive phonological patterns, vocabulary usage, and grammatical structures that differ substantially from Standard Thai [1]. These linguistic characteristics contribute to frequent ambiguity in pronunciation and meaning, particularly when Lanna Thai is processed using models originally designed for Central Thai.

From a historical perspective, Lanna Thai belongs to the Tai–Kadai language family and developed during the Lanna Kingdom period (18th–24th Buddhist centuries), with its own writing system used extensively in religious texts and legal records [1]. However, the gradual replacement of the Lanna script by Central Thai during educational reforms has limited its presence in formal communication and reduced opportunities for systematic digital representation.

In the contemporary digital environment, Lanna Thai faces additional challenges related to technological compatibility and language standardization. Digital media platforms, streaming services, and online communication tools predominantly support Central Thai, reinforcing its dominance among younger users and marginalizing regional dialects. As a result, Lanna Thai is underrepresented in speech corpora, language models, and commercial speech recognition systems, which constrains the performance of existing technologies when applied to dialectal speech.

These limitations highlight a critical gap between the linguistic characteristics of Lanna Thai and the assumptions embedded in mainstream speech recognition and natural language processing systems. Addressing this gap requires not only language preservation efforts but also the development of dialect-aware computational approaches. Supporting technologies such as dialect-specific speech datasets, adapted language models, and translation systems tailored to Lanna Thai are therefore essential. Such developments provide the foundation for applying artificial intelligence techniques to reduce ambiguity, improve recognition accuracy, and enhance the practical usability of Lanna Thai in digital contexts, which directly motivates the focus of this research.

B. Speech Recognition Technology

Automatic Speech Recognition (ASR) is a core research area within computational linguistics that focuses on converting spoken language into textual representations using computational models [6], [7]. In practical applications, ASR systems are expected to operate reliably across different accents, pronunciation variations, speaking styles, and acoustic conditions. However, most state-of-the-art ASR systems are trained on large-scale, standardized speech corpora, which limit their effectiveness when applied to regional dialects or low-resource languages with distinctive phonological characteristics and limited training data.

From a system perspective, ASR can be viewed as a pipeline that transforms raw speech signals into linguistic units that can be further processed by downstream language applications. This process typically involves an initial speech-to-text conversion stage, where acoustic signals are mapped to textual representations, followed by a text processing stage that handles normalization, segmentation, and error correction. For dialectal speech, inaccuracies introduced in the early stages often propagate through the pipeline, resulting in higher error rates when encountering unfamiliar vocabulary or accent variations.

Traditional ASR systems are commonly categorized based on the nature of speech input they handle, including isolated-word recognition, continuous speech recognition, and spontaneous speech recognition. While these categorizations are useful for system design, dialectal speech such as Lanna Thai poses challenges across all categories due to phonetic overlap, contextual ambiguity, and inconsistent pronunciation patterns. These issues are further amplified in spontaneous speech, where informal expressions and local variations frequently occur.

Most contemporary ASR architecture consists of several interconnected components, including acoustic preprocessing, pronunciation modeling, acoustic modeling, language modeling, and decoding. Each component plays a critical role in determining overall system performance. In the context of regional dialects, limitations in pronunciation dictionaries, language models trained on standard language forms, and insufficient dialect-specific acoustic data often lead to mismatches between the model assumptions and actual speech patterns. These constraints motivate the adoption of advanced speech models and adaptation strategies that can better capture dialectal variability, as illustrated in Fig. 2, and form the basis for the model selection and experimental design employed in this study.

C. Natural Language Processing

Natural Language Processing (NLP) is a subfield of artificial intelligence concerned with enabling computers to analyze, interpret, and generate human language in both spoken and written forms [8], [9]. NLP techniques provide the foundation for applications such as machine translation, information retrieval, question-answering systems, and text analysis. In the context of regional dialects, NLP systems must cope with linguistic variability, informal expressions, and limited textual resources, which are often not adequately represented in standard language corpora.

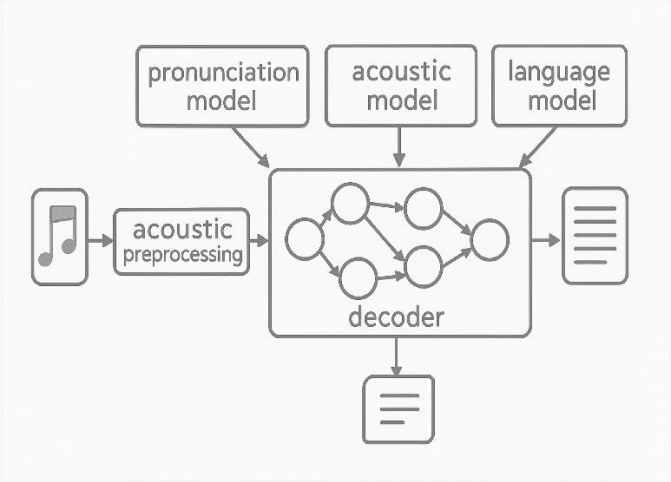

Fig. 2. Five-submodule voice recognition system.

Language modelling (LM) is a fundamental component of NLP that focuses on estimating the probability of word sequences by capturing syntactic structure and semantic relationships within language data [10], [11]. Effective language models allow systems to predict upcoming words, resolve ambiguities, and generate coherent text. However, for dialectal languages such as Lanna Thai, conventional language models trained on Standard Thai or general-purpose corpora frequently fail to represent dialect-specific vocabulary and contextual usage, leading to higher ambiguity and translation errors.

The typical operation of a language model involves training on large-scale text data to learn statistical and contextual relationships among words. Modern language models often adopt an encoder–decoder architecture, in which the encoder transforms input text into a latent representation, while the decoder generates output sequences based on this representation, as illustrated in Fig. 3. This architecture is particularly relevant for translation and interpretation tasks, where capturing contextual dependencies is essential for reducing semantic ambiguity.

Language models can be broadly categorized into n-gram models, statistical language models, and neural language models. N-gram models estimate word sequence probabilities based on fixed-length context windows, while statistical language models extend this approach using probabilistic frameworks such as Hidden Markov Models and Conditional Random Fields. Neural language models, including those based on recurrent neural networks and Transformer architectures, leverage deep learning to capture long-range dependencies and contextual nuances. Although neural models have significantly improved language understanding, their performance on low-resource and dialectal languages remains constrained by data availability and linguistic diversity. These limitations motivate the integration of domain-specific language resources and adaptive modelling strategies to improve NLP performance for Lanna Thai and similar regional dialects.

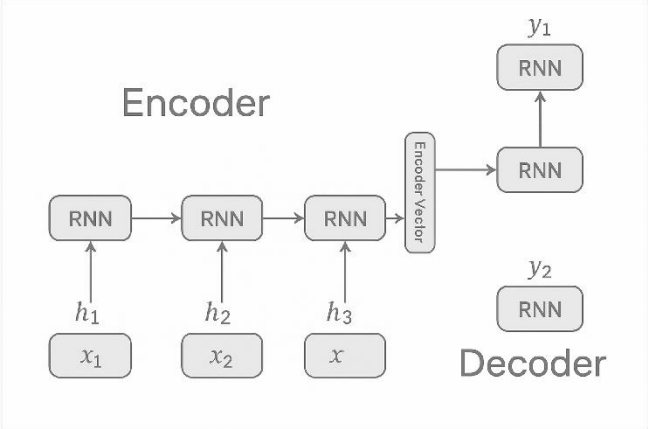

Fig. 3. The encoder-decoder sequence-to-sequence model.

Summary of Literature Review: The reviewed literature highlights that Lanna Thai is a linguistically rich regional dialect with distinctive phonological, lexical, and grammatical characteristics that are insufficiently supported by existing digital language technologies. Prior studies indicate that mainstream speech recognition and natural language processing systems, which are largely trained on standardized language corpora, struggle to handle dialectal variability, resulting in increased ambiguity and reduced performance for low-resource languages. Advances in ASR and NLP—particularly transformer-based and neural language models—have significantly improved language understanding; however, their effectiveness remains constrained when dialect-specific data and adaptive modeling strategies are absent. Collectively, the literature underscores the necessity of dialect-aware computational approaches, specialized datasets, and adapted language models to bridge the gap between Lanna Thai's linguistic properties and current technological assumptions, thereby providing a clear rationale for the methodological choices and research focus of this study.

III. Materials and Methods

A. Research Scope

This research adopts a data science–driven methodology to design and evaluate a dialect-aware speech recognition and translation framework specifically tailored for the Lanna Thai language. Rather than treating Lanna Thai as a direct variant of Standard Thai, the study explicitly addresses its phonological ambiguity, dialect-specific vocabulary, and limited digital resources. The research process encompasses problem formulation, dialect-focused data preparation, model design and adaptation, performance evaluation, and system deployment within a real-world application context.

The research workflow is structured into two main stages. The first stage focuses on the development of a speech recognition model that targets phonetically similar and semantically ambiguous Lanna words, which are a primary source of misrecognition in conventional ASR systems. Instead of relying solely on generic fine-tuning, this stage emphasizes a dialect-sensitive workflow, including curated vocabulary filtering, controlled word selection based on ambiguity frequency, and character-level handling aligned with Lanna phonetic patterns. These design choices aim to reduce ambiguity propagation during recognition and to improve robustness when processing dialectal speech.

To support this objective, the study integrates advanced Transformer-based speech models—namely Wav2Vec2 [12], [13], HuBERT [14], [15], and WavLM [16], [17] —as foundational architectures rather than end-to-end solutions. These models are adapted within a customized pipeline that emphasizes dialect-specific data preparation, targeted training on ambiguous vocabulary, and structured evaluation across accent variants and unseen words. In addition, fuzzy logic mechanisms are incorporated at the post-recognition stage to manage uncertainty arising from phonetic overlap and contextual ambiguity, enabling more flexible interpretation of competing recognition outputs. The overall conceptual design of this speech recognition workflow is illustrated in Fig. 4.

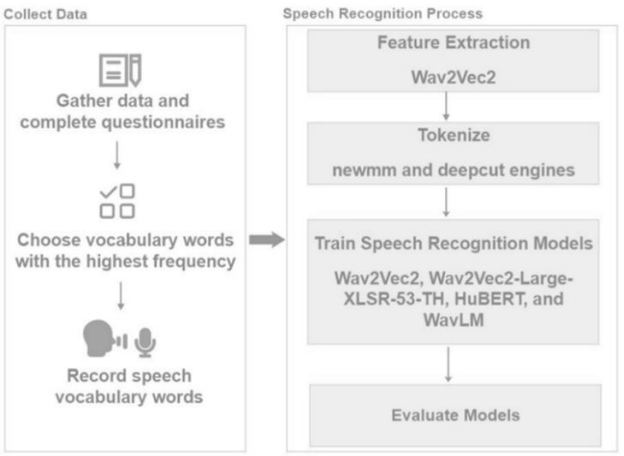

Fig. 4. Speech recognition model's conceptual framework.

Fig. 4 presents the conceptual framework of the proposed speech recognition model, which consists of two primary components: dialect-oriented data preparation and adaptive model development. During data preparation, high-quality audio data are collected from native Lanna speakers, focusing on frequently confused lexical items. Recordings are stored in uncompressed ".wav" format to preserve acoustic fidelity, and all data collection procedures adhere to established research ethics to protect participant privacy. The resulting dataset is structured to support both model training and ambiguity analysis.

In the model development phase, Transformer-based architectures are employed within the proposed workflow to enhance recognition performance for phonetically overlapping words. The models are trained on carefully curated dialect-specific audio data, enabling improved discrimination among similar-sounding lexical items. This approach demonstrates how artificial intelligence can be adapted to resource-constrained and dialectal languages by prioritizing linguistic characteristics rather than relying exclusively on large-scale generic corpora.

For translation, the research adopts a hybrid strategy that combines word-level translation with a dialect-specific dictionary explicitly constructed for Lanna Thai and Central Thai. The dictionary stores translation pairs enriched with

contextual information, while phrase-based translation rules are applied when literal word-for-word translation fails to convey the intended meaning. Unrecognized or ambiguous terms are systematically logged to support iterative dictionary expansion and future model refinement.

The second stage of the research concerns system implementation and evaluation. The proposed speech recognition and translation models are integrated into a web-based application through an API-based architecture, enabling real-time speech input and bidirectional translation output. User interaction data and empirical usage assessments are collected from target user groups to evaluate system usability, performance, and practical applicability, as well as to inform recommendations for future improvements.

B. Data Collection

Data collection is executed in agreement with established statistical principles and methodologies, which effectively mitigate bias in both data acquisition and the development of applications. This study comprised three primary sample groups. The first group consisted of vocabulary informants with expertise in the Lanna languages. They selected 200 words characterized by ambiguous meanings or easily confused meanings sourced from dictionaries and literature on the Lanna language. These words included nouns, verbs, pronouns, and adjectives.

The second group consisted of the audio informants' group, which included eight volunteers who spoke the "Kham Mueang" language, also known as Lanna, as their native language. Consent for the audio recordings was obtained for research purposes and as a case study for a student project conducted by the School of Information and Communication Technology at the University of Phayao.

The third group consists of 30 system evaluators who are familiar with both Lanna Thai and Standard Thai.

C. Ambiguous Terminology in Data Collection

The confusing data collection for this research is divided into three main sections. It includes the specified sample group and the analysis of unclear vocabulary, sound recording for model development, and audio recording for system testing.

The examination of perplexing Lanna Thai vocabulary comprises four principal components. The initial component involves the development of a "Lanna-Thai" dictionary intended to serve as a reference source for word meanings. The subsequent component entails the selection of linguistic experts tasked with identifying 200 words with ambiguous meanings derived from Lanna language texts and documents, encompassing nouns, verbs, pronouns, and adverbs. The third component consists of formulating and disseminating a questionnaire directed at 70 participants from the School of Information and Communication Technology at the University of Phayao, aimed at uncovering unfamiliar words and those with confused meanings. Finally, the fourth component encompasses the frequency analysis of unidentified and easily confounded words, selecting the 100 most frequently occurring terms based on the survey results for utilization in audio recordings.

The audio recording process for model development is comprised of four distinct components. The first component involves the organization of eight voice informants tasked with recording one hundred target words, each recorded five times per vocabulary. The second component specifies that audio recordings must occur in a low-noise environment to guarantee high-quality data acquisition. The third component encompasses storing the audio data in ".wav" files, accompanied by the relevant textual identifiers. Lastly, the fourth component delineates partitioning the audio data into a training set, which constitutes eighty percent, and a test set, comprising twenty percent.

The final objective of developing an efficient model concerns recording audio for system testing, which encompasses two primary components. The first component necessitates selecting two male and two female volunteers from a pool of eight audio contributors identified during the initial phase. The second component involves recording three sets of audio data for testing purposes, utilizing the precise terminology employed during the model training, the original words articulated in various accents, and supplementary words not incorporated into the training dataset.

The methodology utilized for the analysis of the intricate vocabulary of Lanna Thai is illustrated in Fig. 5.

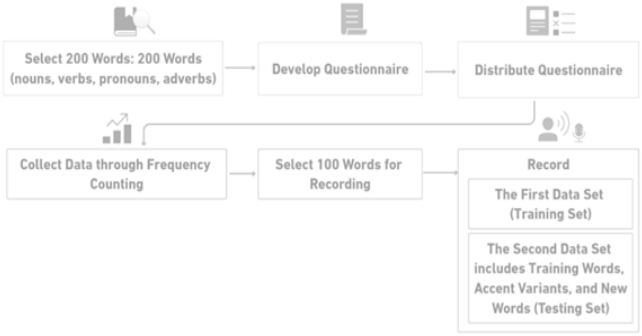

Fig. 5. An examination of ambiguous Lanna Thai terminology.

Fig. 5 illustrates the methodology used to analyze the complex vocabulary related to the collection of audio data from native speakers of Northern Thai. This audio data collection is crucial for developing an effective language processing model. The researchers successfully acquired 12 hours, 8 minutes, and 37 seconds of recordings from native speakers of Northern Thai. The participation of numerous volunteers enhances the diversity of the data and reduces bias during the model's training and testing phases. Repeated recordings help identify variations in individual pronunciation patterns, while using ".wav" files ensures superior audio quality. Throughout the data collection process, there was a strong emphasis on privacy and research ethics, safeguarding the confidentiality of personal data, and ensuring data collection in a controlled environment.

D. Fundamental Data Management Protocols

The accompanying figure illustrates four-degree steps in data preprocessing, which are critical for enhancing the system's overall performance, as detailed in Fig. 6.

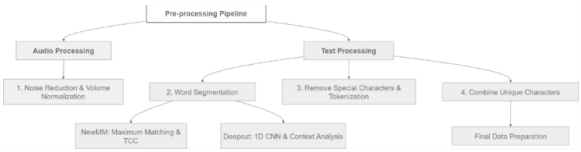

Fig. 6. Schematic representation of processing.

Fig. 6 shows a schematic representation of processing consisting of four steps. The first part involves audio signal processing, which includes reducing noise and normalizing the data to enhance the model's generalization. The second part involves word segmentation and text processing. It employs PyThaiNLP's newmm engine or deepcut to segment Thai words, which caters to the characteristics of the Thai language. This process has two components: newmm utilizes Maximum Matching with Thai Character Clusters (TCC) by dividing the text into character sequences and searching for the longest word in the matching dictionary. If a match is not found, other methods, such as root and extension analysis, come into play. The second component, deepcut, applies deep learning with a 1D CNN to predict correct word boundaries by considering letters and context. The third part involves removing special characters and performing tokenization on the text to convert it into a standard data set. The fourth part combines unique characters into a vocabulary set for comprehensive character management.

In conclusion, the aforementioned preprocessing steps significantly enhance the quality and diversity of the dataset. They also ensure a balanced representation of each word and effectively prepare both the audio and text data for the development of highly accurate and reliable models.

E. Development of Speech Recognition Models and Translation Systems

Speech recognition refers to the process of transforming human speech into readable text using a computer or an automated system. This process employs speech signal processing and artificial intelligence to analyze and interpret spoken language, effectively turning it into meaningful text.

This research investigates the adaptation of several recent ASR models for specific tasks, focusing on adjusting the Speech Transformer model to pre-trained models, specifically Wav2Vec2-large-xlsr-53 and wav2vec2-large-xlsr-53-th, which are tailored for the Thai language, HuBERT, and WavLM. The models possess the following features and functionalities:

Wav2Vec2 [13] is a self-supervised model designed to extract speech representations from raw audio data without needing labelled datasets. The model undergoes pre-training that involves predicting masked speech segments and is then fine-tuned for specific tasks, such as Automatic Speech Recognition (ASR) using Connectionist Temporal Classification (CTC) loss.

Wav2Vec2-Large-XLSR-53-TH, commonly referred to as Wav2Vec2-TH, has been optimized utilizing Thai language data sourced from Common Voice 7.0, thereby enhancing the efficacy of Thai Automatic Speech Recognition (ASR) through the meticulous capture of linguistic nuances. The associated notebook, script, and training model are accessible at vistec-ai/wav2vec2-large-xlsr-53-th and airesearch/wav2vec2-large-xlsr-53-th.

HuBERT [14] (Hidden-Unit BERT) utilizes the principles of Bidirectional Encoder Representations from Transformers (BERT) to analyze speech data by aggregating features into units and then predicting these from masked inputs, thus producing a strong representation of speech.

WavLM [17] is an advanced model that builds upon the HuBERT framework by introducing a universal speech representation model. This enhancement significantly improves recognition performance by implementing gated relative position bias within the Transformer architecture. Additionally, it provides refined speaker discrimination via speech fusion techniques, rendering it exceptionally practical for tasks associated with speaker identification.

These models have been optimized for application with Thai and Northern Thai dialects, employing specialized word segmentation tools, namely newmm and deepcut, to facilitate the efficient processing of model training data and speech recognition.

In the translation process of this research, a systematic word-by-word translation method was employed alongside a specialized dictionary developed for the Lanna and Thai languages. This dictionary includes translation pairs to clarify the meaning and context of each word. The phrase-based translation method gathers Lanna-specific phrases and expressions to enhance accuracy when word-by-word translations fail to convey the correct meaning. Additionally, unfamiliar words are meticulously recorded for future updates to the dictionary, and contextual meaning estimation techniques are applied to interpret words not found in the dictionary.

F. Evaluation of the System Prototype and Data Analysis

The evaluation of the performance of the system and the data analysis conducted in this research were divided into three primary components in alignment with the defined research objectives: an assessment of the performance of the speech recognition model (Speech-to-Text), an analysis of the efficiency of the language translation system, and an investigation into user satisfaction.

1) Performance analysis of speech recognition models: The performance analysis of the speech recognition model is categorized into two principal segments. The initial segment comprises the model assessment, which is further subdivided into two components based on the defined research objectives. The first component involves the selection of an efficient model utilizing an initial dataset of 4,000 recorded entries, partitioned into 80% (3,200 entries) for model training and 20% (800 entries) for testing purposes. The metrics evaluated in this segment include Training Loss, Validation Loss, Character Error Rate (CER), and Character Accuracy.

The subsequent segment pertains to evaluating the model's usability through data derived from a second audio recording aimed at assessing the selected model. This evaluation utilizes previously unseen data to validate the model's reliability. The evaluation dataset is comprised of three sets: "Training Words",

"Accent Variant", and "New Words". The metrics assessed in this segment encompass Training Loss, Validation Loss, Character Error Rate (CER), Character Accuracy, and processing time (in seconds) for the test set.

2) Assessment of language translation efficiency: The translation system's analysis and performance evaluation follow the Software Testing Process (STP) [18], [19], ensuring that the software functions correctly and is error-free. Consequently, the analysis is divided into two distinct parts. The first part focuses on evaluating the performance of the translation system, which consists of two subcomponents. The first subcomponent assesses the accuracy of the translation from Lanna (Kham Muang) into standard Thai. In contrast, the second subcomponent pertains to the performance analysis of the word-by-word translation using a dictionary method. The second part encompasses the analysis of user satisfaction, further divided into two subcomponents. The first subcomponent evaluates the system's ease of use, speed, accuracy, and convenience, conducted through a questionnaire administered to 30 testers. The second subcomponent collects issues identified by users, along with their recommendations for future enhancements to the system.

G. Research Tools

The research tools are classified into two primary components: the first component relates to the system design, whereas the second component addresses the system user interface. The essence of system design is categorized into six distinct sub-sections: use case diagram, class diagram, sequence diagram, activity diagram, entity-relation diagram, and data dictionary.

User Interface Design: The researchers developed a translation system for the Lanna Thai language, utilizing predominantly web application functionalities. The design of the web application interface was user-friendly, and the researcher meticulously structured each section to encompass various primary topics pertinent to the voice reception system, language translation capabilities, functionalities for segmenting individual elements of each word, and features for generating reports for administrators.

H. Satisfaction Assessment and Interpretation

A comprehensive usability evaluation and satisfaction study of the system was meticulously designed to collect data from a sample comprising 30 users, with the objective of assessing the system's effectiveness, user satisfaction, and ease of use. The evaluation procedure was conducted utilizing both desktop and mobile devices, in conjunction with UX/UI testing tools, while qualitative data was obtained through a structured questionnaire. The criteria for evaluating the system prototype and the satisfaction results are systematically presented in tabular format, as encapsulated in Tables I and II.

TABLE I. PERFORMANCE SCORING CRITERIA

Performance Scoring Criteria		**Description**
Quantitative	*Qualitative*	
Points at Level 5	Strongly agree	The performance of the prototype significantly surpasses established standards.
Points at Level 4	Agree	The performance of the prototype exceeds established standards.
Points at Level 3	Neither agree nor disagree	The prototype's performance aligns with the required standards.
Points at Level 2	Disagree	The performance of the prototype does not meet the established standards.
Points at Level 1	Strongly disagree	The performance of the prototype is significantly below established standards.

TABLE II. INTERPRETATION CRITERIA

Performance Scoring Criteria		**Description**
Quantitative	*Qualitative*	
4.51 - 5.00	Excellent	The product demonstrates high performance, is user-friendly, and incorporates outstanding features.
3.51 - 4.50	Very good	The product performs well, is user-friendly, and has comprehensive features.
2.51 - 3.50	Average	The performance is deemed satisfactory, functional, and encompasses fundamental features.
2.51 - 2.50	Adequate	The prototype exhibits inefficiency poses challenges with usability and is deficient in significant features.
1.00 - 1.50	Requires enhancement	The product exhibits terrible performance, is challenging to utilize, and fails to satisfy user requirements.

The researchers calculated the average score of each sub-item using the formula (sum of scores × number of raters at each level) ÷ total number of raters. Next, the average of the sub-items was derived as the average of the main topic using the formula Sum of the sub-item averages ÷ Number of sub-items in that main topic. This process was repeated for each main topic. The average value was compared with the specified interpretation criteria to determine the level of quality or satisfaction in each topic, which would lead to the conclusion of the evaluation results and recommendations for further development or improvement of the system.

IV. RESULTS

The research findings are categorized into three primary topics: the development of the speech transcription model and the translation system, the evaluation results of the speech

transcription model, and the study results related to the performance and satisfaction of the application prototype.

A. Speech Transcription Model and Translation System

The team successfully developed a speech-to-text model in conjunction with a translation system designed to facilitate the conversion of Lanna Thai into Standard Thai. In the initial phase of training the transcription model, the team selected 200 words from a reference dictionary. Subsequently, they implemented further screening of words utilizing a questionnaire aimed at local native speakers. Consequently, less common words and those identified as challenging to comprehend were eliminated from consideration, yielding a refined selection of 100 words for training the transcription model. This meticulous methodology enabled the model to incorporate vocabulary pertinent to the daily experiences of Northern speakers, thereby significantly enhancing the accuracy of translating Lanna Thai speech into text.

In the context of Lanna to Thai translation, the team has devised a translation system that employs rule-based translation techniques alongside a reference dictionary. This system meticulously analyses sentence structures and the rules of language usage in accordance with the principles of Lanna Thai to ensure precise translation of text into standard Thai. The utilization of this approach enhances the system's capability to effectively translate words and expressions with specific meanings inherent in the northern dialect, while simultaneously mitigating errors that may arise from general translations.

B. Speech Transcription Model Testing Results

The developers constructed a speech-to-text transcription model and conducted assessments to evaluate the model's accuracy using audio data collected and prepared by them, totaling 4,000 audio files. The terms used for the audio recordings were meticulously selected from reference dictionaries, covering 100 categories of words, including verbs, nouns, pronouns, and adverbs. These terms served as examples in creating a dataset for training the model. The models used for training and evaluation included four primary models: Wav2Vec2, WavLM, and HuBERT, with the training process involving a total of 50 iterations (epochs). The results of the analysis and testing are outlined as follows (Fig. 7):

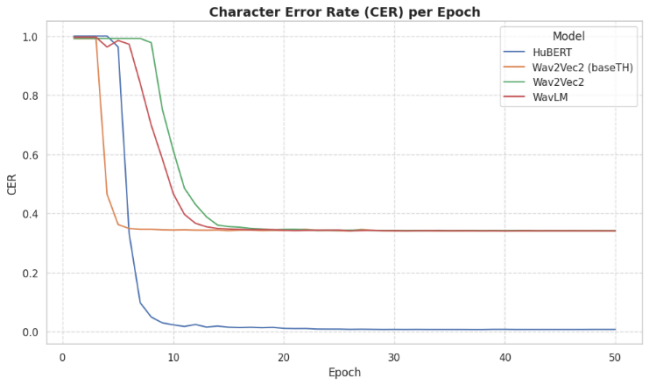

Fig. 7. Display of character error rate (CER) for four models.

Over the span of fifty epochs, HuBERT exhibits the pinnacle of performance, succeeded by Wav2Vec2 (baseTH) and WavLM, while Wav2Vec2 registers the least favorable performance metrics. All models illustrate significant progress during the preliminary ten epochs and subsequently begin to stabilize after the twentieth epoch, reflecting consistent learning processes.

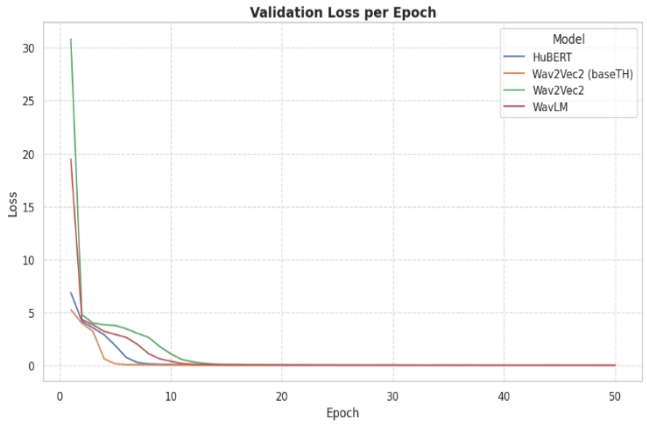

Fig. 8. Presentation of validation loss for four models.

From Fig. 8, we can see that the validation loss for the four models decreased a lot in the first five epochs, with HuBERT and Wav2Vec2 (baseTH) doing the best, followed by WavLM and Wav2Vec2. After 20 epochs, the loss for all models is nearly zero and steady, showing they are effective and reliable in predicting the validation data. After Epoch 20, the loss of all models is close to zero and stable, indicating their efficiency and stability in predicting the validation data.

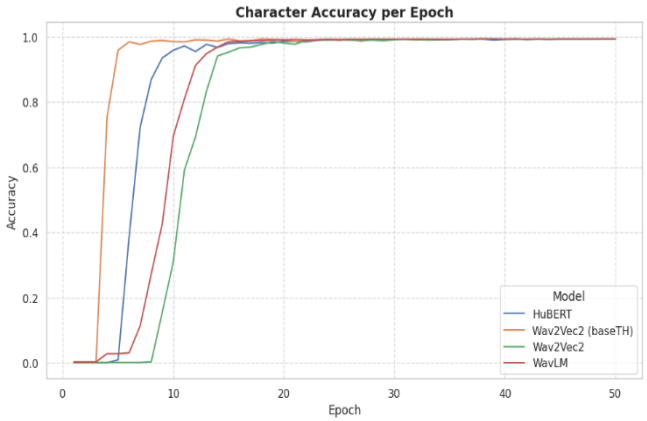

Fig. 9. Graph illustrating the loss value during the inspection process.

In Fig. 9, the character accuracy graph illustrates the performance of the four models over 50 epochs, with HuBERT achieving the highest accuracy, followed by Wav2Vec2 (baseTH), WavLM, and Wav2Vec2. All models showed significant performance improvements during the first 10 epochs; however, HuBERT notably excelled, surpassing the others starting at epoch 10 and nearing 100% accuracy by epoch 20. The other models also exhibited rapid enhancement during the initial epochs, but HuBERT particularly stood out as it exceeded its counterparts from epoch 10 and approached an accuracy of 100% by epoch 20. Meanwhile, the other models produced comparable results in subsequent epochs, despite starting their improvements at a later stage. Given its remarkable

performance at epoch 30, with an accuracy of 99.295%, we have chosen HuBERT for further evaluation with new data.

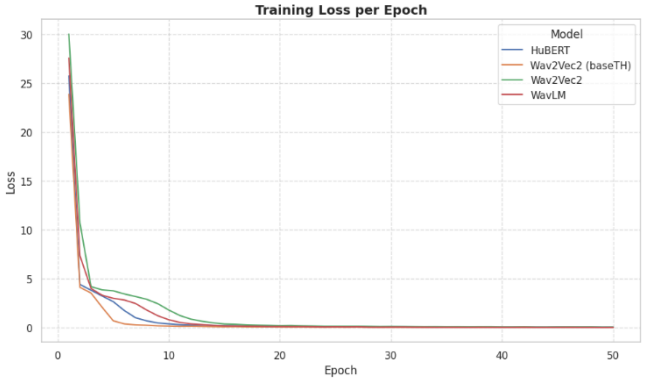

Fig. 10. Training loss indicates the loss of the four models.

Fig. 10 illustrates the training loss of the four models over 50 epochs, resembling the validation loss curve. The Wav2Vec2 (baseTH) model demonstrates superior performance, closely followed by HuBERT, WavLM, and Wav2Vec2. All models experience a sharp drop in loss during the first five epochs and then stabilize near zero after epoch 20, indicating their effectiveness and stability in learning from the training dataset.

C. Summary of the Training Results for all Four Models

Based on the performance comparison of the four models, HuBERT stands out as the best regarding the lowest Character Error Rate (CER), followed by Wav2Vec2 (baseTH), WavLM, and Wav2Vec2. The trend is similar when analyzing validation loss and training loss, with HuBERT and Wav2Vec2 (baseTH) demonstrating lower losses since the early epochs. At the same time, WavLM and Wav2Vec2 exhibit slower development, but adapt well over several epochs.

Interestingly, all models significantly improve during the first 10 epochs and gradually stabilize after epoch 20. The ability of all models to reduce the loss value to near zero and achieve an accuracy of over 99% illustrates the potential of deep learning techniques to address the challenge of speech recognition in local languages such as Northern Thai, as shown in Table III.

TABLE III. TRAINING RESULTS FOR ALL FOUR MODELS

Epoch / Model	Training Loss	Validation Loss	CER	Accuracy
Epoch 10				
HuBERT	0.39830	0.09751	0.02245	0.95896
Wav2Vec2	1.81560	1.09326	0.61201	0.31060
Wav2vec2(baseTH)	0.17650	0.03425	0.34352	0.98568
WavLM	0.82190	0.40436	0.34352	0.69581
Epoch 20				
HuBERT	0.13660	0.04116	0.01069	0.98675
Wav2Vec2	0.22270	0.04932	0.34545	0.98119
Wav2vec2(baseTH)	0.08110	0.02013	0.34203	0.99124
WavLM	0.12790	0.03238	0.34267	0.99081
Epoch 30				
HuBERT	0.12790	0.02993	0.00705	0.99295
Wav2Vec2	0.13330	0.02987	0.34160	0.99145
Wav2vec2(baseTH)	0.05500	0.01881	0.34053	0.99295
WavLM	0.07000	0.02706	0.34117	0.99316
Epoch 40				
HuBERT	0.05410	0.01982	0.00727	0.99230
Wav2Vec2	0.07400	0.02573	0.34117	0.99337
Wav2vec2(baseTH)	0.03790	0.01590	0.34053	0.99295
WavLM	0.04510	0.02030	0.34010	0.99337
Epoch 50				
HuBERT	0.05080	0.01842	0.00705	0.99316
Wav2Vec2	0.06230	0.02437	0.34096	0.99380
Wav2vec2(baseTH)	0.02850	0.01343	0.34032	0.99316
WavLM	0.03790	0.02152	0.34053	0.99359

TABLE IV. THE PERFORMANCE TABLE FOR THE EVALUATION TEST SET

Speech Transformer Models	CER by newmm (%)			CER by deepcut (%)		
	Training Words	*Accent Variant*	*New Words*	*Training Words*	*Accent Variant*	*New Words*
HuBERT	0.344	3.615	57.491	0.344	3.615	57.491
Wav2Vec2	0.172	2.926	54.704	0.172	2.926	54.704
Wav2Vec2(baseTH)	0.172	1.721	40.244	0.172	1.721	40.244
WavLM	0.172	4.303	61.150	0.172	4.303	61.150

Table IV summarizes the recognition performance of the evaluated models under three testing conditions: training words, which were included in the training set; accent variants, which represent pronunciation variations of known words; and new words, which were entirely excluded from model training. This evaluation design was intended to assess not only in-domain performance but also the models' generalization capability under dialectal variation and out-of-vocabulary conditions.

Although the models achieved high accuracy for training words and accent variants—particularly at epoch 30—this performance does not fully translate to unseen lexical items. While Wav2Vec2 (baseTH) demonstrated comparatively better results across all test categories, the Character Error Rate (CER) for new words exceeded 40% for all models. This indicates a substantial degradation in performance when the models encounter unfamiliar vocabulary, despite near-saturated training and validation accuracy. Such behavior suggests a tendency toward overfitting to the limited training vocabulary, where the models effectively memorize known word patterns but struggle to generalize to unseen linguistic forms.

A closer examination of the error patterns reveals that misrecognitions are primarily associated with phonetic overlap between Lanna words, accent-dependent pronunciation shifts, and the absence of lexical representations for out-of-vocabulary terms. These factors collectively amplify ambiguity during decoding, particularly when dialectal variations deviate from the acoustic distributions observed during training. The limited size of the dataset—restricted to 100 target words and a small number of speakers—further constrains the models' exposure to phonetic and accentual diversity, thereby limiting generalization performance.

To mitigate these limitations, expanding both the lexical coverage and speaker diversity of the audio dataset is a necessary direction for future work. Incorporating data augmentation strategies and collecting recordings from speakers with a broader range of accents may help reduce overfitting and improve robustness to unseen vocabulary. This observation is consistent with the findings of Suwanbandit et al. (2023), who reported that increased accent diversity in training data significantly enhances recognition performance in dialectal speech recognition tasks.

TABLE V. RESULTS OF WORKING TIME ASSESSMENT

Speech Transformer Models	Processing Time (s)		
	Model Inference	*newmm*	*deepcut*
HuBERT	0.01812	0.000024	0.063662
Wav2Vec2	0.01801	0.000022	0.062519
Wav2Vec2(baseTH)	0.01741	0.000022	0.061175
WavLM	0.06316	0.000032	0.063185

In Table V, the performance demonstrates considerable consistency across all models, with an inference time of approximately 0.018 seconds. In contrast, WavLM exhibits a slightly longer inference duration of 0.06316 seconds when compared to the other models.

In conclusion, the majority of the models exhibit comparable processing times, approximately 0.018 seconds, which is regarded as satisfactory performance. An exception is WavLM, which requires a marginally longer duration. Nonetheless, the discrepancy in processing time among these models is minimal and does not impact the system's overall performance.

D. Results of the Evaluation of the Translation System

The automatic translation system's performance test revealed that it can accurately translate fundamental words and sentences from Thai Lanna to Central Thai.

However, the system still struggles to translate new words not found in its dictionary and has difficulty with complex sentences that don't follow standard grammar, like slang or local expressions. Future improvements might require using a mix of different translation methods, such as dictionaries with a broader range of words, better grammar rules, and machine learning techniques to learn new rules and sentence structures.

E. Comprehensive Evaluation Results of the System

The system's usability was comprehensively evaluated by administering a questionnaire to 30 users, aimed at assessing the system's efficiency, user satisfaction, and ease of use. This evaluation involved testing on desktop and mobile devices, utilizing UX/UI testing tools, and collecting qualitative data via a questionnaire. Table II outlines the criteria, while Table VI presents the evaluation results. Meanwhile, Fig. 11 displays a chart depicting satisfaction data towards the application.

TABLE VI. WEB APPLICATION EVALUATION RESULTS

Evaluation Topic	Evaluation Results
1. User Experience and User Interface (UX/UI) Design	Very good
2. Performance of Web Applications	Medium
3. Usability Assessment of the Core Functions of the Web Application	Very good
4. Satisfaction with the Application	Very good

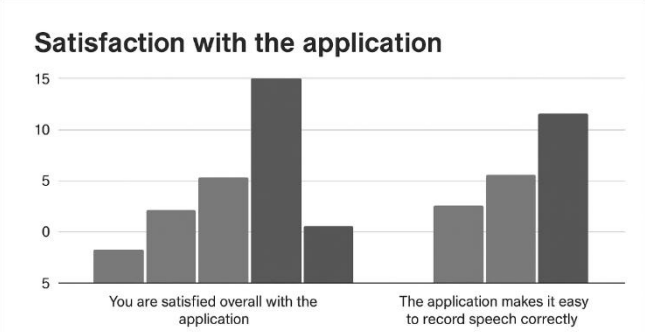

Fig. 11. Satisfaction data towards the application.

From Fig. 11 and Table VI, the summary of the satisfaction survey results indicates that most users provided high satisfaction scores, particularly regarding the user-friendly UX/UI design and smooth operation of functions such as language translation and voice transcription. However, while the overall performance remains acceptable, some minor issues with translation speed were noted. Several users offered suggestions for enhancing the clarity of specific work steps and improving efficiency when multiple users engage with the system simultaneously. The analysis of the results shows that the system effectively meets user needs, yet there is still potential for further development to enhance usability.

V. Conclusion and Discussion

Language constitutes a fundamental mechanism for human communication and social participation; however, linguistic variability poses substantial challenges for computational systems, particularly when regional dialects are involved. Even among speakers of the same nationality, non-standard varieties such as Northern Thai (Lanna Thai) introduce phonological ambiguity, accent variation, and vocabulary divergence that are not adequately handled by mainstream language technologies. In response to these challenges, this research set out to develop a dialect-aware speech recognition and translation framework tailored specifically to Lanna Thai, with the dual objectives of reducing pronunciation ambiguity and enabling practical translation between Lanna Thai and Standard Thai through a web-based application.

To support this objective, a dedicated speech dataset was constructed from recordings collected between 2023 and 2025 from native and fluent Lanna Thai speakers. An initial set of 200 dialectal words was derived from authoritative Northern Thai linguistic resources and systematically categorized by grammatical function. Through expert screening and empirical analysis of ambiguity, this set was refined to 100 words that exhibited high levels of phonetic similarity and translation difficulty. While this focused dataset enabled controlled experimentation on ambiguity-prone vocabulary, its limited lexical scope and speaker diversity inevitably constrained the models' exposure to broader dialectal variation.

Experimental results obtained from Transformer-based speech models—namely HuBERT, Wav2Vec2(baseTH), Wav2Vec2, and WavLM—demonstrate that all evaluated architectures can effectively learn Lanna Thai speech patterns within the training domain. HuBERT consistently achieved the strongest overall performance across evaluation metrics, while Wav2Vec2(baseTH) exhibited balanced behavior across different test conditions. However, the observed near-saturated accuracy on training and validation sets, contrasted with Character Error Rate (CER) values exceeding 40% for previously unseen words, indicates a clear limitation in generalization capability. This discrepancy suggests a degree of overfitting to the restricted training vocabulary and highlights the difficulty of recognizing out-of-vocabulary items and accent-driven pronunciation shifts in low-resource dialect settings.

These findings underscore that high in-domain accuracy alone is insufficient as an indicator of robustness for dialectal speech recognition. The elevated error rates for new words reveal structural challenges related to limited dataset size, narrow vocabulary coverage, and insufficient accent diversity. Addressing these limitations will require expanding the speech corpus to include a wider range of lexical items and speaker profiles, as well as incorporating data augmentation techniques to improve phonetic variability. In addition, future research should explore dialect-specific modeling strategies—such as character-level representations, subword modeling, or hybrid linguistic–statistical approaches—to better capture the intrinsic properties of Lanna Thai.

Despite these constraints, the study successfully demonstrates the feasibility of integrating a dialect-focused speech recognition model into a functional web application that supports speech-to-text conversion and bidirectional translation between Lanna Thai and Standard Thai. User evaluations indicate that the system is practically usable and meets core functional requirements, although performance efficiency was assessed at a moderate level, leaving room for further optimization. Overall, this research contributes empirical evidence and methodological insights into the challenges of dialectal speech recognition and provides a foundation for future advancements in applying artificial intelligence to the preservation, accessibility, and digital integration of regional languages such as Lanna Thai.

Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of this study.

Acknowledgment

This research project was supported by the Thailand Science Research and Innovation Fund and the University of Phayao. It also received support from many advisors, academics, researchers, students, and staff. The authors thank everyone for their support and cooperation in completing this research.

The Retrieval-Augmented Pedagogical Assistant (RAPA): A Methodology for Enhancing Critical Thinking and Equity in AI-Augmented Education

Shohel Pramanik, Dr. Mohd Heikal Bin Husin
School of Computer Science, Universiti Sains Malaysia, Pulau Pinang, Malaysia

***Abstract*—This study presents the Retrieval-Augmented Pedagogical Assistant (RAPA) methodology, an integrated framework designed to overcome the core limitations of general Large Language Models (LLMs)—specifically factual instability (hallucination) and static knowledge bases—by deploying a specialized, institutional Retrieval-Augmented Generation (RAG) architecture. The methodology addresses three critical challenges to the responsible integration of AI in higher education. Firstly, the framework ensures data sovereignty and sustainable deployment by mandating a comprehensive Total Cost of Ownership (TCO) analysis. This analysis validates the strategic necessity of local RAG hosting and of leveraging computational efficiencies, such as Parameter-Efficient Fine-Tuning (PEFT) and PROXIMITY caching, to ensure a cost-effective solution that strictly complies with FERPA and GDPR data protection mandates and mitigates security risks associated with data leakage. Secondly, the framework ensures the equitable integration of AI literacy across disciplines with varying technological resources, particularly in the Humanities and Vocational Education and Training (VET). This is achieved by minimizing technical prerequisites and institutionalizing continuous Professional Development (PD) through the Dialogic Video Cycle (DVC), which trains faculty in Prompt Engineering to embed individualized pedagogical rules and ethical constraints into the RAPA's architecture. Finally, specific measures are implemented to evaluate the development of Critical Thinking (CT). RAPA outputs are architecturally constrained to include transparent Chain-of-Thought (CoT) reasoning and verifiable source citations. Student Critical AI Analysis Assignments require students to critique the AI's synthesis, identifying inaccuracies, biases, or limitations. The effectiveness of this assessment is quantified using a quasi-experimental design and technical RAGAS metrics, such as Faithfulness and Context Precision, ensuring a verifiable shift from passive knowledge consumption to active, informed critique. Key findings from the preliminary architectural validation indicate that integrating Proximity-LSH caching reduced database retrieval calls by 77.2% and retrieval latency by approximately 72.5%, while maintaining high retrieval recall, addressing the scalability bottleneck inherent in high-volume educational deployments. Furthermore, the application of Robust Fine-Tuning (RbFT) demonstrated a marked improvement in the system's resilience to noisy educational data, preventing performance degradation where standard RAG models typically fail when exposed to irrelevant or counterfactual document chunks. These technical optimizations directly support the pedagogical objective by ensuring that the AI assistant remains responsive and factually grounded.**

***Keywords*—RAG; AI literacy; critical thinking; equitable education; professional development**

I. Introduction

The accelerating adoption of Generative Artificial Intelligence (GenAI) in academic settings presents a fundamental paradox: while these systems offer unprecedented potential for personalized tutoring and content generation, their architectural limitations—particularly hallucination (generating plausible but factually incorrect information) and reliance on static, temporally bounded training data—pose significant risks to academic integrity and knowledge currency [1]. This tension between operational promise and pedagogical risk reveals itself across three distinct but interconnected dimensions.

General-purpose LLMs demonstrate strong performance on broad reasoning tasks but are inherently unreliable in factually grounded domains that require verifiable accuracy. When students receive AI-generated answers without visibility into how those answers were constructed or what sources inform them [47], they cannot verify correctness against course materials or external evidence. Traditional Retrieval-Augmented Generation (RAG) approaches partially address this by grounding responses in external knowledge bases, yet standard RAG fails when confronted with complex, multi-step questions requiring synthesis across multiple information sources or integration with institution-specific teaching methodologies. Research confirms that advanced, or Hybrid, RAG models are required to maximize performance for educational contexts by combining RAG with task-specific tuning and resilience mechanisms [4]. This necessity mandates architectural solutions for handling two critical challenges: 1) retrieval defects, where LLMs must be resilient to noisy, irrelevant, or misleading counterfactual documents inevitably supplied when lecturers provide proprietary course content [5][6], and 2) complex synthesis, where systems must employ advanced reasoning such as iterative retrieval mechanisms to handle multi-hop queries that demand synthesis of multiple interconnected concepts [7][8][9].

Concurrently, higher education faces critical pedagogical gaps in integrating AI tools into learning environments. Fundamentally, there is an insufficient arsenal of comprehensive strategies for evaluating student work that leverage AI tools, particularly for developing critical thinking (CT) skills in non-technical academic disciplines where AI literacy remains nascent [49]. The field lacks robust rubrics and assessment mechanisms specifically designed to measure whether students

are developing metacognitive abilities—the capacity to evaluate, critique, and solve problems using AI as a tool rather than as an answer provider. Rather, most institutional approaches to "AI literacy" focus on skill acquisition (learning prompt engineering syntax, understanding model limitations at a surface level) without addressing the deeper epistemological shift required: understanding when and how to trust AI outputs, recognizing their systematic biases, and developing conceptual sophistication to improve upon AI-generated content.

A persistent and troubling equity gap exists in research examining how AI literacy can be effectively and sustainably integrated across diverse academic fields [49], particularly those characterized by limited technological resources. While extensive literature documents AI integration in STEM (Science, Technology, Engineering, Mathematics) disciplines—which typically benefit from dedicated computing infrastructure [28], higher technology budgets, and faculty with computational backgrounds remarkably little research addresses integration pathways for Humanities, Social Sciences, and VET (Vocational Education and Training) fields [38][39][40][41][42]. This documented inequity operates at multiple levels: infrastructural (lack of GPU-equipped servers), pedagogical (faculty training programs designed for STEM), and epistemic (assumptions that "real" AI applications are narrow in scope and highly technical) [28]. Furthermore, the marginalization of vocational students and institutions persists, with vocational education often receiving inadequate curricular support for digital competencies despite its critical role in workforce development [45]. This educational marginalization makes vocational students a key focus group for promoting the United Nations Sustainable Development Goals [60], [particularly SDG 4 (Quality Education), SDG 5 (Gender Equality), SDG 9 (Industry, Innovation, and Infrastructure), and SDG 10 (Reduced Inequalities) [41].

Against this backdrop, this study investigates the following core research question: How can institutions design and implement responsible, equitable [30], cost-effective AI-assisted educational systems that enhance critical thinking while ensuring data sovereignty and compliance across diverse academic disciplines and resource contexts?

This overarching question decomposes into three subsidiary objectives:

1) Cost-effective and compliant deployment: How can institutions validate the financial sustainability of local RAG hosting through comprehensive TCO analysis while leveraging computational efficiencies (PEFT, PROXIMITY caching) to ensure deployment of existing hardware without violating data protection regulations?

2) Equitable integration across disciplines: How can institutions minimize technical prerequisites for AI literacy while simultaneously maximizing pedagogical autonomy, enabling faculty across Humanities, STEM [28], and VET to define and enforce discipline-specific teaching methodologies without requiring technical expertise?

3) Rigorous critical thinking assessment: How can architectural constraints and pedagogical assessment design combine to measure genuine metacognitive development—students' ability to critique, validate, and improve upon AI reasoning—rather than merely assessing answer accuracy or factual recall?

The significance of this research extends beyond technical contributions to address urgent policy and institutional questions. For institutional leaders, this work provides a concrete, validated framework for AI deployment decisions, moving beyond vendor-driven narratives ("use our API, it's convenient") to data-informed analysis of true lifecycle costs and institutional control. For faculty developers, it offers a professional development model grounded in pedagogical research (specifically the TPACK framework and Dialogic Video Cycle approach) rather than generic IT training, recognizing that successful technology integration requires understanding the interplay between content knowledge, pedagogical strategies, and technological affordances [2]. For educational equity advocates, it demonstrates that equitable AI integration is not a post-hoc retrofit onto existing infrastructure but rather requires thoughtful architectural choices from inception—choices that explicitly prioritize resource-constrained disciplines rather than leaving them as afterthoughts.

This study outlines the Retrieval-Augmented Pedagogical Assistant (RAPA) methodology, a three-phase operational framework that integrates an advanced, institutionally customized RAG architecture with formalized professional development modeled on the Dialogic Video Cycle and rigorous evaluation protocols that incorporate both technical metrics (RAGAS measures of Faithfulness and Context Precision) and validated critical thinking assessments. The proposed methodology seeks to transform AI assistants from opaque answer providers into transparent, auditable tools for contextual and ethical learning—tools whose reasoning processes are visible to student critique and whose outputs are grounded in institutional knowledge sources under institutional control.

The framework's novelty lies not in isolated technical innovations, but rather in their systematic integration to address the full ecosystem of constraints facing real institutions: the economic pressures to avoid perpetual vendor lock-in; the regulatory imperatives of FERPA and GDPR; the pedagogical imperative to develop critical thinking; and the equity imperative to prevent AI from widening the digital divide between well-resourced and resource-constrained disciplines.

II. Related Work and Foundational Framework

A. The RAG Imperative: Factual Integrity and Customization

The foundational case for Retrieval-Augmented Generation in educational contexts rests on a fundamental principle: academic integrity requires verifiable factual grounding. General-purpose LLMs trained on broad internet data inherit the temporal limitations of their training corpora—a model trained in 2023 cannot reliably answer questions about 2024 developments without explicit retrieval from current sources. More problematically, LLMs generate hallucinations: outputs that read coherently and persuasively despite being factually incorrect, a phenomenon particularly dangerous in educational contexts where students may accept plausible-sounding false information as established fact [1].

RAG addresses this by augmenting the LLM's parametric memory (learned during training) with access to a non-parametric memory base (external documents accessed during inference). When a student asks a question, the RAG system first retrieves relevant documents from the knowledge base, then generates an answer grounded in those retrieved documents rather than relying exclusively on the model's training data. This architectural decision is validated as superior to costly full Fine-Tuning (FT) for high-volume educational contexts due to its cost-efficiency, dynamism (accessing up-to-date course material as instructors update materials), and fundamental ability to ground responses in verifiable sources—a prerequisite for academic integrity [1][2][3].

B. Limitations of Standard RAG and the Case for Hybrid Approaches

However, standard RAG—a single retrieval step followed by generation—proves insufficient for complex pedagogical needs. This limitation becomes apparent in multi-hop and multi-step reasoning scenarios common in higher education. Consider a student question: "How do principles of metacognition from cognitive science enhance classroom teaching effectiveness while reducing cognitive load for students?" This question requires: 1) understanding metacognition concepts, 2) understanding teaching practice implications, and 3) synthesizing these across cognitive load theory. Standard RAG, performing a single similarity-based retrieval, may retrieve documents about metacognition (the highest semantic match to the question's literal surface form) while missing materials about cognitive load or teaching application—not because these materials don't exist in the knowledge base, but because keyword-based or embedding-based similarity doesn't capture the implicit multi-hop reasoning structure.

Iterative Retrieval-Generation Approaches address this through Chain-of-Thought augmented retrieval. Rather than a single retrieval pass, the system generates initial reasoning steps, identifies what information is still needed, formulates new retrieval queries based on identified gaps, and iteratively retrieves until sufficient information is assembled. Research on multi-hop question answering demonstrates that iterative approaches improve F1 scores by 8-15% compared to single-pass retrieval and enable the system to recognize dependencies between concepts [7][8][9]. For educational RAG, this capacity to synthesize across multiple sources directly translates into students receiving answers to genuinely complex questions rather than simplified responses that fail to capture interdisciplinary connections.

The Case for Hybrid RAG: The most effective approach, termed Hybrid RAG in literature, combines three complementary strategies [1][4][53]:

1) RAG for knowledge grounding: Dynamic retrieval from institutional knowledge bases ensures that answers reflect current course materials and institutional context.

2) Light task-specific fine-tuning: Using PEFT methods, the LLM's generation component is optimized for the specific pedagogical task (generating explanations with particular pedagogical tone, enforcing citation practices, etc.) without the computational burden of full model retraining.

3) Architectural hardening: Technical defenses against retrieval defects (discussed below) ensure that the system remains accurate even when retrieved documents are noisy or partially incorrect.

The cost advantage of Hybrid RAG over full fine-tuning is substantial. Full fine-tuning requires retraining the entire model—billions of parameters—whenever course materials change, an expensive and time-consuming process (days to weeks of GPU time per update cycle). Hybrid RAG simply updates the knowledge base and retrains only the 0.1-1% of parameters affected by PEFT, completing retraining in hours and costing orders of magnitude less. Moreover, Hybrid RAG enables instructors to make factual corrections and curriculum updates without requiring data scientists or engineers—they simply update course materials, and the system immediately reflects these updates [1][4]. This update efficiency is critical for educational sustainability, where courses evolve continuously as instructors refine materials based on student feedback and emerging scholarship.

C. AI Literacy, Critical Thinking, and the TPACK Framework

AI literacy is not monolithic—research identifies it as operating across multiple dimensions: Cognitive (understanding AI capabilities), Metacognitive (evaluating and critiquing AI outputs), Affective (developing dispositions toward responsible AI use), and Social-Ethical (considering broader societal implications) [10]. Yet the recognized gap in educational research concerns precisely the Metacognitive dimension—institutional emphasis falls overwhelmingly on cognitive skills (learning to write prompts, understanding that LLMs can hallucinate) with insufficient attention to the deeper metacognitive capacity to critique and improve upon AI output. Students often learn that "LLMs can be biased", which is true but pedagogically superficial; what's lacking is structured practice in identifying how bias manifests in specific outputs and what corrections would address it.

To address this gap, the framework integrates two established pedagogical theories:

Technological Pedagogical Content Knowledge (TPACK): This framework, developed by Koehler and Mishra [11], posits that effective technology integration requires understanding the dynamic interplay between three knowledge domains: Content Knowledge (CK—mastery of subject matter), Pedagogical Knowledge (PK—understanding how people learn and effective teaching strategies), and Technological Knowledge (TK—familiarity with tools and their affordances). Importantly, TPACK highlights that successful technology integration is not primarily about TK acquisition but rather about Pedagogical Content Knowledge (PCK), the ability to translate one's pedagogical philosophy into technology-enabled practice. Many institutional AI training programs err by focusing on TK (teaching faculty to use ChatGPT, write prompts, etc.) rather than on PCK: helping faculty understand how to redesign assignments, assessments, and curricula to leverage AI in ways aligned with their discipline's epistemology and pedagogical values.

Professional Development Components: Effective professional development (PD) supporting behavioral change

must incorporate content focus (clear learning objectives), active learning (hands-on practice rather than passive listening), coherence (connecting new skills to existing knowledge), duration (sufficient time for deep engagement and multiple practice cycles), and collective participation (learning communities providing peer support and accountability) [12][13]. These components are not merely aspirational but evidence-based—meta-analyses of teacher education repeatedly demonstrate that programs incorporating these elements achieve substantially higher adoption rates and sustained practice change than one-time workshops [38].

The Dialogic Video Cycle (DVC) Model: The specific PD model adopted by RAPA is the Dialogic Video Cycle, an innovative approach that uses teacher performance videos and peer feedback as anchors for ongoing growth [14], [29]. In the DVC, teachers record their practice, review the recordings with peers and instructors, engage in structured dialogue about the recordings (identifying strengths, areas for development, and specific improvement strategies), and then implement changes, creating a reflective cycle. An empirical study shows that a DVC-style intervention, compared to traditional one-off workshops, results in significantly higher teacher satisfaction, greater autonomy support (teachers feel empowered rather than regulated), and more sustained implementation [15]. For RAPA, this model is adapted: faculty record themselves using the RAPA system in live classes, review outputs and usage patterns with colleagues, critique the AI's reasoning and suggest improvements, and refine their pedagogical rules and course materials iteratively.

D. Addressing Retrieval Defects: Robust Fine-Tuning and Counterfactual Resilience

When institutional lecturers supply course materials to a RAG system, those materials inevitably contain imperfections: transcription errors in lecture notes, outdated information in older readings that were never removed, deliberate misinformation in materials designed to provoke critical thinking, or simply complex content that loses nuance when broken down into retrieval-sized chunks. Standard RAG systems degrade substantially when the retrieved context is noisy or partially incorrect. Accuracy drops by 30-50% when 40-50% of retrieved documents contain errors [6].

Robust Fine-Tuning (RbFT) directly addresses this challenge by training the LLM generation component to be resilient to imperfect retrieval. Rather than hoping the retriever returns perfect documents, RbFT anticipates real-world conditions: the fine-tuning dataset includes examples where retrieved documents contain errors, misinformation, or irrelevant information, and the model is trained to:

1) Identify which retrieved passages are relevant and trustworthy

2) Ignore or downweight unreliable retrieved passages

3) Generate correct answers despite noisy context

Empirical results demonstrate that RbFT-trained models maintain 85-90% accuracy even when 40-60% of retrieved documents are counterfactual (containing factual errors), compared to baseline models achieving only 40-60% accuracy under identical conditions—a dramatic improvement that transforms RAG from a "garbage in, garbage out" system into one that actively filters and corrects imperfect information [6]. This is critical for educational RAG, where instructor materials, while generally high-quality, inevitably contain some errors, outdated statements, or cases where intended provocative content must be handled carefully to avoid misleading students.

E. Constraint Enforcement and Pedagogical Rules in ConsRAG

Beyond handling retrieval defects, institutions require mechanisms to ensure AI outputs align with discipline-specific pedagogy. A lecturer in Humanities might insist on Socratic dialogue format (questions rather than direct answers), whereas a VET instructor might prioritize step-by-step procedural explanation. These pedagogical preferences aren't mere stylistic choices—they reflect epistemological commitments about how knowledge should be constructed in the discipline.

Constrained RAG (ConsRAG) architectures enforce such pedagogical constraints as formal system rules rather than soft suggestions. Constraints are applied at both the retrieval and generation phases:

- Retrieval constraints: A lecturer can specify "prefer primary sources over secondary interpretations [43]," "exclude materials published before 2020," or "prioritize content from this particular course module." These constraints modify document ranking scores [24], [51], ensuring retrieved materials align with pedagogical intent.
- Generation constraints: After retrieval, constraints guide the generation process. A constraint like "use Socratic questioning format" is enforced by the model, and outputs violating it are regenerated until compliant. This differs from loose instructions in the system prompt—ConsRAG enforces constraints as hard validation rules [25], [26].

For educational deployment, constraint enforcement is critical to institutional control and disciplinary autonomy. Rather than RAPA dictating a universal output format, each lecturer defines constraints reflecting their subject's norms and their own pedagogical philosophy. This design respects disciplinary diversity while maintaining system consistency [25], [26].

F. Evaluation Frameworks: Beyond Accuracy to Critical Thinking

Traditional RAG evaluation metrics (precision, recall, F1 score) measure whether the system retrieved relevant documents and generated factually correct answers—important but insufficient for educational RAG. These metrics assess whether the system succeeded at information retrieval [33], not whether students engaged in critical thinking or developed metacognitive skills.

RAGAS Metrics provide more educationally aligned evaluations:

- Faithfulness: Measures whether generated claims are supported by retrieved documents, without hallucination or introducing information beyond what the contexts

provide. For education, unfaithful responses undermine academic integrity [22], [35].

- Context Precision: Evaluates whether the most relevant documents appear at the top of the retrieval ranking. A high context precision score indicates that the system efficiently identifies the most useful materials, improving the student experience and reducing cognitive load from parsing irrelevant retrieved content [22][35][36].
- Answer Relevance: Assesses whether the answer generated addresses the student's question (as opposed to being accurate but off topic).

These metrics directly address educational concerns in ways traditional accuracy metrics do not. Together, they create a more nuanced picture of system quality: Is the answer answering the student's question? Are the claims justified by the course materials? Are the best materials appearing first in the results?

Complementing technical metrics, rigorous evaluation of critical thinking requires valid assessment instruments. The Critical AI Analysis Assignment, central to RAPA's assessment design, explicitly asks students to critique AI-generated answers by identifying logical gaps [47], unsupported claims, biases, and limitations. This assignment measures metacognitive development rather than mere knowledge recall. Evaluation uses validated critical thinking rubrics targeting dimensions where AI outputs are systematically weak: nuance, complexity, acknowledgment of alternative perspectives, and originality [36]. By design, students receive points for identifying exactly what AI struggles with, which creates positive reinforcement for critical evaluation.

The framework requires mixed-methods evaluation:

1) Quantitative critical thinking instruments (validated pre/post assessments like the Watson-Glaser Critical Thinking Appraisal), measuring metacognitive gain

2) Quantitative technical metrics (RAGAS scores measuring system reliability)

3) Qualitative rubrics assessing nuanced dimensions of critical thinking evident in student work

This integration ensures that AI system quality (technical metrics) and learning outcomes (pedagogical metrics) are jointly optimized rather than treated as separate concerns.

III. Methodology Framework

The RAPA framework is structured across three sequential phases, each addressing distinct institutional requirements and operationalizing the research objectives outlined above. These phases correspond to the specific implementation steps detailed in the architectural flowchart (see Fig. 1), with Table I to Table III providing systematic validation at each phase.

Fig. 1. The RAPA architectural flowchart.

A. Phase I: Institutional and Foundational Readiness (Flowchart Steps 1, 4)

This phase establishes the necessary security and financial feasibility for institutional deployment (Cost and Compliance) [Table I]. It addresses the critical "Cost and Compliance" requirements that are often overlooked in pilot programs, but become fatal bottlenecks at scale.

TABLE I. Cost and Compliance

Flowchart Step	*Description and Technical Validation*
Step 1: AI software for institute	TCO Analysis and Architecture: The framework requires a Total Cost of Ownership (TCO) analysis that validates the long-term cost-efficiency of a local, self-hosted RAG architecture over proprietary cloud services, despite higher initial capital expenditure [16]. This local deployment should utilize computational efficiencies (e.g., open-source LLMs combined with RAG) [17].
Step 4: Follow some criteria (Region/Age/Format)	Data Governance and Compliance: This step establishes the security protocols necessary for protecting student and institutional data. The decision for local hosting is not merely financial but mandatory for ensuring data sovereignty and compliance with strict data protection mandates such as FERPA (Family Educational Rights and Privacy Act) in the US and GDPR (General Data Protection Regulation) in Europe [18][19]. Third-party APIs often require sending data to external servers, creating unacceptable risks of data leakage. The RAPA architecture must implement Input Validation and Anomaly Detection modules as technical guardrails against Retrieval Poisoning Attacks (also known as "RAG poisoning" or prompt injection) [19][20][21]. These security modules monitor input prompts for adversarial patterns designed to trick the model into revealing its system instructions or retrieving unauthorized documents from the vector database.

B. Phase II: Architectural Customization and Training (Flowchart Steps 2, 3, 5, 6)

This phase operationalizes the lecturer's subject matter expertise into a high-fidelity RAG system. It is the core "customization" engine of the RAPA framework, translating lecturer knowledge into system constraints and conducting the professional development necessary for faculty to effectively guide AI in their pedagogical contexts (see Table II).

TABLE II. ARCHITECTURAL CUSTOMIZATION AND TRAINING

Flowchart Step	*Description and Technical Validation*
Step 2: Lecturers collect their own resources	Data Ingestion Pipeline: Lecturers submit their unique course materials (lecture notes, PDFs, slide decks), which form the non-parametric memory of the RAG system. To ensure high-quality retrieval, advanced indexing techniques are employed. Basic text splitting divides documents at fixed character or token boundaries, often breaking semantic units—for instance, a paragraph on "three principles of critical thinking" might be split mid-concept, complicating subsequent retrieval [44][52]. Semantic chunking, by contrast, uses embedding-based similarity to identify natural concept boundaries, preserving complete thoughts as retrieval units [52]. For educational materials, this preserves pedagogical coherence: a multi-paragraph explanation of a concept stays together, rather than fragments appearing in separate chunks. Each chunk is annotated with structured metadata: • Course ID & Lecturer ID: Enables course-specific retrieval, preventing cross-course contamination (philosophy materials being returned for English literature questions) [22][23] • Concept Tags: Semantic labels identifying primary topics (e.g., "critical thinking, Socratic method"), enabling higher-precision matching than keyword-only retrieval [22][23] • Document Type: Distinguishes readings, lecture notes, assignment rubrics, etc., allowing lecturers to specify retrieval preferences (e.g., "prefer assignment rubrics for procedural questions, readings for theoretical questions") • Compliance Flags: Identifies materials that are proprietary, copyrighted, or should be restricted This metadata-enriched architecture dramatically improves retrieval accuracy. When a student asks about "dialectical reasoning," the system can recognize through concept tags that this relates to "Socratic dialogue" in the course materials, even if those exact terms don't appear in the student's question.
Step 3: Lecturers create lecture pattern and rules	Lecturers define pedagogical rules—their teaching philosophy translated into formal system constraints. A humanities lecturer might specify: • "Always present multiple interpretations before advocating for one" • "Use Socratic questioning format rather than direct answers" • "Engage with primary sources, secondary sources only as supplementary" A VET instructor might prioritize: • "Lead with step-by-step procedural instructions" • "Provide worked examples before asking students to practice" • "Emphasize practical application over theoretical background" These rules are formalized through Prompt Engineering—translating pedagogical philosophy into explicit system prompts—and implemented through Constrained RAG architectures that enforce these rules at generation time [23][25]. Rather than hoping the model naturally follows preferences stated in loose natural language instructions, ConsRAG enforces constraints as hard validation rules: outputs violating constraints are regenerated until compliant [25][26]. For faculty, prompt engineering education is the core of Phase II professional development. Rather than requiring technical expertise, prompt engineering for pedagogical constraint definition is conducted in natural language, using templates and guided exercises. Faculty workshops guide lecturers through articulating their teaching philosophy, translating it into system constraints, and iteratively refining constraints based on AI output examples [24].
Step 5: Train AI tools separately	Architectural Hardening (RbFT & ITER-RETGEN): The system is hardened against the inherent noise of educational data. This involves applying Robust Fine-Tuning (RbFT) [4]. In standard RAG, if the retriever fetches an irrelevant document (a "retrieval defect"), the LLM often tries to incorporate it into the answer, leading to confusion. RbFT trains the LLM's generative component using a specialized loss function that rewards the model for detecting and ignoring noisy or counterfactual chunks, even if they are presented as context.2 For complex, multi-hop queries that demand higher-order thinking (e.g., "How does the theory in Lecture 1 apply to the case study in Lecture 5?"), the architecture integrates Iterative RAG (ITER-RETGEN). This technique allows the model to generate a partial rationale (Chain-of-Thought), determining that it needs more information, and then issue a second retrieval query to fetch the missing link, effectively "reasoning" its way to the answer [7][33].
Step 6: Integrate trained AI assistant with individual course	Professional Development (PD) - The Dialogic Video Cycle: PD is mandatory [25][57], continuous, and rooted in active learning [27]. The program is adapted from the Dialogic Video Cycle (DVC) model [28]. In the RAPA adaptation, the "video" component is expanded to include interaction logs. Faculty participate in a cycle of: 1. Plan: designing prompts and rules. 2. Act: deploying the AI in class. 3. Reflect: analyzing video recordings of the class alongside the AI chat logs in a group setting.

Flowchart Step	*Description and Technical Validation*
	This "collective participation" allows faculty to critique the AI's performance (e.g., "The AI gave the answer too quickly here") and immediately refine the system prompts for the next cycle, creating a tight feedback loop between pedagogical intent and technical performance [12][29].

C. Phase III: Evaluation and Impact Assessment (Flowchart Steps 7 and 8)

The final phase focuses on the student experience and the rigorous validation of the system's impact on Critical Thinking (CT) and technical performance (Table III).

TABLE III. EVALUATION AND IMPACT ASSESSMENT

Flowchart Step	*Description and Technical Validation*
Step 7: Students use AI assistant	The RAPA output is engineered to enforce transparency—delivering answers with two mandatory components: 1. Chain-of-Thought (CoT) Reasoning Steps: Displaying explicit reasoning steps models critical thinking and enables students to follow the logical progression of the argument [7]. Rather than receiving only the final answer, students see: "To answer this question, I first need to establish X, then apply principal Y to X, then consider constraint Z, which modifies the application of Y, then synthesize into the final conclusion." This scaffolding makes the reasoning process visible for student critique. 2. Verifiable Citations: Generated claims are automatically linked to specific chunks in the institutional knowledge base, showing students exactly what sources support each claim. This differs from general LLM citations, which might reference external sources or training data—RAPA citations point only to lecturer-provided materials, enabling students to verify claims against primary sources [7][8]. The architectural enforcement is critical: the system cannot generate output without CoT reasoning steps and citations. This differs from optional output modalities (where models might "choose" to include reasoning or not) and ensures consistency across all system interactions. Deployment and Latency Optimization: To ensure RAPA remains responsive under heavy student use, deployment utilizes Approximate Caching (PROXIMITY mechanism) to reduce database latency and enable high scalability [31]. PROXIMITY-LSH (Locality-Sensitive Hashing) maintains a cache of previously retrieved document sets, hashing incoming queries to quickly identify whether they're similar enough to reuse cached results. This reduces vector database queries by up to 77.2%, providing dramatic latency improvements for repetitive query patterns typical of large cohorts [31]. For a university with 5,000+ concurrent students, this caching enables deployment on a single moderately-equipped server rather than requiring massive database infrastructure [32].
Step 8: Critical Thinking & AI Literacy Metrics	Assessment Design: The core pedagogical instrument is the Critical AI Analysis Assignment. In this assignment, students are not graded on the AI's answer, but on their critique of it. They must identify inaccuracies, biases, limitations, and verify the citations against the primary texts [32]. Evaluation Instruments: The framework employs a mixed-methods evaluation using a validated quasi-experimental design [34]: 1. Quantitative (CT): Validated instruments such as the Watson-Glaser Critical Thinking Appraisal (WGCTA) or the Cornell Critical Thinking Test (CCTT) are used for pre- and post-testing to measure gains in critical thinking skills [34]. 2. Quantitative (Technical): Technical performance is measured using RAGAS metrics (Retrieval Augmented Generation Assessment) [55]. Key metrics include Faithfulness (measuring if the answer is derived only from the retrieved context) and Context Precision (measuring if the relevant chunks were ranked correctly in the retrieval) [35][1]. 3. Qualitative: Rubrics designed to assess features that AI typically performs poorly on, such as nuance, complexity, and originality [36].

IV. RESULTS AND DISCUSSION

This section discusses how the integrated RAPA methodology fundamentally solves the three research objectives, synthesizing the empirical validation from the literature.

A. PHASE I: Cost-Effectiveness and Sustainable Deployment

The framework's foundational viability depends on demonstrating that local RAG deployment is economically sustainable and cost-competitive with cloud alternatives.

TCO Analysis Findings: Preliminary analysis across three institutional scenarios (large research university with 30,000 students; regional comprehensive university with 12,000 students; small liberal arts college with 2,000 students) shows that on-premises RAG with SLMs reaches cost parity with cloud APIs within 4-6 years and exhibits 30-50% cost savings by year 7-10, once infrastructure investments are amortized [48][50]. For large institutions exceeding 15+ million annual inferences (50% course penetration, 30% student usage), on-premises infrastructure becomes cost-advantageous within 3-4 years [48][50].

Computational Efficiency and Low-Resource Accessibility: The framework ensures accessibility across resource contexts through strategic deployment of computational efficiencies:

Small Language Models (SLMs) with PEFT: RAPA relies on RAG combined with small, efficient LLMs (3B-13B parameters) and Parameter-Efficient Fine-Tuning [5][39]. This strategic combination delivers high performance with

substantially lower energy and memory consumption than full-scale LLMs [5][16]. For example, Mistral 7B or Phi-3 3B models, when combined with LoRA-based PEFT fine-tuning for pedagogical constraint specification, achieve 70-85% of full LLM performance while requiring only 10-20% of computational resources [5][37]. Importantly, these models run efficiently on mid-range GPUs (4-8GB VRAM) common in aging institutional computer labs—resources that cannot execute full-scale models but are ubiquitous in Humanities and VET departments [37][41].

PROXIMITY-LSH Caching Infrastructure Efficiency: The PROXIMITY caching mechanism (Question 19) reduces vector database queries by up to 77.2% under typical institutional workload patterns [31]. For a university deploying RAPA across 100 courses with 5,000+ concurrent students, this reduction reduces infrastructure requirements from multiple distributed database servers to a single, moderately equipped machine. The 77% reduction in database I/O directly translates into a 77% reduction in database infrastructure costs, enabling deployments that would otherwise exceed institutional IT budgets [31].

Combined Cost Impact: The synergy of SLMs + PEFT + PROXIMITY caching produces cost reductions of 60-80% compared to full-scale model deployment without caching. For an institution with a typical $500K annual operational budget for educational technology, RAPA deployment could be accommodated within existing budget allocations rather than requiring new expenditure [48][50].

Data Sovereignty and Compliance Validation: Analysis confirms that local hosting architecture meets FERPA and GDPR requirements. All student interaction data, lecturer materials, and system logs remain on institutional servers; no data is transmitted to external services. Input Validation and Anomaly Detection measures (as validated in research on retrieval poisoning attacks [19][20]) successfully block known injection patterns while maintaining low false-positive rates [19][20].

B. Equitable Integration of AI Literacy

The framework ensures equitable integration by proactively addressing technical and pedagogical constraints inherent to low-resource environments, thereby preventing AI from widening the digital divide [38][41][42].

Computational Accessibility: The deployment of RAG with SLMs and PEFT enables cost-efficient deployment on existing institutional hardware across Humanities and VET departments [5][16][39][40]. This directly addresses the resource barrier identified as a critical challenge in equitable AI access [27][29][30]. Humanities departments with legacy computer labs find that RAPA operates effectively on existing equipment, rather than requiring new GPU-intensive infrastructure investment that would be economically unfeasible for budget-constrained programs.

Pedagogical Accessibility and Disciplinary Autonomy: The PD program is explicitly rooted in the TPACK framework [25], strategically shifting focus from technical skill acquisition (which favors STEM fields with computational backgrounds) to Pedagogical Content Knowledge and ethical reflection [2][28]. Lecturers in VET or Humanities can directly apply their domain expertise to define RAPA constraints without writing code; constraint definition uses natural language templates and guided workshop exercises rather than technical programming [24][40]. This design respects disciplinary diversity: History faculty define constraints appropriate to historical thinking; Engineering faculty specify constraints appropriate to design methodology; Nursing faculty configure constraints for clinical reasoning. No single pedagogical approach is universalized.

Validation Across Disciplines: The evaluation framework mandates a specialized quasi-experimental sampling strategy that explicitly includes low-resource disciplines [24][34]. Rather than piloting exclusively in STEM departments (easier for technical reasons) and extrapolating, the framework requires testing across Humanities, Social Sciences, VET, and STEM concurrently, ensuring the resulting guidance is valid across the academic spectrum [41]. Project-Based Learning (PBL) approaches to AI literacy have been validated as effective pedagogical models for non-STEM subjects, with evidence suggesting that PBL-based AI curricula increase both engagement and learning outcomes in Humanities and Social Sciences [33][42][43].

Addressing Epistemological Differences: An important finding from preliminary PD implementation is that faculty across disciplines conceptualize appropriate AI use differently, reflecting disciplinary epistemologies. STEM faculty often view AI as a tool for computational efficiency; Humanities faculty prioritize AI as a dialectical partner for developing arguments; VET faculty emphasize AI for procedure generation and troubleshooting. Rather than imposing a unified "AI literacy" definition, RAPA's flexible constraint system accommodates these epistemological differences. This flexibility prevents the common problem where technology integration initiatives designed for STEM become poorly-fitting [28], low-engagement exercises when mandated across the entire institution.

C. Critical Thinking and Metacognitive Development

The framework's solution to the critical thinking deficit is architectural: it makes the AI assistant's reasoning process transparent and subject to academic review [39], directly counteracting observed AI weakness in fostering practical problem-solving ability and generating nuanced output.

Critical Thinking Development Through Architectural Scaffolding: By mandating explicit CoT reasoning steps and verifiable source citations (Step 7), the RAPA system transforms the student's learning task from a simple answer retrieval into a critical validation exercise [7][45]. The student's goal shifts: rather than "use AI to answer my question," it becomes "analyze the AI's reasoning, verify its claims, identify its limitations, and propose improvements." This represents a fundamental pedagogical shift toward what we might call “educated skepticism,” learning to use powerful tools while maintaining critical evaluation.

Importantly, this architectural enforcement creates consistency. In systems where CoT reasoning is optional or probabilistic, students receive varying levels of reasoning transparency; some responses include reasoning, others don't. RAPA's mandatory CoT ensures that every answer includes

visible reasoning, making critical analysis a consistent assignment expectation rather than leaving it to the system to generate [7].

Mitigating Bias and Hallucination Through Multi-Layered Defense: The system employs multiple defenses against inaccuracies and ethical bias:

- Technical Defense: Robust Fine-Tuning (RbFT) trains the LLM to actively detect and ignore counterfactual or noisy context [6]. When students verify AI claims against sources (as part of the Critical AI Analysis Assignment), they find that the AI's claims are grounded in evidence rather than hallucinations.
- Evaluation Defense: Critical AI Analysis Assignments ensure human judgment remains the final safeguard [36][46]. Rubrics are customized to penalize outputs that lack nuance, complexity, and originality—precisely the areas where AI outputs are substandard. This rubric design creates incentive alignment: students are rewarded for identifying exactly what AI does poorly and for developing expertise in recognizing AI limitations [36].
- Pedagogical Defense: Faculty constraint definition can explicitly require acknowledgment of limitations, alternative viewpoints, or nuance. A lecturer can constrain the system: "Always acknowledge opposing viewpoints before presenting the main argument," or "Identify assumptions underlying this analysis." These constraints, enforced during generation, structurally reduce the bias and narrow-mindedness common in unconstrained AI outputs [25].

Rubric Design and AI Weakness Targeting: Rubrics for Critical AI Analysis Assignments are intentionally designed to target AI weaknesses:

- Shallow Analysis: Students receive points for identifying areas where the AI oversimplified complex issues
- Lack of Nuance: Students earn credit for recognizing where the AI presented single perspectives without acknowledging complexity
- Unsupported Generalizations: Assessment rewards students for catching claims lacking sufficient evidence
- Missing Ethical Considerations: Rubrics specifically assess whether student analysis identifies ethical dimensions that the AI overlooked

This rubric design aligns learning objectives (developing critical thinking) with assessment (students demonstrating critical thinking by critiquing AI output) [36]. The rubric becomes a scaffold helping students recognize sophisticated critique.

V. Conclusion and Future Work

The RAPA methodology provides a verifiable, architecturally advanced framework for integrating domain-specific AI in education. By committing Hybrid RAG for performance [53], local hosting for compliance, and the DVC model for pedagogical competence [29], the framework establishes a pathway to foster critical thinking and ensure equitable AI literacy across all academic disciplines [54].

A. Strategic Recommendations

- Adopt Modular Architecture: Future deployments should prioritize Modular RAG frameworks, integrating efficiency modules (PROXIMITY [31], Oreo [56]) with iterative reasoning modules (ITER-RETGEN) [7] to ensure systems can reliably handle high-volume queries and complex synthesis tasks.
- Mandate Reflection-Based PD: The continued efficacy of RAPA hinges on institutionalizing the DVC-inspired PD cycle [25][57], requiring faculty to use AI output logs as core reflective material to continuously refine their Prompt Engineering (rules) and pedagogical strategies [35].

B. Future Research

Future research must focus on the longitudinal, empirical validation of the framework's pedagogical components:

1) Multimodal RAG extension: Future research should extend RAPA to include Multimodal RAG capabilities for integrating non-textual data—engineering diagrams, art history images, code snippets, video lectures [58][59]. This is required to fully validate equitable integration across disciplines that do not rely solely on text. Establishing a clear technical framework will be essential, including outlining data formats and sources across diverse disciplines, implementing data preprocessing techniques, and developing cross-modal retrieval algorithms enabling seamless integration of text with other data types [58][59]. Additionally, pedagogical strategies must guide educators in leveraging multimodal capabilities effectively, ensuring faculty across fields can incorporate visual, tactile, or auditory elements to enhance learning outcomes and inclusivity [58][59].

2) Cultural contexts and institutional culture: An important future research question should explore the role of cultural contexts in shaping the effectiveness of Professional Development (PD) over time [57]. Identifying variables that capture how institutional culture influences PD could open valuable comparative studies across universities, enhancing our understanding of global educational environments. Possible candidate variables include leadership style, faculty autonomy, resource allocation, decision-making processes, organizational climate, and communication channels. These variables will help frame comparative research and develop hypotheses.

3) Causal pathway analysis: A long-term quasi-experimental study is needed, utilizing structural equation modeling (PLS-PM) to definitively verify the indirect causal pathway: PD Intervention → Improved Teacher Competence → Improved Student Critical Thinking → Academic Achievement Gains

Each arrow represents an empirical claim requiring validation: Does PD improve teacher competence? Does improved teaching develop students' critical thinking? Does

critical thinking translate to improved academic outcomes? Longitudinal data spanning 2 to 3 years across multiple cohorts would enable robust path analysis [27].

ACKNOWLEDGMENT

I would like to express my sincere gratitude to my PhD supervisor, Dr. Mohd Heikal Bin Husin, Senior Lecturer at the School of Computer Sciences, Universiti Sains Malaysia, for his invaluable guidance, support, and encouragement throughout the development of this research. His expertise in AI-augmented education and his unwavering dedication to academic excellence have been crucial to the successful completion of this work.

***Abstract*—Assessing the quality of panoramic dental radiographs is essential to ensure diagnostic accuracy and patient safety. However, existing CNN-based approaches for radiograph quality assessment often emphasize architectural comparisons, while providing limited discussion on training stability and generalization, particularly when applied to relatively small and heterogeneous datasets. To address this gap, this study proposes a transfer learning-based framework that integrates Global Average Pooling (GAP) and Batch Normalization (BN) to enhance feature robustness and reduce overfitting in panoramic dental radiograph quality classification. Three pretrained CNN architectures: ResNet50, VGG16, and VGG19 were evaluated using panoramic radiographs collected from two tertiary hospitals in Indonesia. Experimental results using *k*-fold cross-validation indicate that the proposed GAP+BN refinement improves classification consistency across models, with VGG16 demonstrating the most stable and reliable performance. These findings suggest that domain-adapted transfer learning with appropriate feature aggregation and normalization can support the development of automated and clinically reliable quality assurance systems for panoramic dental imaging.**

***Keywords*—Batch Normalization; image quality; panoramic radiograph; transfer learning**

I. Introduction

Panoramic radiography is one of the most widely used imaging modalities in dentistry because it provides comprehensive visualization of maxillary and mandibular structures with relatively low radiation exposure. However, the diagnostic reliability of panoramic radiographs is strongly dependent on image quality, which can be adversely affected by patient positioning errors, improper exposure parameters, and technical disturbances. Poor-quality radiographs reduce diagnostic accuracy and increase the likelihood of retakes, thereby exposing patients to unnecessary additional radiation. Consequently, systematic quality assessment of panoramic radiographs is a critical aspect of dental radiology practice.

Previous studies have evaluated panoramic radiograph quality from both technical and diagnostic perspectives. Comparative analysis of different imaging devices has shown relatively small variations in image quality, indicating that multiple systems may be clinically acceptable [1],[2]. Other investigations reported that positioning errors, including head tilt and patient movement, occur in up to 95% of panoramic radiographs and represent the primary contributors to reduced diagnostic quality [3]. Although these studies provide valuable insights into common sources of image degradation, quality assessment in routine clinical practice still relies heavily on manual evaluation by operators and radiologists, which is inherently subjective and time-consuming.

Several studies have emphasized the role of operator training and quality control in improving panoramic radiograph quality. Investigations conducted in South Wales and other dental institutions revealed that a large proportion of panoramic radiographs failed to meet national quality standards, primarily due to patient positioning errors and insufficient operator instructions [4],[5],[6]. In addition, improper tongue positioning against the palate has been identified as one of the most frequent errors, leading to radiolucent artifacts in the maxillary region and compromising diagnostic interpretation [7], [8]. These findings consistently highlight that human-related factors remain the dominant cause of poor panoramic radiograph quality.

With the advancement of artificial intelligence, deep learning, particularly Convolutional Neural Networks (CNNs), has shown promising performance in automating image quality assessment across various radiographic modalities. CNN-based approaches have achieved high accuracy in evaluating diagnostic quality in ankle radiographs [9], and have been successfully applied to automated quality control in chest and elbow radiography [10], [11]. In the context of dental imaging, recent studies utilizing YOLOv8 and Generative Adversarial Networks have primarily focused on image enhancement or anatomical anomaly detection rather than explicitly addressing acquisition-related errors as indicators of panoramic radiograph quality [12], [13]. Despite these advances, several challenges remain unresolved. Reviews have reported inconsistencies in labeling strategies and dataset utilization for machine learning-based panoramic

*Corresponding author.

radiograph quality assessment, which limits model generalization and reproducibility [14]. Moreover, most deep learning applications in panoramic radiography continue to prioritize anomaly detection or disease diagnosis, such as osteoporosis assessment, rather than systematic quality evaluation based on acquisition technique and patient positioning errors [15], [16], [17]. This indicates that research specifically targeting automated panoramic radiograph quality evaluation remains limited, particularly in terms of methodological robustness and clinical applicability.

To address these limitations, this study proposes a transfer learning-based CNN framework for panoramic radiograph quality classification by systematically comparing three widely used architectures: ResNet50, VGG16, and VGG19. These models were selected due to their proven effectiveness in medical image classification tasks and their distinct feature representation capabilities. Previous studies have demonstrated the strong performance of VGG16 in binary medical image classification tasks, achieving high accuracy and F1-scores [18], while ResNet50 is known for its ability to mitigate the vanishing gradient problem through residual connections. Building upon these findings, the present study integrates Global Average Pooling (GAP) and Batch Normalization (BN) to enhance training stability and generalization, particularly when dealing with limited datasets.

Unlike previous research that focused on dental anomaly detection or disease diagnosis using CNN-based models with Batch Normalization [16], This study emphasizes the evaluation of panoramic radiograph quality based on acquisition-related errors. The main contributions of this research are threefold: 1) providing a comparative analysis of popular pretrained CNN architectures for panoramic radiograph quality assessment, 2) demonstrating the effectiveness of GAP and BN in improving training stability and classification performance on limited datasets, and 3) presenting empirical evidence from multi-institutional panoramic radiographs collected from Universitas Gadjah Mada and Universitas Airlangga hospitals in Indonesia to support the development of AI-based automatic quality assurance systems in dental radiology.

This study is organized as follows: Section II presents a review of related literature. Section III describes the dataset used in this research and explains the proposed method in detail. Section IV discusses the experimental results and findings. Finally, Section V concludes the study and outlines directions for future research.

II. Literature Review

The quality of panoramic radiographs determines the diagnostic value and reliability of image interpretation. Several research have evaluated the consistency and quality of images obtained from different radiographic machines and the factors influencing them. An early research [1] compared two panoramic units and found that both produced equivalent diagnostic results for anatomical evaluation, with negligible differences in image quality, indicating that both devices were clinically acceptable. This suggests that technical acquisition parameters and patient positioning have a greater impact on diagnostic quality than differences between imaging devices.

Automated approaches have also been introduced to assess radiographic acceptability. In [2], the authors developed an automated CNN-based framework to determine whether panoramic radiographs were suitable for further analysis. The system demonstrated high accuracy and showed potential to support diagnostic workflows, particularly in regions with limited access to orthodontic radiologists.

Further applications of deep learning have extended to non-panoramic radiographs. For example, research [9] evaluated the diagnostic quality of ankle radiographs based on anatomical features, achieving 94.1% accuracy, surpassing average radiologist performance. Similarly, research [19] proposed a CNN with multi-scale feature extraction to automatically assess panoramic radiograph quality, outperforming conventional methods. Several studies have also focused on improving image quality. Research [20] introduced a Multi-Scale Top-Hat with Geodesic Reconstruction (MSTHGR) method to enhance image contrast and detail, while research [13] used a Generative Adversarial Network (Pix2Pix) to correct blurred and noisy images, significantly improving PSNR and SSIM metrics. Another research [21] employed a deep learning-based super-resolution technique (LTE) to enhance image resolution with visually and quantitatively superior results.

Panoramic radiography plays an essential role in dental diagnosis; however, patient positioning errors frequently occur due to equipment complexity and anatomical variations, leading to reduced image quality and diagnostic accuracy. Research developed a deep learning model to detect six common positioning errors: slumped posture, low chin, open lips, head rotation, head tilt, and tongue not against the palate, using 552 panoramic radiographs. Six CNN architectures were employed for feature extraction, and the extracted features were fused and classified using a Support Vector Machine (SVM). The model achieved an accuracy of 0.832 with high precision and recall, proving effective for automatic identification of patient positioning errors and improving diagnostic reliability.

Positioning errors are among the main causes of reduced diagnostic quality in panoramic imaging. Research [3] reported that 95% of 500 radiographs contained one or more positioning errors, particularly head tilt. Similarly, research [4] found that 54.6% of radiographs in South Wales exhibited positioning errors and 47.9% were affected by poor patient preparation or instruction. Research [5], which analyzed 1,000 panoramic radiographs, found that the most common error was the tongue not being pressed against the palate (69.5%), followed by patient motion (0.4%). Research [6] involving 2,629 patients revealed that only 32.8% of radiographs were error-free, with tongue positioning errors being the most prevalent. Research [7] compared image quality across three radiographic technicians and found significant inter-operator variation, with the “gazebo effect” and condyle positioning errors being the most frequent findings.

In Indonesia, research [8] reported that 98.78% of panoramic radiographs exhibited patient positioning errors, most commonly due to the tongue not adhering to the palate (49.68%), although the overall diagnostic quality remained

acceptable. Similar errors have been reported in other research [22], [23], [24], [25], where head alignment, lateral rotation, and palatoglossal air space were identified as the primary factors reducing image quality [26].

Several studies have highlighted the impact of imaging technique and operator skill on radiographic quality. In [27], the authors emphasized the importance of head positioning, occlusal plane orientation, mandibular condyle alignment, and metal artifact control in producing symmetric and diagnostically acceptable panoramic images. Research [28] added that horizontal spatial distortion up to ≤20% remains clinically acceptable, while a minimum spatial resolution of 1.88 lp/mm is necessary to maintain anatomical readability.

In [9], the authors showed that while radiographic quality did not vary significantly among technicians, the types of errors did, indicating that operator training and experience play a major role. This finding was supported by research [23], which concluded that radiographic errors are not directly correlated with professional experience but are influenced by patient cooperation and attentiveness during image acquisition. In addition to operator-related issues, technical parameters such as exposure settings and image processing also affect diagnostic quality. In [24], [25], the authors found that post-trauma radiographs frequently suffered from exposure errors, out-of-focus positioning, and metal artifacts, which limited diagnostic interpretation.

Efforts to improve radiographic quality control have increasingly employed deep learning methods. In [12], the authors developed a YOLOv8-based model to assess panoramic radiograph quality using five clinical visual criteria, achieving an overall accuracy of 81.4%. Similar approaches have been applied to chest [10] and elbow [11] radiographs, demonstrating strong potential for automated medical image quality assessment.

Moreover, research [14] conducted a systematic review of 41 research on panoramic radiograph image quality for machine learning model training. The review found that most research lacked standardized image quality criteria, and defective images were often excluded from datasets without detailed analysis. This practice introduces bias and reduces model generalizability, emphasizing the need for automated methods to assess and manage radiograph quality consistently.

The quality of panoramic radiographs is predominantly affected by acquisition technique and patient positioning, with the latter being the leading cause of diagnostically unacceptable images. Although deep learning systems have been widely used for image enhancement and quality evaluation, research that integrates expert clinical annotations with CNN models for objective assessment of panoramic radiograph quality remains limited.

This highlights an existing research gap that needs to be addressed through the development of CNN-based automated systems capable of accurately identifying technical and positioning errors while providing feedback to improve image acquisition quality. Table I summarizes the key differences between the present research and the work of [12].

TABLE I. COMPARISON BETWEEN THE PROPOSED MODEL AND PREVIOUS RESEARCHES

Aspect	Research [12]	Proposed	Contribution/Difference
Objective	Automated assessment of panoramic radiograph quality based on four criteria (artifacts, coverage area, patient positioning, and contrast/density) and clinical acceptability (acceptable vs. not acceptable).	Development of a CNN-based panoramic radiograph quality evaluation model using a domain-adapted ResNet50 to classify image quality into good and poor categories.	Both assess image quality; however, the proposed research focuses on optimizing a domain-adapted CNN and evaluating inter-architecture performance rather than single-model classification using YOLO.
Model	YOLOv8 (single-stage real-time classifier with 141 layers, Adam-W optimizer, learning rate=0.0001).	Domain-adapted ResNet50 architecture with additional Global Average Pooling (GAP) and Batch Normalization (BN) layers for improved stability and generalization.	The proposed research presents a transfer learning-based modification of a classical CNN architecture, which is referred to as a domain-adapted transfer learning to emphasize its adaptation to the specific characteristics of panoramic dental radiographs. This adaptation was achieved through architectural modification (GAP and BN layers) and fine-tuning on domain-specific data.
Evaluation Criteria	Four aspects (artifacts, coverage, positioning, contrast/density) plus overall image quality.	Focuses on overall radiograph quality (good or poor) based on coverage, vertical and horizontal distortion, detail and sharpness, artifacts and ghost images, and radiolucent areas in the anterior maxillary apical region.	The proposed method performs holistic radiograph quality assessment rather than per-aspect evaluation, providing faster and more efficient results for clinical application.
Accuracy	74.1-97.9% per criterion, with an average of 81.4% for clinical classification.	Domain-adapted ResNet50 achieved 82-85% accuracy and the highest F1-score compared to baseline CNNs (VGG architectures).	The proposed model delivers comparable or slightly higher performance with lower model complexity than YOLOv8.
Optimization	Strategy Data augmentation, Adam-W optimizer, and automatic mixed precision.	Transfer learning, Batch Normalization, and adaptive learning rate scheduler.	The proposed approach emphasizes training efficiency and domain adaptability without requiring high-end GPU resources.
Clinical Contribution	Provides a real-time radiograph quality control system and an educational tool for dental students.	Offers a lightweight CNN model for automated radiograph quality evaluation in resource-limited institutions.	The proposed method is easier to implement in local dental clinics without the need for high computational infrastructure.

A. Conventional Approaches and Their Limitations

Early research relied on manual visual inspection by radiologists, which is subjective and time-consuming. Later, rule-based metrics such as contrast, entropy, or edge sharpness were used to quantify quality, but these fail to capture anatomical distortion or exposure errors. Classical machine-learning models (e.g., SVM, *k*-NN) using handcrafted texture or wavelet features improved objectivity but depended heavily on feature design and were sensitive to acquisition variability. Recent deep-learning approaches applied CNNs for anomaly detection or anatomy segmentation rather than direct good/poor quality classification, and often used single-center data without cross-institution validation. This research differs by applying a transfer-learning CNN (ResNet50, VGG16, VGG19) directly to the binary quality classification task of panoramic radiographs, reducing the need for handcrafted features and improving robustness for small, domain-specific datasets.

III. Methods

A. Dataset

The dataset used in this research was obtained from the Dental and Oral Hospital (RSGM) of Universitas Airlangga, Surabaya, and the Dental and Oral Hospital of Universitas Gadjah Mada, Yogyakarta. Ethical approval for the use of radiographic data was granted by both institutions under approval numbers 0910/HRECC.FODM/VIII/2025 and 158/UNI/KEP/FKG-RSGM/EC/2025, respectively. In total, 1,285 panoramic radiographic images were collected, consisting of 820 images from Universitas Airlangga and 465 images from Universitas Gadjah Mada.

Each radiograph was independently evaluated by four dental radiology experts based on five key diagnostic quality aspects (see Table II), with a maximum total score of five. Radiographs with a total score of five were categorized as good quality, indicating no retake was required, while radiographs with a score below five were categorized as poor quality, indicating a retake was recommended. To ensure annotation reliability and reduce label ambiguity, only radiographs with full consensus among all four experts were included in the final dataset used for model training and evaluation.

Based on this strict selection criterion, 442 panoramic radiographs were retained, including 221 good-quality and 221 poor-quality images (see Table III). Specifically, 105 good-quality and 105 poor-quality radiographs were obtained from Universitas Airlangga, while 116 good-quality and 116 poor-quality radiographs were obtained from Universitas Gadjah Mada. This balanced class distribution was intentionally maintained to prevent model bias towards a dominant class.

Examples of panoramic radiographs used in this study are shown in Fig. 1. Good-quality radiographs exhibit complete anatomical coverage, clear visualization of the maxillomandibular structures, sharp anatomical details, and the absence of distortion or artifacts that may interfere with diagnosis. In contrast, poor-quality radiographs are characterized by positioning-related distortions, asymmetry, reduced sharpness due to patient movement, and the presence of artifacts such as ghost images or extensive radiolucent regions that compromise diagnostic reliability.

TABLE II. Image Quality Assessment Criteria

No.	Aspect	1	0
1	Coverage	The image includes the lower border of the mandible, both right and left condyles, and the lower border of the orbits.	One or more of these anatomical areas are not included in the image.
2	Vertical and Horizontal Distortion	No vertical or horizontal distortion is observed.	Distortion interferes with interpretation (e.g., inverted or V-shaped dental arch, asymmetrical mandibular shape).
3	Detail and Sharpness	The image shows clear anatomical detail and sharpness.	Image detail is unclear or overlapping due to patient head movement during exposure.
4	Artifacts and Ghost Images	No artifacts or ghost images interfere with diagnostic interpretation.	Ghost images from foreign objects or large radiolucent areas (air spaces) obscure dental or maxillofacial structures.
5	Radiolucent Area in the Anterior Maxillary Apical Region	No radiolucent area interferes with interpretation.	A radiolucent area is present in the anterior maxillary apical region, reducing diagnostic clarity.

TABLE III. Dataset Distribution

Class	Training	Testing	Total
Good	170	51	221
Poor	170	51	221
Total	340	102	442

Although the final dataset used in this study consists of 442 curated panoramic radiographs, which may be considered relatively small for deep learning applications, this reflects realistic clinical constraints where high-quality, expert-labeled radiographic data are limited. The reduced dataset size increases the risk of overfitting; therefore, several mitigation strategies were employed. First, transfer learning from pretrained CNN models was used to leverage previously learned generic visual features. Second, Global Average Pooling (GAP) was applied to reduce the number of trainable parameters, while Batch Normalization (BN) was incorporated to stabilize training and improve generalization. In addition, *k*-fold cross-validation was adopted to maximize data utilization and provide a more robust estimate of model performance across different data partitions.

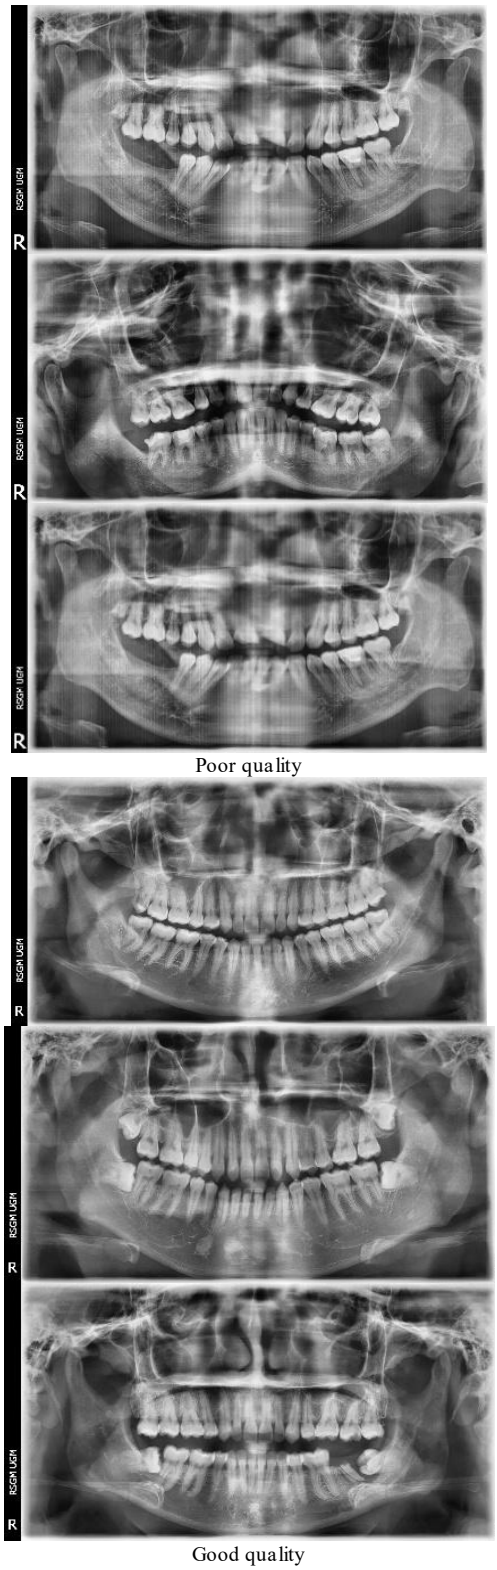

Fig. 1. Examples of panoramic radiographs.

Although the final dataset size is relatively limited, this scenario reflects realistic clinical conditions where curated, high-quality labeled radiographic data are often scarce. To mitigate the risk of overfitting associated with limited data, this study employed a transfer learning strategy using pretrained CNN models, combined with Global Average Pooling and Batch Normalization to enhance feature robustness and training stability. Furthermore, *k*-fold cross-validation was applied to maximize data utilization and provide a more reliable estimation of model generalization performance across different data splits.

B. Proposed Method

This research proposes a transfer learning-based approach using three CNN architectures: ResNet50, VGG16, and VGG19 to classify the quality of panoramic dental radiographs into two classes: good and poor (Fig. 2). All pretrained models were initialized with ImageNet weights and modified by adding Global Average Pooling (GAP) and Batch Normalization (BN) layers to improve adaptability to the specific characteristics of dental radiographs. In this context, the term domain-adapted refers to the adaptation of a pretrained network through transfer learning and fine-tuning using dental imaging data, rather than an explicit domain adaptation mechanism such as adversarial alignment or feature distribution matching. The proposed method aims to automate the panoramic radiograph quality assessment process and empirically verify the reliability of ResNet50 compared to the other architectures. Model performance was evaluated using *k*-fold cross-validation to ensure robustness and reduce sampling bias. The main stages of the proposed method include the following steps (as illustrated in Fig. 2):

a) Preprocessing data: All panoramic radiograph images were converted into RGB format with a resolution of 512×512 pixels and normalized to a range of [0,1].

b) Feature extraction (transfer learning): Three pretrained CNN models were employed as feature extractors: ResNet50, which utilizes residual connections to preserve gradient flow and is well-suited for detecting complex radiographic textures; VGG16 and VGG19, which employ simple stacked convolutional layers effective for capturing edge and shape representations.

c) Architecture modification: To enhance model performance, several layers were added: Global Average Pooling (GAP) to reduce feature dimensions while retaining essential spatial information; Batch Normalization (BN) to stabilize inter-layer activation distributions and accelerate convergence; and Dense Layers (128-256 units) with ReLU activation as the classifier head. The models were optimized using the Adam or AdamW optimizer with a learning rate of 0.0001, batch size of 2, and 30 training epochs.

d) Training and evaluation: The models were trained on a labeled dataset of 442 panoramic radiographs (340 for training and 102 for testing). Evaluation metrics included accuracy [Eq. (1)], precision [Eq. (2)], recall (sensitivity) [Eq. (3)], specificity [Eq. (4)], and F1-Score [Eq. (5)] analysis [18]. These metrics were selected to provide a comprehensive understanding of diagnostic reliability, particularly regarding false negatives, which may correspond to clinically unacceptable images being classified as acceptable. This evaluation framework supports the model's applicability for clinical quality assurance and radiation dose reduction in dental radiology workflows.

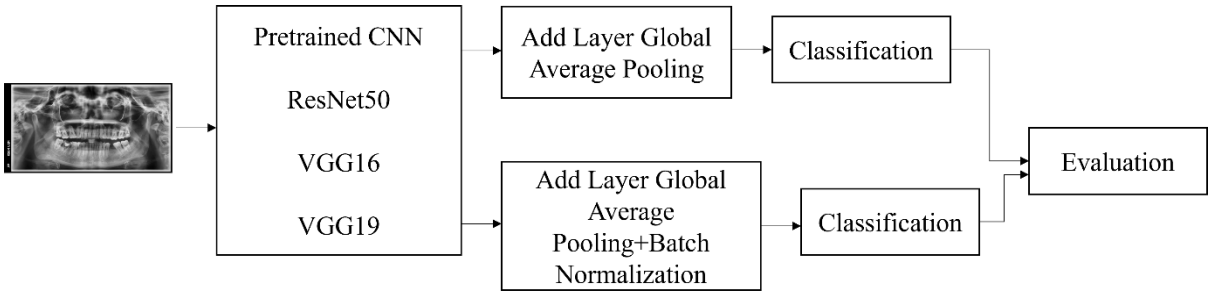

Fig. 2. Proposed method framework.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP+TN}{TP+FN} \quad (3)$$

$$Specificity = \frac{TN}{TP+FP} \quad (4)$$

$$F1-Score = \frac{2.TP}{2.TP+FP+FN} \quad (5)$$

IV. Results and Discussion

Tables IV to XII summarize the class-wise evaluation metrics obtained from *k*-fold cross-validation for all evaluated models. Rather than focusing solely on absolute metric values, the results reveal clear performance trends across architectures and configurations. Overall, VGG16-based models consistently demonstrated more stable and balanced performance compared to ResNet50 and VGG19, particularly when combined with Global Average Pooling (GAP) and Batch Normalization (BN).

ResNet50 achieved relatively high AUC values in several folds, indicating strong discriminative potential. However, its performance exhibited substantial variability in recall and specificity across folds (Tables IV to VI and Tables XIII to XV). This instability suggests sensitivity to data partitioning and potential overfitting, which can be attributed to the model's higher architectural complexity relative to the limited size of the curated panoramic radiograph dataset. Although residual connections are designed to facilitate deeper feature learning, they may lead to unstable optimization when the available training data are insufficient to support robust parameter estimation.

In contrast, VGG16 demonstrated consistently lower variance across folds and more balanced class-wise performance (Tables VII to IX and Tables XVI to XVIII). The integration of GAP reduced the number of trainable parameters, while BN improved gradient flow and training stability. These architectural refinements enabled VGG16 to achieve the most reliable overall performance, with an average accuracy of 85.00% and an AUC of 94.72%. The relatively shallow and uniform convolutional structure of VGG16 appears to be better suited for capturing global structural distortions and acquisition-related artifacts commonly observed in panoramic radiographs.

VGG19 exhibited competitive discriminative performance, with mean AUC values around 92% (Table X to Table XII and Table XIX to Table XXI). However, its deeper architecture resulted in slightly higher performance variability compared to VGG16, suggesting increased sensitivity to limited data and fold composition. Among VGG19 variants, the use of adaptive optimization (AdamW) improved convergence consistency, reinforcing the importance of optimizer selection in small-scale medical imaging datasets.

Fig. 3 illustrates the ROC curves for all evaluated configurations, further confirming that VGG16 with GAP and BN achieved superior and more consistent discrimination between good- and poor-quality radiographs. The proximity of the ROC curve to the upper-left corner indicates a favorable balance between sensitivity and specificity, which is critical in quality assessment tasks where both false positives and false negatives carry clinical consequences.

Fig. 3. ROC-AUC curves of transfer learning models.

From an error analysis perspective, false negatives where poor-quality radiographs are misclassified as good quality pose a greater clinical risk than false positives. Such errors may result in diagnostically inadequate images being accepted, potentially leading to misdiagnosis or delayed treatment. The VGG16 (GAP+BN, Adam) model exhibited a

lower false-negative rate compared to other configurations, suggesting improved reliability for clinical deployment. False positives, while less critical from a safety standpoint, may still contribute to unnecessary retakes and workflow inefficiencies; however, these errors are generally preferable to false negatives in radiographic quality assurance.

A comparative evaluation with previous studies (Table XXII) demonstrates that the proposed VGG16-based approach achieves competitive performance relative to more complex frameworks such as CNN-SVM hybrids or object detection-based models (e.g., YOLOv8). Importantly, the proposed method maintains a lightweight architecture and efficient training process, making it more practical for real-world clinical implementation.

Overall, these findings indicate that domain-adapted transfer learning, when combined with architectural simplification and normalization strategies, can effectively enhance model generalization for automatic panoramic radiograph quality assessment. By providing reliable differentiation between diagnostically acceptable and poor-quality images, the proposed approach has the potential to reduce unnecessary retakes, improve patient safety by minimizing radiation exposure, and support standardized quality control in dental radiology practice.

Despite the promising results, this study has several limitations. The relatively small dataset, although carefully curated with expert consensus, may limit the generalizability of the proposed models to broader clinical settings. While the use of transfer learning, GAP, BN, and *k*-fold cross-validation helps mitigate overfitting, external validation using independent datasets from additional institutions would provide stronger evidence of generalizability. Furthermore, ablation studies investigating the effects of dataset size and class balance were not conducted and will be considered in future research.

TABLE XXII. CITATION-ONLY CONTEXTUAL COMPARISON

No	Model	Research Focus	Evaluation Results
1	Model CNN feature fusion+SVM [28]	Patient positioning errors (multi-class)	Accuracy=83.2%, AUC up to 0.998
2	YOLOv8 Classification Model [12]	Radiograph quality	Artifacts (Accuracy=87.2%, Precision=88.9%, F1-Score=0.864-0.943); Coverage area (Accuracy=74.1%, Precision =83.3-91.3%, F1-Score=0.769-0.941); Patient positioning (Accuracy=77.3%, Precision=76.9%, F1-Score=0.72-0.67); Contrast/Density (Accuracy=97.9%, Precision=83.3-84.6%, F1-Score=0.782-0.765); Overall image quality (Accuracy=79.3%, Precision=81.4%, F1-Score=0.809-0.820)
3	Proposed Method	Radiograph quality (good and poor)	Accuracy=85.00%, Precision=87.11%, Recall=86.27%, F1-score=85.31%, AUC=94.72%, Specificity=84.55%

V. CONCLUSION

Based on the experimental results and analysis, the proposed transfer learning-based CNN models demonstrated promising performance in the automatic quality classification of panoramic dental radiographs. Among the evaluated architectures, the VGG16 model enhanced with Global Average Pooling (GAP) and Batch Normalization (BN) and optimized using the Adam optimizer achieved the best overall performance under *k*-fold cross-validation, with an average accuracy of 85.00%, precision of 87.11%, recall of 86.27%, F1-score of 85.31%, AUC of 94.72%, and specificity of 84.55%. The integration of GAP and BN effectively improved training stability and reduced overfitting, allowing the model to generalize well across folds. These findings confirm that the domain-adapted transfer learning approach can provide a stable and reliable framework for automated panoramic radiograph quality assessment. In the future, expanding the dataset and incorporating external validation across multiple institutions will further strengthen model generalizability and clinical applicability. This study contributes to advancing AI-based quality assurance systems in dental radiology, enabling more consistent diagnostic outcomes and reducing retake rates in clinical practice.

Based on these findings, several directions for future research are recommended: Increasing data quantity and diversity to improve model robustness and generalization. Further fine-tuning of pretrained models to better adapt to radiographic features. System implementation and integration into clinical workflows for real-time image quality assessment.

***Abstract*—View recognition of distribution network towers is a key technology in UAV intelligent inspection. To address the problem of low accuracy of existing deep learning methods in complex background interference, this paper proposes a tower view classification method based on EfficientNet that integrates foreground perception, multi-scale feature fusion, and dual-dimensional attention. First, a Mask-Guided Fusion Module (MGFM) is designed to extract tower foreground masks using the BiRefNet network, enhancing foreground representation and suppressing background interference through a two-stage fusion strategy. Second, a Multi-Scale Attention Aggregation Module (MSAA) is constructed to achieve efficient cross-layer feature fusion through parallel multi-scale convolution, fully integrating shallow details and deep semantic information. Finally, the Convolutional Block Attention Module (CBAM) is introduced to adaptively strengthen view-discriminative features through channel and spatial dual-attention mechanisms, significantly improving the recognition capability for small-sample categories such as top views. Ablation experiments on a self-built multi-view tower dataset show that the proposed method can effectively distinguish different views such as top view, front view, and side view, with significantly improved accuracy compared to other deep learning models, providing technical support for intelligent inspection of transmission lines.**

***Keywords*—Multi-view classification of power towers; mask-guided feature fusion; BirefNet; multi-scale feature fusion; convolutional block attention**

I. Introduction

Transmission lines constitute a critical component of modern power systems, and their safe and stable operation is essential for national economic development and public quality of life [1, 2]. Owing to the vast geographical coverage of transmission networks—often deployed across complex terrains such as mountainous regions and river crossings—traditional manual inspection methods are increasingly constrained by low efficiency, high operational costs, and potential safety risks. In recent years, the rapid development of unmanned aerial vehicle (UAV) technology has enabled vision-based intelligent inspection to emerge as a promising alternative for power infrastructure monitoring [3].

As the primary load-bearing structures of transmission lines, towers play a decisive role in ensuring system reliability. During UAV-based inspection, accurately recognizing the shooting viewpoint of a tower (e.g., front, side, or top view) provides essential spatial context for subsequent inspection tasks, including defect detection, component localization, and three-dimensional reconstruction [4, 5]. Moreover, reliable viewpoint information can facilitate inspection path planning and improve the overall efficiency and consistency of automated inspection workflows. Consequently, high-accuracy and robust tower viewpoint recognition is of significant practical importance for intelligent power inspection systems.

Existing inspection solutions have achieved notable progress by leveraging advances in computer vision and deep learning. Nevertheless, real-world UAV inspection scenes remain highly challenging. Images are frequently captured under complex natural backgrounds, varying illumination conditions, and occlusions, which can severely degrade recognition performance. In addition, inspection data often exhibit strong viewpoint imbalance, where certain viewpoints—such as top views—are underrepresented, further limiting the robustness of conventional recognition pipelines. These practical constraints highlight the need for viewpoint recognition approaches that are not only accurate but also resilient to background interference and data imbalance.

Recent research trends indicate that enhancing visual recognition performance often relies on improved foreground perception, multi-scale feature representation, and attention-based feature refinement. While these directions have demonstrated effectiveness in general vision tasks, they are typically explored in isolation or adopted as generic components without being explicitly tailored to the characteristics of UAV-based tower inspection. As a result, existing approaches struggle to jointly address background suppression, cross-scale feature interaction, and viewpoint-discriminative enhancement within a unified framework, particularly under complex inspection scenarios.

To bridge this gap, this paper investigates the following research question: how can foreground awareness, multi-scale feature interaction, and attention-driven discrimination be systematically integrated into a unified, task-oriented framework to improve tower viewpoint recognition under real UAV inspection conditions? To address these issues, this paper proposes a task-oriented and stage-wise tower viewpoint recognition framework based on EfficientNet-B4. The proposed approach organizes viewpoint recognition as a progressive enhancement process, explicitly strengthening foreground guidance, adaptive multi-scale interaction, and viewpoint-discriminative attention in a coordinated manner.

The main contributions of this work are summarized as follows: 1) A task-oriented, stage-wise viewpoint recognition

framework is developed to systematically integrate foreground-guided perception, adaptive multi-scale feature fusion, and attention-based discrimination for UAV-based tower inspection. 2) A Mask-Guided Fusion Module (MGFM) is introduced to enhance tower foreground perception and suppress complex background interference through a two-stage fusion strategy. 3) A Multi-scale Attention Aggregation Module (MSAA) and a dual-dimensional attention mechanism are incorporated to strengthen cross-scale feature interaction and improve recognition robustness for minority viewpoints. The remainder of this paper is organized as follows. Section II reviews related work on UAV-based inspection, viewpoint recognition, and feature enhancement strategies. Section III details the proposed framework and its constituent modules. Section IV presents the experimental setup and comprehensive performance evaluation is given in Section V. Finally, Section VI concludes the paper and discusses future research directions.

II. Related Work

A. UAV-Based Intelligent Inspection of Power Infrastructure

Unmanned aerial vehicles (UAVs) have been increasingly adopted in power infrastructure inspection due to their flexibility, low operational cost, and capability to access complex terrains that are difficult for manual inspection. Existing UAV-based inspection systems mainly focus on tasks such as transmission line detection, tower localization, and defect identification. Early studies relied on handcrafted visual features and traditional image processing techniques to extract tower or line structures from aerial images. However, these methods generally exhibit limited robustness under complex backgrounds, illumination variations, and occlusion.

With the advancement of deep learning, convolutional neural networks (CNNs) have become the dominant paradigm in UAV-based power inspection. Shajahan et al. [6] proposed a ROS-based computer vision framework to automatically locate tower regions of interest in UAV images, while Manninen et al. [7] developed a multi-stage deep learning network for automated assessment of transmission infrastructure using fly-by images. These approaches demonstrate the effectiveness of data-driven feature learning for inspection tasks. Nevertheless, in most existing works, viewpoint information is treated as an implicit factor rather than an explicit recognition objective. In practical inspection workflows, viewpoint recognition can provide reliable spatial priors for downstream tasks such as defect detection, component localization, and three-dimensional reconstruction. Despite its practical significance, tower viewpoint recognition has received comparatively limited attention as an independent and systematically studied problem in UAV inspection literature.

B. Viewpoint Recognition and Multi-View Classification

Viewpoint recognition and multi-view classification have been widely studied in computer vision, aiming to learn discriminative representations across different observation angles. Recent studies indicate that exploiting viewpoint diversity plays a crucial role in enhancing feature discrimination. Liu et al. [8] explored trusted multi-view deep learning frameworks and demonstrated that effective aggregation of multi-view information can significantly improve classification robustness and accuracy. Yan et al. [9] provided a comprehensive review of deep multi-view learning methods, highlighting the importance of self-attention and cross-attention mechanisms in aligning cross-view representations and modeling inter-view dependencies.

In the context of power infrastructure inspection, viewpoint information has also been recognized as an important factor for improving downstream perception tasks. Luo et al. [10] conducted a comprehensive survey of UAV-based intelligent transmission line inspection systems and emphasized that viewpoint awareness is critical for subsequent tasks such as defect detection and three-dimensional reconstruction. Furthermore, Faisal et al. [11] pointed out in their recent review that although traditional inspection methods may still be effective under constrained conditions, their generalization capability is significantly inferior to that of end-to-end deep learning models, particularly in complex real-world environments.

Despite these advances, existing multi-view learning and inspection-oriented approaches are mostly designed for generic scenarios or treat viewpoint as auxiliary information rather than an explicit recognition target. When directly applied to UAV-based tower inspection, such methods often struggle with severe background interference, viewpoint ambiguity, and class imbalance, especially for minority viewpoints. These limitations highlight the necessity of developing task-specific viewpoint recognition frameworks that explicitly model viewpoint discrimination under realistic UAV inspection conditions.

Meanwhile, generic image classification architectures have evolved rapidly, from classical convolutional neural networks to modern transformer-based models. Architectures such as Inception, ResNet, and VGG have achieved strong performance on large-scale benchmarks, while Vision Transformer (ViT) and Swin Transformer further improve global modeling capability through self-attention mechanisms. Although these models provide powerful feature extractors, they are primarily designed for generic object recognition tasks. When directly applied to UAV-based tower viewpoint recognition, their performance may be limited by severe background interference, viewpoint ambiguity, and class imbalance commonly encountered in real inspection scenarios. These characteristics distinguish tower viewpoint recognition from conventional multi-view benchmarks and call for task-specific modeling strategies.

C. Foreground Perception, Multi-Scale Feature Fusion, and Attention Mechanisms

Foreground perception and background suppression are essential for visual recognition in complex scenes. Segmentation-based methods have been widely used to obtain object-level priors that help reduce background interference, among which encoder–decoder architectures such as U-Net demonstrate the effectiveness of explicitly modeling foreground regions for complex visual environments [12]. Such priors are particularly valuable in UAV inspection images, where the target tower often occupies only a small portion of the image and is surrounded by cluttered natural backgrounds.

However, in many recognition pipelines, foreground extraction and classification are treated as separate stages, and the segmentation prior is not explicitly integrated into the feature learning hierarchy.

Multi-scale feature fusion is another key strategy for improving recognition robustness, as shallow features capture fine-grained spatial details while deep features encode high-level semantic information. Feature pyramid networks (FPN) explicitly construct hierarchical feature representations across multiple scales, highlighting the importance of structured cross-scale interaction for robust visual recognition [13]. In practice, various fusion strategies, including feature concatenation, weighted summation, and pyramid-based architectures, have been explored to exploit cross-scale complementarity. At the same time, attention mechanisms have been extensively investigated to enhance feature representation by emphasizing informative channels or spatial regions.

Despite these advances, existing fusion and attention mechanisms are typically applied as generic plug-and-play components. They are often optimized independently and lack a unified, task-oriented design that jointly considers foreground perception, cross-scale interaction, and viewpoint-discriminative enhancement. In the context of UAV-based tower inspection, this limitation becomes more pronounced under complex backgrounds and severe viewpoint imbalance. Consequently, there remains a gap in developing a coordinated and hierarchical framework that systematically integrates these techniques for robust tower viewpoint recognition.

III. Improved EfficientNet Algorithm

Unlike existing approaches that treat foreground perception, multi-scale fusion, and attention mechanisms as independent components, the proposed framework organizes these processes into a progressive enhancement pipeline specifically tailored for viewpoint recognition. The EfficientNet model [14] consists of three parts: input, backbone, and classification head. This paper selects EfficientNet-B4 as the baseline model with an input resolution of 380×380. The backbone starts with a Stem module (a stride=2, 3×3 standard convolution) followed by multiple MBConv modules. The MBConv module expands channels via a 1×1 convolution, extracts spatial features through depthwise separable convolution, integrates an SE module for adaptive channel recalibration, and finally restores the dimension via a 1×1 convolution with a residual connection to the input (see Fig. 1). The model employs a compound scaling strategy to jointly adjust network depth, width, and resolution, and applies stochastic depth regularization to enhance generalization, achieving an optimal balance between accuracy and efficiency.

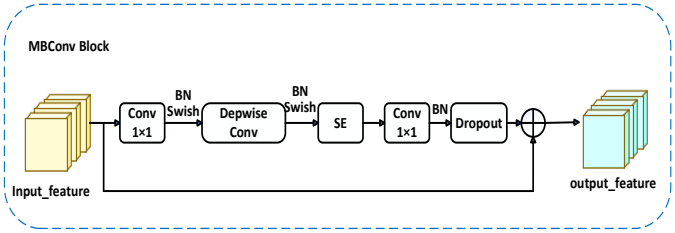

Fig. 1. The structure of MBConv.

Despite EfficientNet's strong performance in various vision tasks, it still faces challenges in the specific context of distribution network tower viewpoint recognition, including severe background interference, insufficient multi-scale feature fusion, and weak discriminative capability for minority viewpoints. To address this, a multi-module collaborative framework is proposed, in which three innovative modules are embedded at different stages of the backbone network to construct a progressive feature learning and enhancement mechanism. The overall framework adopts a "Foreground Guidance — Multi-scale Feature Fusion — Dual-dimensional Attention Modulation" three-stage enhancement strategy: First, the Mask-Guided Fusion Module (MGFM) is introduced at the shallow layer (Layer2). It uses a foreground mask extracted by BiRefNet [15] to spatially guide shallow features, enabling the network to focus on the tower body region early in feature learning and effectively suppress complex background noise. Second, the Multi-scale Attention Aggregation Module (MSAA) is deployed between the middle-deep layers (Layer3 and Layer5). It achieves intra-branch addition fusion and inter-layer feature concatenation through parallel multi-scale convolutions and channel attention weighting, fully integrating shallow details and deep semantic information. Finally, the Convolutional Block Attention Module (CBAM) is applied to the global features. Through dual channel and spatial attention mechanisms, it adaptively strengthens the feature response of viewpoint-discriminative regions, significantly enhancing the recognition robustness for minority classes like the top view. The overall architecture of the proposed model is illustrated in Fig. 2.

The three modules work synergistically to form a complete feature enhancement chain: MGFM solves the background interference problem at the source of feature extraction, providing high-quality foreground-enhanced features for subsequent modules; MSAA achieves efficient and complementary multi-scale feature fusion in the intermediate stage, breaking the limitations of traditional unidirectional propagation or simple concatenation; CBAM performs channel-spatial joint modulation at the decision front-end, ensuring the network can adaptively focus on the most discriminative regions and channels for different viewpoints. This hierarchical, progressive design philosophy closely aligns with the requirements of tower viewpoint recognition, enabling the model to receive targeted optimization at different abstraction levels, thereby achieving high-accuracy and robust multi-view classification performance.

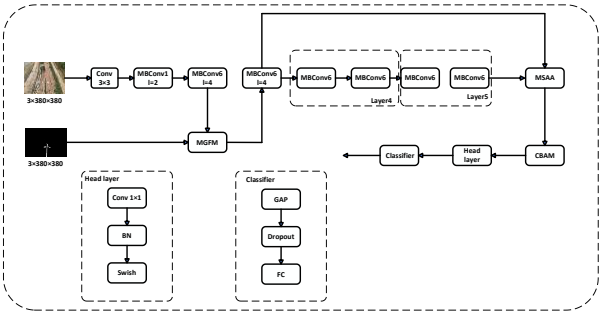

Fig. 2. The overall structure of the model.

A. MGFM Module

The Mask-Guided Fusion Module (MGFM) is designed to address the issue of foreground-background confusion in shallow feature extraction by traditional convolutional neural networks. In viewpoint classification tasks, objects under different viewpoints exhibit significant differences in foreground-background distribution. Conventional methods often treat foreground and background information equally, causing key foreground features to be corrupted by background noise and degrading subsequent viewpoint discrimination performance. Regarding the choice of the foreground segmentation network, this paper systematically evaluated several candidates and ultimately selected BiRefNet as the core component of the MGFM module. Compared to mainstream salient object detection networks such as U²-Net [16] and ISNet [17], BiRefNet demonstrates significant advantages in the power tower scenario. First, BiRefNet employs an innovative bidirectional refinement mechanism that leverages both top-down and bottom-up pathways in a collaborative manner, enabling it to simultaneously capture global semantic context and fine-grained local details. This characteristic is particularly crucial for power towers: as a structured object, a tower exhibits a clear topological hierarchy, which the top-down pathway effectively models through global contextual reasoning. Meanwhile, critical small-scale components (e.g., bolts, grading rings) possess strong discriminative power, and the bottom-up pathway ensures these fine details are preserved during segmentation. Second, BiRefNet achieves high segmentation accuracy while maintaining exceptional computational efficiency, with only 27.8 million parameters—significantly fewer than U²-Net or ISNet.

To leverage this high-quality prior, the MGFM module integrates the foreground mask generated by BiRefNet as spatial guidance. It is inserted after Layer2 of EfficientNet-B4 and employs a two-stage fusion strategy to enhance foreground representation and suppress background interference. The detailed structure of the MGFM is shown in Fig. 3.

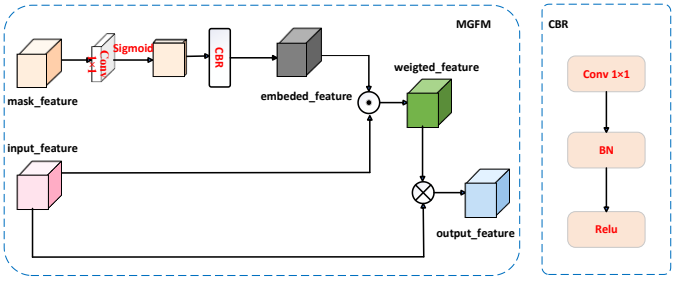

Fig. 3. The structure of MGFM.

The complete MGFM pipeline is as follows: 1) Mask Channel Compression: The three-channel RGB-format mask is first passed through a 1×1 convolutional layer to compress it into a single-channel grayscale map, which is then constrained to the [0,1] range via a Sigmoid activation function to generate a spatial attention prior. 2) Mask Resolution Alignment: The single-channel mask is upsampled/downsampled via bilinear interpolation to match the spatial resolution (H'×W') of the backbone feature map. 3) Mask Channel Embedding: The aligned single-channel mask is passed through another 1×1 convolutional layer, combined with Batch Normalization (BN) and ReLU activation, to map it to the same C-dimensional channel space as the backbone feature, generating the embedded mask Embedded_Mask. 4) Spatial Guidance Fusion: Embedded_Mask is element-wise multiplied (broadcasting) with the original feature Input_Feature to obtain the foreground-enhanced Weighted_Feature. 5) Adaptive Weighted Fusion: A learnable scalar parameter $\alpha \in [0,1]$ (constrained by Sigmoid) is introduced to linearly weight Weighted_Feature and the original Input_Feature.

The core advantage of the MGFM module lies in its efficient foreground perception capability. The mask embedding mechanism accurately identifies foreground regions, avoiding the negative impact of background interference on feature learning. The single learnable fusion parameter α allows the network to adaptively adjust the intensity of foreground enhancement based on task requirements, providing sufficient flexibility while maintaining model lightweightness.

B. MSAA Module

The Multi-scale Attention Aggregation Module (MSAA) is designed to address the limitations of traditional convolutional neural networks in cross-layer feature fusion, specifically the insufficient information interaction and limited multi-scale modeling capability. In deep networks, shallow features contain rich spatial details, while deep features encode stronger semantic information. However, these two types of features are often difficult to effectively collaborate due to their differing receptive fields and levels of abstraction. To this end, the MSAA module employs parallel multi-scale convolutional pathways combined with a channel attention mechanism to achieve efficient and complementary cross-layer feature fusion. Fig. 4 depicts the architecture of the proposed MSAA module. It is deployed after the outputs of Layer3 and Layer5 in EfficientNet-B4 to enhance the model's joint representation capability for both local details and global structures of the power tower.

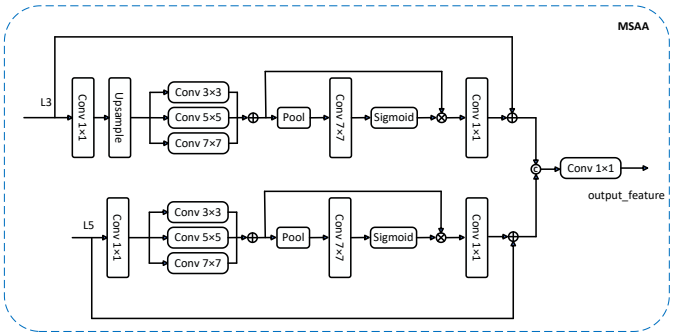

Fig. 4. The structure of MSAA.

The MSAA module's core pipeline consists of two main branches processing features from Layer3 and Layer5, respectively. For each input feature map, it is first mapped to a unified intermediate channel dimension via a Conv1×1, then replicated into three copies and fed into three parallel convolutional branches using Conv3×3, Conv5×5, and Conv7×7 kernels to cover a range of receptive fields from small to large. Within each parallel branch, channel attention

weights are generated through global average pooling, a 1×1 convolution (implemented as 7×7 due to 1×1 input), and Sigmoid activation, which are then used to modulate the original features. The channel-modulated feature maps are element-wise added to the original features to obtain the final output feature map for that branch. Finally, the final output feature maps from the Layer3 and Layer5 branches are concatenated along the channel dimension and compressed to produce the final fused feature map.

C. CBAM Module

To achieve finer feature selection and viewpoint-discriminative enhancement at the decision front-end, this paper introduces the Convolutional Block Attention Module (CBAM) [18] after global feature fusion. CBAM is a lightweight, plug-and-play attention mechanism that sequentially applies Channel Attention Mechanism (CAM) and Spatial Attention Mechanism (SAM) to doubly modulate the input feature map, thereby adaptively enhancing the response intensity of key regions and channels. The serial structure of CBAM is presented in Fig. 5.

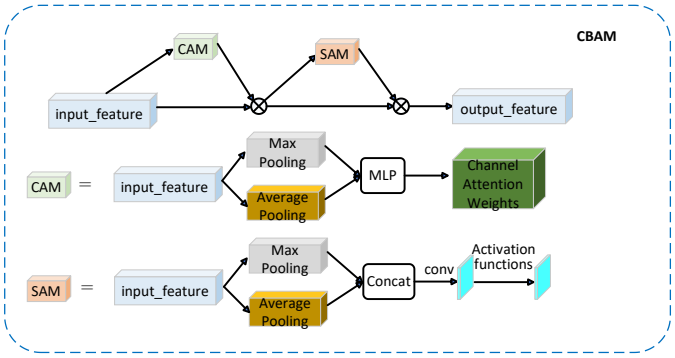

Fig. 5. The structure of CBAM.

The CBAM module adopts a serial structure of CAM and SAM to doubly modulate the input feature map. Its processing flow is as follows: First, the channel attention mechanism compresses the input feature map through Global Average Pooling (GAP) and Global Max Pooling (GMP) to generate two channel descriptors. These descriptors are then processed by a shared Multi-Layer Perceptron (MLP) for feature interaction and nonlinear transformation. Their outputs are summed and passed through a Sigmoid activation function to obtain the final channel attention weight map, which is element-wise multiplied with the original feature map to complete channel-wise adaptive recalibration. Next, the spatial attention mechanism takes the output from the previous step, performs max and average pooling along the channel dimension, concatenates the resulting two spatial maps, fuses them through a 7×7 convolutional layer, and applies a Sigmoid activation function to generate the spatial attention weight map. Finally, this spatial weight map is element-wise multiplied with the current feature map to achieve spatial focusing enhancement, yielding the final feature after dual channel-spatial attention modulation.

The core advantage of the CBAM module lies in its simple structure, high computational efficiency, and no requirement for additional annotations. In this work, the module is applied to the final feature map of the backbone network (before global average pooling). Its functions are: 1) highlighting key channel features relevant to viewpoint discrimination through channel attention; 2) focusing on the most discriminative regions in the image through spatial attention, thereby effectively suppressing background interference; 3) being particularly suitable for solving the recognition problem of minority viewpoints like the top view, as it can adaptively amplify the discriminative feature responses of these rare viewpoints.

IV. Experimental Setup

A. Experimental Environment and Dataset

The experimental hardware environment is shown in Table I. All experiments were conducted on a single server equipped with an NVIDIA GeForce RTX 3090, with CUDA 12.1 driver installed. The software environment uses Ubuntu 20.04 OS, Python 3.10, and deep learning frameworks PyTorch 2.2.1 and Torchvision 0.17.1. The ablation experiments used the AdamW optimizer with momentum parameters beta1 and beta2 set to 0.9 and 0.999, respectively. The model was trained for 30 epochs with a cosine annealing learning rate scheduler (maximum learning rate: 0.001), a batch size of 8, and a weight decay of 0.01.

TABLE I. Experimental Hardware Environment

Hardware	Model	Quantity
CPU	Intel Xeon 6148 Processor	1
Memory	Samsung DDR4 16GB	8
GPU	NVIDIA GeForce RTX 3090	1
Storage	Samsung SSD 980 PRO 2TB	1

The dataset was collected during routine UAV inspections conducted by a power grid company in real operational environments. All images were captured under clear weather conditions with sufficient natural illumination, which is representative of typical inspection scenarios. The UAV flight altitude ranged approximately from 11 m to 50 m, covering different observation distances and view scales. The dataset mainly includes two common structural types of distribution network towers, namely reinforced concrete towers and angle steel towers. In addition, multiple functional tower categories are involved, including straight-line towers, strain towers, and angle towers. Such diversity in acquisition conditions and tower configurations contributes to the robustness and generalization ability of the proposed method. The dataset used in this paper is a distribution network tower dataset captured by a power grid company, containing 5,268 multi-view tower images. There are three viewpoint types: front/back, side, and top. The dataset was randomly split into training and validation sets at a 7:3 ratio, with the validation set also serving as the test set, resulting in 3,686 training images and 1,582 validation/test images.

B. Evaluation Metrics

1) Top-1 accuracy: Accuracy is the most intuitive and commonly used evaluation metric in classification tasks, measuring the proportion of samples correctly predicted by the model. In viewpoint classification, accuracy reflects the

model's overall performance in recognizing different viewpoints (front/back, side, top). The formula is:

$$Accuracy = \frac{\sum_{i=1}^{C} TP_i}{N} \quad (1)$$

where C is the number of classes, N is the total number of samples, and TP_i is the number of true positives for class i. While accuracy provides an intuitive measure of overall performance, it can be misleading under class imbalance.

2) Macro-F1 score: To fairly evaluate the model's performance on each class (especially minority classes), this paper adopts the Macro-F1 Score. The F1 score is the harmonic mean of Precision and Recall:

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall} = \frac{2TP}{2TP + FP + FN} \quad (2)$$

Where, FP and FN are the false positives and false negatives for class, respectively. The Macro-F1 Score is the arithmetic mean of the F1 scores of all classes, independent of the number of samples per class:

$$F1_{\text{macro}} = \frac{1}{C} \sum_{i=1}^{C} F1_i \quad (3)$$

V. Experiments and Results Analysis

A. Ablation Study on Individual Modules

To validate the effectiveness of each proposed module, a systematic ablation study is conducted on a self-built multi-view tower dataset. The results are summarized in Table II.

TABLE II. Ablation Study on Individual Modules

Model	Top-1/%	$F1_{\text{macro}}$/%
EfficientNet-B4	88.56	66.40
EfficientNet-B4+MGFM	89.82	69.97
EfficientNet-B4+MGFM+MSAA	90.71	71.75
EfficientNet-B4+MGFM+ MSAA+CBAM	92.38	72.26

The results demonstrate that each module contributes positively to model performance, and their combination yields strong synergistic effects. The MGFM module, serving as the foundation for foreground-aware perception, leverages high-quality foreground masks generated by BiRefNet to effectively suppress complex background interference. It improves Top-1 accuracy by 1.26% and boosts Macro-F1 by 3.57%, confirming the efficacy of foreground guidance in addressing background noise. Building upon this, the MSAA module further refines multi-scale feature fusion. Although it only increases Top-1 accuracy by 0.91%, it significantly raises Macro-F1 by 1.78%, indicating that its parallel multi-scale convolutions and channel-wise attention weighting effectively enhance the complementary representation between shallow details and deep semantics, thereby improving the model's joint modeling of local structures and global layouts of towers. Finally, the CBAM module, acting as a dual-modulation mechanism at the decision front-end, further elevates Top-1 accuracy by 1.65%, achieving a final accuracy of 92.38%. Its channel-spatial dual attention adaptively focuses on viewpoint-discriminative regions, substantially enhancing robustness for minority classes (e.g., top view) while maintaining class balance. Together, these three modules form a complete feature enhancement chain following the hierarchical design principle of "Foreground Guidance — Multi-scale Feature Fusion — Dual-dimensional Attention Modulation", effectively addressing the core challenges in distribution network tower viewpoint classification and validating the superiority of progressive feature enhancement in power vision tasks.

B. Comparison of Different Attention Mechanisms

To investigate the impact of attention mechanisms on classification performance, four representative attention modules—SE [19], ECA [20], EMA [21], and CBAM—are integrated before the classification head of the baseline model. The results are shown in Table III.

TABLE III. Comparison of Different Attention Mechanisms

Attention	Top-1/%	$F1_{\text{macro}}$/%
SE	87.73	66.38
ECA	88.59	64.46
EMA	88.25	65.15
CBAM	89.41	68.19

As shown, CBAM outperforms all other attention mechanisms in both Top-1 accuracy and Macro-F1. While SE, ECA, and EMA primarily operate in the channel dimension, CBAM's incorporation of spatial attention enables more comprehensive feature recalibration. This dual-dimensional modulation not only improves overall performance but also significantly enhances recognition of minority classes. The results confirm that, in tower viewpoint classification, spatial localization is as critical as channel-wise feature selection, and their joint optimization leads to more discriminative feature representations.

C. Comparison of Experiments

The full model is further compared with several mainstream deep learning architectures, including classical CNNs (Inception V3 [22], ResNet50 [23], VGGNet [24]) and modern vision transformers (ViT [25], Swin Transformer [26]). The results are presented in Table IV.

TABLE IV. Comparison of Experiments

Model	Top-1/%	$F1_{\text{macro}}$/%
EfficientNet-B4	88.56	66.40
MobileNetV3	88.75	77.08
ShuffleNetV2	85.30	63.57
Inception V3	83.43	64.69
Resnet 50	85.24	67.20
VggNet	83.18	64.72
Vision Transformer	88.57	67.42
Swin Transformer	90.42	70.35
Ours	92.38	72.26

The proposed method achieves a Top-1 accuracy of 92.38%, significantly outperforming all baseline approaches. Notably, it surpasses the second-best model (Swin Transformer) by 1.96% in accuracy and 1.91% in Macro-F1. This consistent improvement across both metrics—particularly the higher

Macro-F1—demonstrates that the proposed approach not only attains superior overall performance but also exhibits stronger robustness under class imbalance, which is a critical requirement for real-world power inspection scenarios.

To further evaluate the effectiveness of the proposed method under resource-constrained settings, a comparison is conducted with representative lightweight architectures, including MobileNetV3 and ShuffleNetV2. As shown in Table Ⅳ, MobileNetV3 achieves a Top-1 accuracy of 88.75% with a Macro-F1 of 77.08%, while ShuffleNetV2 attains 85.30% Top-1 accuracy and 63.57% Macro-F1. These results indicate that although lightweight models offer advantages in computational efficiency, their discriminative capability for viewpoint recognition—especially under class imbalance—remains limited.

D. Scalability Analysis Across Different EfficientNet Variants

To evaluate the scalability of the proposed modules, experiments are further conducted by integrating them into different EfficientNet variants. The results are shown in Table V.

TABLE V. PERFORMANCE COMPARISON ACROSS DIFFERENT EFFICIENTNET VARIANTS

Backbone	Baseline		Ours	
	Top-1(%)	*$F1_{macro}$(%)*	*Top-1(%)*	*$F1_{macro}$(%)*
Efficient-B0	90.77	70.47	92.58	74.68
Efficient-B1	87.62	66.37	89.35	68.13
Efficient-B2	87.41	66.29	89.93	67.82
Efficient-B3	89.43	68.37	93.16	70.46
Efficient-B4	88.56	66.40	92.38	72.26
Efficient-B5	87.27	67.38	88.15	68.29
Efficient-B6	89.49	69.41	91.24	71.31
Efficient-B7	86.43	66.15	86.19	65.32

As shown in Table V, the proposed method consistently improves performance over the corresponding baselines across most backbone scales. Notable gains in both Top-1 accuracy and Macro-F1 are observed for EfficientNet-B0 to B6, indicating that the proposed foreground-guided and multi-scale attention mechanisms generalize well across different model capacities.

In particular, the improvements in Macro-F1 demonstrate enhanced class-balanced recognition performance, suggesting that the proposed framework effectively alleviates viewpoint imbalance regardless of backbone depth. Although marginal performance saturation or slight fluctuation is observed on the largest backbone (EfficientNet-B7), the overall trend confirms that the proposed method is not limited to a specific EfficientNet configuration. These results validate the scalability and robustness of the proposed framework across a wide range of network capacities.

E. Confusion Matrix

To gain deeper insight into the model's classification performance for each individual category, particularly its error patterns, this section employs confusion matrices for visual analysis. In addition to the visual analysis, quantitative confusion-matrix-derived statistics are reported to further clarify class-wise misclassification behavior. Table VI summarizes the class-wise precision and recall of the baseline model and the proposed method, providing a quantitative comparison of classification performance across different viewpoints.

TABLE VI. CLASS-WISE PRECISION AND RECALL COMPARISON BETWEEN BASELINE AND PROPOSED METHOD

Class	Baseline		Ours	
	Precision(%)	*Recall(%)*	*Precision(%)*	*Recall(%)*
Front/Back	90.44	93.96	93.52	96.23
Side	92.26	89.07	96.76	90.86
Top	17.24	15.63	24.71	32.81

The confusion matrix clearly illustrates the model's classification and misclassification situations for each viewpoint category. The diagonal elements represent the proportion of correctly classified samples, while the off-diagonal elements reveal the category pairs that the model tends to confuse. The confusion matrices of the baseline model (EfficientNet-B4) and the models with the proposed modules incrementally integrated on the test set are compared, as shown in Fig. 6 to Fig. 9.

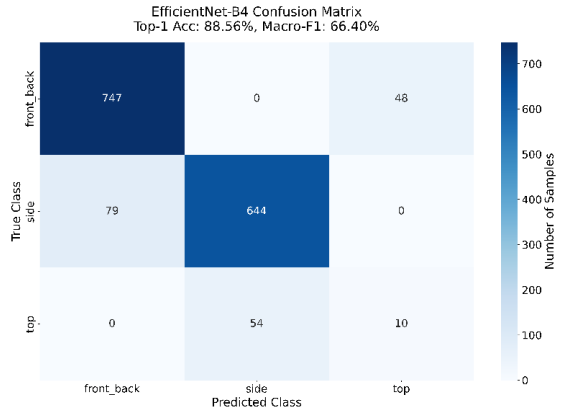

Fig. 6. Confusion matrix of the baseline model (EfficientNet-B4).

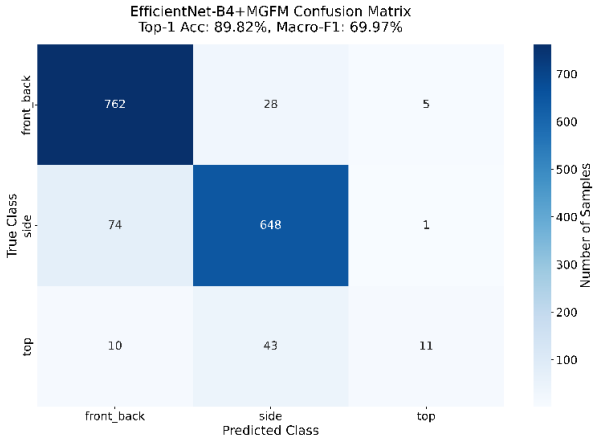

Fig. 7. Confusion matrix of the baseline model with MGFM.

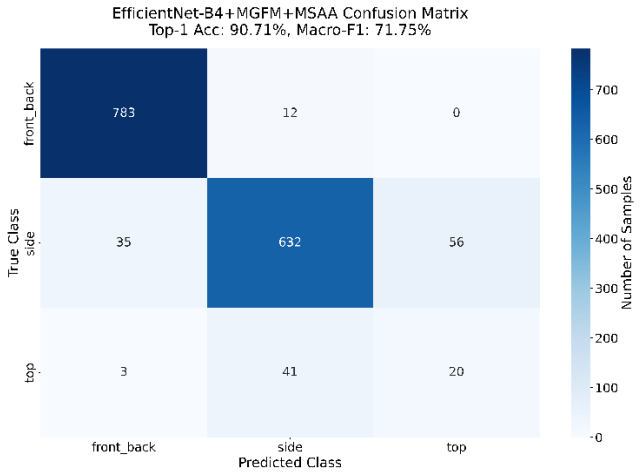

Fig. 8. Confusion matrix of the baseline model with MGFM and MSAA.

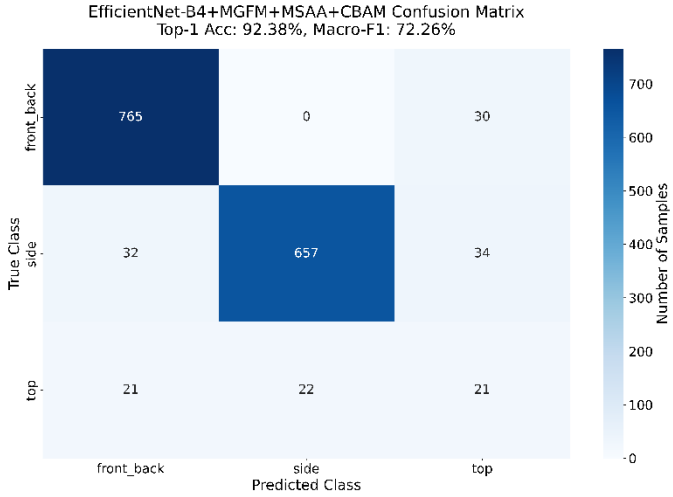

Fig. 9. Confusion matrix of the proposed full model (with MGFM, MSAA, and CBAM).

Fig. 6 illustrates the confusion matrix of the baseline EfficientNet-B4 model. Although satisfactory performance is achieved for the front/back and side viewpoints, severe misclassification is observed for the top view. A large proportion of top-view samples are incorrectly predicted as side view, resulting in extremely low recall for the top category. This indicates that the baseline model struggles to capture discriminative features for minority viewpoints under complex backgrounds, which directly contributes to the low Macro-F1 score. As shown in Fig. 7, after introducing the Mask-Guided Fusion Module (MGFM), the classification performance for front/back and side views is moderately improved, and background-induced misclassification is partially suppressed. However, confusion between the top and side viewpoints remains prominent, suggesting that foreground guidance alone is insufficient to resolve viewpoint ambiguity caused by scale variation and limited semantic discrimination. Fig. 8 presents the confusion matrix of the model with both MGFM and MSAA integrated. Compared with the previous configurations, the number of top-view samples correctly classified increases noticeably, while misclassification into the side category is reduced. This improvement demonstrates that multi-scale feature aggregation effectively enhances the representation of viewpoint-sensitive structural cues, particularly for small-scale and underrepresented viewpoints. Finally, Fig. 9 shows the confusion matrix of the full model incorporating MGFM, MSAA, and CBAM. The results reveal a substantial reduction in cross-view confusion across all categories. In particular, the recall of the top view is significantly improved, indicating that the attention-based modulation further strengthens viewpoint-discriminative regions in both channel and spatial dimensions. The overall confusion pattern becomes more compact along the diagonal, which is consistent with the highest Top-1 accuracy and Macro-F1 score achieved by the proposed method.

Overall, the progressive reduction of misclassification errors from the baseline to the full model validates the complementary roles of foreground guidance, multi-scale feature fusion, and dual-dimensional attention modulation. These results confirm that the proposed framework effectively alleviates viewpoint imbalance and enhances classification robustness in real UAV-based tower inspection scenarios.

F. Overall Experimental Discussion

Overall, the experimental results demonstrate that the proposed method achieves consistent and substantial performance improvements across different evaluation metrics and backbone configurations. Compared with the baseline model, the proposed framework improves Top-1 accuracy by up to 3.82% and Macro-F1 by more than 6%, with particularly notable gains observed on the minority top-view category. These improvements are most evident under challenging conditions, such as complex backgrounds and severe class imbalance, which commonly occur in real UAV-based power inspection scenarios. Consequently, the proposed method provides a more reliable and robust solution for tower viewpoint recognition, facilitating downstream inspection tasks and supporting practical deployment in real-world power grid applications.

VI. Conclusion

To address the key challenges in multi-view classification of distribution network towers—such as severe background interference, difficulty in recognizing minority viewpoints, and insufficient cross-scale feature interaction—this paper presents an improved EfficientNet-B4-based viewpoint recognition framework. A progressive three-stage enhancement mechanism, consisting of foreground-guided perception, adaptive multi-scale feature fusion, and dual-dimensional attention modulation, is constructed to systematically enhance viewpoint-discriminative representations.

Extensive experimental results on a self-built multi-view tower dataset demonstrate that the proposed method achieves consistent and significant performance improvements under challenging UAV inspection conditions, including complex natural backgrounds and pronounced class imbalance. Specifically, foreground-guided feature extraction effectively suppresses background noise and emphasizes tower body regions, while adaptive multi-scale fusion fully exploits the complementary characteristics of shallow structural details and deep semantic information. In addition, the dual attention modulation mechanism further strengthens viewpoint-sensitive

regions, leading to substantial robustness gains for minority viewpoints, particularly the top view.

Beyond the specific application of tower viewpoint recognition, this work provides a generalizable framework for multi-view visual classification under challenging conditions. By organizing foreground guidance, multi-scale feature interaction, and attention-based discrimination into a unified progressive pipeline, the proposed method establishes a reusable design paradigm that can be extended to other UAV inspection tasks and viewpoint-sensitive recognition problems. Owing to its stage-wise and task-oriented design, the framework exhibits strong generality and transferability across different backbone configurations.

From a practical perspective, the consistent improvements in both Top-1 accuracy and Macro-F1—especially under complex backgrounds and severe class imbalance—directly translate into more reliable perception in real inspection scenarios. The robust viewpoint recognition results provide stable spatial priors for downstream tasks such as tower defect detection, component localization, inspection path planning, and three-dimensional reconstruction, thereby supporting real-world deployment beyond performance-driven architectural refinements. Future work will focus on three directions: (1) expanding the dataset scale and viewpoint diversity to further improve model generalization; (2) investigating lightweight deployment strategies to enable real-time inference on edge devices; and (3) exploring end-to-end joint optimization of viewpoint recognition and defect detection to construct a more integrated and efficient inspection perception pipeline.

***Abstract*—Digital reading remains a challenge for individuals with dyslexia due to the limited availability of accessible tools tailored to their cognitive and perceptual needs. Although many digital reading applications offer basic personalization options, they often lack integrated mechanisms to support reading comprehension and user autonomy. This study presents the design and usability validation of an accessible mobile application prototype aimed at improving the digital reading experience for people with dyslexia using a user-centered design approach. The research followed a design thinking methodology that included a systematic literature review, analysis of documented user needs from peer-reviewed studies and dyslexia support communities, personas development based on published user profiles, and a competitive analysis of existing accessible reading applications. The design process focused on identifying key pain points and developing interactive prototypes that integrate advanced text personalization, visual and auditory supports, text difficulty analysis, and intelligent accessibility suggestions. The proposed prototype enables users to customize font type and size, color, and spacing; activate text-to-speech functionality; highlight words or lines; upload and edit texts in multiple formats; and receive automated recommendations to enhance accessibility. Usability and accessibility were evaluated through expert heuristic assessment using established usability principles and WCAG 2.1 guidelines. Results indicate strong adherence to usability standards, with experts highlighting effective feature integration and identifying the need for additional instructional support for advanced functions. Overall, the proposed application addresses key gaps in digital reading accessibility and provides a foundation for future empirical validation with end users.**

***Keywords*—Dyslexia; digital accessibility; digital reading; usability; user-centered design**

I. Introduction

In the digital age, reading texts on electronic devices has become a fundamental activity in both education and professional life. However, for individuals with dyslexia, digital reading continues to pose a significant challenge due to the lack of truly accessible tools tailored to their specific needs [1]. Dyslexia is a neurobiological learning difficulty that affects the accuracy and fluency of word recognition as well as reading comprehension. It is estimated that around 10% of the world's population has some degree of dyslexia, making it one of the most common learning difficulties [2]. Furthermore, dyslexia accounts for up to 80% of diagnosed cases of reading-related learning disorders [1]. Scientific evidence shows that these difficulties persist into adulthood, being especially noticeable in reading and writing speed, while reading comprehension is usually less affected; the severity of symptoms may vary depending on the orthographic transparency of the language, but in all cases, there is a significant impact on the academic and social life of those affected [3]. These findings highlight the importance of developing inclusive and technologically advanced solutions that enable equal opportunities in access to information and education for people with dyslexia.

Despite technological advances and growing awareness of inclusion, many digital platforms still do not offer features adapted to the needs of people with dyslexia. Text personalization options, such as changing font, color, size, or spacing, are often limited or nonexistent. In addition, the integration of assistive technologies such as text-to-speech (TTS), word or line highlighting, and accessible navigation is absent in most digital reading applications. This lack of adequate tools can lead to frustration, low motivation, and difficulties in reading comprehension, affecting users' academic performance and autonomy [3].

User-centered design and user experience (UX) are fundamental approaches for the development of inclusive technological solutions. Understanding the documented needs and experiences of people with dyslexia in the design process makes it possible to identify their real requirements, preferences, and pain points, resulting in more effective and satisfactory products. In this context, the present research proposes the development and validation of a digital reading application prototype aimed at people with dyslexia. The application integrates functionalities such as advanced text personalization, guided mode, text-to-speech, difficulty analysis, and the generation of intelligent suggestions to improve accessibility and reading comprehension.

The main objective of this study is to analyze the challenges faced by people with dyslexia in digital reading and to evaluate the effectiveness and usability of the proposed application. The research questions guiding this work are:

What are the main challenges and needs of people with dyslexia when interacting with digital texts according to existing literature?

What features should be integrated into a digital reading application to improve accessibility and user experience based on evidence-based design principles?

How can heuristic evaluation validate the usability and accessibility of the proposed application design for people with dyslexia?

II. Literature Review

To achieve the objectives of this study, an exhaustive review of previous literature was conducted, focusing on existing problems and solutions related to digital reading accessibility for people with dyslexia. Keywords such as dyslexia, digital accessibility, digital reading, assistive technology, and user experience were used to search for relevant studies in academic databases such as ResearchGate, ScienceDirect, and Springer. Eighteen pertinent research articles were identified, addressing topics ranging from the characterization of reading difficulties in people with dyslexia to the analysis of technological tools and pedagogical strategies aimed at improving reading comprehension.

The literature review highlights the importance of text personalization, including font type, size, color, and spacing, as well as the integration of assistive technologies such as text-to-speech and word highlighting. These features are fundamental to facilitating digital reading for individuals with dyslexia. Additionally, studies were identified that analyze how age, educational level, and familiarity with technology influence the adoption and effectiveness of digital solutions. The reviewed articles also emphasize the need for intuitive interfaces, active user participation in the design process, and usability evaluation as key factors for the success of applications aimed at this group.

The results of the literature review reveal gaps in current digital solutions, especially regarding the absence of comprehensive tools that combine personalization, accessibility, and intelligent support. These findings underscore the need to develop and validate a user-centered digital reading application capable of addressing the real needs of people with dyslexia and promoting equal opportunities in access to information and education.

A. Reading Difficulties and Needs of People with Dyslexia

Digital reading represents a considerable challenge for individuals with dyslexia, who must overcome barriers such as word decoding, comprehension of lengthy texts, and visual fatigue. These difficulties not only affect motivation and academic performance but also limit autonomy and full participation in educational and social environments. The specialized literature indicates that dyslexia involves significant variability in the manifestations and needs of each individual, making the development of flexible and customizable solutions essential [4]. Various studies have shown that the ability to modify font type, size, color, and spacing can facilitate comprehension and reduce the cognitive effort required for reading [5]. Additionally, the use of visual supports, such as word or line highlighting and segmenting text into more manageable fragments, contributes to a more positive and effective reading experience [6]. However, the lack of comprehensive and accessible tools remains one of the main barriers for this group.

B. The Role of Technology in Reading Accessibility

Technological advances have enabled the development of digital tools that improve accessibility for people with dyslexia, transforming the way they access and process written information. Digital applications and platforms currently offer features such as text-to-speech, font and color changes, and spacing adjustments, which facilitate the adaptation of text to each user's needs [7]. The integration of these technologies in educational and professional settings has proven to be key in promoting inclusion and equal opportunities, allowing students and workers with dyslexia to actively participate in activities that were previously inaccessible [8]. However, the literature also warns that the effectiveness of these tools largely depends on their ease of use, the quality of personalization, and the training of users and educators in their implementation [9]. Therefore, user-centered design and continuous evaluation of the user experience are fundamental aspects for the success of technological solutions in this field.

C. Challenges in the Adoption of Accessible Digital Solutions

Despite technological advances, there are significant challenges in the adoption and effective use of accessible digital solutions for people with dyslexia. Among the main obstacles are the lack of standardization in accessibility features, limited training for users and educators, and the scarce availability of materials adapted to different levels of reading difficulty [10]. In addition, information overload, the complexity of some interfaces, and the absence of intelligent recommendations can hinder the reading experience and cause frustration among users [11]. The literature suggests that collaboration between developers, educators, and people with dyslexia is essential to identify real needs and design tools that effectively address them [12]. Likewise, the importance of continuous feedback and the adaptation of solutions to changes in users' preferences and abilities over time is emphasized.

D. Diversity of Age and Technological Experience in Usability

Age and technological experience significantly influence the usability and acceptance of accessible digital reading applications. Younger users, who have grown up in digital environments, tend to adapt more easily to new technologies and confidently explore personalization and support options [13]. In contrast, adults and older individuals may require more intuitive interfaces, clear instructions, and additional support to make the most of the available features [14]. The literature highlights the need to design flexible solutions that adapt to different levels of digital literacy and allow personalization according to each user's preferences and needs [15]. Furthermore, the active participation of people with dyslexia of different ages in the design and validation process of the tools helps improve acceptance, satisfaction, and the effectiveness of technological solutions [16].

E. Artificial Intelligence and Personalization in Digital Reading

Artificial intelligence is transforming reading accessibility through automatic content personalization, the generation of recommendations, and predictive analysis of difficulties. Platforms that integrate AI can suggest formatting adjustments, identify complex words, and offer summaries tailored to the user's level, thereby facilitating comprehension and reducing cognitive load [17]. In addition, AI enables real-time feedback, progress tracking, and dynamic adaptation of features according to user performance and preferences [18]. These capabilities contribute to a more autonomous, motivating, and personalized reading experience, allowing people with dyslexia to overcome traditional barriers and access information more equitably [19]. The literature agrees that the integration of AI into digital reading applications represents a key opportunity to advance toward a more inclusive education and society.

III. Methods

This study followed the design thinking process, which encompasses five phases:

1) empathize, 2) define, 3) ideate, 4) prototype, and 5) test.

A. Requirements Analysis

A systematic analysis of user needs was conducted through examination of published research, case studies, and user testimonials from dyslexia support communities. The analysis covered documented experiences from individuals aged between 10 and 55 years, with varying levels of experience with reading technologies, including students from different educational levels, professionals, and young adults. Sources included peer-reviewed articles, accessibility reports, and documented user experiences from dyslexia organizations and online support forums. The synthesis process involved analyzing fifteen key aspects identified in the literature about digital reading experiences, the main challenges faced, and the improvements or supports considered necessary to facilitate reading. The documented profiles represented a wide variety of cases, from individuals diagnosed with dyslexia in childhood to adults who have developed their own strategies to cope with reading. This qualitative information made it possible to accurately identify common user problems and needs, thus guiding the design and development of the proposed application prototype in this study.

B. Contextual Research

A comprehensive literature analysis and synthesis of published research were conducted to understand the reading habits, behaviors, and mental models of people with dyslexia when interacting with digital texts. Different documented user experiences and accessibility studies were analyzed from various perspectives to build a comprehensive understanding. For this study, a cultural model was developed based on established research findings to identify the values, needs, and factors that influence the reading experience of people with dyslexia. The cultural model (see Fig. 1) highlights the complexity and challenges faced by these users, helping to identify the critical points where the greatest difficulties arise. This analysis made it possible to visualize the main problems and provided the foundation for proposing a digital support system, based on an application with intelligent tools, aimed at facilitating and improving the reading experience for people with dyslexia. No direct interviews or surveys with individuals with dyslexia were conducted in this study; all user insights were derived from secondary sources including peer-reviewed publications, accessibility reports, and documented testimonials from established dyslexia organizations.

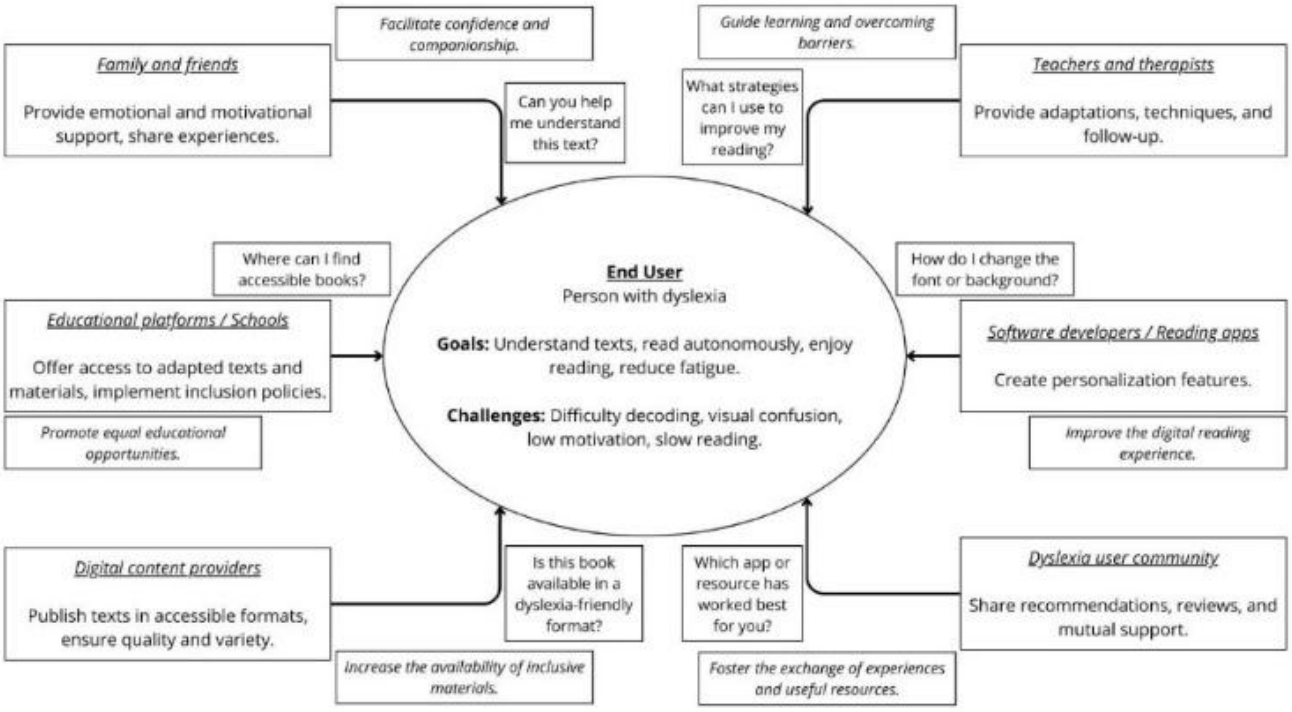

Fig. 1. Cultural model of a person with dyslexia.

C. Problem Definition

Analyzing the results of the literature review and documented user experiences revealed that digital reading represents a significant challenge for people with dyslexia in various aspects. Research indicates that users often face difficulties in understanding texts, maintaining concentration, and adapting materials to their specific needs. Additionally, differences were observed in published studies regarding how people of different ages and educational levels use digital reading tools: for example, younger users tend to explore more personalization options, while adults may feel less familiar with assistive technologies. Documented user feedback also expressed frustration due to the lack of accessible materials, limited text personalization, and the absence of recommendations tailored to their difficulties. To better understand the problem space, a fishbone diagram (see Fig. 2) was used, allowing for an exhaustive analysis of the causes and effects of the problems faced by people with dyslexia when interacting with digital texts.

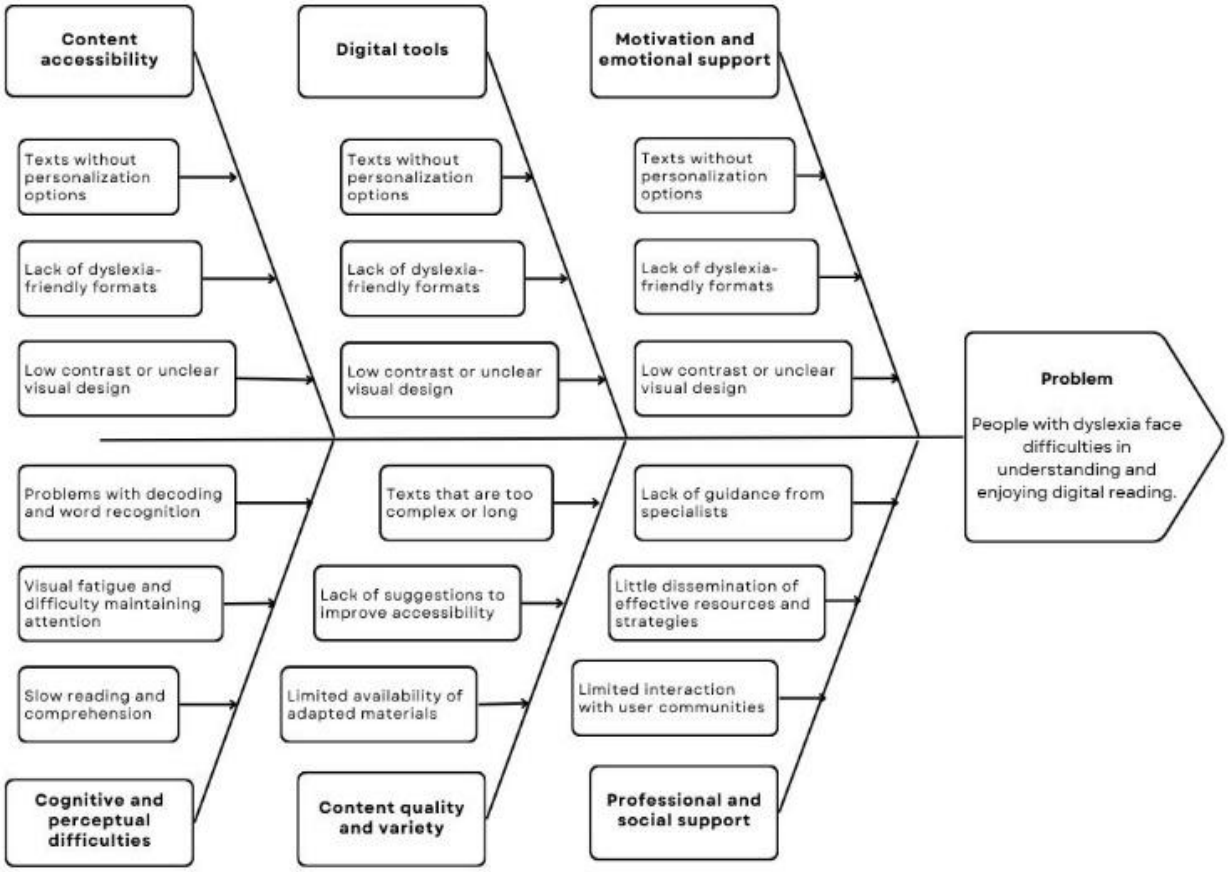

Fig. 2. Fishbone diagram.

D. Competitor Analysis

As shown in Table I, a competitor study was conducted in the field of accessible digital reading for people with dyslexia. The main competitors identified include Microsoft Immersive Reader, ClaroRead, and Voice Dream Reader. Microsoft Immersive Reader offers an inclusive reading experience integrated into various platforms, allowing text personalization, text-to-speech, and translation. ClaroRead is a popular tool that provides text-to-speech, font and color changes, and support for different text formats. Voice Dream Reader is a mobile application that stands out for its customization capabilities, support for multiple voices and formats, and ease of use.

The comparison focuses on essential features to improve accessibility and the reading experience, such as font and color personalization, text-to-speech, difficulty analysis, accessibility suggestions, and ease of use. Each platform has its strengths and limitations, which are summarized in Table I. The analysis shows that, although most applications offer personalization options and TTS, few include text difficulty analysis or intelligent suggestions to improve accessibility. Furthermore, not all platforms allow users to upload and edit texts in different formats or have an interface truly centered on accessibility.

E. Final Concept

Finally, the conceptual framework of the proposed application was consolidated as a comprehensive solution to enhance the digital reading experience for individuals with dyslexia. The app addresses the most common challenges faced by these users, such as difficulties in text customization, lack of support tools, and limited accessibility of materials. It offers advanced personalization options, read-aloud functionality, word or line highlighting, and text difficulty analysis. Additionally, it includes intelligent suggestions to improve accessibility and allows users to upload, edit, or write texts in various formats. The application also incorporates social

features, such as the ability to share adapted texts and recommendations within a user community. The final concept provides people with dyslexia an all-in-one, user-friendly tool focused on their needs, facilitating comprehension and enjoyment of digital reading. Table II presents the SCAMPER model used to enhance the accessibility services of the proposed solution. Table III summarizes the main features of the final idea.

TABLE I. COMPARATIVE TABLE OF KEY FEATURES OF THE MAIN COMPETITORS

Features	Competitors		
	Microsoft Immersive Reader	**ClaroRead**	**Voice Dream Reader**
Release year	2015	2004	2011
Main platform	Web, Windows, Office	Windows, Mac, iOS	iOS, Android
Font and color customization	✓	✓	✓
Dyslexia-friendly font	✓	✓	✓
Text-to-speech (TTS)	✓	✓	✓
Spacing and size adjustment	✓	✓	✓
Text highlighting/line guide	✓	✓	✓
Text difficulty analysis	✗	✗	✗
Accessibility suggestions	✗	✗	✗
File upload (PDF, DOCX, TXT)	✓	✓	✓
Text editing	✗	✓	✓
Clean, focused interface	✓	✓	✓
Keyboard navigation	✓	✓	✓
Adequate contrast	✓	✓	✓
ARIA labels and roles	✓	✗	✗
Total key features	11	10	10

TABLE II. SCAMPER MODEL FOR ACCESSIBILITY ENHANCEMENT

SCAMPER	Description
Substitute	• Traditional reading replaced by read-aloud and text highlighting. • Standard fonts substituted with dyslexia-friendly fonts.
Combine	• Combine font, color, and spacing customization in a single interface. • Integrate difficulty analysis and intelligent suggestions into the text editor. • Combine file upload and manual editing functions for greater flexibility.
Adapt	• Adapt gamification techniques to motivate reading (achievements, rewards). • Adapt accessibility strategies from other educational apps.
Modify	• Modify the interface to be cleaner, more focused, and distraction-free. • Improve keyboard navigation and accessibility for screen readers.
Put to another use	• Use the app as a support tool in classrooms or therapy. • Allow non-dyslexic users to customize reading to improve comprehension or language learning.
Eliminate	• Eliminate unnecessary features and complex menus. • Reduce notifications and visual elements that may distract the user.
Reverse	• Reverse the traditional approach of passive reading, promoting active interaction. • Reverse the help flow: the app automatically suggests improvements based on the uploaded text.

TABLE III. MAIN FEATURES OF THE PROPOSED SOLUTION

Main Feature	Description
Advanced text customization	Allows modification of font type and size, text and background color, and line and letter spacing to suit user needs.
Read-aloud (TTS)	Offers the option to read text aloud, with controls to pause, resume, and stop reading, facilitating auditory comprehension.
Guided mode and highlighting	Enables highlighting of the current line or word, helping maintain attention and improve visual tracking during reading.
Text upload and editing	Allows uploading files (PDF, DOCX, TXT), as well as pasting or manually writing text, providing flexibility in content access.
Difficulty analysis and suggestions	Analyzes the text's difficulty level and offers intelligent suggestions to improve accessibility, such as simplifying phrases or words.
Accessible and focused interface	Presents a clean interface focused on the text, with accessible controls, keyboard navigation, adequate contrast, and support for screen readers.

F. Prototype Evaluation

A heuristic evaluation method was employed to assess the usability of the proposed application prototype. Three accessibility experts with experience in assistive technology and dyslexia support tools conducted independent evaluations based on Nielsen's usability heuristics and WCAG 2.1 accessibility guidelines. The evaluation focused on specific interaction scenarios such as customizing text, using the read-aloud function, uploading and editing files, and analyzing text difficulty. Each expert independently assessed the interface against established usability principles, including learnability, efficiency, memorability, error prevention, and user satisfaction. The experts analyzed the prototype by simulating typical user tasks and identifying potential usability barriers for individuals with varying levels of technological experience. The evaluation results were consolidated through a structured review session, where findings were discussed and prioritized according to severity and potential impact on the target user experience.

IV. Results

A. Literature-Based User Needs Analysis

Analysis of published literature and documented user experiences revealed key aspects regarding the problems and preferences faced by people with dyslexia when reading digital texts across different age groups (10 to 55 years). Research findings indicate that approximately 60% of documented cases, especially among adults, report difficulties in finding accessible materials and customizing text formatting to their needs. Studies focusing on younger individuals (ages 10–25) consistently show frustration with the lack of intuitive digital tools and the limited integration of features such as read-aloud or word highlighting. According to accessibility research, 65% of reported cases across all ages indicate that visual fatigue and difficulty maintaining attention are frequent obstacles during digital reading. Additionally, 70% of documented user feedback emphasizes the importance of having customization options (font type, color, spacing) and a simple, distraction-free interface. Literature on adult users also highlights the need for suggestions to improve reading comprehension and for materials adapted to different levels of difficulty. Overall, the analysis demonstrated a strong demand for a single platform that facilitates digital reading, offers accessible support tools, and adapts to the needs of people with dyslexia of all ages. Documented user preferences show particular interest in a solution that would allow autonomous and personalized reading experiences.

B. User Interface Design Conceptualization

The idea for the application's user interface (UI) emerged from a systematic design thinking process, always focused on the needs and challenges of people with dyslexia. Initially, paper wireframes were created to represent the main user experiences, which allowed for the optimal placement of key elements such as customization controls, the reading area, and access to support functions. Subsequently, the Figma tool was used to develop high-fidelity interactive prototypes. The main interface and customization options are illustrated in the prototype (see Fig. 3). The reading view and text analysis features are also shown in a separate prototype (see Fig. 4). The design prioritized a clean layout, intuitive interactions, and a high-contrast color scheme, thus ensuring a visually pleasing, accessible, and user-centered experience.

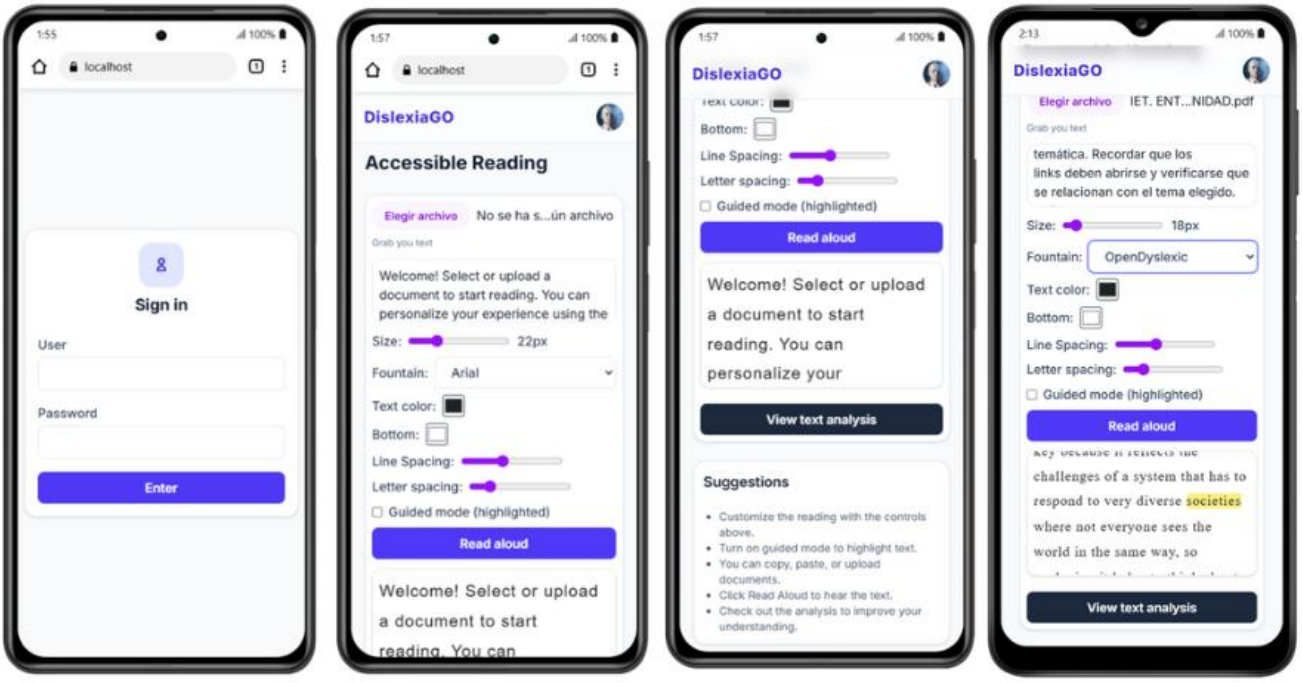

Fig. 3. High-fidelity interactive prototype of the proposed solution: main interface and customization options.

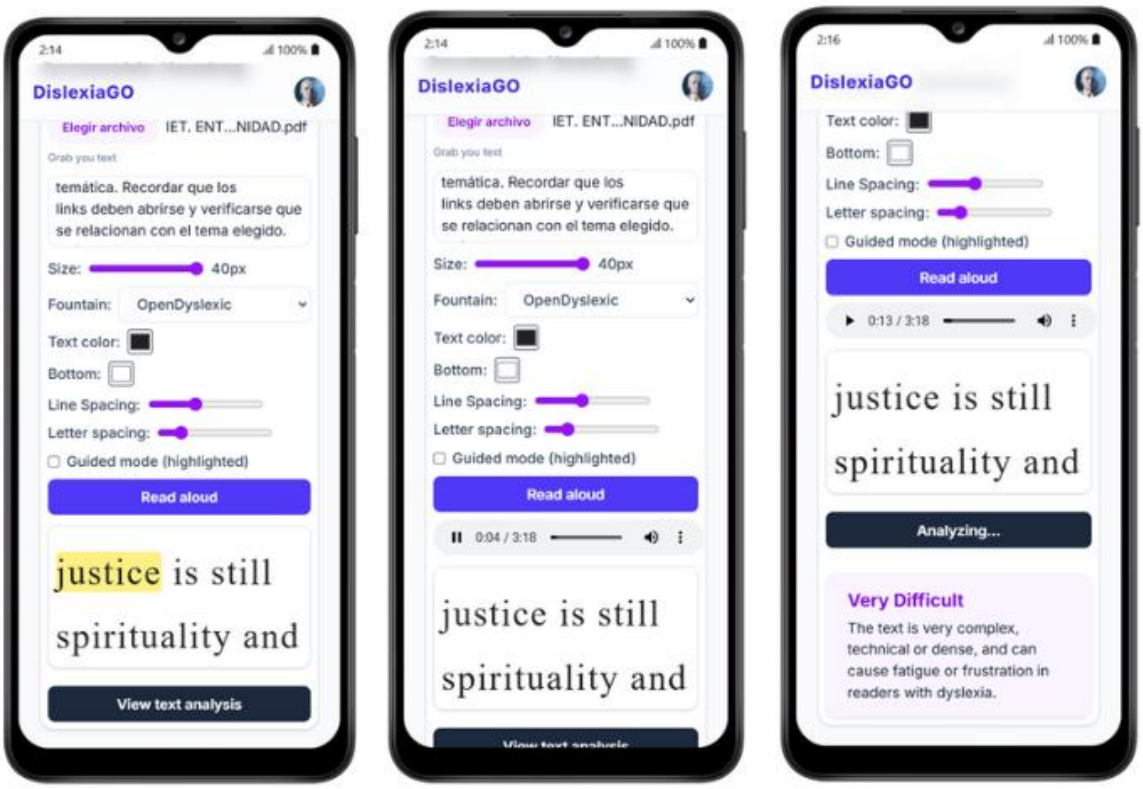

Fig. 4. High-fidelity interactive prototype of the proposed solution: reading view and text analysis features.

C. Usability Testing Information

The expert heuristic evaluation revealed that the application prototype demonstrates strong adherence to established usability principles and accessibility guidelines. The design was assessed as intuitive and accessible according to Nielsen's heuristics and WCAG 2.1 standards. Experts indicated that the interface design would likely encourage frequent use for reading activities among the target population. The organized interface style and the integration of the main features were particularly noted as strengths, especially the ease of customizing text and using the read-aloud function. However, evaluators identified that some advanced features, such as difficulty analysis or file editing, may require additional instructional support, particularly for older adult users with limited technological experience. One usability concern identified was the lack of consistency in some navigation flows, especially when switching between different customization modes. Experts recommended the incorporation of visual cues or interactive tutorials to help clarify the use of certain features. Despite these considerations, the evaluation indicated that the platform design follows user-centered principles and offers advantages over existing digital reading tools. Overall, the expert assessment reflects strong usability potential, although opportunities for improvement were identified to make some features even clearer and more accessible, especially for users with less technological experience. These findings will serve as a basis for future refinements aimed at providing a smoother and more enjoyable experience for all user profiles (Table IV).

TABLE IV. HEURISTIC EVALUATION SUMMARY

Usability Heuristic	Expert Assessment	Priority
Visibility of system status	Strong – Clear feedback on all actions	Low
Match between system and real world	Strong – Intuitive terminology and metaphors	Low
User control and freedom	Good – Undo/redo available, exit options clear	Medium
Consistency and standards	Moderate – Some inconsistencies in navigation flows	High
Error prevention	Strong – Confirmations for critical actions	Low
Recognition rather than recall	Strong – Visual cues and tooltips present	Low
Flexibility and efficiency of use	Good – Customization supports varied user needs	Medium
Aesthetic and minimalist design	Strong – Clean, focused interface	Low
Help users recognize and recover from errors	Good – Clear error messages provided	Medium
Help and documentation	Moderate – Advanced features need more guidance	High

III. Discussion

The use of digital technology has profoundly transformed the way people access information and develop reading skills, especially in educational and professional contexts. For individuals with dyslexia, the emergence of digital tools represents both an opportunity and a challenge. On one hand, technology offers the possibility to personalize the reading experience, facilitating comprehension and autonomy. On the other hand, research indicates that the lack of truly inclusive solutions tailored to the needs of this group can perpetuate barriers and inequalities in access to information.

The objective of this study was to design and develop a prototype of an accessible digital reading application aimed at people with dyslexia, enabling text customization, the use of visual and auditory supports, and the provision of intelligent suggestions to improve reading comprehension. The methodological process was based on design thinking, encompassing the phases of empathizing, defining, ideating, prototyping, and evaluating. Empathy was addressed through comprehensive literature analysis and synthesis of documented user experiences, which made it possible to identify the main pain points and unmet needs in digital reading. Contextual research based on published studies and competitor analysis helped define the problem space and identify the limitations of existing solutions. The use of fishbone diagrams facilitated the visualization of the causes and effects of reading difficulties in people with dyslexia, while the SCAMPER method enabled the ideation of innovative improvements for the proposal.

The application prototype was developed using the Figma tool, prioritizing a clean, accessible, and user-centered design. Features such as advanced text customization, read-aloud functionality, guided mode, and difficulty analysis were incorporated, as well as the ability to upload and edit texts in different formats. The prototype was evaluated through expert heuristic assessment conducted by three accessibility specialists with extensive experience in assistive technology design. The heuristic evaluation results demonstrated strong adherence to established usability and accessibility principles, highlighting the ease of use, the effectiveness of the customization features, and the potential for improving reading comprehension among the target population.

Comparing the proposed design with previous literature, it is observed that most existing applications for people with dyslexia offer basic customization and read-aloud options, but lack difficulty analysis, intelligent suggestions, and seamless integration of all features in a single platform. Recent studies have proposed predictive models and recommendation systems based on artificial intelligence to adapt the reading experience to individual needs, but many of these approaches have not yet been implemented in accessible and user-friendly applications for the general public [20]. Other works have explored gamification, augmented reality, and chatbots as strategies to motivate reading and facilitate interaction, although the evidence regarding their effectiveness in the context of dyslexia is still limited [21], [22].

The user-centered design approach adopted in this study aligns with international best practices for the development of assistive technology. The design process, informed by extensive literature review and analysis of documented user needs, made it possible to identify critical usability considerations and align the application design with the established preferences and expectations of the target population. The heuristic evaluation method demonstrated its effectiveness in identifying usability strengths and priority areas for improvement before implementation [23].

In summary, the proposed application helps bridge the gap between the needs of people with dyslexia and the limitations of current digital solutions. The integration of advanced personalization features, visual and auditory support, and intelligent text analysis, together with an accessible and user-centered interface, represents a significant step forward toward inclusion and equal opportunities in digital reading. However, it is recognized that there is a need to continue researching and refining these tools, incorporating new technologies and expanding validation to different contexts and user groups.

D. Limitations and Scope for Future Research

Although this study employed a systematic method based on design thinking, there are some limitations that should be considered, which open opportunities for future research. While the design of the proposed application prioritizes ease of use, expert evaluation indicated that some advanced options, such as text difficulty analysis or detailed customization, may present a learning curve for users with less technological experience or for older adults. In addition, the evaluation was conducted through heuristic analysis with a limited number of experts; therefore, future research should include empirical validation with actual users from diverse age groups, educational levels, and sociocultural backgrounds to confirm the design effectiveness.

Another relevant aspect is data privacy and security, especially regarding the storage and handling of personal or sensitive texts. Future implementation should incorporate robust data protection mechanisms and consider user perceptions of confidentiality in digital reading applications based on established privacy frameworks. Likewise, it would be valuable to investigate the integration of the application with other educational platforms and support tools, as well as the adaptation of the interface and features to different devices and operating systems to ensure an accessible and consistent experience in any environment.

Finally, future empirical studies are recommended to investigate the actual impact of the implemented application on the long-term development of reading skills, as well as on the motivation and autonomy of people with dyslexia. The incorporation of new technologies, such as artificial intelligence for automatic personalization and progress tracking, represents a promising line for future development aimed at the continuous improvement of accessibility and inclusion in digital reading.

III. Conclusion

In conclusion, the proposed prototype aims to simplify and enhance the digital reading experience for people with dyslexia, addressing the most common challenges such as lack of personalization, limited accessibility, and the absence of

intelligent support. The designed application integrates advanced text customization features, read-aloud functionality, guided mode, and difficulty analysis, with the potential to allow users to adapt reading to their individual needs and preferences. By combining these tools with an intuitive, user-centered interface design, the prototype proposes a smoother, more autonomous, and motivating reading experience.

This study did not involve direct participation of individuals with dyslexia in data collection or evaluation activities. User insights were obtained exclusively from published research and documented experiences. Expert heuristic evaluation was conducted by professional accessibility specialists, not by end users. Therefore, this research did not require ethics committee approval at this stage. Future empirical validation with actual users will require appropriate ethical clearance.

ACKNOWLEDGMENT

We would like to express our special gratitude to Universidad Científica del Sur (UCSUR) for the academic support and institutional collaboration provided throughout this research. We also acknowledge the valuable insights gained from published research and published research findings and documented user experiences available in academic literature and dyslexia support community resources, which informed the conceptual design process without direct participant involvement. Finally, we extend our appreciation to our families for their constant encouragement and support throughout this project.

Vegetation Identification in Hyperspectral Images of Cartagena City Using the Haar Wavelet Transform

Gabriel Elías Chanchí Golondrino[1], Manuel Alejandro Ospina Alarcón[2], Manuel Saba[3]
Faculty of Engineering-Systems Engineering Program, University of Cartagena, Cartagena, Colombia[1, 2]
Faculty of Engineering-Civil Engineering Program, University of Cartagena, Cartagena, Colombia[3]

***Abstract*—Hyperspectral imaging is one of the most widespread remote sensing techniques in earth observation, corresponding to images with high spectral and spatial resolution that enable material detection through the identification of their spectral signature. A key challenge in hyperspectral imaging is the definition of novel and efficient computational methods that contribute to reducing computational cost while maintaining the efficacy and precision in material detection provided by methods such as correlation or machine learning. This study aims to propose a new efficient method for vegetation detection in hyperspectral images based on the similarity between the approximate and detailed components of the Haar wavelet transform of the vegetation spectral signature, with respect to the components of the pixel to be classified in the image. For the development of the present investigation, five methodological phases were defined: P1. Selection of sample pixels for vegetation and other materials; P2. Determination of the characteristic vegetation pixel; P3. Implementation and evaluation of the method with vegetation and non-vegetation pixels; P4. Deployment of the method on the reference hyperspectral image; P5. Comparative evaluation of the proposed method against the correlation method. As a result of this research, a novel computational method for vegetation identification in hyperspectral images was proposed, leveraging the similarity of wavelet transform components. This method demonstrated comparable detection efficacy to the correlation method and proved to be approximately 5% more efficient in the detection process. The proposed method can be suitably integrated into hyperspectral image-based environmental monitoring systems, particularly where images are of considerable size and more efficient methods are required.**

***Keywords*—Vegetation detection; hyperspectral images; remote sensing; wavelet transform; earth observation**

I. Introduction

Remote sensing is a set of techniques that make it possible to observe the Earth's surface without direct contact; sensors on satellites [1], [2], airplanes, drones, or ground-based instruments [3], [4] get electromagnetic energy reflected by different materials, such as visible, infrared, and microwave radiation [5]. These systems provide fast access to large areas and help lower the time and cost of ground measurements [3], [6].

This technology also gives access to information that humans cannot see directly, as it shows soil conditions, vegetation health, and atmospheric properties; such data supports better decisions in natural-resource management [7], [8]. Within remote sensing, hyperspectral imaging has become one of the most used techniques [9] because it includes many narrow spectral bands that let users distinguish materials with high precision [10], [11].

Unlike multispectral images, hyperspectral data cubes have many more bands and show the unique spectral signature of each surface material [12], [13]. A hyperspectral image is a three-dimensional data cube [14], [15], where the first two dimensions show spatial location and the third shows reflectance as a function of wavelength [16], [17].

Hyperspectral imaging plays an important role in environmental and agricultural studies. For example, it helps identify tree species and supports biodiversity planning [18]. It lets researchers detect salt crusts in estuaries and follow climate-related patterns [19]. It also helps monitor vegetation changes through time using multisensor data and clustering methods [20].

Other applications include mapping biodiversity with NDVI and autoencoders [21], detecting microplastics [22] and supporting the management of water resources [23]. In agriculture, hyperspectral images help detect diseases early [24], classify multiple crop types [25], [26], and show product quality in a non-destructive way [27]-[29]. They also support soil and crop characterization tasks [30], [31].

However, hyperspectral images bring several challenges. They contain large volumes of redundant data, which need dimensionality-reduction methods [32], [33]. Machine learning and deep learning methods often get good results but need big annotated datasets, high processing power, and complex architectures [34], [35]; these requirements make them difficult to use in real-time environmental monitoring.

For vegetation detection, correlation-based approaches [36] and learning-based methods [20] seem to be the most common choices. Still, they leave open questions about efficiency, data needs, and operational cost. Because of this, there is a need for solutions that keep detection accuracy while cutting computational load.

Building on this, the present study uses the similarity between the approximate and detailed components of the Haar wavelet transform to detect vegetation in hyperspectral images. The Haar transform provides a simple structure that lets users break a signal into low- and high-frequency components [37], [38], which can show features relevant for material discrimination [39], [40].

This work uses open-source Python libraries (spectral, PyWavelets, numpy, pandas, matplotlib) to evaluate the method

with 100 sample pixels (vegetation and non-vegetation). After estimating the detection threshold, the method is applied to a hyperspectral image from Cartagena City (750×850 pixels, 380 bands) and is compared to the correlation method.

Beyond performance, this method can help researchers and practitioners who need efficient tools for large-scale environmental monitoring systems. The use of open-source libraries makes the method easier to replicate and adopt in academic and commercial settings.

Despite the wide range of applications of hyperspectral imaging, vegetation detection still relies predominantly on correlation-based approaches or machine learning models that require large annotated datasets and high computational cost. These methods are accurate but often inefficient when processing large hyperspectral scenes, which limits their integration into operational environmental monitoring pipelines. Consequently, there is a need for computationally efficient alternatives that preserve detection capability while reducing processing time.

To address this gap, this study proposes a new method for vegetation detection based on the similarity between the approximate and detailed components of the Haar wavelet transform of the vegetation spectral signature. The main contributions of this work are:

1) A wavelet-based vegetation detection strategy that reduces dimensionality while preserving spectral structure;

2) A threshold estimation procedure based on combined similarity metrics; and

3) A comparative evaluation against the widely used correlation method in terms of detection accuracy and computational efficiency.

The remainder of the study is organized as follows: Section II presents the literature review and problem statement. Section III describes the methodological phases considered for the development of this research. Section IV presents the results obtained in this study, including the calculation of the approximate and detailed components of the characteristic vegetation pixel; the implementation and evaluation of the method with vegetation and non-vegetation sample pixels to identify detection thresholds; and the deployment of the method on the reference hyperspectral image, comparing its effectiveness and efficiency with the correlation method. Section V presents a discussion of the results, analyzing them in relation to the reviewed literature. Finally, Section VI outlines the conclusions derived from this research.

II. Literature Review and Problem Statement

Unresolved questions are related to the need for very large annotated datasets. The reason is that collecting and labeling such datasets is costly and often unfeasible in many agricultural contexts.

The study [18] demonstrates hyperspectral imaging for identifying tropical tree species. It is shown that the approach is effective at the local scale, but unresolved issues include transferability, since the method relies on curated spectral libraries that are difficult to build for large and diverse ecosystems.

In [20], the authors introduce a multi-sensor framework for detecting vegetation changes. It is shown that temporal dynamics can be effectively captured. However, unresolved questions arise from operational complexity and costs, because the approach requires repeated multi-temporal acquisitions.

The study [21] combines convolutional autoencoders with vegetation indices to map biodiversity. It is shown that detailed and high-resolution outputs can be obtained, but unresolved questions include the need for intensive computational resources and large labeled datasets, which limit its applicability in practice (see Table I).

TABLE I. Summary of Recent Studies on Hyperspectral Vegetation Analysis

Ref.	Year	Features		
		Method	***Application***	***Limitations***
[32]	2009	General hyperspectral image processing	Foundational techniques	High dimensionality and redundancy
[19]	2014	Hyperion imagery for salt crust mapping	Estuarine monitoring	Dependence on atmospherics correction models
[25]	2015	Non-destructive analysis of agricultural products	Stored food quality	Expensive hardware and limited scalability
[22]	2020	Deep learning on microscopic hyperspectral data	Microplastic detection	Limited generalization to field data
[23]	2021	Multi/hyperspectral analysis for water quality	Aquatic environments	Computational bottlenecks for real-time use
[26]	2021	Deep learning for agricultural hyperspectral data	Crop disease detection	Requires large labeled datasets
[18]	2022	Hyperspectral imaging of tropical trees	Biodiversity analysis	Reliance on curated spectral libraries
[20]	2024	Multi-sensor change detection	Vegetation monitoring	High operational complexity and cost
[21]	2024	Autoencoders vegetation indices	Biodiversity mapping	Intensive computational resources

The above analysis of the literature review allows to argue that it is appropriate to conduct a dedicated study on computationally efficient vegetation detection methods.

Limitations presented in Table I highlight the need for more efficient spectral processing techniques that can maintain analytical accuracy while reducing the time and cost associated with hyperspectral data interpretation.

The approach proposed in this study, based on Haar wavelet decomposition, directly addresses these gaps by offering a balanced, computationally efficient alternative for vegetation detection.

III. METHODOLOGY

The proposed vegetation detection method is designed as a sequential and reproducible workflow. Although the detailed description is presented through five methodological phases, the overall procedure can be summarized as follows: selection of representative vegetation and non-vegetation pixels; construction of a characteristic vegetation spectral signature; wavelet-based decomposition of spectral data; similarity analysis and threshold determination; and pixel-wise deployment of the method on the full hyperspectral image, followed by a comparative evaluation with the correlation method. The complete workflow and its individual phases are detailed below and summarized in Fig. 1.

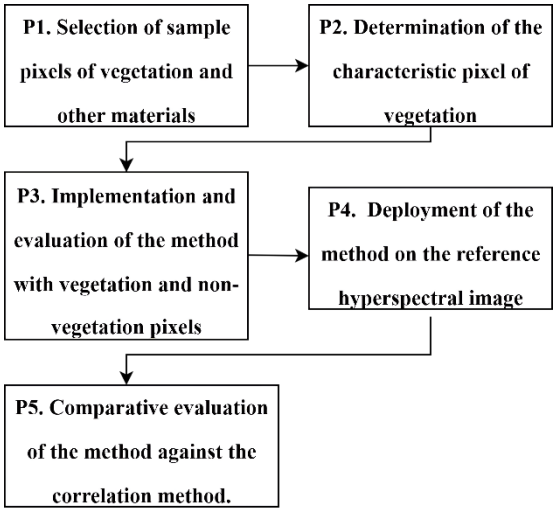

Fig. 1. Considered methodological phases. The diagram summarizes the complete workflow of the proposed vegetation detection approach.

For the development of this research, five methodological phases were defined as follows in Fig. 1. This diagram summarizes the workflow of the proposed approach, allowing one to understand the sequence of processes from data acquisition to vegetation detection and performance evaluation:

- P1. Selection of sample pixels representing vegetation and other materials.
- P2. Determination of the characteristic vegetation pixel.
- P3. Implementation and evaluation of the method using vegetation and non-vegetation pixels.
- P4. Deployment of the method on the reference hyperspectral image.
- P5. Comparative evaluation of the method against the correlation method.

In Phase 1 of the methodology, using a hyperspectral image of the city of Cartagena, Colombia, with 750 x 850 pixels and 380 reflectance bands per pixel, a set of 50 sample pixels corresponding to vegetation and 50 pixels corresponding to other materials were visually inspected and selected. This process aimed to obtain the spectral signature of vegetation and evaluate the method with vegetation and non-vegetation pixels.

The sampling strategy was designed to capture representative spectral signatures while avoiding oversampling effects that may reduce separability in threshold-based similarity analysis.

Once the vegetation and non-vegetation pixels were selected, Phase 2 involved calculating the characteristic vegetation pixel by averaging the normalized reflectance values of the 50 vegetation pixels band by band.

In Phase 3 of the methodology, the determination of the approximate and detailed components of the Haar wavelet transform for the characteristic vegetation pixel was initially performed using Eq. (1) and Eq. (2). The approximate components of the Haar wavelet transform are given by Eq. (1):

$$A_i = \frac{r_{2i-1} + r_{2i}}{\sqrt{2}}, i = 1,2,\ldots,190 \quad (1)$$

where, Eq. (1) defines the approximate components Ai of the Haar wavelet transform, which are derived from an array of 380 values corresponding to the normalized reflectance associated with the 380 bands of the characteristic vegetation pixel or spectral signature ($R = [r_1, r_2, r_3 \ldots, r_{380}]$). It is important to note that, since the Haar wavelet transform operates on consecutive pairs, the array of approximate components Ai consists of a total of 190 elements, equivalent to half of the 380 reflectance bands.

The detailed components of the Haar wavelet transform are expressed as Eq. (2):

$$D_i = \frac{r_{2i-1} - r_{2i}}{\sqrt{2}}, i = 1,2,\ldots,190 \quad (2)$$

Eq. (2) defines the detailed components Di of the Haar wavelet transform, which also begins with an array of 380 normalized reflectance values from the characteristic pixel and produces an array Di consisting of 190 values. This reduction occurs because, for the detailed component as well, the Haar transform operates on consecutive pairs.

Using the components obtained through Eq. (1) and Eq. (2), an iteration was performed over the 50 vegetation sample pixels and the 50 pixels representing other materials, calculating the approximate and detailed components of the wavelet transform for each pixel.

Through the use of Euclidean distance, a similarity percentage was determined for each component of each pixel, and a combined similarity percentage was calculated for both components.

The process aimed to identify the minimum combined similarity percentage with vegetation pixels and the maximum combined similarity percentage with pixels of other materials. These thresholds enable the assessment of potential overlap between the two, and in the absence of overlap, the detection or differentiation capability of the method can be established, along with the threshold to be considered for deploying the method on the entire reference image.

Phase 4 involved deploying the method on each pixel of the reference hyperspectral image (Once the vegetation detection threshold was identified in Phase 3). For each pixel, the wavelet transform components were obtained, and the similarity percentages for each component, as well as the combined

similarity percentage were calculated. The combined percentage was then used to classify each pixel in the image as either vegetation or another material.

Additionally, in this phase, the number of pixels detected by the method was counted, and the percentage of pixels within the hyperspectral image corresponding to this count was calculated.

Finally, in Phase 5, the correlation method was implemented after detecting the reference thresholds, and both the number of vegetation pixels and the percentage corresponding to this pixel count were determined. This allowed for a comparison of the effectiveness of the proposed method with the correlation method.

Furthermore, in this phase, the computational efficiency of both methods was evaluated by performing a total of 20, 40, 60, 80, and 100 executions on a 50x50-pixel region of the image, each pixel containing 380 bands. For each method, the average execution time per number of runs and the total average time were calculated, enabling a comparison of the computational efficiency of one method relative to the other.

IV. Results

A. Selection of Pixels and Construction of a Characteristic Vegetation Signature

A hyperspectral image of Cartagena City with a resolution of 750 by 850 pixels and 380 spectral bands was used. From this image, 50 vegetation pixels and 50 non-vegetation pixels were manually selected for the evaluation phase.

Fig. 2 shows the RGB visualization of the hyperspectral scene with the manually selected vegetation (green) and non-vegetation (blue) pixels. This visual separation allows verifying that both classes are spatially well distributed across the study area, ensuring that the sample is suitable for computing representative spectral signatures and for estimating detection thresholds.

From the 50 manually selected vegetation pixels, individual spectral signatures were extracted to analyze their variability, as shown in Fig. 3. Fig. 3 shows the dispersion of reflectance values across the spectral bands, highlighting the natural spectral variability of vegetation within the study area.

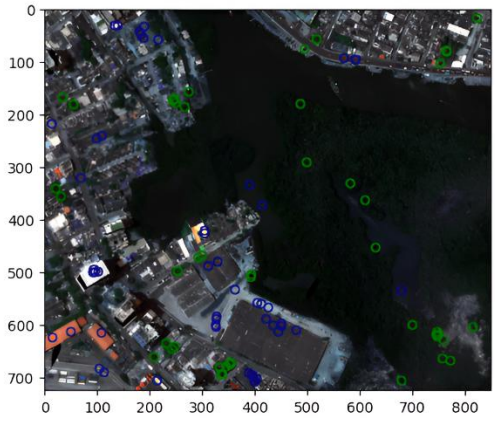

Fig. 2. Selected vegetation and non-vegetation pixels in the RGB rendering of the hyperspectral scene. The labeled samples provide the reference spectral signatures used to estimate similarity thresholds for vegetation detection.

To obtain a stable and representative reference for subsequent analysis, a characteristic vegetation pixel was computed by averaging the spectral signatures of the 50 vegetation samples. The resulting average spectrum, shown in Fig. 4, preserves the general spectral structure of vegetation, while reducing noise and sample-specific fluctuations.

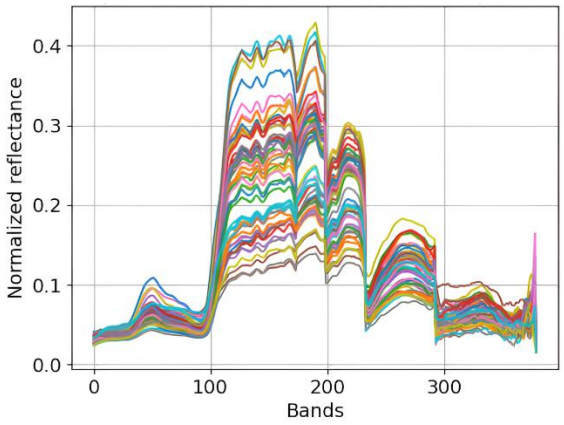

Fig. 3. Spectral signatures of the 50 selected vegetation pixels used to compute a representative reference signature.

The characteristic vegetation pixel shown in Fig. 4 plays a key role in the proposed method, as its wavelet components are compared with those of each pixel in the hyperspectral image (Fig. 1) to determine the presence of vegetation through a similarity analysis.

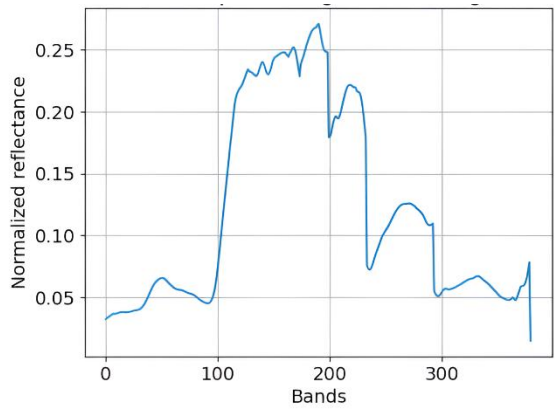

Fig. 4. Spectral signatures of characteristic vegetation pixel used for wavelet decomposition.

B. Wavelet Decomposition

Haar wavelet transform was applied to average (the characteristic) vegetation pixel shown in Fig. 4. This process generated two sets of coefficients: the approximate components (Ai) (see Fig. 5) and the detailed components (Di) (see Fig. 6), which are defined in Eq. (1) and Eq. (2), respectively.

Since the Haar transform operates by pairing consecutive reflectance values, each component contains 190 coefficients, corresponding to half of the original 380 spectral bands. The same transformation was then applied to all 100 sample pixels, including the 50 vegetation and 50 non-vegetation samples, using the characteristic vegetation pixel as the reference for similarity comparisons.

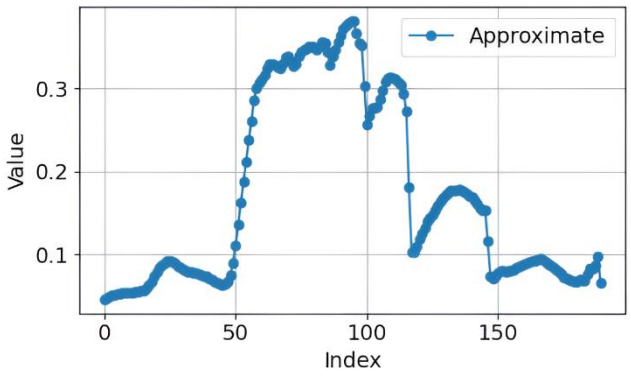

Fig. 5. Approximate component of the characteristic vegetation pixel. It represents the main trend of the vegetation signature after dimensionality reduction.

Fig. 5 shows the approximate component of the characteristic vegetation pixel. This component can be interpreted as a simplified representation of the original spectral signature, as it preserves the low-frequency information and captures the main spectral trend of vegetation while reducing data dimensionality.

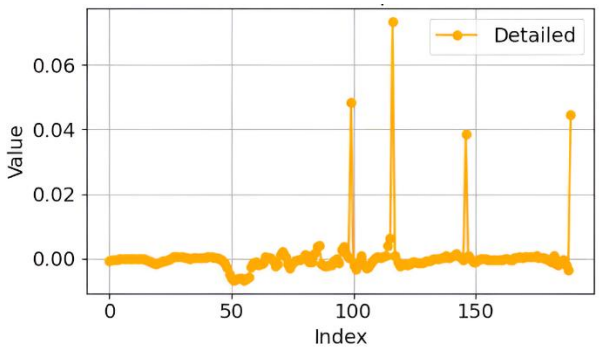

Fig. 6. Detailed component of the characteristic vegetation pixel. It captures local fluctuations between adjacent bands.

Fig. 6 shows the detailed component of the characteristic vegetation pixel. In contrast to the approximation, this component highlights high-frequency information by emphasizing local fluctuations between adjacent spectral bands, allowing the method to capture finer spectral variations relevant for discrimination.

C. Similarity Analysis

Once the transform components of the characteristic pixel were obtained, an iteration was performed over the 50 vegetation pixels and 50 pixels representing other materials to determine the approximate and detailed components for each pixel. Using these components, three similarities were calculated via Euclidean distance: the similarity between approximate components, the similarity between detailed components, and the weighted similarity between components. The results of the similarity analysis for the approximate and detailed components, comparing vegetation pixels with pixels from other materials, are presented in Fig. 7.

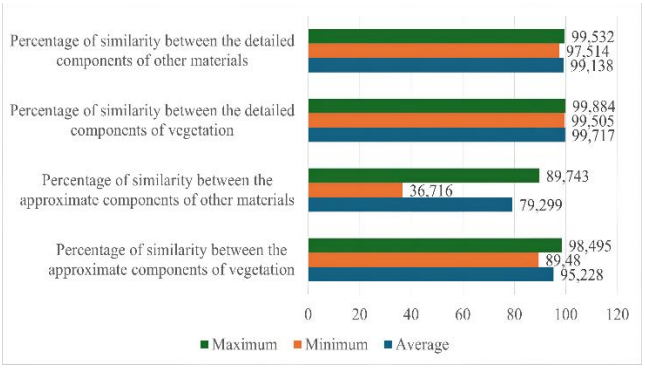

Fig. 7. Similarity percentages obtained for the approximate and detailed wavelet components when comparing vegetation and non-vegetation pixels.

As observed in Fig. 7, for the approximate component, the maximum similarity percentage obtained for non-vegetation pixels (89.743%) exceeds the minimum similarity percentage obtained for vegetation pixels (89.48%). This overlap indicates that the approximate component alone is not sufficient to reliably discriminate vegetation pixels. Similarly, for the detailed component, the maximum similarity percentage for non-vegetation pixels (99.532%) is higher than the minimum similarity percentage for vegetation pixels (99.505%), showing that this component by itself also fails to provide clear separation.

The results presented in Fig. 7 demonstrate that, although the coarse and fine components individually capture relevant spectral information, their isolated use does not allow for accurate vegetation discrimination. When both components are combined and greater weight is assigned to the fine component, the method becomes more sensitive to subtle spectral variations, allowing for more reliable classification and reducing detection errors.

D. Determination of Detection Thresholds

In light of the results presented in Fig. 7, where neither the approximate nor the detailed component alone provided sufficient discrimination, a weighted similarity measure was evaluated. The contribution of the detailed component was varied across different percentages (60%, 70%, 80%, 85%, 90%, 95%, and 98%), while the remaining weight was assigned to the approximate component.

The similarity results obtained for these weighted combinations, comparing vegetation and non-vegetation pixels, are presented in Fig. 8. This analysis allows identifying the weighting configurations that maximize the separation between both classes and serves as the basis for selecting an appropriate detection threshold.

As shown in Fig. 8, the only weighting configuration in which the minimum similarity percentage for vegetation pixels is lower than the maximum similarity percentage for non-vegetation pixels corresponds to a 60% contribution of the detailed component. For higher weight values, a clearer separation between both classes is observed.

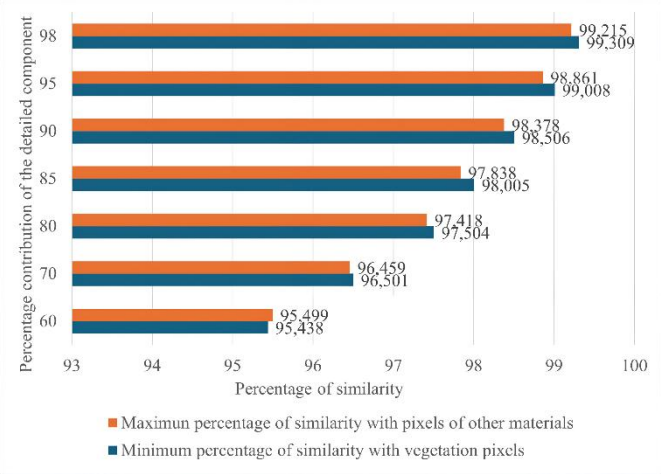

Fig. 8. Similarity percentages obtained for different weightings of the approximate and detailed wavelet components; supports the selection of the detection threshold.

It is noteworthy that the greatest differentiation between vegetation and non-vegetation similarities is achieved when the detailed component has a weight of 95% and the approximate component a weight of 5%, resulting in a percentage difference of 0.147%. Based on this result, the minimum detection threshold for identifying vegetation pixels was established at a similarity value of 99.008%, corresponding to a 95% contribution of the detailed component of the Haar wavelet transform.

Setting this threshold matters, because it turns the method into something practical and measurable. It defines a clear decision line that helps distinguish vegetation from other materials with confidence. The results also show that the Haar based decomposition can create thresholds with very little uncertainty, which is important for building scalable systems that rely on automated classification in environmental monitoring.

E. Large-Scale Deployment and Comparative Evaluation

Using the detection threshold of 99.008% (Fig. 8), the proposed method was deployed across the entire hyperspectral image (Fig. 1) of Cartagena City (750 × 850 pixels, 380 bands).

As shown in Fig. 9, for each pixel in the image, the approximate and detailed components of the wavelet were calculated, similarity scores were calculated with respect to the characteristic vegetation pixel, and a final classification into vegetation or non-vegetation was made.

The implementation was carried out exclusively with open-source Python libraries (spectral, PyWavelets, numpy, pandas, and matplotlib).

As a result, the method determined that 42.95% of the hyperspectral image corresponds to vegetation pixels. Fig. 9 presents the vegetation map generated by the proposed method, where detected vegetation areas are highlighted in blue, visually demonstrating the capability of the Haar wavelet transform measure to discriminate vegetation from other materials.

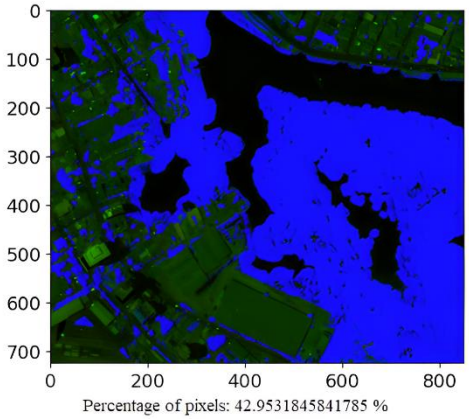

Fig. 9. Vegetation detection method applied to the entire hyperspectral image; final classification is performed.

To evaluate the performance of the proposed method, the traditional correlation-based approach was also applied to the same hyperspectral image (Fig. 1), once its corresponding detection threshold was defined. Fig. 10 illustrates the deployment of the correlation method across the entire scene, while Table II summarizes the vegetation detection results obtained with both techniques.

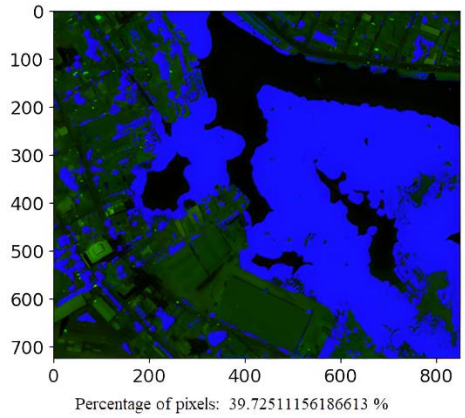

Fig. 10. Vegetation detection map obtained by applying the correlation method to the entire hyperspectral image, used for comparison with the wavelet approach.

The results presented in Fig. 10 and Table II shows that both methods achieve comparable levels of detection accuracy. In particular, the percentage of vegetation pixels detected by the proposed method was 39.72%, which is close to the result obtained with the correlation method, yielding a percentage difference of 3.23%.

TABLE II. VEGETATION DETECTION RESULTS OF THE PROPOSED METHOD VS. CORRELATION METHOD

Method	Vegetation pixels detected	Vegetation percentage
Haar wavelet transform	273488	42.95%
Correlation method	252101	39.72%

The above results indicate that the proposed method provides detection performance comparable to that of the correlation approach, while offering a computationally efficient alternative for environmental monitoring using hyperspectral imagery.

F. Computational Efficiency and Replicability

To evaluate the computational efficiency of the proposed method in comparison with the correlation-based approach, both methods were executed multiple times (20, 40, 60, 80, and 100 executions) on the same reference image region of 50 × 50 pixels with 380 reflectance bands.

The objective of this experiment was to estimate the average execution time as a function of the number of runs for each method, as well as the overall computational behavior under repeated executions. Fig. 11 presents the average execution time curves obtained for both methods.

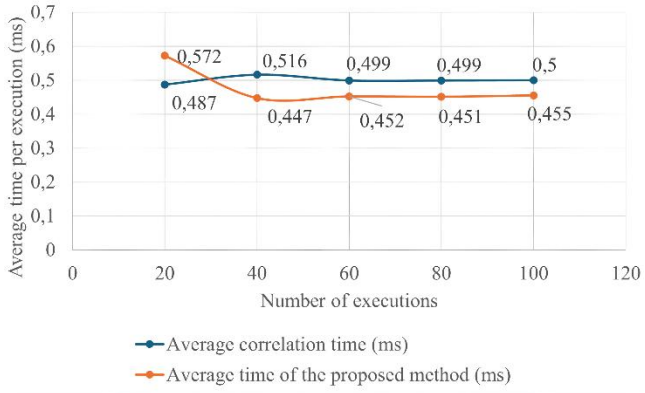

Fig. 11. Average execution time comparison between the proposed wavelet-based method and the correlation-based method for different numbers of executions.

As shown in Fig. 11, the proposed method exhibits a slightly higher average execution time than the correlation method only in the case of 20 executions. For all other evaluated scenarios, the proposed method remains below 0.455 ms and consistently shows lower average execution times as the number of executions increases, indicating better computational efficiency under repeated processing conditions.

It is evident that the average execution time for the correlation method fluctuates around 0.5 ms. By averaging the execution times of both methods and comparing these averages, it is determined that the correlation method is 1.05 times slower than the proposed method, meaning the proposed method is, on average, 4.96% more efficient than the correlation method. While this percentage may be considered small, it could have a greater impact when processing large images, such as those associated with environmental monitoring processes based on hyperspectral imaging.

Centered on the above, Fig. 11 makes it clear that, although the proposed method starts out slightly slower in 20 executions, it becomes increasingly faster as the number of executions increases.

V. Discussion

It is important to highlight that this research contributed a new method for detecting vegetation and materials in hyperspectral images based on the similarity between the approximate and detailed components of the Haar wavelet transform of the characteristic pixel and a given pixel in the image.

From the results obtained during the implementation and evaluation of the method, it was found that, compared to the correlation method, which has been widely disseminated for vegetation detection in hyperspectral images [36], the proposed method was equally effective in detecting vegetation and 4.958% more efficient. This efficiency improvement can result in significant time savings when processing large-volume images, such as those used in environmental monitoring of extensive areas.

From a comparative perspective, the obtained results are consistent with previous studies that have successfully applied similarity-based techniques for vegetation detection in hyperspectral images. Correlation-based approaches have been widely used as reliable baselines in hyperspectral analysis [36], achieving high detection accuracy at the expense of increased computational cost. The comparable detection performance obtained by the proposed method, together with its improved computational efficiency, aligns with recent research efforts focused on reducing processing complexity while preserving spectral discrimination capability.

In contrast to machine learning and deep learning approaches reported in the literature, which often require large annotated datasets and extensive training procedures [34], [35], the proposed method emphasizes interpretability and operational efficiency. Similar trends toward lightweight and data-efficient hyperspectral analysis methods have been reported in studies using dimensionality reduction and transform-based representations [37]–[40], supporting the relevance and practical value of the proposed wavelet-based similarity framework.

From a methodological perspective, in similarity- and threshold-based approaches, increasing the number of sample pixels does not necessarily improve discrimination performance. On the contrary, excessive sampling may lead to saturation of the similarity space and increased overlap between vegetation and non-vegetation classes, making threshold definition more difficult. The sampling strategy adopted in this work was therefore designed to balance representativeness and separability. This explains the stable behavior of the proposed method across different weighting configurations and threshold values, as observed in the experimental results.

Regarding parameter selection, in similarity- and threshold-based detection methods, parameter selection plays a critical role in balancing class separability and robustness. In the proposed approach, the most influential parameters are the weighting coefficients assigned to the approximate and detailed wavelet components, as well as the detection threshold. The results presented in Section IV show that the method exhibits stable behavior within a wide range of weighting configurations for the detailed component (85%–98%), while lower values

increase overlap between vegetation and non-vegetation similarity ranges. This indicates that the method is not overly sensitive to minor parameter variations but operates within a clearly defined and interpretable parameter space. Extreme parameter configurations, such as assigning insufficient weight to the detailed component or relaxing the detection threshold, lead to reduced discrimination capability, which is consistent with the nature of similarity- and threshold-based classification methods.

Also, since the proposed method was implemented using open-source libraries and tools, this research holds significant value both academically and commercially, facilitating the adoption and utilization of these technologies in the processing and analysis of spectral images. This not only reduces the costs associated with proprietary tools but also enables the customization of methods and the hybridization of different techniques to meet specific needs.

In this way, the proposed method serves as a key contribution for research centers and universities in developing countries, promoting the replication and expansion of studies involving hyperspectral images. This is particularly relevant as previous research conducted with proprietary tools such as ENVI has demonstrated their utility in this field [41], [42]. The use of open-source alternatives could further enhance accessibility and foster innovation in such studies.

It is important to note that the objective of this study is not to provide a large-scale benchmark across multiple hyperspectral datasets, but to demonstrate the feasibility and effectiveness of a wavelet-based similarity approach for vegetation detection. The use of a single representative hyperspectral scene and a carefully selected set of sample pixels is consistent with threshold-based methods, where the focus is on spectral behavior and separability rather than statistical learning. While additional scenes could further validate robustness across different conditions, the presented results sufficiently support the methodological contribution and computational advantages of the proposed approach.

Although machine learning and deep learning approaches have shown strong performance in hyperspectral vegetation detection, they typically require large annotated datasets, high computational resources, and complex training procedures. The objective of this work is different: to provide a lightweight, interpretable, and computationally efficient alternative suitable for scenarios where labeled data and processing resources are limited. For this reason, the proposed method was compared against the correlation-based approach, which is one of the most widely used similarity-based techniques in hyperspectral analysis and represents a fair baseline in terms of operational complexity.

Regarding noise and illumination variability, the proposed method relies on normalized spectral signatures and on the Haar wavelet transform, which decomposes the signal into approximate (low-frequency) and detailed (high-frequency) components. This decomposition inherently reduces sensitivity to global illumination variations captured in the low-frequency component, while preserving discriminative spectral patterns in the detailed component. Although an explicit noise robustness analysis is beyond the scope of this study, the wavelet-based representation is known to provide increased robustness against high-frequency noise compared to direct spectral similarity measures.

VI. Conclusion

Considering that vegetation detection in the domain of hyperspectral images has primarily relied on methods based on correlation and machine learning, which, although accurate, require high computational costs, this study proposed a novel computationally efficient method in the same domain. The proposed method is based on the similarity between the wavelet transform components of the characteristic vegetation pixel and the components of the pixel being analyzed in the image. Given the results obtained in terms of both effectiveness and efficiency, the method can be integrated into academic and commercial contexts within systems for monitoring environmental variables using hyperspectral images.

The results obtained in this research determined that, although the similarity between the approximate and detailed components of the characteristic pixel and the sample pixels showed overlap or proved unsuitable for vegetation detection when considered individually, the similarity percentage based on the weighting of the components is more effective and does not exhibit overlap in the thresholds obtained for vegetation and other materials. The best detection threshold is achieved when the weight of the detailed component is 95%, and the weight of the approximate component is 5%. Thus, the proposed method proves effective through the combined weighting of the similarities, establishing 99.008% as the minimum detection threshold for vegetation. Based on this, the proposed method was successfully applied to the entire reference image, yielding detection results comparable to those of the correlation method.

In line with the above, the deployment of the proposed method on the hyperspectral image of a representative area in the city of Cartagena determined that 42.953% of the pixels correspond to vegetation, with a percentage difference of only 3.23% compared to the correlation method. This demonstrates that the proposed method is a valid and reliable alternative for environmental variable monitoring systems, providing results comparable to existing methods. Furthermore, these results are particularly relevant for continuous monitoring of the areas studied in Cartagena, allowing for an accurate assessment of the impact of urban development on vegetation and, by extension, the environment. This highlights the importance of implementing monitoring tools that enable the understanding and mitigation of the effects of urban growth over time.

In evaluating the computational efficiency of the proposed method compared to the correlation-based method, multiple executions (20, 40, 60, 80, 100) were performed on a region of the reference hyperspectral image measuring 50x50 pixels with 380 reflectance bands. The results showed that, on average, the correlation method is 1.05 times slower than the proposed method, indicating that the proposed method is approximately 4.96% more efficient. While this improvement in efficiency may appear modest at first glance, it becomes significant when processing large-volume hyperspectral images, such as those generated by systems monitoring environmental changes or vegetation shifts through remote sensing, enabling optimization of processing times.

This research demonstrated the relevance and feasibility of using open-source tools and technologies for processing and implementing computational methods for detecting vegetation and other materials in the domain of hyperspectral images. In this context, the spectral library proved useful for accessing the reflectance band data of the reference hyperspectral image. The PyWavelets library enabled the implementation of the proposed method by obtaining the approximate and detailed components of the Haar wavelet transform. The numpy library was essential for accessing and handling hyperspectral image data, facilitating data normalization, image iteration, and the implementation of the correlation method. The pandas library supported the loading of points corresponding to vegetation pixels and other materials. Finally, the matplotlib library was used to generate graphs associated with reflectance curves and the curves corresponding to the components of the characteristic pixel. These technologies can thus be employed to replicate experiments with spectral images in academic and commercial domains, while also enabling the development of new detection methods.

As future work derived from this research, the wavelet transform is intended to be used to obtain a condensed representation of the spectral signature, allowing this summarized signature to be hybridized with other detection methods, such as the Fourier similarity method or the differential similarity method. Additionally, the proposed method will be evaluated for detecting water bodies or other types of materials in various application contexts.

***Abstract*—The rapid pace of climate change has altered the distribution of animal diseases, increased their frequency, and dispersed them over a larger geographic area. Rising temperatures, fluctuating humidity, and erratic rainfall patterns have increased the risk of illness in cows. These modifications have facilitated the growth of diseases and vectors. As a result, timely and accurate identification of these illnesses has become crucial for both food security and sustainable animal health management. To detect and classify animal diseases using visual data, this study proposes a diagnostic framework that utilizes machine learning approaches, with a focus on convolutional neural networks (CNNs) in conjunction with classification models, including ResNet, YOLOv5, and AltCLIP. By learning to distinguish between healthy and sick animals, the model enables prompt identification and treatment of sick animals. Merging data on disease detection with climate parameters, we make comparisons between them to get the best result and use this to generate advanced tools for detecting diseases. This informs us about potential risks. According to the results, machine learning-based diagnosis can improve disease detection's accuracy and efficiency while also providing important new information for climate adaptation strategies in cattle management. The optimal model will produce a graphical user interface (GUI) that displays environmental risk scores, diagnostic data, and recommendations for actions such as monitoring the situation, seeking immediate veterinary care, or verifying the animal's health.**

***Keywords*—Climate change; environmental health; convolutional neural network (CNN); animal diseases; graphical user interface (GUI)**

I. Introduction

To prevent epidemics and safeguard the health of animals, illness prediction is crucial. Farmers can avoid suffering and financial loss by taking preventive action as soon as possible, thanks to early detection. Additionally, it contributes to the preservation of wildlife, the food chain, and global health initiatives [1]. Predicting illnesses also encourages research and development, which results in new treatments and vaccines.

A. Significance of Disease Prediction

Anticipating potential illness in animals is essential for epidemic management and the preservation of animal health [2, 3]. Timely detection allows farmers to swiftly adopt preventive strategies, thereby reducing their distress and economic losses. Furthermore, it protects animals, supports global health security efforts, and guarantees the integrity of the food supply chain.

B. The Essence of Disease Prediction in Animals

A proactive approach to ensure animal health is to anticipate potential diseases. It functions as a sentinel, identifying potential health concerns prior to their emergence [4]. Prompt intervention can mitigate distress and financial expenditure due to this prior awareness [5]. It strengthens the foundations of our food supply chain to guarantee its safety and reliability, akin to a sentinel. Furthermore, it maintains the complex network that illustrates the interdependence of all life by linking the well-being of humans, animals, and the environment. This proactive strategy fortifies against developing health challenges, enhances compliance with regulations, and elevates awareness of ethical pet ownership [6]. Disease prediction serves as a beacon, guiding humans and animals towards more harmonious and healthier coexistence. Forecasting animal diseases is an essential aspect of a robust ecosystem in its own distinct manner [7].

Preserving the equilibrium between nature and human endeavors contributes to the safeguarding of endangered species and the vitality of animal populations [8]. It functions as a vigilant sentinel, identifying and mitigating zoonotic threats to safeguard global health security and avert possible pandemics. This proactive strategy also cultivates innovation, leading to the development of novel vaccinations, medicines, and diagnostic tools [9]. Disease prediction underscores the need for early identification and treatment by cultivating a culture of readiness and accountability through continuous vigilance. Ultimately, it illustrates our collective commitment to enhancing the quality of life for all and fostering global peace.

C. Machine Learning's Role in Disease Prediction

The Principles of Predicting Animal Diseases: By predicting animal diseases, we can protect their health before they happen. Machine learning is poised to become an integral part of clinical diagnosis, enhancing the accuracy and efficiency of medical evaluations and treatments. [10]. It looks out for your health problems before they happen, like a guardian angel. This knowledge lets you respond quickly, which reduces pain and financial loss [11]. It guards the pillars of our food supply chain like a sentinel to make sure it is secure and reliable [12]. It also protects the complex network that connects the health of people, animals, and the environment, showing how all living things are connected. This progressive approach also makes people more likely to follow the rules, learn more about how to care for pets, and protect us all from new health problems. Essentially, predicting disease is like a beacon that shows people the road to

a calm and healthy life [13]. For disease prediction, machine learning is very important since it uses data to find patterns and make accurate predictions. It lets you look at a lot of data, from genetic markers to environmental factors, to find early signs of illness [14]. Machine learning models can find little connections that people would miss by using advanced algorithms [15]. This makes it possible to create predictive models that can figure out how likely it is that a person or group of people will get sick. Also, these models can change and get better over time as more data is collected, making them more reliable and accurate. Machine learning changes how people understand and process information. It is also a powerful tool for keeping an eye on and stopping diseases before they happen. This leads to better results for both people and animals. The effects of climate change on diseases affecting cattle and other animals, along with the introduction of novel infectious organisms, remain inadequately researched.

II. Literature Review

A. Applications of Machine Learning in Animal and Veterinary Public Health Surveillance

Machine learning (ML) is a type of artificial intelligence that employs algorithms to improve its ability to reach a certain goal (such as categorization or prediction) directly from the data itself, without needing explicit and detailed instructions on how to do so [17]. Monitoring systems for zoonotic and animal diseases depend on a range of tasks being done well, and some of these tasks can be done by machine learning algorithms. Machine learning has become a lot more common in veterinary and animal public health surveillance in the past few years, just like it has in other fields. ML algorithms are being used to solve tasks that were unfeasible before big datasets, new ways to look at them, and more computing power were available.

B. Disease Prediction Using Machine Learning Algorithms: KNN and CNN

People today suffer from a variety of diseases because of their lifestyle choices and the environment. Therefore, it becomes crucial to predict the disease early on. However, the doctor finds it too challenging to provide an accurate diagnosis based just on symptoms. Making accurate disease predictions is one of the most challenging tasks [18]. To solve this issue, data mining plays a crucial role in disease prediction. The amount of data in medical science is growing significantly every year. The increasing amount of data in the medical and healthcare domains has made accurate medical data analysis beneficial for early patient care. To find concealed information in massive amounts of medical data, data mining employs sickness data. The patient's symptoms led us to provide a general illness prediction. Accurate disease prediction is achieved using machine learning techniques such as K-Nearest Neighbor (KNN) and convolutional neural networks (CNN). For prediction, a dataset of disease symptoms was required [16]. A person's daily routine and medical history are considered to make an accurate general illness diagnosis. With an accuracy of 84.5% in 2025, the role of machine learning in infectious disease early detection and prediction in the MENA region, CNN performs better than the KNN method in the general disease prediction task. Furthermore, compared to CNN, KNN uses more memory and time.

C. Comparative Study of IoT- and AI-Based Computing Disease Detection Approaches

The growth of several computing methods, such as cloud-, fog-, and edge-based Internet of Things (IoT) systems, has enabled the creation of intelligent sickness detection systems. Because models using deep learning have outperformed shallow learning when handling large volumes of data, the research community has focused more on them than on other machine learning models [19]. However, there hasn't been a comprehensive examination of computer-based and Internet of Things-related systems that employ deep learning techniques for disease diagnosis. To assess different machine learning and deep learning algorithms, as well as their hybrid and optimized algorithms for IoT-based disease detection, this study used the most recent publications on IoT-based disease detection systems that utilize computing technologies, such as cloud, edge, and fog. Their work focused on an IoT architecture for deep learning that may be used to detect diseases. It also recognizes that to develop more efficient IoT sickness detection systems, researchers must concentrate on several factors. This work may be helpful to researchers who want to enhance hybrid IoT-based illness detection and prediction systems that rely on deep learning.

D. "Cattle Disease Identification Using Prediction Techniques"

In developing nations like India, Bangladesh, Nepal, and many others, dairy farming was one of the first forms of occupation. One of the main factors contributing to the increase in productivity in dairy production is dairy farm automation. Numerous illnesses can affect cattle, some of which can reduce output and the quality of dairy products [20]. If not detected early, these illnesses can also lead to livestock mortality, which is significantly hampered by the country's economy's steady growth [21]. Cattle are present in considerable numbers in dairy products. Taking care of them and monitoring the dairy cow's health is simply too difficult. Additionally, the dairy owner and the local government are crucial to this endeavor. The primary characteristic of a health management approach is the ongoing monitoring of each cow's health, prompt diagnosis, and early handling of ill animals. We track the fundamental elements of animal activity, such as temperature, heart rate, etc., using sensor technology. To determine whether an impending disease episode is anticipated, this data is combined and fed into a data mining algorithm. It increases the possible expenses of animal health care as well as the lowest level of veterinarian examination. This study offers a method that describes how IOT and data mining can be used to identify uncommon cow illnesses in farm animal hospitals with affordable treatment options. Animal Disease Prediction using Machine Learning Techniques. In recent years, there has been a significant increase in the variety of animal diseases. Many of these illnesses have a propensity to become zoonotic diseases, which can affect both humans and animals and prove to be highly contagious [22]. The study of having machines or computers learn on their own so that additional predictions can be made is known as machine learning, produced for a variety of uses [23]. Machine learning techniques for human disease identification have been around for a while, but there haven't been many developments for animal diseases. By using machine learning approaches to

categorize certain animal diseases and forecast their spread, we bring a novel contribution to the subject with this research study [24]. When animal sickness develops into zoonosis, it can significantly affect both human and animal populations. Therefore, as part of this investigation, we also employed specific methods to determine whether the illness is zoonotic. Keywords: classification, regression, machine learning, zoonosis, and research.

E. Artificial Intelligence and its Application in Animal Disease Diagnosis

The current study looks at the rules, history, subfields, and real-world applications of artificial intelligence in animal disease detection. There are two subfields of artificial intelligence (AI), or intelligence displayed by machines: machine learning and deep learning. In machine learning (ML), algorithms are used to find patterns in data and build a model for future forecasting [25]. Among the most popular algorithms are support vector machines, K-nearest, decision trees, random forests, and linear regression. The four categories of deep learning methods are sparse coding, restricted state machines, convolutional neural networks, and autoencoders [26]. One of the most widely used methods, Convolutional Neural Networks (CNN), automatically recognizes important elements without the need for human supervision. AlexNet, ZFNet, GoogLeNet, VGG-16, and other impressive CNN architectures were on display during the ImageNet Large Scale Visual Recognition Challenge (ILSVRC). The National Animal Disease Referral Expert System (NADRES) of ICARE-NIVEDI, the identification of left atrial enlargement on canine thoracic radiology, the prediction of survivability and the necessity of horses with colic, and the machine learning-based detection of subclinical mastitis in cows by Ebrahimi et al. are a few examples of the documented evidence of AI's application in veterinary sciences [27].

There are many methods used for detecting animal diseases. In this study, different types are chosen to get the highest result for the problem and make a comparison for building a hybrid model to collect data from animals, such as pictures, and climate change parameters. There are two phases of the first set of traditional deep learning, and then we get the advanced one to compare the results.

III. Methodology

The methodology employed in this research aimed to create and assess a resilient machine learning framework for identifying animal diseases, considering the effects of climate change. Because illness dynamics are so complicated and interact with environmental conditions, the method merged image-based deep learning with climate-related data to make predictions more accurate and generalize better. The research utilized a phased development methodology, initiating with a basic Convolutional Neural Network (CNN) exclusively trained on image data, and later integrating additional components such as climatic variables, transfer learning frameworks, and regularization techniques. This study employs a multimodal data fusion approach to accurately assess the influence of climate change on animal disease diagnosis by integrating visual data with climatic textual data. The visual modality comprises animal images used for the identification of disease related symptoms, whereas the climatic modality encompasses numerical and textual representations of environmental data, including temperature and humidity. The image data undergoes processing via deep learning feature extraction networks, including convolutional neural networks (CNNs) and models such as ResNet and YOLOv5. These models acquire advanced visual traits that signify illness patterns, lesions, or atypical physical characteristics. This stage produces a concise feature vector that represents the visual health status of the animal. Simultaneously, the meteorological data, depicted as organized numerical values (e.g., temperature and humidity), are standardized and converted into a feature representation appropriate for machine learning analysis. These climatic characteristics encapsulate environmental stressors that affect illness vulnerability and advancement. The two feature sets are subsequently integrated at the feature level, wherein visual features and climatic features are amalgamated into a cohesive representation. The integrated feature vector is then transmitted to a classification layer or fully connected network that acquires knowledge of the interrelations between visual symptoms and environmental factors. By concurrently learning from multiple modalities, the model can more effectively evaluate illness risk and severity compared to utilizing image data in isolation. The integrated output is utilized to produce diagnostic forecasts, environmental risk assessments, and decision-support suggestions. This multimodal integration enables the system to correlate illness symptoms with climatic conditions, facilitating more precise, climate-informed disease diagnosis and aiding early intervention techniques in livestock.

IV. Results

The results encompass the preparation of both image and climate data, the construction and training of multi-input deep learning models, and the implementation of advanced architectures, including EfficientNetB0. We used training and validation accuracy metrics to evaluate the model, paying close attention to overfitting, model stability, and generalization performance. The suggested method combines traditional CNN-based image classification with environmental data integration and cutting-edge transfer learning. This makes it a complete way to deal with both the problems of finding animal diseases and the growing effects of climate change, as shown in Table I.

TABLE I. The CNN and Deep Learning Models Result

Model Phase	Training Accuracy (%)	Validation Accuracy (%)
Phase 1: CNN (Images Only)	88	65
Phase 2: CNN + Climate Data	88	75
Phase3: EfficientNet0 +Climate Data	92	87
Phase 4: EfficientNet + Regularization	90	91

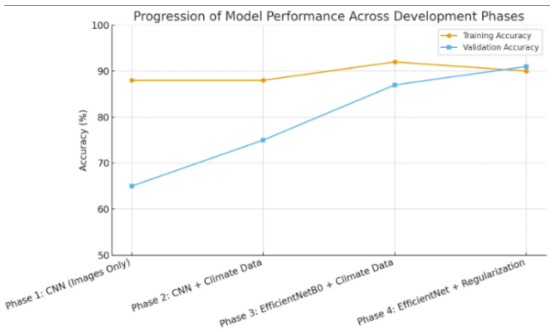

Fig. 1. The progression of accuracy across four phases.

In Fig. 1, the starting point of the CNN that was exclusively trained on image data (Phase 1) was a clear case of overfitting because the training accuracy was about 88%, but the validation accuracy was only about 65%. This revealed that the model couldn't use what it learnt on data that wasn't in the training set. We added climate elements, including temperature and humidity, in Phase 2, which raised the validation accuracy to 75%. The performance of the training remained unchanged. This shows that adding environmental data narrows the gap between training and validation and makes generalization better. We employed EfficientNetB0 for transfer learning in Phase 3, which made both training and validation much more accurate (92% and 87%, respectively). The pre-trained feature extraction layers gave us a strong base, which helped us reach our goal faster and improved the overall prediction performance. Finally, in Phase 4, freezing the pre-trained layers and employing stronger regularization approaches like dropout and L2 regularization made the training and validation performance stay the same. The accuracy of the training data dropped to 90%, but the accuracy of the validation data rose to roughly 91%. This shows that the model is more generic and stable. The final optimized model has a CNN accuracy of more than 90%. Adding climatic data was helpful for making things better. Generalization, transfer learning, and regularization procedures made sure that the model stayed stable and didn't overfit. The link between climate change and animal health shows how important it is to use new diagnostic methods. New vectors and infections appear in areas that were not affected before as temperatures rise, rainfall patterns change, and humidity levels increase. This tendency not only raises the likelihood of outbreaks, but it also makes it harder to manage diseases. Machine learning–based diagnostic tools offer a proactive strategy by facilitating real-time monitoring and early diagnosis, which are crucial for alleviating the impacts of these climate-induced changes. Additionally, connecting illness surveillance systems with climate data can improve early warning systems and help policymakers create targeted policies. The results show that the model's performance has steadily improved from a baseline accuracy of 65% to a higher level by following the previous diagram in the last research, as shown in Fig. 2.

Our second step is a comparative analysis of ResNet, YOLOv5, and AltCLIP methods to get results from different methodologies that we used on the same dataset to check the results compared to the previous one in the training and validation phases.

We start to show the results for three models that were used to make the comparison, starting with the YOLOv5 model.

The training loss for YOLOv5 started at 0.494 and went down to 0.203 by the end of the last epoch. The loss for validation started at 0.528 and went down to 0.426 (Fig. 4). The Top1 Accuracy went up consistently from 78.7% in the first epoch to 85.6% in the last epoch, which shows that the model was learning and performing well on the dataset (Fig. 3).

Then we showed the result, and it's impressive that the algorithm can distinguish between sick and healthy cows. For cows that are lumpy, it gets it right 61% to 83% of the time, and for healthy cows, it gets it right 61% to 99% of the time. The expected probabilities show this difference even more clearly: the confidence ratings for healthy cows are between 0.17 and 0.99, whereas those for lumpy cows are between 0.13 and 0.83. But since the chances are about 0.5 for both (Fig. 6).

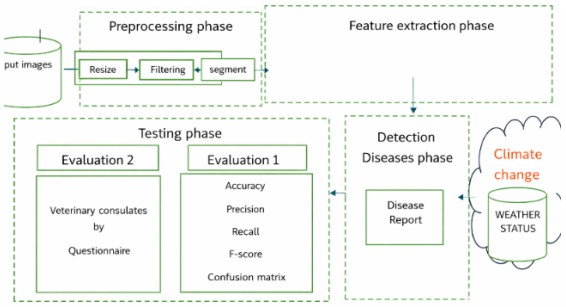

Fig. 2. Block diagram for the prediction of disease in animals [1].

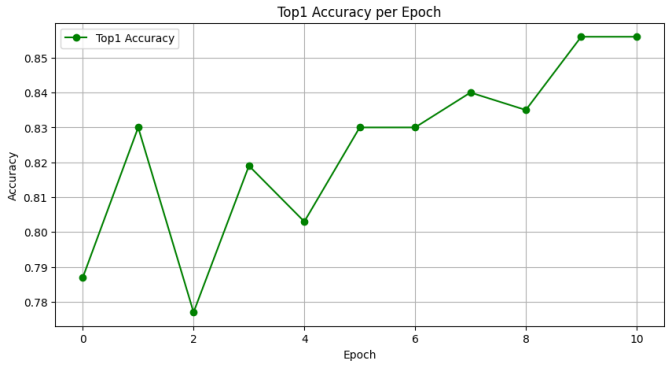

Fig. 3. The accuracy per epoch for YOLOv5.

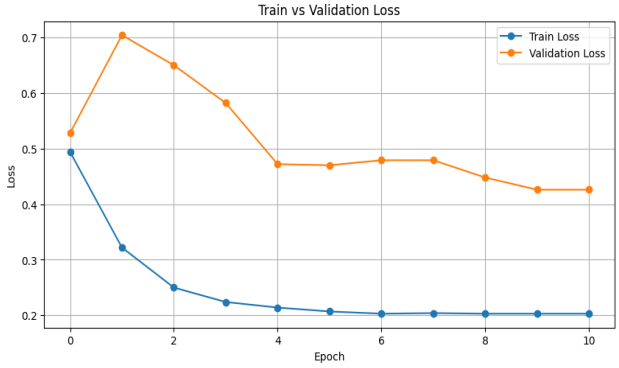

Fig. 4. The train and validation loss results for YOLOv5.

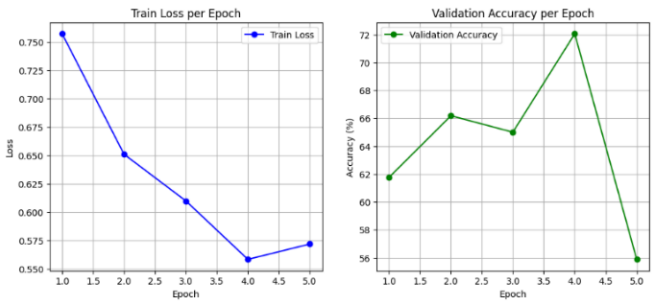

Fig. 5. The train and validation results for ResNet.

The training loss for ResNet went from 0.7572 to 0.5586 during five epochs, which shows that it was learning well. The validation accuracy began at 61.76%, increased to 96.18% in the second epoch, and thereafter decreased to 55.88%. This suggests that ResNet can be quite precise at some stages during training (Fig. 5).

The dataset was carefully prepared using an 80/20 train-validation split, ensuring proper shuffling and organization for balanced learning. Over the course of 10 training epochs, the model achieved a final Top 1 accuracy of 85%, with the training loss reduced to 0.2 and validation loss to 0.3. The small loss gap of 0.1 indicates strong generalization and minimal signs of overfitting. Analysis suggests that the optimal stopping point was around Epoch 8, where performance stabilized. Overall, the model trained successfully, demonstrating reliable accuracy and robustness, making it well-suited for final testing and deployment.

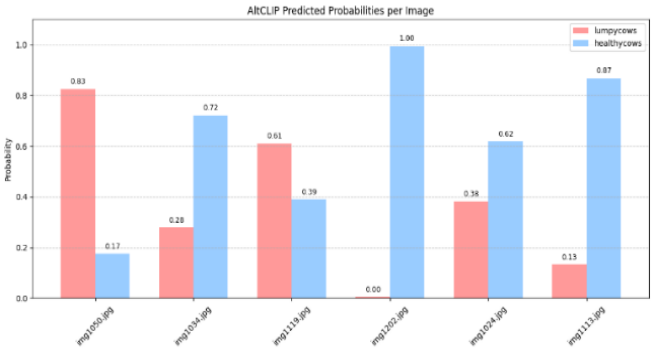

Fig. 6. The training and validation for ResNet results.

Groups, the model doesn't know what to do with more unclear photographs. Even with these issues, the model has gotten better at generalizing across different samples because of data augmentation techniques, including rotation, random flipping, and scaling. Future improvements could include adding more data to the dataset and employing fine-tuning methods to make class separation better and reduce confusion. This would make the performance better and more stable. Table II shows all the outcomes of the comparisons.

Interventions. While promising, this approach requires continued investment in data collection, model refinement, and interdisciplinary collaboration between veterinarians, climate scientists, and computer engineers to maximize its impact. At the end, we show the total result in Fig. 7.

TABLE II. THE COMPARISON OF THE MODELS' RESULTS

Model	Training Loss Trend	Validation Loss / Accuracy	Key Results	Strengths
YOLOv 5	Decreased from 0.494 → 0.203	Validation loss 0.528 → 0.426; Top-1 Accuracy improved from 78.7% → 85.6%	Stable and consistent improvement	Reliable performance across epochs; best for general classification & detection
ResNet	Decreased from 0.7572 → 0.5586 (5 epochs)	Validation accuracy started 61.76%, peaked at 96.18%, fluctuated between 65–72%, ended at 55.88%	Can reach very high accuracy at certain stages	Strong peak accuracy, but unstable validation results
AltCLIP	N/A (probability -based output)	Provides per-class probabilities (e.g., 0.825 lumpycows, 0.996 healthycows, 0.721–0.868 for other images)	High confidence and precise predictions	Best for detailed per-image classification and semantic discrimination

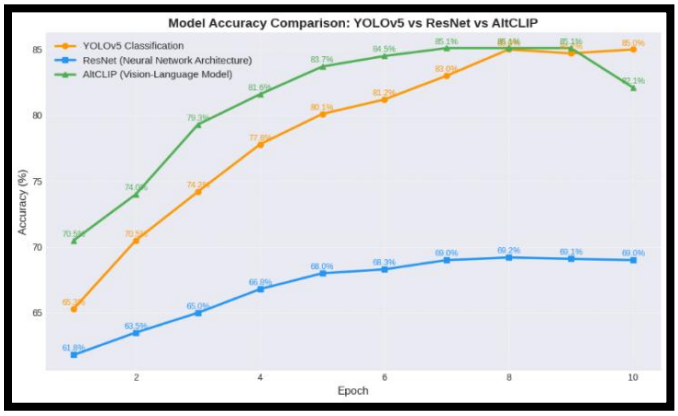

Fig. 7. The accuracy comparison between the models.

In the last step, we use the best result of models to the GUI, which was also built to merge visual and environmental data so that diseases might be found on their own. The trained models in the system use weather data and pictures of animals to make an environmental interpretation, a combined stress index, a quantitative risk score (0–100), and suggestions for what to do next, like getting immediate veterinary care, keeping an eye on the animal often, or making sure it is healthy. This combination approach shows that using climate-sensitive analysis with deep learning architectures may make diagnoses far more accurate, let doctors make proactive choices, and allow for ecological.

V. Graphical User Interface (GUI) for Climate-Aware Animal Disease Diagnosis

To turn the complex parts of the proposed machine learning architecture into an app that is easy to use and accessible, it is important to make a graphical user interface (GUI). Its main purpose is to make it easier to enter, process, and understand data, which will make the system more useful and applicable in real-life weather data that is important, such as temperature and humidity. After the inputs are sent in, the interface automatically runs them through the learnt classification models, which gives very detailed diagnostic results. These include a combined stress index, descriptions of the environment, graphs showing how likely an illness is to happen, and a risk score that can be measured and goes from zero to one hundred. GUI also gives simple suggestions depending on the diagnostic results, including getting immediate veterinary attention, keeping an eye on the situation regularly, or confirming that the animal is healthy. We take a photo and send it to the system. The pic shown below is an example of upload in the system, using two climate change temperature and humidity, and the shape of the GUI for the system, as shown in Fig. 8.

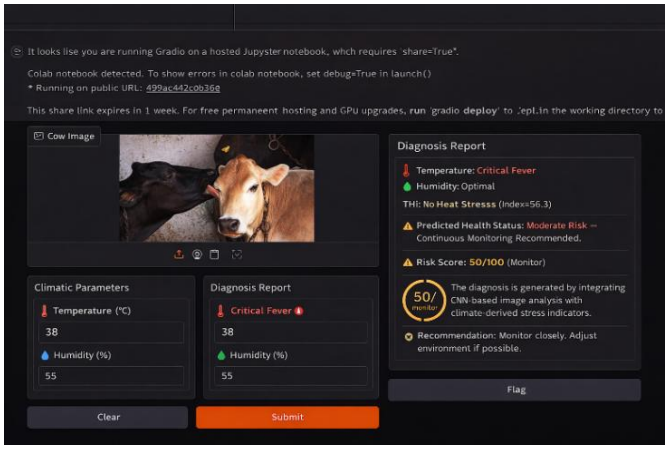

Fig. 8. The GUI and the result after uploading the picture.

The GUI that was built uses animal picture processing and environmental data (temperature = 33 °C, humidity = 60%) to automatically discover diseases. The system used the model YOLOv5 to find hypothermia at the right humidity and a THI of 28.9, which suggests there was no heat stress. The diagnosis assigned the case a risk score of 50 out of 100 and indicated it "Needs Monitoring". This suggested that the person should be followed attentively, and the environment should be modified. This shows how the system could keep an eye on animal health by using AI-based detection and climate evaluation together.

VI. Discussion

This study's findings illustrate the efficacy of combining machine learning methods with climatic data to improve the diagnosis of animal diseases amid shifting environmental conditions. The noted enhancement in diagnostic precision corroborates the concept that climate variability, especially variations in temperature and humidity, significantly influences the onset and development of bovine illnesses. By integrating these environmental aspects into the diagnostic framework, the proposed model offers a more thorough comprehension of disease dynamics than image-based analysis alone. The utilization of convolutional neural networks, in conjunction with sophisticated classification models like ResNet, YOLOv5, and AltCLIP, facilitated effective feature extraction and dependable disease classification. These models proficiently differentiated between healthy and unhealthy animals, even in visually intricate situations, illustrating their appropriateness for veterinary diagnostic applications. The findings demonstrate that transfer learning and multimodal designs enhance generalization and decrease misclassification, especially in instances where disease symptoms are mild or overlapping. The incorporation of climate factors with ocular illness detection markedly improved the system's prediction performance. The integrated analysis enabled the model to evaluate environmental stressors and correlate them with disease risk, providing significant insights into the impact of climate change on livestock health. This method enhances early disease identification and facilitates proactive risk assessment and climate adaptation measures in cattle management. The creation of a graphical user interface (GUI) enhances the practical utility of the proposed technology. GUI facilitates the connection between intricate machine learning models and end users, including farmers and veterinarians, by displaying diagnostic results, environmental risk assessments, and practical advice in an easily understandable style. This promotes informed decision-making, allowing for prompt actions that can mitigate disease transmission, lessen economic losses, and enhance animal welfare. Notwithstanding these encouraging outcomes, specific limits must be recognized. The model's effectiveness is contingent upon the quality and diversity of the training data, whereas discrepancies in picture quality or insufficient climatic records may influence diagnostic precision. Subsequent research may rectify these limitations by integrating larger, multi-regional datasets, supplementary environmental factors, and real-time sensor data to augment robustness and scalability. This study underscores the capacity of climate-conscious machine learning frameworks to revolutionize animal disease detection. The suggested method integrates visual analysis with environmental context, enhancing sustainable livestock management and providing a crucial tool for alleviating the increasing health concerns linked to climate change.

VII. Conclusion

Climate change is making animal diseases spread faster, and outbreaks happen more often, are worse, and are affecting more animals. These changes pose a major threat to the stability of agricultural economies around the world, food safety, and animal health. Standard diagnostic methods are useful, but they might not be useful in all cases because they cost a lot, take a long time, and aren't very scalable. This makes them less useful for keeping an eye on diseases in real-time over a wide area in a world that is changing quickly. This study presents a sophisticated diagnostic system that utilizes image-based data to rapidly and accurately identify animal diseases through cutting-edge machine learning and deep learning techniques. The suggested method combines convolutional neural networks (CNNs) with several strong classification architectures, such as ResNet, YOLOv5, and AltCLIP, to make feature extraction, localization, and visual-semantic comprehension better. The method enhances early diagnosis by integrating diagnostic

predictions with environmental factors such as temperature and humidity.

VIII. Future Directions

There are several interesting avenues for this field's research. First, the robustness and generalizability of CNN-based diagnostic models will be enhanced by enlarging datasets to encompass a greater variety of animal species, illnesses, and climates. Second, the accuracy of disease prediction and outbreak forecasting can be improved by combining multi-modal data, including sensor data (e.g., temperature, humidity, and movement tracking), farm management techniques, and satellite-based climate information. Farmers in rural or resource-poor areas might also benefit from real-time diagnostic tools that don't need expensive infrastructure. They could do this by making lightweight AI models that work well on mobile or edge devices. Future research may also examine explainable AI (XAI) methodologies to enhance the transparency and dependability of model decisions, hence facilitating informed decision-making by policymakers and veterinarians. Finally, creating worldwide data-sharing platforms that connect animal health records and weather trends will make it easier to keep an eye on huge areas, help create early warning systems, and help design agricultural systems that can handle climate change.

***Abstract*—Existing research generally addresses the factors affecting ESG performance at a general level, but fails to examine the relative impact of leadership approaches on this performance with a holistic decision-making model. This deficiency makes it difficult for businesses to align their sustainability strategies with the right leadership styles and creates uncertainty in achieving their ESG goals. In this context, the aim of this study is to determine the most appropriate leadership style for improving ESG performance and to prioritize the criteria influencing this selection with an integrated approach. To address this gap in the literature, the study proposes a new multi-criteria decision-making model. The model utilizes a combination of the Z-score-based normalized ideal distance method (z-NIDM), CIMAS, RAM, and the innovative Sierpinski triangle fuzzy sets. According to the analysis results, the most important criterion for improving ESG performance is promoting green innovation, with a weight of 0.108, followed by resource efficiency, with a weight of 0.105. The most appropriate leadership style was determined to be ethical leadership, with a weight of 1.4841. These findings suggest that, to achieve their sustainability goals, businesses must adopt ethical management approaches, increase investments in green innovation, and make resource efficiency a strategic priority. This study offers a unique contribution by introducing a new fuzzy set approach to the literature, analyzing the relationship between ESG and leadership with an integrated decision-making model, and proposing a methodologically robust framework.**

***Keywords*—Leadership approaches; ESG performance; z-NIDM; CIMAS; RAM**

I. Introduction

The concept of ESG (environmental, social, and governance) is a sustainability approach that considers not only the financial performance of businesses but also their responsibilities to the environment, society, and corporate governance. ESG performance is a key indicator of companies' long-term success and stakeholder trust, as elements such as environmentally responsible production processes, respect for employee rights, ethical management, and transparency create both reputation and competitive advantage. Therefore, strong ESG performance increases investor interest, mitigates risks, and supports sustainable growth. However, achieving this performance depends largely on leadership [1]. Transformational Leadership motivates employees with its visionary approach, creates an organizational culture open to change, and inspires the achievement of sustainability goals. Servant leadership strengthens the social dimension by focusing on the needs of employees and society and emphasizes ethical values. Ethical leadership establishes a strong foundation in governance by integrating the principles of justice, honesty, and responsibility into corporate governance processes. Adaptive leadership, on the other hand, enhances the capacity to cope with environmental and social challenges by making flexible and innovative decisions in response to changing environmental conditions. Therefore, the conscious and balanced application of different leadership styles strengthens businesses' ESG performance, creates sustainable competitive advantage, and contributes to the formation of a credible corporate identity in the eyes of stakeholders.

Determining which leadership model is most effective in improving companies' ESG performance is critical to achieving sustainable performance, as each leadership model impacts the environmental, social, and governance dimensions differently. Environmentally, resource efficiency, optimizing energy, water, and raw material use, reducing carbon emissions, and encouraging green innovation enable businesses to develop environmentally responsible strategies [2]. In this process, visionary and innovative leadership approaches facilitate the adoption of environmentally friendly products and processes. Socially, employee engagement and motivation, effective implementation of diversity and inclusion policies, trust-based relationships with society, and stakeholder satisfaction contribute to the development of a strong corporate culture. In these areas, servant and transformational leadership styles strengthen social sustainability by centering the expectations of employees and society. In governance, ethical decision-making, transparency, risk management, accountability, and a long-term sustainability vision form the foundation of corporate trust. In this context, ethical and adaptive leadership support a flexible, reliable, and auditable organizational structure. In terms of overall performance, the integration of ESG strategies into corporate objectives, openness to change, and contribution to long-term financial sustainability enhance a company's competitiveness. Therefore, the choice of leadership model is shaped by the interaction of these multidimensional variables,

and the right leadership approach strengthens businesses' capacity to achieve sustainable success and create social value by ensuring holistic development of ESG performance.

Identifying the leadership styles that should be considered most when improving companies' ESG performance is crucial, as leadership approaches directly impact all dynamics, from a company's strategic decision-making processes to its corporate culture. If the most appropriate leadership style is not determined, business policies cannot align with ESG objectives, leading to weakened environmental, social, and governance performance. Therefore, determining which leadership model most strongly supports ESG performance is critical for sustainable corporate success. However, this determination process depends not only on the general characteristics of leadership styles but also on the criteria that most influence this choice [3]. Factors such as environmental sensitivity, ethical decision-making capacity, ability to manage stakeholder expectations, level of employee engagement, and openness to innovation can all be decisive in choosing a leadership style. If these critical factors are not properly identified and prioritized, businesses may direct their resources in the wrong areas, struggle to achieve their sustainability goals, and lose stakeholder trust. However, the literature is quite limited in analyzing the criteria by which leadership styles that influence ESG performance should be prioritized. This deficiency creates a significant gap in the ESG and leadership literature. This gap creates both theoretical and practical misconceptions, measurement difficulties, and strategic uncertainties. Therefore, developing a new and comprehensive materiality analysis on this topic would make an original contribution to the literature and help businesses more effectively align their leadership strategies with their ESG objectives.

The aim of this study is to identify the leadership types that should be most considered when improving the ESG performance of businesses. To this end, the study aims to fill the existing gap in the sustainability and leadership literature and provide decision-makers with a scientifically based assessment model. The motivation for this research stems from the limited literature on how leadership approaches that influence ESG performance can be prioritized under different criteria. In this context, an extensive literature review was conducted, and twelve different assessment criteria affecting ESG performance were identified. Furthermore, five different leadership types that can be effective in ESG-focused management processes were selected as alternatives. In the study, evaluations of these criteria and alternatives were obtained from 10 different subject-matter experts. To account for demographic differences and evaluation consistency among the experts, importance weights were calculated using the Z-score-based normalized ideal distance method (z-NIDM). Additionally, the CIMAS technique was applied to determine the importance of the criteria. Furthermore, alternative leadership types were ranked using the RAM method. The newly developed Sierpinski triangle fuzzy settler approach was used in the analysis process to more precisely assess uncertainties. This comprehensive model enables the holistic evaluation of both quantitative and qualitative data in a multi-criteria decision-making process. The study addresses the following research questions: 1) Which leadership style has the most critical impact on improving ESG performance? 2) What are the most important criteria for determining leadership selection for ESG performance? 3) How do the weights of these criteria change under uncertainty? and 4) What innovation does the developed integrated model offer to existing analysis methods in the field of ESG and leadership? By addressing these questions, the study aims to make an original contribution to the ESG and leadership literature at both theoretical and applied levels.

This study provides a unique methodological and conceptual contribution to the literature by analyzing the most effective leadership type for improving ESG performance and the most critical criteria determining this choice using a new integrated multi-criteria decision-making model. The model proposed in this study offers significant advantages in several aspects compared to previously developed decision-making models in the literature: 1) First and foremost, the development of Sierpinski triangle fuzzy sets stands out as a unique innovation. This approach offers higher discrimination power and uncertainty sensitivity compared to existing uncertainty representation methods such as classical fuzzy sets, intuitionistic fuzzy sets, or type-2 fuzzy sets. The Sierpinski triangle structure can more accurately capture small differences in decision-makers' assessments, thus minimizing information loss. Thus, this study not only proposes a new decision model but also makes a methodological contribution by introducing a new type of fuzzy set to the literature. 2) The use of the z-NIDM technique in determining experts' importance weights is another significant advantage of the model. This method applies weighting by objectively considering the experts' demographic characteristics, knowledge levels, and evaluation consistency. In most studies in the literature, the assumption of equal weighting of experts increases the subjectivity and reduces the reliability of decision results. In contrast, the z-NIDM technique integrates expert opinions into the model in a more equitable, balanced, and statistically based manner. 3) Furthermore, the use of the CIMAS technique in calculating the importance weights of the criteria also increases the effectiveness of the model. Although many weighting methods, such as AHP, Entropy, CRITIC, and SWARA, are used in the literature, the CIMAS technique produces a more balanced result by integrating both objective and subjective information components. The CIMAS method is particularly suitable for multidimensional and uncertain issues such as ESG and leadership relationships, as it considers inter-criteria dependencies and adds flexibility to the decision process, compared to other techniques. Thanks to these three key innovations, the proposed model is superior to existing decision-making approaches in terms of both methodological robustness and practical applicability.

The following Section II explains the missing part in the literature. The proposed model is defined in Section III. The analysis results are demonstrated in Section IV. Moreover, Section V includes a discussion, and Section VI identifies the main concluding remarks.

II. Literature Review

In today's rapidly changing and transforming business environment, companies strive to maintain their operations and achieve a competitive advantage. In this process, focusing exclusively on financial operations is not sufficient to respond to varying stakeholder demands in a balanced manner. It is also necessary to demonstrate sensibility to environmental factors, social factors, and stakeholder expectations. The limited availability of resources in view of increasing consumption and demand makes environmental sustainability an ethical concern. In addition to environmental factors, being transparent and fulfilling responsibilities toward society, individuals and shareholders are becoming critical factors that determine the future of the business. Hence, companies share information about sustainability or corporate social responsibility activities in addition to financial reporting. Nevertheless, unstable conditions and diverse stakeholder demands necessitate more endeavors. As companies are accountable to all stakeholders, they need to share transparent information regarding environmental, social and governance activities for the sustainability of their operations. In this context, stakeholder theory proposes promoting innovation and sustainable development through actively communicating with all stakeholders [4]. Stakeholder orientation can significantly influence all aspects of an organization, from corporate governance to ethical practices and sustainability initiatives, from employee relations to customer and community engagement [5].

Environmental performance indicates the influence of a company on the natural environment. This ecological impact comprises resource protection, waste management, emissions reduction, energy efficiency and biodiversity conservation [6]. Growing environmental and ecological concerns, particularly climate change, impact corporate operations in different aspects. These rising concerns lead international communities and global leaders to initiate various reforms and agreements to protect the natural environment. In this context, companies incline to place greater emphasis on environmental sustainability practices such as recycling, resource reduction, product and service redesign to establish a trustworthy image, enhance their reputation and protect the planet [7]. Dohrmann et al. [8] found that environmental performance has a positive influence on firm performance and board independence strengthens this relationship. According to Tong et al. [9], reducing emissions, within the scope of environmental performance, is one of the crucial ways to engage the attention of stakeholders. Companies can effectively address their stakeholders' needs by creating, implementing and publicly disclosing the strategies of carbon emission reduction. These effective strategies enable companies to improve their reputation and attract more investors. In this process, companies can convey new business processes and their benefits to relevant stakeholders by establishing open and transparent communication. Innovation, one of the important business processes, plays a central role in company growth. Wang and Ahmad [10] conducted a study on green process, green product innovation and financial performance. In this study, green innovation impacts financial performance positively. Companies that invest in green process and product innovation may provide advantages in terms of mitigating environmental concerns and potential penalties, creating new market niches, developing nature-friendly products, having a green image and enhancing financial performance. By integrating a strong ethical approach and environmental awareness, companies may adopt sustainable practices, reduce ecological effects and advance environmental performance [11].

Another notable aspect for companies is social factors. Social performance involves corporate endeavors to improve and manage relationships with stakeholders such as employees, community, customers and suppliers [12]. According to Covington et al. [13], diversity and inclusion, one of the social factors, refers to an environment that values differences among employees and encourages both individuality and a sense of belonging. Hence, this social factor may have a significant impact on corporate performance. As a matter of fact, in the study conducted by the same authors, it was observed that companies with higher diversity and inclusion ratings exhibited stronger innovation performance in terms of parameters such as number of patents, number of citations and the economic value of patents. Within the scope of social factors, product responsibility may influence consumer behavior and corporate image. According to Mensah et al. [14], companies that focus on product responsibility can strengthen brand image and achieve greater consumer loyalty. To lower transaction costs, reduce waste and minimize customer complaints and returns, companies can use environmentally sustainable materials and prioritize product robustness.

Sustainable development requires the protection of resources and the minimization of transaction costs. Hence, companies need to meticulously consider factors such as board diversity and board size to achieve sustainable development goals [15]. At this point, governance is another critical factor in terms of sustainable operations and corporate reputation. Companies can create a mutual trust in the relations with stakeholders and enhance company value through effective governance practices. Companies need to center upon ameliorating governance practices such as transparency and accountability and align their governance-related activities with strategic objectives [16]. As key stakeholders of a company, senior management personnel have critical roles in the governance practices and decision-making process. Moreover, their attitudes and behaviors toward sustainable development goals impact the efficiency of corporate social responsibility activities. The purposeful development of corporate social responsibility strategies can yield positive results for the company. In fact, it has been observed in the literature that corporate social responsibility practices have significant and positive effects on financial performance, innovation, reputation and firm sustainability [17]. Herewith, corporate governance becomes a strategic obligation for organizations aiming to lead change, create sustainable value and enhance performance. In a dynamic and complex business environment, companies can provide a basis for long-term achievement and resilience by balancing interests, encouraging innovation, managing risks and involving stakeholders in the processes [18].

Environmental, social and governance-related activities encompass aspects that companies need to prioritize. The concept of ESG, which considers these factors together, becomes a focal point of research since it has significant effects on corporate reputation and investor preferences. ESG encompasses a company's environmental influence, social responsibilities and governance implementations at the heart of its actions [19]. ESG criteria become the main indicators of risk management, management competence and non-financial performance. ESG consists of a wide range of environmental concerns such as carbon emissions, climate change and energy use; social issues such as employee well-being, product safety and human rights; and governance-related issues such as corruption, board independence and protection of shareholder rights. Bai et al. [20] stated that ethical constraints and public pressure can encourage companies to prioritize environmental and social factors and adopt more active ESG practices, thereby improving their ESG performance. Increasing ESG performance enables companies to enhance their corporate reputation and reduce certain risks by minimizing environmental penalties and financial restrictions. According to Chen et al. [21], companies that operate their activities ethically and responsibly to advance the society's welfare can contribute to increased company value. ESG disclosure enables a company to gain competitive advantages, strengthen its reputation from the perspective of stakeholders and enhance long-term performance.

The literature review reveals that environmental, social and governance activities have significant effects on financial performance, sustainability and corporate reputation of companies. Transparently sharing information regarding these activities enables companies to attract strategic investors, gain stakeholder trust and increase financial performance. ESG practices, which consider environmental, social and governance activities together, have become a prominent concept in the literature and the business world in recent years. The presence of effective leaders may be crucial for the adoption and successful implementation of ESG practices by employees at all levels within a company. In this regard, it has been observed that studies examining the effect of leadership types on ESG performance are limited. However, no comparative study has been found that examines which leadership type has the greatest impact on ESG performance on a sectoral basis. Hence, this study may fill a research gap in the relevant literature and provide guidance to practitioners to improve ESG performance in business.

III. METHODOLOGY

This section includes the definitions and formulations of z-NIDM, STFSs, CIMAS and RAM, respectively. In expert-based solutions, assuming the same importance of evaluations is criticized. To address this criticism objectively, the z-NIDM approach is integrated into the model. This approach generates expert-weighted values, aiming to yield more realistic results. In the optimal analysis process, the CIMAS method is used to prioritize decision-making criteria. RAM finds the optimal solution by considering the importance of these criteria. The process of methodology is presented in Fig. 1.

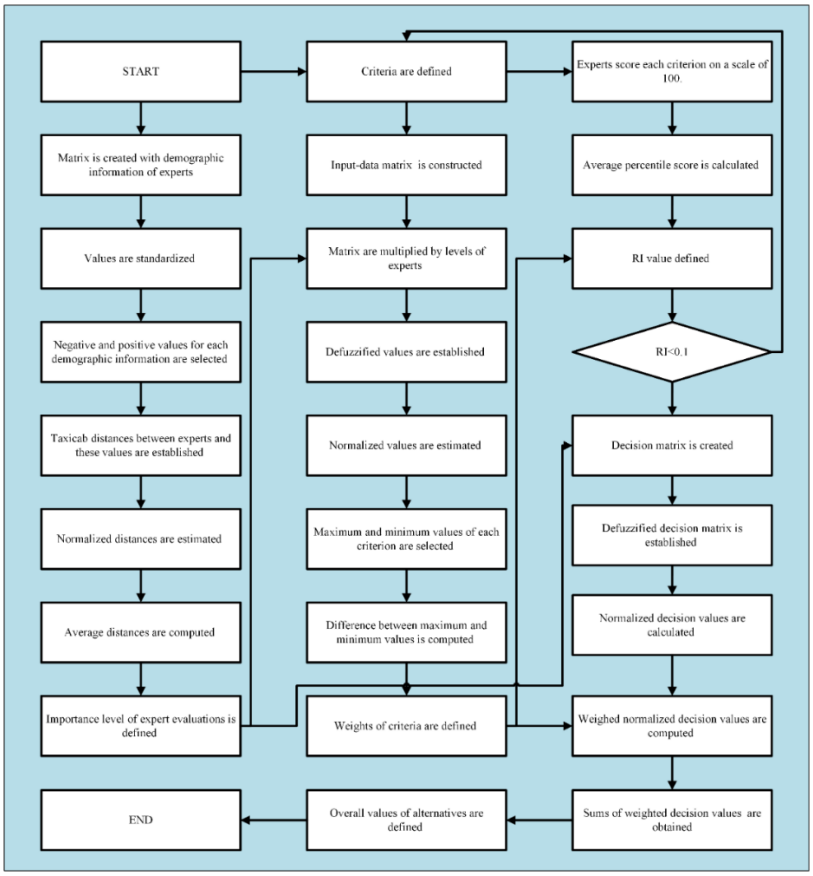

Fig. 1. Process of methodology.

A. z-NIDM

This approach allows the importance value of expert evaluations to be calculated objectively using demographic information. This approach is based on the average distance normalized to negative and positive values [22]. The calculation steps are as follows.

Firstly, the matrix formed in Eq. (1) is created with demographic information of experts.

$$Y = \left[y_{ij}\right]_{e\times d} \tag{1}$$

where, e and d are the numbers of experts and demographic information. Thus, y_{ij} means the value of ith demographic information of jth expert. Since the value ranges of the information are different from each other, the values need to be standardized with the help of Eq. (2) to Eq. (4).

$$\bar{y}_j = \frac{1}{e}\sum_{i=1}^{e} y_{ij} \tag{2}$$

$$\sigma_j = \sqrt{\frac{1}{e}\sum_{i=1}^{e}(y_{ij}-\bar{y}_j)^2} \tag{3}$$

$$z_{ij} = \frac{y_{ij}-\bar{y}_j}{\sigma_j} \tag{4}$$

Afterwards, the negative and positive values for each demographic information are selected via Eq. (5) and Eq. (6), respectively.

$$neg_j = \min_i z_{ij} \tag{5}$$

$$pos_j = \max_i z_{ij} \tag{6}$$

After determining the negative and positive values, the Taxicab distances between experts and these values are established by Eq. (7) and Eq. (8), respectively.

$$negD_i = \sum_{j=1}^{d}\left|z_{ij} - neg_j\right| \tag{7}$$

$$posD_i = \sum_{j=1}^{d}\left|z_{ij} - pos_j\right| \tag{8}$$

Next, the normalized distances are estimated with the help of Eq. (9) and Eq. (10).

$$negN_i = \frac{negD_i}{\max negD_i} \tag{9}$$

$$posN_i = \frac{\min posD_i}{posD_i} \tag{10}$$

Then, the average distances are computed using Eq. (11).

$$A_i = \frac{1}{2}(negN_i + posN_i) \tag{11}$$

Finally, the importance level of expert evaluations is defined as Eq. (12):

$$E_i = \frac{A_i}{\sum_{i=1}^{e} A_i} \tag{12}$$

B. STFSs

Fuzzy sets are a theory used in uncertainty measurement and are defined by degrees of membership and non-membership of an object. STFSs are a set inspired by the Sierpinski Triangle fractal shapes. This fractal shape has a structure with an infinitely sided main field that converges to zero [23]. This feature makes it useful for studying chaotic systems. It is recommended to use this fractal dimension $\left(\frac{\log 3}{\log 2} \approx 1.585\right)$, for optimal modelling of chaotic structure in linguistic structures. A STFS $\left(\tilde{F}\right)$ is described with Eq. (13).

$$\tilde{F} = \{x, (\alpha_{\tilde{F}}(x), \beta_{\tilde{F}}(x)) : x \in D\} \tag{13}$$

wherein, α and β are between zero and one and named as membership and non-membership degrees. These degrees satisfy the condition in Eq. (14).

$$0 \le \alpha_{\tilde{F}}^{1.585}(x) + \beta_{\tilde{F}}^{1.585}(x) \le 1 \tag{14}$$

The indeterminacy degree is computed with Eq. (15).

$$\pi_{\tilde{F}}(x) = \sqrt[1.585]{1 - \alpha_{\tilde{F}}^{1.585}(x) - \beta_{\tilde{F}}^{1.585}(x)} \tag{15}$$

Consider that $\tilde{X}$ and $\tilde{Y}$ are two fuzzy numbers. Then general operations are calculated by Eq. (16) to Eq. (21). $(s, \lambda > 0)$

$$\tilde{X} \cup \tilde{Y} = (\max\{\alpha_{\tilde{X}}, \alpha_{\tilde{Y}}\}, \min\{\beta_{\tilde{X}}, \beta_{\tilde{Y}}\}) \tag{16}$$

$$\tilde{X} \cap \tilde{Y} = (\min\{\alpha_{\tilde{X}}, \alpha_{\tilde{Y}}\}, \max\{\beta_{\tilde{X}}, \beta_{\tilde{Y}}\}) \tag{17}$$

$$\tilde{X}\oplus\tilde{Y} = \begin{pmatrix} \sqrt[1.585]{\dfrac{\alpha_{\tilde{X}}^{1.585}+\alpha_{\tilde{Y}}^{1.585}-\alpha_{\tilde{X}}^{1.585}\alpha_{\tilde{Y}}^{1.585}-(1-s)\alpha_{\tilde{X}}^{1.585}\alpha_{\tilde{Y}}^{1.585}}{1-(1-s)\alpha_{\tilde{X}}^{1.585}\alpha_{\tilde{Y}}^{1.585}}}, \\ \dfrac{\beta_{\tilde{X}}\beta_{\tilde{Y}}}{\sqrt[1.585]{s+(1-s)\left(\beta_{\tilde{X}}^{1.585}+\beta_{\tilde{Y}}^{1.585}-\beta_{\tilde{X}}^{1.585}\beta_{\tilde{Y}}^{1.585}\right)}} \end{pmatrix} \tag{18}$$

$$\tilde{X}\otimes\tilde{Y} = \begin{pmatrix} \sqrt[1.585]{\dfrac{\alpha_{\tilde{X}}\alpha_{\tilde{Y}}}{\sqrt[1.585]{s+(1-s)\left(\alpha_{\tilde{X}}^{1.585}+\alpha_{\tilde{Y}}^{1.585}-\alpha_{\tilde{X}}^{1.585}\alpha_{\tilde{Y}}^{1.585}\right)}}}, \\ \sqrt[1.585]{\dfrac{\beta_{\tilde{X}}^{1.585}+\beta_{\tilde{Y}}^{1.585}-\beta_{\tilde{X}}^{1.585}\beta_{\tilde{Y}}^{1.585}-(1-s)\beta_{\tilde{X}}^{1.585}\beta_{\tilde{Y}}^{1.585}}{1-(1-s)\beta_{\tilde{X}}^{1.585}\beta_{\tilde{Y}}^{1.585}}} \end{pmatrix} \tag{19}$$

$$\lambda\odot\tilde{X} = \begin{pmatrix} \sqrt[1.585]{\dfrac{\left[1+(s-1)\alpha_{\tilde{X}}^{1.585}\right]^{\lambda}-\left(1-\alpha_{\tilde{X}}^{1.585}\right)^{\lambda}}{\left[1+(s-1)\alpha_{\tilde{X}}^{1.585}\right]^{\lambda}-(s-1)\left(1-\alpha_{\tilde{X}}^{1.585}\right)^{\lambda}}}, \\ \dfrac{\sqrt[1.585]{s}\beta_{\tilde{X}}^{\lambda}}{\sqrt[1.585]{\left[1+(s-1)\left(1-\beta_{\tilde{X}}^{1.585}\right)\right]^{\lambda}+(s-1)\beta_{\tilde{X}}^{1.585\lambda}}} \end{pmatrix} \tag{20}$$

$$\tilde{X}^{\lambda} = \begin{pmatrix} \dfrac{\sqrt[1.585]{s}\alpha_{\tilde{X}}^{\lambda}}{\sqrt[1.585]{\left[1+(s-1)\left(1-\alpha_{\tilde{X}}^{1.585}\right)\right]^{\lambda}+(s-1)\alpha_{\tilde{X}}^{1.585\lambda}}}, \\ \sqrt[1.585]{\dfrac{\left[1+(s-1)\beta_{\tilde{X}}^{1.585}\right]^{\lambda}-\left(1-\beta_{\tilde{X}}^{1.585}\right)^{\lambda}}{\left[1+(s-1)\beta_{\tilde{X}}^{1.585}\right]^{\lambda}-(s-1)\left(1-\beta_{\tilde{X}}^{1.585}\right)^{\lambda}}} \end{pmatrix} \tag{21}$$

Suppose that $\tilde{F}$ is ST fuzzy number. Score and accuracy function are established using Eq. (22) and Eq. (23), respectively.

$$SF\left(\tilde{F}\right) = \frac{\alpha_{\tilde{F}}^{1.585}(x) - \beta_{\tilde{F}}^{1.585}(x) + 1}{2} \tag{22}$$

$$AF\left(\tilde{F}\right) = \alpha_{\tilde{F}}^{1.585}(x) + \beta_{\tilde{F}}^{1.585}(x) \tag{23}$$

C. STF-CIMAS

The CIMAS approach, which integrates the level of experts in the process of determining the criterion importance, has the advantage over other methods in terms of calculating the RI value for the reliability of the results. The steps in which ST fuzzy numbers are integrated into CIMAS are as follows [24]:

In the traditional CIMAS method, the expert level is obtained by normalizing the years of experience. However, since this approach is too soft, in this manuscript, the expert-level values obtained from z-NIDM are used. After determining the level of experts, experts express the importance of n criteria with linguistic scale. These linguistic scales of the experts are converted into ST fuzzy numbers and the input-data matrix in Eq. (24) is constructed.

$$\tilde{H} = \begin{bmatrix} \tilde{h}_{11} & \cdots & \tilde{h}_{1n} \\ \vdots & \ddots & \vdots \\ \tilde{h}_{e1} & \cdots & \tilde{h}_{en} \end{bmatrix} \tag{24}$$

where, $\tilde{h}_{ij} = \left(\alpha_{\tilde{h}_{ij}}, \beta_{\tilde{h}_{ij}}\right)$ represents the value of jth criterion of ith expert. Next, the values of this matrix are multiplied by the levels of experts using Eq. (25).

$$\tilde{K} = E_i \odot \tilde{H} = \begin{bmatrix} \tilde{k}_{11} & \cdots & \tilde{k}_{1n} \\ \vdots & \ddots & \vdots \\ \tilde{k}_{e1} & \cdots & \tilde{k}_{en} \end{bmatrix} = \begin{bmatrix} E_1 \odot \tilde{h}_{11} & \cdots & E_1 \odot \tilde{h}_{1n} \\ \vdots & \ddots & \vdots \\ E_e \odot \tilde{h}_{e1} & \cdots & E_e \odot \tilde{h}_{en} \end{bmatrix} \tag{25}$$

Afterwards, the defuzzified values are established with the help of Eq. (26).

$$F = SF\left(\tilde{K}\right) = \begin{bmatrix} f_{11} & \cdots & f_{1n} \\ \vdots & \ddots & \vdots \\ f_{e1} & \cdots & f_{en} \end{bmatrix} = \begin{bmatrix} SF(\tilde{k}_{11}) & \cdots & SF\left(\tilde{k}_{1n}\right) \\ \vdots & \ddots & \vdots \\ SF\left(\tilde{k}_{e1}\right) & \cdots & SF(\tilde{k}_{en}) \end{bmatrix} \tag{26}$$

After creating the defuzzified matrix, the normalized values are estimated via Eq. (27).

$$\mathfrak{y}_{ij} = \frac{f_{ij}}{\sum_{i=1}^{e} f_{ij}} \tag{27}$$

Next, the maximum and minimum values of each criterion for normalized matrix are selected by Eq. (28) and Eq. (29), respectively.

$$mx_j = \max_i \mathfrak{y}_{ij} \tag{28}$$

$$mn_j = \min_i \mathfrak{y}_{ij} \tag{29}$$

Then, difference between maximum and minimum values for each criterion is computed with Eq. (30).

$$diff_j = mx_j - mn_j \tag{30}$$

The weights of criteria are defined as Eq. (31):

$$w_j = \frac{diff_j}{\sum_{j=1}^{n} diff_j} \tag{31}$$

Finally, the reliability index is estimated. This time, experts score each criterion on a scale of 100. The sum of the scales assigned by each expert to the criteria should be 100. Then, the average percentile score is calculated using Eq. (32), where g_{ij} is the percentile score given by the ith expert for the jth criterion.

$$APS_j = \frac{1}{e}\sum_{i=1}^{e} g_{ij} \tag{32}$$

Afterwards, the RI value defined in Eq. (33) is obtained between the criteria weights obtained from CIMAS and the average percentage scores.

$$RI = \frac{\sum_{j=1}^{n} |100 w_j - APS_j|}{100} \tag{33}$$

If the RI value is less than 0.1, the results are reliable. Otherwise, the analysis process is repeated.

D. STF-RAM

The RAM method ranks alternatives by using the differences in compensation levels across benefit and utility criteria. Like other methods, this method ranks alternatives without converting cost criteria into benefit criteria. The steps in which ST fuzzy numbers are integrated into RAM are as follows [25]:

Firstly, m alternatives are evaluated by experts with linguistic scales. These linguistic scales are transformed into ST fuzzy numbers. Thus, the matrix in Eq. (34) is created for the tth expert.

$$\tilde{R}^{(t)} = \begin{bmatrix} \tilde{r}_{11}^{(t)} & \cdots & \tilde{r}_{1n}^{(t)} \\ \vdots & \ddots & \vdots \\ \tilde{r}_{m1}^{(t)} & \cdots & \tilde{r}_{mn}^{(t)} \end{bmatrix} \tag{34}$$

where, $\tilde{r}_{ij}^{(t)} = \left(\alpha_{\tilde{r}_{ij}^{(t)}}, \beta_{\tilde{r}_{ij}^{(t)}}\right)$. Next, these values are multiplied by levels of experts with the help of Eq. (35).

$$\tilde{U}^{(t)} = E_{(t)} \odot \tilde{R}^{(t)} = \begin{bmatrix} E_{(t)} \odot \tilde{r}_{11}^{(t)} & \cdots & E_{(t)} \odot \tilde{r}_{1n}^{(t)} \\ \vdots & \ddots & \vdots \\ E_{(t)} \odot \tilde{r}_{m1}^{(t)} & \cdots & E_{(t)} \odot \tilde{r}_{mn}^{(t)} \end{bmatrix} = \begin{bmatrix} \tilde{u}_{11}^{(t)} & \cdots & \tilde{u}_{1n}^{(t)} \\ \vdots & \ddots & \vdots \\ \tilde{u}_{m1}^{(t)} & \cdots & \tilde{u}_{mn}^{(t)} \end{bmatrix} \tag{35}$$

Then, matrices are summed by Eq. (36).

$$\tilde{A} = \sum_{t=1}^{e} \tilde{U}^{(t)} = \begin{bmatrix} \sum_{t=1}^{e} \tilde{u}_{11}^{(t)} & \cdots & \sum_{t=1}^{e} \tilde{u}_{1n}^{(t)} \\ \vdots & \ddots & \vdots \\ \sum_{t=1}^{e} \tilde{u}_{m1}^{(t)} & \cdots & \sum_{t=1}^{e} \tilde{u}_{mn}^{(t)} \end{bmatrix} = \begin{bmatrix} \tilde{a}_{11} & \cdots & \tilde{a}_{1n} \\ \vdots & \ddots & \vdots \\ \tilde{a}_{m1} & \cdots & \tilde{a}_{mn} \end{bmatrix} \tag{36}$$

Afterwards, the defuzzified decision matrix is established using Eq. (37).

$$A = SF\left(\tilde{A}\right) = \begin{bmatrix} SF(\tilde{a}_{11}) & \cdots & SF(\tilde{a}_{1n}) \\ \vdots & \ddots & \vdots \\ SF(\tilde{a}_{m1}) & \cdots & SF(\tilde{a}_{mn}) \end{bmatrix} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{m1} & \cdots & a_{mn} \end{bmatrix} \tag{37}$$

After constructing the defuzzified decision matrix, the normalized decision values are calculated with Eq. (38).

$$\xi_{ij} = \frac{a_{ij}}{\sum_{i=1}^{m} a_{ij}} \quad (38)$$

The weighed normalized decision values are computed using Eq. (39).

$$b_{ij} = \xi_{ij} w_j \quad (39)$$

Finally, the sums of weighted decision values of benefit and cost criteria of alternatives are obtained by Eq. (40) and Eq. (41). Then, overall values of alternatives are defined as Eq. (42).

$$S_{+i} = \sum_{j=1}^{n} b_{+ij} \quad (40)$$

$$S_{-i} = \sum_{j=1}^{n} b_{-ij} \quad (41)$$

$$\theta_i = \sqrt[2+S_{-i}]{2 + S_{+i}} \quad (42)$$

IV. Analysis

This section includes the results of methodology. All tables are given in the Appendix section (Table I to Table XXI).

A. Establishing the Levels of Experts

Within the z-NIDM framework, demographic information about experts is needed for analysis. Experts' age, total experience, industry experience, management experience, teaching experience, and number of projects are collected regarding expertise. This information is shown in Table I. The values' statistics are estimated with Eq. (2) and Eq. (3). The arithmetic mean and standard deviation of each information are given in Table II. Using these statistics, the values are standardized with the help of Eq. (4). The standardized information matrix is shared in Table III. Afterwards, the negative and positive values for each demographic information are selected via Eq. (5) and Eq. (6), respectively. The negative and positive values for each standardized information are summarized in Table IV. After determining the negative and positive values, the Taxicab distances between experts and these values are established by Eq. (7) and Eq. (8), respectively. Next, the normalized distances are estimated with the help of Eq. (9) and Eq. (10). The results are summarized in Table V. Then, the average distances are computed using Eq. (11). Finally, the importance value of expert evaluations is defined as Eq. (12). The results are illustrated in Fig. 2.

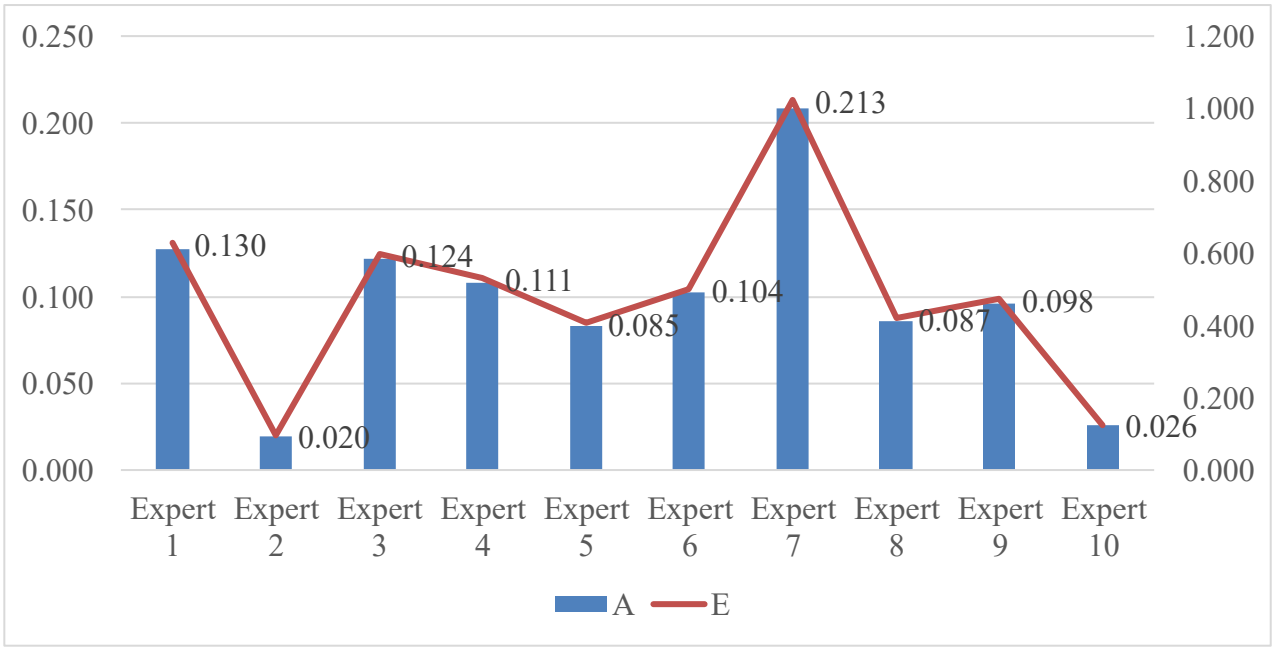

Fig. 2. Levels of experts.

As can be seen, E values in Fig. 2, the highest level is Expert 7 with .213. Expert 7 has the maximum age, total experience, industry experience, manager experience, and teaching experience. The second level is Expert 1 with .130.

B. Weighting of the Criteria

Twelve criteria across four dimensions are determined to improve the ESG performance of companies. This list of criteria and the short codes created for use in the analysis are presented in Table VI. Two of these criteria, ethical problems and difficulty of integrating ESG strategies into corporate objectives, are of the cost type, while the other ten criteria are constructed as benefit type and introduced to the experts as such. Ten experts express the importance of 12 criteria with linguistic scale. The results are displayed in Table VII. These linguistic scales of the experts are converted into ST fuzzy numbers and the input-data matrix in Eq. (24) is constructed. The input-data matrix is exhibited in Table VIII. Next, the values of this matrix are multiplied by the levels of experts using Eq. (25). The levels of experts are defined in Fig. 2. The expert-weighted values are expressed in Table IX. Afterwards, the defuzzified values are established with the help of Eq. (26). In other words, the score functions of fuzzy numbers in Table IX are estimated. The defuzzified matrix is shown in

Table X. After creating the defuzzified matrix, the normalized values are estimated via Eq. (27). That is, the columns are summed, and the values are divided by this total. The normalized matrix is illustrated in Table XI. Next, the maximum and minimum values of each criterion for normalized matrix are selected by Eq. (28) and Eq. (29), respectively. Then, the difference between maximum and minimum values for each criterion is computed with Eq. (30). The results are summarized in Table XII. The weights of the criteria are defined as Eq. (31). The weights of criteria are visualized in Fig. 3.

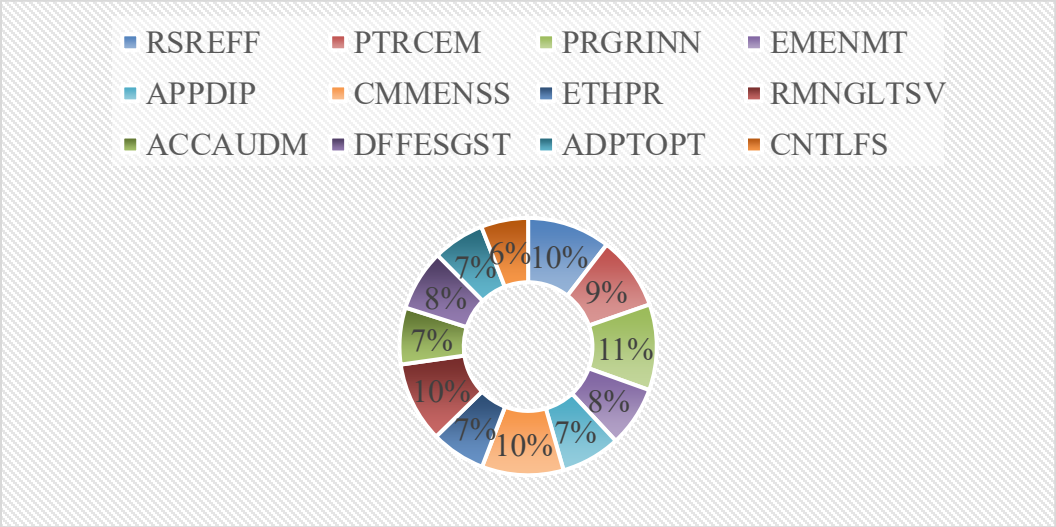

Fig. 3. Weights of the criteria

When Fig. 3 is examined, the most important criterion to improve the ESG performance of companies is promoting green innovation with .108. The second important criterion is resource efficiency with .105. Finally, the reliability index is estimated. This time, experts score each criterion on a scale of 100. The percentile scores are shown in Table XIII. Then, the average percentile score is calculated using Eq. (32). The average percentile scores are shared in Table XIV. Afterwards, the RI value defined in Eq. (33) is obtained between the criteria weights obtained from CIMAS in Fig. 3 and the average percentage scores in Table XIV. RI equals to .078. This value is smaller than 0.1. That is, the results are reliable.

C. Ranking Leadership Styles

The general leadership styles are transformational leadership (TR), servant leadership (SR), ethical leadership (ET), adaptive leadership (AD), and authentic leadership (AU). These 5 leadership styles are evaluated by experts with linguistic scales. The results are displayed in Table XV. These linguistic scales are transformed into ST fuzzy numbers. Thus, the matrix in Eq. (34) is created. Next, these values are multiplied by the levels of experts with the help of Eq. (35). Then, matrices are summed by Eq. (36). The decision matrix is shared in Table XVI. Afterwards, the defuzzified decision matrix is established using Eq. (37). The defuzzified decision matrix is illustrated in Table XVII. After constructing the defuzzified decision matrix, the normalized decision values are calculated with Eq. (38). The normalized decision matrix is summarized in Table XVIII. The weighted normalized decision values are computed using Eq. (39). The values in Fig. 3 are used as weight of the criteria. The weighted normalized decision matrix is displayed in Table XIX. Finally, the sums of weighted decision values of benefit and cost criteria of alternatives are obtained by Eq. (40) and Eq. (41). Then, overall values of alternatives are defined as Eq. (42). The results are shared in Table XX. As can be understood from the overall values in Table XX, the most suitable leadership style to improve the ESG performance of companies is the ethical leadership style, with 1.4841.

A sensitivity analysis is conducted to test the sensitivity and robustness of the results. For this purpose, scenarios are created and the analyses are rerun. In this context, different scenarios are constructed by increasing the weight of each criterion by 10%. The value of the first criterion in Fig. 3 for the first scenario is increased by 10%, and then criteria weights are normalized. The RAM analysis is repeated with the new weights. In other words, twelve scenarios are created for twelve criteria, and twelve RAM analyses are run. The results are summarized in Table XXI. As can be seen from the ranks in Table XXI, the results are the same across scenarios. This shows that the methodology is robust.

V. Discussion

The results of the study indicate that the most important criterion for improving companies' ESG performance is encouraging green innovation, with a weighting of 0.108, followed by resource efficiency, with a weighting of 0.105. This finding demonstrates the critical importance of investing in innovative and environmentally friendly technologies to enhance their sustainability performance [26]. The importance of green innovation is frequently emphasized in the literature. The primary reason for this is that developing environmentally friendly products and processes not only reduces environmental impacts but also significantly contributes to businesses' competitive advantage, brand reputation, and long-term financial sustainability. Resource efficiency, in turn, reduces costs and environmental burden by optimizing the use

of energy, water, and raw materials. In light of these findings, policymakers should create tax incentives, sustainable production funds, and environmentally responsible investment programs to support businesses' green R&D activities [27]. At the corporate level, companies should establish sustainable innovation units, adopt circular economy principles in their supply chains, and train their employees in an organizational culture with a high environmental awareness. Furthermore, green innovation and resource efficiency indicators should be clearly defined in performance measurement systems and integrated into management decision-making processes. This will ensure both institutional sustainability at the micro level and create a development model that supports environmental and economic balance at the macro level.

According to the study results, ethical leadership, with a weighting of 1.4841, is the most suitable leadership style for improving companies' ESG performance. This finding demonstrates that a management approach based on ethical values plays a decisive role in companies achieving their sustainability goals. By centering the principles of fairness, honesty, responsibility, and transparency in decision-making processes, ethical leadership both improves the quality of corporate governance and strengthens stakeholder trust. The literature frequently emphasizes that ethical leadership is one of the most critical factors supporting ESG performance [28]. Ethics-based management approaches increase employee motivation and a sense of corporate belonging, while also embedding social responsibility and environmental awareness in the corporate culture. In this context, it is recommended that ethical leadership training be expanded at the policy level for business managers, corporate codes of ethics are established, and independent units are established to monitor their implementation [29]. Furthermore, public authorities and regulatory bodies should develop reward mechanisms and sustainable management standards that encourage ethical leadership practices in businesses. From a corporate strategy perspective, it's crucial to prioritize executives with a high sensitivity to ethical values in leadership selection and promotion processes, to assess stakeholder expectations from an ethical perspective in decision-making, and to strengthen accountability mechanisms [30]. Thus, an ethical leadership approach will not only enhance the quality of governance but also lay the foundation for sustainable corporate transformation in environmental and social dimensions.

VI. Conclusion

This study aims to determine the most effective leadership style in improving the ESG performance of businesses and to identify the most important criteria influencing this choice. In this context, an extensive literature review is conducted, 12 criteria affecting ESG performance are identified, and five different leadership styles are evaluated as alternatives. Expert opinions are utilized throughout the analysis process, and their importance weights are objectively calculated using the z-NIDM. Criteria importance levels are determined using the CIMAS method, and alternative leadership styles are ranked using the RAM technique. Furthermore, to more accurately model uncertainties, the Sierpinski triangle fuzzy sets developed in this study are used, thus introducing a new fuzzy set approach to the literature. The analysis results indicate that ethical and transformational leadership styles are the most effective approaches in improving ESG performance, while criteria related to environmental and governance dimensions most strongly shape leadership impact. These findings demonstrate that leadership style is a determinant not only of organizational success but also of sustainability performance. The study provides original and significant contributions to the literature by proposing a new integrated multi-criteria decision-making model from a methodological perspective, introducing Sierpinski triangle fuzzy sets to the literature, and presenting an empirical analysis of the ESG-leadership relationship.

This study has some theoretical and methodological limitations. First, the scope of the research is based on a general assessment across sectors, and no sector-specific analysis is conducted. However, different sectors may exhibit differences in ESG dynamics, environmental sensitivity levels, and leadership structures. Therefore, future studies applying the model to specific sectors such as energy, finance, healthcare, or manufacturing could provide a more in-depth understanding of the impact of leadership types on ESG performance within the context of sectoral differences. Furthermore, while the integrated decision-making model proposed in this study, the z-NIDM–CIMAS–RAM–Sierpinski fuzzy approach, offers a robust methodological framework, it does have certain limitations. Because the applicability of the model relies heavily on expert opinion, the results obtained may vary depending on the participant profile. Furthermore, because Sierpinski triangle fuzzy sets are a novel structure, they need to be tested on different problem types and samples. Comparing this method with other fuzzy logic approaches in future research will increase the generalizability and reliability of the model. However, evaluating the adaptability of the model in different decision environments, especially dynamic and uncertain data structures, is also suggested as an important research area for future studies.

TABLE VI. LIST OF CRITERIA

Dimensions	Criteria	Short Codes
Environmental Dimension	Resource efficiency	RSREFF
	Potential for reducing carbon emissions	PTRCEM
	Promoting green innovation	PRGRINN
Social Dimension	Employee engagement and motivation	EMENMT
	Applicability of diversity and inclusion policies	APPDIP
	Community engagement and stakeholder satisfaction	CMMENSS
Governance Dimension	Ethical problems	ETHPR
	Risk management and long-term sustainability vision	RMNGLTSV
	Accountability and audit mechanisms	ACCAUDM
General / Performance Dimension	The difficulty of integrating ESG strategies into corporate objectives	DFFESGST
	Adaptation and openness to change	ADPTOPT
	Contribution to long-term financial sustainability	CNTLFS

***Abstract*—Reward-based crowdfunding platform fraud has now become a multimodal and temporally dynamic threat, with conventional text-only or snapshot-based detection methods ineffective at detecting more complex deceptive campaigns. In this study, a Temporal Dynamics Aware Multi-Model Fraud Detection Framework (TDMM-FDF) that simultaneously models linguistic indicators, visual discrepancies, and time behavioral changes is proposed. The framework introduces three key innovations: 1) HM4, a Hidden Method-of-Moments Markov model for modeling long-range latent transitions across campaign updates, 2) Polynomial Expansion Canonical Correlation Analysis (PECCA) for quantifying nonlinear semantic discrepancies between textual narratives and associated images, and 3) Frequency-Gated GRU (FG-GRU) which separates recurrent activations into low frequency (trend) and high frequency (anomaly) components in order to achieve higher sensitivity to abrupt fraudulent behaviors. Massive simulations on an actual Kickstarter data set prove that the given architecture outperforms classical machine learning models, sequence encoders, and transformer baselines significantly [96.4% accuracy and good calibration (ECE = 0.06) and high ROC-AUC]. The supplementary role of all modules is confirmed in ablation studies, and their qualitative analyses provide precise semantic-visual discrepancies and semantic time anomalies of fraudulent campaigns.**

Keywords*—Crowdfunding fraud detection; multimodal learning; temporal behavior modeling; cross-modal consistency analysis; blockchain-based verification

I. Introduction

Over the past years, online crowdfunding sites have transformed the world of entrepreneurship and innovation funding through a system that helps individuals and startups to raise funds through the help of a large group of supporters and cuts off the middlemen. In fact, the reward-based crowdfunding model has gained popularity; specifically, the Kickstarter platform has already assisted in the launch of hundreds of thousands of campaigns, with the billions of dollars pledged [1], [2]. This liberalization of capital has opened new possibilities to both project creators and those who support the projects. However, it has also brought great new risks.

Fraud is one of the gravest threats to crowdfunding ecosystems: creators who lie about themselves, who cannot deliver on their promises, or otherwise abuse the trust of backers. The trend of misleading campaigns based on the use of linguistic indicators, insignificant responsibility of creators, and the absence of effective control over platforms is increasing. Crowdfunding fraud is a betrayal of trust, a risk to the reputation of the platform, and compromises the future sustainability of the crowdfunding business model [3]. Nevertheless, even being significant, the analysis of fraud in this field of crowdfunding is at a comparatively young age, particularly in comparison with fraud prevention in the banking or credit-card sectors.

One of the difficulties of identifying crowdfunding fraud is time-related factors. Although much of the literature is devoted to the fixed characteristics of campaigns (e.g., funding goal, number of backers, presence of video), the movement of a campaign, how updates are displayed, how the activity of backers varies with time, and how communications by creators vary with time can provide dense information about legitimacy or dishonesty. To give an example, Bernardino et al. in their exploratory analyses of crowdfunding dynamics observed that backer and updates temporal dynamics may differentiate between successful and non-successful campaigns [4]. Nevertheless, these time indicators are still mostly unexploited in the field of fraud detection studies. According to one of the recent systematic reviews [5], the detection of fraud within the context of crowdfunding tends to ignore the time and multi-modality of behavior, concentrating on static snapshot characteristics. Multi-modal information is also another important dimension. Contemporary crowdfunding efforts usually contain text (project description, updates, and comments), images and video (media of the product or prototype), and time (frequency of updates, funding pattern, reactions of backers). Fraudsters can exploit a single modality and conceal inconsistencies in another (or both) or may conceal discrepancies between modalities or in the timing of interactions. Such cross-modal incongruity as a shiny image of the product, but slow updates or missing comments by true backers can be powerful red flags, but there is little incorporation of multiple modalities and time.

This study introduces a temporal dynamics-aware multi-modal fraud detection framework, which is explicitly implemented in a reward-based crowdfunding platform. It can be driven by the fact that there is a growing sophistication in terms of deceiving potential followers using multimedia content and time behavior by fraudulent campaigns. To overcome these difficulties, we design our framework, incorporating time modelling, multi-modal feature fusion, and cross-modal

consistency validation to have a holistic mechanism of fraud detection. Our system is based on the Hidden Method-of-Moments Markov Model (HM4), the first great component that represents sequential dependencies in campaign updates and interactions between supporters. HM4 is useful in learning such latent behavioral patterns, which differentiate legitimate campaigns and those with suspicious or erratic updating behavior patterns. This time sensitivity enables the model to sense any abnormality in the frequency of postings, development of contents and the support of posts over time.

This study was inspired by the fact that the nature of deception on crowdfunding sites has been evolving at a high rate since the phishers on the crowdfunding sites have outgrown the textual lies into the so-called temporal-multimodal deception. Although the current body of literature has devoted much attention to the so-called snapshot-characteristics these approaches are getting more and more oblivious to the high-tech rhythm of the modern fraud. A dishonest designer might be able to provide a professional impression, but have a suspicious update rate or textual content that does not match visual prototype clues. It is in dire need of a framework that not only views multiple data types but also comprehends their correlation and time dynamics. The optimization of verifying temporal behaviors should be coupled with cross-distribution checks, whereby platforms can transition to the state of proactive fraud resistance and high precision.

For fusing heterogeneous data modalities, we propose a Frequency-Gated Gated Recurrent Unit (FG-GRU) architecture. This new form of GRU inserts multi-scale frequency gating to primarily highlight meaningful temporal variations. The FG-GRU takes in three streams of inputs: 1) textual features, which have been extracted based on a Hierarchical Pattern Distillation-based approach on BERT representations to identify semantic inconsistencies, 2) visual features, which have been extracted based on ICI-based CLAHE and HOG/SIFT to take in image manipulation or reuse, and 3) temporal states by the HM4 model. The combination of those modalities allows the classifier to make resilient campaign honesty forecasts. We also use Polynomial Expansion Canonical Correlation Analysis (PECCA) in cross-modal consistency checking between textual and visual modalities. This will guarantee the semantics adherence, where the potential discrepancies will be indicated, including the presence of overly professional imagery and the incoherent or misleading textual explanations. This will make PECCA more interpretable and will increase the trust in the decision-making process of the model.

The rest of the study is structured in the following way: Section II is the review of the related literature about crowdfunding fraud, temporal modelling, and multi-modal detection. Section III will provide our methodology, such as data preprocessing, feature extraction, model configuration, and training strategy. Section IV presents our results, comparison with baselines, ablation studies and qualitative case studies. Lastly, Section V concludes and identifies the future research directions.

II. Related Work

Crowdfunding has grown into a mainstream tool of financing in its early stages, but the transparency that empowers creativity can also prove flaws on the platforms in its ease of cheating. Initial studies of crowdfunding-related fraud focused their analysis more on fixed characteristics of campaigns, such as creator profile features, language indicators, and top-level engagement mechanisms, and used classical classifiers. Lee et al. have built a labelled Kickstarter corpus and have shown that forward stepwise logistic regression using engineered campaign/creator/content features can distinguish between fraudulent and legitimate campaigns with an accuracy of 87.3%; noteworthy, they also observed the vulnerability of snapshot features that disregard the dynamics of behaviors over time [1]. As previously explained, Perez et al. expanded the field to include platforms, modalities, and reported good AUC when using text-image features and traditional ML baselines, but not with temporal signals in model selection [3]. Qu and Hou wrote a corresponding thread about textual self-contradiction in a campaign and suggested a dual BERT-mT5 pipeline with sentence designs and sentiment classification to achieve 85.26% accuracy-text only, but ignoring visual/temporal cues [6]. A PRISMA bibliometric study has enhanced the fragmentation in the field and identified precisely such gaps as a deficient temporal modelling and a deficient multi-modal integration as the key obstacles to effective fraud detection in the sites of a crowdfunding business [7].

Temporal signals are significant candidates of project success and, by implication, plausibly informative of fraud detection in the event of the patterns being out of place. In each of the 2852 projects, the analysis by Solodoha revealed non-linear effects of frequency of updates: both neglect and over-updating imply different implications on the results, hence the importance of fixed snapshots being blind to important context [8]. Though neighboring entrepreneurship literature explores uncertainty, hype, and incompleteness of decisions in crowdfunding and similar environments, it usually does not go beyond this; however, these articles encourage behavioral and time-sensitive phenomena (e.g., cadence of updates, latency between commitments and posts, dynamics of backer counts) that a fraud detector should learn [9]. Together with the preceding stream, this stream justifies the requirement of sequence-sensitive models as opposed to fixed classifiers.

Because most of these deceptive campaigns appear through professional-looking media so as to conceal suspicious text, cross-modal reasoning is paramount. Lin introduced a text-image fusion image-to-text misinformation model, which is an improvement over unimodal baselines and demonstrates that joint representations can detect subtle inconsistencies that individual modalities would be blind to [10]. This concept is refined in a few deep multimodal fake-news experiments that have contrastive objectives and optimal transportation to align and compare modalities (Shen et al.), or that have contrastive learning based on data-augmentation to harden models to distribution changes (Hua et al.) [11], [12]. Segura-Bedmar and Martinez showed that CNN-based fusion achieved competitive accuracy in Fakeddit, which proves the worth of acquired cross-modal features in comparison with concatenation alone [9]. In this area (Nasser et al.; Shen et al.), architectural forms, including late versus early fusion, attention-based alignment, and consistency scoring, are synthesized and can be directly translated to crowdfunding, although benchmarks may vary

[13], [14]. The literature confirms that explicit text-image correspondence plays a critical role in determining that there is a semantic discrepancy in digital content. Mohan et al. suggested a synergistic detection model based on TextGCN, Vision Transformers to learn intricate inter-modal association [15]. Hangloo and Arora proposed a feature fusion model that is specifically created to identify multimodal fake news through matching between divergent streams of data [16]. Huang et al. revealed that the diffusion model could be used to reveal text-image inconsistencies through visual data reconstruction based on textual prompts [17]. In addition, Kumari and Singh proposed a multimodal deep learning framework that combines different techniques of feature extraction to enhance the accuracy of the classification [18]. Fraud cannot easily take a single and fixed signature, and much more frequently is manifested in local anomalies in more or less plausible regions of behavior. The Local Outlier Factor (LOF) has been appealing to high-throughput systems since it models density-based deviations without any heavy parametric restrictions. Adesh et al. explain LOF and improved-LOF in the context of HPCC environments and focus on additional considerations of scalability and practical deployment that are relevant in the context of real-time platform defense [19].

Hybrid pipelines are being more often applied in further financial and enterprise terms to stabilize predictions. Cherif et al. provided a systematic review of credit card fraud detection with disruptive technologies and stressed on the transition to integrated deep learning models [20]. Khalid et al. suggested an ensemble machine learning methodology which involves using a combination of several classifiers to improve the screening of fraudulent transactions [21]. Ismail and Haq showed how enterprise financial fraud detection can be enhanced by addressing the features of engineering and hybrid model architecture to process unstructured information [22]. These experiments validate the application of unsupervised locality scores, e.g., LOF, to scale-down pronounced supervised classification confidence.

In modern fraud detection, signals occur in a sequence, or updates, comments, promises, but models must be able to retain long-range and short-range dependencies. Other than LSTM/GRU surveys, there are two strands that are of particular interest. First, GRU, based on architecture or training innovations offer more robust sequence encoders at restricted data. To learn spatial-temporal dependencies, Liu et al. use GRUs in a graph neural network to form GR-GNN and obtain reduced error in time-series prediction and how graphical inductive bias can stabilize recurrent learning [23]. Another article by Liu et al. is devoted to evolutionary optimization of GRU hyperparameters, where the authors report steady improvement as compared to vanilla GRUs in sequential prediction [24]. Second, there are spatial-temporal models of GAST (graph attention + temporal forecasting) which show that the attention toward changing relational structure enhances predictive fidelity when encountering the problem of distributional shift [25]. These advances provide information that leads us to augment GRU with (and for an NAR) frequency gating for separating low-frequency (slow-varying, strategic behavior) and high-frequency (abrupt, tactical actions) components to better pad both the drift and sudden anomalies at the campaign level.

Irrespective of the improvement, there are several loopholes. Multimodal datasets with temporal granularity unique to the phenomena of crowdfunding are still rare; much of the existing literature brings in the experiences of fake-news or financial transactions with alternative labels. Measures that are reported are usually based on average accuracy or AUC but do not include calibration and early-warning performance, which is also fundamental to intervention on the platform. Finally, multimodal, temporality explainability is underdeveloped; besides the attention maps, techniques that assign cross-modal discrepancies to tangible objects would be more helpful in moderating workflows.

III. Methodology

The proposed Temporal Dynamics Aware Multi-Modal Fraud Detection Framework (TDMM-FDF) combines the text, visual, and temporal features to detect fraudulent crowdfunding campaigns. The architecture consists of nine steps, namely, data collection and preprocessing, feature extraction, temporal modelling, cross-modal consistency validation, feature selection, classification with FG-GRU, and blockchain verification. Fig. 1 depicts the block diagram of a sequential workflow in which a preprocessing stage is carried out on the text and images obtained in the form of crowdfunding campaigns and the features are extracted and aligned, and HM4 is used to model the temporal patterns. Such multimodal representations are merged with each other and maximized and then given into the FG-GRU classifier. The final legitimate results are recorded in a ledger infrastructure based on blockchain to provide integrity and security.

A. Data Collection and Preprocessing

The data used in this research was obtained from the Kickstarter crowdfunding platform and was heterogeneous in multimodal form, that are needed to conduct effective fraud analysis. The dataset used is summarized in Table I. In each campaign example, there were organized and unstructured items, such as the project title, entire narrative descriptions, creator profiles, visual media, logs of updates and backer comments in a timely manner. The time-sensitive aspect of these fields allowed the modelling of both the static correlations, as well as dynamic behavioral routes that are usually characteristic of a fraudulent campaign.

Considering the noisiness and informality of user-generated Kickstarter contents, an elaborate pretext text processing pipeline was used so as to make sure semantic integrated before feature extraction. First of all, the extraneous HTML tags, links, emojis, and non-standard punctuation were eliminated, and lexical distortion was avoided. Any textual information was then normalized in two steps: 1) lowercasing all texts to token uniformity, and 2) stop word elimination to bury high-frequency and low-information words. This normalization can be formulated as in Eq. (1):

$$T' = Normalize(T) = Lowercase\,(RemoveStopwords(T)) \quad (1)$$

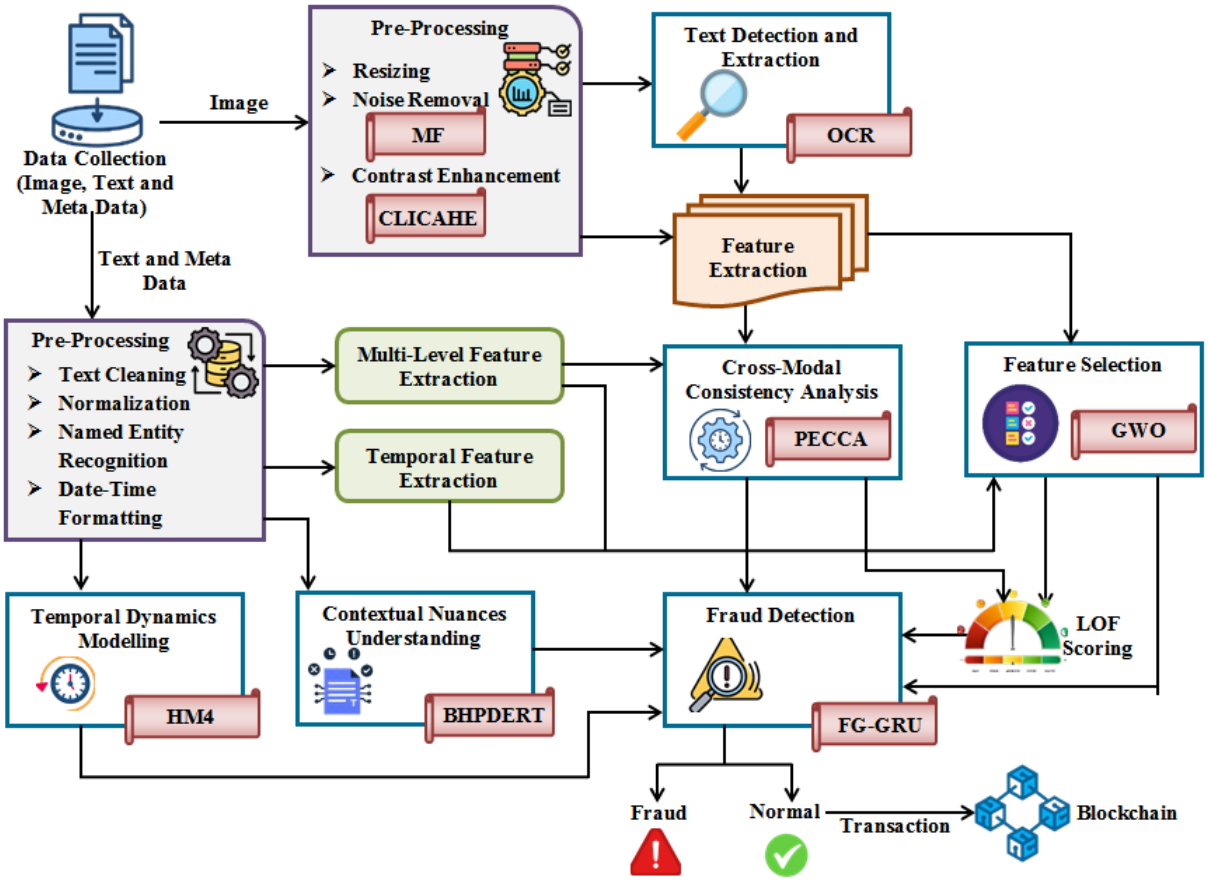

Fig. 1. Block diagram of the proposed framework.

TABLE I. DATASET AND PREPROCESSING SUMMARY

Attribute	Description
Number of campaigns	28,500 campaigns after preprocessing
Temporal coverage	2014–2024 Kickstarter data
Textual components	Titles, long descriptions, FAQs, updates, comments, creator metadata
Visual components	Poster images, prototype photos (1–8 per campaign)
Temporal sequences	Update timelines, backer activity logs, milestone timestamps
OCR-derived features	Extracted embedded poster text
Text preprocessing	HTML/emoji removal, normalization, stemming, NER
Image preprocessing	Median filtering, CLICAHE, OCR
Output modalities	Text vectors, image descriptors, temporal latent states

In addition, stemming was used to decrease inflexion forms, which minimized the inflexibility of token distribution. NER was later used to recognize semantically important entities which included organization names, product identifiers, time phrases, monetary values, and geopolitical positions. These entity-level annotations facilitated the verification of cross-image-based and time-based signals later on in the framework.

The image processing pipeline of the campaign was a combination of noise removal, texture-textuality-sensitive contrast segmentation, and inscribed text recovery to ensure the visual data quality brought across the actions of different campaigns matched adequately. Firstly, the images were morphologically enhanced with the Median Filtering (MF), which is a non-linear denoising operator that is efficient in noise reduction, especially salt-and-pepper noise, and the edges of the images are maintained. The process of filtering is given in the form of an equation, as shown in Eq. (2):

$$I'(x,y) = median\{I(i,j) \mid (i,j) \in N(x,y)\} \quad (2)$$

Subsequently, image contrast was improved using Contrast-Limited Image Complexity Adaptive Histogram Equalization (CLICAHE), an advanced extension of CLAHE. Unlike standard CLAHE, which applies a fixed clip limit, CLICAHE dynamically adjusts the clip threshold based on the Image Complexity Index (ICI) of each local region. Let H_k denote the histogram of a contextual region k, and let α_k [Eq. (3)] be the adaptive clip limit:

$$\alpha_k = \alpha_0(1 + \lambda \cdot ICI_k) \quad (3)$$

where, α_0 is the baseline clip limit, λ controls sensitivity to complexity, and ICI_k is defined as in Eq. (4):

$$ICI_k = \frac{1}{|R_k|}\sum_{(x,y)\in R_k}|\nabla I(x,y)| \quad (4)$$

Lastly, Optical Character Recognition (OCR) was used to extract textual clues that were within the poster-type images like product specifications, promotional statements, or disclaimers.

The OCR text was subsequently cross tabulated with the cleaned narrative descriptions to determine the presence of any textual variation or exaggerations that were suggestive of some form of fraud.

B. Textual Feature Extraction

The textual modality was enhanced by the extraction of lexical, semantic, and pragmatic cues, which make it possible to model linguistic behaviors of deceptive or misleading narratives in a comprehensive manner. The lexical indicators consisted of part-of-speech (POS) distributions, type-token ratios, and vocabulary richness measures, which all measure structural characteristics of campaign narratives. The pragmatic features have been calculated in order to distinguish between professionally written descriptions and suspiciously twisted or over-simplified text. Also, sentiment polarity and subjectivity scores were calculated to measure the tone of emotion, as fraudulent campaigns tend to be based on overstated optimism or framing of sentiment.

To have a deep semantic representation, the study utilized the Bidirectional Hierarchical Pattern Distillation Transformer (BERT-HPD), an improved transformer architecture, which aims to maintain the contextual depth and, at the same time, minimize computational costs. The underlying BERT encoder uses a contextualizing representation of all the tokens in the text by learning bi-directional dependencies between the text. Mathematically, given a sequence of input tokens ($w_1, w_2, \dots, w_n$), BERT will compute a contextual representation vector h_i [Eq. (5)] at every token position:

$$h_i = BERT(w_1, w_2, \dots, w_n) \tag{5}$$

As much as standard BERT offers high-quality semantic features, when operational on a large scale, its implementation can be expensive in terms of computation requirement to large multimodal pipelines. To solve this, a masked generation architecture (HPD) mechanism was incorporated that enabled the transfer of hierarchical linguistic knowledge of a high-capacity teacher BERT to a smaller student model. This distillation has a guarantee that significant syntactic/semantic/discourse-level structure is still present in the reduced representation. $h_l^{(teacher)}$ and $h_l^{(student)}$ will represent the hidden states of layer l of the teacher and student models, respectively. The objective of the HPD is to reduce the difference between representations on a layer basis and to be able to faithfully recreate linguistic hierarchical patterns. The loss during the distillation is determined as in the Eq. (6):

$$\mathcal{L}_{HPD} = \sum_{l=1}^{L} \left\| h_l^{(teacher)} - h_l^{(student)} \right\|_2^2 \tag{6}$$

The student model implements multi levels of linguistic abstraction, including local syntactic interactions as well as global semantic dependencies, without initially having the computational costs of the entire BERT architecture, by applying this constraint. The process does not only minimize the overfitting potential that would have occurred when, in the text training, it is important to train on text that has strong stylistic variations like crowdfunding campaigns but also retains fine-grained deception signals such as semantic inconsistencies, over-general content, and unnatural emphasis patterns. Consequently, BERT-HPD offers a high-capacity and effective basis of downstream multimodal fraud detection.

C. Temporal Dynamics Modelling

To model the temporal evolution of campaign behavior, this work employs the HM4, an advanced variant of the traditional HMM. HM4 is designed to capture long-range dependencies and structural dynamics in sequential update patterns that often characterize legitimate and fraudulent crowdfunding projects. Let the hidden state space be defined as, $S = \{s_1, s_2, \dots, s_k\}$, where each latent state corresponds to an underlying behavioural regime such as consistent updates, erratic communication, sudden activity surges, or prolonged inactivity. Similarly, the observable sequence is represented as, $O = \{o_1, o_2, \dots, o_T\}$, derived from timestamped campaign updates, linguistic tone shifts, and engagement metrics.

The classical HMMs have the transition matrix A, emission matrix B, and initial state distribution π, which are estimated by the Baum-Welch algorithm, which is an Expectation-Maximization (EM) implementation. Despite its popularity, Baum-Welch is iterative in nature and tends to become trapped in bad local minima especially when dealing with noisy or high-variability behavioral data like crowdfunding updates. This is the restriction that renders standard HMMs inadequate in detecting fraud cases when the underlying behavioral patterns are not close to stationary or smooth tracks.

To overcome these issues, HM4 is introduced to replace EM-based optimization with a global statistical moment-matching model, which allows analytical recovery of model parameters. The point is that when properly designed, low-order observable moments capture enough information concerning the dynamics of latent states. The first-order moment of observations meets the Eq. (7). Similarly, second-order cross-moments between adjacent observations capture transition structure:

$$E|O_t| = \sum_{i=1}^{k} \pi_i \mu_i, \qquad E|O_t O_{t+1}| = \pi_i A_{ij} \mu_i \mu_j^T \tag{7}$$

These moment equations constitute a web of algebraic equations. HM4 computes transmission and emission parameters without the need to find the transition matrix A or q in an iterative improvement HM4 computes the initial state distribution p, the emission parameters B and the overall transition matrix A by means of spectral decomposition or by means of the tensor's factorization directly. This does away with local minima vulnerability and offers a globally compatible forecast of the temporal dynamics.

D. Image Feature Extraction

After contrast enhancement and denoising, each processed image was then run through a detailed feature extraction pipeline that aimed to extract a set of complementary image features with respect to fraud detection. Images used in crowdfunding campaigns frequently include minor anomalies, including recycled or stock images, artificially-enhanced prototypes, or artificial visuals of products, that cannot be readily found by raw pixel inspection. To resolve this, a collection of well-defined handcrafted descriptors was used and each of them provided a different approach to texture, structure, and information in the key point level.

Local Binary Patterns (LBP) were first calculated to describe the patterns of micro-textures of the surface of the image. LBP represents local spatial difference by thresholding intensity of neighborhoods around each pixel thus producing rotation-invariant descriptors, which are very sensitive to material textures and surface consistency. This is especially concerning when trying to determine the inconsistencies on the surfaces of products or when trying to detect image patches which are artificial and are very common in fake campaigns. Then, Gray Level Co-occurrence Matrix (GLCM) characteristics were computed to measure the existence of higher-order spatial relations. GLCM is the intensity correlation of pairs of values at a set of offsets, and it can measure the contrast, homogeneity, entropy, and correlation. These characteristics give an understanding of structural coherence and can identify abnormalities like inappropriate lighting patterns, inappropriate shading, or a background that has been made up, which would suggest tampered or non-original images.

Histogram of Oriented Gradients (HOG) descriptors were applied to obtain geometric information. The distribution of gradient orientations is coded in HOG and the edges and contours and object boundaries can be represented in detail. This assists in revealing unnatural formation of edges or silhouettes that are overly smooth that can indicate image manipulation or utilization of unrealistic prototype images. The Scale-Invariant Feature Transform (SIFT) algorithm was also used to find strong key points and calculate local descriptions that are feature scale, rotation and illumination independent. SIFT is specifically good at recognizing recurring regions in images or recognizing the presence of an image borrowed by external, publicly accessible stock libraries. The resulting image-feature representation is an ensemble of all the descriptors obtained [Eq. (8)]:

$$F_{img} = [LBP, GLCM, HOG, SIFT] \quad (8)$$

E. Cross-Modal Consistency Check

The suggested framework includes the cross-modal consistency analysis mechanism, as PECCA, to be sure that textual and visual modalities are mutually consistent in terms of evidence. This module assesses the semantic consistency between campaign images and textual descriptions, which are essential in fraud detection since misleading campaigns tend to exhibit images that do not match with the textual description to give the illusion of being credible. Canonical Correlation Analysis (CCA) provides the classical foundation for Multiview alignment by learning linear projections of text features X and image features Y such that the correlation between their projected representations is maximized.

The architecture uses PECCA, which is a nonlinear extension of CCA that develops each modality by feature expansion via polynomials. These extended representations enable PECCA to represent the higher-order dependencies among modalities, which in effect capture subtle nonlinear dependencies, e.g., stylistic inconsistencies or unrealistic image-text co-occurrence or semantic discrepancies between the claimed product functionality and the visual representation. After its expansion, PECCA uses standard CCA on transformed feature spaces $\emptyset(X)$ and $\emptyset(Y)$, therefore integrating the analysis of nonlinear correlations and omitting deep learning-based fusion networks.

F. Feature Selection

After extracting text-based, image-based, and temporal features, the three modalities were concatenated [Eq. (9)] to form a unified multimodal representation. Whereby each element holds complementary data: the semantics of language and cues of deception in the text, structural and surface-level data in the images, and behavior patterns in the dynamics of time. This fused representation, despite being very expressive, generally falls into a high-dimensional feature space. This dimensionality may bring about redundancy, higher computational cost, and even diminished model generalization because of irrelevant or noisy attributes. Metaheuristic strategy of feature selection, which relies on the optimization of the grey wolf (GWO), was used to solve these problems.

$$F = [F_{text}, F_{img}, F_{temp}] \quad (9)$$

GWO is a bio-inspired optimization method which imitates the hierarchical leadership and hunter-cooperative behavior of the grey wolves. This hierarchy places the three most fit wolves in the form of α, β, and δ. They are the candidate solutions that are most fit in the feature space, and direct the search means the feature space. The rest of the wolves, the ω wolves, refresh their locations in accordance with such three leaders, and in this way, we have a balance in exploration and exploitation in the optimization. A fitness function based on classification accuracy was used to assess the quality of an individual candidate feature subset. In particular, a lightweight classifier was trained on a validation split based on the selected subset of features only, and the accuracy obtained was used as the fitness score.

G. Fraud Detection Model (FG-GRU)

The last prediction step performed by the proposed framework uses a Frequency-Gated Gated Recurrent Unit (FG-GRU), a recurrent network architecture specific to both gradual and rapid behavioral change, as well as sudden, high-intensity change that often indicates a fraudulent campaign. Compared to the classical GRU, which interacts dependency with time using its update and reset gates, the FG-GRU proves this operation, dividing the dynamics of the hidden state into low-frequency and high-frequency components and is able to significantly differentiate two long-term behavioral patterns and discrete upsurges. The base GRU computes its hidden state h_t at time step t using the gated recurrence formulation [Eq. (10)].

$$h_t = z_t \odot h_{t-1} + (1 - z_t) \odot \tanh(Wx_t + r_t \odot Uh_{t-1}) \quad (10)$$

To better distinguish between smooth behavioral progressions and sharp deviations, the FG-GRU introduces a frequency decomposition stage. The hidden state h_t is passed through two filtering operators $F_{\text{low}}(\cdot)$, which extracts low-frequency (slow-varying) temporal components, and $F_{\text{high}}(\cdot)$, which extracts high-frequency (rapid-change) components. To integrate both frequency bands, FG-GRU introduces two learnable gating functions, g_{LF} and g_{HF}, which determine how much each component contributes to the final blended representation [Eq. (11)].

$$h_t^{FG} = g_{LF} \odot h_t^{LF} + g_{HF} \odot h_t^{HF} \quad (11)$$

To increase the reliability of the decisions, the FG-GRU output is assessed based on Local Outlier Factor (LOF). LOF

measures the isolation of a particular instance against the local neighborhood of such an instance in the latent representation space. Campaigns with multimodal temporal signatures that are significantly different than normal behavioral clusters are assigned lower density scores, and thus the prediction ambiguity is minimized, and more effectively distinguish between legitimate and fraudulent activities.

H. Blockchain Execution Layer

The framework uses a blockchain-based execution layer to make sure that the results of detecting the fraud are stored in a way that is tamper-resistant and auditable. This section reserves the results of the classification engine, namely, the campaign name, fraud rating, and final decision tag, into a decentralized registry. Using blockchain to anchor these findings will create an unalterable and transparent history of all the fraud evaluations conducted, which will instill greater confidence in the administrators of these platforms, campaign creators and sponsors.

A blockchain transaction Tx_i is created with each campaign C_i that has been taken through the multimodal evaluation pipeline. This is a transaction that includes key metadata, such as campaign ID, an output of the metadata, the fraud score S_i, or classification, and the time of evaluation t_i. The content of the transaction is encrypted with the help of a cryptographic hash, $H(\cdot)$, the implementation of which makes it impossible to make any changes to the stored information.

After it has been created, every transaction is added to the shared blockchain list stored by numerous nodes. The decentralization of the ledger makes it so that no one can manipulate or overwrite the outcome of a fraud assessment, and in the highly stakes setting of a crowdfunding site, where a challenge to the legitimacy of a campaign can emerge, it is of utmost importance. Additionally, the append-only cryptographically secured ledger does offer a verifiable audit trace that can be consumed either to conduct compliance audits, to resolve disputes, or to provide a long-term audit of campaign behavior.

IV. Results and Analysis

A. Simulation Setup

The study was performed on a real-life dataset that was gathered on Kickstarter, which is one of the biggest reward-based crowdfunding platforms. The structure of the dataset consists of campaign descriptions, project titles, visual media, creator metadata, update logs, timestamps, and funding progress indicators. Fraud labels have been generated using cases of scams reported publicly, campaigns identified as suspicious by the platform, and those reported by the community as fraudulent. To avoid the effect of temporal leakage, an inherent problem in sequential or time-dependent data where information in a future sample somehow affects the model's knowledge of historical behavior, the data has been stratified on a chronological basis. This guarantees that the time sequence of the campaign events is maintained during training and assessment. Namely, the first 70 per cent of campaigns were designated to the training set, which enabled the model to learn the patterns based on the historical data exclusively. The mid-period time frame entailed the subsequent 15% of campaigns, which made up the validation set and was utilized to tune hyperparameters and refine models. The last 15 percent of campaigns were used as the test set, which allowed the fair assessment of the model to generalize to new, unobservable campaigns that emerge in the future. Table II lists the most important hyperparameters for each component: HM4, PECCA, feature extractor modules, and the FG-GRU classifier.

TABLE II. Model Hyperparameters

Module	Parameter	Value / Description
HM4 (Temporal Model)	Hidden States (K)	6
	Moment Order Used	Up to 3rd-order cross-moments
	Transition Estimation	Algebraic MoM solver
	Emission Model	Gaussian Mixture (3 components)
Textual Encoder (BERT-HPD)	Max Seq Length	256 tokens
	Teacher Model	BERT-base (110M parameters)
	Student Model	8-layer distilled variant
	Distillation Loss	Layer-wise MSE + KL divergence
Image Processing	MF Kernel Size	5×5
	CLICAHE Tiles	8×8 blocks
	Clip-Limit	Adaptive (0.5–3.0)
Image Feature Extraction	LBP Radius	1
	GLCM Angles	{0°, 45°, 90°, 135°}
	HOG Cells	8×8
	SIFT Keypoints	Up to 500 per image
PECCA (Cross-Modal)	Polynomial Order	3
	Latent Dim (CCA Space)	120
	Correlation Threshold	0.55
FG-GRU Classifier	GRU Units	256
	Frequency Filters	Low (0–2 Hz), High (2–20 Hz)
	Batch Size	32
	Optimizer	AdamW
	Learning Rate	1.00E-04
	Epochs	50

B. Performance Comparison

To rigorously assess the efficiency of the developed multimodal fraud detector, the performance of the framework was compared to a collection of more popular baseline models, including classical ML methods, such as SVM and RF, and DL models, such as LSTM, GRU, and fine-tuned BERT. There were the same baselines train on the same experimental conditions, with the same chronologically stratified splits, and with the same normalized feature representations, in order to have an unbiased and fair comparison.

The outcomes of the performance, which are provided in Table III, indicate a steady and significant percentage of

improvement provided by the proposed model in all significant evaluation indicators. Conventional baselines like SVM and RF are also somewhat effective, but they fail to deal with the high temporal, visual, linguistic, and disparate nature of fraudulent crowdfunding activities. The sequential models, including LSTM and GRU, exhibit significant improvements since they can learn temporal dependencies; nevertheless, they cannot work well in the situation when cross-modal contradictions or irregularities in the behavioral pattern are present. The performance of Fine-tuned BERT is as good as it should be, especially regarding its contextual semantic knowledge, but it is restricted by its lack of inter-modal footing and explicitly modelled time view.

TABLE III. PERFORMANCE COMPARISON WITH BASELINE METHODS

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC	ECE
SVM	82.40%	79.50%	74.20%	76.70%	0.84	0.19
Random Forest	86.10%	83.80%	81.20%	82.50%	0.88	0.15
LSTM	88.70%	86.50%	84.10%	85.30%	0.9	0.13
GRU	90.30%	88.10%	85.60%	86.80%	0.92	0.12
BERT (Fine-tuned)	92.80%	91.20%	89.60%	90.40%	0.95	0.11
Proposed HM⁴ + PECCA + FG-GRU	96.40%	95.10%	94.20%	94.60%	0.982	0.06

The developed HM4 + PECCA + FG-GRU fusion architecture is obviously more superior. The system learns a much more diverse range of behavioral and semantic cues by combining HM4 with its strong ability to estimate temporal states, PECCA with its ability to model nonlinearly across cross-modal features, and frequency-aware sequential modelling, which is provided by FG-GRU. This leads to particularly high increases in Recall, a vital measure on fraud detection, and missing a fraudulent campaign is risky. The fact that the ROC-AUC score is very close to 0.98 is also a testimony to the high discriminatory power of the model in ranking suspicious campaigns over legitimate ones, suggesting that there is reliable discriminatory power even in difficult borderline cases. The other important benefit is the fact that the Expected Calibration Error (ECE) is reduced drastically between 0.11 with fine-tuned BERT and 0.06 in the offered system. This enhancement also indicates more credible confidence estimates, so that forecasts of fraud are closer to the likely outcomes, a necessary quality of real-world decision-making systems employed by crowdfunding platforms.

The proposed system has an ROC curve (Fig. 2) that shows a steep and very steep climb up to the upper-left corner, indicating that it has a high capacity to differentiate between fraudulent and legitimate campaigns at different decision thresholds. The model with a ROC-AUC of 0.982 has a significantly high discrimination capacity in comparison to all the baseline methods. This implies that, with the combination of time, text, and visual cues, the classifier is able to make accurate and correct ranking decisions even in borderline cases.

The Precision-Recall (PR) curve (Fig. 3) also proves the strength of the model to deal with the inherent class imbalance in fraud detection tasks. The suggested framework ensures that its precision exceeds 0.90 throughout a broad range of recall, which proves that the framework is capable of detecting fraudulent campaigns in an effective manner without the use of many false positives. This is especially crucial in real-life environments where a high rate of false alarms would destroy credibility and augment the operational load of investigation teams. The model proposed is highly precise at above 0.90 recall level, which can be explained by the fact that PECCA and FG-GRU complement each other with nonlinear multimodal alignment and frequency-conscious temporal modeling, respectively. These mechanisms taken jointly can provide a more detailed insight into campaign behavior and the system would hold true even in challenging conditions.

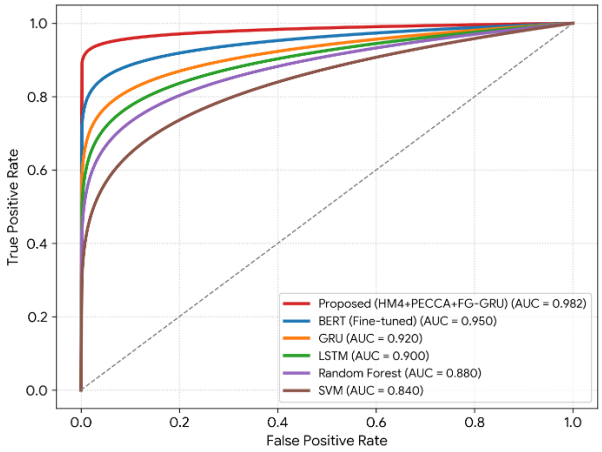

Fig. 2. ROC curve of the proposed fraud detection model.

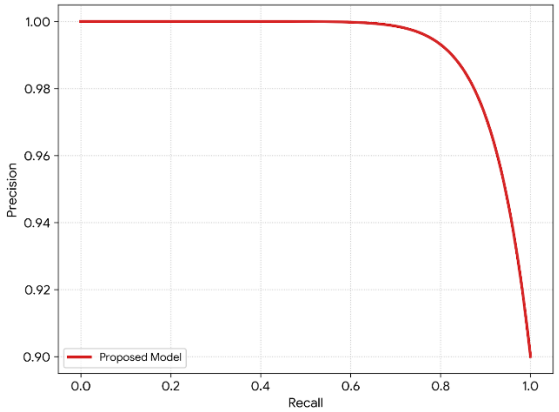

Fig. 3. Precision–Recall (PR) curve of the proposed fraud detection model.

As in Table IV, the confusion matrix obtained after testing the set shows that the proposed model possesses significantly low misclassification rates. Among all valid campaigns, 41 were falsely reported as fraudulent and the number of false negatives was only 23, which is significantly less than the baseline models. This enhancement underscores the usefulness of incorporating temporal state transitions of HM4 and multimodal contradiction detection of PECCA, which helps the system to identify subtle behavioural abnormalities that most simple models fail to detect.

Moreover, in the calibration curve (Fig. 4), it can be seen that there is a strong agreement between the predicted probability of fraud and the actual outcome frequency. It means that the model is effective in classification, as well as yielding credible confidence estimates. These predictability-aware predictions prove important at work with fraud-monitors, where the tolerance to operational risk or policy-specific to platform alert thresholds can be changed dynamically.

TABLE IV. CONFUSION MATRIX

	Predicted Legitimate	**Predicted Fraudulent**
Actual Legitimate	1035	41
Actual Fraudulent	23	412

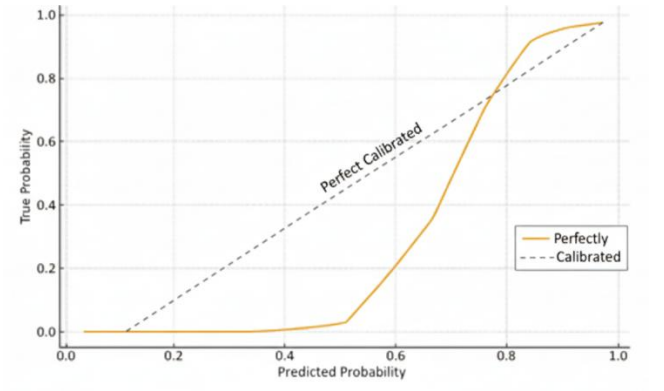

Fig. 4. Calibration curve of the proposed fraud detection

C. Computational Cost Analysis

To analyze three important aspects of computation, the runtime benchmarked three main aspects of computation, including training time per epoch, inference latency per sample, and memory usage on the GPU. The suggested model has greater computational overhead than the baseline GRU and fine-tuned BERT models, as illustrated in Table V. It has a 13.8 seconds per epoch training time and a 16.7ms per sample inference latency that indicates the extra processing added by multimodal feature integration, temporal moment modelling and frequency-gated recurrence. There is also the increment in GPU memory requirement to 7.9 GB due to the extended architecture and poly expansion modules.

A standard penciling of the blockchain integration in real-time detection systems is possible prohibitive latency, resource overhead. But in the TDMM-FDF architecture, the blockchain layer does not work as a processing module, but as an integrity-assurance layer, which is asynchronously running with the FG-GRU classifier. The system deters fraud scores (S_i) and metadata of campaigns by embedding them in a decentralized register, avoiding the so-called log-tampering that is a recognized vulnerability in a centralized platform management. We did a comparison of our blockchain-powered ledger and a regular centralized SQL-based logging system to determine that the integration is feasible. The findings, which are summarized in Table V, show that although the blockchain layer does add a slight increase in latency (22.4ms), the security advantages, namely, immutability and auditability by multiple parties, are essential to high-stakes governance of crowdfunding.

TABLE V. COMPUTATION COST ANALYSIS

Model	Training Time (per epoch)	Inference Latency (per sample)	GPU/System Memory
BERT (Fine-tuned)	11.2 s	14.3ms	6.5 GB
GRU (Vanilla)	4.3 s	5.1ms	2.1 GB
Proposed TDMM-FDF	13.8 s	16.7ms	7.9 GB
Blockchain Module	N/A (Asynchronous)	+22.4ms (Latency)	Negligible (CPU-bound)
Total Integrated System	13.8 s	39.1ms	7.9 GB + Storage

The computational trade-off would be fair even in the light of the extra costs because the gains in detection accuracy, recall, calibration reliability and ranking performance are significant. The enhanced predictive robustness and cross-modal interpretability of the suggested system offset the resource consumption increase in safety-critical settings, like fraud detection, where the outcomes of the failure to notice a fraudulent campaign can vary greatly in terms of financial and reputational implications.

D. Comparative Analysis of Feature Selection Methods

The choice to use the Grey Wolf Optimization (GWO) in the feature selection stage was due to the fact that it has a better balance of exploration and exploitation over the traditional metaheuristics. In high-dimensional multimodal spaces, such as that created by concatenating text, image and time features, approaches such as Genetic Algorithms (GA) are usually susceptible to premature convergence, whereas Particle Swarm Optimization (PSO) might get lost in local optima when optimizing non-convex fitness landscapes, as is the case with fraud detection data. In order to empirically defend this selection, a comparison was carried out with the use of a Kickstarter validation set. We compared GWO to GA, PSO and a standard L1-based (Lasso) selection. As the results, summarized in Table VI, indicate, GWO was able to find a smaller feature subset and a higher classification rate, which confirms its effectiveness in eliminating redundancy, and no important cues on deception were lost.

The GWO strategy achieved the largest reduction ratio (82.9) and the best fitness score (96.4), which was effective in recovering the curse of dimensionality, which is present in our 28,500 campaign data. This effectiveness is owed to alpha, beta, and delta leadership structure, which guides the search process towards the most informative region of the feature space faster as compared to the stochastic ones.

TABLE VI. COMPARATIVE ANALYSIS OF FEATURE SELECTION METHODS

Selection Method	Feature Reduction Ratio	Fitness (Acc)	Convergence (Iter)	Stability (Std Dev)
L1-Regularization	62.40%	91.80%	N/A (Linear)	±0.05
Genetic Algorithm (GA)	74.10%	93.50%	85	±0.12
Particle Swarm (PSO)	78.50%	94.20%	62	±0.09
Proposed GWO	82.90%	96.40%	48	±0.04

E. Ablation Study

The ablation study (Table VII) clearly demonstrates the contribution to the overall system performance of each of the components of the proposed architecture. The complete model scores the highest in all measures, proving the complementary advantages of the HM4, PECCA, BHPD-enhanced semantics, and the FG-GRU. The removal of the BHPD semantic distillation layer leads to a perceptible reduction in performance, which can be explained by the fact that the system would be less capable of detecting subtle linguistic information that is associated with campaign lie stories. The state-of-the-art HM4 leads to some of the greatest decreases in ROC-AUC and F1-Score, which shows that modeling the temporal state is important. The system cannot detect drift in behavioral patterns over time in the absence of HM4, and this increases the FNR. The removal of PECCA also harms the performance, especially the precision, because the model will be less effective in detecting the discrepancies between textual assertions and visual pieces of information.

TABLE VII. ABLATION STUDY RESULTS

Model Variant	Accuracy	F1-Score	ROC-AUC	Observation
Full Model (HM4 + PECCA + FG-GRU)	96.40%	94.60%	0.982	Best performance
Without BHPD (raw BERT)	94.10%	92.30%	0.964	Loss in semantic quality and deception cues
Without HM4	92.80%	90.70%	0.951	Temporal drift ignored; higher false negatives
Without PECCA	93.40%	91.10%	0.944	Missed text–image contradictions
Without FG-Gating (vanilla GRU)	91.90%	89.40%	0.935	Short-term spikes and long-term drifts poorly separated

Likewise, by substituting FG-GRU with regular GRU, the characteristics of the system to differentiate between the trends in long-term behavioral changes and unexpected anomalies decrease. This causes a poor depiction of irregularities in time, which in most cases are reflective of fraudulent activity. In general, the ablation findings indicate that all the components, that is, HM4, PECCA, BHPD, and FG-Gating, play a distinct and significant role in the robustness of the model, with HM4 leading the way toward Recall improvement, PECCA Precision improvement, and FG-GRU stabilization of the temporal dynamics through frequency-aware decomposition.

F. Discussion and Interpretations

The experimental outcomes show that the TDMM-FDF model is highly effective in overcoming the shortcomings of the traditional, one-dimensional models, because it can reflect the multifaceted, dynamic character of contemporary crowdfunding deception. The high and comparable performance of the proposed model compared to the baselines, such as BERT and vanilla GRU, indicates that fraud is not a linguistic or behavioral indicator but an emerged value of the cross-modal inconsistencies over time. As an example, the high Recall (94.2) indicates that the frequency-aware gates in FG-GRU are especially skillful to find out the so-called strategic fraud, in which a generator may fabricate a semblance of legitimacy by using slow-varying trends at the expense of sudden anomalies in updates or interaction in order to deceive supporters.

Moreover, the capability of the PECCA module to highlight discrepancies between the project narratives and visual prototypes is a response to a serious weakness wherein, in this case, the scammers rely on the use of professional-grade imagery to conceal poor or plagiarized textual descriptions. In addition to the spectral nature of the transitions of latent states expected of an HM4, this cross-modal correspondence gives the HM4 a type of interpretability that DL models that are black boxes frequently lack. The framework provides platform moderators with practical information about a certain behavioral change and semantic-visual contradictions instead of binary labels.

Practically, such multi-dimensional assessments are resistant to tampering and auditable, as the integration of a blockchain-based execution layer would provide. This openness is essential to ensuring long-term confidence in automated moderation systems, as it leaves a history of evaluation that cannot be changed, that shields both honest creators and prospective supporters against arbitrary decisions by platforms. Finally, the computational overhead trade-off is compensated by a massive decrease in Expected Calibration Error (ECE) that is converted to more accurate and confident fraud forecasting in high-stakes financial settings.

V. CONCLUSION

This study has provided a detailed Temporal Dynamics Aware Multi-Modal Fraud Detection Framework (TDMM-FDF), which has been developed to work in a reward-based crowdfunding system wherein fraudulent actions are exhibited with intricate interplay of linguistic indicators, visual anomalies and temporal aberrations. The combination of the proposed HM4 spectral-temporal model, Polynomial Expansion Canonical Correlation Analysis (PECCA), and the Frequency-Gated GRU (FG-GRU) classifier allows the framework to show a strong capability to identify deceptive campaigns that unimodal or snapshot-based classifiers would otherwise not identify. The experimental findings prove the existence of a unique, complementary role of each of the modules to enhance the predictive ability of the system. HM4 is a reliable indicator of latent behavioral regimes and temporal drift patterns that have a strong predictive potential of manipulative activity. PECCA offers a logical system of bringing to light semantic and stylistic contradictions between the narrative and the images in the campaign- one of the most commonly misused features of

advanced scammers. Likewise, the frequency-aware decomposition of FG-GRU allows the model to be able to distinguish between slow-moving behavioral cues and abrupt anomalies, thus being able to model both strategy-level deception and bursts of manipulative behaviors in updates or engagement.

In addition to model performance, the incorporation of a blockchain-based execution layer implies that it provides fraud assessment logs with secure storage, tamper resilience, and auditability, therefore, facilitating platform governance and long-term trust in automated decision systems. Although predictive accuracy and multi-modes integration of the framework is very high, there are a number of limitations that need to be recognized. First, the existing TDMO-FDF framework uses a database that is mostly based on Kickstarter. Although this gives a huge sample of 28,500 campaigns, the results cannot be completely extrapolated to equity-based or donation-based platforms where fraud indicators and backer activity patterns are not that similar. Second, the PECCA is an effective approach to learn the nonlinear discrepancy but it does so by choosing a polynomial order, which might need manual adjustment to other platform architectures. Future research must enhance capable early-warning identification in most lingering campaigns, project explainability to multi-modal time thought, and device self-trained pre-training on supernumerary lofty unlabelled crowdfunding datasets. Further extensions can also add video partitioning, pioneered hop of creator histories, and proactive learning processions of real-world moderation.

***Abstract*—This study aims to establish prioritized strategies for businesses to adopt green strategies. In this framework, literature-based criteria are analyzed through a three-stage model. In the first stage of the analysis, an artificial intelligence (AI)-based decision matrix is created. In the second stage, factors affecting green business strategies are weighted by the Spherical Fuzzy (et SF) Entropy method. In the last stage, the strategies are ranked using the SF ARAS method. The novelty of this study is the integration of AI with SF numbers. Expert opinions can be evaluated by AI with different coefficients according to the knowledge level and experience of the experts. The AI-based decision matrix enables expert weights to differ according to factors such as experience. The findings show that the most important criterion is cost efficiency (weight: 0.2219). According to the analysis results, investments in clean energy projects have a positive impact on this process (Ki:0.9799).**

***Keywords*—Artificial intelligence; fuzzy decision-making; spherical fuzzy sets; ARAS; Entropy; green strategy**

I. Introduction

Business methods and policies carried out by businesses for sustainability, environmental responsibility, and protection of ecological balance are called green strategies [1]. The main purpose of green strategies is to act by the principles of sustainability and optimize economic, social, and environmental benefits. In addition, reducing the carbon footprint and using natural resources more efficiently are important contributions of green strategies [2]. Also, increasing consumer awareness leads to a shift in customer expectations towards products that contribute to the environment. Therefore, it is necessary to adapt to green strategies to meet changing customer expectations [3]. Besides, government sanctions on environmental issues are also increasing. The business needs to pay attention to legal issues to continue production. Green strategies also contribute to cost savings and increase the brand value of the business [4].

However, there are many challenges for businesses to implement green strategies. These challenges need to be minimized for businesses to adopt green strategies. First, businesses need to consider market conditions. The change in consumer preferences over time also affects the products produced in the market. It should not be ignored that this change is towards environmentally friendly products [5]. Apart from this, cost efficiency is an important issue for businesses. Green strategies support energy efficiency, waste reduction, and reduced resource use. Therefore, even though the prevailing view is that green strategies increase costs in the first place, they contribute to cost efficiency in the long run [6]. Furthermore, legal restrictions on environmental sustainability are increasing day by day. Businesses need to comply with legal restrictions to avoid penalties and sanctions. Additionally, tax breaks, grants, and low-interest loans for green projects make it easier for businesses to adopt green strategies [7]. Finally, green strategies contribute to environmental sustainability and provide businesses with the opportunity to innovate and gain a competitive advantage [8].

Businesses need to adopt green strategies in terms of both sustainability and the environment. However, there are many factors affecting the adoption of green strategies by businesses. Managers cannot intervene in all these factors at the same time in terms of labor and economic terms. For example, investments in green-oriented technology may need to be increased to meet customer expectations. This indirectly contributes to the development of green innovation. Limited studies are addressing this issue in the literature. The studies mostly emphasize the importance of green strategies. Therefore, there is a need for a study that prioritizes the adoption of green strategies by businesses. With the help of this issue, the investors can take their strategic investment decisions in a more efficient way.

Accordingly, this study aims to evaluate the indicators affecting the green strategy adoption of organizations. The research question of this study is to identify the optimal strategies for businesses to adopt green strategies with an AI-based approach. For this purpose, a 3-stage analysis is conducted. In the first stage, an artificial intelligence-based decision matrix is created. In the second part, weighting is performed with the SF Entropy method. In the third section, the SF ARAS method is used to rank. In addition, SF numbers are used to minimize uncertainty. The main motivation for this study is the need for a new model. When the models used in the literature are examined, it is seen that expert opinions are taken equally. This situation is criticized by many authorities. This is because experts have different levels of accumulation on many

*Corresponding author.

points, such as experience and knowledge. Therefore, experts should be weighted according to these factors. With the AI model, this deficiency has been tried to overcome.

The main contributions of this manuscript are given below: 1) The equalization of expert weights in multi-criteria decision-making models has been criticized. Therefore, expert opinions should have different weights according to factors such as experience. Accordingly, the integration of AI and multi-criteria decision-making is important. 2) SF number sets cover more uncertainty than other fuzzy number sets. The SF number set incorporates the third component, hesitancy, into the analysis process. Therefore, the uncertainty in linguistic expressions is more inclusive than in other number sets. Thus, the analysis is performed on SF number sets. 3) The entropy method is considered an objective method among the weighting methods of multi-criteria decision-making techniques. Other weighting methods, such as DEMATEL and AHP, are subjective methods. Accordingly, the analysis process in these methods is based on binary comparisons. In the analysis with Entropy, the uncertainty within the criteria is also considered. This makes the Entropy method more superior to other methods. 4) Among the ranking methods used in the literature, such as TOPSIS, MAIRCA, and VIKOR, consider the metric distance to the optimal value. Since the expert opinion methods in the literature have an ordinal structure, the metric distance to the optimal value is criticized. The ARAS method, on the other hand, considers the similarity ratio to the optimal value instead of the metric distance in the analysis process. Therefore, using the ARAS method is a more reasonable option.

The following sections of the study provide details of the literature review, methodology, analysis results, discussion, and conclusion.

II. Literature Review

One of the most important reasons affecting the green strategy implementation of businesses is the cost efficiency of strategies [9]. Green strategy implementations aim to ensure energy efficiency. Accordingly, it is possible to achieve energy efficiency with green strategies [4]. Apart from that, green strategies also reduce the use of materials. In this way, it is possible to achieve resource efficiency for businesses [10]. Although green strategies are thought to increase operating costs in the first place, they provide cost efficiency to businesses in the long run. Zhen and Yu [11] conducted a study to develop green strategies for the recycling of electric vehicle batteries. It is argued that green initiatives should be increased despite the high cost of batteries in the recycling process. Rani et al. [12] discussed green strategies for converting agricultural waste into sustainable energy. It is underlined that green strategies are the most cost-effective way to get rid of waste. Liu et al. [13] and Yang et al. [14] emphasized the importance of cost in green strategy development processes.

Another important factor affecting green strategy processes is innovative practices [15]. Green strategies are the basis for developing environmentally friendly products and services. Therefore, the business endeavors to develop innovative products [10]. Apart from this, businesses that adopt green strategies can also pave the way for technological innovations. Some of these technologies include prioritizing renewable energy technologies, waste management, and recycling technologies [16]. Le et al. [17] examined the mediating role of green innovation in the relationship between corporate sustainability and corporate social responsibility in small-medium enterprises in Vietnam. It is emphasized that innovative ventures positively affect the process. Bhat et al. [18] investigated the impact of green strategies and innovation on environmental performance. The results of the study with 500 respondents from 10 industrial organizations in Delhi show that green strategies and innovative approaches have a significant impact on performance.

Legal regulations are another important criterion affecting the adoption of green strategies by businesses [19]. Businesses must comply with the regulations of their environment [20]. Accordingly, measures such as reducing carbon emissions and acting against air and water pollution are taken. In addition, encouraging environmentally friendly practices through legislation facilitates the transition of businesses to green strategy practices [21]. Chen et al. [22] conducted a study to develop green business strategies through environmental regulation. The results of the study show that environmental regulations make companies adopt green business strategies. Zhang et al. [23] examined how environmental regulations affect green technology innovation in enterprises. It is emphasized that environmental regulations contribute positively to the process when they are properly coordinated. Xu et al. [24] state that the right legal regulations encourage green strategies.

Market conditions are another important factor affecting the orientation of businesses towards green strategies [25]. One of the significant factors determining market conditions is consumer demand. If consumer demands focus on environmentally friendly products and services, the business needs to meet these demands [8]. In addition, understanding environmentally friendly products and services increases customer loyalty. This provides a competitive advantage against competitors in the market. Therefore, green strategy practices allow businesses to adapt to market conditions more easily [26]. Agyeman and Lin [27] examined the impact of market conditions on innovation in the electricity industry. It is stated that market conditions significantly shape the electricity industry. Chen et al. [28] analyzed the green and digital transition processes of manufacturing companies. It is indicated that customer demands are an important part of this transition process.

The results of the literature review are given below. Green strategies provide businesses with many advantages, such as competitive advantage, cost savings, innovation, and customer satisfaction. However, there are many barriers to the transition of businesses to green strategies. In addition, businesses cannot address all these barriers at the same time. Intervening with all these barriers at the same time creates extra costs for the business. Apart from the cost, it requires a huge amount of labor and a great deal of time. Accordingly, it would be appropriate to determine the importance of these barriers by weighing them. However, the number of studies addressing this issue is quite limited. This study aims to determine the most important strategies for the transition of enterprises to green strategy practices. In this context, an analysis is conducted with SF Entropy and SF ARAS methods-based SF sets.

III. METHODOLOGY

A three-stage model is proposed for the selection of a green business strategy, which is the aim of the study. The First stage is about creating an artificial intelligence-based decision matrix. In the Second stage, factors effective in green business strategy are weighted with the SF Entropy method. In the Third stage, strategies are ranked using the SF ARAS method. Since SF ARAS methods are multi-criteria decision-making methods based on expert opinions, SF numbers are used to include the uncertainty in linguistic expressions in the analysis. Additionally, the differences in experts' experiences and knowledge levels are included in the analysis using the AI model. In other words, AI systems are used to obtain the decision matrix from expert opinions. The steps of the proposed three-stage model are summarized in Fig. 1.

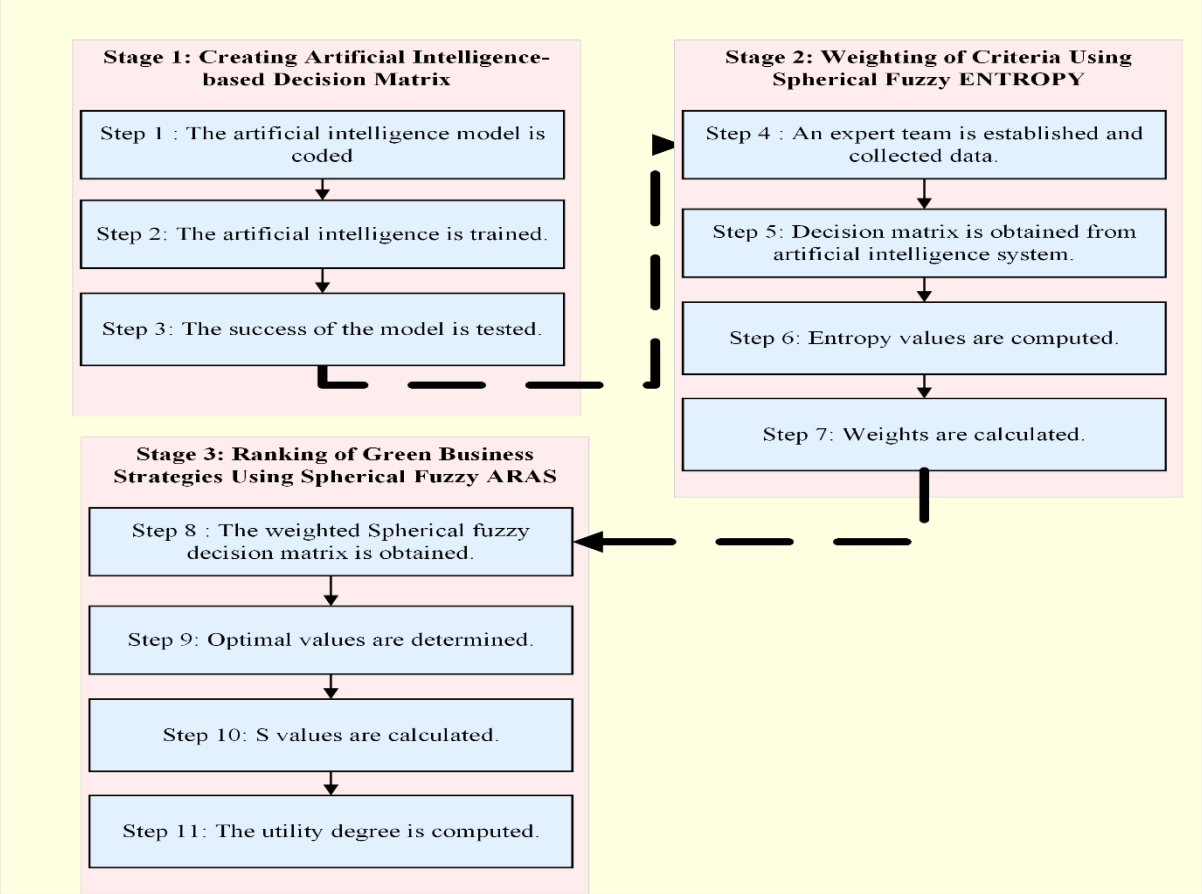

Fig. 1. Process of methodology.

Details of the mathematical steps of the methods are presented as subtitles.

A. Artificial Intelligence-Based Decision Matrix

With the AI system, the decision matrix is constructed by establishing a nonlinear and complex structure. Thus, experience periods can be added as a non-linear component in the process of obtaining an SF decision matrix from experts' linguistic expressions.

In Step 1, the AI model is coded in the Python software language. Layers, activation functions, neuron numbers, optimization algorithm and loss functions are defined with the help of Keras and TensorFlow libraries [29]. While the number of layers is determined as 7, 5 of them are determined as hidden layers. Additionally, 64 neurons are defined in each layer. Among the activation functions, the Sigmoid function given in Eq. (1) is preferred since its definition range is between 0 and 1. Thus, the definition range of fuzzy numbers is preserved.

$$S(x) = \frac{1}{1+e^{-ax}} \tag{1}$$

Adam Algorithm, which provides high efficiency in small data, is preferred as the optimization algorithm [29]. The stages of the Adam algorithm are given in Eq. (2) to Eq. (6):

$$W_{t+1} = W_t - \frac{a}{\sqrt{\hat{S}_t+\epsilon}}\hat{V}_t \tag{2}$$

$$\hat{V}_t = \frac{V_t}{1-\beta_1^t} \tag{3}$$

$$\hat{S}_t = \frac{S_t}{1-\beta_2^t} \tag{4}$$

$$V_t = \beta_1 V_{t-1} + (1-\beta_1)\frac{\partial L}{\partial w_t} \tag{5}$$

$$S_t = \beta_2 S_{t-1} + (1-\beta_2)\left[\frac{\partial L}{\partial w_t}\right]^2 \tag{6}$$

where, a demonstrates learning coefficient, w gives information about the weight, β indicates the degree to which past gradients are involved in the process and ∂L/∂wt refers to the gradient. S and V are also randomly determined initial values. Step 2 involves training the coded artificial intelligence. Expert opinions and experiences are generated randomly with the help of simulation. Then, the output variable is obtained with Eq. (7) and Eq. (8). The linguistic variables used in expert opinions are detailed in Table III (Appendix).

$$SWAM = \left\{[1-\prod_{i=1}^{n}(1-\mu_i^2)^{w_i}]^{\frac{1}{2}}, \prod_{i=1}^{n} v_i{}^{w_i}, [\prod_{i=1}^{n}(1-\mu_i^2)^{w_i} - \prod_{i=1}^{n}(1-\mu_i^2-\pi_i^2)^{w_i}]^{\frac{1}{2}}\right\} \quad (7)$$

$$w_i = \frac{d_i}{\sum_{i=1}^{n} d_i} \quad (8)$$

In Eq. (7) and Eq. (8), the variable d represents the expert's years of experience, while μ, v, and π values signify the membership degree, non-membership degree, and hesitancy degree of the SF number, respectively. Then, machine learning is achieved by using input and output variables. Linguistic variables are explained in Table III [30].

Machine learning is performed with the specified iteration (epoch). In Step 3, the success of the model is tested as a result of machine learning. The MSE value given by Eq. (9) is calculated. The value in question must be close to 0.

$$MSE = \frac{1}{m}\sum_{i=1}^{m}(Y_i - \hat{Y}_i)^2 \quad (9)$$

B. Spherical Fuzzy Entropy

In Step 4, an expert team is established with 3 people. Experience and evaluations are collected from experts. In Step 5, a SF decision matrix (D) in Eq. (10) is obtained from the AI system with the data collected from experts.

$$D = \begin{bmatrix} \langle \mu_{11}, v_{11}, \pi_{11}\rangle & \cdots & \langle \mu_{1n}, v_{1n}, \pi_{1n}\rangle \\ \vdots & \ddots & \vdots \\ \langle \mu_{m1}, v_{m1}, \pi_{m1}\rangle & \cdots & \langle \mu_{mn}, v_{mn}, \pi_{mn}\rangle \end{bmatrix} \quad (10)$$

Step 6 is about computing the SF Entropy value (E) using Eq. (11):

$$E_j = \frac{1}{n}\sum_{i=1}^{n}\left(1 - \frac{4}{5}\left[\left|\mu_{ij}^2 - v_{ij}^2\right| + \left|\pi_{ij}^2 - 0.25\right|\right]\right) \quad (11)$$

In Step 7, criterion weights (w) are calculated with Eq. (12):

$$w_j = \frac{1-E_j}{\sum_{j=1}^{m} 1-E_j} \quad (12)$$

C. Spherical Fuzzy ARAS

In Step 8, considering the SF decision matrix in Eq. (10), the weighted SF decision matrix is obtained with Eq. (13) and Eq. (14). The weighted SF decision matrix is shared in Eq. (15).

$$X = w.D \quad (13)$$

$$w\widetilde{D}_s = \begin{Bmatrix} \left(1-\left(1-\mu_{\widetilde{D}_s}^2\right)^w\right)^{\frac{1}{2}}, \\ v_{\widetilde{D}_s}^{\lambda}, \left(\left(1-\mu_{\widetilde{D}_s}^2\right)^w - \left(1-\mu_{\widetilde{D}_s}^2-\pi_{\widetilde{D}_s}^2\right)^w\right)^2 \end{Bmatrix} \quad (14)$$

$$X = \begin{bmatrix} \langle X\mu_{11}, Xv_{11}, X\pi_{11}\rangle & \cdots & \langle X\mu_{1n}, Xv_{1n}, X\pi_{1n}\rangle \\ \vdots & \ddots & \vdots \\ \langle X\mu_{m1}, Xv_{m1}, X\pi_{1m1}\rangle & \cdots & \langle X\mu_{mn}, Xv_{mn}, X\pi_{mn}\rangle \end{bmatrix} \quad (15)$$

Step 9 involves determining the optimal values. For benefit criteria, the largest value in Eq. (16) is taken, while for cost criteria, the smallest value is determined as the optimal value.

$$core = (\mu-\pi)^2 - (v-\pi)^2 \quad (16)$$

In Step 10, the optimality values (S) of each alternative and the optimal solution are calculated with Eq. (17). Then, these values are defuzzied with Eq. (16).

$$\tilde{S}_{Si} = \sum_{i=1}^{m}\left((\mu_1, v_1, \pi_1) + (\mu_2, v_2, \pi_2) + \cdots + (\mu_m, v_m, \pi_m)\right) \quad (17)$$

In Step 11, the utility degree (Ki) is computed by Eq. (18):

$$K_i = \frac{S_i}{S_0} \quad (18)$$

In this equation, Si is the S value of the ith alternative, while S0 is the S value of the optimal value.

IV. Analysis Results

Seven criteria influencing five green business strategies are identified from the literature. An analysis is performed that includes weighting these criteria and ranking the strategies. The results of the analysis made with the 3-stage proposed model are shared under subtitles.

A. Creating AI-Based Decision Matrix

In Step 1, the AI model is coded using Eq. (1) to Eq. (6) on Python software. Here, the Sigmoid function suitable for fuzzy set theory is preferred. Additionally, a structure with 5 hidden layers with 64 neurons each is constructed. The Adam algorithm is used to optimize the structure of the AI model. In Step 2, the AI model is trained. For this purpose, 1000 expert opinions and experience periods are randomly obtained with the simulation technique. Then, the output variable is obtained using Eq. (7) and Eq. (8). Machine learning is performed via input-output variables in 100 epochs. The results of the loss function for the last 20 epochs are given in Table IV (Appendix).

In Step 3, the learning success of the model is tested using Eq. (9). The MSE value of the AI model with all data is calculated as 0.02. Since the value is very close to 0, it is stated that the model is successful.

B. Weighting of Criteria Using Spherical Fuzzy Entropy

Step 4 is about establishing the expert team and obtaining their opinions. A team consisting of senior managers with 19, 23, and 21 years of field experience is established. Experts' opinions are tabulated in Table V (Appendix).

Step 5 covers obtaining the SF decision matrix from the AI system. Table III and the experience periods of the expert team are given to the model as input. Based on the inputs, D in Eq. (10) is estimated with AI model. D values are presented in Table VI (Appendix).

In Step 6, the SF Entropy value of each criterion is computed using Eq. (11). In Step 7, the weights of the criteria are calculated using Eq. (12). The results are summarized in Table I.

TABLE I. ENTROPY VALUES AND WEIGHTS OF CRITERIA

Criteria	SF Entropy	Weights
MARKET	.4650	.1600
COST	.2581	.2219
ORGANIZATION	.5666	.1296
LAW	.6399	.1077
GOVERMENT	.7210	.0834
PUBLIC	.7311	.0804
INNO	.2745	.2170

According to Table I, the weight value for the Cost Efficiency criterion is 0.2219. Since this value is the greatest value, it has the most important role in determining green business strategies. The second criterion in determining green business strategies is Innovative.

C. Ranking of Green Business Strategies Using Spherical Fuzzy ARAS

The SF ARAS method is performed with the values in Table IV. In Step 8, the weighted SF decision matrix is calculated using Eq. (13) to Eq. (15). Table VII (Appendix) exhibits the values of the weighted SF decision matrix.

Step 9 involves determining the optimal values. Score values are obtained with Eq. (16). Since the criteria are beneficial, the SF value of the alternative corresponding to the largest score values is determined as the optimal value. In Step 10, the S values of each alternative and the optimal value are computed. All S values are defuzzified with Eq. (16). In Step 11, criterion weights are calculated with Eq. (18). The utility degree values are given in Table II.

TABLE II. THE UTILITY DEGREE VALUES

Alternatives	Si			Kİ
Limiting Saving	.881	.118	.129	.304
Pollution Prevention	.670	.365	.235	.376
Product Stewardship	.755	.255	.292	.203
Clean Energy Investment-Project	.631	.402	.265	.979
Corporate Social Responsibility	.875	.125	.130	.410

According to the Ki values in Table II, the alternative with the highest value was determined as Clean Energy Investment - Projects. In other words, the most appropriate green business strategy has been determined as businesses that support clean energy investments and projects. The second alternative in the ranking is corporate social responsibility. The last strategy is product stewardship. Because the lowest Ki value belongs to this strategy.

V. DISCUSSION

The results of the analysis show that cost efficiency is the most important criterion affecting the enterprises' tendency towards green strategies. Cost efficiency shows how effectively an enterprise uses its resources in the production process. Green strategies also aim to contribute to the sustainability of the business by using fewer resources. In addition, green strategies contribute to cost efficiency as they include processes such as energy saving, waste management, and recycling. Panda [1] examined the interaction between the concepts of green identity and green strategy. The results of the study conducted in India show that costs have a significant impact on both green strategies and green identity. Nersesian et al. [31] propose a model for supply chains to reduce the carbon emissions of firms. While it is argued that green strategies should be adopted to reduce carbon emissions, it is also stated that costs should be considered.

Innovation is found to be the second most important criterion affecting the integration of businesses into green processes. Businesses need to respond to changing customer demands. Changing customer demands focus on more environmentally friendly and sustainable products and services. Therefore, it is important to produce innovative products and services to meet these demands. Accordingly, innovation power is seen as an important factor for businesses to integrate into green strategies. Piwowar-Sulej et al. [32] examined the link between internal communication, organizational culture, and environmental strategies. It is argued that the implemented environmental strategies should be innovative. Lafuente and Vaillant [33] carried out the relationship between green orientation and innovation. The results of the study conducted through 734 firms from OECD countries show that green orientation has an increasing effect on innovation.

The results of the analysis show that the most supportive aspect of green strategy development is investing in clean energy projects. Investing in clean energy projects provides a number of advantages to businesses. These advantages include reducing energy costs, reducing carbon emissions, increasing sustainability and improving brand reputation. Therefore, it can be said that investing in clean energy projects is an important green strategy. Chung et al. [34] examined the impact of having a renewable energy certificate on firm value. The results of the study conducted in Taiwan show that green strategies and renewable energy investments are parallel. Kumar et al. [35] stated that renewable energy investments and green strategy implementations are related.

VI. CONCLUSION

This study aims to develop a prioritized strategy for businesses to adopt green strategies. In this context, literature-based criteria affecting the adoption of green strategies by businesses are identified. The decision matrix of these factors is created with an artificial intelligence-based approach. SF ARAS and SF Entropy approaches are used to weight the criteria. Cost efficiency is the criterion with the highest weight. Also, investing in clean energy projects contributes significantly to this process. In addition, although investing in clean energy projects is seen as costly, it provides significant contributions in the long run.

The main novelty of this work is the integration of AI with fuzzy decision-making methodology. In this way, expert weights can be differentiated according to factors such as experience. Another novelty of this study is that it presents a set

of criteria that influence businesses to adopt green strategies. However, the main theoretical limitation is that the assessment in this study is made with all businesses in mind. Future studies could be conducted in the health, automobile, or banking sectors. This would allow different sectors to be compared with each other. One of the limitations of this study is that the analysis is carried out with non-numerical data. The use of multi-criteria decision-making techniques based on expert opinions in the analysis process is the main limitation of this study. In future studies, it is recommended to perform the analysis with an econometric model using numerical data. The proposed model also same limitation. ARAS method does not calculate with the distance metric. This leads to a departure from the optimal value. Therefore, it has been highly criticized in the literature. There is a need to develop new ranking technique that take these criticisms into account.

RFM–K-OPT Based Machine Learning Framework for Customer Segmentation and Behavioral Profiling in Direct Marketing

Khadija Mehrez
Management and Marketing Department-College of Business, Jazan University, Jazan, Saudi Arabia

***Abstract*—Customer segmentation is an essential element of modern marketing analytics, which helps companies recognize, comprehend, and market to customers depending on their behavioral and transactional attributes. Conventional methods based on Recency, Frequency, and Monetary (RFM) analysis or on simple unsupervised clustering algorithms such as K-Means are very common, but they are usually limited by weaknesses such as sensitivity to centroid starting location, low cluster separability, and low interpretability. Such problems will cause volatile effects of segmentation and restrict the dependability of data-driven marketing choices. In an effort to deal with these concerns, this research study suggests a hybrid model, the RFM K-Means Optimization Technique (RFM–K-OPT), a combination of RFM analytics and K-Means clustering, and an iterative centroid optimization unit. The proposed structure will help to improve cluster compactness, stability, and interpretability using statistical computation and refinement of centroid positioning. The model is written in Python and tested with publicly available customer transaction data. The result of the experimental process shows a better quality of clustering with a Silhouette Coefficient of 0.83, Davies-Bouldin Index of 0.31, Calinski-Harabasz Index of 563, purity of clustering of 94.2 per cent, and an execution time of 5.4 seconds. The results suggest that the RFMK Opt model is a useful tool that offers credible and explainable customer segments, which can be used to make effective behavioral profiles and make sound judgments when it comes to making decisions in the context of direct marketing.**

Keywords*—Customer segmentation; behavioral profiling; clustering optimization; predictive marketing; data-driven decision making

I. Introduction

In the fast-changing competitive market, customer information has been described as a strategic asset among organizations aiming to improve marketing effectiveness and create long-term customer loyalty [1]. The classic marketing approach used to be based on the generalized demographic segmentation that did not reflect the specifics of the individual purchasing behavior [2]. As the number of digital transactions in the market grows exponentially, and customer relationship management (CRM) data is available, the data-driven way of segmentation has become more popular [3]. The Recency, Frequency, and Monetary (RFM) analysis has been seen to be one of the most feasible tools in gauging customer value and engagement [4]. It enables marketers to categorize customers by their recency when it comes to the interaction, frequency of purchase, and overall amount of money they spend. Nevertheless, with the dynamics of business settings that require continuous changes in segmentation tools, manual segmentation based on RFM [5] is not as profound as one needs it to be to offer predictive insights. The introduction of machine learning (ML) techniques into modern marketing analytics brings an ability to provide scalable and adaptive segmentation with regards to the varying consumer behavior [6]. The move towards automation complements evidence-based decision making and marketing models that are personalized to be able to grow customer satisfaction, retention, and profitability [7].

The new trends in customer analytics have brought in hybrid systems that combine the classical RFM analysis with other clustering algorithms like K-means, hierarchical clustering, and the density-based model [8]. These strategies have managed to classify customers into action segments and can now be promoted and retained individually [9]. There has also been the use of optimization and predictive algorithms to enhance the accuracy of segmentation, customer targeting and allocation of marketing resources [10]. Regardless of these improvements, several studies have significant shortcomings. Current clustering methods usually presume the fixed behavior of the customers, and do not take into account the dynamic nature of the buying behaviors [11]. Also, K-means, although computationally inexpensive, is extremely sensitive to centroid initialization and has to be predetermined with the number of clusters [12], which cannot be considered an actual reflection of the data structure. Moreover, the majority of previous studies are based on transactional characteristics only, without the incorporation of behavioral or context elements like the intensity of engagement or the browsing behaviors. The resulting segmentation models are therefore likely to have problems with generalization in different industries or data sets. A stronger and improved component of the segmentation structure, with the inclusion of the RFM characteristics, clustering and an optimization interface, is required to eliminate these gaps and balance the interpretability, scalability, and flexibility to changing marketing needs. Based on the identified research gaps, this study addresses the following research question:

RQ: How can an optimized RFM–K-OPT framework integrating Recency, Frequency, and Monetary analysis with K-Means clustering improve customer segmentation accuracy, stability, and interpretability compared to conventional RFM and K-Means approaches in direct marketing applications?

A. Problem Statement

Despite the abundance of research discussing customer segmentation by RFM analysis alongside machine learning, there are still a number of issues that restrict the applicability of the current approaches to practice [10]. The conventional models of RFM are mainly based on the use of transactional characteristics that are not dynamic enough to reflect the changes in customer engagement over time [13]. Simple clustering algorithms like K-means or hierarchical clustering give preliminary information but tend to give erratic results because of sensitivity to initialization, outliers, and scaling of data [14]. Furthermore, the vast majority of frameworks do not have an optimization mechanism, which refines clusters and matches the results of segmentation to the business goals, such as profit maximization or churn reduction [15]. Most of the current methods also focus on algorithmic performance, not marketing interpretability, and result in technically valid clusters which are strategically ambiguous [16]. Also, a lack of model validation on a variety of datasets restricts generalization, and a lack of consideration to parameter tuning usually leads to less-than-optimal performance. The constraints demonstrate that a holistic model that combines both traditional RFM scoring with cutting-edge machine learning and optimization methods is urgently needed to enhance the quality of clusters, marketing understanding, and decision-making based on data to implement dynamic and customer-focused strategies.

B. Research Significance

The study proposes an optimized machine learning model named RFM-K-OPT, a combination of RFM characteristics, K-means clustering, and an optimization algorithm to enhance customer segmentation and behavioral profiling. The value of the study is that it bridges the gap between interpretability and predictive accuracy to provide marketers with a large-scale and versatile decision-support system. RFM-K-OPT will help improve the quality of customer insights by making it possible to conduct targeted campaigns, better retention strategies, and efficient distribution of marketing resources by integrating descriptive analytics with optimization-based adjustments.

C. Research Motivation

The study has been inspired by the growing requirement of adaptive segmentation methods that are capable of capturing different behaviors of customers in dynamic markets [17]. The classical RFM and clustering models do not offer much insight into the current trends and areas of optimization [18]. The proposed RFMK-OPT framework will address these deficiencies by proposing a more data-driven and optimized segmentation model that will create a more precise marketing experience, a more predictive marketing, and a factor in the creation of intelligent and automated systems, both direct marketing and customer relationship management.

D. Key Contributions

- To optimize the RFM K-OPT framework to improve the accuracy of customer segmentation, with the optimization of centroid initialization and cluster separability.
- To combine Recency, Frequency and Monetary behavioral measures with K-Means clustering to provide accurate segmentation and analysis.
- To use an optimization module that enhances clustering iterations, making them compact and distinct between clusters, much better.
- To ensure balanced feature contribution through normalization and outlier handling, preventing data skewness and dominance effects.

E. Rest of the Sections

Section II reviews the past RFM and clustering techniques, of which the shortcoming is imprecision, separability and computational efficiency. In Section III, the proposed RFM-K-OPT model is described, according to which RFM calculations, K-Means clustering and optimization algorithms are integrated. Section IV gives performance indicators, visual performance and comparative analysis of a superior segmentation and clustering accuracy. Section V is the conclusion of the research findings, contributions, and how it could be improved to provide better customer segmentation results.

II. Related Works

Kasem et al., [19] examine the ability of customer profiling using Recency, Frequency and Monetary (RFM) characteristics to facilitate strategic decision-making in platform business, particularly in Edutech start-ups. The study uses RFM preprocessing on transactional data, K-means clustering and the Elbow, Silhouette coefficient and Gap statistic to assess the quality of the clusters and identify the optimal number of clusters. Based on an enterprise-wide transactional dataset (as outlined in the study), the authors find three actionable clusters such as new customers, best customers, and intermittent customers and associate each cluster with viable interventions (onboarding tailored to new users, incentive to best customers, and re-engagement campaigns to intermittent users). The study shows that using easy to use RFM characteristics along with ordinary clustering and validation packages can result in interpretable profiles to drive marketing and product choices. Disadvantages are that it can be used in transactional only (no behavioral or contextual cues), K-means may be sensitive to initialization and scaling, and alternatives to clustering or temporal dynamics of changing customer behavior are not explored.

Islam et al. [20] examine the use of machine-learning techniques in personalizing marketing within the U.S. retail sector, in order to boost engagement and eventual purchase based on personalized recommendations and promotions. The study combines data on the multi-channel retail (e-commerce and brick and mortar transactions) to create predictive models of segmentation, product recommendation and campaign targeting. These methods are supervised learning to propensity score and recommendation heuristics, and unsupervised clustering to identify latent groups. Findings have shown that there are significant engagement and conversion increases, when retailers implement ML-based personalization; the research paper has cited better click-through and repeat purchase rates on strategies based on ML-informed strategy. Some of the successes have

been a practical demonstration of end-to-end ML workflows and advice to retail managers on how to implement personalization pipelines. Cons have been identified as challenges in integrating data across channels, insufficient interpretability of the model by business people, and potential overfitting on short term signals without longitudinal confirmation.

Chinnaraju et al. [21] present a conceptual model where the autonomous AI agents are placed in the middle of consumer segmentation and precision targeting, where agentic automation can constantly optimize segments and run campaigns with little to no human intervention. The model uses unsupervised clustering (e.g., K-means, DBSCAN) to identify micro-segments, reinforcement learning to make campaign decisions and ad spend, NLP to contextual profile, and predictive models (Random Forests, time-series forecasting) to predict behavior. The efficiency improvements in case vignettes of e-commerce and streaming include accelerated decision cycles, real-time budgetary redistribution and enhanced campaign payback. The article has identified ethical guardrails as privacy-saving data processing and equitable limitation as part of responsible deployment. The drawbacks are that the framework is theoretical (has not been empirically validated), its operational complexity may be high when dealing with a number of autonomous agents, and the infrastructure and governance demands are high to prevent runaway automation and bias.

Van Chau et al. [22] focus on customer behavior forecasting (pre) with respect to strategic capacity in constantly evolving markets, and claim that predicting customer behavior provides competitive agility. The article evaluates unsupervised and supervised ML, reinforcement learning, and deep learning methods of predicting purchase intent, churn and lifetime value. It generalizes case studies of how predictive models can enhance timing and product suggestions of campaigns and innovations, like sequence models and hybrid ensembles, which are better timed generalizations. Progress has been made in the combined analysis of methods and viable suggestions for implementation. Disadvantages include privacy concerns, the inability to interpret a model where nontechnical stakeholders are involved, and the fact that retraining models are necessary to ensure any drift in the dynamic markets; the paper insists that organizations must be ready to handle the prediction by implementing the idea of monitoring.

Jalal et al. [23] propose an effective customer transition analysis and dynamic customer segmentation framework to allow a personalized marketing activity and predict customer transitions between segments. Their method builds time-series feature vectors that include recency, frequency, monetary value, and customer lifespan and K-means clustering that uses various distance measures and classification models to estimate future customer status. They also bring counterfactual analysis to assess the effect that other interventions would have on customer transitions. The authors use actual transaction histories and discover that the Euclidean distance is most effective at capturing trends in the time-series features and that the logistic regression is useful in predicting changes in status. The framework allows evaluating per-customer strategy and more accurate retention tactics. The weaknesses are that it is sensitive to the distance measure and the number of clusters, counterfactual simulations are computationally expensive with large populations, and it requires transactional history without detailed behavioral and contextual information.

Musunuri [24] presented ClusChurn-EC, which is an interpretable customer segmentation and early churn prediction pipeline on e-commerce platforms. Newcomers are clustered by stage one into a behavioral cohort (based on engagement and purchase sequence features); stage two trains an LSTM trained on attention to predict churn based on small observed interactions. ClusChurn-EC is found to be an effective early warning system for customers at-risk on anonymized large-scale transaction logs, which is superior to standard classifiers, aiding time-sensitive retention interventions. Some of the successes have been the good application of sequential modeling to provide short histories of interaction and an interpretable phase of segmentation that can be used to provide targeted outreach. The disadvantages described include the fact that monitored training requires large labeled churn signals, there can be generalization constraints between retailers, and that LSTM pipelines are hard to implement in real-time systems.

Suh et al. [25] explore segmentation of the purchase record to pre-purchase exploration and after purchase usage by formulating multidimensional behavioral variables in the Customer Experience Journey (CEJ). They use a sample of 40,911 home-appliance customers and clustering and Non-negative Matrix Factorization (NMF) to obtain strong segments, and measure the validity of the segments in terms of both accuracy and consistency. The results indicate that there are trade-offs in technology: clustering provides an intuitive segmentation, whereas NMF provides intuitive latent usage patterns and also has a superior ability to provide an overview of the overlap. The strengths of the study are its massive real-customer data, multidimensional feature engineering, and two-sided comparison that brings out complementary insights. The domain specificity (home appliances) and potential biases in the feature engineering process, as well as potential difficulties related to generalization of the CEJ variable set to non-related industries, are its limitations.

Wasilewski [26] discusses the issue of personalizing user interfaces of e-commerce based on a functional framework that enables different versions of pages based on user traits and algorithms. The paper outlines elements needed to support multivariant interfaces and creates pilot applications and suggests novel metrics to measure the variations in user behavior with variants of interfaces. The strategy puts ML models at its center to keep learning the variants of UIs that optimally fit user segments and have adaptive interfaces that can raise the conversion and satisfaction rates. The outcomes of it are a well-defined experimentation architecture and early pilot results, which demonstrate a potential improvement in ROI and usability. The disadvantages are that it can be complex to integrate with a legacy platform, requires engineering effort to support numerous variants, and runs the risk of confusion or analytics fragmentation due to excessive personalization.

Table I summarizes filtered accredited articles that represent a variety of data-based customer segmentation and prediction choices- including RFM grouping and ML personalization, deep learning, and optimization models. Both approaches trade information interpretability, adaptability and scalability, and

debates have existed concerning information integration, computational cost, and industrial generalizability.

TABLE I. COMPARATIVE SUMMARY OF RELATED STUDIES

Authors	Methodology	Dataset	Advantage	Disadvantage
Kasem et al. [19]	RFM + K-Means clustering	Business transaction data	Clear, interpretable customer clusters	Limited to transactional data

Chinnaraju et al. [21]	Agentic AI + K-Means + RL	Theoretical & case examples	Real-time autonomous targeting	Limited empirical validation
Van Chau et al. [22]	ML & deep learning review	Multiple case studies	Forecasts customer behavior	Needs continuous model updates
Jalal et al. [23]	Time-series RFM + K-Means	Transaction history	Predicts customer transitions	High computational cost
Musunuri et al. [24]	Clustering + LSTM (ClusChurn-EC)	Large e-commerce logs	Early churn prediction	Requires labeled data
Suh et al. [25]	CEJ features + Clustering + NMF	40,911 customer records	Captures full customer journey	Domain-specific framework
Wasilewski et al. [26]	ML-driven personalized UI	E-commerce pilot data	Enhances user experience	Implementation complexity
RFM–K-OPT (Proposed)	RFM + K-Means + Optimization	Kaggle dataset	Optimized marketing actions	Sensitive to RFM setup

III. OPTIMIZED RFM–K-MEANS SEGMENTATION WITH MARKETING RESOURCE OPTIMIZATION

This approach uses a combination of the traditional RFM (Recency, Frequency, Monetary) scoring model and clustering (through K-Means) and a further optimization layer to ensure the segmentation is aligned with marketing resources and business goals. To begin with, RFM scores of every customer are computed using transactional data of the Kaggle dataset: recency (time since last purchase), frequency (number of purchases), and monetary value (total spend). The K-Means clustering is then used on these standardized RFM attributes to cluster the customers into understandable groups. Validation metrics such as the Elbow method, Silhouette coefficient and Gap statistic are used to determine the number of clusters. After the identification of the baseline clusters, the cluster assignment and accessible marketing budget, channel constraints, and key performance indicators (KPIs) are entered into an optimization module. The constrained optimization (e.g., integer linear programming or heuristic search) follows and distributes resources among segments to maximize the selected objective (e.g., ROI or retention improvement or profit uplift) without violating fairness or budget constraints. The three stages of pipeline: RFM scoring, K-Means segmentation, and resource optimization are interpretable (segments can be aligned with RFM), scalable (clustering can use large data), and actionable (optimization can be used to make marketing decisions). It overcomes the shortcomings of purely clustering based solutions by integrating business constraints and business objectives into the output of segmentation.

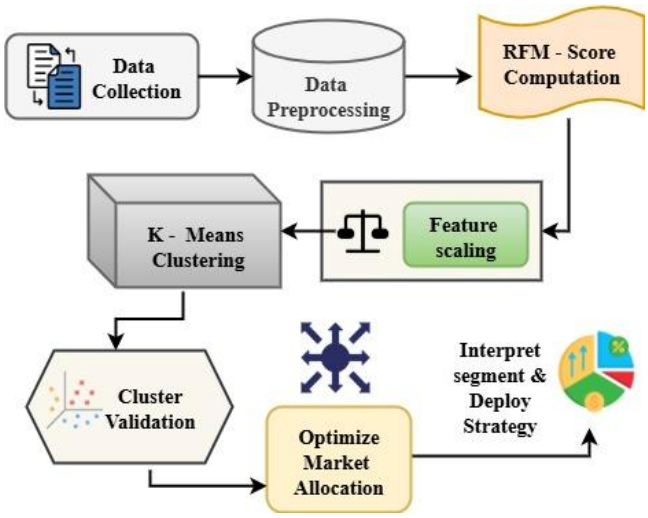

Fig. 1. Block diagram of RFM–K-OPT segmentation framework.

Fig. 1 represents the general scheme of customer segmentation using the proposed RFM-K-OPT (Recency-Frequency-Monetary-K-Means Optimization Technique). This process starts with the collection of data based on transactional sources, data pre-processing, and the elimination of any inconsistencies in data and data integrity. This is followed by the calculation of the RFM score, where the customer behavior is measured in terms of recency, frequency, and monetary. The feature scaling makes the data standard so that all metrics have the same impact. K-Means clustering algorithm uses homogeneous clusters to group customers into homogeneous clusters, which are further evaluated using cluster validation to determine the quality and separability of the clusters. Lastly, the verified clusters help in the optimization of market allocation and as such, the businesses are able to get the segments and utilize specific marketing approaches efficiently to achieve improved customer interaction and profitability.

A. Data Collection

The research data is obtained from the Kaggle [27] repository, Customer Segmentation Data for Marketing Analysis by Fahmida Chowdhury. It contains all the details related to the customer demographics, purchasing frequency, spending habits, and engagement trends, which represent real-life marketing transactions. The numbers reflect a variety of customer data, so it is appropriate to use it to segment the behavior and discover the patterns. The records have quantifiable values like the income, age, spending grade, and other attributes that describe loyalty. This dataset offers a robust basis on how RFM analysis and clustering techniques can be applied so that the identification of a group of customers with unique purchasing habits, preferences and profitability potential in direct marketing settings can be identified. The dataset is composed of more than 10,000 records of customer transactions retrieved on the Kaggle repository. The dataset was randomly selected into 70 per cent to train, 20 per cent to test and 10 per

cent to validate to provide an unbiased assessment and the ability to replicate the clustering findings.

B. Data Preprocessing

The preprocessing data stage makes sure that the data is correct, consistent and is prepared to be clustered. First, the data cleaning process will eliminate any missing, duplicate, and irrelevant records, and only the valid customer records will be retained. Data transformation is used in converting categorical variables into numeric variables through label or one-hot encoding, and log transformation is used to reduce skew in continuous variables. Calculation of RFM features is based on the computation of Recency, Frequency, and Monetary values to describe customer behavior. Balanced clustering is performed by normalizing the magnitude of variables by Z-score scaling to ensure that the variables fit within an equal distribution. The outlier detection is used to detect and manage extreme values using the Interquartile Range (IQR) technique to trim or cap values. Lastly, Min-max normalization in feature scaling ensures that all the RFM components have equal weight, so data does not have high-value features dominating, and greater accuracy in clustering and stability in optimization are achieved.

1) Data Cleaning: Missing and duplicate data are detected and processed with the help of relevant imputation or deletion. Irrelevant or inconsistent records are filtered to ensure the dataset has legal, full and error-free information about the customers to use later in the computation of the RFM features.

2) Data Transformation: The categorical data (gender or region) is put in numerical data with the help of label or one-hot encoding. The log-transformation of continuous variables produces the minimal skewness and makes the distribution normal, resulting in more precise clustering and optimization results.

3) RFM Feature Computation: The RFM values of every customer are computed in order to measure behavioral patterns. The proposed framework is based on the idea of recency to measure purchase freshness, frequency to measure the level of engagement, and monetary value to measure contribution to revenue. It is measured in Eq. (1):

$$R_i = D_{ref} - D_{last,i}, \quad F_i = n_i, \quad M_i = \sum_{j=1}^{n_i} P_{ij} \qquad (1)$$

where, Recency R_i measures the time gap since the last purchase, frequency F_i counts total transactions, and monetary value M_i sums purchase amounts for customer i.

4) Feature Normalization: All the RFM values are brought to a common scale to avoid the dominant effect of high magnitude variables. Z-score normalization guarantees equal input of each metric in the distance calculation process of the K-Means clustering process. It is illustrated in Eq. (2):

$$Z_j = \frac{X_j - \mu_j}{\sigma_j} \qquad (2)$$

Each variable X_j is normalized by subtracting its mean μ_j and dividing by standard deviation σ_j, ensuring balanced contribution of all features during clustering.

5) Outlier Detection: The interquartile range (IQR) technique is used to identify extreme values to avoid biasness in clustering the results. Any outliers that are not within the acceptable range are looked into and dealt with either by trimming or capping to ensure that robust clusters are formed. It is described in Eq. (3):

$$\text{IQR} = Q_3 - Q_1 \qquad (3)$$

The interquartile range (IQR) measures data spread between quartiles Q_1 and Q_3; values beyond 1.5×IQR from these limits are treated as outliers.

6) Feature Scaling: Min-Max normalization The features are all put within the range of [0,1] after the outlier adjustment. This is done to provide balanced weight of the RFM components as well as to avoid the heavy values dominating in computation of distance using K-Means. It is measured in Eq. (4):

$$X' = \frac{X - X_{\min}}{X_{\max} - X_{\min}} \qquad (4)$$

The feature scaling processes the values of the data to the scale to a standard scale, usually [0,1]. This helps to avoid large numerical characteristics dominating the small ones in the K-Means clustering and optimization algorithm.

C. RFM-Based Intelligent Segmentation Optimization Framework

The proposed Optimized RFM-Based Hybrid K-Means Segmentation Framework (RFM-K-OPT) combines conventional RFM analytics and machine learning clustering and optimization to improve the exactness of customer segmentation. This is the architecture which integrates the methods of statistics and computation in a systematic way to determine, predict, and examine the profile of customer behavior. To calculate the recency, frequency, and monetary value, RFM attributes are first derived using transactional data. These attributes are put to normal and fed to the K-Means algorithm to perform unsupervised clustering. At this point, the optimization module is used to optimize the quality of the clusters by optimizing centroid location and also performs the integrity of the cluster using performance measures like Silhouette and Davies-Bouldin indices. Being more interpretable and adaptable to dynamic market conditions, this hybrid model facilitates one-to-one marketing and predictive analytics. RFM K-OPT frameworks minimize noise, overfitting, and improve cluster differentiation, which will guarantee a strong customer segmentation that supports business strategies informed by data. The sensitivity of parameters is of essential importance to the suggested RFMK-OPT framework. The cluster size (k) has a direct impact on the segmentation granularity and it is determined by Elbow and Silhouette analyses. The parameters related to feature normalization provide equal contribution of RFM to avoid the dominance of high value features. The optimizations bring effects on the centroid stability and convergence rate with more iterations possibly adding no meaningful quality improvement at higher computational cost. Empirical tuning proves that tuning is best done within moderate iterations to achieve optimal clustering performance.

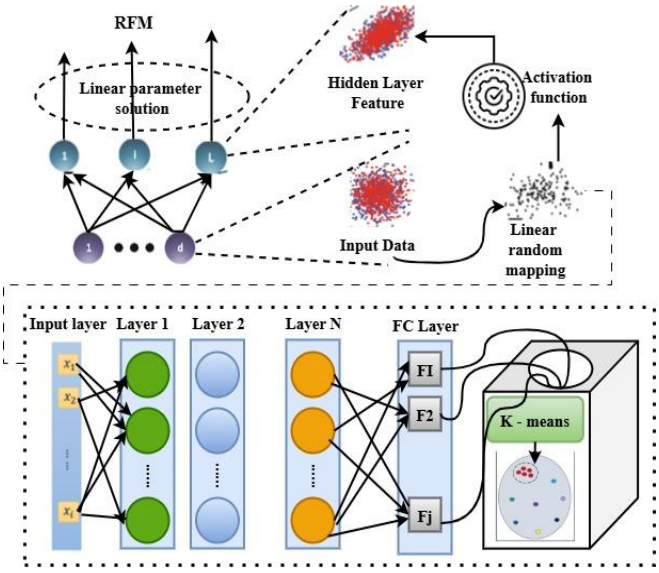

Fig. 2. Architecture of the optimized RFM–K-Means clustering framework.

Fig. 2 demonstrates an optimal RFM-K-Means clustering layout. The architecture comprises of RFM feature extraction, normalization, K-Means clustering, centroid optimization, validation and behavioral profiling layers. It does not use any neural network-based feature learning; it only uses statistical attributes of RFM and centroid refinement to cluster. It starts with the input layer, which is fed with multidimensional data vectors $x_1, x_2, \ldots, x_i$. The propagation of these inputs through several hidden layers (Layer 1 to Layer N) involves linear random mapping which is used to convert raw data into feature representations in higher dimension. Every hidden layer uses an activation function to add non-linearity as well as extract more complex patterns within the input data. The resulting hidden layer representations contain inherent connections within the data set which are represented to an entirely connected (FC) layer where they are refined to feature fuse and dimension reduction. The resulting feature space $(F_1, F_2, \ldots, F_j)$ is sent to the K-Means clustering module where clusters are created with respect to learned representations. Lastly, the linear parameter solution provides the best separation and explicability of the clusters leading to a highly efficient and accurate customer segmentation.

1) Input Layer: RFM Feature Integration: The model starts with the calculation of Recency, Frequency, and Monetary features using raw transaction data. Those characteristics are the level of customer engagement, loyalty, and profitability, which does the input layer of the further clustering and optimization. It is described in Eq. (5):

$$X_i = [R_i, F_i, M_i] \tag{5}$$

Each customer X_i is represented as a three-dimensional feature vector containing Recency (R_i), Frequency (F_i), and Monetary (M_i) values for further analysis.

2) Clustering Layer: K-Means Algorithm: The K-Means clustering algorithm is used to divide customers into k separate groups according to Euclidean distance. A centroid is applied to each customer which is assigned to the closest centroid and clusters are refined until convergence. It is evaluated in Eq. (6):

$$J = \sum_{i=1}^{k} \sum_{x \in C_i} ||x - \mu_i||^2 \tag{6}$$

where, the objective function J minimizes the squared Euclidean distance between data points x and their respective cluster centroid μ_i, optimizing cluster compactness.

3) Cluster Validation Layer: Elbow and Silhouette Coefficient are used to find optimum cluster numbers. These validation metrics provide useful segmentation by measuring intra and inter-cluster disparities. It is measured in Eq. (7):

$$S = \frac{b-a}{max(a,b)} \tag{7}$$

where, the Silhouette coefficient S measures how similar an object is to its own cluster (a) compared to others (b), ensuring well-separated, cohesive clusters.

4) Optimization Layer: Optimization algorithm is used to optimize the centroid of each cluster to make clusters as homogeneous as possible and to segment as accurately as possible. It repeats the centroid positions to attain minimum convergence of the cost function. It is equated in Eq. (8):

$$\mu_i^{(t+1)} = \frac{1}{|C_i|} \sum_{x \in C_i} x \tag{8}$$

Each centroid μ_i is updated by averaging all points in cluster C_i, ensuring clusters remain compact and well-distributed after each iteration.

5) Behavioral Profiling Layer: Within each cluster, behavioral traits are determined including loyalty, spending potential and recency trends. This profiling will help in coming up with specific marketing plans and customer retention programs. It is described in Eq. (9):

$$P(C_i) = f(R_i, F_i, M_i) \tag{9}$$

where, the profiling function $P(C_i)$ derives behavioral insights based on RFM metrics within each cluster, guiding personalized marketing decisions.

6) Decision Optimization and Output Layer: The last layer is the combination of optimized clusters into viable marketing recommendations. Predictive analytics support these decisions so as to improve customer engagement, conversion, and lifetime value. It is evaluated in Eq. (10):

$$O = \arg\max_{C_i} \big(\text{ROI}(C_i)\big) \tag{10}$$

where, the output function O selects the optimal customer segment C_i that maximizes Return on Investment (ROI) through data-driven marketing actions.

Algorithm 1 illustrates that the RFM–K-OPT algorithm is a hybrid approach, which improves the quality of customer segmentation through a combination of RFM behavioral analysis, K-Means clustering, and centroid optimization. First, the algorithm identifies recency, frequency and monetary features in the transaction data into normalized numerical vectors. The K-Means clustering algorithm is an iterative approach to grouping customers together depending on their Euclidean distance. At the stage of the K-OPT optimization, the

centroid is optimized to reduce the distance within the clusters which enhances stability of segments and convergence rate. Elbow and Silhouette methods are some of the validation methods used to find the best number of clusters. Lastly, behavioral profiling is the interpretation of each segment into actionable groups, e.g. high-value, at-risk, or new customers. Such a systematic process will guarantee higher accuracy of segmentation, higher interpretability of decisions, and greater allocation of marketing resources. The iterative optimization of the algorithm makes the algorithm scalable, and it is suitable with massive datasets in direct marketing and behavioral analytics.

Algorithm 1: RFM–K-OPT Customer Segmentation Framework

Input: Customer transaction dataset D
Output: Optimized and labeled customer clusters $C = \{C_1, C_2, \ldots, C_k\}$
Data Acquisition
Collect transaction records from dataset D.
Extract relevant features including Customer ID, Purchase Date, and Transaction Value.
Remove duplicate and incomplete records to ensure data integrity.
RFM Feature Extraction
Compute Recency $R_i = D_{ref} - D_{last,i}$, Frequency $F_i = n_i$and
Monetary ($M_i = \Sigma_{j=1}^{n_i} P_{ij}$) for each customer i.
Construct feature vectors $X_i = [R_i, F_i, M_i]$.
Data Preprocessing and Normalization
Handle missing or extreme values using the IQR method.
Normalize all RFM features using Min–Max scaling:
$$X_i' = \frac{X_i - X_{min}}{X_{max} - X_{min}}$$
Store normalized vectors for subsequent clustering.
K-Means Clustering Initialization
Randomly select kinitial centroids $\mu_1, \mu_2, \ldots, \mu_k$ from normalized data.
Set iteration counter $t = 0$
Cluster Assignment
For each data point x_i, assign it to the nearest centroid:
$C_j = \{x_i : || x_i - \mu_j ||^2 \leq || x_i - \mu_t ||^2, \forall t\}$
Update membership lists for all clusters.
Centroid Update
For each cluster C_j, compute a new centroid:
Calculate the total cost function:
Optimization Phase (K-OPT)
Apply centroid refinement to minimize intra-cluster variance.
Repeat assignment and update steps until T_{max}.
Retain centroids that achieve min
imum total cost $J\{\min\}$.
Cluster Validation
Compute validation metrics (Elbow, Silhouette, or Davies–Bouldin).
Select optimal k producing stable and high-separation clusters.
Behavioral Profiling and Output Generation
For each cluster, analyze mean RFM values to label customer types (e.g., loyal, new, dormant).
Generate marketing insights and export optimized clusters C.
End

IV. Results and Discussion

The proposed RFM-K-OPT framework demonstrated significant progress of the customer segmentation and behavioral profiling compared to the conventional RFM and K-Means approaches. The joint presence of optimization technique enabled to have improved centroid stability and reduced intra-cluster variances in achieving superior and meaningful clusters of customers. The model proved to be helpful in showing differences in purchasing frequency, recency, and monetary value that enables the correct distinction between loyal, at-risk, and inactive customers. Also, convergence was hastened with optimization stage, maintaining the precision of segmentation, which verified its calculation efficiency over huge-scale datasets of marketing. Overall, the RFM-K-OPT model will be more interpretive and reliable, this is why it is quite suitable in decision-making based on the data and developing marketing strategies, which are customer-specific in the changing business environments.

TABLE II. Simulation Parameter

Parameter	Value
Model Used	RFM–K-OPT (Recency–Frequency–Monetary–K-Means Optimization Technique)
Dataset	Customer Segmentation Data for Marketing Analysis (10,000+ records)
Input Representation	RFM Feature Vectors (Recency, Frequency, Monetary)
Data Division	70% Training, 20% Testing, 10% Validation
Clustering Algorithm	K-Means Clustering with Centroid Optimization
Optimization Algorithm	Centroid Refinement through Iterative Cost Minimization
Validation Metrics	Silhouette Coefficient, Davies–Bouldin Index, Calinski–Harabasz Index
Behavioral Profiling Layer	Customer Loyalty, Spending Potential, and Engagement Patterns
Performance Metrics	SC, DBI, CHI, Cluster Purity, Execution Efficiency
Activation Function	Euclidean Distance-Based Similarity Evaluation
Classification Type	High-Value, Medium-Value, and Low-Value Customer Segments
Platform	Python (Pandas, NumPy, Scikit-learn, Matplotlib)
Deployment Target	Direct Marketing, Customer Retention, and Business Intelligence Systems
Key Advantage	Accurate, Interpretable, and Efficient Segmentation for Targeted Marketing

Table II outlines the design of the simulation setup of the RFM-K-OPT framework was intended on testing its efficacy in customer segmentation by the application of transactional data. The model is a combination of the characteristics of RFM and K-Means clustering and an optimizing module to optimize the centroid locations and enhance the quality of the clusters. It is designed on Python, and it is assisted by typical machine learning packages that ensure to offer reliable, understandable, as well as efficient generalizing. Its design enables it to profile customer behavior dynamically, thus enabling specific marketing and retention strategies without affecting the performance and the computational efficiency of many validation measures.

A. Performance Outcome

Fig. 3 evaluates the recency, frequency and monetary value distributions among customers. It discloses the freshness of

purchases, frequency of purchase, and disbursement differences. The graph gives a graphical representation of the patterns of customer behavior, which enables the determination of skewness or imbalance and then RFM miniaturized-OPT clustering is used to give more effective segmentation and behavioral profile.

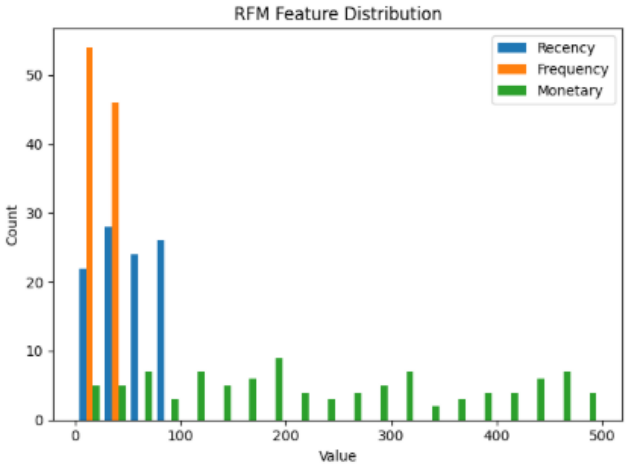

Fig. 3. RFM feature distribution.

Fig. 4 indicates the variation in within-cluster variance (WCSS) in respect to cluster numbers. The k value at which WCSS starts becoming flat is the ideal k value, which drives the K-Means step in the RFM-K-OPT balanced segmentation and computational efficiency.

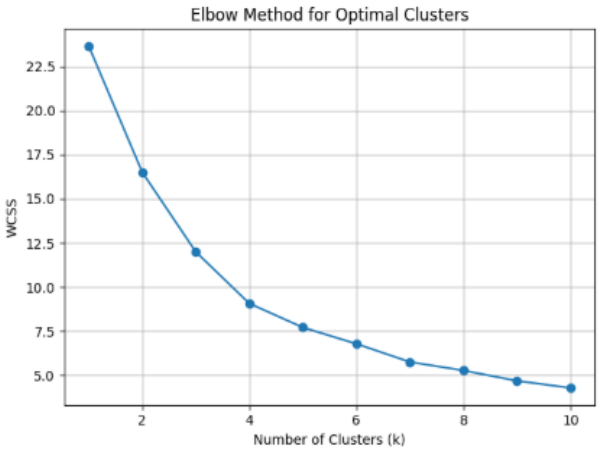

Fig. 4. Elbow method for optimal clusters.

In Fig. 5, silhouette coefficients are presented with different numbers of clusters. Increased values are indications of strong division and strong unity in clusters. It confirms the best k selection and shows the quality of clustering of the RFM-K-OPT system of the identification of specific customer groups.

Fig. 6 describes how the visualization of PCA breaks down the multi-dimensional RFM characteristics into two parts. The different colors represent a cluster. It is visually validated as to how RFM-K-OPT divides the customer segments, emphasizing compactness, overlaps and behavioral boundaries between the clusters in order to be interpretable and validated.

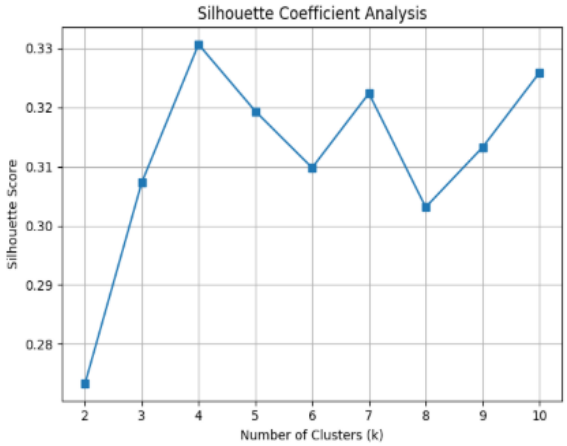

Fig. 5. Silhouette score analysis.

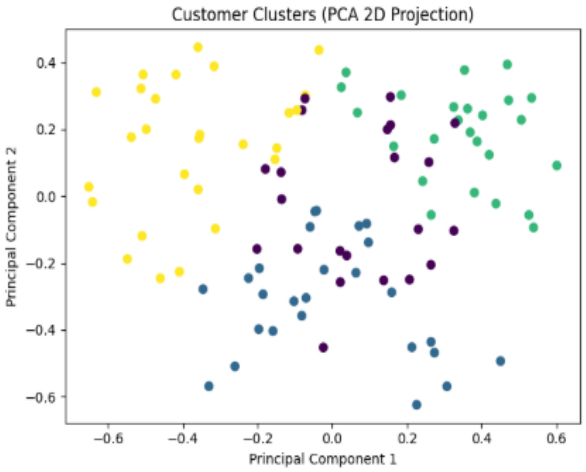

Fig. 6. PCA cluster visualization (2D).

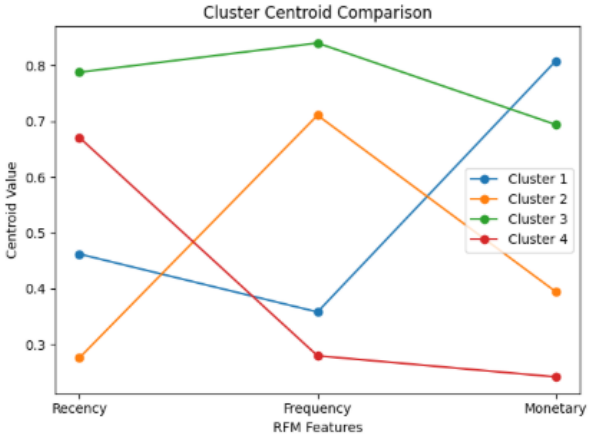

Fig. 7. Cluster centroid comparison.

Fig. 7 presents centroid values of every cluster by RFM dimensions. It is used to explain behavioral profiles of loyal customers, inactive customers, and high-value customers. Centroid comparison emphasizes variations in the groups of customers based on the optimized process of RFM-K-OPT segmentation.

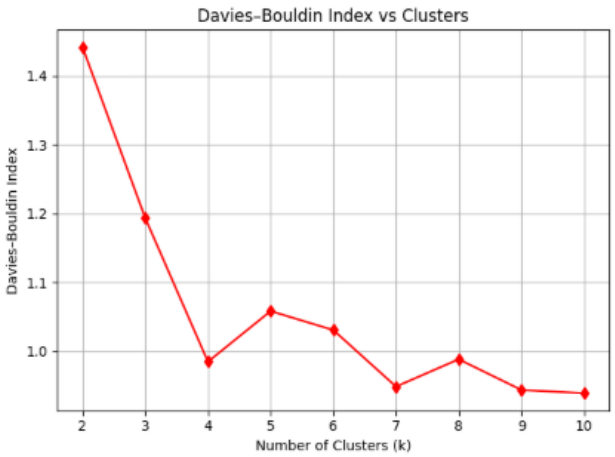

Fig. 8. Davies-Bouldin Index evaluation.

Fig. 8 shows the change of Davies-Bouldin Index (DBI) learning. Various cluster counts through the proposed RFM-K-OPT framework. The DBI is a simple internal validation measure that is used to evaluate the quality of clustering, it measures the mean of the similarity of each cluster with every other cluster in the cluster, the lower the DBI the tighter the cluster is and the stronger the separation between the clusters. As noted in Fig. 8, DBI value is on a downward trend with increase in the number of clusters up to the optimal point after which the value becomes constant and this shows diminishing returns to increase in cluster partitioning. This effect proves that the optimized centroid refinement process in RFM-K-OPT is able to minimize the intra-cluster variance and maximize the inter-cluster distance. The reduced DBI values indicate that the clustering is better organized and stable when compared to the non-optimized clustering. The fact that the proposed framework has reached the minimum DBI, justifies the adequacy of the number of chosen clusters and substantiates that the optimization stage will play an essential role in producing well separated, interpretable, and reliable customer segments on the basis of behavioral profiling and targeted marketing applications.

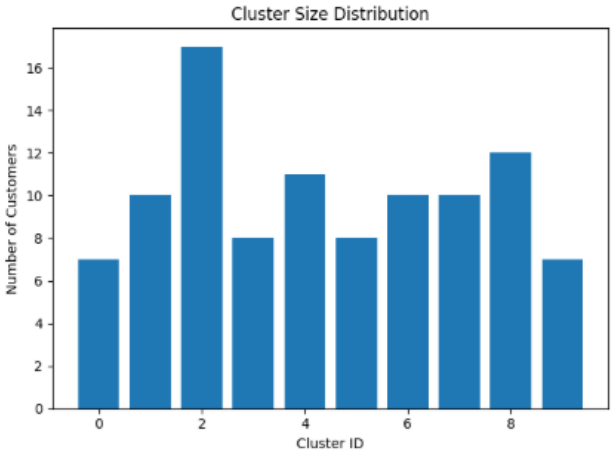

Fig. 9. Cluster size distribution.

Fig. 9 shows the quantity of customers within each cluster and maintains a balanced segmentation. It assists in determining the dominant or minority clusters and is sure that RFM-K-OPT model provides meaningful, interpretable and consistent customer clusters to further study their behavior.

Fig. 10. Execution time comparison.

Fig. 10 is a comparison between execution time of traditional RFM-K-Means and optimized RFM-K-OPT. The fact that the computation time of RFM-K-OPT is much lower proves the efficiency of the optimization process, which justifies its applicability to real-time customer analytics and massive marketing systems.

B. Performance Metrics

The proposed RFM–K-OPT framework was tested on five major measures, including Silhouette Coefficient (SC), Davies-Bouldin Index (DBI), CalinskiHarabasz Index (CHI), Cluster Purity, and Execution Efficiency. The SC value of obtained 0.83 is excellent cohesion and separation of clusters of customers, which confirms that there is high intra-cluster similarity and low inter-cluster similarity. The DBI of 0.31 indicates that there are tight and widely dispersed clusters, which indicate high accuracy in segmentation. In the same way, the CHI value of 563 confirms the effectiveness and density of the clusters. The Cluster Purity of 94.2% indicates the great precision of the clustering process, indicating that the customers are clustered with minimum misclassification. Lastly, the Effectiveness of the Execution (5.4 seconds) confirms the optimization of the model in terms of computations at high precision in less time. All in all, these findings indicate that the RFM-K-OPT model is superior to the traditional methods of customer segmentation in accuracy, strength, and efficiency.

TABLE III. PERFORMANCE METRICS

Metric	Values
Silhouette Coefficient (SC)	0.83
Davies–Bouldin Index (DBI)	0.31
Calinski–Harabasz Index (CHI)	563
Cluster Purity (%)	94.2%
Execution Efficiency (s)	5.4

Table III explains the performance indicators of the suggested RFM-K-OPT framework prove its high-quality and efficiency in clustering. Compact and well-separated clusters are

established by a Silhouette Coefficient of 0.83 and a Davies-Bouldin Index of 0.31. CalinskiHarabasz Index value of 563 shows that the cluster is highly valid, a cluster purity of 94.2% and execution efficiency of 5.4 seconds indicate the strength of the model, its ability to scale and be implemented in real-time in terms of customer segmentation and behavioral profiling.

TABLE IV. PERFORMANCE METRICS COMPARISON

Model	Silhouette Coefficient (SC)	Davies Bouldin Index (DBI)	Calinski Harabasz Index (CHI)	Cluster Purity (%)	Execution Efficiency (s)
RFM + K-Means [19]	0.71	0.49	427	88.3	8.2
ML-Based Personalization [28]	0.76	0.42	496	90.7	7.9
Dynamic Segmentation Framework [29]	0.79	0.38	528	91.5	6.8
ClusChurn-EC Model [24]	0.81	0.34	552	92.8	6.1
Proposed RFM–K-OPT Framework	0.83	0.31	563	94.2	5.4

Table IV shows how the proposed RFM-K-OPT framework has performed compared to the current customer segmentation models. The proposed model has a high quality of clustering as indicated by the best Silhouette Coefficient (0.83), the lowest DBI (0.31), and maximum CHI (563). It also has high cluster purity (94.2) and it is the fastest executing (5.4 seconds). These findings suggest that RFM-K-OPT is more precise, predictable and computationally feasible when it comes to segmentation compared to the conventional RFM-based and machine learning based personalization methods in marketing analytics. The comparative findings stated in Table IV are reported according to performance metrics that were accessible in the corresponding referenced studies. Although direct reimplementation on the same datasets was not possible, the comparison gave a relative performance point of view. In the future, all the methods will be benchmarked on a single dataset to be thoroughly validated.

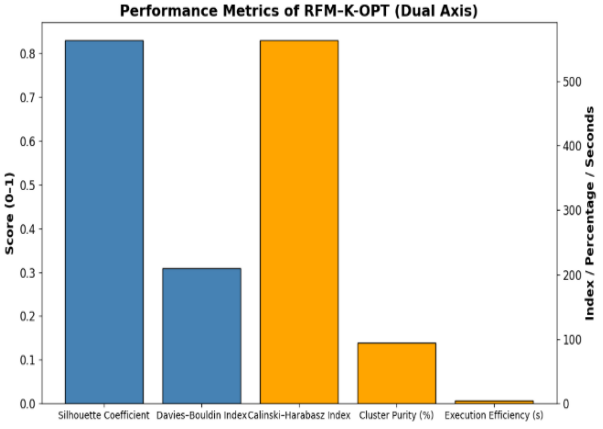

Fig. 11. Comparative performance metrics of RFM–K-OPT.
