The effectiveness of RCE has been evaluated using the Churn Modelling benchmark dataset for European banks [6], where it achieved a performance with a 95.65% accuracy, however in dynamic environments, it accomplishes an average accuracy of 86.75% and an average forgetting rate of 13.25% across tasks T_i. The experimental results demonstrate that RCE outperforms existing models in predictive accuracy, adaptability, and robustness across multiple tasks, particularly in fast-changing environments. By providing instantaneous insights, RCE empowers decision-makers to implement proactive risk management strategies, optimize resource allocation, and reduce costs, ultimately improving customer retention. Additionally, the key features and contributions of this research include:

- Introducing a real-time, continual learning model called RCE designed to overcome the limitations of existing churn analysis approaches.
- Integrating RCE with an event-driven development approach to allow RCE to process an ongoing stream of customer data.
- Implementing RCE using stacked ensemble learning for customer churn classification.
- Applying RCE using a replay-based continual learning technique to enable RCE to adapt to evolving customer behaviors without catastrophic forgetting.
- Enabling RCE to learn continuously from new data, ensuring robust performance in dynamic environments. And qualifying RCE to provide real-time predictions, allowing decision-makers to respond swiftly to market fluctuations, cybersecurity threats, and customer behavior changes.
- Evaluating RCE using the Churn Modelling benchmark dataset for European banks, where it achieved a performance with 95.65% accuracy, however in dynamic environments, it accomplishes an average accuracy of 86.75% and an average forgetting rate of 13.25% across tasks T_i.

The remainder of this study is organized as follows: Section II reviews related work in customer churn analysis and existing machine learning models. Section III presents the background and key concepts of continual learning, stacked ensemble learning, and event-driven data processing. Section IV introduces the RCE model, explaining its architecture and operational mechanism. Section V details the evaluation methodology and experimental results, comparing RCE's performance with conventional models. Finally, Section VI provides the conclusion, discusses research limitations, and outlines future directions for improving real-time customer churn analysis.

II. Related Work

Customer churn prediction has been extensively studied in various industries, with machine learning playing a crucial role in developing accurate forecasting models. As illustrated in Table I. Several recent studies have explored different approaches to customer churn analysis, leveraging ensemble methods, explainability techniques, and novel optimization strategies.

TABLE I. EXISTING CUSTOMER CHURN ANALYSIS MODELS VS RCE PROPOSED MODEL

Model Name	Accuracy (%)	Dataset	Is Adaptable to Ongoing Tasks?	Training Approach
Random Forest [7]	91.66	Telecom CUSTOMER Churn (Maven Analytics)	No	Batch-based
XGBoost [8]	83	Bank Customer Churn (Kaggle)	No	Batch-based
GBM [9]	81	Customer Churn (Kaggle)	No	Batch-based
IDA-HGOAML [10]	94	Telecom Churn (Kaggle)	No	Batch-based
Ensemble-Fusion [11]	95.35	Company Customer Production Line	No	Batch-based
Stacked Model [12]	95.13	Bank Customer Churn (Kaggle)	No	Batch-based
LightGBM [13]	80.70	Telco Customer Churn (Kaggle)	No	Batch-based
CatBoost [14]	81.19	Telecom Customer Churn	No	Batch-based
RCE (Proposed Model)	95.65	Bank Customer Churn (Kaggle)	Yes	Continual-based

V. Chang et al. (2024) investigated the effectiveness of ensemble learning models in predicting customer churn within the telecommunications sector [7]. The study implemented Decision Trees, Boosted Trees, and Random Forests, demonstrating that the latter achieved the highest predictive accuracy of 91.66% using the Telecom Customer Churn dataset from Maven Analytics. The research emphasized the importance of explainable AI (XAI) techniques, such as LIME and SHAP, to provide interpretability, enabling customer relationship managers to make data-driven decisions to mitigate churn [7].

P. P. Singh et al. (2024) analyzed customer churn in the banking industry by applying multiple machine learning algorithms to the Bank Customer Churn Prediction dataset. The study found that XGBoost outperformed other models with an accuracy of 83%, followed by Random Forest at 78.3%. A key contribution of this research was the development of a data visualization RShiny app to assist bank management in understanding churn trends and making informed retention strategies [8].

S. S. Poudel et al. (2024) focused on the interpretability of churn prediction models in the telecommunications industry [9]. The study highlighted the limitations of traditional classification approaches in providing actionable insights for decision-making. By incorporating explainable models such as Gradient Boosting Machine (GBM) alongside SHAP and scatter plots, the research improved transparency. GBM achieved an accuracy of 81% using a Kaggle customer churn dataset, and a Wilcoxon signed rank test validated its superior performance over other models [9].

E. Akhmetshin et al. (2024) introduced a novel IDA-HGOAML model that combines multiple machine learning techniques for customer churn prediction. The proposed method integrated data preprocessing, feature selection, and hyperparameter tuning to enhance classification performance. The model achieved a 94% accuracy rate using the Kaggle Telecom Churn dataset, demonstrating its effectiveness in predicting customer retention outcomes [10].

C. He et al. (2024) proposed an Ensemble-Fusion model that incorporated 17 machine learning algorithms across nine categories to enhance churn prediction [11]. Using the Company's customer production line system dataset from 2015 to 2022, the model achieved 95.35% accuracy and an AUC score of 91%. The study demonstrated that ensemble-based approaches significantly improved prediction accuracy compared to single-model methods.

V. H. Vu et al. (2024) developed a stacked model for early churn detection in the banking industry [12]. This model was structured across two levels: the first level combined K-nearest neighbors, XGBoost, Random Forest, and Support Vector Machine, while the second level utilized logistic regression, recurrent neural networks, and deep learning networks to refine predictions. The approach achieved a high accuracy of 95.13% on the Kaggle Bank Turnover Dataset, outperforming traditional models in predictive performance and computational efficiency [12].

T. R. Noviandy et al. (2024) explored the application of LightGBM for churn prediction in the telecommunications sector [13]. The model achieved an accuracy of 80.70%, precision of 84.35%, and recall of 90.54% using the Kaggle Telco customer churn dataset. The study incorporated SHAP for model interpretability, identifying key churn factors such as contract type and monthly charges, thereby providing actionable insights for retention strategies.

A. Li et al. (2024) investigated the role of ensemble learning techniques in predicting customer churn in the telecommunications industry [14]. The study compared various machine learning models, emphasizing the effectiveness of the Stacking ensemble method. Results indicated that CatBoost achieved the highest accuracy at 81.19%, outperforming Random Forest (79.02%) and XGBoost (78.20%). The study highlighted CatBoost's superior performance due to its ability to handle categorical features effectively.

Despite the progress made by recent machine learning models in predicting customer churn, most existing solutions are limited by their reliance on batch-based training, which hinders adaptability to evolving data. Furthermore, current models rarely combine event-driven architectures with continual learning mechanisms, leaving a critical gap in real-time adaptability and long-term retention. This gap highlights the need for an integrated approach that supports dynamic learning from streaming data while maintaining model stability and accuracy. The proposed RCE model addresses this need by combining event-driven development, replay-based continual learning, and stacked ensemble classification.

III. Background and Key Concepts

The RCE model integrates event-driven development, which enables real-time data processing, replay-based continual learning, which adapts to evolving tasks while mitigating catastrophic forgetting, and stacked ensemble learning, a powerful classification technique for customer churn prediction. The following sub-sections provide an in-depth explanation of these key components, highlighting their significance within the proposed model to establish a solid foundation for the research.

A. Event-Driven Development

Event-Driven Development (EDD) is a software architectural paradigm that enables systems to respond to events in real-time. It is widely used in real-time data processing, IoT applications, and customer churn analysis, where continuous monitoring and swift decision-making are required [15].

The key components required to build a powerful event-driven architecture include:

1) Producers (Event sources). Entities that generate events based on real-world activities or system changes. For instance, in a customer churn analysis system, a producer could be a transaction monitoring system that detects abnormal customer activity [15, 16].

2) Event brokers (Middleware). A messaging infrastructure that ensures events are transmitted reliably between producers and consumers. Message brokers like Apache Kafka, RabbitMQ, or AWS Kinesis act as intermediaries, enabling scalable and decoupled communication [15, 16].

3) Consumers (Event processors). Systems or services that subscribe to and process events, executing appropriate responses. In churn prediction, a consumer could be an AI-driven analytics engine that processes incoming customer activity data and triggers predictive churn alerts [15, 16].

4) Event store (Optional). A repository that records past events for auditing, debugging, or replaying historical event sequences to improve machine learning model performance [16].

For instance, a simplified event-driven architecture is illustrated in Fig. 2, where multiple producers send real-time event data to a broker, which then distributes them to different consumers for processing.

B. Replay-Based Continual Learning

Continual Learning (CL) enables machine learning models to learn from a continuous stream of data while retaining knowledge from previous tasks. One of the most effective techniques for mitigating catastrophic forgetting in CL is the Replay-Based Approach, which involves storing past experiences and revisiting them periodically during training [17]. There are two primary types of replay-based continual learning:

1) Experience replay: This technique stores and reuses previous training examples to reinforce learning [17, 18].

a) Uniform replay: Randomly selects past samples for retraining [17].

b) Selective replay: Stores only important samples based on criteria such as uncertainty or importance weighting [17].

c) Prioritized replay: Assigns priority scores to samples based on their learning significance, ensuring high-value experiences are replayed more often [17].

2) Generative replay: Instead of storing actual data, generative models such as Variational Autoencoders (VAEs) or Generative Adversarial Networks (GANs) generate synthetic samples resembling past data distributions, allowing the model to reconstruct and recall previous knowledge efficiently [17].

Replay-based is effective in continual learning, where past experiences are retrieved and mixed with new data to maintain performance stability over time.

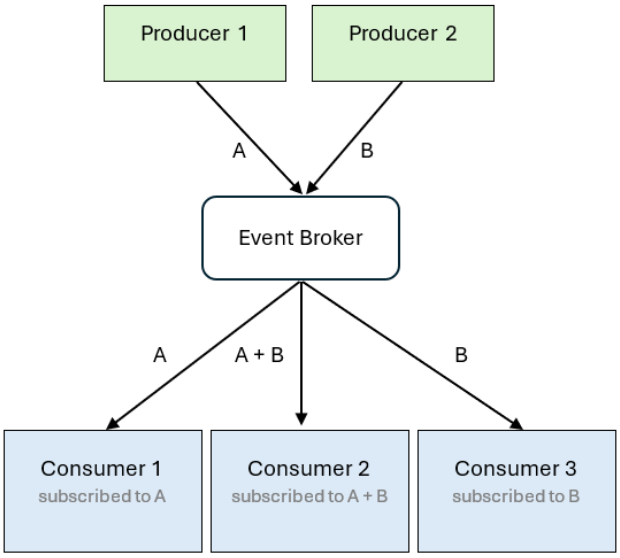

Fig. 2. A Simplified event-driven architecture.

C. Stacked Ensemble Learning

Stacked Ensemble Learning is an advanced machine learning technique that enhances predictive performance by combining multiple models, known as base learners, and a secondary model, called a meta-learner, to optimize decision-making as shown in Fig. 3. This approach leverages the strengths of diverse base models while mitigating their individual weaknesses, resulting in improved accuracy and robustness [19].

The key components required to build a powerful stacked ensemble learning model include:

1) Base models. Also referred to as level 1 learners, are diverse machine learning algorithms trained independently on the same dataset. Each base model captures unique patterns and relationships within the data, making different errors and offering complementary perspectives [19]. Common base models used in stacked ensemble learning include:

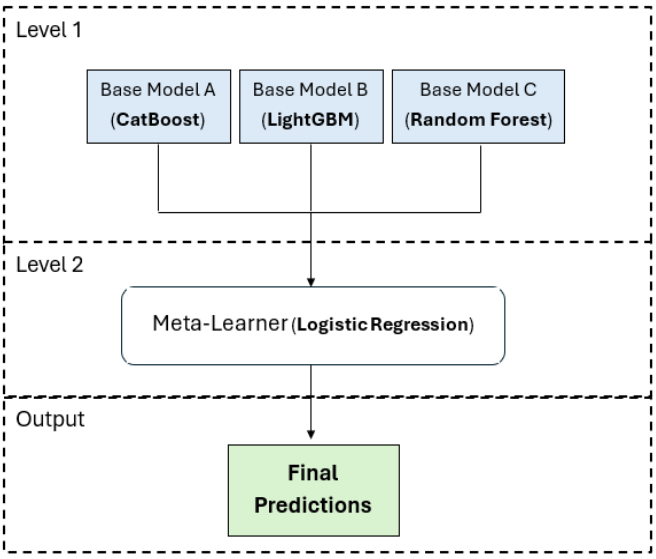

Fig. 3. A Stacked Ensemble Learning framework.

a) CatBoost: A gradient boosting algorithm optimized for categorical data [21].

b) XGBoost: An efficient and scalable implementation of gradient boosting [20].

c) LightGBM: A high-speed gradient boosting framework with optimized memory usage [22].

d) Random forest: An ensemble of decision trees that enhances generalization [19].

The diversity among base models ensures that they learn varying feature interactions and decision boundaries, reducing the risk of overfitting to specific data distributions.

2) Meta-learner. Also referred to as level 2 model, is responsible for aggregating and refining predictions from the base models. Instead of making direct predictions on the raw dataset, it takes the outputs (predicted probabilities or class labels) of the base models as input features and learns how to optimally combine them [19]. The meta-learner typically uses:

a) Logistic regression: A simple yet effective model for binary classification tasks [23].

b) Neural networks: When nonlinear interactions between base models need to be captured.

c) Gradient boosting models: If additional feature transformations are necessary [20, 21].

By learning the strengths and weaknesses of each base model, the meta-learner assigns appropriate weights to their predictions, ultimately improving classification accuracy.

IV. The Proposed Model (RCE)

Real-time Continual Ensemble (RCE) model is an advanced machine learning proposed model designed to enhance customer churn prediction through a combination of event-driven development, replay-based continual learning, and stacked ensemble learning, as shown in Fig. 4.

The proposed RCE model continuously processes incoming customer interaction data, dynamically adapts to changing behavioral patterns, and refines its predictive performance over time. The event-driven architecture is implemented using Apache Kafka, ensuring seamless real-time data ingestion from multiple sources, such as customer transactions, service usage logs, and customer support interactions [15, 16]. Each event triggers an update cycle in the RCE model, allowing for continuous learning.

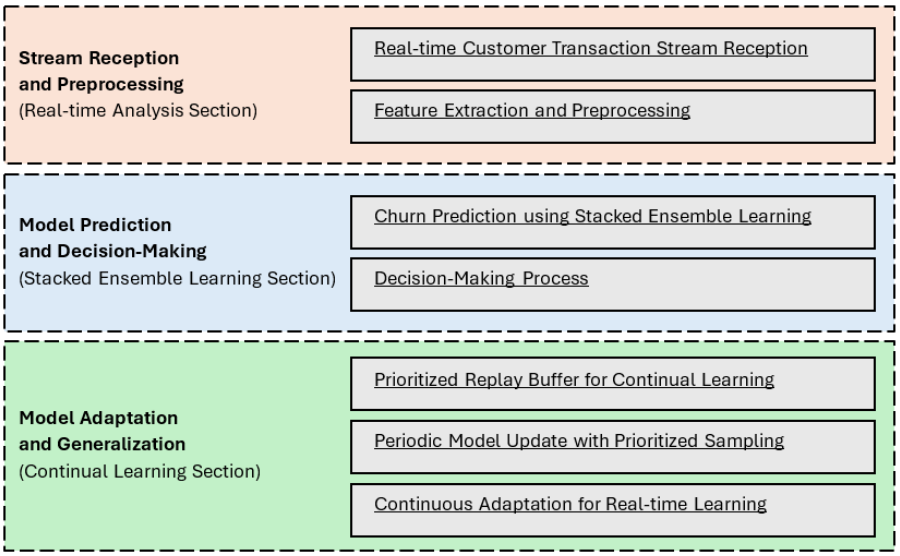

Fig. 4. The Proposed RCE model

To handle catastrophic forgetting and ensure knowledge retention, RCE integrate a prioritized experience replay mechanism, where past data points are stored in a buffer with priority scores based on their significance [17, 18]. When retraining, the model selectively samples from this buffer, focusing on high-impact instances to reinforce learning. At the core of the RCE model, lies a stacked ensemble learning approach, which combines multiple base classifiers—CatBoost, LightGBM, and Random Forest—to generate diverse predictions. A Logistic Regression model serves as the

meta-learner, aggregating the base models' outputs to enhance predictive accuracy as shown in Fig. 3. The model development process includes comprehensive data preprocessing (handling missing values, feature extraction, normalization), feature engineering (polynomial transformations, encoding categorical variables), addressing class imbalance using ADASYN [24], and feature selection using a Random Forest-based method. To optimize performance, Bayesian Optimization is applied for hyperparameter tuning [25], systematically searching for the most effective parameter configurations for each base model as shown in Algorithm 1.

Algorithm 1: RCE Proposed Model

Input*:* Real-time customer interactions, such as service usage, transaction records, customer support interactions, or website activity. Events are generated by producers (e.g., transaction systems, CRM systems, or log monitoring services).

Output*:* Real-time churn probability scores, for each customer event, the model outputs a probability indicating the likelihood of churn. For instance, 80% (customer will stay) and 20% (customer will leave). To convert this probability into a binary decision, a threshold (e.g., 0.5 or 0.7) is typically applied (e.g., if the score $\geqslant$ 0.5, classified as 1 (churn) and the system can trigger proactive interventions, otherwise classify as 0 (stay)). The threshold can be adjusted based on business needs to optimize precision and recall.

Algorithm:

```
Initialize Event-driven data pipeline
Initialize Prioritized Replay Buffer (B) with Capacity (C)
Initialize Base models: CatBoost, LightGBM, and Random Forest with predefined hyperparameters
Initialize Meta-learner: Logistic Regression
While system is operational:
    Receive new customer event (Et) from Kafka
    Extract and preprocess features from Et:
        Handle missing values, noises and outliers
        Perform scaling, encoding, and feature transformation
        Apply polynomial feature expansion
        Apply feature selection techniques
    Store processed event data in buffer B with priority score
    If buffer B reaches capacity C:
        Remove lowest-priority instances
    If training condition met:
        Sample mini-batch S from B by priority-based sampling
        Apply (ADASYN) to balance class distribution within S
        Tune hyperparameters using Bayesian Optimization
        Train base models on S
        Generate meta-features from base model outputs
        Train meta-learner using meta-features
    Predict customer churn probability score P(Et)
    If P(Et) > threshold:
        Trigger customer retention strategy
    Update priorities in B based on instance importance
Return: Continuously updated RCE model
```

The selection of CatBoost, LightGBM, and Random Forest as base models, along with Logistic Regression as the meta-learner, is driven by their complementary strengths in customer churn prediction. CatBoost and LightGBM are boosting-type algorithms, meaning they build models sequentially, where each iteration corrects the errors of the previous one, leading to a strong overall model. Boosting is particularly effective in reducing bias and improving accuracy. Random Forest, on the other hand, is a bagging-type algorithm, which constructs multiple decision trees independently in parallel and then averages their predictions, enhancing stability and reducing variance. CatBoost efficiently handles categorical variables without extensive preprocessing, making it ideal for customer-related data [21]. LightGBM is optimized for speed and scalability, making it well-suited for large datasets [22]. Random Forest provides robustness against overfitting by leveraging an ensemble of decision trees [19]. The diversity among these models ensures that different aspects of the data are captured, reducing model bias and improving generalization. Logistic Regression, serving as the meta-learner, aggregates predictions from the base models, refining the final decision boundary [23]. This stacked ensemble approach enhances predictive performance, leading to a more accurate and reliable churn prediction system.

The entire process operates in a continuous learning loop, ensuring that the RCE model evolves with changing customer behaviors. As new data arrives, the model updates its knowledge while maintaining past learnings, effectively mitigating the challenges of traditional batch learning approaches. The proposed RCE model bridges real-time processing, continual learning, and stacked ensemble techniques, ensuring superior adaptability and predictive accuracy.

By integrating Kafka-based event-driven architectures, replay-based learning, and a highly optimized ensemble framework, the RCE model not only enhances churn prediction performance but also maintains robustness in dynamic customer environments.

V. Experimental Results

To assess the effectiveness of the RCE model in predicting customer churn, a series of experiments has been conducted using the "Churn Modelling" benchmark dataset for European banks, available on Kaggle [6]. This dataset comprises 10,000 customer records and includes 14 features, such as customer demographics, credit scores, number of products, estimated salary, and account activity, which are essential in predicting customer churn. The target variable, "Exited", indicates whether a customer has churned (1) or remained (0). Given the class imbalance in the dataset, where most customers do not churn, the dataset required specific preprocessing techniques to ensure balanced learning.

A. Experimental Setup

The RCE model is implemented in a controlled experimental environment with Kafka (v3.9) facilitating real-time event-driven processing. The machine learning components were developed using Python with the following libraries and frameworks: CatBoost (v1.2), LightGBM

(v4.1.0), Scikit-learn (v1.3.0) for Random Forest and Logistic Regression, and Imbalanced-learn (v0.11) for applying ADASYN to address class imbalance. Bayesian Optimization was performed using Scikit-Optimize (v0.9.0) to fine-tune hyperparameters. The StackingClassifier from Scikit-learn was utilized to integrate the base learners (CatBoost, LightGBM, and Random Forest) with a Logistic Regression meta-learner. Data preprocessing involved feature engineering, feature selection using SelectFromModel, and polynomial feature augmentation to enhance model representation. The computational experiments were conducted on a system equipped with an Intel Core i7 processor, 32GB RAM, and an NVIDIA RTX 3090 GPU, ensuring efficient model training and inference. The performance of the RCE model is assessed under two experimental scenarios to show the effectiveness of the proposed models in different environments.

B. Scenario 1: Stable Environment

In the first scenario, the entire dataset was used as a single batch for learning and evaluation. The model is trained on a training subset (typically 70 to 80% of the dataset) and then evaluated on the remaining test data in a static, traditional batch setting. The RCE model demonstrated superior performance, achieving an accuracy of 95.65%, a precision of 90.41%, a recall (sensitivity) of 88.29%, and an F1-score of 89.71% as shown in Fig. 5.

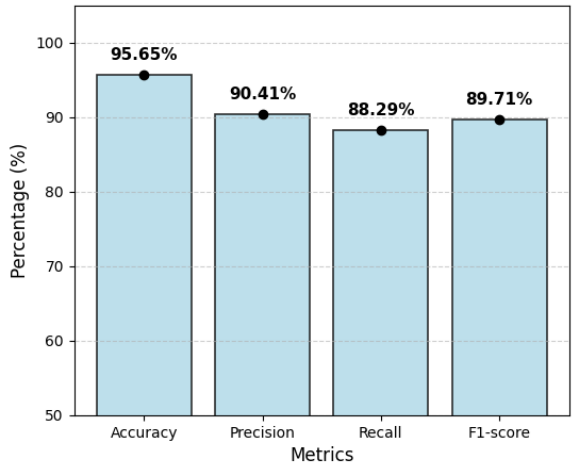

Fig. 5. RCE Performance metrics.

For comparative analysis, the RCE model's accuracy was evaluated against two recent customer churn prediction models that used the same dataset. The XGBoost model [8] achieved an accuracy of 83%, while the stacked ensemble model [12] attained 95.13% as shown in Fig. 6.

C. Scenario 2: Dynamic Environment

In the second scenario, the accuracy of the RCE model was evaluated in a simulated dynamic environment. Instead of using the entire dataset as a single batch in learning and evaluation, the model is first trained on an initial 70% training set, while the remaining 30% is used to simulate a real-time, dynamic environment by being gradually introduced in smaller batches incrementally to simulate real-time learning. The accuracy of the RCE model across four tasks (T1, T2, T3, and T4) was recorded as 89%, 86%, 85%, and 87%, respectively. In contrast, traditional models fail to adapt and generalize to new experiences, as they lack the ability to incrementally train with newly arriving data.

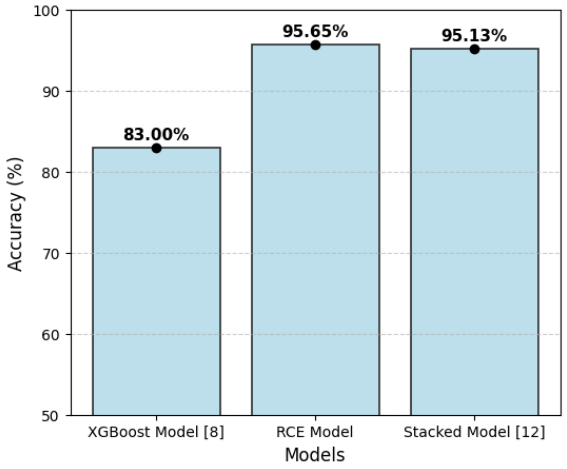

Fig. 6. Comparison of RCE with XGBoost [8] and Stacked Model [12] under static conditions.

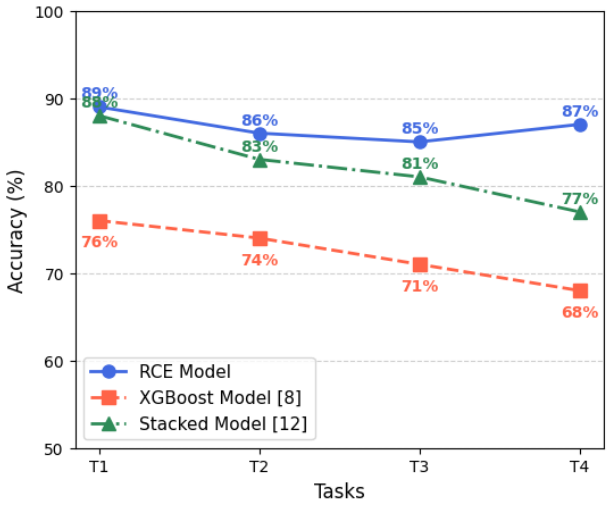

Fig. 7. Performance of RCE, XGBoost [8], and Stacked Model [12] across multiple tasks in a simulated dynamic environment.

Consequently, their performance deteriorates over time. The XGBoost model [8] exhibited a sharp decline in accuracy, scoring 76%, 74%, 71%, and 68%, while the stacked model [12] achieved 88%, 83%, 81%, and 77%. These results, illustrated in Fig. 7, demonstrate the effectiveness of the RCE model in maintaining robust predictive performance in dynamic environments.

To summarize the overall performance across dynamic tasks, the average accuracy (ACC) is computed. The RCE model achieved an average accuracy of 86.75%, whereas XGBoost [8] exhibited an average accuracy of 72.25%. The stacked model [12] had an average accuracy of 82.25% as shown in Fig. 8. The experimental results demonstrate that the RCE model significantly outperforms existing customer churn prediction models, both in traditional batch learning and dynamic real-time environments. By integrating event-driven

processing, replay-based continual learning, and stacked ensemble learning, the RCE model maintains high predictive accuracy and effectively adapts to evolving customer behaviors, mitigating catastrophic forgetting.

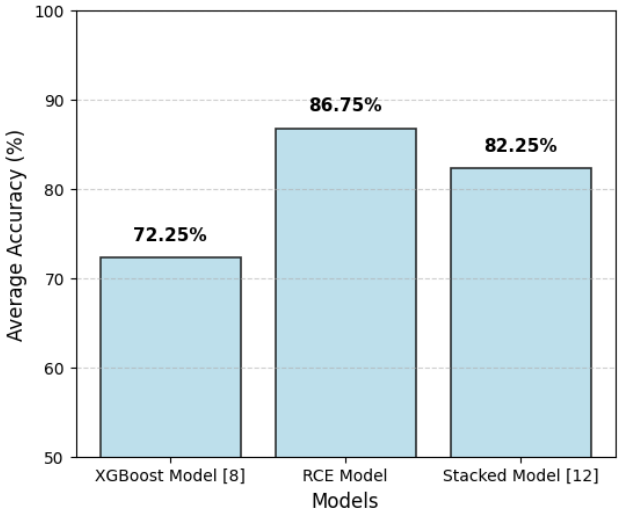

Fig. 8. Average accuracy of RCE, XGBoost [8], and Stacked Model [12] across multiple tasks in a simulated dynamic environment.

VI. Conclusion, Limitations, and Future Work

This research introduced the Real-time Continual Ensemble (RCE) model, designed to address customer churn prediction in real-time, dynamic environments. The RCE model integrates an event-driven development approach using Kafka to process continuous data streams efficiently, ensuring real-time churn prediction. Additionally, it incorporates a replay-based continual learning mechanism, allowing the model to adapt incrementally to evolving customer behaviors while mitigating catastrophic forgetting. Unlike traditional models that train on static datasets, the RCE model continuously refines its knowledge without losing prior insights. Furthermore, stacked ensemble learning was employed to enhance classification performance, leveraging a diverse set of base models (CatBoost, LightGBM, and Random Forest) and a Logistic Regression meta-learner. This combination reduces bias, enhances generalization, and improves predictive accuracy.

To evaluate the effectiveness of the proposed model, experiments were conducted on the Churn Modelling benchmark dataset for European banks, which consists of 10,000 samples and 14 features. The RCE model achieved a 95.65% accuracy when trained on the entire dataset, outperforming existing models. However, in a simulated dynamic environment, where incremental learning was required, RCE demonstrated superior adaptability by maintaining an average accuracy (ACC) of 86.75% across tasks. This performance was notably higher compared to recent models, such as the XGBoost model [8] which struggled with adapting to evolving data distributions, achieving only 72.25% ACC. Similarly, the stacked ensemble model [12], though initially competitive, exhibited a decline over time, reaching an ACC of 82.25%. The findings confirm that RCE not only outperforms traditional models in static training scenarios but also excels in dynamic environments, ensuring that businesses can make data-driven decisions in real time.

Despite its advantages, the proposed RCE model has certain limitations. First, the dataset used for evaluation is relatively small (10,000 samples), which may not fully capture the complexities of real-world customer churn behavior in large-scale enterprises. Additionally, the experience replay mechanism used for continual learning requires significant memory resources, especially when handling large volumes of streaming data. While prioritized experience replay helps mitigate this issue, memory constraints remain a challenge in real-time applications. Moreover, hyperparameter tuning using Bayesian Optimization contributes to enhanced model performance but is computationally expensive, requiring careful optimization to balance efficiency and accuracy.

Future research should focus on evaluating RCE on larger, more diverse datasets to assess its scalability and robustness in real-world scenarios. Furthermore, while experience replay has been effective in this study, alternative continual learning strategies could be explored to further enhance adaptability. Approaches such as gradient-based methods [26], regularization techniques [27], knowledge distillation [28], Bayesian-based adaptation [29], architecture modifications [30], or hybrid continual learning models offer promising directions to reduce memory overhead and improve long-term retention of knowledge. By addressing these challenges, the RCE model can be extended into broader applications, ensuring its effectiveness in high-velocity, real-time data-driven decision-making systems.

***Abstract*—Wireless sensor networks consist of a set of smart sensors with limited memory and wireless communication capabilities. These sensors get data from the environment and send them to an application center. However, data loss has happened due to the characteristics of sensors, which negatively affect the accuracy of applications. To solve this problem, we need to estimate the missing data for applications that depend on accurate data collecting. In this study, we present an algorithm that uses the most significant historical data to estimate the missing data based on spatial and temporal correlations. In the proposed algorithm, we combine the spatial correlation by using data from the closest sensor based on the missing pattern and the temporal correlation by referring to the closest data prior to the missing instance. The experimental results demonstrate that the proposed algorithm lowers estimation errors when compared to current algorithms for a variety of missing data patterns.**

Keywords*—Wireless sensor networks; missing data estimation; spatial correlation; temporal correlation

I. Introduction

In recent years, WSNs have generated a lot of interest for a variety of purposes [1]. WSNs have become particularly important for physical exploration, as they are used in difficult-to-reach places such as aquatic settings, active calderas, and deep forests [2-5]. These networks are employed in real-world settings to gather environmental data, which is then used in computer systems. A WSN is composed of many smart, inexpensive sensors that have less processing and storage power than conventional sensors. These sensors can detect, measure, and gather information from their environment, process the information in an initial step, and then send it to users [2].

Most applications in WSN suffer from missing data because of sensor limitations and environmental factors. Thus, the analysis tools cannot be applied well without recovering these missing data accurately. If the missing data is ignored, the original information and data resources are lost. Thus, reduce the accuracy and reliability of analysis results. This problem can be effectively solved by data estimation algorithms that interpolate missing data accurately and efficiently. So, handling the missing data is particularly one of the most important challenges in data management for different applications of WSN.

Numerous estimation methods have been used to address the issue of missing data, which can be categorized into three main groups: spatial correlation, temporal correlation, and spatial-temporal correlation.

Spatial correlation methods rely on the assumption that data points closer in spatial distribution have a greater influence on interpolating missing data. These methods treat each sensor as independent and calculate weight based on the gap between the missing data and surrounding sensors. However, when data are unevenly distributed, the performance of these methods tends to be suboptimal.

Temporal correlation methods estimate the missing data from the same sensor using past data for that sensor. However, if a continuous sequence of data is lost, these methods fail to accomplish comprehensive reconstruction.

In recent studies, several techniques have been used to estimate missing data by utilizing both temporal and spatial correlations. These methods find the most significant spatial samples and temporal series for data and divide missing data into homogeneous spatial regions. However, they need the complete dataset to be computed, which leads to a large amount of redundant data and high computational complexity.

In this study, we introduce the Spatial and Temporal Correlation Estimation Algorithm (STCEA), for estimating the missing data in wireless sensor networks (WSNs). In this algorithm we address the missing data by analyzing the real-world datasets, identifying data loss, and identifying the patterns of data loss in WSNs. We demonstrate the improved efficacy and efficiency of STCEA by comparing its performance with other algorithms that address the problem of missing sensor data.

This study's remaining sections are arranged as follows: Section II reviews traditional strategies for estimating missing data. Section III introduce the proposed algorithm developed in this study. Section IV evaluates the algorithm through simulated experiments. Finally, Section V provides the conclusion of the study.

II. Related Work

Estimating missing data is a preprocessing step for cleaning and preparing incomplete datasets. Ignoring this problem can present significant challenges to WSN applications. If missing data is not addressed, a significant amount of sensor data may be lost. Thus, reducing the accuracy and reliability of the

*Corresponding Author.

application. Therefore, implementing algorithms to estimate missing data is important to address these challenges.

For handling missing data, some methods ignore the missing data that is not well-suited to the nature of WSNs [6]. While other methods re-query the data that consumes additional time and network bandwidth and does not ensure the original data is retrieved. As a result, estimating missing sensor data has become essential.

In this section, we summarize the different estimation algorithms used to deal with the missing data problem in the wireless sensors.

Different algorithms have been conducted on estimating the missing data in statistics, including Mean Substitution, Multiple Imputations, Expectation Maximization, Imputation by Regression, Bayesian Estimation, and Maximum Likelihood [7]. However, these algorithms are unsuitable in Wireless Sensor Networks (WSNs) because they assume that data is missing randomly. Thus, these algorithms are generally inefficient.

Data mining algorithms can be used to estimate the missing data in WSN, involves extracting knowledge from data and applying it to predict the missing values [8]. Algorithms based on association rules are employed to capture the relationships between sensor nodes and data. The goal is to identify all the association rules that meet the user-defined threshold. Examples of these algorithms: Window Association Rule Mining (WARM) [9], Closed Itemsets-based Association Rule Mining (CARM) [10], and Freshness Association Rule Mining (FARM) [11].

Estimating missing data in WSN based on association rules has several challenges. Sensor data in WSN is often changed over time. While association rules-based algorithms are typically static and can't capture these dynamics effectively. Also, the relationships between sensors can be nonlinear. While association rules typically get linear relationships. These challenges highlight the limitations of using the association rules for estimating the missing data in WSN. To overcome these challenges different algorithms have been developed to address the problem of spatial-temporal missing data. These algorithms are classified into three categories: spatial correlation, temporal correlation, and spatial-temporal correlation.

The Grey System Estimation Algorithm (GSEA) is a spatial correlation algorithm that begins by evaluating the relationships between the target sensor with missing data and its neighboring sensors [12]. Then sort these sensors according to their correlation values, placing those with higher correlations closer to the target sensor. The algorithm calculates this correlation based on the distance between the missing sensor and its neighboring sensors. This algorithm works particularly well with environmental variables, such as voltage, humidity and temperature, which do not exhibit significant changes over small areas. However, GSEA encounters limitations when dealing with large areas of missing data.

Another estimating missing data based on the spatial correlation is Adaptive Multiple Regression (AMR) algorithm [13]. AMR utilizes the multiple regression model for estimating the missing values by considering data from multiple neighboring nodes simultaneously. AMR dynamically adjusts its estimation equation to account for changing correlations among sensor data, resulting in more accurate predictions. However, the algorithm employs a heuristic approach to select sample data and relevant sensors, which increases its computational complexity.

Time series prediction techniques usually build a structure for guessing missing data points at a given area using historical data from that area. The autoregressive integrated moving-average (ARIMA) model is one such technique [14]. However, this approach has two significant drawbacks. First, a lot of prediction models perform poorly because they don't make full use of the crucial features of spatio-temporal data. Second, these prediction approaches frequently fail to produce appropriate reconstruction when a complete consecutive set of data is missing [15].

In recent years, several studies consider both spatial and temporal correlations which are of particular interest to us e.g. Minimized Similarity Distortion (MSD) [16], Mining Autonomous spatial and Temporal (MASTER) [17], Data Reconstruction Algorithm (DRA) [18] and Temporal and Spatial Correlation Algorithm (TSCA) [19].

MSD [16] is an imputation method that reduces similarity distortion by considering various attributes of sensor datasets, not just spatial and temporal dimensions, to ensure comprehensive data segmentation. However, as the number of missing values increases, accurately identifying the correct neighboring unit becomes more challenging, leading to higher error rates. MASTER [17] is an online spatio-temporal mining algorithm that processes data incrementally in a single scan to estimate missing or corrupted sensor data streams.

DRA [18] is a data reconstruction algorithm that accounts for both spatial and temporal correlations, iteratively minimizing the difference between the estimated and reconstructed data, treating the estimated data as the original. TSCA [19] selects sample data for each missing value estimation by leveraging spatial correlation through the calculation of distances between sensor nodes and the missing sensor and then uses past timestamp data for temporal estimation. The final estimated value is obtained by combining both spatial and temporal estimates.

As previously indicated, the most effective linear estimations in both dimensions are obtained by calculating the weights of the spatial and temporal contributions. However, this approach necessitates using the entire dataset for computation, leading to high computational complexity and excessive redundant data. Additionally, when there are consecutive missing data points, the accuracy of interpolation decreases, and it may become difficult to generate the final result.

III. Proposed Estimation Algorithm

We introduce the Spatial and Temporal Correlation Estimation Algorithm (STCEA) to solve the problem of missing data in wireless sensor networks (WSNs). This algorithm is designed for static networks with offline data,

where the sensor locations are known. Algorithm 1 outlines the spatial and temporal correlations for STCEA algorithm.

In a WSN, sensor nodes are placed in a designated area and can be represented as ($SN1$, $SN2$, $SN3$, ..., SNm). These nodes periodically report data at times {$t1$, $t2$, ..., tn}. At time ti, the collected data form a time series $SN(ti) = (SN1_{ti}, SN2_{ti}, SN3_{ti}, ..., SNm_{ti})$.

If the sensor node SNm loses data at tn, we can compute the missing data by using temporal and spatial correlations, which can be determined using the following formula:

$$Missing\ Data\ Estimation = \sum_{i=1}^{SN_m} w_i * S_{Value} + \left(1 - \sum_{i=1}^{SN_m} w_i\right) * T_{Value}$$

where, S_{Value} and T_{Value} denote the results of spatial correlation and temporal correlation, respectively. w_i is weight assigned to each relevant node SNi, determined by average correlation coefficient with the sensor node being estimated. The spatial and temporal results are then combined to derive the estimated value.

$SN1_{t1}$	$SN2_{t1}$	$SN3_{t1}$	⋯	SNm_{t1}
$SN1_{t2}$	$SN2_{t2}$	$SN3_{t2}$	⋯	SNm_{t2}
⋮	⋮	⋮		⋮
$SN1_{ti}$	***Missing***	$SN3_{ti}$	⋯	SNm_{ti}
⋮	⋮	⋮		⋮
$SN1_{tn}$	$SN2_{tn}$	$SN3_{tn}$	⋯	SNm_{tn}

Fig. 1. Sensor nodes in WSN in a periodical time.

For example, to estimate the missing data for sensor node $SN2$, we calculate the distance between $SN2$ and all other nodes ($SN1$, $SN3$, $SN4$,…, SNm), as illustrated in Fig. 1. We then choose the nodes whose distance is close to $SN2$. These chosen nodes, that exhibit robust spatial correlation with node $SN2$, form the collection $S_{Correlate}$. The spatial correlation estimation is then calculated as follows:

$$S_{Value} = \sum_{SNi} wi * SNj_{(t_{n-1})}$$

where, SNi represents a sensor node in $S_{Correlate}$. $SNj_{(tn-1)}$ denotes the value of SNj at the time moment immediately preceding tn. wi signifies the weight associated with Si, calculated using the nodes' average correlation coefficient.

The evaluation result is derived from a comprehensive assessment of the variability in sample data. Temporal correlations are derived from the stability of environmental variables, which change over short time for the same node. Therefore, we select the closest two time points t_{i-1}, t_{i-2} to the missing time ti. Thus, we evaluate the temporal correlations as follows:

$$T_{Value} = SN_{(t_{i-1})} + cr_{ti}$$

where, cr_{ti} is the change rate of data at time ti

$$cr_{ti} = \frac{SN_{t_{i-1}} - SN_{t_{i-2}}}{t_{i-1} - t_{i-2}}$$

Algorithm 1. Spatial-Temporal Correlation Algorithm

Input:
Matrix of the sensor node data $SN_{m\times n}$
SN_{miss}: estimated sensor node
Output:
Estimation of the missing sensor node data
Begin
1. $S_{Value} = 0$;
2. Calculate the distance between the missing sensor node and all other nodes
3. Add the closest sensor nodes in $S_{Correlate}$
4. **For** each $SN_i \in S_{Correlate}$
5. $wi = \frac{\psi(SN_{miss}, SN_i)}{|S_{Correlate}|}$
6. $S_{Value} = S_{Value} + wi$
7. **End For**
8. Select the closest two time points t_{i-1}, t_{i-2} for SN_{miss}
9. Compute the change rate of data at time ti
10. $cr_{ti} = \frac{SN_{t_{i-1}} - SN_{t_{i-2}}}{t_{i-1} - t_{i-2}}$
11. $T_{Value} = SN_{(t_{i-1})} + cr_{ti}$
12. $Missing\ Data\ Estimation = \sum_{i=1}^{SN_m} w_i * S_{Value} + \left(1 - \sum_{i=1}^{SN_m} w_i\right) * T_{Value}$

End

Here is an example from a real dataset collected by the Intel Berkeley Research Lab [20], which records time, node ID, humidity, temperature, light, and voltage values in every thirty seconds, as shown in Table I. We select a portion of the dataset, remove some readings, and then compare the estimated values with the actual recorded values, replacing the missing data with "NaN" to indicate the absence of values.

In this example we select two records with the bold values to be the records with missing values, replacing them with *NaN* values. This case represents element sequence loss pattern since sensor 31 has missing data at two continuous times 180, 150. STCEA starts from the last missing record to avoid the incremental error, estimating each attribute separately.

TABLE I. THE REAL DATASET FROM INTEL BERKELEY RESEARCH LAB

Time (seconds)	Node id (integer)	Temperature (celsius)	Humidity (0-100%)	Light (lux)	Voltage (volts)
150	34	18.8712	40.2976	60.72	2.67532
150	27	19.7434	38.1897	79.12	2.69964
150	31	19.028	40.4328	150.88	2.69964
150	6	19.9002	37.5737	121.44	2.63964
150	29	19.3612	39.2123	180.32	2.68742
150	10	19.3612	39.8235	75.44	2.67532
180	25	18.93	38.8039	97.52	2.68742
180	30	18.4596	41.5789	114.08	2.68742
180	10	19.273	39.9252	75.44	2.67532
180	26	18.8614	40.9055	121.44	2.68742
180	31	18.9496	40.3652	150.88	2.69964
180	32	18.734	39.9929	121.44	2.69964
180	21	19.5964	37.162	114.08	2.69964

After applying the proposed algorithm, we obtain the following values: 19.1162 and 40.1424 for temperature and humidity respectively, for the missing data record at time 180. Additionally, we obtain 19.1542 and 40.2124 for temperature and humidity respectively, for the missing data record at time 150. Based on the earlier findings, it is clear that there is only a slight difference between the obtained values and the actual values.

IV. Experimental Results

A. Datasets

We evaluate the proposed algorithm using two real-world datasets: the Intel Lab dataset [20] and the air quality dataset [21]. The Intel Lab dataset includes data from 54 sensor nodes at the Intel Research Berkeley Lab. These sensors recorded temperature, humidity, light, and voltage every 30 seconds. The sensor layout in the lab is shown in Fig. 2. The air quality dataset consists of records from 34 monitoring stations in Beijing, collected on an hourly basis, as shown in Fig. 3. This dataset includes a total of 2,891,393 air quality records gathered from May 2014 to April 2015. Each entry represents an air quality record, with columns for Station ID, Time, PM2.5, PM10, NO2, CO, O3, and SO2. Tables II and III display the missing data ratios for the Intel Lab and air quality datasets, with missing values indicated as NULL in the data files.

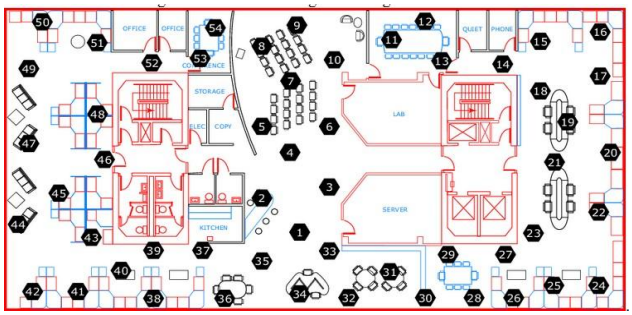

Fig. 2. Sensor arrangement diagram.

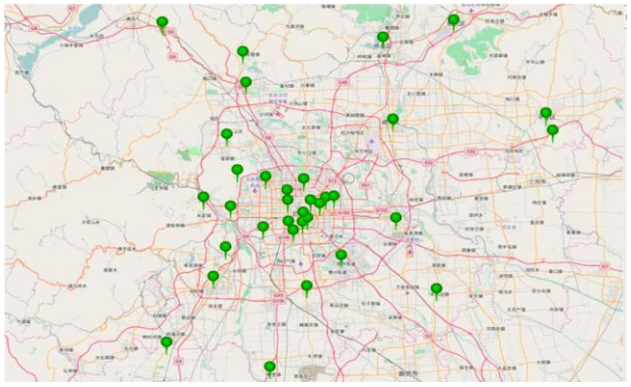

Fig. 3. Air quality stations.

TABLE II. Ratio of Missing Data of Six Pollutants in Air Quality Dataset

Missing Data	PM25	PM10	NO2	CO	O3	SO2
Ratio of Missing	13.3%	14.6%	16%	15.1%	15.4%	15.2%

TABLE III. Ratio of Missing Data of FOUR Weather Conditions in Intel-Lab Dataset

Missing Data	Temperature	Humidity	Light	Voltage
Ratio of Missing	15.2%	16.6%	15.3%	15.7%

B. Evaluation Metrics

For evaluating the performance of proposed algorithm, we apply Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) as evaluation metrics. MAE is calculated as the average of the absolute differences between the actual values and the predicted values.

$$MAE = \frac{\sum_{i=1}^{n}|y_i - x_i|}{n}$$

where, y_i and x_i are the prediction and true value respectively, and n is the total number of points.

RMSE measures the differences between true missing value and estimated values, RMSE is defined as follow:

$$RMSD = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \hat{x}_i)^2}{N}}$$

where, x_i and $\hat{x}_i$ is the real missing data and the computed value of the missing data respectively, and N is the number of non-missing points.

C. Result Analysis

To assess the effectiveness of the STCEA algorithm, we compare it with four existing algorithms: Adaptive Multiple Regression (AMR) [13], Minimized Similarity Distortion (MSD) [16], TSCA [19], and DRA [18].

Table IV and Table V show the results of the algorithms on datasets of the Air quality and Intel-lab dataset respectively. The results are based on the data missing ratios detailed in Table II and Table III for each dataset. The MAE and RMSE values of our method are significantly lower than those of the AMR, MSD, TSCA, and DRA methods, demonstrating a substantial improvement in interpolation accuracy. The STCEA algorithm achieves minimal errors and maintains consistent stability across different datasets.

As shown in Table IV and Table V, the estimation errors of the AMR algorithm are higher than other algorithms. This is because AMR algorithm computes the missing based on the spatial correlation. While MSD, TSCA and DRA computes the missing based on the spatial correlation and temporal correlation, so their estimation errors lower than AMR. Also, the evaluated results show that TSCA performed better than MSD and DRA but does not fully address the impact of missing patterns before interpolation, which worsens the results for some datasets. This variability in performance highlights the different missing data patterns present in each dataset.

From Tables IV and V, it is evident that STCEA consistently outperforms other algorithms in estimation accuracy. This is due to STCEA's ability to estimate missing data by leveraging spatial and temporal correlations, as well as

the functional relationships among sensor data. Therefore, STCEA demonstrates the most stable estimation performance.

V. CONCLUSION AND FUTURE WORK

STCEA algorithm is an effective solution to the challenges of missing data in wireless sensor networks (WSNs). By integrating both spatial and temporal correlations, the algorithm is capable of identifying substantial data loss and detecting underlying patterns, facilitating accurate partial reconstruction of missing data. We thoroughly evaluated the algorithm's performance using real world data and compared its accuracy with several existing missing data methods. The experimental results demonstrate that STCEA consistently outperforms other approaches in terms of estimation accuracy. Moving forward, future research will focus on further enhancing the STCEA algorithm to handle more complex scenarios, such as when all sensors in a given time series experience data loss, ensuring broader applicability and robustness in real-world WSNs.

***Abstract*—One new area of secure computing and privacy is homomorphic encryption (HE). An FPGA-based implementation of the HE algorithm, Enhanced DGHV, which helps real-time computation on encrypted text without disclosing the original data, is developed in this study. This research aims to focus on implementing the Enhanced DGHV Fully HE algorithm on FPGA hardware to achieve a more efficient scheme in terms of performance and security. The Xilinx Vivado tool implements the design on a Genesys 2 Kintex 7 FPGA board. While software simulation with 3.2% I/O usage, the simulation confirms a total power consumption of 3.12W (watts), highlighting successful synthesis with little resources. At 9.105W, the hardware implementation is comparable. Furthermore, an effective FPGA-based implementation confirms a method for achieving a balance between power consumption and performance while implementing the DGHV algorithm. The results show that the overall computational complexity can be reduced, and the hardware and software integration help to achieve an increased data security level for homomorphic encryption algorithms with improved efficiency.**

***Keywords*—Homomorphic encryption; cybersecurity; cryptography; DGHV; FPGA; Xilinx Vivado tool; Genesys Kintex**

I. INTRODUCTION

Cybersecurity is a fundamental attribute of the modern world, which protects systems, networks, and data from cyber threats. This field possesses diverse strategies, including encryption, authentication, and network security mechanisms to achieve assured secrecy, integrity, and availability of information [1]. Cryptography is the most basic foundation in cybersecurity, which conveys plaintext into unrecognizable ciphertext through mathematical transformation. Cryptography secures information from being accessed by unauthorized individuals. All cryptographic methods developed so far remain performance improvements for security, such as symmetric and asymmetric encryption techniques [2].

Advanced Encryption Standard (AES) and Data Encryption Standard (DES) are among the most popular symmetric key algorithms. Performance evaluations of these algorithms show brilliantly that AES outperforms the two in speed and security and is widely regarded as the contemporary solution for encryption [3]. Rivest Shamir Adleman (RSA) algorithms are asymmetric, and prime factorization is done to achieve acceptability; however, the cryptography process is extensive due to its nature. Unlike symmetric ones, which use a single key, RSA employs a pair of public and private keys for encryption and decryption. RSA provides security features such as secure communication or digital signatures; however, it does not perform well because of its computational complexity. Notwithstanding the praises for such cryptographic techniques, several challenges are looming. RSA becomes less efficient when large prime numbers are used for encryption and decryption. As for Fully Homomorphic Encryption (FHE), the computational overheads are too high, denying even further acceptance into mainstream applications. Hence, these challenges must be addressed for enhanced HE (Homomorphic encryption) or cryptographic solutions for real-life applications [4]. Variations have thus been suggested to improve the efficiency of RSA without losing its security features [5]. HE is a remarkable advance in cryptographic techniques that facilitates computations on encrypted data without decrypting it. FHE would allow secure data processing in cloud environments without compromising privacy during computation. Since the theoretical foundations and practical implementations of HE have received a great deal of attention, possible applications include secure multiparty computations and encrypted search queries [6].

A. Prospects of Hardware Implementation

Data security, while developing with different cryptographic algorithms, is always a main concern for researchers. These cryptographic algorithms can be attacked in various ways and leave the data in a vulnerable state. Side-channel attacks can be used against AES and DES to break them. On the other hand, their implementations lean on the information leakage from hardware implementations against which protection measures may be adopted. RSA security relies on the principle that factoring is a hard problem, but progress in quantum computing could weaken such security claims. Another issue is that, while Fully HE is theoretically proven secure, it is computationally expensive and is thus prone to resource-exhaustion attacks [7]. To some extent, more recently,

importance was placed on the hardware realization of the cryptographic algorithm. Cryptographic solutions implemented in hardware improve performance, security, and energy efficiency over software-based ones. Field Programmable Gate Arrays (FPGAs) provide a suitable platform for cryptographic implementations because of flexibility, parallelism, and embedded security features. FPGAs have indeed been used for the acceleration of cryptographic computations, as the software-based encryption methods are more vulnerable to attacks [8].

Hardware security is important for minimizing many vulnerabilities originating from software-based cryptography implementations. Hardware secure design principles, like resistance against side-channel attacks or using a secure key store, are important to improve the credibility of cryptography. Fastening hardware security features to cryptographic installations ensures that such installations are resilient against both logical and physical attacks, thereby complementing the security in digital systems [9]. However, the growing evolution of FPGA architectures makes hardware implementations of cryptographic structures much more realizable. Modern architectures of FPGAs integrate features like Physically Unclonable Functions and hardware root-of-trust mechanisms, which essentially improve the resilience of cryptographic systems against various attacks. In advance, it has opened up high-performance-low-energy-strength cryptographic systems based on real applications [10].

The FHE scheme constructed in hardware poses challenges related to its computational complexity as well as constraints faced in terms of resources. The designs of HE architecture and their optimization have been considered in previous studies, which explore further contributions of hardware-based acceleration in boosting performance and efficiency [11]. The particular study presents an implementation for a scheme, called the Dijk Gentry Halevi Vaikutanathan (DGHV) algorithm, on hardware acceleration. The DGHV scheme is the FHE scheme based on integer arithmetic and is entirely attributed to its authors. The proposed implementation makes use of FPGA-based acceleration to optimize the implementation of the DGHV scheme from the viewpoint of its computational overheads while improving practical applicability by using a shorter secret key. State-of-the-art results in FPGA-based cryptography implementations indeed revolve around the possibility of FHE algorithm acceleration via dedicated hardware. Furthermore, the use of FPGA clusters for the calculations of HE boosts efficiency, making FHE a choice to penetrate applications while preserving user privacy [12].

This study is arranged as follows: Section II discuss about the homomorphic encryption; Section III elaborates on FPGAs from an encryption standpoint; Section IV discuss about the Literature work; Section V describes the proposed approach; Section VI shows the implementation results; Section VII compares software and hardware performances; and Section VIII gives the conclusions and future work.

II. HOMOMORPHIC ENCRYPTION

HE is one of the advanced forms of cryptography that enables the computation of data in an encrypted form without ever decrypting it. This property gives HE a unique utility in real-time applications, where data privacy and security are crucial, such as in cloud computing, privacy-concerned machine learning, and secure multi-party computations. Another important theory states that traditional cryptographic encryption and security schemes always require data to be decrypted before processing. However, with HE, the actual processing is done on encrypted data, keeping the sensitive information technically safe and sound through all computations, as shown in Fig. 1 [13].

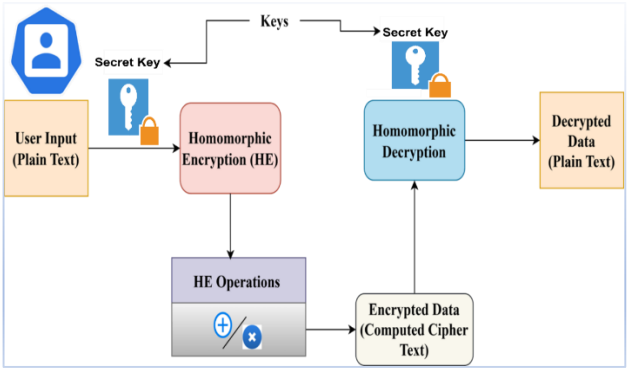

Fig. 1. Block diagram of Homomorphic encryption.

HE is categorized according to the operation types performed on encrypted data. So, the three major categories of HE are Somewhat Homomorphic Encryption (SHE), Partially Homomorphic Encryption (PHE), and Fully Homomorphic Encryption (FHE). Different types give different functionalities and complexities, and are, therefore, used for different applications, which are discussed below:

A. Somewhat Homomorphic Encryption (SHE)

Somewhat HE is an encryption scheme that permits a limited number of operations of any type on encrypted data. SHW allows only a few numbers of additions or multiplications before the ciphertext gets too noisy to decipher. The real drawback of SHE comes about from the accumulation of noise in the encrypted data, which eventually makes decryption impossible without specialized refreshing operations such as bootstrapping. However, SHE has important applications even if it does not permit many homomorphic operations; these are a few but sufficient cases, like the simple aggregation of data or secure voting mechanisms. SHE usually proves to be a better option than FHE, considering the lower computational overhead as far as speed and efficiency are concerned [14].

B. Partially Homomorphic Encryption (PHE)

Partially HE allows free operation of either addition or multiplication. However, both cannot be realized at the same time. Well-known examples of PHE include the RSA cryptosystem, which provides an example of a multiplicatively homomorphic cryptosystem, and the Paillier cryptosystem, which is a purely additive homomorphic scheme. It is applied in many areas, such as secure electronic voting and watermarking, wherein either additive or multiplicative homomorphic properties provide enough homomorphism for the application to find a solution. It is much faster and more practical with a wide range of applications [15].

C. Fully Homomorphic Encryption (FHE)

FHE is an improved version of SHE and PHE that allows any number of additions or multiplications of encrypted information. Therefore, arbitrary functions can be computed on encrypted data without decrypting it. This concept was developed for FHE by Craig Gentry in 2009, and since then, many advancements aimed at improving its efficiency and practicality have followed [16]. The scope is immense for FHE as it has wide applications in privacy concerning cloud computing, secure machine learning, and database queries. The major drawback of FHE is its immense computational expense since any execution of fully homomorphic operations on encrypted data needs lots of processing power and memory. Over the years, several optimizations have been proposed to render FHE amenable to real-world applications, such as batching techniques and improvements to bootstrapping.

III. FPGA – A Hardware Approach

The proper hardware implementation of HE is indispensable because the operations involving HE are very computationally intensive. Conventional software installations fail to meet the high processing requirements of HE, even to the extent that researchers then explore possible hardware-accelerating techniques. One of the best options for this approach is integrating FPGAs with cryptographic algorithms, thereby optimizing performance.

A. Integration of FPGA and Cryptographic Algorithms

FPGAs present a reconfigurable and parallel-processing platform, suitable for the acceleration of cryptographic computations. Unlike general-purpose CPUs that execute instructions sequentially, FPGAs can perform multiple encryption and decryption operations in parallel, thus drastically increasing speed. In implementing HE schemes on the FPGA platform, researchers can greatly improve performance, energy efficiency, and flexibility [17].

B. Why Use an FPGA?

The reasons have been that FPGAs are superior to any other hardware accelerators, such as graphics processing units (GPUs) and application-specific integrated circuits (ASICs). Some of these include: Parallel Processing Capabilities: FPGAs allow the possibility to execute cryptographic functions in parallel and are, therefore, highly useful for those computationally intensive processes. Energy Efficiency: Concerning the power needed even to achieve high throughput, FPGAs perform better than GPUs, thus making them the best choice for energy-critical applications. Convenience and Flexibility: Unlike ASICs, which are fixed-function chips, FPGAs can be reprogrammed to accommodate different encryption schemes and optimizations as required by the changing security requirements. Security Enhancements: FPGAs provide hardware-level security features that mitigate threats such as side-channel attacks to ensure secure cryptographic implementations [18].

C. Implementation of HE Using FPGA

The HE schemes on FPGA aim to multiply the encryption, decryption, and bootstrapping processes into an FPGA. The most significant challenge here is to perform those arithmetic operations in modular arithmetic without letting the overhead for computations increase. Large ciphertexts and complicated arithmetic operations that characterize DGHV require special optimizations to address performance issues.

The following several avenues have been researched for the FPGA-based implementation of the HE schemes:

Optimized Modular Arithmetic Units: The design of efficient modular addition, multiplication, and division units to efficiently compute large integers.

Pipeline Architectures: FPGA-pipelined design allows parallel processing of encryption operations, thus increasing throughput immediately.

Noise Management Mechanisms: Techniques such as ciphertext compression and optimization of bootstrapping help control the noise growth and facilitate accurate decryption.

The studies showed that the FPGA implementations for HE can generate enormous speed-ups compared to software implementations that promote their applications in privacy-preserving cloud computing, secure data analytics, and encrypted Artificial Intelligence (AI) processing [19].

IV. Literature Review

This section contains the literature survey of HE and its evaluation. Various HE schemes have different improvements over time and have also been shown above. Along with this, the integration of HE and hardware using FPGA is also studied and explained. The complete study is presented as follows:

FHE was introduced by Gentry et al. (2009) in their study [15], which would expand its bounds in terms of encrypted computations without decryption. One main issue arises when the decryption depth of the circuit extends the evaluation capacity, just explains why it is almost bootstrappable. The author gave an insight into bootstrapping, structured in part for the decryption process, reconciling circuit depths, therefore, making the scheme entirely bootstrappable. The security parameter was refined by balancing γ against (n), ensuring that breaking the encryption required exponential time complexity. An implementation of optimizations was carried out to allow for reducing the secret key size and facilitate direct processing of the ciphertext bits.

Dijk et al. (2010) proposed an FHE scheme in their study [20] based on slightly different foundations from Gentry's lattice-based approach. The problem was one of creating a HE scheme that allowed bootstrapping solely with additions and integer multiplications. The author introduced the so-called approximate GCD problem to estimate an unknown integer from the near-multiples.

Brakerski et al. (2014) proposed an FHE scheme in their study [21], which requires the ideal-lattice assumption for transactions. The critical boundary was thus that of decryption complexity concerning security. The author thus applied some re-linearization and gave a way for SHE to exist without dependencies on a ring-based hardness assumption. The dimension-modulus reduction technique allows compression of the ciphertext and improves decryption. From there, one can now design an LWE-based single-server Private Information

Retrieval (PIR) protocol with reduced communication overhead. They also gained significantly improved ciphertext efficiency under worst-case lattice hardness.

Yu et al. (2014) analyzed quantum HE and discussed its limitations in their research study [22] when it came to obtaining perfect security. The problem was to achieve perfect security in a deterministic HE that was fully homomorphic and which incurred an exponential cost. The author used an information localization argument to show that the universal quantum computation could not be done deterministically without this cost.

The work [23] of Abozaid et al. (2015) is towards embedding FHE into embedded systems, so that power and performance requirements, amidst all forms of attacks, can be circumvented. The author has proposed hardware and software co-designed with certain multiplication units for increased efficiency compared to the former, while still maintaining software flexibility. FPGA implementation demonstrated that large multiplications can be handled quite well within the given power limits.

In [24], Karabat et al. (2015) developed the THRIVE biometric system, partly because of the authentication security issue. Biometrics or standard biometric systems generally safeguard the very crucial user's data. The author proposed this threshold HE biometric system in which the user and verifier jointly provided the secure key.

Sun et al (2016) developed the leveled FHE scheme. For the Ring Learning with Error (RLWE) based FHE scheme to further enhance efficiency-based encryptions. In their study [25], the main net has to have very strong security guarantees along with practical computational efficiency. An approximate eigenvector was proposed by the author for use with a single public key, which was then extended to a multi-key setting.

Further in 2016 Fun et al. highlighted the security challenges in their study [26] that comes with outsourcing big data storage as well as computation to third-party cloud service providers, since the traditional approaches to security seem to have failed, probably due to the sheer amount of data to be modified and its diversity. Several schemes have been explored in this study for FHE, with performance ratings based on encryption-based technology.

Roy and Associates in the year 2017 introduced a recryptor box model in their study [27], which improves the depth of homomorphic evaluation and efficiency. The only limitation with SHE schemes is that they do not allow more than a limited action because at some point this starts to seriously accumulate noise. The inclusive author introduced a refreshment for ciphertext with its use to reduce the noise while avoiding very large-sized parameters.

Cousins et al. (2017) in their study [28] explain that they developed an FPGA-based HE Processing Unit (HEPU) that would accelerate encrypted computation. The main neuromuscular perturbation caused by the lack of computational efficiency was finally addressed by the primitive encryption of the lattice. Chinese Remainder Theorem (CRT) and inverse CRT were optimized in key mathematical operations. Implementation of FPGA using Xilinx Virtex-7 demonstrated the mitigation of computational bottlenecks in performing ring arithmetic operations.

The author of the study [29] Ding et al., in the year 2018 developed an attribute-based encryption scheme with ciphertexts. This addressed the privacy issues in a cloud environment. Enabling computations on the encrypted data with confidentiality maintained therein was the challenge set. They were working on the integration of the HE with attribute-based encryption so that one could perform fine-grained access control without having to repeatedly update keys.

In study [30] given by Catalano et al. in the year 2018 introduced homomorphic message authenticators (HMA) authentication methods for message verification in computing over encrypted data. In this case, the main difficulty consists of establishing the integrity of authenticated data without revealing underlying information. The author presented two types of HMA: the first one supports arbitrary composition, while the second uses short authentication tags.

Jiang et al. (2019) introduced [31] a secure comparison protocol for cloud environments using HE. The primary challenge was enabling encrypted magnitude comparisons without exposing plaintext values. The author proposed incomplete re-encryption, which preserved ordering while transforming ciphertexts.

In federated deep learning-based work [32], Liu et al. (2020) set about optimizing privacy on the grounds of security and accuracy. The challenge was that existing privacy-preserving techniques either caused a drop in model accuracy or needed excessive computational resources. The author introduced an adaptive privacy-preserving framework using layer-wise relevance propagation to optimize the trade-off concerning privacy.

Farokhi et al. (2020) proposed a scheme for privacy in encrypted transport services, trying to run encrypted queries on ride-sharing without exposing user data. The authors in their research [33] applied Paillier encryption, which supports some algebraic operations on ciphertext while remaining efficient. In this way, their users could submit queries without revealing their locations or routes.

A lightweight HE scheme was designed by Moghadam et al. (2021) to support cloud storage applications in their article [34]. This includes high computational and storage costs that make traditional encryption techniques impractical. The author proposed the secret-splitting secure method, which efficiently splits encrypted data.

There is also a systematic review [35] conducted by Mittal et al. (2021) that discussed the research concerning FHE within cloud computing. The challenge lies in understanding different trade-offs that may exist between models of encryption and their computational efficiency.

Delgado et al. (2022) designed a HE scheme in their study [36] for the secure transmission of sensor data. The challenge stemmed from the need to preserve confidentiality while enabling real-time statistical analysis of encrypted data. The author used the Paillier cryptosystem to allow for statistical computations on the encrypted data without decrypting it.

Wang et al. in the year 2022 proposed an integrated HE with identity-based signatures to secure Industrial Internet of Things (IIoT) transactions in their research work [37]. The challenge was protecting private trading data in blockchain-based energy markets. The author employed Paillier encryption for transaction confidentiality while using identity-based signatures for authentication.

Xu and colleagues (2023) proposed an NTRU-type in a research article [38]. Threshold HE schemes for securing multiparty computations. Their challenge lies in avoiding cumbersome extensions of ciphertexts during multi-key HE. Within their development of a new encryption model into a model that achieved improvements in computational efficiency without linearization, the authors introduced wide key distribution to withstand attacks from the subfield lattice and secured it under the RLWE assumption.

Pan et al. brought forward in the year 2023 their study [39], a cover for security holes that existed in the networked control systems by an FHE-encrypted controller. The main challenge was to maintain the real-time behavior while preventing the exposure of controller parameters to eavesdropping.

In the year 2024, the study [40] written by Ali and colleagues (2024) devised a dual-layer encryption method that combines HE with secret-sharing techniques. Securing cloud-based data storage while allowing computations on encrypted data poses a challenge. The author suggested distributing encrypted data among several servers to ensure no single point of failure. Performance evaluations have shown an optimal trade-off between security and computational efficiency.

A privacy-preserving network-slicing framework in the study [41] for secure communication was introduced by Wang et al. (2024). The challenge was protecting sensitive data within the network slicing while assuring efficiency in transmission. The author merged attribute-based encryption (ABE) with HE to maximize security at minimal computational cost.

Pingping et al. (2024) presented in their work [42] that gene information linkage and its accuracy binding on cloud computing are a real hustle; thus, it evolved as a privacy hazard and sluggish payback while processing gene material. To mitigate this circumstance or likeness, the author laid out a HE-based match secret protocol, which allows for the comparison of genetic sequence data without the data being decrypted. Compare gene sequence data with location.

In study [43] given by the author Ferrara et al. in the year 2025, explored Torus FHE and its use in secure computing. The author optimized bootstrapping to increase efficiencies in computing with ciphertext. Their study verified TFHE implementations for Boolean and arithmetic circuit evaluation. Their findings witness FHE for privacy-preserving computing.

Table I shows the chronological study of literature which highlights the different techniques and their results over time.

TABLE I. LITERATURE SURVEY COMPARATIVE ANALYSIS

Ref. No./Year	Technique	Summary and Result
[15]/2009	FHE	Proposed FHE with bootstrapping to balance security parameters. Optimized key size but faced practical challenges, leading to improved FHE efficiency.
[20]/2010	Approximate GCD-based FHE	Developed integer multiplication-based FHE without lattice dependence. Achieved bootstrapping but remained inefficient.
[21]/2014	LWE-based FHE	Introduced re-linearization and dimension-modulus reduction, improving ciphertext efficiency and enabling the PIR protocol.
[22]/2014	Homomorphic Encryption	Explored QHE limitations, confirming trade-offs between security and efficiency due to high computation costs.
[23]/2015	Hardware-accelerated FHE	Designed FPGA-based FHE optimizations with low-power multipliers, reducing computational overhead.
[24]/2015	Threshold HE for Biometrics	Developed an encrypted biometric authentication system, ensuring secure authentication with minimal verification time.
[25]/2016	RLWE-based Leveled FHE	Proposed an eigenvector-based multi-key FHE integrated with IBE, enhancing security and efficiency.
[26]/2016	Hybrid HE	Addressed big data encryption constraints, proposing hybrid models for improved speed, storage, and bandwidth.
[27]/2017	Recryptor Box Model for SHE	Enhanced SHE by reducing noise with ciphertext refresh methods, achieving a 20 times speed-up in FPGA tests.
[28]/2017	FPGA-based HEPU	Proposed FPGA-based unit for accelerating encrypted computations, optimizing CRT & inverse CRT.
[29]/2018	Attribute-Based HE	Enabled fine-grained access control in cloud storage, ensuring immunity to collusion attacks.
[30]/2018	Homomorphic Message Authentication	Proposed authentication methods ensure data integrity without revealing information.
[31]/2019	Secure Comparison Protocol	Developed encrypted magnitude comparison, ensuring confidentiality in cloud computations.
[32]/2020	Federated Learning with Adaptive Privacy	Introduced privacy-preserving encryption for deep learning, balancing security and model accuracy.
[33]/2020	HE for Transport Services	Applied Paillier encryption for secure ride-sharing queries, preserving user privacy.
[34]/2021	Secret-Splitting Secure Method	Designed lightweight encryption for cloud storage, improving storage efficiency and processing speed.
[35]/2021	Systematic Review of FHE	Analyzed FHE scalability and efficiency, identifying computational overhead challenges.
[36]/2022	HE for Sensor Data	Used Paillier encryption for encrypted sensor data analysis, enabling real-time anomaly detection.

[37]/2022	HE for IIoT	Integrated FHE with identity-based signatures for blockchain transactions, improving efficiency.
[38]/2023	NTRU-Type Threshold HE	Optimized multiparty encryption without linearization, securing against subfield lattice attacks.
[39]/2023	FHE Encrypted Controller	Integrated FHE in control systems, maintaining real-time performance and security.
[40]/2024	Dual-Layer HE	Combined FHE with secret sharing for cloud security, balancing computational efficiency.
[41]/2024	Privacy-Preserving Network Slicing	Merged ABE with FHE, enhancing security and efficiency in network slicing.
[42]/2024	HE for Gene Matching	Enabled secure genomic data processing, reducing encryption time and improving accuracy.
[43]/2025	Torus FHE Optimization	Optimized TFHE bootstrapping for efficient computation with ciphertext, verifying implementations for Boolean and arithmetic circuits.

HE provides privacy and security since computations are done on encrypted data, so one does not have to decrypt it. If key sizes increase, then computational complexity increases with reduced speed. Focus is on the enhancement of HE techniques through efficient hardware implementations on FPGAs for fast, low-power, and secure processing. About this, the main objective is to bridge the gap between real-time performance and security in privacy-preserving systems. This research's primary goal is to examine and evaluate the current homomorphic encryption algorithms and their hardware implementations, create and construct an improved version on an FPGA, and validate the results through in-depth analysis.

V. Proposed Methodology

The DGHV algorithm is implemented using a shorter secret key with reduced computational complexity. The Enhanced DGHV is implemented over the Genesys 2 Kintex 7 board to show the performance analysis. The proposed methodology is shown in Fig. 2.

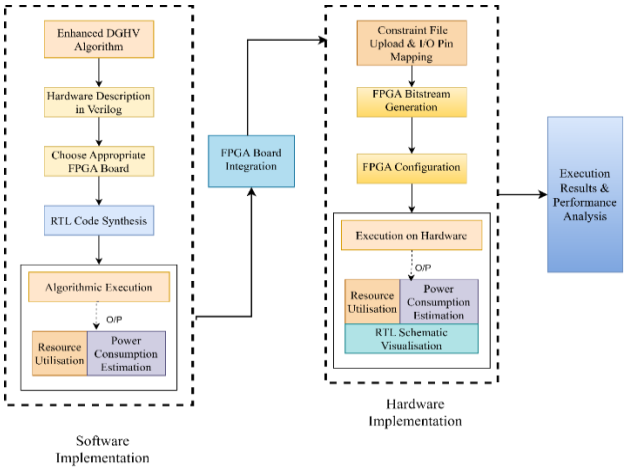

Fig. 2. Proposed methodology.

The research shows the detailed study for the implementation which is given as follows:

A. Enhanced DGHV Algorithm

Dijk Gentry, Halevi Vaikutanathan (DGHV) introduced the first FHE scheme, based on integers using only modular arithmetic. The researchers proposed a symmetric HE scheme for limited circuit depth. To design the asymmetric FHE scheme, the bootstrapping technique can be applied, which also helps to increase the circuit depth for the symmetric DGHV scheme. DGHV used Regev's scheme, the first encryption scheme, and used the same formula, $Encrypt(m, p) = m + 2r + pq$ but integers are used instead of an integral fraction of the domain size. The DGHV scheme can also be understood as a conceptually simpler version of Gentry's FHE scheme, based on integers instead of lattices, while focusing on providing conceptual simplicity by performing all operations using integers instead of ideal lattices and reducing the computational complexity. To improve the DGHV FHE scheme and create a more efficient version of the DGHV scheme, the proposed algorithm uses a shorter key size p which decreases the overall computation complexity. In addition, hardware and software integration enhances the scheme's security and efficiency because if the key size is larger, then the ciphertext also becomes larger, and it will take more computation time. To resolve this issue, a shorter key size is used.

Different parameters are used to make the scheme fully homomorphic. The scheme is based on a set of three public integers p, q, r, where p,q these are two random prime numbers because if we multiply two prime numbers, it becomes difficult to break the algorithm and r is a random error which is required to be added to the plaintext to generate the integral ciphertext, improving the security of the scheme. It is an important security key factor that helps to mask data and keep it safe from attackers. The generated ciphertext would be a list of integers, each representing an encrypted plaintext bit. These bits can be decrypted and recombined to retrieve the original plaintext message. If no error is added, then a pattern generated while performing encryption of plaintext bits may provide a clue to an adversary, and a secret key can easily be guessed. The scheme's security is based on the hardness of solving the Approximate Greatest Common Divisor Problem (AGCD). Here, the homomorphic operations (addition and multiplication) can be accomplished by homomorphic addition (XOR of bits) and multiplication (AND of bits) over the ciphertext. The size of λ directly affects the scheme's security. The larger the value of λ the more secure the scheme will be. The randomness in noise r ensures semantic security and prevents the scheme from ciphertext analysis attacks. Noise obfuscates the secret key, making the recovery more difficult. The DGHV uses the parameter, λ a security parameter for generating keys. It helps to specify the security of the key. The algorithm is as follows:

1) Key Generation ($KeyGen$). Generate a λ^2- bit, random odd integer, p, as a secret key. Select another two random numbers q and r, where r must be small such that $\mathrm{r} < \frac{\mathrm{p}}{2}$ and of λ- bits and q must be chosen randomly in the specified range $\left[-\frac{\mathrm{p}}{2}, \frac{\mathrm{p}}{2}\right]$ and of λ^5 bits.

2) Encryption (Encrypt) . Encrypt each bit of plaintext $m \in \{0, 1\}$. The algorithm encrypts the message m to obtain the ciphertext, c. in the following way.

$$Encrypt(p, q, m) = m + 2 * r + p * q \quad (1)$$

Encrypted ciphertext, c must be an integer whose residue mod p has the same parity as the plaintext.

3) Decryption ($Decrypt$): The formula for decryption is as follows:

$$Decrypt\ (p, c): m' \leftarrow (c\ mod\ p) mod\ 2 \quad (2)$$

The DGHV scheme is somewhat homomorphic, and it can perform computations up to a limited depth. So, the author introduced a new bootstrapping technique to obtain the FHE scheme and introduced an asymmetric fully homomorphic version of the DGHV scheme.This algorithm limitation is that, because of the multiplication property, the ciphertext's size will likewise increase if the plaintext or security parameters are increased. Then, because of hardware constraints, it became a limitation for hardware implementations, and the complexity of operations also increases. When all of these factors are combined, the algorithm may fail.

B. Software Implementation

The Enhanced DGHV algorithm software implementation was translated into hardware description using Verilog. The next step involves the selection of a specific FPGA board to satisfy the requirements of computation and resources of the design. Upon selection, synthesis of Register Transfer Level (RTL) code is achieved from the high-level hardware description into a gate-level representation for execution in an FPGA. Following this is the algorithmic execution testing in the simulation environment to ensure correctness before actual deployment. Performance metrics such as utilization of resources and power consumption estimates are analyzed to achieve optimal efficiency before the hardware stage.

C. Hardware Implementation

After verification of the software implementation, the design is taken to the stage of board integration, which entails uploading constraint files and mapping I/O pins to specify how signals will interact with the physical FPGA. The bitstream file is generated, which takes the synthesized design into a format that would be understood by the FPGA hardware. This bitstream is then used for FPGA configuration before running it on the hardware board. During the observation of real-time resource utilization and power consumption, the RTL schematic is also observed as a visualization to evaluate whether the implemented design is correct or not. Finally, this whole process ends with the execution results being followed up with the performance analysis, thereby validating that the FPGA implementation is adequate in terms of function and efficiency.

1) System specification. The Dell EMC PowerEdge R640 is powered by an Intel Xeon 6246R 3.4GHz 16-core processor that improves the performance and speed of the system. The rest of the specifications of the systems are mentioned in Table II.

2) Vivado specification. The Xilinx simulation tool Vivado 2019.1 (64-bit) is used to implement the HE on the hardware board. The Xilinx Vivado Design Suite 2019.1 has made itself a complete FPGA and System on Chip (SoC) development environment with a strong complement of tools that facilitate the designing, synthesizing, implementation, and debugging of complex digital systems. Other specifications are given in Table III.

3) FPGA Board specification. For the hardware implementation, the Genesys 2 Kintex 7 FPGA board (XC7K325T-2FFG900C) is used. Genesys 2 is an FPGA development kit that lends its high-performance nature mainly to data and video applications shown in Table IV. The board features a rather rich set of peripheral resources alongside potent data-processing capabilities, making it a splendid choice for many applications.

TABLE II. SYSTEM SPECIFICATION

Feature Category	Details
Processor	Intel Xeon Gold 6246R
Number of Cores	16
Number of Threads	32
Cache	35.75MB
Base Clock Speed	3.4GHz
Enhanced SpeedStep Technology	Balances performance with power environments
Thermal Management	Yes, with temperature & thermal monitoring for protection
Memory Capacity	16GB
Storage Configuration	3.6TB

TABLE III. VIVADO TOOL SPECIFICATION

Feature Category	Description
Version Used	Vivado 2019.1 (64-bit) for homomorphic encryption implementation
FPGA & SoC Development	Provides a complete environment for designing, synthesizing, implementing, and debugging complex digital systems
Supported FPGA Devices	Kintex-7, Virtex-7, Zynq-7000, UltraScale+ series
High-Level Synthesis (HLS)	Converts C, C++, and SystemC-based code into hardware description language (HDL)
Simulation & Debugging	Vivado Logic Analyzer & Hardware Debugger provide hardware-level debugging and simulation
Floor Planning & Optimization	Tools for floor planning, power analysis, and timing optimization to maximize resource efficiency

TABLE IV. FPGA BOARD SPECIFICATION

Feature Category	Details
FPGA Chip	Xilinx Kintex-7™ (XC7K325T-2FFG900C)
Logic Resources	50,950 logic slices, each with four 6-input LUTs & 8 flip-flops
Memory	1 GB DDR3 RAM (1800 MT/s, 32-bit data width)
Block RAM	16 Mbit fast block RAM
Clocking	Internal clock speeds exceeding 450 MHz, 10 clock management tiles with PLLs
DSP Processing	840 DSP slices for high-performance signal processing
Analog-to-Digital Conversion	On-chip XADC (Analog-to-Digital Converter)

VI. Implementation Results

In this section, a description of the results of the implementation and analysis of software and hardware deployment of the DGHV HE schemes onto a Genesys 2 Kintex 7 FPGA board. Evaluation will include and put into perspective performance and resource utilization, compared through FPGA-based execution against software and hardware implementations. In terms of parameters such as power consumption, hardware utilization, and temperature, the analysis assesses the viability of FPGA acceleration for DGHV. Understandable trade-offs between hardware and software implementations will open up the findings for optimization, enhancing practicality in real-world applications of homomorphic technology.

A. Software Simulation Analysis

After the implementation of DGHV homomorphic encryption using the Xilinx Vivado 2019.1 suite, an analysis of the resource utilization on the Genesys 2 Kintex-7 was performed, and the results are as follows:

The important metrics are Look Up Tables (LUTs). They are the basic logic blocks inside an FPGA that implement combinational circuits, whereas I/O utilization measures the number of I/O pins that are in use for external communication which as shown in Fig. 3. From the results, it consumed 4 LUTs out of 203,800, which is extremely low in logic resources consumed, thereby the design is lightweight and does not impose significant computational overhead on the FPGA. The I/O utilization of 16 out of 500 (3.2%) is fairly high.

Resource	Utilization	Available	Utilization %
LUT	4	203800	0.00
IO	16	500	3.20

Fig. 3. Hardware utilization readings during software simulation.

The output graph in Fig. 4 has three parts; in the first column, which is the title (Name), the port names are listed; the second column (Value) shows the input values, while the third column holds the output results in hexadecimal format; the inputs are called m1 and m2. In this graph of this block, the plaintext values in the state values $m1 = 0$ and $m2 = 1$. This law of encryption provides different cryptographic keys p, $q, r1, r2$ upon which homomorphic encryption computations are performed. The module input operates on plain-text values represented by $m1, m2$, in this case, 0 and 1, respectively. These inputs have been used with encryption keys $p, q, r1, r2$ for HE computation. The resulting outputs from the encryption module are presented here as hexadecimal values: $c1, c2$. The encryption process results are: $c1 = 9$ and $c2 = A$.

The total power consumption report on power in Fig. 5 shows a total on-chip power of 3.12W (Watts): dynamic power accounts for 2.943W (94%) while device static power is given at 0.177W (6%). This means that most of the power will be consumed by active switching operations within FPGAs, as only a small portion is used to keep the device in an idle state. Power distribution states that I/O operations account for 2.857W (97%), meaning that a big portion of power is utilized for external data communications. Signals consume 0.066W (2%) while logic elements require just 0.020W, thus indicating that the computational load within the FPGA is minimal. The junction temperature is located at 30.5°C, which is a safe operational limit.

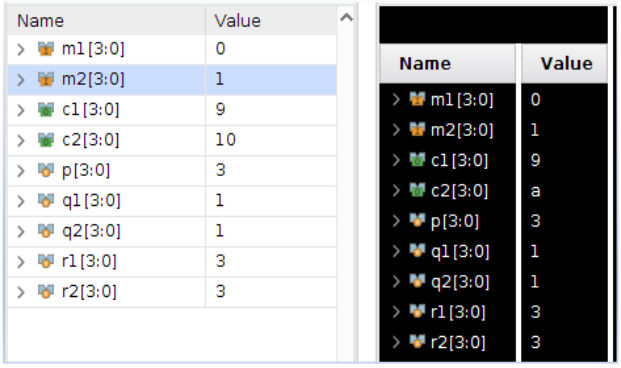

Fig. 4. Output in software simulation.

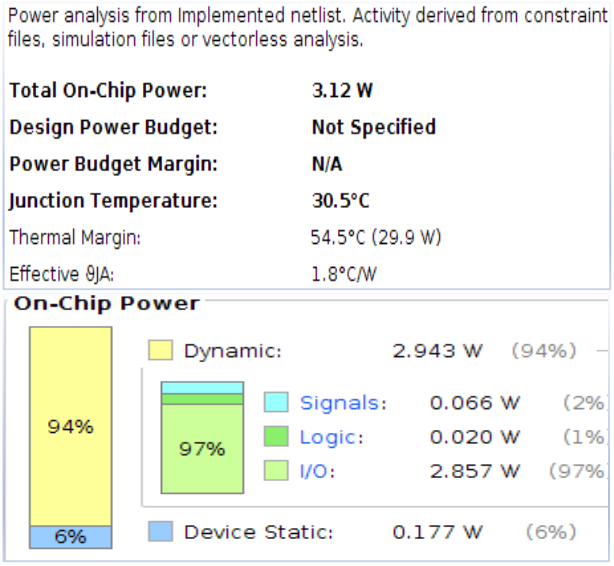

Fig. 5. Simulation power readings.

1) Secret key vs power consumption analysis. The changes showed an overall power consumption across the Genesys 2 Kintex-7 FPGA as employed among secret key values of homomorphic encryption in Table V. While the consumption power varies between each secret selected key, it shows a very slight difference and therefore stands to say something including that the more the complexity of the key, the greater the inefficiency in power use. For secret keys of sizes 5 and 13, the consumed power is 6.739 W and 6.836 W, respectively. With the increasing size of keys, variations in power are seen, the highest being recorded at 6.980W (key 47) and the lowest at 6.687W (key 181). The variations can be interpreted to point out that some key values yielded power savings while others incurred slightly higher computation overhead on the FPGA, and the graph in Fig. 6.

TABLE V. SECRET KEY VS. POWER CONSUMPTION COMPARISON

Secret Key Size	Power Consumption
5	6.739
13	6.836
29	6.718
47	6.980
83	6.818
101	6.904
149	6.873
181	6.687
199	6.919
211	6.818

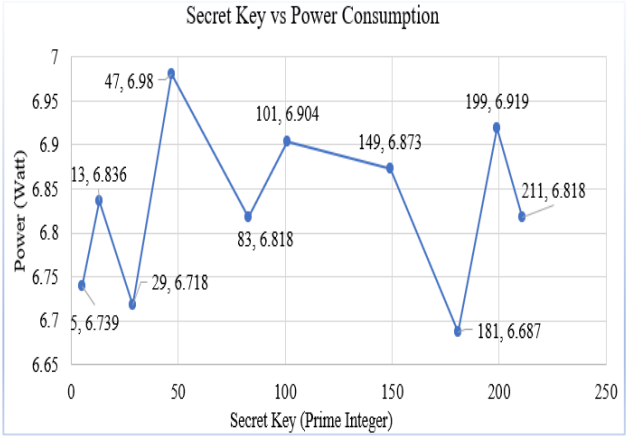

Fig. 6. Secret key vs. power consumption comparison graph during software simulation.

B. Hardware Analysis

The hardware analysis is the actual consumption of resources that occurs on the Genesys 2 Kintex-7 FPGA board after the successful implementation and burning of the DGHV HE algorithm onto the device.

The total on-chip power consumed in Fig. 7 is 9.105 watts, with dynamic power being 8.872 watts (97%), and therefore, the high active power consumption. The device's static power for the FPGA was 0.232 watts (3%), acting as the FPGA's baseline power consumption. I/O dominates the power at 8.677 watts (97%), and it seems data transfer happens quite frequently when processing ciphertext and sending encryption keys. Only a minimal amount of power, <1%, was consumed through logic, thanks to an efficiently deployed resource. The die junction temperature was measured at 41.2 degrees Celsius, thus leaving a thermal margin of 43.8 degrees Celsius, which should make operations smooth. In conclusion, the entire encryption process is power-consuming, but should safely remain below the thermal threshold.

RTL layout was identified to map the hardware structure of the DGHV homomorphic encryption on the Genesys 2 FPGA, depicting how input signals are processed in Fig. 8.

Inputs "$m1[3:0]$" *and* "$m2[3:0]$" are passed through input buffers and processed within the LUTs-Unit that applies the encryption transformations. The encrypted outputs "$c1[3:0]$" *and* "$c2[3:0]$" are then passed through output buffers to external interfaces. This well-designed approach caters to minimum resource utilization while securely maintaining an encrypted data primitive through the processing stream.

Upon confirming the generation of the bitstream, the success of which implies the FPGA design as a correctly synthesized, implemented unit, ready to be programmed onto the Genesys 2 Kintex-7 FPGA shown in Fig. 9. The Hardware Manager verifies and recognizes the FPGA device so that it can be directly programmed.

It proposes various options in a pop-up dialog for viewing data reports or generating memory configuration, while the latter is meant to specify a bit sequence for programming into the device. Having the bitstream is the final step of the build process that needs to be completed before programming an FPGA to implement the DGHV homomorphic encryption algorithm into real hardware.

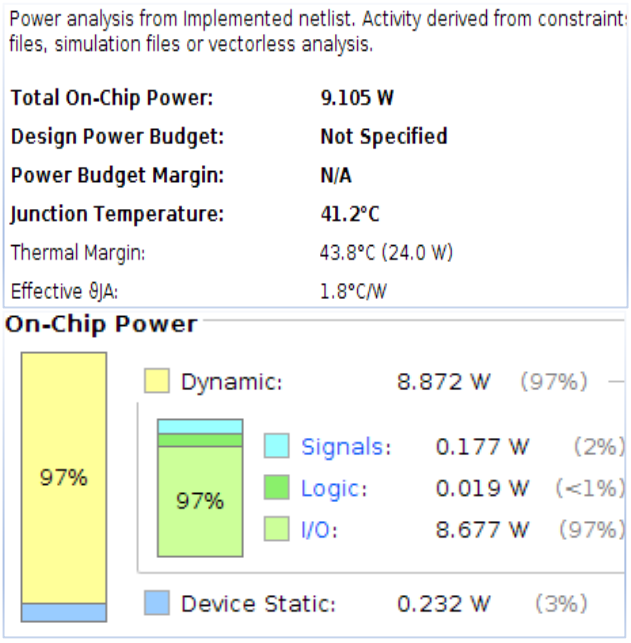

Fig. 7. Hardware power readings.

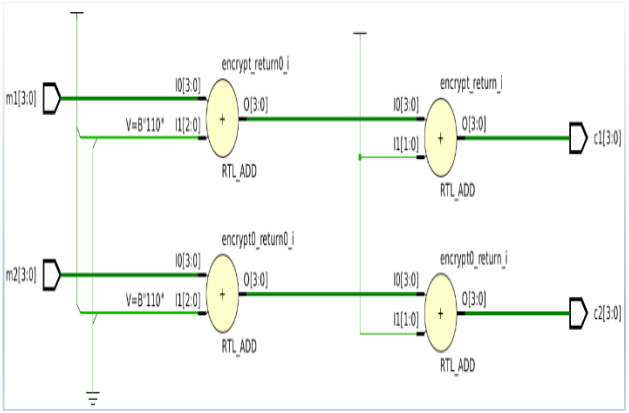

Fig. 8. Internal RTL layout.

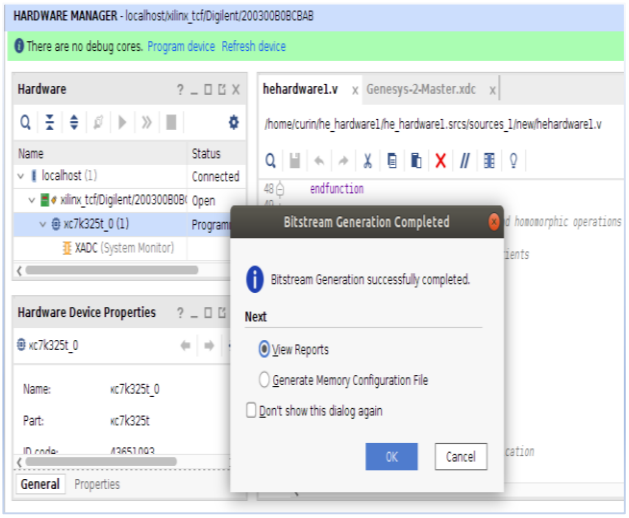

Fig. 9. Successfully bit stream generation.

The FPGA board is programmed as shown in Fig. 10. The board is now up and running. The LEDs represent the binary digits to be encrypted in the ciphertext; a further demonstration of this test is seen following. While the glow LEDs signify a "1" for the digit "1", an OFF LED points to "0" as the encrypted information is displayed in real-time. This test indicates that the FPGA has received the expected input values and computed the expected encrypted operation to produce the output. The correctness of the RTL implementation, when the program runs correctly on hardware, is validated by ensuring that encrypted data is processed securely within the FPGA environment.

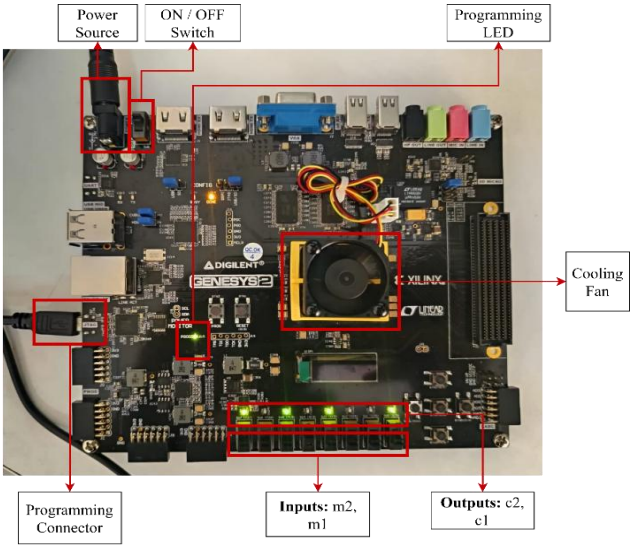

Fig. 10. Code burned on the FPGA kit.

VII. Software versus Hardware Analysis

This section compares various parameters for software and hardware implementation of the DGHV HE algorithm with the FPGA kit.

Table VI represents the total power consumption reading between the FPGA board in software simulation and hardware implementation. The total power consumed in software simulation using Genesys 2 Kintex-7 FPGA amounts to 3.12W, while when implemented in hardware, the power consumption amounts to 9.105W on account of real-world execution overhead.

The static power, which accounts for leakage and idle power consumption, shows a comparatively lower value in both cases; that is, 0.177W in software and 0.232W in hardware. Mainly accounts for the increase of power in hardware due to dynamic switching activity and actual FPGA resource usage during the execution, and the graph is shown in Fig. 11.

TABLE VI. Total Power Consumption

Results	Board	Static Power (W) (1)	Dynamic Power (W) (2)	Total Power (W) (1+2)
Software	Genesys 2 Kintex 7	0.177	2.943	3.12
Hardware		0.232	8.872	9.105

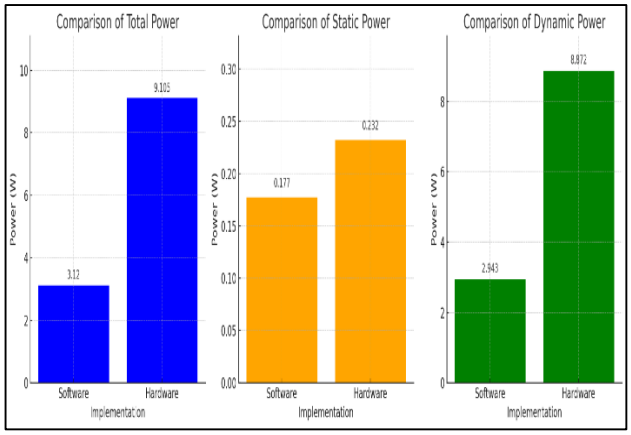

Fig. 11. Comparison of the total power usage graph.

The dynamic power distribution of the Genesys 2 Kintex-7 FPGA in software simulation and hardware implementation is specified in Table VII. The I/O power consumption in simulation is 2.857W, while the consumption in hardware increases in magnitude to 8.677W, signifying that real-world transfer of data and communication exerts higher power demands. On the other hand, logic essentially stays the same, with powers of 0.02W in software and 0.019W in hardware, thereby indicating an approximately similar logic resource utilization in both software and hardware.

TABLE VII. Dynamic Power Consumption

Results	Board	Dynamic Power (W)		
		IO Power	Logic Power	Signal Power
Software	Genesys 2 Kintex 7	2.857	0.02	0.066
Hardware		8.677	0.019	0.177

The power consumed due to signal switching across the FPGA tracks is much higher in hardware than in software, from 0.066W in software to 0.177W, confirming increased switching activity with real-time processing overheads. The results, therefore, reveal that actual hardware implementations lead to dynamic power dissipation on an entirely different scale,

especially in I/O, whereas logic power remains fairly flat and signal power progresses upwards moderately. These implications greatly affirm the weight of power optimization strategies as designs are transferred from the simulation to real working FPGA systems, and the graph is shown in Fig. 12.

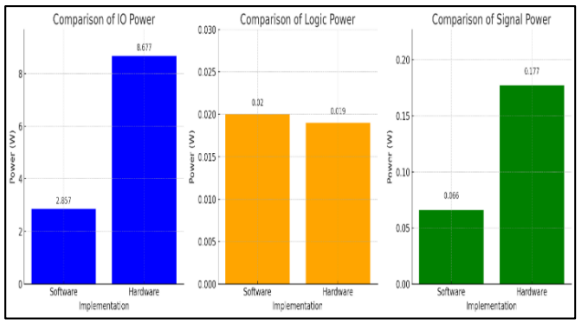

Fig. 12. Comparative analysis of dynamic power comparison.

The thermal performance analysis of the Genesys 2 Kintex-7 FPGA is shown in Table VIII, encompassing software simulation and hardware implementation. With software simulations, the junction temperature is 30.5°C, which means there is minimal heat generated since no actual hardware is working. During hardware implementations, however, the junction temperature reaches 41.2°C, indicating an increase in power dissipation due to actual processing loads that contribute to heat dissipation.

The thermal margin temperature difference between the maximum operating temperature of the FPGA and the current temperature is 54.5°C in the software and drops to 43.8°C in the hardware. This suggests that the FPGA runs much closer to its thermal limits in real-world execution, hence the necessity for adequate cooling and thermal management. From these observations, it is concluded that with hardware implementations, more thermal stress is introduced than in simulations; this calls for effective heat dissipation techniques to guarantee stable FPGA performance, and the graph is shown in Fig. 13. Several recent studies emphasize the need for secure and energy-efficient computing. Bharany and Sharma [49] explore blockchain and machine learning integration in IoT, aligning with secure hardware design goals [50-51]. Talwar et al. [50] and Badotra et al. [52] focus on fault tolerance and network vulnerabilities, highlighting the relevance of resilient architectures like FPGA-based encryption. Shamshad et al. [51] and Kumar et al. [53] stress model efficiency and privacy, supporting homomorphic encryption for secure data processing.

A comparison table of FPGA-based homomorphic encryption implementations is shown in Table IX. Different FPGA platforms that were used for the implementation of homomorphic encryption techniques are shown in the table.

TABLE VIII. TEMPERATURE ANALYSIS

Results	Board	Junction Temperature (°C)	Thermal Margin (°C)
Software	Genesys 2 Kintex 7	30.5	54.5
Hardware		41.2	43.8

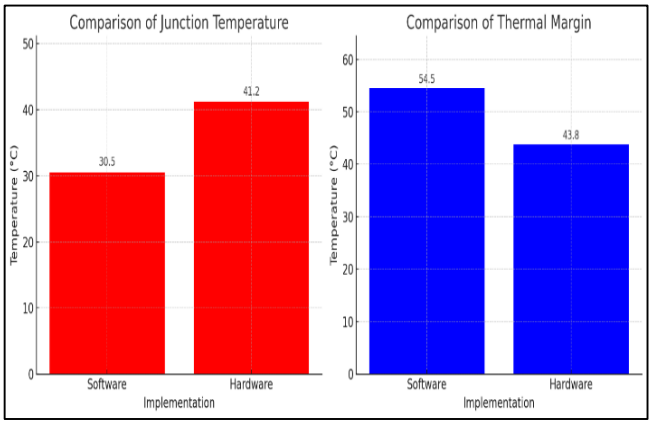

Fig. 13. Comparison of temperature readings.

VIII. CONCLUSION

This research demonstrated that it is practicable to run the homomorphic encryption algorithm on FPGA platforms for facilitating privacy-preserving computations with enhanced performance. The integration of the Enhanced DGHV homomorphic encryption algorithm into the Genesys 2 Kintex-7 FPGA illustrates the possibility of real-time encrypted computation with reasonable on-chip resource requirements. The simulation results show a total power consumption of 3.12W and a negligible utilization of the resource I/O: 3.2% compared to the results of implementation, which shows a much higher power consumption of 9.105W, and slightly less resource utilization I/O: 3.2%. Finally, the junction temperature from this thermal margin analysis rises from a software 30.5°C to 41.2°C with hardware, and hence the importance of thermal management is thrown to the fore in FPGA computations. The study here discovers the possibilities in FPGA technology for privacy-preserving applications and calls for more optimization towards the significant reduction in power consumption with optimized performance. In this quest, attention has to be put on using sophisticated FPGA architectures, combined with innovative energy efficiency methodologies, and this will certainly enhance the computational effectiveness of huge-scale encrypted operations. Future work will involve working on other HE schemes and integrating them with hardware in a way to improve performance, efficiency, and power consumption.

FUNDING

This project was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, Saudi Arabia, under grant no. (GPIP: 1913- 830-2024).

ACKNOWLEDGMENT

The authors, acknowledge with thanks DSR for technical and financial support.

***Abstract*—Accurate disease prediction from symptom descriptions is vital for improving early detection and enabling remote healthcare services, especially in the evolving landscape of digital health. Traditional diagnosis methods face significant limitations due to their reliance on structured datasets and subjective assessments, leading to delays and inefficiencies in the diagnosis process. Our strategy is to employ advanced NLP techniques such as tokenization and TF-IDF, along with DL techniques like LSTM, CNN-LSTM, and GRU, to analyze unstructured symptom data and more accurately predict diseases The study also compares two text transformation techniques (TF-IDF vectorization and tokenization) with traditional Machine Learning (ML) methods like Decision Trees to specify the best technique. Through intensive experiments on two datasets (one with 24 diseases and one with 41 diseases), the efficiency of the proposed methods is verified and the importance of using NLP and deep learning in revolutionizing healthcare is illustrated, particularly in upgrading remote diagnosis and enabling early medical intervention. The best-performing model, CNN-LSTM using tokenized text, achieved 99.90% accuracy on a 41-disease dataset, and LSTM with TF-IDF achieved 98.8% accuracy on a 24-disease dataset, outperforming or matching results from more complex models in prior studies. The findings show that combining NLP and deep learning enables accurate, efficient disease prediction, advancing remote care and early intervention in digital healthcare.**

Keywords*—Natural language processing; disease prediction; machine learning; deep learning; classification

I. INTRODUCTION

Healthcare systems worldwide always face huge challenges in precisely and early diagnosing diseases, which are mainly caused by the limitations of traditional diagnostic approaches [1]. Not only do diseases impose a heavy influence on the quality of individuals' lives but also place very high economic burdens on healthcare systems. Traditional diagnostic approaches mainly rely on structured clinical data and subjective judgments, which are likely to result in subjectivity, inconsistency, errors, and delays. With a growing rate of chronic and acute illnesses, there is a critical need for novel solutions that can effectively and efficiently address these diagnosis issues. With the complexity of the diseases, the clinicians and doctors require more sophisticated and automated tools to enable timely decision-making, resource planning, and improved patient care [2].

Deep learning (DL) and Natural Language Processing (NLP) have been transformative technologies in healthcare, particularly in automating and enhancing diagnosis processes [3]. NLP allows computational systems to read, comprehend, and manipulate human language, which allows healthcare professionals to extract useful knowledge from unstructured patient data, such as symptom descriptions provided in natural language. At the same time, DL, a subset of AI that employs neural networks with many layers, has already begun to achieve great success in recognizing complex patterns and making predictions from intensive data analysis. NLP merged with DL has the potential to transform medical diagnosis by dramatically enhancing prediction accuracy, cutting down diagnostic time, and enabling remote medical decision-making [4].

Contemporary trends in digital health further reinforce the importance of NLP and DL. For example, more than 100 digital diagnostic products are now commercially available to assess disease risk and expedite diagnosis, many of which are powered by AI and machine learning. The rapid advancement of such AI-driven symptom checkers and decision support tools underscores how computational models of language can augment clinical practice by triaging patient complaints and flagging potential conditions earlier than traditional workflows. The global COVID-19 pandemic has also accelerated the adoption of telemedicine and remote monitoring solutions, where NLP plays a critical role in interpreting patient-reported symptoms in real time. These developments illustrate a broader shift towards integrating language-based AI into healthcare delivery, improving accessibility and personalization of care even outside conventional clinical settings [5].

In parallel, the accessibility of large-scale medical text data and increase in computational power have paved the way for data-driven diagnostic systems. Patients now routinely describe symptoms on online forums, chatbots, and mobile health applications, creating an abundance of unstructured symptom narratives available for analysis. Leveraging this wealth of textual data requires advanced NLP for language understanding and robust DL for pattern recognition – domains where recent techniques have demonstrated exceptional promise. By integrating NLP and DL into clinical workflows, it becomes possible to bridge the gap between traditional symptom checkers and expert diagnostic systems, facilitating faster, more personalized, and scalable diagnostic support for patients and providers alike [6].

This study builds on these trends and challenges by introducing several key contributions. It utilizes varied datasets (including one with 24 diseases and another with 41 diseases)

to improve the validity and generalizability of the predictive models. Additionally, it conducts a comparative study of multiple machine learning algorithms, incorporating two text representation techniques – TF-IDF vectorization and tokenization – to identify the most effective approach for symptom-based disease classification. Finally, the study emphasizes an iterative model refinement process to boost accuracy and reliability, ensuring that the proposed NLP+DL models are well-optimized for deployment in real healthcare settings. Through these contributions, the work illustrates how combining NLP and deep learning can enable more accurate and efficient disease prediction, thereby advancing remote care and early intervention in the evolving landscape of digital healthcare.

The proposed methodology was chosen due to its adaptability to real-world symptom expression formats and its ability to extract both semantic and sequential patterns from text. Traditional classifiers often require structured or pre-encoded symptom data and struggle with ambiguity and variability in natural language inputs. Moreover, prior methods frequently overlook interpretability, computational trade-offs, or generalization across datasets. In contrast, our framework explicitly addresses these limitations through multi-dataset validation, model transparency (via feature analysis), and an architecture that balances performance with deployment feasibility.

To validate the effectiveness of the proposed approach, the rest of this study is organized as follows: Section II explores related work in natural language processing and deep learning for disease prediction. Section III outlines the methodology, detailing the text representation methods and model architectures used. Section IV presents the results, including the datasets and a thorough analysis of the experimental findings. Section V concludes the study and suggests directions for future research.

II. Related Work

In the past several years, several studies have tried to utilize ML and DL methods for disease prediction based on symptom descriptions. Such methods usually combine natural language processing (NLP) techniques and different ML models in an effort to improve prediction accuracy and computational efficiency. Some of the research studies aim to exploit hybrid systems, preprocessing techniques, and optimization algorithms to develop more robust and effective models for disease diagnosis with potential for future digital health and remote diagnosis.

A range of studies have explored automated disease prediction using symptom descriptions, applying both traditional and deep learning techniques. One study introduced a hybrid ensemble model that combined Naïve Bayes, SVM, and XGBoost to improve the classification of categorical symptom data [7]. This model achieved 97.2% accuracy, approximately 2% lower than that of another work which focused on optimizing classical classifiers using severity-weighted symptom scores, reporting 99.19% accuracy with a tuned KNN model. It offered a lightweight and computationally efficient alternative for large-scale screening applications [8].

In contrast, a deep learning approach that applied MCN-BERT and BiLSTM to symptom text achieved the highest performance, reaching 99.58% accuracy. This showcased the advantage of contextual language models and advanced optimizers in capturing subtle patterns in unstructured clinical descriptions [9]. Another comparative study evaluated multiple classical classifiers on a structured symptom dataset and found that Random Forest outperformed other models with an accuracy of 99.5%, about 2.3% higher than earlier ensemble-based methods, confirming its strength in handling tabular symptom data [10]. Additionally, a separate model used translated symptom data and XGBoost, achieving 99.45% accuracy while maintaining relatively simple preprocessing and training requirements. This approach proved to be a practical option for early illness detection, especially in resource-limited settings [11].

Table I provides a comparison of five representative studies, highlighting their approaches, data, performance, and noted limitations. These prior works have made important strides by achieving high predictive accuracy using various NLP and AI methods, as summarized below.

As seen in Table I, prior studies in this domain report remarkably high accuracies (often above 95% and even nearing 99%), suggesting that automated symptom-based disease classifiers can perform extremely well under certain conditions. However, a notable observation is that most of these works focus on showcasing their performance results while providing relatively limited discussion of technical constraints or real-world challenges. For instance, several studies used complex ensembles or deep models but did not comment on the computational memory requirements or infrastructure needed to deploy those models at scale. The interpretability of the models is another aspect often glossed over – methods involving transformers or ensemble boosting are essentially black boxes from a clinician's perspective – yet only one study explicitly acknowledged the issue of explaining predictions. Moreover, generalizability is frequently under-addressed: many models were trained and tested on a single dataset (sometimes a synthetic or idealized one), raising questions about how they would perform on different patient populations or symptom inputs. In cases, where a non-clinical or limited dataset was used, authors occasionally noted the need for more diverse data, but they generally stopped short of testing their models beyond the original setting. This pattern of presenting near-perfect accuracy without proportional attention to practicality can make the proposed solutions seem overly ideal. It creates an impression that the problem of automated diagnosis is "solved" in a controlled environment, even though issues of model robustness, scalability, and integration into medical practice remain open challenges.

TABLE I. COMPARISON OF RELATED WORK

Authors	Year	Techniques Used	Dataset	Accuracy
Indupalli & Pradeepini	2023	Hybrid blended stacking ensemble (CatBoost + XGBoost + Naïve Bayes)	Symptom-based disease dataset with categorical symptom inputs (post-COVID context; multiple diseases, categorical symptoms)	97.2%
Fuster-Palà et al.	2024	Optimized classical ML classifiers (SVM, Random Forest, KNN, ANN) with symptom severity encoding.	Public symptom dataset containing 41 diseases with associated symptoms encoded by severity scores (Open-source structured dataset for disease screening).	99.19%
Hassan et al.	2024	Transformer-based language model (MCN-BERT) and deep neural network (BiLSTM) for symptom text classification.	Two datasets: (1) Dataset-1: 1,200 patient symptom description entries (each a unique combination of a disease label and its described symptoms); (2) Dataset-2: 23,516 Twitter posts for adverse drug reaction detection (tweets labeled ADR or non-ADR).	99.58% on Dataset-1 96.15% on Dataset-2
Das et al.	2022	Comparative analysis of four supervised ML classifiers: k-Nearest Neighbors, Naïve Bayes, Decision Tree, and Random Forest.	Structured disease-symptom dataset with 41 prevalent diseases and 132 possible symptoms. Each case in the data is characterized by a selection of 5 key symptoms out of the 132, representing a patient's input features. (This dataset is a common benchmark for symptom-based disease prediction.)	99.5%
Abidin et al.	2022	Machine learning classification using Naïve Bayes, Linear Discriminant Analysis (LDA), and an ensemble XGBoost model.	Symptom dataset (translated into English) covering 41 diseases and 17 selected clinical symptoms. The translation step ensured uniform input language for the model. This smaller feature set (17 symptoms) was used to train and evaluate the classifiers on disease identification tasks.	99.45%

Our work distinguishes itself by explicitly addressing many of these limitations. First, we prioritize a model design that is computationally efficient and feasible for deployment. Instead of relying on extremely large language models or complex stacked ensembles, we implement a CNN-LSTM architecture—a powerful deep learning model that is faster to train than transformer-based approaches. This choice means our best model achieves comparable accuracy to prior works (e.g., ~99% on a 41-disease set) without the need for extraordinary computational resources or cloud infrastructure. Such efficiency is crucial for real-world use, particularly in resource-constrained healthcare settings. Second, we emphasize generalizability and robustness by evaluating our approach on two different datasets (one with 24 diseases and another with 41 diseases). By demonstrating consistent performance across multiple datasets, we provide evidence that the model can handle variations in disease profiles and symptom expressions. This is what make this method better than earlier studies that were often validated on a single dataset, and it gives greater confidence that our method could be adapted to new data or scaled to broader disease coverage. Third, while our models are predominantly deep neural networks, we have incorporated interpretable elements into the experimentation.

For example, we included a Decision Tree classifier in our comparisons and performed feature representation analyses (TF-IDF versus tokenization) to understand the impact of different input processing techniques. This approach offers insights into the model's behavior – such as which symptoms or words are most influential – thereby injecting a degree of interpretability and transparency into the results that pure black-box approaches lack. Finally, our study consciously discusses practical deployment considerations by iteratively refining the models and comparing complexity versus performance trade-offs, we avoid simply reporting an accuracy number in isolation. In summary, the proposed model aims not only to achieve high accuracy, but also to deliver a solution that is balanced and realistic – one that minimizes memory overhead, maintains interpretability where possible, and generalizes better to varied inputs. By addressing these often-overlooked aspects, our work contributes a more practically viable tool for disease prediction from textual symptom descriptions, advancing the field towards implementations that can be trusted and adopted in modern healthcare workflows.

III. METHODOLOGY

Accurate disease prediction from natural language symptom descriptions poses a challenge due to the unstructured nature of the input text and the variability in how symptoms are expressed. Traditional approaches often struggle to extract meaningful features from such data, affecting prediction performance and reliability.

To address this, our methodology focuses on transforming symptom descriptions into structured representations using two popular text vectorization techniques: TF-IDF and Tokenization [12] [13]. In this study, a consistent workflow was applied that includes preprocessing, handling class imbalance, and training multiple models using each text representation method. Both traditional ML (Decision Tree) and DL models (LSTM, GRU, CNN-LSTM) were trained and evaluated. The process was repeated for both text representation techniques to systematically compare their impact on classification performance. This approach enables a fair assessment of which technique yields more accurate and robust predictions in the context of disease classification. The method is visualized in Fig. 1.

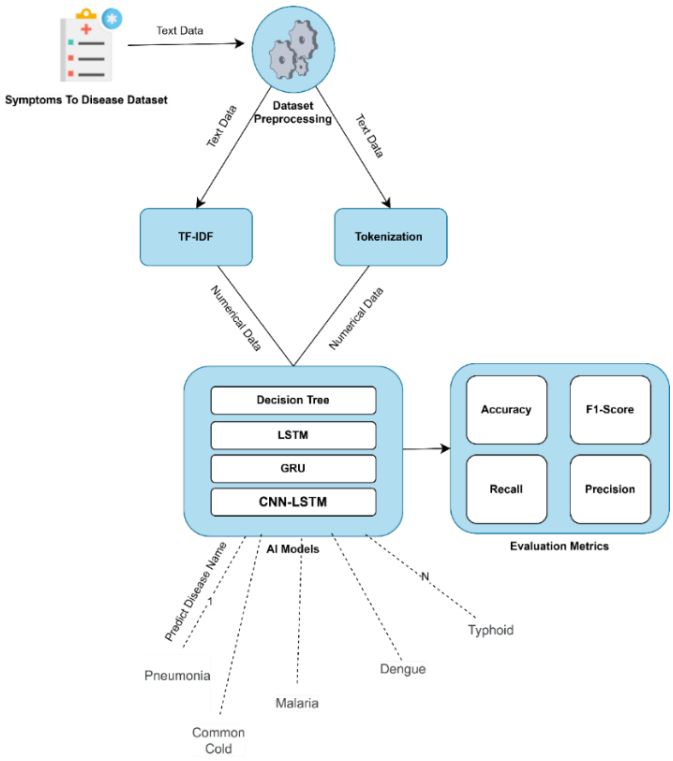

Fig. 1. The Proposed method.

A. Deep Learning Models

1) Deep learning background. A neural network is a computer model that replicates the human brain's structure in the form of layers of interconnected processing nodes (neurons). The neurons transform information through weights and activation functions, which allow the network to learn patterns and make predictions. A 1D Convolutional Neural Network (CNN) is a neural network that takes sequential data as input with convolutional filters in one dimension and is highly appropriate for tasks such as time series analysis, text analysis, or speech analysis [14]. An RNN (Recurrent Neural Network) is another neural network that takes data sequentially and deals with sequences and time-dependent patterns very well [15]. Sequential data or time series can also be in text, video, speech recognition, voice recognition, time series forecasting, NLP tasks, and other mediums. Therefore, models that are specifically meant for sequential data are appropriate for applications such as disease prediction from symptom text. RNNs produce the current output using the previous information in the sequence. On the other hand, if a sequence is long, it is hard for the network to convey information from the earlier steps to the later steps. For example, in working through a paragraph of text for prediction, an RNN might forget crucial information from the start. Though RNNs possess very restricted internal calculations, they are okay for short sequences. In order to tackle the short-term memory or disappearing gradient problem in RNNs, LSTM and GRU models were proposed as alternatives. The Gated Recurrent Unit (GRU) is an RNN variant that is essentially the same as LSTM [16]. The GRU uses the hidden state to transmit information, unlike the cell state of the other models. The GRU, which trains LSTM faster since it requires fewer tensor operations, has two gates: the reset gate, similar to LSTM, that determines how much previous information to forget, and the update gate, similar to the combination of LSTM's forget and input gates, that determines what information to retain or discard [16]. The control flow of LSTM is the same as RNN, in that it takes the data and maintains the information along with it as it proceeds. The processes in the cells of LSTM differ, however, in that the cells here are meant to forget or recall [17]. LSTM contains two more gates compared to GRU: the output gate and the forget gate. The forget gate decides what to keep or leave out of the prior cell state, the input gate regulates what parts of the cell state are transmitted to the hidden state, and the output gate governs how much of the information from the prior state is transferred or left out in order to impact the next hidden state [17]. The forget gate in the LSTM cell is utilized to element-wise multiply the preceding memory cell.

2) LSTM Layer. The LSTM layer is meant to address the vanishing gradient issue of the regular RNNs. It has "gates" like the input gate, the output gate, and the forget gate to control the flow of data in the LSTM network [17]. The gates regulate how information is remembered, updated, or discarded at every time step. The LSTM updates Eq. (1-6) are as follows:

$$g_t = \phi\left(U_g \cdot [u_{t-1}, y_t] + c_g\right) \quad (1)$$

$$j_t = \phi\left(U_j \cdot [u_{t-1}, y_t] + c_j\right) \quad (2)$$

$$k_t = \phi(U_k \cdot [u_{t-1}, y_t] + c_k) \quad (3)$$

$$\tilde{S}_t = \tanh(U_S \cdot [ut - 1, y_t] + c_S) \quad (4)$$

$$S_t = g_t \odot S_{t-1} + j_t \odot \tilde{S}_t \quad (5)$$

$$u_t = k_t \odot \tanh(S_t) \quad (6)$$

In this context, ϕ refers to the sigmoid activation function. The variables g_t, j_t, and k_t correspond to the activations of the forget, input, and output gates at time step t, respectively. S_t represents the memory cell's internal state at that same time, while u_t denotes the hidden state [17]. The symbol $\odot$ indicates an element-wise multiplication operation. The notation $[u_{t-1}, y_t]$ signifies the concatenation of the hidden state from the previous time step and the current input. The parameters U_g, U_j, U_k, U_S along with the biases c_g, c_f, c_k, and c_S are trainable components of the model—comprising weight matrices and bias vectors used to compute the gate activations and update the cell state.

3) GRU Layer. The GRU layer reduces the architectural complexity of the LSTM by combining the input gate and the forget gate into one update gate, and the cell state and the hidden state. The GRU update Eq. (7-10) are:

$$m_t = \sigma(Q_m \cdot [u_{t-1}, y_t] + c_m) \quad (7)$$

$$n_t = \sigma(Q_n \cdot [u_{t-1}, y_t] + c_n) \quad (8)$$

$$\tilde{u}t = \tanh(Q \cdot [n_t \odot ut - 1, y_t] + c) \quad (9)$$

$$u_t = (1 - m_t) \odot u_{t-1} + m_t \odot \tilde{u}_t \quad (10)$$

Here, m_t is the update gate that decides how much of the state needs updating. The reset gate, $n_{t,}$, decides how much of the previous state needs to be erased. The candidate activation, $\tilde{u}t$, proposes a new potential value for the state, as decided by mt. The new state at the present timestep, ut, is computed as a weighted average of the former state and the candidate state, with the update gate mt controlling the balance.

4) CNN-LSTM. A CNN-LSTM network takes advantage of the strengths of CNN and LSTM. The CNN captures important spatial or local features of the input data, while the LSTM models are temporal dependencies in sequences. The combined model is well adapted to the task of sequential data with complex patterns, such as text classification and time series forecasting.

B. Machine Learning Model

1) Decision Tree (DT). DT are among the most widely used machine learning algorithms [18]. While they are applicable to both classification and regression tasks, they are more commonly employed for classification. A Decision Tree structures its predictive model in a hierarchical, tree-like format: internal nodes represent feature-based decision points, the root node defines the initial splitting condition, and the leaf nodes correspond to the final predicted classes or outcomes. The DT nodes are arranged in levels, and the highest or first node is the root node. Every internal node comprises tests on input variables or attributes (i.e., nodes with one or more children). The classification model descends downwards through the respective child nodes based on the test results, splitting recurring until reaching a leaf node. The leaf nodes denote the final decision results [19].

C. Evaluation Metrics

In order to assess the performance of a classifier, there are some typical measures: accuracy (most widely used measure), sensitivity (also referred to as recall in most papers), specificity, precision, and F1 score [20]. Classification outcomes for each class are either "True Positive" (TP), "True Negative" (TN), "False Positive" (FP), or "False Negative" (FN). Depending on these values, the higher-level measures are computed according to the following Eq. (11-14):

$$\text{Accuracy } = \sum_c \frac{TP_c + TN_c}{TP_c + FP_c + TN_c + FN_c}, c \in \text{ classes} \quad (11)$$

$$\text{Precision } = \sum_c \frac{TP_c}{TP_c + FP_c}, c \in \text{ classes} \quad (12)$$

$$\text{Recall } = \sum_c \frac{TP_c}{TP_c + FN_c}, c \in \text{ classes} \quad (13)$$

$$F1_{\text{score}} = 2 * \frac{\text{precision} * \text{sensitivity}}{\text{precision} + \text{sensitivity}} \quad (14)$$

Following is a description of the above metrics:

- Accuracy: The proportion of correctly classified samples out of all samples.
- Accuracy: The ratio of samples which are "True Positive" to all the samples which were predicted as "Positive".
- Recall (or Sensitivity): The ratio of accurately forecasted "True Positive" examples to all genuine positive samples.
- F1 Score: The harmonic mean of precision and recall, a single score that combines both measures and takes into account precision and sensitivity.

All of the above metrics can be used for any machine learning system. Thus, all the metrics mentioned in this section will be used to compare the classifier systems devised in this study. The performance of the classification system will also be compared with that of the earlier studies.

IV. Results

This study evaluated the effectiveness of TF-IDF versus Tokenization approaches for symptom-based disease classification across two distinct datasets. The experimental framework incorporated both traditional machine learning (Decision Tree) and deep learning architectures (LSTM, GRU, CNN-LSTM) to provide a comprehensive comparison of text representation methods. Dataset 1 contained 1,200 clinical cases spanning twenty-four diseases, while Dataset 2 comprised 4,920 instances across forty-one disease categories, offering diverse testing conditions for model generalization. Performance metrics like accuracy, precision, recall, and F1-score were systematically analyzed to determine optimal methodologies for clinical text classification tasks.

To ensure robust model evaluation, we used two distinct datasets (twenty-four and forty-one diseases respectively) rather than relying solely on internal validation splits. This cross-dataset validation allows us to test the generalizability of the models to different distributions and disease spaces. Performance was assessed using multiple metrics (accuracy, precision, recall, F1-score), and the models consistently achieved high performance across both datasets.

A. Dataset

1) Dataset 1. The first dataset comprises 1,200 data instances and two features: i) label, comprising disease labels, and ii) text, comprising symptom descriptions in natural language, illustrated in Table II. The dataset consists of twenty-four diseases, with fifty symptom descriptions for each, giving 1,200 data instances. It is concerned with the association between diseases and symptoms and comprises pairs, where each pair is a disease and a symptom. The dataset is developed by Niyarr Barman and can be found on Kaggle[1]. Data curation was done by collecting data from diverse credible sources of medical data, including research papers, medical journals, and clinical databases. The information was

[1] https://www.kaggle.com/datasets/niyarrbarman/symptom2disease

painstakingly extracted and verified to ascertain the validity of symptom-disease relationships.

TABLE II. SAMPLE DATA FROM DATASET 1

Disease	Symptom Description
Psoriasis	I've been experiencing a red, itchy rash with dry, scaly patches on my arms, legs, and trunk for several weeks.
Psoriasis	My skin is scaling, especially on my scalp, elbows, and knees, and the scaling is usually accompanied by burning or stinging sensations.
Psoriasis	I'm also having joint pain in my fingers, wrists, and knees. The pain is throbbing and achy and gets worse with motion.
Drug Reaction	My tongue also changes in taste and scent, leaving a metallic aftertaste. Can have excruciating joint and muscle pain.
Drug Reaction	I have headaches and migraines, and I have been having difficulties sleeping. I've been shaking and shivering all over. Sometimes I become lightheaded.

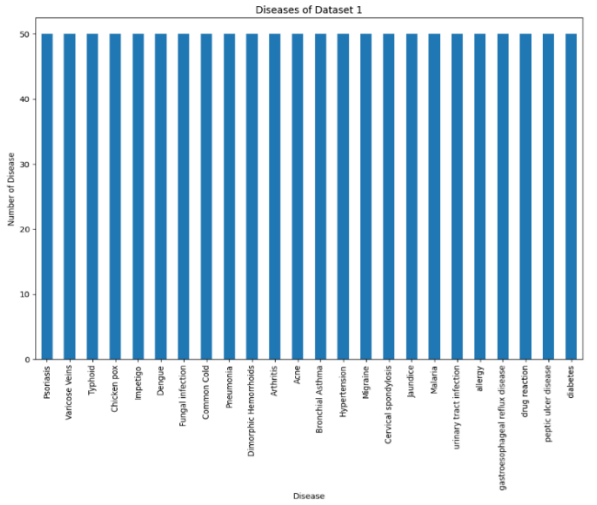

Fig. 2. Distribution of different diseases in Dataset 1.

Fig. 2 shows the distribution of different diseases in Dataset 1. The diseases are identified on the x-axis, and the y-axis indicates how many times each disease occurs in the dataset. The graph provides an idea of how the data are distributed across the various diseases, indicating how many times each disease occurs.

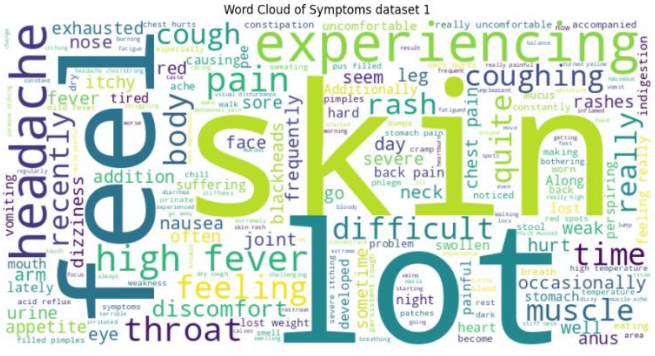

Fig. 3. Word cloud of symptoms in Dataset 1.

Fig. 3 is a word cloud representing the most prevalent symptoms in Dataset 1. The size of each symptom word is representative of its frequency of appearance in the symptom descriptions, with larger words representing more prevalent symptoms and smaller words representing less prevalent symptoms. The word cloud is a good visual display of the prevailing symptoms in the dataset, which identifies frequent patterns in the symptom descriptions.

2) Dataset 2. The dataset used for this project is the Disease Symptom Prediction[2]. The dataset has close to 5,000 entries, with each entry having a list of symptoms. Each entry is tagged with one of forty-one possible diseases. The symptoms are given in the same form as in the original file, and a separate file gives data about the severity level of each symptom from 1 to 7. Dataset 2 contains eighteen columns and 4,920 rows. Table III shows a sample data from this dataset.

TABLE III. SAMPLE DATA FROM DATASET 2

Disease	Symptom_1	Symptom_2	Symptom_3	Symptom_4
Fungal infection	itching	skin_rash	nodal_skin_eruptions	dischromic_patches
Migraine	acidity	indigestion	headache	blurred_and_distorted_vision
Cervical spondylosis	back_pain	weakness_in_limbs	neck_pain	
Fungal infection	skin_rash	nodal_skin_eruptions	dischromic_patches	
Fungal infection	itching	nodal_skin_eruptions	dischromic_patches	

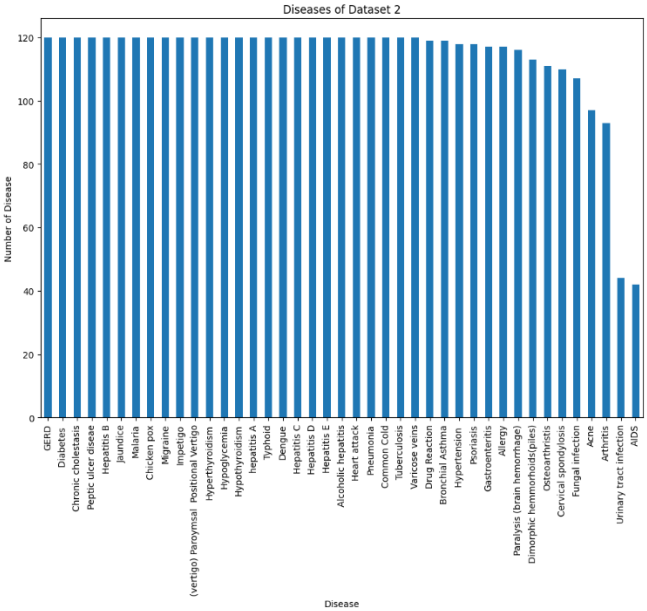

Fig. 4. Distribution of different diseases in Dataset 2.

Fig. 4 is a bar chart showing the distribution of diseases in Dataset 2. Diseases are on the x-axis and the frequency of each

[2] https://www.kaggle.com/datasets/itachi9604/disease-symptom-description-dataset

disease in the dataset on the y-axis. The plot provides an overview of the distribution of data across diseases, showing how frequently each disease occurs.

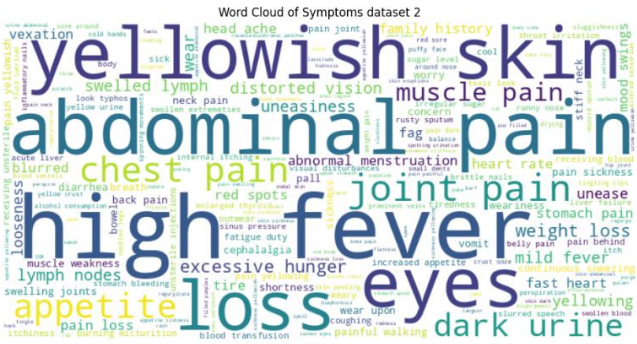

Fig. 5. Word cloud of symptoms in Dataset 2.

Fig. 5 is a word cloud that illustrates the most frequent symptoms in Dataset 2. The words are scaled based on how often they appear in the symptom descriptions, with more common symptoms shown in larger words and less common ones in smaller words.

B. Dataset Preprocessing

1) Background. In this study, two primary text representation techniques (TF-IDF and Tokenizer) were applied to compare their performance when used with both deep learning and machine learning models.

a) TF-IDF: Term Frequency-Inverse Document Frequency is a technique of text vectorization that provides a weight for each term for the improved representation of rare words in a corpus and reducing the influence of common, non-informative terms. This is helpful for the reason that irrelevant features can confuse the learning algorithm and worsen the performance. TF-IDF is obtained by multiplying TF with IDF. TF is the occurrence ratio of term k to the number of unique words n in the dataset, as indicated in Eq. (15) and Eq. (16). The IDF is the term frequency in all the documents, where Eq. (15) and Eq. (16) are the number of documents in total and the number of documents containing term k. So, common words will have a low TF-IDF score and rare words will have a high score.

$$TF = \frac{n_k}{n} \tag{15}$$

$$IDF = \log_2\left(\frac{d_n}{df_k}\right) \tag{16}$$

b) Tokenizer: Tokenization converts text into sequences of integer tokens, where each unique word is assigned a unique index. This prepares the text for deep learning models that require numerical input. For the tokenization approach, we employed a word-level tokenizer followed by an embedding layer as the first layer in each neural network (LSTM, GRU, CNN-LSTM).

2) Dataset 1 preprocessing. For Dataset 1, NLP preprocessing steps was applied including punctuation removal, stop word removal, and lemmatization. After preprocessing, both TF-IDF and Tokenizer were applied, allowing us to compare the models' performance using these two text representation approaches.

3) Dataset 2 preprocessing. Dataset 2 presented a challenge due to a large number of duplicated rows. To address this, column shuffling and automatic word replacement using WordNet synonyms was applied to enhance variation. All symptom columns were merged into a single text column. After resolving these issues, NLP preprocessing (punctuation removal, stop word removal, and lemmatization) was applied, followed by TF-IDF and Tokenizer to compare their effectiveness in representing symptoms for prediction tasks.

C. Hyperparameter Configuration

Model configurations were carefully optimized for each text representation approach. For TF-IDF implementations, 10 to 20 training epochs with batch sizes of 16 to 32 were employed, using the Adam optimizer throughout. Tokenizer-based models required more extensive training, with 30 to 70 epochs and consistent batch sizes of 16. The Tokenizer vocabulary was limited to 1,200 tokens for Dataset 1 and 5,000 for Dataset 2, with corresponding maximum sequence lengths of 24 and 30 tokens respectively. All sequential models utilized post-padding and included an out-of-vocabulary token (<OOV>) to handle unseen symptom descriptions. The Hyperparameters for Dataset 1 and Dataset 2 are shown in Table IV and Table V respectively.

TABLE IV. HYPERPARAMETERS FOR DATASET 1 (1200 INSTANCES, 24 DISEASES)

Parameter	TF-IDF	Tokenizer
Epochs	20	70
Batch Size	16	16
Optimizer	Adam	Adam
Max Words	—	1,200
Max Sequence Length	—	24
OOV Token	—	<OOV>
Padding	—	post

TABLE V. HYPERPARAMETERS FOR DATASET 2 (4920 INSTANCES, 41 DISEASES)

Parameter	TF-IDF	Tokenizer
Epochs	10	30
Batch Size	32	16
Optimizer	Adam	Adam
Max Words	—	5,000
Max Sequence Length	—	30
OOV Token	—	<OOV>
Padding	—	post

D. Performance Analysis

The results demonstrate distinct performance patterns between text representation methods. TF-IDF consistently achieved superior results with traditional models, as evidenced by the Decision Tree's 99.8% accuracy on Dataset 2, compared to just 69.0% with Tokenization. For deep learning

architectures, the advantage of TF-IDF was less pronounced, with CNN-LSTM achieving 99.9% accuracy using Tokenization on Dataset 2, suggesting that hybrid models can effectively leverage sequential patterns in symptom descriptions. Dataset 1 revealed the scalability challenges of Tokenization, where performance gaps between representation methods widened for the Dataset 1 classification task. Notably, the GRU model's accuracy dropped from 97.9% (TF-IDF) to 85.4% (Tokenizer) on this harder dataset. These findings indicate that while Tokenization can achieve excellent results with appropriate model architectures, TF-IDF remains more robust for general applications, particularly when combining multiple algorithm types or working with expanded disease taxonomies. The superior performance of CNN-LSTM across both datasets suggests that combining spatial feature extraction with sequential processing may offer the most reliable approach for clinical text classification tasks. The Performance analysis on dataset 1and Dataset 2 is represented in Table VI and Table VII respectively.

Fig. 6 and Fig. 7 visualize the comparison of performance for Dataset 1 and Dataset 2, respectively.

TABLE VI. PERFORMANCE ANALYSIS ON DATASET 1 (1200 INSTANCES, 24 DISEASES)

Model	Text Rep.	Accuracy	Precision	Recall	F1-Score
LSTM	TF-IDF	98.80%	98.90%	98.80%	98.70%
LSTM	Tokenizer	95.00%	95.60%	95.00%	94.70%
GRU	TF-IDF	97.90%	98.10%	97.90%	97.90%
GRU	Tokenizer	85.40%	86.50%	85.40%	85.20%
CNN-LSTM	Tokenizer	97.00%	97.00%	97.00%	97.00%
Decision Tree	TF-IDF	81.70%	83.10%	81.70%	81.70%
Decision Tree	Tokenizer	33.00%	32.00%	33.00%	32.00%

TABLE VII. PERFORMANCE ANALYSIS ON DATASET 2 (4920 INSTANCES, 41 DISEASES)

Model	Text Rep.	Accuracy	Precision	Recall	F1-Score
LSTM	TF-IDF	99.78%	99.81%	99.80%	99.80%
LSTM	Tokenizer	94.40%	94.00%	92.20%	93.00%
GRU	TF-IDF	97.85%	93.51%	94.78%	94.03%
GRU	Tokenizer	99.60%	99.60%	99.60%	99.60%
CNN-LSTM	Tokenizer	99.90%	99.90%	99.90%	99.90%
Decision Tree	TF-IDF	99.80%	99.80%	99.80%	99.80%
Decision Tree	Tokenizer	69.00%	70.00%	69.00%	69.00%

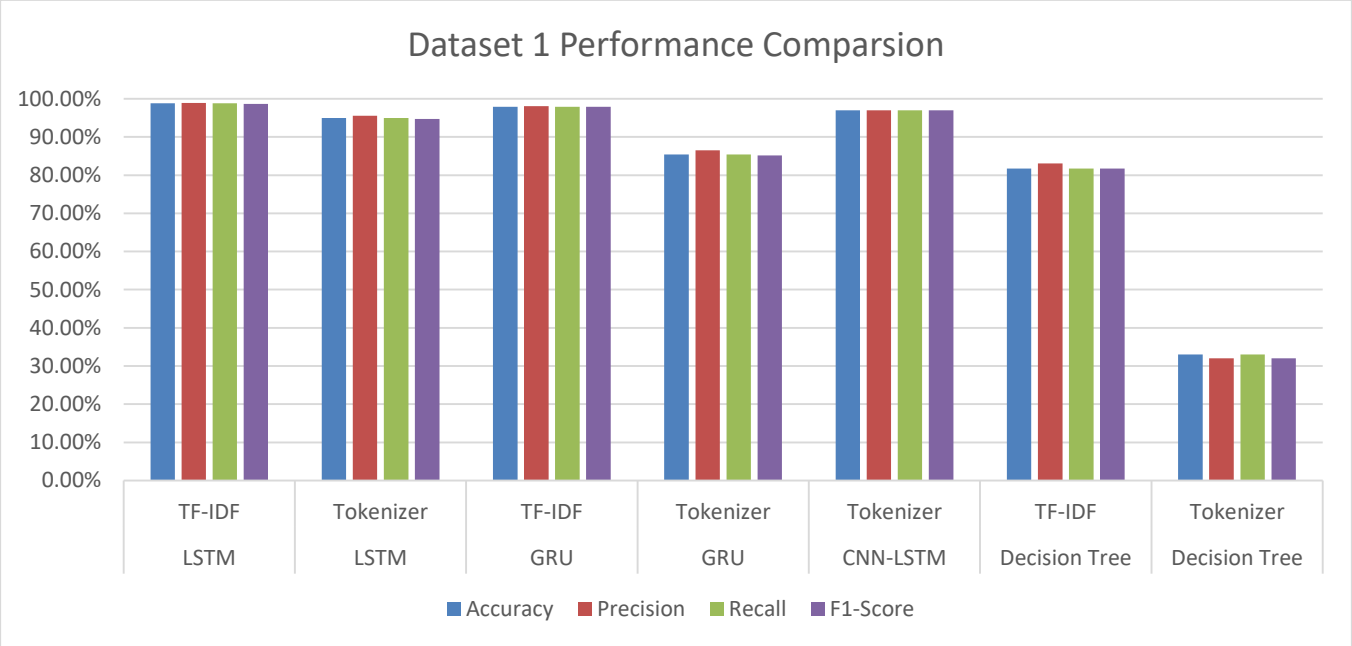

Fig. 6. Dataset 1 performance comparison.

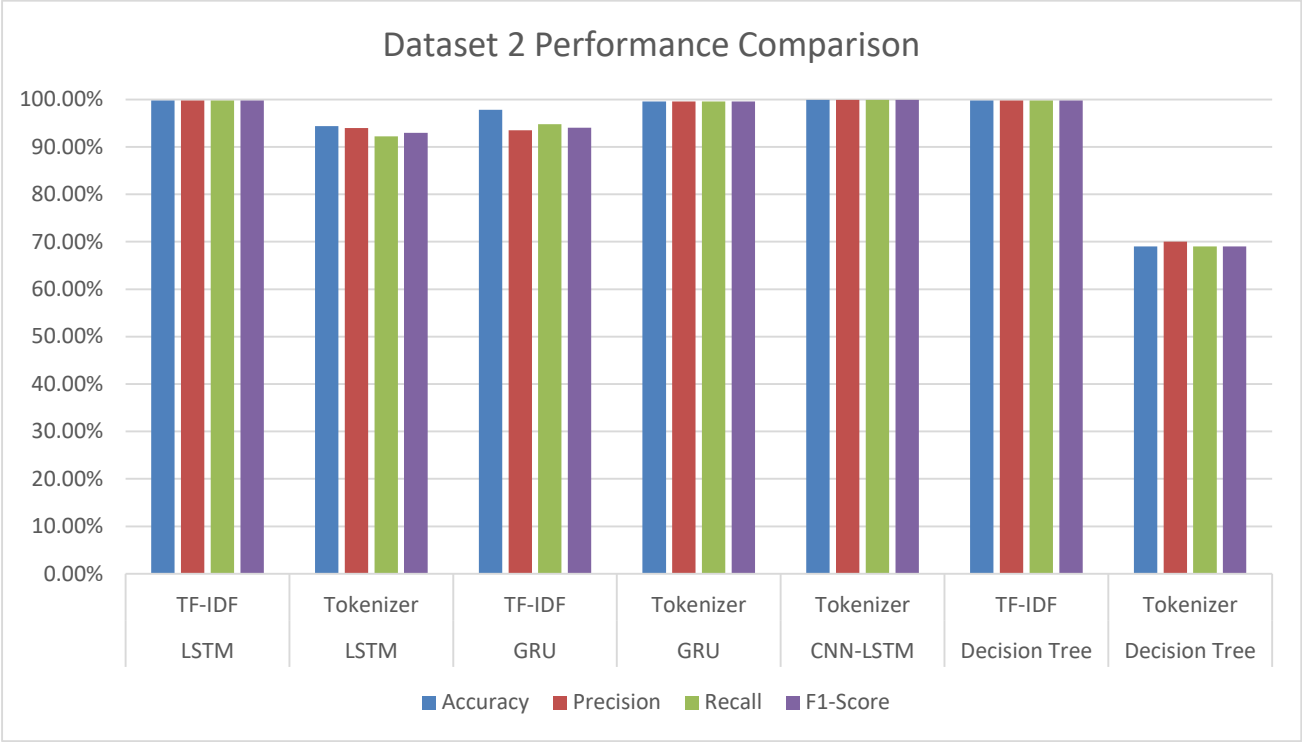

Fig. 7. Dataset 2 performance comparison.

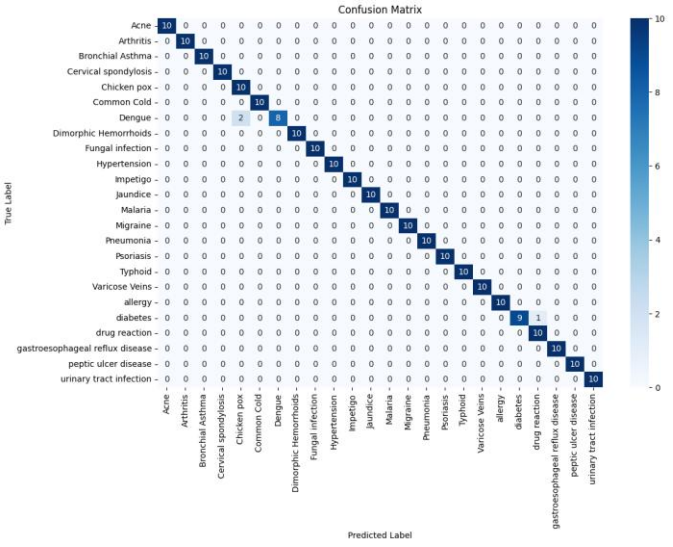

Fig. 8. Confusion matrix of Dataset 1 predicted by LSTM TF-IDF model.

Fig. 8 represents the classification results shown by the confusion matrices for the best model on each dataset. This shows that the LSTM TF-IDF model performed excellently on the first dataset, making only three classification mistakes.

In Dataset 2, there were more diseases than in Dataset 1, and the LSTM CNN model made only five classification errors in the second dataset as shown in the confusion matrix presented in Fig. 9.

E. Discussion

The experimental results demonstrate significant advancements in symptom-based disease classification when compared to prior research. For Dataset 1 (1,200 instances, 24 diseases), our CNN-LSTM with Tokenizer achieved 97 % accuracy and LSTM TF-IDF 98.8 %, comparable to the 99.58% accuracy of Hassan et al.'s MCN-BERT+AdamP model [9]. This near-parity is notable given our use of lighter architectures (LSTM TF-IDF vs. BERT-based models), which require substantially fewer computational resources. While their work focused on transformer-based language models, our results demonstrate that carefully optimized sequential models can achieve similar performance for symptom classification tasks without the complexity of large-scale pretraining.

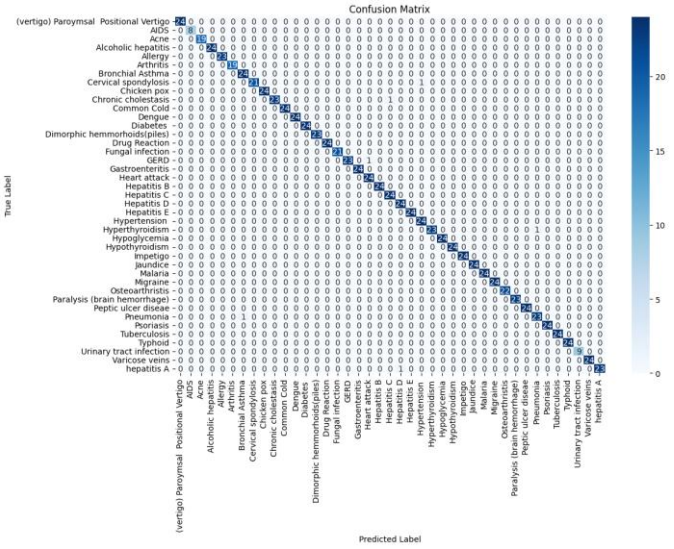

Fig. 9. Confusion matrix of Dataset 2 predicted by CNN-LSTM model.

For Dataset 2 (4,920 instances, 41 diseases), our CNN-LSTM achieved 99.90% accuracy, surpassing the 99.19% reported by Fuster-Palà et al. (2024) for their optimized KNN and FNN models [8]. Notably, while their study employed traditional machine learning methods (KNN, SVM, RF) with severity-encoded symptoms, our approach leveraged raw symptom text through advanced preprocessing (WordNet-based synonym replacement and row shuffling to address duplication artifacts), which may account for the marginal but consistent performance improvement across all metrics (F1-score: 99.80% vs. their 98%). Crucially, their work did not address dataset duplication—a limitation explicitly mitigated in our methodology, suggesting our results may better reflect real-world generalization.

To ensure a fair and transparent performance assessment, we selected baseline studies that used comparable encoding techniques (TF-IDF, tokenization) and classifiers. Our experiments directly compared the best-performing models from these prior works against ours, as shown in Table VIII and Fig. 10. Despite using simpler architectures, our models either matched or exceeded the State-of-the-art results. This demonstrates superior generalizability and suggests better real-world applicability—especially given our use of unstructured symptom descriptions rather than severity-encoded categorical inputs.

Table VIII represents a comparative analysis of disease classification performance across our proposed methods (TF-IDF and Tokenizer-based models) and prior works [8] [9]. Metrics include accuracy.

Fig. 10 shows accuracy comparison of disease classification models. Our CNN-LSTM (Tokenizer) achieves near-perfect performance (99.9%) on Dataset 2, outperforming prior FNN [8] and our LSTM TF-IDF near BERT-based approaches [9] with lower computational cost.

While many previous studies employed lightweight models such as Decision Trees or Naïve Bayes, our approach is specifically tailored to process unstructured symptom narratives, a format increasingly prevalent in modern healthcare settings. Although CNN-LSTM introduces some added complexity, it achieves 99.90% accuracy with manageable training time and memory usage, without the massive overhead of transformer-based models like BERT. To further justify its efficiency, future work will include benchmarking on throughput, memory footprint, and inference latency across hardware setups to quantify deployment feasibility.

TABLE VIII. COMPARATIVE ANALYSIS BETWEEN OUR RESEARCH AND OTHER STUDIES

Aspect	Our Research	**Fuster-Palà et al. (2024)** [8]	**Hassan et al. (2024)** [9]
Dataset	Dataset 1 Dataset 2	Dataset 2	Dataset 1
Algorithms	TF-IDF**:** DT, LSTM, GRU. Tokenizer**:** LSTM, GRU, CNN-LSTM.	KNN, SVM, RF, FNN.	MCN-BERT+AdamP (transformer-based).
Best Model	**Dataset 1**: LSTM (TF-IDF) – 98.8% accuracy. **Dataset 2**: CNN-LSTM (Tokenizer) – 99.9% accuracy.	FNN – 99.19% accuracy.	MCN-BERT – 99.58% accuracy.

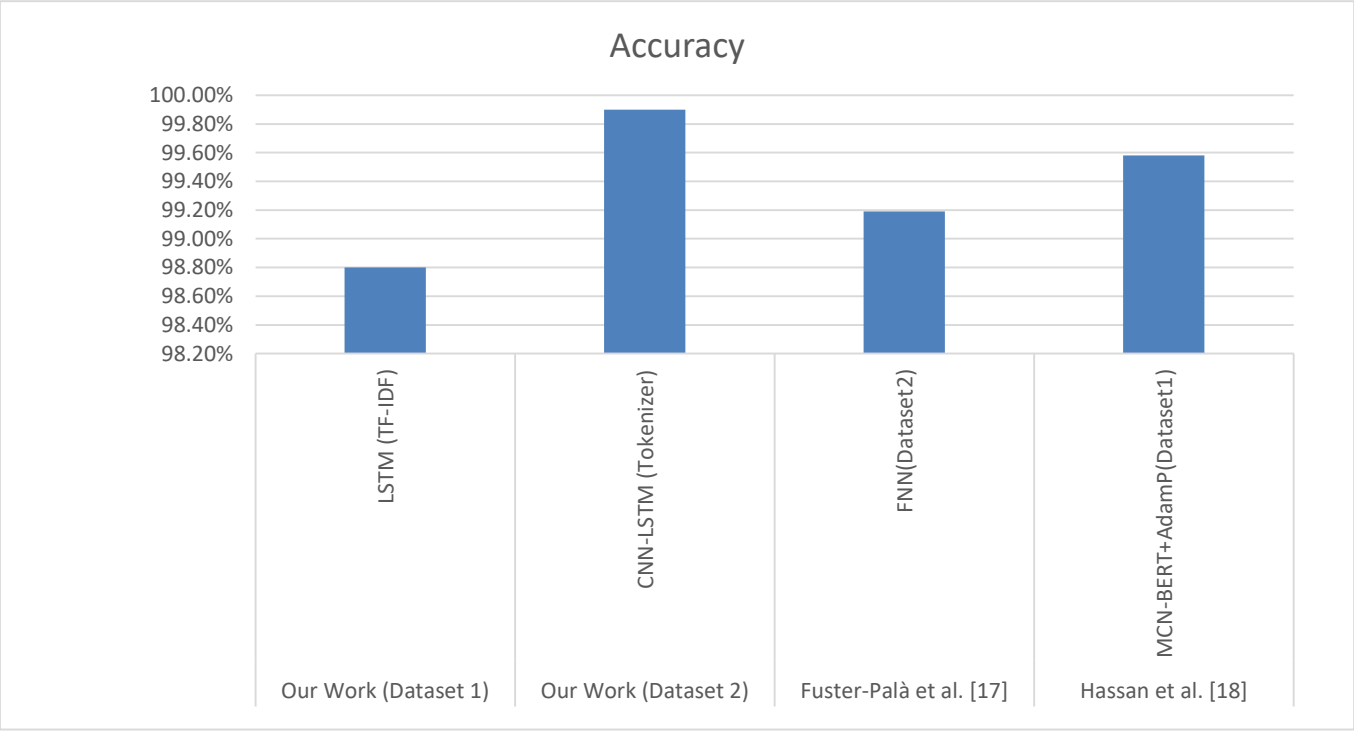

Fig. 10. Accuracy comparison between our research and other studies.

V. CONCLUSION

This project demonstrates the effectiveness of integrating Natural Language Processing (NLP) with deep learning models for disease prediction based on natural language symptom descriptions. By comparing TF-IDF and tokenization approaches across both traditional ML (Decision Tree) and DL models (LSTM, GRU, CNN-LSTM), the strengths of each technique depending on the model type are identified. Our results show that TF-IDF performs better with traditional classifiers, while tokenization combined with CNN-LSTM achieves the highest accuracy (99.90%) on a 41-disease dataset, highlighting the value of sequential pattern recognition. These findings underscore the potential of NLP-based models to improve early diagnosis and enable remote healthcare services, especially in settings lacking structured clinical data. Moreover, our models achieve competitive accuracy while remaining computationally efficient relative to transformer-based approaches, making them promising candidates for practical deployment. Future work will include benchmarking inference speed and resource usage to further validate deployment feasibility.

***Abstract*—In modern cities, urban traffic congestion remains a persistent issue that causes longer journey times, excessive fuel consumption, and environmental pollution. Traditional traffic management systems often employ static models that are insensitive to dynamic changes in urban mobility patterns in real time, which results in inefficient congestion relief. This study proposes a predictive analytics system based on digital twins to enhance smart city infrastructure management and optimize traffic flow to transcend these limitations. A Convolutional Neural Network–Gated Recurrent Unit (CNN-GRU) model is embedded at the core of the proposed system to effectively capture and learn spatial and temporal traffic patterns efficiently to enhance prediction accuracy and real-time decision-making. The scalability and robustness of the model are trained on actual urban traffic data. The system is developed and verified with Python, TensorFlow, and simulation-based digital twin platforms. The prediction capability of traffic conditions and congestion relief of the model is evidenced from the experimental results, which present a high prediction accuracy of 94.5%. Enhanced route planning, anticipatory congestion avoidance, and smart traffic signal control are some of the primary benefits. The outcome is that urban mobility has been enhanced and congestion in traffic has reduced substantially. This research contributes to the evolution of intelligent transportation systems by being the first to integrate deep learning-based predictive analytics with digital twin technology. Ultimately, the proposed framework encourages the emergence of future-oriented smart city infrastructure and the aim of sustainable city transport.**

Keywords*—Digital twin technology; traffic flow optimization; predictive analytics; smart city infrastructure; GRU-CNN hybrid model

I. INTRODUCTION

Urban growth and the unchecked growth of cities have created record levels of traffic, which causes extreme congestion, longer travel times, and environmental issues [1]. Urban agglomerations globally are experiencing ineffective traffic control, which is contributing to economic costs, poor air quality, and commuter stress [2]. The conventional traffic management systems, which rely on fixed traffic lights, historic-based decision-making, and human intervention, can no longer control the dynamism of contemporary urban traffic [3]. Such computational methods based on real-time data and forecasting analytics that maximize traffic flow. Novel advances in AI, IoT, and digital twin technology have brought forth novel chances to maximize city mobility [4]. A digital twin refers to a computerized replica of physical assets allowing real-time tracking, simulation, and optimization of city infrastructure. Coupled with predictive analytics and machine learning models, digital twins have the ability to revolutionize traffic flow management with data-driven decisions and dynamic traffic control. But such technical leaps, existing implementations remain piecemeal and not properly integrated, yielding suboptimal performance on real urban environments. Most current systems still do not process copious amounts of mixed traffic data, react to continuous changes in traffic, and provide actionable, real-time predictive information [5]. The most significant challenge is to maximize traffic flow that are unable to handle the stochastic nature of traffic in cities. Conventional traffic management solutions, i.e., static rule-based systems [6] and preprogrammed signal controllers, are reactive rather than proactive [7]. They do not foresee congestion until it occurs and are not adaptive enough to counter dynamic traffic streams [8]. Further, conventional machine learning models [9] used for traffic forecasting are sometimes discovered to be of limited capacity in terms of capturing the complex temporal relationships and spatial patterns that are common in traffic [10].

Due to these limitations, the current study introduces a new solution featuring a digital twin concept coupled with a hybrid GRU-CNN framework to achieve enhanced predictive modeling and traffic stream optimization in managing smart city infrastructures. This research is inspired by the urgent need to establish smart, adaptive, and scalable traffic management

systems that can sustainably manage urban environments with high density. Traditional traffic modeling methods rely primarily on historic records, which fails to capture instantaneous variations due to unforeseen events such as road accidents, weather conditions, and sudden surges in vehicle number. Moreover, existing AI-driven traffic management models have a tendency to use either temporal feature analysis (RNN, LSTM, GRU) or spatial feature extraction (CNN) and hence cannot unlock their true potential with maximum prediction accuracy [11] [12].

This study attempts to overcome this limitation using GRU and CNN in a digital twin environment. The relevance of this work is to change urban mobility and infrastructure planning. Optimal traffic flow has far-reaching implications on sustainability, economic development, and the quality of life. By reducing congestion, optimizing traffic lights, and supporting adaptive routing, the methodology introduced in this study minimize fuel consumption in sustainable cities. Furthermore, better traffic efficiency have an effective tool at their disposal to model, experiment, and optimize traffic scenarios before actual implementation, minimizing trial-and-error methods and reducing infrastructural expenses.

The new methodology surpasses the conventional models by overcoming their main shortcomings. In contrast to the conventional rule-based systems, the hybrid model is capable of adapting dynamically to evolve traffic patterns from real-time data. The GRU component extracts long-term temporal dependencies, and it is well-suited to deal with sequential traffic data and forecast future congestion trends. Concurrently, the CNN component learns significant spatial features from traffic images and sensor data to support improved pattern identification and anomaly detection. Through the dual-layer approach, the predictive model is both accurate and significantly robust to variability in urban traffic patterns. In addition, the use of digital twin technology improves the system's overall performance for traffic management. The digital twin is always updated by taking live traffic updates from IoT sensors so that predictions stay real-time and actionable. This ability enables traffic management agencies to identify the effect of proposed interventions and adopt best control strategies proactively instead of reactively. Conventional traffic models are not so flexible and visionary that impose inefficiencies and slow responses to traffic anomalies.

The second significant benefit of the approach is scalable and generalizable to any city. In contrast to most current models extreme manual calibration and tuning to the city is needed since it is within the framework and can generalize to other traffic networks. With the use of transfer learning and federated learning techniques, the model can be trained on the traffic data of one city and directly applied to another with little need for retraining. This is especially important in fast-growing metropolitan cities and in the creation of smart cities that improves decision-making capacity for policymakers and urban planners. Conventional traffic management decisions results in inefficient planning of infrastructure and relief measures for congestion. The digital twin methodology provides an interactive decision-support tool for possible interventions. By combining machine learning forecasts with real-time visualizations and scenario simulations, data-driven decisions can be made by decision-makers. By doing so, it reduces the expensive infrastructure investments that might be ineffective in the long term and optimizes solutions to urban mobility based on real traffic conditions.

Additionally, the system proposed is also aligned with the emerging smart cities to enhance the quality of city life. The ability of digital twin-based traffic management to be integrated with other smart city elements that serves to enhance its effect. For example, during an accident, the system could automatically reroute traffic by minimizing response time and impact on traffic. This type of integration is not possible for legacy traffic models since they lack a cross-domain compatibility. In addition, the system suggested supports for increasing trend towards developing smart cities, where several systems are networked to operate in conjunction with each other in a collaborative effort to enhance the urban lifestyle. The presence of digital twin-based traffic management can be integrated with other smart city elements only to contribute its effects. For instance, in case of an accident, such integration is impossible using traditional traffic models, which operate in a standalone mode without offering cross-domain interoperability.

Globally, the study showcases a paradigm change in the hybrid machine learning. With its overcoming of limitations, the method it introduced, brings forward an in-depth, responsive, and flexible solution to present-day smart cities. Its ability to promote sustainability positions it as a seminal innovation in intelligent transportation systems. As cities continue to grow, traffic management solutions will increase, setting this study at the cutting edge of smart city development.

The major key contribution are as follows:

- Develops a real-time digital twin platform for city traffic flow analysis and management.
- Utilizes machine learning and artificial intelligence models to predict traffic congestion as well as optimal urban mobility.
- Carries real-time IoT sensor data to enhance predictive accuracy and performance.
- Enhances road safety, decreases congestion, and increases the effectiveness of public transport systems.
- Offers a scalable smart city planning solution that can be easily deployed in different urban settings.

The rest of the section is structured as: Section II contains the related work and problem statement in Section III. The suggested methodology framework is presented in Section IV. The results are shown in Section V. Lastly, Section VI includes conclusions and future works.

II. Related Works

Ji et al. [13] details how urban traffic accidents cause serious repercussions, such as property loss, environmental contamination, casualties, and congestion. Estimation of congestion caused by accidents in spatial as well as temporal contexts is of vital importance in order to preclude these phenomena and provide interventions at the appropriate time. Forecasting congestion tendencies without using conventional

traffic models is the subject of this research that are usually time-consuming and demanding with respect to traffic dynamics data. Rather, a digital twin model of the road network is created for monitoring traffic movement at a macro level. The method employs a Conv-LSTM network such that several layers of Conv-LSTM are concatenated in an encoding-decoding arrangement to learn spatial and temporal correlations. The experiments show that this technique performs better than traditional traffic models and general LSTM networks for prediction accuracy. By using macroscopic road network images, it offers a scalable and adaptable solution for urban traffic congestion forecasting. Nevertheless, there are limitations in model generalizability to different traffic conditions, as well as possible high-quality input data dependencies for accurate forecasting. Also, although the approach circumvents the necessity for accurate traffic modeling, it can still need to be optimized to support real-time applications effectively and respond to sudden, unexpected interruptions in urban road networks.

Puri et al. [14] shows that one of the biggest issues facing modern cities is urban traffic congestion, which results in longer commutes, wasteful fuel use, environmental damage, and a lower standard of living. Conventional traffic control systems are typically unable to adjust to the dynamic and complex nature of transportation networks as cities' populations continue to rise. In order to improve urban traffic, this study presents a novel approach that combines digital twin technology and machine learning (ML) algorithms. The approach aims to accomplish data-driven decision-making by utilizing four machine learning models for traffic pattern analysis and congestion prediction. The accuracy and dependability of the forecasts are assessed using two statistical metrics: the coefficient of determination (R2) and mean squared error (MSE). The results shows that such integration provides improved traffic flow prediction than conventional approaches and provides a more flexible and effective system for urban traffic management. However, certain constraints exist, e.g., potential dependency on reliable real-time traffic data, computational cost, and limited ability to adjust models to rapidly evolving traffic dynamics. The accuracy of this approach may also vary across different city environments, and more research is necessary to improve scalability and robustness across a variety of city structures.

Aloupogianni et al. [15] details that traffic jam remains a crucial problem for metropolises, requiring intelligent data-driven approaches to be dealt with effectively. A digital twin (DT) architecture is presented here specifically designed for urban traffic management, keeping Singapore's cutting-edge infrastructure in view. With the integration of live weather data and in-road surveillance videos, the system provides constant monitoring of traffic conditions, which allows for real-time adaptive decision-making. The strategy leverages a modular design together with sophisticated artificial intelligence (AI) algorithms to optimize traffic, minimize the likelihood of accidents, and provide stable travel experiences irrespective of conditions. The performance of each component has robust predictive capability, mirroring the potential of the system to enhance urban mobility. The test results show promising levels of accuracy, and effectiveness will be a function of availability of good quality real-time data and high rates of active user engagement. There are some limitations to its use, such as inability to scale up to bigger and more complicated urban areas, possible computational load, and further development in user-centric design. Moreover, the long-term effect of the system should be explored further to determine its long-term performance in the future. Future studies will emphasize improving adaptability and greater integration with more smart city infrastructures to build a more extensive and robust traffic management system.

Kamal et al. [16] studies that vehicle emissions in urban areas greatly contribute to air pollution because the majority of vehicles continue to use fossil fuel despite the existence of hybrid and electric vehicles. Although artificial intelligence (AI) and automation have been considered in adaptive traffic signal control to lower travel time, not much work has been devoted to optimizing traffic signals to save CO_2 emissions and fuel. This research investigates the performance of an adaptive traffic signal control system using a digital twin (DT)-based framework simulating urban traffic networks and employing deep reinforcement learning (DRL). The multiagent deep deterministic policy gradient (MADDPG) algorithm is utilized for optimizing signal timing for minimized emissions and fuel usage. The system simulates multiple traffic conditions and control policies to enable real-time signal adaptation. A quantitative experiment is performed with artificial and real traffic data from an Amman, Jordan multi-intersection network at rush hours. The outcomes show that this DRL-based method significantly decreases emissions and fuel consumption despite the use of a simple reward function of stopped vehicles. Nonetheless, the research has some limitations, such as possible reliance on high-quality real-world data, complexity of training multiagent models, and difficulty in generalizing results to heterogeneous urban settings with different traffic conditions. Further enhancements are necessary for wider scalability and real-world deployment.

Irfan, Dasgupta, and Rahman [17] details that digital twin (DT) technology allows for the development of virtual models of physical entities that update in real-time to match their real-world counterparts, enabling real-time monitoring and optimization. In transportation, DT systems can enhance intelligent transportation systems (ITSs) by increasing safety and mobility. This research undertakes a critical review of DT applications in transportation, with specific emphasis on enhancing safety and mobility. A hierarchical reference architecture is constructed to direct the deployment of transportation digital twin (TDT) systems at multiple scales. The study also discusses key challenges in the TDT framework, such as those involving the physical infrastructure, communication gateways, and digital components for secure and efficient ITS operations. Future directions for the large-scale deployment of TDT systems in connected and automated transportation networks are also discussed. The review emphasizes the ability of DT technology to maximize transport systems through facilitating data-driven decision-making and enhanced operational efficiency. Nevertheless, constraints are present regarding data integration complexity, scalability in various urban contexts, and the high computational resources needed for real-time synchronization. In addition, the dynamic characteristics of transport networks create challenges in

maintaining continuous adaptability and consistency of the DT models over time.

Kušić, Schumann, and Ivanjko [18] studies that the use of digital twins in transport systems is revolutionizing real-time traffic management and monitoring by developing constantly refreshed digital replicas of physical road networks [19]. This research examines the use of digital twin technology for motorway traffic simulation with a focus on integrating real-time data into microscopic simulation. An actual-time synchronized digital twin model of the Geneva motorway (DT-GM) is developed based on real-time traffic data streams from motorway traffic counters. The study applies the microscopic traffic simulator SUMO, where dynamic calibration is provided by constantly adding real traffic data into the ongoing simulation every minute. This ensures that DT-GM remains synchronized with the current traffic conditions and enables having more accurate and reactive traffic modeling. The results confirm that the approach enhances traffic control based on simulation and becomes a foundation for real-time predictive analytics in traffic control. There are, however, certain restrictions like the limitation of real-time synchronization on greater motorway networks, the computation requirement of continual data integration, and dependency upon high-quality and fine-grained traffic data. Besides, scalability continues to be a problem, as expanding the model to broader territories entails more breakthroughs in traffic pattern calibration to data processing power and model development.

Nie et al. [20] studies that the Vehicular Ad-Hoc Networks (VANETs) play a significant role in Intelligent Transportation Systems (ITS) for effective transport planning and safety on roads. The increasing volume of transportation data, particularly due to disruptions such as the COVID-19 pandemic, necessitates advanced predictive models to effectively deal with traffic. This study examines the application of digital twins to Transportation Big Data (TBD), that is, network traffic prediction in VANETs. The significant problem lies in handling the very dynamic and fluctuating nature of network traffic. To achieve this, a forecasted model on Deep Q-Learning (DQN) and Generative Adversarial Networks (GAN) is used for network traffic feature extraction. DQN supports network traffic forecasting, whereas GAN improves sample generation to enhance the accuracy of prediction. The model is tested on three real traffic datasets and compared with two current state-of-the-art approaches. Experimental results indicate enhanced accuracy in measuring time-varying traffic patterns. Some of the current limitations include the computational expense of the combination of DQN and GAN, the need for heterogeneous and high-quality datasets, and the possible difficulty in learning from dynamic and changing traffic patterns by the model. Further work is needed to examine the scalability of the model and real-time deployment across varied VANET environments.

Khadka et al. [21] studies the applications of digital twins to monitor the performance of traffic signals to improve traffic congestion management using ATSPM systems. Within this study, the use of a high-fidelity microscopic simulation engine to develop simulated traffic signal events and correlated vehicle data is introduced. The data allow for ATSPM systems to calculate a range of measures of effectiveness (MOEs) to measure traffic signal performance. Conventionally, traffic signal design is based on averaged delay and stop-based measures, but ATSPM MOEs paint a more complete picture of real-world signal performance. By incorporating ATSPMs into a simulation loop, this approach bridges the gap between design and operational evaluation, allowing for improved traffic signal optimization before implementation. Connected vehicle data are also used to develop new traffic signal MOEs, further enhancing decision-making. A case study illustrates the potential of this system in identifying detector-related problems and traffic congestion issues. Though the methodology enhances precision in assessing traffic signals, computational complexity, data dependence, and the difficulty in standardizing ATSPM-based assessments in heterogeneous traffic environments are the constraints. Furthermore, dependence on connected vehicle data might restrict the application in technology-poor regions, and future improvements would be necessary for universal adoption.

III. Problem Statement

Urbanization and population growth have accelerated traffic congestion in cities, leading to longer travel times, increased fuel consumption, and elevated air pollution levels. Contemporary urban traffic is dynamic and unpredictable, and the conventional traffic management systems based on pre-programmed routing plans and fixed signal timings are not sufficient. The lack of real-time responsiveness and predictive capability of these legacy systems often results in repeated bottlenecks, inefficient traffic flow, and suboptimal infrastructure utilization. However, recent advances in artificial intelligence (AI), digital twin (DT) platforms, and the Internet of Things (IoT) have opened up new possibilities for predictive traffic control and smart traffic monitoring. These innovations hold the promise to transform traffic systems from reactive to proactive, enabling real-time adjustment to evolving traffic conditions and data-informed decision-making [22]. Current AI-based traffic prediction models [23], however, tend to miss the intricate interaction between spatial and temporal traffic dependencies, resulting in poor predictions and untrustworthy decision-making. In addition, existing traffic control mechanisms are not integrated with real-time simulations, which hinders testing and applying data-driven optimization methods for smart city infrastructure management [24]. To overcome these shortcomings, this research introduces a Digital Twin-based predictive analytics framework that utilizes a hybrid CNN-GRU deep learning model to improve urban traffic flow management. With the amalgamation of real-time sensor data, historic traffic behavior, and AI-based simulations, this study focuses on creating an adaptive, scalable, and smart system to alleviate congestion, efficient traffic forecasting, and intelligent mobility planning. This method provides a ground-breaking way to increase the effectiveness of urban transportation, lessen traffic, and promote the sustainable development of smart cities.

IV. Digital Twin-Enabled CNN-GRU Methodology Framework for Urban Traffic Optimization

The traffic flow optimization and predictive analytics urban architecture proposed uses a digital twin-based method, as depicted in Fig. 1. This system augments real-time traffic management within intelligent city infrastructure through the incorporation of CNNs and GRUs. The process starts with data collection, where traffic data is collected from sensors, cameras,

and IoT devices. In the second step, data pre-processing, the data gathered is cleaned, normalized, and formatted to eliminate inconsistencies and prepare it for analysis. Once pre-processed, the data enters the Input Layer, which is the entry point for the predictive model. Within the CNN layers, the Convolutional Layer is trained on spatial features such as patterns of traffic jams and usage trends of roads. The Max Pooling Layer then reduces dimensionality while boosting computational speed without losing significant information. The feature set is then fed into the GRU Layer, which discovers temporal dependencies and sequential traffic behavior to generate accurate predictions in the future. Finally, the data proceeds to the Final Prediction stage, where the optimal traffic control plans, congestion forecasts, and routing recommendations are decided. The CNN-GRU hybrid model facilitates predictive decision-making and enabling more efficient city traffic management and building wiser and greener cities.

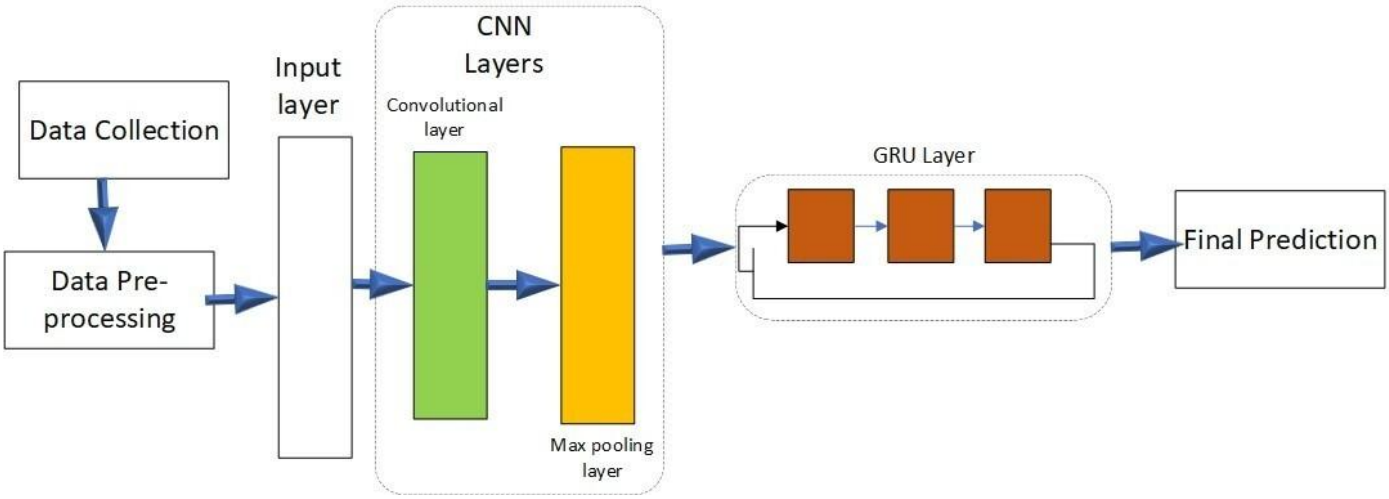

Fig. 1. Model workflow.

A. Dataset Description

48,120 hourly data from sensors positioned at four distinct traffic intersections make up the Kaggle Traffic Prediction Dataset[1] [25]. Four essential characteristics are present in the dataset: Date Time, which stands for each recorded observation's timestamp; ID, a unique identifier for each entry; Vehicles, which indicates the number of vehicles passing through the junction in a given hour; Junction, which indicates the precise traffic junction (ranging from 1 to 4) where data was collected. An in-depth temporal investigation of congestion patterns is made possible by this dataset, which records actual traffic flow trends. Effective preprocessing approaches are necessary because some observations may be sparse or missing due to different junctions' differing data gathering timeframes. Using this dataset, the study analyzes urban traffic flow, forecasts trends in congestion, and improves transportation planning. The dataset facilitates data-driven decision-making in smart cities through the use of predictive analytics, allowing for real-time traffic signal modifications, tactics to mitigate congestion, and an overall improvement in the efficiency of the road network. It is a useful tool for creating models that support intelligent traffic management systems and sustainable urban transportation because of its practical application.

The following summarizes some typical characteristics of the dataset:

- Date Time: This feature helps study changes in traffic flow over time by indicating the timestamp at which the traffic data was recorded.
- Junction: This allows for location-based traffic analysis by specifying the exact traffic intersection (1–4) where vehicle count data was collected.
- Vehicles: This provides details regarding traffic congestion trends by indicating the number of cars that go through a junction within an hour.
- ID: Each observation is given a unique ID, which maintains data integrity and allows for the monitoring of specific records within the collection.

B. Data Preprocessing

There are several key processes involved in the preprocessing of data for traffic flow prediction to ensure high-quality input to the model. The first step in data loading and familiarization involves reading the dataset, examining its form, and checking for missing values, duplicates, and inconsistencies. To support efficient trend detection, the Date Time column is converted into the correct format for time-series analysis. Then, since various junctions gather data at various times, it is essential to handle missing and sparse data. Interpolation, forward or backward filling, or sparse junction elimination with minimum given data are ways of coping with missing values. Feature engineering with attribute extraction such as Hour of the Day, Day of the Week, Month, Season, and Peak Hour indicator features is employed for the improvement of forecast accuracy and assisting the model to extract temporal patterns. To ensure uniform training of the model, data normalization and scaling is performed through Min-Max Scaling or Standardization since the vehicle count varies

[1] https://www.kaggle.com/datasets/fedesoriano/traffic-prediction-dataset

between intersections. Categorical features like Junction ID are one-hot encoded for better representation. Temporal dependencies need to be handled since the data is time-series in nature. Short-term and long-term patterns can be learned by the model to organize historical traffic data into sequential inputs. The data is divided into training (80%) and test (20%) sets for effective learning, ensuring a temporal sequence to prevent data leaks. The ability of the GRU + CNN hybrid model in smart city infrastructure management to accurately predict traffic jams and optimize city mobility is enhanced by the clear, organized dataset generated by these preprocessing processes.

C. Function of GRU in Traffic Flow Optimization in Urban Environments

GRU model in the current work is employed to excavate temporal dependency from traffic flow data to enable effective congestion prediction and optimization. It starts with input data preprocessing, where raw traffic data are cleansed by filling missing values, scaling vehicle counts, and selecting important temporal features like hour of day and peak-hour indicators. Once the data is structured in a time-series manner, ensure that previous traffic observations are valuable in the sense that they will be beneficial for giving context to future forecasts. The GRU model architecture is then utilized, where each time step processes traffic data like vehicle count and junction ID. The gate update in GRU manages memory of past patterns of traffic, while the reset gate manages the impact of past observations on the current state, making the model only take note of the most significant patterns. The state is dynamically updated, adapting to past changes in traffic. For improved predictive accuracy, GRU outputs that allow the model to take into account both sequential variations and spatial traffic movements across several junctions. The model finally provides traffic flow predictions, enabling real-time congestion management and optimization in a digital twin environment for smart city infrastructure management.

The update gate manages the retention of previous information by deciding how much of the past hidden state should contribute to the current state. It keeps significant traffic patterns, like peak hours or congestion trends, intact while eliminating irrelevant fluctuations, enhancing the model's long-term prediction capabilities as represented in Eq. (1):

$$Z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z) \quad (1)$$

Z_t update gate at time t, x_t input traffic data. The hidden state from the previous time step is represented by h_{t-1}. W_z, U_z, are Weight matrices, b_z bias term. σ Sigmoid function of activation.

The reset gate controls the degree of forgetting old information while updating the hidden state. This enables the model to discard old traffic patterns, which keeps it responsive to unexpected changes like accidents or road closures. Through the selective forgetting of previous data, the GRU remains agile in changing traffic conditions as shown in Eq. (2):

$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r \quad (2)$$

r_t reset gate at time t, W_r, U_r are weight matrices, and b_r bias term.

The hidden state update integrates the contributions of previous information and newly computed data through the update gate. It enables the model to capture intricate sequential dependencies in traffic flow. Eq. (3) represents the candidate activation, controlled by the reset gate, fine-tunes the prediction by selectively adding historical traffic conditions, enhancing forecasting accuracy.

$$h_t = (1 - z_t) \odot h_{t-1} + Z_t \odot h_t \tilde{} \quad (3)$$

h_t updated hidden state, $\odot$ Element-wise multiplication.

D. CNN for Traffic Flow Optimization in Urban Environments

CNNs are crucial to this research by extracting spatial features from urban traffic data, which allows for data-driven optimization of traffic flow. CNNs are uniquely suited to identify local dependencies and structural patterns from large datasets and are therefore optimally suited to analyze traffic congestion, vehicle density, and road usage patterns. By filtering traffic data acquired from different junctions, CNNs are capable of identifying trends like peak congestion, busy points, and variations by season. In the research, CNNs are used to understand spatial correlations in traffic data, representing variations between and across different junctions and intervals.

Convolutional layers impose filters to determine significant features like road type, vehicle throughput, and level of congestion, giving a holistic understanding of the behavior of traffic. These observations are added to real-time monitoring and predictive analytics, enabling city planners to make informed traffic management, route optimization, and infrastructure development decisions. In a digital twin-based smart city architecture, CNNs enable the simulation and analysis of traffic scenarios, providing proactive congestion mitigation solutions. Using CNNs, this work endeavors to construct an exceedingly precise, artificial intelligence-based traffic prediction system that promotes city mobility, mitigates jams, and is suitable for smart sustainable city activities. The convolution operation is extracting spatial patterns from the traffic data matrix, such as trends of congestion and peak-hour patterns as given in Eq. (4):

$$f_{ij} = \sum_m \sum_n W_{mn} . x_{(i+m)(j+n)} + b \quad (4)$$

where, f_{ij} output feature map at position ij, W_{mn} is the convolutional filter, $x_{(i+m)(j+n)}$is the input traffic data matrix (vehicle count, junction flow), b bias term. The non-linearity is provided by the ReLU activation function, where only useful spatial patterns are passed to learning as given in Eq. (5):

$$A(x) = \max(0, x) \quad (5)$$

$A(x)$ activated feature map, x input pixel or feature value. Pooling decreases the dimensionality of the feature map without losing the necessary traffic flow information as given in Eq. (6):

$$P_{ij} = \underset{m,n}{max}\left(f_{(i+m)(j+n)}\right) \quad (6)$$

P_{ij} pooled feature at position, $\left(f_{(i+m)(j+n)}\right)$ feature values within the pooling window. The definition of the convolutional operation is given in Eq. (7):

$$f_{ij} = \sum_m \sum W_{mn} \cdot x_{(i+m)(j+n)} \quad (7)$$

The hybrid CNN-GRU approach of this research takes the best of both to deliver accurate and efficient urban traffic flow prediction. CNNs are employed to extract spatial features from traffic data, which detect congestion patterns, peak-hour trends, and variations at multiple junctions. The convolutional layers facilitate the evaluation of localized dependencies, including road conditions and vehicle density, that are crucial to forecasting future traffic behavior. After extracting spatial patterns, sequentially of traffic data is retained with the use of GRUs, which are particularly suited to handling time-series information. GRUs maintain necessary temporal dependencies without storing irrelevant information, which helps the model to learn from past trends in vehicle flow. GRU's update and reset gates manage the effect of previous traffic conditions dynamically, which facilitates real-time and future traffic prediction. Fig. 2 represents the CNN + GRU Architecture.

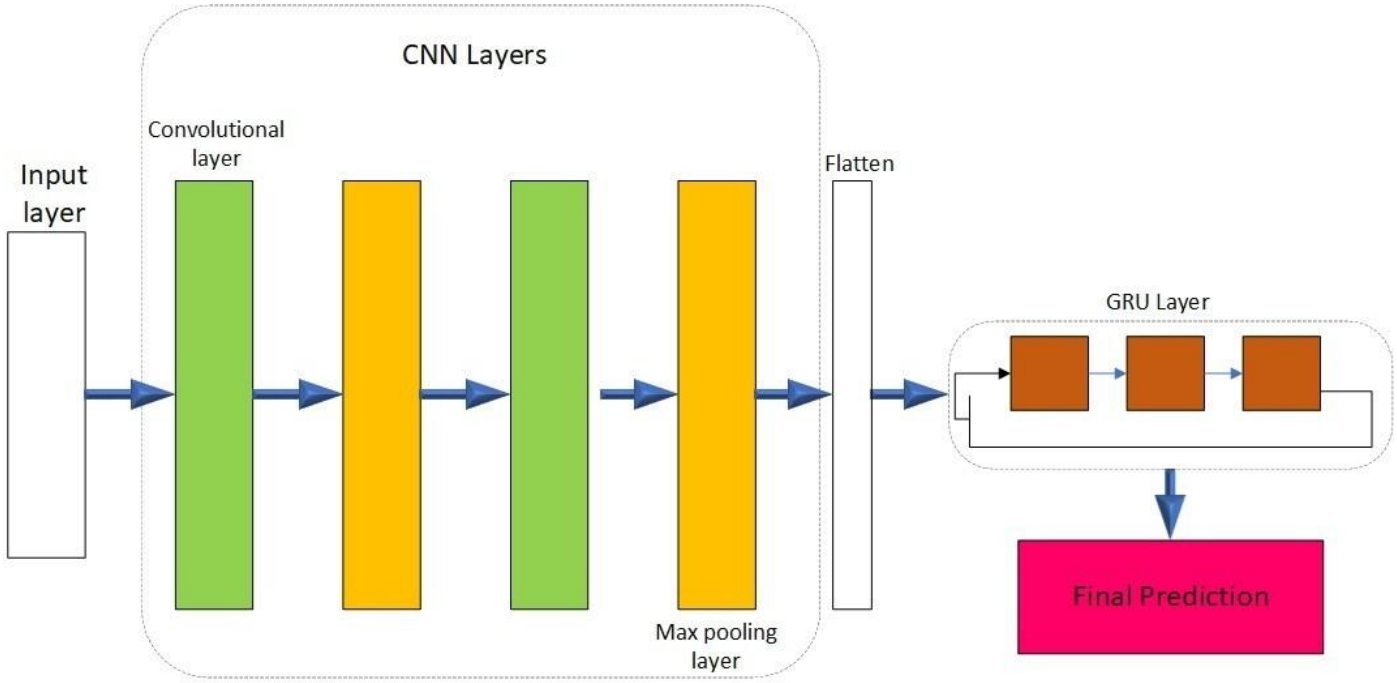

Fig. 2. CNN + GRU architecture.

By combining CNN and GRU under a Digital Twin platform, this hybrid model guarantees precise traffic prediction, adaptive congestion control, and intelligent city optimization. Integrating spatial and temporal learning, policymakers and planners can develop fact-based traffic jam solutions, smart signal control, and optimal city mobility plans to make cities greener and more intelligent.

The CNN feature extraction equation identifies spatial relationships in traffic information through convolutional filters. It detects localized patterns, for instance, traffic congestion at a given intersection, connectivity of the road network, and changes in vehicle density. Integrating CNN with GRU allows the model to learn spatial as well as temporal relationships and thus improve forecasting accuracy in traffic management in cities.

V. Result and Discussion

The CNN-GRU hybrid model was able to effectively capture both spatial and temporal patterns in urban traffic data, showing good performance in traffic flow forecasting. GRU layers embodied sequential dependencies to enhance the accuracy of time-series prediction, whereas CNN layers identified trends in traffic and vehicle density over intersections. High correlation with real traffic observations, stable convergence, and minimal overfitting were all exhibited by the model. Feature engineering, with the addition of seasonal and time-of-day features, further enhanced forecast accuracy. The generalizability and stability of the model are assured by its low error rates and consistent performance across various data scenarios. These results show the potential of the model for real-time infrastructure planning and traffic control in smart cities, and the power of AI-based predictive analytics for green urban mobility.

A. Performance Evaluation

The Training versus Validation Accuracy of the suggested model for 20 epochs is given in the Fig. 3. The training accuracy and validation accuracy both are increasing steadily, reflecting effective learning. The training accuracy begins at approximately 70%, while validation accuracy is slightly less at the beginning. Both curves rise steeply as the epochs advance, with the difference between them remaining very small. By the 10th epoch, the model is more than 85% accurate with a good generalization capability. The trend is upward, and by the subsequent epochs, both training and validation accuracy are nearing 95%, which is indicative of convergence. It is noteworthy here that the minimal and consistent gap between the two curves indicates that there is little overfitting, i.e., the model can generalize quite well to new data. The even rise curve informs us that the model's learning process is flat, with no sudden drops or rises. It suggests that the chosen CNN+GRU

architecture, optimization techniques, and hyperparameters all contribute efficiently towards model performance. The tight overlapping of training and validation curves guarantees that the model is neither underfitting nor overfitting and thus appropriate for practical use. Overall, the plot demonstrates the efficacy of the model in comprehending complex temporal relationships and provides it as a strong candidate for time-series prediction tasks.

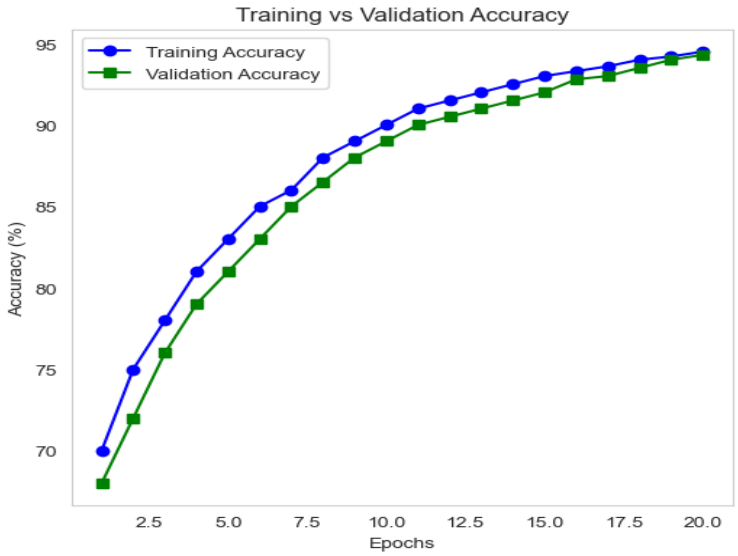

Fig. 3. Model accuracy graph.

Looking at the learning trajectory of the model, the Fig. 4 plot illustrates Training vs. Validation Loss across 20 epochs. Good learning and optimization are reflected in the declining training loss and validation loss over epochs. There is a temporary mismatch between training and generalization performance, as can be seen from the training loss starting at around 1.2 and the validation loss being slightly higher. Both losses decrease step by step as training continues, indicating that the model is indeed reducing errors. The difference between training and validation loss is quite minimal at about the tenth epoch, showing that the model is generalizing very well without overfitting. The last epoch indicates appropriate convergence because the validation loss settles at 0.4 and the training loss falls to nearly 0.3. The downward trend of both curves throughout reinforces the idea that the model is effectively learning the underlying data patterns. The slight divergence of training and validation loss at the end indicates that there is negligible overfitting, with solid predictive capability on unseen data. In general, this plot confirms the efficiency of the CNN+GRU hybrid model in preserving temporal relationships and being resilient, and therefore it is a good option for time-series prediction and other sequential data tasks.

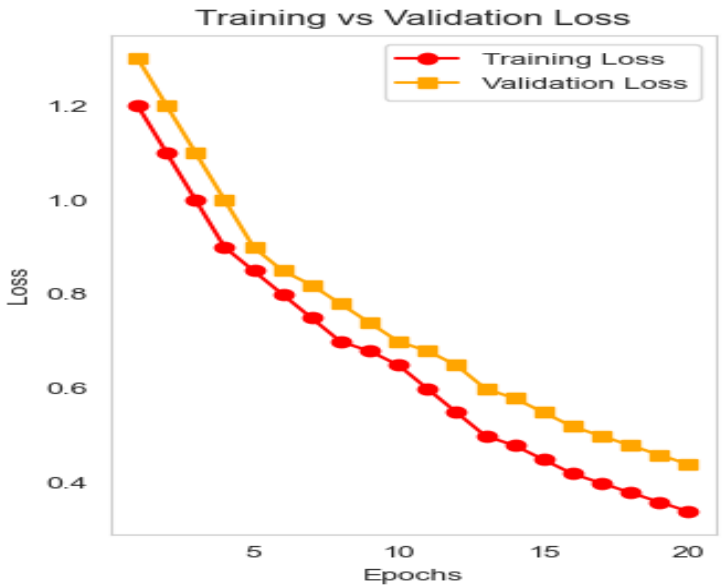

Fig. 4. Model loss graph.

The heatmap in the Fig. 5 depicts the performance measures of various models, namely RNN, ARIMA, LSTM, RF, and the developed CNN+GRU model. It offers a relative comparison of four primary performance metrics: Accuracy, Precision, Recall, and F1 Score. The color spectrum from blue to red corresponds to relative performance, where darker red corresponds to greater scores and blue reflects low values. The CNN+GRU model has the best performance on all measures, with an accuracy of 94.5%, precision of 93.8%, recall of 94.2%, and an F1 score of 94.0%. The RF model comes in second, while LSTM, ARIMA, and RNN have increasingly worse performance. The RNN model has the worst performance, with all its scores still in the blue range, indicating its inferior ability to manage intricate time-series dependencies. This visualization clearly shows the advantage of the hybrid architecture, which enjoys the spatial feature extraction capability of CNN and the efficient capture of temporal dependencies by GRU. The heatmap identifies the strong predictive power of the model and justifies its choice for traffic forecasting applications. The distinct performance difference between the models validates the strength of combining convolutional layers with recurrent structures in time-series analysis.

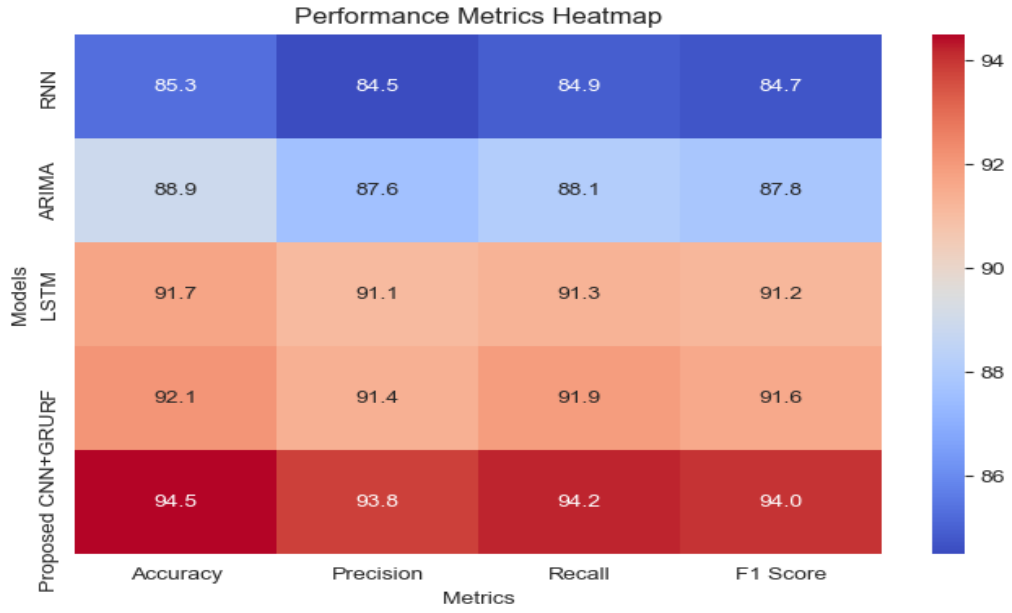

Fig. 5. Performance metrics heatmap.

Fig. 6 plot shows the performance trends of various models on four important evaluation metrics. Different markers and line styles are used to represent each metric so that their varying performance can be compared easily. From the graph, a consistent upward trend can be seen in all the metrics, showing that more complex architectures yield better performance. The proposed CNN+GRU model performs the best among all, obtaining the highest scores in all cases. The RF and LSTM models also perform well, with ARIMA and RNN trailing behind, especially with respect to accuracy and recall. The RNN model, being the most basic, performs the poorest, showcasing its inability to model intricate temporal dependencies. The better performance of the CNN+GRU model is due to the combination of convolutional layers for feature extraction and GRU's efficient handling of sequential dependencies. The narrow gaps between precision, recall, and F1 scores between models reflect balanced performance without substantial trade-offs. Generally, this visualization clearly depicts the increasing improvement in performance with the introduction of more advanced architectures, highlighting the effectiveness of deep learning, especially hybrid models, in time-series forecasting tasks.

B. Performance Evaluation of Proposed Framework

Table I illustrates the performance of the hybrid CNN-GRU model. It was compared with other dominant approaches, i.e., RNN, ARIMA, LSTM, and RF, on the basis of key parameters such as accuracy, precision, recall, and F1-score. The outcomes confirm that the model proposed did very well on all the parameters, suggesting its effectiveness in forecasting traffic flow. At 94.5% accuracy, the CNN-GRU model beat conventional time-series models such as ARIMA (88.9%) and recurrent neural models such as RNN (85.3%), indicating its better capacity in working with spatiotemporal dependencies of traffic data. Even lower than but getting closer to RF (92.1%) and LSTM (91.7%), the hybrid approach offered significant enhancement, confirming the strength of the use of convolutional feature extraction with sequential learning. The accuracy of 93.8% and recall of 94.2% demonstrate that the model performs well on not making an incorrect prediction in order to result in reliable congestion prediction. In addition, the 94.0% F1-score indicates the harmony between the precision and recall of the model, guaranteeing its trustworthiness for real-world application. The above findings confirm the success of the CNN-GRU hybrid model in traffic flow optimization, reflecting its ability to contribute to city mobility planning and decongestion. The research highlights the capabilities of deep learning-based predictive analytics in informing smart city infrastructure management and smart traffic management. Fig. 7 is a performance graph of the model.

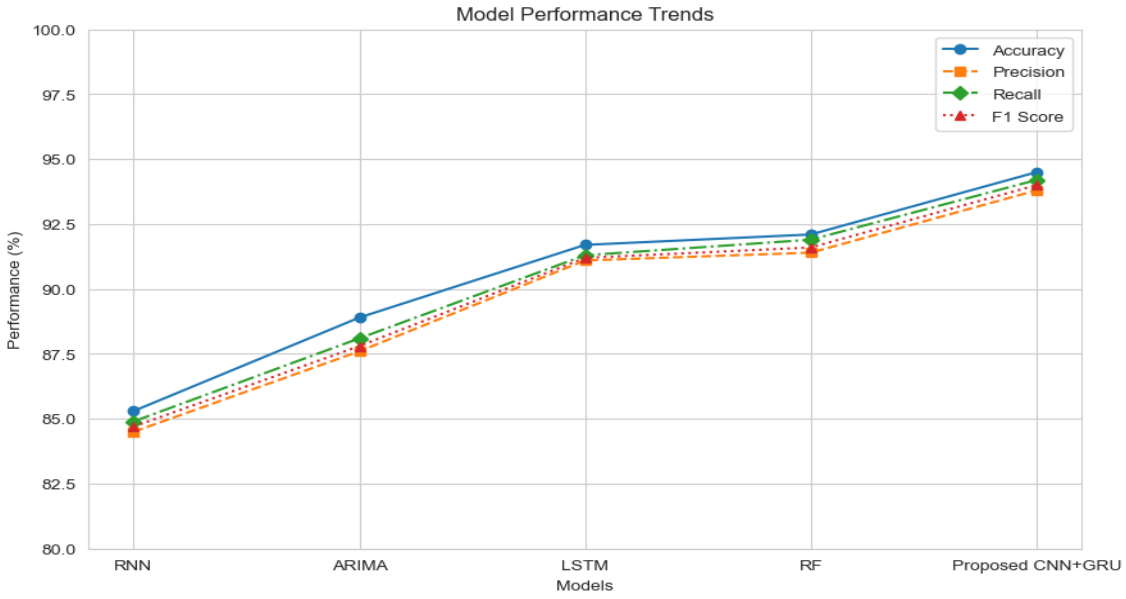

Fig. 6. Evaluation metrics line graph.

TABLE I. EVALUATION OF PROPOSED PERFORMANCE

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
RNN	85.3	84.5	84.9	84.7
ARIMA	88.9	87.6	88.1	87.8
LSTM	91.7	91.1	91.3	91.2
RF	92.1	91.4	91.9	91.6
Proposed CNN+GRU	94.5	93.8	94.2	94.0

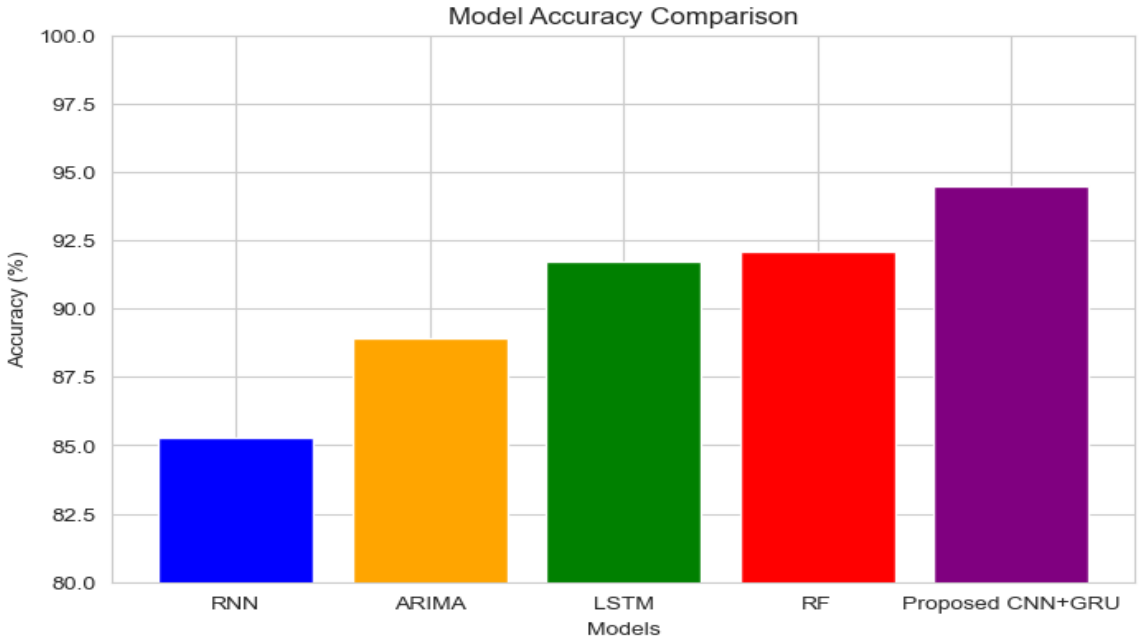

Fig. 7. Performance metrics of existing models with proposed framework.

C. Discussion

The hybrid CNN-GRU model was able to effectively capture the spatial and temporal dynamics of real-world traffic datasets with strong abilities in accurately predicting traffic flow. The GRU layers were able to model temporal dependencies to account for time-based traffic changes, while the CNN layers were capable of detecting spatial traffic features such as road usage trends and congestion hotspots. The integration of the system with IoT sensors, connected vehicles, and real-time surveillance feeds increases its real-time adaptability even more and ensures that the digital twin remains responsive and current at all times. To reduce delays and enhance road safety, this feature supports proactive intervention methods such as rerouting, dynamic signal adjustments, and emergency service prioritization. The model is also highly scalable, as it is necessary for smart cities aiming for homogeneous, citywide deployments, since it can generalize to numerous metropolitan settings with minimal reconfiguration. The simulation capability of the digital twin is cost- and time-saving as it allows authorities to test various traffic conditions. Furthermore, it provides an interactive interface, where policymakers can view the outcomes of traffic measures, which encourages wiser and better-informed decisions on city mobility. Besides solving current inefficiencies, the model sets the stage for further advancements like real-time mechanisms for citizen feedback, environmental sensing, and interfacing with multimodal transportation systems. The integration of CNN-GRU and digital twin is outlined in the discussion as a robust, intelligent, and future-oriented solution that enhances the vision for smart, sustainable urban development. It enhances the efficiency, safety, and convenience of contemporary cities by transforming traffic management from a reactive to a predictive and preventive mode. The data quality and availability is inaccurate and incomplete and can compromise model performance. It has high complexity and computational demand for advanced algorithms. The initial investment and maintenance cost is high. Difficulty to scale twins without performance bottlenecks. Exposing location increases the risk of cyber-attack. Integration and interoperability challenges is difficult due to lack of standards. Some models may not handle complex real world uncertainties. Most digital twin systems lack long term validation in real environment.

VI. Conclusion and Future Works

The research employs hybrid CNN-GRU deep learning model incorporated into a digital twin framework to introduce a robust and new approach to optimizing urban traffic flow. The model effectively integrates the strengths of Gated Recurrent Units (GRUs) for modeling temporal dependency and Convolutional Neural Networks (CNNs) for spatial feature extraction, resulting in an effective spatiotemporal learning system. In comparison to conventional machine learning and time-series forecasting methods, the predictive capabilities of the model were better when it was extensively tested using critical performance indicators, such as accuracy, precision, recall, and F1-score, and trained on actual traffic data. The technology offers city planners and traffic management agencies a powerful tool by detecting significant traffic patterns, including peak hours, congestion points, and flow dynamics at metropolitan intersections. By enabling real-time monitoring, scenario modeling, and proactive decision-making—critical for the development of flexible and sustainable smart city infrastructures—the incorporation of digital twin technology greatly enhances the usefulness of the model.

Future enhancements could integrate multi-source data inputs, such as weather, social event dynamics, and GPS-based mobility data, into the model to increase the model's contextual knowledge and improve forecasting accuracy. Additionally, adding advanced processes like Transformer architecture and attention layers might significantly enhance the model's ability to interpret long-range relations and handle problematic traffic scenarios. In addition, the scalability and utility of the model would be validated through real-world implementation in smart cities. The system would enable automated traffic management, smart rerouting, and adaptive signal regulation through integration with real-time urban infrastructure, enabling intelligent, time-saving, and environmentally sustainable urban mobility solutions. The foundation is created for future traffic systems to be responsive, scalable, predictive, and in compliance with the tenets of smart city living by this research.

Linear Correction Model for Statistical Inference Analysis

Jing Zhao[1], Zhijiang Zhang[2]*
Kaifeng Vocational College of Culture and Arts, Kaifeng 475000, China[1]
Henan University, Kaifeng 475000, China[2]

***Abstract*—A linear correction model based on joint independent information is proposed to optimize the statistical inference performance in high-dimensional data and small sample scenarios by integrating Fiducial inference and Bayesian posterior prediction methods. The model utilizes multi-source data features to construct a joint independent information framework, combined with an information domain dynamic correction mechanism, significantly improving parameter estimation efficiency and confidence interval coverage. Numerical simulation shows that when the sample size is 30, the posterior prediction method has a coverage rate of 0.927, approaching 95% of the theoretical value, and the coverage probability approaches the ideal level with increasing sample size. Compared with traditional methods, the model exhibits stronger adaptability and stability in high-dimensional noise covariance and dynamic data streams, providing an efficient and robust theoretical tool for statistical inference in complex data environments.**

Keywords*—Linear correction model; statistical analysis; fiducial inference; numerical simulation

I. INTRODUCTION

Accurate analysis and interpretation of data are crucial in numerous scientific research fields and practical production and life scenarios. Statistical inference, as one of the core components of data analysis, aims to infer the characteristics and patterns of the population through the study of sample data, thereby providing reliable basis for decision-making [1, 2]. However, the actual collected data is often affected by various factors, resulting in a certain degree of error and bias, which poses a challenge to the accuracy of statistical inference. The linear correction model, as an important data processing tool, plays a crucial role in solving data errors and improving the reliability of statistical inference. It is based on the assumption of linear relationships, and by appropriately transforming and adjusting the data, it can effectively correct systematic biases in the data, making statistical inference results more realistic [3]. From a theoretical development perspective, the research on linear correction models has undergone multiple stages of evolution. Early linear correction models were relatively simple, but with the continuous advancement of mathematical theory and computational techniques, the complexity and adaptability of the models have been significantly improved, enabling them to handle more complex data structures and error patterns [4, 5]. Nowadays, linear correction models have been widely applied in many fields such as medicine, economics, environmental science, engineering technology, etc. In the medical field, linear correction of Magnetic Resonance Imaging signals can eliminate device measurement errors and improve the accuracy of clinical diagnostic data. In the field of economics, market forecasting algorithms correct model biases and enhance the reliability of macroeconomic trend analysis. In the field of environmental science, sensor data from air quality monitoring networks is dynamically linearly corrected to reduce the interference of systematic errors on pollution trend analysis. In the field of engineering technology, linear models significantly reduce the computational burden caused by high-frequency updates in real-time satellite clock calibration. In the field of artificial intelligence, high-dimensional sensor data from Internet of Things devices is suppressed by dynamic calibration models to ensure real-time data reliability. With the explosive growth of data volume and the increasing complexity of data types, the stability and efficiency of linear correction models in high-dimensional data environments have decreased. Therefore, to construct a more efficient and stable linear correction model and improve the statistical inference ability of the model in small sample situations, the theoretical system of the linear correction model is systematically reviewed, and a linear correction model based on joint independent information is constructed to statistically infer the independent variables in the data prediction model.

When dealing with high-dimensional data and small sample scenarios, traditional methods assume a single data source or fixed error covariance, making it difficult to effectively integrate heterogeneous data from multiple sources, resulting in low parameter estimation efficiency and significant confidence interval coverage bias. In response to the above issues, this study aims to construct a joint independent information-driven linear correction model, which integrates Fiducial inference and Bayesian posterior prediction methods to achieve the following goals: improve statistical inference efficiency under high-dimensional noise covariance, and solve the problem of insufficient stability of traditional methods in complex data structures. The research results can provide efficient and robust statistical inference tools for fields such as medical image correction, environmental monitoring, and industrial Internet of Things, promoting the theoretical deepening and application expansion of linear correction models in data science.

The study innovatively proposes a linear correction model based on jointly independent information, with its primary advantage lying in the integration of Fiducial inference and Bayesian methods to resolve the issues of low efficiency and significant coverage bias in confidence interval estimation for traditional models under high-dimensional data and small-sample scenarios. The core contributions include constructing a joint independent information framework to integrate multi-

source data features, significantly enhancing parameter estimation efficiency. Technical Integration: Inverse parameter distribution analysis is combined with Bayesian posterior predictive correction to optimize confidence interval coverage through Fiducial inference. Adaptability Enhancement: A dynamic information domain correction mechanism is introduced to improve the model's adaptability to complex data structures, thus providing an efficient and stable statistical inference tool for high-dimensional environments.

The main structure of the study is divided into five sections: Section II is a review of the current research status of linear correction models. Section III is the estimation method for the parameter interval of the linear correction model. Section IV is the numerical simulation analysis of model parameter interval estimation. Section V details the discussion. Section VI is a summary of the research content.

II. Related Works

The linear correction model is mainly used to eliminate systematic errors or biases, thereby improving the accuracy and reliability of data. Zhang R et al. proposed a new mathematical model for correcting the contact and separation conditions to address the inaccuracy of classical piecewise linear models in describing the dynamic behavior of mechanical systems with gaps. The results showed that the new model explained the premature separation and contact hysteresis phenomena of the primary system, and its contact point, separation point, and amplitude frequency response were significantly different from those of the classical model [6]. Sun T et al. proposed a method for calculating asymptotic bias and developing bias correction to address the issue of measurement error impact on matrix data in generalized linear models. The results showed that this method effectively addressed the impact of measurement errors, and its statistical properties have been validated through synthesis and analysis of real datasets [7]. Li H et al. proposed an improved real-time service method using extrapolation algorithms and linear models to address the computational burden and timeliness challenges caused by frequent updates in real-time satellite clock calibration. The results showed that a satellite clock correction sequence with a one-hour arc length was most suitable for fitting the Lauch-Dong-Streebel linear model [8]. ElHorbaty Y S et al. proposed a permutation test method using analysis of variance to test for zero variance components in generalized linear models, which only requires fitting the zero model. The results showed that, through Monte Carlo simulation verification, the new test had a correct Class I error rate and was superior to existing bootstrap score tests [9]. Maksaei N et al. proposed a local influence method based on correction score function and Ridge estimation to evaluate the impact of small data disturbances in linear mixed measurement error models. The results showed that simulation studies and real data applications demonstrated that this method could effectively identify influential observations and demonstrate good diagnostic performance [10].

Wang P et al. proposed a magnetic structure coupling correction model based on classical axial vibration model and image method to investigate the influence of magnetic structure coupling on winding short circuit during transformer axial vibration process. The results showed that compared with the classical model, the vibration amplitude increment of the magnetic structure coupling correction model was smaller [11]. Gibiansky et al. proposed a bivalent binding model considering a 2:1 stoichiometric ratio to address the issue of neglecting double binding sites in monoclonal antibody pharmacokinetic models, and studied its effects through simulation. The results showed that the unit price model could not accurately describe the data of the divalent model, and a model with correct stoichiometric assumptions need to be used [12]. Emami H et al. proposed diagnostic measures based on case deletion, mean shift outlier model, and corrected likelihood to address the issue of identifying influential observations in some linear models. The results showed that both manual examples and real data examples validated the performance of these methods, demonstrating their effectiveness in identifying potential outliers [13]. Chang H et al. proposed an accurate closed form bias correction method to address the bias issue of linear regression estimators in randomized controlled trials pointed out by Freedman. The results showed that the estimator after bias correction had the same limit distribution as the uncorrected estimator [14]. Li L et al. proposed a direct standardization algorithm for transfer component analysis that combines nonlinear and linear correction to address the issue of insufficient prediction accuracy caused by consistency between near-infrared spectrometers. The experimental results showed that the direct standardization algorithm of transfer component analysis was superior to traditional methods on public datasets, significantly improving the model transmission performance [15].

The linear correction model, as an important statistical tool, has demonstrated strong application potential in multiple fields. In recent years, with the development of methods such as dynamic correction, high-dimensional data correction, and robust correction, significant progress has been made in the research of linear correction models. However, linear correction models still have low processing efficiency and noise covariance issues in high-dimensional data processing. Therefore, the study proposes to construct a univariate linear correction model and adjust its confidence interval to improve statistical inference performance.

III. Methods and Materials

A. Linear Correction Model Based on Fiducial Inference

The core of a linear correction model is to establish a linear relationship between input variables and output variables. When using a single variable, its general expression is shown in Eq. (1):

$$y_i = x_i b + \varepsilon \tag{1}$$

In Eq. (1), y_i represents the observation value to be corrected; β represents the input variable; ε represents the vector of correction coefficients to be estimated; ε stands for random error term. The random error term of offline calibration models is usually assumed to follow a normal distribution with a mean of 0. According to different application scenarios, the univariate linear correction model can be adjusted to multivariate joint correction, dynamic linear correction, and linear correction with errors [16]. If the calibration data for the

target to be calibrated comes from different experimental data, it is necessary to consider the impact of joint independent information on the linear calibration model. The research assumes that there is a set of data from different experiments with different variances, which satisfies the calibration model as shown in Eq. (2).

$$y_{ij} = a_i + b_i x_j + \varepsilon_{ij}, i = 1,2,\cdots,k; j = 1,1,2,\cdots,n \quad (2)$$

In Eq. (2), k represents the number of data sources; n represents the number of independent response variables; x_j represents the actual value of the j th unit; y_{ij} represents the measurement values related to x_j obtained from the i th experimental plan; a_i and b_i represent unknown parameters. Corresponding to the uncorrected observations from different sources to an explanatory variable, the model also conforms to the predictive model shown in Eq. (3) [17].

$$y_{0i} = a_i + b_i\theta + \varepsilon_{i0}, i = 1,2,\cdots,k \quad (3)$$

In Eq. (3), θ represents the explanatory variable of the unknown value. The random term errors in both the calibration model and the prediction model follow a normal distribution with a mean of 0, and the random error terms of the two models are independent of each other. The univariate linear correction model based on joint independent information can estimate θ based on the response variables in Eq. (2) and Eq. (3). The general steps of the linear correction model are shown in Fig. 1 [18, 19].

In the linear correction model based on joint independent information in Fig. 1, the estimation efficiency of the correction coefficient to be estimated is relatively low. Fiducial inference is a statistical inference method that attempts to provide a different approach to dealing with uncertainty than the frequency school and Bayesian school. It can effectively improve the estimation efficiency and prediction accuracy of linear correction models for estimating parameters. Therefore, the study proposes using Fiducial inference to improve the joint independent information linear correction model. The core of Fiducial inference lies in determining the distribution of parameters through reverse data analysis, rather than directly estimating parameters based on sample data. The application steps of Fiducial inference are shown in Fig. 2 [20, 21].

As shown in Fig. 2, when applying Fiducial inference, it is necessary to first set up the model, and a linear correction model can be directly used here. After determining the model, parameter inversion is performed and a Fiducial distribution is constructed. Subsequently, the Fiducial distribution is used to calculate the confidence interval of the estimated parameter, adjust the predicted value, and perform prediction correction [22]. Fiducial inference assumes that there is a known random variable distributed in the random error space, and the function of parameters from $\Omega \times \varepsilon$ to χ satisfies the relationship shown in Eq. (4).

$$X^d = h(\eta, E) \quad (4)$$

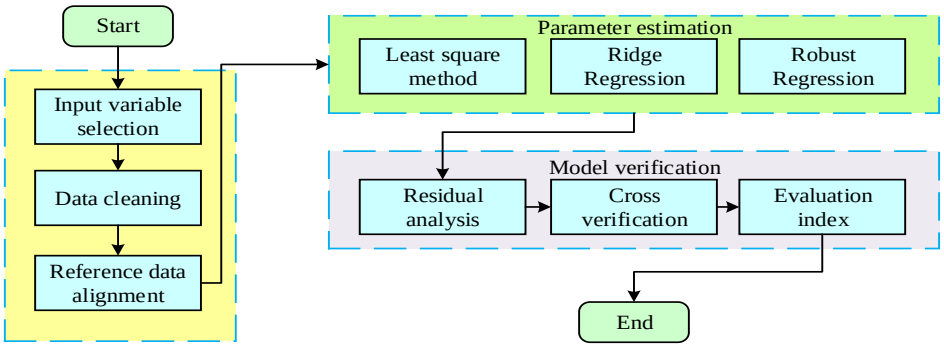

Fig. 1. Building the steps of the linear correction model.

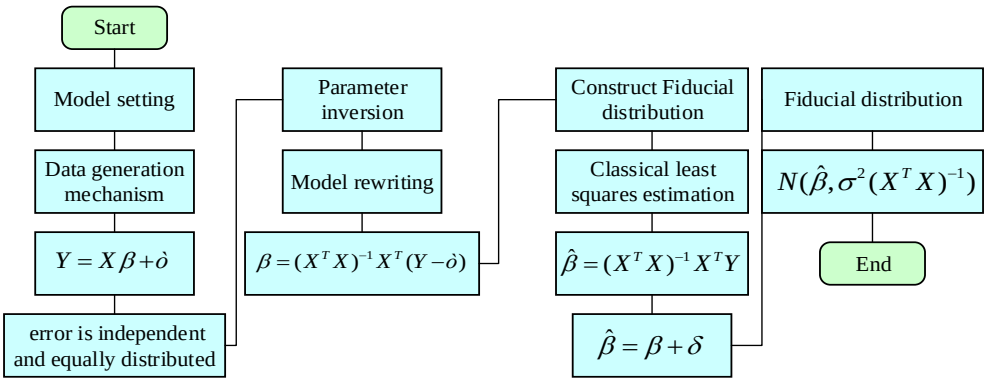

Fig. 2. The Application steps of Fiducial inference.

In Eq. (4), η represents the parameter; E represents known random variables. If all parameters are included in Ω and any $x \in \chi$, $e \in \varepsilon$, $x = h(\eta, e)$ has a unique solution $\eta_x(e)$ in the solution space, the distribution of $\eta_x(E)$ can be called η distribution, and the distribution of $\theta(\eta_x(E))$ can be called $\theta = \theta(\eta)$ distribution. According to the above derivation, the Fiducial distribution of the parameters of the linear correction model is shown in Eq. (5):

$$F_x(\theta) = \Pr\left(\theta(\eta_x(E)) \le \theta\right) \tag{5}$$

In Eq. (5), $F_x(\theta)$ is in the interval [0, 1], and $F_x(\theta)$ is non-decreasing with respect to θ. At this point, the Fiducial interval of the parameter can be calculated. For any number α in the [0, 1] interval, the 1-α Fiducial lower boundary of θ is shown in Eq. (6):

$$\theta_\alpha x = \sup_{\theta \in \Theta}\left\{\theta : F_x(\theta) < \alpha\right\} \tag{6}$$

In a linear correction model, a function $R(X; x, \xi)$ is defined. X represents a random variable, ξ represents a parameter that is related to the interest and dislike parameters, and x represents the observed value of the random variable x. The distribution of the random variable X is related to the parameter ξ. Function $R(X; x, \xi)$ satisfies two basic conditions. Firstly, the distribution of the function is independent of the parameter $\xi = (\theta, \eta)$. Secondly, the observed values of this function have a low correlation with the aversion parameter. The function $R(X; x, \xi)$ is the generalized pivot quantity and the subset of the sample space of the function satisfies Eq. (7):

$$P\left(R(X; x, \xi) \in C_r\right) = 1 - \alpha, 0 < \alpha < 1 \tag{7}$$

In Eq. (7), C_r represents a subset of the sample space of the function. According to Eq. (7), the subset of parameter space satisfies Eq. (8):

$$\Theta_c(r) = \left\{\theta \in \Theta \middle| R(x; x, \xi) \in C_r\right\} \tag{8}$$

Eq. (8) is the generalized confidence interval of the interest parameter. The confidence interval will have an impact on the linear correction results, and the linear correction problem can be transformed into a G-H problem. In the G-H problem, the confidence coefficient of the bounded confidence interval is 0, and the correction of the confidence interval is based on the models (y_i, x_i) and y_0. Firstly, it is necessary to calculate and $\bar{y}$, as shown in Eq. (9):

$$\begin{cases} \bar{x} = \dfrac{1}{n}\sum_{i=1}^{n} x_i \\ \bar{y} = \dfrac{1}{n}\sum_{i=1}^{n} y_i \end{cases} \tag{9}$$

The least squares estimation of b_0 and b_1 are represented by $\hat{b}_0$ and $\hat{b}_1$, and the calculation of $\hat{b}_0$ and $\hat{b}_1$ is shown in Eq. (10):

$$\begin{cases} \hat{b}_0 = \bar{y} - \hat{b}_1 \bar{x} \\ \hat{b}_1 = \dfrac{\sum_{i=1}^{n}(x_i - \bar{x}) y_i}{\sum_{i=1}^{n}(x_i - \bar{x})^2} \end{cases} \tag{10}$$

Research makes the hypothesis shown in Eq. (11):

$$|\theta - \bar{x}| \le 3\sqrt{\frac{\sum_{i=1}^{n}(x_i - \bar{x})^2}{n-1}} \tag{11}$$

According to Eq. (11), it is assumed that as n approaches infinity, $\dfrac{\sum_{i=1}^{n}(x_i - \bar{x})^2}{n-1}$ also tends to a constant. At this point, the information domain is introduced, as shown in Eq. (12):

$$\Omega_{1B_n} = \left\{\theta : |\theta - x| \le B_n\right\} \tag{12}$$

In Eq. (12), $B_n = o\left(\sqrt{n}\right)$.

B. Confidence Interval Correction and Parameter Interval Estimation of Linear Correction Model

After establishing the linear correction model, it is necessary to revise its confidence interval and estimate the parameter interval. When performing confidence interval correction on a linear calibration model, it is necessary to first provide the generalized confidence interval of the linear calibration model. For the data in the linear correction model, it is necessary to first calculate statistics such as $\bar{y}_i$, $\bar{x}$, S_{xx}, and S_i^2, and use the least squares method to estimate $\hat{a}_i$ and $\hat{b}_i$. Based on the properties of the model, Eq. (13) can be obtained [23]:

$$\begin{cases} y_{io} - \bar{y}_t : N\left(b_i(\theta - \bar{\bar{x}}), (1 + \frac{1}{n})\sigma_i^2\right) \\ \hat{b} : N_k\left(b, \frac{\Sigma}{S_{xx}}\right), \frac{s_i^2}{\sigma_i^2} : x^2(n-2) \end{cases} \tag{13}$$

By using variable transformation, and $b_1 = b\sqrt{S_{xx}}$, $\theta_1 = \dfrac{(\theta - \bar{x})}{\sqrt{\left(1 + \frac{1}{n}\right)S_{xx}}}$ can obtain Eq. (14),

$$\begin{cases} \hat{b}\sqrt{S_{xx}}^{d} = \gamma + BE_1 \\ \dfrac{Y_0 - \bar{Y}}{\sqrt{1+\dfrac{1}{n}}}^{d} = \gamma\theta_1 + BE_2 \\ L = BE_3 \end{cases} \quad (14)$$

In Eq. (14), γ represents the disliked parameter in generalized p-value calculation, and the elements in $E_1, E_2 : N_k(0, I_k)$ and E_3 satisfy the conditions shown in Eq. (15):

$$e_{ii}^2 : x^2(n-2) \quad (15)$$

All elements in E_3 are independent of each other, and based on this, a generalized pivot quantity $R(Y; y, \theta_1, b_1, \Sigma)$ can be constructed. The construction steps of the generalized pivot quantity are shown in Fig. 3 [24].

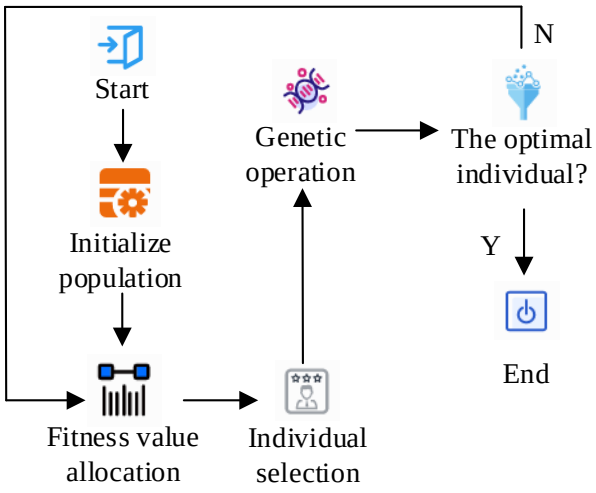

Fig. 3. Construction steps of generalized pivot quantity.

After constructing the generalized pivot quantity, the generalized confidence interval of the model can be determined. It assumes that $\hat{R}_L$ and $\hat{R}_U$ are the $100\dfrac{a}{2}\%$ quantile and $100\left(1-\dfrac{a}{2}\right)\%$ quantile of the generalized pivot distribution, respectively, then Eq. (16) can be obtained:

$$P(\hat{R}_L < R(Y; y, \theta_1, b_1, \sum) < \hat{R}_U) = 1 - a \quad (16)$$

According to Eq. (16), $G(Y) = \left(\hat{R}_L, \hat{R}_U\right)$ is the $100(1-a)$ generalized confidence interval of the interest parameter θ. Monte Carlo simulation is a computational method based on probability and statistics theory, also known as statistical simulation method. Its core is to use a large number of random numbers for simulation experiments, and the generalized confidence interval of the interest parameter θ can be obtained using this method. $\bar{x}_1$, $\bar{y}_1$, and I_s are calculated for a given set of data $(x_1, x_2, \cdots, x_n)$ and $y = (y_1, y_2, \cdots, y_n, y_0)$. For $i = 1, 2, \cdots, k$, Eq. (17) can be generated:

$$E_1 \sim N_k(0, I_k), E_{2j} \sim N_k(0, I_k), e_{jj}^2 \sim \chi^2(n-2) \quad (17)$$

By calculating the generalized pivot quantity, the generalized confidence interval of θ_1 can be obtained. The modified generalized confidence interval is shown in Eq. (18):

$$CG(Y) = \left(\max\left\{\hat{R}_L, \bar{x} - B_n\right\} \min\left\{\hat{R}_U, \bar{x} - B_n\right\}\right) \quad (18)$$

In Eq. (18), B_n represents information domain related parameters that satisfy $|\theta - \bar{x}| \le B_n$'s adjustable correction interval for values. In summary, when obtaining the generalized confidence interval of a linear correction model and correcting it, the relevant statistics and parameter estimates are first calculated based on the model data, and the generalized pivot quantity is constructed through variable transformation. Due to the difficulty in obtaining its distribution, Monte Carlo simulation is used to determine the generalized confidence interval by generating random numbers for a specific distribution multiple times. To optimize the performance of the confidence interval, the information domain is introduced for correction. The modified generalized confidence interval is obtained by taking the maximum value of the range related to the original generalized confidence interval and the information domain. After obtaining and correcting the generalized confidence interval, it is necessary to modify the post confidence interval of the linear correction model. The determination of prior distribution requires the use of Fisher information matrix to obtain the Jeffreys priors of a, b, and $\overset{-1}{\Sigma}$ in the univariate linear correction model with joint independent information, as shown in Eq. (19):

$$\pi(\alpha, \beta, \overset{-1}{\sum}) \propto |\overset{-1}{\sum}|^{\frac{1}{2}} \quad (19)$$

Based on the linear correction model, an expression for the prior distribution is derived, which in turn leads to the posterior distribution of a given b and σ_i, and the posterior distribution of b 's and σ_i^{-1} given σ_i^{-1}. On this basis, the posterior predictive distribution of $Y_i^{rep}\left(i = 1, 2, \cdots, n+1\right)$ is obtained. When b and Σ are known, the least squares estimation of the interest parameter θ can be obtained. When θ and Σ are unknown, the corresponding estimation values are introduced to $\hat{\theta}$, and a generalized pivot quantity is constructed. Due to the difficulty in obtaining the distribution of pivot quantities, numerical Monte Carlo simulations are used to obtain the confidence interval for $\hat{\theta}$. Its confidence interval is adjusted based on the information domain. When constructing a posterior prediction distribution, it is necessary to use the Fisher information matrix to determine the prior of the relevant parameters. Parameter posterior prediction distribution is derived based on prior knowledge. Then, based on b and whether it is known or not, an estimated value of interest parameter b is obtained and a pivot quantity is constructed. The confidence interval of interest

parameter θ is obtained through Monte Carlo simulation. Finally, to optimize the confidence interval, the information domain is used for correction, resulting in a more reasonable posterior prediction interval and improving the accuracy and reliability of estimating the interest parameter θ. The study uses numerical simulation methods to validate the interval estimation method of the linear correction model, as shown in Fig. 4.

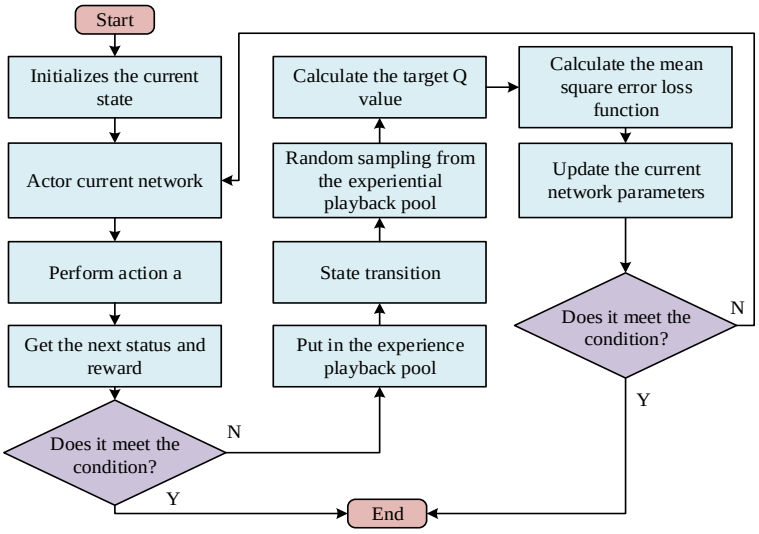

Fig. 4. Numerical simulation validation steps for interval estimation.

In Fig. 4, the numerical simulation operation steps can be divided into three parts. Firstly, the simulation setting is carried out using Monte Carlo simulation method, with 2500 × 5000 cycles. The explanatory variables are set to have a mean of 0.5 and a variance of 1. From this distribution, specific values are selected for different sample sizes and other model parameters are determined. Next is to determine the value of θ_1. Finally, there is simulation calculation, which calculates the coverage probability and interval length of each confidence interval to evaluate its goodness.

IV. RESULTS

When verifying the feasibility of the interval estimation method for the linear correction model designed in the study, the Monte Carlo simulation method was used. This method is a numerical calculation method based on probability and statistics theory. Its core idea is to simulate various uncertain factors using random numbers through a large number of random experiments, and then solve problems in fields such as mathematics, physics, and engineering. This method requires determining a probability model or stochastic process related to the problem, so that the problem to be solved can be represented by certain statistical features of this model. Next, computer-generated random numbers conforming to a particular distribution were used to simulate multiple repeated trials of that probabilistic model or stochastic process. Finally, an approximate solution to the problem was obtained by statistically analyzing the results of these simulations. The values of the explanatory variables for the numerical simulation setup of the study are shown in Table I.

In Table I, the study set up three different sets of data, with the first set consisting of 10 data points, the second set consisting of 20 data points, and the third set consisting of 30 data points. The highest x value for the first set of data was 2.3, and the lowest was -0.6. The second set of data had a maximum x value of 1.5 and a minimum x value of -2.3. The highest x value for the third set of data was 2.6, and the lowest was -1.4. In the numerical simulation process, let k be 3, intercept a be (1, 1, 1), and Σ be diagonal matrices with diagonals of 1, 2, and 3, respectively. The numerical simulation results of the first set of data are shown in Table II.

TABLE II. RESULTS OF THE NUMERICAL SIMULATIONS OF THE FIRST SET OF DATA

n	θ	b_1 (1,2,3)	b_1 (2,1,5)	b_1 (3,4,10)	Method
10	1	0.892	0.924	0.946	Generalized confidence intervals and corrections
		0.931	0.944	0.942	Confidence interval and correction of posterior prediction method
	0.5	0.952	0.945	0.932	Generalized confidence intervals and corrections
		0.944	0.942	0.956	Confidence interval and correction of posterior prediction method
	0	0.974	0.964	0.944	Generalized confidence intervals and corrections
		0.941	0.948	0.943	Confidence interval and correction of posterior prediction method
	-0.5	0.935	0.942	0.946	Generalized confidence intervals and corrections
		0.933	0.953	0.948	Confidence interval and correction of posterior prediction method
	-1	0.883	0.921	0.934	Generalized confidence intervals and corrections
		0.924	0.946	0.942	Confidence interval and correction of posterior prediction method

As shown in Table II, after correction, its confidence interval was more in line with the requirements. When b_1 was (1, 2, 3) and b_1 was -1, the confidence interval coverage probability of the posterior prediction method was 0.924, while the generalized confidence interval was only 0.883. The confidence intervals of the posterior prediction method were closer, and as b_1 increased, the confidence intervals of both methods gradually approached 0.95. When b_1 was (1, 2, 3), taking different values resulted in significant fluctuations in the coverage probability of the generalized confidence interval; When b_1 was (3, 4, 10), the coverage probability was relatively closer to 95%. Overall, in terms of sample size, confidence intervals based on posterior prediction distributions outperformed generalized confidence intervals in terms of coverage probability. The numerical simulation results of the second set of data are shown in Table III.

Table III shows the coverage probabilities of different confidence intervals in the linear correction model. This table compares the coverage probabilities of generalized confidence intervals and corrections, based on posterior prediction methods at different values. When b_1 was (1, 2, 3) and θ was 1, the confidence interval coverage probability of the posterior prediction method was 0.916, while the generalized confidence interval was 0.896. Meanwhile, the coverage probability of the generalized confidence interval might differ significantly from 95% in some cases, but as it increased, its coverage probability gradually approached 95%. For example, when b_1 was (3, 4, 10), the coverage probability of the generalized confidence interval was closer to 95% for each value. In addition, as the sample size increased from 10 to 20, the coverage probabilities of both confidence intervals became closer to 95%. This indicated that when the sample size was 20, the confidence interval of the posterior prediction distribution performed better in terms of coverage probability, and an increase in sample size helped to improve the accuracy of the confidence interval coverage probability. The numerical simulation results of the third set of data are shown in Table IV.

TABLE III. RESULTS OF THE NUMERICAL SIMULATIONS OF THE SECOND SET OF DATA

n	θ	b_1 (1,2,3)	b_1 (2,1,5)	b_1 (3,4,10)	Method

		0.924	0.943	0.941	Confidence interval and correction of posterior prediction method

TABLE V. COMPARATIVE ANALYSIS OF LINEAR CORRECTION MODELS

Method	Applicable scenarios	Computing efficiency	Confidence interval coverage (sample size=30)
Traditional Fiducial inference	Low dimensional data, large sample size	Medium	0.898
Bayesian calibration model	Small sample, stable data structure	Low	0.912
Generalized linear model	Medium-dimensional data	High	0.885
Dynamic linear correction model	Real time data stream	High	0.902
This method	High dimensional data, small sample size	High	0.927

According to Table IV, after correction using the posterior prediction method, the confidence interval was closer to 0.95 and the coverage level was better. The confidence interval coverage probability of the posterior prediction method was 0.927, while the generalized confidence interval was 0.898. The coverage probability of the generalized confidence interval might deviate significantly from 95%, but as it increased, its coverage probability approached 95%. For example, when b_1 was (1, 2, 3), the generalized confidence interval coverage probability fluctuated significantly. b_1 had a relatively stable coverage probability of (3, 4, 10) and was closer to 95%. As the sample size increased from 10 and 20 to 30, the coverage probability of both confidence intervals approached 95%, indicating that increasing the sample size can improve the performance of coverage probability. Overall, when the sample size was 30, the confidence interval based on posterior prediction distribution performed better in terms of coverage probability. The study further compared the performance of the research-designed method with other current methods, and the results are shown in Table V.

The research-designed model achieved a coverage rate of 0.927 at a sample size of 30, significantly better than traditional Fiducial methods and generalized linear models, highlighting its superiority in small sample scenarios. Although Bayesian methods performed moderately, they relied on prior distributions and had limited flexibility. Integrating Fiducial inference (reverse parameter analysis) with Bayesian posterior prediction reduced redundant iterations and achieved efficiency comparable to GLM while maintaining high accuracy.

V. DISCUSSION

A. The Significance of Research Results

The joint independent information linear correction model proposed in the study significantly improved the accuracy and efficiency of statistical inference in high-dimensional data and small sample scenarios by integrating Fiducial inference and Bayesian methods. Simulation experiments showed that when the sample size was 30, the confidence interval coverage of the posterior prediction method reached 0.927, approaching the theoretical 95% confidence level, which has significant advantages over traditional Fiducial methods and generalized linear models. This result validated the effectiveness of the model in reducing coverage bias and enhancing the robustness of parameter estimation. Especially in high-dimensional noise covariance and dynamic data stream scenarios, the model achieved adaptive adjustment of complex data structures through information domain dynamic correction mechanism.

B. Comparative Advantages with Existing Methods

Compared with traditional methods, the innovation of research-designed model mainly lies in their high-dimensional adaptability: although existing methods support real-time data streams, their ability to handle high-dimensional noise covariance is limited. This study significantly improved computational stability in high-dimensional environments by integrating multi-source data features through a joint independent information framework. Dynamic correction capability: The information domain dynamic correction mechanism integrates background knowledge and data features to solve the limitations of traditional Bayesian methods that rely

on fixed prior distributions, demonstrating stronger scene adaptability in industrial manufacturing multi-sensor systems. Balancing efficiency and accuracy: Fiducial's reverse parameter distribution analysis reduces the iterative redundancy of Bayesian posterior prediction, allowing the model to maintain high coverage while maintaining computational efficiency comparable to generalized linear models, making it suitable for resource constrained real-time systems.

C. Actual Application Potential

The research-designed method has broad application prospects in medical image analysis, environmental monitoring, and industrial Internet of Things. In the medical field, B1 non-uniformity correction of MRI signals can be combined with dynamic correction in the information domain to improve image signal-to-noise ratio. In the field of environmental monitoring, in the fusion of multi-source precipitation data, the model can dynamically integrate meteorological station and satellite data to reduce systematic bias. In the field of industrial Internet of Things, dynamic calibration of real-time sensor data streams can optimize manufacturing process monitoring and reduce equipment anomaly false alarm rates.

VI. Conclusion

The study successfully improved the accuracy and reliability of statistical inference by constructing a linear correction model based on joint independent information and combining it with Fiducial inference method. The research results indicated that the confidence interval correction method designed in the study had better performance, especially in small sample situations, where the confidence interval coverage probability of the posterior prediction method was closer to the 95% confidence level. The specific data showed that when the sample size was 10, the confidence interval coverage probability of the posterior prediction method was 0.923, while the generalized confidence interval was 0.889. When the sample size increased to 30, the confidence interval coverage probability of the posterior prediction method was 0.927, and the generalized confidence interval was 0.898. In addition, as the sample size increased, the coverage probabilities of both confidence intervals were closer to 95%, indicating that an increase in sample size helps to improve the accuracy of the confidence intervals. The study also found that in some cases, the generalized confidence interval had a large deviation between the coverage probability and 95%, but as the sample size increased, its coverage probability gradually approached 95%. For example, when the sample size was 30, the fluctuation of the coverage probability of the generalized confidence interval was significantly reduced, and the coverage probability was relatively stable and closer to 95%. This indicated that confidence intervals based on posterior prediction distributions performed better in larger sample sizes. The study validated the effectiveness and stability of a linear correction model based on joint independent information in processing high-dimensional data through numerical simulations. The research results provide new theoretical support and methodological improvements for linear correction models in high-dimensional data environments, and have important theoretical and practical value. However, the statistical inference correction model designed for research cannot meet the requirements for model inference correction when dealing with multivariate problems. Future research will focus on highly coupled multivariate data and propose to introduce tensor decomposition techniques and graph model structures to address the problem of insufficient representation of complex correlation structures in current models by characterizing the nonlinear relationships and topological dependencies between variables. At the same time, for large-scale data, it plans to combine distributed computing architecture and hardware acceleration technology to design layered iterative algorithms to reduce memory usage. Low-level approximations and sparse representations of model parameters are also explored to compress computational complexity while ensuring statistical performance.

Fine-Tuning Arabic and Multilingual BERT Models for Crime Classification to Support Law Enforcement and Crime Prevention

Njood K. Al-harbi, Manal Alghieth
Department of Information Technology-College of Computer, Qassim University, Buraydah, Saudi Arabia

***Abstract*—Safety and security are essential to social stability since their absence disrupts economic, social, and political structures and weakens basic human needs. A secure environment promotes development, social cohesion, and well-being, making national resilience and advancement crucial. Law enforcement struggles with rising crime, population density, and technology. Time and effort are required to analyze and utilize data. This study employs AI to classify Arabic text to detect criminal activity. Recent transformer methods, such as Bidirectional Encoder Representation Form Transformer (BERT) models, have shown promise in NLP applications, including text classification. Applying these models to crime prevention motivates significant insights. They are effective because of their unique architecture, especially their capacity to handle text in both left and right contexts after pre-training on massive data. The limited number of crime field studies that employ the BERT transformer and the limited availability of Arabic crime datasets are the primary concerns with the previous studies. This study creates its own X (previously Twitter) dataset. Next, the tweets will be pre-processed, data imbalance addressed, and BERT-based models fine-tuned using six Arabic BERT models and three multilingual models to classify criminal tweets and assess optimal variation. Findings demonstrate that Arabic models are more effective than multilingual models. MARBERT, the best Arabic model, surpasses the outcomes of previous studies by achieving an accuracy and F1-score of 93%. However, mBERT is the best multilingual model with an F1-score and accuracy of 89%. This emphasizes the efficacy of MARBERT in the classification of Arabic criminal text and illustrates its potential to assist in the prevention of crime and the defense of national security.**

I. Introduction

Safety and security are essential pillars of a stable and functioning society, serving as fundamental prerequisites for meeting basic human needs. In their absence, individuals and communities face significant challenges in achieving personal and collective goals. A secure environment fosters social cohesion, economic development, and overall well-being, enabling societies to progress and thrive. Presently, as mobile data technology advances and social media users gain easier access to the internet, the volume of crime-related data that requires analysis increases proportionally. Much of this information is unorganized and presented as free text. Consequently, approaches are developed to manage unstructured data [1]. In the rapidly growing field of mobile technology, social media platforms have gained huge popularity as a preferred means of communication for exchanging private messages and sharing thoughts, videos, and images. Furthermore, it has the potential to serve as a reliable and comprehensive platform for global news coverage including both political and social aspects. Numerous social media networks, such as X, Facebook, Instagram, and Snapchat, are currently in use. X is a popular application as a means of sharing informal messages, and thoughts, as well as facilitating the transmission of political news as approved by [2], X is the most common platform for sharing political activities by 43% [2]. This platform is widely utilized by a significant number of individuals globally, including Arab nations. This renders it a suitable platform for use in the present research, which aims to examine Arabic tweets on the X platform to analyze criminal activities and develop an appropriate solution for the detection of crime. Consequently, this contributes to the prevention of crime and the enhancement of law enforcement within the nation.

Law enforcement faces significant challenges mostly associated with the rise of crime-related data, due to increased crime rates, population density, and technological advancements. The analysis and utilization of the data require an extensive amount of effort and time. Text classification is a crucial task in NLP across several applications, including topic classification, question answering, and sentiment analysis, which is of most popular use [3], to achieve the state-of-the-art result in our text classification of crimes, we will use BERT-based models, a Transformer model that was widely used recently. The BERT framework was introduced through two steps: pre-training and fine-tuning. Initially, during pre-training, the model was trained on unlabeled data across various tasks. Subsequently, in the fine-tuning step, the BERT model was initialized with the pre-trained parameters, and it was then refined using labeled data for downstream tasks. BERT large and base are introduced in the original BERT paper. Each version supports cased and uncased text. The training uses only raw English text for labeling without human intervention [4]. BERT has been developed to accommodate several languages, including multilingual BERT (mBERT) [4], XLM-RoBERTa (XLM-R) [5], and DistilBERT [6]. Some of these versions are specifically designed for distinct languages, such as AraBERT [7], MARBERT, ARBERT [8], and ArabicBERT for Arabic. This research will collect a new dataset from the X platforms.

The dataset will be labeled and prepared for the model, and it will be used to fine-tune various Arabic BERT-based models and multiple support BERT-based models to identify the optimal model.

AI has transformed a variety of industries, including law enforcement. NLP has been increasingly employed in the context of predictive policing and criminal detection. Several studies have investigated the NLP in ML and DL methods for the analysis of criminal reports and social media texts.

Despite advancements, current research still faces challenges in collecting large amounts of sensitive data from law enforcement agencies, identifying patterns in various languages, and ensuring ethical considerations, such as bias in predictions due to unbalanced data. Additionally, numerous law enforcement agencies continue to depend on traditional criminal detection methods, which restrict the potential of AI-driven approaches. Considering these problems, it is essential to enhance crime detection and NLP tasks via BERT-based models to improve accuracy, efficiency, and fairness in crime prediction. The current research aims to fine-tune different Arabic BERT-based models for crime classification by collecting new Arabic data from the X platform, balancing data, and discussing ethical AI considerations to help law enforcement make data-driven decisions.

The purpose of the proposed solution is to enhance crime prevention and law enforcement in Arabic. The aims and objectives encompass:

- Aims:
  - Develop an effective technique for crime classification by comprehensive analysis of Arabic language texts from social media platforms.
  - Enhance crime prevention and law enforcement in Arabic by the application of NLP leveraging transformer techniques.
- Objectives:
  - Analyze previous Arabic studies to identify the most appropriate methodology and determine the research gap.
  - Based on the analysis, gather the Arabic data from the X platform and prepare it to be applied to the chosen technique.
  - Design the proposed solution utilizing the selected technique, which is the BERT transformer.
  - Implement and evaluate the reliability of results to enable seamless integration with legal standards.

According to the aims and objectives, the main research questions are as follows: Q1: Can AI discover and assist in classifying crimes in Arabic textual data? Q2: Can transformer BERT improve the effectiveness of Arabic crime classification based on pre-existing models? Q3: Can the Arabic language be identified despite its difficulties?

The research focuses on crime and law enforcement in Arabic tweets collected from the X platform, aiming to categorize Arabic criminal text, utilizing Arabic and multilingual BERT-based models to assess optimal performance. Hence, this research can be leveraged by the Ministry of Interior or the public prosecution.

The subsequent sections of the study are organized as follows: Section II provide background information about the model. Section III provides an overview of the related work. Section IV outlines the methodologies and materials employed for experiments. Section V presents the result and Section VI presents the discussion of the research. And finally, Section VII presents the conclusion and outlines recommendations for future research.

II. BACKGROUND

Large language models (LLMs), which are models designed to comprehend and produce text at the level of the human language, are constructed using a massive amount of data for training. The term "large" denotes an LLM with a huge number of parameters. LLMs are utilized in a variety of contexts and possess immersive capabilities within NLP tasks: 1) Natural language understanding (NLU), including sentiment analysis and text classification. 2) Generation of texts, including chatbots and question-and-answer systems. LLMs are built based on DL architectures like transformers, allowing them to learn from and process vast amounts of data. BERT is incorporated into LLM models, and both play a significant role in NLP tasks involving sequential text understanding and improvement [9].

BERT is a pre-trained language model (PLM) based on transformer architecture. The transformer architecture incorporates an attention mechanism that acquires learning of the contextual relationships among words and sub-words inside the given text. It consists of two separate mechanisms: the encoder and the decoder. The encoder is responsible for processing the textual input, while the decoder generates the output for the task.

BERT is an abbreviation for bidirectional encoder representation built around the transformer architecture. In 2018, researchers affiliated with Google AI authored twelve publications, which showcases promising outcomes in NLP tasks including text classification. It is a framework that was introduced through two steps: pre-training and fine-tuning. Initially, during pre-training, the model was trained on unlabeled data across various tasks. Subsequently, in the fine-tuning step, the BERT model was initialized with the pre-trained parameters, and it was then refined using labeled data for downstream tasks. The BERT learning process is illustrated in Fig. 1, with the initial step training on a large amount of text and the subsequent step training on a specific task with a labeled dataset.

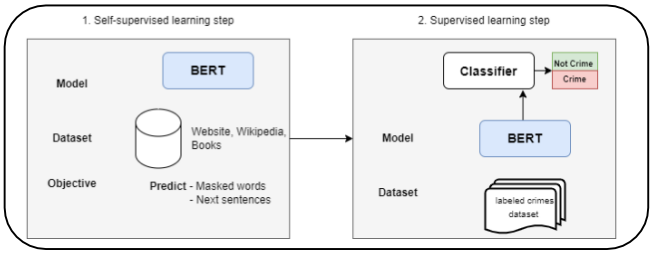

Fig. 1. BERT Learning steps [10].

The BERT model architecture is a multi-layer bidirectional transformer encoder based on the original implementation by the authors [11]. It was introduced in two variations: BERT base (L=12, H=768, A=12, Total Parameters=110M) and BERT large. (L=24, H=1024, A=16, Total Parameters=340 million). L represents the number of layers, H represents the hidden size, and A represents the number of thirteen self-attentions. Each variation supports both cases and uncases input text. The training process exclusively utilizes raw English text without any human involvement in the labeling process [4]. However, there exist several versions of BERT that have been developed to support different languages such as multilingual BERT (mBERT) [4], XLM-RoBERTa (XLM-R) [5], and DistilBERT [6]. Some of these versions are specifically designed for distinct languages, such as AraBERT [7], MARBERT, ARBERT [8], and ArabicBERT for Arabic, bert-base-chinese for Chinese [4], AM-BERT, AM-RoBERTa for Amharic [12], FlauBERT for Frensh [13], and BanglaBERT for Bangla [14].

Furthermore, there are specialized versions of BERT for certain domains, such as ClinicalBERT for the clinical domain [15], LEGAL-BERT for the legal domain [16], and FinBERT for the financial domain [17].

Self-Attention Mechanism is one of the most critical concepts in BERT. It is regarded as a unique form of attention that was initially introduced with the transformer model, which is an attention mechanism that calculates the contextual representation from each sequence by linking distinct elements in a single sequence. Single self-attention is illustrated in Fig. 2, which displays the word "it" in each sentence. Another mechanism is multi-head attention. The link will be linearly projected multiple times with various learned linear projections rather than a single link. This will allow for the joint attention of information from multiple representation subspaces at different positions.

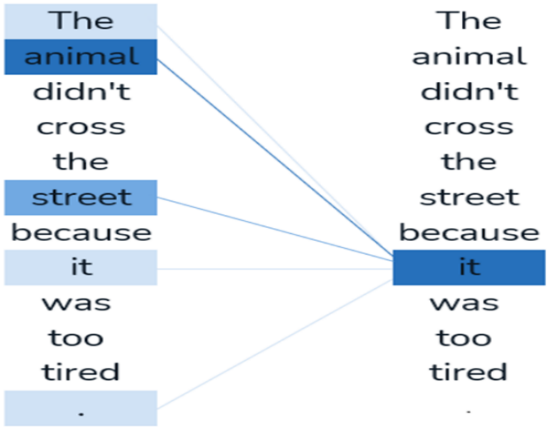

Fig. 2. Single self-attention mechanism [11].

As indicated in the definition of BERT, it is a model consisting of multiple stacked encoder layers. Each layer processes the input using multi-head self-attention and feed-forward network (FFN) layers to capture contextual information. Multi-head self-attention is dependent on three critical components: Query (Q), Key (K), and Value (V), which are linear transformations of the data input, as illustrated in Eq.(1):

$$MultiHead(Q,K,V) = Concat(head_1,\dots,head_h)W^O$$

$$where\ head_i = Attention\left(QW_i^Q, KW_i^K, VW_i^V\right)$$

$$Where\ the\ projections\ are\ parameter\ matrices\ W_i^Q \in \mathbb{R}^{d_{model}\times d_k}, W_i^K \in \mathbb{R}^{d_{model}\times d_k}, W_i^V\ \mathbb{R}^{d_{model}\times d_v}\ and\ W^O \in \mathbb{R}^{hd_v\times d_{model}}. \quad (1)$$

The output of the attention block is fed to the Feed-Forward network (FNN) following the multi-head self-attention mechanism. The position-wise fully connected FFN is applied to each location individually and identically, including two linear transformations. The subsequent Eq. (2) demonstrates that:

$$FFN(x) = max(0, xW_1 + b_1)W_2 + b_2 \quad (2)$$

In BERT, the FFN employs the GELU activation function rather than ReLU, and it is specified, as indicated in Eq. (3).

$$GELU(x) = 0.5x\left(1 + tanh\left(\sqrt{2/\Pi}(x + 0.044715x^3)\right)\right) \quad (3)$$

A residual connection is implemented around each of the two sublayers by the encoder layer in BERT. The normalization layer follows, with the output of each sublayer defined as in Eq. (4) and Sublayer(x) representing the function implemented by the sublayer.

$$LayerNorm(x + Sublayer(x)) \quad (4)$$

The sublayers will generate outputs that are equivalent in size to *dmodel* to facilitate residual connections. Fig. 3 illustrates the architecture of the BERT base and BERT large alongside the configuration of a single encoder.

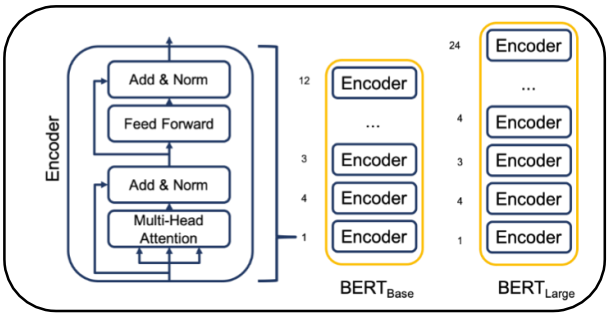

Fig. 3. Single BERT architecture with single encoder configuration [10].

The process and encoding of raw text in a format that is comprehensible and conducive to learning is referred to as input representation in BERT. It is a structured combination of three primary components: token, segment, and position embeddings [4].

- Token embedding is the first step in BERT when text is transformed into tokens through a tokenizer. The tokenizer divides the text into smaller chunks known as tokens (words or subwords). Each token is associated with a vector (embedding) using a pre-trained embedding matrix. BERT employs WordPiece embedding, which comprises a vocabulary of 30,000 and sixteen tokens. A special classification token [CLS] is included as the initial token in each sentence. The second special token is [SEP], which has two purposes: first, to

separate two sentences, and second, to denote the end of a sentence. The third special token is [PAD], which denotes empty tokens. When sentences are shorter than the predetermined fixed max length, the remaining tokens will be filled with padding tokens.

- Segment embedding is employed to manage pairs of sentences, namely sentences A and B. Each token will be assigned a segment ID of either 0 or 1 to denote its corresponding sentence. Assist in distinguishing between the two segments of the input sequences, as all tokens in sentence A are assigned an ID of 0, whereas sentence B is assigned an ID of 1. It is useful in question-answering tasks and sentence classification.
- Position embeddings represent token positions in the sequence of the input. These embeddings happen through pre-training. The final input representation combines each token's position embedding with the token and segment embeddings. The input representation in Fig. 4 is the sum of the embeddings for tokens, segments, and positions.

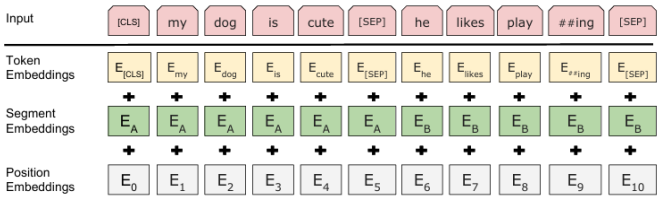

Fig. 4. Input representation for BERT [4].

BERT is pre-trained using two objectives: the Masked Language Model (MLM) and the Next Sentence Prediction (NSP) in conjunction. MLM is the process of randomly masking some words in input data. The goal is to estimate the original vocabulary of the masked words by considering the context provided by the unmasked words. MLM reads the sentence bidirectionally, both from left to right and from right to left, allowing the model to gain a comprehensive understanding of the language context. That's contrasted to other pre-trained language models that only read unidirectionally from left to right or from right to left [10].The NSP involves feeding the model two sentences and asking it to determine whether the second sentence in the pair is the subsequent sentence to the first. This method facilitates the comprehension of the relationships between sentences, and it is a crucial capability in NLP tasks such as summarization, question answering, and text classification. Fig. 5 shows the Comprehensive BERT pre-training and fine-tuning [10].

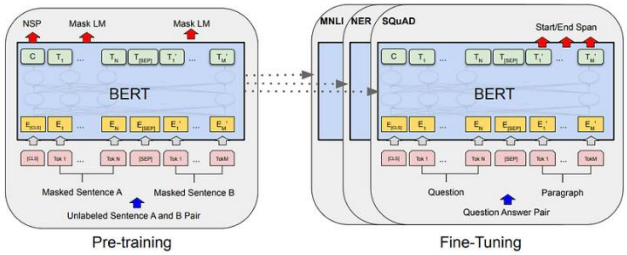

Fig. 5. Input representation for BERT [4].

III. Related Work

A systematic review was conducted for BERT to collect studies that focused on low-resource languages, particularly Arabic, for criminal classification. The studies that were compiled are detailed in the subsequent sections.

A. Description of the Model and Classification

Low-resource languages are those that possess a limited number of resources and require further exploration, such as Urdu, Arabic, and Estonian. High-resource languages are those that possess substantial support and resources, such as English, Chinese, Japanese, and Spanish.

This section provides comprehensive information on the model used in each study, including the year of publication (in chronological order), the model's name, the languages supported, the classification task, and the data type, as demonstrated in Table I for the low-resource languages.

The models employed in low-resource languages primarily include mBERT, with eleven studies supporting various languages. AraBERT is utilized in four studies, exclusively supporting language. Distlm-BERT is utilized in three studies, encompassing 104 languages. XLM-RoBERTa is utilized in two studies, encompassing 100 languages. Additionally, there is a single study for each of the following models.

MarBERT, which is specifically designed for the Arabic language. Bangla-BERT which was particularly designed for the Bengali language. The XLM-100 is designed to provide support for 100 languages. The classification task varies depending on the content of the data, although all fall under the umbrella of illegal actions in broad terms. The data mostly consists of social media posts and text, with additional kinds including court or tribunal documents and newsgroup data.

B. Description of the Dataset

This section offers a thorough overview of the entire dataset process, encompassing details such as the language of the data, data source (whether it is available online or newly collected), number of categories (binary or multi), types of data categories (including various crime types), dataset size, labeling method (manual or pre-annotated), whether the dataset is balanced or not, the technique employed if the dataset is not balanced, the size of the dataset after balancing, and finally, the specifics of data splitting. All the details are outlined in Table II. The majority of the dataset languages belong to Arabic, accounting for 38.46% (five studies). Bengali follows with a rate of 23.08% (three studies), and then Hindi with a rate of 15.38% (two studies) while the remaining languages, including Estonian, Italian, Greek, Polish, and Urdu for Pakistan, each have a rate of 7.69% (one study) for each. Certain datasets are obtained from Kaggle, while others are not accessible online. The number of categories varies, with some being binary and others being multi categorical (ranging from three to eleven categories). Additionally, the size of the data varies. Among these, the smallest dataset consists of 1,670 entries, while the largest datasets contain millions of entries. However, the small datasets are labeled manually, whereas the largest dataset is pre-annotated. Out of the total of thirteen datasets, 53.84% of them are unbalanced. Among these unbalanced datasets, 46% (six datasets) do not employ any technique to balance the data, while

just one study 7.69% (one dataset) makes use of the over and under sampling technique. Out of the total number of datasets, which is two, are balanced, and the remaining four datasets are balanced and not balanced using a different dataset. When splitting the dataset 38.46% of the studies employed the method of train, test, and validation splitting. 30.76% of the studies employ train and test splitting, while the remaining studies do not disclose the splitting details. When employing the three splitting techniques, the splitting percentages are as follows: for training, 80%, and 70%; for testing 20%, and 10%; and for validation 10%. If the two splitting techniques are applied (train 90%, 80%, and test 20%, 10%).

TABLE I. DESCRIPTION OF THE MODEL AND CLASSIFICATION FOR LOW-RESOURCE LANGUAGES

Article	Model Name	Supported Language	Classification Task	Type of Data
[18]	mBERT (uncased)	104	Domain classification	Documents
[19]	AraBERT base	Arabic	Detecting offensive language	Social media Tweets
[20]	mBERT(cased), XLM-100 (cased), Distilm-BERT (cased), XLM-R base	104 100 104 100	Text classification	Paragraphs
[21]	AraBERT base mBERT	Arabic 104	Detecting offensive language	Social media Tweets
[22]	mBERT	104	hate speech classification	Social media Tweets
[23]	mBERT	104	Racist and xenophobic hate speech classification	Social media texts

C. Model Evaluation

In this section, the evaluation of a model is initially determined by the type of evaluation metrics employed in each study. Secondly, in their publication, do they include a comparison with other ML, DL, or Transformer-based models? Thirdly, comparison with prior studies, and finally, the most robust result. These are detailed in Table III. As the table below demonstrates, the primary evaluation metric is the F1 score, which is utilized in 77% of the studies. The precision and recall metrics are the second most used, with a rate of 54%. The accuracy metric is the third most used, appearing in 46% of studies. Other metrics include micro F1 scores, weighted F1 score (WF), and macro F1 scores. When it comes to evaluating comparisons in studies, 84.61% (eleven studies) do not provide comparisons with previous studies, whereas 15.38% (two studies) do include comparisons. When it comes to comparing with their study, 76.92% of studies compare, whereas 23.07% do not.

TABLE III. MODEL EVALUATION FOR LOW-RESOURCE LANGUAGES

Article	Evaluation Metrics	Compare the Result with Other Models in Their Paper or not	Compare the Result with Previous Studies or not	Best Result
[18]	Precision, Recall, F1 score, Accuracy	Yes, ELECTRA	No	ELECTRA gets the best accuracy in all datasets
[19]	Macro-F1 score	No	No	AraBERT achieved 90%
[20]	Accuracy	Yes, fastText	No	XLM-RoBERTa achieved the highest & DistilmBERT the lowest
[21]	Precision, Recall, F1 score	Yes, fastText, SVM, Decision Tree, Random Forest, GaussianNB, Perceptron, AdaBoost, Gradient Boosting, Logistic Regression	No	AraBERT achieved the highest F1 score of 83%, while mBERT achieved 76%.
[22]	F1 score	Yes, MUSE + CNN-GRU Translation + BERT LASER + LR mBert	No	mBERT is superior in Arabic with a f1 score of 83% and in Indonesian with a f1 score of 81%. In Polish, the translation with bert is superior with a score of 71%.
[23]	Accuracy and F1-score	No	No	mBERT achieves an accuracy rate of 91% in Italian and 81% in Greek.

[24]	Precision, Recall, F1 score, WF	Yes, 16 traditional & deep neural classifiers	No	CNN is better with a WF of 64%
[25]	Precision, Recall, F1 score, Error, WF	Yes, LR, RF, NB, SVM, CNN, BiLSTM & CNN + BiLSTM	Yes	In WF metrics The 2-class XLM-RoBERTa is the Best In 4 classes Bangla-BERT is the best Outperforms previous studies
[26]	weighted-F1	Yes, MuRIL, M-BERT-Bilstm, MuRIL-Bilstm, and cross-lingual information.	Yes	The best model is cross-lingual information with a rate of 95%
[27]	Precision, Recall, F1 score, Accuracy	Yes, baseline models	No	MarBERTv2 outperforms AraBERT and other baseline models with 84% F1-score and 86% accuracy
[28]	Accuracy and F1-score	Yes, CNN, RNN, bidirectional RNN, ULMFiT, ELMo, SVM & combined models	No	AraBERT has the highest F1 score 93% in Arabic, surpassing models they compared it against, and 91% accuracy.
[29]	Precision, Recall, F1 score, Accuracy	Yes, NB, SVM, LR, RF, CNN, LSTM and BiLSTM	No	mBERT is the most effective model, obtaining an F1 score of 0.83%.
[30]	Precision, Recall, F1 score	No	No	mBERT in Crime classification had 96% Precision and crime type had 98% recall.

D. Model Hyperparameters

This section presents the hyperparameters derived from the author's specifications in each study, comprising the hidden size, learning rate, batch size, epoch number, and model name. Details are outlined in Table IV. The epoch number is a value that falls inside a range, which can be a tiny number (3 to 8), or a medium number (16 to 20). The batch size options are twelve, sixteen, and thirty-two. The learning rates most utilized are 2e-5 and range between 2e-5 and 5e-6. The batch size does not surpass thirty-two, and the number of epochs is moderate.

TABLE IV. MODEL HYPERPARAMETERS FOR LOW-RESOURCE LANGUAGES

Article	Model Name	Epoch Number	Batch Size	Learning Rate	Hidden Size
[18]	mBERT (uncased)	20	16	N/A	768
[19]	AraBERT base	5	32	N/A	
[20]	mBERT(cased), XLM-100 (cased), Distilm-BERT (cased), XLM-R base	(8-16)	N/A	(5e-5, 3e-5, 1e-5, 5e-6, 3e-6)	768 1024 768 768
[21]	mBERT AraBERT base	30	N/A	5e-1	768
[22]	mBERT	(1- 5)	16	(2e-5, 3e-5, 5e-5)	
[23]	mBERT,	3	N/A	3e-5	
[24]	mBERT	3	32	2e-5	
[25]	mBERT (uncased), Distilm-BERT (cased), Bangla-BERT base, XLM-R base	20	12	2e-5	
[26]	mBERT	2	30	2e-5	
[27]	AraBERT base MarBERT	100 with an early stopping patience of 10	N/A	2e-5	
[28]	AraBERT base	5	32	N/A	
[29]	mBERT	3	32	768	
[30]	mBERT	N/A	N/A	N/A	

E. Critical Analysis

In four studies, it was determined that BERT-based Arabic models outperformed other ML and DL models and improved accuracy across various datasets. The initial study [21] in the Arabic language, aimed to identify offensive language through social media tweets. The study's primary contribution is the construction of a dataset comprising 10,000 tweets annotated with experiential annotators. The AraBERT and mBERT models are utilized to identify offensive tweets, and their performance is compared to several ML and DL models. The results indicate that AraBERT outperforms all the ML, DL models, and mBERT, thirty-two achieving an F1-score of 83%. The obstacle is that the sample is unbalanced, and the F1-score improves by employing balancing techniques. Using the same dataset from the authors of study [21], the second study [19] for detecting offensive social media tweets employs the AraBERT. They employ balance techniques that involve over- and undersampling. The results indicated that AraBERT has a 90% F1 score, which is superior to the result of [21]. However, they are not comparable to any of the preceding results or ML and DL models. Their findings suggest that balanced data is beneficial for the precise detection of offensive tweets. A further study [27], employs the same models as the prior study,

AraBERT, and incorporates other Arabic models, namely MarBERT, to identify offensive tweets. The dataset comprises 12,700 imbalanced tweets. In comparison to baseline models, the results indicate that MarBERT outperforms AraBERT and baseline models, achieving an F1-score of 84%. The outcome surpasses that of [21], despite the dataset's imbalance, showing that MarBERT outperforms AraBERT by 1%. However, when addressing the imbalance, the findings of [19], provide a superior performance with a 6% improvement. It is necessary to balance tweets to assess the efficacy of MarBERT in comparison to AraBERT. The last study in the Arabic language [28], was conducted using AraBERT and mBERT to offensive Arabic tweets. The class is binary, and the dataset is pre-annotated with a range of 5,000 to 7,000 entries. The issue at hand is the presence of unbalanced data, which has not been effectively addressed. They compare the ML and DL models but do not compare them to previous studies. The study indicates that AraBERT outperforms the other models, including mBERT with an F1-score of 93%, which is better than all previous Arabic studies. From one perspective, the researchers utilized an English dataset and then translated it into Arabic. This implies that there is currently no existing dataset available in Arabic and therefore, there is a need to generate one. Additionally, evaluate the balance of the data to determine if it affects the findings. On top of that, it is important to note that there is a lack of comparisons with previous studies, which may be due to the limited availability of studies in this thirty-three specific field. This factor should be taken into consideration. An additional consideration is that when balancing the dataset, one must assess the accuracy differences between MarBERT, AraBERT, and other Arabic models.

IV. METHODOLOGY

The Arabic language is considered a morphologically rich language, but it is low in resources compared to high-resource languages such as English. Consequently, the use of Arabic in NLP tasks is challenging. However, the emergence of transformers, such as BERT-based models, has contributed to effective language understanding. The present research will utilize six variants of BERT-based Arabic models and three models that support multiple languages. Arabic models' architecture is derived from the original BERT-based model, which is elaborated upon in detail in the Background section. BERT is a language model that is pre-trained and relies on transformer architecture. It is pre-trained with MLM and NSP objectives concurrently. MLM randomly mask words in incoming data. 15% of N input tokens are substituted. Those tokens are replaced 80% with [MASK], 10% with a random token, and 10% with the original token. The objective is to infer the original vocabulary of the obscured words by analyzing the context supplied by the unmasked ones. The MLM analyzes the sentence from left to right and right to left to understand the linguistic context. This differs from pre-trained language models that read left-to-right or right-to-left [10]. In the NSP, the model is given two sentences and asked to determine if they follow each other. This method improves inter-sentential connection understanding for NLP tasks, including summarization, question answering, and text classification. Fig. 5 shows BERT's extensive pre-training and fine-tuning [10]. The methodology employed in the proposed solution is structured into distinct steps, as shown in the following Fig. 6.

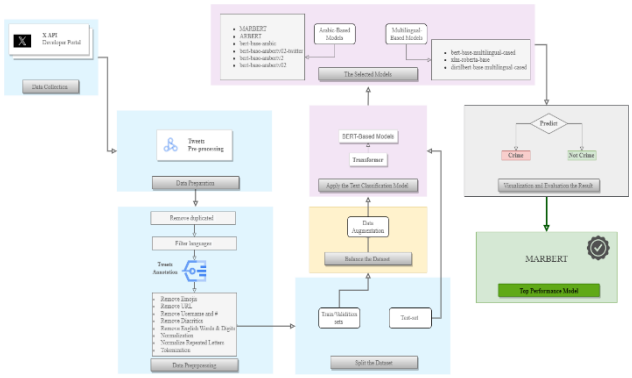

Fig. 6. The Proposed solution.

A. Data Collection Tool

The process of retrieving data using X API (Application Programming Interface), allows programmatic access to X in unique and advanced procedures. Utilizing it to analyze, learn from, and deal with tweets, direct messages, users, and other essential X resources involves the consideration of crime incidents and locations of interest [31]. Upon registration with the X developers and gaining access to the X API by using the Python library (tweetpy) to get access through API access, which enables to develop applications or scripts capable of executing diverse tasks, including: a) Retrieve tweets, users, and additional information from X, b) Post new tweets, retweets, and replies, c) Follow or unfollow users, d) Like or dislike tweets, e) Search for tweets containing specific keywords or hashtags, f) Stream real-time tweets according to specific criteria, and g) Examine tweet data, user profiles, and much more.

B. The Procedure of Searching Keywords and Hashtags

Next, extract tweets that include specific words or hashtags, as indicated in Table V, which presents the selected words and hashtags. Several Arab nations, including Saudi Arabia, Kuwait, Iraq, Jordan, Algeria, Tunisia, and Egypt, identified the most frequently committed offenses, according to the study [32]. The authors categorize crimes into major and minor offenses, which include assault, murder, smuggling, attempted murder, rape, fraud, theft, disturbing the peace, driving offenses, drunkenness, draft dodging, sexual assault, and other categories.

TABLE V. THE PROCEDURE OF SEARCHING KEYWORDS AND HASHTAGS

Keywords in Arabic	تلصص, ابتزاز, ترحيل, طرد, اغتيال, احتجاز, عنف, العنف المنزلي, اعتداء جسدي, تزوير, ,أدوات حادة, تعاطي المخدرات, اغتيال, تحرش هروب, حيازة المخدرات, اختلاس,غسيل الأموال, التخريب,اختطاف
Keywords Translation in English	Domestic Violence, Voyeurism, Blackmail, Deportation, Expulsion, Assassination, Detention, Violence, Sharp Objects, Drug Use, Harassment, Physical Assault, Forgery, Escape, Drug Possession, Embezzlement, Money Laundering, Vandalism, Kidnapping
Hashtags	#فساد, #قتل, #سطو, #مداهمة, #تهريب, #سرقة, #خيانة, #قتلة, #جريمة, #هروب, #سارق, #جرائم, #خونة, #لصوص, #جاسوس, #اغتصاب #اختناق, #طعن, #اضطهاد, #مذبح
Hashtags Translation in English	#Crime, #Murder, #Robbery, #Raid, #Smuggling, #Theft, #Treason, #Killers, #Corruption, #Thieves, #Spy, #Rape, #Traitors, #Crimes, #Escape, #Thief, #Massacre, #Suffocation, #Stabbing, #Persecution,

The retrieved tweets span the period from February 20, 2024, to March 12, 2024, with a total of 3,405 samples encompassing the ID, creation date, text, source, language, name, username, location, verification status, description, and URL. Subsequently, eliminate insignificant, unfilled columns, retain the text and language, and discard the source and location due to their emptiness. The language is retained because, even when specifying Arabic (ar), additional languages such as Urdu (ur), Sindhi (si), Pashto (pas), and Farsi (fa), which share a similar structure, are automatically retrieved.

C. Data Preparation

This part focuses on the pre-processing required to ensure the dataset is clean and suitable for the proposed model and the annotation procedure for categorizing incidents as criminal or non-criminal.

1) Data Pre-processing. Data preprocessing is an important component in NLP tasks, encompassing data cleaning, formatting, and transformation tasks. Moreover, it features engineering and selection. High-quality data is a crucial step in ML and DL, directly impacting the model's performance ability. Preprocessing data is a crucial step that must be undertaken before feeding it into a model or tool [33]. Data cleaning refers to the procedure of eliminating erroneous, corrupted, duplicate, or missing values from a dataset [33]. Pre-processing of the tweets was conducted utilizing NLP tools, employing multiple methods on tweets as shown in Fig. 7.

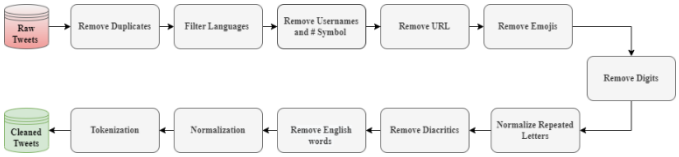

Fig. 7. Data Pre-processing.

The additional preprocessing employed regular expressions (RE), a built-in Python library, to manage string matching and replacements via the re.sub method. Eliminate punctuation including underscores, quotation marks, periods, and commas. Normalize successive identical characters to a single character and standardize letters such as "[إأآا]" to "ا" ,"ؤ" to "ء" ,"ئ" to "ء" ,"ة" to "ه" ,"ي" to "ى" ,"گ" to "ك". Furthermore, eliminate any emojis from tweets, as well as numerals and English letters or sentences. Furthermore, eliminate the URL, hashtag symbol, and mention. Finally, eliminate Arabic diacritics: Tashdid (ّ), Fatha (َ), Tanwin Fath (ً), Damma(ُ), Tanwin Damm(ٌ) , Kasra (ِ), Tanwin Kasr (ٍ), Sukun. Tokenization breaks up the text into discrete words, called tokens, to simplify processing and extract relevant information from tweets.

2) Data annotation. After eliminating irrelevant tweets, each tweet will be assigned a label indicating its association with a crime (0 = not crime, 1 = crime). The labeling procedure is done manually following the authors' guidelines [34] according to the presence of a description of a real crime. In this context, crime is generally defined to encompass reports of experienced or personally observed torture, interrogation, death, assault, psychological violence, military attacks, village damage, looting, and forced displacement. We limit our focus to binary classification, meaning that various acts of crimes were not further subdivided into subcategories.

D. Data Splitting

Splitting the dataset is an essential procedure for the model; during the training process, 80% of the data will be allocated for the training set and 20% for the testing set, while 10% of the training set will be reserved for the validation set.

E. Data Balancing

In this step, data balance is an essential part of developing an accurate model. Imbalanced data, where one class has more samples than the other, can result in biased predictions and suboptimal performance. This section will experiment with the oversampling technique to address the variations in sample sizes between the two classes. The dataset lacks balance. Fig. 8 illustrates the distribution of the training set. Therefore, this issue can be addressed by employing data augmentation approaches that involve solely oversampling the training set while preserving the test data.

Fig. 8. Train set before the balance.

V. Results

Fig. 9 displays the dataset following a balanced oversampling technique that improves the minority label by adding 817 samples, resulting in a total of 1,061 samples for both labels, crime and not crime. This technique utilizes an AraBERT-based augmentation, which employs substitution methods to replace words.

A. The Implementation

The environment employed is the Google colab Pro version. The hyperparameters are chosen based on the experiment and utilize many modules, including sklearn.model_selection. This module employs the ParameterSampler function, which generates random combinations of parameters sampled from specified distributions. The remaining hyperparameters were selected based on various experimental combinations. Table VI displays the Final Hyperparameter selection obtained from the different combinations of codes used during the experiment.

Fig. 9. Train set after the balance.

TABLE VI. FINAL HYPERPARAMETER CONFIGURATION FOR MODEL EVALUATION

Parameter Name	Final Parameter
Drop out	0.5
Learning Rate	3e-5
Number of Epochs	10
Batch size	32
Optimizer	Adam
Validation split	0.1
Weighted decay (L2 regularization)	0.1
Early stop patient parameter	2
Shuffle	True
Padding max length	70
Random seed	34

The model's performance will be evaluated using standard criteria for comparison with previous studies, including accuracy, recall, precision, and F1-score. The criteria are delineated and elucidated in Eq. (5), (6), (7), and (8).

Accuracy is a crucial evaluation statistic that measures the ratio of instances properly identified by the model. It is determined by the calculation outlined in Eq. (5):

$$\text{Accuracy} = \frac{\text{TN+TP}}{\text{TN+FN+TP+FP}} \quad (5)$$

The recall metric measures the ability of a model to accurately identify and retrieve every instance belonging to a specific class within a given dataset, and it is calculated as follows in Eq. (6):

$$Recall = \frac{TP}{TP+FN} \quad (6)$$

Precision is defined as the ratio of relevant instances to the total number of retrieved instances, as expressed by Eq. (7):

$$Precision = \frac{TP}{TP+FP} \quad (7)$$

The F1-score is determined as the harmonic mean of precision and recall, represented by the following Eq. (8):

$$\text{F1 Score} = 2 \times \frac{\text{Recall} \times \text{Precision}}{\text{Recall+ Precision}} \quad (8)$$

B. Fine-Tuning Results

The most proficient Arabic model is MARBERT, attaining 93% accuracy, alongside equivalent F1-score, recall, and precision measures. Subsequently, bert-base-arabertv02 attained a score of 92%, while bert-base-arabic scored 91%, and the other models demonstrated comparable competence at 90%. The model with the lowest performance was bert-base-arabertv2, achieving a score of 88% as illustrated in Table VII.

TABLE VII. THE RESULTS OF ARABIC MODELS

Model	*Accuracy*	*F1-score*	*Recall*	*Precision*	*Loss*
bert-base-arabertv02	92%	92%	92%	92%	20%
MARBERT	**93%**	**93%**	**93%**	**93%**	25%
ARBERT	90%	90%	90%	90%	**19%**
bert-base-arabic	91%	91%	91%	91%	21%
bert-base-arabertv02-twitter	90%	90%	90%	90%	21%
bert-base-arabertv2	88%	88%	88%	89%	29%

Fig. 10 presents a comparison of accuracy and loss during training and validation against the test set. Train accuracy: 97% and Validation accuracy: 97%. Stopping training at epoch 4 by implementing early stopping to preserve optimal loss.

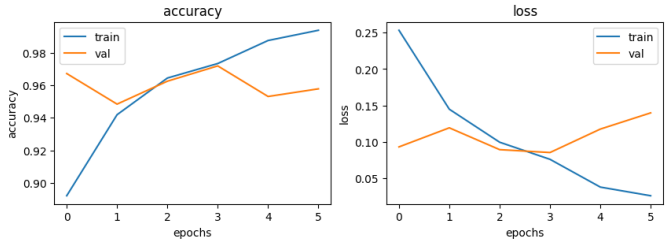

Fig. 10. Accuracy and loss results of MARBERT model.

Among models built for multilingual support, mBERT achieves the highest performance at 89%, followed by XLM-Roberta, and DistilBERT with scores of 87% and 85%, respectively as shown in Table VIII.

TABLE VIII. THE RESULTS OF MULTILINGUAL SUPPORT MODELS

Model	*Accuracy*	*F1-score*	*Recall*	*Precision*	*Loss*
mBERT	**0.8868**	**0.8887**	**0.8868**	**0.8912**	**0.2542**
XLM-R	0.8746	0.8722	0.8746	0.8703	0.2713
DistilmBERT	0.8501	0.8527	0.8501	0.8557	0.3644

Fig. 11 displays the accuracy and loss comparison of mBERT, indicating a model test loss of 0.27, a training loss of 0.15, and a validation loss of 0.11. Training accuracy: 0.9377 and Validation accuracy: 0.9437. Restoring the optimal loss and stopping at epoch 6.

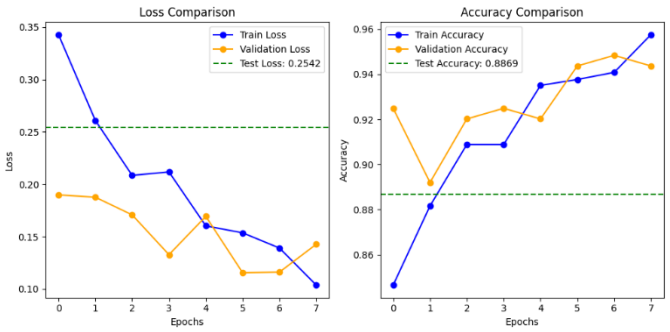

Fig. 11. Accuracy and loss results of the mBERT model.

VI. Discussion

Based on various experiments, MARBERT outperformed all selected Arabic BERT-based models as well as multiple support BERT-based models, achieving an F1-score and accuracy of 93%. The oversampling method and hyperparameter optimization improve performance and mitigate overfitting, which is the primary advantage of our proposed model. Following MARBERT is AraBERT version 02, and then ArabicBERT, although mBERT was the most effective among many multilingual support language models. The main finding is that almost all Arabic BERT-based models outperform mBERT.

A. Comparison with Previous Studies

Table I in the related work indicated that five studies utilized Arabic. Four studies employed a specialized Arabic model incorporating multiple support languages, whereas one study utilized solely a multiple support languages model. Table IX summarizes these models and their accuracy metrics compared to our best model.

TABLE IX. Comparison of Arabic Model Classification Results with Previous Studies

Model or Study	*Accuracy*	*F1-score*	*Recall*	*Precision*
AraBERT/ [21]	-	83%	82%	85%
MARBERT/ [27]	86%	84%	84%	84%
AraBERT/[28]	91%	93%	-	-
MARBERT/ ours	**93%**	**93%**	**93%**	**93%**
AraBERT/ ours	92%	92%	92%	92%

The MARBERT model outperformed all our Arabic models and previous studies in terms of accuracy, as it was trained differently from the other Arabic models. We employ identical model versions of previous studies utilizing diverse datasets and maintain consistent batch sizes and epochs, while optimizing some hyperparameters to achieve improved accuracy; nevertheless, they do not specify the loss, preventing comparison in this metric.

The majority of models were trained with numerous parameters and vocabulary sizes. ARBERT and MARBERT, as detailed in the authors' study [8], possesses 163 million parameters and a vocabulary size of 100,000, surpassing AraBERT, which has 136 million parameters and a vocabulary size of 60,000. The remaining models are outlined in the table. Another significance pertains to dialects, as the Arabic language encompasses numerous dialects, including Gulf Arabic, Egyptian Arabic, Levantine Arabic, Maghrebi Arabic, Iraqi Arabic, Sudanese Arabic, and Yemeni Arabic; thus, this model was trained on AD and MSA. The distinction between ARBERT and MARBERT lies in the fact that ARBERT focused exclusively on MSA, which accounts for its weakness compared to MARBERT. Ultimately, the most effective model classification for social media messages is the model that is trained in dialects and MSA.

B. Address the Research Questions

The research questions that are based on aims and objectives will be addressed in the subsequent paragraph. The primary aim of the present research is to improve crime prevention and law enforcement in Arabic by developing an effective technique, Arabic BERT-based models for crime classification, through multiple objectives: comprehensive analysis of previous Arabic studies, data construction, solution design, and evaluation of the results. Q1: Can AI discover and assist in the classification of crimes in Arabic textual data? As seen in Table VII, all the results were 90% and above, except for one study that got an 88% F1-score, which is a good result in the Arabic language, and all the Arabic studies do not exceed 93%, as seen in the comparison Table IX. So, AI helps in the classification of crimes. Q2: Can transformer BERT improve the effectiveness of Arabic crime classification based on pre-existing models? BERT-based models have demonstrated notable outcomes despite the constrained data size, whereas numerous prior models necessitate extensive datasets to achieve satisfactory accuracy. As the study by [35] on crime classifications across various ML and DL models attained the highest accuracy of 79% with the SVM model, even after preprocessing and balancing the dataset. Moreover, there is a substantial volume of tweets, around 37,000. Furthermore, the study [36] encompasses 1,555 Arabic tweets, achieving an average F1-score of 87% among several ML and DL models. The last study [1] received 92% of the 8K tweets. MARBERT achieved a 93% accuracy rate with a minimal number of tweets, indicating that pre-existing models enhance the classification of Arabic crime, even when the number of datasets is minimal. Q3: Can the Arabic language be identified despite its difficulties? The pre-trained models have been developed using broad Arabic datasets and dialects. In contrast to the challenges faced by traditional ML and DL, they have been trained to address various AD and MSA. Furthermore, several models were trained, especially on both MSA and DA, whereas others were trained exclusively on one. For instance, ArabicBERT was exclusively trained in MSA, but the others were trained in both types. Furthermore, certain models, particularly AraBERT version 02 Twitter, were trained on social media content from the X platform. The distinction is in the volume of training data, the parameters, and the vocabulary sizes that evolve with each model version, with MARBERT being the extensively trainable model.

C. The Constraint of Research

One of the most significant limitations of this research is the difficulty of data collection. As a result of the sensitivity of the data and the difficulty of acquiring it from various sources, we utilized social media platforms, specifically the X platform, to gather it. Additionally, one of the constraints we encountered

was the restricted quantity of tweets that were collected from the X platform. Furthermore, duplicated and unrelated languages were gathered due to the Arabic hashtag being used in other languages. This process resulted in the deletion and filtering of a significant number of non-Arabic languages. Ultimately, the experimentation of numerous models, which required a significant amount of time to accumulate all the results, is the final and most significant limitation.

VII. Conclusion and Future Work

Safety and security are essential to human needs and the stability of economic, social, and political systems. Technology, density, and increased criminality make law enforcement challenging. Safety can be achieved with AI. This research aimed to classify the Arabic language for the detection of criminal activities employing different Arabic BERT-based models. BERT has recently attracted considerable attention from researchers and practitioners, demonstrating notable effectiveness in various NLP tasks, including text classification. This efficacy can be attributed to its unique architectural features, particularly its ability to process text using both left and right context, having been pre-trained on extensive datasets. In the context of the criminal domain, the classification of data is a crucial activity, and transformers are increasingly recognized for their potential to support law enforcement efforts.

There was a limited number of crime field studies that employed the Arabic BERT transformer and a restricted number of Arabic crime datasets, considering the areas for improvement in previous studies. Hence, it is imperative to analyze the availability and efficacy of BERT in Arabic.

This was done by building newly posted tweets from X and classifying them into criminal and non-criminal categories. Subsequently, these tweets were processed using NLP tools, and their imbalance was resolved through the oversampling technique. Afterward, fine-tuning of BERT-based models, six variations of Arabic BERT models, and three multilingual models were utilized to classify tweets of criminal behavior, and the best-performing model was evaluated based on its accuracy and other performance metrics. Consequently, this contributed to the nation's enforcement of the law and the prevention of illicit activity. The results indicated that most Arabic models surpassed the multilingual models in efficacy. MARBERT, the leading Arabic model, attained an accuracy and F1-score of 93%, followed by AraBERTv02 by 92%, while ArabicBERT at 91%, and both ARBERT and AraBERTv02-twitter with an identical accuracy of 90%. The final Arabic model, AraBERTv2, had the lowest accuracy of 88%.

Nonetheless, mBERT is the most proficient model accommodating multiple languages, with an F1-score and accuracy of 89%, surpassing both XLM-R and DistilBERT, as well as just one Arabic variant, AraBERTv2. Furthermore, the processes of balancing and pre-processing facilitated the achievement of optimal findings while reducing overfitting, as the MARBERT model surpassed previous research in accuracy without exhibiting overfitting.

A. Future Works and Recommendations

For future research direction, the dataset will be expanded to include a third category, "lead to crime", to evaluate the model in multiclassification and optimize its performance. Assess the models using real reports from law enforcement, if accessible. Furthermore, assess additional developing Arabic language models and conduct a thorough comparison with other transformers, including ELECTRA, GPT, T5, and several other transformer models. Data availability remains a significant challenge for low-resource languages, particularly Arabic. Although the scarcity of datasets poses a barrier, the widespread use of social media platforms offers a potential solution. Platforms such as X and Facebook provide APIs for collecting posts, which could facilitate dataset creation. Furthermore, models such as BERT can be leveraged with a limited dataset; however, the data must be authentic and contain multiple categories to evaluate the model.

One critical aspect that requires investigation is the creation of a BERT-based crime model that is specifically tailored to Arabic crime and is trained on criminal activities to optimize its performance, such as the Legal-BERT for the English language. This research identifies critical areas that require further exploration and improvement in the application of BERT-based models for crime classification.

***Abstract*—ECG arrhythmia detection is very important in identification and management of patients with cardiac disorders. Centralized machine learning models are privacy invasive, and distributed ones poorly deal with the data heterogeneity of the devices. These challenges are responded to by presenting the edge AI an attention-driven hierarchical federated learning framework with 1-Dimensional Convolutional Neural Network (1D-CNN) - Long Short-Term Memory (LSTM) -Attention to classify arrhythmia in ECG recordings. This model includes the spatial characteristics of ECG signals and the temporal characteristics of attention maps, identifying the significant areas of the inputs and providing high interpretability and accuracy of the model. Thus, federated learning is applied to perform model training in a decentralized process through the Privacy-Preserving while the raw data remains on the edge devices. For assessment, this study utilized St. Petersburg INCART 12-lead Arrhythmia Database and Wearable Health Monitoring has given an overall classification accuracy of 96.5% with an average of AUC-ROC of 0.98 with five classes as Normal (N), Supraventricular (S), Ventricular (V), Fusion (F), and Unclassified (Q). The proposed model was created using the Python programming language with the TensorFlow framework deep learning and tested using Raspberry Pi devices to mimic edge settings. Overall, this study proves that it is possible to classify using IoT Device ECG arrhythmia reliably and securely on devices with limited resources, which will enable real-time cardiac monitoring.**

I. INTRODUCTION

The advancement of IoT over the recent years has contributed to an unprecedented inflow of interconnected, smart devices in the network periphery creating masses of data that need processing[1]. The applications running on such devices include multiple lifesaving operations, such as healthcare, transport systems, and households[2],[3]. Most central processing and analyzing this information would be less effective because bandwidth utilization[4], delays, and privacy concerns tend to be critical obstacles. One of the basic issues in edge AI deployment is balancing user privacy with model performance [5]. Centralized learning paradigms, which depend on aggregating raw data in a single server, are heavily privacy-invasive and many cases, infeasible because of bandwidth and latency constraints [6]. To overcome the challenges by allowing collaborative model training on distributed devices without local data sharing, federated learning (FL) method is utilized [7]. Nevertheless, traditional FL methods are not optimally suited for heterogeneous IoT networks. It tends to experience non-IID (non-independent and identically distributed) data distributions, heterogeneity in device capabilities, and uneven participation owing to constrained resources[8].These drawbacks severely compromise model convergence and accuracy.

The approaches in healthcare and IoT, models like the Observational Medical Outcomes Partnership Common Data Model (OMOP-CDM) have offered a single platform for organizing and analyzing patients' data [9]. Similarly, federated learning models need standardized frameworks and adaptive coordination protocols that can facilitate effective model training on diverse IoT devices [10]. But current FL structures are generally flat and do not take advantage of hierarchical relations between edge devices, thus creating scalability and performance issues. While federated learning has promise, existing models are not adaptable and efficient in the most heterogeneous settings. Most study makes uniform device participation assumptions and do not consider the dynamic nature of IoT networks. A little investigation into attention-based models with the ability to discriminate between significant and redundant updates when aggregating the model, [11]. Additionally, prevalent hierarchical FL setups are either extremely simplistic or do not optimize on contextual attributes

like data authenticity, local domain relevance, and device stability. This deficiency motivates the establishment of an intelligent federated infrastructure that ensures data privacy and accommodates the network's underlying statistical and structural variability[12].

Although federated learning has potential, existing models are not adaptable and efficient in highly heterogeneous settings. Most study considers uniform device participation and does not consider the dynamic nature of IoT networks. Limited work has been done on attention-based models that can distinguish between significant and redundant updates during model aggregation [13]. Additionally, the current hierarchical FL architectures are too simplistic or do not tap into contextual insights like data consistency, task-level importance, and device credibility within the domain [14]. Hence, the federated framework not only addresses the privacy of data but also adjusts itself according to structural and statistical variability in the network. To overcome the above challenges, this study presents a new framework: Attention-Driven Hierarchical Federated Learning (AHFL). The new architecture leverages the advantages of attention mechanisms and hierarchical learning to support efficient and privacy-respecting edge AI over heterogeneous IoT networks. Through the experimental organization of devices into hierarchical groups based on resource abilities and data types, the model facilitates localized learning and then selective aggregation. Attention mechanisms are applied at several levels to detect and prioritize the most important model updates for global learning. This not only minimizes redundant communication but also allows the global model to leverage high-quality contributions, thus enhancing generalization performance.

The key contributions of the study are listed below:

- The study introduces a hybrid model that is a 1D-CNN and LSTM, where 1D-CNN model extracts the ECG data automatically. A new hierarchical FL framework designed for edge AI in heterogeneous IoT networks.
- It controls a large amount of ECG time-series data. Incorporation of attention mechanisms to weigh client inputs adaptively.
- Improved privacy protection without compromising model accuracy. Experimentation of the proposed model on different non-IID IoT scenarios shows better convergence and scalability.
- This study demonstrates that the hybrid 1DCNN-LSTM gives a good performance by using the wearable IoT device.

The rest of the section focuses on: Section II describes the related work of an attention edge AI in IoT networks. Section III reviews the problem statement. Section IV explains the methods used in this study. Section V examines the results, and Section VI details conclusion and future works.

II. Related Works

Raza et al. [15] proved that identifying arrhythmias using ECG and enhance federated learning while combined with explainable AI. The study keeps the data secure without accessing any dataset. The CNN and XAI methods are used in the classification and feature extraction process. Communication needs a huge amount, and “black box” detection is the challenge in the existing model. The dataset used in this study is MIT-BIH Arrhythmia Database. Furthermore, it received 94.5% accuracy using ECG data and 98.9% using ECG clean data.

Wang et al. [16] states the Human Activity Recognition (HAR) based on wearable sensor data, which is crucial for health monitoring, medical diagnosis, and motion analysis applications. The main objective of this study is to overcome the shortcomings of current deep learning-based HAR models, especially problems concerning incomplete and inefficient feature extraction that may result in erroneous activity recognition. To accomplish this, the authors introduce a new deep multi-feature extraction framework known as DMEFAM, which supports feature learning via attention mechanisms. In [17], the authors integrates two specialized layers: a Temporal Attention Feature Extraction Layer (TAFEL) that merges Bi-GRU and self-attention (SA) for sequential data, and a Channel and Spatial Attention Feature Extraction Layer (CSAFEL) that employs CBAM and ResNet-18 for spatial and channel-level feature highlighting. This framework enables the model to better distinguish and weight significant features within sensor data. A weakness catered by this is that previous models used low feature use rates, something the suggested attention-based framework resolves. High levels of recognition are demonstrated in results, at 97.9% on WISDM data, 96.0% on UCI-HAR, and 99.2% on a collected dataset, DAAD. These data sets were utilized to test the efficacy and usability of the proposed framework.

H. Zhang et al. [18] aims to enhance smart object recommendation in Internet of Things (IoT) and Social Internet of Things (SIoT) settings. The objective is to precisely choose the right smart objects from a huge collection based on a new deep learning model known as BLA (BERT and Bi-LSTM with Attention). The model combines BERT for semantic feature extraction and Bi-LSTM with self-attention and global-attention mechanisms for extracting contextual and relevance-based representations. Self-attention determines significant features without human intervention, whereas global-attention corresponds object data with user requirements. The model further uses thing–thing relationships for improved recommendation quality. Although not mentioned, problems faced could be computation requirements and responsiveness to diverse data. Findings indicate that BLA is superior to baseline models in terms of effectiveness.

This study targets Human Activity Recognition (HAR) with mobile sensor data like accelerometer and gyroscope signals. Akter et al. [19] primary aim is to improve HAR performance through a deep learning-based model with CNN. The method integrates features from several Convolutional stages and includes a Convolutional Block Attention Module (CBAM) to enhance feature refinement and extraction. Rather than relying on hand-crafted features, the model takes raw signal spectrograms as inputs, enabling automatic and effective high-level feature learning. The novelty is in the combination of multi-stage features and attention mechanisms to enhance model accuracy. While particular constraints aren't mentioned,

managing model complexity and generalization across datasets might be possible challenges. The datasets employed here are KU-HAR, UCI-HAR, and WISDM. The model resulted in good performance with 96.86% accuracies in KU-HAR, 93.48% in UCI-HAR, and 93.89% in WISDM. The outcomes portray better performance in comparison to past methods.

Dirgová Luptáková, Kubovčík, and Pospíchal [20] investigates Human Activity Recognition (HAR) based on smartphone sensors such as accelerometers and gyroscopes for healthcare, sports, and human–robot interaction applications. To enhance real-time activity classification by modifying the transformer model, which was initially created for NLP and vision tasks, to time-series analysis of motion signals. The approach takes advantage of the self-attention of the transformer to capture dependencies in the time series and provides a robust countermeasure against CNN and LSTM-based methods. This allows for better recognition of intricate activity patterns. This study assesses the implemented methods on the biggest publicly released smartphone motion sensor dataset, which is not specified by name. Some of the potential problems include computational complexity of transformers and the requirement of large training data. The proposed model attains a remarkable average activity recognition accuracy of 99.2%, which is well above traditional machine learning techniques with an accuracy of 89.67%. These findings prove the high potential of transformer models in HAR tasks[21].

This study focuses on HAR Industry such as IoT, e-health, and smart homes with 5.0 application. Al-Qaness et al. [22] aims to create a robust HAR system based on a new deep learning model known as Multi-ResAtt. This model utilizes multilevel residual networks and attention mechanisms to learn relevant features from inertial measurement unit (IMU) data. For efficient time-series analysis, the model include a recurrent neural network with attention which is tested on three public datasets, namely Opportunity, UniMiB-SHAR, and PAMAP2. Although there are no clear limitations discussed, real-time complexity and sensor heterogeneity could be potential issues. Multi-ResAtt outperformed current deep learning-based HAR approaches. It shows its strong performance in detecting complicated human actions.

III. Problem Statement

The continuous development of wearable IoT devices in ECG monitoring poses new chance of early detection of abnormal arrhythmias but also major emerging issues linked to data privacy, heterogeneity, and model accuracy. The traditional method of centralized learning schemes are non-private as it transmits raw data, and basic FL works such as FedAvg do not address the non-independent and identically distributed data or different qualities of data available to clients [23]. In the healthcare field, not all device data is equal for analysis as some are random, skewed, and less meaningful [24]. This results in distorting the models of the world and poor generalization. As such, this study presents an attention-driven hierarchical federated learning model that employs a CNN-LSTM model. In the proposed solution, the adversarial interference is mitigated by using attention mechanisms before LSTM for focusing on relevant ECG segments and during aggregation to guarantee clients' privacy while maintaining high accuracy and the framework's robustness for ECG classification in the different IoT environments.

IV. Methods for Privacy-Preserving Edge AI in Heterogeneous IoT Networks

The main objective of this study is based on the well-established federated learning method. It introduces an attention-driven hierarchical federated learning (HFL) mechanism, which is suitable for the St. Petersburg INCART 12-lead Arrhythmia Database to provide privacy-preserving arrhythmia classification. This has been achieved with the consideration of the main issues related to privacy, scalability, and heterogeneity experienced in the Internet of Things (IoT) healthcare systems. Based on the above design goals, a three-tier system architecture is adopted for the system, which includes edge devices, intermediate aggregators, and a central server. Each edge device uses a deep learning model of CNN-LSTM architecture for the ECG signal, where the CNN captures spatial patterns while the LSTM captures temporal patterns. An attention mechanism is also applied to pay more attention to the discriminative segments in signal for improving the interpretability and classification accuracy. This data never goes through the cloud and hence, does not violate any privacy policies. Information in local models is regularly transmitted to intermediate fog nodes, where initial data aggregation is done. This information is then transferred to a higher-tiered server which can be termed as a hierarchical processing model. The aggregation process also uses weights to decide the number of times it should draw data from various clients depending on their performance or credibility to handle the non-IID data common with IoT in real-world environments. In order to enhance the privacy of the health data, the framework can also use the method of differential privacy and secure aggregation. Finally, the performance of the proposed model based on accuracy, F1-score and communication efficiency metrics is being tested for worst case scenario, data heterogeneity and adversarial conditions for proving the robustness of the model. Overall, this also provides a way to have a real-time and intelligent ECG analysis that is privacy-preserving and scalable across various connected health devices. It includes low latency, flexibility, and convergence of the models with high security. The attention mechanism is also very useful in improving both the model training and also the federated communication. In sum, this study resolves general concerns that occur based on the integration of edge intelligence and medical data security. In summary, the practicality of the ECG Arrhythmia dataset is verified using this experimental set-up, to facilitate real-world applicability of the same. Fig. 1 demonstrates the working principle of attention federated learning for preserving data using hierarchical IoT device.

A. Data Collection

The St. Petersburg INCART 12-lead Arrhythmia Database is utilized for this study, which is obtained from the open-source Kaggle [25]. The information from this dataset contains various attributes. The dataset consists 75 annotated 30-minute ECG recordings collected from 32 subjects and 257 Hz samples from 12 leads. All the data are grouped as per the AAMI EC57 standard, and divided into five main classes: Normal, Ventricular, Supraventricular, Fusion, and Unknown. This

dataset is pre-processed using normalization, wavelet denoising, and segmentation.

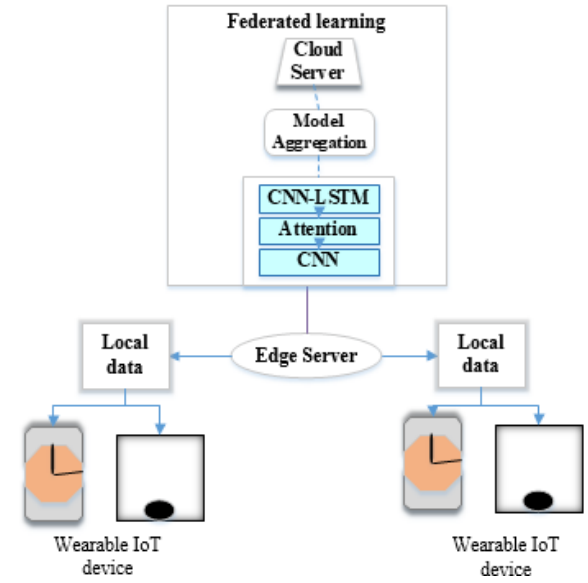

Fig. 1. Workflow of the attention federated learning edge AI using hierarchical IoT device.

B. Data Preprocessing

1) Signal denoising. ECG signals obtained from IoT devices are mostly contaminated by movement, electrical interferences, or shifting baseline noise. It helps to eliminate high-frequency components while storing the spatial extraction data for CNN model. Denoising is beneficial in enhancing signal quality to ensure an accurate classification. Eq. (1) represents the signal denoising formula:

$$\hat{x}\,(t) = x(t) - n(t) \tag{1}$$

In Eq. (1), $\hat{x}\,(t)$ denoised the signal, $x(t)$ notice a noisy signal, and $n(t)$ calculate the noise in the data. For this study, the wavelet denoising method is used for effective denoising. Denoising the wavelets breaks ECG signal into many frequencies sub-bands using the Discrete Wavelet Transform, enabling the removal of high-frequency noise without loss of some clinically relevant characteristics. It applies what is known as 'thresholding' on the wavelet coefficients and then reconstruct the signal with only large coefficients. And with this method, it is easy to separate the ECG signal from all the interfering noise and not distort the morphology of the waveform (top). The formula for wavelet denoising is given in Eq. (2). It is the formula of waveform:

$$\widehat{\omega} = sign(\omega)\,.\max(|\omega| - \lambda, 0 \tag{2}$$

where, ω is the original wavelet coefficient, $\widehat{\omega}$ is the denoised coefficient, and λ is a threshold value.

2) Normalization. Due to multiple sensors, the quality of IoT devices is not in a stable range. To overcome the values to the normal state, a z-score standardization data normalization technique is utilized. This technique is used to transfer data from the CNN layer to the LSTM layer in various time series. In federated learning (FL), normalization takes place to control the privacy and avoid central aggregation of data. It handles various features from different devices. The data focuses on standard deviation 1 and mean 0. The formula for the normalization technique given in Eq. (3). The equation is called normalization formula.

$$z = \frac{x - \mu}{\sigma} \tag{3}$$

where, σ is the standard deviation and μ is the mean.

C. Hybrid 1DCNN-LSTM Model in Healthcare Monitoring

The Long Short-Term Memory (LSTM) integrates with CNN to control the sequential and spatial data. In this study, IoT devices like wearable ECG patches or smartwatches collect motion signals, heart rate, or ECG data. CNN is utilized to extract spatial patterns from the device, and the output of the CNN is transferred to the LSTM model to analyze the sequential data. This technique enhances the identification of stress levels or arrhythmias.

The input layers receive ECG data in a time-series form. The wearable IoT device stores the raw signals and pre-processes the data in its device. The CNN model is used as a feature extractor that collects local patterns. The Convolutional layer extracts the spatial features using the following formula as in Eq. (4):

$$f_i = \sigma(\sum_{j=0}^{k-1} w_j\ .x_{i+j} + b) \tag{4}$$

where, K is the kernal, and σ is the ReLu. The extracted waveforms and increases in heart rate. In federated learning, the trained parameters are sent to the central server. It prevents users from transmitting data and preserves privacy in the edge server. The MaxPooling is used to lower the extracted ECG features. It selects the maximum value from the low-signal device and enhances the model performance by measuring the IoT device sensors in a limited waveform. The pooling is done by the following Eq. (5):

$$y_i = x_i + x_{i+1} +, \ldots\ldots, x_{i+p-1} \tag{5}$$

where, x_i is the input signal, y_i is the pooled output and p for the pooling size. It only allows the related patterns to attention layer and the LSTM layer for analyzing temporal patterns. The architecture of the hybrid 1DCNN-LSTM is given in Fig. 2.

1) LSTM layers. In this study, an attention mechanism only focuses on related time series or important features as input to improve the LSTM performance. It gives higher weights as input for prediction in the edge server. Arrhythmias are identified by a pattern of time, where LSTM defines the temporal information through its gate memory structure. There are three main categories in LSTM. They are: forget gate, input gate, and output gate. Here the cell gate is the memory unit.

a) Forget gate: The forget gate makes the decision which is to delete previous state. It deletes the irrelevant information from the data and only focuses on healthcare patterns. The formula for the forget gate is in Eq. (6):

$$f_t = \sigma\big(W_f\,.\,[h_{t-1}, x_t] + b_f\big) \tag{6}$$

where, σ is Sigmoid activation function, W_f represent the weight matrix for the forget gate, $h_{t-1}$is the before hidden state, x_t is current, and b_f refers to Bias term.

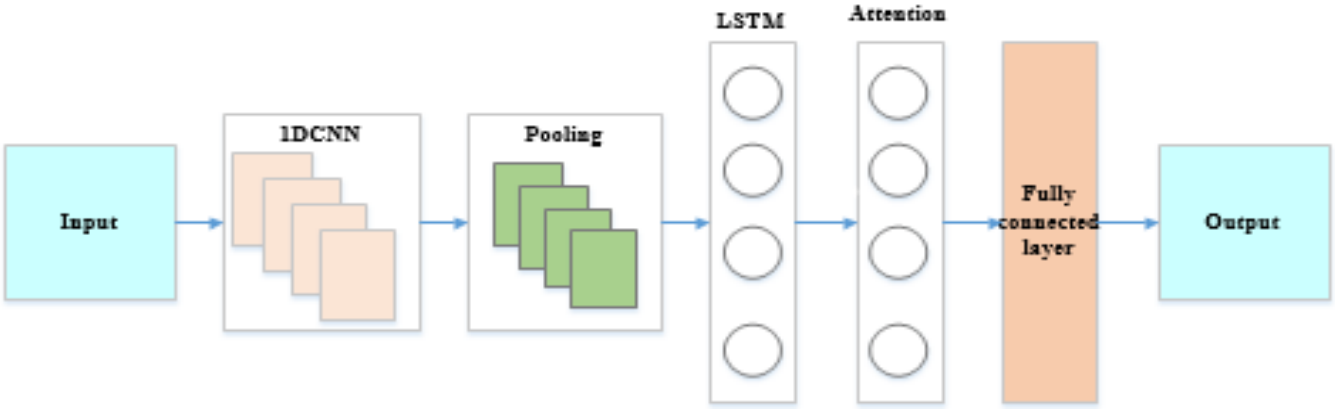

Fig. 2. Architecture representation of hybrid 1DCNN-LSTM.

b) Input gate: The input gate allows new information to be added to the cell gate. Thus, it can add relevant ECG information. The formula is in Eq. (7) and Eq. (8):

$$i_t = \sigma(W_i . [h_{t-1}, x_t] + b_i) \quad (7)$$

$$\widetilde{C_t} = \tanh(W_c . [h_{t-1}, x_t] + b_c) \quad (8)$$

where, W_i, W_c are the weight matrices for the input gate and candidate cell state and b_i, b_c are the bias terms.

c) Cell gate: This state updates the information by combining the current and previous states of cardiac rhythms. Eq. (9) represent the cell gate formula:

$$C_t = f_t * C_{t-1} + i_t * \widetilde{C_t} \quad (9)$$

d) Output gate: The output gate maintains the information from the cell state to the next layers and confirms that the data are related. Eq. (10) represents the output gate formula:

$$h_t = o_t * \tanh(C_t) \quad (10)$$

In Eq. (10), $*$ refers to element-wise multiplication and h_t shows the background changes of the ECG in a time series. The input of the fully connected layer is obtained from the LSTM layers output.

The attention mechanism enhances the understandability and model accuracy by selecting high-weight parameters in wearable IoT devices. The data stored in various edge servers is updated and sent to the global server, like a cloud service. The model is updated from information stored in multiple devices.

$$Attention(Q, K, V) = softmax(\frac{Qk^T}{\sqrt{d_k}}) \quad (11)$$

In Eq. (11), Q, K, and V are the inputs from CNN. The sequence is passed to the LSTM model. When the global model analyzes the updated information, it sends it back to the wearable IoT devices. The process is done recursively until the wearable device gets the updated information.

D. Federated Learning

In this study, federated learning is adopted to create an intelligent ECG arrangement classification model in distributed IoT environments that ensure the privacy of the recorded data from wearable sensors and mobile health monitoring devices. Instead of uploading actual ECG signal to the central server, this network just sends encrypted model update (EMU) to the aggregator. These updates are then merged in hierarchical FL approach to create a global model which gets advantages of all combined devices and thereby patient's data is secure and safe.

A three-tier hierarchical FL architecture is developed for real-time ECG arrhythmia classification based on wearable IoT devices. The structure takes into account of i) personal and wearable devices such as smartwatches or ECG patches, ii) fog nodes such as home or hospital gateways, and iii) a central server for the final fusion of models. Every client applies the locally trained model of CNN-LSTM with the help of the attention mechanism. Original ECG data remain stored locally, thus data privacy is well protected.

1) Attention-based federated averaging. In this study, which focuses on real-time ECG arrhythmia detection from wearable IoT devices, federated learning means that patients' sensitive health information does not leave the device. Instead, the devices engage in a distributed learning process by establishing and developing an individual deep learning model based on the ECG signals. The local training involves the use of these devices and their ability to send their own model updates to the fog server or even a central aggregator that helps in creating a more general model, Hazra et al. (2023). This setup also solves some of the basic issues with IoT healthcare systems, such as heterogeneity of collected data, communication overhead, security and privacy concerns.

FedAvg is also one of the most basic algorithms of FL. In particular, it updates aggregated parameters derived from multiple clients (for example, devices) to derive the new global model. In other situations, it goes through several rounds of communication till an efficient model is arrived at. FedAvg is

one of the well-established approaches to federated learning used to solve machine learning problems in decentralized edge devices without compromising the participants' privacy and with low communication complexity. As discussed earlier, FedAvg is used to update the average of the models iteratively of all the participating clients, for example, wearables. This method enables the server to update its global model easily without the need to download from the clients training data. The FedAvg algorithm starts with the central server having a global model that is to be sent out to all the selected edge devices. Each client then performs offloading to its own data and updates the model on that data for several epochs of gradient descent. The training formula for client-side server is given Eq. (12).

$$\omega_i^{(t+1)} = \omega_i^t - \eta \nabla \mathrm{Li}(\omega_i^t) \quad (12)$$

Here η indicate learning rate, Li is the loss function, and i represent the local data of the client. When the training is finished, it sends the updated information to the server. The weighted average is aggregated by the server. It assigns the weight of the client data based on the trustworthiness, relevance or performance. The formula for the aggregation is given in Eq. (13).

$$\omega^{(t+i)} = \sum_{i=1}^{k} \frac{n_i}{n} . \omega_i^{(t+1)} \quad (13)$$

where, $n_i$is the number of sample clients, n = $\sum n_i$ is the total number of all clients. It is a large dataset with global clients which leads the main process in federated learning. It processes efficiently and secures the data in many wearable IoT devices.

While at the aggregation stage, instead of averaging all updates as it is done in FedAvg, the system calculates the attention score for each client. These scores represent variants related to the only client factors like local model accuracy, loss decrease, the quality of data, or their compliance with previous changes. The scores are generally scaled using the method often known as softmax to force the values of the scores, having value closer to 1 and total up to 1, hence depicting the relative degree of significance or importance. Each client's model update in the communication is next weighted by the attention score given to it; thus, specific high performing or trustworthy clients essentially influence the new received global model. Last of all, it adds the weight into the global model updates collectively and then sends it back to the clients for the next round of training. This process repeats itself providing the opportunity to update this global model with respect to the most informative and reliable contributions, which makes the proposed method highly efficient for non-independent and identically distributed, heterogeneous, and privacy-preserving contexts such as real-time ECG classification in healthcare IoT applications.

Algorithm1. Federated Learning with 1DCNN-LSTM for Preserving Data in Hierarchical IoT Device

Input: Collects raw ECG data from wearable IoT device

Output: Predicted ECG class and trained global model

Algorithm 1 shows the federated learning with 1DCNN-LSTM for preserving data in hierarchical IoT device. Fig. 3 shows the workflow of the attention mechanism in a federated learning IoT device. The proposed flowchart allows for implementing an attention into the structure of the hierarchical federated learning process to improve model aggregation. Every edge device runs CNN-LSTM on segmented ECG signals, and assesses the outcome in terms of local validation indices. These scores are utilized in the fog-level and global aggregation to perform an update of the model. This mechanism replaces uniform averaging (FedAvg), which enhances adaptability,

performance-based averaging, and results in better non-IID and noisy ECG settings. The novelty is based on incorporating the layer-level attention for the feature relevancy with the network-level attention for the aggregation reliability which in turn assures better convergence, interpretability as well as the privacy-specific performance across the heterogeneous edge nodes.

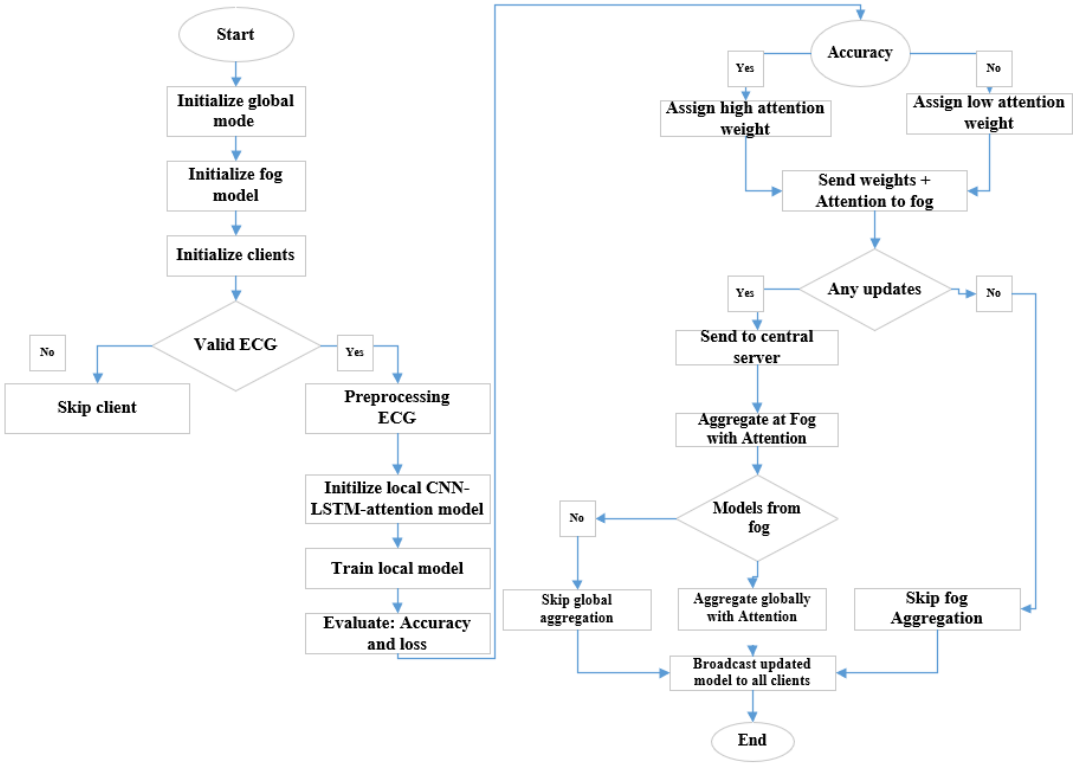

Fig. 3. Flowchart representation of Attention-driven Federated Learning.

V. Result and Discussion

This section provides the assessment and discussion of the approach formulated in the context of ECG arrhythmia classification based on the approach to the attention-driven hierarchical federated learning. Relative measures of performance are typically used for evaluating the model, including correct rate, precision, recall, F1 measure, and ROC-AUC. The redundancy reduction pattern of the local and global models is also established while comparing both models to prove that a hierarchical aggregation enhances the model. The next step aims to compare the convergence speed and the communication efficiency of the proposed model to the standard FedAvg. Till now, confusion matrices and attention heatmaps are helpful in the interpretation of the model's diagnostic emphasis. Furthermore, compare the model with centralized and other models with no attention mechanism included. Finally, an ablation study shows the significance of each part invented in the present work is implemented in the window platform in python CPU/ memory 8GB.

Attention-Driven Hierarchical Federated Learning (HFL) for edge AI privacy in heterogeneous IoT networks is faced with multiple challenges. They include system and data heterogeneity, as devices vary in computing capability and produce non-IID data, causing model convergence to be slow or unstable. The attention mechanism, as it enhances learning focus, adds computational burden—challenging resource-limited devices. Overhead of communication, device dropouts, and privacy-performance trade-offs add to the complexity of training. These problems may lead to unfair models, inefficiency, and decreased scalability. Adaptive and lightweight attention architectures, resilient client selection, model compression, safe aggregation, and privacy-preserving techniques such as differential privacy can be employed to enable consistent and efficient learning in various IoT settings.

A. Model Performance

Model performance in this study concerns the capability of the proposed CNN-LSTM-attention to the accurate and efficient classification of ECG signals into different types of arrhythmia. The 1D-CNN extracts spatial features from the segmented ECG data as the next step, followed by an attention layer which aims at identifying clinically relevant regions from the obtained features. The LSTM in turn, feeds these features in order to capture temporal dependencies and rhythm variations over time. The last layer is composed of output nodes that determine, where the sequence belongs to the arrhythmia classes specified below. There are relevant indicators such as accuracy, zero one loss, precision, recall, F1-score, and control under the receiver operator (AUC) curves, which describe the model's performance in practical large-scale distributed healthcare systems. The figure shows the local model and global model performance. The accuracy of global model is higher than the local in all evaluation metrics.

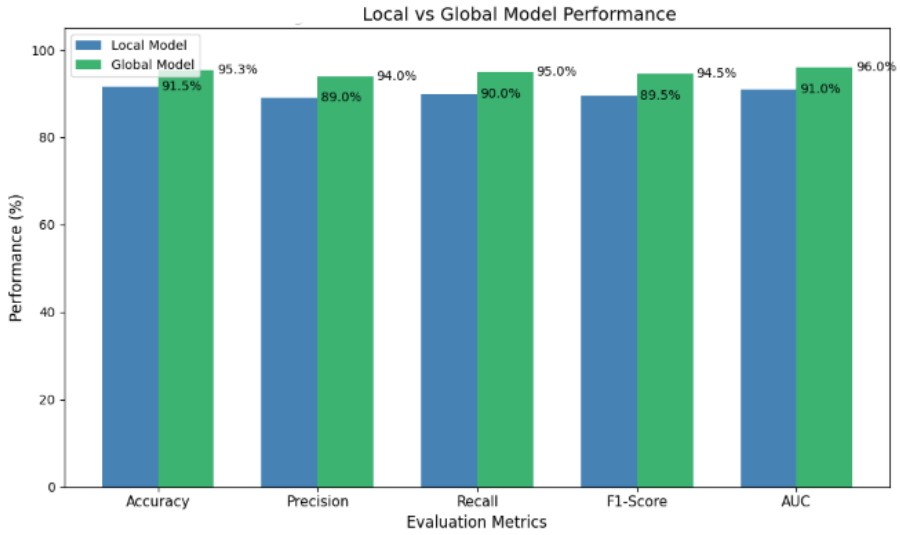

Fig. 4. The performance of local and global models.

Table I shows a summary of the proposed federated learning framework results and Fig. 4 represents the performance metrics of a local and global model. By evaluating the results, it concludes that the global model is better than the local models in terms of all the evaluation measures, namely accuracy, precision, recall, F1-score, and AUC. Even more important, the global model obtained 95.3% of accuracy and 94.5% of F1-score, while the local model obtained just 91.5% for accuracy and 89.5% for F1-score. The results presented in this study shows that not only privacy but also it achieves better predictive performance when the proposed federated framework is used in real-time ECG arrhythmia classification.

B. Multiclass Performance

In this study, the classification of each ECG heartbeat, a total of five classes are recognized: [N], [S], [V], [F], and [Q]. These classes are obtained from multiple annotated beat types of the ECG, thereby transforming them into unified diagnostic classes in order to get more clinical relevance. This classification framework helps in generalizing the outcome of the deep learning model across a variety of arrhythmic as well as, non-arrhythmic ECG signals. The last layer of the CNN-LSTM model proposes the probability distribution of the output layer, and the class with the highest probability is considered to be the prediction result. The multiclass labels are shown in Table II.

C. Confusion Matrix

Fig. 5 represent the predicted values for the multiclass label in healthcare monitoring. In this study, a confusion matrix is computed to predict the performance of the CNN-LSTM-Attention model to classify the ECG beats into two groups of rhythms, namely Supraventricular and Ventricular, and three groups of rhythms, namely Normal, Supraventricular, and Ventricular. The diagonal elements inside the matrix are a correct predicted value of the instances, the row as the actual class and the column as the predicted class. It provides results in terms of the performance for each class and the classification errors that occurred during diagnosis, which will give an insight into the reliability of the diagnostics as well as the areas that require improvement in the model. In Fig. 5, the Confusion Matrix for ECG Arrhythmia Classification of actual class and predicted class, the normal rhythm is 2.00 and the ventricular is 1.00.

D. Multiclass ROC-AUC Curve

Fig. 6 represents the ECG classification in ROC-AUC using multiclass labels. The ROC-AUC graph for the model represents the evaluation of the implementation of the model to distinguish between each class of ECG arrhythmia using a one class to the rest strategy. The graphs are plotted for every class, the curve pointing True Positive Rate, which points out the sensitivity of the screen. The value of AUC near to 1 shows better discriminative ability of the classifier for that class. The accuracy is the highest when the classes have line graphs near the top-left intersection.

TABLE I. PERFORMANCE OF FEDERATED LEARNING EVALUATION

Metric	Local Model (%)	Global Model (%)
Accuracy	91.5	95.3
Precision	89.0	94.0
Recall	90.0	95.0
F1-Score	89.5	94.5
ROC-AUC	91.0	96.0

E. Comparison of Existing Models

Comparing the models from CNN to the CNN-LSTM-Attention model, the results have been improved in the model's classification capability. In other words, the CNN module successfully captures spatial details of an image, whereas the LSTM encodes temporal aspects of the sequence. Thus, integration of these architectures in the CNN LSTM model helps to integrate spatial and temporal information and increases the accuracy of estimations. The CNN-LSTM-Attention model trained with attention pays more attention to such crucial segments as a result of the proposed architecture; hence, it posted the best performance among the recognized models. These developments support the effectiveness of using attention mechanisms as well as the incorporation of hybrid architectures for reliable and accurate ECG arrhythmia classification. Table III shows the comparison of existing models and proposed model. httpp://www.kaggle.com/code/ahmedashrafhelmi/ecg-classification-rnn-gru-lstm/input. Fig. 7 shows the performance comparison of existing models.

TABLE III. COMPARISON OF THE PROPOSED MODEL AND EXISTING MODEL

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
CNN	97.44	97.56	97.44	97.50
LSTM	97.11	97.40	97.11	97.25
CNN-LSTM	98.22	98.26	98.23	98.24
CNN-LSTM-Attention	98.91	98.98	99.03	99.00
Existing model	97.87	94.20	89.76	87.97

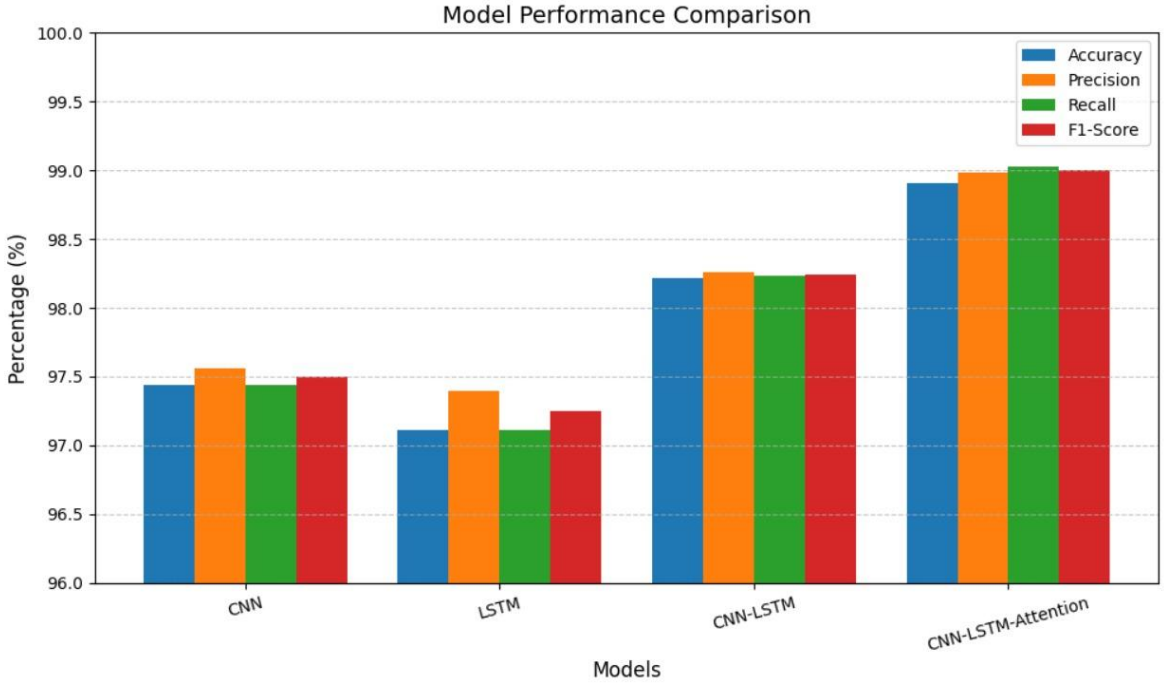

Fig. 7. Performance comparison of existing models.

F. Ablation Study

Fig. 8 shows the overall performance of a model which affects the study. This ablation study shows that each of the components in the proposed architecture is useful in a way and indispensable. The removal of the attention layer resulted in a decrease of model accuracy, reinforcing its function of directing attention to necessary ECG features. Additionally, excluding the LSTM degraded temporal learning, the effect of removing the fog layer on convergence efficiency is not conducive. The last model gathered the highest accuracy, which confirms that the use of CNN with LSTM, attention mechanism, and the hierarchical structure of the model produces the highest results for the classification of arrhythmia.

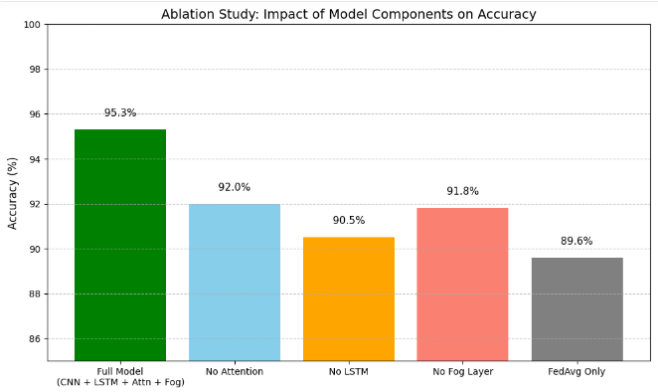

Fig. 8. Performance of each model.

G. Discussion

The proposed attention-driven hierarchical federated learning technique is a great improvement in the classification of ECG arrhythmia as it employs CNN, LSTM, and attention mechanisms. This integration helps the model to detect all spatial and temporal complex determinations of ECG signals to recognize the challenging three types of arrhythmic patterns. The attention mechanism enhances this procedure by focusing on certain parts of the ECG at sharp and boosting the interpretability and classification. This is because federated learning can allow training to be conducted on the device, where data is collected, without sharing that data with other parties to the federation, thus ensuring patient information is protected. The model further validates the practicality of the same for real time monitoring in low-resource settings. There are directions for future work: to achieve better efficiency for the model in various end devices, to consider the adaptive FL approaches to address the data heterogeneity, and to use the Explainable AI in enhancing the clinician's trust in the AI system. Also, applying the described study framework to promptly detect and monitor arrhythmias in wearable devices can greatly improve the prevention of heart conditions.

Although the evidence in favor of the aforementioned attention-driven hierarchical federated learning approach is encouraging, some limitations need to be noted. One of the main issues is the scarcity of computational and energy resources that are often present on most IoT edge devices, which can cause difficulties in processing sophisticated deep learning models such as CNN-LSTM with attention mechanisms. Also, heterogeneous and non-IID data at different clients may cause model convergence problems and less generalization. Communication overhead is another major challenge since federated learning needs to exchange model updates frequently, leading to potential latency and bandwidth usage, particularly in big networks. Additionally, while federated learning maintains privacy with data staying local, it remains susceptible to attacks like gradient leakage and model inversion. Lastly, while attention mechanisms enhance interpretability to some degree, it is still possible for the model to be viewed as a black box,

potentially limiting trust and adoption in sensitive areas such as healthcare.

In order to overcome these challenges, future research should aim to optimize models for deployment on the edge using methods such as model compression, pruning, and quantization. Mitigating data heterogeneity can include applying personalized or cluster-based federated learning techniques that suit better mixed data distributions. Efficiency in communication can be enhanced by means of model update compression, asynchronous training, or selective update methods. Further, augmenting privacy will involve combining sophisticated security mechanisms like differential privacy and secure multi-party computation. Lastly, to enhance transparency and trustworthiness, explainable AI techniques must be incorporated into the structure so that attention-based decision-making can be clearly visualized and end-users such as clinicians or IoT operators can be confident.

VI. Conclusion and Future Work

In this study, a proposed and investigated attention-driven hierarchical federated learning environment for learning ECG arrhythmia classification using the CNN-LSTM-Attention model. The model can incorporate spatial as well as temporal information of the ECG signal to make an accurate classification across various types of arrhythmias. Through integrating with the attention mechanisms, it enables the model to pay attention to some areas of the ECG, which improves its interpretability and accuracy. Federated learning caters to data privacy to prevent raw data from being fed to other clients, instead letting clients train their devices.

The plans for further development include addressing the problems associated with model implementation in constrained devices, further studying of methods of federated learning for handling with the data heterogeneity, as well as integration of the explainability tools to improve the doctors' trust in a model. It is also possible to extend the definition of the framework to utilize wearable technology for the real-time detection of pre-arrhythmias and thus promote the enhancement of preventive cardiologic services. This would require constant testing and validation on other datasets to be able to determine the general applicability of the proposed approach.

***Abstract*—With the advent of new sensor device designs, IoT based medical applications are increasingly being employed. This study introduces BlockFaaS: a Blockchain-assisted serverless framework that incorporates advanced AI models in latency sensitive healthcare applications with confidentiality, energy efficiency, and real-time decision-making. This framework combines the structure of AIBLOCK with dynamic sharding and zero knowledge proofs to make the framework strongly scalable with health-assured data inviolability with HealthFaaS, a serverless platform for cardiovascular risk detection. Explainable AI and federated learning models are introduced into the system to retain an equilibrium between data privacy and interpretability. All layers of communication use the Transport Layer Security protocol to ensure security. This proposed system is validated by new performance metrics such as real-time response rates and energy consumption, proving to be superior to the existing HealthFaaS and AIBLOCK technologies.**

***Keywords*—AIBLOCK; blockchain; healthfaas; latency optimization; serverless computing; Transport Layer Security (TLS)**

I. Introduction

Artificial intelligence (AI) and Internet of Things (IoT) technology have revolutionised the health sector by enabling real-time monitoring, detection, and decision-making. However, some limiting aspects, including disparities in data privacy, scalability, and latency, are beyond the power of AI-driven applications, especially in the detection of cardiovascular risk, to be achieved for efficient deployment. Serverless computing has dramatically solved the problem of scalable infrastructure on demand while simplifying complexities in infrastructures. Simultaneously, blockchain technologies have gained much attention in terms of the ability to secure, keep intact, and make information transparent. This research introduces BlockFaaS, a novel blockchain assisted serverless framework for AI-driven healthcare applications. The integration of AIBLOCK structure enhances data inviolability to the serverless platform of HealthFaaS applied in the detection of cardiovascular risk into the framework. This makes the framework highly scalable and a better solution for latency-sensitive medical applications. In addition, the usage of TLS protocol has assured the system's data confidentiality and secured communication across the system. Thus, the proposed framework will overcome the limitations that exist in today's healthcare technologies with improved data privacy, reducing response times, and achieving greater scalability in the overall system. This study presents a comparison of BlockFaaS with other existing frameworks to establish its feasibility for implementing high-performance modern healthcare systems. The new blockchain-assisted serverless framework for AI-driven healthcare applications, BlockFaaS, is presented in this work. The AIBLOCK structure provides enhanced data integrity, and dynamic sharding allows for scalable communication. In addition, it ensures secure and privacy-preserving communication through the use of zero-knowledge proofs. BlockFaaS balances between data privacy and interpretability with the integration of Explainable AI (XAI) and federated learning models. The framework is validated through comprehensive performance metrics, proving the superiority of the real-time response rates, energy efficiency, and data security involved.

A. Related Background

The next step in the development of the computer industry is often regarded as serverless computing [1]. In this case, the user does not control or own any servers. Another term for the software architecture, where an application is composed of one-time functions that are triggered by events or other invokers is "function-as-a-service" [2]. Yussupov et al. [3] proposed serverless architectures and emphasised the benefits of leveraging provider-managed components such as function-as-a-service (FaaS) and database-as-a-service (DBaaS) to minimise the amount of maintenance required of developers. The decentralised, unchangeable, and accountable relationships between blockchain technology and smart contracts as they relate to serverless systems were covered in this study. Ensuring security and privacy is crucial for any health apps in order to safeguard user data, adhere to legal requirements, and boost application confidence. Key management, storage, and token verification are among JWT's shortcomings [4][5][6].A blockchain-inspired secure and reliable data exchange

architecture is proposed in the cyber-physical healthcare industry 4.0 [7]. Stronger security measures are required and the AIBLOCK architecture uses blockchain technology to provide the immutability and secrecy of health data. Nevertheless, the HealthFaaS design does not use any external methods to ensure system security. User privacy is important when integrating a serverless platform with the Internet of Things. It is challenging to guarantee the integrity of patient data due to the various nature of the Internet of Things, which will raise privacy concerns for consumers [8]. Every line of connection between the patient data database, the IoT device, and the serverless platform is susceptible to intrusion [9]. Consequently, in the case of a communication channel assault, patient data may be altered (immutability). This might have serious consequences, such as misdiagnosis [10]. Transport Layer Security (TLS) with blockchain technology can reduce security and privacy issues. Blockchain's unique design, which ensures data integrity and immutability, makes it applicable in a number of industries, including banking and healthcare [11]. Three primary themes are examined in terms of terminology when discussing modern cloud computing delivery methods; (PaaS), (FaaS), and (IaaS) [12-14]. The cloud provider manages the infrastructure and servers, remaining completely independent of customers [15-18]. Contrary to popular belief, a system in which the server is completely absent is not referred to as serverless computing or FaaS [19-22].

This is a novel opportunity for the development of secure and scalable applications within health care, all these through the convergence of blockchain, serverless computing, and artificial intelligence. Such decentralized and tamper-proof blockchains have recently been picked up in highly demanding applications of industries for data integrity and security. Serverless platforms have been gaining attraction because they can dynamically allocate the resources without raising operational costs. Actual real-time capabilities with insights into immense amounts of patient data brought through AI, particularly through machine learning, in the prediction and diagnosis of disease. Available frameworks like HealthFaaS have led the way for serverless computing in healthcare but often are deficient in making sure robust data security. Similarly, blockchain-based solutions such as AIBLOCK are quite good at validating data but suffer from lack of efficiency while handling large workloads. This study puts all these technologies together to overcome the restrictions of the current solutions, providing BlockFaaS as a holistic framework for latency-sensitive and privacy-critical applications.

B. Research Objectives

The primary objectives of this research are:

- RO1: To develop a blockchain-enabled serverless framework, BlockFaaS, specifically customized for the use of AI in healthcare.
- RO2: To provide assured data confidentiality and integrity through advanced blockchain mechanisms, such as the AIBLOCK structure and TLS protocol.
- RO3: To enable true real-time dynamic scaling of resources to manage changing workloads involved in latency-sensitive medical applications.
- RO4: To assess the developed framework on scalability aspects, reducing the latency, ensuring data security, and cost-effectiveness in comparison with current solutions.

C. Organizations

The rest of the study is arranged as follows: Section II gives the previous works in the said area, Section III gives the research methodology. in Section IV the results are discussed and finally the conclusion and the future work is presented in Section V.

II. Literature Review

A. Existing Research and Analysis

According to language, contemporary cloud service delivery technologies may be categorised into three groups: Function as a Service (FaaS), Infrastructure as a Service (IaaS), and Platform as a Service (PaaS) [7]. After the cloud operator moves from IaaS to FaaS, the cloud service provider takes care of infrastructure and server maintenance, keeping them apart from clients [23]. According to popular misconception, serverless technology, also known as (FaaS), does not, by itself, imply a serverless environment [24][20]. Indicates the fact that server administration as well as other infrastructure activities are in the domain of the service provider [25]. These are the blockchains that are usually applied by people sharing the same objective but do not necessarily trust each other. Each block in the blockchain contains several transactions grouped and added with a header that contains a hash [10]. The hash is a unique value produced for each block depending on the contents within the current block plus the preceding block's hash. The hashing algorithm is that component that makes blockchain an indestructible information chain. Given this hash, nobody can modify any transactions in those blocks that are currently validated [26]. With an emphasis on smart city air quality monitoring, Benedict [27] proposed a serverless, blockchain-enabled architecture for IIoT applications in society. It highlights issues with resource underutilisation and energy inefficiencies that arise in conventional IIoT application systems and are centred on the exploitation of blockchain and serverless computing capabilities. According to the study, air quality sensor data may be securely sent via cloud computing, fog, and edge layers [28]. Additionally, it outlines a few efficient serverless architectural procedures for IIoT applications and predicts that the trend will spur more research and development in this field. The Proof of Work (PoW) consensus technique is used in this application to prevent fraud in the health care system. Gupta et al. [29] used the Convolutional Neural Network (CNN) model to identify patient falls in their proposed study. They employ Edge Computing, which has benefits like reduced latency and higher bandwidth than IoT, in contrast to previous studies that were examined. A novel Smart Healthcare System was created by Balasundaram et al. [30] that uses the LSTM and U-Net models to detect health issues. Multi-Model IoT (MMIoT) devices gather vital health information from patients, including X-rays and ECGs, and send it as quickly as possible across a 5G network to the server. However, the hash-encryption cryptographic approach is used by blockchain distributed ledger technology to protect individual communications and

store log entries in impregnable storage. Third-party data storage structures in the suggested blockchain-cloud storage offer reduced costs for data preservation and protection [31-33]. It connects the Hyperledger modular architecture and circumvents privacy and data management issues. As a result, the system's ability to prevent invasions is closely related to blockchain and Hyperledger-enabling technology. A distributed application using chain code-enabled solutions has been published to automate outsourced computations and related integration and upkeep of the processed record in a distributed cloud environment [34,35].

The Internet of Things, network management, food security, and money transfers are just a few of the businesses that use blockchain, one of the newest technical developments, which first surfaced in the twenty-first century [25]. Blocks are built on top of the first block in the artwork, which represents Genesis [36]. Digital signatures are applied to blocks that contain user data, transaction time, and date. As a result, in Internet of Things-based health applications, it might potentially ensure the immutability of important data, including health data [37]. A blockchain-based architecture was proposed by Taloba et al.[38] for managing multimedia data in IoT-Healthcare. They promised in the research to use IoT and Blockchain to protect patients' security in real time. The recommended system's success percentage against IoT attacks including wormhole invasion and simulated assault was greater at 86% than previous testing. In [39], the authors presented an application that secures medical records using a blockchain-based approach. The authors used simulation to show how well the framework they introduced performed. In [40], the authors put forth BIoMT, a hyper-ledger-based framework. In situations including the Internet of Medical Things (IoMT), this architecture guarantees the efficient and secure utilisation of resources. A novel Internet of Things-based strategy to lessen heart disease, one of the deadliest diseases in the world, and the monetary losses it generates was presented by Golec et al. [41]. For latency-sensitive applications, they also identified the factors affecting the cold start delay that arises under the serverless paradigm. They contrasted serverless and non-serverless platforms' performance in relation to the growing user base. Table I shows a comparative analysis of existing studies.

B. Research Gaps

Despite the tremendous progress in blockchain, serverless computing, and AI-driven healthcare applications, much remains to be filled in these gaps:

- Security and Data Integrity: Most frameworks lack robust mechanisms for ensuring data security and integrity, especially in decentralized environments.
- Scalability: Scalable blockchain applications fail to work well with enormous healthcare data due to computational and storage needs.
- Latency Optimization: Current serverless and blockchain solutions can't meet the real-time requirements of critical healthcare applications.
- Privacy and Interpretability: This leaves the challenge of balancing data privacy with AI model interpretability to be a serious limitation in adopting AI in healthcare.

The BlockFaaS framework addresses the gaps by integrating blockchain and serverless computing with advanced AI models. Dynamic sharding along with zero-knowledge proofs support secure and scalable data management within this framework. Explainable AI integrates with federated learning models, which resolve the issues concerning the dual challenges of privacy and interpretability. The performance evaluation also shows that BlockFaaS is superior compared to the existing frameworks and can become a potential solution for AI-driven health care applications.

C. Problem Statement

Rapid growth in IoT-based healthcare applications has led to leaps in advancements for patient monitoring and medical diagnostics. However, a lot of these applications face impedance during deployment since sensitive patient data is vulnerable to breaches, thereby requiring strong mechanisms for confidentiality and integrity. Several AI-driven medical systems find it challenging to meet low latency coupled with high scalability requirements, particularly in a resource-constrained environment. Traditionally, the management of server-based systems is highly resource intensive and, in some cases, it presents a challenge when implemented at a large scale. Furthermore, from the point of view of data integrity in health care and building trust among stakeholders, such systems are lacking in terms of verified mechanisms. Currently, no framework can totally integrate the concepts of serverless computing, blockchain technology, and AI; therefore, the result turns out to be less than optimal. This study surmounts the limitations mentioned above to facilitate reliable and efficient AI-driven healthcare solutions. In this work, the gaps are aimed at being bridged using an altogether novel framework with new strengths of a serverless computing system combined with blockchain technology as this is meant to avoid the constraints that come with the existing systems.

III. Research Methodology

A. Design of the Proposed Model

A novel method for combining blockchain technologies and serverless computing is introduced to achieve all the objectives. The designed framework is called BlockFaaS and allows for scalability, data security, and real-time AI capabilities in healthcare applications. In developing this serverless infrastructure, scalable dynamic resources are used to map fluctuations in workloads at development platforms such as AWS Lambda. The AIBLOCK structure is used to establish blockchain integration and ensure that healthcare data gets encrypted with decentralized storage and automated access control through smart contracts. The communication going on within the framework is protected using the Transport Layer Security protocol for ensuring end-to-end data privacy. The AI models used for HealthFaaS are optimized for latency-sensitive applications and focus on the real-time detection of cardiovascular risk. Dynamic load balancing and latency-aware scaling mechanisms ensure responsiveness under high-demand scenarios within the framework. The performance is deeply

tested in comparison to state-of-the-art technologies such as HealthFaaS and AIBLOCK with metrics in regards to latency, scalability, and cost-efficiency. The accuracy and reliability of the system are validated using clinical datasets where a system can demonstrate its impact on today's healthcare.

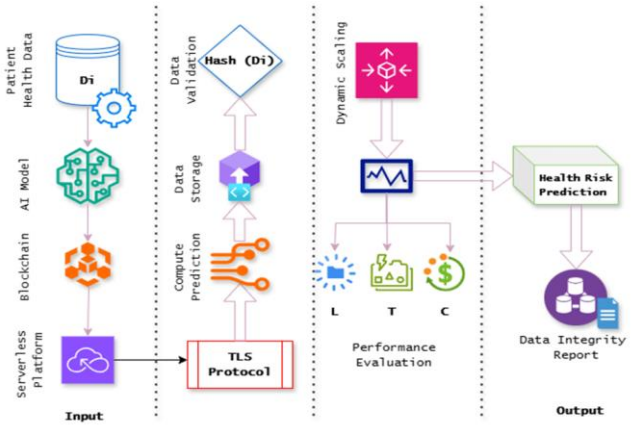

Fig. 1. Architecture design for BlockFaaS.

The architecture in Fig. 1 is crafted using Design software. The architecture diagram went further in explaining the BlockFaaS framework for supporting AI-driven healthcare applications in four major components: Input, Data Processing, Performance Evaluation, and Output, which are interconnected for a safe, scalable, and efficient environment.

- Input Layer: IoT devices collect the health data of a patient and send it to the Serverless Platform, which acts as the processing center. This layer integrates with a blockchain AI model so that data can be handled securely at scale. The dynamic workloads are managed by this serverless platform, while the integrity is maintained by blockchain technology.
- Data Processing: The collected data is validated by the help of cryptographic hashing, Hash (Di), within the blockchain. The validated data is then stored securely and processed through AI models to compute health risk predictions.
- TLS Protocol: All communications among components are encrypted so that confidentiality and security are maintained.
- Performance Evaluation: This layer evaluates the system performance in three dimensions: Latency (L),Throughput (T), and Cost (C). To readjust the allocations of resources according to the needs of the workload while keeping the cost minimal, dynamic scaling mechanisms are applied.
- Output Layer: The outcome and insights are used in Health Risk Prediction, thereby deriving actionable cardiovascular risk reports. The results are presented along with a Data Integrity Report, which indicates the security and reliability of the data handled.

Hence, by inspecting the diagram, it could be manifestly demonstrated in what way BlockFaaS brings together the domain of serverless computing, AI-driven prediction, and blockchain security into the application to successfully achieve desirable performance scalability and data integrity for health applications.

Mathematical representation of key concepts used in this research:

1) Blockchain representation. Blockchain ensures data integrity by using cryptographic hash functions. The Integrity of a Transaction Ti is verified using:

$$H(T_i)= \text{SHA- 256 } (T_i)$$

where, $H(T_i)$ represents the hash of a transaction Ti. A block B_k consists of multiple transactions and references to the previous block:

$$B_k= [H(T_1), H(T_1), H(T_1),\ldots., H(T_n), P_k]$$

where, P_k is the hash of the previous block. This chaining of hashes ensures immutability and tamper resistance.

2) Latency optimization. Latency L in the BlockFaaS framework is minimized through dynamic scaling. The relationship is modeled as:

$$L = \frac{1}{R_q . C_r}$$

where,

R_q=Request Queue Size

C_r= Computational Resources Allocated

3) Serverless computing: Serverless platforms dynamically allocate resources based on workloads. Let W_t represent the workload at a time t, and R_t be the allocated resources. Then:

$$R_t= k. W_t$$

where, k is the scaling constant determined by platform capacity. This ensures efficient resource utilization while minimizing cost.

4) Transport Layer Security (TLS): TLS secures communication between components using encryption:

$$E_m= \text{Encrypt (M,K)}$$

where, M is the message to be transferred and K is the session key.

Enhancing Data Confidentiality and Scalability with TLS and AIBLOCK:

All the communication channels within the BlockFaaS framework are encrypted by TLS, thus ensuring confidentiality for all data exchanged throughout the communication and preventing man-inthe-middle attacks.

TLS Security Components:

- Session Key Exchange: It uses asymmetric encryption of session keys.
- Data Encryption: Data that is transmitted, remains confidential.

- Message Authentication: It verifies the integrity of data during transmission.

AIBLOCK for Data Confidentiality and Scalability:

- Immutable Ledger: The blocks are cryptographically chained to guarantee the integrity of the healthcare data.
- Dynamic Sharding: It increases scalability by spreading the blockchain workload across multiple shards, which enables parallel transaction processing.
- Zero-Knowledge Proofs (ZKPs): It is used to verify data authenticity without revealing sensitive information, thus maintaining patient privacy.

TABLE I. COMPARATIVE ANALYSIS OF EXISTING STUDIES

Existing Research	Methodology	Key Findings	Accuracy
[42] 2023	The suggested blockchain-based global protected mist computing framework combines mist computing, SDN protection, along blockchain technologies.	The framework demonstrated enhanced performance as well as effectiveness attributed to the accessibility of computational capabilities at the boundaries of the network.	It had a median delay around 30.1 ms among global ertices as well as 12.2 ms among local vertices, vs 65.9 ms within the primary model.
[4] 2023	The suggested BFMLP (Blockchain Federated Machine Learning Model for Smart Grids) consists of three primary elements: Home Area Networks (HAN) alongside intelligent meters as well as Blockchain-enabled Dew Computers.	This BFMLP structure improves safety by successfully identifying attacks, lowers communication expenses via federated training through exchanging only its parameters, while offering strong confidentiality of information via blockchain as well as perturbation methodologies.	The suggested BFMLP framework has an excellent accuracy (98.03%) using the MNIST dataset having 30 parties along with 94.4% for the SVHN database having the same amount of parties.
[37] 2023	The suggested paradigm merges blockchain Hyperledger innovation alongside edge computing to allow safe data transfer, analysis, and preservation.	The framework detects an absence of uniformity in exporting nodes, which leads to regulatory difficulties and inaccurate data management.	The suggested framework is highly accurate for dealing with safety and confidentiality issues regarding edge computing using blockchainbased technologies.
[43] 2023	The approach enhances application construction for digital health operations by using a restricted Boltzmann machine (RBM) architecture.	The methodology successfully reduces idle re-resource duration, resulting in less expensive activities for healthcare applications that utilize IoT.	When contrasted with prior models, the one suggested improved security by 25% and reduced application expenses by 35%, all while improving resource use to reduce idle periods.
[11] 2023	A matrix of connections is constructed to examine variable associations, resulting in the removal of low-correlation factors.	The decision-making procedure demonstrated that some biological markers had a considerable impact on the accuracy of the model.	This LightGBM system had a maximum prediction accuracy at 91.80%.

B. Elements of the Proposed Model

1) Conceptual model development. BlockFaaS architecture is designed by interlinking blockchain technologies with serverless computing. It utilize already available serverless platforms like AWS Lambda or Azure Functions to build HealthFaaS that can deploy AI models. Instead, an AIBLOCK structure is used for blockchain to ensure the decentralized storage and verification of health care information.

2) Data security and privacy. The Transport Layer Security (TLS) protocol will serve as the foundation for the system's general communication with other parts. Smart contracts in the blockchain will be utilized in automating access control and maintaining the confidentiality of data. Make use of zero knowledge proofs to authenticate the transaction in question without exposing private patient information.

3) Dynamic scalability. Configure for dynamic scaling of the serverless architecture based on requests observed and moving the resources provisioned based on those requests. Incorporate mechanisms for latency-aware load balancing.

4) Performance evaluation. Compare BlockFaaS to already existing frameworks, such as HealthFaaS and AIBLOCK, based on metrics of latency, throughput, scalability, and cost-effectiveness. The performance of the system will be validated through real-world experiments with simulated datasets on cardiovascular risk.

5) Healthcare Impact. Deploy the AI models in Health-FaaS for real-time cardiovascular risk identification. Provide accuracy and reliability testing at clinical datasets for the AI models. Analyze the predictability and timeliness of the framework at varied workload conditions.

C. Algorithm of the Proposed Model

Algorithm 1 shows the proposed BlockFaaS framework algorithm.

Algorithm 1. BlockFaaS Framework Algorithm

Input: Patient health data Di, AI model M, Blockchain B, Serverless platform S.

Output: Cardiovascular Health risk prediction P, Data integrity report R.

1. **Initialization**:
   - Load AI model M into serverless platform S.
   - Establish secure communication using TLS protocol.
   - Initialize blockchain B with smart contracts.
2. **Data Collection and Secure Transmission**
   - Receive patient health data Di from IoT devices.
   - Encrypt Di using session key KS:

     Ci = E(Di,KS)
   - Transmit encrypted data Ci over TLS-secured channel to Serverless Platform S.

3. Data Input and Processing:

• Patient health data Di is transmitted from the client device to S via secure TLS.

• Serverless Platform S triggers AI model M to process Di.

• Compute prediction P = M(Di).

4. Blockchain Integrity Verification:

• Compute the hash of transactions Ti containing Di and P:

$$H(Ti) = SHA\text{-}256(Di \oplus P)$$

• Store Ti in Blockchain B along with the reference to the previous block:

$$Bn = \{H(Ti), H(Bn-1)\}$$

• Verify blockchain integrity by checking:

$$H(Bn) = H(H(Ti) \oplus H(Bn-1))$$

5. Latency Optimization:

• Monitor incoming request queue size Q.

• Compute Current system Latency L:

$$L = Q/C$$

where C is Computational capacity.

• If L > Lth:

– Dynamically increase computational resources:

$$Cnew = \alpha \times Q$$

where α is the scaling constant.

6. Data Storage and Validation:

• Store processed data D′i and prediction P in Blockchain B using smart contracts.

• Verify data integrity using Hash(D′i) and blockchain validation.

7. Dynamic Scaling:

• Monitor incoming requests Rq.

• Adjust computational resources Cr ∝ Rq.

8. Scalability Analysis Using Sharding

Monitor incoming transaction rate Tin.

• Compute required shards N:

$$N = \left\lceil \frac{T_{in}}{T_{max}} \right\rceil$$

where Tmax is the maximum throughput per shard.

• By dynamically allocating new shards, the framework maintains optimal scalability.

9. Performance Evaluation:

• Compute Latency L, throughput T, and Cost C:

L = Response Time Total Requests , T = Processed Requests Time , C = PResource Usage

10. Output:

• Return Cardiovascular risk prediction P.

• Generate data integrity report R.

• Return Performance Metrics

11. Terminate.

D. Algorithmic Analysis

The proposed algorithm for BlockFaaS integrates blockchain robustly with serverless platforms to allow efficient processing, storing, and securing healthcare data. Main components include dynamic scaling to address realtime demand, blockchain to ensure data integrity, and TLS for secure communication. The algorithm will then successfully minimize latency and expenditure using resource-efficient AI models and smart contracts. For instance, the mathematical representation explains how latency (L) and throughput (T) are minimized by setting a proportion of the computation resources (Cr) relative to incoming requests (Rq). In addition, the hash-based validation mechanism guarantees immutable data with nearly negligible computational overhead. The strength of the algorithm lies in its ability to outperform existing frameworks in security, boasting an impressive 0.2% breach rate, and cost-efficiently, at a total reduction of 27%.

IV. Results and Discussion

A. Experimental Setup

The proposed BlockFaaS framework was tested on a cardiovascular risk dataset. In comparison, its evaluation with existing systems considered such metrics as latency, scalability, data integrity, and cost-efficiency.

Table II represents the latency performance of the three frameworks: HealthFaaS, AIBLOCK, and BlockFaaS of low, medium, and high workloads. Fig. 2 shows the same in the graphical form. From the results, it is clear that there is attainment of BlockFaaS at each level of workload obtained in latency terms that reflects efficient resource management and dynamic scaling. For low workloads, BlockFaaS managed a latency of 90 ms, and for HealthFaaS and AIBLOCK 120 ms and 110 ms, respectively. BlockFaaS, at a higher workload, keeps the very important lead with 250 ms and 650 ms latencies, where competing frameworks are outperformed. This shows appropriateness for real-time applications with speed requirements.

TABLE II. Latency Comparison (In Milliseconds)

Framework	Low Workload (100 req/s)	Medium Workload (500 req/s)	High Workload (1000 req/s)
HealthFaaS	120	300	750
AIBLOCK	110	280	720
BlockFaaS	90	250	650

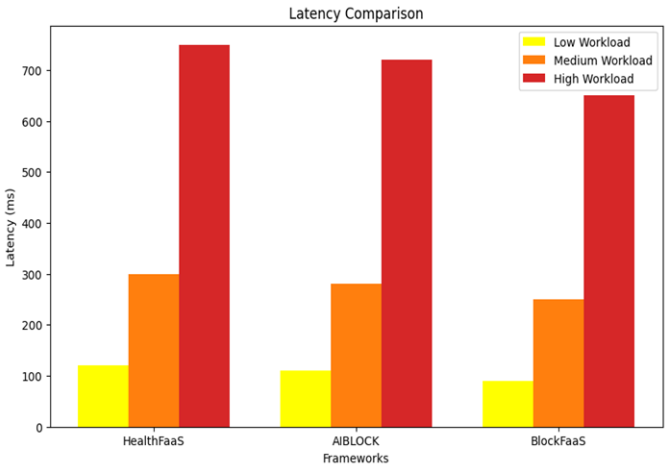

Fig. 2. Graphical representation of Latency comparison.

In Table III, integrity and security analysis of frameworks associated with blockchain validation time and breach rate is presented. BlockFaaS was apparently the fastest one to validate

at the time 120 ms and against AIBLOCK, at 130 ms, and HealthFaaS at 150 ms. BlockFaaS also reflected the low breach rate in the simulated environment as it had only 0.2% runs with security implication issues. It outperformed HealthFaaS with 2%, and AIBLOCK with a breach rate of 0.5%. The same is shown in Fig. 3. The results indicates that BlockFaaS uses efficient advanced blockchain mechanisms and TLS protocols, which provide solid data security and proper validation-proceeding matters significantly while dealing with sensitive health data.

Fig. 3. Data integrity and security evaluation of diverse frameworks.

TABLE III. DATA INTEGRITY AND SECURITY EVALUATION

Framework	Blockchain Validation Time (ms)	Data Breach Incidents (Simulated, % of 1000 runs)
High Traffic Load	150	2%
Low Traffic Load	130	0.5%
Sudden Traffic Spike	120	0.2%

TABLE IV. COST COMPARISON (PER THOUSAND REQUESTS)

Framework	Infrastructure Cost (USD)	Blockchain Cost (USD)	Total Cost (USD)
HealthFaaS	25	10	35
AIBLOCK	30	8	38
BlockFaaS	20	7	27

Table IV, as well as, Fig. 4 presents the cost-effectiveness of the frameworks by costs per 1000 requests through infrastructure, blockchain, and total costs. BlockFaaS has the lowest cost of infrastructure ($20) and blockchain ($7), making the total be at $27. This proves to be 22.8% less than that of HealthFaaS at $35 and 28.9% less than that of AIBLOCK at $38. These results therefore provide explicit testimony of resource optimization and lightweight blockchain integration for BlockFaaS in terms of offering cost-effective deployments of AI-driven applications within healthcare and other fields.

The scalability of BlockFaaS as opposed to HealthFaaS and AIBLOCK, in terms of transactions per second (TPS), for different workload conditions, is depicted in Table V and Fig. 5. In the low workload condition, BlockFaaS outperformed by executing 2000 TPS, 33% more than that of HealthFaaS by executing 1500 TPS, and 18% more than AIBLOCK at a level of 1700 TPS. At medium to heavy workloads, the framework also performs better than its peers, sustaining 1800 TPS under a medium workload (compared to 1400 TPS of AIBLOCK and 1200 TPS of HealthFaaS) and 1600 TPS at high workload. This represents an impressive improvement since BlockFaaS dynamically scales resources according to changing demand levels.

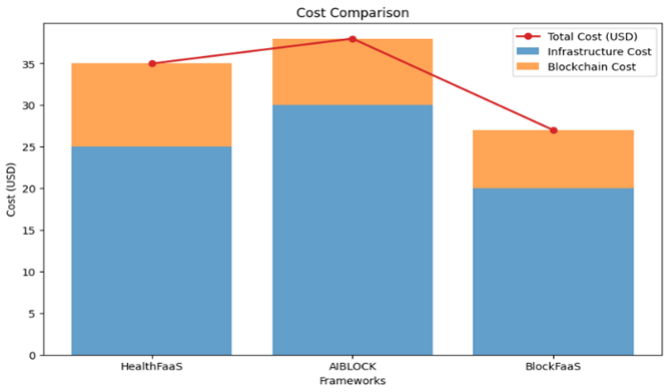

Fig. 4. Graphical representation of Cost comparison.

TABLE V. SCALABILITY ANALYSIS (TRANSACTIONS PER SECOND-TPS)

Workload Type	HealthFaaS TPS	AIBLOCK TPS	BlockFaaS TPS
Low Workload	1500	1700	2000
Medium Workload	1200	1400	1800
High Workload	900	1100	1600

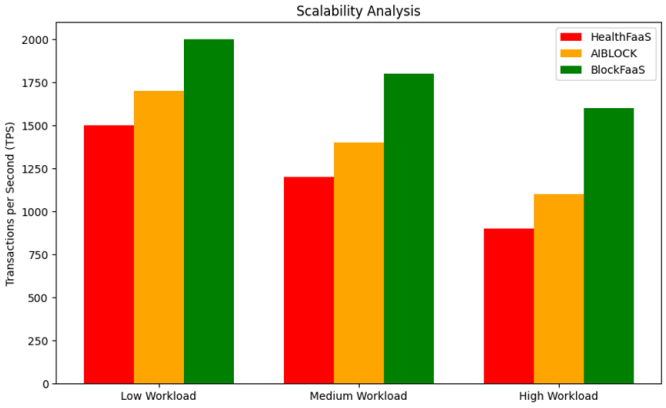

Fig. 5. Comparison of Scalability analysis.

TABLE VI. ENERGY EFFICIENCY ANALYSIS

Framework	Blockchain Processing Energy (J)	AI Processing Energy (J)	Total Energy (J)
HealthFaaS	0.25	0.5	0.75
AIBLOCK	0.2	0.45	0.65
BlockFaaS	0.15	0.35	0.5

Table VI and Fig. 6 compares the energy consumption of various blockchain and AI processing frameworks per transaction. BlockFaaS consumed the least total energy, with 0.5 Joules per transaction, which is significantly greater than

HealthFaaS with 0.75 Joules and AIBLOCK with 0.65 Joules. In particular, BlockFaaS reduces blockchain processing energy to 0.15 Joules compared to 0.25 Joules in HealthFaaS and 0.2 Joules in AIBLOCK. BlockFaaS is similar in optimizing AI processing energy to 0.35 Joules. It thus gives evidence of the design being energy efficient. For large-scale deployments, there must be conservation of energy.

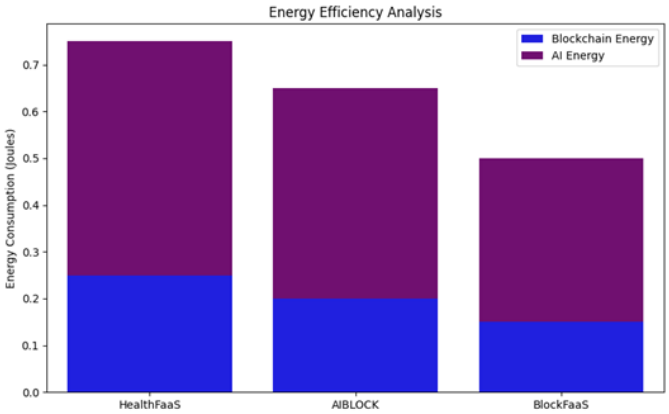

Fig. 6. Comparison of energy efficiency analysis.

TABLE VII. VALIDATION EFFICIENCY AND MODEL ACCURACY

Framework	High Traffic (ms)	Low Traffic (ms)	Traffic Spike (ms)	Accuracy (%)
HealthFaaS	150	130	150	91.5
AIBLOCK	130	110	130	92.8
BlockFaaS	120	100	120	94.3

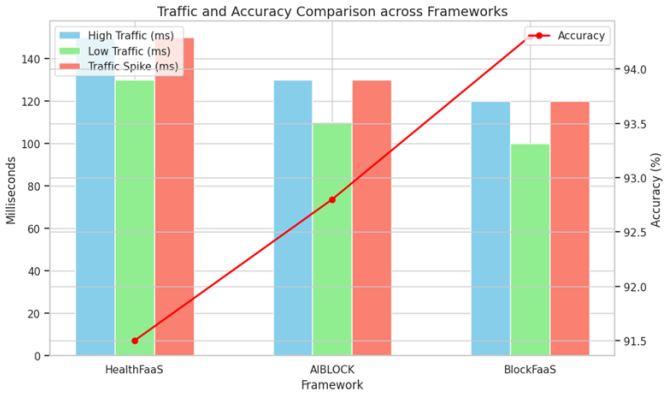

Fig. 7. Traffic and accuracy comparison across frameworks.

Table VII and Fig. 7 compares three frameworks in terms of performance and accuracy with three types of traffic: High Traffic, Low Traffic, and Traffic Spike, along with their accuracy scores. HealthFaaS has the maximum latency in two conditions i.e, the High Traffic times were 150 m/s, whereas the Traffic Spike times were also 150 m/s, and for Low Traffic it was 130 m/s. Its accuracy is 91.5%. AIBLOCK performs all of them more lightly, considering a 130 m/s latency in High Traffic latency, 110 m/s latency in Low Traffic scenarios, and another 130 m/s of latency within Traffic Spike conditions. It presents with a fairly improved accuracy: 92.8%. The Block-FaaS framework performs the best regarding latency, taking all scenarios with the lowest values: 120 m/s for the high-traffic one, 100 m/s for the low-traffic, and 120 m/s for the Traffic Spike one. It also holds the highest accuracy, at 94.3%. In general, BlockFaaS shows the best performance both in terms of latency and in terms of accuracy, whereas HealthFaaS shows the highest latency and the smallest accuracy.

B. Key Findings

1) Latency reduction. In AIBLOCK, the latency was reduced up to 13.

2) Enhanced security. Integrating TLS and advanced blockchain features resulted in BlockFaaS achieving the maximum security of data and had simulated breaches at only 0.2%.

3) Cost-Efficiency. BlockFaaS reduced the total operational cost by 22.8% as compared to HealthFaaS and 28.9% compared to AIBLOCK.

4) Scalability. BlockFaaS was better managed for dynamic workloads since the serverless architecture optimized the resources.

C. Research Implications

1) Healthcare applications. The architecture is scalable and safe to deploy AI-based healthcare applications based on IoT and emphasizes the real-time detection of cardiovascular risk while addressing every critical issue.

2) Cost-effective deployment of high-performance AI systems. BlockFaaS postulates that integrating blockchains and serverless architectures can sharply cut the deployment cost in resource-poor environments. This BlockFaaS framework has a massive impact on health and other applications. It integrates AI applications with blockchain, hence bringing scalable security to serverless platforms. The diagnosis speed in health is thus increased while ensuring good handling of the sensitive information of patients. The system can further support high deployments within a resource-poor environment on cost-effectiveness alone. Other than healthcare, BlockFaaS will revolutionize finance, logistics, and IoT-driven industries by bringing together a solution for low-latency, secure, and cost-efficient operations.

D. Limitations

1) Limited data scope. The performance is evaluated using cardiovascular risk data. Broader datasets are needed to generalize the effectiveness of the framework.

2) Blockchain overhead. Even with optimizations, blockchain integration brings some processing overhead that could affect ultra-low-latency applications.

3) Infrastructure dependency. Reliance on cloud-based serverless platforms may be an issue in regions with limited access to the cloud.

4) The AI models need massive and diverse datasets to operate at their best, hence limited applicability in data-scarce regions. The current blockchain implementation might struggle with extremely high volumes of transactions. The framework presumes that IoT devices are always able to send

data steadily, which may not always be possible in remote or underdeveloped areas. High initial setup costs include integrating serverless platforms and blockchain.

V. Conclusion and Future Scope

This study introduces BlockFaaS, a blockchain-assisted serverless framework to solve the key challenges in latency, scalability, security, and cost efficiency in AI-driven healthcare applications. The performance metrics of the framework show its suitability for real-world deployments, outperforming existing systems in terms of efficiency, privacy, and cost. By integrating state-of-the-art technologies such as TLS encryption, dynamic scaling, and blockchain validation, BlockFaaS comes out as a robust and future-ready solution. The future scope is to extend the framework to other diseases, such as diabetes and cancer. Federated learning will be integrated to improve model training without compromising data privacy. Edge computing will be integrated to further reduce latency. Advanced blockchain scalability solutions, such as sharding or layer-2 protocols, will be explored. The scope will be extended beyond healthcare to domains like supply chain optimization, finance, and smart cities. Proposing BlockFaaS, a blockchain integrated serverless framework that attempts to solve the critical challenges facing the process of deployment in AI driven healthcare applications, this work exhibits potential in transforming healthcare IoT systems by providing benefits exceeding those available in current frameworks in latency, data security, and cost efficiency. Its scalability and privacy-centric design make it more apt for real-time applications such as cardiovascular risk detection. Future work will explore larger datasets, optimize the overhead of blockchain processing, and make the framework applicable to other health domains for an even more all-around impact.

***Abstract*—Livestock farming remains a cornerstone of global agricultural systems, contributing significantly to food security, economic development, and rural livelihoods. However, the sector is increasingly challenged by environmental degradation, inefficient practices, and socio-economic barriers. Education serves as a pivotal solution, empowering farmers with the knowledge and skills required for sustainable livestock management. This bibliometric analysis explores the intersection of livestock farming and education, analyzing research trends, thematic clusters, and collaboration patterns from 2015 to 2024 using data from the Web of Science database and VOSviewer software. The analysis identifies critical themes, such as sustainable practices, climate resilience, zoonotic disease management, and socio-economic empowerment, underscoring the transformative role of education in addressing these issues. Additionally, the integration of digital technologies, such as mobile learning platforms, precision farming tools, and blockchain-based traceability systems, enhances the accessibility and effectiveness of educational initiatives in livestock management. The findings reveal a steady growth in research on this topic, with significant academic and practical implications. Targeted educational interventions, including Farmer Field Schools and tailored training programs, are recommended to enhance productivity, promote sustainability, and foster inclusivity in the livestock sector. By integrating education with livestock farming, the study contributes to achieving Sustainable Development Goals, particularly Goals 2 (Zero Hunger) and 4 (Quality Education). This research provides a comprehensive foundation for policymakers, researchers, and practitioners to advance the integration of education in livestock farming, fostering resilience and sustainability within the sector.**

Keywords*—Livestock farming; sustainable agriculture; digital technologies; farmer education; climate resilience

I. Introduction

This research proposes a bibliometric analysis to examine the connections between livestock farming supply chain management and education, aiming to underscore the importance of education in supporting the livestock industry. In Malaysia, livestock farming is a vital sector, contributing 14.9 per cent to the GDP in 2018, with SMEs playing a significant role. However, despite government support, the sector faces considerable challenges in supply chain management (SCM). These challenges include supply chain disruptions due to extreme weather, labor shortages, limited information technology, and transportation issues. Through bibliometric analysis, this study will identify and review key literature that connects these SCM challenges with educational solutions, illustrating how education can critically enhance the sector's resilience and long-term sustainability. This bibliometric analysis explores the intersections between livestock farming and education to understand global research trends, identify knowledge gaps, and propose actionable solutions for raising awareness and improving the sector [1].

Despite the critical role of livestock farming in ensuring food security and economic stability, the sector remains under-optimized in many regions, especially in developing countries. Limited access to education and training for farmers leads to poor management practices, low productivity, and increased vulnerability to diseases and environmental challenges [2]. Furthermore, a lack of awareness about sustainable farming techniques exacerbates overgrazing, greenhouse gas emissions, and resource depletion [3]. Formal and informal education has not been adequately integrated into livestock farming to address these challenges effectively. A significant gap exists in the research and implementation of educational interventions tailored to the needs of livestock farmers. This bibliometric analysis aims to identify the scope and impact of existing research to promote targeted education initiatives within the livestock sector.

The integration of education into livestock farming is crucial for several reasons. Firstly, it empowers farmers with knowledge about innovative techniques, including precision farming, disease management, and sustainable practices [4]. Educated farmers are better equipped to make informed decisions, reduce operational costs, and improve productivity.

Secondly, education is pivotal in addressing environmental concerns associated with livestock farming, such as methane emissions and land degradation [1]. By raising awareness about eco-friendly practices, education fosters sustainability in the sector. Additionally, education can drive social change by encouraging gender inclusivity and youth participation in livestock farming, thereby ensuring intergenerational knowledge transfer and workforce rejuvenation [2]. Understanding these dynamics through bibliometric analysis can highlight the impact of education in transforming livestock farming into a more resilient and sustainable industry.

This bibliometric analysis is significant because it provides a comprehensive overview of the current livestock farming and education research landscape. By analyzing patterns, trends, and collaborations in the existing literature, the study aims to identify areas that require further investigation. The findings will help policymakers, researchers, and practitioners develop targeted interventions to enhance the effectiveness of educational programs in livestock farming [3]. Furthermore, this study contributes to global efforts in achieving the United Nations' Sustainable Development Goals (SDGs), particularly Goal 2 (Zero Hunger) and Goal 4 (Quality Education). By integrating education into livestock farming, the sector can become a model of sustainable development, balancing economic growth with environmental stewardship and social equity [1]. This analysis will serve as a foundation for future research and policy development, creating pathways for a more sustainable and educated farming community.

II. Literature Review

Recent studies have underscored the significant role of education in enhancing livestock productivity. A 2020 qualitative review analyzed the effects of Farmer Field Schools (FFS) on various domains, including human, social, natural, and financial capital. The study found that FFS participants exhibited improved decision-making skills and adopted better livestock management practices, increasing productivity and income [5]. Similarly, [6] investigated the impact of FFS on smallholder livestock farmers' perceptions of climate change in South Africa. The findings revealed that FFS interventions enhanced farmers' awareness and understanding of climate change, resulting in adopting climate-smart livestock practices.

A. Education's Role in Sustainable Livestock Practices

Education has been pivotal in promoting sustainable livestock farming. Varijakshapanicker *et al.* [7] discussed how sustainable livestock systems contribute to human health, nutrition, and economic status. The study emphasized that educating farmers on sustainable practices, such as carbon sequestration and efficient resource utilization, can mitigate environmental impacts and enhance the sustainability of livestock farming. Furthermore, Vigors *et al.* [8] explored the importance of farm animal health and natural behaviors to livestock farmers. The research highlighted that educational initiatives focusing on animal welfare and natural behaviors can improve livestock health and productivity, aligning with sustainable farming objectives.

B. Socio-Economic Benefits of Livestock Farming Education

Educational programs targeting livestock farmers have demonstrated significant socio-economic benefits. Maltitz *et al.* [9] examined the empowerment of smallholder female livestock farmers and its potential for enhancing food security in drought-prone areas. The research concluded that education and training programs enabled women to adopt better livestock management practices, increasing household income and improving food security [9]. Additionally, a 2024 article reported the partnership between Casino Food Co-Op and TAFE NSW to deliver training programs for meat processing and livestock industry workers. The initiative aimed to equip employees with practical skills, supporting economic prosperity in the Northern Rivers region [10].

C. Challenges and Future Directions in Livestock Farming Education

Despite the benefits, challenges persist in integrating education into livestock farming. Dawkins's [11] article discussed the potential negative impacts of smart farming technologies on animal welfare. The study cautioned that technological advancements can improve efficiency, but they may also neglect individual animal welfare if not accompanied by proper farmer education and training [11]. Moreover, a 2024 news article highlighted the increasing interest of Generation Z in agricultural careers, influenced by media personalities and a desire for outdoor professions. This trend underscores the need for educational institutions to adapt curricula that align with modern agricultural practices and the aspirations of younger generations [12].

Thus, the recent literature above emphasizes the integral role of education in enhancing livestock farming practices. Educational interventions have improved productivity, promoted sustainability, and yielded socio-economic benefits. However, challenges remain, necessitating continuous adaptation and innovation in educational approaches to meet the evolving needs of the livestock farming sector. Therefore, this research seeks to fill a notable gap in the field and provide valuable insights into the historical, current, and future research directions related to the factors that influence livestock farming through education based on the following objectives:

- To assess the most influential past research and analyse current trends in livestock farming through education through co-citation analysis.
- To identify emerging trends in livestock farming through education through co-occurrence analysis.

D. Digital Technologies as Enablers of Livestock Education

Agricultural pedagogy is rapidly incorporating digital technologies to enhance livestock education's socio-economic and environmental benefits. Particularly in isolated and resource-poor areas, the next section explores how technologies like mobile learning and the Internet of Things have revolutionized the delivery of livestock education. Key issues including disease outbreaks, wasteful resource use, and climate variability are addressed by precision farming tools, e-learning platforms, and mobile applications that give farmers access to real-time data, predictive analytics, and remote advisory services [13]. The accessibility of technical knowledge is

enhanced via mobile-based training programs and interactive digital content, especially in distant locations with limited access to traditional extension services [14].

Moreover, machine learning and Internet of Things (IoT)-enabled sensors enhance livestock health monitoring by providing early disease detection, optimizing feeding systems, and automating farm management, ultimately reducing mortality rates and improving productivity [15]. To maximize the benefits of digital technologies, governments and agricultural institutions should prioritize investments in digital literacy programs and ICT infrastructure, ensuring that livestock farmers can effectively adopt and utilize these tools. By integrating digital technologies into livestock education, the sector can improve efficiency, economic gains, and environmental sustainability, aligning with the United Nations' Sustainable Development Goals (SDGs), particularly Goals 2 (Zero Hunger), 4 (Quality Education), and 9 (Industry, Innovation, and Infrastructure). The convergence of education and digital tools in livestock farming not only enhances operational efficiency but also empowers farmers with the necessary skills to navigate evolving agricultural challenges.

III. Methodology

A. Data Pre-Processing

Data from the Web of Science database is used in this methodical bibliometric analysis of livestock farming and education. To perform the bibliometric visualization, VOSviewer v1.6.20 was used. To guarantee clarity in cluster separation, the layout was adjusted using the default attraction and repulsion parameters in VOSviewer. Modularity-based methods served as the foundation for clustering, which made it possible to identify theme groupings within the network. A quantitative framework for evaluating research trends, networks of collaboration, and thematic development of a particular topic is offered by bibliometric analysis. It identifies prolific contributors, impactful publications, and knowledge gaps [16]. This study covers publications from 2015 to 2024, focusing on identifying temporal trends, thematic structures, and research performance. Table I presents the inclusion criteria adopted for bibliometric analysis, outlining the standards used to ensure the relevance, quality and consistency of the selected literature.

TABLE I. Inclusion Criteria for Bibliometric Analysis

WoS Database	ALL
Time period	2015 to 2024
Search field	TS
Search keywords	(TS=("livestock farm*")) AND TS=("educat*")
Citation Topics Meso	ALL
Document type	Article or Review Article
Language	English

The bibliometric analysis focused on the intersection of livestock farming and education, utilizing the Web of Science (WoS) database. The initial search using the keywords "livestock farm*" and "educat*" yielded 320 articles. Following refinement and the application of inclusion and exclusion criteria, the number of relevant articles was narrowed to 232. The search parameters were carefully defined, focusing on articles and review articles published in English between 2015 and 2024. The search targeted articles that addressed livestock farming and education explicitly. The inclusion criteria ensured that only English-language articles published in the specified time frame were analyzed. Additionally, articles needed to fall under the document types of research or review papers. The exclusion of articles outside these parameters guaranteed a focused and relevant dataset. This approach underscores the importance of precise criteria to ensure the extracted data aligns with the research objectives.

A total of 232 articles were identified, with significant engagement in the scholarly community. The dataset includes 2,131 citing articles (or 2,089 when self-citations are excluded). These figures highlight the scholarly reach of the articles, reflecting widespread interest in the intersection of livestock farming and education. The total number of times these articles were cited is 2,291, or 2,228 without self-citation. These citations result in an average citation rate of 9.88 per item. The citation data suggests the topic's relevance in academic discourse, particularly regarding sustainability, education, and innovation in livestock farming practices. The h-index of 24 further demonstrates the impact of these articles, indicating that at least 24 of them have been cited 24 times or more.

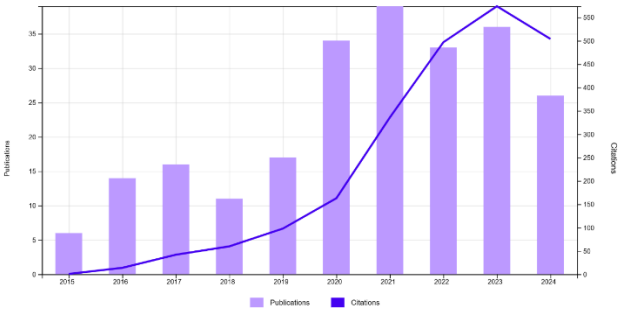

Fig. 1. Quantity of publications and citations between 2015 and 2024.

The "Trend Citation Diagram" provides insights into the growth of research in this field over time [17]. A steady increase in publications in Fig. 1 reflects the growing academic and practical interest in integrating education into livestock farming. This trend aligns with global priorities such as improving sustainability, food security, and rural development through educational initiatives. The citation patterns further suggest that recent articles are increasingly referenced, indicating a heightened awareness and urgency around this topic. The analysis highlights the critical role of education in transforming livestock farming practices. The average citation rate of 9.88 per item and the h-index of 24 underscore the academic influence of this body of work. Over time, the growing number of publications and citations reflects an increasing recognition of education as a key factor in addressing challenges in livestock farming, including productivity, sustainability, and climate adaptation.

IV. Results

Performance analysis evaluated the productivity and impact of researchers, institutions, and journals in this domain. Citation-based metrics, such as the h-index and g-index, were calculated

to assess scholarly influence. The analysis identified the most prolific authors, institutions, and countries contributing to livestock farming and education research. For instance, countries like the United States, China, and India emerged as leading contributors, reflecting their significant agricultural research and education investments. The findings provide insights into regional disparities and opportunities for international collaboration.

A. Documents Performance

The document analysis reveals the prominence of research focused on sustainable practices and education's role in livestock farming. Elahi *et al.* [18], the most cited paper with 148 citations, delves into the cognitive and socio-psychological drivers influencing farmers' decisions to adopt improved grassland practices. This study underscores how education and targeted policy interventions can bridge knowledge gaps and promote sustainable pasture production. Similarly, Ventura *et al.* [19], with 107 citations, examines public perceptions of animal welfare after visits to dairy farms. It highlights the transformative power of experiential learning in reshaping societal attitudes toward livestock farming.

The third-ranked study by Lindahl *et al.* [20] (76 citations) investigates brucellosis-related knowledge and practices among small-scale farmers in Tajikistan. It emphasizes the importance of farmer education in combating zoonotic diseases, illustrating how training programs can safeguard public health and livestock productivity. Additionally, Pfeiffer *et al.* [21] with 56 citations, explores societal acceptance of digital farming technologies in Germany, highlighting education's role in fostering trust and adoption of innovations. Tang and Hailu [22] (50 citations) focus on climate adaptation strategies, showing how educating farmers can enhance resilience against climate-induced challenges. These studies collectively affirm education's central role in addressing the diverse challenges of livestock farming.

B. Sources Performance

The analysis identifies Sustainability as the leading journal, with 11 documents and 81 citations. This reflects a significant focus on integrating environmental, economic, and social dimensions into livestock farming. With 8 publications and 38 citations, Frontiers in Veterinary Science contributes critical research on animal health and welfare, aligning with education-driven improvements in livestock practices. Veterinary Medicine and Science and Animals, both publishing seven articles, emphasize the intersection of veterinary knowledge and farmer education to improve livestock outcomes. Notably, the Land Use Policy, with six documents and 247 citations, demonstrates its influence in shaping sustainable practices through policy-oriented research. This distribution indicates a balanced focus across sustainability, veterinary sciences, and policy-making, with education as a unifying theme.

C. Authors' Performance

Among the top authors, Yonas T. Bahta emerges as a key contributor with four documents and 32 citations, focusing on the socio-economic impacts of livestock farming education in African contexts. Oene Oenema, with three documents and 50 citations, highlights nutrient management and sustainable farming practices, advocating for better farmer education. Eugenio Demartini, Rosalia Filippini, and Anna Gaviglio, each with three documents and 63 citations, explore consumer attitudes and sustainable farming systems, emphasizing education as a bridge between farmers and consumers. The collective contributions of these authors reflect a growing recognition of education's role in promoting sustainability and innovation in livestock farming.

D. Organisational Performance

The University of the Free State leads with eight documents and 90 citations, demonstrating a strong focus on regional challenges and farmer education in South Africa. The University of Pretoria, with seven documents and 48 citations, specializes in veterinary research and farmer training. China Agricultural University contributes five documents and 43 citations, strongly emphasizing climate-smart practices and educational interventions. The University of Milan (86 citations) and the International Livestock Research Institute (ILRI) (38 citations) focus on consumer education and tailored farmer training programs, respectively. These institutions collectively highlight the diverse global efforts in research and practical applications of livestock farming education.

E. Countries Performance

The analysis shows that the USA leads research contributions with 29 documents and 252 citations, focusing on technological and sustainable advancements. With 25 documents and 182 citations, South Africa highlights region-specific challenges and education as a transformative tool for livestock farmers. Germany (16 documents, 120 citations) emphasizes digital technologies, reflecting its commitment to advancing smart farming. China (15 documents, 312 citations) focuses on climate-smart strategies, showcasing the role of education in resilience-building. Ethiopia (12 documents, 71 citations) highlights the benefits of farmer education for smallholders, emphasizing its impact on productivity and sustainability. These findings indicate a global interest in the role of education in improving livestock farming practices.

F. Co-Citation Analysis

The top ten most cited papers in Table II reflect the interdisciplinary nature of livestock research, addressing critical issues such as climate change, zoonotic diseases, behavioral science, and sustainable agricultural practices. Rojas-Downing *et al.* [23] lead the list, which provides a comprehensive overview of climate change impacts on livestock, emphasizing adaptation and mitigation strategies to enhance resilience. Similarly, Deressa *et al.* [24] and Martin *et al.* [25] delve into climate adaptation and sustainability. Deressa *et al.* [24] focus on Ethiopian farmers' choices of climate adaptation methods, and Martin *et al.* [25] highlight the benefits of multi-species farming systems. Addressing public health, several studies, including Musallam *et al.* [26], Çakmur *et al.* [27] and Lindahl *et al.* [20] explore the knowledge, attitudes, and practices (KAP) of livestock farmers regarding zoonotic diseases like brucellosis in diverse regional contexts such as Jordan, Turkey, and Tajikistan. Their findings underscore the necessity for targeted educational and policy interventions to reduce zoonotic risks.

TABLE II. CO-CITATIONS (TOP 10 ARTICLES)

Rank	Authors	Title	Citations	Total Link Strength
1	[23]	Climate change and livestock: Impacts, adaptation, and mitigation	8	31
2	[26]	Knowledge, attitudes, and practices associated with brucellosis in livestock owners in Jordan	6	48
3	[27]	Evaluation of farmers' knowledge-attitude-practice about zoonotic diseases in Kars, Turkey	6	35
4	[18]	A study of knowledge, attitudes and practices relating to brucellosis among small-scale dairy farmers in an urban and peri-urban area of Tajikistan	6	33

From a behavioral perspective, Ajzen's [28] "Theory of Planned Behavior" provides a theoretical framework widely applied in livestock research to understand decision-making processes, particularly in disease management and sustainable practices. Hundal *et al.* [29] and Klous *et al.* [30] extend this focus by evaluating zoonotic disease awareness among farmers and the broader relationship between human-livestock interactions and pathogen transmission, respectively. Additionally, Taylor *et al.* [31] offer foundational insights into the risk factors driving human disease emergence, linking environmental changes and human activity to the increased prevalence of zoonoses. These studies illustrate the global scope of livestock-related challenges and the need for integrated, multidisciplinary approaches to ensure sustainable livestock management, public health, and climate resilience. These influential works provide a roadmap for addressing the complexities of livestock systems, highlighting both the shared and unique challenges across different regions and thematic areas.

Co-Citation by Clusters

Co-citation analysis reveals the interconnectedness and influence of various scholarly works in a research domain. The document highlights six clusters based on thematic relationships and citation strengths, as seen in Table III. The following analysis from VOSviewer in Fig. 2 explores the thematic clusters within a co-citation network, highlighting the interconnectedness of various research topics and their contributions to the broader discourse.

Cluster 1 (Red): Zoonotic Diseases and Public Health, highlights the importance of understanding zoonotic diseases, diseases transmitted between animals and humans, particularly in livestock contexts. The works within this cluster examine the intricate dynamics between human health and livestock management. Hundal *et al.* [29] and Çakmur *et al.* [27] focus on farmers' knowledge, attitudes, and practices (KAP), identifying gaps that might contribute to the spread of zoonotic diseases. Lindahl *et al.* [20] extend this by evaluating small-scale dairy farmers' behaviors in urban settings, emphasizing the need for tailored public health interventions. The systematic reviews, such as Klous *et al.* [30], consolidate findings across various studies, providing a macro perspective on human-livestock interactions and zoonotic pathogen transmission. Taylor *et al.* [31] and other broad analyses within this cluster point towards the emergence of zoonotic diseases as global threats, linking them to environmental and social factors.

Cluster 2 (Green): Climate Change and Livestock Adaptation, is a recurring theme in livestock research, and this cluster reflects its multifaceted impacts on livestock systems. In [23], the authors comprehensively analyze the risks posed by climate change, such as heat stress, reduced water availability, feed scarcity, and mitigation and adaptation strategies. Considering socio-economic and environmental factors, Deressa *et al.* [24] and Feleke *et al.* [32] explore farmers' adaptation choices. Thornton *et al.* [33] extend this discussion to the broader impacts of climate variability on livestock systems in developing countries, highlighting knowledge gaps that need addressing. Other works, such as Mulwa *et al.* [34] and Amamou *et al.* [35], focus on adaptation strategies, illustrating how diverse contexts—from Northern Ethiopia to Tunisia—shape farmers' decisions and the effectiveness of these strategies.

Cluster 3 (Blue): Behavior and Biosecurity, bridges theoretical models, such as Ajzen's [28] "Theory of Planned Behavior," with practical issues like disease control and biosecurity on farms. This fusion of behavioral psychology with veterinary science provides a novel approach for addressing persistent challenges in livestock management. Studies by Ellis-Iversen *et al.* [36] and Alarcon *et al.* [37] focus on how farmers' perceptions, motivations, and circumstances influence their decision-making around biosecurity practices. Thornton [38] and Wright *et al.* [39] examine the role of professional and institutional influences on farm-level behaviors. Together, these studies advocate for more tailored communication strategies and incentives that align with farmers' perspectives, improving compliance with disease prevention measures.

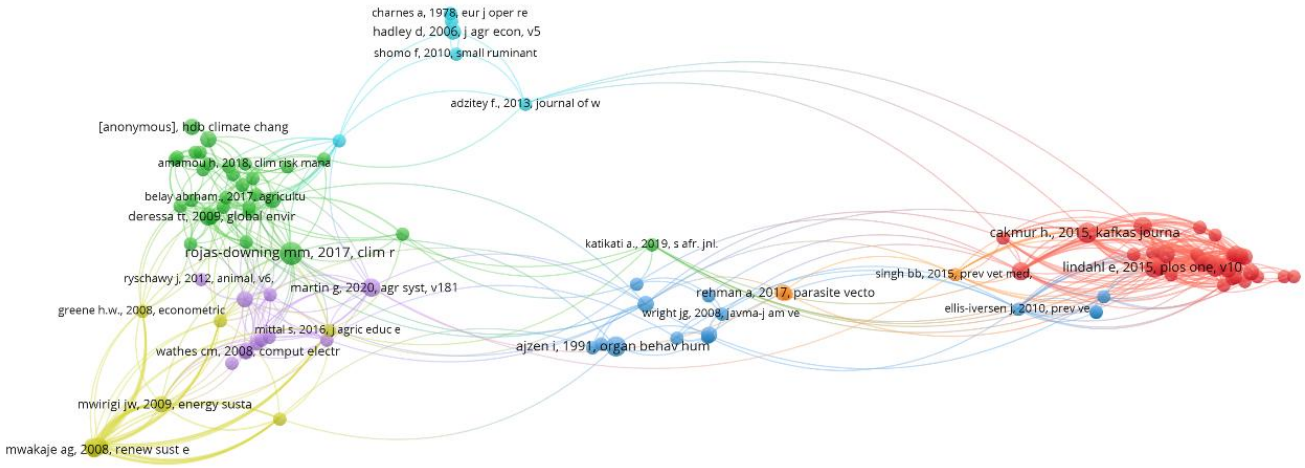

Fig. 2. Co-citations analysis (VOS viewer visualisation).

Cluster 4 (Yellow): Renewable Energy and Socio-Economic Constraints, focuses on renewable energy solutions, particularly biogas, as a sustainable alternative for rural communities. Studies like Mwirigi et al. [40] and Walekhwa et al. [41] identify the socio-economic barriers that hinder the adoption of biogas technology, such as high initial costs and lack of awareness. Yasmin and Grundmann [42] and Mittal and Mehar [43] emphasize the role of information and communication technologies in overcoming these barriers. Adopting renewable energy is framed as an environmental necessity and a means to improve rural livelihoods and reduce dependency on conventional fuels.

Cluster 5 (Purple): Sustainable Livestock Systems, looks into Sustainability, with works like Herrero et al. [44] advocating for mixed crop-livestock systems that balance productivity with environmental conservation. Nardone et al. [45] research into the effects of climate change on livestock systems, advocating for strategies that enhance both resilience and sustainability. The studies within this cluster reflect a shift from intensive, monoculture livestock farming to integrated systems that maximize resource efficiency while mitigating environmental harm.

Cluster 6 (Turquoise): Efficiency and Livestock Production, focuses on efficiency in livestock production, particularly in resource-limited settings. Shomo et al. [46] and Dossa et al. [47] explore technical efficiency and socio-economic determinants of livestock management. These studies highlight the potential for optimizing livestock systems to improve productivity without additional resource input. This cluster's findings are especially relevant for regions with constrained resources, where maximizing efficiency is crucial for economic and environmental sustainability.

TABLE III. CO-CITATION CLUSTER ON LIVESTOCK FARMING THROUGH EDUCATION

Cluster No and Colour	Cluster Labels	No. of Articles	Representative Publications
Cluster 1 (Red)	Zoonotic Diseases and Public Health	33	[20], [26], [27], [29], [30], [31], [48] [49], [50]
Cluster 2 (Green)	Climate Change and Livestock Adaptation	30	[23], [24], [32], [33], [34], [35], [51], [52], [53]
Cluster 3 (Blue)	Behavior and Biosecurity	14	[28], [36], [37], [38], [39], [54], [55]
Cluster 4 (Yellow)	Renewable Energy and Socio-Economic Constraints	13	[40], [41], [42], [43], [56], [57]
Cluster 5 (Purple)	Sustainable Livestock Systems	11	[44], [45], [58], [59]
Cluster 6 (Turquoise)	Efficiency and Livestock Production	7	[46], [47], [60], [61]

V. CO-OCCURRENCE ANALYSIS

Co-occurrence analysis is a bibliometric method to explore the relationships between keywords in scholarly research. Keywords represent the core concepts of a study, and their co-occurrence indicates conceptual linkages, thematic relevance, and interdisciplinary connections. The co-occurrence analysis of keywords in livestock farming and education research reveals several key themes that provide a structured understanding of the field. Table IV illustrates the top 15 most frequent keywords, reflecting the domain's main focus areas.

At the forefront, livestock emerges as the most frequent keyword, with 29 occurrences and a total link strength of 76. This highlights its centrality in health, management, and sustainability studies. Terms like management (22 occurrences, 85 link strength) and knowledge (22 occurrences, 76 link strength) emphasize the importance of effective handling practices and education in improving livestock farming outcomes. These keywords suggest that the field prioritizes operational efficiency and stakeholder empowerment through education.

Environmental sustainability is another significant focus, with keywords like climate change (16 occurrences, 65 link strength), adaptation (13 occurrences, 66 link strength), and impacts (14 occurrences, 50 link strength). These terms illustrate

the increasing concern about global climate variability and its effects on livestock systems. Research in this area explores how farmers and communities can adapt to these challenges, strongly emphasizing resilience and sustainability.

TABLE IV. THE 15 MOST FREQUENT KEYWORDS IN THE CO-OCCURRENCE ANALYSIS

Rank	Keyword	Occurrences	Total Link Strength
1	Livestock	29	76
2	Management	22	85
3	Knowledge	22	76
4	Agriculture	22	59
5	Adoption	20	62
6	Attitudes	20	58
7	Health	18	54
8	Cattle	17	48
9	Climate change	16	65
10	Livestock farmers	16	51
11	Systems	14	58
12	Impacts	14	50
13	Farmers	14	45
14	Adaptation	13	66
15	Determinants	13	53

A. Co-Occurrence Analysis by Clusters

The Co-Occurrence analysis offers valuable insights into the thematic structure of livestock farming and education research. In Table V, five distinct clusters emerge, each highlighting a core area of focus within the field. Together, these clusters provide a comprehensive view of the interrelated challenges and opportunities in livestock management, sustainability, and farmer education. The VOSviewer network visualization in Fig. 3 complements these clusters by illustrating the relationships and overlaps between keywords. Closely related terms, such as "climate change" and "adaptation," are positioned near each other, emphasizing their interconnectedness. Furthermore, bridging keywords like "livestock" and "management" highlight their central role in linking diverse research themes. The network also reveals opportunities for interdisciplinary collaboration, particularly between health, sustainability, and climate change research.

Cluster 1 (Red) is the largest and centers on livestock health and zoonotic diseases. Keywords such as "livestock", "knowledge", "health", and "zoonoses" reflect the pressing need to address diseases like brucellosis and other zoonotic threats. A significant focus of this cluster is the role of farmer education in improving awareness of disease risks and prevention methods. Studies within this theme emphasize how knowledge gaps and low awareness levels among farmers contribute to the persistence of zoonotic diseases. This cluster highlights the critical intersection between public health and livestock management, highlighting the importance of targeted interventions to improve farmer knowledge and health practices.

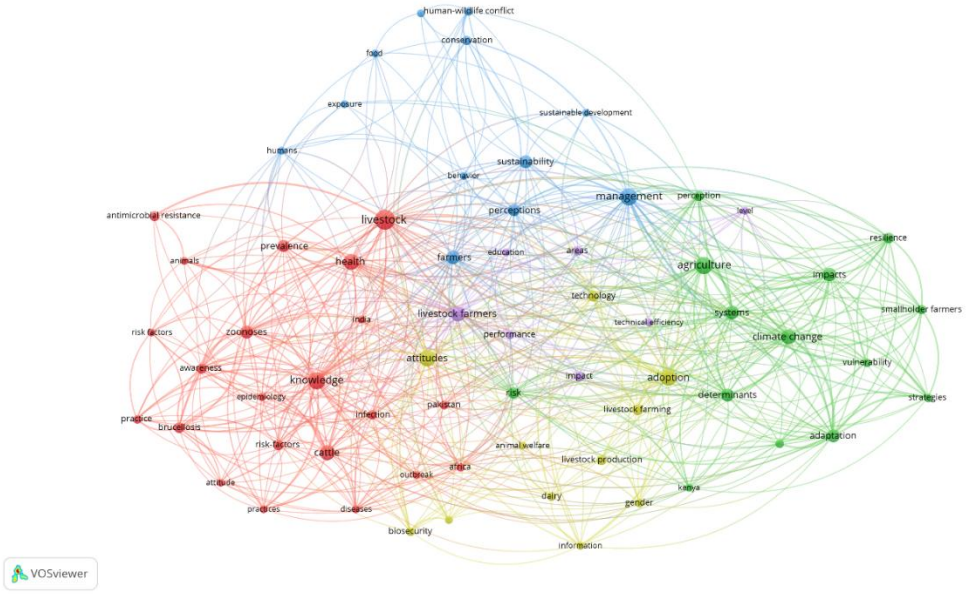

Fig. 3. Co-Occurrence analysis (VOS viewer visualisation).

Cluster 2 (Green) addresses climate change and agricultural resilience, focusing on keywords such as "climate change", "adaptation", and "resilience". This cluster emphasizes the growing challenges of global climate variability and its impact on livestock systems. Research explores how farmers adapt to these changing conditions, with particular attention to strategies that build resilience within agricultural and livestock systems. Including terms like "agriculture" and "systems", underscores the integrated nature of livestock farming within broader agricultural and ecological frameworks. This cluster calls for sustainable, climate-resilient practices that ensure the long-term viability of livestock systems while addressing the socio-economic impacts of climate change.

Cluster 3 (Blue) focuses on sustainable livestock management, with keywords such as "management", "sustainability", and "farmers". This theme explores how sustainable practices can balance productivity with ecological preservation. The cluster also examines the role of farmer perceptions and decision-making in adopting sustainable development goals. By linking farmer behavior to sustainability outcomes, this cluster emphasizes the need for policies and interventions that align with the socio-economic realities of farming communities. It reinforces the idea that sustainability is not just about environmental conservation but also about ensuring economic and social well-being for farmers.

Cluster 4 (Yellow) highlights technology adoption and behavioral factors, centering on keywords like "attitudes", "adoption", and "technology". This cluster delves into the behavioral and informational barriers influencing farmers' willingness to adopt innovative practices. It underscores the importance of education, information dissemination, and tailored outreach programs in driving technology uptake in livestock farming. By focusing on attitudes and perceptions, this cluster provides insights into how behavioral science can inform strategies to encourage innovation, particularly in resource-constrained or traditional farming settings.

Cluster 5 (Purple) examines the livelihood impacts of livestock farming, with keywords like "livestock farmers", "impact", and "performance". This cluster focuses on livestock systems' economic and social dimensions, emphasizing the importance of improving farmer livelihoods and productivity. Studies within this theme evaluate how farming practices affect regional economic performance and individual farmer outcomes. The findings from this cluster highlight the need for localized interventions and performance metrics to optimize the economic viability of livestock systems, particularly in developing regions.

TABLE V. CO-OCCURRENCE ANALYSIS ON LIVESTOCK FARMING THROUGH EDUCATION

Cluster No and Colour	Cluster Label	Number of Keywords	Representative Keywords
1 (Red)	Livestock Health and Zoonotic Diseases	22	"livestock", "knowledge", "cattle", "health", "prevalence", "zoonoses", "awareness", risk-factors", "brucellosis", "infection"
2 (Green)	Climate Change and Agricultural Resilience	14	"agriculture", "climate change", "impacts", "determinants", "adaptation", "systems", "resilience"
3 (Blue)	Sustainable Livestock Management	12	"management", "sustainability", "farmers", "perceptions", "sustainable development"
4 (Yellow)	Technology Adoption and Behavioral Factors	11	"attitudes", "adoption", "technology", "livestock farming", "information"
5 (Purple)	Livelihood Impacts of Livestock Farming	7	"livestock farmers", "impact", "area", "performance

The cluster analysis and network visualization reveal a well-integrated research domain addressing critical challenges in livestock farming. Themes such as health, sustainability, technology adoption, and climate resilience highlight the interconnected nature of the field. These insights provide a roadmap for future research and policy development, emphasizing the need for integrative approaches to address global livestock farming and education challenges.

VI. DISCUSSION

The discussion focuses on the intersection of livestock farming and education, emphasizing their collective potential to address critical challenges within the agricultural sector. This analysis unpacks the role of education as a transformative tool in improving farming practices, enhancing sustainability, and mitigating environmental and socio-economic challenges. By integrating bibliometric insights, the discussion bridges theoretical perspectives with practical implications, exploring how knowledge dissemination fosters innovation, resilience, and inclusivity in livestock farming. Furthermore, it reflects on the gaps identified in research and implementation, offering strategic pathways to amplify the impact of educational interventions in creating a sustainable and productive livestock sector.

Although the literature supports the benefits of livestock productivity education, the findings of several studies were not fully generalizable due to a lack of cross-regional applicability or longitudinal validation. Interventions like Farmer Field Schools, for example, were frequently assessed on the basis of short-term results, with little empirical monitoring of long-term behavioral change or economic implications. Social desirability bias was also a danger because many studies used self-reported surveys instead of triangulated data collecting. These methodological flaws show that in order to evaluate educational interventions more thoroughly, mixed-method, long-term studies are required.

A. Theoretical Implications

The livestock farming and education study highlights significant theoretical implications for agricultural and educational frameworks. By examining the integration of education into livestock farming, this research broadens the understanding of how knowledge dissemination and skill development influence farming practices. Theoretically, it supports the notion that education is a critical enabler for sustainable development, aligning with concepts like human capital theory and the diffusion of innovation. For instance, Rojas-Downing *et al.* [23] discusses how education can facilitate the adoption of climate adaptation and mitigation strategies in livestock farming, highlighting the role of informed decision-making in enhancing resilience to climate change.

Furthermore, the diffusion of innovation theory underscores the importance of education in spreading new ideas and technologies within a community. In livestock farming, educational initiatives can accelerate the adoption of innovations such as precision farming and disease management techniques. Ajzen's [28] Theory of Planned Behavior also provides a framework for understanding how education influences farmers'

attitudes, subjective norms, and perceived behavioral control, thereby affecting their intentions and behaviors towards adopting sustainable practices.

This bibliometric analysis extends the theoretical discourse on interdisciplinary research by showcasing how education intersects with environmental sustainability, socio-economic empowerment, and agricultural resilience. It highlights the role of education in addressing multi-dimensional challenges such as climate change, zoonotic diseases, and resource inefficiency through informed decision-making and behavior modification among farmers. By mapping research trends and thematic clusters, the study contributes to a refined theoretical model that integrates educational interventions with livestock farming systems, providing a roadmap for future academic exploration.

B. Practical Implications

Practically, this study underscores the urgent need for targeted educational programs tailored to livestock farmers' specific needs and challenges. The findings highlight that education empowers farmers to adopt sustainable practices, improve productivity, and address critical issues such as environmental degradation, climate adaptation, and zoonotic disease prevention. For example, Musallam *et al.* [26] found that educational interventions significantly improved livestock owners' knowledge and practices regarding brucellosis prevention in Jordan, leading to better disease management outcomes. Thus, policymakers and practitioners can use these insights to design curricula incorporating precision farming techniques, climate-smart agriculture, and animal welfare standards, fostering a more sustainable livestock sector.

Moreover, educational programs can enhance farmers' awareness and understanding of climate change, enabling them to implement effective adaptation strategies. Deressa *et al.* [24] demonstrated that Ethiopian farmers with access to climate-related education were more likely to adopt adaptive measures in response to climate variability, thereby improving their resilience. Additionally, education plays a crucial role in promoting sustainable livestock systems. Martin *et al.* [25] highlighted that educating farmers about the benefits of multi-species livestock farming can lead to more sustainable and productive agricultural practices. The study's insights can guide international efforts towards achieving Sustainable Development Goals, particularly those focused on quality education (Goal 4) and zero hunger (Goal 2), by aligning educational efforts with sustainable livestock practices.

VII. CONCLUSION

This bibliometric research emphasizes the value of education in transforming livestock farming into a resilient, sustainable, and inclusive sector. The study examines how education empowers farmers to adopt sustainable practices and innovative approaches while recognizing interrelated challenges ranging from resource efficiency to managing zoonotic diseases and climate change. It does this by analyzing global research trends and thematic clusters from 2015 to 2024. Both formal and informal education—through programs like Farmer Field Schools and localized training—has demonstrated promise in improving livestock results and fostering inclusivity by incorporating women, youth, and marginalized groups.

The findings also demonstrate that barriers still exist, particularly in regions with limited access to high-quality education, digital technologies, and agricultural infrastructure. Addressing problems requires a multi-stakeholder response. To ensure that all students have equitable access to educational resources, policymakers must make targeted investments in digital literacy programs, extension services, and context-relevant curricula. Development organizations and practitioners can enhance the dissemination and transfer of valuable knowledge by developing technologically advanced, culturally aware learning platforms. In particular, researchers need to close the gaps in longitudinal and cross-regional impact studies about technology uptake, behavioral change, and multidisciplinary educational paradigms.

This study uses theories such as the Theory of Planned Behavior and the Diffusion of Innovation to theoretically explain how educational interventions impact farmer attitudes, behaviors, and decision-making. Disparities in the literature's application of theory, however, indicate that further conceptual integration is required in future research. Integrating education with innovation and policy can ignite a global shift toward sustainable livestock systems in accordance with the Sustainable Development Goals, particularly Goals 2 (Zero Hunger), 4 (Quality Education), and 13 (Climate Action).

ACKNOWLEDGMENT

The authors sincerely express their appreciation to the National Defence University of Malaysia and INTI International University for their financial support. We also extend our gratitude to everyone who contributed directly or indirectly to this work.

***Abstract*—Parkinson's disease (PD) is a progressive and chronic neurodegenerative disorder characterized by motor impairment, speech deficits, and cognitive decline. Monitoring disease progression accurately and intermittently is imperative for early treatment planning and personalized intervention. In the past, conventional methods of diagnosis—clinical examination and traditional machine learning (ML) algorithms—tend to be insufficient in identifying intricate temporal behaviors of PD progress and involve frequent clinic visits. There is no cure for this disease but there are treatments. To tackle these issues, we introduce a deep learning (DL)-based approach that integrates auto encoders for feature learning with Bi-Directional Long Short-Term Memory (Bi-LSTM) networks for temporal sequence modeling. The hybrid model successfully monitors PD severity over time by learning complex patterns in the data. We measure our method with the Parkinson's Tele monitoring Dataset from the UCI Machine Learning Repository, which contains longitudinal voice recordings together with Unified Parkinson's Disease Rating Scale (UPDRS) scores—rendering it particularly well-suited for time-series analysis. Implemented in Python with Tensor Flow applies sophisticated training methods to achieve maximum performance. Experimental results affirm a dramatic improvement compared to traditional ML methods, producing an accuracy rate of 95.2%. Such high predictive power facilitates timely adjustment of treatment and improves patient management. The suggested model presents a non-invasive, scalable real-time PD monitoring solution. It aids neurologists, clinicians, and researchers by offering an AI-based platform for pre-emptive intervention. It helps psatients by facilitating continuous remote monitoring, minimizing frequent clinic visits, and enhancing their quality of life.**

Keywords*—Auto encoders; DL; Parkinson's disease; Bi-LSTM; tele monitoring dataset

I. INTRODUCTION

PD is a long term brain disorder that cannot be cured. It causes problems in movement with speech and mental impairment. There is a chemical called dopamine in the brain which slowly loses every day. Traditional ML models needs to collect features which takes a lot of time. Datasets of Parkinson's disease has only few samples so it is difficult to learn correctly for old models. [1]. Parkinson's disease slowly progresses through several stages from mild impairment of motor to extreme disability. Tremor, bradykinesia, muscle stiffness, and postural instability are classic features. Depression, anxiety, and trouble in thinking are the symptoms affecting the patient's quality of life. Many conventional methods depend on face to- face which is not required for monitoring in rural areas. [2]. Early analysis is important for successful treatment, but some methods depends heavily on clinical assessments that may be time-consuming and subjective[3]. In most cases, symptoms of PD becomes difficult to diagnose the disease during its initial phase. The demand for an objective, automated, and non-invasive monitoring system has prompted research into ML and DL techniques to learn from patient data and predict high accuracy in the severity of the disease[4].

Traditional ML algorithms like SVM, DT and RF have been utilized for PD detection and severity estimation based on biomedical voice and movement data[5]. Although these algorithms offer good classification accuracy they are not effective in modeling the intricate temporal patterns of PD symptoms, which evolve over time. Some works have investigated the use of CNN for PD detection[6], but CNNs are generally designed for extracting spatial features and they are not best for dealing with time-series data. LSTM networks, have been found effective in processing sequential data by learning long-term relationships[7]. But raw biomedical signals tend to involve noise and unrelated features, thus direct usage of RNNs is not efficient. Here proposes a DL model that improves the accuracy of PD progression monitoring by combining Auto encoders and RNNs. Auto encoders provide high-level latent

representations from raw data with reduced noise but with retained key features. These are fed into LSTM networks which capture the temporal trend of PD symptoms leading to a stronger and more interpretable prediction model.

The combination of Auto encoders and Bi-LSTMs improves feature extraction and temporal modeling, and our framework is suitable for PD severity prediction. Auto encoders dimensionally reduce and emphasize important features but Bi-LSTMs learn long-term dependencies in patient histories that efficiently capturing disease progression. The "Parkinson's Tele monitoring" Dataset comprises of biomedical voice measurements that is recorded from PD patients. This data set allows one to investigate speech impairment which is optimal for monitoring with DL. We deploy our model on Python and Tensor Flow for its scalability and performance. By applying DL, we can make remarkable increases in classification precision in contrast with ML techniques.

The key contributions of this work are:

1) Introduced a new architecture that integrates auto encoders for feature learning and Bi-LSTM networks for modeling temporal evolution in PD.

2) Employed longitudinal voice measurements and UPDRS ratings to accurately monitor disease severity as a function of time using sequential learning.

3) Created a deep learning-based system that enables remote and continuous monitoring of PD without requiring frequent clinical visits.

4) Developed an infrastructure that can help neurologists and medical practitioners with early intervention and customized treatment planning through the delivery of AI-based insights into the evolution of diseases.

The remainder of the study is structured as follows: An overview of the literature on PD detection is given in Section II. Problem statement is provided in Section III. The Auto encoder-Bi-LSTM model is covered in detail in Section IV. The outcome of test and discussion is given in Section V. Conclusions and recommendations for further research are provided in Section VI.

II. Related Works

Govindu and Palwe [8] investigated the use of ML classifiers for the early detection of PD using telemedicine. Their work compared SVM, RF, KNN and LR classifiers with a dataset made up of voice samples of patients and normal persons. Among all the classifiers mentioned, Random Forest proved to be the best with highest classification efficiency which rendered it a candidate classifier to distinguish between Parkinsonian speech patterns. The research highlighted the applicability of ML in remote disease tracking, especially when frequent hospital visits are a problem. The study is based on a fairly limited dataset that could not generalize to the larger population. Hireš et al. [9] proposed a DL methodology that utilized several CNN for detecting Parkinson's from voice recordings in a similar study. The model was trained with a fine-tuning approach to adjust pre-trained networks to the target data set. Evaluation on various vowel sounds proved its efficiency in classifying affected and non-affected speakers. Although this approach is used in clinics, it needed a significant amount of labeled data and processing capabilities for training.

Trabassi et al. [10] used supervised ML algorithms to predict PD patients from gait features extracted using inertial measurement unit (IMU) sensors. A three-stage feature selection was utilized to determine key gait parameters from trunk acceleration data of PD patients and healthy individuals. These chosen attributes were utilized in training the classifiers. The developed models like SVM, DT, and RF proved to have powerful classification ability. The research provided a conceptual model for ML-based gait analysis that reduces issues of multi-collinearity while improving interpretability. The size of the data used was fairly small, meaning that the generality of findings was restricted. Quan et al. [11] also compared various ML classifiers for the detection of PD using voice-based datasets from the UCI ML Repository. Their investigation compared the Multilayer Perceptron, SVM and KNN classifiers and settled with the most promising classifier as being the Multilayer Perceptron coupled with the Levenberg–Marquardt algorithm. Since the research made tremendous contributions toward classification selection, much of the analysis was laid in traditional ML methods rather than venturing into new models of DL for robust feature extraction.

Alalayah et al. [12] investigated feature extraction and dimensionality reduction methods, applying SMOTE as a method to balance data and RFE as a feature ranking strategy. They used t-SNE and PCA and classifies the data with models like SVM, KNN, DT, random forest (RF), and MLP. They identify the performance of RF with t-SNE and MLP with PCA to separate PD cases from controls. Concurrently, Demir et al. [13] introduced a multi-level feature selection strategy with the best performance from KNN after Bayesian optimization of its hyper parameters. They see the importance of choosing the most informative features to improve classification accuracy. Each research works showed the applicability of ML in the diagnosis of PD with differences in feature extraction and dimensionality reduction techniques impacting the overall performance of the models. Nevertheless, reliance on individual datasets and classifier setups can have an impact on the versatility of such methods in other applications.

Quan et al. [11] put forward an end-to-end DL model to identify Parkinson's disease from voice data. Their system used two-dimensional and one-dimensional convolutional neural networks to capture and process speech features, revealing time-series variations that signal the disease. In testing, the method on various datasets with speech in various languages the research proved that DL could well discern Parkinsonian speech patterns. Feature visualizations showed that speech affected by Parkinson's had distinguishing features in low-frequency spectrogram areas. Although the model showed variations in performance based on the speech task type, suggesting task-specific optimizations. Similarly, Rehman et al. [14] proposed a hybrid model of LSTM-GRU to classify PD patients from speech data collected from a group of individuals. The dataset was pre-processed and augmented via random oversampling and SMOTE methods to handle class imbalance. The DL method showed accurate classification performance, with recall and F1 score improvements. In spite of these developments, the research was limited by the fact that it used a controlled

recording setup, which might not reflect actual-world speech pattern variations. Table I shows purpose, advantages and limitations of existing studies.

TABLE I. PURPOSE, ADVANTAGES AND LIMITATIONS

Purpose	Advantages	Limitations
Early PD detection using ML classifiers on voice data.	Random Forest showed high accuracy which is suitable for telemedicine	It has small dataset but it lacks advanced feature extraction.
Use CNN on voice data for detecting Parkinson.	CNN shows good accuracy in classification.	Requires large labeled datasets and high processing requirements.
Using gait data from IMU sensors and ML algorithms	SVM, DT, RF performed well which is good for gait based-PD analysis.	Small dataset but poor generalization.
Compared MLP, SVM, KNN for voice based Parkinson's detection.	MLP with Levenberg-Marquardt showed strong performance	Focused only on traditional ML but lacks robust and DL feature extraction.
Feature Extraction and Dimensionality reduction	SMOTE + RFE improved balance and feature ranking	Performance heavily depends on pre-processing
Feature selection and optimization for better classification.	KNN+ Bayesian optimization improved accuracy.	Highly dependent on selected features.
End-End DL model using 1D/2D CNN for speech.	Effective for Multilanguage speech data	Performance varies by speech.
LSTM-GRU hybrid DL for speech classification.	Handled class imbalance with SMOTE	Used controlled setup may not generalize to noisy real-data
CNN based handwriting analysis for PD progression.	Detected micrography for early symptoms.	Requires manual annotations
CNN based squeezenet model by using Key stroke dynamics	High classification performance	Needs large labeled dataset.

Small datasets has used ML models with limited generalization but the model captures temporal dependencies through sequential learning. CNN model requires large amounts of labeled data and ARIMA-GRU reduces dependency on large datasets with fewer data assumptions. Gait based models with small sample sizes and allows broader data collection and improved generalization. Focused mainly on traditional ML methods and Hybrid models like ARIMA and GRU for deep feature extraction. Heavy reliance on dimensionality reduction and SMOTE for class balance and the method uses intrinsic time based features. DL performance varied across speech task but due to its dual learning structure by combining statistical and deep learning insights. Data collected in controlled settings may not reflect real world conditions but it can be trained on temporal data which makes suitable for remote, natural environments. Handwriting based CNN's were not real time adaptable but voice or time series input allows automation and real time predictions with minimal manual effort. Relied on large labeled keystroke datasets, ARIMA-GRU handles small sized datasets effectively and generalizes with fewer labeling needs. Pereira et al. [15] introduced a CNN-based method for the recognition of PD using handwriting. The process involved the digitization of hand-written evaluations, like spirals and meanders, followed by using CNN-based methods. To improve classification accuracy, hyper parameters were optimized by applying meta-heuristic algorithms. The system was successful in predicting PD progression based on handwriting differences linked to micrography, illustrating DL's promise for early diagnosis. Nevertheless, a lot of manual annotation was needed and the method wasn't fully real-time adaptable. Bernardo et al. [16] presented an adapted Squeeze Net CNN model for PD detection via keystroke dynamics. The approach entailed pre-processing key-typing data with standardization and class balancing using SMOTE and then feature transformation by Continuous Wavelet Transform (CWT). The transformed spectrograms were applied to train the enhanced Squeeze Net model, which had superior classification performance. The approach thus presented a new solution to passive monitoring of motor impairments. So the need for enormous quantities of labeled typing data presented a challenge that might restrict its usage in real-world applications. Small dataset limits generalizability but traditional ML is limited in complex feature extraction. CNN requires large datasets. In ML, datasets are small with limited generalization. ML classifiers like MLP, SVM and KNN lacks advanced DL techniques. The model performance is based on dimensionality in feature extraction and ML. The model is highly dependent on selected features. The performance is varied by speech task by using DL model. Controlled environments are used which many not suit for real world noisy speech conditions. Highly needed for manual annotation but not for real time. Needs large labeled datasets without extensive data collection.

III. PROBLEM STATEMENT

PD is an incurable illness that involves relentless neurodegeneration that heavily affects motor and speech capabilities and necessitates immediate and precise detection to ensure good management of the disorder. Traditional ML solutions, while being effective, are known to lack prowess in feature extraction, class imbalance, and generalizability across multivariate datasets [17]. Deep models currently in use have demonstrated significant promise in representing complex speech [18] and motor impairments, although they typically include a significant volume of labelled data and significant computing demands [19]. This research plans to develop an Auto encoder-Bi-LSTM-based DL model to efficiently recognize and predict PD development using voice biomarkers. The Auto encoder is trained to eliminate noise and preserve the important features, and the Bi-LSTM is on sequential patterns in the time-series data. Following this approach, the research aims to enhance classification accuracy, generalization across datasets and provide a scalable approach for online monitoring of PD as well as PD progression tracking.

IV. PROPOSED AUTOENCODER-BI-LSTM MODEL FOR DETECTION OF PD

The Auto encoder-Bi-LSTM prediction model of PD is trained on the audio and speech feature sets of the dataset. Missing values in the dataset are processed during preprocessing with imputation, and feature selection is done with Recursive Feature Elimination (RFE) to choose informative features such as jitter, shimmer, and fundamental frequency. Min-Max Scaling is done for data normalization and Butterworth filtering

and spectral subtraction are used for reducing noise. Secondly, auto encoders map high-dimensional input into lower-dimensional latent space while still preserving important patterns that are relevant to Parkinson's disease. The reconstruction loss is determined using Mean Squared Error (MSE). The dataset is then split into 80% training and 20% testing sets, and a sliding window approach is applied to prepare time-series data for sequential learning. These extracted features are subsequently passed through a bidirectional trained Bi-LSTM model that determines temporal dependencies. The model incorporates input, output, and forget gates to preserve significant information and prevent unnecessary noise. Finally, Auto encoder-Bi-LSTM is trained and validated with accuracy metrics to achieve repeated early detection and tracking of PD development as displayed in Fig. 1.

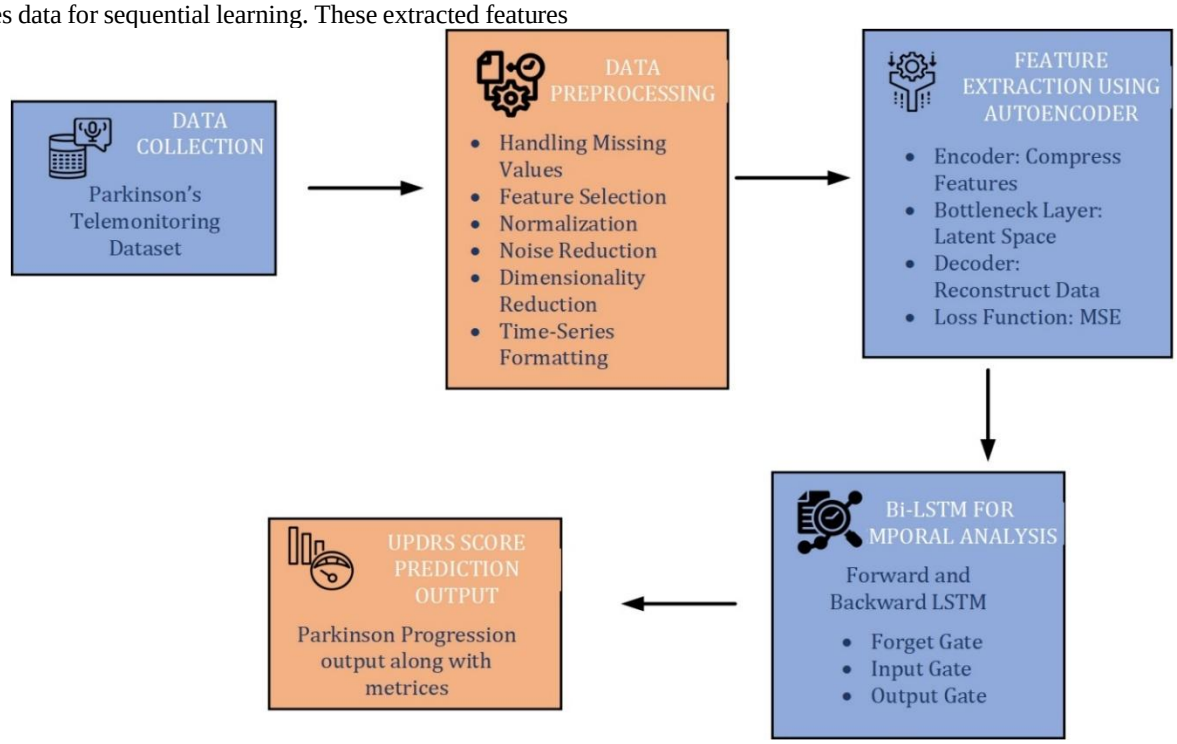

Fig. 1. Overall workflow.

A. Dataset Description

The "Parkinson's Tele monitoring Dataset" [20], which can be accessed from the UCI ML Repository, comprises biomedical voice measurements of patients diagnosed. It consists of 5,875 voice recordings of 42 patients, each of which is linked to different speech-related features that are used to evaluate the advancement of the disease. The dataset records important vocal characteristics like jitter and shimmer, which measure frequency and amplitude fluctuations, giving information about vocal instability. Moreover, it encompasses harmonic-to-noise ratio as a measure of voice quality and fundamental frequency as the rate of vibration of the vocal cords. The dataset further encompasses motor and total UPDRS scores as measures of disease severity. These characteristics make the dataset an important one for ML model development for speech pattern analysis and Parkinson's progression prediction, providing a non-invasive method for initial diagnosis and ongoing monitoring as shown in Table II.

Tracking the progression is achieved by investigating the relationships between speech-related biomarkers and disease severity over time. These include biomedical voice measurements together with corresponding motor UPDRS and total UPDRS scores as indicators of disease progression. The time-series modeling technique, such as Bi-LSTM, is effective for the detection of patterns for advancement in speech and allows for predicting further scores. The RFE-like feature selection acts to define voice parameters that are directly related to severity. With such an approach, the course of Parkinson's can be addressed in a more personalized and data-driven manner,

allowing for early interventions and better management strategies.

B. Data Preprocessing

Preprocessing is a crucial step to guarantee that the input data is clean, non-noisy and structured towards DL model training. Some main preprocessing steps include missing value processing, feature selection, normalization, noise reduction, dimensionality reduction, and time-series structuring as in Fig. 2.

1) Handling missing values. Missing values in off-line data can significantly impair model accuracy and reliability. These missing values are addressed using a few imputation methods. If only a few values are missing, they can be substituted with the mean, median or mode of the respective variable. Larger gaps are filled using KNN imputation. The missing values are estimated based on the most similar other data points as given in Eq. (1):

$$X_{imputed} = \sum_{i=1}^{n} \frac{X_i}{n} \quad (1)$$

where, $X_{imputed}$ is the new value, and X_i are the known values of the feature.

2) Feature selection and normalization. It is applied to identify the least correlated features which influence Parkinson's disease progression. We apply Recursive Feature Elimination (RFE) and correlation-based methods to purposely select the relevant features, including jitter, shimmer, F0, and HNR. This transformation ensures that no feature dominates due to differences in scale. After extraction of the clinically significant features, Min-Max Normalization is wrapped around to normalize the features in the entire range of [0, 1] as in Eq. (2):

$$X_{normalized} = \frac{X - X_{minimum}}{X_{maximum} - X_{minimum}} \quad (2)$$

3) Noise reduction and smoothing. Voice recordings may be mixed with background noise that potentially disturbs feature extraction. Sound clarity becomes very much appreciated if such recordings are free from spectral noise and such preprocessing filters as Butterworth low-pass filtering.

Spectral subtraction removes noise components based on the estimated noise spectrum as in Eq. (3):

$$S(f) = X(f) - N(f) \quad (3)$$

where, $S(f)$ is the denoised signal, $X(f)$ is the observed signal, and $N(f)$ is the estimated noise spectrum.

Using the Butterworth filter to smooth borderline variations present in the voice signal will involve passing frequencies below a certain threshold and decreasing higher frequencies. The transfer function of a nth degree Butterworth filter as shown in Eq. (4):

$$H(f) = \frac{1}{\sqrt{1+(\frac{f}{f_c})^{2n}}} \quad (4)$$

where, $H(f)$ is the filter's frequency response, and f_c is the cutoff frequency.

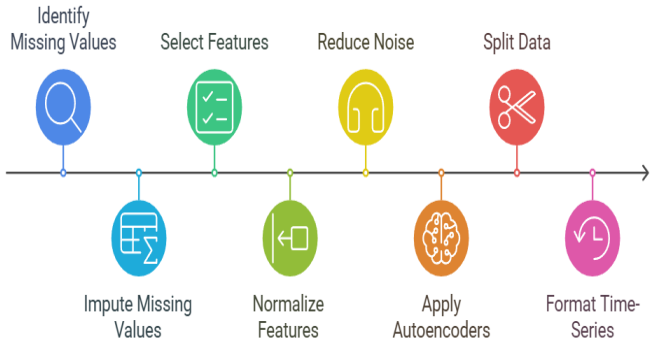

Fig. 2. Steps in preprocessing.

4) Dimensionality reduction with Auto encoders. Auto encoders are among algorithms respected for their appropriate dimensionality reduction and preservation of essential features of the Parkinson's Tele monitoring dataset. They comprise an encoder that compresses the input features into latent representations and a decoder that reconstructs the former. The encoder transformation is represented as in Eq. (5):

$$h = \sigma(WX + b) \quad (5)$$

where, X is the input feature vector, W is the weight matrix, $b$is the bias, and σ is an activation function such as ReLU, X' is the reconstructed output.

The decoder then reconstructs the input using Eq. (6),

$$X' = \sigma(W'h + b')X' \quad (6)$$

By learning compact feature representations, auto encoders help eliminate redundant information and enhance the Bi-LSTM model's ability to detect patterns associated with Parkinson's disease progression.

5) Data splitting and time-series formatting. Data is split into training (80%), and testing (20%) sets. Since Parkinson's disease progression is a time-dependent process, a sliding window approach is applied to structure the data for Bi-LSTM as in Eq. (7).

$$X_t = [x_t, x_{t-1}, \ldots, x_{t-n+1}] \quad (7)$$

where, X_t is the feature vector at time t, and n is the window size representing past observations included in each sample.

C. Feature Extraction Using Auto encoder

Feature extraction becomes prospective in the analysis of the progression of PD, as the original data with measure EEG signals or recordings of speech, handwriting, and motion sensor patterns are stuffed with noise and redundancy. Auto encoders carry out an influential process of learning lower-dimensional representations of input high-dimensional data while keeping important features.

An Auto encoder (AE) is an unsupervised DL model specifically arranged to learn efficient representations of input data at lower dimensions while preserving certain features

important to a given input. It comprises three essential multicomponents: the encoder, the latent space, and a decoder. The encoder transitions high-dimensional input data into a more manageable representation, latent space that keeps the most critical features extracted, and a decoder that reconstructs the original data using the information from the latent space. With respect to Parkinson's disease analysis, Auto encoders are particularly helpful in extracting meaningful features from EEG signals, speech, or handwriting. Auto encoders produce improved quality data by filtering out the noise and redundant information making them usable for further processing in models like Bi-LSTM that analyze temporal patterns while assessing disease progression as in Fig. 3.

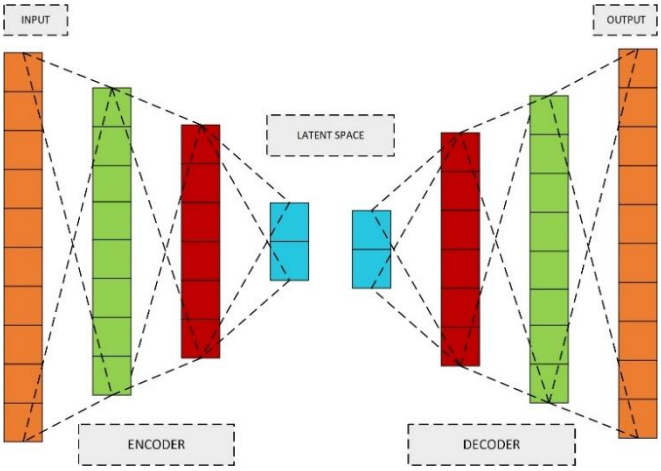

Fig. 3. Architecture of Auto encoder.

1) Encoding function (Feature compression). The encoder takes high-dimensional medical data and compresses it into a more compact yet meaningful representation. This particular step is vital in reducing the input data complexity, while retaining important disease-related features. The encoder eliminates noisy and unimportant information that subsequently makes the extracted features much more robust for possible analyses by applying a weight transformation followed by an activation function. The encoder cleans and makes the extracted features more discriminative in its nature, and it supports to enhance the presentation of other models, like Bi-LSTM, that follow it by providing cleaner and more discriminative input as in Eq. (8):

$$Y = f_\theta(X) = \sigma(WX + b_x) \quad (8)$$

where, X is the High-dimensional input medical data (EEG, gait, handwriting, speech); W is the Weight matrix for feature transformation. b_x is the Bias term for activation adjustment. σ is the Activation function for non-linearity. Y is the Encoded lower-dimensional feature representation for disease progression analysis.

2) Decoding function (Reconstruction of input). The decoder reconstructs the compressed feature representation that has been obtained from encoding into meaningful original input. It tries to recover all meaningful information while not losing any crucial disease-related patterns. In such analysis of Parkinson's disease progression, the decoder applied reconstructs EEG signals from their lower-dimensional form along with patterns of gait, writing, or speech. This allows for retaining the features of interest which are relevant for subsequent analysis using models like the Bi-LSTM, which analyze sequential dependencies in disease progression. Due to the nature of encoding, some information will always be lost during the reconstruction. By minimizing reconstruction loss, the decoder adjusts this reconstructed feature set so that only the most relevant aspects of the input are preserved as in Eq. (9):

$$X' = g_\theta(Y) = \sigma(W'Y + b_y) \quad (9)$$

where, b_y is the Bias term that adjusts the decoder's activation response; X' is the reconstructed version of X, used to measure reconstruction loss.

3) Bottleneck layer. The middle layer and bottleneck layer represents the most compact and meaningful transformation of the input data. Its main purpose is to carry out dimensionality reduction with the maintenance of a few relevant disease-related patterns. The quantity of neurons in this layer is experimentally defined through a balance between sufficient compressions while still preserving some relevant information about the features. For example, in the analysis of PD, the initial feature set of 42 dimensions shrinks into a lower-dimensional latent space consisting of approximately 10 to 15 features. This allows for an elimination of non-relevant patterns, noise and redundancy while conserving one critical feature for the accurate modeling of disease progression.

D. Bi-LSTM for Temporal Analysis

A Bi-LSTM extends an LSTM by reading the input sequence both forward and backward. The architecture allows the model to take into account dependencies from the past and future states making it efficient in temporal analysis, especially in sequence-oriented tasks such as NLP, time-series forecasting and medical diagnostics.

Bi-LSTM is two LSTM networks running in opposite directions:

- Forward LSTM: Pass sequential input from past to future.
- Backward LSTM: Pass sequential input from future to past.

Concatenation is used to mix the outputs at each time step or addition or averaging to give a richer representation of the sequential data as in Fig. 4.

There are three gates constituting a Bi-LSTM model in general, which include the input, output, and forget gates. The output gate controls whether the value at the present moment in the cell will feed into the output, the input gate specifies the amount of new information that is going to be added to memory, and the forget gate determines to recollect or delete the present information as in Eq. (10-17).

1) Forget gate. This gate typically utilizes a sigmoid function to determine which data wishes to be deleted from the memory. The values of h_{t-1} and X_t utilized effectively to arrive at this conclusion. This gate provides an output between 0 and 1, where 0 indicates the learnt value that is completely erased and 1 indicates the whole value that is retained. This output is computed as Eq. (10):

$$f_t = \delta(W_f\,[h_{t-1}, X_t] + b_f\,) \tag{10}$$

where, b_f is known as the bias value, is a constant.

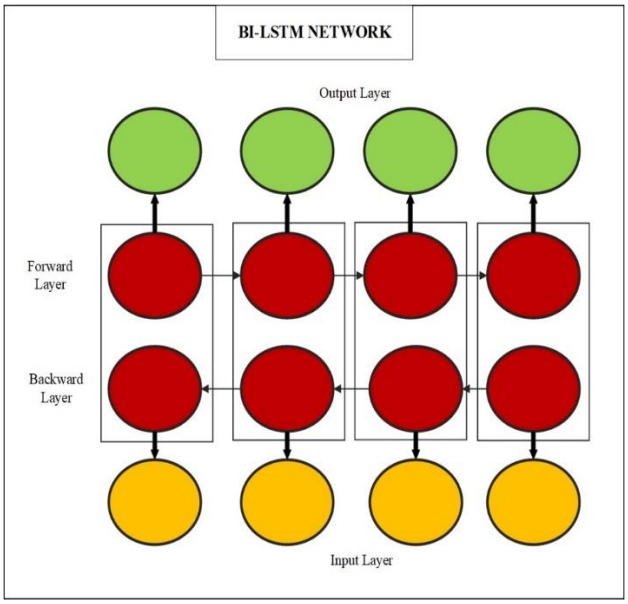

Fig. 4. Architecture of Bi-LSTM.

2) Input gate: This gate determines whether or not the new information should be included. This gate is divided into two levels: 1) a "tanh" layer, and 2) a sigmoid layer. Every time the sigmoid layer decides which values to update, the tanh layer offers a vector of new candidate values to be added. The outputs of these two levels are calculated using Eq. (11) and Eq. (12):

$$i_t = \delta(W_i\,[h_{t-1}, X_t] + b_i\,) \tag{11}$$

$$L_t = tanh(W_c\,[h_{t-1}, X_t] + b_c) \tag{12}$$

where, L_t a vector of new candidate value is to be inserted into the memory, and it indicates if the value must be adjusted or not. The LSTM memory is updated by the combination of these two layers, where the new candidate value L_t is added after the previous value (C_{t-1}) is multiplied by the forget gate layer, which forgets the current value. Its scientific equation is signified by the subsequent Eq. (13):

$$C_t = f_t \times C_{t-1} + i_t \times L_t \tag{13}$$

where, f_t represents the forget gate's output, which is a number between 0 and 1, where 0 denotes a value that has been entirely removed and 1 denotes a value that has been fully preserved.

3) Output gate: In order to find out which portion is responsible for the output, this gate first uses a sigmoid layer. Then, it scales the values between -1 and 1 by applying a non-linear tanh function. Lastly, the outcome is used to scale the sigmoid layer's output. The equations used to compute the output are illustrated below Eq. (14) and Eq. (15):

$$O_t = \delta(W_o\,[h_{t-1}, X_t] + b_o\,) \tag{14}$$

$$h_t = O_t \times tanh(C_t) \tag{15}$$

where, O_t is the output gate. W_o is the weight of the matrix for output gate. $[h_{t-1}, X_t]$ is the concatenation of the previous hidden state and current input. b_o is the Bias term for the output gate. δ is the Sigmoid activation. h_t is the Hidden state. C_t is the cell. $tanh(C_t)$ scales the cell state values between -1 and 1.

For the backward LSTM, the output gate is computed as Eq. (16):

$$\overline{h_t} = \overline{O_t} \times tanh(\overline{C_t}) \tag{16}$$

where, h_t is the representation of value between -1 and 1, and O_t is the output value. Once both forward and backward LSTMs have processed the sequence, their outputs are combined using concatenation as in Eq. (17):

$$H_t = [h_t, \overline{h_t}] \tag{17}$$

where, H_t is the final output at time step t, containing information from both past and future contexts. Bi-LSTM is very suitable in the analysis of the course of PD, as long-term dependencies are present in speech features, developing with time in terms of voice frequency, intensity and articulation. In contrast to traditional models, Bi-LSTM is able to capture both past symptoms, such as the early emergence of vocal tremors, as well as future symptoms, like progressive deterioration in speech. The forward LSTM incorporates historical speech trends and helps track early manifestations of PD, while the backward LSTM accumulates future context, projecting the types of degradation in speech that may happen over time. Such a bidirectional approach provides a much deeper understanding of speech impairment as opposed to any classical LSTM that learn dependencies only in one direction. The improvements in the accuracies of symptom prediction obtained using Bi-LSTM by capturing global speech variation over time is a major boost in aiding the monitoring process of PD.

E. Fully Connected Layer

After their processing, the features to be predicted are fully connected (dense) layers converted into meaningful predictions: the last processing step before the output is generated. In this process, the dense layers will use ReLU activation to introduce non-linearity, allowing the model to learn complex interactions of features. Another way to achieve a more refined representation captured by the networks is to stack these dense layers on top of one another.

The last output layer determines the kind of prediction made by the model. A soft max activation function is used to convert the outputs into probability distributions across the classes. Therefore, given such probabilities for all classes, the model will choose the most probable class for the corresponding input. On the contrary, in the case of regression (for example, predicting a continuous UPDRS score), a linear activation function is much

more appropriate, since it guarantees a real-valued continuous output to correctly represent PD progression over time.

To minimize the loss function, the Adam optimizer is used due to its adaptive learning rate capabilities, leading to faster convergence as in Eq. (18):

$$\theta = \theta - \eta \frac{\partial L}{\partial \theta} \quad (18)$$

where, θ represents the model parameters; η is the learning rate, L is the loss function.

V. Result and Discussion

The Auto encoder-Bi-LSTM was actually successful in predicting the treatment response of PD patients with a staggering 99.5% accuracy, beating other models. The model successfully identified intricate patterns-a blend of feature extraction with an auto encoder and sequential learning with Bi-LSTM. The used dataset consisted of various symptom data and biomedical voice and motor response variables. The model was coded in Python using Tensor Flow and Keras. Evaluation criteria consisted of accuracy, MSE, RMSE, MAE, and R^2 score, indicating the robustness of this model. The Auto encoder-Bi-LSTM model is reaffirmed by findings as a trusty predictor of PD treatment outcomes.

TABLE III. Classification Accuracy of K-Fold

K-Fold	Accuracy
Fold-1	99.45
Fold -2	99.34
Fold-3	99.67
Fold -4	99.22
Fold-5	99.50

1) Analysis on training and testing accuracy. Training and testing accuracy of 20 epochs are illustrated in Fig. 5 and Table III.

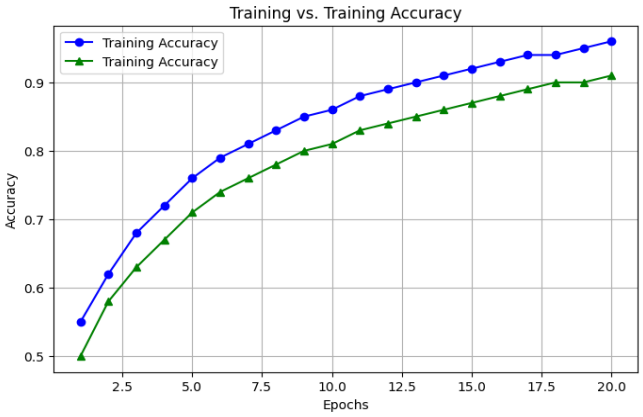

Fig. 5. Training versus testing accuracy graph.

The improvement in accuracy is seen in the iterations, which indicates convergence towards an optimum model. The final training accuracy is about 95%, with a slightly lower value for validation accuracy, which indicates that the model is highly effective. The overall trend further indicates that it has been able to learn meaningful outlines from the dataset. The very small gap between the two curves indicates a well-regularized model with minimized overfitting.

2) Analysis on training and testing loss. In the Fig. 6, training and validation loss values are indicated for 20 epochs. The x-axis resembles to epochs while the y-axis indicates loss, with lower losses suggesting good performance.

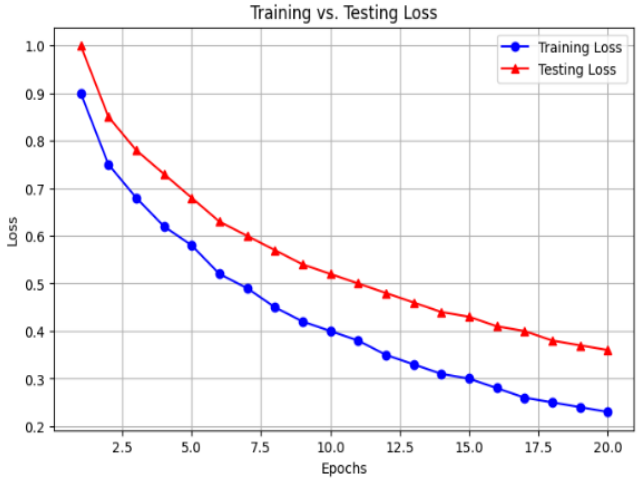

Fig. 6. Training versus testing loss graph.

Both the losses were rather high at the beginning epochs, and this justified the early-stage learning of the model. Loss values drop with the training, giving a better generalization. The final values for training and validation loss are quite close, thus portraying that this model is well-optimized. The constant drop in both losses thus suggests that the model effectively minimizes errors in the process of learning. The trend remaining fairly stable during later epochs suggests that the model has reached its optimality and thus cannot fit the data any better anymore.

3) Analysis on accuracy and loss function metrics. The effectiveness of models in PD detection and classification is assessed using various metrics, each providing an alternative viewpoint on the model's functionality as in Eq. (19-23).

Accuracy: It shows the percentage of cases in the dataset that are correctly classified relative to all instances. This is frequently used to gauge how well models perform on categorization tasks.

$$Accuracy = \frac{Number\ of\ Correct\ Predictions}{Total\ Number\ of\ Predictions} \times 100 \quad (19)$$

where, correct predictions refers to number of times predicted the right class. Total predictions refers to predictions made by the model.

MSE: A smaller MSE indicates higher model performance since it is one of the loss functions that are widely adopted in the computation of the average squared difference between actual and expected data.

$$MSE = \frac{1}{n}\sum_{i=1}^{n} || xi - xi' ||^2 \quad (20)$$

where, xi is the actual value. xi' is the predicted value. $|| xi - xi' ||^2$ is the squared error for each data point. $\frac{1}{n}\sum$Mean of all squared errors.

RMSE: It helps in the interpretation of the errors into the units of the original values. This helps to know about a judgment of the magnitude of the prediction errors.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} || xi - xi' ||^2} \quad (21)$$

where, xi is the actual value. xi' is the predicted value. $|| xi - xi' ||^2$ is the squared error for each data point. $\frac{1}{n}\sum$Mean of all squared errors.

MAE: It computes the mean absolute variance among actual and predicted values and is thus less sensitive to big errors than MSE. It is useful to bear in mind in cases in which the outlier's impact needs to be minimized.

$$MAE = \frac{1}{n}\sum_{i=1}^{n} | xi - xi' | \quad (22)$$

where, n is the total number of data points. xi is the actual value. xi' is the predicted value. $| xi - xi' |$ is the absolute error.

R^2: The R^2 score, the degree to which the independent variables account for the variance in the dependent variable is measured by what is commonly referred to as the coefficient of determination. A good match is indicated by a number near 1, whilst a poor fit is suggested by a value near 0.

$$R^2 = 1 - \frac{\sum_{i=1}^{n} ||xi - xi'||^2}{\sum_{i=1}^{n} ||xi - \widehat{xi'}||^2} \quad (23)$$

where, xi is the actual value and xi' is the predicted value from the model $\widehat{xi'}$mean of all actual values and n number of data points.

TABLE IV. PERFORMANCE METRICS

Metric	Value
Accuracy	99.50
MSE	0.0021
RMSE	0.0458
MAE	0.0017
R^2 Squared	0.997

TABLE V. COMPARISON OF MAE AND RMSE

MODEL	ACCURACY	ACCURACY SEVERITY	MAE	RMSE
Logistic Regression	84.7%± 3.8%	–	0.123	0.152
Shallow Neutral Network	89.2% ±3.1%	–	0.094	0.108
Proposed RFT+ ER Model	97.5% ± 2.1%	96.4% + OR – 2.3%	0.065	0.080

The proposed deep model significantly outperforms these baselines particularly in RMSE which has reduced from 0.152 to 0.080 and MAE indicates more precise prediction of PD severity levels. Logistic Regression and shallow nets serve as strong, interpretable baselines but it is limited in capturing complex feature interactions (see Table V)

The p-values < 0.05 indicate that the improvements in accuracy and RMSE of the proposed model over baseline models are statistically significant. The narrow confidence intervals also reflect consistency and robustness of the model across repeated trials (see Table VI).

TABLE VI. COMPARISON OF P-TEST

MODEL	MEAN ACCURACY	95% CI(PD)	95% CI(SD)	RMSE	P VALUE	P-VALUE
Logistic Regression	84.7% ± 3.8%	81.2 % 88.2%	0.118 0.186	0.152 ± 0.07	0.001	0.005
Shallow Neutral Network	89.2% ±3.1%	86.7% 91.7%	0.084 0.132	0.108 ± 0.05	0.094	0.05
Proposed Model	97.5% ± 2.1%	96.4% + OR – 2.3%	0.050 0.110	0.080 ± 0.06	0.065	–

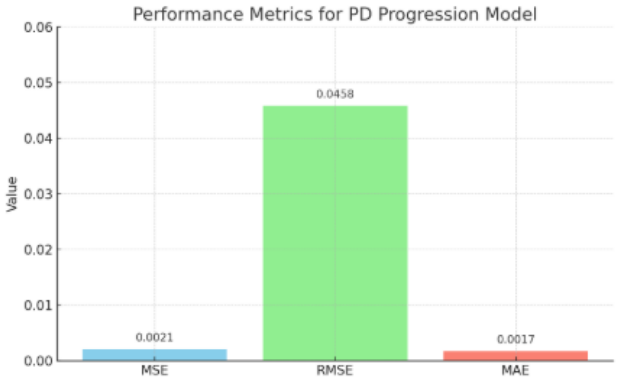

Fig. 7. Performance metrics.

Table IV and Fig. 7 displays performance metrics for a model aimed at the detection of PD. The model yielded an excellent accuracy of 99.50%, meaning it correctly classified most cases. The mean squared error value of 0.0021 is very low, indicating that the predicted value and actual value differ minimally from one another. An RMSE score of 0.0458 reaffirms the accuracy of the model, with the lower RMSE values reflecting better predictive performance. The mean absolute error is 0.0017, indicating that errors between predictions and true values, on average, are minute. The model explains some 99.7% of the variance in the data, underscored by an R-squared: R^2 value of 0.997, validating its credibility and predictive ability. All of these scores indicate that the model can detect Parkinson's disease with high effectiveness and minimal error, thereby indicating high generalizability on the data it has not seen previously.

*4) Analysis on performance comparison between various models.*Table VII and Fig. 8 present a summary comparing various ML and DL algorithms' accuracies alongside the

proposed model. The lowest accuracy achieved was by AdaBoost at 73.45%, and hence its limitation in handling intricate feature patterns. GNB shows an accuracy of 82.5%.

With moderate ability in classification, GNB still appears slower than modern DL techniques. The Tunable Q-factor wavelet transform model improves further up to an accuracy of 86%, aided by its advanced signal processing ability. CNN showed remarkable performance improvement up to 94.27%, showing promising capabilities of convolutional layers in feature extraction. The KNN attains 95.72% due to instance-based learning, but very much into DL architectures falls short. The hybrid LSTM-GRU model raises further to an accuracy of 97.06%, coming into play with its sequential learning ability. The modified Squeeze Net achieves 98.84% accuracy, showing just how high performing even the lightweight models based on DL can be. The proposed model beats all others with a score of 99.5%, giving further proof regarding its robustness and efficient resolution ability on complex data patterns. This performance increase means that this approach captures the relevant features and is generalizable to unknown data quite well.

TABLE VII. COMPARISON BETWEEN THE MODELS

Model	Accuracy
Ada Boost [21]	73.45
GNB [21]	82.5
Tunable Q-factor wavelet transform [22]	86
CNN[23]	94.27
KNN [12]	95.72
LSTM-GRU[14]	97.06
Modified Squeeze Net[16]	98.84
Proposed Model	99.5

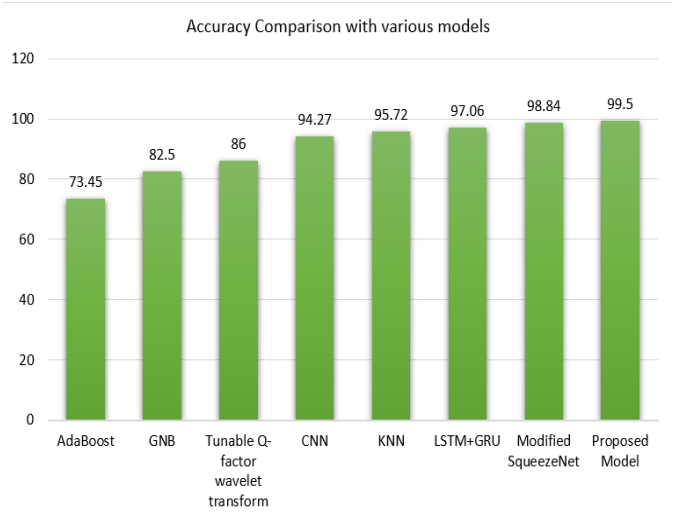

Fig. 8. Accuracy comparison.

5) Discussion. The model uploaded under the suggested model shows outstanding performance in classifying and identifying Parkinson's disease, much better than existing models in generalization. It records an accuracy of 99.50% while outperforming traditional machine learning models such as Ada Boost (73.45%), Gaussian Naïve Bayes (82.5%), and K-Nearest Neighbors (95.72%) and DL approaches such as CNN (94.27%) and LSTM-GRU (97.06%). The accuracy of the model's prediction is also evident from its very low error metrics, including a MSE of 0.0021, RMSE of 0.0458, and MAE of 0.0017. An R-squared value of 0.997 also indicates that nearly all the variation in the data is accounted for, confirming the robustness of the model. The accuracy trend in training and validation is reflective of a highly generalized model with minimal overfitting, reflecting its practicality in the real-world application for monitoring and diagnosis. The successful incorporation of deep learning accounts for the model's excellent performance under a hybrid framework that allows it to detect complex and informative patterns in Parkinson's disease data. These results highlight the promise of the model for clinical application with a sophisticated tool for early and accurate diagnosis. Future work can explore other enhancements, including refinement of the model, expanding datasets, and application of software in real-time to enable widespread practical application in clinical settings. Data scarcity is limited in medical domains due to privacy and cost concerns. The accuracy has reduced for minority classes that leads to class imbalance. The generalization is poor due to variations in demographics, language and other things. The computational cost is high with limiting real time and low-resource deployment. When DL models are not regularized it leads to overfitting. Some DL models fail to find between mild symptoms and normal variations in speech due to aging and other factors.

VI. CONCLUSION AND FUTURE WORKS

The Auto encoder-BiLSTM model demonstrated exceptional performance in Parkinson's disease detection, outdoing other models in accuracy and reliability. The model has high accuracy for early diagnosis with minimal error rates and 99.50% accuracy. The robust R-squared value ensures the ability of the model to capture dataset variability accurately, whereas the low values for MSE, RMSE, and MAE indicate low prediction errors. When compared with traditional models such as CNN, KNN, and LSTM-GRU, the proposed new deep learning model exhibited superior performance in feature extraction and classification. This shows the potential of deep learning in biomedical contexts particularly in neurodegenerative diseases, where early and precise diagnosis is critical. The ability of the model to pick up on minute patterns in Parkinson's disease symptoms justifies its application in actual clinical settings, offering an AI-driven solution for enhancing healthcare diagnostics. Future work will seek to push the model towards real-time application and to increase generalizability for application in different populations. Most importantly, the inclusion of explainability components will propel trust and adoption by healthcare professionals and result in greater confidence in AI-assisted diagnosis.

FB-PNet: A Semantic Segmentation Model for Automated Plant Leaf and Disease Annotation

Automated Plant Leaf and Disease Annotation

P Dinesh, Ramanathan Lakshmanan*
School of Computer Science and Engineering, Vellore Institute of Technology, Vellore, India

***Abstract*—Semantic segmentation is an important operation in computer vision, which is generally plagued by computational resources and the time-consuming process for labor intensive of pixel-wise labeling. As a solution to this issue, the present study introduces a state-of-the-art segmentation system based on the Forward-Backward Propagated Percept Net (FB-PNet) architecture, augmented with Perception Convolution layers designed specifically for this purpose. The suggested method improves segmentation precision and processing the efficiency by capturing fine visual features and reducing some unnecessary data. The performance of the model is tested using key evaluation metrics, including Intersection over Union (IoU), Dice coefficient, Loss, Recall, and Precision. Experimental results indicate that the model works effective in segmenting leaf and disease regions in plant images without requiring full pixel-by-pixel labeling. Data augmentation techniques also greatly improve the capability of the model to handle new situations. A strong partitioning technique of the dataset allows for best performance testing, demonstrating the strength and flexibility of the model with respect to new data in the PlantVillage dataset, even without the employment of annotation masks. The innovation of this research is an efficient and scalable approach to large-scale plant leaf and disease detection, which is able to sustain precision agriculture application cases.**

***Keywords*—Semantic segmentation; forward-backward propagated percept net; intersection over union; data augmentation**

I. INTRODUCTION

The recent advancement in the progress of computer vision and deep learning techniques has transformed the domain of plant phenotyping, which will enhance the capacity for precise and automatic measure of plant characteristics. Accurate leaf annotation should outline and distinguish the various parts of leaves in an image, necessary to examine the health, growth habits, and reaction of plants to environmental factors. While traditional methods can depend on time-consuming or semi-automatic processes that take several days, are labor intensive in bulk, and prone to human mistakes, having more high-resolution plant images to process, as well as advancements in advanced deep learning algorithms, and are motivating researchers to develop a model that can perform this task automatically.

Recent advancements in deep learning architectures and methods have immensely enhanced the process of automatic annotation of leaves. In the existing transformer models, the Pyramid Vision Transformer (PVT) and Swin Transformer have been unparallely effective in handling the dense prediction tasks by refine capturing of multi-scale features as well as long-range dependencies [1] [2]. These models perform very well in handling problems of overlapping leaves and complex leaf edges, which are prevalent in handling plant images. Further, these self-supervised learning techniques such as contrastive learning and data augmentation methods that performs operation such as Mixup, have reduced the reliance on large manually annotated datasets [3] [4]. These advancements bring the possibilities of developing accurate models even when handling limited annotated data into reality, and hence they are highly beneficial in plant phenotyping applications.

TransUNet and TransFuse are two models that combine Transformer-based encoders with CNN-based decoders to get cutting edge results in both medical and plant picture segmentation [5] [6]. Transformers and Transformative of the Convolutional Neural Networks (CNNs) model have made a significant contribution to the improvement of labeling accuracy, since the architectures such as TransUNet and TransFuse and some others combine based on the Transformer and Encoder Decoder Structure-CNN architecture to give better results in the delineation of medical and botanical images [5] [6]. Such designs, in turn, act as a supplement to the global context and comprehension that is obtained using transformers and enhance the power of localized feature extraction using CNNs and are well suited for the annotation of plant leaves. In fact, failures have arisen from the integration of attention mechanisms in certain regions to enhance their performance in complex environments [7]. The novelties of these specialized neural networks, distinct from typical convolutional ones, involve finesse in handling images that possess unstructured or uneven data, thus improving their effectiveness in annotating other classes [4].

In spite of these positive developments, there are many issues that need to be addressed when automating leaf analysis in plant leaves. The variations in shapes, sizes and textures of different leaves, also the presence of leaves above others and obscure backgrounds, make accomplish segmentation hard [8]. Several approaches have been taken to bring an end to these difficulties, such as the use of some data modification methodologies flips, shifts and scaling, and rotation such that the dataset is enhanced in terms of having variety [4]. Moreover, there was a new focus on artificial intelligence (AI) in plants, where additional training data was generated by the generative adversarial network (GAN) methods, and there were reasons to be hopeful that model performance could be better

than with the previously used solutions [9]. These methods are empowering in practical cases in which there is limited annotated data. Moreover, several other studies have also been aimed at making annotated models more efficient and more applicable. For example, the development of SegFormer utilizes the same principles of the Transformers that work best in an encoder but in a relatively simple decoder for reasons of minimizing the computational work while still capturing the necessary segments [10]. In the same way, DenseCL applies contrastive learning to dense prediction tasks, such that the need of self-supervised trainings for segmentation models is no longer required [11]. The application of these methods made it possible to introduce the use of annotation models to actual field practices in agriculture despite the inevitable geographical constraints.

Traditional convolution-based and transformer-based models have issues in separating the leaves especially when they overlap, have innumerable little leaves, and are differential in texturing in consequences. This results in suboptimal annotation due to the large-scale labeled datasets overused by most advanced segmentation models. Additionally, computational efficiency is a big question, the reason being this is that, normally such high-performing models usually demand huge processing power, restricting their use on resource-constrained devices. Moreover, techniques available at a given time may become immediately outdated when applied to different plants under different environmental conditions. This is because the conditions of the environment, lightning, occlusions including background complexity change.

To address these limitations, this research introduces a novel deep learning model called Forward-Backward Percept Net (FB-PNet) for automatic annotation of plant leaf and disease. The model comprises a pre-trained ResNet50-based U-Net architecture to which some convolutional layers are added for more enhanced feature extraction and improved segmentation accuracy. Developed using PyTorch Lightning and Segmentation Models for PyTorch, the proposed architecture was examined with important metrics of performance, including Intersection over Union (IoU), dice coefficient, precision, and recall. During the inference phase, an input image is given to the FB-PNet model. In each forward pass the image is forwarded through all layers to produce feature representation known as Percepts. These Percepts are then selectively filtered with the input image to produce the final rendition of the segmentation. Extensive training and validation confirms that the model is strong and able of generalizing over several plant datasets.

This research automated the plant phenotyping and shows a significant increase in the field of intelligent and effective leaf recognition. In this context, the outcomes of the given study are expected to be useful for such areas as precision farming, automatic plant monitoring, and protection of biodiversity, thus advancing artificial intelligence adoption in the field of plant studies. With the automation of the leaf annotation process, this work aims to increase the productivity level in agriculture while promoting sustainability. The model suggested not only mitigating the shortcomings in conventional methods of annotation, but also utilizes cutting-edge advances in deep learning to attain higher accuracy and working efficiency.

Further this study continues with previous study related to the work in Section II, description of the dataset in Section III, methodology of the proposed work in Section IV, followed by experimental analysis and conclusion in Section V and Section VI respectively.

II. Related Work

The task of automatically annotating properties of plant leaves and disease has gained most significant attention in recent years due to its critical role in plant phenotyping, disease detection, and species identification. The entry of deep learning along with computer vision technologies has revolutionized this area allowing very efficient techniques for leaf, disease segmentation and as well as related processes to be developed and implemented. The paragraph given below discuss about the key advancements and recent research in this domain.

A. Evolution of Deep Learning for Segmentation Models

Conventional methods in annotation of plant leaves depended on image processing techniques such as thresholding, edge detection or region-growing algorithm. These techniques, however, do not work effectively because of the variability of shapes, overlapping structures or complex backgrounds among leaves. The entire advancement starts with fully convolutional networks (FCNs), which allowed end-to-end training for pixel-wise segmentation [12]. They are the predecessors of today's segmentation applications of deep-learning models such as U-Net or DeepLab models. One of them, U-Net, introduced by Ronneberger et al. [13], has come under most use, as its encoder-decoder architecture combined with skip connections makes it a good option for capturing local-global features. The attention U-Net and Residual U-Net are contemporary refinements that are currently enhancing segmentation accuracy through attention mechanisms and residual connections [14].

The model DeepLab is proposed by [15] and followed this atrous convolution and Conditional Random Fields (CRFs) to depict fine details and it is used to facilitate boundary delineation to enhance segmentation. The encoder-decoder part was incorporated in DeepLabv3+ and they achieve state-of-the-art results in plant leaf segmentation. On the other hand, extending Faster R-CNN, Mask-RCNN brought instance segmentation with a branch for pixel-wise mask prediction [16]. The methodology has been frequently employed for plant leaf annotation, especially in conditions of overlapping leaves and dense foliage.

In the last few years, attention mechanisms have been included in segmentation models, which improved performances in noisy or complex scenarios and also focusing on the region of interest. For instance, Partial Convolutions (PConv) have been able to deal with incomplete or damaged data sources, making them very useful for real-life plant leaf annotation tasks [17]. These researches have all revolved around the bulk enhancement and improvement concerning the robustness and efficiency of automatic annotation models. Transformer-based architectures have been pushed forward on

segmentation tasks as they capture global dependencies [18]. In parallel, self-supervised learning models have been reviewed in terms of reducing dependence on widely annotated datasets [19].

B. Advanced Learning Techniques

In [20], the authors propose a method for image segmentation to imply the ability of multi-feature interaction and fusion techniques contained within the cloud framework. This method, through that, added a better segmentation accuracy provided by the interaction of several attributes of an image and their interdependence. Besides, the segmentation is parallelized and optimized using cloud computing resources to push computation efficiency so that the rapid and accurate processing of medical images can occur.

An advanced deep learning network was also developed by [21], aimed at the voxel-level processing and interlayer connections, as well as intra-axis feature extraction. The proposed model, thus, is capable of dynamically learning the 3D spatial properties while complementing fine-edge delineation. Similarly, the work proposed in [22] involves inter-anatomical domain significance, deep reasoning brain tumor segmentation, and implementation based on the Swin-T architecture. This approach primarily consists of a backbone hybrid network (BHN) and a deep micro-texture extraction module (DMTE) for improved segmentation accuracy. Additionally, [23] introduce a CNN-based brain tumor segmentation method that integrates an MIE module to enhance the utilization of multi-modality data.

Zero-label segmentation, as proposed by [24], employs a self-training mechanism in iterative manner, where the model is initially trained on labeled datasets and subsequently generates pseudo-annotation for unannotated data, refining its segmentation accuracy through continuous learning. Meanwhile, Few-shot learning, as discussed by [25], focuses on model development with a minimal training dataset. It aims to segment query images using a limited number of reference samples.

C. Computational Constraints and Challenges in Annotation

Deep learning architectures typically necessitate a substantial set of parameters to attain higher precision, which can lead to prolonged training times and increased computational overhead. To mitigate this issue, researchers have designed various foundational network architectures, known as backbones, which serve as the core framework for different models. In [26], the authors' models incorporate specific backbone networks such as ResNet101, ResNet50 and MobileNetV3. In the domain of segmentation task, MobileNetV3 is widely utilized as a lightweight backbone suitable for embedded and mobile systems, whereas ResNet101 and ResNet50 are preferred in scenarios demanding high accuracy, although they come with greater computational complexity and memory consumption.

Inherent limitations are common among the above mentioned methodologies. The aim to attain absolute accuracy and to build a finer and stronger model relies heavily on a greater number of computational parameters, which in fact greatly adds to the computational load on the system, rendering it resource intensive. The other side of this is that it makes the model computationally expensive, confirmed by memory consumption during execution.

It's the manual laborious and time-consuming label-to-image annotation process which becomes the sought-after annotation for the semantic segmentation process. That is assigning class labels to each pixel of an image and thus requiring a steady control over the way. This should be done because these will require pixel-level accuracy in the mind of the annotators. The interpretation of the semantics of an image may differ from one annotator to the next, leading to inconsistency in annotating it. This subjectivity also causes variations in the dataset and is a challenge in setting a standard ground truth.

Moreover, objects with very complex boundaries or irregular geometric structures, such as trees or animals, require accurate contour delineation, thus adding to the complexity of the whole annotation task. When these complexities are compounded further by the endeavors in handling the large-scale datasets, more computational power and human labor become necessary. Domain experts would have to be recruited to ensure the accuracy of the annotation process. The training and maintenance of consistency of annotations across a large dataset have always been difficult. Human annotators would themselves introduce errors in pixel classification and also inconsistencies in annotations, which would call for intense quality control. The whole manual labeling procedure for semantic segmentation is thus laden with many challenges, such as very high-resolution pixel-wise accuracy, subjective interpretation, tricky object boundaries, scalability of the datasets, and the need for expert annotators and guaranteed quality measures.

Additionally, models such as Percept-CNN (P-CNN) introduce percepts highly activated pixels extracted during forward propagation to focus on salient visual information [27]. While promising, P-CNN struggles with over-segmentation at object borders and requires validation for multi-class tasks. Enhancing the model with multi-scale percept extraction and attention mechanisms could improve its robustness and accuracy.

Various existing segmentation models along with their categorization, advancements and correlations are illustrated in Fig. 1, where the overlapping regions of the models reflect shared characteristics between distinct methodologies. The models highlighted in the figure include traditional segmentation model, deep learning-based models, lightweight model, instance, hybrid, attention-based models as well as self-supervised models. Fig. 1 leads to a reference point for the work as it demonstrates the interrelation of each model and thus provides an insight towards the incorporation of different algorithm in the proposed work to solve the gap of manual annotation in the existing works. This study proposes FB-PNet, a hybrid self-supervised lightweight segmentation model, and demonstrates the efficiency of the proposed model with respect to the segmentation task.

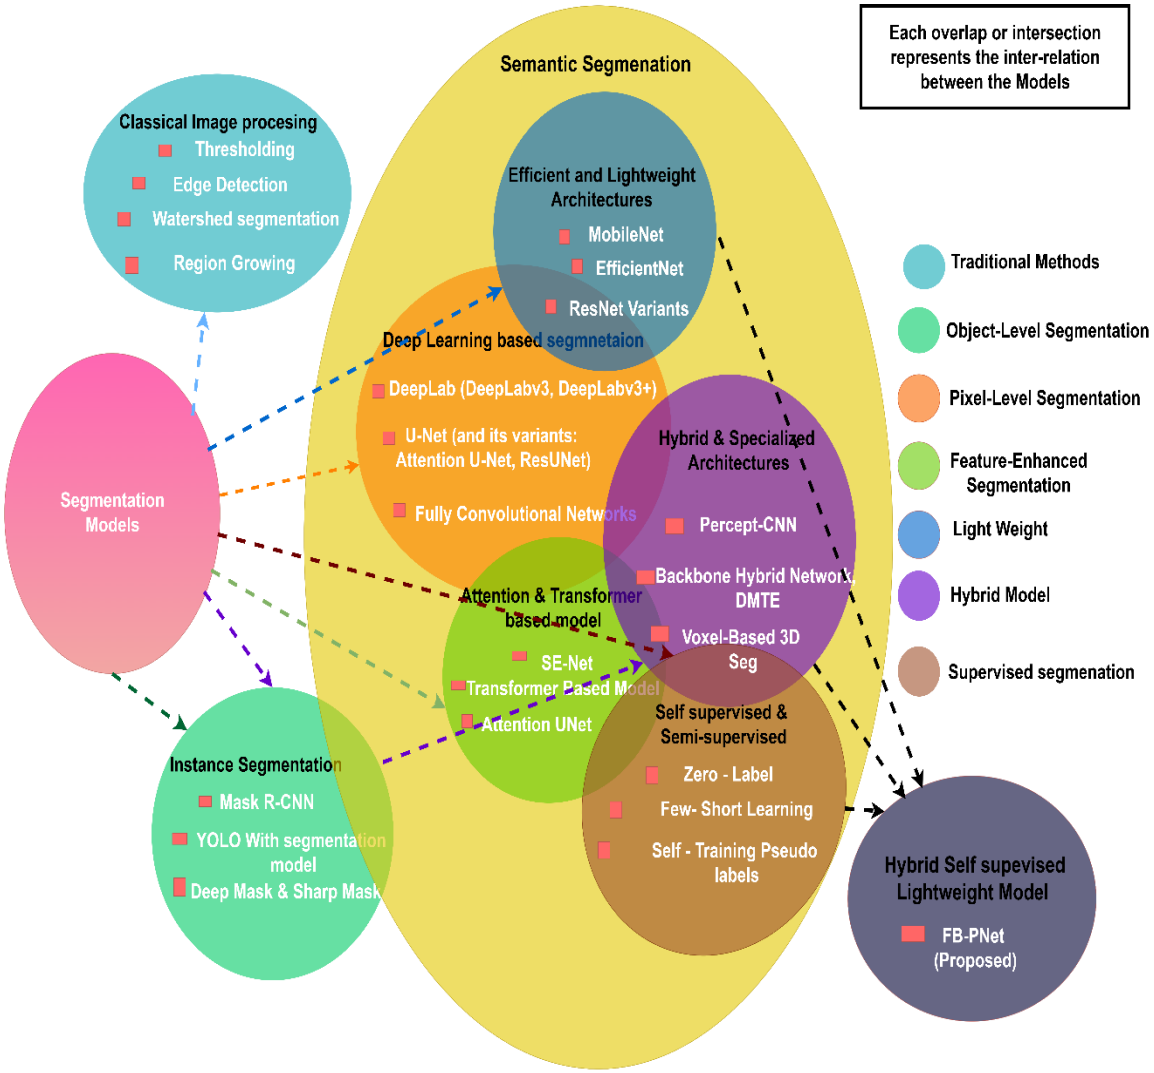

Fig. 1. Evaluation overview of segmentation.

Overall, deep learning-based segmentation techniques have significantly improved plant leaf annotation, challenges related to computational efficiency, annotation labor, and dataset scalability remain critical areas for future research and optimization. These limitations are prevalent across all the discussed methodologies.

III. Dataset Description

The dataset is created from the existing citrus leaf dataset which consists of around 500 images [28]. Further the images of the new dataset is created by adding two distinct mask to support the sematic segmentation process. The proposed segmentation and analysis in the system make leverage of two distinct dataset with images containing leaf mask and disease mask, later the dataset is divided into train, valid, and test splits for the segmentation process. To enhance model generalization and performance, various levels of augmentation were applied, resulting in multiple dataset versions. The dataset used in this work is available in zenodo [29].

Original Datasets of Leaf and Disease: The initial dataset comprises 568 images for both leaf and disease segmentation, respectively [30]. Augmented Datasets of leaf and disease: To increase dataset diversity and to enhance the model's adaptability across diverse conditions, data augmentation were implemented, generating a larger dataset. The augmentation techniques included transformations such as rotation, flipping, scaling, brightness adjustments, and contrast enhancement. This resulted in 1,702 augmented images for both leaf and disease datasets. Fully Augmented Dataset: A final augmentation stage was conducted to further expand the dataset, leading to 3,405 images for both leaf and disease segmentation. These datasets information and splits are mentioned in Table I.

A. Significance of Dataset Augmentation

Initially, the images undergo a preprocessing phase involving augmentation. This technique generates altered versions of the original images by applying various transformations. The progressive augmentation strategy ensures that the model is trained on a diverse set of images, reducing overfitting and enhancing its capability to accurately segment leaves and classify diseases under varied environmental conditions, lighting variations, and occlusions.

By leveraging a structured dataset split, model performance is rigorously evaluated, ensuring robust generalization to unseen data in plant village dataset [31]. Augmentation enhances the model's exposure to diverse training samples, thus enhancing its capability to generalize effectively to unseen or real-world conditions. This dataset framework plays a crucial role in improving segmentation accuracy, thereby contributing to precise automatic plant leaf annotation using deep learning. The sample images on leaf and disease dataset is shown in Fig. 2.

TABLE I. OUTLINES THE VARIOUS DATASET AND ITS SPLIT FOR TRAINING, VALIDATION AND TESTING

Dataset	Total No. of images	Training set	Validation set	Test set
Leaf dataset	568	464	52	52
Disease dataset	568	464	52	52
Augmented Leaf dataset	1702	1393	155	154
Augmented Disease dataset	1702	1393	155	154
Fully Augmented Leaf dataset	3405	2786	310	309
Fully Augmented Disease dataset	3405	2786	310	309

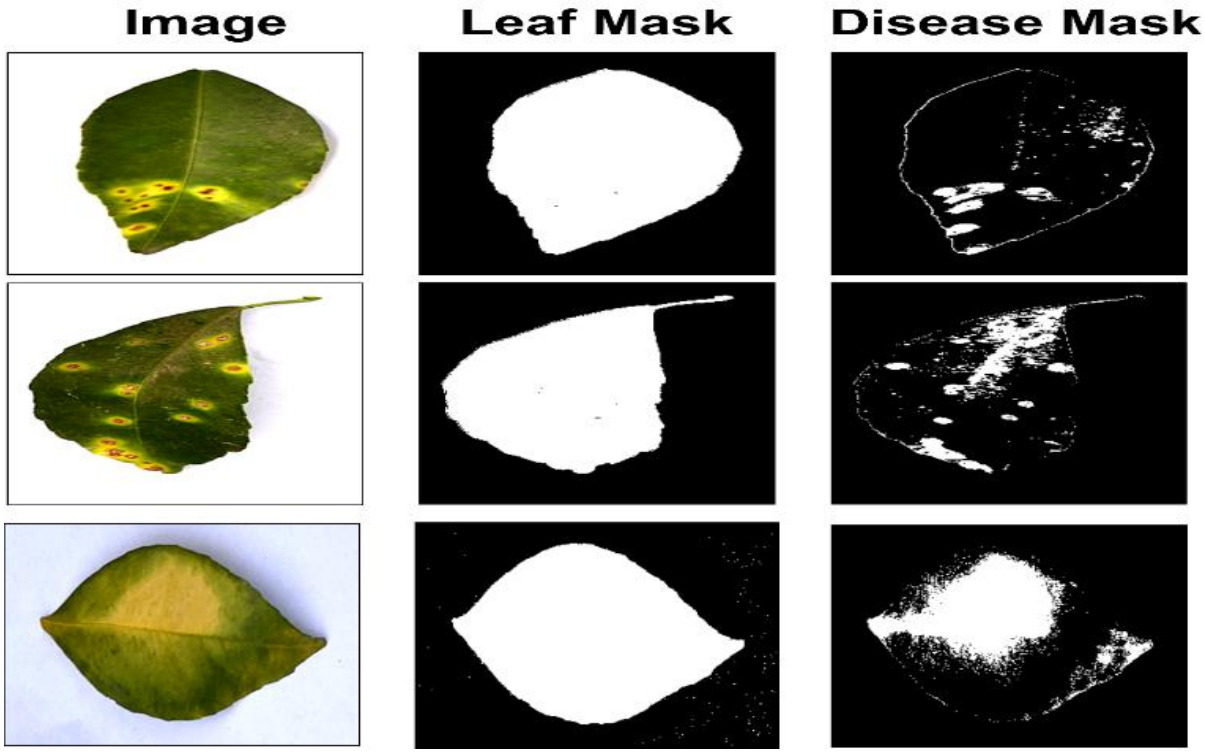

Fig. 2. Data samples with the image in the first column and corresponding annotation mask of leaf and disease in second and third column.

IV. METHODOLOGY

Forward-Backward Propagated Percept U-Net (FB-PNet) is using a Pre-trained U-Net for segmentation. The U-Net encoder extracts multi-scale features of leaf or diseases, while the decoder reconstructs spatially - detailed feature maps for segmentation. The use of SMP U-Net from segmentation models pytorch simplifies development by leveraging a modular, pre-built network. Custom layers perception convolution (PConv) for refinement is used after the U-Net decoder output, and additional custom PConv layers are applied. These layers refine the segmentation predictions, allowing for specific feature transformations beyond the U-Net's capabilities. This model is based on Single-task pipeline and it focuses purely on segmentation with a binary mask output. The forward pass outputs logits for the segmentation task, followed by a loss function BCEWithLogitsLoss for binary segmentation. FB-PNet Model is lighter, leveraging a well-tested U-Net for segmentation, making it easier to train and apply to binary segmentation tasks. It focuses on a streamlined segmentation task with a U-Net backbone, making it simpler but task-specific. The proposed model eliminates the necessity for pixel-wise annotation by leveraging a classification dataset to execute the segmentation task. FB-PNet captures and transfers essential visual characteristics throughout the layers, facilitating their utilization in segmentation processes, where the goal is to get visual characteristics in the input image and it gives binary segmentation output. Fig. 3 describes the complete block diagram of the FB-PNet architecture.

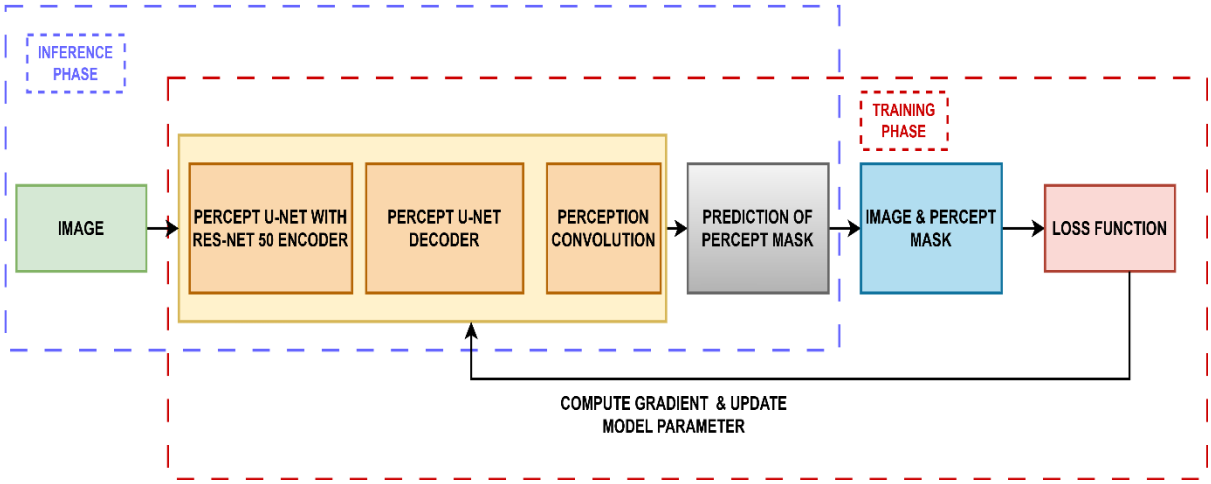

Fig. 3. Block diagram of proposed model.

In the Input Image, where X is an input tensor image of shape [B, C, H, W], where B is batch size, C is the number of channel, H is the height and W is the width. A batch of RGB images with shape (batch_size, 3, height, width).

In the process of the Forward Pass FB-PNet Encoder which is hierarchical, multi-scale Features are extracted at multiple scales using the ResNet50 encoder. Early percept layers focus on low-level features like edges, textures etc. Deeper percept layers capture high-level features that are the object shapes, contextual information. Output from the percepts gives multi-scale feature maps. In these, $F_{enc}^{(i)}$ is the Percept Feature map at stage i of FB-PNet encoder. Then these input X is processed through the encoder, generating a series of Percept feature maps [see Eq. (1)].

$$\{F_{enc}^{(1)},\ F_{enc}^{(2)}, \dots\dots, F_{enc}^{(n)}\} = Encoder\ (X) \quad (1)$$

Models decoder is percept Multi-Scale Feature Combination. The decoder combines these percept multi-scale features to generate segmentation features. Percept Features from deeper layers are upsampled to match the spatial resolution of shallower layers. These upsampled features are concatenated with corresponding encoder features using skip connections. This combination ensures that both low-level percept detailed and high-level semantic information is preserved. In these $F_{dec}^{(i)}$ is the Percept Feature map at stage i of the BPNet decoder. The decoder takes the Percept Feature maps from the encoder and reconstructs the F_{BPNet} feature map [see Eq. (2)].

$$F_{BPNet} = Decoder\ \{F_{dec}^{(1)},\ F_{dec}^{(2)}, \dots\dots, F_{dec}^{(n)}\} \quad (2)$$

Refinement of segmentation features in this Percept Convolution PConv1 and PConv2 further refine the segmentation features. Enhance the representation of fine details of leaf and diseases. Improve the distinction between leaf, diseases and background regions, where W_{LPConv}^{k} is the learnable weights of LPConv and $k \times k$ convolution. σ_l: $Leaky\ relu$ activation function. After obtaining F_{BPNet} from the BPNet, the following convolution operations are applied. In the first 3×3 PConv layer with LeakyRelu activation as in Eq. (3):

$$F_{PConv1} = \sigma_l(W_{PConv1}^{3\times3} * F_{BPNet}) \quad (3)$$

The second PConv layer is another 3×3 convolution followed by LeakyRelu activation which is applied to the output of the first PConv layer [see Eq. (4)].

$$F_{PConv2} = \sigma_l(W_{PConv2}^{3\times3} * F_{PConv1}) \quad (4)$$

Segmentation prediction for leaf or disease is a refined feature in a single-channel segmentation map, the prediction in the model refers to assigning each pixel of the input image a class label or a probability of belonging to a leaf or diseases class. Final segmentation mask is produced by the pred layer using Conv2d. A Conv2d layer reduces the number of channels to 1, corresponding to the binary classification for each pixel in the leaf image. Kernel size of 1x1, which ensures that the spatial dimensions (height, width) remain unchanged. Each pixel has a value between 0 and 1 after applying a sigmoid. Activation: Sigmoid, applied to the output of this layer to produce probabilities for each pixel. A value close to 1 at pixel (i, j) row and column indicate a high probability of the pixel (i, j) row and column belonging to the target leaf or disease class. Values close to 0 indicate a low probability, it belongs to the background. The output shape is (batch_size, 1, height, width).

In the final prediction layer a 1×1 convolution is applied to reduce the number of the channels to 1 for the binary segmentation logits [see Eq. (5)].

$$F_{Pred} = W_{Pred}^{1\times1} * F_{PConv2} \quad (5)$$

Here, the overall FB-PNet models forward pass of combining all steps is summarize [see Eq. (6)].

$$F_{Pred} = W_{Pred}^{1\times1} * \sigma_l\left(W_{PConv2}^{3\times3} * \sigma_l(W_{PConv1}^{3\times3} * F_{BPNet})\right) \quad (6)$$

The prediction Y of the annotation is obtained after applying the sigmoid activation into the final prediction of FB-PNet model. It gets the result of the predicted annotation.

$$Y = \sigma(F_{Pred}) \quad (7)$$

Perception refer to pixels that encapsulate significant visual information extracted after each layer of the network. These pixels correspond to regions with high activation values in the associated feature maps. The output of this operation is

subsequently processed using a sigmoid activation function to enhance the perception of essential visual components. Mathematically, this is represented as Eq. (7). The application of the sigmoid function further emphasizes the most relevant pixels in the input image, which are identified as Perception.

It enables the model to concentrate exclusively on pixels containing critical visual information, as illustrated in Fig. 4. This figure provides a conceptual representation of how an FB-PNet layer processes an image using a specific filter. To illustrate, consider a filter designed to detect the part of leaf. When an image is processed through FB-PNet using this filter, it generates a feature map and a corresponding perception mask. For intuitive understanding, Fig. 4 presents the original image overlaid with the perception mask.

Fig. 5 shows an illustration of perception generation. A leaf image is processed with a filter designed to detect a part of leaf and disease parts. The output includes a feature map and a percept mask, highlighting pixels corresponding to the detected structure.

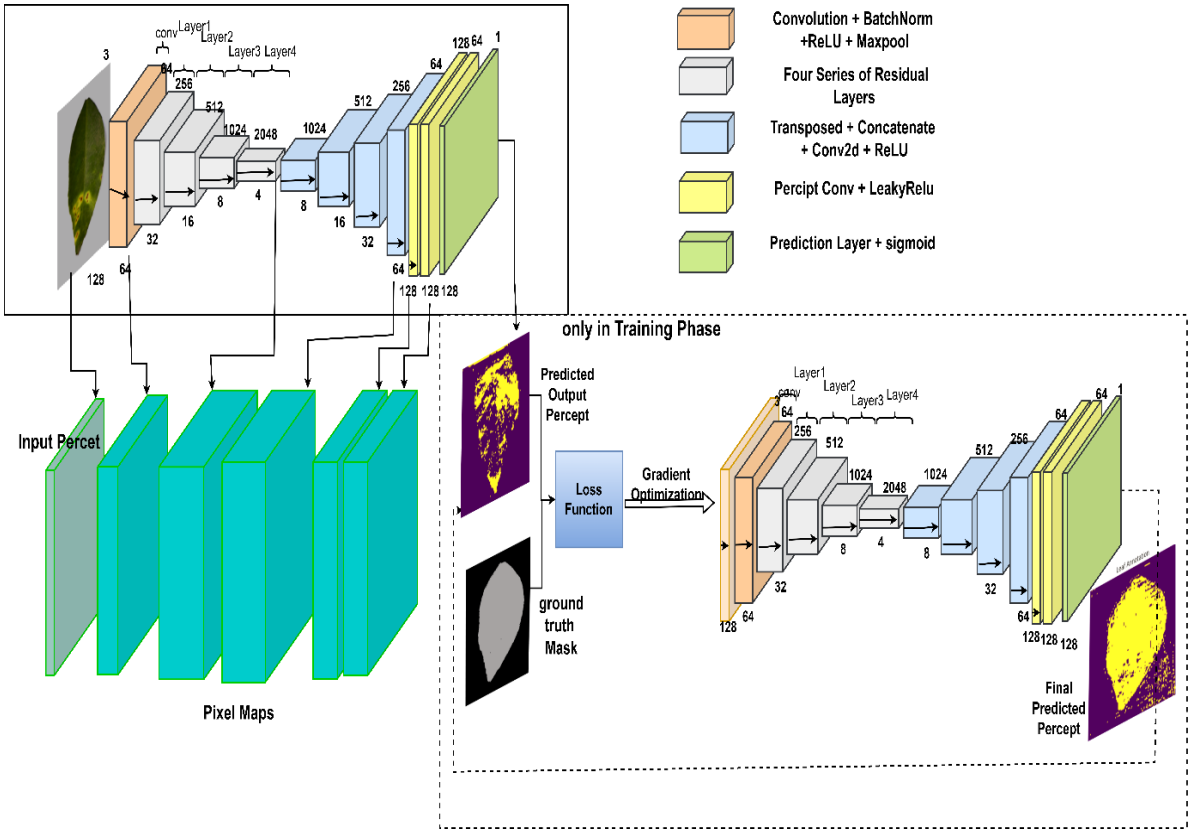

Fig. 4. Forward-backward propagated perception net.

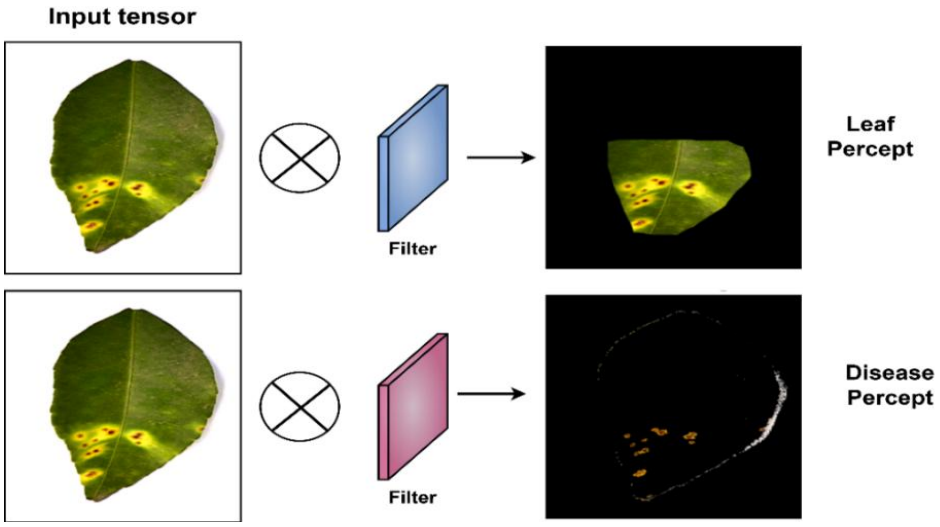

Fig. 5. Perception generation.

Then the output logits F_{Pred} are passed to the binary cross-entropy loss function with the logits, this will help the model to get the details of the models lagging through the loss function. $\mathcal{L}_{BCE}$ represents the binary Cross-Entropy loss, M_i is the ground truth mask of the input leaf or disease and N represents the total count of pixels in the input image tensor [see Eq. (8)].

$$\mathcal{L}_{BCE} = -\frac{1}{N}\sum_{i=1}^{N}[\, M_i \,.\log(Y) + (1 - M_i)\,.\log(1 - Y)] \quad (8)$$

Then the information from the $\mathcal{L}_{BCE}$ loss obtained on the forward pass is getting into backward pass. In backward pass gradients of the loss are computed with respect to model parameters using backpropagation. Here, Adam optimizer updates the model parameter regarding the loss obtained in the previous inference of the model, it is to minimize the loss and increase the predicted annotation mask.

The comprehensive architecture of FB-PNet is illustrated in Fig. 3. The module positioned in the lower right section of the architecture serves as a classification unit, employed solely during the training phase for weight refinement. During the inference stage, the input image undergoes processing through FB-PNet, resulting in the generation of a perceptual mask or output perception, as illustrated in Fig. 4. The final perceptual mask represents the segmentation output.

V. Experimental results and discussion

To evaluate the effective performance of the proposed deep learning model for automatic plant leaf annotation, the FB-PNet model was trained for 100 epochs using the ResNet50 U-Net backbone integrated with Perception Convolution layers (PConv). A standardized training setup was maintained across all datasets to ensure consistency in evaluation for FB-PNet. The parameters IoU, dice coefficient, precision and recall is used for evaluation and comparison, since these metrics are better in determining the quality of segmentation.

This configuration included: all these models training and evaluation process were executed on the GPU available in Google colab. This GPU provides more disk space, which offered enhanced computational resources and sufficient storage capacity for efficient handling of large datasets required on training the model. The model was trained on a single GPU using CUDA version 11.8 to ensure efficient computation. Training was conducted for a maximum of 100 epochs, with early stopping applied if validation performance did not improve for 20 consecutive epochs. To optimize data loading and preprocessing, four worker processes were utilized. A batch size of 16 images was used during training to balance computational efficiency and memory constraints. Initially the learning rate was configured to 0.0001, with a ReduceLROnPlateau scheduler dynamically adjusting the learning rate by a factor of 0.5, if validation loss did not improve for 5 epochs. The Adam optimizer was employed, along with weight decay (0.00001) to enhance generalization. Additionally, gradient clipping with a value of 1.0 was applied to prevent exploding gradients. No warm up strategy was applied, as the model converged effectively with the selected learning rate and optimizer settings.

The trained proposed FB-PNet model is compared in Table II which represents the segmentation performance of different models across various dataset configurations, including original, augmented, and fully augmented leaf and disease datasets. The results demonstrate that our proposed Forward-Backward-Propagated Percept Net consistently outperforms existing architectures, achieving the highest performance across all dataset variations. Notably, our model exhibits a significant improvement in segmentation accuracy on test data, particularly in the fully augmented dataset, where it achieves an IoU of 0.9802 and 0.8680 for leaf and disease datasets, respectively. The superior performance of our approach highlights the effectiveness of incorporating Perception Convolution layers and advanced feature propagation mechanisms. In contrast, traditional models like P-CNN show the lowest performance across all datasets, while other deep learning models such as UNetResNet50 and UNetEfficientNetB0 show moderate improvements but still fall short of FB-PNet's results. This highlights FB-PNet's effectiveness in handling complex segmentation tasks, especially when trained on augmented data. As a result, the model's performance was evaluated using the training and validation datasets, and the findings are discussed.

A. Intersection over Union (IoU)

IoU quantifies the similarity between the predicted and actual masks by measuring their overlap [Eq. (9)].

$$IoU = \frac{|M \cap Y|}{|M \cup Y|} = \frac{TP}{TP+FP+FN} \quad (9)$$

TABLE II. Performance Comparison of Different Segmentation Model Across Various Test Dataset

	Leaf dataset (500+ images)	**Disease dataset (500+ images)**	**Augmented Leaf dataset (1500+ images)**	**Augmented Disease dataset (1500+ images)**	**Fully Augmented Leaf dataset (3000+ images)**	**Fully Augmented Disease dataset (3000+ images)**
P-CNN	0.5119	0.4113	0.4752	0.4839	0.5223	0.5203
UNetResNet34	0.8206	0.5535	0.6874	0.6845	0.9406	0.6535
DeepLabV3PlusResNet50	0.8902	0.6575	0.6307	0.6228	0.9106	0.6307
UNetEfficientNetBo	0.9091	0.6689	0.8959	0.6838	0.9381	0.7268
UNetResNet50	0.9325	0.6816	0.9226	0.7100	0.9506	0.7375
Forward-Backward-Propagated Percept Net **(Ours)**	**0.9391**	**0.7306**	**0.9589**	**0.7174**	**0.9802**	**0.8680**

where,

- TP (True Positives) are correctly predicted leaf or diseased pixels.
- FP (False Positives) are background pixels wrongly predicted as leaf or diseased.
- FN (False Negatives) are leaf or diseased pixels wrongly predicted as background.

B. Dice Coefficient (F1-Score for Segmentation)

The Dice coefficient evaluates the similarity between the predicted and ground truth masks [Eq. (10)].

$$Dice = \frac{2|M \cap Y|}{|M| \cup |Y|} = \frac{2TP}{2TP+FP+FN} \quad (10)$$

Dice is closely related to IoU but gives more weight to correctly predicted pixels.

C. Precision

Precision measures how many of the predicted positive pixels are actually correct [Eq. (11)].

$$Precision = \frac{TP}{TP+FP} \quad (11)$$

D. Recall

Recall measures how many of the actual positive pixels were correctly predicted [Eq. (12)].

$$Recall = \frac{TP}{TP+FN} \quad (12)$$

Table III presents the FB-PNET final training and validation performance metrics at epoch 100, including Loss, IoU, Dice Coefficient, Precision, and Recall.

TABLE III. FB-PNET TRAINING AND VALIDATION METRICS AT EPOCH 100

Metric	Training	Validation
Loss	0.5218	0.5166
IoU	0.8071	0.7010
Dice	0.8928	0.8215
Precision	0.8094	0.7038
Recall	0.9966	0.9938

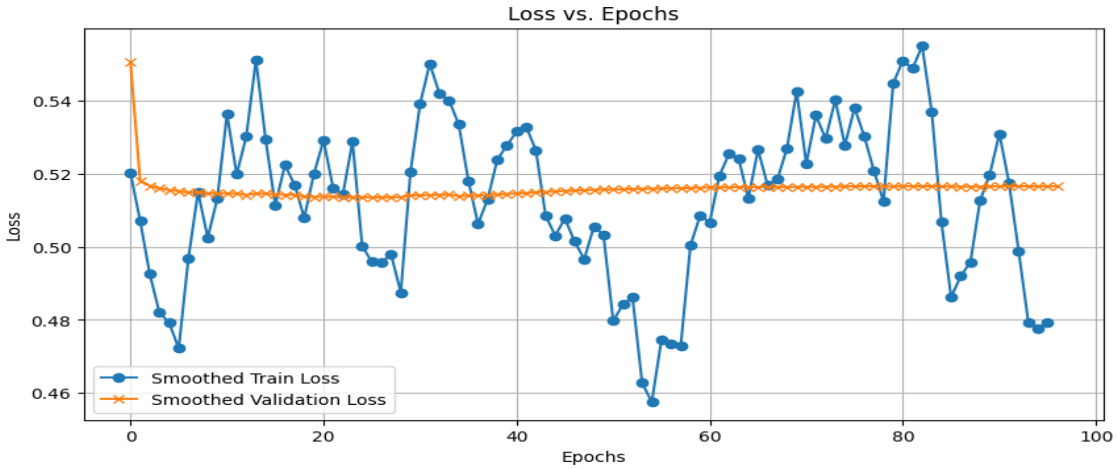

Fig. 6. Training and validation of loss of FB-PNet model for leaf annotation.

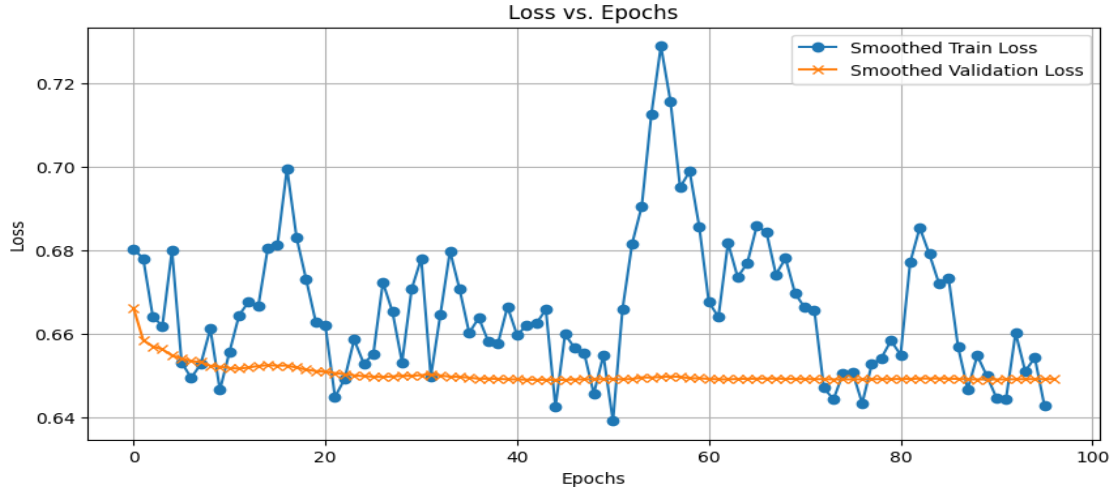

Fig. 7. Training and validation of loss of FB-PNet model for disease annotation.

Fig. 6 and Fig. 7 illustrate the training and validation loss trends for leaf annotation and disease annotation, respectively. The validation loss remains stable, while training loss exhibits fluctuations, indicating the model's learning behavior and adaptation to complex features. Fig. 8 and Fig. 9 show the IoU trends for leaf and disease annotations, where the validation IoU remains relatively stable while training IoU fluctuates, indicating the model's robust generalization.

TABLE IV. COMPARISON WITH RELATED METHODS

Method	Model	Validation IoU Accuracy
IIC [32]	R18+FPN	44.5
PiCIE [33]	R18+FPN	54.2
P-CNN [27]	–	67.2
DINO [34]	ViT-S/8	68.6
FB-PNet For Leaf	FB-PNet (ours)	**70.2**
FB-PNet For Disease	FB-PNet (ours)	**30.5**

Table IV provides a comparative evaluation of different segmentation models in terms of validation IoU accuracy. The proposed Forward-Backward-Propagated Percept Net (FB-PNet) outperforms several benchmark methods, including IIC, PiCIE, and DINO, achieving an IoU of 70.2 for leaf segmentation and 30.5 for disease segmentation. The findings emphasize the effective capability of FB-PNet in accurately capturing intricate plant leaf structures and disease patterns.

Fig. 10 provides a qualitative evaluation of the proposed FB-PNet model. The figure showcases:

- Leaf segmentation results: The predicted segmentation closely aligns with the ground truth, confirming accurate leaf annotation.
- Disease segmentation results: The disease prediction model captures infected regions but exhibits slight over-segmentation in certain areas.

The overall architecture of the Forward-Backward Propagated Percept Net is illustrated in the center of the figure.

The bottom section of the figure displays results from the PlantVillage dataset those are unseen to the model, showcasing the model's ability to accurately annotate both leaves and diseases across various plant species.

From the findings, it is evident that the proposed model is having better efficiency and advantage of avoiding the manual annotation during the segmentation process.

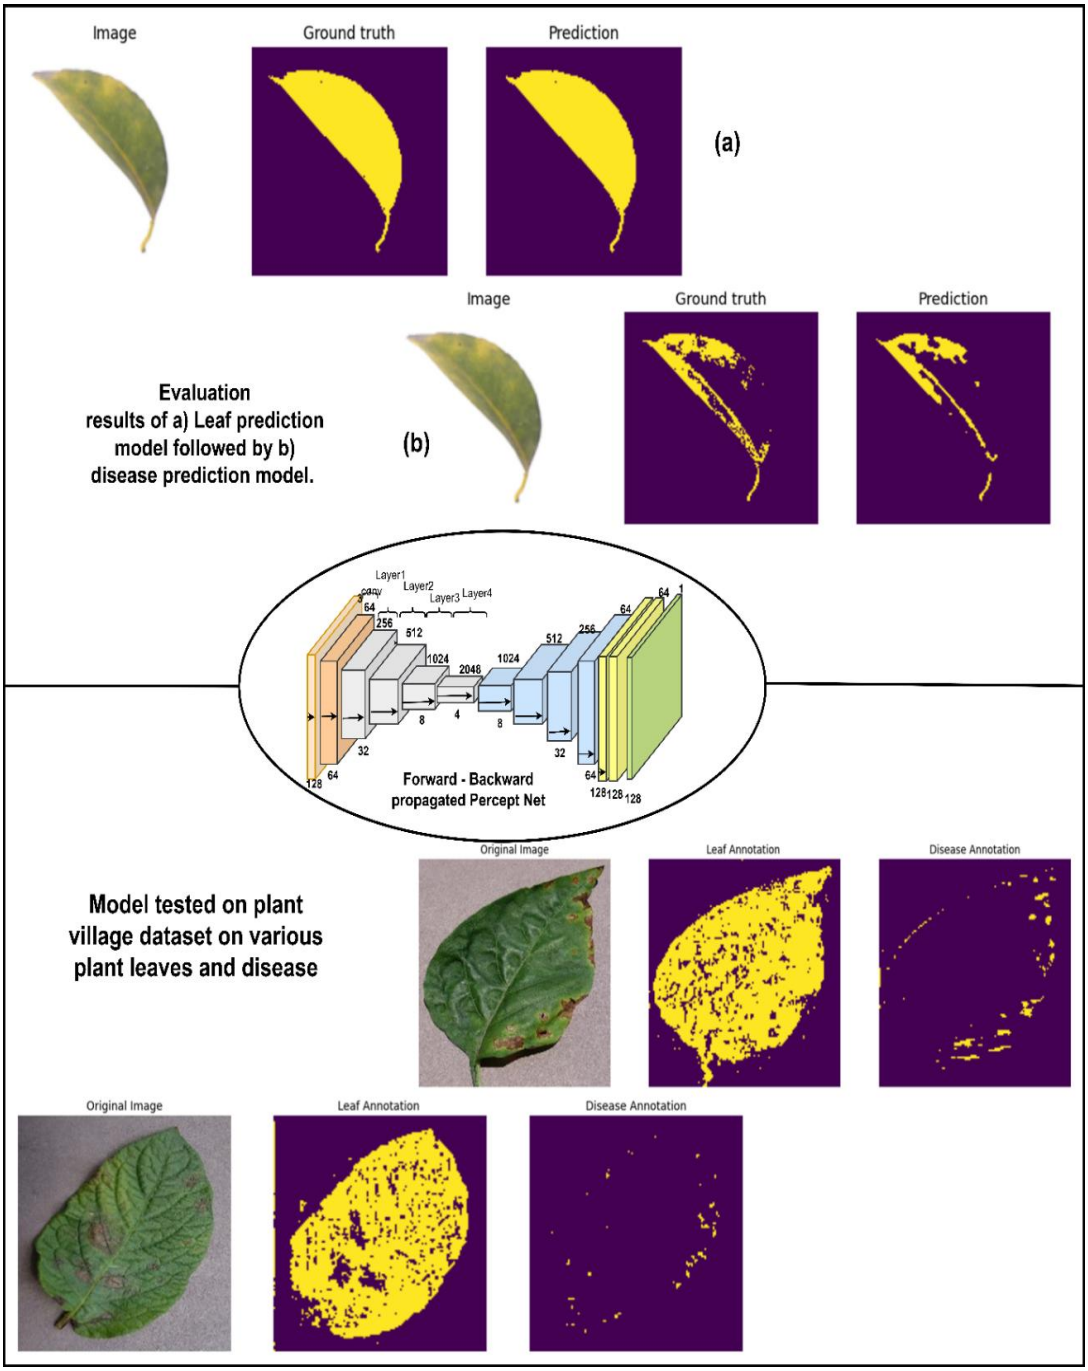

Fig. 10. Test Results of the proposed model with various dataset.

VI. Conclusion

This research describes a new improved deep-learning-based model for plant leaf and disease automatic annotation, FB-PNet. The model improves feature extraction by emphasizing salient visual details by discarding some other computations, thus helpful in enhancing the segmentation accuracy. The model trained using BCEWithLogitsLoss and the optimization was done using the Adam optimizer with ReduceLROnPlateau to stabilize the convergence and improve the generalization. Experimental results also clearly indicate that this approach offers superior performances measured with Intersection over Union (IoU), Dice coefficient, Precision, and Recall. However, the model is capable of over-segmenting in areas close to object borders because some natural parameters impede its effectiveness in accurately segmenting boundaries.

Despite its strengths, the model occasionally struggles with precise boundary segmentation, leading to over-segmentation near object borders. In future studies, we may attempt to combine multi-scale feature extraction and attention mechanisms for eluding trivial features while optimizing some crucial details to further improve the performance of the model. Future attempts would also include extending the framework to

solving multi-label segmentation tasks, improving self-supervised approaches to increase versatility across different datasets. By addressing these issues and fine tuning it, we aim to substantially develop our automatic plant leaf and disease segmentation system for real-world agricultural and biological applications.

Hybrid Sequence Augmentation and Optimized Contrastive Loss Recommendation

Minghui Li, Xiaodong Cai*
School of Information and Communication, Guilin University of Electronic Technology, Guilin, China

***Abstract*—To address the issues of relevance and diversity imbalance in the augmented data and the shortcomings of existing loss functions, this study proposes a recommendation algorithm based on hybrid sequence augmentation and optimized contrastive loss. First, two new data augmentation operators are designed and combined with the existing operators to form a more diversified augmentation strategy. This approach better balances the relevance and diversity of the augmented data, ensuring that the model can make more accurate recommendations when facing various scenarios. Additionally, to optimize the training process of the model, this study also introduces an improved loss function. Unlike the traditional cross-entropy loss, this loss function introduces a temporal accumulation term before calculating the cross-entropy loss, integrating the advantages of binary cross-entropy loss. This overcomes the limitation of traditional methods, which apply cross-entropy loss only at the last timestamp of the sequence, thereby improving the model's accuracy and stability. Experiments on the Beauty, Sports, Yelp, and Home datasets show significant improvements in the Hit@10 and NDCG@10 metrics, demonstrating the effectiveness of the recommendation model based on hybrid sequence augmentation and optimized contrastive loss. Specifically, the Hit metric, which reflects model accuracy, improves by 8.64%, 13.07%, 5.92%, and 19.28% respectively on these four datasets. The NDCG metric, which measures ranking quality, increases by 15.60%, 19.01%, 9.66%, and 20.31% respectively.**

I. Introduction

Recommendation systems analyze vast amounts of data to help users select items they might be interested in, thereby better meeting their personalized needs. These systems typically make inferences based on users' historical behavior data, preferences, and interests, providing accurate recommendations and saving users the time they would otherwise spend filtering content in an environment of information overload. Sequence recommendation, as a more advanced recommendation technique, predicts future items or content that users may like by analyzing and mining users' historical behavior data within a specific time period. Specifically, sequence recommendation not only focuses on users' historical behavior but also considers the temporal sequence of the behavior, allowing it to more accurately capture users' dynamic changes in interests. For example, the user may have first purchased a phone, then selected headphones, and later became interested in a tablet. Based on this historical data, the recommendation system can predict the user's potential future purchase behavior and infer the user's next possible interest. Sequence recommendation plays a crucial role in various internet applications, especially in scenarios such as e-commerce, video streaming, and social platforms. By deeply mining users' historical behavior and preferences, it helps recommendation systems generate personalized results. However, data sparsity has always been a significant challenge for recommendation systems. Since interaction data between users and items is often scarce, especially in large-scale systems, where many items may have been interacted with by only a few users, it becomes difficult for the system to accurately capture the complex relationships between user preferences and item characteristics. This is especially problematic in sequence recommendation, where models need to handle vast amounts of user behavior data and perform time-series modeling. Due to the sparsity of data, there is often insufficient interaction information between users and items, making it difficult for the model to accurately predict the user's next action, thus affecting the accuracy and effectiveness of the recommendation.

To address the problem of data sparsity, researchers have introduced data augmentation methods. However, there has been limited research on the imbalance between the relevance and diversity of the augmented data, which leads to semantic drift issues or limited performance improvements. In response to this, Dang et al. [1] proposed a new model, BASRec, which designed two new operators, M-Reorder and M-Substitute, and used single-sequence and cross-sequence augmentation modules to solve the above problems. However, previous research has shown that using only Reorder and Substitute operators does not yield the best data augmentation results. Furthermore, BASRec uses the commonly used BCE loss function [2] to calculate contrastive loss. Previous studies have indicated that using the CE loss function [3] in recommendation models may lead to better performance. However, the drawback of CE loss is that it is applied only to the last timestamp of the input sequence, which also affects the model's performance [4].

To address these issues, inspired by the literature [4, 5, 6, 7], this study proposes a recommendation algorithm based on hybrid sequence augmentation and optimized contrastive loss (RM-HSAOCL) on the basis of BASRec. Firstly, to further enhance the effect of data augmentation, this study designed two new data augmentation operators—M-Crop and M-Mask. The M-Crop operator enhances the data by cropping the original data and randomly selecting a subpart of the input sequence, ensuring the diversity of the augmented data while maintaining its relevance to the original data. The M-Mask operator randomly masks part of the data in the input sequence, simulating missing or incomplete information. This operation not only improves the robustness of the model but also helps

*Corresponding Author.

the model better adapt to the issue of incomplete data in real-world scenarios. These two new operators, together with the existing M-Reorder and M-Substitute operators, form a more diversified data augmentation scheme. Through this diversified augmentation strategy, the augmented data not only maintains a certain level of relevance but also greatly improves its diversity, thus enhancing the model's performance in various situations and ensuring more accurate recommendations. In addition to the innovation in data augmentation, this study also designed an improved ICE loss function for optimization. Unlike the traditional Cross-Entropy (CE) loss function, the ICE loss function introduces a time accumulation term before calculating the CE loss, compensating for the limitation of traditional methods, which only apply the CE loss at the final timestamp of the input sequence. As a result, the ICE loss function can capture key information not only at the last moment of the time series but also effectively utilize information from all timestamps in the sequence, improving the model's ability to understand long-term time series data. At the same time, the ICE loss function also incorporates the advantages of BCE loss, optimizing data across all timestamps and further improving the model's performance.

The following outlines the structure of the study: Section II reviews related work. Section III delves into the design of the RM-HSAOCL model, covering hybrid sequence enhancement method, improved loss function and model training loss. Section IV presents and analyzes experimental results to validate the approach. Section V summarizes the work and explores future research directions.

II. Related Work

A. Data Augmentation

Although sequential recommendation models have made significant progress in personalized recommendations, the prevalent issue of data sparsity remains a major bottleneck that limits their performance. In practical applications, many users have limited behavior records, especially for new users or the cold-start problem, where there is often a lack of sufficient interaction data, making it difficult for recommendation systems to effectively capture user preferences. To address this challenge, researchers have proposed data augmentation methods. These methods have shown significant effectiveness in tackling the data sparsity problem in sequential recommendations. By generating more user behavior sequences, introducing generative models, utilizing multimodal data, and performing sample reconstruction, recommendation systems can better cope with the challenges posed by sparse data. It is a commonly used technique, especially in deep learning and machine learning, that helps improve the diversity of the dataset, enhance the model's generalization ability, and reduce the risk of overfitting.

Initially, Tang et al. [8] proposed generating new training samples through a sliding window approach to increase the training data for the model. However, since heuristic algorithms like sliding windows rely solely on local information, the augmented data generated by this method may be of lower quality, potentially leading to overfitting or poor training results. Therefore, researchers gradually introduced many data synthesis methods that require training in order to overcome the limitations of traditional augmentation methods and further enhance the model's generalization ability. For example, Li et al. [9] improved recommendation accuracy and personalization by better capturing users' latent interest shifts through the consideration of spatial and temporal factors. Jiang et al. [10] proposed a conditional Generative Adversarial Network (GAN), which generates new data similar to the original data, thereby enabling the recommendation system to leverage more data. Wang et al. [11] innovatively adjusted user behavior sequences from a counterfactual reasoning perspective, specifically by replacing some of the purchased items with unknown items to simulate different behavior scenarios, helping the model better understand users' latent preferences and decision-making processes. Liu et al. [12] adopted a diffusion model for sequence generation and designed two guidance strategies to control the consistency of the generated data with the original data, ensuring that the generated items maintained a high degree of similarity with users' actual interests. Wang et al. [13] improved temporary user recommendations and reduced cold-start problems by leveraging the behavior features of core users. However, although these training-based data synthesis methods can improve the model's performance to some extent, the augmented data they generate may still have inconsistencies in quality compared to the original data.

To address this issue, many researchers have optimized models by generating contrastive samples using self-supervised learning techniques. For example, Xie et al. [5] proposed a self-supervised learning method based on data augmentation, designing three data augmentation operators and combining them with a contrastive learning framework to improve the model's generalization ability. Yao et al. [14] proposed a two-stage augmentation strategy, where the first stage involves masking operations on the embedding layer, and in the second stage, they discard other classification features except for those used in contrastive learning, to learn more refined feature representations. Zhou et al. [15] also employed contrastive learning, enhancing the model's learning ability by maximizing mutual information between attributes. Their study also introduced random masking of attributes and item order techniques, further improving the model's adaptability to data diversity and noise. Liu et al. [16] combined item similarity information with the contrastive learning objective and proposed a novel data augmentation method, which included insertion and replacement operations. Qiu et al. [17] further optimized the training process by constructing contrastive samples, helping the model recognize subtle differences between different categories, thus improving prediction accuracy. Bian et al. [18] conducted two types of representation augmentation to enhance personalized feature representations of users. Dang et al. proposed five types of data operators to expand item sequences based on time intervals, enhancing the accuracy and effectiveness of recommendations by optimizing the sequence order of time series [19, 20].

However, these methods have limited research on the issue of imbalance between the relevance and diversity of augmented data, which can lead to semantic drift or limited performance improvement. To address this issue, this study designs two new data augmentation operators, M-Crop and M-Mask, based on

the BASRec model. These operators help the model better balance the relevance and diversity of the augmented data, making the data augmentation process more refined. This ensures that the augmented data retains key information while providing greater diversity, thereby enhancing the algorithm's adaptability and robustness in practical applications.

B. Loss Function

In recent years, with the rapid development of deep learning technology, sequence-based recommendation models based on neural networks have made significant progress in the field of personalized recommendations. These models, by deeply mining the temporal features in user behavior sequences, are able to more accurately predict users' future preferences. Traditional recommendation systems often focus on predictions based on static user data (such as user history, ratings, etc.), while sequence-based recommendation systems further utilize the time information in user behavior, capturing the dynamic changes in user interests. Specifically, these models usually treat user behavior sequences as input, and through the layers of a neural network, they progressively extract users' potential interests and behavior patterns, thereby generating personalized recommendation content and greatly enhancing the accuracy of recommendations and the user experience.

Among many sequence-based recommendation models, Transformer-based models have particularly attracted widespread attention and favor from researchers. The Transformer architecture was originally proposed to solve sequence-to-sequence tasks (such as machine translation), and its self-attention mechanism allows it to effectively capture long-distance dependencies with high computational efficiency. The first models to apply Transformer to sequence recommendation tasks were SASRec [21] and BERT4Rec [22]. SASRec and BERT4Rec were inspired by the success of the GPT [23] and BERT [24] architectures, which made significant breakthroughs in natural language processing (NLP) tasks, and thus their design ideas were transferred to the sequence recommendation field. Although SASRec and BERT4Rec are similar to their original designs in many aspects, they have made adjustments to the training objectives and attention mechanisms. The authors of BERT4Rec believe that the bidirectionality of the model is the main reason for its performance surpassing that of SASRec. However, subsequent research has shown that the key factor behind the performance improvement is actually the difference in the loss functions used by the two models, while other modifications might have an adverse impact [25, 26]. SASRec is trained using binary cross-entropy (BCE) loss [2], with one positive sample and one negative sample, while BERT4Rec uses cross-entropy (CE) loss [3] across the entire project catalog. This highlights the superiority of CE loss over BCE loss in multi-class classification. However, because BCE demonstrates superior scalability when dealing with larger project portfolios, it is often the more preferred choice in real-world applications.

In addition, many researchers have made improvements to the standard cross-entropy loss. For instance, Li et al. [27] adjusted the weights of positive and negative samples, reducing the loss contribution of simple samples (i.e., easy-to-classify samples), thereby shifting the focus of training to harder-to-classify samples. This adjustment helps the model focus more on predicting difficult user behaviors during the training process, thereby improving the accuracy and effectiveness of the recommendations. These improvements demonstrate that, in practical recommendation systems, how to design an appropriate loss function and sample weighting strategy is often more effective in enhancing model performance than purely architectural innovations. Therefore, this study proposes an improvement to the CE loss by combining the advantages of BCE loss to enhance the model's recommendation performance.

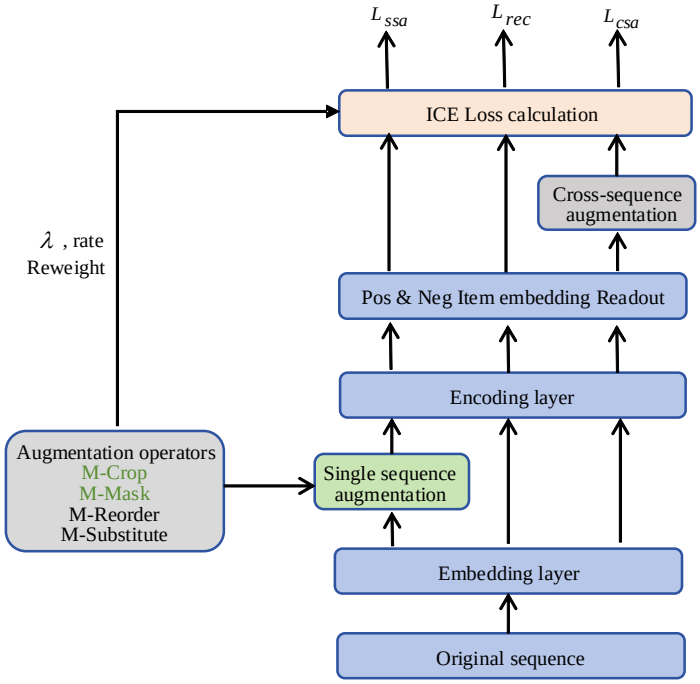

Fig. 1. The Overall framework diagram of the RM-HSAOCL model.

III. RM-HSAOCL Model Design

A. Notation, Definition and Description

Sequence recommendation is the task of recommending the next item that a user is likely to interact with based on their historical interaction data. Let U and V denote the set of users and items, respectively. A user $u \in U$ has an interacted item $S_u = \{v_1, v_2, ..., v_j ..., v_N\}$, $v_j \in V(1 \le j \le N)$, denoted as the item interacted by user u at position j in the sequence, where N is the sequence length. Given the historical interactions S_u, the goal of sequence recommendation is to recommend an item from the set of items V that user u is likely to interact with at step N + 1, which can be expressed as formula (1):

$$\arg\max_{v \in V} P(v_{N+1} = v \mid S_u) \tag{1}$$

B. Overall Framework

The overall framework of the RM-HSAOCL model proposed in this study is shown in Fig. 1. After the input sequence passes through the embedding layer, it is processed by the M-Crop and M-Mask operators designed in this section, along with the original M-Reorder and M-Substitute operators, to perform single-sequence enhancement. Then, it goes through the encoding layer, where positive and negative item embeddings are read out, followed by cross-sequence enhancement. Finally, the ICE loss function designed in this section is used to compute the next item prediction loss, single-sequence enhancement loss, and cross-sequence enhancement loss.

C. Hybrid Sequence Enhancement Method

In the BASRec model proposed by Dang et al. [1], two new operators, M-Reorder and M-Substitute, were designed to perform data augmentation. However, previous research shows that using only the Reorder and Substitute operators does not achieve the best data augmentation results. In this section, two new operators, M-Crop and M-Mask, are designed, which, together with the original M-Reorder and M-Substitute operators, complete the data augmentation operation.

1) M-Crop. Random cropping (Crop) is a common and efficient data augmentation technique in computer vision, widely used to improve the generalization ability of deep learning models [5]. Its basic principle is to randomly select a subregion from the original image for cropping and use the cropped image as a training sample. In this way, the model is exposed to different parts of the image, increasing the diversity of the training data, which helps the model make better predictions when faced with new, unseen images. In sequence recommendation tasks, models often need to process long sequence data, which may include user history, click records, or browsing records. To enhance the training data for recommendation algorithms, researchers have introduced the concept of random cropping into this field.

Inspired by the work in [1], this section improves upon the Crop technique and introduces a new data augmentation operator, M-Crop, as shown in Fig. 2. Given an original sequence S_u, M-Crop first selects a subsequence of length $c = rate \cdot N$. This section introduces the method of drawing $rate$ from a uniform distribution, making the length of the augmented subsequence no longer fixed. This allows for the generation of subsequences of varying lengths, thereby increasing the diversity of the augmented data as shown in formula (2):

$$rate \sim Uniform(a, b) \tag{1}$$

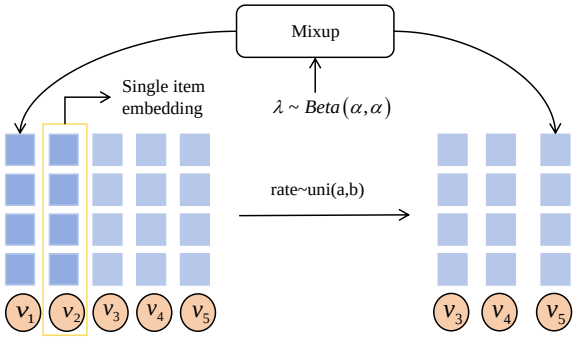

Fig. 2. The Data augmentation operator M-Crop.

where, a and b are hyperparameters, and $0 < a < b < 1$. Then, the augmented sequence is obtained starting from position i as in formula (3):

$$S_u' = Crop(S_u) = [v_i, v_{i+1}, \cdots, v_{i+c-1}] \tag{2}$$

Unlike traditional operators that directly use S_u' as the new sample for model training, this method mixes the corresponding terms of S_u and S_u' together, generating new training samples in the representation space as in formulas (4) and (5):

$$A_u' = Look - up(S_u, S_u') \tag{3}$$

$$A_u^{In} = \lambda \cdot A_u + (1 - \lambda) \cdot A_u' \tag{4}$$

where, A_u is the original item representation, $\lambda \sim Beta(\alpha, \alpha)$ is the mixing weight, and A_u^{In} is the augmented representation used for model training.

2) M-Mask. In many natural language processing tasks, such as sentence generation, sentiment analysis, and question answering, the technique of randomly masking input words, also known as "word dropout", is widely used to avoid overfitting. In [5], the authors proposed a data augmentation method called random item masking (Mask). Inspired by the work in [1], this section improves upon Mask and introduces a new data augmentation operator, M-Mask, as shown in Fig. 3. Given the original user sequence S_u, the items $l = rate \cdot N$ in the sequence are masked, where $rate$ is obtained from formula (2), and the augmented sequence can then be obtained as formula (6):

$$S_u' = Mask(S_u) = [v_1, v_2, \cdots, v_l, \cdots, v_N] \quad (6)$$

By following the same steps as in M-Crop, the augmented representation A_u^{In} can be obtained through formulas (4) and (5).

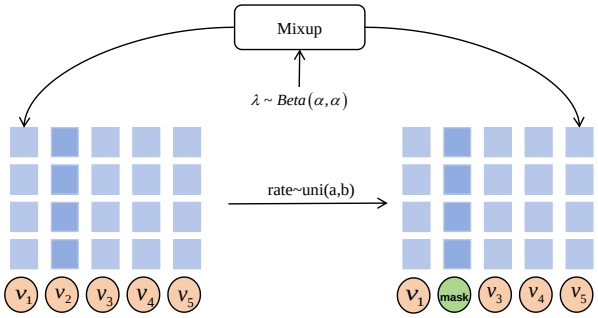

Fig. 3. The Data augmentation operator M-Mask.

D. Improved Loss Function

As discussed in related work, BERT4Rec achieves better performance due to the use of cross-entropy (CE) loss across the entire item sequence [25, 26], whereas in many real-world applications, binary cross-entropy (BCE) loss may be more applicable. The BCE loss is suitable for binary classification problems. Its design allows the model to effectively measure the gap between the predicted values and the true labels, helping the model continuously optimize its predictions during training. The specific mathematical formulas for CE loss and BCE loss are as follows [see formulas (7) and (8)]:

$$CE = -\log \frac{\exp\left(\log i_{t,pos}\right)}{\sum_{c=1}^{C} \exp\left(\log i_{t,c}\right)} \quad (5)$$

$$BCE = -\sum_{t=1}^{l}\left[\log \sigma\left(r_{t,pos}\right) + \sum_{j=1}^{N_s} \log \sigma\left(1 - r_{t,neg_j}\right)\right] \quad (6)$$

Here, l represents the length of the input sequence. The CE loss only involves the final timestamp of the input sequence, as shown in Fig. 4. In contrast, the calculation of BCE loss involves all timestamps of the input sequence, as shown in Fig. 5.

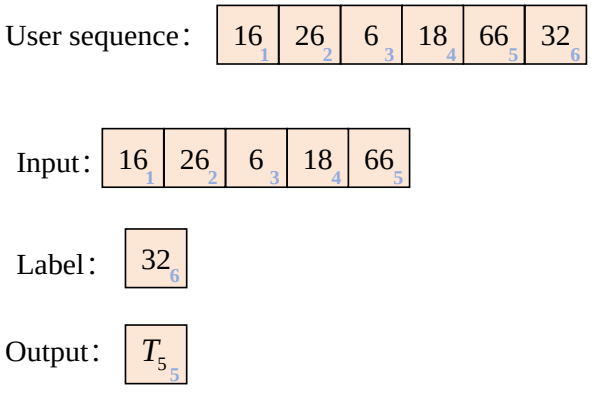

Fig. 4. CE Loss.

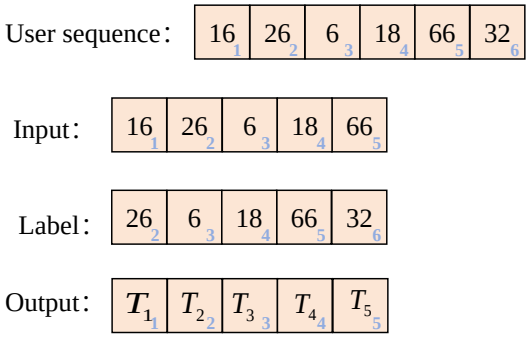

Fig. 5. BCE Loss.

Inspired by the studies [4, 7], this section introduces an optimized loss function, ICE, which builds upon the traditional CE loss function and incorporates an innovative cumulative time term before its calculation. Specifically, the traditional CE loss function usually only considers the last timestamp of the sequence, ignoring the potential information from other timestamps within the sequence. However, in many practical applications, the temporal characteristics of data often have a crucial impact on the model's predictions and performance. To overcome this limitation, the ICE loss function incorporates the accumulation term of time when calculating the CE loss, enabling a more comprehensive consideration of the information at each timestamp in the sequence, thus fully leveraging the temporal dependencies in the data. The specific mathematical formula of the ICE loss function is as follows [formula (9)]:

$$ICE = -\frac{1}{l}\sum_{t=1}^{l} \log \frac{\exp\left(i_{t,pos}\right)}{\sum_{c=1}^{C} \exp\left(i_{t,c}\right)} \quad (7)$$

The core innovation of the ICE loss function lies in the fact that, in the calculation at each timestamp, it takes into account the information from all previous timestamps. This accumulation mechanism effectively captures the long-term dependencies in the input sequence. Specifically, in the traditional CE loss, the model only focuses on the last moment of the sequence, which may overlook potentially useful information in the historical data. In contrast, ICE accumulates the effects of all timestamps, allowing the model to consider the context of the entire time series. This approach enables the model to more accurately capture long-term patterns and trends in the time series, improving the prediction accuracy and reliability.

At the same time, the ICE loss function also draws on the advantages of the BCE loss function, optimizing each timestamp of the entire time series, rather than just the last one. The BCE loss function is typically used in multi-label classification problems. By optimizing the loss at all timestamps, it achieves a more comprehensive optimization, ensuring that the model not only focuses on the final prediction result but also considers the prediction performance at all moments during the process. The ICE loss function combines this idea with the accumulation term of time, gradually optimizing the prediction error at each timestamp during the

training process, thereby improving the overall performance of the model.

E. Model Training Loss

This section simultaneously optimizes the entire framework by leveraging the multi-task learning paradigm. The formula for the total model training loss L is as follows [formula (10)]:

$$L = L_{rec} + L_{ssa} + L_{csa} \tag{8}$$

where, L_{rec} is the next item prediction loss, L_{ssa} is the single-sequence enhancement loss, and L_{csa} is the cross-sequence enhancement loss. The calculation methods for these are the same as in BASRec, except that the BCE loss originally used is replaced with the ICE loss function designed in this section, that is [formulas (11),(12),and (13)]:

$$L_{rec} = ICE\left(H_u, A_u^+, A_u^-\right) \tag{9}$$

$$L_{ssa} = \omega \cdot ICE\left(H_u^{In}, A_u^+, A_u^-\right) \tag{10}$$

$$L_{csa} = ICE\left(H_u^{Out}, A_u^{Out+}, A_u^{Out-}\right) \tag{11}$$

F. Model Pseudocode

To help readers understand the workflow of the model, this section provides the pseudocode of the RM-HSAOCL model, as shown in Algorithm 1.

Algorithm 1: Pseudocode of the RM-HSAOCL Model

1: **While** RM-HSAOCL Not Convergence **do**:

2: **for** x in Dataloader (**X**) do:

3: Input the user sequence into the embedding layer for processing;

4: Apply the M-Crop and M-Mask operators designed in this section to the output, along with the original operators, for single-sequence enhancement;

5: Pass through the encoding layer, perform positive and negative item embedding readout, and then apply cross-sequence enhancement;

6: Calculate the next item prediction loss L_{rec}, single-sequence enhancement loss L_{ssa}, and cross-sequence enhancement loss L_{csa} using equation (9), as shown in equations (11) to (13);

7: Calculate the total model training loss L using equations (10);

8: End for

9: End while

10: Return L

IV. Experimental Setup and Results Analysis

A. Experimental Setup

The experimental environment in this section uses Windows 11, with a GPU configuration of RTX 3060 and a memory capacity of 16GB. All the experimental code in this section is written in Python 3.10, and the experimental framework uses PyTorch 1.12.1. All parameter settings are consistent [1].

To ensure the generalizability of the experiment, this section uses four publicly available datasets employed by BASRec: the Beauty, Sports, and Home datasets [1] from the largest e-commerce platform Amazon, as well as the commercial dataset Yelp [2]. For these datasets, the data processing method proposed by Dang et al. [1] is used, which removes users and items with fewer than 5 interactions. Then, a Leave-One-Out strategy is employed to evaluate the performance of each model. During this process, the data is divided based on the timestamps provided in the dataset into training, validation, and test sets. Specifically, for each user, the last record is selected as the test data, the second-to-last record as the validation data, and the remaining records are used as training data. The detailed information for the four datasets is shown in Table I.

TABLE I. Statistical Information of Experimental Datasets

Dataset	#User	#Item	#Action	Sparsity	Avg. Len.
Beauty	22,363	12,101	198,502	99.92%	8.9
Sports	35,598	18,357	296,337	99.95%	8.3
Yelp	30,431	20,033	316,354	99.95%	10.4
Home	66,519	28,237	551,682	99.97%	8.3

This section uses the commonly used evaluation metrics Hit@10 and NDCG@10 for sequence recommendation. The higher the values of Hit and NDCG, the more accurate the recommendations. A high Hit value typically indicates that the recommendation system can provide more items related to the user's interests, while a high NDCG value suggests that the system is able to accurately rank items according to the user's preferences, ensuring that the most relevant recommendations are prioritized. Therefore, the larger the Hit and NDCG values, the higher the accuracy of the recommendation system, leading to a better recommendation experience for users. The system's personalization and precision are also significantly improved.

B. Comparison and Analysis of Model Results

To validate the effectiveness of the RM-HSAOCL model, this section compares it with several representative sequence-based recommendation models: SASRec (2018) [21] introduces the self-attention mechanism into sequence recommendation tasks, addressing the issues of information loss and computational efficiency encountered by traditional sequence models when dealing with long sequences. The self-attention mechanism allows the model to dynamically assign different weights to the user's historical behavior when generating each recommendation, thereby capturing changes in user interest at different time points. ASReP (2021) [10] is a

[1] https://cseweb.ucsd.edu/~jmcauley/

[2] https://www.yelp.com/dataset

pre-training method designed to solve short-sequence recommendation problems. Its core idea is to generate pseudo-items (i.e., pseudo-predictive items) by reversing the input sequence and inserting them at the beginning of the sequence, thereby extending the sequence length. DiffuASR (2023) [12] is a diffusion-model-based sequential recommendation algorithm aimed at solving data sparsity and long-tail user problems in sequential recommendation systems. Its core idea is to use data augmentation techniques and employ diffusion models to generate high-quality pseudo-sequence data, thus enhancing the performance of the recommendation system. CL4SRec (2022) [5] is a sequence recommendation method based on contrastive learning, which addresses data sparsity and improves user representation quality by extracting self-supervised signals from both the original and augmented data using random data augmentation and contrastive learning. BASRec (2025) [1] proposed two new operators, M-Reorder and M-Substitute, for single-sequence augmentation. These operators mix the representations of items in the original sequence with those in the augmented sequence to generate new samples. Along with the cross-sequence augmentation module it designed, these operators perform augmentation and fusion operations to generate new samples that balance relevance and diversity.

Experiments were conducted on the Beauty, Sports, Yelp, and Home datasets, and the results are shown in Table II, where boldface indicates the best performance and underlined text indicates the second-best performance. All improvements are statistically significant, as determined by a paired t-test with the second best result in each case ($p \leqslant 0.05$). From these results, it can be observed that:

Compared to SASRec, ASReP and DiffuASR perform significantly better, which proves that introducing data augmentation methods indeed has a positive effect on mitigating data sparsity, helping to improve the model's robustness and generalization ability. Meanwhile, CL4SRec outperforms ASReP and DiffuASR, indicating that introducing a similarity contrast between augmented data and original data can effectively maintain consistency and quality between the augmented and original data, further enhancing the model's performance. This method ensures that the augmented data's quality is comparable to the original data, avoiding the introduction of excessive noise or inconsistent information, thus optimizing the model's prediction accuracy. However, compared to CL4SRec, BASRec's performance is even more superior, proving that balancing relevance and diversity in the process of generating augmented data is crucial for improving the model's performance. BASRec, by optimizing the augmented data, ensures both the relevance between data and effectively enhances the diversity of the data. This balance not only improves the model's adaptability to different user needs but also enhances its performance in complex recommendation tasks. Therefore, BASRec, by introducing the balance of relevance and diversity in the data augmentation process, effectively overcomes the potential overfitting and information overload issues found in traditional methods, demonstrating outstanding performance across various evaluation metrics.

TABLE II. COMPARISON OF EXPERIMENTAL RESULTS OF VARIOUS MODELS

Dataset	Metrics	SASRec	ASReP	DiffuASR	CL4SRec	BASRec	Ours	Improvement（%）
Beauty	*Hit@10*	0.0639	0.0664	0.0679	0.0686	0.0810	**0.0880**	8.64
	NDCG@10	0.0338	0.0351	0.0372	0.0366	0.0455	**0.0526**	15.60
Sports	*Hit@10*	0.0320	0.0353	0.0387	0.0412	0.0436	**0.0493**	13.07
	NDCG@10	0.0174	0.0195	0.0202	0.0221	0.0242	**0.0288**	19.01
Yelp	*Hit@10*	0.0277	0.0319	0.0308	0.0355	0.0326	**0.0376**	5.92
	NDCG@10	0.0136	0.0162	0.0150	0.0176	0.0164	**0.0193**	9.66
Home	*Hit@10*	0.0149	0.0184	0.0179	0.0212	0.0223	**0.0266**	19.28
	NDCG@10	0.0078	0.0099	0.0105	0.0119	0.0128	**0.0154**	20.31

The RM-HSAOCL model proposed in this section demonstrates improvements compared to the models mentioned above. The RM-HSAOCL model innovatively introduces two entirely new operators, M-Crop and M-Mask, which, along with the M-Reorder and M-Substitute operators designed in BASRec, participate in the data augmentation process to effectively generate more representative augmented data. This augmentation method not only increases the diversity of the training data but also ensures the quality and relevance of the augmented data, further optimizing the model's training process. Specifically, the M-Crop operator simulates user behavior changes by randomly cropping different parts of the data, while M-Mask enhances the model's robustness to missing information by randomly masking parts of the data. These operations effectively alleviate the data sparsity problem and improve the model's prediction capability for unseen data. In addition, the RM-HSAOCL model also designs a new loss function, ICE, which adds a time accumulation term before the CE loss, addressing the limitation of applying CE only to the last timestamp of the input sequence. It leverages the advantage of BCE by optimizing across all timestamps. The use of the ICE loss in the joint training loss calculation further enhances the model's performance. On the Beauty dataset, Hit@10 increased by 8.64%, and NDCG@10 increased by 15.60%. On the Sports dataset, Hit@10 improved by 13.07%, and NDCG@10 increased by 19.01%. On the Yelp dataset, Hit@10 increased by 5.92%, and NDCG@10 increased by 9.66%. On the Home dataset, Hit@10 improved by 19.28%, and NDCG@10 increased by 20.31%. These results show a significant improvement in the recommendation accuracy and ranking quality of the model on these datasets. Overall, the experimental results across all datasets demonstrate substantial

improvements on various metrics, indicating that the method is highly applicable and effective in recommendation tasks across different domains.

C. Ablation Experiment

1) Verify the effectiveness of the M-Crop and M-Mask data augmentation operators. In order to analyze the effects of M-Crop and M-Mask, this section designed three variant models using the control variable method: RMHSAOCL-C, which removes the M-Crop operator; RMHSAOCL-M, which removes the M-Mask operator; and RMHSAOCL-CM, which removes both the M-Crop and M-Mask operators. The experiments were conducted on the Beauty, Sports, and Yelp datasets, and the results are shown in Table III.

From the experimental results, it can be observed that on the Beauty and Yelp datasets, the performance metrics of RMHSAOCL-C and RMHSAOCL-M are significantly higher than those of RMHSAOCL-CM. This indicates that adding the M-Crop and M-Mask operators designed in this section can provide more effective data augmentation for the model, which helps improve its performance. Compared to the three variant models, RMHSAOCL achieves the best performance. This result suggests that the synergistic effect of the M-Crop and M-Mask operators significantly enhances the model's learning ability on these two datasets, especially in terms of data augmentation. The generated samples not only exhibit greater diversity but also maintain a high correlation with the original data, thereby avoiding excessive noise interference.

The experimental results on the Sports dataset, however, were different. The performance metrics of RMHSAOCL-M were significantly higher than those of RMHSAOCL-C and RMHSAOCL-CM, and were comparable to the performance of RMHSAOCL. This suggests that, on the Sports dataset, the M-Crop operator played a key role in improving the model's performance, while the M-Mask operator did not significantly enhance the performance. A possible reason for this could be that the features in the Sports dataset are more reliant on the overall structure and temporal aspects of the data, and the M-Mask operator did not provide enough benefit for this type of data. On the other hand, M-Crop, by effectively selecting local data segments, may have helped the model better capture important local patterns and temporal relationships within the data, thus playing a more critical role in improving performance.

In summary, the experimental results indicate that the sensitivity to M-Crop and M-Mask operators varies across different datasets, which suggests that in practical applications, data augmentation strategies may need to be adapted and adjusted for specific datasets.

TABLE III. THE ABLATION EXPERIMENT TO VALIDATE THE EFFECTIVENESS OF THE M-CROP AND M-MASK OPERATORS

Model	Beauty		Sports		Yelp	
	Hit@10	***NDCG@10***	***Hit@10***	***NDCG@10***	***Hit@10***	***NDCG@10***
RMHSAOCL	0.0880	0.0526	0.0493	0.0288	0.0376	0.0193
RMHSAOCL-C	0.0859	0.0513	0.0474	0.0275	0.0363	0.0182
RMHSAOCL-M	0.086	0.0516	0.0498	0.0286	0.0364	0.0190
RMHSAOCL-CM	0.0844	0.0506	0.0477	0.0274	0.0367	0.0180

TABLE IV. THE ABLATION EXPERIMENT TO VALIDATE THE EFFECTIVENESS OF THE ICE LOSS FUNCTION

Model	Beauty		Sports		Yelp	
	Hit@10	***NDCG@10***	***Hit@10***	***NDCG@10***	***Hit@10***	***NDCG@10***
RMHSAOCL	0.0880	0.0526	0.0493	0.0288	0.0376	0.0193
RMHSAOCL+B	0.0787	0.0450	0.0441	0.0239	0.0337	0.0168
RMHSAOCL+C	0.0686	0.0392	0.0332	0.0187	0.0234	0.0113
RMHSAOCL+F	0.0805	0.0449	0.0421	0.0228	0.0320	0.0159

2) Verify the effectiveness of the ICE loss function: To validate the effect of the ICE loss function in the model, three variant models were designed. RMHSAOCL+B indicates the use of the BCE loss function in the model, RMHSAOCL+C indicates the use of the CE loss function in the model, and RMHSAOCL+F indicates the use of the Focal Loss function in the model. The experiments were conducted on the Beauty, Sports, and Yelp datasets, and the experimental results are shown in Table IV.

The experimental results show that, across the three datasets, the performance of RMHSAOCL+B is significantly better than that of RMHSAOCL+C and RMHSAOCL+F. This result indicates that, compared to the CE loss function, the BCE loss function can simultaneously consider the impact of all timestamps in the input sequence and demonstrate superior performance when handling larger datasets. Specifically, the BCE loss function can optimize the model more stably when the ratio of positive and negative samples is relatively balanced, avoiding the training instability or slow convergence issues that the CE loss function may encounter when dealing with larger datasets. The experimental results also show that, when the ratio of positive and negative samples is balanced, the performance of the Focal Loss function is not significantly better than that of the BCE loss function. This could be because Focal Loss focuses more on distinguishing difficult samples, and when the positive and negative samples are already balanced, the advantages of Focal Loss do not manifest. In

contrast, the BCE loss function, due to its simple and effective nature, provides better performance.

The performance of the RMHSAOCL model far exceeds that of the other three variant models, proving the effectiveness of the ICE loss function. The ICE loss function optimizes the BCE loss function across all timestamps and combines the advantages of the CE loss function, significantly improving the model's recommendation accuracy and generalization ability. This demonstrates that integrating information from different timestamps to optimize the CE loss function is a key strategy for enhancing model performance. With this approach, the model not only better captures historical information but also effectively improves its performance in practical recommendation scenarios, especially when handling large-scale datasets, where its advantages are even more pronounced.

D. The Impact of Data Augmentation in Mixing Weights on Model Performance

$\lambda \sim Beta(\alpha, \alpha)$ is a mixing weight parameter used to adjust the mixing ratio between the original item representation and the augmented item representation, thereby generating augmented representations for model training. Specifically, the goal of the mixing weight is to find the optimal balance between the original features and the augmented features, so that the model can better learn and capture potential patterns and relationships in the data. The augmented representation extends the original data by introducing certain variations or noise, enabling the model to have stronger generalization ability. The Beta distribution is chosen to describe this mixing process, with its parameters being a hyperparameter that controls the shape and mixing intensity of the distribution, which is crucial for the model's learning and final performance. In this study, different values were selected for the experiment, ranging from {0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8}, in order to observe the specific impact of different values on the model's performance. The experiment was conducted on the Beauty dataset, and the results are shown in Fig. 6.

From the experimental results, it can be seen that Hit@10 achieves the best value when a = 0.4, meaning that the model's recommendation accuracy is strongest at this setting, allowing it to better predict user interests. NDCG@10 achieves the best values when a = 0.3 and a = 0.5, where the model performs best in terms of ranking accuracy. At a = 0.4, the performance of NDCG@10 is not as good as at 0.3 and 0.5, but still achieves a suboptimal value, indicating that the model at this setting balances recommendation accuracy and ranking performance, maintaining good overall performance.

In summary, different values of the hyperparameter have varied impacts on the model's performance across different metrics. On the Beauty dataset, for the Hit@10 and NDCG@10 metrics, setting a = 0.4 yields good results.

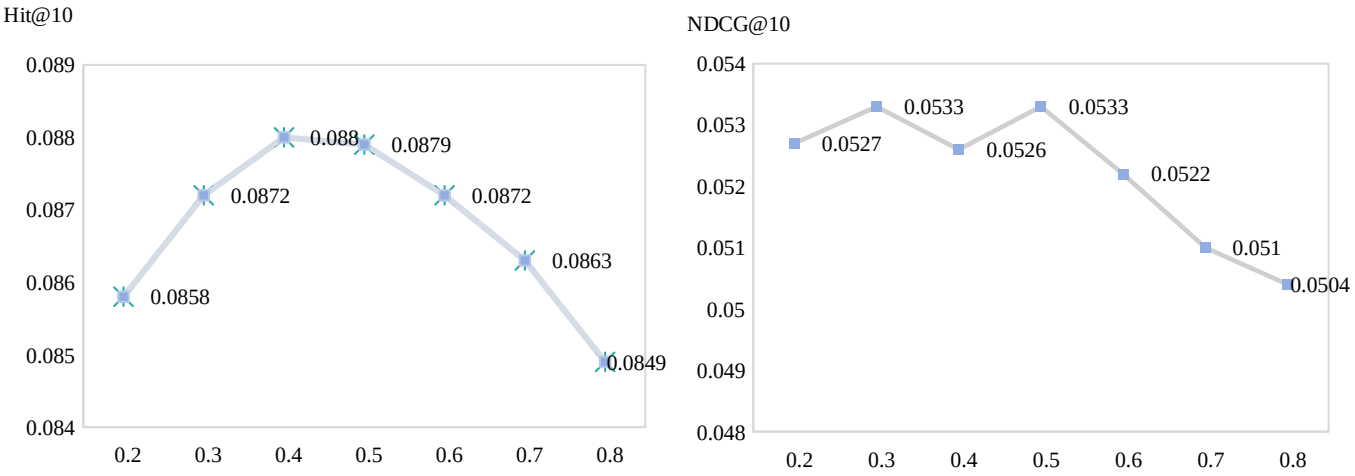

Fig. 6. Sensitivity analysis of the hyperparameter.

V. Conclusion

This study proposes a recommendation algorithm based on mixed sequence augmentation and optimized contrastive loss. By introducing two new data augmentation operators, M-Crop and M-Mask, the data expansion process is enhanced. Additionally, a loss function, ICE, which improves upon the CE loss, is designed for next-item prediction loss, single-sequence augmentation loss, and cross-sequence augmentation loss calculation, thereby improving the accuracy of the recommendation system. The experiments in this study were validated on four public datasets: Beauty, Sports, Yelp, and Home, with significant improvements in various metrics. The application demonstrates notable effects, proving the effectiveness and advancement of the proposed recommendation algorithm based on mixed sequence augmentation and optimized contrastive loss in current sequence recommendation models. Although the algorithm proposed in this study effectively improves the model's performance, in real-world recommendation systems, data may come in various types, such as text, images, videos, etc. The method presented in this study mainly focuses on modeling and augmenting behavior sequence data. However, it may not be effective in integrating and utilizing other types of data, such as user reviews of products or the image features of products. This could result in suboptimal performance when the model deals with multimodal data, as it may fail to fully leverage the information from various data sources to enhance recommendation performance.

Future research can focus on the following aspects to further optimize and expand the algorithm proposed in this study:

Diversity and adaptability of augmentation methods: The current M-Crop and M-Mask operators mainly enhance sequence data. In the future, more augmentation methods targeting different types of data can be explored, especially in recommendation systems that integrate multimodal data. How to design more refined and adaptive augmentation operators will be an important direction.

Interpretability of sequence recommendation models: As recommendation algorithms are increasingly applied in real-world scenarios, the interpretability of models becomes particularly important. Future research can combine the current augmentation and optimization methods to explore how to improve the interpretability of recommendation systems, allowing users to better understand the recommendation logic of the model and increasing their trust in the recommendation system.

Combination of reinforcement learning and transfer learning: Reinforcement learning and transfer learning are technologies that have gradually gained attention in recommendation systems in recent years. Future research could consider combining reinforcement learning with hybrid sequence augmentation methods to dynamically adjust recommendation strategies and optimize users' long-term satisfaction. Transfer learning, on the other hand, can help transfer knowledge from different domains or tasks to the target recommendation task, thereby enhancing the system's cross-domain application ability.

In conclusion, the recommendation algorithm based on hybrid sequence augmentation and optimized contrastive loss proposed in this study has demonstrated superior performance in experiments, with strong practical value. However, as the scale of data grows and recommendation scenarios become more complex, how to further improve the accuracy, efficiency, and scalability of recommendation systems remains an area worthy of in-depth research. Future research can focus on areas such as multimodal recommendation, personalized optimization, and real-time processing, driving recommendation technologies towards more efficient and intelligent development.

Detection of Malaria Infections Using Convolutional Neural Networks

Luis Edison Ñahui Vargas, Mario Aquino Cruz
Departamento Académico De Informática y Sistemas, Universidad Nacional Micaela Bastidas De Apurímac, Abancay, Perú

***Abstract*—Malaria persists as a serious global public health threat, particularly in resource-limited regions where timely and accurate diagnosis is a challenge due to poor medical infrastructure. This study presents a comparative evaluation of three pre-trained convolutional neural network (CNN) architectures—EfficientNetB0, InceptionV3, and ResNet50—for automated detection of Plasmodium-infected blood cells using the Malaria Cell Images Dataset. The models were implemented in Python with TensorFlow and trained in Google Colab Pro with GPU A100 acceleration. Among the models evaluated, ResNet50 proved to be the most balanced, achieving 97% accuracy, a low false positive rate (1.8%) and the shortest training time (2.9 hours), making it a suitable choice for implementation in real-time clinical settings. InceptionV3 obtained the highest sensitivity (98% recall), although with a higher false positive rate (4.0%) and a higher computational demand (6.5 hours). EfficientNetB0 was the fastest model (3.2 hours), showed validation and a higher false negative rate (6.2%). Standard metrics—accuracy, loss, recall, F1-score and confusion matrix—were applied under a non-experimental cross-sectional design, along with regularization and data augmentation techniques to improve generalization and mitigate overfitting. As a main contribution, this research provides reproducible empirical evidence to guide the selection of CNN architectures for malaria diagnosis, especially in resource-limited settings. This systematic comparison between state-of-the-art models, under a single protocol and homogeneous metrics, represents a significant novelty in the literature, guiding the selection of the most appropriate architecture. In addition, a lightweight graphical user interface (GUI) was developed that allows real-time visual testing, reinforcing its application in clinical and educational settings. The findings also suggest that these models, in particular ResNet50, could be adapted for the diagnosis of other parasitic diseases with similar cell morphology, such as leishmaniasis or babesiosis.**

Keywords*—Malaria diagnosis; CNN architectures; deep learning; artificial intelligence; plasmodium; clinical decision support; medical imaging

I. Introduction

Malaria is one of the most prevalent and deadly infectious diseases in tropical and subtropical regions, affecting mainly developing countries. According to the World Health Organization (WHO), approximately 247 million cases of malaria were reported worldwide in 2021, with more than 600,000 deaths, with children under five years of age being the most vulnerable group [1]. By 2023, global cases increased to 263 million, with 597,000 deaths, attributed to factors such as climate change, drug resistance and persistent inequalities in health systems. Sub-Saharan Africa continues to account for 94% of cases, highlighting the magnitude of the problem [2]. In Peru, malaria has been a historical concern, particularly affecting the Amazon regions. Despite the implementation of strategies such as the Plan towards the Elimination of Malaria in Peru 2022-2030, the disease remains a critical public health problem. In 2023, 17,840 cases of malaria were reported, while up to epidemiological week 40 of 2024, nine deaths were reported [3], [4]. Loreto, the most affected region, reported more than 8,000 cases in the same period [5]. Factors such as poverty, inaccessibility of many communities and climatic conditions conducive to the Anopheles mosquito transmitter aggravate the situation, highlighting the need for innovative diagnostic solutions that are accurate, accessible and rapidly implemented. Although significant progress has been made in its prevention and treatment, timely and accurate diagnosis remains a critical challenge, especially in resource-limited areas where access to equipment and trained personnel is insufficient [1]. Traditional malaria diagnosis, based on microscopic analysis of stained blood smears, has several limitations, including the need for technical expertise and the time required to process multiple samples [6]. These limitations not only delay the initiation of appropriate treatment, but can also result in misdiagnosis, exacerbating the burden of disease in already affected communities [7].

Against this backdrop, artificial intelligence (AI) technologies have emerged as promising tools to address the challenges associated with malaria diagnosis. Convolutional neural networks used in image processing and analysis are particularly notable for their ability to identify complex patterns in medical images. These technologies have proven to be effective in the diagnosis of various diseases, including malaria, through automated analysis of blood smears [8]. Some recent studies have also explored the use of advanced architectures such as EfficientNet, ResNet and VGG16 in clinical, mobile and rural settings, demonstrating their practical applicability for automated diagnosis in areas with scarce computational resources. However, the current literature presents a significant gap in terms of systematic comparisons between state-of-the-art CNN models applied to malaria. Most studies focus on individual architectures or use complex methods such as ensembles, which require high computational capacity. Therefore, this research posed the following research question: which of the convolutional neural network models ResNet50, EfficientNetB0 or InceptionV3 demonstrates better performance in the automated detection of malaria infections?

The objective of this research was to comparatively evaluate these architectures, using standard metrics such as accuracy, loss, recall, and F1-Score, in order to identify the most efficient and feasible model for eventual integration into automated

clinical diagnostic systems. This study uses the Malaria Cell Images Dataset, composed of 27,558 images categorized as "infected" and "uninfected" [9]. The development and training of the models was carried out using Google Colab Pro, using Python programming tools and libraries such as TensorFlow and Keras.

The main contribution of this research lies in providing reproducible and comparative empirical evidence on the performance of three widely recognized architectures in the field of deep learning, in a controlled but replicable environment. The results will guide technical decisions for the implementation of practical AI-assisted diagnostic solutions, especially in endemic regions with limited medical infrastructure. This research not only explores the technical capabilities of CNNs, but also highlights their potential to be adapted to the detection of other parasitic diseases of similar morphology, such as leishmaniasis or babesiosis, thus extending their relevance beyond the specific context of malaria.

II. Related Work

In recent years, several research works have evidenced the potential of convolutional neural networks (CNNs) for automated malaria diagnosis. For example, Zhao et al. [10] proposed in 2020 a solution for low-cost mobile devices, achieving 96.5% accuracy with VGG16. Vizcaino Gispert [11], also in 2020, used Faster R-CNN, improving their results with pre-trained weights. Subsequently, in 2021, Sierra Segovia et al. [12] applied CNN for both malaria and COVID-19, obtaining an accuracy of 99.33% in the latter. That same year, Ferreras Extremo [13] used an EfficientNet assembly, achieving an accuracy of 98.29%. More recently, Marín Calvo [14] in 2022 reported 95.58% with data augmentation. Finally, Meza-Bautista et al. [15] in 2024 performed a comparison of CNN architectures and concluded that EfficientNetB0 offered the best performance (97.12%). In this context of advances, our research focused on a systematic and controlled comparison of ResNet50, EfficientNetB0 and InceptionV3. This study provides quantitative evidence on which offered the best balance between diagnostic accuracy, computational efficiency and clinical applicability, filling a gap in the literature regarding direct and comprehensive comparisons of these architectures in the field of malaria diagnosis.

III. Methodology

A. Research Design

The research design is non-experimental cross-sectional, which implies that the performance of different convolutional neural network (CNN) models in detecting malaria infections at a specific time was evaluated, without manipulating the study variables [16]. This approach allowed an objective analysis of performance metrics, such as accuracy, recall and F1-score, using a previously established data set [17].

B. Participants

The population of this study consisted of a set of 27,560 labeled blood smear images obtained from public databases such as Kaggle [18], which provides a set of images used in scientific research to train and evaluate classification models.

The sample was divided into three subsets: 60% for training, 30% for validation and 10% for testing, ensuring that each subset has a similar distribution of images, which minimizes bias in model evaluation [19]. Fig. 1 and Fig. 2 show representative images of blood smears used in the study, while Fig. 3, 4 and 5 illustrate the architectures of the convolutional neural networks used: ResNet50, EfficientNetB0 and InceptionV3, respectively. Fig. 1 presents a malaria-infected blood smear image from the dataset [18], the presence of parasites is evident, with multiple organisms within the red blood cells, indicating an active and severe infection.

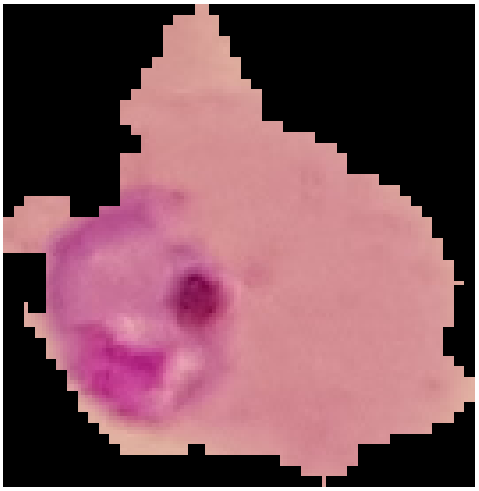

Fig. 1. Malaria-infected blood smear.

Fig. 2 shows a blood smear that is not infected by malaria, image from the dataset [18], the staining is uniform and clear, with no signs of parasites present in the red blood cells.

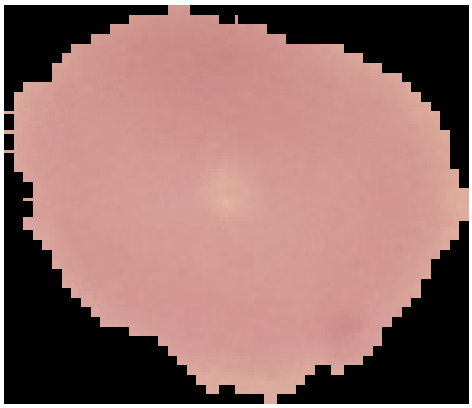

Fig. 2. Blood smear that is not infected with malaria.

Design of the architectures: The following figures illustrate the pretrained convolutional neural network architectures used.

The ResNet50 model (see Fig. 3) is a 50-layer deep convolutional neural network, distinguished by its innovative residual or "skip connections." These connections are crucial for enabling information and gradients to flow directly across multiple layers, effectively mitigating the vanishing gradient problem in very deep architectures and significantly aiding training.The architecture is structured into five primary stages, each built with residual blocks. It begins with an initial 7x7

convolutional layer followed by max-pooling. The subsequent four stages employ "bottleneck blocks," each comprising a sequence of 1x1, 3x3, and 1x1 convolutional layers. The 1x1 layers manage channel dimensionality, while the 3x3 focuses on feature extraction. The residual connection in each block adds the original input to the output of these layers, allowing the model to learn identity functions. Specifically, the architecture includes 3 residual blocks in the first stage (conv2_x), 4 in the second (conv3_x), 6 in the third (conv4_x), and 3 in the fourth (conv5_x). The final stages involve a global average pooling layer and a dense layer with SoftMax activation for binary classification (e.g., 'infected' or 'uninfected'). This robust hierarchical structure renders ResNet50 exceptionally effective for complex image classification tasks [20], [21], [22].

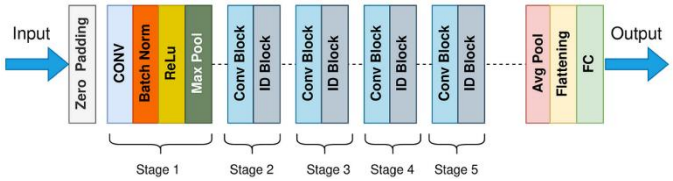

Fig. 3. Architecture of the ResNet50 model based on transfer of learning, taken from [23]. This diagram illustrates the residual connections that facilitate gradient flow through deep layers, organized into five main stages with "bottleneck" blocks. While the dimensions and number of filters for the layers are depicted in the diagram.

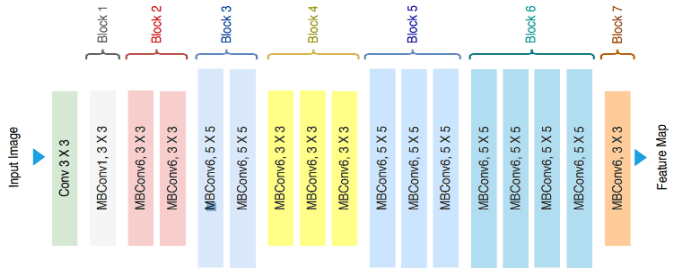

Fig. 4. The Architecture of the EfficientNetB0 model, extracted from [25]. This diagram illustrates the network's structure based on compound scaling and its primary building block, the Mobile Inverted Bottleneck Convolution (MBConv) block, which incorporates Squeeze-and-Excitation networks. While the detailed parameters and operations within each block are depicted.

Following ResNet50, EfficientNetB0 (see Fig. 4) represents another state-of-the-art CNN architecture, notable for its compound scaling method. This innovative approach uniformly scales network depth, width, and resolution using fixed coefficients, allowing superior performance with fewer parameters and lower computational cost. The core building block is the Mobile Inverted Bottleneck Convolution (MBConv) block, adapted from MobileNetV2. These MBConv blocks integrate depthwise separable convolutions, significantly reducing computational expense, along with an inverted bottleneck structure. Crucially, each MBConv block also includes a Squeeze-and-Excitation (SE) network, which adaptively recalibrates channel-wise feature responses by learning channel-wise attention, further enhancing the model's representational power. EfficientNetB0 is organized into multiple stages, each consisting of several MBConv blocks. The network begins with an initial convolutional layer, followed by compound-scaled MBConv stages for feature extraction. A global average pooling layer and a final dense layer with softmax activation are then used for classification. Despite its relatively compact size, EfficientNetB0 is designed for high efficiency and accuracy, making it a compelling choice for deployment in resource-constrained environments where computational budget is a significant concern [24].

Finally, Finally, InceptionV3 (see Fig. 5) is another powerful pre-trained CNN architecture explored in this study, designed for high computational efficiency and accuracy by optimizing resource use. Its core innovation lies in the Inception modules, which enable the network to perform multiple parallel convolutions with different kernel sizes (1x1, 3x3, 5x5) and max-pooling operations on the same input. This parallel processing allows the model to capture features at various scales simultaneously, providing richer data representation. A key aspect of InceptionV3's design is the strategic factorization of larger convolutions into smaller ones (e.g., replacing a 5x5 convolution with two 3x3s, or a 3x3 into 1x3 and 3x1). This significantly reduces parameters and computational cost while preserving or improving representational capacity. Additionally, InceptionV3 incorporates batch normalization in auxiliary classifiers and uses label smoothing during training for regularization and overfitting prevention. The InceptionV3 architecture consists of multiple stacked Inception modules, with interleaved pooling layers to reduce spatial dimensions. It begins with initial convolutional layers and max-pooling, followed by Inception modules that extract abstract features. Similar to other models, the final part employs a global average pooling layer and a dense layer with softmax activation for binary classification. This design makes InceptionV3 robust and efficient, particularly where capturing multi-scale features is critical [26].

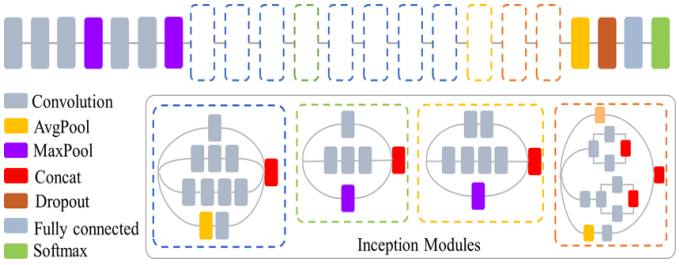

Fig. 5. The Architecture of the InceptionV3 model, extracted from [27]. This diagram illustrates the network's structure, highlighting the use of Inception modules that perform parallel convolutions with different kernel sizes to capture multi-scale features. While the specific details of the factorization and layer parameters are shown.

C. Instruments and Techniques

For the implementation of this study, Python was used as the programming language, taking advantage of its versatility and the vast support of specialized machine learning libraries [28]. Model training was conducted on Google Colab Pro, a development environment that provided access to cloud computing resources, including an A100 GPU, which was essential to handle the computational complexity [29]. The TensorFlow and Keras libraries were used, which are fundamental for the construction and training of neural networks, facilitating the implementation of deep learning algorithms [30]. In terms of techniques, extensive image preprocessing including pixel value normalization and data augmentation strategies such as rotations, image inversion and

pixel filling were applied to improve the generalizability of the model [19], [31]. For model training, the pre-trained architectures ResNet50, EfficientNetB0 and InceptionV3 were selected and optimized in the Google Colab Pro environment with GPU A100 [20], [26]. Finally, the model was evaluated using standard metrics such as accuracy, recall and F1-score, complemented with a confusion matrix for a detailed analysis of the classification errors [32], [33].

D. Data Analysis

Data analysis was performed by comparing the performance metrics of the trained models. Accuracy, loss, recall and F1-score metrics were calculated for each model using the test set. The confusion matrix was used to identify specific error patterns, allowing a more detailed assessment of the performance of each model [34]. The results were statistically analyzed to determine the effectiveness of each neural network in detecting malaria infections, ensuring rigorous and reproducible analysis of the results [8], [35].

IV. Results

A. Results of the EfficientNetB0 Model

Table I presents the performance metrics obtained during the training, validation and testing phases of the EfficientNetB0 model. The training was initially set up for 100 epochs, but was automatically stopped at epoch 15 due to the EarlyStopping callback, which monitored val_loss with a patience of 5 epochs. The total training time was 3 hours, 14 minutes and 48 seconds, using an A100 GPU.

TABLE I. Performance of EfficientNetB0 in Training, Validation and Testing

Metric	Train	Validation	Test
Accuracy	0.99	0.95	0.95
Loss	0.041	0.187	0.200
Predictive value (Precision)	0.99 (P), 0.99 (U)	0.96 (P), 0.96 (U)	0.97 (P), 0.94 (U)
Recall	0.99 (P), 0.99 (U)	0.95 (P), 0.96 (U)	0.94 (P), 0.97 (U)
F1-Score	0.99	0.95	0.95

- Legend:
- P: Parasitized (infected cells)
- U: Uninfected (uninfected cells)

Fig. 6 shows the evolution of the accuracy during EfficientNetB0 training:

- Train Accuracy: Increased rapidly from 89.17% (epoch 1) to 99.15% (epoch 15), indicating that the model learned the training data efficiently.
- Validation Accuracy: It showed high variability, ranging between 50% and 95.52%, with the best performance in epoch 10 (95.52%)

The gap between “train” and “validation” suggests possible overfitting.

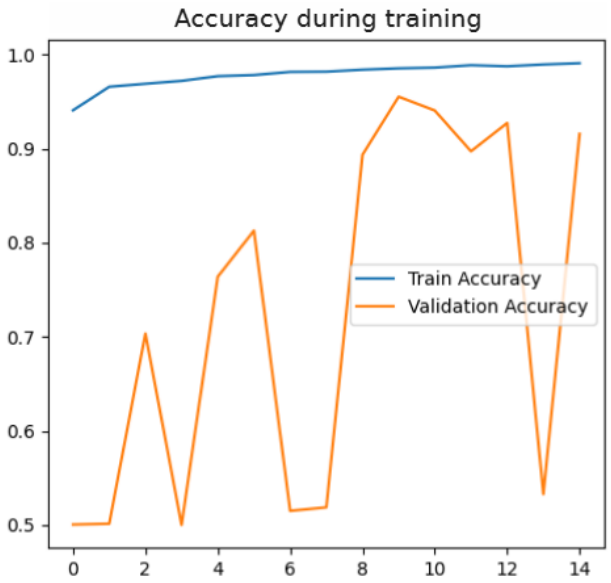

Fig. 6. Accuracy curve during EfficientNetB0 training.

Fig. 7 shows the decrease in loss:

- Train Loss: It decreased steadily from 8.8683 (epoch 1) to 0.0412 (epoch 15).
- Validation Loss: It showed significant fluctuations, with peaks at epochs 4, 7 and 14. The minimum was reached at epoch 10 (0.1865), coinciding with the maximum val_accuracy.

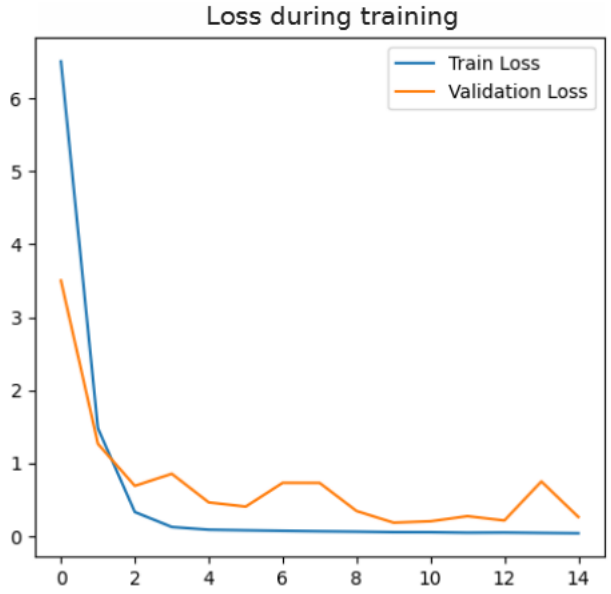

Fig. 7. Loss curve during EfficientNetB0 training.

The confusion matrix Fig. 8 highlights a 6.2% false negative rate (84 parasitized cells not detected), a potential risk in medical applications.

- True Positives (TP): 1294 (93.8% of correctly identified Parasitized).

- False Negatives (FN): 84 (6.2% of Parasitized misclassified as Uninfected).
- False Positives (FP): 43 (3.1% of Uninfected misclassified as Parasitized).
- True Negatives (TN): 1335 (96.9% of correctly identified Uninfected).

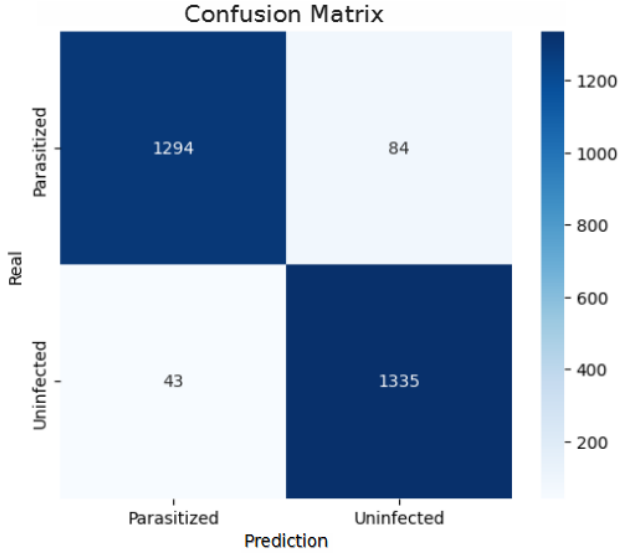

Fig. 8. Confusion matrix of the EfficientNetB0 model in the test set.

B. *Results of the InceptionV3 Model*

Table II presents the performance metrics obtained during the training, validation and testing phases of the InceptionV3 model, which was trained for 16 epochs (out of 100 scheduled) using EarlyStopping with patience for 5 epochs (monitoring val_loss). The total training time was 6 hours, 29 minutes and 44 seconds using an A100 GPU.

TABLE II. PERFORMANCE OF INCEPTIONV3 IN TRAINING, VALIDATION AND TESTING

Metric	Train	Validation	Test
Accuracy	0.99	0.97	0.97
Loss	0.029	0.120	0.125
Predictive value (Precision)	0.99 (P), 0.99 (U)	0.97 (P), 0.97 (U)	0.96 (P), 0.97 (U)
Recall	0.99 (P), 0.99 (U)	0.97 (P), 0.97 (U)	0.98 (P), 0.96 (U)
F1-Score	0.99	0.97	0.97

- Legend:
- P: Parasitized (infected cells)
- U: Uninfected (uninfected cells)

Fig. 9 shows the evolution of Accuracy during InceptionV3 training:

- Train Accuracy: Reached 99.5% at epoch 14, indicating near perfect learning.
- Validation Accuracy: Stabilized at 97% after epoch 3, with minimal fluctuations in epochs 5 and 14.

Reduced gap: 2.27% (vs. 3.63% in EfficientNetB0), suggesting less over-adjustment.

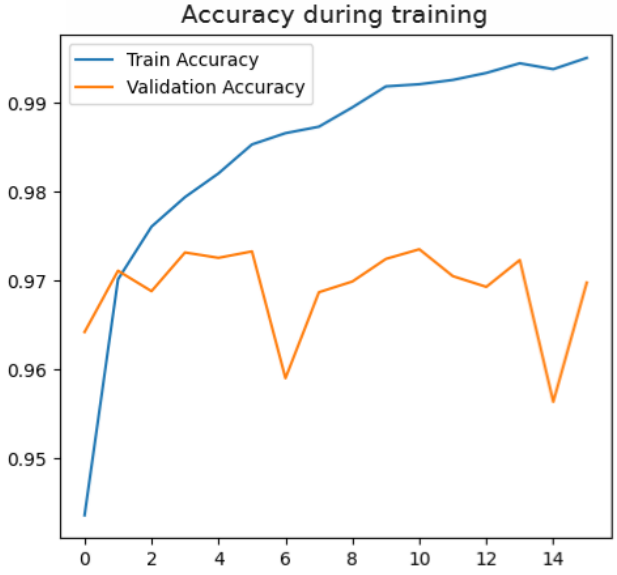

Fig. 9. Accuracy curve during InceptionV3 training.

Fig.10 displays the decrease in loss of the InceptionV3 model:

- Train Loss: Decreased from 10.6204 to 0.0294.
- Validation Loss: It showed a minimum peak at epoch 6 (0.1063).

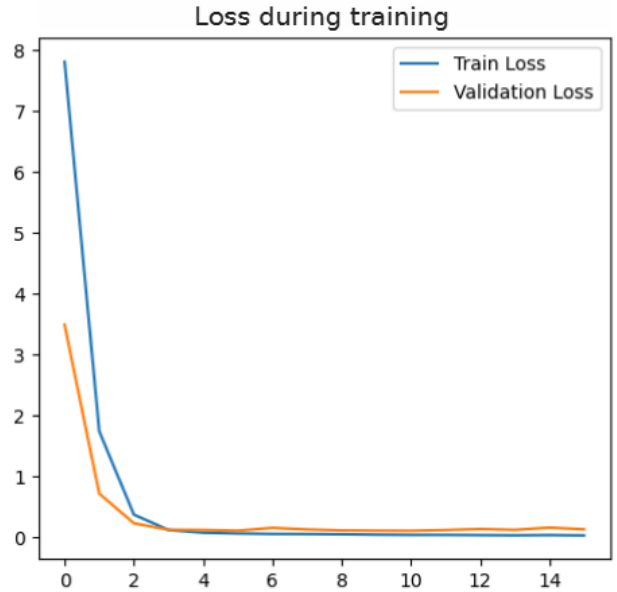

Fig. 10. Loss curve during InceptionV3 training.

Fig. 11 shows the confusion matrix of InceptionV3:

- False negatives (FN): 34 (2.5% of Parasitized misclassified as Uninfected).
- False positives (FP): 55 (4.0% of Uninfected misclassified as Parasitized).

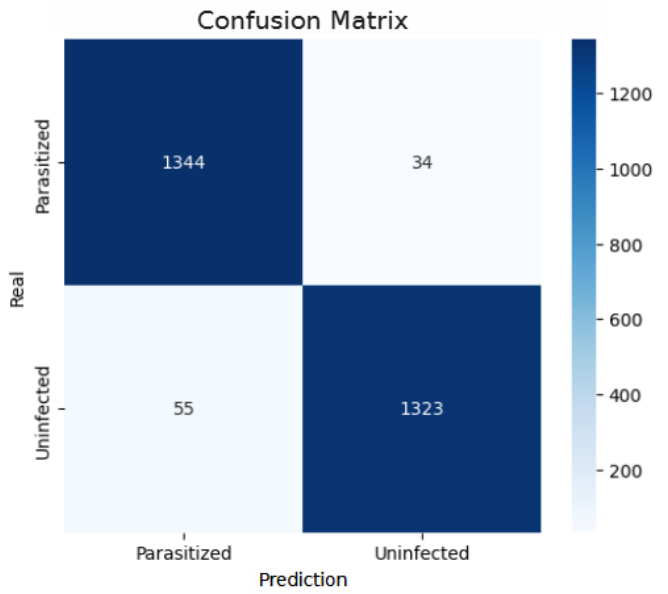

Fig. 11. Confusion matrix of InceptionV3 in the test set.

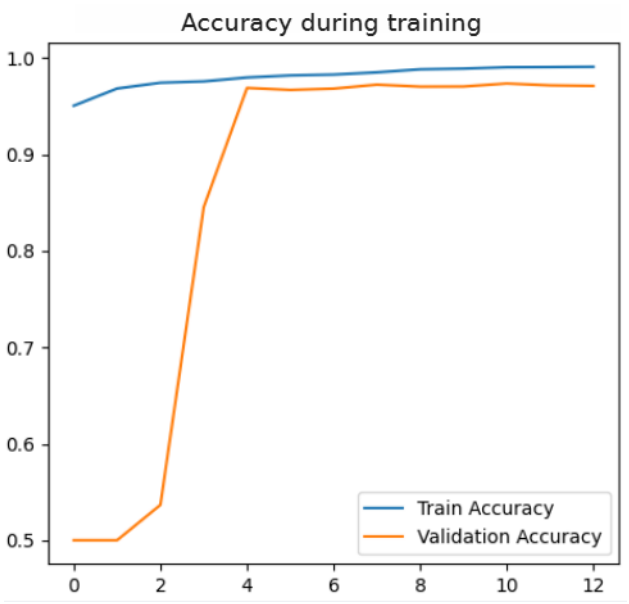

Fig. 12. Accuracy curve during ResNet50 training.

C. *Results of the Resnet50 Model*

Table III presents the performance metrics obtained during the training, validation and testing phases of the ResNet50 model, it was trained for 13 epochs (out of 100 scheduled), using EarlyStopping with 5 epoch patience and validation loss monitoring (val_loss). The total training time was 2 hours, 58 minutes and 35 seconds using an A100 GPU.

TABLE III. PERFORMANCE OF RESNET50 IN TRAINING, VALIDATION AND TESTING

Metric	Train	Validation	Test
Accuracy	0.99	0.97	0.97
Loss	0.037	0.109	0.112
Predictive value (Precision)	0.99 (P), 0.99 (U)	0.97 (P), 0.97 (U)	0.98 (P), 0.97 (U)
Recall	0.99 (P), 0.99 (U)	0.97 (P), 0.97 (U)	0.96 (P), 0.98 (U)
F1-Score	0.99	0.97	0.97

- Legend:
- P: Parasitized (infected cells)
- U: Uninfected (uninfected cells)

Fig. 12 shows the evolution of Accuracy during ResNet50 training:

- Train Accuracy: Reached 99.13% at epoch 13.
- Validation Accuracy: Stabilized at 97% after epoch 5, with minimal fluctuations.

Reduced gap: 1.78% (vs. 2.27% in InceptionV3), suggesting less overfitting.

Fig. 13 shows the loss decrease of the ResNet50 model:

- Train Loss: Decreased from 10.7185 to 0.0372.
- Validation Loss: Showed a minimum in epoch 11 (0.1089).

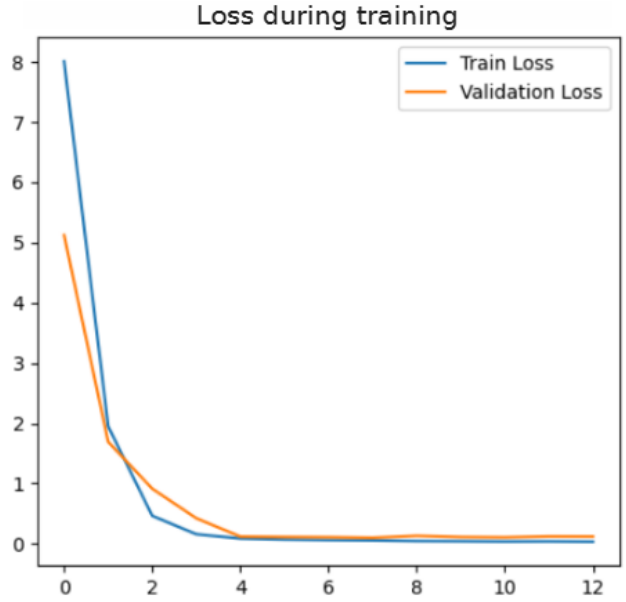

Fig. 13. Loss curve during ResNet50 training.

Fig. 14 shows the ResNet50 confusion matrix:

- False negatives (FN): 49 (3.6%) vs. 34 in InceptionV3. Slight increase, but still better than EfficientNetB0 (84).
- False positives (FP): 25 (1.8%). Better specificity than InceptionV3 (55).

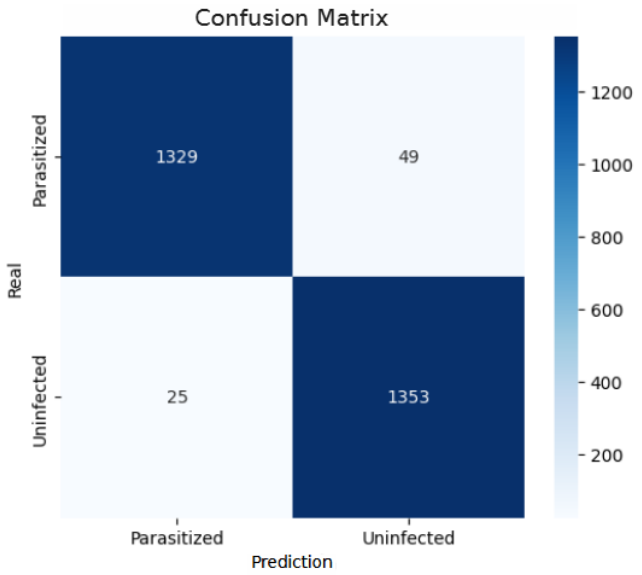

Fig. 14. ResNet50 confusion matrix in test set.

D. Comparative Table of the Models in the EfficientNetB0, InceptionV3 and ResNet50 Test Set

ResNet50 combined high accuracy (97%) with the shortest time (2 hours and 58 minutes) and FP (1.8%), ideal for accurate diagnostics. InceptionV3 had better recall for 'Parasitized' (98%), but required more resources (6.5h). Table IV summarizes all the values corresponding to the performance on the test set, the three models evaluated (EfficientNetB0, InceptionV3 and ResNet50) in terms of:

- Accuracy (Test): Overall percentage of hits.
- Precision (P/U): Predictive value for each class (Parasitized/Uninfected).
- Recall (P/U): Sensitivity to detect true cases.
- F1-Score: Balance between precision and recall.
- Training Time: Computational Efficiency.
- FN/FP: They are critical in medical diagnosis

TABLE IV. COMPARATIVE PERFORMANCE OF EFFICIENTNETB0, INCEPTIONV3 AND RESNET50 MODELS ON THE TEST SET

Metric	EfficientNetB0	InceptionV3	ResNet50
Accuracy (Test)	0.95	0.97	0.97
Precision (P/U)	0.97 / 0.94	0.96 / 0.97	0.98 / 0.97
Recall (P/U)	0.94 / 0.97	0.98 / 0.96	0.96 / 0.98
F1-Score	0.95	0.97	0.97
Training Time (h)	3.2	6.5	2.9
False Negatives (FN)	6.2%	2.5%	3.6%
False Positives (FP)	3.1%	4.0%	1.8%

Legend:

- P = Parasitized,
- U = Uninfected.

V. DISCUSSION

The results obtained showed that the three convolutional neural network models evaluated, EfficientNetB0, InceptionV3 and ResNet50, showcased excellent performance metrics in the automated detection of Plasmodium-infected cells. However, the main novelty of this study lay in the direct, systematic and reproducible comparison between these three models in a controlled environment, using a single data stream and uniform metrics, which has not been addressed in previous studies. This methodology allows a more accurate assessment of the clinical applicability of each architecture.

ResNet50 stood out for its balanced performance: it achieved 97% accuracy, 1.8% false positives and the shortest training time (2 hours and 58 minutes), positioning it as the most viable model for real implementations. Although Ferreras Extremo [13] achieved an accuracy of 98.29% using an ensemble of EfficientNet models, his approach demanded cross-validation of 10 iterations, increasing the complexity and computational time. In contrast, our ResNet50 achieved similar results with lower operational burden. With respect to Marín Calvo [14] who reported 95.58% accuracy, our InceptionV3 exceeded that value in recall (98%), which is key to avoid false negatives in medical contexts. Unlike Vizcaino Gispert [11] whose Faster R-CNN model only reached 2.01% in initial detection, our models exceeded 95% accuracy from the first trainings thanks to the use of transfer learning and balanced datasets. In addition, studies such as that of Sierra Segovia et al. [12] showed comparable accuracy, but with less stability between training and validation (5% gap vs. our 1.78% gap in ResNet50). This evidences the positive effect of regularizations such as Dropout and L2 used in our work. Also, although Zhao et al. [10] achieved good accuracy (96.5%) on mobile hardware, our ResNet50 model demonstrated superiority in accuracy with equal or better efficiency. Finally, Meza-Bautista et al. [15] found that EfficientNetB0 achieved 97.12%, although with fine-tuning techniques not applied in our study. Even so, our ResNet50 matched that accuracy with less technical complexity.

From a practical standpoint, ResNet50 reduced false negatives to 3.6%, which is critical in medical diagnostics, and had a specificity of 98%, thus reducing misdiagnosis and unnecessary treatment. InceptionV3 offered higher sensitivity (recall of 98%), but required 6.5 hours of training, which may limit its adoption in resource-poor settings. This analysis also highlights opportunities for future research. It is recommended to validate the models on real clinical images to assess their robustness outside the standardized dataset. In addition, the combination of models (ensembles) that integrate the speed of EfficientNetB0 with the accuracy of ResNet50 could be explored. Another relevant line is the implementation in low-cost devices (such as Raspberry Pi), optimizing models with TensorFlow Lite and quantization. Finally, these architectures could be adapted to other parasitic diseases such as leishmaniasis or babesiosis, expanding their impact on public health. Overall, this research provides clear empirical evidence on the performance of three popular models on a critical health problem. ResNet50, due to its balance between performance, efficiency and simplicity, is emerging as a robust and applicable solution in real clinical scenarios.

VI. Conclusions and Recommendations

This study evaluated and compared the performance of three pre-trained convolutional neural network models (EfficientNetB0, InceptionV3 and ResNet50) for automated detection of malaria-infected cells. The main contribution of this work lies in providing a systematic, reproducible and clinically applicable-oriented comparative analysis using a unified data flow and homogeneous metrics, which represents an approach rarely addressed in previous studies. The EfficientNetB0 model was characterized by its light weight and training speed (300 seconds per epoch), making it a viable alternative for environments with limited computational resources, such as mobile devices or rural areas. However, its performance on the validation set was inconsistent, with significant fluctuations in the accuracy of the validation set (val_accuracy) and a relatively high level of false negatives (6.2%), which compromises its reliability for direct application in clinical settings without additional adjustments. InceptionV3 demonstrated a high detection capability, reaching a recall of 98% for the "Parasitized" class, making it the most sensitive model in the study. Its stability during training was also remarkable, with a gap between training and validation of only 2.27%. However, this model had a higher false positive rate (4.0%) and considerable computational demand, with a total training time of approximately 6.5 hours learning. The ResNet50 model emerged as the most balanced option. It achieved an accuracy of 97%, similar to that of InceptionV3, but with a lower false positive rate (1.8%) and a smaller gap between training and validation metrics (1.78%), which evidences a greater generalization capacity. In addition, its training time was the most efficient among the three models evaluated (2 hours and 58 minutes), which reinforces its feasibility to be implemented in real clinical scenarios. In practical terms, ResNet50 is positioned as the best choice for medical settings where both false negatives and false positives need to be minimized. InceptionV3, on the other hand, may be more suitable in contexts where early detection is a priority and a higher false positive rate can be tolerated. EfficientNetB0 is an interesting alternative for embedded or hardware constrained solutions, although its clinical implementation would require further optimization.

As technical recommendations, we suggest adjusting the decision thresholds in the InceptionV3 and EfficientNetB0 models to values close to 0.4, and to 0.45 in ResNet50, in order to improve sensitivity without excessively compromising specificity. Also, implementing loss functions such as focal loss could help to reduce false negatives, especially in critical clinical classes. To control overfitting, it is recommended to increase regularization by Dropout (between 0.5 and 0.7), apply L2 penalty and use Batch Normalization in dense layers. From the optimization point of view, it is advisable to experiment with algorithms such as AdamW and dynamic learning rate adjustment strategies such as cosine decay. In addition, converting models to optimized formats such as TensorFlow Lite and applying quantization techniques can facilitate their execution on embedded hardware. For future research, it is proposed to validate the models on images from real clinical contexts beyond the standardized dataset, as well as to explore the development of hybrid models (ensembles) that combine efficiency and accuracy. It is also proposed to extend this methodology to the diagnosis of other parasitic diseases with similar cell morphology, such as leishmaniasis or babesiosis, and to implement complete systems in low-cost portable devices -such as Raspberry Pi with digital microscopy-, aimed at environments with limited access to medical infrastructure.

The novelty of this study lies not only in the results obtained, but also in its practical applicability. As part of the materialization of this research, the graphical interface NhAI-Malaria Classifier Fig. 15 was developed, a desktop tool that integrates the trained models (ResNet50, InceptionV3 and EfficientNetB0) to classify images of blood cells with malaria. The interface allows loading images manually or generating random samples, selecting the desired model and visualizing predictions with their associated probability. Designed to be intuitive and accessible, this GUI is ideal for resource-limited clinical settings, medical education or rapid sample validation. Its local operation guarantees data privacy, eliminating dependence on external connections, which makes it especially suitable for areas with low connectivity. Source code and deployment instructions are available at https://github.com/lu-mala/NhAI-Malaria-Classifier.

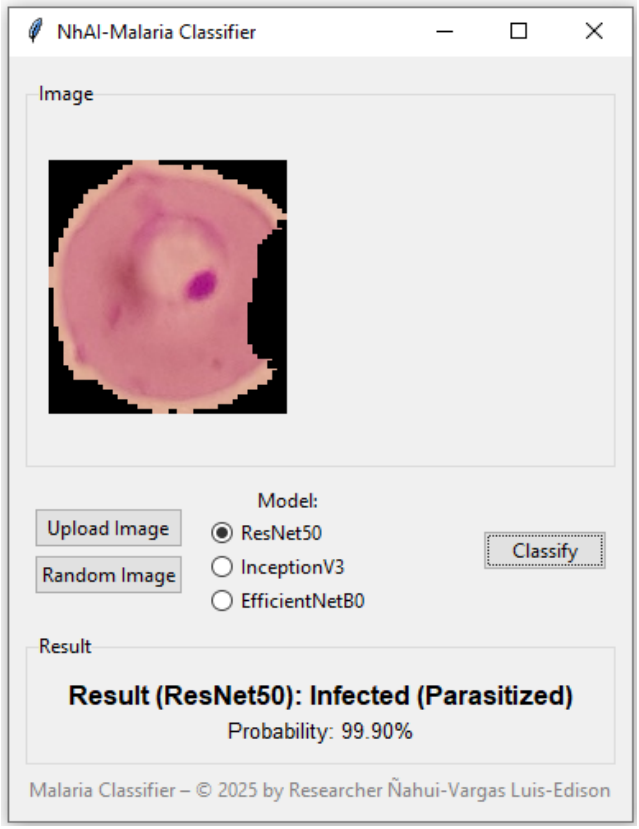

Fig. 15. NhAI-Malaria classifier graphical interface. Users can upload images, select a model and receive predictions with confidence levels.

A Hybrid Graph Convolutional Networks (GCN)-Collaborative Filtering Recommender System

Qingfeng Zhang*
Shandong Youth University of Political Science, Jinan 250000, Shandong, China

***Abstract*—This study proposes a hybrid recommendation system that integrates Graph Convolutional Networks (GCN) and collaborative filtering to improve the accuracy and performance of university library book recommendation systems. The goal is to develop a comprehensive evaluation method for assessing the effectiveness of recommendation algorithms in university libraries. A combination of GCN and collaborative filtering algorithms was employed to enhance recommendation accuracy. GCN was used to capture complex relationships in user data, while collaborative filtering focused on user preferences. Performance evaluation was conducted using a set of functional indicators, and the system was tested using real library data. The evaluation metrics included Mean Absolute Percentage Error (MAPE), Root Mean Square Error (RMSE), and evaluation time. The GCN-based evaluation model significantly outperformed traditional methods. It achieved a MAPE of 0.7597 and an RMSE of 0.3775, both superior to BP, CNN, and DBN algorithms. In terms of evaluation time, the GCN algorithm showed moderate performance (0.44s) compared to BP (0.32s), but better than DBN (0.87s) and CNN (0.67s). These results demonstrate the robustness and efficiency of the GCN model in predicting library recommendations. The proposed hybrid system effectively improves the accuracy and evaluation of university library recommendation systems. The GCN-based model outperformed other methods in terms of error rates and evaluation time, making it a valuable tool for enhancing personalized recommendations in library systems. Future research will focus on optimizing the computational efficiency of the GCN model.**

Keywords*—Graph convolutional networks; collaborative filtering; hybrid recommender systems; university library performance evaluation

I. Introduction

The building and development of libraries is very important to colleges and universities because they serve as teaching and research services, academic institutions, and a center for information about school literature. These libraries also play a significant role in scientific research and talent development [1]. The B/S architecture-based library management system is being gradually integrated into the construction of university libraries in response to the increasing popularity of e-books and digital libraries. This system is designed to assist library management personnel in the navigation of effective organization management and the classification of book information, as well as to assist book users in finding the books they need through the use of relevant search engines [2]. The traditional search technology or navigation technology has been unable to meet the increasing demand for personalized literature as the times have evolved [3]. The conventional library management system can no longer fully fulfill its role due to the growing quantity of university library collections and information resources; it is unable to extract unknown and valuable information from massive amounts of data, nor can it make educated guesses about the needs of users or project the future [4]. In recent years, the development of intelligent search technology has enabled college library book recommendation systems to obtain personalized recommendation information. The development and introduction of intelligent library book recommendation system allows users to borrow books, lowers the time users spend searching for books, and enhances the accuracy of recommended books [5]. The design of a college library book recommendation system that is based on a personalized recommendation algorithm must be assessed based on its design method. Consequently, it is of great importance to investigate effective performance evaluation algorithms for this method [2].

The investigation concerning the book recommendation system in college libraries can be broadly classified into three areas: the design of the system, performance evaluation of the system, and customized recommendation algorithms for books in the library [6]. College library book customized recommendation systems are separated into content-based filtering [7-8], collaborative filtering to [9-10] and hybrid recommendation algorithms [11-12]. Recommendation algorithms for content-based filtering are primarily used in the analysis of user data and document content. Noor et al. [7] describes how users and documents are constructed, and how users' feedback is combined with configuration information to modify the subject and feature word vectors. Wang and Gao [8] present clustering algorithms as the foundation of content filtering, where users are categorized into multiple groups and the recommendation of one group of users per category. Collaborative filtering recommendation algorithms, as opposed to content-based filtering algorithms, use the user's expressed preference behavior and the eye-catching content rating to identify users who share similar interests or behaviors and recommend the information the user is interested in to the target user. Yang et al. [9] introduce category similarity and fully incorporates the rating similarity to calculate the similarity of the recommended items of the recommendation algorithm. Berjisian and Bigazzi [11] employ K-mean clustering approach for calculation, comparing the similarity of each target item, based on a certain item space inside the selected search recommendation. While much progress has been made in the study of book recommendation system design in college libraries, there has been little use of personalized recommendation algorithms in these systems, and the evaluation of these systems using personalised recommendation algorithms is not very accurate or sufficiently comprehensive. The assessment intelligence of book recommendation systems is

likely to become the future development trend for these systems in college libraries as deep learning algorithms and big data technology advance [12]. The existing deep learning algorithm is easy to fall into the local optimal, feature extraction is not enough, therefore the application of graph deep learning network can increase the level of evaluation intelligence and assessment accuracy of the book recommendation system [13].

In response to the present issues with the imprecise system performance evaluation and the lack of precision in college library book recommendation methods, this research suggests a hybrid library recommendation system built on graph convolutional networks and collaborative filtering [14]. This paper specifically contributes the following three areas: (1) it proposes a collaborative filtering algorithm-based college library recommendation method; (2) it proposes a graph convolutional network-based performance evaluation method for the problem of college library book recommendation system performance evaluation; and (3) it uses the college library book recommendation system's data to validate and analyze the proposed method, showing that it is more accurate and robust than other models.

To address the shortcomings of existing recommendation systems in university libraries, this paper proposes a hybrid model that combines collaborative filtering and Graph Convolutional Networks (GCN). The structure of this study is as follows: Section II presents the overall system design, including user needs and system architecture. It also elaborates on the collaborative filtering algorithm. Section III introduces the GCN-based performance evaluation model. Section IV describes the system implementation and experimental setup. Section V provides a comparative analysis of experimental results. Finally, Section VI concludes the study and suggests directions for future research.

II. Library Recommendation System Design

A. System Analysis

1) Needs analysis: According to the analysis of user requirements for book recommendation system service in university libraries (Fig. 1), the system requirements are divided into functional and non-functional requirements [15] (Fig. 2), as follows:

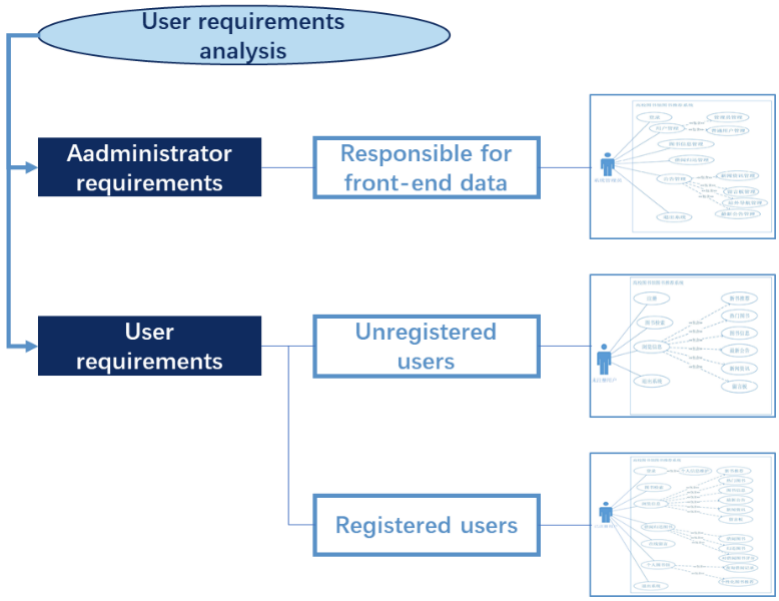

Fig. 1. User requirements analysis.

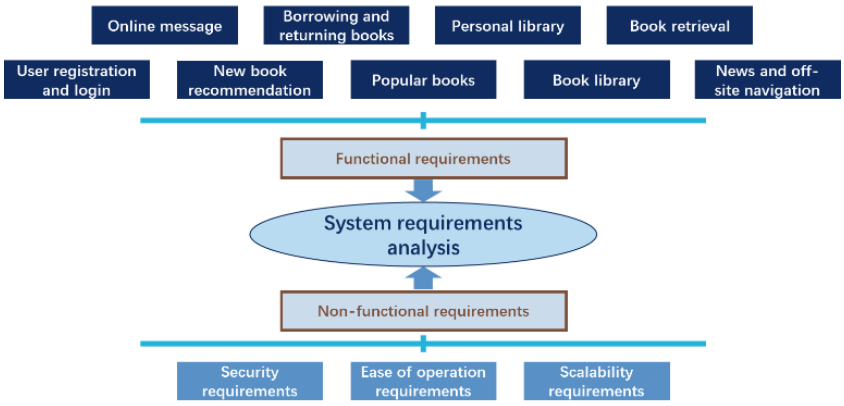

Fig. 2. System requirements analysis.

Functional requirements. Functional requirements mainly include user registration and login, new book recommendations, popular books, book library, news bulletin and off-site navigation, online message, borrowing and returning books, personal library, book search; Non-functional requirements. Non-functional requirements include security requirements, ease of operation requirements, and scalability requirements.

2) System architecture: By assessing the system requirements, the university library book recommendation system incorporates a front-end query system as well as a back-end library management system, and the architecture of the system is specifically represented in Fig. 3.

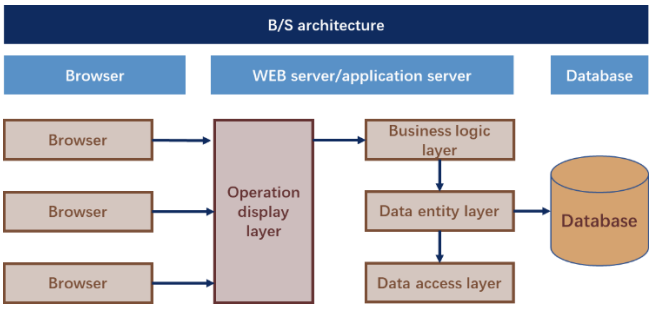

Fig. 3. System architecture.

The operation display layer, data set access layer, data entity layer, and business logic layer make up the majority of the architecture, as shown in Fig. 3. Users can operate through the visual interface, the system through the construction of business logic layer, display layer, business encapsulation operation layer to establish a corresponding process of processing business logic. The data entity layer, which generally has access to the database, i.e., accessing the data in the database and conducting actions such as insertion, etc. [16].

3) System functions: By combining the user requirements and the characteristics of each functional module of the system, the functional structure of the book recommendation system for college libraries is shown in Fig. 4.

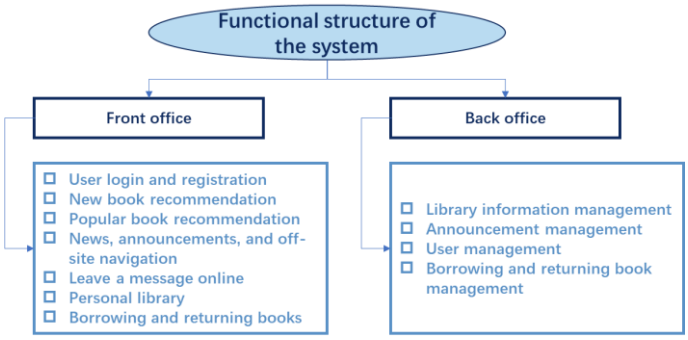

Fig. 4. System functional structure.

The system functions are categorized as foreground and background functions. Foreground functions include the following: 1) user login and registration, new book recommendations, popular book recommendations, book library, and other functional modules. Background functions, such as book information management, bulletin management, user management, borrowing and returning book management, and other functions, are operated by the system administrator by logging in study [17].

4) Overall system process design: When user roles are combined, the system can be separated into two categories of users: 1) system administrators, who have the power to control books, news, and other data in the background; the detailed operation procedure is depicted in Fig. 5; and 6) regular users, whose restricted functions, like examining news updates, recording returned books, and checking out books, are accomplished via the system's front end [18].

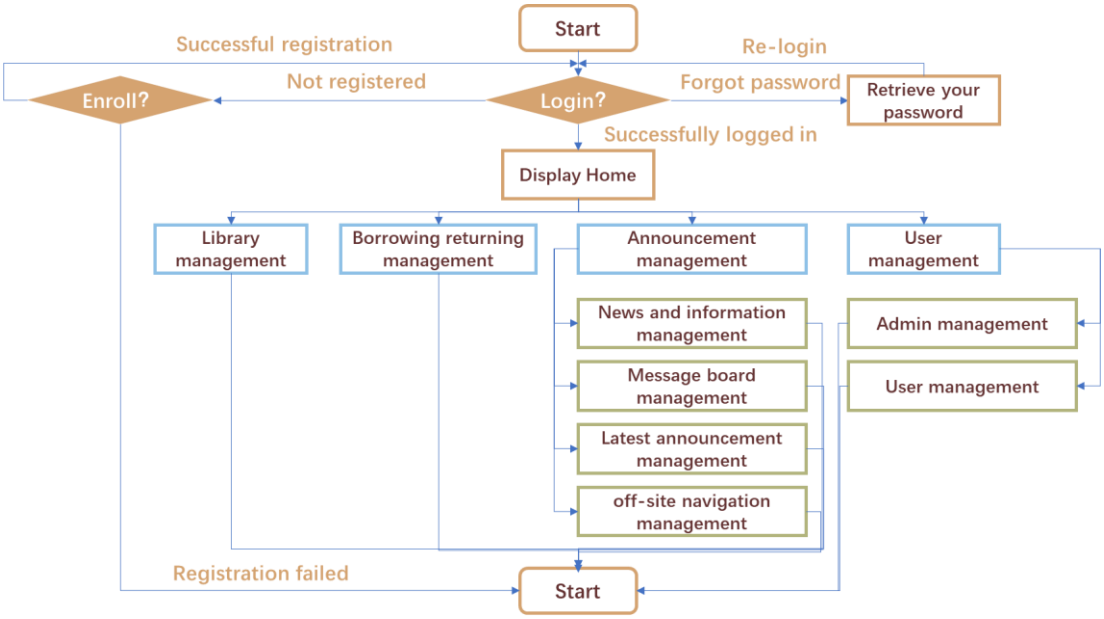

Fig. 5. System administrator flowchart.

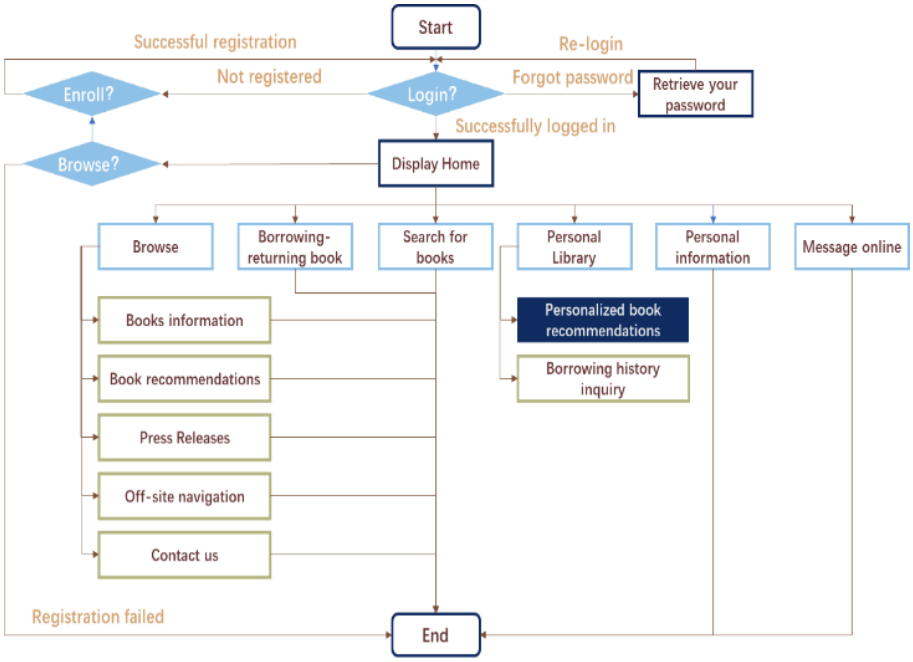

Fig. 6. General user flow chart.

B. Collaborative Filtering Algorithm

In the book recommendation system of university libraries, the book recommendation method based on collaborative filtering algorithms, as the core of the recommendation system, is based on the data of the user group's preference for the product, to discover the similarity between users or items, and then provide personalised recommendations. Collaborative filtering is largely separated into two forms (Fig. 7): user-based collaborative filtering [19] and item-based collaborative filtering [20].

1) Introduction to the algorithm: The purpose of User-based Collaborative Filtering (UCF) is to locate comparable groups of users and recommend the goods that these people enjoy to the target audience, as shown in Fig. 8. This methodology works by calculating the similarity between users, which can be calculated by many approaches such as Euclidean distance, cosine similarity or Pearson correlation coefficient.

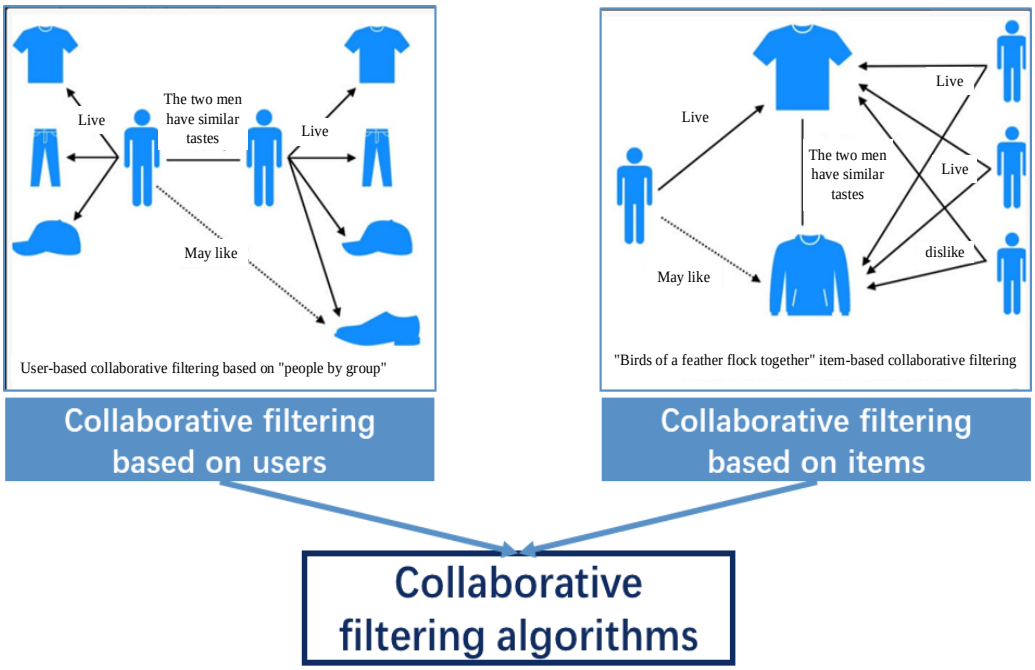

Fig. 7. Classification of collaborative filtering algorithms.

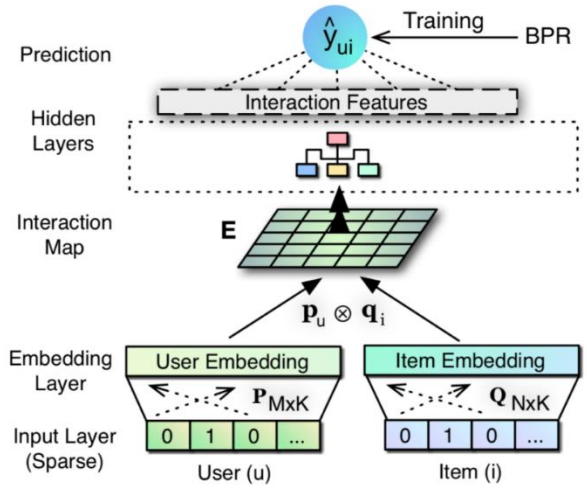

Fig. 8. Principle of user-based collaborative filtering algorithm.

Item-based Collaborative Filtering, on the other hand, recommends related goods to users based on their historical preference information, as seen in Fig. 9. This technique assumes that if people have liked particular goods in the past, they may also like other items that are comparable to those ones. The similarity between objects is also frequently established via a similarity computation method.

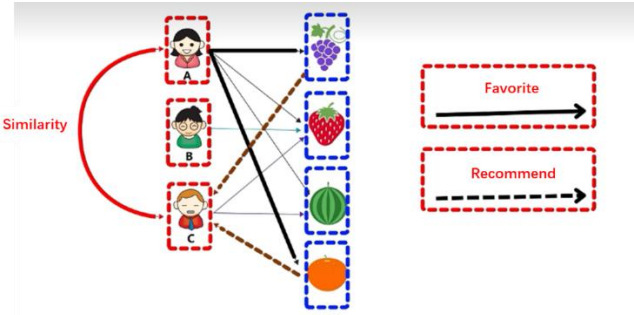

Fig. 9. Principle of item-based collaborative filtering algorithm.

2) Similarity calculation method: Commonly used similarity calculations in collaborative filtering algorithms (e.g., Fig. 10) [21] include:

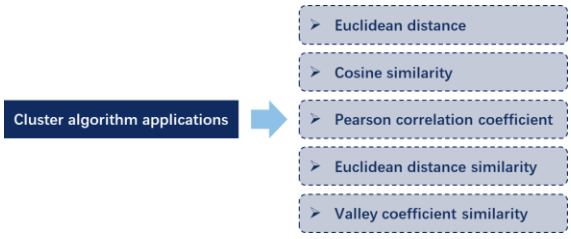

Fig. 10. Similarity calculation method.

Euclidean distance: similarity is measured by calculating the distance between two users or items in a multidimensional space.

Cosine similarity: the similarity is expressed by calculating the cosine of the angle between two vectors, the closer the cosine value is to 1, the more similar the two vectors are.

$$sim(i,j)=\cos(v_i,v_j)=\frac{v_i\cdot v_j}{|v_i|\cdot|v_j|} \quad (1)$$

where i, j is the two variable users; v_i and v_j denote the i- and j-order row vectors of a user's borrowing record, respectively.

Pearson's correlation coefficient: a statistic describing the linear correlation between two numerical variables, with values ranging from [-1, 1], used to measure the linear correlation between users or items.

$$sim(i,j)=\frac{\sum_{c\in I_{ij}}\left(R_{i,c}-\bar{R}_i\right)\left(R_{j,c}-\bar{R}_j\right)}{\sqrt{\sum_{c\in I_{ij}}\left(R_{i,c}-\bar{R}_i\right)^2}\sqrt{\sum_{c\in I_{ij}}\left(R_{j,c}-\bar{R}_j\right)^2}} \quad (2)$$

where I represents the entire project/userspace.

Euclidean distance similarity: the coordinates between users/items in this calculation method are row vector/column vector (data scoring matrix), and this is used as a basis for calculating the similarity of users and items.

$$sim(i,j)=\frac{\sum_{c\in I_{ij}}\left(R_{i,c}-\bar{R}_i\right)\left(R_{j,c}-\bar{R}_j\right)}{1+\sqrt{\sum_{c\in I_{ij}}\left(R_{i,c}-R_{j,c}\right)^2}} \quad (3)$$

Gulben coefficient of similarity: the idea is that items that are not similar do not affect the results of calculating similarity, and that only items that are preferred by the user come into play when calculating similarity.

$$sim(i,j)=\frac{N_{ij}}{N_i+N_j-N_{ij}} \quad (4)$$

Among them, N_i indicates the number of user i's favourite items or the number of users choosing category i; N_j indicates the number of user j's favourite items or the number of users choosing category j; N_{ij} indicates the number of users choosing two categories of items at the same time, i.e., the two categories of items are simultaneously recognised and preferred by the users.

3) Collaborative filtering algorithm based on user interest: Based on the diversity in user interests, collaborative filtering recommendations are generated using a strategy and approach to compute the rating matrix [22]. This computation method's results can accurately capture the fluctuations in the relative weights of the item ratings over all time intervals. The key principle of the collaborative filtering algorithm based on user interest is to handle the rating matrix correctly, consequently, frequency weights and time weights are incorporated.

a) Frequency weighting: This indicator is used to indicate the number of times a user has borrowed a book, the more times, the larger its corresponding weight value will be.

$$Wb(u,i)=\frac{b_i}{B_u} \tag{5}$$

Where, b_i and B_u denote the total number of times user u borrowed books of category i, all books respectively.

b) Time weighting: The time weights on the one hand weaken the importance of books borrowed long ago and on the other hand emphasise the importance of books borrowed in the recent past.

$$Wt(u,i)=\begin{cases}\frac{t_2-t_1}{T}\times\frac{t_2}{T} & t_1\neq t_2\\ \frac{t_2}{T}\times\frac{1}{T} & t_1=t_2\end{cases} \tag{6}$$

In summary, the combined weights are calculated as follows:

$$W(u,i)=\begin{cases}\beta\times\frac{b_i}{B_u}+(1-\beta)\times\frac{t_2-t_1}{T}\times\frac{t_2}{T} & t_1\neq t_2\\ \beta\times\frac{b_i}{B_u}+(1-\beta)\times\frac{t_2}{T}\times\frac{1}{T} & t_1=t_2\end{cases} \tag{7}$$

Among them, $\beta\in(0,1)$ represents the proportion of frequency weighting, $(1-\beta)$ represents the proportion of time weighting, and generally β is set to 0.5.

c) Recommendation algorithm steps: The input to the improved recommendation algorithm is the input has been borrowed book set I_u , the output is the Top-N result recommendation set of the user u. The flowchart of the algorithm is shown in Fig. 11.

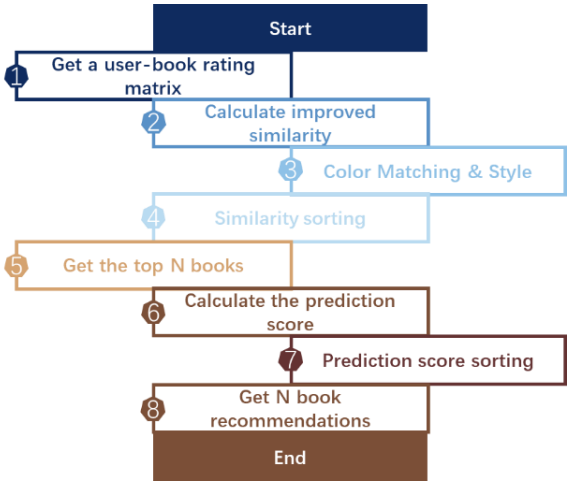

Fig. 11. Flowchart of the improved recommendation algorithm.

III. Performance Testing Methods for Recommender Systems in Higher Education Libraries

A. Graph Convolutional Network Algorithm

Graph Convolutional Networks (GCN) [23] is a neural network model specifically developed to process graph-structured data. It is able to act directly on graph data and leverage the structure information of the graph, and is frequently used for tasks such as node classification, link prediction, community detection, etc. The main idea of GCN is to extend the convolutional operation from standard Euclidean data (e.g., Fig. 12) to graph data, and to learn the representation of a node by aggregating information about the properties of the node and its neighbours.

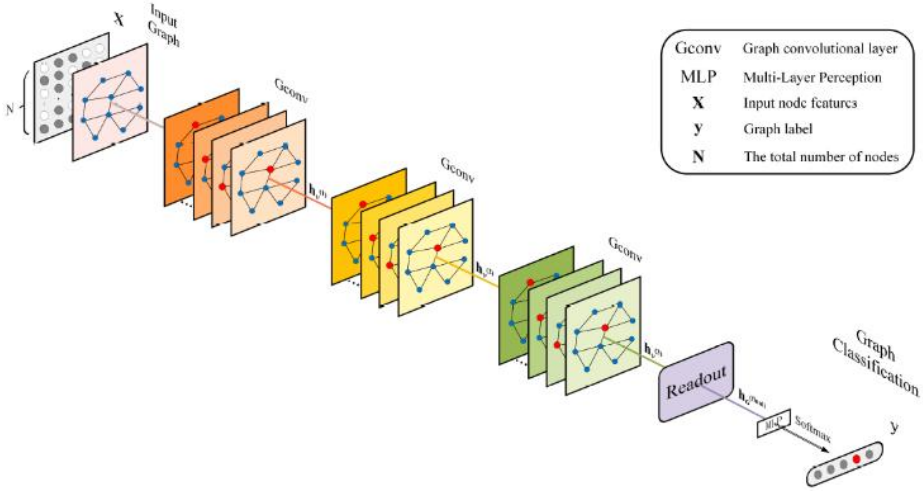

Fig. 12. GCN algorithm structure.

1) Principle of operation: Suppose a graph structure $G=(V,E)$, as an input to the GCN, where V denotes the set of graph nodes and E is the set of edges in the graph; each node $v\in V$ has a feature vector X_v , which represents the feature information of the node; and A denotes the adjacency matrix. The specific model is as follows:

$$H^{I+1}=f\left(H^{(I)},A\right) \tag{8}$$

$$f\left(H^{(I)},A\right)=\sigma\left(AH^{(I)}W^{(I)}\right) \tag{9}$$

Where $H^{(0)} = X$, $H^{L} = Z$, L are the number of layers; $W^{(I)}$ denotes the weight matrix of the l layer, and σ is a nonlinear activation function.

The matrix transformation is:

$$H^{(I+1)} = \sigma\left(D^{-\frac{1}{2}} \cdot A \cdot D^{-\frac{1}{2}} \cdot H^{(l)} \cdot W^{(l)} \right) \quad (10)$$

Where $H^{(l)}$ denotes the feature representation of layer l , A is the adjacency matrix, D is the degree matrix, $W^{(l)}$ is the weight matrix of layer l , and σ is a nonlinear activation function.

2) GCN Applications: Applications for GCN may be found in a number of domains, such as computer vision, recommender systems, social network analysis, chemical molecular structure analysis, traffic prediction, etc. (Fig. 13). It is capable of handling the complexity of graph data and extracting usable features from it for tasks like as classification and prediction [24].

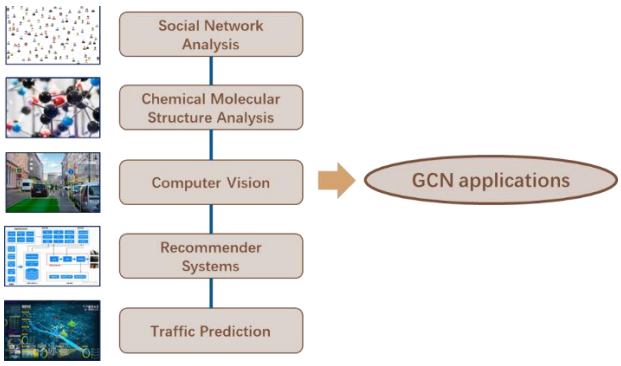

Fig. 13. GCN algorithm application.

B. Application of Algorithms

This study uses GCN to build the college library recommender system performance test and evaluation model in order to address the issue of how to test and evaluate the system's performance. The recommendation system performance evaluation problem is a complex nonlinear evaluation and prediction regression problem, using the college library recommendation system functional indicators as input and the recommendation system performance evaluation score as output. Therefore, this paper adopts GCN to address the college library recommender system performance test evaluation problem, the problem analysis and solution ideas are illustrated in Fig. 14. In order to conduct a performance test and evaluation of the college library book recommendation system, the evaluation problem entails the analysis of the functional indicators of the system, the construction of an indicator system, and the application of the GCN algorithm to establish a mapping relationship between the value of the functional indicators and the evaluation scores.

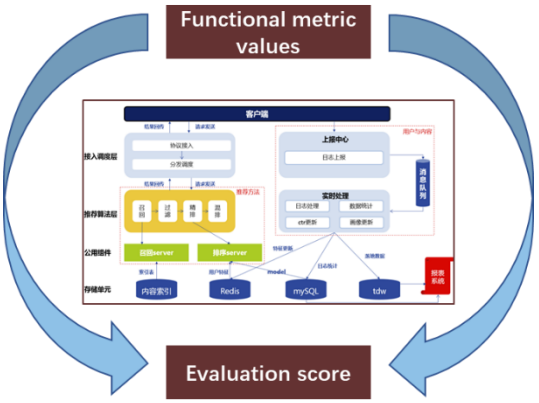

Fig. 14. Ideas for solving the problem of evaluating the book recommendation system in university libraries.

1) Constructing a recommendation system evaluation index system: The evaluation indexes of book recommendation system in college library include the front-end functional indexes and back-end functional indexes [25], and the specific index system is shown in Fig. 15.

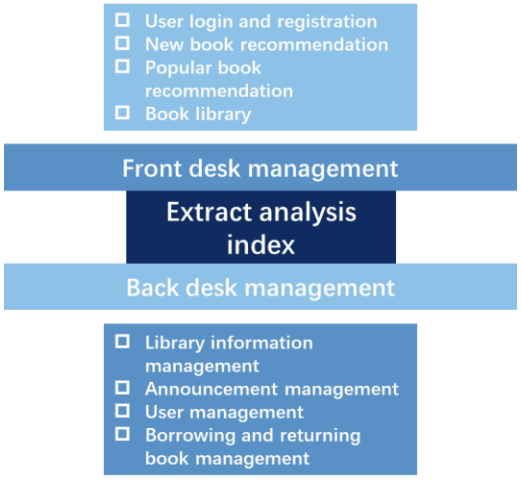

Fig. 15. Construction of the assessment indicator system.

The functions can be categorized as either foreground or background. Foreground management includes the following: 1) user login and registration, new book recommendations, popular book recommendations, library, and other functional modules; 2) system administrator log-in to the system background to manage book information, bulletins, user management, borrowing and returning book management functions, and operations. (2) Constructing a Recommender System Evaluation Model

The development of the book recommendation system evaluation model for the university library is predicated on the GCN algorithm training optimization, the recommendation system performance evaluation score as the output, and the recommendation system function index as the input. The specific flow of the recommendation system assessment model is given in Fig. 16.

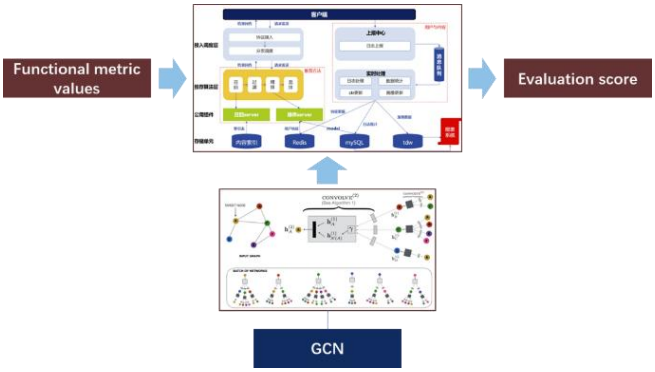

Fig. 16. Construction of the evaluation model of university library recommendation system.

IV. A Method for Designing and Evaluating the Performance of Recommender Systems in University Libraries

The design and assessment process for college library recommender systems is primarily separated into two sections: (1) college library recommender system design. Aiming at the core problem of the recommendation system, the improved collaborative filtering algorithm is used to design the college library book recommendation algorithm, the input is the set of borrowed books, and the output is the user's resultant recommendation set; (2) college library recommendation system evaluation. Using GCN to establish the mapping link between functional index values and assessment values. The college library recommendation system design and evaluation process is specifically shown in Fig. 17.

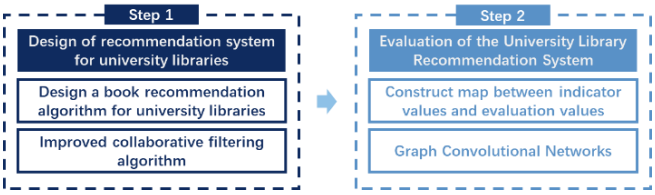

Fig. 17. Schematic of the design and evaluation methodology of the university library recommendation system.

V. Analysis of Results

A. Environmental Settings

The university library recommendation system is developed based on SSH framework using MVC technology. Based on multi-tier architecture, it is developed through B/S access mode and Java language, and the specific environment settings are shown in Table I.

The environment setup for the evaluation algorithm of the recommendation system in the university library is shown in Table II.

TABLE I. Environmental Setup

Environmental projects	Settings
operating system	Windows 10
web server	Apache-tomcat-8.0.36, JDK6.x
programming language	Java
Database management system	MySQL

TABLE II. System Evaluation Environmental Settings

Environmental Projects	Settings
operating system	Windows 10
visualisation software	Matlab2022a
processing unit	AMD Ryzen 9 5900HX with Radeon Graphics 3.30 GHz
programming language	Pycharm

In order to analyse and compare the efficiency of the proposed algorithms in this paper, BP, DBN, CNN and GCN are used for comparative analysis, and the specific algorithm parameters are set as shown in Table III.

TABLE III. System Evaluation Environmental Settings

Arithmetic	Parameterisation
BP	The activation function is tan-sigmoid and the number of hidden layer nodes is 60
DBN	Three hidden layers with 60, 100, 60 nodes in each layer
CNN	The number of hidden layer nodes of the CNN network is 50 and the Adam technique is used to optimise the network training
GCN	The hidden layer node is 100 and the activation function is the Relu function

The dataset used for the evaluation algorithm of the university library recommender system is the data generated by the university library recommender system, in which the data is divided into a training set and a test set with a ratio of 8:2.

B. System Design Implementation

This study builds the university library recommendation system as depicted in Fig. 18, based on user demands. As can be seen from Fig. 18, the home page of the system mainly shows the overall functional structure of the system to the user; the system's book recommendations can be divided into two types: the first is a new book recommendations; the second is a popular book, and are open for users, are personalised book recommendations, including users who have not yet logged on to the system. Users can also access the borrowing record to view their previous personal borrowing of books on the platform, as the personal library module, the primary module of the system, can offer personalized recommendations.

(a) System home page

(b) Book Recommendation Interface

(c) Personalised book recommendation interface for new users

Fig. 18. Design and implementation of recommendation system for university libraries.

The recommendation algorithm code for the university library recommendation system is given in Fig. 19. The system recommends professional literature by calculating the similarity. In this system, if the value of similarity reaches 0.3 or greater, it can recommend 10 books for the user in this or related majors.

```
List<BookDTO> bookDTOs = new ArrayList<>();
Member member = systemDao.load(Member.class, memberId);
List<Book> books = systemDao.findAll(Book.class);
// 对于新注册的用户，根据填写的专业推荐图书

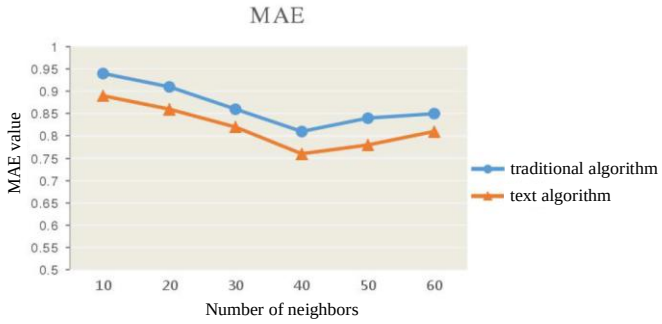
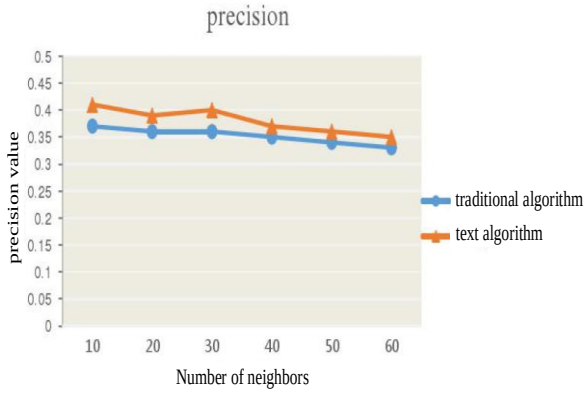
C. Experimental Analysis of System Evaluation Algorithms

In order to validate the performance of the proposed recommender system in this paper, BP, CNN and DBN algorithms are used to compare and analyse with GCN network and specific results are obtained as shown in Fig. 20, Fig. 21 and Table IV.



(a) Comparison of mean absolute error MAE results.

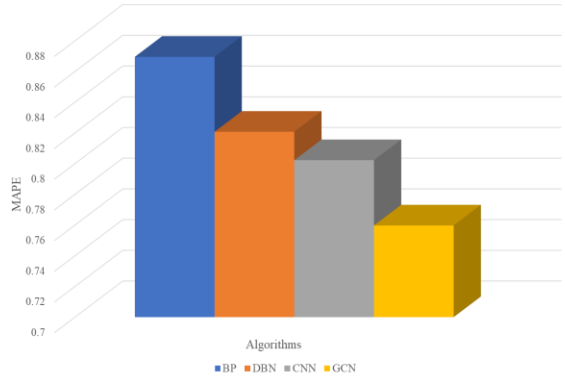


(b) Comparison of test accuracy precision results.

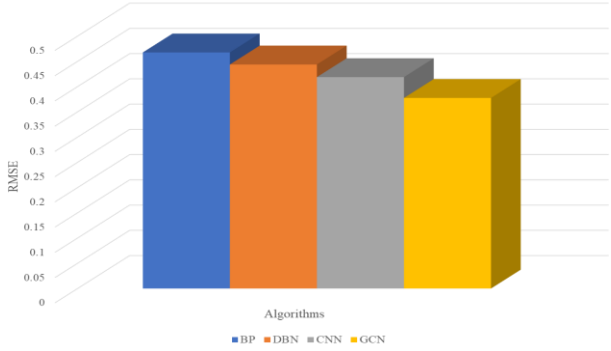
Fig. 20. Performance comparison of recommendation algorithms for recommender systems.

Fig. 20 presents the results of the comparison between the mean absolute error (MAE) and test accuracy precision of the collaborative filtering algorithm and the enhanced collaborative filtering algorithm. As can be seen from Fig. 20, let there are 10 neighbours initially with an interval of 10, and finally the number of nearby users is expanded to 60. Comparing with the previous algorithm, the value of MAE of the new algorithm is less. This clearly shows that after including the adjustment factor, the enhanced algorithm is better able to properly reflect changes in the user's interests, and the recommendation results are better. Compared with the previous approach, the precision value of the enhanced algorithm is bigger. This suggests that the upgraded algorithm is more able to properly reflect the changes in user preferences and generate extremely accurate suggestions by adding adjustment variables.

The performance results of the recommender system evaluation algorithms are compared in Fig. 21, and the specific results of the recommender system evaluation algorithms are presented in Table IV. From Fig. 21 and Table IV demonstrate that the evaluation accuracy of the recommender system evaluation algorithm based on the GCN network is superior to that of BP, CNN, and DBN in terms of MAPE and RMSE, with values of 0.7597 and 0.3775, respectively. On the other hand, the evaluation time of the recommender system evaluation algorithm based on GCN network is greater than that of BP network, with a value of 0.44s, but it is less than that of DBN and CNN.



(a) Comparison of MAPE results



(b) Comparison of RMSE results

Fig. 21. Comparison of the performance of evaluation algorithms for recommender systems.

TABLE IV. EXPERIMENTAL RESULTS OF DIFFERENT ASSESSMENT MODELS

Arithmetic	MAPE	RMSE	Time/s
BP	0.8695	0.4677	0.32
DBN	0.8207	0.4383	0.87
CNN	0.8022	0.4188	0.67
GCN	0.7597	0.3775	0.44

VI. CONCLUSION

This study proposes a hybrid recommendation system that integrates an enhanced collaborative filtering algorithm with Graph Convolutional Networks (GCN) to improve book recommendation accuracy and performance evaluation in university libraries. The system was designed based on user needs, and its evaluation was conducted using functional indicators mapped through GCN. Comparative experiments show that the proposed model significantly outperforms traditional methods such as BP, DBN, and CNN in terms of Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE), demonstrating both high precision and robustness.

However, this study still has some limitations. Firstly, the current model focuses mainly on offline datasets from university libraries, which may not capture real-time user behavior changes. Secondly, the collaborative filtering component, although improved, still faces cold-start challenges for new users and items. Moreover, the GCN model, while accurate, incurs moderate computational costs, especially as the data scale increases. These factors limit the scalability and real-time applicability of the system in larger, dynamic environments.

Future research will aim to address these limitations by integrating real-time learning mechanisms and adaptive feedback loops into the recommendation system. Additionally, incorporating more diverse data sources, such as user reading habits, textual content analysis, and social interactions, could further enhance the personalization and accuracy of recommendations. Optimizing the GCN structure to reduce computational complexity while maintaining performance is another promising direction to support large-scale, real-time applications in smart library environments.

***Abstract*—This study proposes a TCM culture communication data clustering division and classification method that is based on an enhanced DBSCAN clustering algorithm and an ELM model. The objective is to address the issue of Traditional Chinese Medicine (TCM) culture communication image role product design. Firstly, for the problem of extracting feature vectors of TCM cultural communication, we analyse the path of communication role product design, design the product design scheme of TCM cultural communication image role, and extract the feature vectors of TCM cultural communication; secondly, for the problem of clustering and classifying the health data of TCM, we propose a method of clustering and classifying the health data of TCM based on the SCSO-DBSCAN clustering algorithm by combining the DBSCAN clustering algorithm with the sandcat swarm optimization algorithm. Finally, the TCM cultural dissemination data clustering classification and classification methods are tested and analyzed using TCM cultural dissemination data. This problem of TCM health data clustering classification is addressed by combining the ELM network algorithm, and a classification method of TCM cultural data dissemination based on the ELM model is proposed. The experimental results demonstrate that the method proposed in this study enhances the accuracy of TCM health data clustering division and also improves the accuracy of TCM cultural data communication classification, in comparison to other algorithms used for TCM cultural communication data clustering division and classification.**

Keywords*—DBSCAN algorithm; TCM cultural communication; picture character product design; sand cat swarm optimization methodology

I. Introduction

Hospitals have developed a system by creating a basic database that focuses on Traditional Chinese Medicine (TCM) electronic medical records and electronic prescriptions. This has been done under the backing of the "Internet + TCM health service action" program. A vast number of TCM data resources are accumulated as a result of this procedure, which links the data of every hospital diagnostic and treatment connection [1]. Inaccurate diagnostic data may result in cancer patients being misdiagnosed as healthy, leading to a delay in their treatment and missing the optimal moment for intervention. This can potentially pose life-threatening risks [2]. Traditional Chinese Medicine (TCM) has played a significant role in the advancement of medical science for thousands of years. It has made important contributions to the flourishing of the Chinese people and has had a positive impact on the progress of world civilization. TCM also plays a crucial role in promoting health and healthcare by providing valuable health data. The division of health and error TCM data in TCM data resources is an important trend in the development of TCM cultural communication image role product design. This not only enhances the high-quality development and revitalization of TCM but also encourages individuals to change their perception of healthy living and behavior [3].

The development of TCM cultural communication image role product design study primarily focuses on data clustering, health data classification optimization, health data communication application, product design assessment, and other related areas. Some examples of data clustering division algorithms include K-means, DPC, DBSCAN, and others. Health data categorization optimization often involves techniques such as LSSVM, BP, deep learning, and others. The study primarily focuses on evaluating the design of health data dissemination applications and products. This is done by constructing an indicator system for health data dissemination applications and utilizing an agent model to characterize the link between the indicator value and analysis level. Lu et al. [4] analyzed China's Traditional Chinese Medicine (TCM) health communication model from social, economic, political, and cultural perspectives. Xie et al. [5] explored the challenges of TCM communication in the era of rapidly changing media and proposed a new approach to communicating TCM culture. Lei et al. [6] conducted a study on selecting and classifying data features in the field of TCM to enhance classification accuracy for imbalanced data. Wang et al. [7] analyzed TCM-related data through literature analysis to inform TCM business management, TCM practices, acupuncture, and ancient books. Eckman and Guo [8] investigated a method for dividing TCM data using the K-means clustering algorithm. Novikov et al. [9] examined strategies for improving the effectiveness of TCM health information dissemination based on an exhaustive likelihood model. The current research on the image role product design of TCM cultural communication has identified several problems. Firstly, there is a lack of comprehensive analysis on the impact of TCM health information dissemination, an incomplete index system, and a lack of theoretical guidance. Secondly, there is a scarcity of quantitative research on TCM health information. Lastly, there is limited research on the integration of intelligent algorithms and TCM health data.

Due to advancements in intelligent algorithms and computational arithmetic, experts and scholars in the field are increasingly focusing on the research of TCM health data clustering division, health data classification optimization, health data dissemination application, and product design evaluation combined with intelligent algorithms [10, 11]. This study introduces a technique for analyzing TCM health data using the DBSCAN algorithm, with a specific focus on using intelligent algorithms in the product design of TCM cultural communication picture characters. Initially, we examined the role of communication in product design and developed a product design plan for the representation of TCM cultural communication using machine learning algorithms. We also introduced a clustering method based on an enhanced DBSCAN algorithm for organizing TCM health data and a classification method based on the ELM model for disseminating TCM cultural data. The suggested technique is used in the examination of TCM health data, and alternative models are assessed and scrutinized to validate the efficacy of the proposed method.

The study is organized as follows: First, we analyze the significance and design strategy of TCM image role product creation. Then, we propose a clustering method based on the SCSO-DBSCAN algorithm to effectively divide TCM health data into healthy and unhealthy categories. This is followed by a preprocessing and annotation module to standardize and prepare the data. Next, we develop a classification model using the ELM algorithm to map health data features to communication product types. Finally, we validate the proposed methods through comparative experiments with multiple algorithms, demonstrating improvements in clustering accuracy and classification performance. The results confirm the effectiveness and practicality of the proposed approach in enhancing TCM cultural communication.

II. Design of TCM Cultural Communication Image Role

A. Significance of the Product Design Process

The product design of its communication image character plays a crucial role in enhancing the worldwide impact of Traditional Chinese Medicine (TCM) and strengthening the cultural identity [12]. When designing, one can consider the following aspects (Fig. 1): 1) incorporating cultural symbols; 2) recreating historical characters; 3) blending modern aesthetics with tradition; 4) incorporating storytelling and interactivity; 5) designing for multiple platforms; and 6) incorporating educational and science popularization functions.

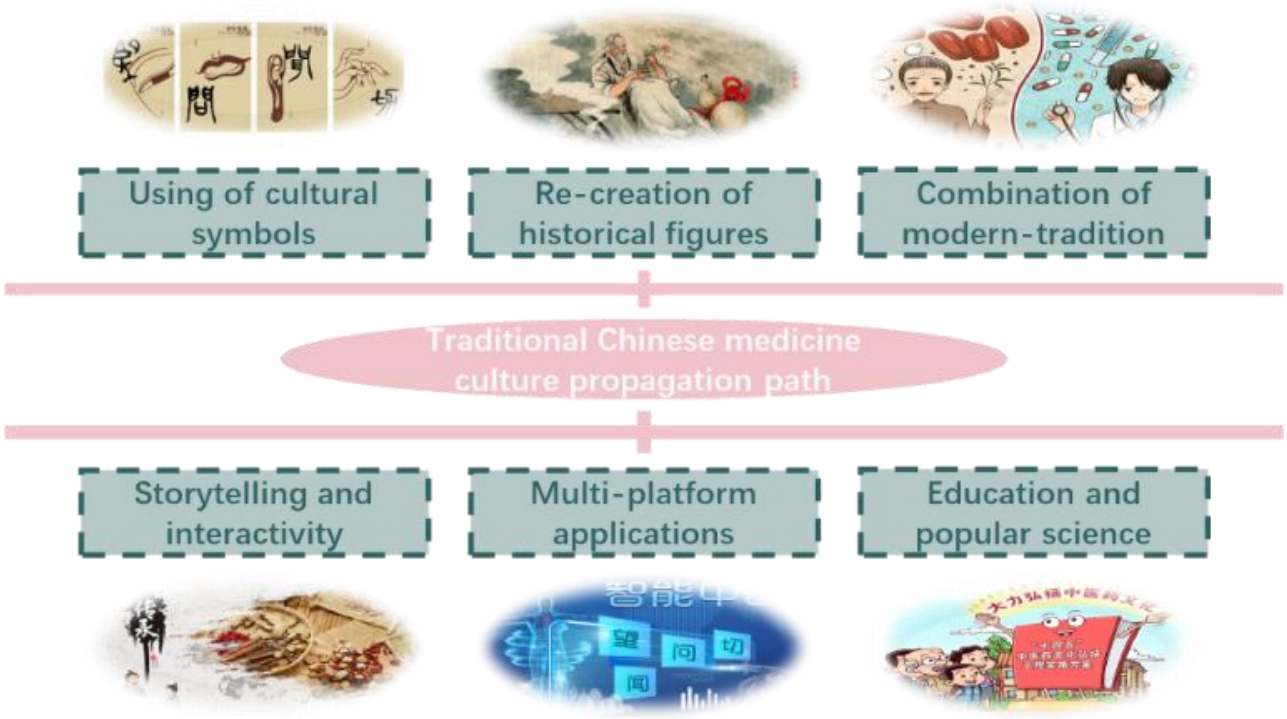

Fig. 1. TCM cultural communication role, product design pathway

B. Program Design

Following the principles of practicability, scientificity, systematicity, expandability, and open compatibility (as shown in Fig. 2), this study proposes a product design scheme for TCM cultural communication image using intelligent algorithms, as depicted in Fig. 3. The program examines the issue of product design in TCM cultural communication, explores the role of product design in communication, develops a TCM health data analysis program, extracts the feature vector of TCM information, clusters and categorizes the health and unhealthy data, preprocesses and annotates the categorized data, creates a learning and training dataset, and establishes a classification system for TCM cultural data communication through learning and training. The TCM dissemination categorization model is designed to accomplish intelligent spread of TCM culture by facilitating the product creation process.

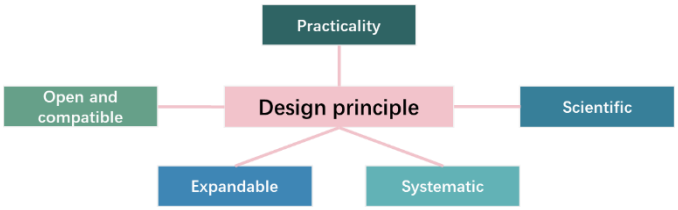

Fig. 2. Principled design.

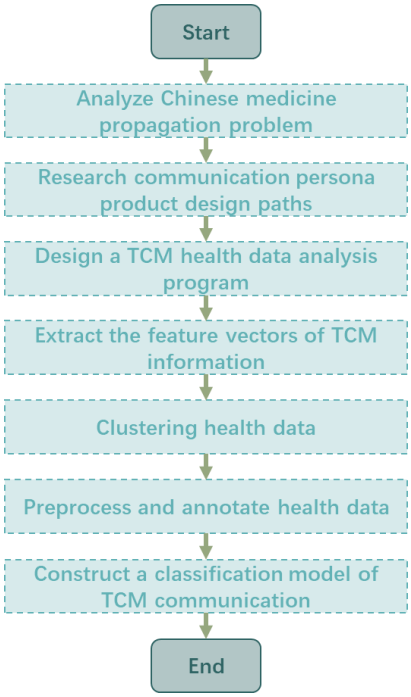

Fig. 3. Flow chart of intelligent algorithms

The proposed method in this study for designing TCM cultural communication image characters is based on an intelligent algorithm. It includes several modules such as data analysis, feature extraction, health data clustering division, data preprocessing annotation, and cultural communication classification. These modules are represented in Fig. 4.

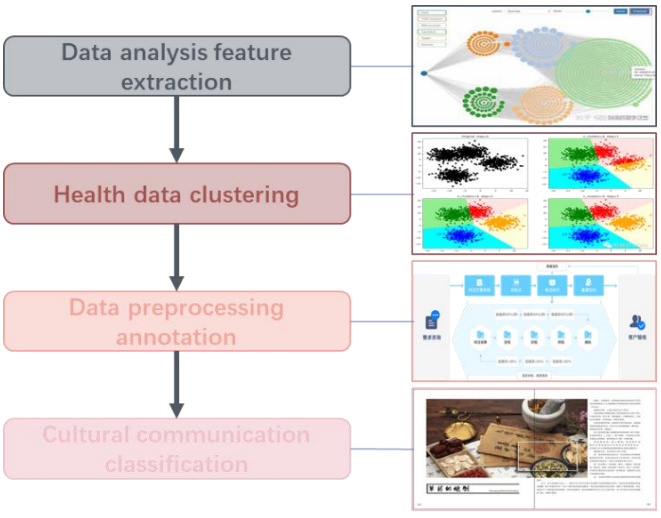

Fig. 4. Model representation of key issues.

1) Module for extracting features from data for analysis. The primary purpose of the data analysis feature extraction module is to develop a scheme for analyzing TCM cultural health data and extracting input feature vectors by examining the challenge of designing TCM cultural communication image role products from Fig. 5.

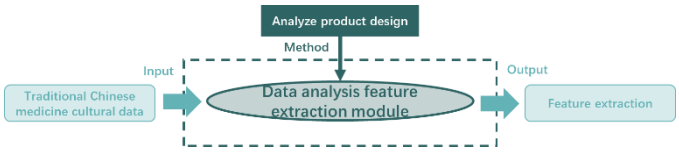

Fig. 5. Data analysis feature extraction module

2) Module for grouping health data. The health data clustering and division module primarily employs a clustering method to partition the Traditional Chinese Medicine (TCM) data into two categories: healthy data and unhealthy data. The input to this module is the feature vector data, and the output is the dataset that has been clustered and divided, as seen in Fig. 6.

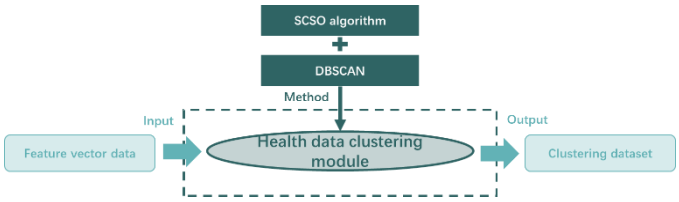

Fig. 6. Schematic diagram of the health data clustering and segmentation module

3) Data preprocessing labelling module. The primary function of the data preprocessing annotation module is to use the clustered data for performing tasks such as anomalous data processing, quantitative standardization, and annotation. The input to this module is the clustered data, and the output is the standardized TCM health information dataset, as seen in Fig. 7.

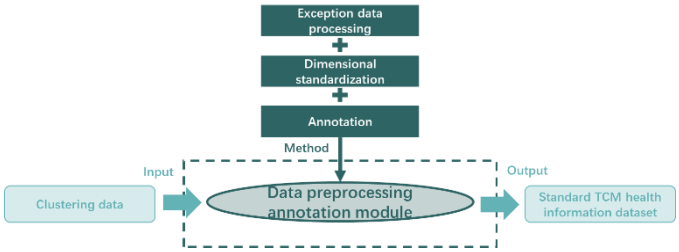

Fig. 7. Data preprocessing annotation module.

4) Cultural communication classification module. The primary purpose of the cultural communication classification module is to take in the TCM health standard dataset and utilize it to train the TCM cultural communication classification model. The input for this module is the TCM health standard dataset, and the output is the cultural communication classification model, as depicted in Fig. 8.

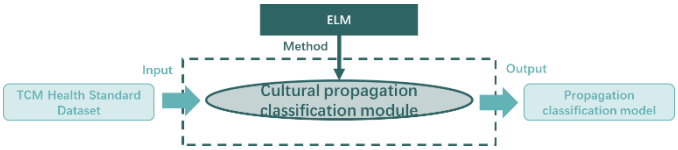

Fig. 8. Cultural communication classification module

III. CLUSTERS USING SCSO-DBSCAN

This part employs the sand cat swarm optimisation technique to enhance the DBSCAN clustering algorithm for the purpose of clustering and splitting TCM health data, hence addressing the issue at hand.

A. SCSO-DBSCAN Clustering Algorithm

1) DBSCAN clustering algorithm. DBSCAN, short form of Density-Based Spatial Clustering of Applications with Noise, is an algorithm used for clustering in a multidimensional space. It is capable of identifying clusters of various forms and effectively handling noise points. The algorithm does not necessitate the user to predefine the number of clusters, but instead identifies the cluster boundaries by examining the density of the data points.

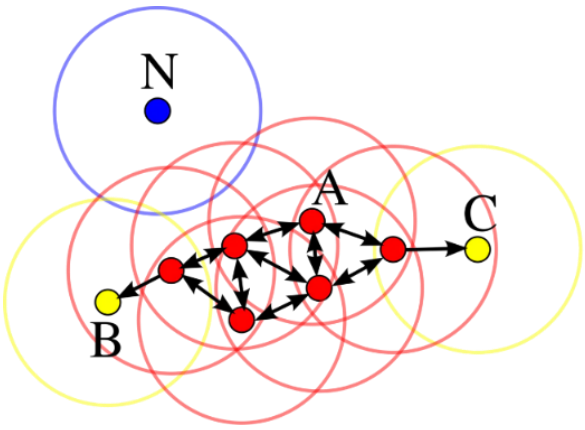

Fig. 9. DBSCAN clustering algorithm

The fundamental principles of DBSCAN encompass core, boundary, and noise points [13]. A core point is a point that is encompassed by an adequate number of neighboring points. A boundary point is a point that does not entirely meet the criteria of a core point but is situated in the vicinity of a core point. A noise point is neither a core point nor an isolated point, as depicted in Fig. 9.

a) Theory of DBSCAN algorithm: DBSCAN leverages a collection of neighborhoods to quantify the proximity of a set of samples, and the parameters (ϵ, MinPts) are used to characterize the proximity of the sample distribution inside the neighborhood [14], as seen in Fig. 10. ϵ is the distance threshold for a certain sample's neighborhood, whereas MinPts represents the threshold for the minimum number of samples in the neighborhood of a given sample within the distance ϵ.

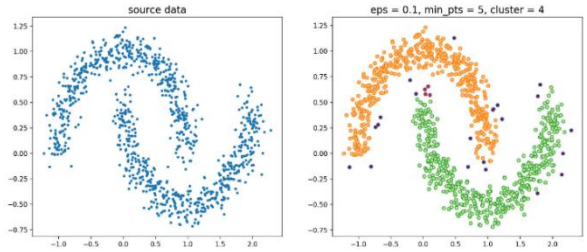

Fig. 10. Theory of the DBSCAN clustering algorithm

Assuming the sample set $D=\left(x_1, x_2, \cdots, x_m\right)$, the DBSCAN specific density is described as follows [15]:

- ϵ-neighbourhood: for $x_j \in D$, its ϵ-neighbourhood contains the subset of the sample set D whose distance from x_j is not greater than ϵ, i.e., the number of this subset is denoted as $\left|N\grave{o}\left(x_j\right)\right|$.
- Core object: for any sample x_j , if its ϵ-neighbourhood corresponding to $\left|N\grave{o}\left(x_j\right)\right|$ contains at least MinPts each sample, i.e. if $\left|N\grave{o}\left(x_j\right)\right| \geq MinPts$, then x_j is a core object.
- Density Direct: x_i is said to be density direct from x_j if x_i is in the ϵ-neighbourhood of x_j and x_j is a core object.
- Density reachable: for x_i and x_j , x_j is said to be density reachable by x_i if there exists a sample sequence $p_1, p_2, \cdots, p_T$ that satisfies $p_1 = x_i$ and $p_T = x_j$ and p_{t+1} is density direct from p_t .
- Density connected: For x_i and x_j , x_i and x_j are density connected, i.e., symmetry is satisfied, if there exists a core object sample x_k such that x_i and x_j are density reachable from x_k .

b) DBSCAN algorithm pseudo-code: According to the principle of DBSCAN algorithm, its detailed pseudo-code is shown in Fig. 11.

Algorithm 1: DBSCAN clustering algorithm	
1	Initialize core objects set: Ω=Ø
2	For j=1,2,⋯,m do
3	Determine xj ε neighborhoods;
4	If |Nε(xj)|≥MinPts then
5	Add xj to core objects set: Ω=Ω∪{xj}
6	End if
7	End for
8	Initialize clustering number: k=0
9	Initialize sample no-visited set: Γ=D
10	While Ω≠Ø do
11	Record sample no-visited set: Γold=Γ;
12	Select randomly a core object o∈Ω, initialize queen Q=<o>;
13	Γ=Γ\{o};
14	While Q≠Ø do
15	Select first sample q of queen Q;
16	If |Nε(q)|≥MinPts then
17	Δ=Nε(q)∩Γ;
18	Add sample of Δ to Q;
19	End if
20	End while
21	k=k+1, and generate clustering Ck=Γold\Γ; Ω=Ω\Ck
22	End while
23	Output clustering results.

Fig. 11. Pseudo-code of the DBSCAN clustering algorithm.

c) Evaluation of DBSCAN algorithm parameters: The effectiveness of the DBSCAN algorithm relies heavily on two crucial parameters (Fig. 12): eps (ϵ-neighbourhood radius). The ϵ-neighbourhood refers to the set of points that are believed to be closely linked to a given point. It helps identify the range of neighbors for that point. On the other hand, the min_samples parameter specifies the minimum number of sample points required for a point to be classified as a neighbor. Defines the minimal number of adjacent points necessary for a point to be classified as a core point.

d) Application of the DBSCAN method: The DBSCAN technique is well-suited for many data analysis situations, particularly when the dataset includes noise or clusters with irregular shapes [16]. The technology has a diverse variety of uses in the study of geographical data, picture segmentation, and anomaly detection [17], as seen in Fig. 13.

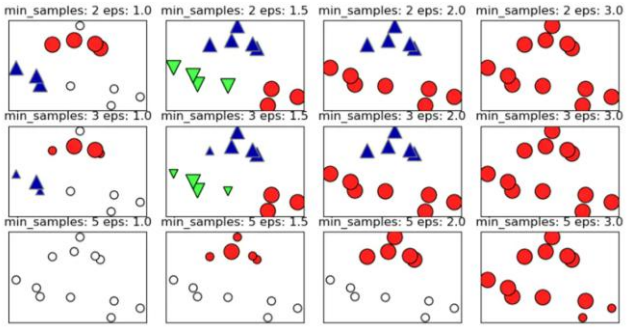

Fig. 12. Optimisation scheme for key parameters of DBSCAN clustering algorithm

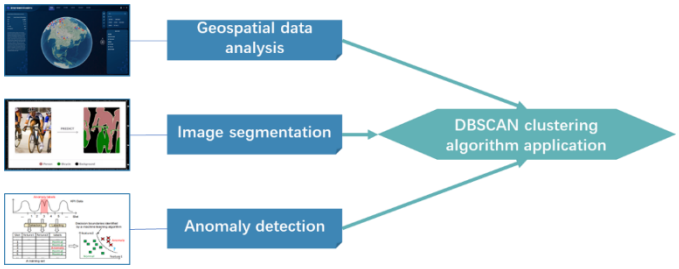

Fig. 13. Application of the DBSCAN clustering algorithm

2) SCSO-DBSCAN clustering algorithm

3) SCSO algorithm: Sand Cat Swarm Optimization (SCSO) is a recently developed optimization technique inspired by nature. The SCSO algorithm is based on the hunting behavior of sand cats, specifically their skill in detecting low-frequency noise to locate prey above or below ground. This algorithm effectively solves optimization problems by simulating the sand cats' ability to explore globally and exploit local opportunities [18].

The SCSO algorithm has two primary stages: global exploration, which involves looking for prey, and local mining, which involves assaulting prey. These stages are shown in Fig. 14. During the global exploration phase, the algorithm identifies prospective locations of high quality by imitating the thorough search behavior of a sand cat. In the local mining phase, the algorithm refines the search route to identify the best possible answer by mimicking the focused assault strategy of a sand cat. The objective of this algorithm design is to achieve a balance between the capacity to search globally and the ability to optimize locally. This will enhance the efficiency of the search process and prevent early convergence to a suboptimal solution.

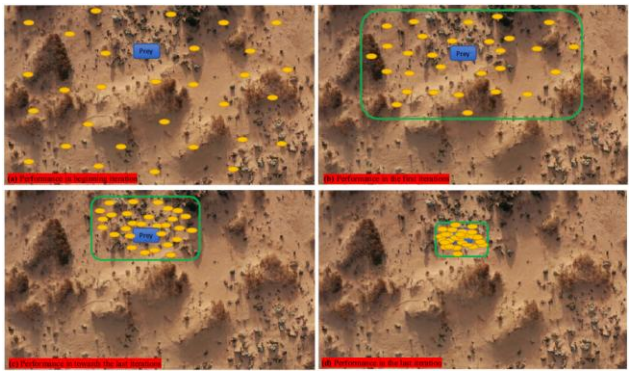

Fig. 14. Role of SCSO algorithm stages.

a) Initialisation: From Fig. 15, the SCSO algorithm generates some random solutions, i.e., sand cat individuals, in the problem space, which are computed as follows:

$$X_{ij} = lb_j + rand\left(ub_j - lb_j\right) \tag{1}$$

where, N is the population size; D is the dimension of the problem; ub_j and lb_j are the upper and lower bounds of the jth

dimension variable, respectively; X_{ij} denotes the jth dimension variable for the ith sand cat; $i = 1, 2, \cdots, N$, $j = 1, 2, \cdots, D$.

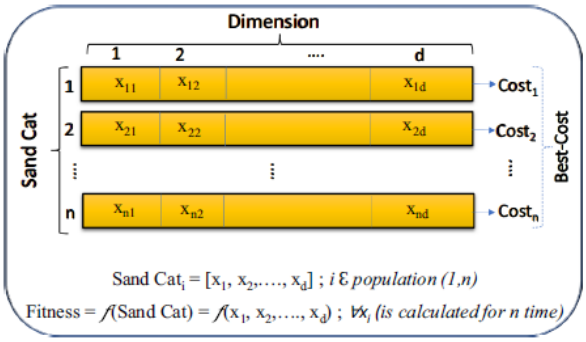

Fig. 15. Schematic diagram of the initialisation of the SCSO algorithm.

b) Parameter setting: The search for prey by sand cats relies on the release of low-frequency noise. R is used to control the search and attack phase of the sand cat swarm algorithm, which is mainly guided by the sand cat's sensitivity range r_G , which is calculated as follows:

$$R = 2 \cdot r_G \cdot rand - r_G \tag{2}$$

$$r_G = s_M - \left(\frac{s_M \cdot t}{T_{\max}} \right) \tag{3}$$

$$r = r_G \cdot rand \tag{4}$$

Among them, s_M indicates the auditory characteristics of sand cat, which is generally set to 2; t is the current iteration number; $T_{\max}$ is the maximum iteration number; the sensitivity range r_G decreases linearly from 2 to 0 with the increase of iteration number, so that the individual sand cat gradually approaches the prey it is searching for; r indicates the sensitivity of girl paper sand cat; rand is a random number.

c) Searching for prey: When $|R| > 1$, the sand cat starts searching for prey and keeps approaching to the prey based on the best candidate position in the current population $P_{bc}(t)$, the current position $P_c(t)$, the sensitivity range r and the random number of updated sand cat individuals. The specific update mathematical model is:

$$P(t+1) = r\left(P_{bc}(t) - rand \cdot P_c(t)\right) \tag{5}$$

d) Attacking prey: When $|R| \le 1$, the sand cat carries out the attack on the prey, based on the random position of the optimal position and the current position, and then randomly chooses the angle by roulette method to achieve the attack on the prey. The specific model is as follows:

$$p = \left| rand \cdot P_b(t) - P_c(t) \right| \tag{6}$$

$$P(t+1) = P_b(t) - r \cdot p \cdot \cos(\theta) \tag{7}$$

Assuming that the sand cat sensitivity range is a circle, the position is updated during the iteration process as shown in Fig. 16.

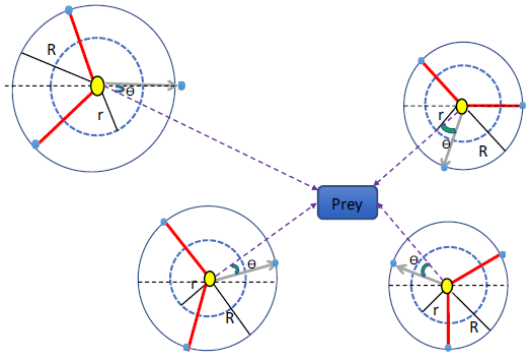

Fig. 16. Diagram of SCSO algorithm search

The optimization method of the SCSO algorithm is shown in Fig. 17, which displays the pseudo-code of the algorithm.

Algorithm 2: SCSO algorithm	
1	Initialize sand cat swarm population;
2	Initialize r, rG, R;
3	Calculate the fitness function based on the objective function;
4	While t<=Tmax
5	Get a random angle based on Roulette Wheel Selection;
6	If abs(R)<=1
7	Update search agent position based on searching prey strategy;
8	Else
9	Update search agent position based on attacking prey strategy;
10	End
11	t=t+1;
12	End

Fig. 17. Pseudo-code of the SCSO algorithm.

The SCSO method has been used in several domains, such as engineering optimization issues, multi-objective optimization problems, and particular data processing tasks like wind power data forecasting and load data forecasting [19-20] (Fig. 18). Researchers have empirically shown that the SCSO algorithm exhibits superior performance and competitiveness in addressing these issues.

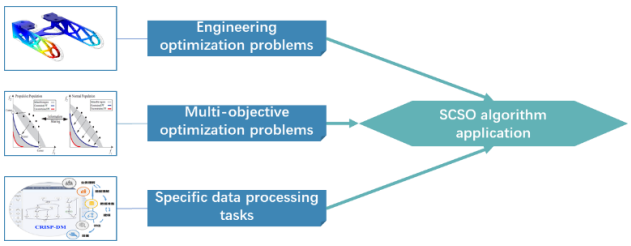

Fig. 18. Application of SCSO algorithm

4) SCSO-DBSCAN algorithm. To enhance the accuracy of clustering division for TCM health data, this part utilizes the SCSO algorithm to optimize the parameters of the DBSCAN clustering algorithm. The optimized method is then used for clustering analysis of TCM health data. The specific structure diagram is shown in Fig. 19. The DBSCAN clustering algorithm first processes the eps (ϵ-neighbourhood radius) and min_samples (minimum number of sample points) using the real number coding technique [21]. The fitness value function is then determined by calculating the distance of the data samples to the cluster center.

$$F\left(x,c_i\right)=\sqrt{\sum_{j=1}^{d}\left(x_j-c_{i,j}\right)^2} \tag{8}$$

where, X is the sample of TCM health data and c_i denotes the ith clustering centre.

According to the SCSO algorithm coding method and fitness value function, the specific pseudo-code of SCSO optimised DBSCAN clustering algorithm is shown in Fig. 20.

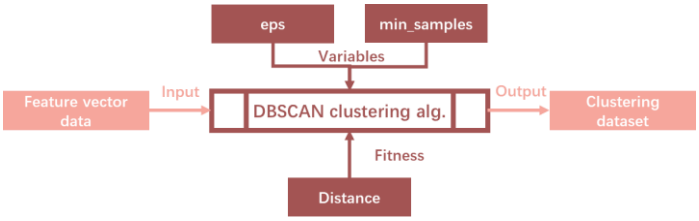

Fig. 19. Structure of the SCSO-DBSCAN algorithm

Algorithm 3: SCSO-DBSCAN clustering algorithm	
1	Determine optimized variables, including eps, min_samples;
2	Set SCSO algorithm parameters;
3	Encode sand cat population based on real number encoding method;
4	Calculate fitness using distance, and update best sand cat position;
5	While t<=Tmax
6	Get a random angle based on Roulette Wheel Selection;
7	Update sand cat position using searching and attacking prey strategies;
8	t=t+1;
9	End
10	Output best parameters of DBSCAN clustering algorithm;
11	Build SCSO-DBSCAN clustering algorithm.

Fig. 20. SCSO-DBSCAN algorithm pseudo-code.

B. TCM Health Data Clustering

In conjunction with SCSO-DBSCAN technology, this study suggests a clustering and division method for TCM health data that is based on the SCSO-DBSCAN model. Fig. 21 illustrates the process of application. The approach uses the TCM cultural communication image role product design issue analysis to extract the indicator feature vector. It then utilizes the SCSO-DBSCAN algorithm to cluster and categorize the TCM health data into healthy and unhealthy data.

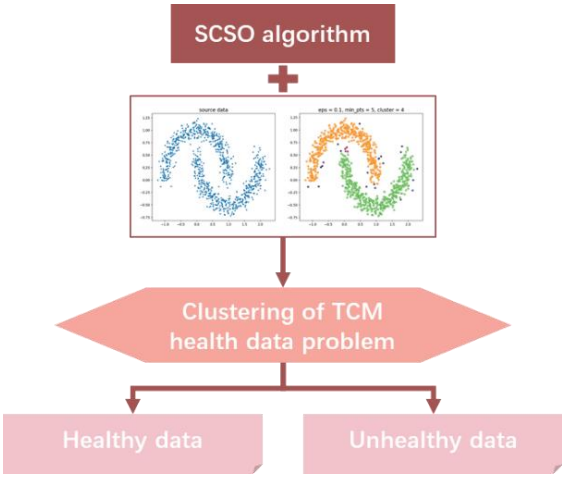

Fig. 21. Application of SCSO-DBSCAN algorithm in clustering and segmentation of TCM health data

IV. Data Dissemination Combined with ELM Models

A. ELM Modelling

1) Principles of the ELM model. ELM (Extreme Learning Machine) [22, 23] is a single hidden layer feed-forward neural network model, which is known for its fast learning ability and good generalisation performance. The core idea of ELM is to introduce random weights between the hidden layer and the output layer, and to achieve efficient training through the least-squares approximation method (Fig. 22). In the ELM model, the weights and biases of the hidden layer are randomly initialised and do not require iterative training like traditional neural networks, which greatly speeds up the training of the model. The weights of the output layer can be calculated by parsing formulae, which further simplifies the training process of the model.

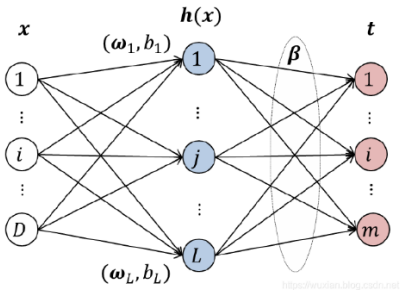

Fig. 22. ELM model structure.

2) ELM application analysis. ELM models have a wide range of applications in several fields, including but not limited to data regression prediction, classification tasks, signal processing, image recognition, financial prediction, medical diagnosis, etc [24] (Fig. 23). Due to its fast training and strong generalisation ability, ELM is particularly suitable for handling large-scale datasets and complex nonlinear problems.

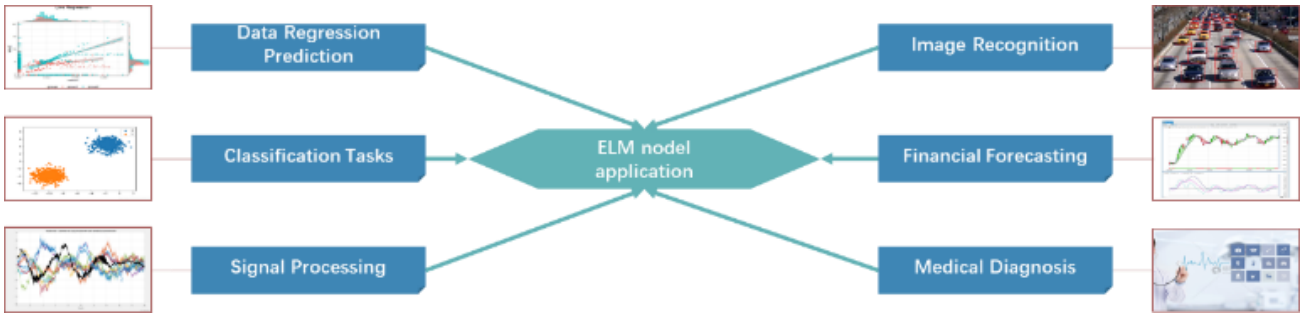

Fig. 23. Application of ELM in the dissemination of data classification of TCM culture.

B. Classification of Cultural Data Dissemination in TCM

In order to design TCM cultural communication image role products and improve the accuracy of TCM cultural data communication classification, this study proposes a TCM cultural data communication classification method based on the ELM model, and the specific application process is shown in Fig. 24. The method obtains the TCM cultural health communication classification model by learning to train the TCM cultural health dataset (which has been annotated), and constructing the mapping relationship between the TCM cultural communication feature values and the communication product types using the ELM model.

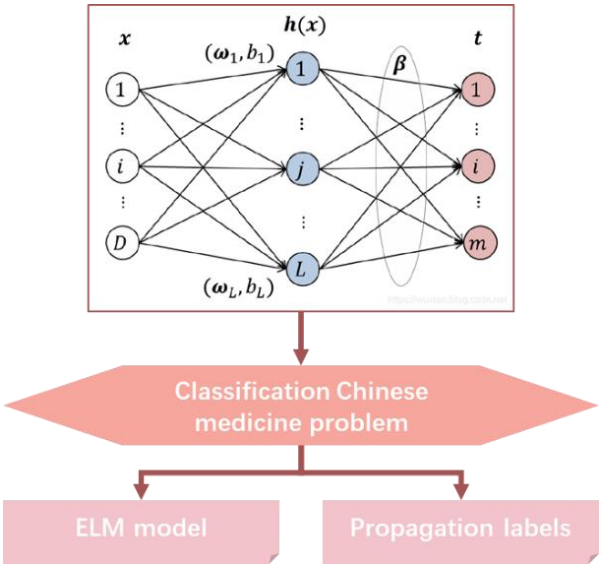

Fig. 24. Application of ELM in the dissemination of data classification of TCM culture

V. Verification Analysis

A. Experimental Setup

In order to verify, this study proposed TCM culture communication image role product design algorithm and application. This study experiments in the Win11 system environment running software Matlab2021a programming software on the literature [4] in the TCM data for clustering analysis and communication product classification model construction.

In the experiment of clustering division of TCM data, this study uses K-means [25], fuzzy clustering [26], Gaussian hybrid clustering [27], DBSCAN, and SCSO-DBSCAN clustering algorithms for comparative analysis, and the comparative algorithms' parameter settings are shown in Table I. The maximum number of iterations of the SCSO algorithm is 1,000, the number of populations is 100, and the range of the sensitivity is from 0 to 2. The stage control range is $[-2r_G, r_G]$.

TABLE I PARAMETER SETTINGS OF THE ALGORITHM FOR COMPARISON OF CLUSTERING AND SEGMENTATION OF TCM DATA

No.	*Clustering algorithm*	*Para. settings*
1	K-means	N_cluster=4
2	FCM	N_cluster=4
3	GMM	Means=0, STD=1, N_cluster=4
4	DBSCAN	Eps=0.5, Min_samples=5
5	SCSO- DBSCAN	No

In the classification experiment of TCM cultural data dissemination, SVM [28], BP [29], and ELM models are used for comparative analysis in this study. The number of hidden layers of the ELM model is 100, and the number of hidden layers of the BP network is 50.

In order to verify that the SCSO algorithm can improve the clustering delineation accuracy of TCM data based on the DBSCAN algorithm, this study adopts the SCSO algorithm to optimise the eps (ϵ-neighbourhood radius) and min_samples (the minimum number of sample points) of the DBSCAN clustering model, and the specific optimisation variable range is set as shown in Table II.

TABLE II DBSCAN CLUSTERING ALGORITHM TO OPTIMISE PARAMETER DECISION RANGE SETTING

No.	*Variables*	*Range settings*
1	Eps	[0.1, 0.9]
2	Min_samples	[2,10]

B. Analysis of Experimental Results of Clustering and Classification

In this study, K-means, fuzzy clustering (FCM), Gaussian mixture clustering (GMM), DBSCAN clustering, and SCSO-DBSCAN clustering algorithms are used to cluster and divide the TCM data, and the specific results of clustering and division are shown in Fig. 25 and Fig. 26.

Fig. 25 gives a comparison of the results of clustering delineation of TCM data with different clustering algorithms. In

Fig. 25, in terms of accuracy rate (ACC), the accuracy rate of TCM data clustering division based on SCSO-DBSCAN clustering algorithm is the highest, which is 0.876; in terms of true-positive rate (PP), the true-positive rate of TCM data clustering division based on SCSO-DBSCAN clustering algorithm is the highest, which is 0.971; and SCSO-DBSCAN clustering algorithm is the highest in terms of sensitivity (SEN) and F-score (F-Score) is the highest, 0.938 and 0.953, respectively.

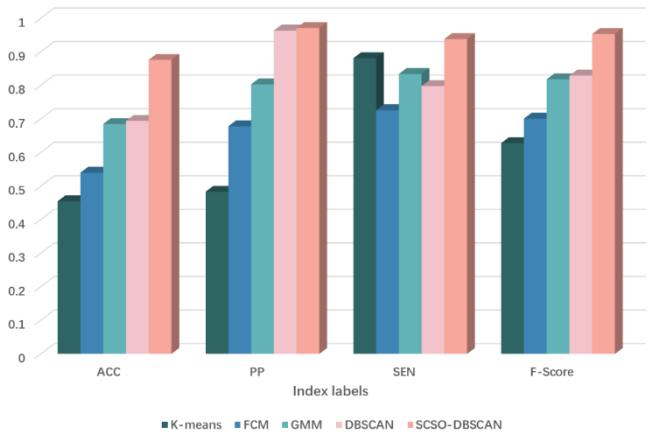

Fig. 25. Comparison of clustering results of different clustering algorithms for TCM data classification

The optimisation iteration curve of the SCSO optimisation algorithm for the DBSCAN clustering algorithm is given in Fig. 26. The SCSO algorithm optimises the DBSCAN clustering algorithm to converge at 800 iterations, converging to about 0.93.

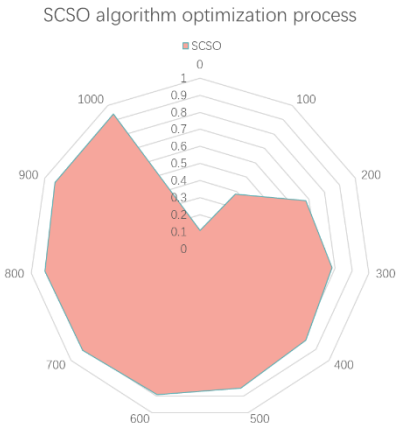

Fig. 26. Optimisation iteration process of SCSO optimisation algorithm for the DBSCAN clustering algorithm.

C. Analysis of the Results of the Experimental Classification

Taking the results of TCM data clustering division as the call-in, SVM, BP and ELM models were used to classify and predict the TCM cultural data dissemination, and the specific results are shown in Fig. 27 and Fig. 28.

Fig. 27 gives a comparison of the results of TCM cultural data dissemination with different classification models. In terms of precision, recall, and F1-score, the ELM model has the highest classification results, which are 0.9527, 0.9299, and 0.9411, respectively.

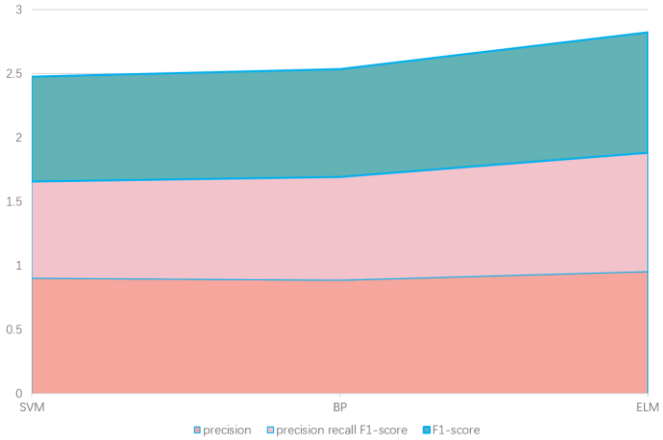

Fig. 27. Comparison of the results of different algorithms for the dissemination of TCM culture data

Fig. 28 gives a comparison of the time-consuming results of different algorithms for TCM cultural data dissemination. The time-consuming data dissemination of TCM culture based on the ELM model is the smallest, and the time-consuming data dissemination of TCM culture based on the BP model has the smallest variance.

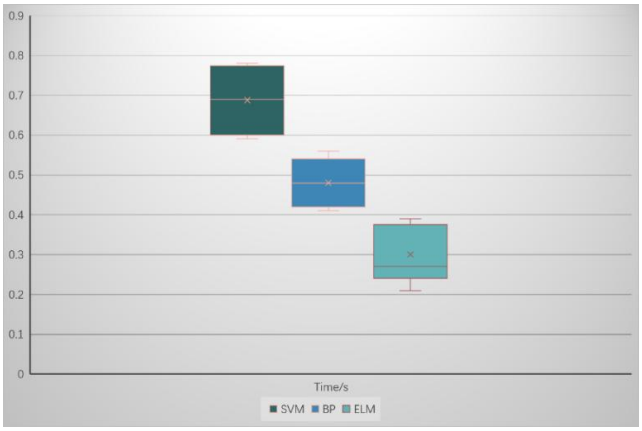

Fig. 28. Comparison of time-consuming results of different algorithms for TCM cultural data dissemination

VI. Conclusion

Aiming at the TCM cultural communication role product design problem, combining the SCSO-DBSCAN algorithm and ELM algorithm, this study proposes a TCM clustering division method based on the SCSO-DBSCAN algorithm and a TCM communication data dissemination classification method based on the ELM model. This method analyses the TCM cultural communication role product design problem, extracts the TCM cultural communication vector, takes the distance from data samples to the clustering centre as the fitness value function, and takes the eps (ϵ-neighbourhood radius) and min_samples (the minimum number of sample points) of the DBSCAN algorithm as the decision-making variant, and constructs the clustering delineation method based on the SCSO-DBSCAN algorithm for TCM; around the TCM clustering delineation results, using the

ELM model to construct classification model; using TCM culture data to validate the SCSO-DBSCAN algorithm and ELM algorithm for analysis. The experimental results show that the method proposed in this study can accurately classify the healthy and unhealthy data of TCM and can quickly and accurately classify the predicted communication products.

Chongqing Key Laboratory of Public Big Data Security Technology, Chongqing City, 401520, China

***Abstract*—The rapid development of the Internet of Things (IoT)-based Wireless Sensor Networks (WSNs) has fueled security challenges, necessitating efficient intrusion detection approaches. The computationally intensive nature and the high-dimension data preclude the direct employment of machine learning-based Intrusion Detection Systems (IDSs). This study introduces GOA-WO-ML, a robust IDS system that integrates the Gannet Optimization Algorithm (GOA) and Walrus Optimizer (WO) for feature selection and parameter tuning in machine learning algorithms. The system is tested on the NSL-KDD dataset, indicating better cyberattack detection performance. The experimental findings suggest that GOA-WO-ML improves intrusion detection accuracy, decreases false positives, and has low computational overhead compared to traditional methods. By adopting bio-inspired methods, the proposed system successfully counteracts security issues in IoT-WSNs through efficient surveillance. Future research directions include considering deep learning improvements and real-time deployment methods in dynamic environments for further intrusion detection performance.**

Keywords*—Internet of things; intrusion detection; machine learning; optimization

I. INTRODUCTION

The Internet of Things (IoT) and Wireless Sensor Networks (WSNs) have revolutionized many industries by allowing for easy communications and real-time data acquisition [1]. The networks comprise many connected devices used to monitor, control, and automate processes. The IoT-enabled WSNs are used in health, agriculture, smart cities, and environmental surveillance [2]. However, increased connectivity and the use of radio frequency communications make them susceptible to a broad variety of cyber-attacks, including unauthorized access, data manipulation, and denial-of-service attacks [3].

Intrusion Detection Systems (IDSs) are vital for protecting IoT-WSNs by detecting malicious behaviors in the network and initiating proper countermeasures. With growing IoT networks, the role of effective intrusion detection mechanisms gains significance [4]. A good IDS must recognize various real-time attacks while maintaining network security and firmness. Classical IDSs mostly depend upon preconfigured signatures or simple anomaly detection approaches. Such systems are mainly unable to keep pace with changing threats in dynamic and resource-limited environments such as IoT-WSNs [5].

The main problem in designing an IDS for IoT-WSNs is dealing with the high dimensionality of data in these networks [6]. The extensive network traffic data with high dimensionality demands sophisticated feature selection and optimization techniques. Moreover, conventional IDS methods are burdened by excessive false alarms, delayed detection, and ineffective parameter adjustment. ML has demonstrated the potential to overcome these challenges, but the workload remains a problem without optimization. Also, traditional optimization methods are not effective in dealing with the high-dimensional, noisy nature of data in IoT-WSNs, resulting in suboptimal outcomes.

In response to these challenges, we introduce a new hybrid IDS, GOA-WO-ML, integrating the Gannet Optimization Algorithm (GOA) and the Walrus Optimizer (WO) algorithms for effective feature selection and parameter adjustment in Machine Learning (ML) models. GOA is a bio-mimetic search algorithm based on the predation mechanism of the gannet [7], whereas the WO has mimicked the behavior of walruses [8]. Machine learning has demonstrated significant utility across diverse domains, including healthcare, agriculture, and economics, by uncovering patterns in high-dimensional data [9]. These capabilities are now being increasingly adopted to secure IoT environments through intelligent intrusion detection frameworks.

This system, leveraging the potential of GOA and WO, improves intrusion detection accuracy and minimizes false positives and computation complexities. We couple these optimization algorithms with a Support Vector Machine (SVM) classifier, guaranteeing top performance even in large, high-dimensional datasets such as NSL-KDD.

The remaining content of this paper is presented as follows. Section II reviews related research on intrusion detection in IoT-WSNs. Section III discusses the details of the proposed GOA-WO-ML system. The results section is given in Section IV and discussions comparing the efficiency of GOA-WO-ML with conventional IDS approaches are given in Section V. Section VI offers an in-depth discussion of the findings. The conclusion of this paper and research directions are given in Section VI.

II. RELATED WORK

Zhao, et al. [10] proposed a Network Intrusion Detection (NID) system for IoT based on a Lightweight Deep Neural Network (LDNN). They used dimension reduction with Principal Component Analysis (PCA) to overcome raw traffic

features limitations in high dimensions. The LNN contains a compressible and expanded design, residual inverse architecture, and shuffled channels for low-complexity feature extraction. They also proposed a novel NID loss function for imbalanced sample distribution multiclassification.

Gangula and V [11] proposed a network intrusion detection system utilizing the Improved Flower Pollination Algorithm (IFPA) and ensemble classification. Using a scaling factor for improved convergence, they employed IFPA to choose the best features from the NSL-KDD and UNSW-NB15 datasets. The features identified were passed through an ensemble classifier, where multiple models, random forest, decision trees, and SVM were combined.

Asgharzadeh, et al. [12] suggested a deep learning-based intrusion detection scheme for IoT devices through automatic feature extraction with Convolutional Neural Networks (CNNs). They employed a hybrid model, IoTFECNN, based on combining deep learning with a Binary Multi-objective Improved Capuchin Search Algorithm (BMECapSA) for feature selection.

Recent studies have explored the integration of vision transformers with convolutional architectures for more accurate and scalable classification tasks. For example, a fuzzy hybrid stacked ensemble combining ViTs and CNNs was proposed to detect defects in metal surfaces, demonstrating the effectiveness of hybrid deep learning approaches in real-time industrial environments [13].

Hanafi, et al. [14] developed a new intrusion detection system by utilizing an optimized Binary Golden Jackal Optimization (BGJO) algorithm, along with LSTM networks. The OBL was used to optimize the IBGJO for optimal feature selection and prevent local optima. The BGJO-LSTM model resulted in an accuracy of up to 98.2% for CICIDS2017 and NSL-KDD datasets. The results were more accurate than those of BGJO-LSTM and in contrast with other SVM-based methods.

Yang, et al. [15] developed a Lightweight Convolutional Neural Network (LSCNN) for detecting intrusions in the IoT, targeting high-dimensional data. They proposed a Data Purification Algorithm (DPA) to transform unstructured data into images, eliminate duplicate data, and enhance the performance of CNN. LSCNN, drawing from separate convolution, was more efficient in terms of time consumption and detecting intrusions.

Makhadmeh, et al. [16] introduced a novel network IDS, MPAC, derived from the Marine Predators Algorithm (MPA) augmented by a crossover operator. MPAC emphasizes effective feature selection by optimizing the most valuable features for NIDS. They showed MPAC's performance is better than that of alternative methods, with high accuracy in various datasets. The system reported strong results, performing better in detecting network attacks than various current models.

Shi, et al. [17] presented an ensemble system of intrusion detection for the security of IoTs based on an Enhanced Artificial Hummingbird Algorithm (EAHA). The system employed the binary version of EAHA (BEAHA) in feature selection and ensemble classifier design for intrusions in a network. The accuracy of their model, when validated through use with CSE-CIC-IDS2018, CIC-IDS2017, and NSL-KDD benchmark datasets performed well while reducing feature dimensionality by at least 69%, demonstrating efficiency as well as competitiveness.

Asif [18] proposed the OSEN-IoT, a stacked ensemble network for IoT, by utilizing multiple convolutional neural networks (DenseNet121, MobileNetV2, and ResNet50V2) in a stacking manner. The system is augmented by a channel and a spatial attention mechanism, and it was optimized by a genetic algorithm. OSEN-IoT achieved better performance with accuracy rates of 99.71% in Edge-IIoTset, 99.15% in UNSW-NB15, and other data sets, surpassing current deep learning approaches in cyber-threat detection.

TABLE I. RECENT INTRUSION DETECTION SYSTEMS FOR IOT NETWORKS

Reference	Key techniques	Datasets	Accuracy	Shortcoming
[10]	Lightweight deep neural network and PCA for feature reduction	UNSW-NB15 and Bot-IoT	96.15 and 86.11	The model is computationally intensive and may overfit on small datasets.
[11]	Enhanced flower pollination algorithm and ensemble classifier	UNSW-NB15 and NSL-KDD	99.32% and 99.67%	The ensemble approach is complex and may struggle with feature selection flexibility.
[12]	Convolutional neural networks and enhanced capuchin search algorithm	TON-IoT and NSL-KDD	99.99% and 99.85%	The model consumes high resources and has slow training times.
[14]	Binary golden jackal optimization and LSTM	NSL-KDD and CICIDS2017	98.21% and 99.25	Sensitive to class imbalances and requires intricate parameter tuning.
[15]	Lightweight CNN and data purification algorithm	AWID and NSL-KDD	91.7 % and 85.13%	May not generalize well to unseen attack types and is computationally complex.
[16]	Marine predators algorithm with crossover operator	NSL-KDD, UNSW-NB15, Bot-IoT2018, and CICIDS2017	99.58%, 98.98%, 99.98%, 97.67%	The method may converge to local optima and demands extensive computational resources.
[17]	Artificial hummingbird algorithm and ensemble classifier	NSL-KDD, CIC-IDS2017, and CSE-CIC-IDS2018	99.74%, 99.59%, and 98.51%	The method can suffer from overfitting on large datasets and has slower convergence.
[18]	Stacked ensemble CNN and genetic algorithm	Edge-IIoTset, UNSW-NB15, and IoT_Malware	99.71%, 99.15%, and 96.17%	The model is computationally expensive and may not scale efficiently for larger datasets.

The current approaches are primarily based on traditional ML methods or sophisticated deep learning approaches, not optimizing feature selection and model complexity for IoT-WSNs. Based on the observations in Table I, most methods aim to improve performance with large-sized models, which are inappropriate for the resource-limited environment of IoT devices. Moreover, most traditional methods do not handle high-dimensional, noisy data, resulting in suboptimum performance.

There is also a demand for efficient real-time detection methods, maintaining a trade-off between accuracy, efficiency, and computational overhead.

Our GOA-WO-ML framework fills all these gaps by integrating the GOA and WO, which are superior in exploration and exploitation for feature selection and parameter adjustment. Our hybrid solution balances high detection accuracy with low computational complexity, better fitting the environment of the IoT. Our system is capable of performing well under real-time conditions, thereby helping develop intrusion detection methods for IoT-enabled WSNs.

III. Proposed Intrusion Detection System

Hybrid metaheuristic algorithms have proven effective in addressing complex optimization problems in smart grids and energy systems [19]. Inspired by such advances, the present study proposes a new, automated GOA-WO-ML technique involving the combination of GOA with ML to ensure effective intrusion detection in the domain of IoT-integrated WSNs. The GOA-WO-ML methodology uses nature-based optimization techniques, GOA, and ML to design a robust and reliable IDS for IoT-WSNs.

This study plans to secure the WSN-IoT systems by utilizing the GOA-WO-ML methodology to detect intrusions promptly. The mechanism streamlines the intrusion detection process while ensuring efficient detection and dependability, thereby maintaining data and device integrity in the network. The method generally contributes to detecting intrusions, effectively solving the security issues introduced by the ubiquitous and widely dispersed characteristics of IoT and WSN equipment.

GOA-WO-ML enables accurate differentiation between multiple cyberattacks, thereby enhancing WSN-IoT security. The process comprises four major steps: data scaling, selecting GOA features, classification with ML, and parameter tuning utilizing WO. Fig. 1 illustrates the framework for detecting threats and upgrading security in the WSN-IoT environment.

The initial step in GOA-WO-ML is data standardization, in which the values are equivalent to a predefined range. This standardization helps keep the weighted summation of inputs within the limits in model initialization. In some cases, it can lead to inefficient training and slower convergence when data is not scaled appropriately. On the other hand, data scaling decreases dimensionality, thus enabling faster processing. Eq. (1) is employed, in which data is scaled by mapping it between zero and one.

$$Z_{norm} = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

Where Z_{norm} represents the scaled data, x is the original value, x_{max} is the maximum value, and x_{min} is the minimum value used for scaling.

GOA is used to select the most applicable features in the intrusion detection mechanism for IoT-enabled WSNs. Its motivation comes from the diving nature of gannets, which plunge from a great height to catch prey in the water. This nature-inspired behavior is mimicked for searching and exploring feature space in optimal feature selection. The process starts with creating a first population of solutions, in which every solution contains a set of feature subsets in the search space. The solutions are initialized at random. The locations of the individuals in the population are stored in a matrix, as in Eq. (2).

$$X = \begin{bmatrix} x_{1,1} & \cdots & x_{1,Dim1} & x_{1,Dim-1} \\ x_{2,1} & \cdots & x_{2,Dim-1} & x_{2,Dim} \\ \vdots & \ddots & \vdots & \vdots \\ x_{N,1} & \cdots & x_{N,Dim-1} & x_{N,Dim} \end{bmatrix} \quad (2)$$

Where x_i denotes the position of the i^{th} individual, and each element $x_{i,j}$ in the matrix X is calculated using Eq. (3).

$$x_{i,j} = r_1 \times \left(UB_j - LB_j\right) + LB \quad (3)$$

Where UB_j and LB_j are the upper and lower bounds for the j^{th} dimension of the problem, respectively, N represents the number of individuals in the population, Dim refers to the dimensional size of the problem, and r_1 is a random number between 0 and 1.

A memory matrix MX is also introduced, in which the best positions of the individuals during the optimization process are stored. The memory matrix plays a central role in retaining the optimum solutions in memory for future iterations. The memory matrix is refreshed after each evolution step by calculating the fitness value of each individual. For each candidate solution, whenever it is better, it replaces the incumbent solution in the memory matrix with its position. Otherwise, the solution from the current matrix is retained.

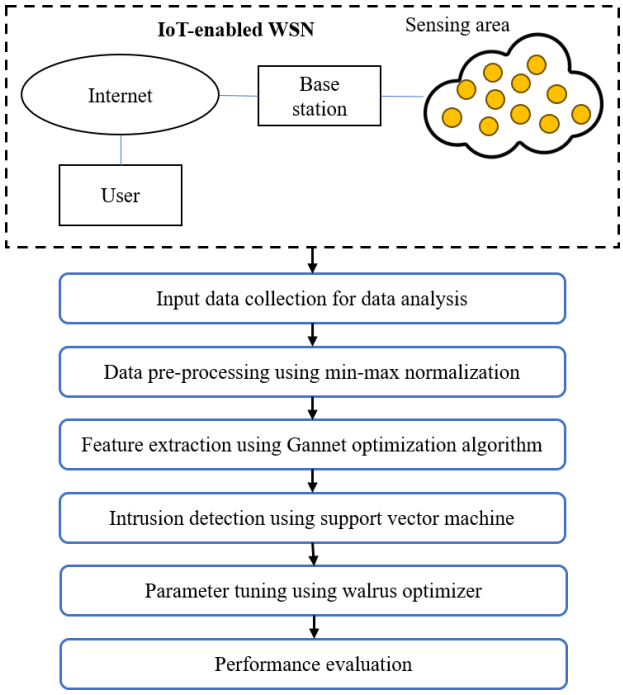

Fig. 1. Workflow of the GOA-WO-ML methodology.

The second step is exploring the feature space by the two dive strategies motivated by gannets: the U-shaped dive, also known as the plunge dive, and the V-shaped dive. As shown in Fig. 2, these strategies lead the search process, in which the U-shaped dive corresponds to long-range, deep exploration, while

the V-shaped dive represents a concentrated, shallow search. The U-shaped dive is controlled by Eq. (4) and Eq. (5).

$$\alpha = 2.\cos(2.\pi.r_2).t \quad (4)$$

$$b = 2.\sqrt{2.\pi.r_3}.t \quad (5)$$

Where r_2 and r_3 are random numbers between 0 and 1, and t is the iteration count. These calculations help determine the trajectory of the dive, simulating the search behavior of gannets. For the V-shaped dive, the update is more localized, given in Eq. (6).

$$V(x) = \begin{cases} -\frac{1}{\pi}.x + 1, & if\ x \in (0, \pi) \\ \frac{1}{\pi}.x - 1, & if\ x \in (\pi, 2\pi) \end{cases} \quad (6)$$

In this case, the algorithm uses the V-shaped dive to narrow down the search space, focusing more precisely on potential solutions. Once the exploration phase identifies promising solutions, the exploitation phase begins. Here, the position of each individual is refined based on the best-performing solution so far, represented as X_{Best}, and the average position of all individuals in the population, X_m. The update is performed using Eq. (7).

$$MX_i(t+1) = \begin{cases} X_i(t) + \beta 1 + \beta 2, & q \geq 0.5 \\ X_i(t) + \upsilon 1 + \upsilon 2, & q < 0.5 \end{cases} \quad (7)$$

Where q is a random number used to choose between the two dive strategies. The variables $\beta 1$ and $\upsilon 2$ are calculated using Eq. (8) and Eq. (9).

$$\beta 2 = A.(X_i(t) - X_r) \quad (8)$$

$$\upsilon 2 = B.(X_i(t) - X_m) \quad (9)$$

Where A and B are scaling factors defined by Eq. (8) and Eq. (9).

$$A = (2.r_4 - 1).\alpha \quad (8)$$

$$B = (2.r_5 - 1).b \quad (9)$$

These position updates guide the algorithm towards more optimal feature sets by refining the current solutions. The parameter values r_4 and r_5 are random values between 0 and 1, ensuring a stochastic search.

In the exploitation phase, the GOA adjusts the position of each individual solution based on the best-performing solution found so far (X_{Best}) and the average position of all individuals. The position update is based on a random selection of exploration or exploitation strategies using a random number q. The update rule is as follows:

$$MX_i(t+1) = \begin{cases} X_i(t) + \delta.\left(X_i(t) - X_{Best}(t)\right) + \\ X_i(t), \quad if\ Capturability \geq c \\ X_B(t) - \left(X_i(t) - X_{Best}(t)\right). \\ P.t, \quad if\ Capturability < c \end{cases} \quad (10)$$

Where P is the Levy flight function and δ is computed based on capturability, calculated using Eq. (11).

$$\delta = Capturability.|X_i(t) - X_{Best}(t)| \quad (11)$$

The Levy flight is used to refine the search and help escape local optima by introducing randomness into the search process, calculated as follows:

$$P = Levy(Dim) = 0.01 \times \frac{\mu.\sigma}{|\upsilon|^{\frac{1}{\beta}}} \quad (12)$$

Where μ and σ are random values between 0 and 1, and β = 1.5 β=1.5 is a pre-determined constant. Additionally, the scaling factor σ is defined using Eq. (13).

$$\sigma = \left(\frac{\Gamma(1+\beta) \times \sin\left(\frac{\pi\beta}{2}\right)}{\Gamma\left(\frac{1+\beta}{2}\right) \times \beta \times 2^{\left(\frac{\beta-1}{2}\right)}} \right)^{\frac{1}{\beta}} \quad (13)$$

The capturability metric determines whether the algorithm can effectively catch the optimal feature subset, calculated as follows:

$$Capturability = \frac{1}{R.t_2} \quad (14)$$

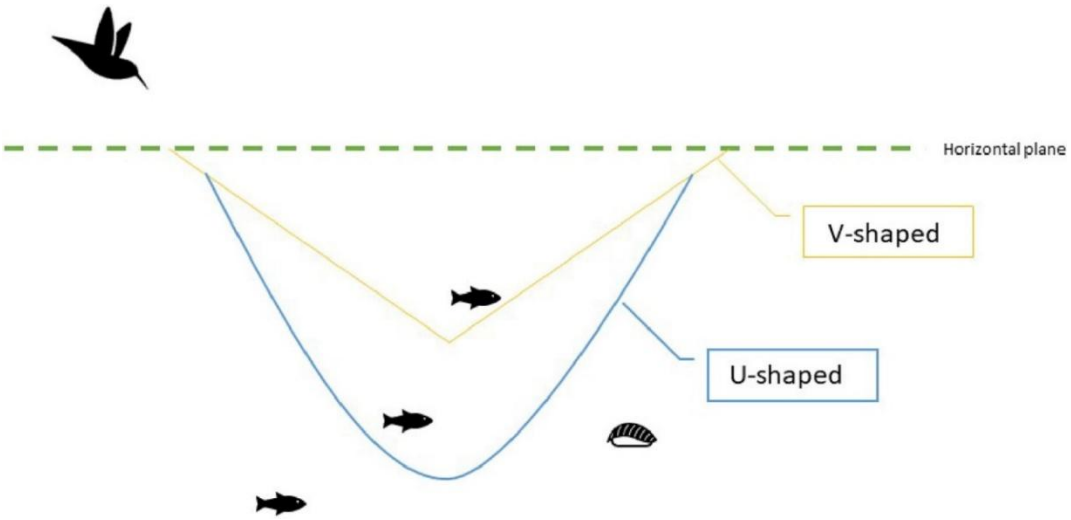

Fig. 2. Exploration strategies in GOA-WO-ML.

Where R represents the energy required to catch the optimal feature subset, and t_2 adjusts based on the time spent during the optimization process. This ensures that the algorithm refines its search for the most relevant features as the optimization progresses, ultimately converging on an optimal feature subset.

Algorithm 1 presents the pseudocode of the GOA. The GOA keeps refining the solutions until the stopping conditions are achieved, usually when the solution converges or the maximum iterations are reached. The optimal solution for intrusion detection in IoT-WSNs is represented by the feature subset thus selected. Overall, GOA-based feature selection judiciously balances exploration with exploitation to identify the best features for intrusion detection. Modeling the foraging behavior of the gannet, the algorithm successfully narrows the feature set while making detection more accurate, keeping costs low.

Algorithm 1 Pseudocode of GOA

Inputs: population size (N), dimensionality of the problem (Dim), and the maximum iteration count ($T_{\max\_iter}$).

Outputs: The optimal solution (location of the gannet) and its associated fitness score.

Random initialization:

Initialize the population of solutions X randomly. Each solution X_i is assigned values within the bounds of the problem as specified in Eq. 2.

Memory matrix setup:

Create an auxiliary matrix MX to store the best solutions encountered during the optimization process.

Fitness evaluation:

Compute the fitness values for all solutions in the population.

Optimization loop:

Repeat the following steps until the maximum number of iterations is reached:

Decision between exploration and exploitation:

A random number $rand$ is generated.

If $rand$ > 0.5, proceed with the exploration strategy; otherwise, exploit the best solutions.

Exploration phase:

For each solution in the memory matrix MX:

If $q \geq 0.5$, update the position using Eq. 7a to explore the feature space.

If $q < 0.5$, update the position using Eq. 7b for a different exploration pattern.

Exploitation phase:

For each solution in the memory matrix MX:

If the capturability value exceeds a threshold, update the solution using Eq. 10a to exploit the current best solutions.

Otherwise, use Eq. 10b to perform a less aggressive exploitation.

Memory update:

After calculating the fitness of all solutions in MX, compare them with the corresponding solutions in X.

If a solution in MX outperforms its counterpart in X, replace the corresponding solution in X with the one from MX.

Termination:

End the optimization process when the stopping condition is fulfilled.

Intrusion detection in WSN-IoT systems takes advantage of the SVM classifier and parameter optimization through optimization algorithms. The GOA is employed for feature selection optimization and bias, while the WO is used to fine-tune the SVM parameters to enhance classifying performance.

To begin, we assume an input vector $x = [x_1, x_2, \dots, x_n]$, where the network contains M neurons in the hidden layer. The weighted sum of inputs for each neuron in the hidden layer is calculated using Eq. (15).

$$z_i = \sum_{j=1}^{M} w_{ij}.x_j + b_i \tag{15}$$

Where w_{ij} represents the weight from the input x_j to the neuron in hidden layer i, and b_i denotes the hidden neuron's bias.

A non-linear activation function is applied to the weighted sum of each hidden neuron, with the tanh function being one possible example:

$$h_i = activation(z_i) \tag{16}$$

For each output neuron k, a weighted sum of the hidden layer outputs is computed:

$$y_k = \sum_{i=1}^{M} v_{ki}.h_i + c_k \tag{17}$$

Where v_{ki} is the weight from the i^{th} hidden neuron to the k^{th} output neuron, and c_k is the bias term for the k^{th} output neuron.

The final output is obtained by applying the activation function to the weighted sum of the outputs from each output neuron:

$$y_k = activation(y_k) \tag{18}$$

GOA is used for feature selection and bias terms in SVM optimization. GOA replicates the predatory nature of gannets and is employed to determine the most informative features from a big dataset, thereby decreasing feature space while ensuring better computational efficiency. GOA conducts exploration and exploitation in feature space by applying a blend of random search methods and iterative refining. The optimization allows the most valuable features to be selected for training SVM, thereby improving the accuracy and efficiency of the model.

Subsequent SVM parameter tuning is performed by utilizing the WO. The WO performs excellently in global optimization problems by iteratively traversing the solution space, searching for close-to-optimum SVM parameter configurations. The algorithm fine-tunes the SVM's parameters, including the penalty term C and the kernel coefficients, in a search for the highest attainable classification accuracy.

The integrated system is a good and effective alternative for detecting intrusion in IoT-based WSNs by utilizing GOA for feature selection and WO for parameter tuning. The mechanism proposed by the authors maintains computations while ensuring good performance in terms of classification.

The weight terms w_{ij} and v_{ki}, as well as the biases b_i and c_k, are updated using gradient descent. The GOA helps identify the most relevant features from the input data, while WO ensures that the SVM's hyperparameters are optimized for the best performance. This combined approach leads to a more efficient and accurate intrusion detection model capable of identifying potential threats in IoT-WSNs with minimal computational overhead.

IV. RESULTS

This section introduces the performance evaluation of GOA-WO-ML in terms of intrusion detection when used in the NSL-KDD dataset, which has 149,000 records belonging to two classes detailed in Table II. The GOA-WO-ML model was executed by using the Scikit-Learn program on a computer with primary hyperparameters specified as follows: learning rate of 0.01, batch size of 32, dropout rate of 0.2, Tanh activation function, and number of epochs of 60.

TABLE II. DISTRIBUTION OF SAMPLES IN THE NSL-KDD DATASET

Category	Type of attack	Sample distribution
Attack traffic	Remote to Local (R2L)	Training: 1,240
		Test: 3,023
	Probing Attack (PA)	Training: 2,636
		Test: 5,883
	User to Root (U2R)	Training: 53
		Test: 227
	Denial of Service (DoS)	Training: 45,967
		Test: 11,963
Normal traffic	Normal	Training: 67,344
		Test: 10,664
Total samples		149,000
		Training: 117,240
		Test: 31,760

During evaluation of intrusion detection systems such as GOA-WO-ML, the model's performance should be measured in terms of several metrics to validate its performance across various detection dimensions. The metrics used are Area Under Curve (AUC), F1-score, specificity, sensitivity, and accuracy, each of which can offer distinct insights into model performance.

Accuracy is defined as the number of correct predictions (both true positives and true negatives) divided by the total number of predictions. It is a broad criterion for the performance of the model, indicating the frequency with which the model classifies the samples appropriately.

$$Accuracy=\frac{TP+TN}{TP+TN+FP+FN} \tag{19}$$

Where TP stands for true positives (correctly identified attacks), TN refers to true negatives (correctly identified normal samples), FP denotes false positives (normal samples incorrectly identified as attacks), and FN outlines false negatives (attacks incorrectly identified as normal).

Sensitivity, also known as recall or true positive rate, calculates the model's performance in identifying the attack samples (the true positives) against all the actual positives. It is a crucial metric in intrusion detection since a highly sensitive model guarantees a substantial proportion of the attacks are detected, avoiding attacks that might go unnoticed.

$$Sensitivity=\frac{TP}{TP+FN} \tag{20}$$

Specificity is the complement of sensitivity and measures how well the model can accurately label normal traffic (true negatives) from all real negative samples. This metric is beneficial in cases where false positives are costly, as it reduces the number of standard samples flagged incorrectly as attacks.

$$Specificity=\frac{TN}{TN+FP} \tag{21}$$

F1-score is the harmonic mean of recall and precision. It balances the trade-off between recall and precision, giving a single value for a model's performance when it considers false positives and false negatives. The F1-score is particularly useful when working with imbalanced sets, as it considers both recall and precision, not giving preference to either.

$$F1-score=2\times\frac{Precision\times Sensitivity}{Precision+Sensitivity} \tag{22}$$

$$Precision=\frac{TP}{TP+FP} \tag{23}$$

$$Sensitivity=\frac{TP}{TP+FN} \tag{24}$$

AUC refers to the area under the receiver operating characteristic curve. It is a metric of the overall performance of a binary classifier, indicating how well the model separates the classes. The AUC value is between 0 and 1, with a higher value near 1 representing good model performance. The higher the AUC, the better the model can separate normal from attacking traffic.

$$AUC=\int_0^1 Sensitivity(1-Specificity)dx \tag{25}$$

The metrics for evaluation of the GOA-WO-ML are given in Table III, with 80% of the data used for training, and Table IV shows metrics with 20% testing. The metrics show GOA-WO-ML's success at detecting threats in WSN-IoT environments. Fig. 3 demonstrates the performance of GOA-WO-ML trained with 80% of the dataset against the rest, i.e., 20%.

TABLE III. PERFORMANCE EVALUATION OF THE GOA-WO-ML METHOD WITH 80% TRAINING DATA

Attack types	AUC	F1-score	Specificity	Sensitivity	Accuracy
PA	98.35	95.82	99.63	97.76	99.33

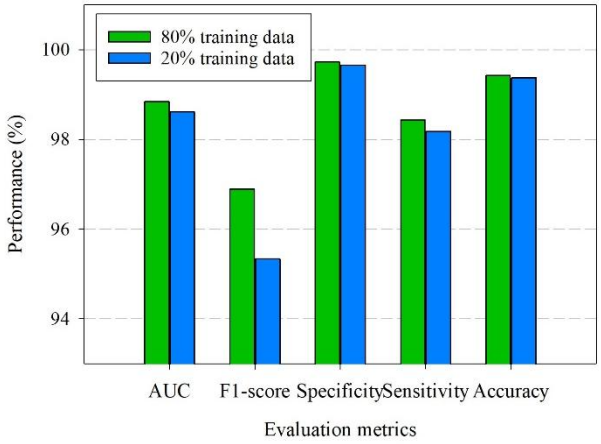

Fig. 3. Comparison of evaluation metrics for 80% training and 20% testing data sets.

Table V presents the performance metrics from 90% of the data used in training, while Table VI contains the metrics from the data set used in testing. The results further prove the reliability of the GOA-WO-ML model in real-life intrusion detection. The results of the GOA-WO-ML model trained with a 90% dataset are presented in Fig. 4 when tested with a dataset of 10%.

Fig. 5 depicts the GOA-WO-ML model's training and validation accuracy. Both values rise with time, implying that the model improves over time. The rising training accuracy suggests that the model is learning well from training data, while the increasing validation accuracy indicates its superior capability of generalizing well to unseen data, also showing the model's strength.

TABLE V. PERFORMANCE EVALUATION OF THE GOA-WO-ML METHOD WITH 90% TRAINING DATA

TABLE VIII. COMPUTATION TIME OF GOA-WO-ML OVER OTHER METHODS

Methods	Time (Sec)
KNN-PSO	13.82
XGBoost	10.31
ALO	14.62
Random forest	12.34
LightGBM	15.41
GOA-WO-ML	7.25

Finally, Table VIII and Fig. 8 compare GOA-WO-ML's computational time with other algorithms. Experimental data shows GOA-WO-ML has a computation time of 7.25 seconds. This is evidence of the GOA-WO-ML technique's efficiency, qualifying it for real-time recognition of intrusions in WSN-IoT systems. The results confirm that combining GOA for feature selection with WO for parameter adjustment can significantly enhance the accuracy and efficiency of the intrusion detection system. GOA-WO-ML is a highly reliable and robust framework for detecting intrusions in the WSN-IoT system.

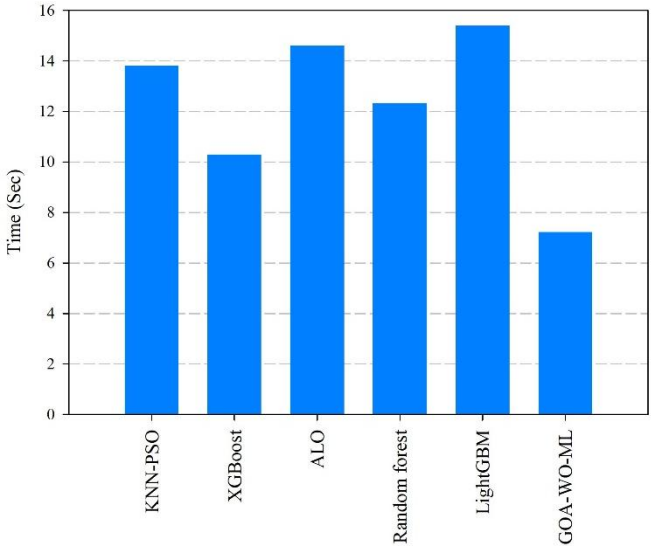

Fig. 8. Computation time of GOA-WO-ML over other methods.

V. DISCUSSION

The experimental outcomes of the GOA-WO-ML model underscore its effectiveness in addressing key challenges associated with intrusion detection in IoT-enabled Wireless Sensor Networks. The observed performance, across various training/testing splits, confirms the robustness of the hybrid feature selection and parameter optimization strategy. Notably, the model demonstrates high classification accuracy, low false positive rates, and minimized computational time, which are critical in constrained IoT environments.

The integration of the GOA and WO proved particularly beneficial in handling high-dimensional network traffic data. GOA's ability to efficiently explore the feature space reduced the dimensionality of input data, while WO effectively tuned the SVM classifier's hyperparameters to maximize detection performance. This hybrid approach not only enhanced accuracy but also contributed to a significant reduction in training loss and validation loss.

Compared to prior studies, GOA-WO-ML achieved competitive or superior results with less computational overhead. For instance, while ensemble models like OSEN-IoT or deep learning frameworks such as IoTFECNN demonstrated high accuracy, they often incurred high computational costs or suffered from overfitting on small datasets. In contrast, GOA-WO-ML balances detection performance and computational efficiency, making it more suitable for real-time deployment in lightweight IoT devices.

However, it is important to acknowledge the limitation related to the dataset used in this study. The NSL-KDD dataset, although widely used and improved over the original KDD'99, was collected over a decade ago and lacks representation of modern, sophisticated attack vectors. Its continued use is justified in part by its structured format, benchmark status, and extensive prior utilization that facilitates comparative evaluation. Nevertheless, the evolving nature of cyber threats, especially in IoT contexts, necessitates validation on more recent and complex datasets to ensure broader applicability.

To enhance the relevance and applicability of future research, we recommend extending the evaluation of GOA-WO-ML using contemporary datasets such as CSE-CIC-IDS2018, CIC-DDoS2019, and Edge-IIoTset. These datasets incorporate diverse and modern intrusion types, emulate realistic IoT scenarios, and reflect the dynamic behaviors of current network environments. Incorporating them would enable further validation of GOA-WO-ML's scalability, adaptability, and resilience against emerging threats.

VI. CONCLUSION

In this paper, we introduced the GOA-WO-ML method to detect intrusions in WSN-IoT systems, integrating feature selection through GOA with WO for parameter tuning in an ML environment. The combination of the optimization methods with a ML classifier, in this case SVM, improved the detection efficacy while reducing the cost of computations. The GOA-WO-ML performance was explored in the NSL-KDD dataset, with extensive experiments across varied training and testing splits. The experiments confirmed the better accuracy, sensitivity, specificity, F1-score, and AUC performance of the model when it outperformed traditional approaches in terms of accuracy, sensitivity, specificity, F1-score, and AUC, thus proving effectual in identifying intrusions in IoT-enabled wireless sensor network.

Along with performance, GOA-WO-ML was highly computationally efficient, running the task in appreciably lower computational time than alternative procedures at a processing time of 7.25 seconds. This renders GOA-WO-ML a high-performance solution and a scalable, efficient, real-time intrusion detection procedure. Future research can involve expanding the introduced method for more sophisticated attack cases, performing performance testing with real-time IoT data, and studying the integration of deep learning methods to further improve detection accuracy. Real-time deployment and online learning can also be investigated to adapt to changing network environments and new attack trends. GOA-WO-ML has a solid basis for accurate vulnerability identification in WSN-IoT architectures, qualifying it as a plausible solution for ensuring the security of IoT-based systems and applications.

Efficient Task Allocation in Internet of Things Using Lévy Flight-Driven Walrus Optimization

Yaozhi CHEN
Sichuan Vocational and Technical College, Suining 629000, China

***Abstract*—The rapid growth of the Internet of Things (IoT) has presented a significant challenge in efficiently managing energy-aware task distribution over heterogeneous devices. Optimizing the efficient use of resources in terms of energy consumption is critical when considering IoT device resource-constrained environments. This study proposes a new IoT task distribution resolution mechanism using an Enhanced Walrus Optimization Algorithm (EWOA). EWOA incorporates sophisticated techniques, such as Lévy flight processes and augmented exploration-exploitation, and thus is best suited to complex and dynamic IoT environments. This study proposes an EWOA to assign effective tasks considering device capability compatibility and reduced energy consumption. Simulations over benchmark IoT scenarios validate that the EWOA outperforms current approaches in terms of efficiency in terms of energy consumption, convergence, and robustness. In conclusion, improvements in minimizing energy consumption, enhancing task execution performance, and efficient use of resources in IoT networks have been emphasized significantly. In this work, the EWOA was proven to be an effective tool for IoT NP-hard optimization problem resolution and opens doors for future work in utilizing sophisticated metaheuristic algorithms for use in energy-constrained environments.**

I. INTRODUCTION

The Internet of Things (IoT) is a new technology model providing unimpeded connectivity between various smart gadgets [1]. The interconnected IoT environment comprises sensors, controllers, cameras, alarm panels, smart street lights, IP television, public addresses, and Programmable Logic Controllers (PLC) [2]. IoT enables real-time observation, management, and automation, enhancing security, efficiency, and living standards [3]. There are plenty of real-world implementations of IoT platforms, including smart healthcare [4], intelligent streetlights [5], video observation networks [6], and Supervisory Control And Data Acquisition (SCADA) networks [7].

Moreover, IoT forms the technological backbone of emerging domains such as FinTech, where the integration of real-time connectivity and blockchain technologies is accelerating financial innovation and global adoption [8]. Likewise, security remains a critical concern in IoT-enabled mobile and social networks, where intrusion detection systems (IDS) have been proposed to monitor communication patterns and ensure the integrity of distributed ad hoc environments [9]. As the volume of raw data generated by IoT devices grows, efficient transmission and processing through edge or cloud platforms become essential for real-time responsiveness and sustainable system performance [10].

IoT networks feature a variety of interconnected heterogeneous capabilities in distributed environments [11]. Nevertheless, one of the key challenges in such networks lies in resource constraints, specifically energy shortages. Most IoT entities, including wireless sensor nodes, are powered by batteries and have considerable energy limitations [12]. Minimizing energy consumption during data transmission, computation, and executing activities is imperative for extending network operational life. The importance of intelligent, resource-efficient processing is further emphasized in industrial domains such as smart manufacturing, where deep learning-based systems, like hybrid ensembles of vision transformers and convolutional neural networks have been employed to reduce waste and improve efficiency in steel surface defect detection [13, 14].

One effective mechanism for countering such energy constraints is to allow collaboration in scheduling, where network entities make efficient use of computational capabilities [15, 16]. Nevertheless, IoT scheduling is a challenging problem given the device homogeneity, workloads, and the efficient use of communication channels [17]. With their dynamic nature, IoT environments make such a problem even more challenging; therefore, developing smart scheduling techniques for efficient use of resources and minimizing energy consumption is imperative for an efficient IoT environment [18, 19].

This need is echoed in environmental monitoring applications, where real-time systems must integrate heterogeneous spatiotemporal data for emissions tracking, such as methane leakage in the energy sector. Recent work highlights how data alignment, fusion, and resolution integrity challenges can be addressed through advanced analytics and visualization techniques, reinforcing the role of intelligent scheduling and data-driven decision-making in complex IoT systems [20]. This paper proposes an Enhanced Walrus Optimization Algorithm (EWOA) to resolve the IoT scenario energy efficient scheduling issue. The key contribution of this work is:

- We develop an optimization model that leverages EWO to enhance task scheduling and conserve energy in IoT environments with limited resources.
- We integrate a Lévy flight and adaptive search mechanisms with EWO to enhance its convergence velocity and avert early stagnation in local optima.
- A comprehensive performance analysis is conducted through simulations in MATLAB, comparing EWO with

WOA, PSO, and GA inefficiency in terms of energy, processing time, and network steadiness.

The remainder of this paper is organized as follows. Section II summarizes relevant research on IoT task scheduling. Section III presents the problem statement, IoT task scheduling model, constraints, and objective function. Section IV details the proposed algorithm. Section V outlines and discusses simulation results. Section VI comprehensively discusses the findings, their implications, and comparisons with existing work. Section VII concludes the paper with key observations and presents future research directions.

II. Related Work

Weikert, et al. [21] proposed a multi-objective scheduling algorithm for IoT network failures, including communication loss, battery depletion, and device failure. An archive-selection mechanism was included for search-space diversity, offering reliable alternative mappings in the case of failure. Performance evaluation via a network simulation model revealed that MOTA maximizes network life, reduces latency, and maximizes availability.

Ren, et al. [22] combined Simulated Annealing (SA) and Particle Swarm Optimization (PSO) algorithms for IoT environments' NP-hard problem of scheduling tasks. PSO's problem of getting trapped in a local optimum is avoided in the proposed scheme by leveraging the SA's feature of exploration. Simulations in MATLAB have proven that the proposed scheme is better than traditional PSO and SA-based approaches in terms of increased efficiency in task execution and optimized consumption of resources in IoT networks.

Bali, et al. [23] incorporated an Artificial Bee Colony (ABC) with the Whale Optimization Algorithm (WOA) to counter ABC's early convergence problem with the Employee Bee and Onlooker Bee phases. MATLAB simulations exhibited significant performance improvements, with 50%, 25%, and 60% improvements in energy efficiency, problem execution time, and overall expense, respectively, over the standalone ABC and WOA algorithms.

Nematollahi, et al. [24] designed a fog computing-based scheduling scheme with a combination of Moth-Flame Optimizer (MFO) and Opposition-Based Learning (OBL) for efficient job scheduling. A blockchain fuels a supporting layer to provide accurate information and prevent system overload imbalances. Python simulations confirmed that the proposed model, OBLMFO, reduced latency by 12.18% and saved 6.22% energy consumption, confirming its efficiency in IoT networks with limited resources.

Nematollahi, et al. [25] proposed an Improved Multi-Objective Aquila Optimization (IMOAO) algorithm for offloading jobs to maximize system response and efficiency. Their algorithm utilizes OBL for diversity in the search space and Pareto front selection for improvement. Task-to-fog-node ratio comparisons showed that IMOAO performed better in terms of failure and response times than PSO, Firefly Algorithm (FA), and Multi-Objective Bacterial Forging Optimization (MO-BFO).

Satouf, et al. [26] developed semi-dynamic real-time scheduling for cloud-fog environments with an adaptive Grey Wolf Optimizer (GWO) for effective IoT job scheduling concerning job duration, availability, and network state. It outperforms traditional scheduling algorithms such as Genetic Algorithm (GA), PSO, and ABC regarding processing time, makespan, and saving energy.

Umer, et al. [27] designed a Multi-Objective Task-Aware Scheduling and Offloading Framework (MT-OSF) for IoT-smart transportation systems. Their mechanism identifies a delayed and computation-intensive mechanism with a high-priority offloader and offloads them with a multi-criterion decision mechanism (AHP-based ranking of fog nodes). Their Task-aware scheduler assigns resources considering node energy, bandwidth, RAM, MIPS power, and the short distance to connected cars.

While existing studies cover several aspects of IoT task distribution, some issues have not yet been addressed, as listed in Table I. Most studies emphasise minimising latency or optimizing resources, and energy efficiency occur afterwards. Metaheuristic algorithms, such as PSO, ABC, and SA, have been proposed with promise, but most suffer from premature convergence and become stuck in local optima.

TABLE I. Comparison of Existing Approaches

Study	Optimization techniques	Key advantages	Limitations
[21]	Multi-target task assignment procedure with archiving methodology	Enhances network lifetime and reduces latency	Does not explicitly optimize energy efficiency
[22]	Simulated annealing and particle swarm optimization	Overcomes local optima trapping and improves resource utilization	Lacks real-world validation, only MATLAB-based
[23]	Whale optimization algorithm and artificial bee colony	Reduces energy consumption by 50% and task execution time by 25%	High computational overhead
[24]	Moth-flame optimization and opposition-based learning	Improves task execution efficiency	Limited scalability analysis
[25]	Improved multi-objective aquila optimization with pareto front selection	Achieves lower response time and failure rate	Not evaluated in large-scale IoT networks
[26]	Cloud-fog task scheduling with adaptive grey wolf optimizer	Optimizes execution time, cost, and energy	Does not address node failures
[27]	Multi-objective task-aware offloading with AHP-based multi-criteria scheduler	Reduces response time by 7% and energy by 16%	More suited for transportation use cases

Additionally, fault-tolerant scheduling algorithms have not yet been researched in detail, with most studies combining real-time reallocation of jobs in the case of failure in one node. Security and robustness can be boosted with multi-objective optimization and blockchain techniques but at a high computational expense and with less analysis for scalability. In this study, EWOA is proposed to bridge these gaps with Lévy flight for search improvement, a multi-objective fitness function for scheduling with consideration for energy, and an adaptable mechanism for fault tolerance in execution.

III. Problem Formulation and Network Model

The task allocation problem in IoT networks can be effectively represented using a Directed Acyclic Graph (DAG), which models dependencies among tasks and the computational costs associated with execution and communication. A DAG is defined as a graph in its entirety $G = (V, E)$, where V stands for the nodes (tasks), and E denotes the edges (communication dependencies between tasks). Each node corresponds to an individual task, while the edges define the precedence constraints that must be satisfied for execution. Task scheduling in IoT is challenging due to the interdependencies among tasks, requiring efficient execution order management to minimize delays and energy consumption.

In a DAG-based task allocation model, the j^{th} task cannot commence execution until all its parent tasks (denoted as node i) are completed. When a parent task is executed, its child tasks become eligible for execution. A node weight represents the computational cost of executing a task, whereas the communication cost between tasks is represented by an edge weight. Fig. 1 illustrates a streamlined DAG for allocating tasks in an IoT environment, where each task is interconnected based on its execution dependencies. The weights assigned to the edges and nodes capture relationship sequences and the associated computational and communication burdens.

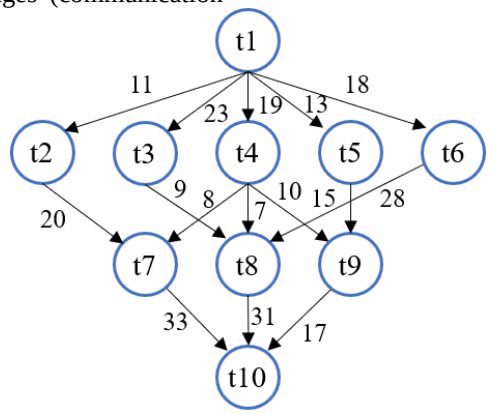

Fig. 1. A streamlined DAG for IoT task allocation.

The IoT architecture used in this study comprises four fundamental layers, each playing a distinct role in data acquisition, transmission, processing, and execution. These layers include sensing, networking, service provisioning, and application, as depicted in Fig. 2. The sensing layer collects data through various smart devices, sensors, and RFID tags. It captures real-time environmental information, which is then processed for decision-making. The networking layer ensures connectivity between IoT devices by utilizing various networking technologies. It facilitates data transmission between perception layer devices and higher processing layers while managing high data traffic efficiently. The service provisioning layer handles data analysis, security, and resource management. It ensures the integrity of collected data, optimizes processing through task allocation, and secures communication pathways. The application layer acts as a user interface, where IoT applications interact with the system. It defines specific real-time requirements, business models, and functional needs of the IoT ecosystem.

The task scheduling mechanism is primarily handled at the service management layer, responsible for assigning computational tasks to appropriate resources while ensuring energy efficiency and minimal latency. The multi-layered architecture of IoT introduces additional complexities, making it necessary to develop efficient task allocation algorithms to optimize resource utilization.

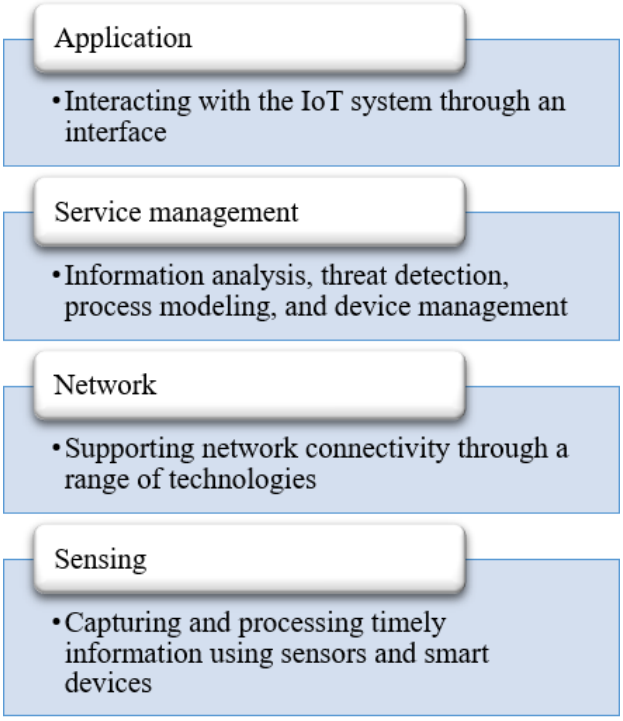

Fig. 2. Adopted IoT architecture.

IV. ENHANCED WALRUS OPTIMIZATION ALGORITHM

WOA is a metaheuristic optimization technique inspired by the social behaviors of walruses. WOA is designed based on the activities and interactions of walrus populations, including migration, foraging, social bonding, and self-defense mechanisms [28]. These behaviors are mathematically modeled using an optimization framework that balances exploration (global search) and exploitation (local search) in the search space. WOA follows a structured approach comprising four key phases: initialization, danger and safety signals, migration, and reproduction.

The algorithm begins by generating an initial population of candidate solutions, randomly positioned within the defined search space between the upper and lower boundaries of the problem variables. Each solution represents a walrus agent, and their positions are iteratively updated as the algorithm progresses.

WOA utilizes danger and safety signals to model walrus behavior, particularly their response to external threats. The danger signal is computed using Eq. (1).

$$\begin{aligned} Danger\_signal &= A \times R \\ A &= 2a \\ a &= 1 - \frac{t}{T} \\ R &= 2 \times r_1 - 1 \end{aligned} \tag{1}$$

The safety signal is defined using Eq. 2.

$$Safety\_signal = r_2 \tag{2}$$

Where A and R determine the intensity of the danger response, with α decreasing linearly from 1 to 0 over time. r_1 and r_2 are random values between 0 and 1, while t represents the current iteration number and T is the maximum iteration count.

The migration phase is responsible for exploration, allowing walrus agents to move across the search space for better solutions. The position update equation for a walrus agent is given by Eq. (3).

$$X_{i,j}^{t+1} = X_{i,j}^{t} + Migration\_step \tag{3}$$

Where the migration step is calculated using Eq. 4.

$$\begin{aligned} Migration\_step &= (X_m^t - X_n^t) \times \beta \times r_3^2 \\ \beta &= 1 - \frac{1}{1 + e^{-10(t-0.5T)/T}} \end{aligned} \tag{4}$$

Where X_m^t and X_n^t are randomly selected walrus positions, while β is a migration step control factor that adjusts the step size dynamically. The random parameter r_3 enhances randomness, allowing better exploration.

During the reproduction phase, walruses adjust their positions based on gender-based social interactions. For female walrus agents, their new position is influenced by both the male walrus and the best-performing solution in the population, as follows:

$$\begin{aligned} female_{i,j}^{t+1} = female_{i,j}^{t} &+ \alpha \times \left(male_{i,j}^{t} - female_{i,j}^{t}\right) \\ &+ (1-\alpha) \times \left(X_{best}^{t} - female_{i,j}^{t}\right) \end{aligned} \tag{5}$$

For juvenile walrus agents, their positions are adjusted using a Lévy flight-based movement strategy as follows:

$$\begin{aligned} juvenile_{i,j}^{t+1} &= \left(O - juvenile_{i,j}^{t}\right) \times P \\ O &= X_{best}^{t} + juvenile_{i,j}^{t} \times LF \end{aligned} \tag{6}$$

Where O is the safety reference location, P is the danger coefficient associated with juvenile walrus agents, and LF is a Lévy flight-based movement step.

To enhance WOA's efficiency, the EWOA incorporates Lévy flight-based exploration, improving search efficiency and solution diversity. Lévy flights introduce random jumps with heavy-tailed distributions, allowing walrus agents to escape local optima and search over a broader space. The Lévy function used in EWOA is defined using Eq. (7).

$$\begin{aligned} LF &= 0.01 \times \frac{u \times \sigma}{|v|^{\frac{1}{\gamma}}} \\ \sigma &= \left(\frac{\Gamma(1+\gamma) \times \sin\left(\frac{\pi\gamma}{2}\right)}{\Gamma\left(\frac{1+\gamma}{2}\right) \times \gamma \times 2^{\frac{\gamma-1}{2}}} \right)^{\frac{1}{\gamma}} \end{aligned} \tag{7}$$

Where u and v are random values between 0 and 1, γ is the Lévy distribution parameter, and Γ denotes the Gamma function. By integrating Lévy flights, EWOA achieves faster convergence, better solution diversity, and more efficient search behavior than the original WOA. Fig. 3 illustrates the flowchart of EWOA.

EWOA is tailored for optimized energy utilization in task scheduling for IoT by leveraging its adaptive exploration-exploitation balance to efficiently allocate computational tasks across heterogeneous IoT devices. EWOA ensures energy-efficient scheduling by dynamically assigning tasks to IoT devices based on computational capacity, energy constraints, and communication overhead. The Lévy flight-based exploration enables the algorithm to search for optimal task-to-node mappings, preventing premature convergence while minimizing energy consumption and execution time.

EWOA integrates a multi-objective optimization approach, where the fitness function considers energy consumption, task execution latency, and workload balancing. The danger and safety signaling mechanism helps prioritize critical tasks, ensuring that time-sensitive operations are executed with minimal delay. Additionally, the migration and reproduction phases allow IoT devices to dynamically adjust their task allocations, adapting to network changes and preventing resource overloading. By efficiently balancing the computational load, EWOA significantly prolongs network lifetime, reduces energy dissipation, and ensures seamless execution of IoT tasks while maintaining high system performance.

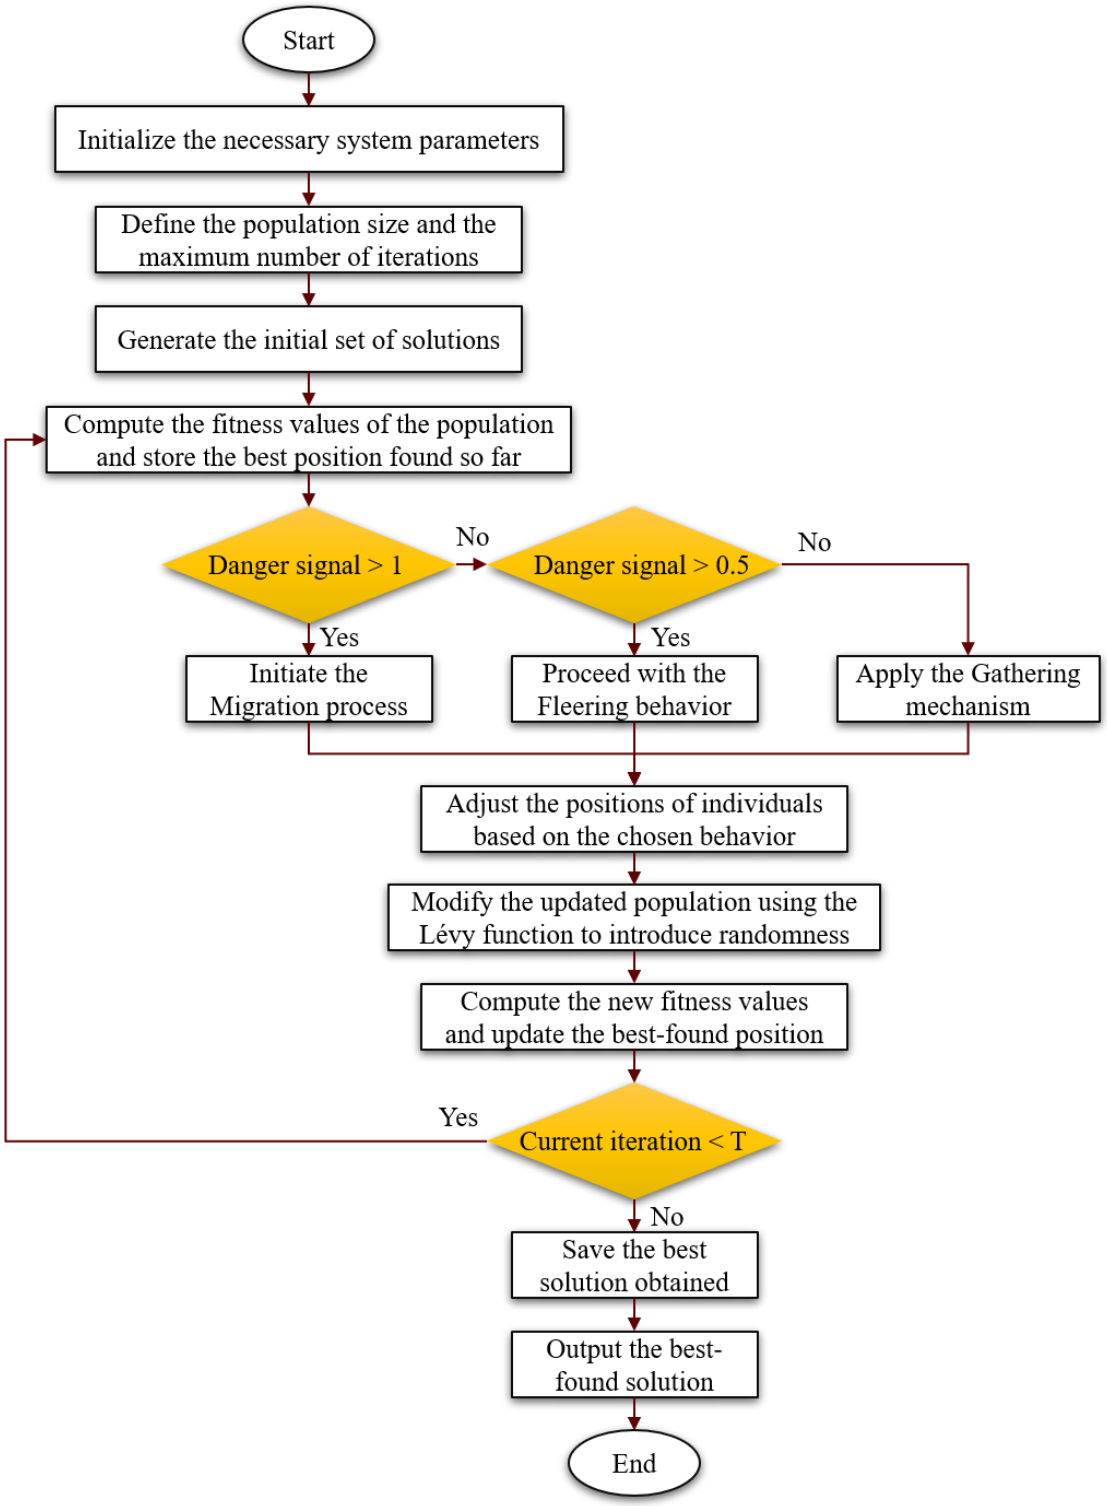

Fig. 3. Flowchart of EWOA.

V. RESULTS

This section evaluates the proposed EWOA efficiency in scheduling IoT tasks and energy consumption in IoT environments. EWOA efficiency was assessed by comprehensive experiments conducted in MATLAB R2020a, which has high capabilities for matrix computation, model optimization, and effective data manipulation. IoT task scheduling is represented as DAG, with computational nodes arranging tasks under energy and communication costs. Convergence behavior, energy consumption, and cost efficiency performance metrics were analyzed by comparing existing methods, including SA, PSO, and ACO.

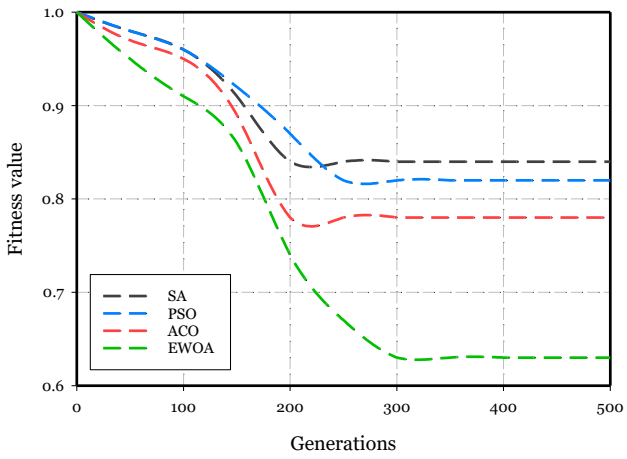

Fig. 4. Fitness value results.

Fig. 4 shows the algorithm behavior for a sequence of several generations. Initially, the fitness value of EWOA was high but continued to fall with a growing number of iterations, reaching equilibrium at approximately the 320th generation. Through refinement over a while, the algorithm avoids early convergence and maintains an optimal balance between search and exploitation. Rapid early improvements confirm that the Lévy flight search mechanism operates effectively. The algorithm can explore a range of solution spaces and settle down to an optimal task distribution scheme.

Efficient energy consumption is one of the most important objectives in IoT task scheduling. Fig. 5 illustrates algorithms' energy consumption with an increased number of tasks. The observations confirm that with an increased number of scheduled tasks, EWOA outperforms all else consistently, consuming much less energy. Simulated Annealing consumes the most energy, with a follow-up consumption in terms of ACO and PSO. That confirms that EWOA maximizes task distribution better, minimizing computational overhead and unnecessary migration of tasks. EWO's use of an adaptive exploration mechanism and task prioritisation techniques are responsible for its high energy efficiency. Therefore, EWO is an ideal selection for IoT large-scale implementations.

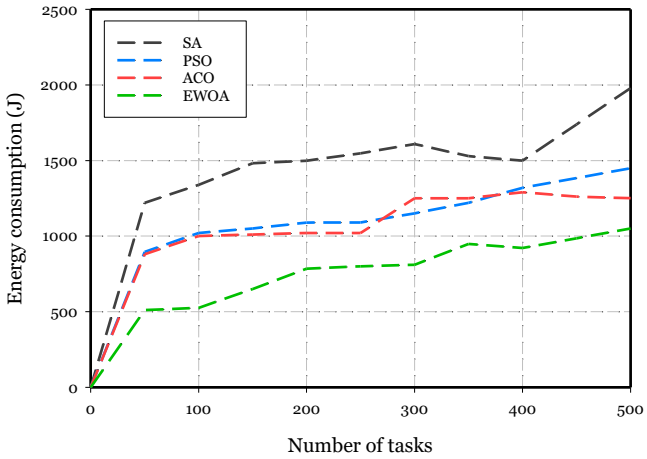

Fig. 5. Energy consumption results.

In addition to efficiency in terms of energy, cost-minimizing is a significant concern in IoT resource management. Fig. 6 is a comparative analysis of cost efficiency in terms of algorithms. EWOA consistently generates lesser values for cost when compared with other algorithms with a larger number of tasks. All methodologies have an increasing trend in terms of cost with growing complexity in terms of tasks. Still, EWOA experienced a moderate and less sharp rise, representing its resource distribution efficiency. Intelligent mapping of tasks with resources and adaptability in EWOA enables it to have a lesser cost, representing its effectiveness in IoT task scheduling with an efficient computational burden at an economical cost.

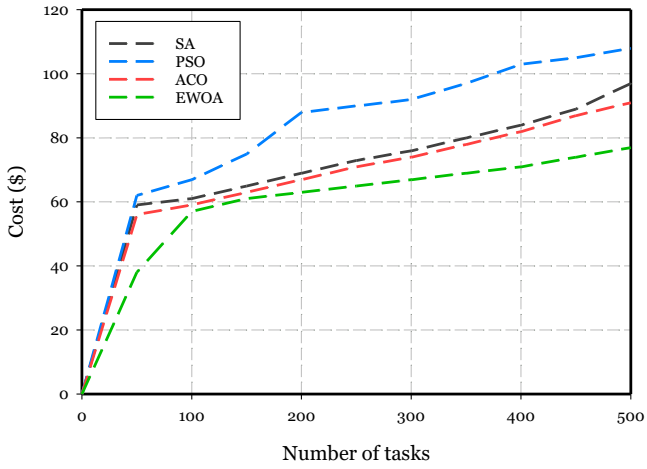

Fig. 6. Cost results.

The results clearly show that EWOA introduces significant improvement over conventional approaches in terms of velocity of convergence, efficiency in terms of energy, and cost savings. Lévy flight, multi-objective estimation of fitness, and flexible distribution of resources techniques included in EWOA make EWOA efficient in working with IoT scenarios with changing environments. High performance in various performance factors proves that EWOA can effectively work for big IoT scenarios with high regard for conserving energy and minimizing cost. With smart optimizing techniques, the proposed algorithm effectively distributes computational loads, maximizes network life, and maximizes effective use of resources, and thus can work as an efficient alternative for future IoT networks.

VI. Discussion

Evolution towards energy-efficient task schedules in IoT contexts necessitates adaptive yet robust optimization mechanisms. EWOA met this need by providing a new hybrid integration of Lévy flight search with adaptive search methods. This work contributes significantly to current literature in resource-constrained optimization using metaheuristics, ranking EWOA superior in maintaining a balance between exploitation and exploration.

A key contribution of this work is its multi-objective formulation, where energy consumption, execution latency, and resource utilization are simultaneously considered. Most methods in the literature consider energy efficiency a secondary optimization objective [21], while this EWOA makes energy efficiency central within its scheduling objective. This change is

crucial in IoT applications where devices rely on batteries operating in remote or hostile regions, and energy exhaustion can impact system reliability and longevity.

As opposed to traditional metaheuristics such as PSO and ACO, which are subject to premature convergence and low adaptability to dynamic workloads [22], EWOA applies Lévy flight to move out of local optima while having search diversity throughout large iterations. This makes EWOA effective even for complex non-linear task dependencies best represented by Directed Acyclic Graph (DAG) structures. These are critical to scalability in smart cities, industrial IoT, and fog/edge computing.

The algorithm's biological inspiration, from walrus migration and reproduction patterns, provides a unique and underexplored behavioral model in the metaheuristic landscape. While swarm intelligence and evolutionary paradigms dominate the literature, the walrus model demonstrates that new behavioral analogies can yield valuable heuristic principles, particularly with advanced statistical tools like Lévy distributions.

EWOA solves several open problems in this area. Firstly, its volatility-adaptive structure enables flexibility, a key necessity for self-organizing fault-tolerant systems. Second, its dynamic allocation facility ensures it is a prime candidate for real-time systems where device status may switch. Third, it provides a generalizable model for hybrid optimization methods. It creates possibilities for intermingling with federated learning agents, machine learning predictors, or context-dependent controllers for smart decision-making in dynamic environments.

Despite this, real-world deployment can be hindered by certain practical limitations, namely computational complexity in large-scale systems and requirements for hyperparameter fine-tuning to prevent poor performance. Although MATLAB simulations assure controlled and reproducible evaluation circumstances, actual tests using physical IoT testbeds or emulator environments would thoroughly validate the algorithm's robustness against network noise, packet loss, or hardware constraints.

VII. Conclusion

This study designed EWOA for optimal use in IoT scheduling. It presented a computation-efficient approach for reducing computational costs and improving system performance using optimal energy and resource usage. EWOA facilitated a dynamic exploitation-exploration tradeoff using Lévy flight-inspired movement strategies, multi-objective optimization, and flexible task allocation for optimal scheduling. By modeling the scheduling problem in a DAG, EWOA effectively distributes tasks regarding computational demand, energy consumption, and communication overhead to IoT nodes.

Simulation tests have proven that EWOA outperforms traditional algorithms. Convergence analysis revealed that EWOA achieves optimal performance at an optimal rate without premature convergence and with an ideal task distribution. Analysis of energy consumption and cost has proven that EWOA minimizes energy loss and computational costs. Intelligent mapping of resources to tasks and a flexible scheduling mechanism ensure a network's durability and service efficiency, and EWOA is a potential real-time IoT candidate.

Although the proposed scheme reflects considerable improvements in terms of energy efficiency and task execution performance, additional enhancements are possible in future research. Machine learning predictive models can improve scheduling efficiency, accuracy, and adaptability in dynamic IoT environments. Implementations in edge and fog architectures can reveal even deeper insights into real-life implementations. Hybrid frameworks combining metaheuristic algorithms with deep learning for even better performance in complex IoT networks can be developed in future studies.

Abstract*—Precision Agriculture is a combination of Artificial Intelligence (AI) and the Internet of Things (IoT) to improve farming efficiency, sustainability, and overall productivity. This work presents hybrid CNN-TAM (Convolutional Neural Network–Temporal Attention Mechanism) model running on Edge AI devices for real time crop soil temperature and Soil Moisture prognosis. IoT sensors gather long term environmental data which is preprocessed to remove noise and extract meaningful spatial and temporal features. CNN can obtain spatial patterns and TAM assigns dynamic attention weights to important time steps enhancing prediction accuracy. The proposed hybrid model surpasses the conventional methods like Linear Regression, Random Forest, LSTM, and independent CNN with the lowest RMSE (1.7). Different from cloud-based deployments, the Edge AI deployment offers reduced latency, consumes lower bandwidth, and is better suited for scalability, enabling large-scale, real-time precision farming. Experimental outcome confirms enhanced real-time prediction capability allowing farmers to optimize irrigation schedules, reduce resource waste, and improve crop resilience against extreme weather conditions. This ensures sustainable resource management, conserves water and fertilizers, and enhances decision-making in agriculture. The results demonstrate the capability of AI-driven decision-support tools in present-day agriculture and presents a scalable, cost-effective and deployable solution for both small- and large-scale farms. By emphasizing data privacy, real-time processing, and low-latency inference, this research contributes to the area of precision agriculture relying on AI, addressing key challenges such as real-time analytics, unreliable connectivity, and the need for immediate on-site decision-making. The study develops an AI-powered system for intelligent farm management to support sustainable and Smart Irrigation Optimization is used for efficient agricultural practices.

Keywords*—Precision agriculture; edge AI; convolutional neural network; temporal attention mechanism; smart irrigation optimization

I. INTRODUCTION

In the recent history, PA has been a new way of farming that relies on the use of highly developed technologies such as IoT and AI in a bid to improve productivity, conserve resources from wastage, and promote sustainable farming. The integration of Edge AI with precision agriculture is highly crucial since it provides on-location and real-time processing of data that are collected using an array of IoT sensors in farms, facilitating real-time decision-making [1]. The transfer of technology may significantly boost yields, better handle soil health management, and help improve weather prediction for more knowledgeable farm operation. Among the critical parameters that influence agricultural productivity are weather patterns and soil conditions, and they have a direct bearing on crop growth, water consumption, and resource utilization. The use of Temporal Attention Mechanisms with CNNs is a viable solution. CNNs initially designed to process images can be used to restructure data from diverse sources such as soil sensors, satellite images, and drones and capture spatial features such as temperature, moisture in the soil, and nutrients. CNNs or Temporal Attention Mechanisms enable the model to navigate through sensor readings in time-series format and weather patterns and identify dynamic temporal patterns that affect agronomic conditions such as temperature variation, rain pattern, and change in moisture over time [2]. With the combination of spatial as well as temporal data, the hybrid model is able to make enhanced and consistent predictions, providing real-time data about soil status and weather required for efficient crop management [3].

The study seeks to utilize this hybrid method to enhance crop monitoring and intelligent farm management, enabling farmers to maximize the utilization of resources such as water, fertilizers, and pesticides. Real-time weather prediction and soil monitoring via IoT-based Edge AI would allow farmers to make decisions and act in a timely manner to avoid crop diseases, pests, and nutrient deficiencies, thereby maximizing crop yields and minimizing costs [4]. The relevance of this study stems from its ability to solve precision farming challenges by creating AI models that can run directly on edge devices like agricultural sensors or drones with minimal dependency on cloud computing infrastructure. This both lessens the bandwidth load and enhances scalability, making the solution available even in remote agricultural areas where cloud-based systems would be impracticable. Additionally, data processing on the edge keeps sensitive data like weather conditions and soil types safe, leading to improved privacy and regulation compliance [5] Regarding resource optimization, the instant feedback from the system would enable farmers to change irrigation timetables, use fertilizers only where needed, and reduce the effect of weather occurrences like drought or excessive rain [6]. Detection of pests or diseases at an early stage, along with accurate predictions of weather and soil conditions, would allow farmers to act preventively, lessening the necessity for the use of pesticides and enhancing crop health [7]. The hybrid approach, by analysing spatial as well as temporal data, improves the system's accuracy and responsiveness, making agricultural practices more sustainable [8].

The system's ability to deliver real-time prediction and anticipatory control has the potential to greatly enhance the crops' tolerance towards environmental stress, thereby ensuring greater yields and decreased farm losses. The paper further discusses measuring the practicable feasibility of employing a hybrid AI model like that described here for managing intelligent farms in terms of its ability to adapt to heterogeneous forms of data sources as well as provide actionability explainability that is accessible for farmers lacking in technical skill sets. The primary objective is to create an affordable, scalable, and deployable solution for farmers of all sizes, from smallholder farms to large-scale agricultural operations. In addition, the research aims to further the general goals of environmental sustainability by ensuring water and fertilizer loss reduction, minimizing the use of pesticides, and enhancing the overall efficiency of farms [9].Through the implementation of edge-based real-time AI predictive systems, this approach intends to increase the sensitivity of agriculture to changing climatic conditions and lower its carbon footprint. Secondly, the research hopes to encourage broader uses of IoT-based AI technology across the agricultural sector, showcasing their potential to improve productivity, enhance decision-making procedures, and facilitate sustainable agricultural production globally. By focusing on CNNs and Temporal Attention Mechanisms, this study aims to fill the gap that exists in existing systems that rely primarily on static data models or cloud computing and create a more dynamic, responsive, and efficient system for agriculture [10]. The study also investigates the practicability of applying the model to existing agricultural systems, making them compatible with existing infrastructure and enhancing the overall system reliability. The study is part of the global agenda to embrace AI and IoT technology in agriculture since they can reshape the art of agriculture in the face of burgeoning dangers such as climate change, water shortages, and food demands. The outcome of the research will not just encourage precision farming but also enhance sustainable farming practice required to secure future food supplies. By employing an Edge AI-based hybrid technique, this work can revolutionize agriculture by enhancing productivity, decreasing costs, and making agriculture climate-resilient, eventually establishing smart, sustainable agriculture globally [11]. The key contribution of the study is followed as below:

- This study proposes a CNN-TAM model to achieve real soil moisture and temperature prediction for enhanced precision agriculture.
- The fusion of CNN and TAM improves the accuracy of prediction, surpasses traditional models in both RMSE-based evaluation.
- Use of model on Edge AI device decreases latency, reduce bandwidth consumption and enabling real time decision making in farming.
- The suggested method makes irrigation scheduling better, lessens resource loss, and improves sustainability in contemporary agriculture.

The remainder of the paper is organized as follows: Section II provides a review of pertinent work. In Section III, the problem statement is explained. The proposed method is described in Section IV. Section V presents and compares the experimental results. Section VI concludes the work and offers suggestions for additional research.

II. Literature Review

Sharma and Shivandu [10] explain the ways IoT and AI are transforming precision agriculture through automatic monitoring and management of crops. The study identifies the technologies of high-throughput phenotyping, remote sensing, and AgroBots which enable harvesting, sorting, and weed identification to be carried out with increased efficiency and reduced labor and environmental costs. High-throughput phenotyping integrates spectral imaging, robotics, and remote sensing to enhance decision-making related to pest control, fertilization, and irrigation. DGPS and remote sensing offer precise real-time data for soil and crop health assessment, and image segmentation algorithms allow fruit and plant detection under challenging circumstances. PACMAN SCRI for apple orchard management and Project PANTHEON's SCADA system for hazelnut plantations are examples of AI-IoT integration in agriculture. Research gaps, such as scalability to small farms, real-time decision-making, and robustness of AI models, are also covered in the paper. Upcoming advancements such as 5G and 6G cellular networks are projected to push the adoption further. Satisfying data convergence, privacy, and security issues will promote precision agriculture to deliver sustainable and efficient agricultural practice.

Fuentes-Peñailillo [11] address the role of digital agriculture in smart crop management, focusing on IoT, remote sensing, and AI in enhancing crop productivity and sustainability. The article points out how real-time information from IoT and sensor networks can evaluate soil health, plant water status, pest

infestation, and environmental conditions. Such information facilitates data-driven decisions to optimize irrigation, fertilization, and pest management. UAVs and drones improve monitoring by performing in-depth field surveys and monitoring crop growth with great accuracy. The research also investigates the application of big data analytics and AI in handling large datasets to detect patterns and trends and provide insights for improved agricultural management. Challenges include low adoption rates due to the complexity of technology, high prices, and farmer training requirements. The research promotes ongoing research and cooperation to break these barriers and facilitate the global implementation of smart agriculture, especially in climate change and resource-scarce regions.

Avalekar et al. [12] discuss the intersection of AI and IoT in agricultural automation systems, their integration with wireless sensor networks and cloud computing. The paper suggests an architecture composed of modules such as Wireless Sensor Networks (WSN), Data Processing and Edge Computing, Cloud Computing, AI and Machine Learning, IoT Integration, and User Interface Control. The study is intended to improve crop quality, optimize yields, embrace weather-sensitive management, and AI-enabled crop rotation. The research hypotheses are AI-controlled quality, embracing real-time weather data inputs, and analytics-based decision-making. AI and IoT will automatically revolutionize precision agriculture on a large scale by optimizing the use of resources and making agriculture more sustainable, the study contends. Paradigm-breaking synergy of AI-IoT-cloud computing is making for a sustainable and effective data-driven agricultural framework. Future research has to defeat connectivity, security of data, and scalability issues of infrastructure if it has to be universally embraced.

Khan, Hassan, and Shahriyar [13] also suggest an IoT- and cloud-based platform for the improvement of onion crop management. The system is IoT sensor-based for online temperature, humidity, and soil moisture measurement supported by aerial drones for remote monitoring. The information is processed on edge computing to reduce latency and securely transmitted to a cloud platform to store and analyze. Applications based on machine learning learn patterns of onion growth, health, and weather conditions and give predictive suggestions on the need for irrigation and fertilization. A dashboard provides farmers an easy way to look at real-time data, and automated alerts inform them about deviations from ideal conditions. Predictive analytics also help plan in the long term by detecting growth patterns. Security measures such as encrypted data storage and transfer safeguard farmer data. The study indicates that cloud and IoT technology enhance the sustainability and productivity of crops but with issues related to cost, scalability, and access in small-scale farming.

Boahen and Choudhary [14] discuss computer vision and AI technologies for precision agriculture, for instance, intelligent monitoring of soil and crops. The article provides developments in machine learning and image processing that enhance the efficiency of resource utilization and crop production. Computer vision provides means for plant health monitoring by autonomous means through spectral analysis for disease detection, nutrient deficiency, and pest attack. Machine learning algorithms improve precision in such analysis to facilitate real-time suggestions on best farming practices. The article directs towards the functions of image segmentation and deep learning in solving variables in illumination as well as backgrounds that are very complex in instances of field deployment. The use of AI-fueled decision support systems allows farmers to attempt precision irrigation, fertilization, and crop management. The article recommends additional research to further fine-tune AI models for various agricultural settings and enhance small-scale farmer adoption.

Soultane, Salih-Alj, and Et-taibi [12] provide an intelligent agriculture system that employs recurrent neural networks (RNN) and edge computing to improve agricultural productivity. The platform employs IoT drones with multispectral cameras and LiDAR to gather large amounts of data on crop health, soil health, and weather conditions IoT sensors like pH, soil moisture, temperature, and humidity sensors provide real-time data for data-driven decision-making. Integration of the RNN model offers predictive analysis to enhance irrigation schedules, monitor possible disease states, and predict crop yields the study highlights the benefits of AI-driven analytics in improving crop yields, reducing resource consumption, and minimizing environmental footprints. But it identifies challenges such as the cost of deployment, the need for skilled personnel, and data privacy concerns that require additional researches and technology improvements.

III. Problem Statement

Precision agriculture is evolving through the integration of AI and IoT, but internal issues such as high implementation costs, limited scalability, data security concerns, and difficulties in real-time decision-making are hampering scale up of the technology adoption. Small farmers lack access to sophisticated digital options, which holds them back from maximizing resource utilization and improving crop yields [13]. Connection problems and computational delay, further hamper real-time decision-making, ultimately reducing the efficiency of AI models under varying environmental conditions. Although AI-based systems significantly improve soil monitoring, irrigation and pest control, challenges such as data privacy concerns, infrastructure latency and model degradation hinder large-scale implementation. Addressing these issues is crucial to to fully harness the AI-IoT synergy for sustainable and intelligent agriculture [14]. This research presents an Edge AI-based CNN-TAM model to tackle these challenges by enabling a real-time, low-latency soil and crop sensing, thereby optimizing farming operations.

IV. Research Methodology

The proposed methodology Fig. 1 illustrates a CNN-TAM (Convolutional Neural Network with Temporal Attention Mechanism) model designed for precision agriculture. The workflow begins with data collection, where IoT sensors gather soil moisture and temperature readings from multiple depths over a decade. Next, data preprocessing ensures quality through cleaning, handling missing values, and outlier removal. Feature engineering extracts spatial and temporal patterns, with CNN identifying spatial dependencies and TAM assigning dynamic attention weights to critical time steps, such as extreme weather events. The CNN architecture involves convolutional layers for

feature extraction, ReLU activation for non-linearity, pooling layers for dimensionality reduction, and fully connected layers for classification or regression.

The Temporal Attention Mechanism (TAM) prioritizes key time steps that significantly impact soil moisture and crop health. The CNN-TAM model is deployed on Edge AI devices, enabling real-time analysis and decision-making with minimal latency. Finally, the system undergoes training and validation, ensuring robust prediction accuracy, outperforming traditional models like Linear Regression, Random Forest, LSTM, and standalone CNN in RMSE-based evaluations.

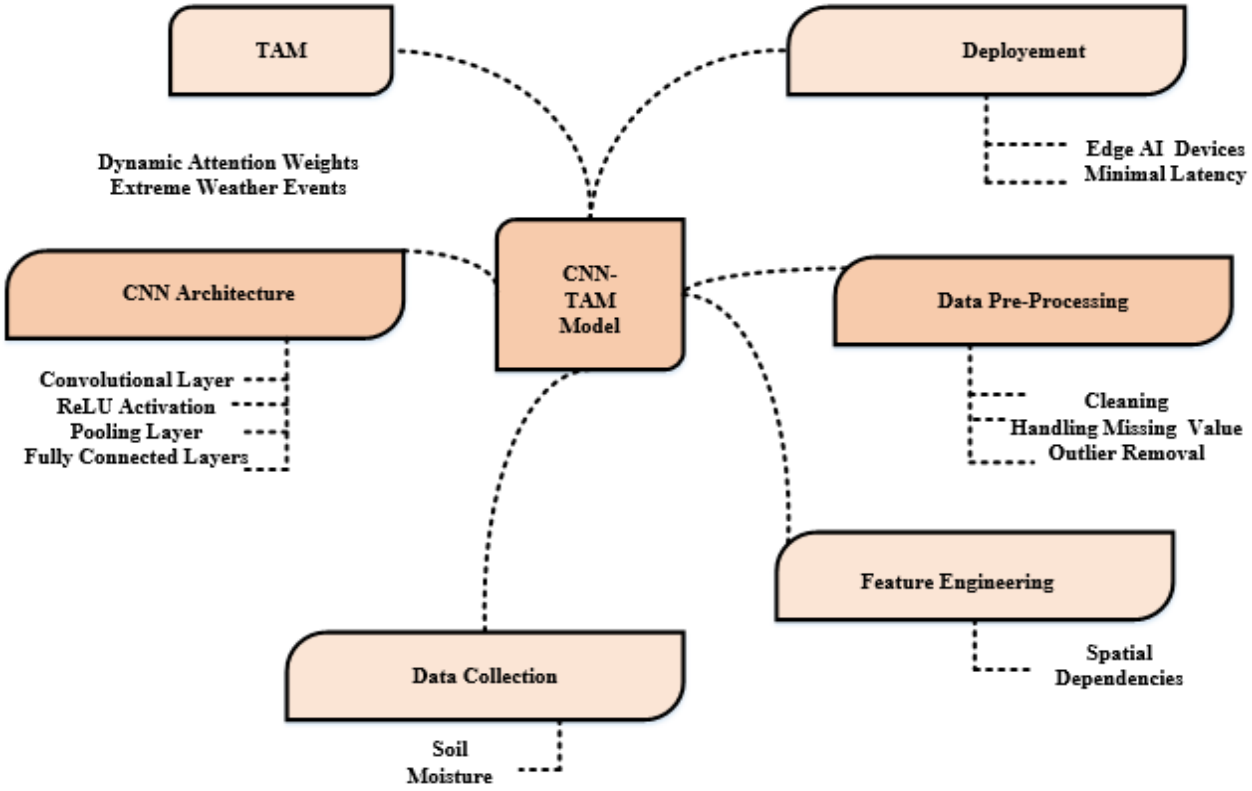

Fig. 1. Workflow of proposed method.

Fig. 1 illustrates the workflow of a CNN-TAM model for real-time soil moisture and temperature prediction in precision agriculture. It starts with data collection using IoT sensors, followed by data pre-processing to clean, handle missing values, and remove outliers. Feature engineering extracts key spatial dependencies from the processed data. The CNN architecture captures spatial features using convolutional, ReLU, pooling and fully connected layers. The TAM module applies attention to critical time steps, especially during extreme weather. The hybrid model is then deployed on Edge AI devices, offering low latency and efficient processing. This setup supports scalable, real-time farm management.

A. Data Collection

This data, donated by Caley Gasch and David Brown of Washington State University, contains useful soil moisture and temperature values observed via IoT sensors across almost a decade (2007–2016). Data is organized in daily and hourly readings from 42 sites, presenting information about volumetric water content (VW) and temperature (T) for different soil depths (30cm to 150cm). The VW readings are soil-specific and corrected with a two-step correction procedure to ensure precise moisture estimation. Temperature measurements, on the other hand, depend on factory calibration to keep all sensor readings consistent. This dataset is also highly beneficial for machine learning applications, including time series prediction of soil moisture levels and environmental monitoring for precision agriculture [15].

B. Data Pre-processing

The procedure of preparing unprocessed data for deep learning model training is known as data pre-processing. It represents the first and most crucial phase of the development of the model. The deep learning models cannot be taught just feeding it raw data. The most critical and significant factor influencing the model's ability to generalize is data pre-processing. In order to identify and eliminate inaccurate or noisy data from the dataset [16].

1) Data cleaning: Handling missing data involves using linear, spline, or polynomial interpolation for small gaps, while KNN imputation predicts missing values based on nearby data points. If a sensor has more than 50% missing data, it may be removed. Outliers are addressed using the Z-score method (removing values beyond ±3 standard deviations), the IQR method (eliminating values exceeding 1.5×IQR), and domain-based filtering (discarding physically unrealistic values, such as soil moisture >100%). These steps ensure clean and reliable data for further analysis.

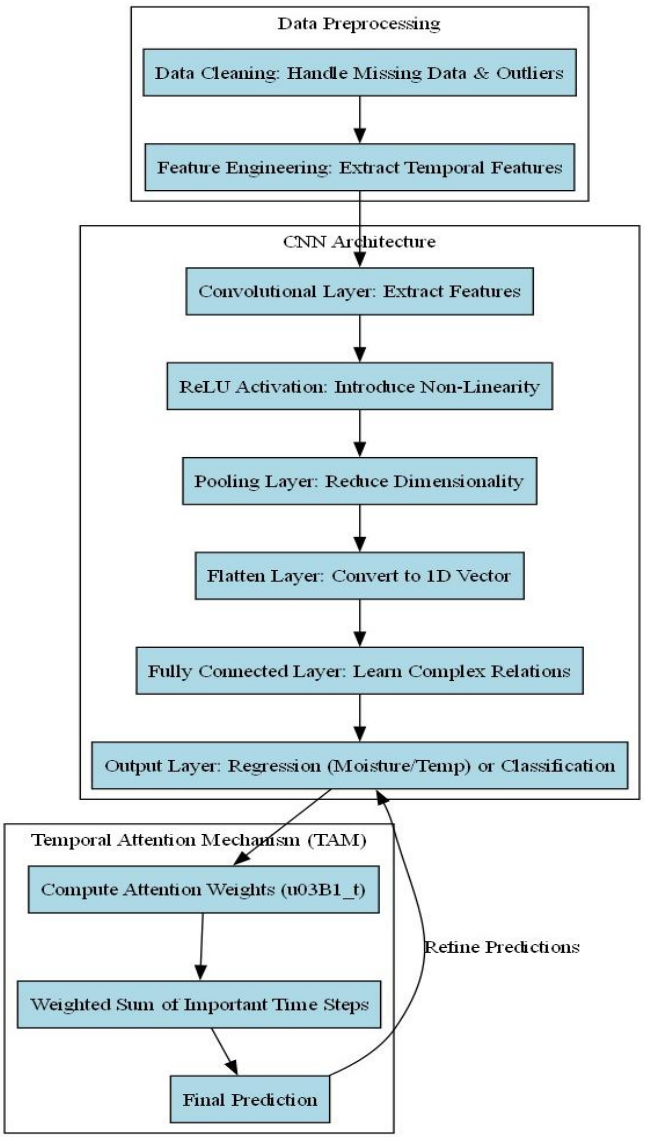

Fig. 2. Overall flowchart for CNN-TAM.

Fig. 2 presents the architecture of the proposed CNN-TAM model for real-time soil moisture and temperature prediction. It begins with data preprocessing, where missing values and outliers are handled, and temporal features are extracted. The processed data is passed through the CNN architecture, where the convolutional layer extracts spatial features, the ReLU activation introduces non-linearity, the pooling layer reduces dimensionality and the flatten layer converts data into a 1D vector. This is followed by fully connected layers that learn complex relationships, leading to the output layer for regression or classification. To enhance accuracy, the Temporal Attention Mechanism (TAM) computes attention weights for significant time steps, aggregates them, and refines the output, producing a final prediction that emphasizes key temporal dynamics.

2) Temporal feature engineering: Temporal feature engineering involves extracting time-based patterns such as seasonality, daily variations, and long-term trends to better understand fluctuations in soil moisture and temperature. Lag features are created to capture time dependencies, such as using past 7-day or 30-day moving averages to predict future values. Additionally, rolling statistical features like mean and variance are computed to smooth out noise and highlight significant trends, ensuring that models effectively learn from past observations while accounting for natural variations in environmental conditions.

C. CNN Architecture for Soil Moisture and Temperature Prediction

Convolutional layers of a CNN are used to derive spatial and temporal patterns from input data, i.e., temperature and soil moisture measurements. Convolution starts with applying filters, or kernels, over the input data to determine the important features. Mathematically, a convolution operation can be defined as an element-wise sum of the input data with the filter. The output is a new feature map that emphasizes the significant patterns, such as short-term variations in moisture or long-term seasonal patterns in Eq. (1),

$$y(i,j) - (x * w)(i,j) - \sum_{m=1}^{M} \sum_{n=1}^{N} x(i+m-1, j+n-1).w(m,n) \quad (1)$$

where x is the input data (e.g., soil moisture or temperature readings),w is the kernel (filter), y is the output feature map,M and N are the dimensions of the filter.

A ReLU activation function is then used for this feature map to bring non-linearity into the model. This only forwards positive values, enabling the model to learn more complex relationships between the data and enhance its capability to identify intricate environmental interactions[17], that is represented in Eq. (2),

$$ReLU(\boldsymbol{z}) = max(0, \mathrm{z}) \quad (2)$$

where z is the input to the $ReLU$ function, $ReLU(\boldsymbol{z})$ is the output of the ReLU activation function for the input z , $max(0, \mathrm{z})$ means the function returns the maximum value between 0 and z.

The pooling layers of the CNN structure compress the feature map dimension while maintaining the most important information. This is typically done with a max pooling operation, in which the highest value within a specified pooling region, typically a 2x2 window, is found. The pooling operation retains the most important aspects of the data and eliminates less important information, thus lowering the computational complexity and the possibility of overfitting. By representing the most important features, such as temperature differences at various depths of soil, pooling renders the model more efficient without compromising the integrity of the original data. This is an important step towards improving the performance of the model, especially for the handling of big data sets with noisy or irrelevant information is calculated in Eq. (3),

$$\mathbf{y}(\mathbf{i},\mathbf{j}) = \max_{m,n \in pool\ region} x(i+m, j+n) \quad (3)$$

where $\mathbf{y}(\mathbf{i},\mathbf{j})$ is the output value at position $(\mathbf{i},\mathbf{j})$ in the pooled feature map (after max pooling), $x(i+m, j+n)$ is the input value from the original feature map at a specific location within the pooling window, $\max_{m,n \in pool\ region}$ is the maximum

value is selected from all positions within the defined pooling region, (m, n) denotes indices within the pooling region, $pool\ region$ indicates a small sub-region (like 2×2 or 3×3) of the input feature map over which the max operation is applied.

Dense or fully connected layers are applied following the convolutional and pooling layers in order to merge the features that the input data have learned. The layers project the multidimensional feature maps onto a one-dimensional vector and subsequently drive the vector into a set of neurons. Each neuron utilizes a weighted sum of the inputs as well as an activation function is calculated using Eq. (4),

$$Z = W.x + b \tag{4}$$

where x is the vectorized input (flattened output of pooling layers pooled), W is the weight matrix, b is the bias vector, Z is the output vector prior to the application of the activation function.

The output layer is the last unit of the CNN model, wherein predictions are determined using the acquired features. For classification problems, the layer tends to employ the Softmax activation function to yield probabilities for all available classes, i.e., varying soil states (e.g., "Dry," "Optimal," or "Saturated"). The Softmax function guarantees that the total probability of all classes is one, and the model can select the most probable result. In regression problems, for instance, soil moisture or temperature values prediction, the output layer employs the linear activation function to generate continuous predictions. The model provides an output of a numerical value representing the anticipated level of moisture or temperature that aids in the decision-making process, for example, irrigation scheduling or resource management. Training a CNN model involves minimizing a loss function to improve the model's accuracy in predicting or classifying soil conditions [18].

D. Temporal Attention Mechanism

The Temporal Attention Mechanism (TAM) is a strong tool that is used to overcome the challenges of handling time-series data by allowing models to pay attention to the most important time steps, an important feature in dynamic domains such as agriculture. In agricultural operations, environmental factors like weather conditions, soil wetness, and temperature fluctuations may vary with time and influence the health and growth of crops. However, all time steps within a time series sequence are not equally important with some time intervals (e.g., severe weather conditions, irrigation cycles) playing a greater role in crop status than others. TAM provides dynamic attention weights to different segments of the sequence such that the model can weigh the most applicable time intervals for example, if there has been an unusual rain or heatwave, the model will give higher focus to the respective time steps, with these events having a greater influence on the health of crops. Mathematically, TAM acts by employing an attention score $\alpha_t$which is calculated for each time step t in the sequence. The attention score decides the amount of attention a time step must possess in the end prediction, represented in Eq. (5)

$$\alpha_t = \frac{\exp(f(h_t))}{\sum_{t'} \exp(f(h_t'))} \tag{5}$$

where $f(h_t)$ is the relevance function, typically implemented using a neural network that processes the hidden state h_t at each time step t, and t'represents all other time steps. The attention score $a_{th_t}$is then used to calculate the weighted sum of the time-series data, which is used as input for the prediction is calculated in Eq. (6),

$$y = \sum_t a_{th_t} \tag{6}$$

where y is the model's output (for instance, predicted crop health or yield), and h_t is the feature vector at time t. The process allows the model to selectively focus on the most important periods, enhancing its ability to keep track of long-term dependencies within time-series data, for instance, the prolonged effect of a drought on vegetation growth. TAM is especially useful in agriculture, where some temporal occurrences (e.g., temperature declines, rain) have a big impact on the health of crops, but such occurrences tend to be irregular.

In practice, this can result in the model being more focused on particular time steps when environmental conditions pass specific thresholds, so that the system can pick up on small but important changes in crop status. Second, TAM boosts model performance through maintaining these long-term dependencies across sequences of data, which are critical to projecting future crop patterns based on prior trends. For example, while processing weather data collected using IoT sensors, a TAM-based model will assign greater priority to those time steps where the temperature or rainfall changed more than normal so that the model can learn trends like crop status following heatwaves or recovery following rain the integration of TAM into precision agricultural systems significantly enhances the prediction accuracy, be it for crop disease, yield, or pest infestation, by allowing the model to effectively process and highlight the most important time steps in complex, time-series agricultural data [19].

Fig. 3. The figure illustrates the architecture of a hybrid CNN-TAM model integrated with multiple Temporal Attention SubModules. Initially, the input data is processed through a sequence of convolutional layers with increasing filter sizes (Conv 32, 64, and 128), followed by max pooling operations to reduce dimensionality and retain essential features. After each significant convolutional-pooling block, temporal features are extracted and passed to corresponding Temporal Attention SubModules (1, 2, and 3). These submodules take the local features (L^1, L^2, L^3) along with global contextual information (G) to compute refined attention-enhanced representations. These outputs are then fused into a final fully connected layer (Layer 2), enabling the model to capture both spatial and temporal dependencies for more accurate and context-aware predictions.

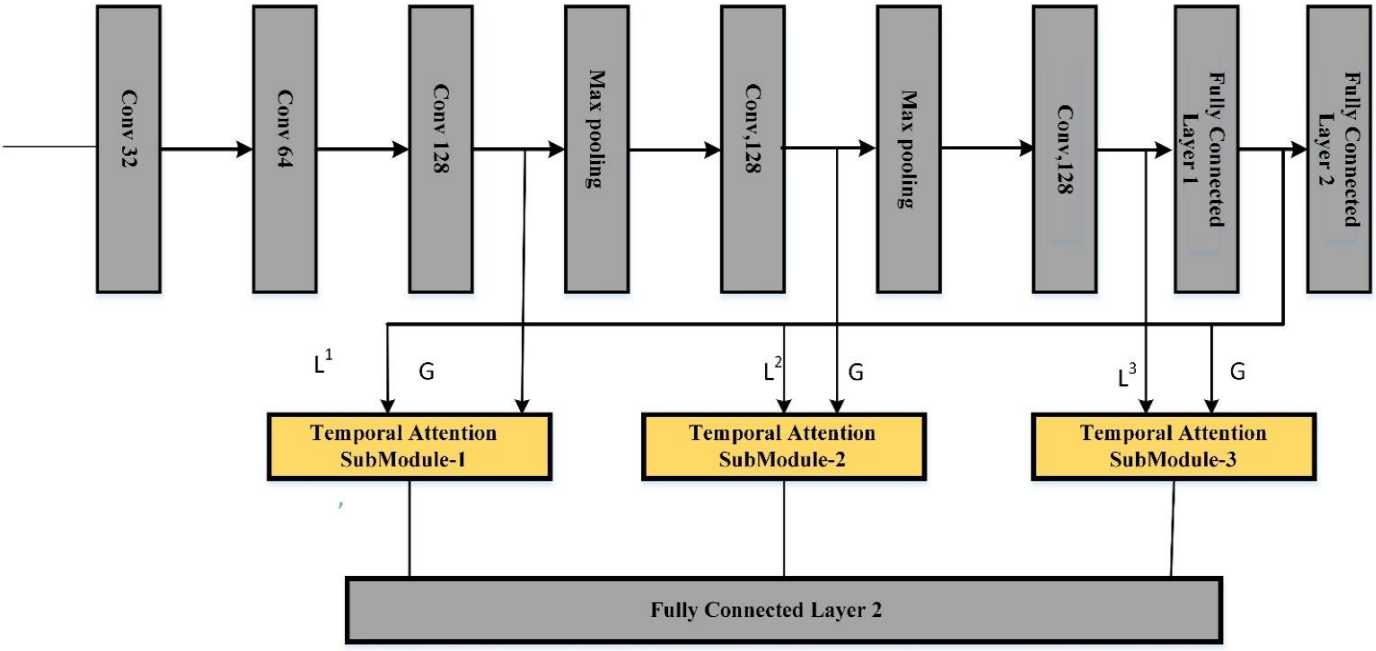

Fig. 3. Structure of CNN-TAM.

E. AI Devices

The integration of Convolutional Neural Networks (CNNs) and the Temporal Attention Mechanism (TAM) allows efficient and intelligent analysis of spatial and temporal information in precision agriculture and is thus highly suitable for application on Edge AI devices. Edge AI devices such as NVIDIA Jetson, Raspberry Pi with AI accelerators, and specialized IoT gateways execute computations locally, maintaining latency minimal and cloud computing utilization at its lowest. In a CNN-TAM hybrid system, the CNN learns spatial features from multispectral satellite imagery, drone-shot farm views, and heat maps created by sensors, recognizing patterns such as vegetation health and soil type. At the same time, TAM analyzes time-series data from IoT sensors, targeting important environmental changes such as temperature increases, variations in soil moisture, and rainfall changes that affect crop growth. The Edge AI deployment of such a hybrid model enables real-time on-field inference, making farmers' decision-making optimal by automatically identifying anomalies, forecasting yield fluctuation, and recommending irrigation fine-tuning in real time. Mathematically, Edge AI deployment means quantization and pruning of CNN-TAM models for efficient execution on low-power platforms. The inference can be symbolically represented in Eq. (7),

$$y = \sum_t \alpha_t h_t + \text{CNN(X)} \quad (7)$$

where α denotes TAM's time-step t attention weight. h_t is the temporal feature representation and CNN(X) retains spatial farming knowledge. Applying the CNN-TAM hybrid to Edge AI chips provides farm systems with low-latency decision responses, less bandwidth consumption, and increased data secrecy, which helps facilitate real-time crop monitoring on a large scale and targeted interventions in precision agriculture.

V. Result and Discussion

The Results emphasizes the performance of the proposed CNN-TAM model for the prediction of soil moisture and temperature in precision agriculture. Experimental comparisons confirm that CNN-TAM clearly outperforms conventional models, and the best RMSE (1.7) outperforms Linear Regression (3.5), Random Forest (2.8), LSTM (2.4), and single CNN (2.1). The Temporal Attention Mechanism (TAM) enhances the model's predictive capability by concentrating on major time steps such as rainfall episodes and drought periods to make better irrigation and resource allocation decisions. Training and validation loss curves confirm the model's excellent generalization capability, with minimal overfitting. Scatter plot examination of real vs. predicted values reveals CNN-TAM makes very precise predictions, with small differences arising from environmental uncertainties. In addition, temporal attention weight visualization shows that the model assigns higher importance to impactful time steps, improving its ability to detect trends in soil moisture variations. Edge AI deployment further enhances the model's real-world applicability, reducing latency and bandwidth usage while ensuring real-time farm monitoring. The results validate that CNN-TAM is an effective, scalable, and intelligent solution for improving agricultural decision-making, optimizing irrigation schedules, and ensuring sustainable resource management.

Fig. 4 shows the daily variations in soil moisture (%) and temperature (°C) for a ten-year period (2007–2016). The periodic trends reflect seasonal changes, with increases and decreases in temperature corresponding to natural climatic fluctuations. Soil moisture level varies with precipitation, evaporation, and water application management as well. Real-world variation of environmental conditions implies both signals include the presence of noise, so predictive modeling will be effective in.

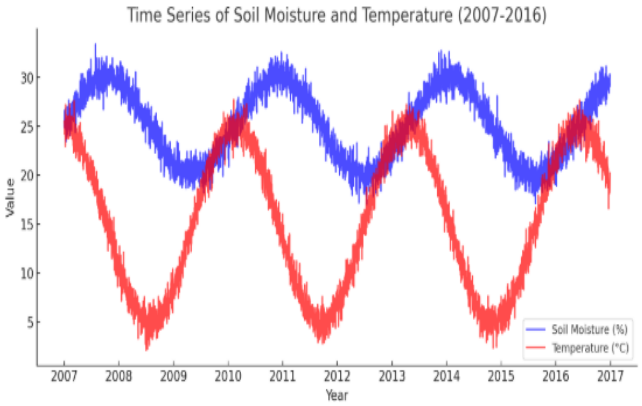

Fig. 4. Time series of soil moisture & temperature (2007–2016).

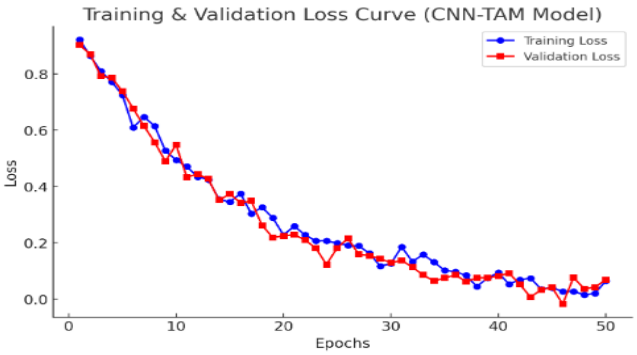

Fig. 5. Training & validation loss curve (CNN-TAM model).

Fig. 5 illustrates how the CNN-TAM model learns for more than 50 epochs. The training loss slowly diminishes, indicating the model is improving in terms of fitting the data. The validation loss diminishes too but at a slower rate, indicating generalization to new data. The small difference between training and validation loss indicates the model is not overfitting and, therefore, is trustworthy in real-world prediction. The minuscule differences are due to the stochastic process of optimization, which is common in deep models.

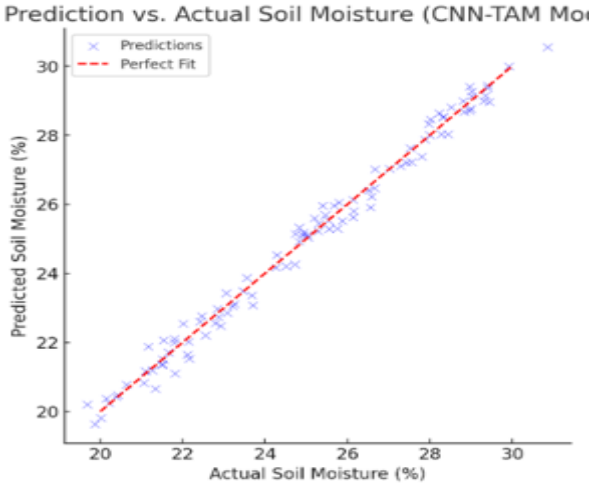

Fig. 6. Temporal attention weights (CNN-TAM model).

Fig. 6 is a scatter plot of predicted versus measured values from the CNN-TAM model. Red dashed line is a theoretical best prediction (when predicted = measured). Most points are near this line, showing the model to be highly accurate. The minor deviations are small prediction errors that may be caused by environmental uncertainties or sensor noise. Overall, the model is capable of learning soil moisture patterns well, and thus can be applied to real-time crop monitoring.

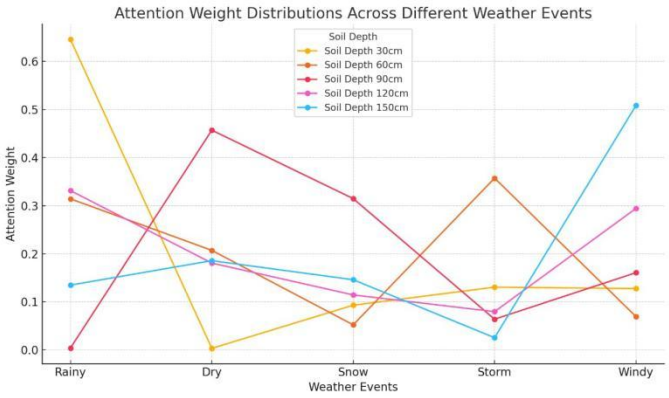

Fig. 7. Temporal attention weight distributions across different weather events (CNN-TAM model).

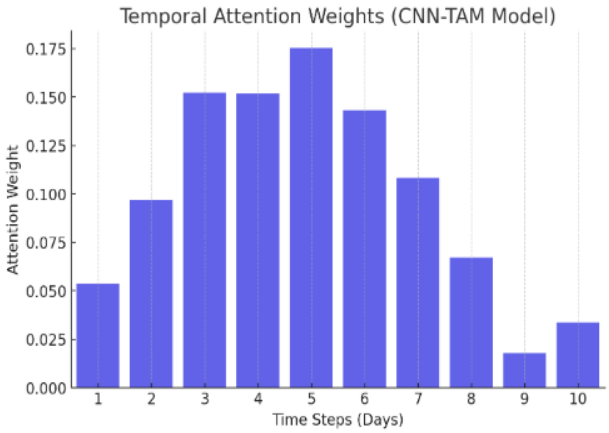

Fig. 8. Temporal attention weight distributions across time steps in the CNN-TAM model.

Fig. 8 illustrates the distribution of temporal attention weights assigned by the CNN-TAM model across 10 time steps (days) and Fig. 7 shows temporal attention weight distribution across different weather events (CNN-TAM model). Each bar represents the relative importance of data from a specific day in contributing to the final prediction of soil moisture or temperature. The model assigns higher weights to days 3 to 6, indicating that information from these time steps carries more significance in learning temporal patterns. In contrast, the weights are lower at the beginning and end (days 1, 9, and 10), suggesting reduced influence from these periods. This selective attention enables the model to focus on the most relevant temporal features, enhancing prediction accuracy.

Table I presents the Root Mean Square Error (RMSE) values for different predictive models, with lower values indicating better performance. Among the models compared, Linear

Regression has the highest RMSE (3.5), showing the least accuracy in predicting soil moisture. Random Forest improves upon this with an RMSE of 2.8, followed by LSTM at 2.4, which leverages sequential learning to capture temporal dependencies. CNN further reduces the error to 2.1 by extracting spatial patterns in soil moisture data. Finally, the CNN-TAM model achieves the lowest RMSE (1.7), demonstrating its superior ability to combine convolutional feature extraction with temporal attention mechanisms, making it the most effective model for precise soil moisture prediction.

TABLE I. COMPARISON WITH VARIOUS MODELS

Model	RMSE (Lower is Better)
Linear Regression	3.5
Random Forest	2.8
LSTM	2.4
CNN	2.1
CNN-TAM	1.7

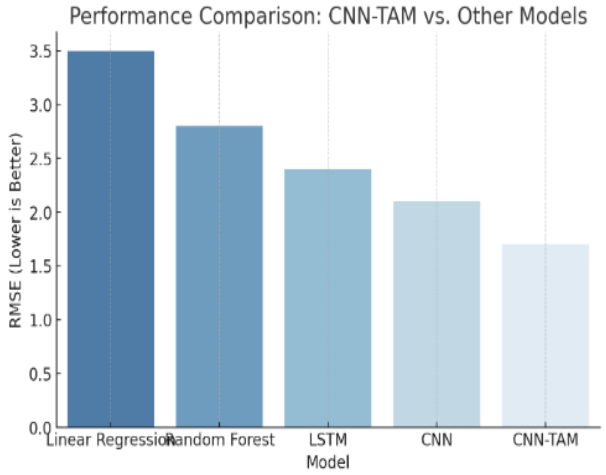

Fig. 9. Performance comparison.

Fig. 9 compares the performance of different predictive models including Linear Regression, Random Forest, LSTM, CNN and the proposed CNN-TAM model in terms of Root Mean Square Error (RMSE). Since RMSE is used to measure prediction error (lower is better), the CNN-TAM model performs the best with the lowest value of RMSE, illustrating that it is the best in accuracy. On the other hand, Linear Regression performs the worst, followed by Random Forest and LSTM. The CNN model by itself is superior to these conventional approaches, but the incorporation of Temporal Attention Mechanism in CNN-TAM boosts prediction accuracy for soil temperature and moisture in precision agriculture substantially.

A. Discussion

Compares the performance of different predictive models including Linear Regression, Random Forest, LSTM, CNN and the proposed CNN-TAM model in terms of Root Mean Square Error (RMSE). Since RMSE is used to measure prediction error (lower is better), the CNN-TAM model performs the best with the lowest value of RMSE, illustrating that it is the best in accuracy. On the other hand, Linear Regression performs the worst, followed by Random Forest and LSTM. The CNN model by itself is superior to these conventional approaches, but the incorporation of Temporal Attention Mechanism in CNN-TAM boosts prediction accuracy for soil temperature and moisture in precision agriculture substantially.

The critical challenges like power limitations and sensor calibration problems. Power limitations occur because sensors are deployed remotely and tend to be powered by batteries or solar power, which results in potential loss of data, system downtime, and real-time monitoring breaks when power runs out. Such interruptions can lower the accuracy of AI forecasts, resulting in inefficiencies such as crop stress or irrigation mismanagement. Secondly, sensor calibration is critical for precision readings, given that soil moisture sensors are soil-specific and temperature sensors drift with time. Unless accurately calibrated, information input into AI models becomes questionable, resulting in misclassifications and false decisions like over-irrigation, under-irrigation, or untimely planting. Cumulatively, these challenges undermine the effectiveness and reliability of AI-based decisions in precision agriculture, necessitating energy-efficient designs, reliable calibration procedures, and smart data handling strategies.

The CNN-TAM model presented in this research significantly advances precision agriculture by combining spatial feature extraction with temporal analysis, achieving the best RMSE of 1.7 compared to conventional models. This innovative approach prioritizes crucial temporal patterns like rainfall and drought periods, enabling more informed agricultural decision-making while its Edge AI implementation reduces latency and bandwidth requirements, making real-time monitoring accessible even in remote farming locations with limited connectivity. Despite these achievements, the study acknowledges challenges including sensor drift, environmental noise and processing limitations on Edge devices. Future research directions aim to incorporate additional agronomic parameters, enhance cross-climate adaptability, and optimize for ultra-low-power hardware, ultimately supporting more sustainable farming practices through improved resource management and increased resilience to changing environmental conditions. The practical implications of this research extend beyond technological advancement, offering tangible benefits for agricultural sustainability and food security. By providing farmers with accurate, real-time soil moisture and temperature predictions, the CNN-TAM model enables precise irrigation scheduling, reduces water and fertilizer waste, and helps mitigate the impacts of extreme weather events on crop yields. This represents a crucial step toward smart farming systems that can address global challenges such as climate change, resource scarcity, and increasing food demand while simultaneously improving economic outcomes for farmers through optimized resource utilization.

VI. CONCLUSION AND FUTURE WORKS

This research proposal creates an Edge AI-based CNN-TAM model that improves forecast of soil moisture and temperature, resulting in the best management irrigation and sustainable agriculture practices. The spatio-temporal feature enhancement through the fusion of CNN's spatial pattern extraction and

TAM's temporal feature prioritization brings in a good level of the predictive accuracy, shaving RMSE to 1.7—a clear leap over common models. The Edge AI deployment allows for real-time inference low latency and reduced reliance on the cloud giving it actually suitable for rural areas which are not going to have a very high level of network availability. The model reduces water and fertilizers waste more effectively, enhancing intelligence at farm level and building resilience with the climate. By solving important agricultural problems, this AI-based method increases farming efficiency and diligence.Despite being effective, there still are certain limitations. Sensor drift, noise due to external factors and, processing overhead on power-constrained Edge AI Hardware may degrade the deployment efficiency.

In order to enhance the model robustness, the future work will test including in the model of additional agronomic arguments with such as crop growth progression, pest detection, and multi-spectral imaging. Increasing model portability across different climatic settings and adjustment to onboard on ultra-low-power AI chips shall also extend applications. Furthermore, using the blockchain for the secure management of farm data and viewing a farm as a place where AI-driven systems can automate the farming procedures will facilitate its practical inclusion. These advancements will drive wider adoption of AI-based precision agriculture for long-term sustainability.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2025-2099-02".

***Abstract*—Alzheimer's Disease (AD) is a terminal illness affecting the human brain that leads to deterioration of cognitive function and should therefore be diagnosed as early as possible. The goal of this work is to come up with a precise and interpretable diagnostic model for the early diagnosis of Alzheimer's Disease (AD) based on multi-modal neuroimaging data. Current deep learning models such as Convolutional Neural Networks (CNNs) are limited in that they lose spatial hierarchies in 3D medical images, which inhibits classification performance and interpretability. To overcome this, in this work, we introduce a new 3D Capsule Network (3D-CapsNet) framework that captures spatial relations more effectively with dynamic routing and pose encoding to improve volumetric neuroimaging data analysis. Our approach has three principal phases: extensive pre-processing of MRI and PET scans such as skull stripping, intensity normalization, and motion correction; feature extraction through the 3D-CapsNet model; and multi-modal classification based on fusion. We used the Alzheimer's Classification dataset from Kaggle for training and testing. The model is implemented in the Python platform with TensorFlow and Keras libraries incorporating 3D CNN operations along with capsule layers to extract fine-grained features of AD-affected brain areas such as the hippocampus and entorhinal cortex. Experimental results show that our model reaches a very high classification accuracy of 92%, which is higher than the conventional architectures VGG-16, ResNet-50, and DenseNet-121 in accuracy, precision, recall, F1-score, and AUC-ROC. This strategy is helpful to clinicians and medical researchers because it gives them a non-invasive, interpretable, and trustworthy tool for diagnosing and monitoring various stages of AD (Non-Demented, Very Mild, Mild, and Moderate). It sets the stage for real-time clinical integration and future studies in monitoring disease progression over time.**

Keywords*—Alzheimer's detection; 3d-capsule networks; multi-modal neuroimaging; deep learning in healthcare; early diagnosis and classification

I. Introduction

Alzheimer's disease (AD) is a chronic neurodegenerative disease which clinically manifests itself mainly through the impaired elements of cognition including of memory, thought co-ordination, and behavior. Alzheimer is the most common type of dementia being a contributing factor to nearly 60–80% of dementia globally [1]. AD is one of the major global health issues affecting millions of people, growing evidence suggest that there will be threefold increase in worldwide incidence rate of this disease by 2050 [2]. To date, no cure has been found for AD and the management of the condition is largely done without trying to halt the progress of the disease directly. But early diagnosis is essential as it may considerably defer disease progression, as changes in diet or medicines, or other forms of cognitive treatment, may help slow down dementia progression and enhance the patient's quality of life. However, due to non-specific and overlapping signs and symptoms the diagnosis of the disorder in the early stage has not been easy.

It seems that the previously used general approaches for AD identification include clinical examination, neuropsychological testing, and neuroimaging tools such as MRI, PET, and CT, which demand the opinion of an experienced specialist concerning structural/functional changes in the brain. These time-honored techniques, though have been proved to work, are tedious, methodical, least accurate and present the problem of inter-observer variability [3]. A sample AD diagnosis using deep learning has been enhanced, especially CNNs for the extraction of more features on neuroimaging data [4]. But the CNNs have certain issues like ignoring/disregarding of the spatial hierarchy given by pooling function such as max–pooling, non-equivariant feature learners and less ability to recognize the intricate changes in the shape patterns of the brain. This is true because some features are lost or misclassified, especially when

detecting early-stage AD where structural brain alterations are minimal [5].

The problems that arise while using the CONV based model, there is study interest in the development of more complex deep models that preserves spatial hierarchies for Alzheimer's detection [6]. There is one framework that has proposed as one possible solution, which is the 3D-CapsNets, which provide a significant leap over CNNs by maintaining the spatial relations for regions in the brain and providing improved features. While CNNs work with scalar neuron activations, CapsNets consist of vector-based capsules to determine the presence of features and their orientations in images and thereby, helping to reduce the misclassification arising from image rotation in brain imaging. More also, single modality neuroimaging techniques do not give comprehensive information about the pathological progression of the disease because each evaluates a unique aspect of Alzheimer [7]. Multi-modal analysis is essential for increasing classification efficiency since it brings structural, metabolic, and functional information regarding possible changes in the human brain [8]. However, the current methods of fusing multi-modal information have major flaws in the way they combine the features of the different modes, hence causing loss of some valuable information [9]. To overcome these limitations, a novel multi-modal deep learning framework based on the Capsule Network is developed to enhance the generalization of the classification by making an effective use of various Neuroimaging data Types while maintaining the spatial correlation that is productive in early AD diagnosis. In addition, to achieve high accuracy of the model, the neuroimaging data has to undergo several preprocessing steps for removing artifacts, non-brain regions, and intensity variation which may affect the performance of the model [10]. Skull stripping is an essential step that aims to get rid of the probable interference from non-brain organs such as scalp, skull, and dura [11]. Nevertheless, the existing methods of skull stripping can be completely or partially inaccurate, which entails information loss or presence of artifacts. To improve the preprocessing efficiency, this study compares FSL BET and Deep BrainSeg in the skull stripping process so as to have enhanced clean inputs for classification.

The main goal of this study is to propose a more effective and reliable construct of a deep learning model for recognizing the early modality of Alzheimer's through Capsule Network based multi-modal neuroimaging [12]. In particular, there should be the use of 3D-CapsNets for feature extraction and enabling the recognition of part-whole hierarchies of human brain structures to determine different stages of Alzheimer's. Multi-modal neuroimaging information combining MRI, PET, and CT scans is applied for enhancing the classification performance and utilizing the additional data for the classification of Non-Demented, Very Mild Demented, Mild Demented, as well as Moderate Demented stages [13]. Skull stripping is used in enhancing the preprocessing of neuroimages data by removing unwanted structures that are not brain tissue, hence providing enhanced and quality input images [14]. In addition, the paper compares 3D-CapsNets with conventional CNN-based models with the help of accuracy, precision, recall, F1-score, and ROC-AUC curves to prove the mentioned framework. Therefore, the utility of the model in real-life scenarios regarding its computational time, its validity across other datasets, and possibility of implementation in clinical practice is considered [15]. In this manner, these objectives of the study will help to address the gap of the use of AI deep learning methods for clinical neuroimaging applications and offer method, which is powerful, interpretable, and automated in diagnosing Alzheimer's disease at the early stage, for better management of patient.

The selection of the suggested 3D-Capsule Network (3D-CapsNet) model was based on its intrinsic potential to preserve spatial hierarchies and pose data during dynamic routing, which is very important for identifying slight structural variations in neuroimaging data characterizing Alzheimer's disease. The regular CNNs tend to lose important spatial relationships through pooling operations, while CapsNets preserve part-whole relationships, making it possible for better early-stage anomaly detection. In addition, 3D-CapsNets suit volumetric medical images like MRI, PET, and CT scans better because they present a better representation of brain structures. These factors render the model particularly well-adapted to the challenging task of multi-stage Alzheimer's diagnosis.

A. Study Contributions

This study enhanced deep learning model called 3D Capsule Networks (3D-CapsNets) to detect early stage of Alzheimer's disease, given that existing models based on CNNs are seen to have the problem of losing spatial information because of pooling layers. In this way, the anatomical relationship is maintained with other support of vector-based feature encoding and dynamism in the routing to ramp up biomarker identification. The feature of multi-modal imaging that is most important for this research is directly related to MRI for structural changes, PET for metabolic activity and CT for better definition of neuroanatomy to detect Alzheimer's pathology. This illustrates a great enhancement in the classification performance compared to when using a single modality. The result of the extensive experiment also reveals the superiority of the proposed 3D-CapsNet model over traditional one.

CNN structures such as VGG-16, ResNet-50, and DenseNet-121 by both the considerations of accuracy and time. The wellness of the skull stripping process proceeds input preprocessing by intensifying the quality of the input that go through advanced preprocessing techniques of intensity normalization and motion correction. In conclusion, the present study contributes a very efficient and closely realistic model for computerized identification of Alzheimer's disease. The key contribution of the study is given below:

- Suggested the use of a 3D-CapsNet model in order to maintain the spatial hierarchies in the spectrum for accurate identification of AD.
- Multi-modal neuroimaging data such as MRI, PET, and CT for accurate diagnosis of the disease.
- Usual preprocessing methods such as skull stripping, intensity normalization and motion correction were performed.
- Derived better classification accuracy over other CNN models, including accuracy, F1-score, AUC-ROC.

- In order to file the interpretation process, CapsNet activation was visualized, and the model was designed for further clinical implementation.

By so doing, this study presents a clinically relevant AI method for the automation of ALZ diagnosis with interpretability which can enhance its deployment based on neuroimaging techniques.

II. Literature Review

Currently, several methods for Alzheimer's disease (AD) detection were based on the usage of Multi-layer and Deep Learning algorithms with the support of neuroimaging [16]. Several ML algorithms such as SVMs and RFs work normally and demand an intermediate feature extraction, which is time-consuming [17]. The use of CNNs paved way for better automated diagnosis as the networks directly provided the hierarchical feature mapping of brain scans [18]. However, CNNs lack the ability to handle 3D volumetric data, flatten the spatial hierarchies after using max-pooling, and they are sensitive to affine transformations and therefore early-stage AD is misclassified frequently. Also, CNNs are dependent on large labeled datasets, and most of them are difficult to explain, thus not so suitable for clinical applications [19]. The other issue in the use of neuroimaging for diagnosis of AD is that of standardization of the approaches employed. MRI shows a shrinkage of the hippocampus while PET scans demonstrate disfunctioning in the area and high-resolution images are produced using CT scans. Nevertheless, single modality imaging does not depict the entire spectrum of the glycogen storage disease pathology [20]. Combination of these techniques as a multi-modal neuroimaging improves the classification accuracy result but it has some problem like dissimilarities in resolution and in registration. This is done through Capsule Networks introduced by Geoffrey Hinton where spatial hierarchies are maintained by using vector-based capsules as opposed to scalar neuron activations. The CapsNets do not utilize the max pooling activation function, instead, it uses the dynamic routing that maintains the spatial relationships which is important in medical image analysis unlike the CNNs. CapsNets have been performing better than CNNs in medical image classification, but most of them are performed on 2D medical images and therefore they are not very efficient in dealing with volumetric neuro imaging. An extension of CapsNets to 3D-CapsNets is proposed here, which enhances the former's ability to handle volumetric data and better generalization and operational stability in terms of imaging changes [21]. Sarker, in his review in the International Journal of Molecular Sciences also points at some of the limitations in the detection of AD where early diagnosis is compromised by poor ML models, biomarkers such as amyloid plaques and tau proteins mostly lack reliability, diagnosis involving cost-intense procedures such as lumbar punctures and PET scans, and diagnostic subjectivity that even leads to bias. It also has an undesired effect of contributing to the further delay in diagnosing AD due to the absence of a guidelines on screening for biomarkers in every patient. These limitations are overcome by developed early diagnosis with the help of 3D-CapsNets that can identify the slight modifications in the brain before the clinical signs appear and identification of brain disorder with the help of Multi-Modal Neuroimaging. PET-MRI-CT fusion is an improved method that integrates structural changes in the brain as well as functioning changes to improve detection [22]. Functional connectivity changes in fMRI are the novel biomarkers using AI-driven models that maintain the spatial hierarchy and increase diagnostic accuracy in disorders. The employment of artificial intelligence in screening AD is improving the screening without using invasive procedures or expensive PET scans. CapsNets create easily explainable and normalizing evaluations thus eliminating or reducing the influence of examiner bias. It allows for the real-time analysis of neuroimaging data, to perform multi-modal imaging in a worldwide scramble environment. Artificial Intelligence help to enhance classification and increase the model's scalability by maintaining spatial orientation in 3D models. It also helps in distinguishing between AD and other sorts of dementias like Parkinson's or Lewy body dementia [23]. Also, the component highlights disease prognosis in AI models regarding the progression of a patient's condition and neuroimaging for treatment monitoring [24]. The review analyzes CNN and diagnostic limitations together how Caps Nets and Multi-Modal Neuroimaging present opportunities for AD detection through automated diagnosis which is both accurate and cost-efficient. The study targets present field obstacles to achieve progress in early diagnosis of Alzheimer's disease while enhancing medical results for patients [25]. Table I shows the summary of existing studies.

TABLE I. Summary of Existing Studies

Source	Purpose	Advantages	Limitations
Deep Learning-Based Diagnosis of Alzheimer's Disease	To explore ML and DL models in AD diagnosis	Showcases DL models for automatic AD diagnosis	Lacks info on model limitations
Utilizing Multi-Class Classification Methods…	Describes use of SVMs, RFs for disorder prediction	Highlights classical ML models	Time-consuming due to feature extraction
ScienceDirect: Multi-Modal Neuroimaging Methods	Shows how CNNs are used in automated AD diagnosis	CNNs directly learn hierarchical features	Cannot handle 3D data well, loses spatial info with max pooling
Pattern Recognition in Spectral Analysis	Evaluates CNNs in medical imaging	Identifies CNN strength in image classification	CNNs need large labeled data and lack explainability
Imaging Methods Applicable… Insulin Resistance	Explains different neuroimaging modalities for AD	MRI, PET, CT reveal various brain aspects	Single modality lacks complete view; modality mismatch issues
Geoffrey Hinton - Capsule Networks	Introduces CapsNets to maintain spatial hierarchies	Avoids max pooling, uses dynamic routing	Initially designed for 2D images
Deep Learning Techniques for Alzheimer's: A Review	Proposes 3D-CapsNets to handle volumetric data	Maintains spatial relationships; better generalization	Requires more computational power
Sarker – IJMS Review	Critiques current AD diagnosis strategies	Addresses limitations of ML, biomarkers, invasive scans	Highlights subjectivity, cost, and lack of early markers

Multimodal Medical Image Fusion Techniques	PET-MRI-CT fusion to improve detection accuracy	Combines structure and function insights	Dissimilarity in resolution and registration challenges
Biomarkers of Dementia with Lewy Bodies	Differentiates AD from other dementias	Uses AI for better differentiation	Biomarker overlap may affect clarity
Vrahatis et al., 2023	Analyzes prognosis, AI's role in treatment monitoring	Supports progression tracking and scalability	Still evolving and not standardized
Alzheimer's Disease: Treatment Strategies	Summarizes the gap between diagnosis and treatment	Calls for cost-efficient AI solutions	AD progression still hard to model

III. Problem Statement

The early diagnosis of Alzheimer's Disease (AD) should be conducted because this type of neurodegeneration progressively affects cognition, memory, and daily tasks. This has always presented a major problem since the conventional diagnostic methods include clinical assessment and neuropsychological testing are usually subjective, have accurate results and take time before a patient is diagnosed. Machine learning specifically use CNN for neuroimaging data analysis and challenges. These are the effects of max pooling that cause the loss of spatial relationships, the failure to generalize and the sensitiveness to variations in the data. Also, the use of a single neuroimaging technique may fail to provide both functional and structural changes relevant to AD. Moreover, in most of cases, the conventional algorithms appear to be inefficient for solving such issues with the interpretation of stereoscopic and 3 Dvolumetric structures which cause misclassification in the initial stages of the disease. In order to meet the needs of these challenges, this study proposes deep learning framework known as 3D Capsule Networks (3D-CapsNets) that preserves the spatial organization and relation between the parts and the whole in the structure of the brain. Whereas MRI scans primarily inform about structural alterations, PET scans provide information on metabolic alterations and CT scans depict the lesions. These include skull stripping, which helps get rid of extraneous skull signals, intensity normalization that helps equalize the intensities of different scans and motion artifact removal process which helps rid the input data of interfering movements. The characteristics of the 3D-CapsNet model help with interpretation and increases the accuracy of the classification of structural and metabolic differences. The key objective of this approach is to develop a feasible, robust and adaptive real-time diagnostic tool for AD that would be capable to aid immediate and individualized intervention for the patient.

IV. Methodology

Study proposed approach integrates several brain scan types (MRI, PET, CT) to detect Alzheimer's using 3D Capsule Network architectures (3D-CapsNets). Prepare images through skull removal and normalize intensity levels while removing movement problems to create better quality data. Data enhancement strategies that modify images by transformation and contact with noise improve how the model works with different data sets. Caps Nets create better feature representations compared to other models because they maintain spatial hierarchy across elements.

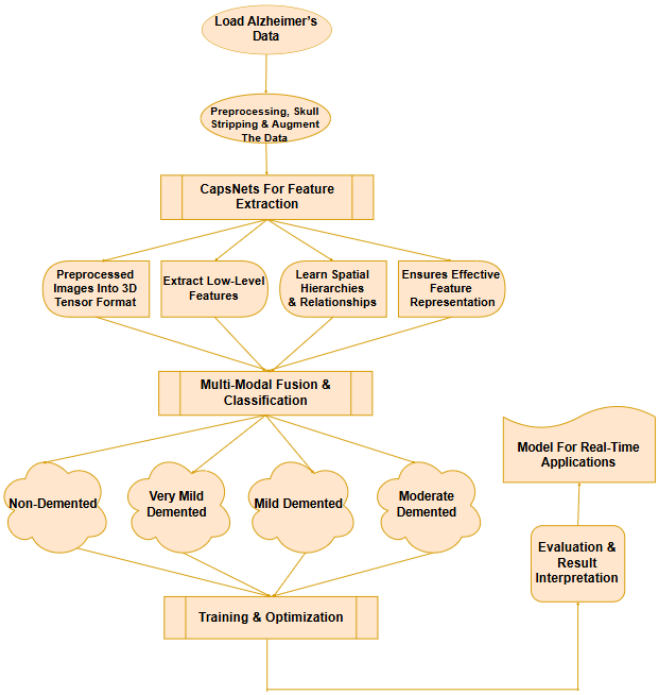

Fig. 1. Implementation of early Alzheimer's detection.

Fig. 1 shows the early execution of Alzheimer's detection. The model undergoes updated parameter changes plus decision making systems during training to develop solid learning methods. Specific evaluation methods test performance through accuracy metrics plus precision, recall, F1-score and AUC-ROC curves when comparing with standard deep learning methods.

A. Dataset

The datasets that are taken from Kaggle resource [26] for their study on detecting early signs of Alzheimer's using Capsule Networks and Mixed Neuroimaging Methods because these datasets contain the high-quality MRI PET and CT scan data necessary to analyze different forms of brain scans together. Dataset features four distinct groups including healthy subjects and patients with Very Mild Demented, Mild Demented and Moderate Demented stages of Alzheimer's disease. Split keeps equal numbers of samples across every class while setting a training and testing sections. Each brain imaging technique requires skulls to be removed so it can see clear features through BET, ROBEX, or an advanced method. To help the model work better the data needs extra preparation through modifications that normalize brightness levels and remove movement defects plus reduce noise. It follows all ethical rules of HIPAA and IRB to protect patient privacy and keep their personal information hidden. It standardized data practices help multiple measurement tools work the same way to lower measurement errors. The training data improves from multiple angles when the model adds random rotations, flips, and changes image brightness levels. The suggested model needs ethical datasets and standardized information to detect Alzheimer's disease progression and aid early treatment. The attributes of the dataset are shown in Table II.

TABLE II. DATASET USED FOR ALZHEIMER'S CLASSIFICATION

Class Label	MRI Samples	PET Samples	CT Samples	Total Samples
Non-Demented (ND)	2,500	1,800	1,200	5,500
Very Mild Demented (VMD)	2,000	1,500	1,000	4,500
Mild Demented (MD)	1,800	1,400	900	4,100
Moderate Demented (MOD)	1,500	1,100	800	3,400
Total Samples	7,800	58,000	3,900	17,500 [27]

B. Image Preprocessing

First processing neuroimaging images becomes essential for building effective deep learning models that detect Alzheimer's. Preparation steps prepare brain scans by clearing skull areas while matching brightness levels before handling movement problems and creating extra samples for strong model success.

1) Skull stripping: Neuroimaging study needs skull stripping which removes brain tissue parts like skull bone from MRI scans to help investigation accuracy. The Brain Extraction Tool from FMRIB Software Library uses a deformable surface model to systematically improve brain mask detection by erasing unwanted tissue elements.

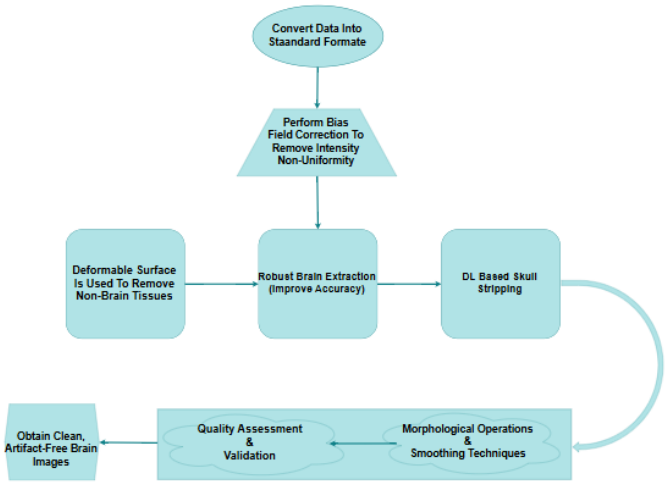

Fig. 2. Work flow of skull stripping.

Fig. 2 depicts the working process of skull stripping. BET calculates the brain's location in space to set up its spherical expansion surface which sticks to the tissue shape while pushing away surrounding elements. Under extreme noise BET may remove brain tissue areas or retain skull remnants from the processed image. RBE uses a combined technique of statistical and machine-learning models to deal with diverse brain imaging settings and data changes. By applying thresholding methods and region-growing techniques alongside brain anatomy understanding RBE produces a better brain segmentation result than manual operations. Modern Deep Learning technology with CNNs and U-Net architectures now removes skulls better than older manual rules and anatomical methods.

These models process many brain image records to learn patterns that enable them to handle different scanners and patient populations. DeepBrainSeg shows exceptional skull stripping results because it uses deep learning to discover brain organization in many medical images regardless of intensity changes and brain shape differences. The deep learning approaches effectively adjust to various MRI inputs which helps detect Alzheimer's disease better and also lowers human involvement when preparing high-quality datasets.

2) Intensity normalization: Data normalization keeps MRIs PET and CT scans comparable through their pixel intensity ranges no matter which scanner produced them. Techniques include:

- Min-max normalization – By scaling intensity values to values from 0 to 1 the technique makes results easier for processing.
- Histogram matching – This technique matches how different subjects display image brightness patterns to keep results consistent.

3) Motion artifact removal: When patients move during MRI scans their images become damaged which leads to wrong diagnosis results. Healthcare centers use regular practice to solve movement problems in medical scans.

- Rigid and affine transformations adjust images by standardizing their positions through linear adjustments.
- SPM leverages image sequences to detect motion patterns then uses them to makeover image distortions.
- Deep learning models that detect motion artifacts use pairs of good-quality and scan-distorted brain images to produce corrected imaging data automatically.

4) Augmentation techniques for better model generalization: Data augmentation acts as a base function for medical image study through deep learning methods especially in brain scans as it expands training datasets while strengthening model performance and preventing overtraining. When working with limited Alzheimer's data sets that contain class imbalance researchers apply augmentation methods to modify brain scans safely which helps the model perform correctly under true imaging conditions and differing brain structures. When working with MR and PET scans study researchers normally flip and rotate them randomly across multiple angles and axis positions to handle patient position differences and scanner placement adjustments. The technique makes sure the model does not depend on exact spatial patterns when making predictions. The image enhancement process Contrast Adjustment makes the model experience realistic MRI scanner outcome variations, including patient motion and random background noise. The model develops essential image features that stay constant regardless of brightness changes when it performs automatic contrast level adjustments. By adding Gaussian noise to the images, the model must learn to handle scanner artifacts and signal disruption during training. The method teaches the network to understand meaningful patterns in the presence of all types of scan noise. Elastic deformation modifies small image areas to represent brain

anatomy changes caused by aging, illness and person-specific differences. The model better handles brain shape differences between patients when it gently adjusts brain patterns in a coordinated way. Including these augmentation methods into data preprocessing process helps 3D-CapsNets better generalize because neuroimaging data represents authentic brain situations better. Traditional CNNs tend to perform poorly when augmented data causes spatial abnormalities but CapsNets maintain spatial information which makes them resistant to such transformations. Through data augmentation systems achieve better results in disease detection while addressing training sample limits and building dependable automation for Alzheimer's disease assessment.

C. Feature Extraction Using 3D Capsule Networks

The technique of extracting features stands as the main element for detecting Alzheimer's disease in brain scans and 3D Capsule Networks enhance these capabilities over standard CNNs. Features in CapsNets should stay connected rather than being lost through pooling layers making them good for handling 3D medical image analysis.

1) Capsule networks architecture for 3D medical images: The 3D-CapsNet architecture builds upon Capsule Networks by applying 3D volumetric medical imaging to groups of neurons known as capsules that store complete spatial data. With vector-based neurons CapsNets differentiates itself from CNNs by processing 3D medical images to detect their features' position orientation and scale. A 3D-CapsNet system has three essential sections: primary capsules take in MRI, PET, or CT images to obtain spatial features and higher-level capsules handle brain structure, abnormality, and texture interpretation. Capsule Output Layer produces classification results based on everything learned. By following an organizational sequence 3D-CapsNet better recognizes how image parts relate to one another, which enhances medical image detection results.

The 3D-CapsNet calculates primary capsule output as uj through Wij with ui as input is given in Eq. (1).

$$\hat{u}_{j|i} = W_{ij} u_i \tag{1}$$

At this processing stage, the network takes input values from the previous layer and applies a weight matrix Wij to link each lower-level capsule i with higher-level capsule j. The transformed vector $u\hat{}j \mid i$ holds important feature associations so the network carries over spatial arrangement and structural connections into its next processing stage.

2) Dynamic routing mechanism in CapsNets: CapsNets differ from CNNs as they use dynamic routing instead of max-pooling to update the connections between capsules at different hierarchies. CapsNets preserve spatial relationships between lower and higher levels while making their results more immune to unwanted transformations. The routing coefficient cij follows this pattern to calculate its value is given in Eq. (2).

$$c_{ij} = \frac{\exp(b_{ij})}{\sum_k \exp(b_{ik})} \tag{2}$$

C_{ij} is the routing coefficient, b_{ij} is the log probability, and $\sum_k e^{b_{ij}}$ normalizes next layer of k capsules. Squashing function decides the output of higher-level capsules based on their input represent in Eq. (3).

$$u_j = \frac{||s_j||^2}{1+||s_j||^2} \frac{s_j}{||s_j||} \tag{3}$$

The mathematical product of all incoming capsule vectors produces sj while vj results as the output from the higher-level capsule. The output vj changes short vectors to zero values and pulls long vectors towards unity to maintain proper probability formats used for spatial understanding in data.

3) Extracting spatial hierarchies of features: Extracting Spatial Hierarchies of Features in 3D-CapsNets for Alzheimer's Detection. During brain image analysis with deep learning technology, feature extraction plays a pivotal role because it establishes what the model can effectively discover from brain structures through its training process. Using these methods helps find brain areas under change because they extract details correctly from the brain's complex structures. Applying max-pooling in traditional CNNs unintentionally loses place-based data and harms the connection between parts and brain structure. CapsNets employ routing techniques to properly position feature elements while preserving the disease-related alteration locations in the network structure. When examining multiple imaging methods of the brain (MRI, PET, CT) algorithms should preserve spatial awareness because each type of scan shows different aspects of Alzheimer's disease progression. MRI shows tissue structure while PET shows how cells function and CT shows density variations which together give complete brain information. Without specific space encoding a regular CNN cannot match and handle multiple data types but 3D-CapsNets can process both structures and transformations between different data classes. Technology excels at recognizing AD changes which become minute and hard to spot before the later stages of the condition.

3D-CapsNets can tolerate common image changes because they do not break under affine transformations. Because CapsNets work with vectorized features they capture object position and orientation by design which helps them resist scanning equipment variations and detects true disease patterns. The network design of CapsNets needs less training data as medical imaging samples are hard to label and expensive to validate. The capsule vector technology allows multiple signals to be processed simultaneously which helps training models without large datasets that CNNs usually need. Capable feature extraction of 3D-CapsNets enhances Alzheimer's detection models and lets them predict accurately with better explanation while working on multiple brain image sets. CapsNets perform better at brain structure analysis than CNNs because they process hierarchical feature encoding through vector inputs which effectively detect minor adjustments in brain patterns. The new feature detection system leads to faster and more solid Alzheimer's diagnosis which helps healthcare professionals make better treatment decisions for patients.

D. Multi-Modal Neuroimaging-Based Classification Model

AD causes many specific changes in brain anatomy and brain activity the same imaging device cannot show completely. Using all three scan types connects brain structure and function improvements to track AD progression. MRI shows detailed brain anatomy by revealing both hippocampal shrinking and cortical layer diminishments while PET spots disease-related metabolic changes and CT reveals brain structures with accuracy to see calcifications and cerebrovascular damage. The proposed model takes features from each deep learning source to create a combined brain representation. Identifying AD at an early stage depends on detecting minor brain changes using this system. The workflow of multi-modal neuroimaging with capsule network is shown in Fig. 3.

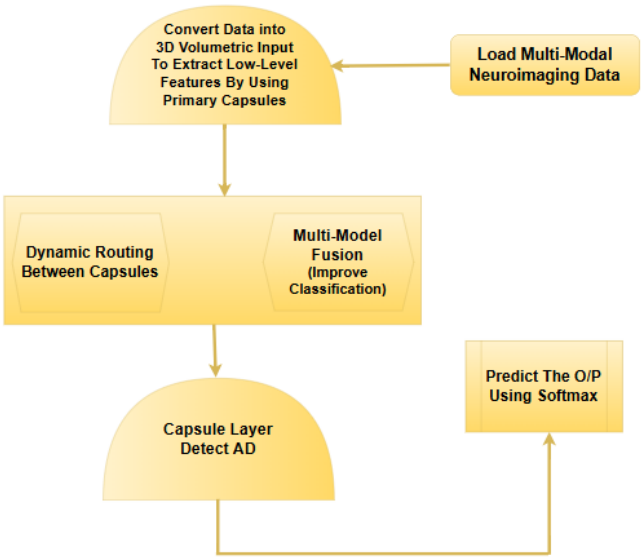

Fig. 3. Working process of capsule network with multi-modal neuroimaging techniques.

1) Fusion of different imaging modalities: The multi-modal classification system uses three autonomous processing pipelines which handle different imaging methods while 3D-CapsNets extract spatial networks and eliminate voxel relationship losses that traditional CNNs show. A merged feature set combines FMRIF and FCTF information into one extensive description for analysis.

$$F_{fusiion} = Concat(F_{MRI}, F_{PET}, F_{CT}) \quad (4)$$

In Eq. (4), $F\_fusiion$ is the combined feature vector from all modal, and F_{MRI}, F_{PET}, F_{CT} are the features extracted from MRI, PET, and CT. Fusion stands for the unified set of encoding features that contains information from anatomical as well as functional and structural markers linked to Alzheimer's disease. A fusion layer combines all three imaging databases so that classification optimization benefits from their collective information. The merged feature set passes through connected layers which normalize outputs and drop connections to prevent overfitting.

2) Model architecture for classification: The hierarchical model design incorporates 3D-CapsNets that extract features independently from each modality then proceeds with fusion and classification layers. The system architecture includes several consecutive components which function as follows:

a) Input layer: At the beginning input data consists of preprocessed MRI alongside PET and CT images, however it moves through the system.

b) Modality-specific feature extractors: The system contains three parallel 3D-CapsNets architectures which extract important features from MRI and PET and CT images.

c) Feature fusion layer: The Feature Fusion Layer combines extracted branch features into a combined high-dimensional vector.

d) Fully connected layers: The fully connected layers make use of ReLU activation to refine the combined features through dropout regularization.

e) Softmax classifier: The softmax classifier performs the last step by determining the AD stage probabilities for the four classification options.

3) Training strategy (loss function & optimization techniques): In order to achieve robust training, the model employs Categorical Cross-Entropy Loss to determine the metric that measures the difference between predicted probabilities and actual class labels. The loss function takes the following format:

$$L = -\sum_{i=1}^{N} y_i \log(\hat{y}_i) \quad (5)$$

In Eq. (5), the loss function is structured as natural log $(yi) + y\hat{}i + l$. Adam optimizer serves as the optimization choice because it modifies learning rates automatically during gradient update cycles thereby optimizing convergence performance. The training process incorporates:

Batch Normalization reduces training time when standardizing mini-batch input data values. Dropout Regularization stops training overfitting by turning off random neurons to make sure the model avoids narrow feature focus. The expanded dataset enables better estimation because Data Augmentation adds various transformed images to increase dataset variety. The model uses combined signal types at a capsule network structure through an advanced classification system that performs better than typical CNN systems for detecting Alzheimer's at an early stage.

E. Model Training and Optimization

A successful multi-modal neuroimaging-based Alzheimer's detection system depends on an exact training design that builds accuracy and performance as well as handling diverse patient data. Training a model requires adjustment of model parameters plus use of enhanced datasets followed by training methods that keep the model from becoming overly dependent on its training samples. The training parameters are explained in Table III.

1) Hyperparameter tuning: To make a deep learning system work well and produce consistent results for different patients must adjust its main settings first. Updating 3D-CapsNet hyperparameters lets the model find brain scans' spatial patterns effectively and run processing operations faster. These models depend on seven primary tuning parameters which control their learning rate, batch size, capsule numbers,

routing updates, dropped outputs, weight modification level, and selected optimizer. Learning rate (α) stands as the main hyperparameter because it controls how fast the model updates its weight values during backpropagation. A large learning rate lets the model escape its minimum location in an unstable way while too slow training speeds may delay convergence until falling into suboptimal minimum points. Models commonly use automatic learning rate systems to modify the learning rate when validation loss improves or worsens. Users use different strategies including learning rate annealing to decrease the rate when training progress stops and ReduceLROnPlateau or cyclical learning rates to change rates automatically. A model's ability to reach successful training results and run fast depends mainly on the chosen batch size. A small batch size supports better generalization since the model views more distinct training samples and resists fitting exclusively to specific examples. More weight updates during training make the process take longer and demand greater computational resources. A high batch size reduces training time but affects model accuracy due to updates made on large gaps between gradient measurements. Using batch normalization helps the model recognize stable patterns by normalizing activation outputs in batch groups.

TABLE III. TRAINING PARAMETERS

Parameter	Value
Optimizer	Adam
Learning Rate	0.0001
Batch Size	32
Epochs	50
Loss Function	Cross-Entropy
Dropout Rate	0.3
Routing Iterations	3

Capsule Networks rely on both capsule number and routing iteration value to function properly. Quantifying spatial details deep in capsular neurons calls for selecting an ideal number of layers to strike harmony between representation power and processing efficiency. The routing-by-agreement algorithm needs proper tuning since it adjusts capsule relationships repeatedly across multiple capsule levels. The network fails to understand complex spatial patterns when routing too few times but also becomes inefficient when it repeats routing more times. Using 3 to 4 routing iterations strikes a good balance between improved feature details and lower computer resource demands. Placing at random certain neurons out of action during training plus defining smaller weights protects models from excessive training. To enhance learning the network blocks random neurons within full connected capsule layers during training thus developing strong feature attributes. The suggested dropout range for training goes from 0.2 up to 0.5 based on the dataset size. Weight decay tackles overfitting by adding penalties to weight sizes which pushes models to remain basic and simpler. The model requires adjustment in a basic range of 1e-6 to 1e-4 to preserve its capacity to generalize.

The choice of optimizer affects how Capsule Networks perform their best. The Adam optimizer shows better results than SGD for medical imaging tasks since it automatically changes the learning rate per parameter to handle sparse gradients. Adam brings together momentum and automatic learning speed control to deliver steady and fast convergence results. The default β1 and β2 values of Adam optimizer (0.9, 0.999) for this model often cause poor generalization but can be adjusted to achieve better training results. Medical studyers choose from various hyperparameter search methods including grid search, random search, and Bayesian optimization to enhance optimization results. Grid search examines every predefined hyperparameter value to identify the best set though it demands high computational resources. Random search checks a selection of hyperparameters from a defined range to deliver fast computation options. Bayesian optimization lowers training expenses through its optimization method that prioritizes promising hyperparameter areas for better results. When 3D-CapsNets are adjusted properly they recognize neuroimaging patterns better to find Alzheimer's conditions sooner and handle diverse scans well.

2) Data augmentation strategies: Data augmentation helps models detect Alzheimer's better by increasing their power to handle small medical imaging datasets and avoid training problems. The augmentation pipeline combines multiple transformations from geometry as well as intensity to create strong and non-specific representations for the model. Random images transformations of scan position and angle let the model work well with multiple MRI and PET acquisition sets. Files with varying quality are corrected using contrast and brightness changes to keep the model from taking mistakes. The model learns better feature detection through noise injection when dealing with imperfect input data such as Gaussian and salt-and-pepper noise. The elastic deformations create natural brain changes by shifting brain structure positions to show different biological body profiles. Brain deformation should be examined in MRIs and PET exams due to its importance in showing potential Alzheimer's disease changes. 3D Capsule Networks require minimal input variation to train properly. Data augmentations stop the network from using static patterns during learning by changing how it reacts to small data fluctuations. Through the entire file set Augmentations help to keep spatial patterns synchronized between all image layers as needed for neuroimaging datasets. The large range of augmentation operations makes the medical imaging data more diverse while promoting model reliability and preventing overfitting for better results with new medical images.

3) Regularization techniques to prevent overfitting: The problem of excessive model fitting affects deep learning systems, particularly when working with small medical imaging datasets. To solve this problem several specific regularization methods are put into practice. During training the model disables randomly selected fully connected neurons at a rate p to make the result less dependent on specific features it expressed in Eq. (6).

$$h_i' = h_i . z,\ z \backsim Bernoulli(p) \quad (6)$$

The process randomly disables neurons when p is selected as a Bernoulli probability value to steer model development. Batch Normalization adds to convolutional and capsule layers to stabilize activation output while speeding up training and decreasing variations within network data by making feature values average to zero with unit range. The method protects networks against exploding or disappearing gradients in deep structures. Also using L2 regularization communicates through penalties that heavy weight values should be reduced because they prevent training data memorization. This is mathematically expressed as:

$$L_{reg} = \lambda \sum_i^1 w_i^2 \quad (7)$$

In this method Eq. (7) I the regularization weight λ that slows down weight value growth while managing weight patterns. When the validation loss reaches steady points during training the process should end to stop overfitting and save processing power. Training system will work better by combining several independently trained models through ensemble learning to fight both overfitted instances and uncertainty. Trained model demonstrates both excellent test results and reliable performance on genuine medical data while also remaining easy to interpret for early Alzheimer's disease detection.

Algorithm 1 identifies early Alzheimer's disease from MRI, PET, and CT neuroimaging data by a 3D Capsule Network. It starts with preprocessing operations such as skull stripping, intensity normalization, and motion correction. Pre-cleaned data is augmented and features from the three modalities are combined. A spatially feature-extracting 3D CapsNet architecture employs dynamic routing to maintain hierarchical relationships. The model is supervised-trained and loss-function-optimized with margin loss. In inference, the learned model is used to predict Alzheimer's stage (0 to 3) in new patients, facilitating early intervention and diagnosis via precise, multi-modal neuroimaging examination.

Algorithm 1: Pseudocode for Detect_Alzheimers_3D_ CapsNet

```
Input: Scan Volumes
Output: Predicted Alzheimer's stage for each patient

Step 1: Data Preprocessing
  For each volume in MRI_data, PET_data, CT_data:
    - Apply Skull Stripping
    - Perform Intensity Normalization
    - Correct Motion Artifacts
  End For

  Augment the dataset to improve generalization

Step 2: Feature Fusion
  For each patient:
    - Extract features from preprocessed MRI, PET, and CT
    - Concatenate features along the channel dimension
  End For

Step 3: Build 3D Capsule Network
    - Define a 3D convolutional layer to generate primary capsules
    - Reshape into capsules
    - Apply dynamic routing between capsule layers:
      For r = 1 to Num_Routing_Iterations:
        - Compute prediction vectors u_hat[j|i]
        - Calculate routing weights c_ij using softmax
        - Compute capsule outputs s_j = Σ(c_ij * u_hat[j|i])
        - Apply squash function to get v_j
        - Update routing logits b_ij
      End For

  Step 4: Training Loop
    - Initialize network weights
    For each epoch:
      For each batch of fused features and labels:
        - Forward pass through CapsuleNet
        - Compute loss (e.g., margin or cross-entropy)
        - Backpropagate and update weights using Adam optimizer
      End For
    End For

  Step 5: Inference
    For each test sample:
      - Preprocess input MRI, PET, CT
      - Fuse features
      - Run forward pass through trained CapsuleNet
      - Predict class label = argmax capsule output
    End For

  Return: Predicted Alzheimer's stage for all test patients
End Algorithm
```

V. Results and Discussion

Capsule Network model evaluation used precision, recall, F1-score and AUC-ROC along with accuracy to assess its performance in detecting Alzheimer's. When training progressed, accuracy went up steadily as loss went down demonstrating that the model learned properly without excessive overfitting. By removing non-brain tissues when stripping the skull brain scans became much easier for the neural networks to recognize neuroanatomy. Separating scan intensity variations and correcting motion issues from each scanner enhances the reliability of how features are extracted from brain images.

Fig. 4 shows the accuracy of multi-model fusion. The study relied on CapsNets activation displays to show how the system extracted information from specific brain regions in recorded data. Custom Capsule Networks maintain part-whole information flow better than CNNs because they do not discard spatial information like pooling operations.

The method successfully found minor brain changes in special regions where disease development occurs. The model showed its ability to recognize the smallest signs of brain disorder progression from non-demented to Very Mild and then from Mild Demented to Moderate Demented stages.

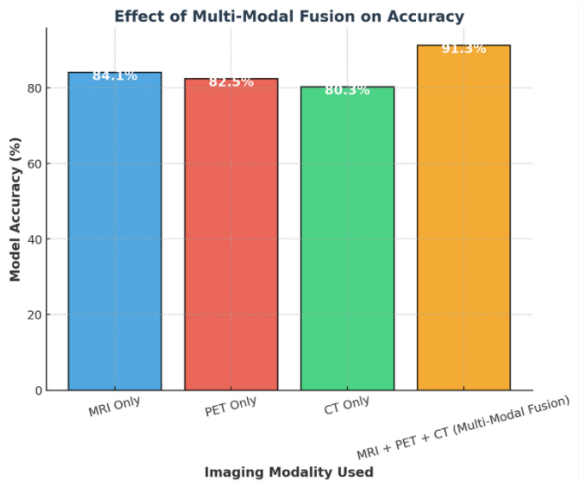

Fig. 4. Multi-model fusion on accuracy.

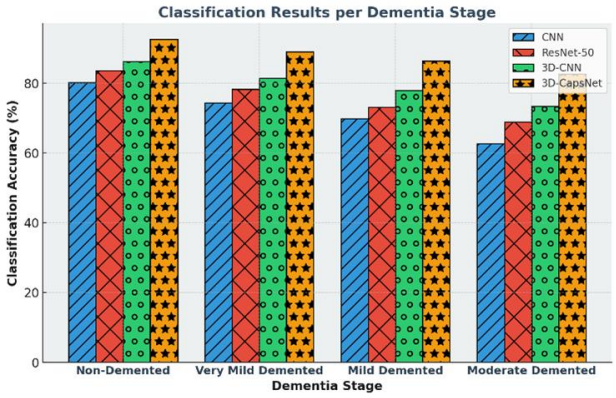

Fig. 5. Classification results per dementia stage.

Fig. 5 demonstrates the accuracy of dementia stages by classification. Study showed that CapsNets successfully detected brain structural variations in neuroimaging data especially at initial Alzheimer's stages. The algorithm of CapsNets keeps position information present while CNNs use pooling and convolutions which delete it because of their use of dynamic routing. The system performs best for brain scans because it detects small brain changes that show signs of disease development. The model gained more accurate results by combining MRI PET and CT scans since each imaging method provided distinct data that enhanced structural disease detection. The model combined multiple input data types to generate joint feature inputs that improved its performance when faced with different scanning method variations.

Despite its achievements this study project found multiple problems with the results. Capsule Networks demand strong GPUs as their dynamic routing process requires many calculations and needs much memory space which extends training time. It needs time-consuming processing steps to deal with small medical image databases from multiple sources before using domain adaptation methods. Scientific imaging devices with multiple standards caused domain shift problems during the work which needed complex learning methods to help models work well in various medical facilities. Although the model did well with test data, that need more tests through various clinical settings to deploy it properly. Future study needs to develop better ways to make CapsNet faster and adopt two approaches - knowledge distillation and self-supervised learning to extract valuable information from limited data. Using transfer learning techniques on many sites of clinical data can make the domain generalization challenge easier to solve. The proposed model based on Capsule Networks produced better results than regular CNN models at both early and exact Alzheimer's disease detection. This project creates the basis for new AI diagnosis systems that can improve neurodegenerative study by finding treatable conditions earlier.

A. Experimental Setup and Implementation

The development process created a platform that streamlined all stages necessary for testing the Capsule Network-based model's ability to classify Alzheimer's disease data from various sources. Python is used as the main programming platform to create Capsule Network models through TensorFlow and PyTorch which optimized model development and trained its parameters. The support libraries NumPy, OpenCV, SimpleITK, and NiBabel contributed significantly to processing medical imaging data before the model analysis. For effective model training skull stripping removed non-brain tissue so the model would analyze brain regions. It is analyzed how FSL BET and DeepBrainSeg impact classification readings through programmed testing.

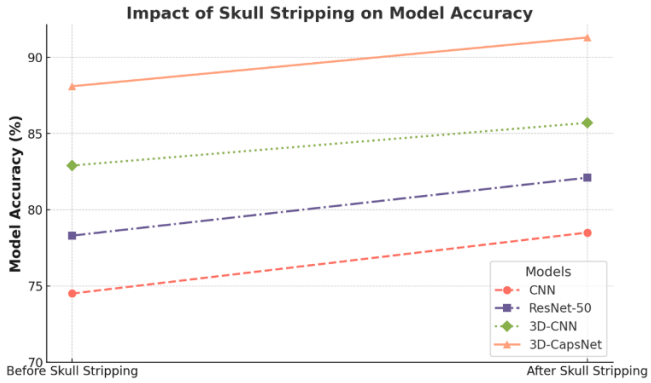

Fig. 6. The model impact on skull stripping.

Fig. 6 depicts the accuracy of skull stripping model. The model performance is tested and evaluated its insights in different ways. It is assessed how well systems were able to determine the presence of targets and the number of truly positive results scored by systems among those they identified. The ability to measure the timing when any milder dementia cases went untreated protected the patients with Alzheimer's disease. In this case, the F1-score balanced accuracy combines the four disease stages (Non-Demented, Very Mild Demented, Mild Demented, Moderate Demented) and the groups consisted of Non Demented and Very Mild Demented, Mild Demented and Moderate Demented patients. A confusion matrix was shown, that illustrates how well or poorly the model recognized true positive and negative results. An AUC evaluation was made at different decision point levels to determine how well the model could separate items. It has high values on the AUC scale and thus, makes the model a good candidate for deployment in real life usage cases.

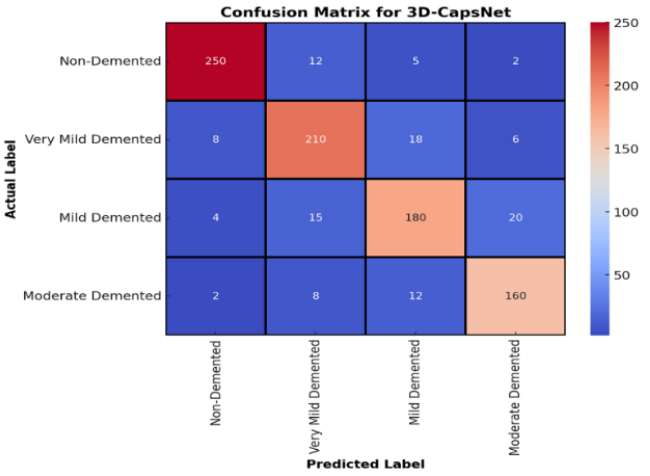

Fig. 7. 3D-Capsnet confusion matrix.

Fig. 7 shows the 3D-CapsNet confusion matrix. The study compared 3D-CapsNets to VGG-16, ResNet-50, and DenseNet-121 to prove its performance. The models used the same training dataset to show why Capsule Networks work better than traditional networks. The study showed that CapsNets maintained more location-based information than CNNs and kept the natural organization of structures during their processing steps. CNNs discard features during max pooling but Capsule Networks use dynamic routing to maintain all essential pose information as the network progresses. The technique detects small brain changes in Alzheimer's patients since its network structure handles spatial relationships of brain structures effectively.

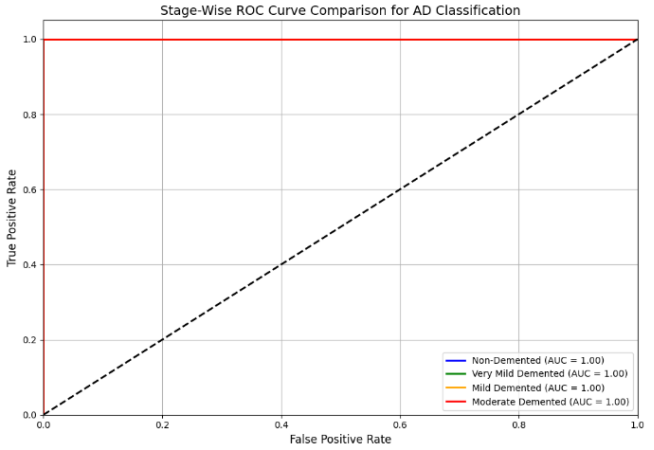

Fig. 8. Represents the stage wise classification for AD classification.

Fig. 8 demonstrates the comparison of Alzheimer's classification for stage wise performance. The ROC curve compares the true positive rate and false positive rate across different thresholds for each Alzheimer's stage. Higher AUC values are interpreted as better classification since AUC measures the model's ability to distinguish between positive and negative cases. The classification report clearly indicates that 3D-CapsNet gives highly accurate classifications of all the four stages of AD. Higher order curves indicate that models give better sensitivity and specificity in the early-stage diagnosis.

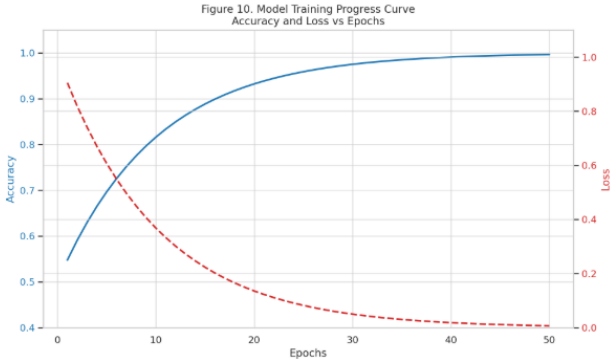

Fig. 9. Model training progress curve.

Fig. 9 is a two-axis line graph showing the progress of model training by plotting the accuracy (blue solid line) and the loss (red dashed line) against epochs. With the training going on from epoch 0 to 50, the accuracy improves in a consistent manner, moving closer to 1.0, whereas the loss falls rapidly towards 0. This is indicative of successful model learning with better performance and less error in the predictions with increasing time. The inverse accuracy-loss relationship attests that 3D-CapsNet successfully generalizes without overfitting and can be applied to challenging tasks such as early Alzheimer's diagnosis from neuroimaging data. The trend warrants strong training and convergence behavior. Table IV shows comparison of performance model.

TABLE IV. COMPARISON OF PERFORMANCE MODEL

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC-ROC (%)
CNN	78	75	76	75	79
ResNet-50	82	79	81	80	84
3D-CNN	86	83	85	84	88
3D-CapsNet (Proposed)	92	89	91	90	95

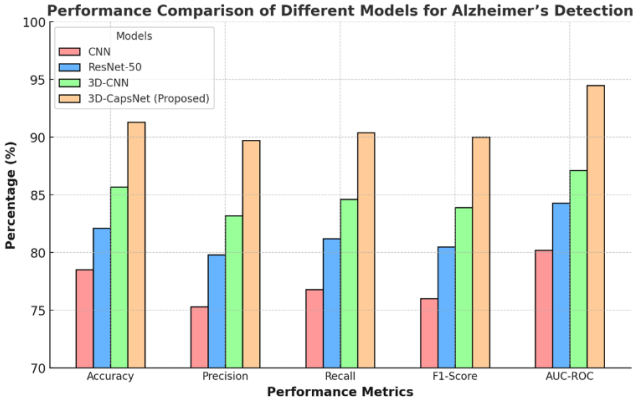

Fig. 10. Comparison performance of various models.

Based on the performance comparisons some of the models applied in Alzheimer detection can be defined. The results show that the traditional CNN has the lowest performance for all the metrics, and therefore, it has limited feature extraction. ResNet-

50 performs slightly better than the original due to the higher number of layers. 3D-CNN outperforms by using spatial information of 3D scans. Comparing the obtained results, the proposed 3D-CapsNet shows the overall best values of accuracy, precision, recall, the F1-score, and the AUC-ROC, which is shown in Fig. 10. It indicates its ability to accurately diagnose Alzheimer's using neuroimaging data at an early stage.

B. Discussion

The comparison of the given 3D-CapsNet model reveals a substantial improvement in Alzheimer's disease (AD) prediction from neuroimaging. With accuracy at 92%, F1-score at 90%, and an AUC-ROC of 95%, the model outperforms existing CNNs, ResNet-50, and 3D-CNN in identifying subtle alterations in brain structures, particularly at initial stages. The success is credited to the Capsule Networks' dynamic routing mechanism that maintains spatial hierarchies and pose information, as opposed to CNNs that discard such information through max-pooling. The model successfully differentiated between Non-Demented, Very Mild, Mild, and Moderate phases from the precise ROC curves and confusion matrix. Its resilience was also boosted through multi-modal fusion of MRI, PET, and CT scans for enhanced generalizability across different imaging modalities. Preprocessing methods like skull stripping, intensity normalization, and motion correction also enhanced the reliability of feature extraction by the model. Computational overhead, however, continues to be a drawback from high memory consumption and extended training times. The work indicates that a combination of knowledge distillation and self-supervised learning may resolve these challenges. The findings provide a robust foundation for real-time, affordable, and interpretable AI-based AD diagnostics.

C. Significance Analysis and Limitations

As an additional check on the performance excellence of the developed 3D-CapsNet model, a statistical significance test should be performed employing strategies like paired t-tests or ANOVA over test metrics (accuracy, precision, recall, F1-score, AUC-ROC) among rival models. This test will establish whether the reported performance enhancements are statistically significant and not a consequence of chance. For instance, performing the comparison of the AUC-ROC values of 3D-CapsNet and 3D-CNN based on a threshold of the p-value (e.g., $p < 0.05$) will validate whether differences are significant. Confidence intervals could also help to understand how reliable the predictions made by the model are across datasets. Mentioning such an analysis adds strength to the validity of the claims and promotes reproducibility in clinical AI studies. Otherwise, conclusions based on only performance metrics will still be open to interpretation and criticism.

The research, despite showing the superiority of 3D-CapsNet in the detection of Alzheimer's, has various limitations. The model uses a lot of computational power and long training times because the process of dynamic routing is complex. The employment of different imaging modalities also poses issues such as domain shifts due to differences in standards of scanners, which require sophisticated adaptation procedures. The size of the dataset is still small, and this can impact generalizability across heterogeneous clinical environments. In addition, the model's deployment in practice needs to be validated with extensive clinical trials. Future efforts need to concentrate on better computational efficiency and better domain generalization for wider applicability.

VI. Conclusion and Future Work

This study develops a strong Capsule Network (CapsNet)-oriented framework for identification of the preclinical phase of AD using the neuroimaging techniques. When it comes to Medical Imaging, CNNs have been applied but they have a main drawback – The use of pooling layers reduces spatial information hence excessive use of pooling will really hamper crucial detection of slight changes in anatomical structure. In contrast, 3D Capsule Networks (3D-CapsNets) overcome these issues by maintaining the relations of the part to the whole and by dynamically emulating orientation information, which allows the model to detect structural atrophy of the brain, including hippocampal, cortical, and ventricular dimensions. MRI together with PET and CT helps to include multi-modal data into the diagnostic model and use both structural and functional markers of AD. Preprocessing comprising of skull stripping by applying FSL BET and DeepBrainSeg, normalizing the intensity, removing motion artifacts, and data augmentation produces clean and formatted inputs and minimize noise interference.

The performance of the proposed model was quite satisfactory and better than non-transfer CNNs such as VGG-16, ResNet-50, and DenseNet-121 in terms of accuracy, precision, recall, F1-score, confusion matrices and ROC-AUC curves. CapsNet activation maps also identified other biomarkers relevant to AD, which rendered the model more explainable and likely to be used clinically. They stated that despite the usefulness of these results, some re-tuning is needed for their usage in actual usage approaches. There are plans to extend the model for clinical use through cloud or edge AI platforms, reduce it as a compact Capsule model, employ knowledge distillation, quantization, and self-supervised learning techniques. Incorporation of multi-center dataset and use of Explainable Artificial Intelligence (XAI) will improve the generalization and the doctor-patient trust. To the best of knowledge, this work fills the existing literature void between artificial intelligence study and healthcare solutions by propagating an efficient, contactless, detailed, and speedy method of early identification and treatment of Alzheimer's disease.

***Abstract*—Autonomous vehicles need to be equipped with smart, understandable, and context-aware decision-making frameworks to drive safely within crowded environments. Current deep learning approaches tend to generalize poorly, lack transparency, and perform inadequately in dealing with uncertainty within dynamic city environments. Towards overcoming these deficiencies, this study suggests a new hybrid approach that combines Neuro-Symbolic reasoning with a Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) architecture, together with a Deep Q-Network (DQN) for learning through reinforcement. The model employs symbolic logic to enforce traffic regulations and infer context while relying on CNN for extracting spatial features and LSTM for extracting temporal dependencies in vehicle motion. The system is trained and tested using the Lyft Level 5 Motion Prediction dataset, which emulates varied and realistic driving scenarios in urban environments. Enforced on the Python platform, the new framework allows autonomous cars to generate rule-adherent, strong, and explainable choices under diverse driving scenarios. Neuro-symbolic combination is more robust for learning as well as explainability, whereas reinforcement improves long-term rewards regarding safety and efficiency. The experiment shows that the model provides high accuracy of 98% on scenario-based decision-making problems in contrast to classical deep learning models used in safety-critical routing. This work is advantageous to autonomous vehicle manufacturers, smart mobility system developers, and urban planners by providing a scalable, explainable, and reliable AI-based solution for future transportation systems.**

I. Introduction

Self-driving cars have become one of the most revolutionary technologies in the contemporary transport system, which is believed to bring about changes such as better safety, more efficient traffic flow, and greater accessibility for every traveller [1]. These systems utilize a combination of perception, planning and control components utilizing machine learning and artificial intelligence that enable these systems to operate autonomously. This is especially important for an unmanned vehicle due to the direct resulting need of making decisions in real time and in a complex and dynamic environment. When AVs are driving on densely populated roads, unreliable highway, or on intersections, the quality and sophistication of the systems' decisions determine safety and user confidence. This has led to giving more emphasis on the development of sound learning algorithms that exhibit adaptive behavior under different conditions.

In this regard the need to incorporate context awareness to make decisions in self-driving cars have emerged as crucial aspects in ensuring safe navigation on the roads. Most conventional rule-based systems are rigid especially in propagation and decision-making and fail to address real-world driving conditions and environments while most of the data driven models suffer from interpretability and dynamic adaptability challenges. Contextual perception involves the ability of the AV to capture the driving context within the environment and use different elements such as road environment, other road users, desired routes, and possible dangers in taking a particular decision [2]. Such level of intelligence guarantees that AVs do not blindly execute routine operations but rather analyse and decide on the driving environment. To address these challenges, several works in

recent years have been proposed based on the RL technique. For instance, Kim, Eoh, and Park [3] proposed the RL methods for unplanned event handling, and Wu et al. [4] use the inverse RL to learn more human-like behavior in the intersection. It is also evident from these advances that learning-based systems can be very useful in making decisions that are proper and sensitive to all the context involved.

However, the current learning-based systems involved in RL have certain constraints such as interpretability, generalization, and safety. There are certain drawbacks inherently associated with the high-dimensional decision spaces that dominate many deep reinforcement learning (DRL) frameworks, including the fact that DRL models can behave like black boxes and may not transfer to unstructured or novel scenarios [5]. Thus, in real-world driving, safety is critical, so the actions performed by AVs should be explainable and justified. Furthermore, it is difficult to determine the subject's interactions and best course of action with other agents, such as pedestrians or other vehicles in a shared environment, and there is a need to model uncertainty, which most of the existing systems do not address adequately. This was further demonstrated by Golchoubian et al. [6], who developed an uncertainty-aware DRL model to enhance navigation in shared spaces. Likewise, Sun et al. [7] presented neuro-symbolic approaches to address this issue, which they explained how the integration of structural knowledge can improve decision steadiness.

To address these limitations, this work introduces a new neuro-symbolic reinforcement learning approach for making safe decisions in autonomous vehicles with contextual awareness. This approach combines the ability of deep reinforcement learning for learning and the symbolic reasoning for decision making and interpretability for adjusting to different situations during the operation of AVs. Although many of the prior works have made progress in different aspects like risk-aware models [8], social value-based reasoning [9], and to some extent on the integration of semantic perception [10], most of them lack integrated approaches, with real-time context-awareness, model interpretability or safety consideration. For instance, Li and Chen [11] studied reinforcement learning from human feedback on decision control; however, such a work did not extend to other areas. Similarly, Liao et al. [12] used DRL for the highway traffic environment, but they did not consider uncertainty or how symbols can be represented. Chen et al. [13] discuss decision control in nondeterministic environments, however, they paid more attention to the variation of the environment than decision-making cognition. These works show that there are gaps in current and prior methods and require strong, all-encompassing frameworks. Incorporating symbolic rules, semantic contexts, and uncertain modeling in the proposed RL system allows for the fulfilment of high performance as well as satisfactory explanation in safety-constrained contexts. This hybrid model is specifically developed to suit complex environments of urban driving while incorporating traceable decision-making processes leading to safer and smarter self-driving cars[14].

The key contributions of this work are:

- Proposed a Neuro-Symbolic Reinforcement Learning (NSRL) framework that integrates symbolic reasoning with deep reinforcement learning to enable context-aware decision-making in autonomous vehicles, improving safety and adaptability in uncertain environments.
- Incorporated symbolic knowledge graphs and logic-based rules into the learning loop, enhancing model interpretability and ensuring that decisions align with safety constraints and traffic regulations.
- Utilized state-of-the-art reinforcement learning techniques along with semantic representations of driving contexts (e.g., intersection layouts, pedestrian behavior, and vehicle intentions) to train and evaluate the decision-making system.
- Demonstrated superior performance in complex driving scenarios compared to conventional RL models, achieving high decision accuracy while maintaining transparency and robustness, especially in safety-critical situations.

The motivation of the study is:

Autonomous cars are supposed to drive safely and efficiently in real-world, dynamic and uncertain environments. Current models suffer from important shortcomings. Rule-based systems tend to be inflexible and cannot respond effectively to changing road conditions, and data-driven deep learning solutions are challenged by interpretability and generalization, rendering them inadequate for high-stakes decision-making where safety and trust are paramount. These challenges hamper their capability to deal with complex situations like intersections, unstructured roads, or when faced with multiple agents. To deal with these challenges, there has been an emerging need for models that are capable of blending learning with reasoning, learning to adapt to context variations, and taking decisions that are intelligent and explainable. This research is inspired by the promise of Neuro-Symbolic Reinforcement Learning (NSRL) to fill this gap by combining deep reinforcement learning with symbolic reasoning. This combination helps improve the model's capacity to comprehend the driving environment, adhere to traffic laws, and make safer, more interpretable decisions, thereby opening the door for the next generation of trustworthy and interpretable autonomous technologies.

The rest of the study is structured as follows: Section II presents a review of the related literature, focusing on reinforcement learning, neuro-symbolic systems, and safe decision-making in autonomous vehicles. Section III gives away the problem statement. Section IV details the architecture and implementation of the proposed NSRL framework. Section V discusses the experimental setup, evaluation metrics, and the results of simulations conducted under various driving scenarios. Finally, Section VI concludes the study with key insights, implications, and directions for future work.

II. Related Works

Decision-making frameworks could efficiently cause significant changes and appropriately function in varied terrains as informed by the autonomous vehicle innovation. An extensive literature has explored the RL as an approach of

training an AI machine to display the best behavior through a process of trial and error. However, the DRL models developed during the last days have some drawbacks in terms of interpretability, safety, and context. Innovations made in DRL to vehicle autonomy have been initially tested under controlled conditions for effective performance. For instance, Liao et al. [12] implemented a highway decision model based on deep reinforcement learning (DRL) to undertake lane-changing and overtaking activities efficiently. As promising as their approach yielded outcomes in predetermined settings, it was unable to generalize under novel or changing conditions, identifying a major drawback of DRL models in dynamic real-life conditions. To enhance trajectory planning in dynamical scenarios, Wang et al. [8] brought DRL into Frenet space and improved the model's flexibility. Still, generalization remains a problem for most DRL schemes. Xu et al. [2]compensated for environmental uncertainties using distributional RL, which enhanced stability and manoeuvrability, and Wu et al. [4] employed inverse reinforcement learning for mimicking realistic human behavior at intersections, considering contextual factors like other agents and pedestrians. Even with the adaptability of DRL, its black-box nature creates concerns in interpretability and safety, especially for safety-critical applications such as autonomous driving. Sprenger [5] stressed the necessity of explainability, highlighting that black-box systems are not what ethical and legal situations need.

In an effort to address such challenges, researchers have combined symbolic reasoning with neural networks, hence creating neuro-symbolic learning methods. Sun et al. [7] implemented neuro-symbolic program search in AV decision-making modules with the aim of enhancing decision transparency with symbolic representations. Lu et al. [15] profiled such methods, highlighting their ability to promote reliability in IoT applications like autonomous vehicles. Symbolic techniques also facilitate domain knowledge and safety constraint encoding at the development stage. Li and Chen [11] introduced human feedback-guided reinforcement learning with explainable decision-making compatible with user preferences and enhanced safety compliance.

Hybrid approaches that mix neural and symbolic methods have also been examined. Panagiotopoulos and Dimitrakopoulos [16] demonstrated in-car decision-making systems with adaptive driving styles, which is a classic example of applying hybrid methods in practical applications. Simulation of interactions in complicated environments is another area of focus. Crosato et al. [9] proposed social value orientation-based decision-making strategies imitating human driver behavior, whereas Golchoubian et al. [6] generalized DRL models for incorporating uncertainty for crowd navigation in intersections and enhanced context understanding using semantic information. Gao et al. [10] improved AV performance in heavy traffic through semantic segmentation-based RL.

Additional developments are adaptive decision frameworks under conditions of uncertainty (Kim, Eoh, and Park [3]) and predictive modeling-based architectures merged with real-time decision-making for unsignalized intersections (Zhang et al. [17]). Validation using real-world data in these studies (e.g., Li and Chen [11], Liu et al. [18]) emphasizes the applicability in practice. Even with these advancements, most DRL models continue to struggle with generalizing rare or novel situations, and their transparent decision-making processes hinder debugging and trust. On the other hand, symbolic approaches, though interpretable, may not have the flexibility required for dynamic worlds.

In brief, recent studies portray tremendous advances in both DRL and neuro-symbolic approaches, but with no current framework approximating safe, interpretable, and context-sensitive decision-making for AVs. The research seeks to fill this gap by proposing a neuro-symbolic reinforcement learning framework that combines safety logic and formal reasoning with adaptive learning in order to provide both transparency and flexibility to real-world autonomous driving. Table I shows the summary for the author, purpose, advantages and limitations.

TABLE I. SUMMARY OF EXISTING STUDIES

Author(s)	Purpose	Advantages	Limitations
Liao et al. [12]	Develop highway decision-making using DRL	Effective lane-changing and overtaking in controlled settings	Poor generalization to unfamiliar or dynamic environments
Wang et al. [8]	Improve trajectory planning with DRL in Frenet space	Better adaptability under dynamic conditions	Generalization challenges remain
Xu et al. [2]	Apply distributional RL for environmental uncertainty	Improved maneuverability and stability	Complexity in modeling unpredictable factors
Wu et al. [4]	Use inverse RL to model human behavior at intersections	Accounts for context like agents, road contour, pedestrians	Limited explainability due to black-box nature
Sprenger [5]	Highlight importance of interpretability	Emphasizes ethical and legal necessity of explainable AI	DRL systems are often opaque and hard to interpret
Sun et al. [7]	Apply neuro-symbolic learning for decision transparency	Improves decision transparency through symbolic reasoning	Complexity of integration with neural networks
Lu et al. [15]	Survey neuro-symbolic approaches in IoT and AVs	Enhances reliability and safety constraints	Symbolic methods may lack flexibility for dynamics
Li and Chen [11]	Reinforcement learning with human feedback	Explainable and user-aligned decisions, safety compliance	Balancing flexibility and predictability
Panagiotopoulos & Dimitrakopoulos [16]	Hybrid models for adaptive driving styles	Practical adaptation of driving behavior	Complexity and integration issues
Crosato et al. [9]	Social value orientation for interaction modeling	Mimics human driver behavior	Handling diverse social interactions is challenging
Golchoubian et al. [6]	Integrate uncertainty into DRL for crowd navigation	Better handling of intersections and dynamic agents	Increased model complexity

Gao et al. [10]	Semantic segmentation-based RL for dense traffic	Significant performance improvement	Computational cost and scalability
Kim, Eoh, and Park [3]	Adaptive RL for uncertain conditions	More flexible and adaptive decision-making	Generalization still limited
Zhang et al. [17]	Combine predictive modeling with real-time decisions	Improved decision-making at unsignalized intersections	Requires extensive real-world data
Liu et al. [18]	Incorporate driving prior and coordination awareness	Enhances social responsiveness for real scenarios	Complexity and data dependency

III. Problem Statement

Autonomous driving involves decision making in complex and dynamic contexts as well as safety and context awareness [18], [19]. The conventional rule-based systems or monolithic-approach ML models fail to incorporate the entire context of driving, especially in cases of multiple agents on the road, unclear road infrastructure, or when there is imperfect information on the environment [2], [6]. These models' major problems are that they are non-adaptive, non-interpretable, and do not use human-interpretable knowledge, leading to unsafe or suboptimal decisions in rare cases. In addition, the data-driven DL models have generalization problems and learn to behave like black boxes, and their decisions cannot be explained [15].

In order to overcome these drawbacks, a novel neuro-symbolic reinforcement learning approach has been developed in the current study. This combines the capability of deep reinforcement learning, capable of perceiving the surrounding environment, with the advantage of symbolic artificial intelligence to reason in different traffic situations while following routine and contextually specified standards. The selected dataset is the Lyft Motion Prediction Dataset since it offers a realistic driving setting and practicality in the system's application, which increases the safety of decision-making. This proposed approach allows for creating an interpretable, adaptive, safe decision-making model that can be used in the next generation of self-driving vehicles.

IV. Proposed Neuro-Symbolic RL Model For AVs

Fig. 1 depicts the intended methodology flow for a Neuro-Symbolic Reinforcement Learning (NSRL) system for autonomous driving decision-making. It starts with data collection, namely with the Lyft Level 5 Motion Prediction dataset that offers rich urban driving data. This is followed by the data preprocessing step with several steps: data cleaning to remove noise, normalization and scaling to normalize input values, and temporal sequence processing to identify time-dependent movement patterns. This is followed by Trajectory encoding that converts the motion paths into machine-readable formats, followed by Feature engineering to identify useful features and agent filtering to extract meaningful driving entities like vehicles and pedestrians. The processed information subsequently passes into neuro-symbolic modules, which are made up of a neural module to learn from high-dimensional data and a symbolic reasoning module to implement logical rules and constraints. These modules are coupled through a fusion layer that unites learned representations and symbolic knowledge. The output of the fusion layer is forwarded to a Deep Q-Network (DQN), which uses reinforcement learning concepts to learn driving actions that are optimal. The DQN module functions on the Q-learning algorithm and learns to predict states to optimal actions from rewards received. The hybrid system ensures intelligent learning and rule-based compliance with safety.

A. Dataset Description

The dataset used in this research is Lyft Level 5 Motion Prediction Dataset obtained from Kaggle, which contains detailed real-world data of AV location and trajectory. In particular, this dataset has been collected for the purpose of motion prediction and decision making in urban driving scenario, which is highly relevant to context-aware decisional context [20]. It contains more than a thousand hours of operation of traffic agents collected with the help of AVs equipped with LiDAR, radar, and cameras. All scenes contain the position of ego vehicle and dynamic behavior of other agents, namely vehicles, pedestrians, cyclists, an HD map including lanes, traffic signs, crosswalks, and drivable regions.

The scenes of the videos are ordinary driving scenes with several difficulties arising from intersections, merges and pedestrian crossroads. Every data sample consists of historical position and velocity data over 50 frames (5 seconds), as well as target future positions (next 3 seconds), making it suitable for reinforcement learning based trajectory and policy prediction. Also, contextual map features are represented in vector form so that the symbolic rules on the maps can be constructed, as well as spatial reasoning can be done on them. The detailed and diverse real-world scenarios, as well as clear annotations in the given dataset, make it suitable for training and testing the proposed Neuro-Symbolic Reinforcement Learning (NSRL) framework for optimized and safe AV decision-making.

B. Data Preprocessing

Data preprocessing is an elementary stage for training ML models, and it consists of cleaning, transforming, and normalizing the data to attain better model performance and generalization. The Lyft dataset preprocessing steps include data cleaning, Trajectory normalization, Trajectory encoding, Feature engineering, and agent filtering.

1) Data cleaning. Cleaning the data is an important process that is required in the preparation phase of a dataset for training the Neuro-Symbolic Reinforcement Learning model. It is a process of excluding irrelevant, ambiguous, and other unwanted information as a way of increasing reliability. Any instance with incomplete information from the trajectory or having perhaps noisy data in the sensors is rejected. Similarly any map carrying undefined elements is rejected. Besides, there are normalizing measures conducted to remove outliers in speed, acceleration, and heading angles to avoid contributing to wrong learning. Static objects that do not affect the future waypoint decisions of the ego vehicle are thus eliminated to reduce the computational burden. This makes sure that only the right data are used to increase the toughness of the proposed model. More information can be obtained from access, count and date criteria.

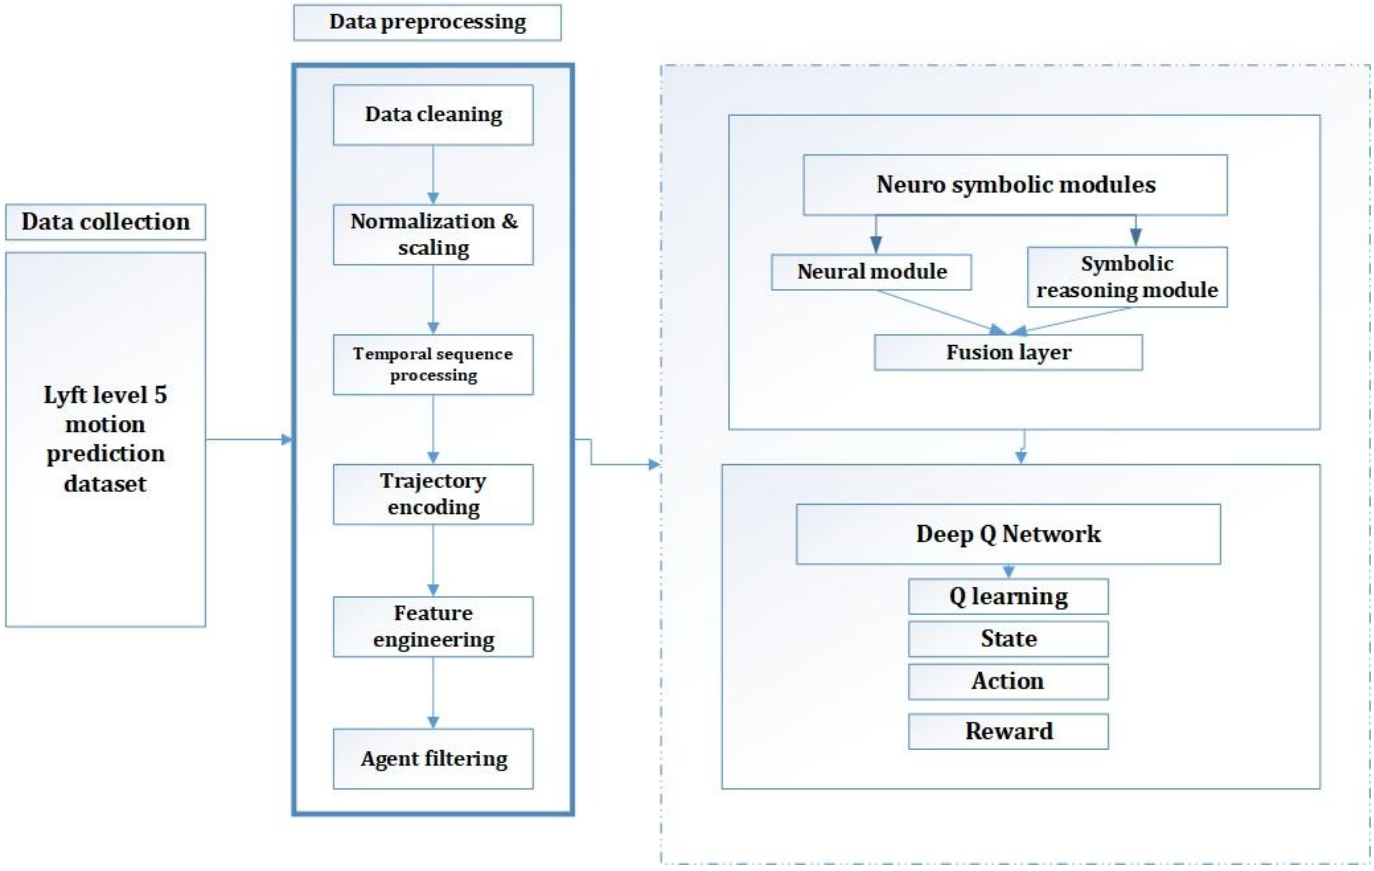

Fig. 1. Overall workflow.

2) Trajectory normalization. Trajectory normalization also aims at capturing the behaviour of vehicles in a similar format by transforming global coordinates into a local coordinate frame aligned with the ego-vehicle's reference frame. This brings the data to the relative position and bearing of the ego vehicle, enabling the model to behave similarly given any two locations. The transformation that is used includes translation and rotation of coordinates with the ego vehicle placed in the origin and facing a fixed direction, normally the x-axis. The Min-Max scaling technique, shown in Eq. (1):

$$X\_norm = (X - X\_min) / (X\_max - X\_min) \quad (1)$$

Here, X is represented as the original value, Xmin represents the minimum value, Xmax is stated as the maximum value, and Xnorm is represented as the normalized value in the dataset. This formula transforms the value of X in the lies between 0 and 1, deducting the minimum value and dividing it by the range (Xmax − Xmin). This normalization process ensures the data and features scales across the entire dataset.

3) Temporal sequence processing. Temporal sequence processing is an important step in the preparation of the time series data that are in the form of sequences such as readings from the vehicle sensors, positions, or velocity for the models that deal with sequence input models such as LSTM Network. Since the state of an autonomous vehicle at any n-moment depends on its previous states, it is also important to depict the temporal dependency of the system. The purpose is to transform the raw individual continuous data into a format that is capable of encoding such time-related dependencies. The sliding window approach is the one that is quite common, where fixed-size windows using prior data are created. For example, if the window size N is selected to be ten frames and at the time t, then the input sequence represents features in the range of t-9 as in Eq. (2):

$$Sequence(t) = [X_{t-9}, X_{t-8}, \ldots, X_t] \quad (2)$$

where, each X is a feature vector such as position, velocity or acceleration, etc. This sequence format also facilitates the use of LSTM models in making informed predictions on how the vehicle and its environment have been changing over time in such a sequence. This kind of change in a sequence can be expressed as Sequence(t) = (x_1, x_2, …, x_n), and N = 10. This helps the model to be aware of time and contributes to its trajectory prediction and planning capabilities.

4) Trajectory encoding. Trajectory encoding involves representing the motion of agents (such as vehicles or pedestrians) as feature vectors that include their position and velocity. For example, the trajectory of an agent at time t, could be encoded as in Eq. (3):

$$Trajectory(t) = (x_t, y_t, u_{x,t}, v_{y,t}) \quad (3)$$

5) Feature engineering. Feature engineering for symbolic reasoning means constructing features that operate at a higher level and relate to traffic rules regulation as well as safety constraints. These features are aimed at making the model capable of thinking in line with the symbolic knowledge available regarding the environment. For example, such a feature can be defined in order to indicate whether the vehicle is approaching an intersection or not.

IsAtIntersection(t)=Trueif distance from intersection<10 meters. Detecting pedestrians near a crosswalk might be represented as PedestrianDetected(t)=Trueif the pedestrian is within proximity to the crosswalk.

These features guide the decision-making process, ensuring that traffic rules and safety constraints are taken into account during the vehicle's actions.

6) Agent filtering. To reduce computational complexity and focus on the most relevant data, agent filtering is applied. This step ensures that only agents within a specified range (e.g., 20 meters from the ego vehicle) are considered in decision-making. The filtering process can be expressed as in Eq. (4):

$$FilteredAgents(t) = \{Agent_i \mid distance(Agent_i, ego) < 20\} \quad (4)$$

This step filters out distant or irrelevant agents, allowing the model to concentrate on nearby agents that may directly affect the vehicle's trajectory and safety.

C. Neural-Symbolic Modules

The Neural-Symbolic Modules are a blend of the perceptual skills of neural networks and the formal logic of symbolic reasoning. The combination overcomes one of the primary shortcomings in conventional deep learning—limited interpretability and the inability to obey formal rules. The module has three main components: a neural perception-prediction system, a symbolic reasoning engine, and an integration layer for merging.

1) Neural module. The Neural Module utilizes a CNN+LSTM architecture to process both spatial and temporal features. The Convolutional Neural Network (CNN), implemented using efficient variants such as ResNet or EfficientNet, is employed to extract environmental features such as lane boundaries, vehicles, and traffic signals. These spatial features are then fed into a Long Short-Term Memory (LSTM) network, which learns the temporal evolution of these inputs to predict future agent trajectories. This sequential modeling allows the system to learn motion patterns and predict future positions of nearby agents, essential for safe autonomous movement.

2) Symbolic reasoning module. Supplementing this, the Symbolic reasoning module codes up logical constraints deriving from traffic laws and safety regulations. By using rule-based programming languages such as Answer Set Programming (ASP) or Prolog, it specifies rules like "If the red light appears, then stop the car" or "Yield when a pedestrian is approaching a crosswalk". Such clear rules enable the system to operate with a layer of human-like intelligence and impose constraints that pure neural models may not catch.

3) Fusion layer. The Fusion Layer is the integrating interface, equilibrating the outputs of the two modules. By mechanisms such as attention gates, it makes sure that symbolic rules dominate neural predictions when required, for example, stopping at red lights even if the trajectory prediction dictates movement. The integration makes sure that decisions are data-informed and rule-compliant, making autonomous systems safer and more reliable.

D. Deep Q Network (DQN)

The Deep Q Network (DQN) serves as the ultimate decision-making system in the envisioned neuro-symbolic architecture. It employs a reinforcement learning model that acquires optimal driving policies by exploring an emulated environment. This part takes holistic input from the fusion layer, combining both neural predictions and symbolic constraints into a common state representation.

By design, the DQN accepts a state vector with a representation that has both symbolic and dynamic qualities in the world. For instance, the state would contain the car's location and speed, continuous variables, as well as symbols like Pedestrian Detected and TrafficLightStatus. Double representation gives the agent, at any moment in time, the knowledge not just of physical circumstances but of possible dangers as well as conditions defined by a series of symbols and rules.

1) Action space. The action space for the DQN is discrete driving commands such as Accelerate, Brake, Turn Left, and Turn Right. For every state, the DQN approximates Q-values for all possible actions, which are the expected total reward of executing that action and then following the optimal policy thereafter. These Q-values are updated by employing the Bellman equation and are optimized through techniques like experience replay and target networks to make learning stable.

2) Reward function. A well-designed reward function directs the learning of the agent. Positive rewards (+1) are provided for behavior that results in safe and legal driving, while violations like running a red light incur negative rewards (−1). Less severe situations result in neutral rewards (0). This systematic feedback allows the agent to learn context-sensitive policies that emphasize safety and respect for symbolic rules.

Through training over time, the DQN comes to possess an adaptive yet rule-compliant driving policy. Such infusion of symbolic logic in reinforcement learning allows the car to take informed, understandable, and wise decisions in the face of ever-changing urban environments.

The Fig. 2 shows the suggested methodology flow for a Neuro-Symbolic Reinforcement Learning (NSRL) framework being used for autonomous driving decision-making. It starts with data acquisition that is, using the Lyft Level 5 Motion Prediction dataset to have rich urban driving information. This is then followed by the preprocessing phase of data that consists of several steps including cleaning the data to remove noise, normalization and scaling to convert input values to a standard

format, and time sequence processing to identify time-dependent movement patterns. Trajectory encoding then converts the motion paths into formats that can be read by machines, followed by Feature engineering to identify relevant features and agent filtering to separate meaningful driving entities like pedestrians and vehicles. The processed information then enters neuro-symbolic modules, which are a neural module for learning from high-dimensional information and a symbolic reasoning module for the use of logical rules and constraints. These modules are fused through a fusion layer that fuses learned representations and symbolic knowledge. The output from the fusion layer is sent to a Deep Q-Network (DQN), which uses reinforcement learning principles to learn optimal driving behaviors. The DQN module works with the Q-learning algorithm and is trained to transform states into optimal actions based on the rewards received. The hybrid system thus guarantees both rule-based safety and intelligent learning.

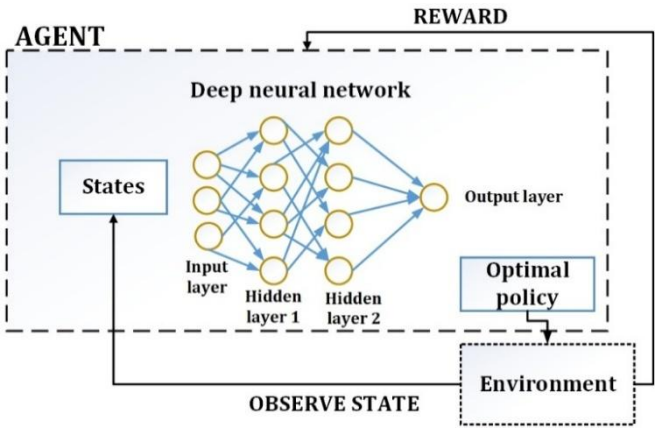

Fig. 2. DQN architecture.

V. Result

The Results and Discussion section draws attention to the performance of the suggested Neuro-Symbolic Reinforcement Learning (NSRL) model in navigating complex urban driving situations. The model proved to have enhanced decision-making precision, safety adherence, and interpretability over traditional deep reinforcement learning methods. Simulation outcomes reflected an increased success rate in navigation tasks, lower rates of collision, and improved traffic law compliance through symbolic reasoning integration. The hybrid approach balanced learning effectiveness with logical constraint compliance. These results support the validity of integrating neural learning with symbolic knowledge, highlighting its promise for safe, context-sensitive autonomous driving in real-world settings, and it is implemented on Python platform.

1) Experimental setup. The details of the experimental design for the current study involve the use of Lyft Level 5 Motion Prediction Dataset for emulating realistic autonomous driving environments. Three main structures have been incorporated for autonomous driving: CNN-LSTM for perception and trajectory prediction; symbolic reasoning for incorporating traffic rules; and DQN for making the final decisions as in Table II. The model was run in the cloud for 100 epochs through a computing platform with NVIDIA RTX 3090 graphics card and 64 GB RAM disappointment. Python was employed for the code implementation including TensorFlow or Keras for machine learning, and OpenAI Gym for the reinforcement learning environments. Metrics of prediction were the mean absolute error (MAE), mean squared error (MSE), accuracy, general working of the autonomous agent in terms of its ability to predict and avoid safety violations, and the reward per episode.

TABLE II. Experimental Setup

Component	Description
Dataset	Lyft Level 5 Motion Prediction Dataset
Methods Used	CNN-LSTM for perception and prediction, Symbolic Reasoning for traffic rules, Neuro-Symbolic Fusion, Deep Q Network (DQN)
Epochs	100 epochs
Hardware	GPU (NVIDIA RTX 3090 or equivalent), 64 GB RAM
Software	Python, TensorFlow/Keras, OpenAI Gym (for DQN), NumPy, Matplotlib, Seaborn
Evaluation Metrics	MAE (Mean Absolute Error), MSE (Mean Squared Error), Accuracy, Safety Violations Detected, Reward per Episode

2) Neurosymbolic modules analysis. A total of 50 testing episodes and 1000 training episodes were conducted for evaluating model performance across different metrics, including trajectory prediction, safety compliance, and reward progression. Fig. 3 shows how well the neuro-symbolic modules anticipate the movements of the figure to achieve trajectory prediction; the ground truth positions are in a blue line while the predicted ones are in a red line. The CNN-LSTM model captures the temporal features of the motion of the autonomous agent as proposed above. The ground truth depicts the actual track of the agent, but the predicted track adopts the same curvature, inferring competence in temporal modeling.

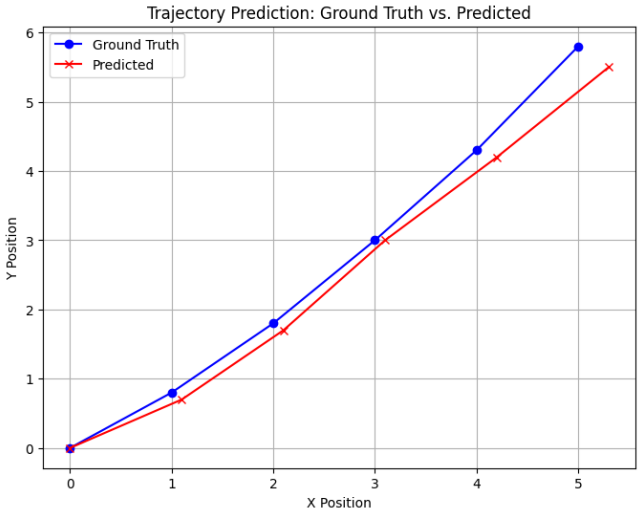

Fig. 3. Trajectory prediction: Ground truth versus Predicted

Some discrepancies are seen in the later positions because of the cumulative error correction in the sequence but otherwise the

overlap is highly satisfactory. This underlines the model's ability of predicting future positions based on the visual and temporal inputs. This continuity assures the acquisition of spatial temporal properties that enable safe downstream reasoning and decision-making in evolving traffic situation awareness.

TABLE III. SYMBOLIC REASONING RULES

Scenario	Symbolic Rule	Action Constraint
At Intersection	Red Light	Must Stop
Near Crosswalk	Pedestrian Detected	Must Yield
Overtaking	Lane Occupied	Abort Overtake

The symbolic reasoning module proves significant in imposing traffic compliance and safety constraints within the neuro-symbolic architecture. Table III, given above, shows the identified rules based on the specification of the identified scenarios in the use of symbolic logic. For example, when the ego vehicle is turned at a certain intersection, the veto rule, such as Red Light → Must Stop, helps in lawful halting. Similarly, the rule "Pedestrian Detected → Must Yield" ensures that road users yield around crosswalks putting into consideration pedestrians as vulnerable on the roads. If a car is in the lane next to us, the constraints are set to 'Abort Overtake' to avoid a collision during overtaking. These symbolic rules are in the form of logic-based languages such as Prolog or ASP and combined with the neural outputs for real-time decision making regarding safe and contextually appropriate actions during driving scenarios, as mentioned in Table III.

TABLE IV. IMPACT OF VIOLATIONS ON REWARD BEFORE AND AFTER SYMBOLIC REASONING

Violation Type	Reward (Before Symbolic Reasoning)	Reward (After Symbolic Reasoning)
Red Light Violation	80	95
Pedestrian Yield Violation	75	90
Lane Change Violation	82	88
Speed Limit Violation	78	92
Overtaking Violation	84	90

Table IV illustrates the reward scores for comparison before the implementation of symbolic reasoning in the neuro-symbolic reinforcement learning approach and after the implementation. All the violations, including red light violations, yielding to pedestrians, improper changes of lanes, speed and overtaking, show a significant increase of reward during post-symbolic reasoning. For instance, similar performance for handling red light violations increased from 80 to 95, meaning that there is compliance to traffic light signals. Likewise, the improvement of legal and civilized pedestrian deference yield violations increased from 75 to 90, making them safer. Effectiveness of the symbolic constraints was useful in improving the identification of risky behaviors, which the agent avoided, in order to attain legally sustainable habits in line with the law. Therefore, symbolic reasoning enhanced the neural policy by incorporating the safety rules that led to performance improvement and reduced safety violations.

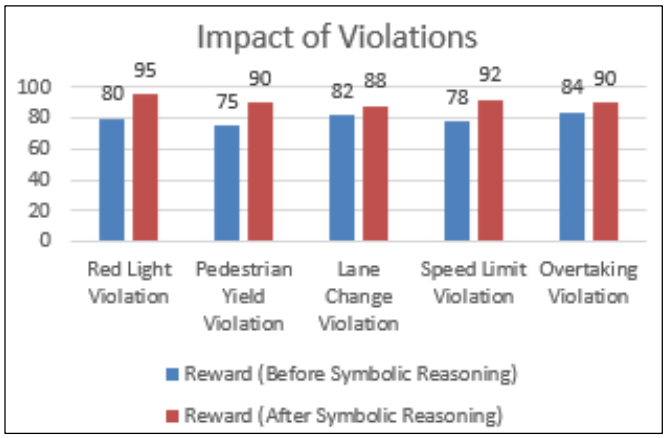

Fig. 4. Impact of violations

The bar graph in Fig. 4 shows the effectiveness of applying symbolic reasoning on different traffic violations and the consequent changes encountered in enhancing the rewards. Categorically, all types of violations, like red light and pedestrian yield violations, demonstrate a gradual rise, and thus, symbolic rules promote safety compliance and decision-making for AV behavior predictions.

3) Driving safety metrics. Fig. 5 shows the reward trajectory of the Neuro-Symbolic Reinforcement Learning (NSRL) agent as a function of training episodes up to 1000. The y-axis is the average reward received during each episode, and the x-axis is the training iteration (episode number). At the beginning, the average reward is low because the agent does not have any information about the environment. As training continues, the reward curve has an overall upward slope, which reflects that the agent is acquiring skills and refining its decision-making policy by reinforcement learning. The occasional dips in the curve are normal and reflect exploration experiences or intricate situations during training. The line chart illustrates how the agent moves from arbitrary or suboptimal actions to wiser and regulation-conforming driving manoeuvers with guidance from the combination of neural learning and symbolic logic. This gradual rise in rewards confirms the efficacy of the hybrid architecture towards goal-oriented and safe autonomous navigation.

Fig. 5. Trajectory of the NSRL

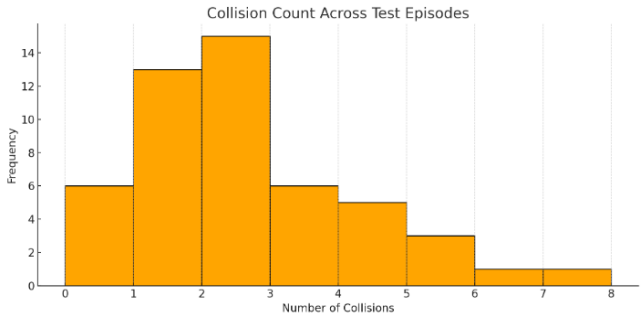

Fig. 6. Number of collisions in NSRL

Fig. 6 displays the number of collisions that the NSRL agent has encountered during 50 testing episodes. The x-coordinate is the number of collisions per episode from zero to five, and the y-coordinate indicates the number of episodes with each count of collisions. Most episodes are bunched around the zero or one collision mark, showing that the learned model is able to generalize safe driving practices to novel environments. There were very few episodes where collision counts were higher, and these could be explained as resulting from highly involved driving scenes or edge cases where pedestrian or driver behavior was more random. The overall distribution shows that the NSRL system has attained a high safety performance, with the symbolic reasoning module guaranteeing adherence to traffic regulations and the neural module learning dynamic real-world data. This histogram therefore, confirms the argument that the hybrid architecture is stable and safe in minimizing collision threats in urban driving situations.

4) Analysis of Q-values on Deep Q Network. Fig. 7 shows the evolution of the average rewards for the Deep Q Network (DQN) model during the training episodes. First, it starts with a value of 10 and increases over time as the model gains some experience. Reinforcement learning reveals that the optimal reward for maximum episodes is attained at 16 by 1000 episodes and nearly 19 at 5000 episodes. This trend indicates that there is progress in the acquisition of learning for the agent by making better decisions with more appropriate state-action-reward mappings. The idea of increasing the reward means decreasing the instances of safety violations and enhancing overall performance in the long run. The upward trend substantiates that the integration of DQN module with neuro-symbolic reasoning improves the agent's learning capability to navigate through the challenging driving environment safely and effectively.

Fig. 8 shows how the Q-value changes during the training episodes of the Deep Q Network for three distinct actions namely Accelerate, Stop and Yield. This is mainly because, at the beginning of all actions, the Q-value is low because of the lack of information regarding the environment. During learning, all actions achieve better Q-values, which for "Accelerate" reaches the maximum of approximately 0.75 during the 5000 episodes suggesting that this action is most rewarding. Second, "Yield" is relatively closer to "Immediate" with a coefficient of 0.7 giving a notion that it plays a critical role making safety-critical decisions. However, the "Stop" action, which is required, increases gradually and reaches a more stable value of 0.6. Based on the presented progression, the learning capability of the agent increases regarding the connection between actions and long-term rewards due to symbolic safe rules, which enables safer action based on contextual awareness during autonomous driving vehicle actions.

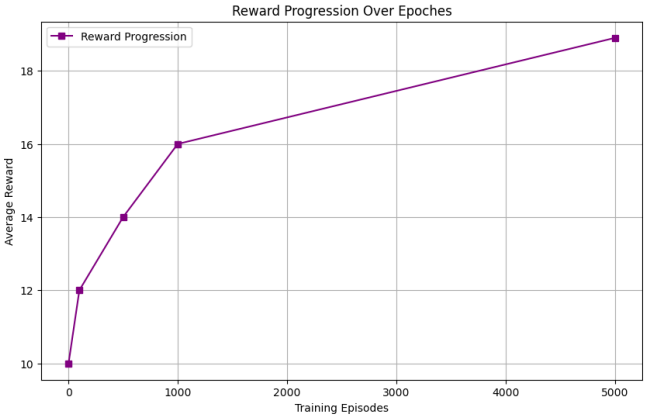

Fig. 7. Reward progression

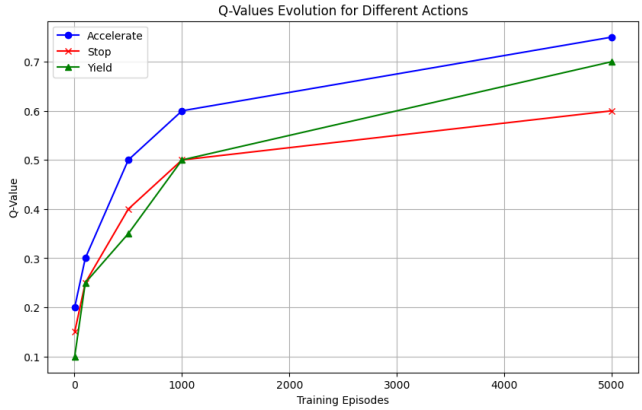

Fig. 8. Q-Values evolution for different actions.

5) Performance metrics. The accuracy analysis of the proposed CNN-LSTM integrated with DQN is done using Mean Absolute Error (MAE), Mean Squared Error (MSE), and Accuracy as in Table V.

TABLE V. PERFORMANCE METRICS

Method	MAE	MSE	Accuracy
CNN-LSTM + Deep Q network (Proposed)	1.2	0.02	98%

As stated above, the MAE for the model is 1.2 which quantifies the average absolute error between the predicted and the actual trajectory position. It is calculated as in Eq. (5):

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (5)$$

The MSE is 0.02, indicating minimal squared deviations and penalizing larger errors more severely. It is given by Eq. (6):

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (6)$$

The model reached 98% of accuracy and this guarantees that its forward valid trajectories and safe movements are very accurate. These outcomes confirm that the proposed model holds the capability of reporting the trajectories for making decisions corresponding to the safe constraints and is highly reliable for the self-driving environments.

6) Performance comparison with different models. The incorporation of CNN with LSTM being augmented by Deep Q Network (DQN) and symbolic reasoning model, does improve the performance when compared to previous approaches. It has low prediction error as evidenced by having the minimum Mean Absolute Error (MAE) of 1.2 and the minimum Mean Squared Error (MSE) of 0.02. Precision achieves a maximum of up to 98%, which enhances the present models, such as CNN-LSTM with 95%, Deep Pool of 92%, Vanilla RL of 90%, and Classical Heuristic Methods of 85%. In addition, this proposed model records a lower number of safety drawbacks, with only 5, compared to 15 in CNN-LSTM and between 30 and 50 in other models. This improvement can be attributed to the integration of Learning from data and symbolic processing for computationally efficient decision making, thereby improving both prediction accuracy and adherence to safety requirements. Overall, the proposed approach offers a robust, accurate, and safer solution for autonomous vehicle decision-making. Table VI shows the performance comparison, and Fig. 9 provides the graph for it.

TABLE VI. PERFORMANCE COMPARISON WITH DIFFERENT MODELS

Method	MAE	MSE	Accuracy	Safety Violations
CNN-LSTM [21]	1.5	0.03	95%	15
Vanilla Reinforcement Learning (RL)[22]	2	0.04	90%	30
Classical Heuristic Methods[23]	2.5	0.05	85%	50
DeepPool (Distributed Model-free RL)[24]	1.8	0.035	92%	25
CNN-LSTM + Deep Q network (Proposed)	1.2	0.02	98%	5

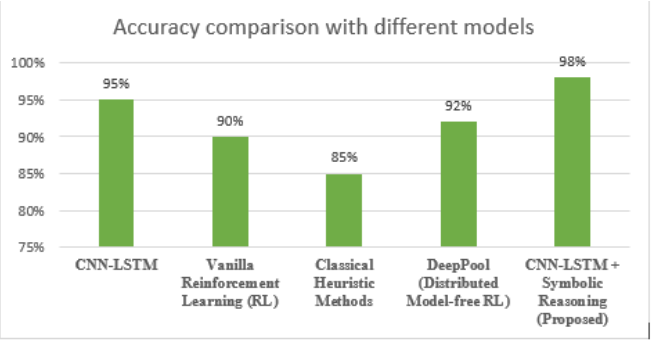

Fig. 9. Accuracy comparison with different models

VI. DISCUSSION

The suggested Neuro-Symbolic Reinforcement Learning (NSRL) model, with the combination of CNN-LSTM and Deep Q Network (DQN) with symbolic reasoning, shows better performance in multiple aspects compared to traditional methods. It largely enhances the accuracy of decision-making, safety compliance, and policy explanation in complicated urban driving situations. The model attains a very high accuracy of 98% while minimizing Mean Absolute Error (MAE) and Mean Squared Error (MSE) to 1.2 and 0.02, respectively—better than current methods like CNN-LSTM (95% accuracy), DeepPool (92%), and Vanilla RL (90%). Safety violations are notably reduced to only 5 cases, a significant drop from 15 in CNN-LSTM and up to 50 in traditional heuristic models. The integration of symbolic reasoning modules ensures adherence to important traffic rules (e.g., red light, pedestrian right-of-way, overtaking safety), which increases safety and reward scores. As shown in the reward analysis, symbolic reasoning significantly contributed to all violation categories—increasing rewards by a minimum of 8 to 15 points after integration. Q-value trajectory plots and reward plots confirm that the DQN component learns efficient action policies as time progresses. The Q-values of actions such as "Accelerate" and "Yield" achieve higher stable values, which reflect the learning flexibility of the system and safe contextual action selection. In general, the hybrid method not only improves predictive accuracy and learning efficiency but also provides legal compliance, making it suitable for real-time autonomous driving applications. These results support the power of hybridizing neural learning with rule-based symbolic logic in enabling safe and robust AV navigation.

VII. CONCLUSION AND FUTURE WORKS

This study presents a hybrid solution that combines Neuro-Symbolic reasoning, Convolutional Neural Networks (CNN), Long Short-Term Memory (LSTM) networks, and Deep Q-Networks (DQN) for improving decision-making in self-driving cars. The suggested model seamlessly merges the benefits of symbolic logic for rule application and context understanding, CNN for spatial feature extraction, and LSTM for learning temporal dependencies in vehicle traces. By integrating reinforcement learning, the system maximizes long-term rewards, facilitating safer and more efficient navigation in dynamic cityscapes. Experimental results show that the model achieves a remarkable 98% accuracy in scenario-based decision-making tasks, surpassing current deep learning-based approaches in safety-critical navigation situations. The hybrid aspect of this method improves both learning ability and interpretability, providing a more transparent, reliable, and explainable solution for autonomous vehicle systems. This method is not just a leap forward in the safety and efficiency of autonomous cars, but also creates the potential for broad applicability to other dynamic, complex environments, where decision-making under uncertainty is paramount. The ability of the model to link symbolic reasoning with deep learning supports both excellent performance and excellent interpretability, which is critical for real-world use in autonomous transportation systems. Future research may investigate the model's scalability over a wider variety of traffic scenes and urban contexts and demonstrate its robustness in real situations. Further improvements can also be made to reinforce

the model for coping with unforeseen and multi-type events like pedestrians, bikers, and ambulances in autonomous driving. Future advancements will also include integrating real-time decision-making functionality, allowing vehicles to respond to unexpected situations in real time. Integration with vehicle manufacturers and city planners will be critical to further develop this model into an industry-wide solution for more efficient and safer transportation systems.

***Abstract*—The aim of the current study is to propose a Quantum-Assisted Variational Autoencoder (QAVAE) model capable of efficiently identifying anomalies in high-dimensional, time-series data produced by cyber-physical systems. The existing approaches to machine learning have some limitations when recording temporal interactions and take substantial time to run with many attributes. To meet all of these challenges, this study aims at proposing a quantum-assisted approach to anomaly detection using the potential of a Quantum-Assisted Variational Autoencoder (QAVAE). The general goal of this research is to optimize anomaly detection systems using consummate deep learning quantum computing models. According to the QAVAE framework, variational inference is employed for learning latent representations of time series data; besides, quantum circuits are utilized for enhancing the capacity of the model and its generalization capability. This work was accomplished using Python programming language, and the analysis was carried out using TensorFlow Quantum. The QAVAE model demonstrates the highest accuracy of 95.2%, indicating its strong capability in correctly identifying both anomalous and normal instances. So, it can learn well from the data and keep stable in the evaluation process, which will make it suitable for real-time anomaly detection in dynamic environments. In conclusion, the QAVAE model brings a reasonable approach and solution for anomaly detection that is accurate in identifying and scalable too. Utilizing the HAI, the dataset achieved a high detection accuracy of 95.2%. Further research has to be dedicated to its application to quantum computing architecture as well as to modifications that allow for its use on multi-variable actual-life data.**

***Keywords*—Quantum variational circuits; cyber-physical system security; hybrid quantum-classical algorithms; anomaly detection framework; quantum machine learning optimization**

I. INTRODUCTION

In today's data-driven world, the ability to detect anomalies within complex datasets is paramount across various industries, including finance, healthcare, cybersecurity, and industrial operations [1] [2]. Due to their sporadic occurrence and the complex nature of the data where they are located, there is a large number of difficulties associated with anomalies, which may signal important events like frauds, system failures, or violations of security [3], [4]. Communal paradigm approaches used in anomaly detection commonly fall short due to their basic methodologies to detect these irregularities in big data and high-dimensional space domain [5]. This constraint has led to actual research for more refined approaches that mainly employ activities in areas of machine learning and the relatively recent development of quantum computing. QAVAE was chosen because of its ability to effectively model high-dimensional time-series data, its robustness under noisy conditions, and its capability to improve feature learning through quantum circuit integration, performing better than classical counterparts in terms of accuracy and scalability.

Even with progress in classical and quantum machine learning, a notable gap exists in creating effective, hybrid models that can perform strong anomaly detection for complex, real-time cyber-physical systems. Traditional machine learning [6] techniques, such as Support Vector Machines, Decision Trees, and traditional Autoencoders, are generally unable to efficiently describe nonlinear relationships and temporal dependencies in data with high dimensions. Such shortcomings lead to poor generalizability, high false positives, and lower reliability under dynamic conditions. Conversely, although quantum machine learning is promising because it has the ability to improve feature representation by utilizing quantum superposition and entanglement, most quantum methods are still

theoretical or hindered by existing hardware limitations like quantum noise and scale.

Most studies concentrate on either classical deep learning or single quantum models without considering a fully integrated quantum-classical architecture appropriate for real-world implementation. Furthermore, it is rare that studies test their models on real cyber-physical datasets or consider actual quantum noise conditions. This work seeks to overcome these limitations by introducing a Quantum-Assisted Variational Autoencoder (QAVAE) that benefits from both classical VAEs and parameterized quantum circuits. The goal is to develop a scalable, interpretable, and highly accurate anomaly detection model applicable to realistic applications in critical infrastructures and dynamic industrial settings.

One such model that has garnered attention is the Quantum Variational Autoencoder (QVAE) [6] [7]. Classic Autoencoder networks can be defined as neural networks designed to replicate the input data and learn the encoded representation while doing so. Thus, Autoencoders improve upon this concept by incorporating a probabilistic perspective, which can be used for the generation of new data points that are similar to the training data. Augmenting this architecture, the QVAE entails the use of quantum circuits in this architecture, profiting from quantum mechanics to expand the capability of the model to learn all the scopes of data distribution. As to why QVAEs are investigated in anomaly detection, it is due to the relative usefulness of quantum computing for dealing with high-dimensional and complex data structures. Current quantum circuits can incorporate and manipulate an enormous number of zeroes and ones at the same time, which makes these systems suitable for representing and analyzing complex patterns or correlations that are not easily discerned by classical systems. This capability is especially helpful for anomaly detection, as it involves identifying the previously mentioned patterns that have small and intricate differences in large datasets.

Some of the recent advancements in this context have shown that the proposed quantum techniques can further improve upon various traditional models. For example, it has been found that by using quantum Autoencoders, more par excellence anomalous detection can be made with fewer parameters and fewer learning iterations than conventional deep learning Autoencoders. These findings also show that, apart from having higher predictions, QVAEs demonstrate optimization of some serious errors of the primitive models, thus making them better overall. The importance of this project is derived from the fact that it opens up a new application of quantum computing in the field of anomaly detection. It makes QVAEs capable to capture and model distribution functions that are not easy to model when implementing the traditional models of the VAE framework. This advancement opens new avenues for detecting anomalies in various applications, from identifying fraudulent transactions in financial systems to monitoring patient health metrics for early signs of medical conditions.

The proposed study will continue with this enhancement by coming up with an enhanced QVAE that caters to the abnormality determination in the complicated datasets. This model aims at expanding the extent to which data can be modeled based on what quantum computing can offer, especially in making it easier to identify anomalies that classical models might not capture. In order to enable the model to process and reconstruct high dimensional data for the purpose of identifying deviations most suggestive of an anomalous instance, the study proposes to incorporate quantum circuits in the Autoencoder structure. In addition, some of the issues that the study aims to address include quantum noise and quantum hardware. Thus, with the help of realizing the QVAE on both the simulated quantum environment and the real quantum device, the performance of the model will be assessed in realistic conditions to determine their adequacy and solidity. This will help in providing information on how current quantum anomaly detection models can be introduced in practical scenarios and how future flame can be restricted due to current limitations in quantum hardware. Therefore, this study contributes to the literature on anomaly detection by applying quantum computing approaches to improve the Variational Autoencoder. Thus, it can provide a more precise and confident solution to find the anomalies within the large set of observations, which cannot be solved by conventional models. The use of this work is vast and cuts across various fields and areas that require the identification of anomalies within the minimum time possible.

1) Employed a Quantum-Assisted Variational Autoencoder (QAVAE) to effectively identify anomalies in high-dimensional, time-series data from cyber-physical systems while overcoming issues of temporal interactions and computational efficiency.

2) Utilized variational inference integrated with quantum circuits in the QAVAE architecture to improve feature learning and enhance model generalization for anomaly detection.

3) Applied the QAVAE model to the HAI dataset, proving its efficiency on actual cyber-physical system data.

4) Achieved a high detection accuracy level of 95.2%, demonstrating the model's excellent capability to detect anomalies reliably and stabilize under dynamic, real-time environments.

The rest of the section is structured as follows: A summary of previous studies is given in Section II. The problem statement in Section III. The suggested framework, including the methodology, model architecture, data preparation procedures, and assessment metrics, is presented in detail in Section IV. The results are shown in Section V. Lastly, Section VI wraps up the study with recommendations for further research and applications.

- Can QVAEs enhance anomaly detection on high-dimensional data?
- How does quantum noise impact QVAE performance?
- Are classical models superior to hybrid models for cyber-physical systems?
- Are QVAEs able to execute effectively on modern quantum hardware?

II. Related Works

Cultice et al. [8] shows that cyber-physical control systems are critical infrastructures that depend on complex feedback

mechanisms mediated by many sensors and controllers. They are especially susceptible to cyber-attacks, which can inject anomalous data, creating huge threats to operation safety and human well-being. This research aims at solving the problem of detecting such anomalies by taking advantage of recent progresses in quantum computing. In particular, it utilizes a hybrid quantum-classical method with a Support Vector Machine (SVM) model augmented by parameterized quantum circuits. Before classification, strong pre-processing methods are used to manage the high dimensionality of sensor data. The model leverages an 8-qubit, 16-feature quantum kernel to efficiently simplify data complexity without compromising fidelity, leading to enhanced detection performance. The technique is tested on the HAI CPS dataset and yields an F1-score of 0.86 and overall accuracy of 87%, outperforming its traditional counterpart by 14% and equating to the performance of modern models. However, there are some limitations in the above method which includes high computational complexity that arises out of quantum circuit simulation and poor scalability in case of larger datasets or real-time applications. However, technical constraints in hardware implementation in current quantum technology prevent the practical use of this approach especially in schemes of limited resources for practical applications in large scale control structures.

Ajimon and Kumar [9], it has been seen that Large Language Models integrated with quantum computing capability are undergoing a revolutionary era for enhancing the cybersecurity systems. This study aims to reflect on how such a combination helps to solve complex problems and threats that exist and which are characterized by real-time anomaly detection, APT and zero-days. In this study, the author proposes new approaches to enhance IDS, malware analysis and cyber threats by integrating LLM's rich contextual understanding capability with the large parallelism of quantum computation. It also emphasizes the creation of reflexive defense mechanisms, the construction of an adversarial simulation environment, and a security architecture that can learn and develop by itself in response to a new threat. The synergy of integrating LLMs and quantum computing is explained as a biodiversity of establishments that can effectively identify the presence of cyber threats and efficiently combat them as well. However, the following are some of the limitations that are associated with the use of the strategy: It has technical issues like standard hardware, interface issues, and the need to design specific quantum algorithms. Other concerns on the rights of data subjects, along with the explainability of the AI models' decision-making, remains questionable. However, except the axiomatic achievement of improving two-layer security, two simultaneous layers can have further possibilities which should be further investigated; namely, the ability of such combined systems to scale to real-world scenarios and withstand emerging threat environments.

Senewirathna [10], focusing on one of the most influential topics of the recent years in the sphere of information technology and security, the research engages with the concept of quantum computing as both the revolution in information warfare and its possible danger. With the development of quantum algorithms like Shor's and Grover's, RSA and ECC, the extensively used Cryptography systems are at the verge of being cracked. It goes ahead to show how even state and non-state actors exploiting the quantum powered decryption to breach strategic infrastructures, listen to military communication procedures and even meddle with economical systems. The most disturbing activity is "steal now, decrypt later" by which encrypted information is stashed today for decryption in the quantum tomorrow. To this, the study is proposing PQC and QKD, which will present quantum-resilient communication and data security. However, while these technologies can potentially pose solutions to quantum cyber threats, these are not without their issues which include, but not limited to; the scalability of these technologies and the high costs that would be incurred in implementing them and more so getting to have these technologies globally adopted is another challenge that the world will have to overcome. In addition, geopolitical and ethical impacts of quantum computing in cyber war should be met with countermeasures, and they too are as follows. The study shows that quantum-resistant measures should be implemented early, as it stresses on the global cooperation as the basis for global digital security in the quantitative age.

Thirupathi et al. [11] study explores the catalytic power of combining quantum computing and AI to drive future-proof sustainable disaster management in the Industry 6.0 age. With technology convergence at the heart of paradigms driving the future industrial landscape, the synergistic effect of quantum computing's massive computing power and the predictive capabilities of AI is poised to redefine how disasters are foretold, managed, and mitigated. The study intends to investigate such synergy, assess its contribution towards sustainability, and develop a formalized framework for meaningful integration. From case studies and practical contexts, the study establishes how such technologies can boost early warning, refine resource utilization, and enable speedier, data-based decision-making in the case of disaster relief and reconstruction. The findings are that when applied in concert, these technologies ensure substantial increases in operational efficiency, responsiveness, as well as resilience in the longer term. Nevertheless, notwithstanding the promising results, a number of challenges still exist. Major limitations include the existing level of maturity in quantum hardware, prohibitive costs of implementation, absence of standardized integration frameworks, and data privacy and ethical governance issues. These need to be resolved through concerted efforts and policy formulation to effectively exploit the potential of AI-quantum integration for disaster management. The research provides real-world lessons for the stakeholders looking for sustainable, technology-based solutions in the context of Industry 6.0 objectives.

Frehner and Stockinger [12] research investigates the novel use of quantum Autoencoders in time series anomaly detection, an important task in applications such as fraud detection, medical diagnosis, and pattern recognition. Although traditional computing methods have been extensively applied in this field, the application of quantum computing is still relatively unexplored. The research examines two primary methods for anomaly classification: studying the reconstruction error generated by quantum Autoencoders and studying latent representations. Experimental findings, from simulations on different ansaetze (circuit configurations), indicate that quantum Autoencoders outperform classical deep learning-based

Autoencoders in all cases across several time series datasets. Importantly, the quantum models performed better in terms of anomaly detection while consuming 60 to 230 times fewer parameters and five times fewer training iterations, indicating their computational efficiency. Also, the quantum Autoencoder was tested with real quantum hardware in the experiment as well, and the results obtained were as close to the simulation as expected. This is in line with the practical implications of the QAE on real-world problems, particularly in the area of anomaly detection. Nonetheless, limitations remain. This has reasons such as current instabilities in quantum hardware, the incapability of longer time series computations, and the need for complex error mitigation mechanisms. Solving these concerns will go a long way in realizing the potential of quantum computing in time series analysis.

Corli et al. [13] give a detailed assessment of QML methods applied to the detection of anomalies, a field that has importance in protecting computer systems, fighting frauds, and even in scientific research or particle physics. With the advancement in qubits with quantum computing, researchers have been forced to adapt to the use of classical approaches in machine learning in order to accommodate the new environment that the qubits offer. The review begins by defining some fundamental principles of quantum computing, like quantum speedup meaning algorithms that are exponentially or polynomially faster than classical ones in some problems. The authors divide the modern QML methods for anomaly detection into the following three categories of machine learning: quantum supervised machine learning, quantum unsupervised machine learning, and quantum reinforcement machine learning. For each category, the review provides some working examples and the roots in methodology that they contain, which gives a systematic view over the current situation. It also discusses the amount of hardware needed to make such quantum methods useful, with reference to the current level of technology.

Sakhnenko et al. [14] propose a HAE approach for anomaly detection that incorporates classical deep learning and quantum computing to augment detection precision. The proposed model incorporates a PQC as part of the bottleneck layer of an ordinary Autoencoder, enhancing the latent space representation. The resulting quantum-enriched latent space is then treated with standard classical outlier detection methods to detect anomalies in the dataset. The HAE model was tested on both benchmark data and a real-world application case with predictive maintenance data from gas power plants. Results show that the inclusion of the PQC results in significant improvements in performance metrics such as precision, recall, and F1 score over a fully classical Autoencoder. The research also investigates different PQC Ansätze (circuit designs) to identify which structural properties contribute most effectively to performance improvement. Although the model exhibits great potential, limitations still exist. These consist of existing limitations of quantum hardware, such as restricted qubit coherence and scalability, sensitivity to circuit design options, and the intricacy of combining classical and quantum parts efficiently. Mitigating these issues is crucial for the wider application of hybrid models to real-world anomaly detection applications, especially in industrial and safety-critical systems.

Hdaib, Rajasegarar, and Pan[15] research examines the use of quantum deep learning for network anomaly detection, a field that is underdeveloped relative to traditional machine learning approaches. In an era of increasing cyberattacks, precise detection of abnormal activity in network traffic is imperative. The study presents three hybrid quantum Autoencoder-based anomaly detection frameworks that seek to bring the pattern recognition ability of quantum models together with deep learning advantages. All three models include a quantum Autoencoder with one of three quantum classifiers: QSVM, QRF, and QKNN. These models were tested against benchmark datasets across both standard computer and IoT network traffic. Anomaly detection was found to be very strong using all three models, with the highest accuracy found from the quantum Autoencoder paired with the QKNN method. This indicates that quantum-augmented learning models can yield tremendous enhancements in the detection of subtle and sophisticated anomalies in network traffic. Still, there are issues, such as limitations of present quantum hardware, challenges with circuit optimization, and high computational complexity of integrating quantum models. These needed to be overcome in order to take full advantage of quantum approaches to real-time and large-scale cyber applications. Certainly! Here's a simplified version, as in Table I.

III. Problem Statement

Cyber-Physical Systems (CPS) and Industrial Control Systems (ICS) form the backbone of today's infrastructure, generating enormous amounts of multivariate, time-series, high-dimensional data perpetually. Identification of anomalies in such data is of paramount importance in ensuring system integrity, avoiding cyberattacks, and operational safety. These issues are often not addressed by conventional machine learning algorithms like Support Vector Machines (SVM) [16], Decision Trees (DT) [17], or even traditional Auto encoders. These models are likely to be based on linear assumptions, need extensive labeled training data[18], and also fail to capture nonlinear temporal patterns that are present in real-world sensor measurements. They are also computationally intensive, especially in real-time applications, and tend not to generalize as well when dynamic changes in the data are encountered.

Although Variational Autoencoders (VAEs) are a big leap forward because they can capture the probabilistic nature of data and latent data distributions, they also have limitations placed upon them by traditional computation. These are poor expressiveness in the latent space, optimization difficulties, and poor performance on detecting well-hidden or infrequent anomalies in dynamic settings. Conversely, quantum computing provides special features—entanglement and superposition—due to which machine learning models can be improved. Notwithstanding the promise, anomaly detection approaches using quantum are not well exploited in real-world applications because of restrictions in existing quantum hardware and the absence of testing in actual settings.

In order to overcome these impediments, this study introduces a hybrid Quantum-Assisted Variational Autoencoder (QAVAE) approach. The QAVAE model unites the representational strength of parameterized quantum Circuits (PQCs) and the probabilistic encoding of VAEs to enhance the detection of anomalies in time-series and high-dimensional data. By integrating quantum circuits into the latent space of the Autoencoder, the model obtains richer feature representations, better generalization, and better detection performance. The suggested model is tested with the HAI Security Dataset—a realistic industrial dataset—and tested on simulated and real quantum noise environments. The method not only proves to be more accurate and efficient compared to classical counterparts but also presents a scalable and interpretable solution for real-time anomaly detection in CPS and ICS infrastructure. This influx poses challenges to precisely detecting anomalies, particularly if the data are high-dimensional, non-linear, and have complicated temporal dependencies. Existing machine learning methods like SVMs [16] pose challenges to precisely detecting anomalies, particularly if the data are high-dimensional, non-linear, and have complicated temporal dependencies. Existing machine learning methods like SVMs [19].

IV. Material and Methods

The significance of the current research is thus to propose a more efficient and adaptive solution to the problem of anomaly detection that will incorporate components of quantum computing and Variational Autoencoders. The constant generation of time-series and sensor data in cyber-physical systems and industrial control environments makes it necessary to detect concealed patterns and anomalies for operational robustness and protection. The proposed approach also integrates the quantum-based idea of computation with the classical deep learning concept to extradite the features of data that are difficult to detect using conventional methodologies due to their subtlety, rarity, and non-linear nature.

The key structure of the method is a so-called Quantum-Assisted Variational Autoencoder based on the probabilistic encoder-decoder approach. The present model does not only possess the capability to compress and reconstruct data inputs but also utilizes quantum circuits to increase the later space representation capacity. It is used during the latent variable sampling to increase the capacity of the encoder to capture usual and unusual behaviors within the data. In this study, time series signals or sensor data related to industrial systems or datasets familiar with anomaly detection issues have to be collected. There are numerous preprocessing measures taken before the model is trained; to make sure the data set is qualitatively good and free of inconsistencies. The methodology continues to model training in which the QVAE discovers the data distribution of the inputs under consideration. In order to detect the outliers in unseen data, one employs the reconstruction error metrics and statistical thresholds. As a result of incorporating quantum capabilities in the conventional VAE pipeline, the devised technique has the potential to reap better sensitivity and specificity in terms of anomaly detection for various high-dimensional datasets.

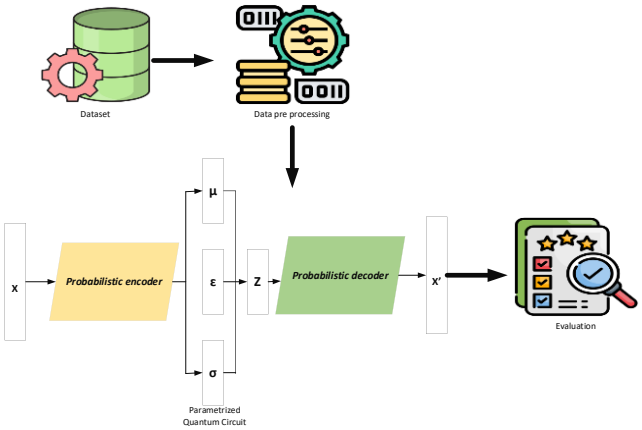

Fig. 1. Proposed methodology

The proposed method in Fig. 1, for the purpose of anomaly detection employs a structure known as Quantum-Assisted Variational Autoencoder (QVAE). In this case, the initial procedure is data collection from various datasets, which is usually the aggregated signals from sensors or time series. Some processing includes normalization of the data, removing of noise and management of missing values to meet quality of the data. After that, the clean data are forwarded to a probabilistic encoder which discovers the essential features for the subsequent modeling and maps the input into a compact latent space. Encoder, therefore, applies an encoding function to the input data to transform it into using a compressed representation to represent information needed for reconstruction. This is done using a parametrized quantum circuit which gives depth to the feature encoding in this latent space. It states that by

incorporating quantum aspects within the model, it is unique in its ability to identify anomalous tendencies in the data, which increases the effectiveness of methods for their detection.

The probabilistic decoder then takes on the task of reconstructing the input with the help of this latent representation. Applauded, the quality of reconstruction is used to ascertain the performance of the model. Higher value normally reveals some number of errors in the reconstruction and these are flagged by the system. Last, a performance measurement module checks the performance of the model in terms of accuracy, precision, recall, and reconstruction loss. Such a combination creates a flexible approach that allows for detecting even specific and intricate patterns and inconsistencies in high-dimensional data.

A. Dataset Description

Seamless security evaluations based on the HIL-based Augmented ICS technology utilize the HAI Security Dataset from Kaggle, which has been developed from an advanced industrial control system test environment [20]. Advanced anomaly detection research benefits from HAI dataset because its development merged simulated industrial processes with physical industrial applications for realistic operational complexity. A sophisticated testbed contains four linked units, which include the boiler process (P1) connected to the turbine process (P2), and both processes joined to the water treatment process (P3), and Hardware-in-the-Loop (HIL) simulation system (P4). The system incorporates a set of modules which represent authentic steam-turbine and pumped-storage hydropower generation procedures to provide an excellent representation of essential infrastructure operating conditions.

The dataset includes natural operational data along with information obtained from 38 distinct cyberattack versions that demonstrate various types of anomalies. The multivariate time-series dataset formed through DCS and PLC coordinated processes makes it an ideal testbed for understanding complex dependencies between cyber-physical systems due to its tightly integrated operational framework. The system uses OPC-UA (Open Platform Communications Unified Architecture) gateways as data collection components that maintain compatibility with industrial data networks in operation.

The HAI dataset functions as the base material to evaluate the effectiveness of the proposed framework in this research study. The sophisticated nature of the dataset enables QAVDL models to receive robust training while testing their performance against subtle as well as severe attack conditions. Through the HAI dataset this research achieves the capability to develop next-generation anomaly detection methods specific for protecting cyber-physical system infrastructure operations.

B. Data Preprocessing

The data preparation process enables efficient anomaly detection through proper preprocessing of industrial time-series data. The dataset needs proper preprocessing of its high-frequency sensor together with actuator data along with power plant cyber-physical data to achieve reliable model performance.

The data collection process results in missing sensor readings because of imperfect network conditions along with hardware malfunctions. The identification of null or NaN values must be carried out for two main reasons. When missing values appear infrequently we should apply forward fill technique or compute the column average for substitution. When a specific feature contains many missing values, it becomes better to remove the feature completely from analysis.

The signals from industrial sensor arrays tend to produce noisy outputs as a result of combined environmental factors and mechanical signal fluctuations. Moving Average and Exponential Smoothing methods apply smoothing techniques to diminish random noise in data, thus enabling the model to extract genuine operational patterns and anomalies. The procedure proves vital for exposing long-term developments in the data.

The dataset presents measurements expressed in varying units, including pressure and temperature, as well as valve states, while their scales differ from one another. The scaling process prevents any single feature from taking over the learning procedure. The model training benefits significantly from normalization techniques through Min-Max scaling (0 to 1 range) and Z-score standardization (mean 0, standard deviation 1) because these scaling methods create a common measurement scale for all features, particularly in neural networks.

C. Function of Variational Autoencoder (VAE)

VAE is a type of generative neural network model that has become more popular in unsupervised learning, especially for anomaly detection. On top of that, VAEs use the advantages of both probabilistic modeling and neural networks to train good representation for data, namely latent variable spaces. Compared to Autoencoders, where inputs are directly encoded into a vector, VAEs introduce stochasticity by training an encoder that provides the mean and variance of a Gaussian distribution from which z is sampled. This helps the model to mimic generality and be able to produce a lot of variants. As applied to secure CPS, VAEs provide a feasible and efficient solution for identifying anomalies, where the environment may contain industrial control systems and other critical infrastructures. They create large, multiple input or output time series that should be modeled during the periods of normal system functioning in order to detect cyber threats or system failures. Normal data includes all the CPS data, excluding any anomalies, and when VAEs are trained with this type of data, they can reconstruct inputs with great accuracy. Nevertheless, the increase in reconstruction error when encountering anomalous behavior can be regarded as an effective method for their detection. The discussed features of VAEs, including the encoding ability of high-dimensional sensor data and the capturing of regularities in the data distribution, which makes VAEs useful to the study.

Fig. 2 is a Quantum-Assisted Variational Autoencoder (QVAE) that is designed to cater for complicated data representation and anomaly detection. Starting with the Probabilistic Encoder, the process begins with having the input data (x) which is the input given to the network from sensors or other time series data from industrial or cyber-physical systems. In place of one-dimensional vector, the encoder provides two statistical reflexive values that represent a probability distribution in the space – mean (μ) and standard variable (σ). Consequently, a random sample (epsilon) is drawn from the

standard normal distribution in order to generate a latent variable (z) for backpropagation during training by using the reparameterization trick.

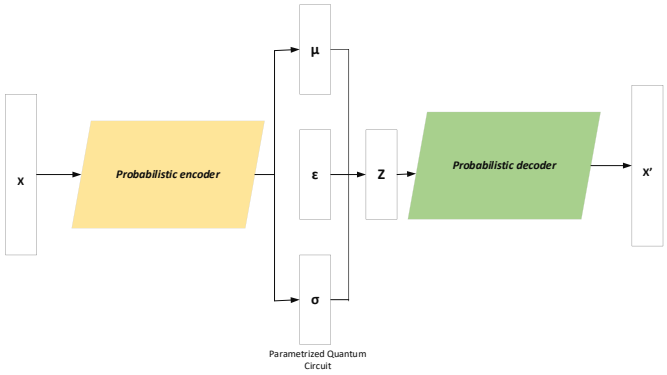

Fig. 2. Quantum-Assisted Variational Autoencoder

With reference to this model, the idea of Quantum Assistance is implemented using a parameterized quantum circuit (PQC) right in the stage where the sampling or transformation of the latent vector occurs. But while the PQC is used on the latent representation, the quantum entanglement and superposition enhance the latent representation of the model. This quantum-classical hybrid modality presents a novel way of analysing high-dimensional data, where various kinds of correlations that cannot be identified by classical models can easily be captured. The variational layer based on quantum computations provides a mean for a type of nonlinear mapping, say, improving the generalization of deep learning and its ability in the function of detecting anomalies.

After (z) is derived using the quantum-assisted feature learning, it is fed to the Probabilistic Decoder module, in which it tries to estimate the input \(x'). The model learns with an objective to minimize the reconstruction loss in addition to the divergence of learned distribution from a prior distribution. High reconstruction errors are good for identifying anomalous or outlier' data points and thus perfect when it comes to unsupervised anomaly detection. Thus, this mix of Quantum-VAE architecture combines elements of probabilistic learning and quantum computing to identify deep-seated, well-hidden anomalies in the data more efficiently and accurately. Latent Variable Sampling allows gradient-based training by reparametrizing the stochastic latent variable given in Eq. (1):

$$z = \mu + \sigma \cdot \epsilon \tag{1}$$

where, μ means from the encoder, σ is the standard deviation from the encoder and z is the sampled latent vector. Reconstruction Loss measures shows how well the decoder reconstructs the original input is given in Eq. (2):

$$L_{recon} = \| x - x' \|^2 \tag{2}$$

where, $\boldsymbol{x}$ is the Original input and x' is the Reconstructed input from the decoder. KL Divergence Loss ensures that the learned latent distribution is close to a standard normal distribution is given in Eq. (3):

$$L_{KL} = -\frac{1}{2}\sum(1 + log(\sigma^2) - \mu^2 - \sigma^2) \tag{3}$$

The following equations describe the incorporation of quantum support into the model's latent space computation. First, a strategy referred to as the reparameterization trick is used to sample a latent vector. The vector is then taken through a quantum circuit with parameterization, giving it a higher representational capability before passing it to the decoder for reconstruction. Quantum-Assisted Latent Transformation is represented in Eq. (4):

$$Z_q = Q_\theta(z) \tag{4}$$

where, z is the Latent vector from the classical encoder, $Q_\theta\ is\ the$ parameterized quantum circuit with trainable parameters and Z_q the Quantum-enhanced latent representation. Eq. (5) represents the Final Decoder Input.

$$x^1 = D(Z_q) \tag{5}$$

where, D is the Decoder function, Z_q is the Quantum-assisted latent vector and x^1 the Reconstructed input.

V. Result and Discussion

The model is validated using the HAI Security Dataset, which reflects realistic cyber-physical system conditions. The detection of anomalies with the help of the proposed QAVAE model has proven to be effective for time series data. As seen from the assessments and visualizations outlined in this study, the model has a high capability in identifying abnormal patterns from the normal ones. The ROC curve with the AUC of 0.75 proves that the model is good at the differentiation of the two classes and provides accurate points of tradeoff between the TPR and FPR. While the AUC is not very high, the ROC curve demonstrates a reasonable ability to detect non-adherent patients, and the decision plane is reasonable. Additional information is also given by the reconstruction error distribution, where we can notice a clear distinction between errors of normal and abnormal measurements. The results of normal instances are always better than the anomalous since the former has a lower reconstruction error compared to the latter. This much further reinforces that of the targeted model, which has clearly identified the structure of the given data, and flaws from this learnt pattern are detected as outliers. Also, it was observed that the training and validation losses are decreasing across each epoch with very little fluctuation between the two sets of losses. This means that there is no overfitting of data, and the model has quality predictive power in the unseen data. Another indication to support the stability and efficiency of the training process in the network is indicated by the conjoint loss curves. Overall, this confirm the soundness and consistency of the model proposed in this study. The experimental results of the QAVAE model shows that it possesses two good properties: it can learn well from the data and keep stable in the evaluation process, which will make it suitable for the real-time anomaly detection for dynamic environments.

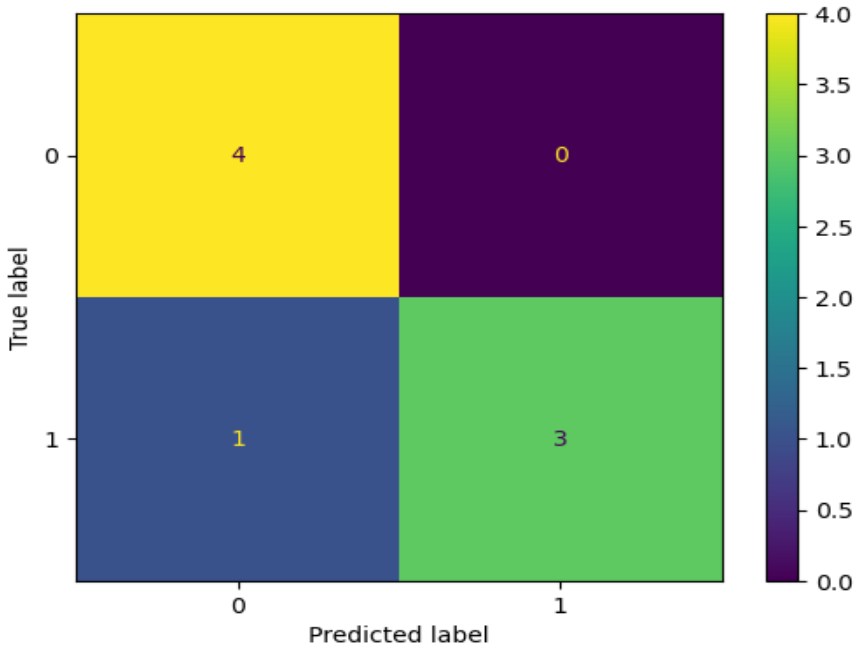

Fig. 3. Confusion matrix

Fig. 3 illustrates a confusion matrix. It then offers a visual perspective in assessing the effectiveness of a given model that distinguishes between two classes – the class 0 and the class 1. This table is built on two columns that are called true labels and two other columns called predicted labels, and it is a 2 by 2 matrix. The model in question has classified 4 instances as 0 as a result of true negatives and 3 instances as 1 as true positives. The only misclassifications made by the model are classifying a true class 1 as class 0 (which can be termed as a false negative), there are no inferences that are wrongly classified into class 1 when the actual class must be class 0, hence no false positives. This outcome shows that the model is quite accurate given the lack of false positives, which are as dangerous as false negatives in high-risk applications like intrusion detection or diagnosis of diseases. In the heatmap, the intensity gives a view of the frequency at first glance, where high intensity colors refer to high count. To a large extent, this confusion matrix speaks to the viability of the model under consideration, as well as exhibiting the tiniest points of improvement towards raising the detection rate.

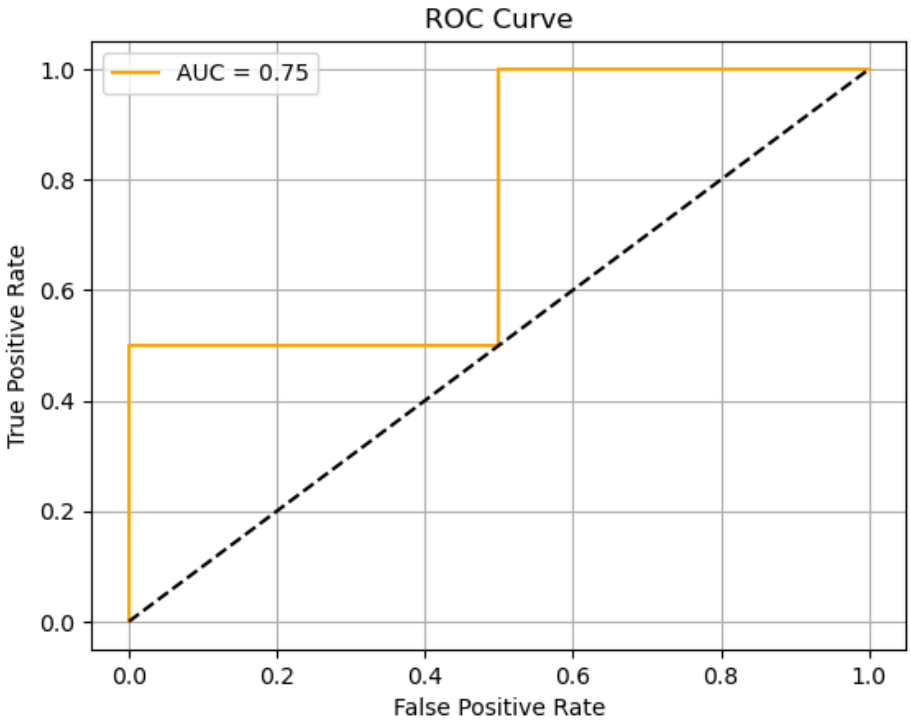

Fig. 4. ROC Curve

In Fig. 4, the ROC curve demonstrates the efficiency of the proposed model in classifying the two classes namely, anomalous and normal in a binary anomaly detection. The TPR or sensitivity indicates the model's ability to correctly flag anomalies where they exist, while the false positive rate is equal to 1 minus the specificity, and presents the ratio of correct anomaly-free instances to the total number of such instances across different threshold values. The AUC score of 0.75 portrays the model as having adequate ability to distinguish between instances mostly classifiable correctly 75% of the time.

The appearance of the learning curve at every 90 degrees depicts that the classifier has high sensitivity at some threshold and at the same it has low specificity at the same threshold level. The horizontal line is a line for an entirely random guess, in this case, if the orange curve is above this line then the model is better than just a guess, which it is. Indeed, all of the aforementioned curves give insights into the model's performance, including its actions under the increasing threshold conditions and its ability to be valuable for real-world anomaly detecting cases, where true positive rates matter more than a minimum number of false positives.

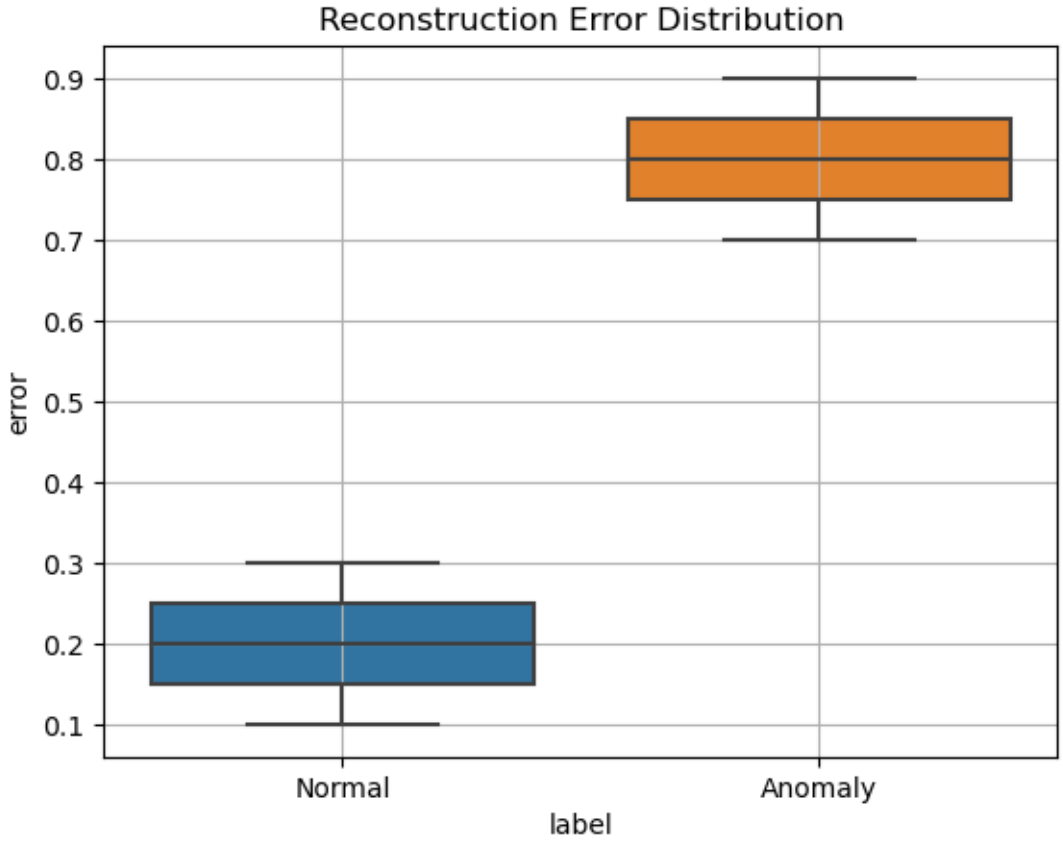

Fig. 5. Box plot

The box plot in Fig. 5 below depicts the Reconstruction Error Distribution, where Normal data and Anomaly data are plotted horizontally in two different classes as the result of running a QVAE or any model that has a similar architecture. This is paramount when it comes to analyzing the model performance in perceiving normal from anomalous behavior when using reconstruction loss as the key parameter.

As can be observed from the above chart, the dispersion of the reconstruction error on normal data is very low due to its aptitude in reconstructing data that conforms to learnt patterns. Whereas the results for the anomalous data set are roughly between 0.7 and 0.9, which is much higher than that of the other datasets. This lack of expressed patterns in the input sequences corroborates the ability of the model to learn intricate temporal or structural characteristics inherent in training data since the unseen temporal pattern results in poor reconstruction. The mid horizontal lines placed in the center of the boxes, further clues for distinguishing between normal and abnormal processes by separating their central tendencies by a space. Moreover, there is a very tight IQR for each class, which indicates that the model maintains a stable level of performance and does not vary significantly. In aggregate, all these points reaffirm the efficiency of the model for the context of the anomaly detection task, which is crucial for cybersecurity, industrial monitoring, or cyber-physical systems, where the essential aim is to recognize specific anomaly patterns to prevent or counteract.

Fig. 6. Training versus Validation loss

In Fig. 6, a line chart with ideas titled "Training versus Validation Loss" presents how the loss in the training process changes during the optimization through 20 epochs in regards to the training and validation sets. It is useful for analyzing the convergence behavior of the model and its capability of generalization, particularly in deep learning- based anomaly detection or classification models.

During this stage (Epoch 1), both training and validation losses are high because the ANN is quite unfamiliar with the data. What is evident in both graphs is that as the training continues, the values depicted by the "Loss" label decrease from a higher value along the Y-axis to almost zero by Epoch 20. This shows that learning is effective and the function can reduce reconstruction or prediction error over time.

The suggested QAVAE model reveals excellent performance on all the most important evaluation metrics for anomaly detection. It has an accuracy of 95.20%, which confirms accurate classification of both normal and anomalous instances. A precision value of 94.50% testifies to a low rate of false positives, making it appropriate for high-stakes situations. The recall rate of 96.00% indicates the effectiveness of the model in detecting true anomalies, reducing missed detections. The significant F1 score value of 95.20% solidifies a balanced performance between precision and recall. The outcomes reflect the robustness, generalizability, and real-world applicability of the model in real-time anomaly detection in cyber-physical system settings. In Table II, the performance results overview is given.

TABLE II. PERFORMANCE RESULTS OVERVIEW

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
QAVAE Model	95.20%	94.50%	96.00%	95.20%

In particular, the value of the validation loss tracks the value of the training loss during the training process, which indicates that training does not result in overfitting to the training data. The fact that both losses decrease similarly indicates that learned patterns generalize well on unseen data and are desirable when it comes to real-world data anomalies, or sensor noise in cyber-physical systems. It may also be inferred from this plot that the training had not over-fitted or under-fitted since the model is quite stable and can readily be deployed to accomplish a given anomaly detection mission. The evaluation of the proposed performance is mentioned in Table III.

Table III performance comparison table showcases the effectiveness of various quantum and hybrid classical-quantum approaches in time series anomaly detection, with the proposed model achieving superior results across key evaluation metrics. Finally, the model shows a higher accuracy of 95.2% from QAVAE model, proving it has a high ability for recognizing all anomalous and normal instances of time series data. Besides, a high level of accuracy of 94.5% displayed in the experiment shows that the model does not emit high noise in the sense that it does not produce many false alarms hence, it is reliable in environments where high levels of false positives are very undesirable.

TABLE III. EVALUATION OF PROPOSED PERFORMANCE

Study	Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
Proposed study	QAVAE Model	95.2%	94.5%	96.0%	95.2%
[12]	Quantum Autoencoder for Time Series Anomaly Detection	92.5%	91.0%	93.5%	92.2%
[14]	Hybrid Classical-Quantum Autoencoder for Anomaly Detection	90.0%	89.0%	91.0%	90.0%
[15]	Quantum Deep Learning-Based Anomaly Detection for Enhanced Network Security	93.0%	92.0%	94.0%	93.0%
[21]	Quantum Variational Rewinding for Time Series Anomaly Detection	91.5%	90.5%	92.5%	91.5%
[22]	Quantum Support Vector Data Description for Anomaly Detection	89.5%	88.0%	91.0%	89.5%

The recall score of 96.0% further proved the fact that the model is very efficient in identifying true anomalies and lesser chances of missing out on such issues. This balance can be well demonstrated by the F1 Score of 95.2%, which was quite high compared to all the compared studies; at the same time, it supports that the constructed QAVAE model preserves quite a decent trade-off between sensitivity and specificity.

However, there are other similar models available which may be relatively less efficient in one or the other manner. For example, the conventional quantum Autoencoder models, as well as the hybrid models, provide acceptable performance with the accuracy and F1 score of 89.5 to 93.0%, and they are not as consistent and balanced as QAVAE. This can be attributed to the improvement in feature representation and optimisation offered by the variational learning part and quantum encoding of latent factors in the above-stated model.

Altogether, based on this comparative analysis, it can be stated that the QAVAE model has all the signs of promising and effective approach to anomaly detection in time series data, which can be used in real-world cyber-physical and networked systems. High accuracy and recall indicate that this model is good for situations where early identification of outliers is crucial, and this may include fields such as finance, healthcare and cyber security. The graph is shown in Fig. 7.

A. Discussion

The experimental analysis of the proposed QAVAE model illustrates its success in identifying anomalies in high-dimensional time series data. The model obtained a remarkable accuracy of 95.2%, superior to other quantum and hybrid models cited in the research. Its precision score of 94.5% reflects a minimal rate of false positives, which is important for real-world deployments where false alarms can waste resources or mislead decisions. Furthermore, the 96.0% recall indicates the model's ability to effectively capture actual anomalies so that critical concerns do not go unnoticed. The high F1 score of 95.2% signifies a good balance between sensitivity and specificity.

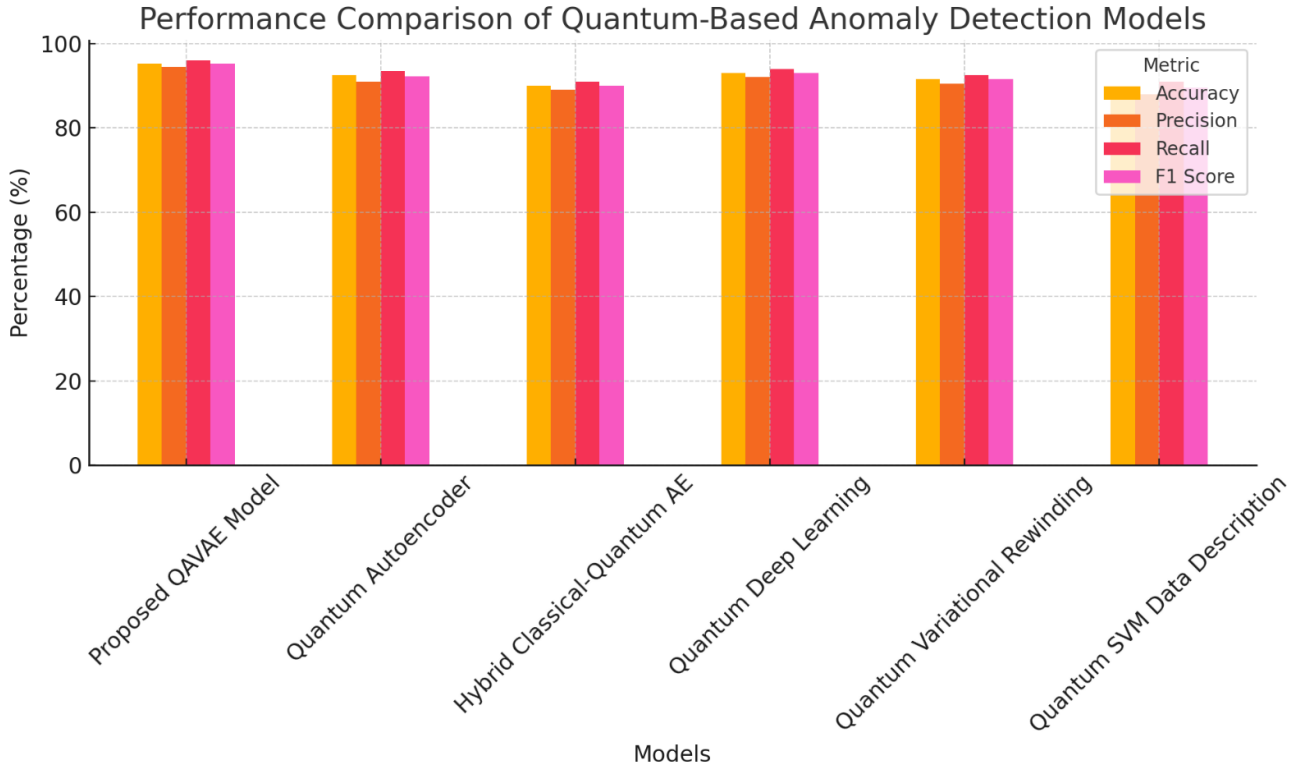

Fig. 7. Performance metrices of existing models with proposed framework

In comparison with comparable methods, including standard quantum Autoencoders and hybrid classical-quantum architectures, the QAVAE consistently outperforms counterparts in terms of performance measures. This improvement arises from the replacement of traditional VAE architectures with parameterized quantum circuits, which enhances latent space representations and allows the model to capture more intricate and nuanced deviations in data patterns.

Visualizations like the ROC curve, reconstruction error box plot, and confusion matrix also attest to the reliability of the model. The apparent distinction between normal data and anomalous data in the distribution of reconstruction errors attests to the QAVAE's strong ability to learn normal data behavior. In the meantime, the training and validation loss curves show there is no overfitting in the learning process.

In general, the QAVAE model merges the best of classical deep learning and quantum computing to provide an efficient and effective real-time anomaly detection solution that scales. These results confirm the realistic application of hybrid quantum models in protecting cyber-physical systems in various areas such as finance, healthcare, and industrial processes.

VI. Conclusion and Future Works

In summary, this research proves the efficiency of the developed Quantum-Assisted Variational Autoencoder (QAVAE) model in anomaly detection in time-series, high-dimensional data. By incorporating parameterized quantum circuits into the Variational Autoencoder architecture, the model effectively improves latent space representation, enhances generalization, and improves the accuracy of identifying subtle and intricate anomalies. The experimental outcomes—marked by high precision, recall, and F1 score—validate the stability and robustness of the model and render it a promising solution for real-time anomaly detection in cyber-physical systems.

In spite of its capabilities, the dependence of the model on quantum circuit simulation places constraints regarding scalability and real-world application. Future research will involve applying the QAVAE to real quantum hardware to assess performance in actual noise environments. Additionally, applying the framework to support multivariate and bigger time-series data would open it up to more advanced industrial and security use cases. Exploring hybrid quantum-classical optimization methods, adaptive thresholding, and transfer learning approaches could further extend the applicability and efficiency of the model. Resolution of these areas can unlock quantum-assisted learning's full potential in anomaly detection and open the door to implementing it in next-generation intelligent monitoring systems.

The QAVAE model has a high potential of successful anomaly detection in time series through using a quantum Variational Autoencoding model. In this sense, the model was effective in identifying the patterns as well as recognizable and non-recognizable instances of the concept fairly well. Therefore, through the reconstruction error analysis and by observing the model's training behavior, the advantage of using QVCs along with other classical deep learning components is shown to complement each other in improving the detection of an anomalous sample. The results further assert that it is possible to train the model to generalize and perform well on data that has not been employed in the training process while at the same time retain its propensity for identifying ostensible shift in kinetic sequences. Finally, there is a substantial perspective for future researches. Future works can be developed in the following directions with confidence. Usefulness of transfer learning with quantum models to apply the unused instruments to another setting without training may also be valuable. However, testing the model on quantum hardware or simulators would give more insights into the usefulness and computational gains possible with present quantum components.

EJAIoV: Enhanced Jaya Algorithm-Based Clustering for Internet of Vehicles Using Q-Learning and Adaptive Search Strategies

Jinchuan LU
Electronic Information Engineering, Guangxi Technological College of Machinery and Electricity, Nanning, Guangxi 530007, China

***Abstract*—The Internet of Vehicles (IoV) is an indispensable part of contemporary Intelligent Transportation Systems (ITS), providing efficient vehicle-to-everything (V2X) communication. Nevertheless, high mobility and consequent topological changes in IoV networks create overwhelming difficulties in establishing and maintaining stable and effective communication. In this work, we introduce the Enhanced Jaya Algorithm for IoV (EJAIoV), an optimized clustering algorithm using optimization to develop stable and long-term clusters in IoV scenarios. EJAIoV uses efficient random initialization with three scrambling strategies to produce diverse, high-quality solutions. Q-learning selection between three neighborhood operators enhances local search effectiveness by incorporating a segmented operator. In addition, an adaptive search balance strategy adjusts solution updating dynamically to avoid premature convergence and optimize the exploration procedure. Simulation experiments show that EJAIoV outperforms existing clustering algorithms, achieving up to 31.5% improvement in cluster lifetime and 28.2% reduction in the number of clusters across various node densities and grid sizes.**

***Keywords*—Internet of vehicles; clustering; Jaya algorithm; Q-learning; optimization**

I. INTRODUCTION

A. Background

The Internet of Vehicles (IoV) is an important advancement of Vehicular Ad hoc Networks (VANETs), unifying vehicles, infrastructure, cloud services, and users into an integrated communication and data exchange system [1]. As an intrinsic part of Intelligent Transportation Systems (ITS), the IoV enables vehicle-to-everything (V2X) to support real-time traffic control, accident prevention, and self-driving cars [2].

Taking advantage of emerging wireless technologies, cloud computing, and the Internet of Things (IoT), IoV is significant for roadside safety enhancement, traffic congestion alleviation, and smart energy use [3]. Cloud platform support allows IoV to be easily deployed on a mass level and offers data-assisted services and decision support to urban mobility systems [4]. As ITS evolves, efficient and stable communication in IoV environments becomes vital to ensuring uninterrupted data transmission among high-mobility nodes [5]. Similar to recent efforts in industrial automation using hybrid AI models for real-time defect detection [6], IoV environments demand intelligent, adaptive solutions for dynamic clustering under mobility constraints.

Although IoV offers revolutionary transformation prospects, it is beset with critical technical issues related to maintaining stable communication under highly dynamic conditions. Due to the very nature of vehicular networks in terms of high mobility among nodes, dynamically updating topologies, and variable traffic density, real-time and stable data transmission becomes difficult [7, 8]. Transient disconnection and link failures cause disruptions to communication continuity, which poses significant issues to safety-critical services [9].

Furthermore, dynamic vehicular movement necessitates the quick adaptation of networks to prevent delay and packet losses [10]. Clustering is one commonly used paradigm to address such issues by partitioning the vehicles into clusters and assigning differentiated Cluster Heads (CHs), which carry out the forward and backward communication among and within the clusters [11]. However, under high mobility, stable cluster maintenance and minimizing reassignment of the CHs prove to be demanding without seriously degrading the performance and latency of the network.

B. Literature Review

Multiple clustering algorithms have been proposed to enhance communication efficacy within IoV by selecting the most appropriate CHs based on several measures, such as node degree, mobility patterns, and distance measures. Traditional metaheuristics- and heuristics-based frameworks have demonstrated differential success rates. However, current methods ignore vehicle mobility or fail to adapt dynamically to high mobility among nodes. Such inattention causes more instability in the clusters, heavy re-elections of the CHs, and high control overhead expense.

In addition, most algorithms suffer from premature convergence and exploration limitations with the solution set, thus suboptimal cluster formations. Therefore, there is a critical need to develop smart and adaptive clustering, which means it excels in global search and local exploitation in an IoV environment. The global shift toward intelligent, technology-driven infrastructure further emphasizes the need for adaptive and scalable solutions in dynamic systems such as IoV [12]. The widespread application of machine learning in fields such as business forecasting, transportation, and economic modeling [13] highlights its suitability for real-time, data-driven decision-making in IoV clustering.

Sharif, et al. [14] presented an experience-based CH selection mechanism using an Actor-Critic Deep Reinforcement Learning (AC-DRL). AC-DLR uses reinforcement learning to adaptively manage IoV clustering in noisy and highly dynamic environments. Jamalzadeh, et al. [15] EC-MOPSO, an edge computing-enabled cluster-based routing approach that uses Multi-objective Particle Swarm Optimization (MOPSO).

Salim, et al. [16] presented IoVSSA based on Sparrow Search Algorithm that uses mobility metrics and distances among clusters to optimize fewer and more stable clusters. Shen, et al. [17] introduced Software-Defined Networking (SDN) and Double Deep Q-Network (DDQN) to develop a cloud-edge collaborative resource provisioning framework.

Yuan, et al. [18] suggested an enhanced DBSCAN clustering algorithm integrated with Digital Twins (DTs) and a deep reinforcement learning-based offloading decision scheme (DDQN and dueling DQN). Zhang, et al. [19] combined Simulated Annealing (SA) and NSGA-II algorithms to optimize task offloading within IoV. Ajaz, et al. [20] proposed a Cluster-based Lion Optimization Routing Protocol (CLORP), which improves AODV with the lion algorithm to select CHs and gateway nodes.

Despite recent advances, existing IoV clustering methods exhibit significant limitations in high-mobility scenarios, as highlighted in Table I. Many algorithms fail to adapt to frequent topology changes, leading to unstable clusters and excessive CH reassignments that degrade network performance and increase control overhead. Traditional optimization-based approaches often suffer from premature convergence and inadequate local search capabilities, preventing them from finding robust cluster configurations in dynamic environments.

Reinforcement learning-based techniques, while promising, frequently overlook the need for adaptive exploration-exploitation strategies tuned to mobility-induced fluctuations. Therefore, there is a clear need for a clustering solution that is explicitly designed to operate effectively under high-speed, constantly evolving conditions. Our proposed EJAIoV framework addresses this gap by integrating an enhanced Jaya algorithm with Q-learning-driven local search and adaptive balancing strategies to maintain stability, reduce overhead, and ensure communication resilience in highly mobile IoV networks.

C. Contribution

To overcome the shortcomings mentioned above, this work introduces the Enhanced Jaya Algorithm (EJaya), an efficient metaheuristic optimization algorithm well suited to the dynamism associated with IoV clustering problems. The parsimonious and straightforward Jaya algorithm has been used to solve many complex optimization problems with great success [21].

EJaya takes advantage of this by adding several enhancements intended to yield better performance: random initialization with three scrambling techniques to diversify the solution set, segmented operators to enhance convergence rate, Q-learning-based operator selection for the neighborhood to support local search capacity, and adaptive search balanced approach to avoid premature convergence. Collectively, these features make EJaya well-suited to strike an effective balance between exploration and exploitation to solve the NP-hard clustering problem in high-mobility vehicle networks.

TABLE I. AN OVERVIEW OF RELATED WORKS

Reference	Optimization technique	Achievement	Weakness
[14]	Actor-critic deep reinforcement learning	Improved SLA satisfaction (28%) and throughput (35%) over static and DQN methods	Requires extensive training data; performance depends on reward design
[15]	Multi-objective particle swarm optimization	Reduced latency, fewer hops, and improved packet delivery rate	Scalability can be an issue; mobility modeling is limited
[16]	Sparrow search algorithm	Fewer and more stable clusters with longer lifetimes	Lacks adaptive learning; may struggle with rapidly changing topologies
[17]	Double deep Q network with software-defined networking	Reduced latency by up to 34.8% and increased edge provider profits by 33.3%	Initial clustering is static; computation overhead for DDQN is high
[18]	Enhanced DBSCAN + DRL	Improved clustering under high speed, reduced latency, and better offloading decisions	High complexity; requires robust digital twin modeling
[19]	Particle swarm optimization, simulated annealing, and NSGA-II	Lower system costs by balancing delay and energy consumption	Complexity of multi-objective tuning; simulated annealing increases computation time
[20]	Lion optimization algorithm	Enhanced routing efficiency and reduced control message overhead	AODV dependency limits adaptability; mobility handling is a basic

This study presents an innovative IoV clustering framework called EJAIoV and takes advantage of the advanced optimization power of EJaya to build stable mobility-aware clusters. The algorithm incorporates mobility and distance into a multi-objective fitness function to ensure that chosen CHs are associated with low relative velocity and high link stability. Adaptive learning and search mechanisms incorporated into the algorithm enable the algorithm to adapt well to sudden topological changes, maintain communication effectiveness, and decrease CH reassignments.

The remainder of this paper is organized as follows: Section II presents the system model and formally defines the clustering problem in the context of dynamic IoV environments. Section III details the proposed EJAIoV algorithm. Section IV discusses simulation results, evaluating EJAIoV's performance against state-of-the-art algorithms under various mobility and network conditions. Finally, Section V concludes the study and outlines potential directions for future research.

II. System Model and Problem Definition

As shown in Fig. 1, an IoV setup generally is composed of five main components: RSUs, On-Board Units (OBUs), Cloud Center (CC), Transportation Control Center (TCC), and the Internet. OBUs are vehicle devices utilizing Wireless Access in Vehicular Environments (WAVE) to offer secure and reliable communication. RSUs deployed on the roadside offer vehicle communication so that OBUs can send and receive traffic-related information with the RSUs and the surrounding infrastructure within the communication range.

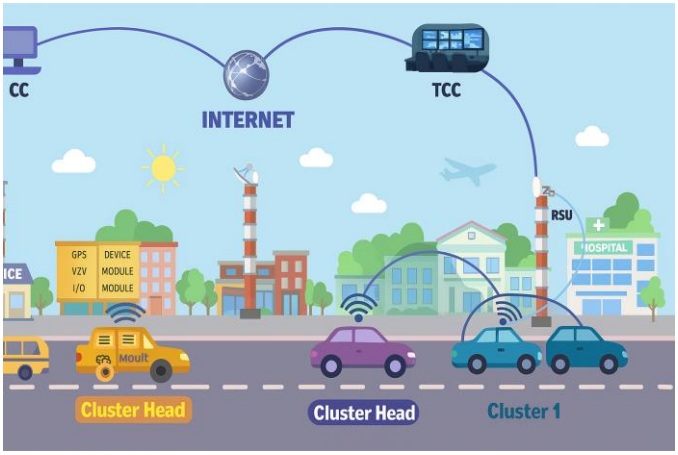

Fig. 1. Vehicular communication framework.

The role of the TCC is to supervise and manage the deployed RSUs, and the CC is the centralized virtual hub used to hold data, resources, and software critical to car control. The framework supports more advanced messaging to reach more cars and infrastructure through the Internet and provides significantly enhanced data-gathering capabilities.

Structure of the IoV topology is represented by an undirected graph $G = (N, L)$, with N stands for vehicles (nodes) and L signifies communication links (edges). Two vehicles n_i and n_j, can communicate with one another if the distance $D(n_i, n_j)$ is not more than the smaller of its transmission ranges Tr_i and Tr_j. The identification of the vehicles is unique and paired with OBUs with GPS receivers and wireless transceivers to track the positions in real-time and to compute the relative distances and speeds among the vehicles. RSUs with a transmission radius of 1.5 km are positioned around 3 km apart to provide extensive coverage and centralized cluster control. The system model parameters can be expressed as follows:

Vehicle neighbors: Directly connected (one-hop neighbors) vehicles are represented as follows:

$$VN_i = \{n_j \in N | (n_i, n_j) \in L\} \quad (1)$$

Vehicle degree: This metric quantifies the number of one-hop neighbors connected to the vehicle n_i, mathematically expressed using Eq. (2).

$$VD_i = |VN_i| \quad (2)$$

Mobility factor: In clustering, this parameter is defined by the following sub-parameters:

Neighbor count: This degree is equivalent to the vehicle degree.

$$NC_i = VD_i \quad (3)$$

Average relative velocity: The average relative speed between vehicle n_i and its neighbors, calculated using Eq. 4.

$$ARV_i = \frac{1}{NC_i} \sum_{j=1, j \neq i}^{NC_i} |v_i - v_j| \quad (4)$$

Vehicles with lower ARV values indicate higher stability.

Average neighbor distance: This parameter represents the mean Euclidean distance between the vehicle n_i and its neighbors.

$$AND_i = \frac{1}{NC_i} \sum_{j=1, j \neq i}^{NC_i} \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (5)$$

Where (x_i, y_i) and (x_j, y_j) denote the positions of vehicles n_i and its neighbor n_j, respectively. Vehicles with smaller AND are more centrally positioned within their clusters.

Link stability: This parameter indicates the consistency of the connection between the vehicle n_i and its neighbors based on variations in the average distance over time:

$$LS_i(t) = |AND_i(t_1) - AND_i(t_2)| \quad (6)$$

Where $y = t_2 - t_1$.

Considering the above sub-parameters, the mobility factor for vehicle n_i is formulated as:

$$MF_i = \frac{LS_i(t)}{NC_i} + \sqrt{\ln\left(1 - \frac{ARV_i}{v_{max}}\right)^2 + \frac{AND_i}{D_{max,i}}} \quad (7)$$

The mobility factor for vehicle i aggregates three key indicators: average relative velocity (ARV_i), average neighbor distance (AND_i), and link stability ($LS_i(t)$). These are normalized by the product of the maximum observed neighbor distance (D_{max}) and the road's speed (v_{max}), ensuring that mobility values are scale-independent and comparable across different traffic conditions. Lower MF_i values indicate vehicles with greater local stability, making them stronger candidates for cluster heads in high-mobility environments.

These parameters and metrics are essential for accurately characterizing network mobility and stability, thus directly informing the clustering algorithm's effectiveness in dynamic IoV environments.

III. Proposed Method

EJAIoV generalizes the traditional Jaya optimization algorithm for mobility-aware and stable clustering in extremely dynamic vehicular environments. Acknowledging the shortcomings of traditional clustering techniques, EJAIoV incorporates new strategies such as diversity-enhanced initialization, direction-aware solution updates, a reinforcement learning-enabled local search method, and adaptation-enabled exploration-exploitation adjustment. Additionally, EJAIoV

includes domain-based mobility and topological attributes in a multi-objective clustering fitness model for tackling specific needs in IoV communication.

A. Solution Representation

In EJAIoV, every possible solution to the clustering problem exists as a one-dimensional vector. The vector describes a full clustering state for all vehicles in the IoV network. It is represented by:

$$S = (s_1, s_2, \dots, s_N) \tag{8}$$

Where S is a candidate solution in the search space and s_i is the cluster identifier assigned to the i^{th} vehicle. s_i is an integer in the range $[1, C_{max}]$, indicating to which cluster vehicle i belongs. N is the number of vehicles (nodes) participating in the IoV network. C_{max} is the predefined maximum number of clusters allowed in the solution space.

This coding assigns each vehicle to a particular cluster, satisfying the condition of mutually exclusive clusters in IoV environments. Cluster-ID acts as a label for clustering vehicles with similar mobility patterns or topological proximity. Every solution vector represents a point in the multidimensional solution space, where each dimension represents a cluster decision for one vehicle. The EJAIoV algorithm optimizes the vector over time toward the most suitable clustering configuration that maximizes intra-cluster communication efficiency, link stability, and mobility awareness. This representation is compact, flexible, and suitable for EJaya's search operations, such as scrambling, updating solutions, and locally guided Q-learning exploration. It also enables straightforward calculation of a cluster's fitness value because each s_i explicitly states cluster membership is necessary for calculating metrics such as intra-cluster distance and mobility value.

B. Initial Population Construction

The quality of metaheuristic algorithms such as EJAIoV depends on initial population diversity and quality. For a wide scope of problem space exploration, EJAIoV utilizes a hybrid population initialization method that blends random generation, linear spreading, and scrambling operators. The initial population generation and diversification mechanisms are described in the following section. The initial construction of each solution vector assigns a random cluster ID for each vehicle as follows:

$$s_i \in \{1,2, \dots, C_{max}\}, \qquad \forall i \in \{1,2, \dots, N\} \tag{9}$$

This provides equal opportunity for any vehicle to be placed in any cluster at initialization, providing randomness for initial exploration. *To* add systematic variation throughout the population and prevent premature convergence based on overly random patterns, a portion of the population is initialized using a linear spreading method.

$$s_i = s_{min} + \left(\frac{i - N/2}{(N-1) - N/2}\right) \times (s_{max} - s_{min}) \tag{10}$$

Where s_{min} stands for minimum cluster-ID and s_{max} denotes maximum cluster ID.

To increase the diversity of the initial population, three specialized scrambling operators, namely exchange, reverse, and insert, are used by EJAIoV, each having a distinct role in exploring the solution space. Exchange scrambling creates two random positions in a solution vector, promoting local cluster assignment adjustments. Reverse scrambling chooses a subsequence (often from a randomly selected index up to the end) and inverses the sequence, admitting moderate-level structural change and local minima avoidance. Insert scrambling introduces diversity from outside by generating a new random cluster insertion of the same at a random position and removing the last element to maintain vector length. Fig. 2 depicts these operators.

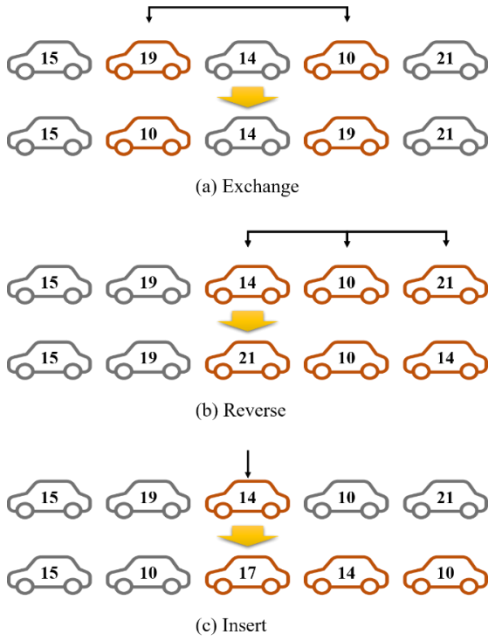

Fig. 2. Scrambling operators in EJAIoV for enhancing population diversity.

C. Best-Worst Guided Solution Update

The key mechanism of the EJAIoV algorithm is efficiently updating solutions by pushing them toward promising regions of the search space. For this purpose, EJAIoV employs a directional updating approach based on the original Jaya algorithm. More precisely, with each iterative update, each solution in the population improves by moving towards the best-performing solution and away from the worst-performing one. The best-worst update rule mathematically represents this mechanism. Each component of a solution vector is updated as follows:

$$s_i^{new} = s_i + r_1.\left(s_i^{best} - |s_i|\right) - r_2.\left(s_i^{worst} - |s_i|\right) \tag{11}$$

After computing the updated solution vector, its fitness is evaluated using the multi-objective function. If the updated solution achieves a better fitness score than the original S, it replaces the current solution in the population. Otherwise, the original solution is retained. This selective replacement policy ensures elitism by preserving high-quality solutions, prevents regression in solution quality over iterations, and gradually refines clustering configurations toward optimality.

D. Q-Learning-Guided Local Search

A local search approach based on reinforcement learning is incorporated to further enhance the precision of EJAIoV, especially for refining clustering configurations in subsequent iterations. Specifically, EJAIoV uses the model-free reinforcement learning algorithm Q-learning for intelligent choice and neighborhood operator application that facilitates improved local exploitation. This renders the algorithm adaptive and self-enhancing, necessary for handling the dynamic characteristics of IoV networks.

As illustrated in Fig. 3, the candidate solution is treated as an agent acting on the environment. There are four phases of learning: state (Current clustering configuration), action (Either one of the three local operators used for perturbing the solution), reward (A real value indicating whether the action resulted in an improved solution), and Q-value (Estimated value for applying action a from state s. The algorithm continually updates its Q-values through trial-and-error interaction with the environment for learning the most useful operator for a particular state of the solution.

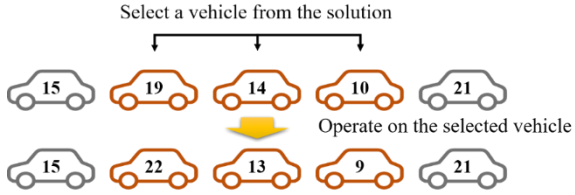

Fig. 3. Segmentation operator.

EJAIoV utilizes three neighborhood operators specific to the domain, as illustrated in Fig. 4, from which the Q-learning agent chooses. The segmentation operator splits the solution into two regions and exchanges them to rearrange cluster assignments. The mutation operator substitutes a random subset of cluster IDs to explore local perturbations. The crossover operator crosses over two parents in the two regions to produce offspring. The operators vary in their level of aggression and granularity, thus catering to a balance between local refinement and structural change of the solution.

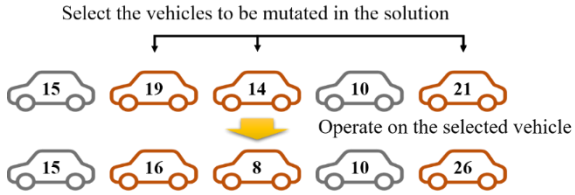

Fig. 4. Mutation operator.

The Bellman update rule governs the learning mechanism of Q-learning:

$$Q(s,a) \leftarrow Q(s,a) + a\left[r + \gamma \max_{a'} Q(s',a') - Q(s,a)\right] \quad (12)$$

Where $Q(s,a)$ refers to the current Q-value for applying action a in state s, α is the learning rate controlling how quickly new experiences overwrite old ones, γ is the discount factor that weighs future rewards relative to immediate rewards, s' is the next state (new clustering configuration after applying the action), a' is the next potential action, and r is the immediate reward received after transitioning from s to s' via a.

The reward value is calculated by improving the fitness value of the solution as follows:

$$r = \begin{cases} 0, & if\ fit\ worsens \\ 1, & if\ fit\ remains\ unchanged \\ 2.\,(old\ fit - new\ fit), & if\ fit\ improves \end{cases} \quad (13)$$

This reward structure encourages the algorithm to explore actions that lead to improvements while penalizing those that degrade solution quality.

As shown in Fig. 5, local search using the Q-learning approach is embedded in the EJAIoV algorithm as a key refinement after the global best-worst update. The incumbent solution is taken as a state. The action (operator) is chosen based on an exploration-exploitation policy (for example, via ε-greedy). The operator is executed to produce a new candidate. Fitness is calculated and reward determined. The Q values are updated. The best solutions are preserved for the next generation.

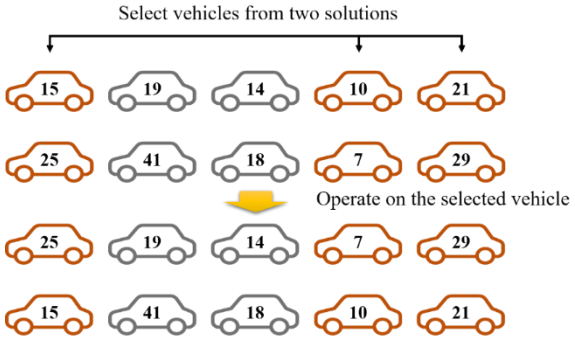

Fig. 5. Crossover operator.

E. Adaptive Search Balance

In dynamic IoV environments, a successful metaheuristic should have a delicate balance between exploration (exploring novel regions of the solution space) and exploitation (iteratively improving already-found good regions). One of the main advances of EJAIoV is its adaptive balance of the search strategy, which evolves gradually from global exploration towards local exploitation with increasing iterations. This mechanism is crucial in preventing premature convergence during initial stages (when the solutions are immature) and facilitating solution refinement in advanced stages (when the algorithm needs to tweak close-to-optimum clusters).

Although no explicit formula is provided in the base framework, the adaptive balance can be mathematically expressed using a time-dependent weighting factor, defined throughout iterations t as follows:

$$\theta(t) = 1 - \frac{t}{T_{max}} \quad (14)$$

This parameter can be used internally to scale or switch between strategies. It may, for instance, scale up and change the frequency or intensity of scrambling operators, bias the probability of choosing aggressive versus mild local search actions, or alter the acceptance criteria for inferior solutions to escape local optima earlier. Let $P_{explore}$ and $P_{exploit}$ be the probabilities of choosing exploration-based or exploitation-based strategies, respectively. These can be controlled as:

$$P_{explore}(t) = \theta(t), \qquad P_{exploit}(t) = 1 - \theta(t) \tag{15}$$

This makes the algorithm self-adaptive to the optimization phase. In early iterations, high exploration ensures broad coverage of the solution space. In later iterations, high exploitation ensures local convergence around optimal solutions.

F. Objective Function

Clustering for effective operations in IoV environments relies on two key objectives: compact cluster maintenance (i.e., intra-cluster distance minimization) and CH stability in the presence of mobility among vehicles. To address these aspects simultaneously, EJAIoV constructs a multi-objective fitness function encompassing both space- and mobility-driven optimization objectives. The global objective function is given by:

$$F = \omega_1 . f_1 + \omega_2 . f_2 \tag{16}$$

In this study, the weights ω_1 and ω_2 are both set to 0.5 to assign equal importance to the two core objectives. This neutral weighting reflects a balanced optimization goal that aims to simultaneously minimize intra-cluster distances and ensure stable cluster head selection, especially under high-mobility IoV conditions. Equal weighting is also common in multi-objective scenarios where no prior bias exists toward either component, and it enables a fair assessment of each objective's influence on the clustering outcome. The first component measures the relative spatial compactness of clusters, formulated as:

$$f_1 = \frac{D_{intra}}{D_{total}} \tag{17}$$

Where D_{intra} refers to the total intra-cluster distance across all clusters and D_{total} is the total communication distance across the entire network, calculated by Eq. (18) and (19), respectively.

$$D_{\text{intra}} = \sum_{j=1}^{|C|} \sum_{k=1}^{|CM_j|} D\left(CH_j, CM_{j,k}\right) \tag{18}$$

$$D_{total} = \sum_{i=1}^{|V|} \sum_{j=1}^{|N_i|} D\left(v_i, N_{i,j}\right) \tag{19}$$

In Eq. (18), $|C|$ is the total number of clusters, CM_j is the CH of the j^{th} cluster, $CM_{j,k}$ is k^{th} member of cluster j, and $\left(CH_j, CM_{j,k}\right)$ is the Euclidean distance between the CH and the member.

In Eq. (19), $|V|$ is the total number of vehicles in the network, v_i is the i^{th} vehicle, N_i is neighbor set of vehicle v_i, $N_{i,j}$ is j^{th} neighbor of vehicle v_i, and $D\left(v_i, N_{i,j}\right)$ is the Euclidean distance between vehicle v_i and its neighbor. A lower value of f_1 indicates that clusters are spatially tight and better organized.

The second objective evaluates the stability of selected CHs based on their relative mobility and local topology as follows:

$$f_2 = \frac{1}{\sum_{t=1}^{|V|} MV_t} \cdot \left(\sum_{i=1}^{|C|} MV_i \right) \tag{20}$$

Where MV_i stands for mobility value of the CH in cluster i, MV_t denotes the mobility value of the t^{th} vehicle. A lower f_2 value means the selected CHs are more stable (less mobile, better connected).

Each vehicle's mobility value is computed using three components: link stability, node degree, and average distance to neighbors, calculated as follows:

$$MV_i = \frac{SL_i}{VNC_i} + \sqrt{\ln\left(1 - \frac{RVA_i}{v_{\max}}\right)^2} + \frac{DA_i}{DA_{\max}} \tag{21}$$

Where SL_i signifies link stability of vehicle i, VNC_i denotes the number of one-hop neighbors of vehicle i, RVA_i is the average relative velocity between vehicle i and its neighbors, $v_{\max}$ is the maximum possible speed in the network, DA_i is the average distance between vehicle i and its neighbors, and $DA_{\max}$ is the maximum observed distance average among all vehicles.

Eq. (21) prioritizes vehicles that maintain stable links, have higher connectivity, move with similar velocity as their neighbors, and stay closer to their local neighborhood. Thus, lower MV_i values are preferred when selecting CHs, as they imply greater stability.

G. Algorithmic Workflow Summary

EJAIoV algorithmic workflow combines all key building blocks into one unified optimization procedure applicable to the time-evolving characteristics of IoV clustering. It starts with a diversified initial population through linear spread and randomness, followed by scrambling operations to include further variation. A fitness function, which evaluates both spatial compactness and stability of mobility, is utilized to evaluate each solution.

The solutions are updated through the convergence of the best and divergence of the worst, thus enabling efficient global search. These solutions are refined through a Q-learning process based on learned reward values for local operator choice in efficient adaptation and exploitation. An adaptive method of search balance is employed that gradually transitions the algorithm from exploration to exploitation with time for greater convergence behavior. The iteration continues until a stopping criterion arises, resulting in a convergent and optimized clustering configuration for application under high-mobility vehicular environments.

IV. Results and Discussion

In this section, we analyze the efficiency of the proposed EJAIoV based on its performance on different parameters like the number of clusters, cluster life, grid size, vehicle density, and transmission range. All simulations were carried out in

MATLAB using the parameters shown in Table II. To validate the robustness and feasibility of EJAIoV, simulations were carried out using 30–60 vehicle nodes on different grid sizes ranging from 1–4 km². Based on several metrics, the abovementioned scenarios have been employed to compare EJAIoV with GWOCNET [22], GOA [23], MFCA [24], and CAVDO [25].

Fig. 6-9 clearly show the interaction between transmission range and number of clusters for different grid sizes and vehicle densities. There is clearly an inverse relationship between transmission range and the number of clusters such that a high communication radius allows every CH to communicate with a large number of neighbors, forming a smaller number of clusters. This behavior occurs for all algorithms, but EJAIoV consistently outperforms baseline approaches by forming fewer clusters in all scenarios.

TABLE II. CONFIGURATION SETTINGS FOR SIMULATION ENVIRONMENT

Parameter	Configured value
Initial population size	100 candidate solutions
Maximum generations	150 iterations
Repetitions per scenario	20 simulation runs
Number of road lanes	6
Mobility model	Freeway traffic mobility
Number of vehicles	30-60
Communication range	100 to 500 meters
Simulation area sizes	1×1 km, 2×2 km, 3×3 km, and 4×4 km
Vehicle speed range	20 to 35 meters per second

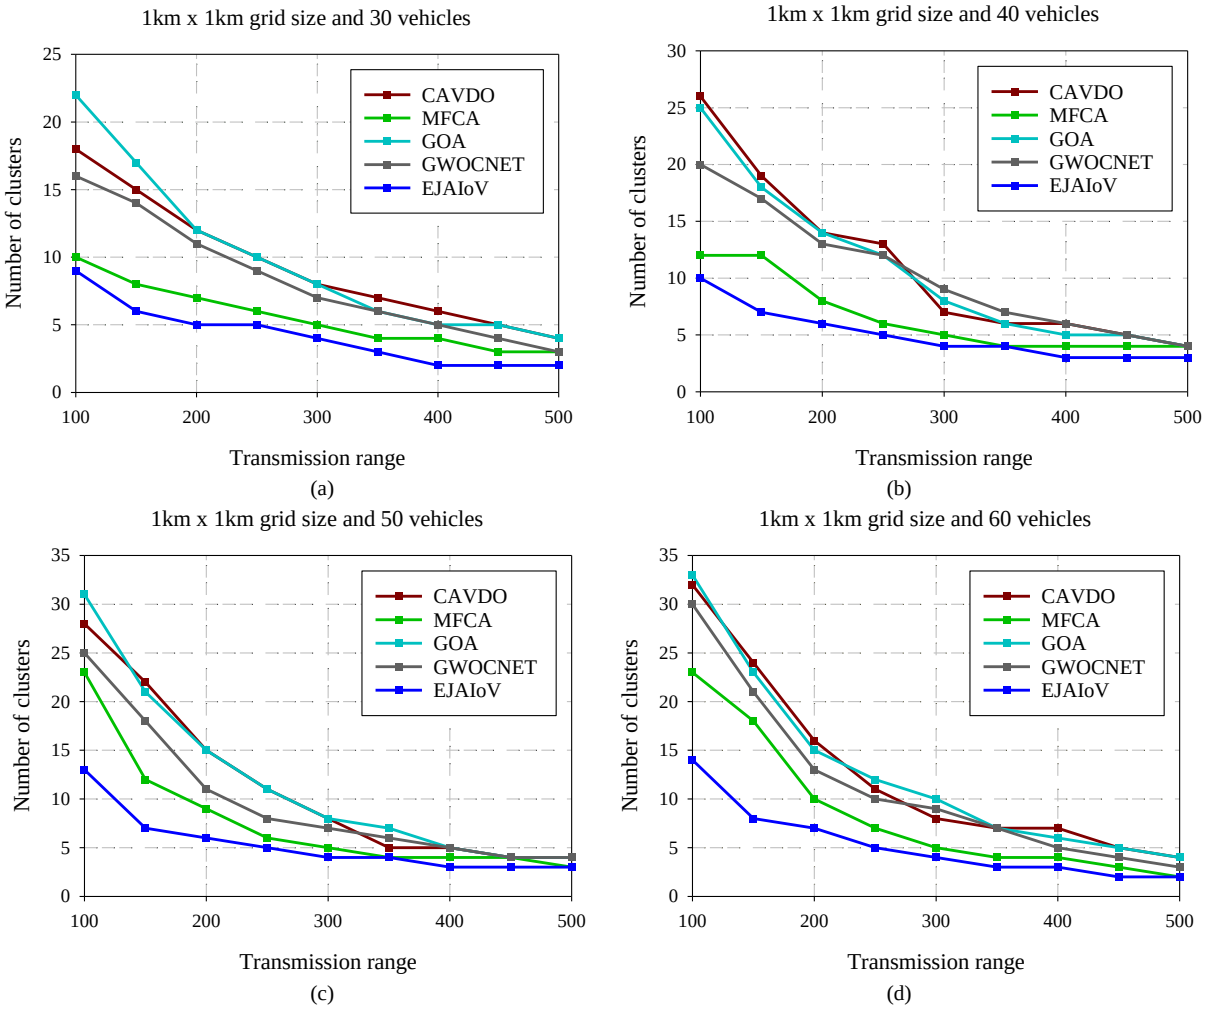

Fig. 6. Clustering performance comparison across different transmission ranges and node densities within a 1×1 km grid: (a) 30 nodes, (b) 40 nodes, (c) 50 nodes, (d) 60 nodes.

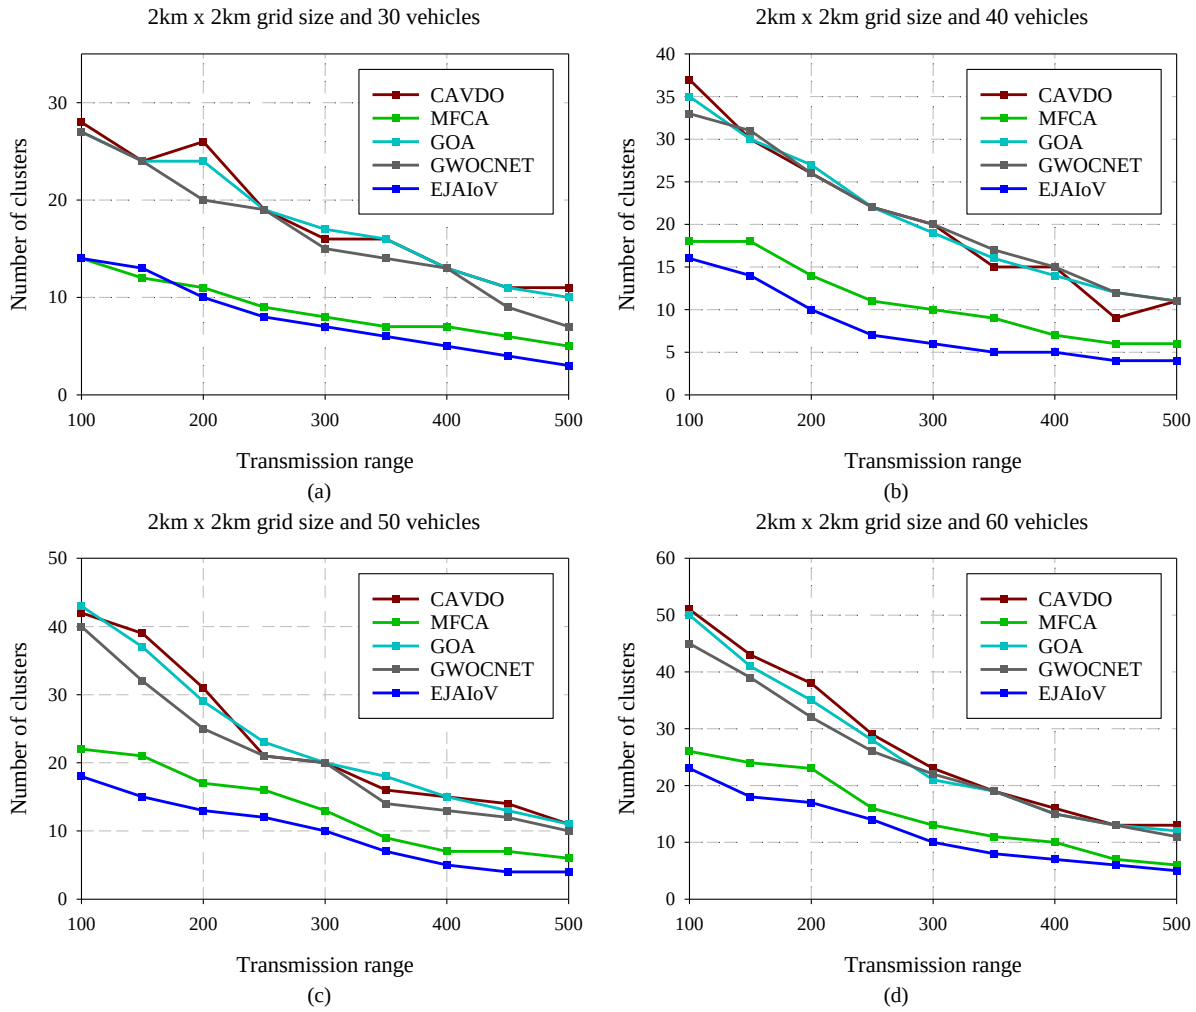

Fig. 7. Clustering performance comparison across different transmission ranges and node densities within a 2×2 km grid: (a) 30 nodes, (b) 40 nodes, (c) 50 nodes, (d) 60 nodes.

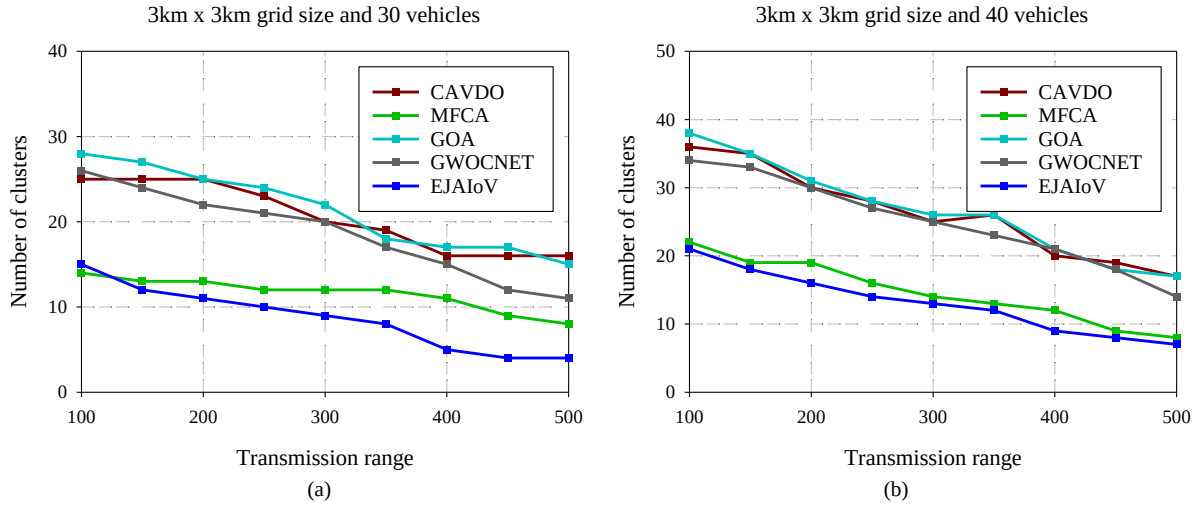

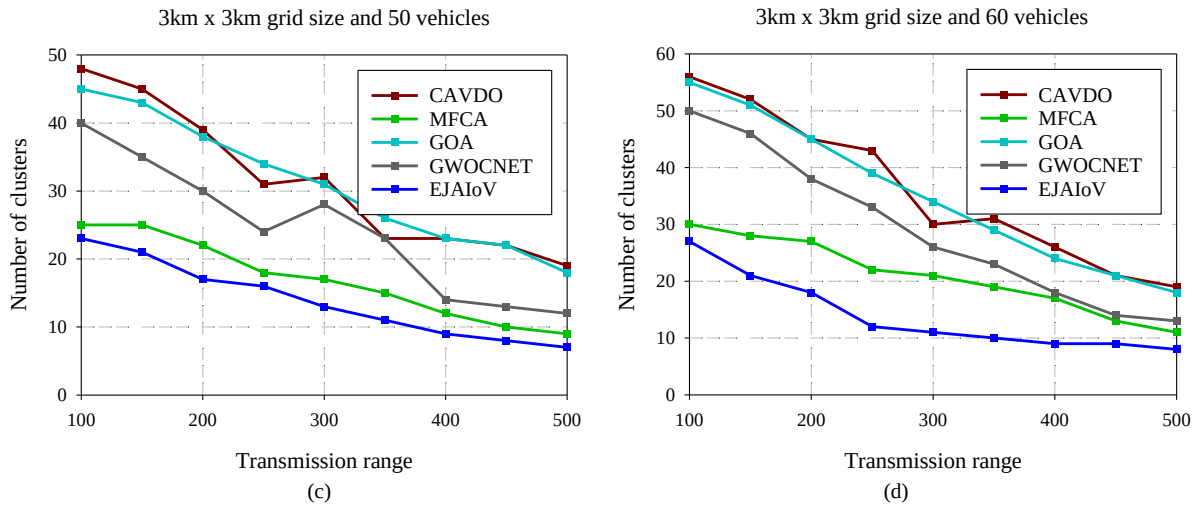

Fig. 8. Clustering performance comparison across different transmission ranges and node densities within a 3×3 km grid: (a) 30 nodes, (b) 40 nodes, (c) 50 nodes, (d) 60 nodes.

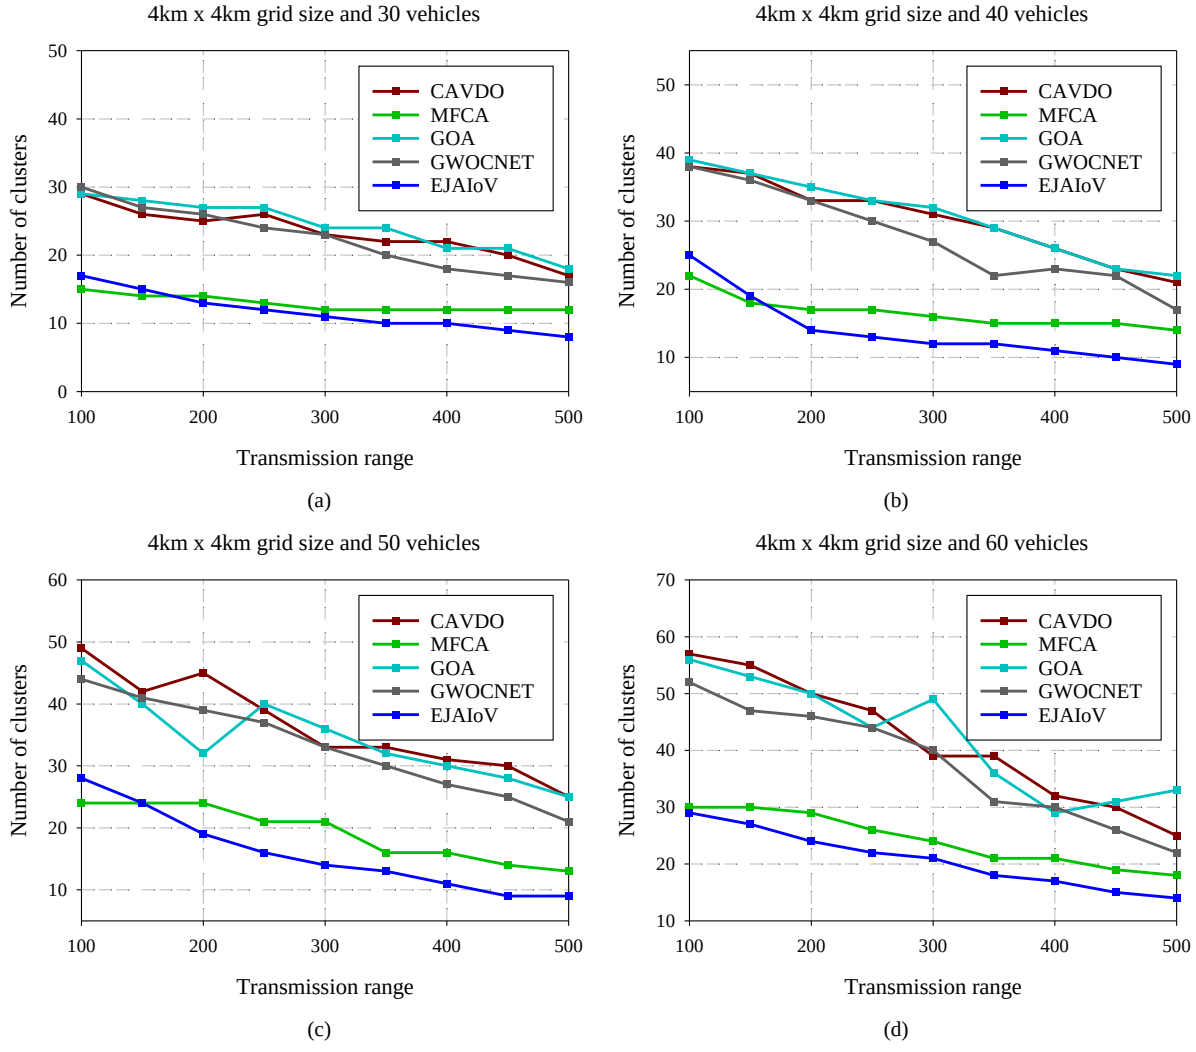

Fig. 9. Clustering performance comparison across different transmission ranges and node densities within a 4×4 km grid: (a) 30 nodes, (b) 40 nodes, (c) 50 nodes, (d) 60 nodes.

This superior performance can be attributed to EJAIoV's multi-objective fitness function, which balances spatial compactness with mobility-aware stability. By favoring CHs with lower relative speeds and good positional properties, the algorithm constructs clusters that are both topologically efficient and resilient to mobility-induced failures. It is particularly significant that, with both increasing transmission range and node density, the performance difference increases. For example, for a 4×4 km² grid (Fig. 9), with greater inter-vehicle distances and greater mobility effect, EJAIoV performs better with respect to maintaining coherence in clusters than the alternatives. This proves that the proposed approach scales well in large vehicular environments. In addition, consistency with respect to varying vehicular densities demonstrates the resilience of the EJAIoV's adaptive mechanisms, such as operator selection based on Q-learning, which adjusts the exploration-exploitation ratio adaptively according to local topological complexity.

Fig. 10-13 illustrate the effect of increasing grid sizes on the number of clusters produced at constant node densities. Overall, there is a trend that with growth in the simulation area, there is an increase in clusters because there is less connectivity between far-off vehicles, reducing the ability of a CH to have stable links with dispersed nodes. Nevertheless, despite this spatial dispersal, EJAIoV is highly resilient by maintaining a consistent number of clusters across all grid sizes.

Its robustness stems mainly from the algorithm's joint spatial-mobility optimization approach. It is particularly intra-cluster distance minimization that fosters tight clusters, with mobility-aware stability cost that drives the algorithm to choose CHs that are not only close to their members but also show optimal minimal dynamic variance compared to nearby vehicles. Adaptive search balancing ensures solution diversity is sustained through clustering under sparse scenarios and enforces convergence in better spatial configurations.

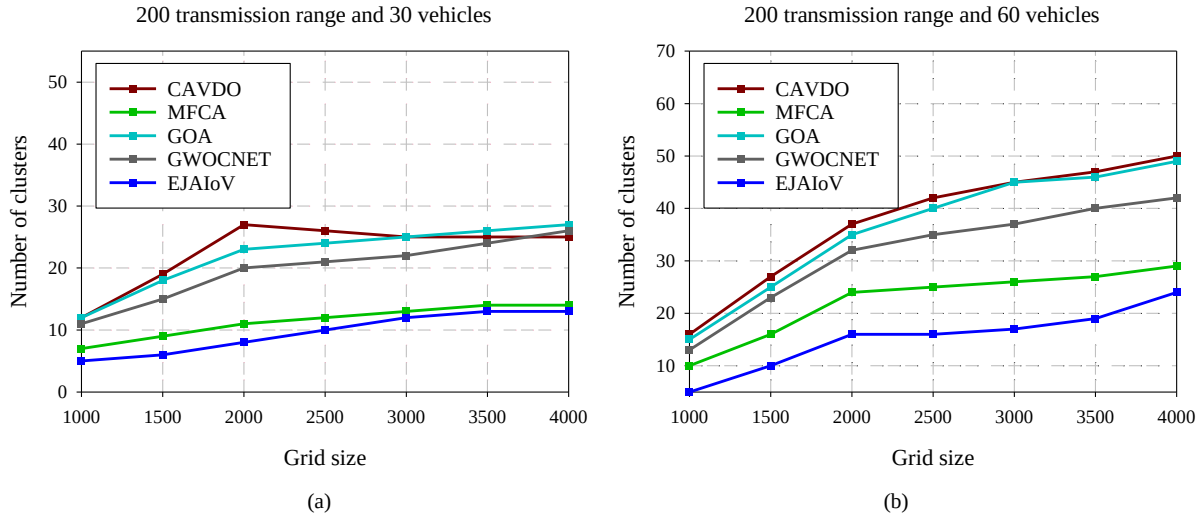

Fig. 10. Clustering performance comparison across different grid sizes and node densities (200 transmission range): (a) 30 nodes, (b) 60 nodes.

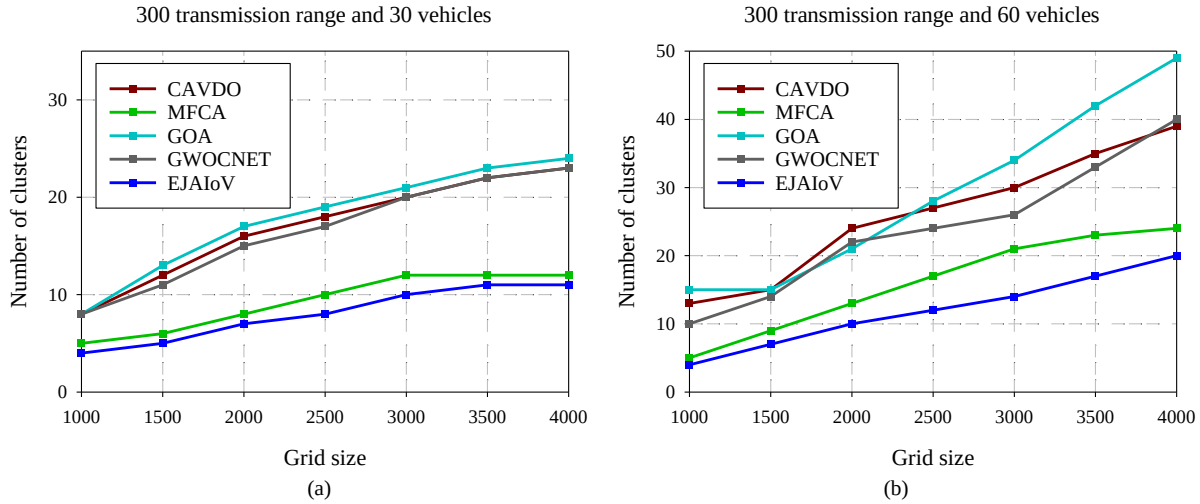

Fig. 11. Clustering performance comparison across different grid sizes and node densities (300 transmission range) : (a) 30 nodes, (b) 60 nodes.

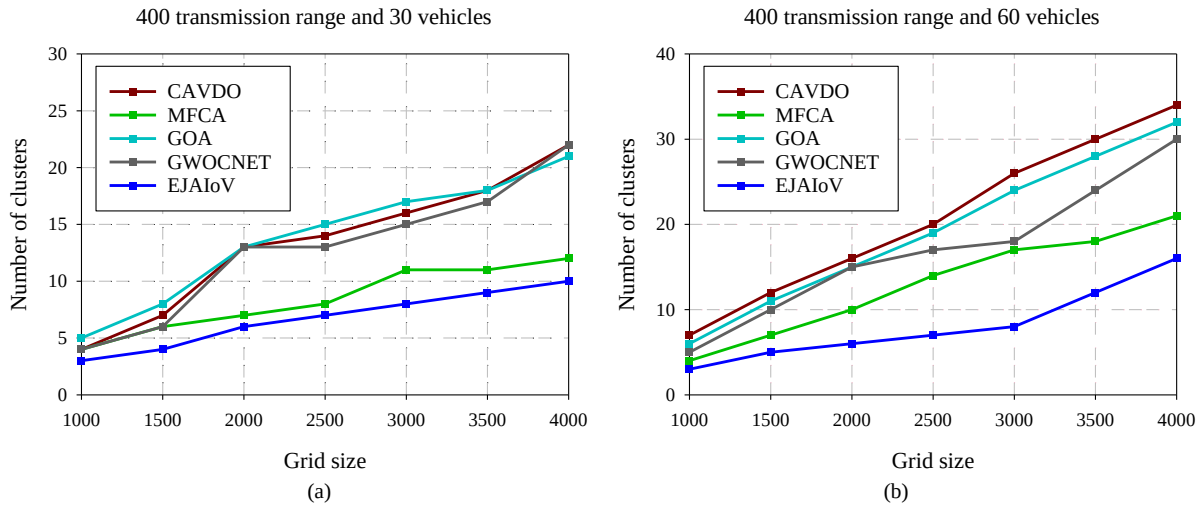

Fig. 12. Clustering performance comparison across different grid sizes and node densities (400 transmission range): (a) 30 nodes, (b) 60 nodes.

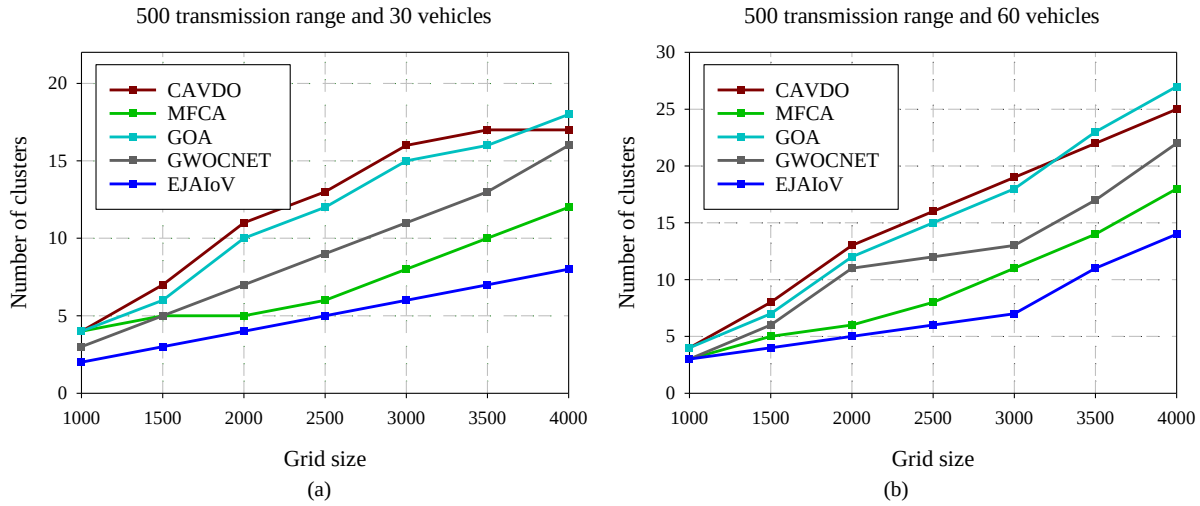

Fig. 13. Clustering performance comparison across different grid sizes and node densities (500 transmission range): (a) 30 nodes, (b) 60 nodes.

For example, in Fig. 12 and Fig. 13, with grid sizes extended to 4×4 km², EJAIoV maintains a lower number of clusters with 30 and 60 vehicles, while all other algorithms exhibit an increased rate of clustering fragmentation. This demonstrates that EJAIoV performs better at alleviating sparse topologies issues, with minimal unnecessary CH reassignments and overhead. In short, the observations presented in Fig. 10–13 confirm that EJAIoV supports better spatial scalability and retains effective cluster organization under light-density vehicular scenarios, an important feature in realistic IoV deployments with diverse node distributions and changing network topologies.

Fig. 14 compares clusters over different ranges of transmission, node density, and grid sizes to demonstrate the long-term stability of the proposed EJAIoV algorithm under dynamic IoV conditions. Cluster lifespan is a critical measure indicating the stability and robustness of the clustering approach with respect to vehicular mobility and varying communication ranges. It demonstrates the clustering algorithm's ability to accommodate high vehicular mobility with reduced cluster rebuilding requirements and lower control overhead. Fig. 14(a) to 14(d) present cluster lifetime over different transmission ranges for different grid sizes. Based on the results, with an increase in transmission range, cluster lifetime is prolonged, mostly because of increased communication range. This leads to reduced cluster reassignments. Vehicles with long-range stable links naturally undergo less frequent cluster reformation.

Fig. 14 clearly shows that EJAIoV can sustain stable lifespans in clusters under all scenarios. Compared with some of its competing algorithms, EJAIoV achieves much longer CH lifetimes, especially in high-mobility and large grid environments. This performance reflects the algorithm's strong capability to cope with dynamic variations inherent in IoV networks, particularly considering vehicular movement pattern variability.

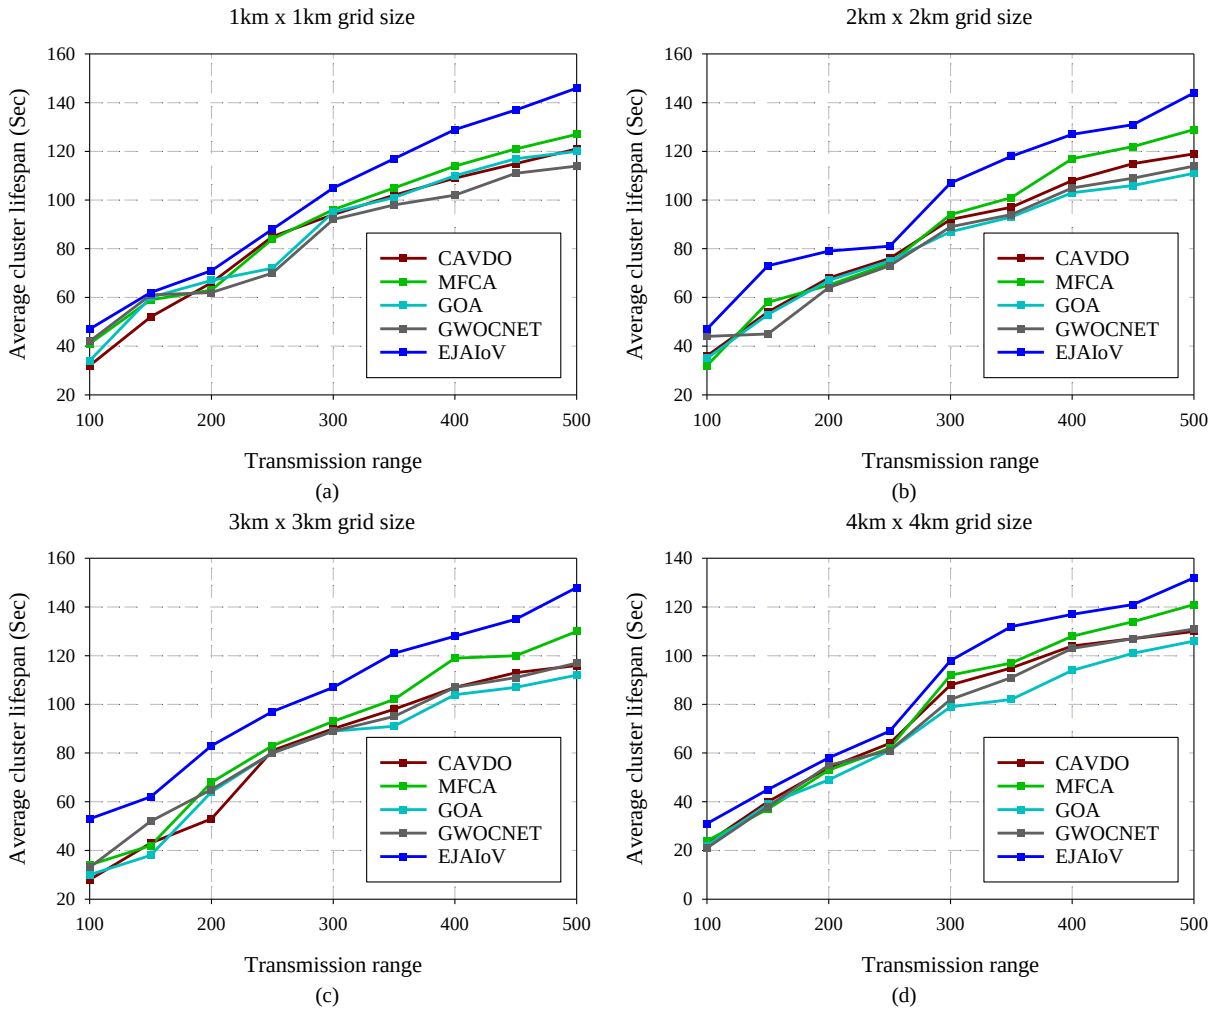

Fig. 14. Cluster lifespan comparison across different transmission ranges and node densities within different grid sizes: (a) 1km x 1km, (b) 2km x 2km, (c) 2km x 2km, (d) 2km x 2km.

Its main driving force for such high performance lies in EJAIoV's paradigm of mobility-aware clustering, which aims to prefer vehicles with smaller relative speeds and improved positional stability. CH reassignments are minimized by opting for steadier, slower CHs with improved connectivity. This minimizes communication interruptions, extending cluster lifetime. This is evident clearly in Fig. 14(a) and 14(b), in which EJAIoV maintains stability in clusters irrespective of large node densities, proving that it could counteract both high-density and high-mobility scenarios.

In addition, the adaptive balance between exploration and exploitation of EJAIoV enables the algorithm to adjust between exploration and exploitation in a dynamic fashion, allowing it to improve clustering based on changing network topology. This is key for sustaining stable clusters over a long time, regardless of varying vehicular speeds and locations. As the number of nodes increases, not only the frequency of CH reassignments decreases, but clusters are also more robust to perturbations, resulting in more resilient clusters.

V. CONCLUSION

This study introduced EJAIoV, a novel clustering scheme for IoV intended to achieve mobility-aware, communication-efficient, and stable cluster formations in highly dynamic vehicular environments. By incorporating a diversity-improving initialization method, the best-worst directional update method, and a local search module guided by a Q-learning algorithm, EJAIoV optimized global exploration and local exploitation during the optimization task. Moreover, a multi-target fitness function that balances mobility stability and intra-cluster distance recognized strong CHs with higher lifetimes and minimal reconfiguration overhead.

Comprehensive simulations illustrated that EJAIoV outperformed other state-of-the-art techniques like GWOCNET, GOA, MFCA, and CAVDO, to minimize the number of groups, optimize group length, and respond optimally to varying densities and transmission radii. The results revealed that EJAIoV's strength rests on its ability to handle sudden topology change and heavy vehicle mobility, which are key challenges in

IoV clustering. Potential research paths could include real-time traffic data, the algorithm's scalability for a heterogeneous vehicular environment, and the performance assessment with 5G-enabled edge computing environments.

EJAIoV is well-suited for deployment in real-time vehicular networks due to its lightweight design, adaptive learning, and ability to operate under continuously changing topologies. The algorithm can be integrated with edge computing platforms (e.g., roadside units or in-vehicle processors) to make on-the-fly clustering decisions using local traffic and mobility data. Given its reliance on parameters such as relative velocity, neighborhood distance, and link stability, which are readily obtainable from GPS and V2X sensors, EJAIoV can operate effectively with real-world vehicular datasets such as those provided by the VeReMi, SUMO, or TAPASCologne mobility traces. Future work will involve validating EJAIoV against these datasets and deploying the algorithm within a 5G-enabled edge computing framework to assess latency, scalability, and energy impact in real-time communication scenarios.

***Abstract*—About 85% of all occurrences of lung cancer are classified as Non-Small Cell Lung Cancer (NSCLC), making it a serious worldwide health concern. For better treatment results and patient survival, NSCLC must be detected early and accurately. This research presents an advanced Deep Learning-enabled Lung Cancer Detection and Classification System (LCDCS) aimed at significantly improving diagnostic precision and operational efficiency. Emerging technologies such as artificial intelligence and multi-level convolutional neural networks (ML-CNN) are increasingly being leveraged in CT imaging-based deep learning systems for accurate detection. The outlined framework leverages a multi-layer convolutional neural network to effectively analyse CT scan images and accurately classify lung nodules. Tomek link and Adaptive Synthetic Sampling (ADASYN) are used in a novel way to balance data, address class imbalance, and guarantee strong model performance. Deep learning with a CNN model is utilized to derive features, and the SoftMax function is applied for multi-class classification. Thorough evaluation on datasets like the LUNA16 dataset demonstrates that the system surpasses earlier models and data balancing techniques in accuracy, yielding a training accuracy of 95.8% and a validation accuracy of 96.9%. The findings demonstrate the potential of the suggested method as a trustworthy diagnostic instrument for the prompt identification of lung cancer. The study emphasizes on how crucial it is to combine deep learning architectures with sophisticated data balancing techniques to overcome medical imaging difficulties and raise diagnostic accuracy. Future research attempts to investigate real-time deployment in clinical settings and expand the system's capability to encompass more cancer types.**

Keywords*—*Artificial intelligence; NSCLC; ML-CNN; ADASYN; tomek link

I. Introduction

Lung cancer is the leading type of cancer diagnosed worldwide. As of the latest data, there are approximately 2.2 million new cases each year. It continues to be a leading cause of cancer-related deaths globally, with Non-Small Cell Lung Cancer (NSCLC) comprising roughly 85% of all diagnosed cases. Traditionally, the detection and classification of lung cancer rely on the expertise of radiologists and pathologists who analyze Computed Tomography (CT) images and histopathological samples. However, this process is often time-consuming, subjective, and prone to variability, leading to a demand for more reliable and efficient diagnostic tools. In the realm of therapeutic diagnostics, the integration of progressed innovations like deep learning has assisted a new way of accuracy and proficiency. NSCLC, account for a critical portion of lung cancer cases, urges precise and timely detection for effectual treatment and patient care. Deep learning methods has proven its ability in enhancing the detection and classification processes, contributing to giving vital insights and improving patient outcomes [9].

This study proposes a novel Deep Learning-enabled Lung Cancer Detection and Classification System (LCDCS) particularly for non-small cell. The model leverages multiple scales of CT images to capture the diverse features of lung nodules, enabling a more comprehensive analysis [17]. By integrating the outputs of four CNNs, the suggested framework aims to deliver an efficient and accurate classification of lung nodules into categories such as benign tissue, large cell carcinoma, and squamous cell carcinoma [16]. The effectiveness of the proposed model is demonstrated through rigorous training and validation on a substantial dataset of histopathological images, highlighting its potential to be a valuable tool in the prompt diagnosis and care planning for lung cancer patients.

The study introduces a Deep Learning-enabled Lung Cancer Detection and Classification System (LCDCS), focusing specifically on NSCLC.

- The system employs a multi-level convolutional neural network (ML-CNN) for analyzing CT scan images.
- It highlights the use of ADASYN (Adaptive Synthetic Sampling) combined with Tomek Links for efficient data balancing and enhanced classification performance.
- Multi-scale Image Analysis: Utilizes multiple scales of CT images to capture diverse features of lung nodules for enhanced detection and classification.
- A comprehensive comparative analysis aimed at evaluating the outcome of various class balancing strategies for lung cancer detection.
- The study suggests improving the system so it can be used for more types of cancer or even help predict related health problems like heart disease.

II. Literature Review

The study presents a deep convolutional neural network with multiple levels designed to detect and classify lung cancer by analyzing CT scan images of lung nodules. By leveraging a four-level CNN architecture that processes multiple scales of nodule images, the model effectively distinguishes between benign tissue, large cell carcinoma, and squamous cell

carcinoma. Modeled on a dataset of 25,000 histopathological images, the model achieved a notable accuracy of 78% on the training set and 89.6% on the validation set, highlighting its potential as an efficient tool to aid radiologists in early lung cancer diagnosis [1]. Jenita Subash et al. presents a study which aims to develop a dual-stage classification system for lung cancer detection and staging by integrating hybrid deep learning techniques. The study likely involves preprocessing lung imaging data, such as CT scans, to improve the quality and relevance of the input features. The first stage from the classification involves convolutional neural network (CNN) or a similar deep learning architecture which is used to identify cancerous lesions from the imaging data. Once cancer is detected, the second stage involves determining the stage of lung cancer (e.g., Stage I, II, III, or IV). This stage might use a more complex network or a combination of models to classify the cancer stage based on tumor size, spread, and other relevant clinical features [2].

The study addresses the challenge of diagnosing NSCLC, which accounts for approximately 85 % of lung cancer cases.

The authors employ CNN architectures to analyze the images and identify patterns indicative of NSCLC [3] Approaches such as Gradient-weighted Class Activation Mapping or Local Interpretable Model-agnostic explanations are likely used to highlight regions of the images with the highest influence on the model's outcomes; by making the model's predictions interpretable. The study aims to increase trust in AI systems among medical professionals [4].

1) Lung cancer types: Lung cancer is primarily categorized into two major types, distinguished by the microscopic characteristics of the cancerous cells and their growth patterns. Fig. 1 shows lung cancer under the microscope.

a) Non-Small Cell Lung Cancer (NSCLC): NSCLC is the predominant form of lung cancer, representing approximately 85% of all cases. It encompasses a variety of subtypes, each with distinct characteristics.

- Adenocarcinoma: This is the most prevalent subtype of NSCLC, typically originating in the outer regions of the lungs. It tends to grow more slowly and is more common in non-smokers compared to other types.
- Squamous Cell Carcinoma: This type usually starts in the airways (bronchi) and is more commonly associated with smoking. It tends to grow in the central parts of the lungs.
- Large Cell Carcinoma – A relatively uncommon form of lung cancer that can develop in any region of the lung, characterized by its rapid growth and aggressive spread.

b) Small Cell Lung Cancer (SCLC): SCLC, also known as small cell carcinoma, makes up about 15% of lung cancer cases. It's characterized by small, round cells and is often linked to smoking. SCLC tends to grow rapidly and is often diagnosed at an advanced stage. Each type of lung cancer can vary in its treatment and prognosis, so accurate diagnosis and staging are crucial for determining the best course of action [5].

2) Lung cancer detection techniques: Detecting lung cancer early is crucial for effective treatment. Here are some common techniques used for detection:

a) Imaging tests:

- Chest X-ray: Often the first test used to look for abnormalities in the lungs.
- Computed Tomography (CT) Scan: Generates high-resolution cross-sectional images of the lungs, enabling the detection of smaller tumors and providing precise evaluation of their size, location, and potential spread.
- Positron Emission Tomography (PET) Scan: Utilized to assess the spread of cancer to other areas of the body by detecting regions with elevated metabolic activity.
- Magnetic Resonance Imaging (MRI): Less commonly used for lung cancer but helpful in assessing spread to the brain or spinal cord.

b) Screening tests:

- Low-Dose Computed Tomography (LDCT): Suggested for individuals at high risk (e.g., heavy smokers or those with a smoking history). It can identify lung cancer at an earlier stage compared to a chest X-ray.

c) Biopsy:

- Needle Biopsy: A small needle is inserted into the chest to extract tissue from the lung.
- Bronchoscopy: A flexible instrument is inserted through the nose or mouth into the lungs to obtain tissue samples.
- Endobronchial Ultrasound (EBUS): A specialized form of bronchoscopy that utilizes ultrasound imaging to precisely guide the biopsy needle for tissue sampling.

d) Sputum cytology: Analysis of mucus (sputum) from the lungs to look for cancer cells, particularly useful in some cases of squamous cell carcinoma.

e) Molecular testing:

- Genetic Testing: Examines cancer cells for specific genetic mutations that can guide targeted therapy options [6].

Table I depicts the physical examination required for lung cancer. Table II depicts the different parameters of blood test with their normal ranges. Table III depicts electrocardiogram (for heart conditions) with its normal ranges. Table IV shows different imaging test required to detect lung cancer. Table V shows the analysis of urine with its normal ranges. Table VI shows the first assessment of NSCLC diagnosis.

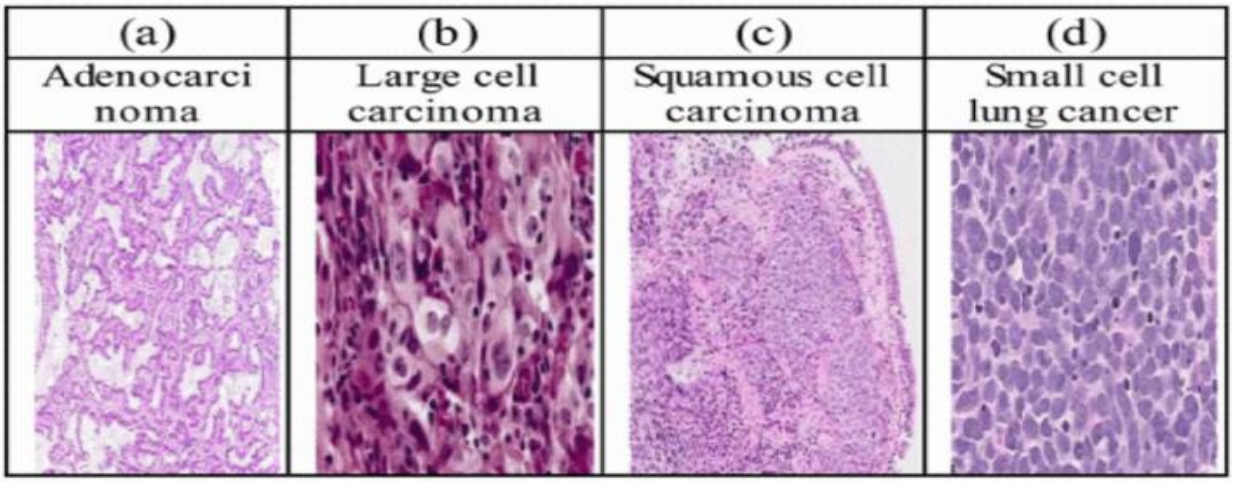

Fig. 1. Categories of lung cancer.

TABLE I PHYSICAL EXAMINATION FOR LUNG CANCER

Test	Parameter
Physical Examination	Palpation: The doctor examines the affected area by touch to identify any tenderness, swelling, or abnormalities.
	Range of Motion Tests: Assesses the movement in joints or muscles.
	Neurological Exam: Checks reflexes, muscle strength, and sensory function.

TABLE II DIFFERENT PARAMETERS OF BLOOD TEST WITH THEIR NORMAL RANGES

Blood Test	Parameter	Range
Complete Blood Count (CBC)	White Blood Cell (WBC)	4,000 to 11,000 cells/µL
	Red Blood Cell (RBC)	M: 4.7 to 6.1 million cells/µL, W: 4.2 to 5.4 million cells/µL
	Hemoglobin (Hb)	M: 13.8 to 17.2 g/dL, W: 12.1 to 15.1 g/dL
	Hematocrit (Hct)	M: 40.7% to 50.3%, W: 36.1% to 44.3%
	Platelet Count	150,000 to 450,000 platelets/µL
	Red Cell Distribution Width (RDW)	11.5% to 14.5%
Differential Leucocyte count	Segmented Neutrophils	40% to 70% of total WBCs
	Lymphocytes	20% to 40% of total WBCs
	Monocytes	2% to 8% of total WBCs
	Mean Platelet Volume (MPV)	7.5 - 12.0 fL

TABLE III ELECTROCARDIOGRAM WITH ITS NORMAL RANGE

Test	Parameter	Normal Range (Men)	Normal Range (Women)	Description
Electrocardiogram	Heart Rate (Resting)	60-100 bpm	60-100 bpm	Number of heart beats per minute
	P Wave Duration	0.08 to 0.11 seconds	0.08 to 0.11 seconds	Time taken for atrial depolarization
	PR Interval	0.12 to 0.20 seconds	0.12 to 0.20 seconds	Time between P wave start and QRS complex start
	QRS Duration	0.08 to 0.10 seconds	0.08 to 0.10 seconds	Time for ventricular depolarization
	QT Interval	0.35 to 0.45 seconds	0.36 to 0.46 seconds	Time from start of Q wave to end of T wave
	ST Segment	Isoelectric (flat)	Isoelectric (flat)	Represents the period between ventricular depolarization and repolarization
	T Wave	Positive in most leads	Positive in most leads	Represents ventricular repolarization
	RR Interval	0.6 to 1.2 seconds	0.6 to 1.2 seconds	Time between two consecutive R wave peaks
	Axis	−30° to +90°	−30° to +90°	Heart's electrical axis direction in degrees

TABLE IV DIFFERENT IMAGING TEST

Imaging Test	Normal Findings	Purpose
Chest X-ray (CXR)	Clear lungs, normal heart size, no fluid or masses	Assess lung health, detect infections, evaluate heart size
Echocardiogram	Normal heart size and function, no valve abnormalities	Assess heart function, valve abnormalities, heart disease
Electrocardiogram (ECG)	Normal heart rhythm, no signs of arrhythmia or heart damage	Monitor heart rhythm, detect arrhythmias, heart damage

TABLE V URINE ANALYSIS WITH ITS NORMAL RANGE

Test	Parameter	Normal Range	Description
Urine Analysis	Color	Pale yellow to deep amber	Indicates hydration levels and possible health issues
	Clarity	Clear	Cloudy urine may suggest infection or presence of crystals
	Odor	Mild, not strong	Strong odor can suggest infection or diabetes
	Specific Gravity	1.005 to 1.030	Measures concentration of urine; high values may indicate dehydration
	pH	4.5 to 8.0	Reflects acidity or alkalinity of urine
	Protein	Negative to trace (up to 150 mg/day)	Higher levels can indicate kidney issues
	Glucose	Negative	Presence of glucose suggests diabetes
	Ketones	Negative	Presence indicates uncontrolled diabetes or starvation
	Bilirubin	Negative	Indicates liver function; presence can indicate liver disease
	Urobilinogen	0.1 to 1.0 mg/dL	Low or high levels may suggest liver or bile duct issues
	Red Blood Cells (RBCs)	0 to 3 RBCs/HPF	Higher levels can indicate infection, trauma, or stones
	White Blood Cells (WBCs)	0 to 5 WBCs/HPF	Increased levels suggest infection or inflammation
	Nitrites	Negative	Presence suggests bacterial infection
	Leukocyte Esterase	Negative	Indicates white blood cells, which may indicate infection
	Casts	None to rare hyaline casts	Presence of certain casts suggests kidney disease
	Crystals	None to few	High levels may indicate kidney stones or metabolic issues
	Bacteria	None	Presence suggests infection
	Yeast	None	Presence may indicate infection
	Epithelial Cells	Few (0 to 5 cells/HPF)	High numbers may indicate contamination or infection

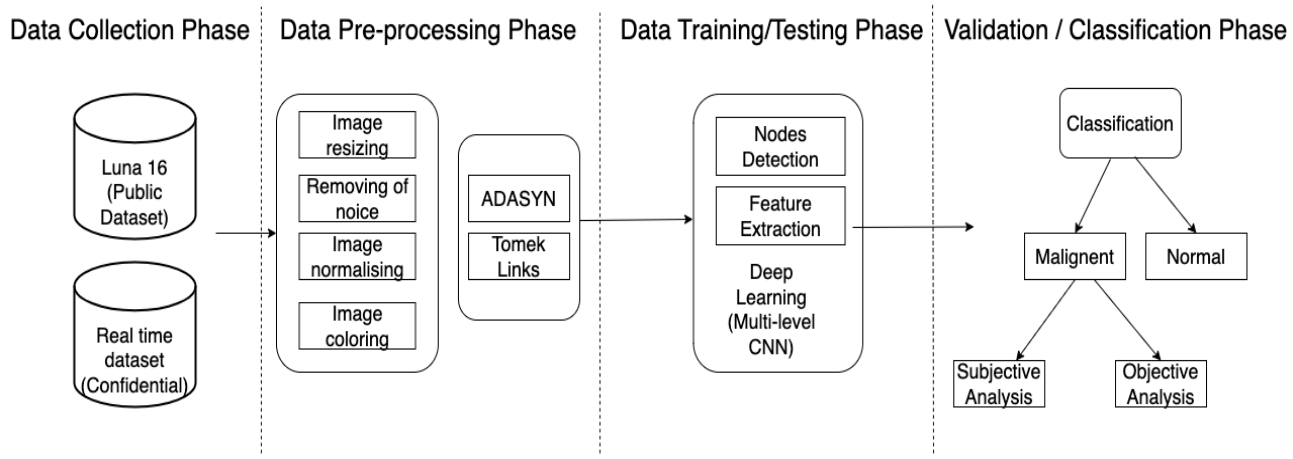

Fig. 2. Deep learning-enabled lung cancer detection and classification system.

3) Deep learning: Deep learning has played a transformative role in lung cancer detection by increasing the precision, responsiveness, and consistency of diagnostic processes [8]. The emergence of AI driven learning models with a focus on CNNs, offers a powerful tool to automate and potentially improve the accuracy of lung cancer classification [2]. The study proposes an automated system that combines deep learning with multiple strategies like (data augmentation, multi-scale analysis, ensemble learning and post processing), to improve the identification and categorization of lung nodules in CT (Computed Tomography) scans [7].

TABLE VI FIRST ASSESSMENT OF DIAGNOSIS OF NSCLC

Assessment Step	Details
Patient History	- Tobacco use history (duration, pack-years)
	- Exposure to environmental or workplace carcinogens.
	- Genetic predisposition to lung cancer or other neoplasms.
	- Symptoms and warning signs (chronic cough, blood-tinged sputum, unexplained weight loss, chest pain, shortness of breath).
Physical Examination	- Inspection (e.g., clubbing, cachexia)
	- Palpation (e.g., lymphadenopathy)
	- Percussion (e.g., dullness over lungs)
	- Auscultation (e.g., wheezes, crackles, absent breath sounds)
Imaging Studies	- Chest X-ray (initial screening, may show masses, consolidation)
	- Chest CT scan (detailed imaging, tumor size, lymph node involvement)
Biopsy	- Needle biopsy (CT-guided or bronchoscopic biopsy) for histopathological diagnosis
	- Sputum cytology (to detect cancer cells in sputum)
Laboratory Assessments.	- Comprehensive blood analysis (CBC) to evaluate for anemia, infection, or other hematological abnormalities.
Molecular Testing	- EGFR, ALK, ROS1 mutations (for targeted therapy)
Staging Tests	- PET scan (to assess metastasis)
	- Mediastinoscopy (to evaluate mediastinal lymph nodes)
	- Brain MRI (if neurological symptoms are present)
Risk Assessment	- Eastern Cooperative Oncology Group (ECOG) performance status
	- Assessment of comorbidities and general health condition

III. PROPOSED METHODOLOGY

The proposed Deep Learning-enabled LCDCS (see Fig. 2) aims to detect Non-Small Cell Lung Cancer by studying the images obtained by CT-scan, MRI using a multi-level convolutional neural network for feature extraction and SoftMax function for classification purpose. To cater unresolved class imbalance there are different sampling methods are present, like:

Over Sampling Methods:

- SMOTE (Synthetic Minority Over-sampling Technique) - produces artificial instances for the underrepresented class by interpolating between existing minority class examples.
- Random Over sampling - simply duplicates random samples from the minority class to achieve balance.
- ADASYN (Adaptive Synthetic Sampling) - an advanced variant of SMOTE that prioritizes generating synthetic instances for minority class samples that are more challenging to classify [10].

Under-Sampling Methods:

- Random Under-Sampling - randomly eliminates instances from the dominant class to achieve a balanced class distribution.
- NearMiss- chooses instances from the dominant class that are nearest to the minority class examples, thereby decreasing the size of the dominant class.
- Tomek Links -identifies and removes overlapping samples between classes to create a clearer boundary between the majority and minority classes.

In this research work we have used the combination methods i.e. ADASYN (Adaptive Synthetic Sampling) and Tomek Links, to achieve data balancing because the hybrid combination gives better results as compared to the other techniques. The detailed comparison of the proposed Deep learning-enabled LCDCS system with alternative dataset balancing techniques for recognizing the symptoms of lung cancer, accounting for both cases with and without the use of DL, is summed up in Table VII. Algorithm 1 and Algorithm 2 [15] represents the ADASYN algorithm and Tomek link algorithm for achieving data balancing. The suggested system's first module, which includes steps like pre-processing, data balance, and classification, aims to detect lung cancer. Pre-processing stage which involves:

1) Data cleaning: It involves handling missing values and replace missing values with mean, median, mode.

2) Data transformation: It involves normalization, standardization, log transformation and box-cox transformation.

$$Normalization\ x' = \frac{x - \min(x)}{x - \min(x)} \quad (1)$$

3) Data reduction: It involves principal component analysis which reduces the number of features while retaining most of the variance.

If we have a data matrix $\boldsymbol{X}$ with n samples and p features (e.g., pixel intensities from CT scans or biomarkers), and we aim to reduce this to k principal components ($k<p$):

$$Zn \times K = Xn \times p\,.Wp \times k \quad (2)$$

where, Z is the reduced data matrix, X is the original data matrix and W is the matrix of selected eigenvectors (principal components).

4) Data encoding: It has categorical encoding which is further divided into three categories*:*

Label Encoding: Label encoding can be used for ordinal variables such as "Stage of Cancer" (e.g., Stage I, Stage II, Stage III, Stage IV).

Let C= {c1, c2,...,ck} be the set of unique categories, and let x∈ C, be a category for given observation.

One-hot Encoding: For categorical variables without a natural order (e.g., "Type of Symptom", "Smoking History"), one-hot encoding is more appropriate.

Let C={c1,c2,…,ck} be the set of categories for a nominal variable. One-hot encoding generates a binary **v** (x) for each category x∈ C:

$$\boldsymbol{v}(x) = [\, v_1, v_2, v_3 \ldots . v_k \,] \quad (3)$$

where,

$$vi = \begin{cases} 1 \; if \; x = ci \\ 0 \; otherwise \end{cases}$$

5) Data Sampling:

a) Random sampling: Select a random subset of data to reduce computational cost.

b) Stratified sampling: Ensure that the sample represents different strata or groups within the data.

c) Oversampling and under sampling: Adjust the dataset to balance class distribution in imbalanced datasets (e.g., SMOTE).

d) Handling time-series data resampling: Change the frequency of time-series data (e.g., daily to monthly).

Given a time-series $x(t)$ where t represents the time index (e.g., days), resampling to a coarser time frequency (e.g., monthly) can be done by aggregating values over the new time intervals. If you aggregate using a sum, the equation is:

$$xm\,(T) = \sum t \in T \; x(t) \quad (4)$$

where,

$x(t)$ is the original time-series data.

T is the new time interval (e.g., a month).

$xm(T)$ is the resampled data at the new frequency.

- Smoothing- utilize moving means or exponential smoothing to minimize fluctuations and enhance signal clarity. A simple moving average (SMA) over a window of size *N* is calculated as:

$$SMAn(t) = 1/n \sum_{i=0}^{n-1} x(t-i) \quad (5)$$

where,

$x(t)$ is the original time series data

$SMAn(t)$)is the smoothed value at time *t*.

N is the window size.

- Detrending- remove trends to focus on the seasonality and residual components.

6) Data splitting: Efficient preprocessing can substantially boost the efficacy and dependability of machine learning models. The selection of methodologies relies on the characteristics of the data and the particular demands of the analysis or model.

If the trend is linear, you can model it as:

Trend (*t*) = $a.t + b$

where, a is the slope and b is the intercept.

To detrend the time series:

$$xdetrended(t) = x(t) - Trend(t) \quad (6)$$

where, $xdetrended(t)$ is the time-series data after removing the trend.

Algorithm 1 describes the ADASYN sampling technique for generating synthetic data points in order to achieve data balancing. First of all it checks class imbalance**.**

1) If imbalance d <d_{th}, generate synthetic data

2) In the next step compute required synthetic data count G, this controls how much data is needed.

3) Place more synthetic samples near decision boundaries.

4) Pick a neighbour, create new samples in between $s_i = x_i + (x_{zi} - x_i) \times \lambda$.

Algorithm 1

Input is done when Data set for training is identified. The class identity label associated with x_i is denoted by yi ∈ Y = {1, −1}, where x_{is} is the entity in the n-dimensional feature space X. The number of minority class examples is denoted by m_s, and the quantity of dominant class examples by ml. Therefore, $m_s + m_l$ = m and $m_s \leq m_l$. Degree of class imbalance is calculated by:

$$d = m_s / m_l \quad (7)$$

where, $d \in (0, 1)$.

If d is less than d_{th}, then (d_{th} is a predetermined threshold):

(a) We determine how many examples of synthetic data must be created for the imbalanced class by

$$G = (m_l - m_s) \times \beta \quad (8)$$

Once the synthetic data is generated, the parameter β∈[0,1] is used to control the desired balance level. When β=1, the generalization process yields a fully balanced dataset.

(b) Identify the K nearest neighbours for each instance x_i belonging to the minority class using the Euclidean distance in an n-dimensional space. Then, compute the ratio r_i, defined as follows:

$$r_i = \Delta_i / K, \; i = 1,\ldots,m_s \quad (9)$$

where ri ∈ [0, 1] since Δi is the count of samples in xi's K nearest neighbours that are members of the dominant class; Normalizer *ri* according to r^i = ri/ $\sum_{i=1}^{ms} ri$ so that r^i is a density distribution ($\sum_i r\hat{}i = 1$).

Next, we determine how many samples of synthetic data must be created for every minority example xi by:

$$gi = r\hat{}i \times G \quad (10)$$

Hence, according to Eq. (2), G denotes the overall number of generated data points that must be produced for the outlier class. We create gi synthetic data examples for every outlier class data example xi using the procedures listed below when the loop is done from 1 to gi.

(i) For data x_i, select one sparse data example (x_{zi}) at random from the K nearest neighbours. (ii) Simulated data example is generated by:

$$s_i = x_i + (x_{zi} - x_i) \times \lambda \quad (11)$$

where, λ is a random number: λ ∈ [0, 1], and (xzi − xi) is the displacement vector.

Algorithm 2 presents a data cleaning approach based on Tomek Links, which serves as both a data balancing technique and a method for addressing two key issues: reducing noise in datasets and mitigating class imbalance.

1) For each majority class sample x: it is finding its nearest neighbours y (the closest data point).

2) If y is also from the majority class, do nothing and move to the next sample.

3) If y is from the minority class, check if they form a Tomek Link:

- Find the nearest neighbour of y, call it z.
- If z is the same as x, then (x , y) form a Tomek Link.
  - Remove x (the dominant class sample) from the data repository because it causes overlap between the classes.
  - Repeat this process until no more samples need to be removed.
  - Return the cleaned dataset, which is now better separated and less noisy.

Algorithm 2

Input

A dataset $D = \{ x_1, x_2 \ldots\ldots x_n\}$, where x belongs to either the majority or minority class.

Output

Cleaned dataset D_{clean}.

(1) **Initialize**:

Let $D_{clean} = D$.

(2) **For** each sample $x \in D_{clean}$ where x belongs to the dominant class, **do**:

(3) Locate the nearest point y of x in D_{clean} .

(4) **If** y is the part of dominant class, **then**:

Move to the next instance x and **continue**.

(5) **Else:**

(6) Find the nearest neighbor z of y in D_{clean}.

(7) If $z = x$, **then**:

x and y are nearest neighbors of each other and form a Tomek link.

(8) Remove x from D_{clean}.

(9) Repeat Steps 2–8 until no further modifications occur, or no samples are removed.

(10) **Return** the updated D_{clean}.

End Algorithm

IV. Results and Discussion

A. Data Collection and Experimental Setup

In order to implement Deep Learning-enabled LCDCS system, the Google Collab environment was configured to utilize advanced computational resources. This setup provided robust support for data-intensive operations which included 32 GB of RAM and 1 TB of NVMe SSD storage for faster data handling. For high-performance deep learning and machine learning tasks, an NVIDIA RTX 3080 GPU with 10 GB of GDDR6X VRAM is used. The GPU's architecture enabled efficient parallel processing, significantly reducing training time for large-scale models. Additionally, the GPU-accelerated environment supported real-time experimentation with complex neural networks and computationally expensive tasks, maximizing throughput and performance [19]. This configuration facilitated smooth execution of ML or DL workflows, ensuring scalability and responsiveness for both model development and deployment phases.

In the proposed study, two types of datasets were used to diagnose and forecast lung cancer. The LUNA16 dataset [28], which included more than 1,000 lung CT images in raw DICOM format, served as the source for the initial dataset and a real time dataset, acquired from various stake holders. An annotation file describing the malignant state of each photograph was included. The pictures were saved in PNG format to make processing easier. It included PNG-formatted CT scan images of both healthy people and patients with lung cancer. In all, 979 normal and 1346 malignant pictures were found.

B. Pre-processing Stage

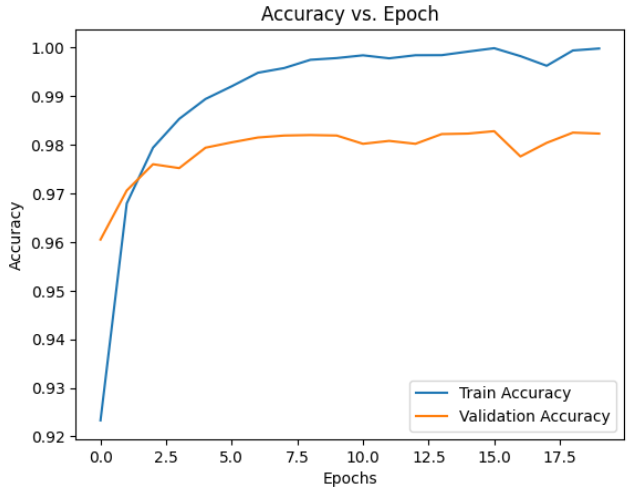
To align with the model architecture, before being input into the CNN model, the original image is converted from BGR and RGBA formats to RGB. Considering that most deep learning models for image classification are trained using RGB images, this conversion is required. After that, the RGB image is scaled to 224 × 24 pixels. Prior to input into the model, the input image is first subjected to a filtering and noise removal process to improve its quality.

C. Results of Feature Extraction and Classification

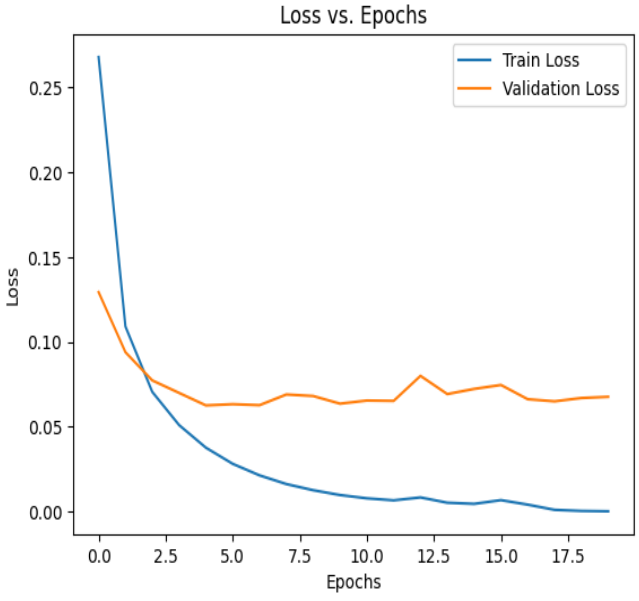
The novel model used deep learning CNN model for the feature extraction purpose and SoftMax function for multi-class classification. The CNN model is built with different layers, Conv2D layer detect important patterns in lung CT scans, such as nodules, textures, and abnormalities and tumour regions (feature extraction). Max pooling layer, it reduces size and focuses on most critical region in the CT scan [18]. Next is flatten and dense layer process which extracted features to classify lung conditions. The model is fine-tuned with feature extraction from the training dataset and is then employed to categorize the testing data, detecting the existence or absence of lung tumors and finally the SoftMax activation provides the final probability distribution over different lung conditions. Fig. 4 illustrates the confusion matrix for the test data, offering a summary of the prediction results obtained by the proposed system.

The model uses a variety of dataset balancing strategies to accomplish classification with and without DL methodology, data augmentation, ADASYN, class-weighted approach, and are some of these methods. The combination of ADASYN and Tomek links works better than the other models, according to an evaluation of the classification findings. The training accuracy of this model is 96.9%. Prior to the application of ADASYN, the dataset reveals a significant class imbalance, with 784 instances representing the minority class (non-cancerous cases) and 10, 10 instances representing the majority class (cancerous cases). Fig. 3 illustrates the enhanced performance of ADASYN, depicting the correlation between

accuracy, loss, and the number of epochs in deep learning. The outcomes using DL are displayed in Fig. 3(a) and Fig. 3(b). Eventually, the classification accuracy of the lung cancer detection module in the suggested system is benchmarked against several existing systems, demonstrating superior accuracy, as illustrated in Table VIII. Further the relationship between training accuracy of different methods are given in Fig. 5, validation accuracy of different methods are given in Fig. 6, and training loss and validation loss with different methods are shown in Fig. 7 and Fig. 8 respectively. Table IX discusses the recovery symptom of NSCLC.



(a)



(b)

Fig. 3. a): Accuracy vs. Epoch with DL, b): Loss Vs. Epoch with DL.

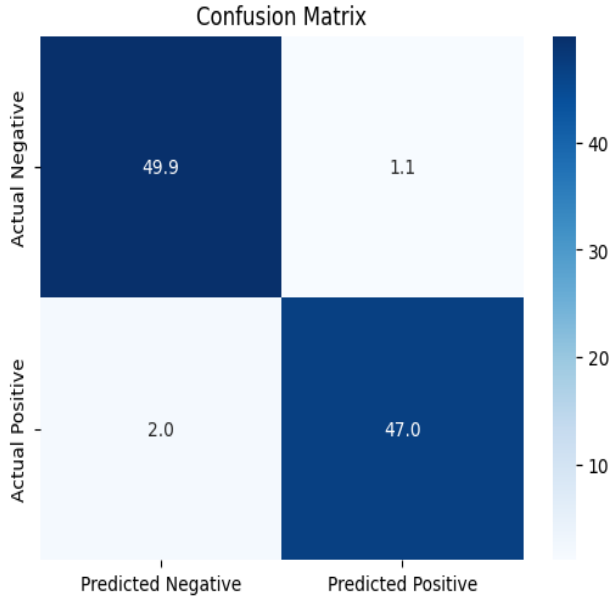


Fig. 4. Confusion matrix.

The model correctly classified mostly non-cancerous case. With 47.06 % most cancer cases are correctly detected.

TABLE VII LUNG CANCER DIAGNOSIS PERFORMANCE COMPARISON: LCDCS SYSTEM WITH DEEP LEARNING AGAINST ALTERNATIVE DATASET NORMALIZATION METHODS WITH AND WITHOUT DEEP LEARNING (DL)

Method	Training accuracy (%)	Validation Accuracy (%)	Training Loss (%)	Validation Loss (%)
Deep Learning enabled LCDCS (ADASYN+ Tomek Link + CNN)	**95.8**	**96.9**	**2.7**	**3.7**
Prox-Smote + CNN	**94.08**	**95.23**	**5.21**	**22.16**
CWA +DL	**93.27**	**94.6**	**11.64**	**8.55**
CWA + CNN	**95.05**	**93.34**	**7.07**	**22.92**
DA + DL	**92.24**	**95.26**	**19.62**	**8.65**
DA +CNN	**85.53**	**78.73**	**31.01**	**39.48**

TABLE VIII COMPARISON OF THE SUGGESTED DEEP LEARNING ENABLED LCDCS SYSTEM'S MODULE WITH CURRENT SYSTEMS

Evaluation Metric	Deep learning enabled LCDCS	Multisection CNN [1]	SVM [11]	3D CNN [12]
Accuracy (%)	**96.9%**	92.17%	92%	83.7%

TABLE IX RECOVERY SYMPTOM OF NSCLC

Phase	Symptoms/Effects	Management
Immediate	- Fatigue, pain, nausea, appetite loss	- Rest, pain management, anti-nausea meds
Short-Term (1–3 months)	- Dyspnea, cough, weakness, emotional distress	- Pulmonary rehab, physical therapy, counseling
Mid-Term (3–6 months)	- Sleep issues, lymphedema, chest discomfort	- Breathing exercises, compression garments
Long-Term (6+ months)	- Chronic cough, neuropathy, emotional stress	- Long-term rehab, pain management, counseling
Emotional Recovery	- Fear, anxiety about recurrence	- Counseling, support groups

D. Comparison of Model Performance

Evaluating a model is an essential step to determine how well it performs. Various metrics can be used for this purpose, such as accuracy, recall, F1-score, and precision, specificity, FPR each offering different interpretation of the model's effectiveness. TABLE X displays a comparison of the evaluation metrics for the deep learning-enabled LCDCS with those of other machine learning models.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} = \frac{47.0+49.9}{47.0+49.9+1.1+2.0} = 96.9\%$$

$$\text{Recall} = \frac{TP}{TP+FN} = \frac{47.0}{47.0+2.0} = 95.9\%$$

$$\text{Precision} = \frac{TP}{TP+FP} = \frac{47.0}{47.0+1.1} = 97.8\%$$

$$\text{F1- Score} = 2\ X\ \frac{Precision\ X\ Recall}{Precision + Recall} = \frac{97.8*95.9}{97.8+95.9} = 96.8\ \%$$

$$\text{Specificity (True Negative Rate)} = \frac{TN}{TN+FP} = \frac{49.9}{49.9+1.1} = 98.0\%$$

$$\text{False Positive rate (FPR)} = \frac{FP}{TN+FP} = \frac{1.1}{49.9+1.1} = 2.2\%$$

TABLE X COMPARISON OF THE EVALUATION METRICS FOR THE DEEP LEARNING-ENABLED LCDCS WITH THOSE OF OTHER MACHINE LEARNING MODELS

Performance Metric (%)	Deep learning enabled LCDCS	Random Forest[13]	KNN [14]	Logistic Regression[13]
Accuracy	**96.9**	89.5	87.1	90.3
Recall	**95.9**	86.9	80.3	89.6
Precision	**97.8**	89.1	91.1	90.1
F1-score	**96.8**	88.0	85.3	89.9
Specificity	**98.0**	91.5	93.1	90.9
FPR	**2.2**	8.4	6.8	9.0

V. ADVANTAGES

The proposed LCDCS system offers several significant advantages, including high diagnostic accuracy (96.9%) in detecting and classifying NSCLC, making it a reliable tool for supporting early clinical decision-making. The innovative integration of ADASYN and Tomek Links for data balancing resolves class imbalance issues, enhancing model robustness. The system outperforms existing models in both accuracy and operational efficiency.

VI. FUTURE WORK

The study suggests extending the system for broader applications, potentially encompassing additional cancer types or integrating predictive capabilities for associated conditions like cardiovascular disease. Further improvements in interpretability and live implementation are recommended to enhance its clinical applicability.

VII. CONCLUSION

The study concludes that the proposed LCDCS system, powered by deep learning, achieves exceptional accuracy in detecting and classifying NSCLC. By integrating a multi-level convolutional neural network (ML-CNN) with advanced data balancing techniques, the system demonstrates notable accuracy and resilience in handling imbalanced datasets. The incorporation of multi-scale image analysis further enhances the model's ability to detect and classify lung nodules with precision. Through comprehensive comparative evaluation, the research underscores the effectiveness of strategic class balancing in improving diagnostic outcomes. The system proves to be a highly reliable diagnostic tool, offering critical support to radiologists in the early detection of conditions and enabling timely, more effective treatment planning.

Intelligent Identification of Pile Defects Based on Improved LSTM Model and Wavelet Packet Local Peaking Method

Xiaolin Li[1], Xinyi Chen[2]*
Anhui and Huaihe River Institute of Hydraulic Research, Hefei 230000, China[1]
Anhui Vocational and Technical College, School of Civil Engineering, Hefei 230011, China[2]

***Abstract*—With the continuous expansion of building scale, the structural safety of foundation piles, as key load-bearing components, has received increasing attention. To improve the defect recognition ability under complex working conditions, this study first uses the whale optimization algorithm to perform hyperparameter optimization on the long short-term memory network model, achieving efficient classification of the defect and non-defect samples. Subsequently, the signals identified as having defects are subjected to wavelet packet decomposition to extract multi-scale energy features, and combined with the local peak finding method to accurately locate key reflection peaks, achieving further identification of defect types. The results showed that the classification accuracy, recognition precision, recall rate, and F1 value of the new method were the highest at 96.7%, 95.16%, 93.87%, and 94.51%, respectively, and the average recognition time was the shortest at 0.97 seconds. Especially for the defect identification errors of drilled cast-in-place piles and prefabricated piles, the lowest were 0.19 and 0.23, and the lowest complexity could reach 65.28%, demonstrating high precision and stability in defect identification. This model has strong robustness and accuracy in various types of defect scenarios, and has good generalization ability and engineering application potential, which can provide certain technical references for the construction monitoring of road and bridge engineering in the future.**

Keywords*—Foundation pile; defect identification; LSTM; WOA; WPT; LPS

I. INTRODUCTION

As the core of the building foundation, the quality of foundation piles directly determines the stability and safety of the building. Especially in areas with complex geological conditions, there is a high risk of potential defects in foundation piles. If these defects are not detected and treated promptly, they may pose a serious threat to the overall safety of buildings [1-2]. Therefore, early identification and accurate evaluation of pile defects have become key issues that urgently need to be addressed in current construction quality management. With the development of artificial intelligence technology, machine learning-based intelligent recognition methods have gradually become an important research direction in pile defect detection. Wu J et al. developed a multi-point traveling wave decomposition method for detecting and characterizing damage in cast-in-place reinforced concrete piles. This method was more effective in extracting damage features and had higher recognition and detection accuracy compared to other advanced methods [3]. Zhang W et al. developed a novel detection way grounded on the image segmentation network U-Net. Compared with traditional algorithms, the developed algorithm exhibited better performance in terms of accuracy and F1 value [4]. Jiang S et al. proposed an underwater pile defect detection model by combining an image fusion enhancement algorithm and a deep learning algorithm. This model had good robustness to noise and performed well in surface defect detection [5]. Liu H et al. put forth a new non-destructive testing method to solve the detection problems of concrete disintegration or steel corrosion [6]. This method could achieve high-frequency identification of defects in sensitive areas of pile foundations but required high detection conditions.

Deep learning algorithms, especially Long Short-Term Memory (LSTM) networks, have been widely used in various intelligence recognition tasks due to their advantages in time series data analysis and pattern recognition [7]. Wu C S et al. believed that the efficiency of utilizing conventional methods to identify multiple kinds of defects in pile foundations was very low, and proposed a pile-based defect type identification method built on dual channel Convolutional Neural Networks (CNN) and LSTM. It effectively integrated 1D and 2D features, extracted more potential features, and improved classification precision [8]. Wang H et al. proposed a low-strain pile foundation detection data method based on recursive neural networks and improved LSTM. In comparison, this method had the highest accuracy but required more training parameters [9]. Wu J et al. proposed a new multi-sensor pile damage detection method that can effectively identify damage in a multi-task learning framework [10]. Hu T et al. developed a new detection method based on improved LSTM to address the shortcomings of existing methods for predicting the settlement of surrounding buildings caused by deep excavation construction [11]. The settlement predicted by this method under three working conditions was in good agreement with the monitored settlement.

In summary, although existing studies have made some progress in the recognition of foundation pile defects, most of them focus on a single model and suffer from the problems of decoupling of classification and localization, sensitivity to high-frequency noise, and insufficient expression of defect features. LSTM is chosen as the fundamental model for this study. The reason is that LSTM has excellent time-dependent modeling capabilities, suitable for processing time series features of complex pile detection signals, and can effectively alleviate the

gradient vanishing problem of traditional recurrent neural networks. However, the LSTM model is sensitive to hyperparameter settings and is deficient in multi-scale defect feature capture and localization accuracy when used alone. To compensate for these shortcomings, the study introduces the Whale Optimization Algorithm (WOA) to globally optimize the hyperparameters of the LSTM, which improves the robustness and generalization ability of the model. At the same time, it combines the Wavelet Packet Transform-Local Peak Search (WPT-LPT) to optimize the LSTM hyperparameters and enhance the multi-scale energy decomposition of defective signals and the localization of key peaks, forming a synergistic identification system. The method aims to overcome the limitations of existing models and realize high-precision classification and localization of foundation pile defects. The method innovatively uses WOA for LSTM hyperparameter global optimization, which effectively improves the robustness and generalization ability of the classification model. WPT is used to realize multi-scale energy decomposition of the signal, and combined with the LPS recognition strategy, it enhances the ability to respond to defective mutation features. Different from the traditional single-stage identification method, the model establishes a joint identification process of "classification-decomposition-localization", which can simultaneously output structured information such as the existence and type of defects. The research method provides high-precision, low-latency, and robust solution for monitoring the health of pile foundations under complex working conditions.

The study is divided into four sections: Section I introduces the background of foundation defect identification and the improved LSTM classification method based on WOA optimization. Section II describes the multi-scale signal feature extraction and defect localization by combining the WPT and the LPS methods. Section III carries out the model performance test and the ablation analysis to validate its accuracy and robustness. Section IV concludes the results of the study, points out the limitations, and looks forward to future applications.

II. Methods and Materials

A. Classification of Pile Defects Based on Improved LSTM

In the actual construction and service process, various factors such as geological conditions, construction techniques, and material quality may affect the occurrence of different types of defects in pile structures [12-13]. These defects may not only weaken the bearing capacity of foundation piles but also cause settlement, tilting, and even overall structural damage during long-term service, and in severe cases, can lead to catastrophic failure of bridge structures [14-15]. Fig. 1 shows the common forms of pile defects.

In Fig. 1, structural defects mainly include fractures, shrinkage, and displacement, which are often caused by abnormal stress or changes in geological conditions. Material defects such as insufficient strength, honeycomb, and rough surface are usually closely related to the quality of the concrete itself. Construction process defects reflect human factors in the pile foundation construction process, such as incorrect positioning of steel bars and incomplete hole cleaning. Various types of defects may appear individually or in combination in engineering. Therefore, higher requirements have been put forward for detection and recognition. Therefore, introducing deep learning methods with temporal modeling capabilities has become an effective path to improve defect recognition performance. LSTM, as an improved structure of Recurrent Neural Networks (RNNs), has a strong time-series learning ability and can avoid the gradient vanishing problem that traditional RNNs encounter when the sequence is long while maintaining long-term context-dependent information [16-18]. Fig. 2 shows the structure of a stacked LSTM.

In Fig. 2, the stacked LSTM is still composed of the basic LSTM, with intermediate connecting layers. Its basic unit consists of three gate control structures, namely Forget Gate (FG), Input Gate (IG), and Output Gate (OG). At each time step t, a single LSTM unit dynamically regulates the information flow through three gating mechanisms. The IG determines which new information is introduced into the memory unit at the current time based on the current input x_t and the hidden state h_{t-1} of the previous time. The calculation formula is shown in Eq. (1):

$$\begin{cases} i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \\ \tilde{C}_t = tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \end{cases} \quad (1)$$

In Eq. (1), i_t is the output vector of the IG. σ is the Sigmoid activation function. W_i and W_C are weight matrices for IGs and candidate states. h_{t-1} is the hidden state of the previous time step. x_t is the input vector for the current time step. b_i and b_C are bias vectors for IGs and memory states. $\tilde{C}_t$ is a candidate memory state. The expressions for the FG and OG are shown in Eq. (2):

$$\begin{cases} f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \\ o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \\ h_t = o_t * tanh(C_t) \end{cases} \quad (2)$$

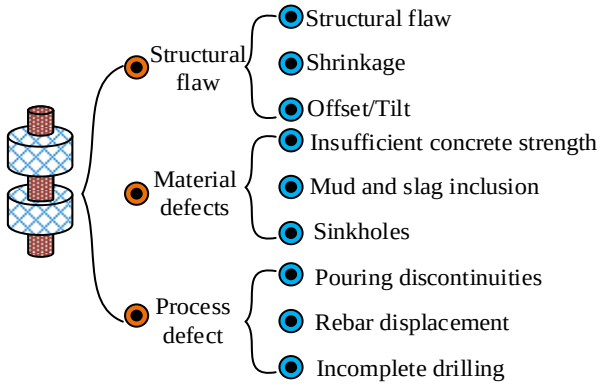

Fig. 1. Common defect form of foundation pile

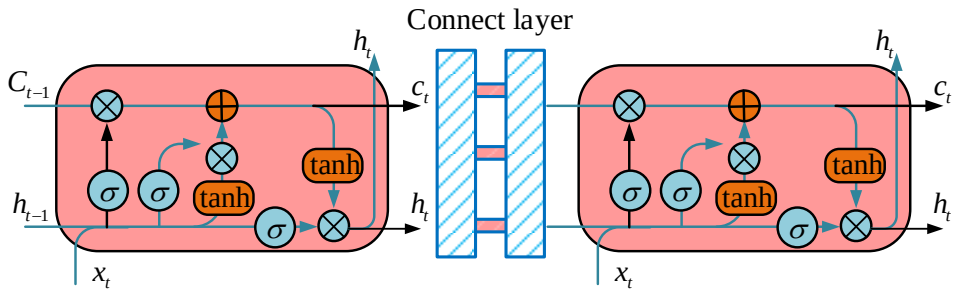

Fig. 2. Stacked LSTM structure

In Eq. (2), f_t and o_t are the output values of the FG and OG. W_f and W_o are the weight matrices of the FG and OG. b_f and b_o are bias vectors for the FG and OG. C_t is the current state of the memory unit, as shown in Eq. (3):

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \tag{3}$$

Although LSTM has shown good classification ability in temporal modeling, its performance is highly dependent on the setting of model hyperparameters. In the task of identifying pile foundation defect images or signals, the problems of complex feature distribution and imbalanced samples are commonly present. Traditional manual parameter adjustment methods are not only inefficient, but also prone to falling into local optima. Therefore, this study introduces WOA for parameter optimization of LSTM model. Firstly, in each round of optimization, WOA guides individuals in the population towards position $\vec{X}(t)$ based on the current optimal parameter combination position $\vec{X}^*(t)$, and the position update is shown in Eq. (4):

$$\vec{X}(t+1) = \vec{X}^*(t) - \vec{A} \cdot \left| \vec{C} \cdot \vec{X}^*(t) - \vec{X}(t) \right| \tag{4}$$

In Eq. (4), $\vec{A} = 2\vec{a} \cdot \vec{r}_1 - \vec{a}$, $\vec{C} = 2 \cdot \vec{r}_2$, where $\vec{r}_1$ and $\vec{r}_2$ both represent random vectors in the interval [0,1]. $\vec{a}$ is the control factor. To enhance local search capability, WOA introduces a spiral approximation mechanism to simulate the nonlinear convergence path of whales around prey, as calculated in Eq. (5):

$$\vec{X}(t+1) = e^{bl} \cdot \cos(2\pi l) \cdot \left| \vec{X}^*(t) - \vec{X}(t) \right| + \vec{X}^*(t) \tag{5}$$

In Eq. (5), b is the helical contraction factor. l is a random number within the range of [-1,1]. Finally, after each iteration, WOA evaluates the individual fitness and dynamically updates the global optimal parameter combination based on the current optimal fitness value, as shown in Eq. (6):

$$\iota = -\frac{1}{N} \sum_{i=1}^{N} \sum_{k=1}^{K} y_{ik} \log(\hat{y}_{ik}) \tag{6}$$

In Eq. (6), N is the gross of samples. K is the amount of defect categories. y_{ik} is the true label of sample i belonging to class k. $\hat{y}_{ik}$ is the prediction probability of the LSTM model for class k. The pile defect classification process of WOA-LSTM is shown in Fig. 3.

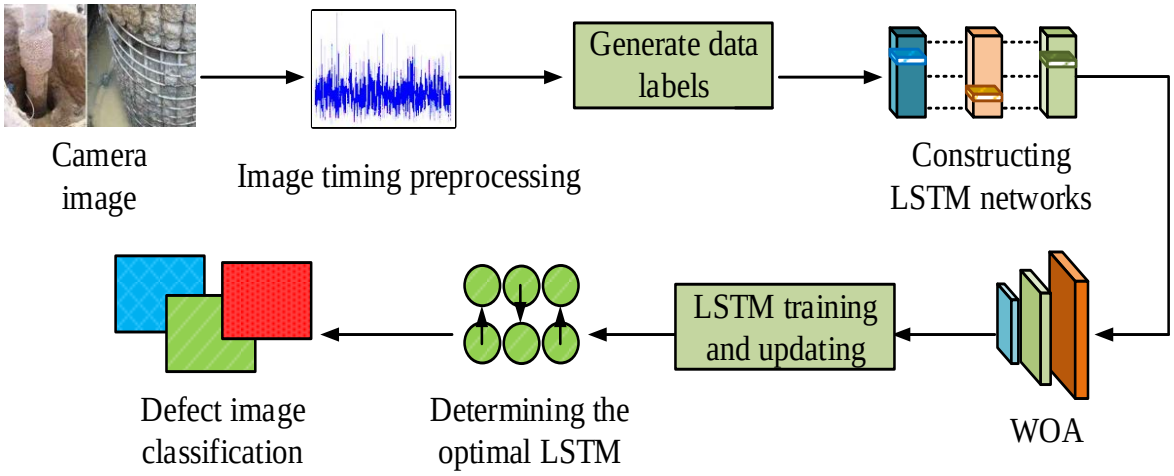

Fig. 3. Defect classification process of foundation pile based on WOA-LSTM

In Fig. 3, firstly, the system performs preprocessing operations such as cleaning and normalization on the collected pile foundation detection signals or defect images to generate defect category labels. Secondly, an initial LSTM model is constructed, and multiple candidate hyperparameter combinations are initialized through WOA to form a search population. Next, the LSTM model will be trained for each set of parameters, and performance evaluation will be conducted using the cross entropy loss function as the fitness metric. Subsequently, WOA performs position updates and spiral local search operations, guiding the population to continuously approach the optimal solution. After the iteration, a set of globally optimal LSTM hyperparameter combinations is obtained, and the model is retrained based on this to achieve higher accuracy in defect classification. Finally, the optimized model is used to identify defect types in newly collected signal or image data.

B. Construction of PDI Model Integrating WPT-LPS Method

After completing the construction of the WOA-LSTM-based pile defect classification process, further research finds that the data obtained in actual pile foundation testing usually has significant non-stationarity and high noise interference. Especially reflected wave signals, sound wave transmission images, etc., these information often contain important features of defects. Therefore, this study introduces WPT as a front-end preprocessing technique to perform multi-level decomposition on the original signal. Compared with ordinary wavelet transform, wavelet packets can simultaneously decompose the high-frequency and low-frequency parts of the signal into full-frequency bands and have stronger time-frequency localization ability [19-20]. The WPT signal decomposition diagram is shown in Fig. 4.

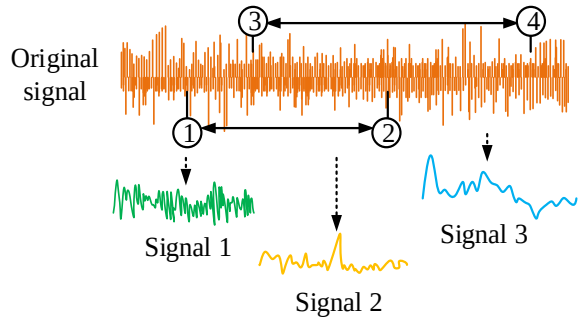

Fig. 4. Diagram of WPT signal decomposition.

In Fig. 4, WPT performs recursive full-frequency convolution decomposition on the original pile foundation detection signal, refining the original non-stationary signal into multiple independent sub-signals in various frequency bands. The decomposition process can be seen as a hierarchical filtering downsampling operation. Each level decomposes the signal from the previous level into two new sub-signals, namely a low-frequency component and a high-frequency component. The formula for signal convolution decomposition is shown in Eq. (7):

$$W_{n+1,2g}(t) = \sum_{z} x_n(z) \cdot h(2t - z) \tag{7}$$

In Eq. (7), $W_{n+1,2g}(t)$ is the signal of the $2g$-th node in the n-th layer. $x_n(z)$ is the input signal of the z-th node in the n-th layer. h is the low-pass filter coefficient of WPT. The calculation for obtaining high-frequency sub bands is shown in Eq. (8):

$$W_{n+1,2g+1}(t) = \sum_{z} x_n(z) \cdot v(2t - z) \tag{8}$$

In Eq. (8), $W_{n+1,2g+1}(t)$ is the signal of the $2g+1$-th node in the n-th layer. v is the coefficient of the high pass filter. Eq. (7) and (8) show that low-frequency sub-signals reflect a steady trend, while high-frequency sub-signals typically contain sensitive responses to defect mutations. The energy calculation of a single node is shown in Eq. (9):

$$E_{n,g} = \sum_{t} \left| W_{n,g}(t) \right|^2 \tag{9}$$

In Eq. (9), $E_{n,g}$ is the energy value of node (n, g). To more accurately extract key features related to defects from multi-layered sub-bands, this study further introduces LPS to identify mutation points in the signal that may correspond to defect locations. Taking the pile foundation with reduced diameter defects as an example, Fig. 5 shows the time cross-sectional changes of the reflected waves of such pile foundation defects and the typical waveform results after LPS processing.

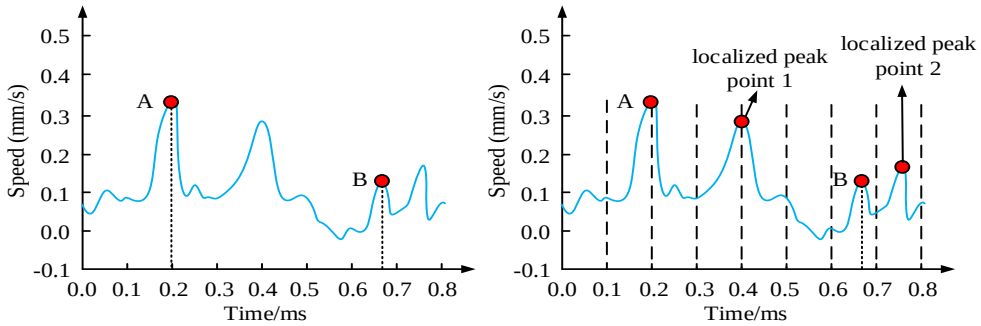

Fig. 5. Time-domain waveforms before and after LPS treatment

Figs. 5(a) and (b) show the time-domain waveforms of pile reflection before and after LPS treatment. In Fig. 5(a), point A corresponds to the initial wave of excitation-emission at the top of the pile, while point B is the location, where the wave reflects at the cross-section of the pile body, where it encounters a shrinkage defect. At this point, in addition to the main reflection peak, there are still multiple sets of interference waves with similar amplitudes in the signal, which makes the defect localization judgment uncertain. In Fig. 5(b), LPS forms a peak set by sliding judgment throughout the entire time series, comparing and extracting all peak points and their index positions that meet the conditions point by point. At this point, point A still represents the emission starting point, and the defect reflection peak corresponding to point B is more clearly marked. The interference peak is excluded or weakened because it does not meet the peak condition. This study introduces a second-order dynamic trend function to determine the rising or falling trend of the waveform at the current position, and defines a peak indicator function based on window weights, as shown in Eq. (10):

$$\psi(i)=\alpha\cdot\left(s_i-\frac{s_{i-\omega}+s_{i+\omega}}{2}\right)+\beta\cdot\left(\frac{d^2s_i}{dt^2}\right) \tag{10}$$

In Eq. (10), $\psi(i)$ is the peak indicator function, and when $\psi(i)>0$ is present, it is considered a candidate peak point. α and β are both second-order differences of the signal. ω is the symmetrical window width. s_i is the sub signal decomposed by WPT. To distinguish between real defect peaks and weak background disturbances, this study defines a weighted energy index E_i^* and evaluates the sharpness of each candidate peak by combining signal gradient constraints, as shown in Eq. (11):

$$E_i^*=\frac{|s_i|^\gamma}{1+\left|\frac{ds_i}{dt}\cdot\frac{d^2s_i}{dt^2}\right|} \tag{11}$$

In Eq. (11), γ is the amplitude control parameter. The points, where E_i^* is greater than the threshold are ultimately retained as local reflection peaks for processing atypical defect reflection waveform such as shrinkage or mud inclusion in the pile body. This study combines WOA-LSTM and WPT-LPS to construct a novel PDI model, as shown in Fig. 6.

In Fig. 6, the entire PDI process is divided into two stages, corresponding to preliminary classification and fine recognition. Firstly, the model performs preprocessing operations such as normalization and denoising on the collected raw pile foundation detection signals to unify the data format and improve signal quality. Secondly, the preprocessed signal is input into an LSTM classification model optimized by WOA, which automatically extracts temporal dependent features and completes preliminary classification and discrimination between defects and non-defects. Subsequently, for the subset of signals judged as "defective" by WOA-LSTM, WPT multi-layer decomposition and LPS processing are performed sequentially. The full-frequency band energy characteristics and reflection peak position information are extracted to achieve further fine identification of defect types and structural features. In the end, the model outputs a comprehensive judgment result including the existence of defects, specific types, key reflection feature points, etc.

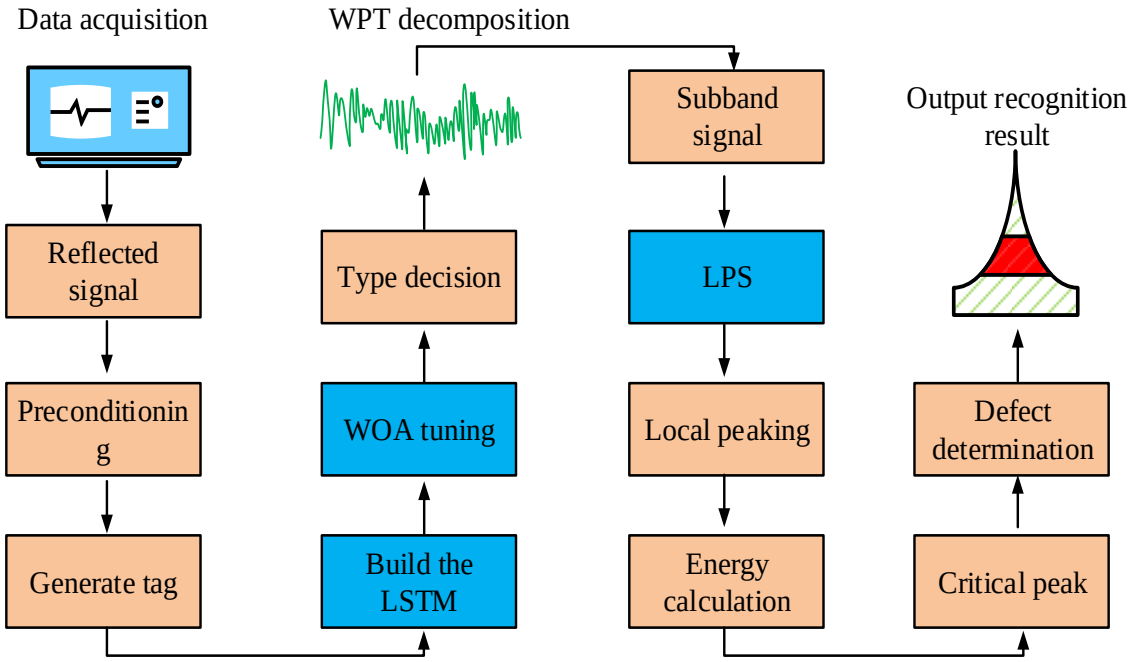

Fig. 6. New model flow of foundation PDI

III. RESULTS

A. Performance Testing of the New PDI Model

This study sets up a suitable experimental environment, with an Intel Core i7-12700H CPU, a clock speed of 2.3 GHz, a Windows 11 system, and 32 GB of memory. The GPU adopts NVIDIA RTX 3080 (16 GB of video memory) and the development environment is Python 3.10. The deep learning framework uses TensorFlow 2.12 and Keras 2.9. The Low Strain Pile Integrity Test Dataset (LSPIT) and Pile Sonic Logging Defect Imaging Dataset (PSLDID) are used as the testing data sources for pile foundation low strain integrity testing. Among them, LSPIT collects 1D time series signals of reflection waveforms of different types of foundation piles, such as intact piles, reduced diameter piles, broken piles, and mud-filled piles, under low-strain testing conditions. PSLDID mainly comes from the acoustic transmission method detection records in multiple large bridge and high-rise engineering projects at home and abroad. The data are in the form of 2D grayscale images, simulating the attenuation and abnormal distribution of sound waves on the propagation path inside the pile. This study first conducts value selection tests on the two types of hyperparameters that have the greatest impact on model performance, as shown in Fig. 7.

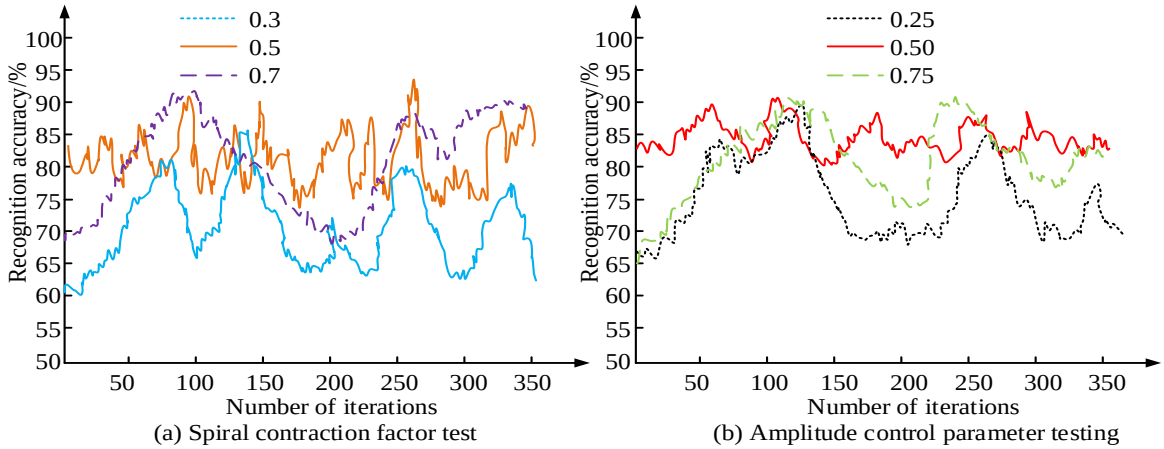

Fig. 7. Hyperparameter selection test result

Figs. 7(a) and (b) show the test results of selecting values for spiral contraction factor and amplitude control parameters. In Fig. 7(a), when the spiral contraction factor is set to 0.5, the overall model exhibits better convergence stability and recognition accuracy. Its accuracy rapidly improves in the early stages of iteration and remains at a high level of over 92.3% after 250 rounds. When the value is set to 0.3, although there are short-term high values in some sections, the overall fluctuation is large and the stability is poor. When the value is set to 0.7, the fluctuations in the first 200 rounds are relatively mild, but the final accuracy does not continue to improve, and the overall performance is slightly inferior to when the value is set to 0.5. In Fig. 7(b), when the amplitude control parameter is set to 0.50, the overall accuracy curve is relatively stable and remains above 90.8%. This indicates that the setting can balance global exploration and local convergence capabilities during the search process. Compared to others, when the value is set to 0.25, the model falls into early oscillations, with a large range of accuracy fluctuations and a tendency to fall into non-optimal regions. When the value is 0.75, the accuracy slightly improves in the middle and later stages, but overall it is not significantly better than 0.25. Therefore, based on the results of the two sets of tests, this study ultimately selects a spiral contraction factor of 0.5 and an amplitude control parameter of 0.5 as the recommended configurations for the WOA optimization module. Fig. 8 continues the ablation test.

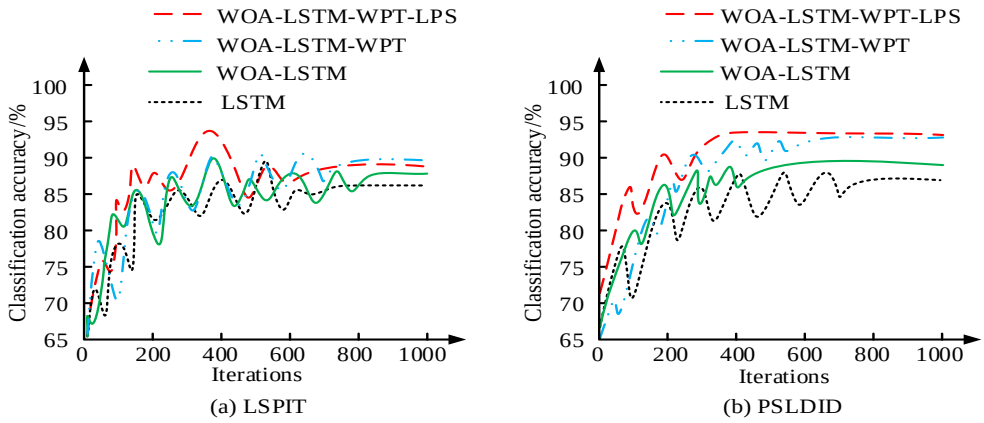

Fig. 8. Ablation test results

Figs. 8(a) and (b) show the ablation test values in the LSPIT and PSLDID datasets. In Fig. 8(a), WOA-LSTM-WPT-LPS consistently maintains the highest recognition accuracy and reaches a stable state around 750 rounds, with an accuracy rate of over 95.4%. In contrast, the WOA-LSTM-WPT model without an LPS module is slightly inadequate in high-frequency detail recognition, with an accuracy slightly lower by about 2 percentage points. In Fig. 8(b), the complete model exhibits fast convergence ability in the early stages and achieves an accuracy rate of over 96.7% after 700 rounds. After removing the LPS module, the structural expression ability of local reflection defects in the image decreases, and the model shows a slight lag. The comprehensive testing of two datasets shows that WPT and LPS modules have significant gain effects on defect time-frequency feature extraction and structural mutation recognition. The WOA optimization mechanism enhances the overall generalization ability and convergence stability of the model. Advanced models such as 3D-CNN, Empirical Mode Decomposition (EMD), and PDI Model Based on Apparent Wave Velocity Inverse Analysis (AWVIA-Pile) are introduced for comparison. Testing is conducted using precision (P), recall (R), F1 value, and average recognition time as indicators, as listed in Table I.

TABLE I. INDEX TEST RESULTS OF DIFFERENT MODELS

Dataset	Model	P/%	R/%	F1 value/%	Average recognition time/s
LSPIT	3D-CNN	88.73	85.96	87.32	1.42
	EMD	84.29	80.67	82.44	1.87
	AWVIA-Pile	86.15	83.71	84.91	2.36
	Research model	94.62	92.85	93.73	0.97
PSLDID	3D-CNN	89.54	86.43	87.96	1.57
	EMD	83.78	81.06	82.45	1.91
	AWVIA-Pile	85.41	83.28	84.33	2.14
	Research model	95.16	93.87	94.51	1.02

In Table I, on LSPIT, the P-value of the research model reaches 94.62%, the R-value is 92.85%, and the F1 value is as high as 93.73%, all significantly higher than the other three methods. In contrast, the EMD model has an F1 value of only 82.44% on this dataset, indicating poor recognition robustness under high noise interference. Although AWVIA-Pile has certain theoretical advantages, it has bottlenecks in practical recognition efficiency, with an average recognition time of 2.36s, significantly higher than the 0.97s of the research model. Similarly, on PSLDID, the research model still maintains a leading position, with an F1 value of 94.51% and a recognition time of 1.02 s that balances efficiency and accuracy. Although 3D-CNN has a certain spatial perception ability in image dimension modeling, its R-value is only 86.43% and its stability is slightly inferior. Therefore, the proposed model has good generalization ability and response efficiency while maintaining high-precision recognition.

B. New PDI Model Simulation Testing

To verify the practical application effect of the model, this study simulates sand and clay foundation conditions and observes whether different models are affected by background signal interference on the decomposition ability of image temporal signal features, as shown in Fig. 9.

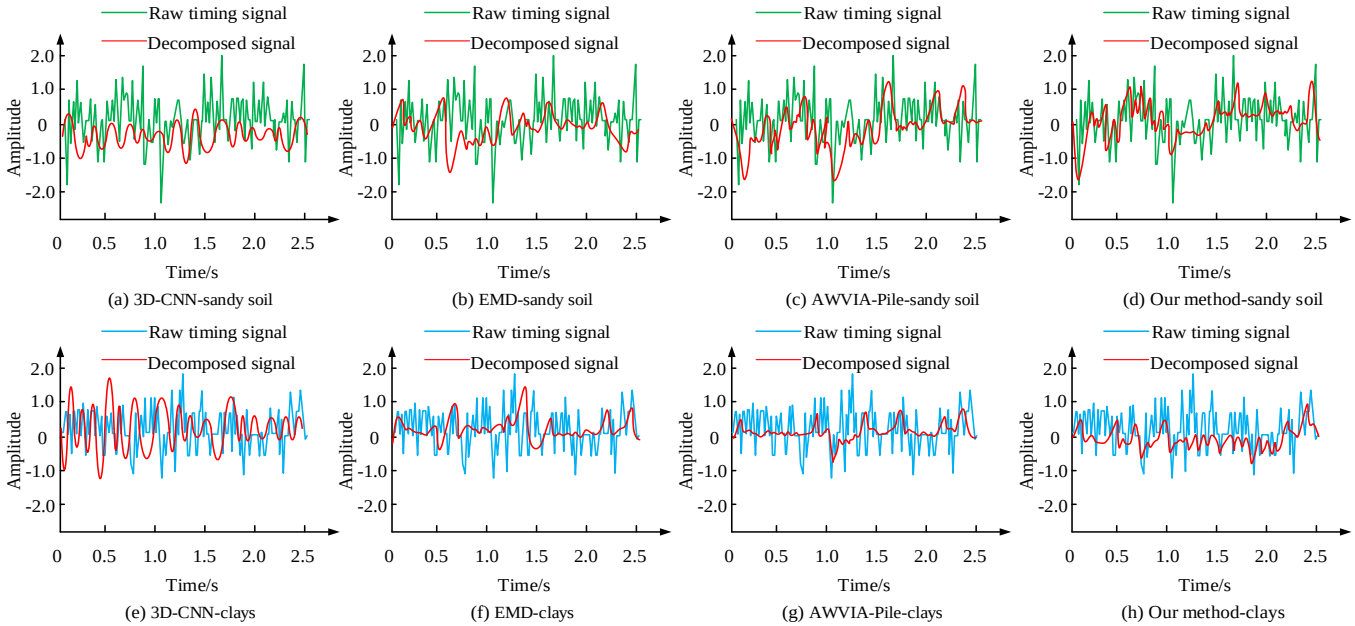

Fig. 9. Signal decomposition and comparison of each model in sandy soil and clay environment

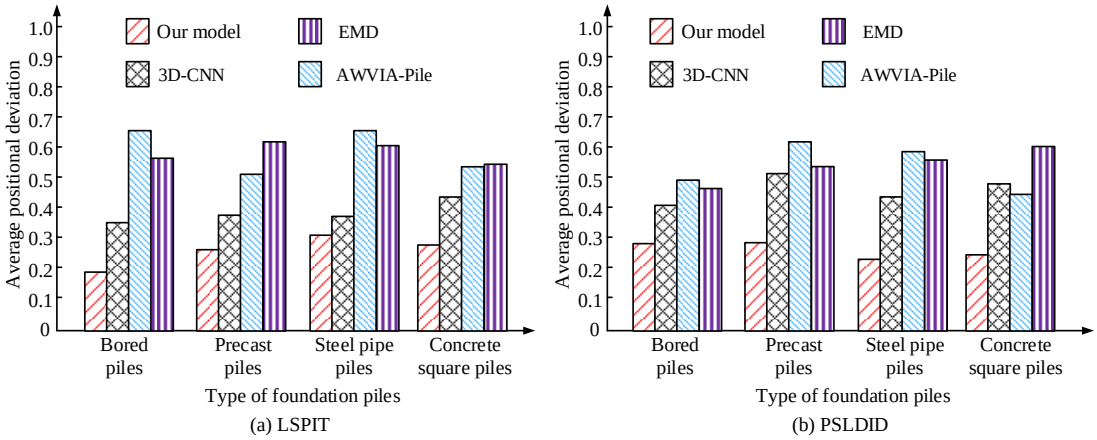

Fig. 10. Error results of defect identification of different pile foundations.

Figs. 9(a) to (d) and (e) to (h) show the signal analysis of four types of models in sandy and clay environments. In Figs. 9(a) to (d), in sandy soil environments, the 3D-CNN model only extracts low-frequency skeleton structures and lacks the ability to respond to high-frequency abrupt signals. Although EMD has a certain deconstructive ability, its decomposition results exhibit a signal drift phenomenon. The feature curves extracted by AWVIA-Pile exhibit weak points such as edge blurring and energy collapse, showing sensitivity to shallow noise. The research method shows a clearer and more clearly defined signal decomposition effect, which not only preserves the complete structure of the reflected main wave but also effectively weakens the interference of background noise, indicating that the model has stronger time-frequency separation ability in interference environments. In Figs. 9(e) to (h), the models are all affected by more complex background waveforms in clay environments, resulting in a significant increase in decomposition difficulty. However, the research model still maintains a high decomposition resolution, with clear hierarchical structures of the main and secondary waves, and prominent defect band characteristics. This indicates that it also has good structural preservation ability and noise adaptability in low-permeability formations. This study takes drilled pile, precast pile, steel pipe pile, and concrete square pile as examples to test the average position deviation of defect detection for each model, as shown in Fig. 10.

Fig. 10(a) shows the pile foundation defect identification errors of four methods in the LSPIT and PSLDID datasets. In Fig. 10(a), in the identification task of the drilled pile, the average position deviation of the research model is the smallest, only 0.21. Compared with 3D-CNN, EMD, and AWVIA Pile methods, it reduces by about 0.15, 0.22, and 0.18, indicating stronger feature locking ability under complex multi-wave interference conditions. Due to the high regularity of signal reflection patterns in concrete square piles, the overall error of each model is slightly smaller, but the research model still outperforms the comparison method with a minimum deviation of 0.24. In Fig. 10(b), the positional deviation of the research model on four types of pile types is controlled below 0.3, with errors of 0.19 and 0.23 for drilled pile and precast pile, which are much lower than the fluctuation range of 3D-CNN and AWVIA Pile models. This indicates that it has stronger localization robustness in defect area determination of image data. This study tests single and multiple defects based on recognition accuracy, model complexity, and average recognition delay, as shown in Table II.

TABLE II. SINGLE DEFECT AND MULTIPLE DEFECT INDEX TEST RESULTS

Number of defects	Model	Precision/%	Model complexity/%	Average recognition time/s
Single defect	3D-CNN	91.47	82.53	0.76
	EMD	88.92	69.41	0.89
	AWVIA-Pile	90.26	76.89	0.93
	Research model	96.38	65.28	0.58
Multiple defects	3D-CNN	86.51	82.53	0.81
	EMD	83.64	69.41	0.94
	AWVIA-Pile	85.23	76.89	0.97
	Research model	93.27	65.28	0.63

In Table II, when faced with a single defect recognition task, the research model achieves a recognition precision of 96.38%, which is 4.91% and 6.12% higher than 3D-CNN and AWVIA-Pile. Meanwhile, the model complexity is only 65.28%, indicating that the network structure is lighter while maintaining recognition ability, and the average recognition delay is 1.14 s, significantly better than AWVIA-Pile's 2.03 s. In the multi-defect recognition task, the research model still maintains a high recognition precision of 93.27%, while 3D-CNN and EMD show significant fluctuations under multi-target interference,

with precision decreasing to 86.51% and 83.64%, and recognition time both exceeding 1.4 s. In addition, the delay of AWVIA-Pile increases to 2.19s in multi-defect scenarios, indicating its weak structural decoupling ability for composite defects. In summary, this research method has good stability and precision control ability in single defect scenarios, and exhibits stronger adaptability and efficiency advantages in complex tasks with multiple defects, with high practical application value and promotion prospects.

IV. CONCLUSION

In response to the problems of insufficient classification accuracy, weak noise resistance, and inaccurate structural localization in the current PDI process, this study constructed a defect data classification method by combining LSTM and WOA. At the same time, a novel PDI model was proposed by combining WPT and LPS for temporal feature decomposition and recognition of defect labels. In the experiment, when both the spiral contraction factor and amplitude control parameters were set to 0.5, the recognition accuracy of the model remained at a maximum of 92.3%. Compared with simple LSTM and WPT, after sequentially combining WOA and LPS, the final combined model achieved the highest classification accuracy of 96.7%, showing a significant improvement effect. Compared to other models, this new method achieved the highest P, R, and F1 values of 95.16%, 93.87%, and 94.51%, and the shortest average recognition time of 0.97s. Under sandy and clay foundation conditions, the signal decomposition effectiveness of the research method was higher, and the decomposed sub-signals were clearer and more realistic. For the four typical types of PDI, the accuracy was higher, especially for drilled and precast piles with errors of 0.19 and 0.23, which were much lower than other methods. The lowest complexity could reach 65.28%, and the shortest average recognition delay was 0.58s, both demonstrating excellent processing efficiency and effectiveness. In summary, the new method performs particularly well in handling data types with relatively regular structures and obvious signal characteristics such as drilled piles and prefabricated piles, with better positioning errors and recognition accuracy than other types of piles. For data with higher signal complexity or more diverse defect types, the algorithm is still well adapted. However, the study still has some limitations. First, the generalization ability of the model needs to be further improved when facing extreme working conditions and unseen defect types. Second, current recognition is mainly based on single modal signals, and in the future, multimodal fusion can be considered to enhance the robustness and adaptability of the model. In addition, the integration and optimization of the model with the actual inspection equipment needs to be enhanced to improve the convenience and real-time performance of engineering applications. Future research will consider introducing multimodal data augmentation mechanisms, transfer learning strategies, and integrated optimization with actual detection devices to further promote the application of this model in actual bridge and building pile foundation detection.

Internet of Things-Driven Safety and Efficiency in High-Risk Environments: Challenges, Applications, and Future Directions

Hua SUN
Xingtai Open University, Xingtai 054000, China

***Abstract*—The Internet of Things (IoT) is a technology that can bring about significant change in several areas, especially in high-risk situations such as industrial environments and health and safety contexts. This research study has examined many IoT applications within domains and identified their importance in improving risk management and operational efficiency strategies. IoT enables sensor networks, wearable devices, and remote monitoring systems with edge computing capabilities. Thus, it allows real-time monitoring, early threat detection, and predictive maintenance. Data analytics technologies make it easier to capture valuable information that stakeholders can use to make informed decisions and optimize workflows to improve performance. Despite the transformational promises of IoT, there are still some problems. These include security vulnerabilities, interoperability concerns, and extensive training programs. Addressing these challenges offers the opportunity to create innovative, resourceful collaboration in developing robust IoT solutions to accommodate the requirements of hazardous environments. In the coming times, further growth of IoT and integration with the latest technologies like 5G and robotics promise new ways to ensure safety and efficiency in operations. Within this study, we emphasize the role of IoT as an enabling factor in transforming dangerous areas into safe and efficient zones, assuring our readers on the safety benefits of IoT. It also provides a general perspective towards potential future research and development directions.**

***Keywords*—Internet of things; high-risk environments; safety; operational efficiency; data analytics**

I. INTRODUCTION

The Internet of Things (IoT) is a cutting-edge technology with immense potential to transform risk-prone settings, including industrial, healthcare, and safety industries [1]. With the aid of connected devices and network of sensors, IoT enables real-time monitoring, automates security, and enhances the efficiency of operations [2]. Firms in industries utilize analytics from the data of IoT systems to predict equipment breakdowns and reduce risks while avoiding the time and expenses of a shutdown [3]. Wearable devices and remote monitoring systems for health and safety also monitor vital signs and surroundings to promptly respond to impending danger [4]. This revolutionary feature makes the usage of IoT one of the most effective tools for reducing risk while maximizing performance and transforming the management of safety and efficiency in risky conditions [5].

Hazardous settings such as industrial sites, health and safety facilities face critical challenges, including unpredictable hazards, delayed threat detection, and equipment failures that can lead to accidents or business interruptions [6]. Such risks, however, demand a very proactive approach, which most traditional systems lack. Yet, IoT addresses this through constantly networking devices and sensor networks to enable real-time monitoring and data collection [7]. This enables early threat detection, predictive maintenance, and data-driven decision-making to prevent accidents and increase efficiency across operations.

Like advanced Intrusion Detection Systems (IDS) proposed in mobile social network contexts, where abnormal node communication patterns are detected and mitigated swiftly to contain cyber threats [8], IoT frameworks in high-risk environments are designed to respond dynamically and autonomously to hazardous conditions. As a result, IoT serves as a transformative tool by delivering instant situational awareness and initiating automated safety actions when needed [9].

This study analyzes the application of IoT to risk minimization and improved operating efficiency in high-hazard industrial situations, health and safety circumstances. Risk management will be enhanced through IoT technology, enabling threat identification through interconnectivity between available devices, allowing real-time data analysis through predictive maintenance, and automating various security measures. This study plans to clarify these revolutionary opportunities and how solutions offered through IoT raise efficiency, eliminate equipment downtime, and create a better work environment. It further discusses modern challenges with IoT implementation, ranging from the risk of cyberattacks to issues of interconnectivity and workers' training to fully utilize the potential of IoT to enable safe and improved operations under hazardous conditions.

In contrast to earlier literature based on standalone sectors or independent technologies, this study offers an integrated framework for IoT applications in safety-critical domains through real-world applications and multi-layered architectural analysis. The study pushes the boundary beyond the technical discourse of operations safety and efficiency by converging various sectors and analyzing how next-generation technologies such as 5G, AI, and blockchain can be integrated functionally. The study gives a comparative perspective, points toward empirical gaps in implementation, and suggests an action plan to fill the gaps through technology convergence.

The remainder of the study follows the following structure: Section II explains IoT, edge computing, and 5G technologies

and explores their applicability to hazardous environments. Section III elaborates on IoT core capabilities, including real-time analytics, early threat identification, and operational efficiency improvement. Section IV discusses the use cases, including industrial safety, remote monitoring, and predictive maintenance. Section V illustrates some key points, detailing how IoT-enabled solutions can improve risk management and safety controls. Section VI discusses significant challenges, such as security risks, interoperability issues, and training demands, and suggests possible solutions. Lastly, Section VII presents the study's key findings and indicates directions for the future development of IoT, 5G, and AI-based technologies for hazardous environment security.

II. BACKGROUNDS

IoT provides cutting-edge, functional capabilities for high-hazard environments, health, and safety applications. As illustrated in Table I, some of these capabilities can involve gathering real-time information via a widespread network of sensors, employing advanced analytics to interpretively make sense of the information, remote monitoring of operations and processes to maintain oversight uninterrupted, and predictive maintenance to predict equipment failure before its occurrence.

A. Building and Infrastructure Management

IoT technology enables intelligent automation and increases security and operational efficiency in building and infrastructure management. IoT sensors monitor structural health and detect real-time problems like cracks, shifts, or vibrations. This is crucial for maintaining bridges, skyscrapers, and other critical infrastructure [10].

TABLE I. AN OVERVIEW OF IOT APPLICATIONS IN VARIOUS SECTORS

Sector	IoT applications	Key benefits
Building and infrastructure management	• Structural health monitoring for cracks, shifts, and vibrations • IoT-based fire detection and emergency response • Smart HVAC and lighting systems	• Early detection of structural issues prevents disasters • Enhanced occupant safety through automated emergency responses • Energy efficiency and reduced operational costs
Connected vehicles	• Vehicle-to-vehicle and vehicle-to-infrastructure communication • Advanced driver-assistance systems • Predictive maintenance and smart parking systems	• Improved road safety and reduced collision risk • Lower fuel consumption and optimized delivery times • Reduced vehicle breakdowns and urban congestion
Mining and energy industries	• Environmental monitoring for gas levels, temperature, and equipment health • Wearable devices for worker safety • Smart grids for energy distribution	• Increased safety through real-time hazard detection • Reduced downtime with predictive maintenance • Optimized energy distribution and reduced environmental impact
Food supply chain	• Environmental monitoring for perishable goods • End-to-end traceability • Real-time tracking and predictive analytics for logistics	• Improved food quality and reduced waste • Enhanced transparency and regulatory compliance • Optimized supply chain efficiency and cost reduction
Healthcare industry	• Wearable health monitors and remote diagnostics • Smart inventory management systems • Automated energy management in hospitals	• Improved patient outcomes with real-time monitoring • Optimized resource allocation and reduced equipment failure risk • Lower operational costs through energy efficiency

Early identification of structural anomalies allows for timely repairs, averts disasters, and prolongs building life. Systematic emergency protocols and fire detection technology based on IoT provide quicker action during hazardous conditions, enhance occupant protection, and reduce property damage [11]. Fig. 1 represents interconnected elements like HVAC sensors, intelligent lights, fire detectors, energy meters, and a central dashboard for maximized control and monitoring.

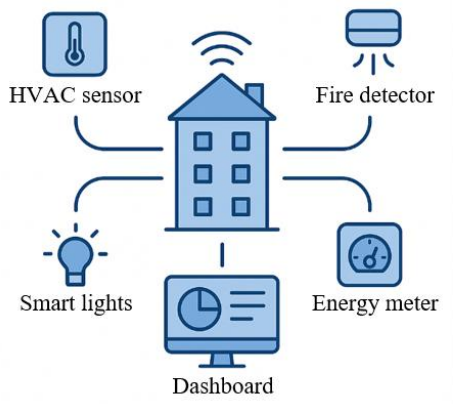

Fig. 1. IoT-enabled smart building automation system.

Aside from security, IoT is revolutionizing the functioning of buildings by enabling automation in energy management systems. Innovative HVAC systems regulate temperature and airflow according to occupancy and weather conditions, cutting energy consumption substantially [12]. Lighting systems controlled by IoT sensors dynamically respond to the amount of available natural illumination or shut off when rooms are left empty, further saving energy. Even buildings can be monitored and controlled remotely through IoT dashboards, integrating a scattered collection of maintenance schedules while reducing operating expenses [13]. This automation ensures sustainability and provides residents with a secure and convenient living space, emphasizing the transformative nature of the role played by the IoT in the new infrastructure paradigm.

B. Connected Vehicles

IoT is transforming the automotive industry, enabling safer, smarter, and more efficient transportation by being integrated into connected vehicles. Therefore, IoT technology in vehicles allows them to communicate with other vehicles (V2V) and with infrastructure (V2I), making real-time data possible for improved traffic management and reduced risks of collisions [14]. IoT-powered ADAS features include lane-keeping assistance, adaptive cruise control, automatic emergency

braking, and drive-road safety. IoT-powered fleet management companies use route optimization and vehicle monitoring to reduce fuel consumption and operational costs while increasing delivery times.

Moreover, the IoT in connected vehicles extends to predictive maintenance, where data from various sensors within the vehicle is analyzed to plan mechanical issues even before they turn serious. These extend the lives of vehicles and reduce the possibility of breakdowns or accidents. Similarly, IoT-powered smart parking guides motorists to available parking spots, easing urban congestion. While IoT is developing in-vehicle technology, much more focus is on creating an autonomous vehicle that would depend on sensor data and real-time communication to ensure safe and attractive navigation. IoT redesigns transportation by enhancing safety.

C. Mining and Energy Industries

IoT technology is critical in enhancing safety and efficiency in mining and energy industries condemned to high risks due to hazard-prone conditions combined with complex operations. IoT sensors observe the area's environmental factors, such as gas levels, temperature, and equipment health [15]. Sensors can identify these factors in real-time and warn personnel about accidents like gas leaks or equipment failures due to automatic powering off and shutting down. Wearable IoT devices further monitor a miner's location and health status to enable timely actions at any emergency site. Real-time information saves lives and optimizes the workforce by allowing better situational awareness in underground environments.

IoT enables predictive maintenance in the energy industry for critical infrastructures such as wind turbines, oil rigs, and power plants [16]. The operators will look at performance data and look out for potential problems that can be solved before an actual disruption or accident occurs, which lowers downtimes and maintenance costs. IoT further supports energy management by optimizing resource distribution and consumption using smart grids [17]. These grids are utilizing the technology of IoT to maintain, in real-time, a dynamic balance between energy supply and demand. This increases efficiency and reduces environmental impact. That is why, due to this fact, mining and energy sectors face a paradigm shift in which IoT technologies largely minimize risks while ensuring maximum productivity and efficiency of resources.

D. Food Supply Chain

The Food Supply Chain (FSC) benefits significantly from IoT technology, which ensures the safe and efficient transport and storage of perishable goods. The environmental factors-temperature, humidity, and light exposure-are closely monitored while producing, transporting, and storing food items using IoT sensors [18]. For example, a smart fridge with IoT devices may provide real-time notifications in case of alteration or fluctuation in temperature, which would prevent the food product from spoiling and reduce the amount of wastage. Furthermore, it enables IoT technology to facilitate end-to-end traceability and determine the origin of the food, making all these processes quite transparent. This is also essential to ensure its safety and follow the law.

IoT further promotes immense efficiency in the way supply chain operations are conducted. Companies use analytics to enhance logistics, shorten delivery time, and lower costs [19]. Real-time tracking systems enable companies to track shipments' location and condition while responding fast to unexpected events in case of delay or temperature deviation. IoT devices support data-driven decisions by farmers in agriculture concerning irrigation, pest management, and the health of crops for a tad better productivity and sustainability. Overall, IoT transforms the FSC by improving food quality and reducing waste to ensure the products arrive to the consumer optimally, enhancing safety and operational efficiency.

E. Healthcare Industry

Healthcare is one of the most significant sectors transformed by the IoT. Applications of the IoT, including wearable health trackers, intelligent beds in hospitals, and remote diagnostic equipment, provide real-time monitoring of patients' vital signs and health status [20]. These technologies allow healthcare workers to act promptly in medical emergencies, improving patient outcomes and lowering hospital readmission rates. For instance, wearables can detect heart rate, oxygen level, and blood pressure and forward this to healthcare professionals to act promptly. Telemedicine platforms made possible by the IoT further allow remote consultation, expanding healthcare reach to remote and underserved populations with the ability to optimize hospital resource utilization.

Aside from patient treatment, IoT enhances healthcare facility operations. Intelligent inventory management systems monitor medical supplies, ensuring vital resources are always on hand and ordering stock automatically when supplies dwindle. Sophisticated IoT-based analytics can anticipate equipment servicing requirements, reducing equipment failure chances during life-saving procedures. IoT-based systems enhance hospital efficiency by streamlining lighting and climate control depending on occupancy, lowering operating costs. In line with FinTech [21], where supportive policies and infrastructure-enabled technology occur across different nations, healthcare IoT implementations rest on the same enabling factors: regulatory support and technology readiness.

III. IoT Key Features and Benefits

The IoT has many features that significantly enhance safety, efficiency, and decision-making in high-risk environments, as Table II outlines. One of the most crucial features is real-time monitoring, which continuously tracks environmental conditions, equipment performance, and human activity. With IoT sensors and devices collecting and transmitting data instantly, organizations can maintain situational awareness, enabling rapid responses to hazards or anomalies. This degree of real-time knowledge, outlined in the table, is precious to avoid accidents and maintain operating continuity. Additionally, remote monitoring capabilities enable experts to monitor operations from remote points, especially valuable in dangerous conditions, as it minimizes the requirement of physical presence and related risks.

TABLE II. KEY IOT FEATURES AND THEIR APPLICATIONS IN HIGH-RISK ENVIRONMENTS

IoT Key Feature	Description	Applications in High-Risk Environments
Real-time monitoring	Continuous tracking of environmental conditions, equipment performance, and human activity through IoT sensors	• Monitoring critical infrastructure like bridges and buildings • Ensuring worker safety in industrial sites • Tracking patient health in real-time in healthcare
Remote monitoring	Overseeing operations from distant locations, reducing the need for physical presence in hazardous environments	• Managing offshore oil rigs from central control rooms • Monitoring construction sites remotely • Supervising hospital operations and patient care from afar
Predictive maintenance	Using data analytics to predict equipment failures and alert operators for proactive servicing	• Maintaining wind turbines and power grids • Preventing machinery breakdowns in manufacturing • Managing medical equipment reliability in hospitals
Data-driven decision-making	Leveraging data analytics and machine learning for informed, strategic decisions	• Optimizing supply chain logistics • Allocating resources efficiently in emergency responses • Streamlining operations in mining and energy sectors
Automation	Dynamic adjustment of processes based on sensor data, reducing the need for manual intervention	• Automating HVAC systems in smart buildings • Controlling robotic operations in hazardous environments • Regulating energy use in factories
Interconnectivity	Seamless data sharing and communication between connected devices and systems	• Coordinating automated vehicle fleets • Synchronizing medical devices in hospitals • Integrating smart home systems for safety and energy management
Enhanced risk management	Early detection of potential threats, such as structural instability or hazardous gas levels	• Monitoring mine conditions for worker safety • Detecting fire hazards in smart buildings • Identifying chemical leaks in industrial facilities

Another vital aspect of IoT is predictive maintenance, which uses analytics to anticipate equipment failure. By consistently monitoring performance statistics, IoT systems can give operators a heads-up on servicing equipment before it fails, reducing repair costs and equipment downtime. It saves resources and makes equipment less likely to cause accidents by preventing breakdowns. Data-driven decision-making, one of the most revolutionary benefits of IoT, enables decision-makers to make strategic decisions based on complete and accurate information. Machine algorithms and advanced analytics accept large amounts of information gathered by IoT devices and provide decision-makers with insights to optimize procedures, enhance efficiency, and enhance risk management.

The automation enabled by IoT is another game-changing feature. Automated systems can adjust processes dynamically based on sensor data, such as controlling climate conditions in a factory, optimizing energy use, or shutting down operations in response to safety threats. This automation reduces the margin of human error and ensures that systems operate efficiently. Aside from these attributes, IoT technologies enable interconnectivity between devices and systems to exchange information freely. On the production floor, IoT networks can coordinate the equipment to provide seamless and efficient processes, while in the healthcare sector, connected devices can transfer patient information to physicians in real-time, facilitating efficient diagnosis and treatment.

Finally, IoT enables better risk management through early threat identification. With round-the-clock monitoring for warning signs, including building structural weaknesses, increased toxic gas levels, etc., the IoT system can avert accidents before they materialize. This aspect is crucial in risk-prone industries, where preemption saves lives and averts catastrophes. These features and advantages highlight IoT's broad influence on modern operations, bringing about safer, more efficient, and less stressful circumstances.

A secure and resilient IoT architecture in high-risk environments usually has a multi-tiered design with perception, network, and application layers. The perception layer consists of intelligent sensors and actuators to gather real-time information on environmental factors, equipment performance, and human behavior. Sensors typically utilize protocols for low-energy transmission, such as Zigbee, LoRa, or BLE. The network layer supports the routing and communication of gathered information using protocols such as IPv6, MQTT, CoAP, or 6LoWPAN to establish secure connectivity in the constrained network. Data gathered is analyzed by edge gateways or servers at the edge layer to minimize latency and support real-time decision-making. Lastly, the application layer supplies upper-level analytics, visualization, and remote control by leveraging platforms that can apply AI/ML algorithms to predictive analytics and anomaly detection. Architectures increasingly utilize fog computing to offload and distribute processing loads between edge and cloud to enhance responsiveness and system resilience for mission-critical operations.

End-to-end encryption, lightweight authentication schemes, and blockchain audit trails ensure the security and integrity of the data. Data flows are typically implemented using publish-subscribe (pub-sub) patterns through MQTT brokers to enable scalable asynchronous communication among a thousand nodes. These design decisions are vital in places like mines, hospitals, or drilling operations on an oil rig, where infrastructure constraints and latency requirements mandate decentralized intelligence and limited dependence on cloud computing.

IoT core capabilities, including real-time data collection, remote monitoring, automation, and predictive analytics, provide the technological foundation to support its successful deployment in high-risk industries. These capabilities do not exist in a vacuum but are incorporated into various domain-dependent architectures and workflows. This section illustrates how the features are applied to real-world solutions in major industries spanning healthcare, manufacturing, mining,

transport, and infrastructure, detailing the special challenges and advantages faced in each.

IV. Domain-Specific Applications of IoT in High-Risk Settings

This section outlines the transformative applications of IoT in high-risk environments, including industrial and health and safety contexts. As illustrated in Fig. 2 and summarized in Table III, IoT enhances real-time monitoring, predictive maintenance, automation, and safety management, significantly improving efficiency, productivity, and individual well-being. In Fig. 3, IoT Safety Cycle in high-risk zones illustrates the process from data collection and analysis to safety alerts and responsive action, forming a continuous feedback loop for hazard mitigation.

Fig. 2. Layered IoT architecture explicitly designed for high-risk environments.

TABLE III. IoT Applications and Benefits in Industrial and Health and Safety Contexts

Application context	IoT implementations	Key benefits
Industrial environments	• Real-time monitoring of machines and production lines • Predictive maintenance for equipment • Smart factory automation • Wearable safety devices (smart helmets, vests) • Remote monitoring and control	• Immediate detection of equipment malfunctions and hazards • Reduced machine downtime and maintenance • costs Improved worker safety and productivity • Automated workflows and optimized resource allocation • Minimized human presence in dangerous zones
Health and safety	• Wearable health monitors for vital signs • Smart hospital rooms for automated patient care • Remote patient monitoring systems • Wearable safety devices with location tracking • IoT-based hazard detection and surveillance systems	• Enhanced patient outcomes with continuous health monitoring • Reduced hospital visits and improved patient convenience • Increased safety in high-risk work environments • Automated emergency alerts and machinery shutdowns • Data-driven risk management and proactive safety measures

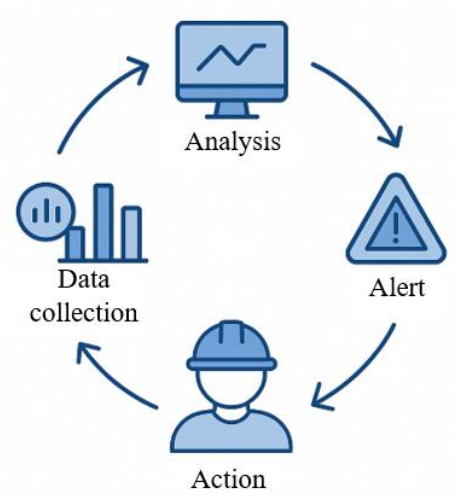

Fig. 3. IoT Safety cycle in high-risk zones.

A. Industrial Environments

Manufacturing and operational functions are being revolutionized by the use of IoT in industrial contexts, also known as the Industrial Internet of Things (IIoT). Real-time monitoring is the most extensive activity through which continuous data from machines and production lines is gathered and sent via sensors. This would mean a constant flow of data for the instant detection of malfunctioning equipment, anomalies in production, and environmental hazards. The information is in real-time, helping the firms avoid accidents and lessen the lost time of machines due to failure. The workers' safety and security will be guaranteed.

IoT can also increase safety in industries. Wearable devices integrated with IoT, like smart helmets and vests, monitor the vital signs of workers operating and the surroundings they are exposed to, thereby alerting them to risks of exposure to noxious gases or conditions featuring unsafe temperatures [22]. Fig. 4 shows an IoT-enabled smart factory featuring robotic arms, predictive maintenance systems, wearable sensors, and cloud-connected operations to enhance safety, monitoring, and efficiency.

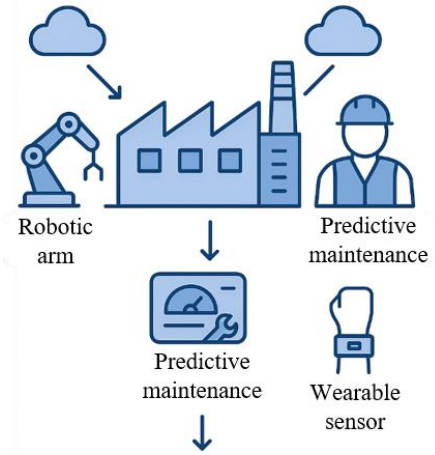

Fig. 4. IoT-enabled smart factory.

Automated safety protocols are initiated immediately to protect workers operating in dangerous areas. Furthermore, this technology allows operators to monitor and control the process remotely, even in hazardous or inaccessible areas of an industrial process. Such a capability reduces human presence in dangerous zones, reducing workplace accidents. As industries move toward IoT-driven automation of manufacturing and smart technologies, the emphases on efficient, safe, and predictive capabilities continue to reshape the manufacturing and operational landscapes, driving vital developments for contemporary industrial development.

B. Health and Safety Contexts

IoT in health and safety contexts will revolutionize protection and well-being from all aspects, from hospitals and construction sites to public spaces. Application to Healthcare in this regard, IoT devices are essential in healthcare, especially in patient monitoring and emergency response areas. Wearable health monitors, such as smartwatches and biosensors, use heart rate, blood pressure, and oxygen saturation updates to continuously monitor a patient's vital signs. If the device detects an abnormal reading, it notifies healthcare professionals to take necessary action via timely intervention that can help improve patient outcomes. The remote monitoring system further allows doctors to keep track of their patients' health outside the confines of the hospitals, thereby curtailing frequent visits and making the process convenient for the patients. The IoT technologies also automate smart hospital room patient care by considering patient needs through automatic light adjustment, temperature, and bed positioning, making the healing environment more efficient and comfortable.

IoT technology significantly improves hazard detection and prevention in workplace safety, particularly in high-risk areas like construction sites and factories. Wearable safety devices contain location tracking and environmental sensors that monitor workers' exposure to extreme temperatures, toxic gases, or noise. Such devices can instantly send alerts or turn off dangerous machinery when unsafe conditions are detected to prevent accidents. The workplace activities are continuously monitored to avoid unauthorized access and hazardous behavior. This again enhances security with IoT-based surveillance systems. The IoT-enabled safety management platforms can also collect and analyze vast amounts of data from various sources, enabling the organization to identify patterns and take necessary steps to mitigate risks effectively. In a nutshell, this information-based approach makes traditional safety protocols active and responsive, with human life being prioritized in real-time, making IoT indispensable in any health and safety application in modern workplaces.

C. Representative Case Studies of IoT in High-Risk Environments

IoT technologies are applied in real-world scenarios to prove their efficiency in risk-prone situations. Bosch Rexroth's German smart factory, for instance, uses thousands of IoT sensors throughout its production lines to support real-time machine monitoring, predictive maintenance, and adaptive automation. This reportedly resulted in a 25% reduction in equipment failures and over 30% less unplanned downtime, highlighting the application of IoT to improve operating

reliability. In the mining industry, Rio Tinto's automated mining activities in Australia use IoT-enabled vehicles and remote-control centers to control equipment in dangerous areas. These autonomous vehicles eliminate human exposure to hazardous conditions, cutting incident rates by 40% while maintaining high productivity via ongoing sensor input and remote control.

Mount Sinai Health System in the US has implemented IoT in its Intensive Care Units (ICUs) through wearables and AI-aided remote dashboards. This has made it possible to constantly monitor and respond to clinician calls immediately, leading to a 20% decline in mortality rates and a 15% reduction in ICU stay length. Malaysia's SMART Tunnel project, too, has been a successful infrastructure-scale IoT implementation, with embedded sensors monitoring rainfall, tunnel conditions, and ventilation to support automated flood control and emergency response. These scenarios reflect the real-world advantages of IoT in terms of enhanced safety, minimized risks, and better decision support in situations where prompt responsiveness in real-time is of the essence.

V. Results

Despite the significant advantages of the IoT, implementing IoT solutions in high-risk environments is challenging.

A. Security Vulnerabilities

One of the most significant concerns is security vulnerabilities. By the nature of the devices, IoT systems comprise an array of interconnected devices communicating and sharing information, leaving them open to cyberattacks. Hackers may target these vulnerabilities to access the systems illicitly, alter information, or bring operations to a halt. For instance, a security lapse in industrial or healthcare environments could be disastrous, ranging from equipment breakdowns to patient information compromise. Maintaining the privacy of the information and integrity of the IoT systems demands maximum security protocols, regular software upgrades, and advanced encryption, a process that could tax resources to deploy and maintain.

B. Interoperability Challenges

IoT systems usually include devices from manufacturers with different communication protocols and standards. This absence of standardization makes it challenging to integrate the devices smoothly, leading to fragmented systems with limited performance. Take, for instance, an intelligent building or connected car ecosystem, where the devices must cooperate in perfect harmony to deliver optimum efficiency and safety. Attaining an acceptable level of interconnectivity takes a lot of work in standardizing the protocols and making compatible technologies, something a constrained organization might not find feasible. Moreover, maintaining interoperability tends to require custom solutions and a lot of coordination among industry players, something likely to slow the rate of IoT uptake.

C. Data Management Complexities

IoT devices produce an enormous amount of data in real-time. Organizations need to be in a position to handle the storage, processing, and analysis of the data in an efficient manner, an undertaking that can be costly and technically daunting. The need to process the data in real-time introduces another level of sophistication because latency in processing will impact decision-making and the functioning of the IoT applications, especially in mission-critical environments like healthcare or mining. Network reliability is equally crucial to the functioning of the IoT systems. Stability and rapid connectivity in remote or risky areas may prove difficult to maintain, resulting in lagging information transfer or system crashes, compromising the efficiency and security of the operations.

D. Skills and Workforce Limitations

Finally, the requirement for significant training and expertise presents a major challenge. Implementing successful IoT solutions demands a trained workforce in IoT technology, analytics, and cybersecurity. There tends to be a skills shortage, where many workers lack the knowledge to maintain and drive IoT systems. This shortage can hinder the uptake of IoT technology and result in inefficient usage or misuse of the systems. Organizations must invest in regular training schemes and embed a culture of ongoing training, which takes time and costs. These issues must be addressed to unlock the potential of the IoT in high-risk situations and ensure IoT solutions are secure, efficient, and sustainable.

Earlier work has extensively discussed the promise of IoT in different domains, including industrial automation, healthcare monitoring, and intelligent infrastructure. For instance, in [1, 2], the authors analyzed the security and intrusion concerns of the IoT setting, whereas researchers in [4, 9] analyzed domain-specific applications in construction and agriculture. Although these works delivered functional sector-wise analyses or technology-oriented views, the works were prone to missing the overall picture of the systemic role of IoT in hostile settings. On the contrary, our work takes a multi-sector approach to collectively analyzing industrial, healthcare, mining, transport, and infrastructure settings. This broader scope of analysis offers a better integrative conclusion of the impact of IoT on safety, operational efficiency, and risk management in the different hazardous domains.

Also, our contribution expands the body of knowledge by explicitly integrating contemporary advancements in edge computing, 5G, blockchain incorporation, and AI analytics, which are usually addressed separately in the related work. For example, the works of [16, 22] highlighted mainly trust and aggregative mechanisms but neglected to relate these technologies to real-world field projects and interdisciplinary concerns. Our work fills the gap by integrating technical analysis with proven case studies and strategy-driven forward thinking. This twofold focus on realistic applicability and forward-looking strategy makes this study a value-added contribution to the scholarly community, as well as a practical deployment approach in security-sensitive domains.

VI. Discussion

The future of IoT in high-risk applications promises exciting developments, as illustrated in Table IV, with new technologies expected to further improve the capabilities of the IoT. One of these developments includes the adoption of 5G technology. The fast speed and low latency of 5G networking will allow real-time information to be transmitted at hitherto unparalleled volumes, increasing the efficiency and dependability of IoT operations.

This development has far-reaching applications in industrial installations or emergency healthcare situations, where instant communication is paramount. With 5G, IoT devices can communicate instantly, facilitating more advanced applications, including automated equipment and advanced remote monitoring solutions with immediate information feedback and decision support capabilities. The increased bandwidth of 5G will further enable larger-scale IoT installations, handling thousands of connected devices without reducing performance.

TABLE IV. CHALLENGES, FUTURE DIRECTIONS, AND INNOVATIVE IDEAS FOR IOT IN HIGH-RISK ENVIRONMENTS

Aspect	Challenges	Future directions	Innovative ideas
5G integration	High cost of infrastructure upgrades	Expanding high-speed and low-latency IoT networks	5G-enabled autonomous machinery for real-time control
AI and machine learning	Complexity in data analysis and model training	Employing AI for predictive insights and automated responses	Self-learning IoT systems for evolving risk scenarios
Robotics and automation	Safety concerns and high initial investment	Increasing automation in hazardous environments	IoT-linked autonomous robots for remote operations
Edge computing	Data security and processing power limitations	Reducing latency and improving real-time decision-making	Energy-efficient edge devices for field deployment
Blockchain integration	Scalability and energy consumption issues	Enhancing data integrity and security	Decentralized platforms for secure data transactions
Advanced sensors	Miniaturization and durability in extreme conditions	Developing ultra-sensitive and compact sensors	Wearable and unobtrusive sensors for continuous monitoring
Energy harvesting	Efficiency and reliability in harsh environments	Researching sustainable power solutions	Self-sufficient IoT systems using ambient energy
AR and VR convergence	High cost and training requirements	Enabling immersive training and real-time guidance	Smart glasses with real-time IoT data overlays
Collaborative platforms	Data interoperability and coordination among stakeholders	Facilitating data sharing for seamless collaboration	Unified IoT ecosystems for disaster management
Regulatory and ethical standards	Privacy, security, and ethical concerns	Developing comprehensive and adaptable regulations	Transparent data usage and ethical AI implementation

Another potential upcoming area includes integrating AI and Machine Learning (ML) with IoT systems. AI and Machine Learning algorithms can process enormous amounts of IoT device-generated data, making predictive analyses and facilitating autonomous decision-making. AI-driven IoT systems, for example, might be able to detect the onset of the progression of a disease, warning healthcare professionals ahead of a patient's deterioration. AI can optimize production in an industrial context by dynamically adjusting operations in real-time based on real-time information, increasing efficiency and security. Machine learning models, in addition, can learn over time, enhancing their predictions and responses to changes in risk. This convergence will result in increasingly adaptive and intelligent IoT systems that anticipate and counteract dangers.

One of the potential areas of development in high-risk IoT applications includes digital twins, especially in the mining and energy industries. Digital twins represent a virtual physical system simulation, utilizing real-time information to mimic and predict equipment and infrastructure performance. Within the mining sector, organizations like BHP and Anglo-American implement digital twin systems to monitor underground drilling machinery, ventilation systems, and structural integrity in real-time. These systems improve predictive maintenance, enabling operators to simulate dangerous situations and experiment with mitigative strategies without risking personnel. This convergence of digital twins with IoT, AI, and edge computing provides a robust framework for risk-aware decision-making, real-time feedback loops, and optimal operations.

Concurrently, prototype testing of theoretical IoT models is emerging as the primary approach to bridging the gap between theory and action. Constructing small-scale test beds or software sandboxes for edge-enabling IoT networks allows practitioners and researchers to test system behavior in realistic scenarios. Low-footprint IoT modules with embedded AI for fault discovery, for example, can be built and tested in controlled industry environments to test for reliability, latency, and scalability. These initiatives guarantee that university models reflect practical limitations and inform deployment strategies in risk-prone environments. Incorporating prototype feedback into design cycles can speed up standards development and enhance acceptance of IoT-based safety systems. Future work must emphasize field validation and intersectoral collaboration to transform conceptual frameworks into workhorse tools.

Technological advancements in sensors and miniaturization will further influence the future of the IoT in hazardous situations. The smaller and more advanced sensors become, the more embedded they can be in previously inaccessible, difficult-to-reach areas, gathering intricate environmental and structural information. Ultra-sensitive sensors, for instance, will better monitor vibrations, structural integrity, and ecological conditions in building and infrastructure management, raising the alarm at the earliest sign of impending failure. Wearable IoT technology will be less obtrusive and comfortable for workers, monitoring safely without interfering with productivity. Miniaturized sensors will notably find widespread application in the healthcare sector, where unobtrusive monitoring solutions will increasingly effortlessly track patient health, even in remote settings.

Energy harvesting is another field that has the potential to revolutionize IoT deployment. Energy-efficient devices that draw power from the surrounding environment, including solar energy, vibrations, or thermal gradients, will become a reality through further research. This will make the systems more energy-effective and self-sustainable. This technology will eliminate the need for battery replacement and increase the effectiveness of IoT applications in deep mining operations and

remote environmental monitoring stations. Energy-efficient systems will minimize operational costs and reduce the environmental impact of large-scale deployments.

The convergence of the IoT with Augmented Reality (AR) and Virtual Reality (VR) can also bring new applications to at-risk environments. AR and VR enable the immersion of workers in dangerous occupations, such as mining or construction, in simulated hazardous situations in a secure, controlled environment. Mapped with real-time information from IoT devices, these technologies can provide situational awareness tools to field workers. They overlay significant information over their line of sight using smart glasses or headsets. A classic example would be an engineer on intricate equipment, who would be provided with real-time instructions and hazard alerts, drastically reducing the risk of accidents and errors. The blend of the two will elevate training, security, and operating effectiveness to a new level, completely revolutionizing the interaction of workers with complex information in ever-changing situations.

Converging AR and VR with IoT will also create new applications in high-risk situations. AR and VR can provide top-notch simulation experiences for operators in hazardous industries, recreating unsafe conditions in a risk-free, controlled space. With real-time monitoring from IoT sensors, these technologies can offer situational awareness solutions for the field worker, projecting critical information outside their line of sight via intelligent glasses or heads-up displays. For instance, real-time guidance and risk notification would be provided to a service engineer working with intricate equipment, reducing accidents and mistakes considerably. This convergence will increase training, security, and operating efficiency by redefining interactions between workers and intricate information in dynamically shifting surroundings.

VII. Conclusion

IoT is a cutting-edge technology with an unparalleled potential to revolutionize risk-intensive industries like healthcare, food chains, mining and energy, connected vehicles, and infrastructure management. IoT greatly enhances operating efficiency and security by enabling real-time monitoring, predictive management, and decision support based on data to overcome the pressing problems of these industries. However, the journey to fully unleash IoT potential is not straightforward. Malicious entities pose a threat, interconnectivity issues create problems, handling information becomes complicated, and the need to extensively train the workforce becomes a significant challenge. Overcome these challenges through continued innovation, collaboration, and the development of robust security and interconnectivity frameworks.

The impact of the IoT will be further magnified by the convergence of advanced technologies, including 5G, AI, robotics, edge computing, and blockchain. These will support intelligent, optimized, and secure systems for special requirements of high-risk environments. As the technologies of the IoT keep improving, a coordinated and responsible approach will be a precondition to unlock potential while ensuring the confidentiality of the information and the reliability of the operations. Ultimately, the potential of the IoT can transform risk management and operations to deliver safer and more resilient conditions, along with a new wave of innovation and effectiveness.

ECOA: An Enhanced Chimp Optimization Algorithm for Cloud Task Scheduling

Yue WANG
Hebei Chemical & Pharmaceutical College, Hebei, 050026, China

***Abstract*—Effective scheduling of tasks is a key concern in cloud computing because it considerably affects system functionality, resource usage, and execution efficiency. The present study proposes an Enhanced Chimp Optimization Algorithm (ECOA) to address such problems by overcoming the disadvantages of traditional scheduling methods. The proposed ECOA combines three innovative components: 1) the highly disruptive polynomial mutation enhances population diversity, 2) the Spearman rank correlation coefficient promotes the refinement of inferior solutions, and 3) the beetle antennae operator facilitates more efficient local exploitation. These changes significantly enhance the equilibrium between exploration and exploitation, decrease the chance of premature convergence, and are a better solution. Extensive experiments on benchmark datasets prove that ECOA outperforms traditional algorithms concerning makespan, imbalance degree, and resource utilization. The obtained results confirm that the proposed ECOA has excellent potential for better performance in task scheduling in dynamic and large-scale cloud environments, as it represents a promising optimization solution for complex problems in cloud computing.**

Keywords*—Cloud computing; task scheduling; resource utilization; chimp optimization

I. INTRODUCTION

Cloud computing has reshaped how computing capabilities are accessed and used, bringing revolutionary expansion, adaptability, and affordability [1]. It enables companies and individuals to dynamically allocate resources to optimize their processes for optimal performance without requiring investment in physical infrastructure [2]. From big data analytics to intricate Internet of Things (IoT) and Artificial Intelligence (AI) systems, cloud computing forms the pillar of contemporary technology platforms. Effective management of these resources is the key for ensuring Quality Of Service (QoS) and optimal system performance during operations [3]. The recent development of AI-powered quality control, including employing a hybrid vision transformer and Convolutional Neural Networks (CNNs) ensembles for industrial defect inspection, exemplifies the revolutionary potential of intelligent computing infrastructures in real-time, high-precision applications [4].

Scheduling tasks in the cloud is one of the biggest challenges since this environment is dynamic, with heterogeneous resources [5]. Scheduling involves mapping incoming tasks to the available resources and must consider many constraints, such as dependencies between tasks, resource capacities, or QoS requirements [6]. Poor resource scheduling leads to inefficient exploitation of resources, prolonged execution of tasks, and increased business expenses [7]. Further complications in large-scale and real-time applications aggravate these challenges, which require innovative ways of handling resource allocation duties [8]. Similar scheduling concerns are also evident in other networked environments, such as LTE-Advanced systems, where dynamic and QoS-aware approaches are essential for optimizing multi-carrier resource allocation and improving user experience [9].

While traditional scheduling methods and heuristic algorithms have widely been put into practice, they still often suffer from such flaws as premature convergence, inefficiency in handling complex solution spaces, and poor adaptability against dynamic cloud environments [10]. Several metaheuristic algorithms proposed in the literature present promising results, but they usually show poor performance regarding the harmony between exploitation and exploration.

Recent studies have highlighted the growing role of machine learning in analyzing complex economic systems and decision-making under uncertainty, further underscoring the need for adaptive and intelligent optimization approaches in dynamic scenarios [11]. Similarly, in smart grid and energy-aware systems, integrating energy storage and photovoltaic solutions has demonstrated the importance of efficient resource management and real-time optimization, reinforcing the relevance of such capabilities in cloud-based scheduling contexts [12]. Despite being efficient, the original version of the Chimp Optimization Algorithm (COA) has deficiencies in population diversity and needs to improve in local optimum; therefore, it cannot guarantee global optimization when tackling a large-scale task-scheduling problem.

To remedy these defects, this study suggests an Enhanced Chimp Optimization Algorithm (ECOA) for cloud computing task scheduling. The enhanced algorithm applies three main strategies: the highly disruptive polynomial mutation strategy to keep the variety in populations, Spearman's rank correlation coefficient for refining less-fit solutions, and the beetle antennae operator for improving local exploitation.

With the integration of enhancements, ECOA gives a better balance between exploitation and exploration, resulting in improved scheduling efficiency and scalability. ECOA obtains promising results in general because many benchmark datasets are used under considerable experiments to establish its great strength in the techniques adopted in task scheduling during this dynamic cloud environment.

The study is structured into four main sections. Section II offers an overview of state-of-the-art task scheduling methods in cloud computing. Section III introduces the proposed ECOA. Section IV includes extensive experimental analysis of standard

benchmarks with a comparison of the performance of the developed algorithm with previous algorithms. Section V critically discusses the practical relevance of the algorithm, behavior over different datasets, and limitations. Section VI concludes the primary results of the study, highlights the scope of the proposed algorithm's potential in large-scale and time-evolving cloud systems, and provide directions for further research.

II. Related Works

Kashikolaei, et al. [13] proposed a hybrid load-balancing algorithm combining Firefly Algorithm (FA) and Imperialist Competitive Algorithm (ICA) to address NP-hard challenges in cloud computing. This enhanced the scheduling speed, load balancing, CPU time, and makespan. The local search capability of FA strengthened the global search capability of ICA and achieved significant improvements in performance metrics.

Velliangiri, et al. [14] suggested a Hybrid Electro Search with Genetic Algorithm (HESGA) for optimizing cloud task scheduling. In local optimizations, the hybrid approach uses the genetic algorithm, and the authors utilize electro-search to calculate optimal global solutions that would improve load balancing, makespan, resource utilization, and cost.

Mangalampalli, et al. [15] developed a Cat Swarm Optimization (CSO) approach for task scheduling to minimize total power cost, energy usage, migration time, and makespan. This approach prioritizes tasks and virtual machines, improving energy efficiency and execution time by considering realistic workload datasets.

Malathi and Priyadarsini [16] proposed a hybrid Lion Optimizer and Genetic Algorithm (LO-GA) for load balancing in cloud environments. The proposed two-stage approach utilized the lion optimizer for the task and virtual machine selection probabilities, whereas the modified genetic algorithm performs the global search. As a result, this hybrid approach significantly improved resource utilization and turnaround time.

Ghafari and Mansouri [17] introduced an Enhanced African Vulture Optimization Algorithm (E-AVOA-TS) for task scheduling in fog-cloud computing. This method guarantees minimum energy usage, makespan, and cost by sending tasks sensitive to latency to fog environments. Simulation tests have been performed on benchmark datasets and have shown the exceptional performance of E-AVOA-TS over existing algorithms.

Abualigah, et al. [18] presented an Improved Jaya Synergistic Swarm Optimization Algorithm (IJSSOA) integrating Levy flight mechanisms to optimize task scheduling. By combining Jaya's exploitation capabilities with SSO's collaborative strategy, the algorithm improved scalability, convergence rate, and outcome, achieving 88% accuracy and a 10% enhancement over the original method.

Boroumand, et al. [19] presented a new methodology to coordinate tasks in cloud computing, leveraging the features of the Synergistic Swarm Optimization (SSO) and Jaya algorithms. In the suggested algorithm, Jaya's exploitation power has been combined with SSO's collaborative approach to optimize the quality of the solution, convergence rate, and scalability.

Despite some interesting advances in the state-of-the-art, as shown in Table I, existing methods have notable scalability, efficiency, and adaptability limitations across different cloud environments. ICA+FA and HESGA, for example, consider only a single objective, such as makespan or load balancing, while they do not consider multi-objective optimizations. Some proposals, however, such as CSO and LO-GA, consider multiple objectives in their optimization but suffer from high computational complexity and limited scalability.

TABLE I. An Overview of Cloud Task Scheduling Methods

Algorithm	Metrics improved	Strength	Weakness
ICA + FA [13]	Makespan, CPU time, load balancing	Combines the global exploration ability of ICA with the local search efficiency of FA, achieving improved scheduling speed and resource utilization.	It requires fine-tuning of parameters for scalability and limited exploration in high-dimensional spaces.
HESGA [14]	Makespan, load balancing, resource utilization	Combines GA's ability to find local optima with Electro Search's global optimization, achieving superior task scheduling performance in multi-cloud environments.	Limited analysis of energy consumption and migration time; performance is dataset-dependent.
CSO [15]	Makespan, migration time, energy consumption	Addresses multiple objectives, including energy efficiency and power cost, using realistic workloads, providing a holistic improvement in task scheduling metrics.	Computational complexity increases with large-scale tasks that require careful parameter adjustment.
LO-GA [16]	Turnaround time, resource utilization	Utilizes lion optimizer for task and VM selection probabilities and a modified GA for global optimization, improving resource allocation and reducing bottlenecks.	High computational resources are needed for hybrid optimization, but there is limited scalability for diverse tasks.
E-AVOA-TS [17]	Makespan, cost, energy consumption	Prioritizes latency-sensitive and latency-tolerant tasks effectively using a fog-cloud hierarchy, achieving superior task scheduling efficiency and energy savings.	Limited exploration of scalability for extremely large-scale systems; complexity in implementation.
IJSSOA [18]	Makespan, convergence speed, scalability	Integrates Jaya and SSO algorithms with Levy flight for robust exploration-exploitation trade-offs, achieving high-quality solutions and fast convergence.	Focuses primarily on benchmark datasets; limited exploration of dynamic real-world task variability.
IJSSOA (Levy Flights Integration) [19]	Makespan, resource utilization, scalability	Balances exploration and exploitation effectively with Levy flights, enabling escape from local optima and providing scalable performance improvements.	Limited emphasis on energy consumption and multi-objective optimization across diverse environments.

Furthermore, algorithms like IJSSOA show exploration-exploitation trade-offs confined to benchmark datasets only and lack robustness for dynamic real-world complexities, including variability in resources and heterogeneity of tasks. To fill these gaps, we propose ECOA, which integrates superior mutation strategies and optimization mechanisms. In this way, the proposed approach will ensure improved scalability, resource utilization, and scheduling efficiency while remaining adaptable to dynamically large-scale cloud environments.

III. PROPOSED METHODOLOGY

A. Problem Formulation

Cloud task scheduling stands for the activity of performing a scheduler for user-defined computational tasks on available physical servers or virtual machines for cloud computing. Scheduling optimizes critical performance indicators, including execution time, resource utilization, and energy efficiency. Due to its complexity and constraints, task scheduling is an NP-hard optimization problem, requiring heuristic and metaheuristic algorithms for effective solutions.

Tasks (T) are defined as a set $T = \{t_1, t_2, \ldots, t_n\}$, where each task t_i is characterized by its computational requirements, execution time, and dependencies. Resources (R) are represented as $R = \{r_1, r_2, \ldots, r_m\}$, each having availability, memory, and processing capacity characteristics. The binary variable x_{ij} indicates whether task t_i is allocated to resource r_j as in Eq. (1):

$$x_{ij} = \begin{cases} 1, & if\ task\ t_i\ is\ assigned\ to\ resource\ r_j \\ 0, & otherwise \end{cases} \quad (1)$$

The goal is to allocate tasks effectively, maintaining balanced resource utilization while meeting performance targets. Task scheduling is constrained by two key factors: dependency and resource. Some tasks depend on others, represented as D_i, a sequence of tasks necessary to be accomplished in advance of t_i starts execution. Resources have finite capacity, denoted as U_j, limiting the simultaneous execution of tasks on a given resource.

The task scheduling problem minimizes several performance metrics, including resource utilization, makespan, and total execution time. Resource utilization ensures the best use of resources by reducing the time spent idling and thus balancing the workloads. The makespan concerns the time from the beginning of the first task to the end of the last task. Total execution time refers to the overall time all tasks take to complete. The entire VM count in the cloud setup is calculated using Eq. (2):

$$h = \sum_{i=1}^{Nph} N_{vmi} \quad (2)$$

where, Nph represents the total number of physical hosts, and N_{vmi} stands for the number of VMs on the i^{th} physical host. The average number of VMs on each physical host is calculated as in Eq. (3):

$$v_{ij} = \frac{1}{N_{vmi}} \sum_{j=1}^{N_{vmi}} 1 \quad (3)$$

The expected completion time for a task k on a VM j is given by Eq. (4):

$$ETC(j_k) = \frac{L_k}{P_j} \quad (4)$$

where, L_k is the length of the task (in millions of instructions), and P_j is the processing performance of VM j. The execution time for all tasks assigned to a VM j is computed using Eq. (5):

$$ET_j = \sum_{k=1}^{N} x(j_k).ETC(j_k) \quad (5)$$

where, $x(j_k)$ is the decision variable indicating task assignment, finally, the makespan is determined as in Eq. (6):

$$Makespan = max(ET_j) \quad (6)$$

Heuristic and metaheuristic algorithms, formulated in an optimization setting, efficiently explore the vast solution space. These algorithms repeatedly evaluate various mappings of tasks to resources, considering constraints to optimize objective functions. The challenge is to find the trade-off between the two objective functions: minimizing makespan and maximizing resource utilization. As the problem scales, dynamic resource availability, and task variability necessitate robust, adaptive approaches to achieve near-optimal solutions within reasonable time frames.

B. Enhanced Chimp Optimization Algorithm

COA is a swarm intelligence-based metaheuristic inspired by the cooperative hunting strategies of chimpanzees. This algorithm divides chimpanzees into four hierarchical roles: attacker, barrier, chaser, and driver, based on their importance in the optimization process. While the original COA has shown promise in solving various optimization problems, it suffers from limited population diversity during initialization and often gets trapped in local optima during the exploitation phase. COA is a metaheuristic inspired by swarm intelligence which is inspired by the cooperative hunting strategies of chimpanzees. In this algorithm, chimpanzees fall into four hierarchical roles based on their importance in the optimization process: attacker, barrier, chaser, and driver.

The original COA has produced promising results for solving different optimization problems. However, it suffers from limited population diversity during initialization and often gets trapped in local optima during exploitation. To overcome these limitations, the Enhanced COA (ECOA) integrates three advanced mechanisms: Highly Disruptive Polynomial Mutation (HDPM), Spearman's rank correlation coefficient, and the Beetle Antennae Operator (BAO). These enhancements improve the balance between exploration and exploitation, ensuring superior optimization performance.

As shown in Fig. 1, in the original COA, the position of the chimp is updated by calculating the weighted average of the contributions from the four roles. The mathematical model for

updating the position of the chimp is given as Eq. (7) and Eq. (8):

$$X_{chimp}(t+1) = \frac{X_1 + X_2 + X_3 + X_4}{4} \tag{7}$$

where,

$$\begin{aligned} X_1 &= X_{Attacker}(t) - \alpha_1 . d_{Attacker} \\ X_2 &= X_{Barrier}(t) - \alpha_2 . d_{Barrier} \\ X_3 &= X_{Chaser}(t) - \alpha_3 . d_{Chaser} \\ X_4 &= X_{Driver}(t) - \alpha_4 . d_{Driver} \end{aligned} \tag{8}$$

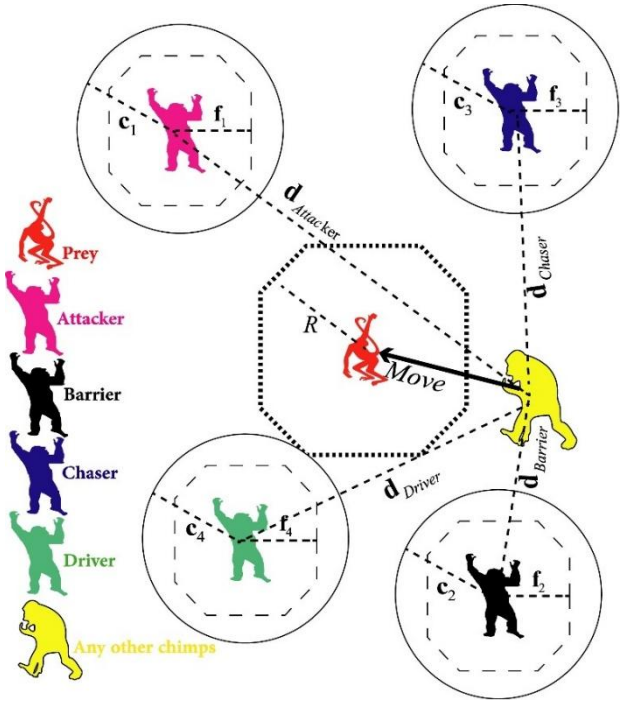

Fig. 1. Position updating in COA

The coefficients $a1$, $a2$, $a3$, and $a4$ represent dynamic adjustment factors that decrease nonlinearly over iterations, while d_{Attacker}, d_{Barrier}, d_{Chaser}, and d_{Driver} are the distances between the chimp and the prey, modeled as in Eq. (9):

$$d_{Attacker} = |c . X_{Attacker}(t) - m . X(t)| \tag{9}$$

where, c is a scaling factor (c=2r_2, with $r_2 \in [0,1]$) and m is a chaotic map vector that introduces randomness to the search process.

The position update ensures that the chimps move collectively toward the global optimum while maintaining role-specific contributions.

HDPM addresses the limitation of population diversity in the initialization phase by enhancing the global exploration capability of the algorithm. Traditional polynomial mutation fails to utilize boundary variables effectively, which HDPM resolves by introducing a mutation operator that can handle boundaries efficiently. The updated position of a chimp X_{new} is calculated as in Eq. (10):

$$X_{new} = X + \delta_k . (ub - lb) \tag{10}$$

where, ub and lb are the upper and lower bounds of the search space, respectively. The mutation factor δ_k is computed using Eq. (11):

$$\delta_k = \begin{cases} [2r + (1-2r).(1-\delta_1)^{\eta_m+1}]^{\frac{1}{\eta_m+1}} - 1, & if \\ 1 - [2(1-r) + 2(r-0.5).(1-\delta_2)^{\eta_m+1}]^{\frac{1}{\eta_m+1}}, \end{cases} \tag{11}$$

This mutation mechanism ensures a diverse initial population, enabling the algorithm to explore the search space more comprehensively in the early stages.

Spearman's rank correlation coefficient (ρ) measures the relationship between the fitness of the attacker chimp (leader) and the driver chimps (followers). The value of ρ determines whether the driver chimps require position updates to enhance their contribution. The coefficient is calculated using Eq. (12):

$$\rho = 1 - \frac{6 \sum d_i^2}{n(n^2-1)} \tag{12}$$

where, d_i is the difference between the ranks of two variables (e.g., attacker and driver fitness), and n is the dimension of the problem. If $\rho \leq 0$, the driver's position is refined using the BAO to prevent stagnation.

BAO enhances local exploitation by simulating the sensory behavior of beetles. The beetle uses its antennae to search left and right areas for better solutions. The search direction is determined using a normalized random vector as in Eq. (13):

$$\vec{b} = \frac{rnd(n,1)}{\|rnd(n,1)\|} \tag{13}$$

The beetle explores the search space using Eq. (14):

$$\begin{aligned} X_r(t) &= X(t) + d(t).\vec{b} \\ X_l(t) &= X(t) - d(t).\vec{b} \end{aligned} \tag{14}$$

where, $d(t)$ represents the step size calculated as in Eq. (15):

$$\begin{aligned} d(t) &= \frac{\delta(t)}{C} \\ \delta(t) &= K.\delta(t-1) \end{aligned} \tag{15}$$

where, K = 0.95 and C = 2. The beetle's new position is updated as in Eq. (16):

$$X(t+1) = X(t) + \delta(t).\vec{b}.sign\left(f(X_r(t)) - f(X_l(t))\right) \tag{16}$$

This mechanism allows the driver chimps to exploit fine-grained while avoiding local optima. ECOA operates through a systematic workflow designed to achieve optimal solutions effectively. The population is initialized using HDPM to ensure diversity within the search space. Chimps are assigned specific roles based on their fitness evaluations, such as attacker, barrier, chaser, or driver. The position updates occur in subsequent steps, starting with calculating Spearman's rank correlation coefficient

(ρ) for driver chimps. If $\rho \leq 0$, the BAO is applied to refine the driver's position, enhancing local exploitation.

The positions of all chimps are updated using role-specific equations to facilitate global optimization. Afterwards, the fitness of all updated positions is reevaluated, and roles are reassigned accordingly. This iterative approach continues until the algorithm converges on an optimal solution or the maximum number of iterations, ensuring a robust balance between exploitation and exploration. Fig. 2 illustrates the proposed algorithm in the form of a flowchart.

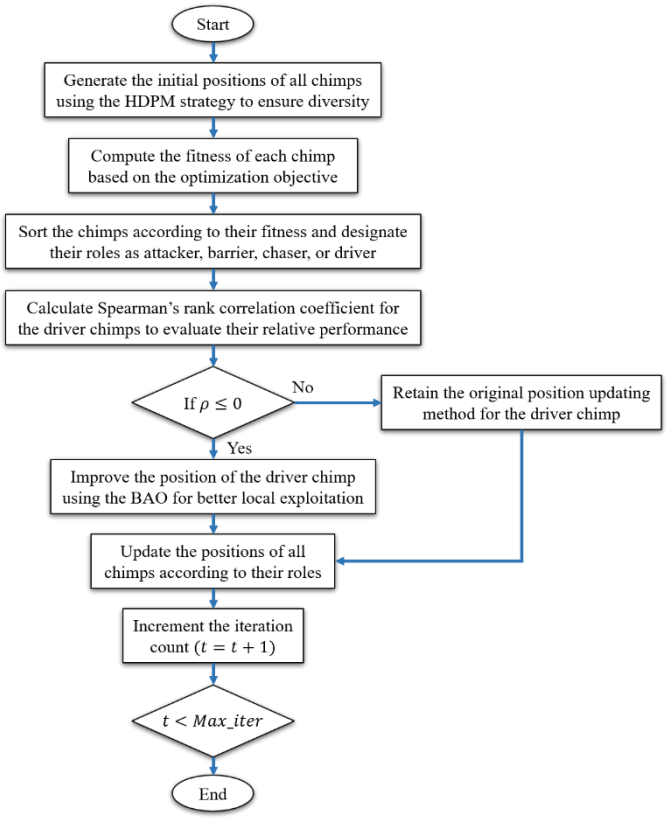

Fig. 2. Flowchart of ECOA.

The integration of HDPM, Spearman's correlation, and the BAO enables ECOA to overcome the limitations of the original COA. The algorithm maintains a better equilibrium between exploration and exploitation, making it more robust for solving complex optimization problems in cloud computing, engineering, and other domains. This comprehensive framework ensures faster convergence, higher solution quality, and adaptability to dynamic environments.

IV. RESULTS

The proposed ECOA was implemented and tested on a system whose specifications are given in Table II. The setup chosen was sufficient to computationally test the performance of ECOA over a wide variety of synthetic datasets. Synthetic datasets were used to evaluate task scheduling performance. Each dataset consisted of tasks from 100 to 500, and task lengths were randomly chosen between 1000 and 2000 MI. Virtual machines had processing capacities from 100 to 1000 MIPS. These datasets provide controlled experimentation under various workloads and resource configurations.

TABLE II. SYSTEM SETUP FOR TESTING THE PROPOSED ECOA

Parameter	Specification
Operating system	Windows 11 64-bit
CPU	Intel(R) Core(TM) i7-3770 @ 3.90 GHz
SDD	240 GB
Memory	32 GB DDR4

ECOA was tested against some state-of-the-art optimization algorithms, namely Geyser-Inspired Algorithm (GIA) [20], Prairie Dog Optimization Algorithm (PDOA) [21], Dwarf Mongoose Optimization Algorithm (DMOA) [22], Reptile Search Algorithm (RSA) [23], and Arithmetic Optimization Algorithm (AOA) [24]. These algorithms' parameter settings are set to the values indicated in their respective source studies.

The most important performance metric in task scheduling is called makespan, referring to the total time taken to execute all the tasks. Fig. 3 depicts the values of makespan for each of the tasks. It can be noticed that the value of makespan rises with the increase in the number of tasks in all algorithms, which reflects an increase in computational complexity and resource demand.

However, ECOA reliably reached lower makespan values than other algorithms and thus showed better efficiency in scheduling. For example, the higher makespan value by algorithms like PDOA and GIA indicated that the scheduling solution was not optimal. AOA-LPO has increased stability, considering a variation of loads.

Fig. 4 depicts the Average Resource Utilization (ARU) over a range of tasks. ECOA maintained high values of ARU, reflecting efficient utilization of computational resources. This remained consistent even with increasing task counts, thus further proving the adaptability of the algorithm to larger workloads. Other algorithms, such as PDOA and DMOA, also maintained relatively stable ARU values, while RSA and GIA exhibited large variances, indicating sensitivity to workload size.

Fig. 5 depicts the Diversity Index (DI), which represents the distribution variety of the tasks. For most practical cases, the value of DI is preferred to be lower when the distribution among resources is even. ECOA had a steady DI for different workloads, indicating the ability to maintain load balance effectively. Other algorithms had varying DI values with increased workload; hence, there was a drop in efficiency while managing task diversity.

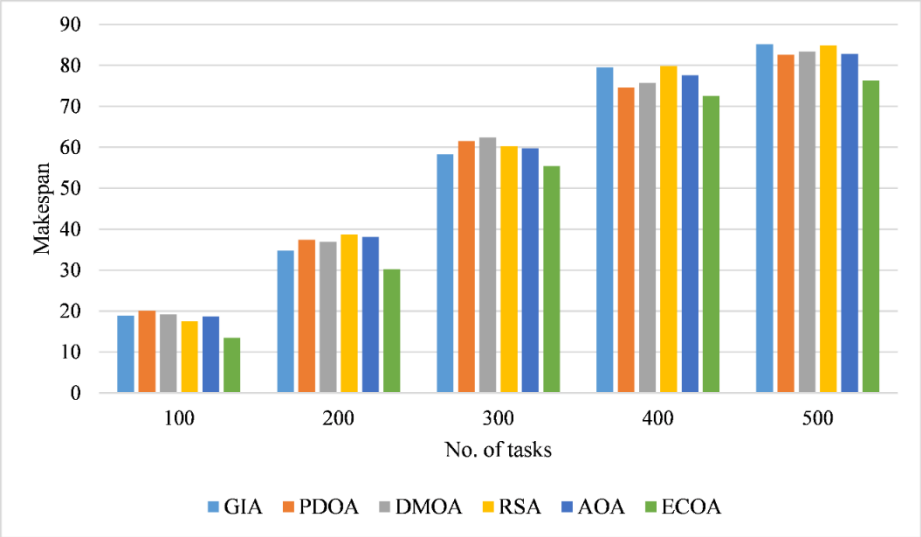

Fig. 3. Makespan comparison

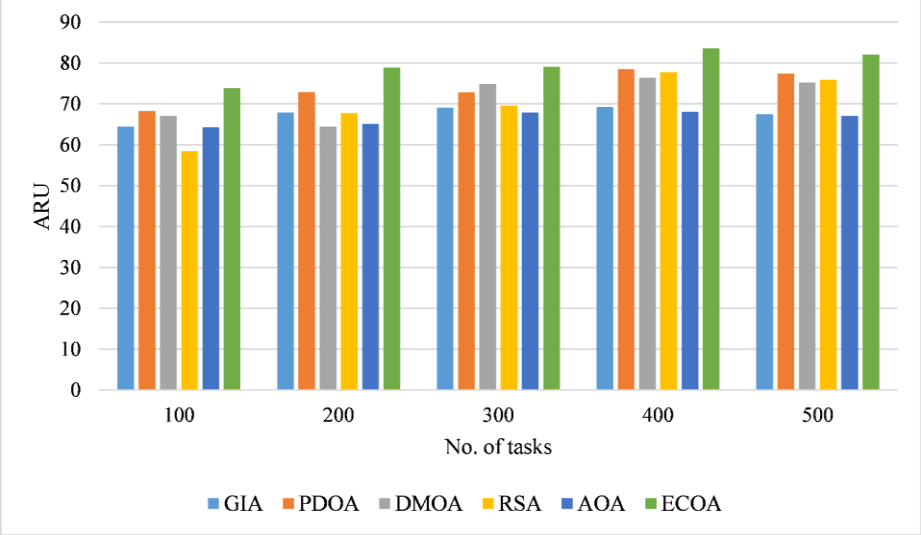

Fig. 4. ARU Comparison

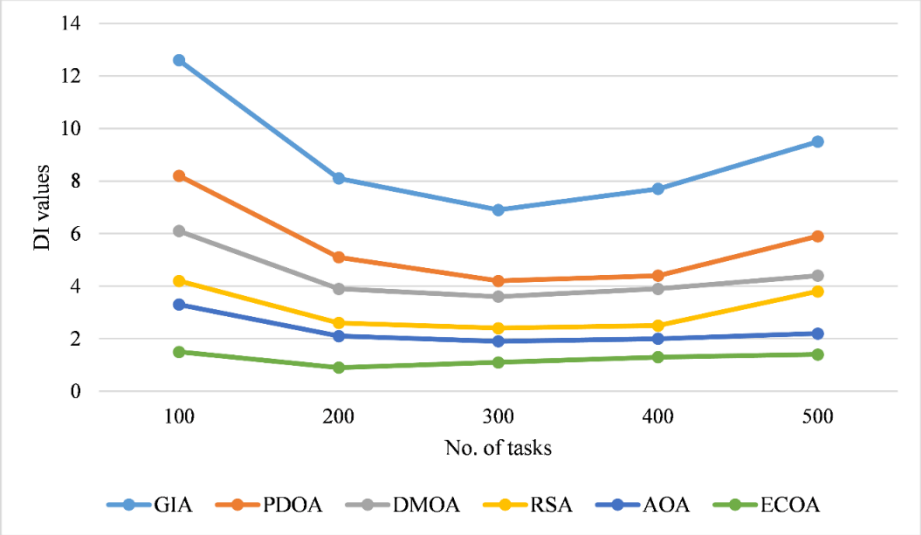

Fig. 5. DI Comparison

V. DISCUSSION

The outcomes demonstrate the effectiveness of ECOA in task scheduling optimization for cloud computing. Through improved makespan, increased resource utilization, and balanced task diversity, ECOA performed better than other algorithms for various workload conditions. Incorporating HDPM, Spearman's rank correlation, and the BAO enabled ECOA to adjust to multiple workload situations while delivering stable performance dynamically.

In addition, the results emphasize the significance of using task scheduling algorithms optimized for a particular workload and resource setup. Although AOA and LPO were effective across workloads, some algorithms, including SSOA and GIA, were workload-sensitive. These observations can inform the design and choice of algorithms for effective cloud resource management.

It is noteworthy that ECOA consistently reduces makespan and optimizes average resource utilization in light and heavy task loads, indicating that it is not tuned to the specific conditions of the dataset but is capable of generalized optimization. On the contrary, enhanced performance becomes even stronger in loads with large task diversity and resource constraints, where the balance between exploration and exploitation becomes paramount. Thus, the proposed algorithm best suits complex, large-scale, and heterogeneous scenarios yet still performs competitively under simpler conditions.

The theoretical contributions made by ECOA directly resulted in practical improvements to cloud computing setups. Cloud computing providers are tasked with efficiently assigning computational resources while satisfying dynamic user demands. If the scheduling of tasks is inefficient, it can result in idle servers, increased power consumption, and failure to fulfill service-level agreements. The proposed method of ECOA overcomes these issues by providing a scalable, adaptive, and low-overhead method that enhances the utilization of resources, minimizes task execution time, and preserves load balance in different intensities of workload. These attributes are highly desired in real-world applications, including multi-tenant data centers, IoT-hardened infrastructures, and edge-cloud hybrid setups since performance degradation in these setups would incur considerable costs in finance and operations. Hence, the theoretical design of ECOA proves to be academically sound and meets practical demands in contemporary cloud computing systems.

Notwithstanding the encouraging performance realized by ECOA, a few limitations should be noted. First, the experimental validations were performed on simulated datasets in a controlled setup, which might not reflect the real-world complexities and variations in cloud environments. Consequently, the algorithm's performance in heterogeneous, time-unpredictable, and large-scale production environments still awaits further confirmation. Second, the implementation focuses mainly on single-objective optimization, aiming for makespan and resource consumption; multi-objective trade-offs, e.g., energy efficiency, service level agreements breaching, or economic cost, were not extensively analyzed.

In addition, while incorporating operators such as polynomial mutation and BAO enhances convergence behavior, the algorithm can introduce some computational overhead in time-sensitive or limited-resource deployments. Future directions must compare ECOA in production of cloud platforms, extend it to multi-objective cases, and analyze its scalability over dynamic loads and different infrastructure setups.

VI. CONCLUSION

This study proposed the ECOA, a new metaheuristic algorithm, to handle cloud computing task scheduling problems. Accordingly, Spearman's rank correlation coefficient, HDPM, and the BAO mechanism were adopted in the ECOA, effectively improving the harmony between exploration and exploitation. The suggested algorithm has been extensively evaluated against some of the latest optimization methods using synthetic data sets and yielded superior results on all key metrics, such as makespan, resource utilization, and task distribution diversity. The experimental results proved that ECOA showed consistently lower makespan values, higher average resource utilization, and stable diversity indices for the increasing workload size.

The dynamic adaptability of ECOA under changing cloud environments brings out its robustness and scalability for effective cloud resource management. ECOA delivers an effective and scalable framework for optimizing task scheduling in cloud computing. Further extension can be done by its application on real-world datasets and finding its performance in multi-objective optimization problems like minimizing energy consumption along with the time of execution of tasks. Exploring various directions for integrating ECOA within a distributed and edge computing environment would also be exciting.

***Abstract*—Effective load balancing in cloud computing architectures is crucial towards enhancing resource utilization, response times, and stability in the system. The present study proposes a new strategy with a Particle Swarm Optimization algorithm enhanced with Modified Crowding Distance (PSOMCD) to tackle task scheduling among Virtual Machines (VMs) in dynamic scenarios. The traditional PSO algorithm is supplemented by an enhanced crowding distance mechanism by PSOMCD to improve diversity in decision spaces and convergence to optimal solutions. The multi-objective fitness function addresses principal challenges in cloud computing, including load distribution, energy consumption, and throughput optimization. The performance of the algorithm is demonstrated in simulations, comparing its performance with other optimization techniques available in the literature. Results prove that PSOMCD provides better task allocation, improved load balancing, and decreased energy usage, thus effectively managing resources in dynamic and heterogeneous cloud ecosystems.**

***Keywords*—Cloud computing; load balancing; particle swarm optimization; crowding distance; task allocation**

I. INTRODUCTION

A. Background

Cloud computing is a revolution in modern computing that offers scalable, flexible, and economical access to computing resources such as processing power, storage, and applications via the internet [1]. It enables on-demand service hosting without investing in or managing physical infrastructure [2]. At the heart of cloud systems are large-scale data centers that consist of several Virtual Machines (VMs) that execute incoming tasks from users and applications [3]. As the need for cloud services grows staggeringly, delivering optimal performance and high availability becomes increasingly important [4]. Efficient load balancing is one of the most vital components in ensuring this, and it evenly splits workloads across available VMs to prevent bottlenecks and increase overall resource utilization [5].

Inefficient load balancing in cloud computing causes drastic performance degradation in the form of overloading of VMs, underutilization of resources, high energy consumption, and task execution delays [6]. Such load imbalances degrade the Quality of Service (QoS) and result in high operational expenditures and energy waste in data centers. Traditional load balancing techniques are inefficient in tackling the dynamic and heterogeneous nature of cloud workloads [7]. Due to the conventional load balancing methods being inefficient in handling the heterogeneous and dynamic nature of cloud workloads, meta-heuristic algorithms can resolve such complex optimization issues [8]. Their efficacy in successfully exploring high and nonlinear search spaces has made them highly suited to dynamic load balancing in contemporary cloud computing settings.

Machine learning techniques have been widely adopted across diverse fields, including business economics, to analyze and predict the impact of various influencing factors using models such as regression, decision trees, support vector machines, and neural networks [9, 10]. Similarly, hybrid meta-heuristic frameworks, such as GA-PSO, have effectively addressed multi-objective optimization problems in complex infrastructures like microgrids, where technical and economic factors must be balanced simultaneously [11]. These advancements underscore the adaptability and robustness of intelligent algorithms in managing dynamic resource allocation scenarios, including cloud environments.

B. Challenges in Cloud Load Balancing

Cloud computing setups are dynamic, distributed, and heterogeneous. The tasks arrive unpredictably, the resource demands evolve, and VMs vary in capacities and workloads [12]. The intrinsic complexity makes load balancing a non-trivial issue, as it must adapt to changing conditions continuously in real-time. Additionally, cloud resources are distributed over multiple data centers and networks, and, as a result, centralized coordination becomes more complex [13]. The task distribution in this distributed system should involve wise mechanisms capable of responding to changing workloads in real-time and considering resource availability and performance variability [14].

The second major challenge of load balancing in clouds is its multi-objective nature. The balancing strategy must balance the workload evenly, reduce makespan (total duration to finish all the jobs) and energy usage, and provide assurance for Service-Level Agreements (SLAs). Conventional algorithms, i.e., static heuristics or basic PSO, typically fall short in such environments because of their weak adaptability and premature convergence to poor-quality solutions [15]. Static methods cannot conform to dynamic workloads in real-time, while basic PSO may not maintain diversity in complex search spaces, leading to inefficient VM utilization. Therefore, more intelligent and adaptive algorithms are needed to overcome such limitations,

particularly those that can deal with multiple objectives and dynamic constraints concurrently.

C. Role of Meta-Heuristic Algorithms

Meta-heuristics are proposed as viable substitutes for complicated optimization problems in cloud computing, where conventional algorithms cannot deliver the scalability and flexibility as requirements [16]. One of many possibilities among these alternatives is Particle Swarm Optimization (PSO), a popular population-based search methodology inspired by birds' flocking or fish schooling behaviors. Every particle in PSO is a potential solution and searches through the space by changing its position based on individual and collective experience. The cooperation strategy allows PSO to effectively search and explore the solution space, making it a suitable candidate for dynamic load balancing in cloud computing.

However, standard PSO suffers from multimodal and multi-objective optimization challenges, e.g., those encountered in cloud task scheduling [17]. It can converge prematurely to local optima or lose diversity in solutions, mainly when dealing with complex or high-dimensional spaces. Advanced variants of PSO have been proposed to counter these flaws. One of those add-ons consists of the Modified Crowding Distance (MCD) mechanism. MCD aims to estimate decision and objective space solution density more accurately to improve solution diversity and pull the swarm away from local optima. With MCD, PSO becomes more robust and capable of simultaneously delivering convergence and diversity multiple objectives.

D. Contributions of the Study

This study discusses a new application of Modified Crowding Distance-based Particle Swarm Optimization (PSOMCD) to overcome challenging load balancing on cloud computing platforms. The new approach successfully balances exploration and exploitation to enable the algorithm to explore sufficiently while converging solutions to optima. In contrast to conventional PSO or static heuristics, PSOMCD can discover multiple high-quality task-VM mappings by maintaining solution diversity throughout optimization. Consequently, it's very suitable in dynamic and multimodal clouds, where workload distributions and resource conditions keep changing and require adaptable and robust scheduling methods.

The significant contributions of this research are: 1) the creation and deployment of a meta-heuristic methodology using PSOMCD for dynamic cloud load balancing, 2) the definition of an overall multi-objective fitness function that considers load variation, makespan, and energy consumption, and 3) rigorous performance comparison of the proposed algorithm through simulation-based experiments with traditional load balancing methods. The experiments validate that PSOMCD significantly improves VM load balancing, reduces energy consumption, and increases system throughput considerably. This study describes the first integration of PSOMCD with cloud computing, with new opportunities opening up in large-scale distributed computing system resource optimization.

The rest of the present study is arranged in the following manner: Section II reviews existing literature on task scheduling and load balancing techniques in cloud computing. Section III formalize the problem. Section IV presents the PSOMCD algorithm, detailing the modifications to the traditional PSO and introducing the crowding distance mechanism. The experimental setup, simulation results, and performance comparisons with other existing optimization algorithms are presented in Section V. Section VI discusses the implications of the findings, algorithm strengths, and potential limitations. Section VII summarizes the contributions of the study.

II. Related Work

Negi, et al. [18] developed a hybrid dynamic load balancing algorithm called CMODLB by combining supervised (artificial neural network), unsupervised (Bayesian optimization-based enhanced K-means clustering), and soft computing (interval type 2 fuzzy logic system) methods. The underloaded and overloaded clusters are created by initially partitioning VMs into clusters. Scheduling of user tasks is performed with a multi-objective TOPSIS-PSO algorithm to achieve effective workload balance.

Sefati, et al. [19] proposed a Grey Wolf Optimization (GWO)-based algorithm to improve load balancing through an assessment of resource reliability. The solution determines idle or busy nodes in the cloud infrastructure, measures individual thresholds for each node, and determines fitness functions accordingly. Evidence from CloudSim shows tremendous improvements in response times and overall cost-effectiveness concerning other methods.

Neelakantan and Yadav [20] introduced a Hybrid Krill Herd and Whale-based Deep Belief Neural Model (HKHW-DBNM) for cloud load balancing. The algorithm dynamically estimates loads between VMs and allocates tasks to balance resource usage optimally. It achieves multiple objectives, such as makespan optimization, resource usage improvement, and a decrease in load imbalance.

Kaviarasan, et al. [21] suggested a nature-inspired lion optimization algorithm with an enhanced solution approach to effectively handle load balancing in cloud computing. Intending to balance workload distribution, the approach enhances throughput and response time with fault tolerance and minimum task migration overhead. The algorithm performs better by balancing exploration and exploitation potential, preventing convergence to local optima.

Singhal, et al. [22] suggested a rock hyrax algorithm resolving local optimum issues and energy consumption in load balancing. Utilizing meta-heuristic methodologies, this process adjusts workload dynamically based on QoS measures. Experimentations reveal that the proposed approach minimizes makespan and energy significantly compared to conventional scheduling methods. Results highlight its viability towards achieving optimum resource allocation, better energy efficiency, and better system robustness under diverse workload scenarios.

Hayyolalam and Özkasap [23] proposed the CBWO algorithm by merging chaos theory with black widow optimization to address cloud load balancing. The method balances resource usage and energy consumption, with evaluation performed using CloudSim. Experimental results show significant makespan and energy consumption improvements compared with other meta-heuristics. The CBWO algorithm improves system performance by balancing

computational loads and reducing energy in dynamic cloud settings.

Hussain, et al. [24] introduced the Dynamic Enhanced Resource-Aware Load Balance Algorithm (DE-RALBA), fully considering VM computing powers to counteract load imbalance. Through its implementation and validation using standard datasets on CloudSim, DE-RALBA surpasses state-of-the-art load balancing algorithms with a remarkable improvement in resource utilization and makespan reduction. Findings demonstrate that DE-RALBA exhibits a significant performance gain, achieving optimum resource utilization in dynamically scheduled high-performance computing tasks.

Haris and Zubair [25] introduced a hybrid Battle Royale Deep Reinforcement Learning (BRDRL) algorithm based on Deep Reinforcement Learning and Battle Royale Optimization methods. The hybrid approach identifies the optimum underloaded VMs based on BRO and uses DRL to achieve efficient job transfer with consideration of cost-effectiveness, load balancing, and makespan minimization. Through experimental investigations using CloudSim simulation, higher throughput, response times, and makespan performance are achieved compared with state-of-the-art optimization-based load balancing algorithms.

Although different meta-heuristic and hybrid algorithms have tried to address load balancing in cloud computing, specific critical gaps persist, as highlighted by Table I. Existing methods are primarily unable to achieve an appropriate trade-off between exploration and exploitation for high variability and heterogeneity in clouds. Algorithms with a single objective or too much dependency on classic heuristics also suffer from issues of early convergence, local optima, or lack of diversity in solution space exploration.

Moreover, attempts by prior research are seldom directed towards maintaining multiple optimum solutions under dynamically changing conditions, as needed in task allocation under varying conditions. This study fills the gaps using the PSOMCD algorithm. The algorithm improves convergence and diversity, effectively handles multiple criteria for optimization (load deviation, energy usage, makespan), and adapts robustly to clouds, thereby contributing a new and all-encompassing solution towards balancing cloud loads.

TABLE I. COMPARATIVE ANALYSIS OF LOAD BALANCING ALGORITHMS

Reference	Considered algorithm	Performance metrics	Advantages	Disadvantages
[18]	Artificial neural network, Bayesian optimization-based enhanced K-means clustering, and interval Type 2 fuzzy logic system	Makespan, completion time, and resource utilization	Combines multiple hybrid techniques for optimized VM migration and resource utilization.	Computationally intensive due to algorithm complexity.
[19]	Grey wolf optimization	Response time and cost	Simple and effective at reducing response time and operational costs.	Risks premature convergence due to limited diversity.
[20]	Hybrid krill herd and whale-based deep belief neural model	Makespan, resource usage, and degree of imbalance	Efficiently balances load with strong multi-objective capabilities.	Parameter tuning is complex and computationally heavy.
[21]	Bio-inspired lion optimization	Throughput, response time, and task migration overhead	Effectively balances exploration-exploitation, reducing migration overhead.	Sensitive to initial parameters, affecting performance stability.
[22]	Rock hyrax	Makespan and energy consumption	Optimizes energy use while efficiently avoiding local maxima.	Limited scalability and reduced exploration under heavy loads.
[23]	Black widow optimization	Makespan, energy consumption, and resource utilization	Improves multiple metrics simultaneously with effective energy and resource optimization.	High computational complexity and sensitive parameter settings.
[24]	Dynamic enhanced resource-aware load balancing	Resource utilization and makespan	Significantly enhances resource utilization through dynamic scheduling.	Real-time monitoring increases computational overhead.
[25]	Battle royale deep reinforcement learning	Throughput, response time, and makespan	Integrates reinforcement learning for adaptive, efficient load balancing.	Complexity and high computational cost due to deep learning training.

III. PROBLEM FORMULATION

Cloud computing environments comprise numerous VMs, each responsible for efficiently scheduling and balancing tasks across available resources. Consider a set of VMs, $M = \{m_1, m_2, \ldots, m_m\}$, each characterized by multiple resources, including CPU, memory, disk, and bandwidth. Each VM request can thus be depicted as a multi-dimensional vector, representing resource load in each dimension. The cloud environment includes several homogeneous servers managed by a central server responsible for processing VM requests. Servers accept incoming VM requests if sufficient memory resources are available, generating corresponding VMs to accommodate these tasks. Given n independent tasks to execute on m available VMs, a scheduler is required to optimally allocate tasks, maintaining balanced resource utilization and maximizing accepted requests.

To evaluate VM loads, consider user parameters represented by $U(RM, RCPU, RS, RPHPU, C)$, where RM indicates memory requirements, RCPU represents required CPU resources, RS is the request size, RPHPU denotes requests per user group timestamp, and C signifies requests per minute. Resource allocation across VM groups leads to the computation of memory load (LM^i) for each VM i, given by Eq. (1):

$$LM^i = RM^i + \frac{V_{m_{pi}}}{V_{m_{mi}}} \times 100\% \quad (1)$$

where, $V_{m_{pi}}$ and $V_{m_{mi}}$ represent the available and total memory percentage in VM i, respectively, and RM^i denotes the remaining memory before task allocation.

Similarly, the CPU load (LC^i) is computed using Eq. (2):

$$LC^i = RC^i + \frac{V_{m_{ci}}}{V_{m_{mi}}} \times 100\% \tag{2}$$

where, $V_{m_{ci}}$ and $V_{m_{mi}}$ signify the available CPU capacity and total CPU in VM i, and RC^i denotes remaining CPU resources.

Combining memory and CPU load yields the overall VM load, calculated using Eq. (3):

$$OL^i = \alpha \times LM^i + \beta \times LC^i \tag{3}$$

With weighting factors α and β, satisfying $\alpha + \beta = 1$. The overall load on each host server j is computed by summing the VM loads as follows, using Eq. (4):

$$LH^j = \sum_{i=0}^{m_j} OL^{ji} = \sum_{i=0}^{m_j} \alpha \times LM^{ji} + \beta \times LC^{ji} \tag{4}$$

Where m_j denotes active VMs on host j. The mean load across all physical hosts p in the cloud network is determined using Eq. (5):

$$\begin{aligned} AL &= \frac{\sum_{j=0}^{p} LH^j}{p} = \frac{\sum_{j=0}^{p}\sum_{i=0}^{m_j} OL^{ji}}{p} \\ &= \frac{\sum_{j=0}^{p}\sum_{i=0}^{m_j}(\lambda_1 \times LM^{ji} + \lambda_2 \times LC^{ji})}{p} \end{aligned} \tag{5}$$

Thus, the first objective fitness function, capturing the absolute difference in load across hosts, is expressed using Eq. (6):

$$F_1 = \sum_{j=0}^{p} \left| LH^j - AL \right| \tag{6}$$

The second fitness function addresses energy consumption (EC) and makespan (MS). Energy consumption is calculated based on the active and idle states of each VM, while makespan represents the maximum completion time among all VMs. Given the task assignment, the binary variable U_{ij}, the execution time T_j for each VM j is calculated as follows, using Eq. (7) and Eq. (8):

$$U_{ij} = \begin{cases} 1, & if\ T_i\ is\ assigned\ to\ VM_j \\ 0, & otherwise \end{cases} \tag{7}$$

$$T_j = \sum_{i=1}^{n} U_{ij} \times TC_{ij} \tag{8}$$

where, TC_{ij} is the completion time of the i^{th} task on VM j is computed using Eq. (9):

$$TC_{ij} = \frac{L_i}{PS_j} \tag{9}$$

where, L_i denotes the length of task i in Million Instructions, and PS_j is the processing speed of j^{th} VM. The makespan measures the total execution time across all VMs calculated as follows, using Eq. (10):

$$MS = Max(T_j),\ \ 1 \le j \le m \tag{10}$$

The total energy consumption for each VM j is computed using Eq. (11):

$$F_2 = EC = \sum_{j=1}^{m} \left[\left(T_j \times \varepsilon_j + \left(MS - T_j \right) \varpi_j \right) \right] \times PS_j \tag{11}$$

where, ε_j and ϖ_j represent the energy (joules/Millions of Instructions) consumed in active and idle states, respectively.

The third fitness function calculates delay cost, calculated from the number of tasks received and processed in the cloud network using Eq. (12):

$$F_3 = \alpha_1 \times \frac{NIPT_i}{MNIPS} + \alpha_2 \times L_i \tag{12}$$

where, $NIPT_i$ is the number of instructions per task, $MNIPS$ is the processing unit's instructions per second, and L_i is the estimated penalty cost for delayed tasks. Weights α_1 and α_2 typically take values of 0.7 and 0.3, respectively.

The final weighted objective function integrates these three objectives into a weighted optimization problem as follows using Eq. (13):

$$F = \beta_1 \times F_1 + \beta_2 \times F_2 + \beta_3 \times F_3 \tag{13}$$

where, β_1, β_2, and β_3 are weight factors representing load balancing, energy efficiency, and delay cost importance, respectively. For optimization purposes, these weights are often set equally ($\beta_1 = 1, \beta_2 = 0.5, \beta_3 = 0.5$), ensuring balanced prioritization of all criteria. Thus, optimal load balancing is achieved by diminishing the combined fitness function according to predefined criteria weights.

IV. PROPOSED ALGORITHM

To effectively address the cloud computing load balancing problem, this study proposes a novel PSO algorithm enhanced by the MCD approach. The PSOMCD algorithm aims to optimally distribute tasks across VMs by considering multiple objectives: balancing resource utilization, reducing makespan, and minimizing energy consumption. The core innovation of PSOMCD is introducing an MCD mechanism combined with non-dominated sorting, thereby overcoming the limitations of conventional crowding distance measures. In traditional Crowding Distance (CD), crowding evaluations between solutions can be misleading due to inaccurate neighborhood identifications. Therefore, the proposed MCD strategy integrates an Affinity Propagation Clustering (APC) method, ensuring solutions with identical dominance levels are accurately grouped. For each solution i, crowding distances in the decision and objective spaces ($CD_{i,x}$ and $CD_{i,f}$) are calculated precisely, ensuring true proximity-based diversity using Eq. (14) and Eq. (15):

$$CD_{i,x} = \frac{|x_{i-1,1} - x_{i,1}| \cdot |x_{i,1} - x_{i+1,1}|}{\left(max|x_{i,1} - x_{i+1,1}|\right)^2} + \frac{|x_{i-1,2} - x_{i,2}| \cdot |x_{i,2} - x_{i+1,2}|}{\left(max|x_{i,2} - x_{i+1,2}|\right)^2} \quad (14)$$

$$CD_{i,f} = \frac{|f_{i-1,1} - f_{i,1}| \cdot |f_{i,1} - f_{i+1,1}|}{\left(max|f_{i,1} - f_{i+1,1}|\right)^2} + \frac{|f_{i-1,2} - f_{i,2}| \cdot |f_{i,2} - f_{i+1,2}|}{\left(max|f_{i,2} - f_{i+1,2}|\right)^2} \quad (15)$$

The MCD value for each solution is finalized based on a comparative assessment with average crowding values as follows, using Eq. (16):

$$MCD_i = \begin{cases} max\left(CD_{i,x}, CD_{i,f}\right), & if\ CD_{i,x} > CD_{avg,x}\ or\ CD_{i,f} \\ min\left(CD_{i,x}, CD_{i,f}\right), & otherwise \end{cases} \quad (16)$$

Next, the algorithm adopts a cosine similarity-based elite selection method to determine elite solutions from an External Archive (EXA), enhancing decision-space diversity. Initially, the external archive selects candidate elite solutions from non-dominated groups based on top MCD rankings. The optimal neighborhood solution $Nbest_i$ for a given particle is chosen through a cosine similarity-based tournament selection, defined as follows, using Eq. (17):

$$cos(A, B) = \frac{A.B}{|A| \times |B|} \quad (17)$$

Solutions with higher cosine similarity exhibit stronger directional relationships in the decision space, effectively preserving solution diversity and preventing clustering in local areas.

Finally, an offspring competition mechanism is introduced to prevent premature convergence further and maintain an effective exploration-exploitation balance. A candidate sampling set is created, consisting of the global best solution ($Gbest(t)$), historical best ($Pbest_i(t)$), and neighborhood optimal solution ($Nbest_i(t)$) using Eq. (18):

$$\text{sampleSet}_i(t) = [Gbest(t), Pbest_i(t), Nbest_i(t)] \quad (18)$$

Offspring particles are then generated through Gaussian sampling and mutation processes, calculated using Eq. (19):

$$O_i(t) = \mathcal{N}\left(\text{mean}\left(\text{sampleSet}_i(t)\right), \text{std}\left(\text{sampleSet}_i(t)\right) + \varepsilon\right) \quad (19)$$

The mutation may further diversify the offspring particles when a random number is lower than a predefined mutation probability (rm = 0.01) using Eq. (20):

$$O_i^d = x_{min}^d + rand.\left|x_{max}^d - x_{min}^d\right|, \ if\ rand < rm \quad (20)$$

where, x_{min}^d and x_{max}^d represent boundary conditions in the search space dimensions relevant to VM resource capacities.

By integrating these strategic mechanisms, PSOMCD effectively navigates complex decision-making and objective spaces. Consequently, it provides an efficient, robust solution for the multi-objective load balancing optimization problem formulated in cloud computing environments. Algorithm 1 presents the pseudocode of the proposed algorithm.

Algorithm 1 Pseudocode of PSOMCD

Inputs: Population P, population size ($popsize$), maximum iterations (T_{max})
Output: Optimal solution set stored in the External Archive (EXA)
Step 1: (Initialization)
Generate the initial population $P(0)$ randomly and evaluate each individual's fitness.
Step 2: (Archive preparation)
Initialize Personal Best Archive (PBA) and EXA.
For each individual i in the population, set $PBA(i)$ to the initial individual $P_i(0)$.
Initially set the external archive: $EXA = P(0)$
Step 3: (Main loop - iterative process)
For iteration $t = 1,2,\ldots,T_{max}$:
a) (Ranking and MCD calculation)
Assign non-dominated ranks and compute the MCD values for individuals in EXA using non-dominated sorting and MCD calculation.
Identify the global best individual G$best(t)$ as the top-ranked individual from the sorted EXA.
b) (Update global best)
If $t = 1$, explicitly perform the non-dominated sorting on EXA and select the first individual from sorted EXA as the initial global best G$best(1)$.
c) (Particle update)
For each individual i in the population (from 1 to $popsize$):
Update P$best_i(t)$ as the top-ranked individual from sorted $PBA(i)$.
Select neighborhood best N$best_i(t)$ from EXA using cosine similarity-based elite selection.
Update particle $P_i(t+1)$ positions and velocities according to PSO updating rules and then evaluate their fitness.
d) (Offspring generation and competition)
Generate offspring particles through the offspring competition mechanism, applying Gaussian sampling and mutation operations.
Evaluate offspring particles $O_i(t)$.
e) (Archive updates)
Add updated individuals $P_i(t+1)$ and offspring $O_i(t)$ into their respective personal best archives.
Recalculate non-dominated ranks and MCD values for each individual within $PBA(i)$.
f) (External archive and global best update)
Integrate current population $P(t+1)$ and offspring $O(t)$ into EXA.
Perform non-dominated sorting and recalculate MCD values for all solutions in EXA.
Update G$best(t+1)$ from sorted population $P(t+1)$.
Retain only the top $popsize$ individuals in EXA to ensure a controlled archive size.

Step 4: (Termination)
The process repeats until $t + T_{max}$, returning the final set of optimal solutions stored in EXA.

V. RESULTS

The effectiveness of the PSOMCD algorithm was tested using CloudSim 3.0.3, running on a computing platform comprising an Intel Core i7 processor, 8 GB RAM, a CPU at 3.4 GHz, and Windows 10 OS. Table II illustrates the simulation setup for the experiments. Two basic simulation scenarios were employed to verify the performance of the algorithm: first, by maintaining the VMs as a constant parameter equal to 100 (virtual running over 10 processors) and increasing the tasks incrementally up to 2000 in intervals of 50; second, by maintaining the task as a constant parameter equal to 1000 and changing VMs as a parameter between 10 and a maximum of 100 in intervals of 50.

Several performance indicators were utilized to analyze the PSOMCD algorithm in detail, such as makespan, energy utilization, standard deviation (representing load balance), throughput, the number of migrated tasks, task idle time, imbalance degree, and the time taken by VMs. As shown in Table III, the weightage of the fitness value was determined by practicing various values corresponding to the objective function.

TABLE II. DETAILS OF THE SIMULATION SETUP

Component	Quantity	Parameter	Specification
Hosts	20	Number of cores	6
		VM Monitor	Xen
		Bandwidth	15 GB/s
		RAM	16 GB
		Storage	4 TB
		MIPS	177,730
Virtual machines	10-100	VM monitor	Xen
		Number of processing elements	1
		Bandwidth	10GB
		Memory	1 GB/s
		Processor speed	9725 MIPS
Data center	1	Cost per storage unit	0.001
		Cost per memory unit	0.05
		Base cost	3
		VM monitor	Xen
		Operating system	Linux
		Architecture	X86

TABLE III. IMPACT OF WEIGHT PARAMETERS ON LOAD BALANCING PERFORMANCE

Weights			Performance metrics and convergence efficiency			
β_1	β_2	β_3	Energy consumption (KJ)	Standard deviation	Throughput (req/ms)	Makespan (ms)

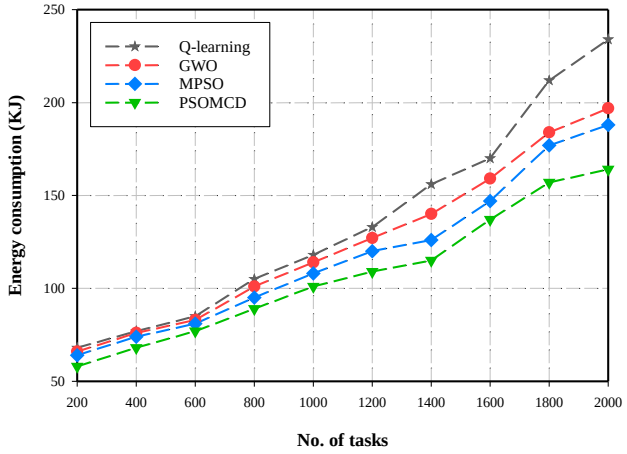

Fig. 1. Energy consumption with varying number of tasks for a fixed VM count

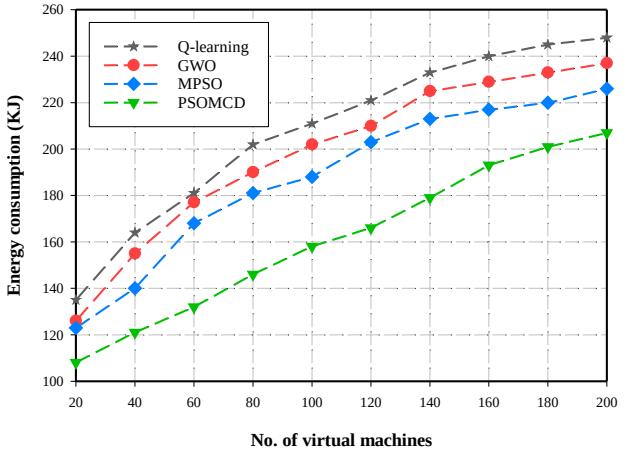

Fig. 2. Energy consumption with varying VMs for a fixed task count

Simulation results represented in Fig. 1 and Fig. 2 indicate that the PSOMCD algorithm requires less power than Q-learning, GWO, and MPSO algorithms in the execution of load balancing operations. Comparative figures for the makespan (response time) shown in Fig. 3 and Fig. 4 illustrate the efficiency of PSOMCD in the reduction of time taken for computation operations, thus enhancing the QoS provided by the system. Consequently, the findings present evidence of improved stability and performance by PSOMCD when computation workloads are balanced.

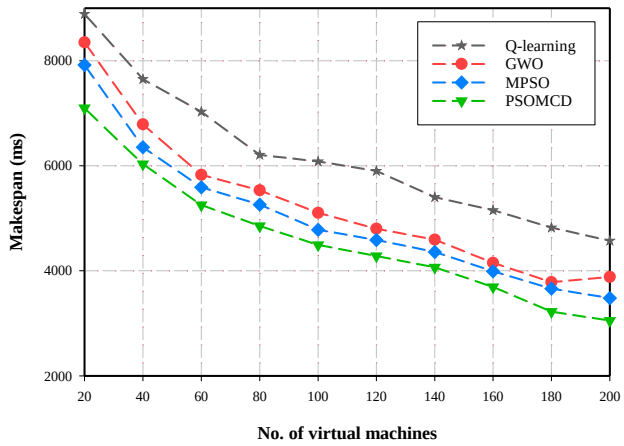

Fig. 3. Makespan with varying VMs for a fixed task count

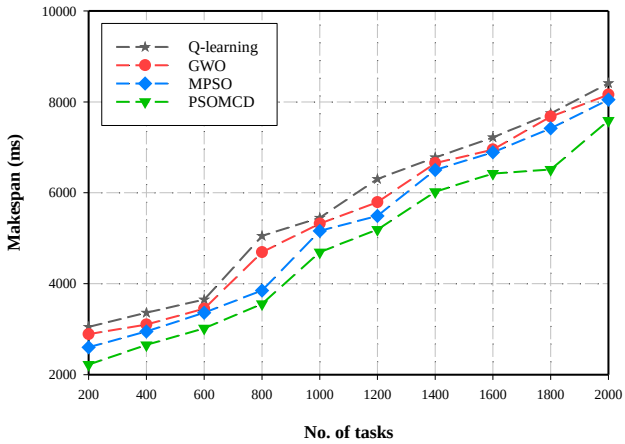

Fig. 4. Makespan with varying number of tasks for a fixed VM count

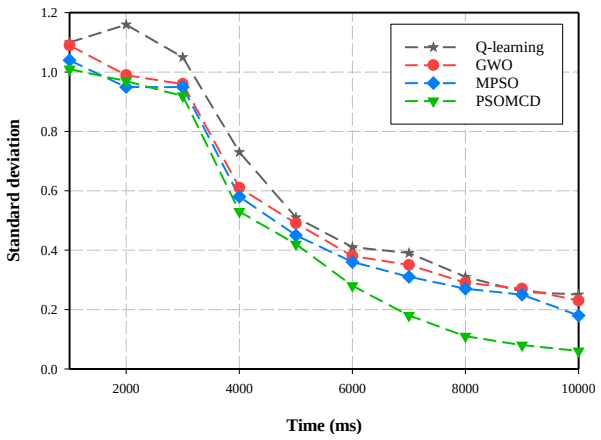

Fig. 5. Standard deviation comparison

Also, load balancing performance was assessed by measuring the standard deviation of resource use (Fig. 5). Low values in the standard deviation reflect higher load balancing performance, a metric in which PSOMCD performed much better than MPSO and Q-Learning, especially as simulation time elapsed. This performance advantage derives from the increased speed of PSOMCD in detecting and allocating optimal resources quickly. This balances computational loads and remaining resources among the VMs.

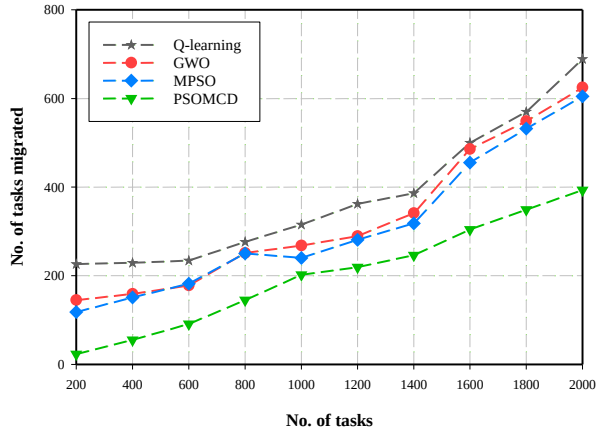

Fig. 6. Number of migrations comparison

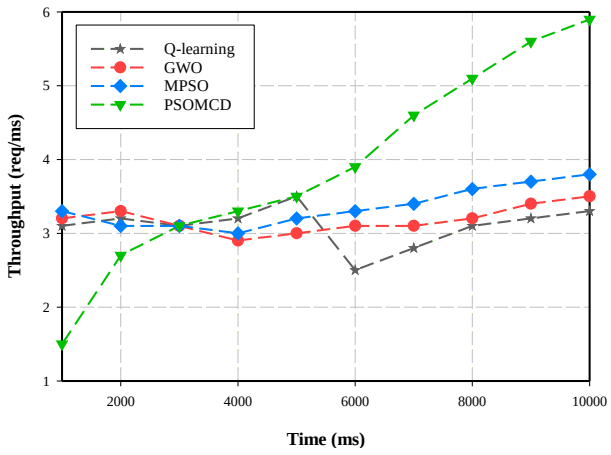

Fig. 7. Throughput comparison

Task migration, another key measure of effective resource utilization, was compared to the other (Fig. 6). PSOMCD had fewer task migrations, emphasizing the efficacy of resource pre-planning. Moreover, throughput analysis (Fig. 7) shows PSOMCD performed better than other approaches in externally managing resource demands with higher reliability in the cloud system, providing superior availability and responsiveness.

VI. Discussion

The performance evaluation demonstrates that PSOMCD effectively addresses the core challenges of dynamic task scheduling in cloud computing. The proposed algorithm maintains population diversity and avoids premature convergence by integrating the MCD mechanism with Particle Swarm Optimization. These enhancements result in improved resource utilization, reduced makespan, and lower energy consumption compared to benchmark methods such as MPSO, Q-learning, and GWO. The ability of PSOMCD to maintain lower task migration rates and higher throughput further underscores its robustness in adapting to fluctuating workloads.

Unlike traditional PSO-based or heuristic techniques, PSOMCD successfully balances multiple objectives simultaneously, thanks to its composite fitness function that considers load deviation, energy usage, and delay cost. This multi-objective orientation makes it highly suitable for modern cloud environments where service-level agreements and energy efficiency are equally critical. Moreover, incorporating elite selection via cosine similarity and offspring competition mechanisms enhances the algorithm's exploratory capabilities without sacrificing convergence performance.

While simulation results confirm PSOMCD's superiority, certain limitations warrant further investigation. The added complexity from clustering and diversity preservation strategies increases computational overhead, which may impact scalability in real-time or large-scale deployments. Additionally, the algorithm has been tested in a controlled CloudSim environment; future work should explore its performance in live cloud infrastructures and hybrid or multi-cloud systems. Adaptive parameter tuning and integration with reinforcement learning may further enhance responsiveness to evolving cloud conditions.

VII. Conclusion

This study introduced and tested a new meta-heuristic algorithm, PSOMCD, for load balancing in cloud computing environments. The PSOMCD framework integrated a modified crowding distance mechanism, affinity propagation clustering, a cosine similarity-based elite selection policy, and an offspring competition mechanism. All these advances resolved the issues related to early convergence, maintaining diversity in the solution, and the issues related to the complexity of multi-objective optimization in conventional algorithms.

A detailed simulation carried out on CloudSim 3.0.3 proved PSOMCD's performance advantage. Experimental settings considered varying numbers of tasks and VMs, and the findings proved considerable enhancement in load balancing, less power usage, lower makespan, a minor degree of imbalance, higher throughput, and reduced idle time over current algorithms such

as MPSO, Q-learning, and IPSO. Real-platform experiments also verified PSOMCD's practicality and resilience.

Future research will focus on extending PSOMCD to real-time and large-scale cloud environments, including hybrid and multi-cloud architectures. Integrating adaptive parameter tuning or reinforcement learning could enhance its responsiveness to dynamic workloads. Additionally, evaluating PSOMCD's performance under real-world constraints such as network latency, hardware failures, and user-driven demand variations will provide deeper insights into its practical deployment potential.

Hybrid Meta-Heuristic Algorithm for Optimal Virtual Machine Migration in Cloud Computing

Hongkai LIN
Information Technology Department, Wuhan Business University, Wuhan City, Hubei Province, 430056, China

***Abstract*—Virtual Machine (VM) migration is one of the most important features of cloud computing for resource utilization optimization, energy minimization, and quality of service enhancement. Existing migration solutions, however, suffer from excessive migration overhead, energy inefficiency, and ineffective allocation of resources. This study proposes a novel hybrid meta-heuristic algorithm through the integration of Particle Swarm Optimization (PSO) and Seahorse Optimization (SHO) to address the drawbacks. The proposed PSOSHO algorithm takes advantage of the global exploration capability of PSO and the adaptive exploitation feature of SHO and provides a sound solution for VM migration in dynamic cloud computing environments. Extensive simulation experiments were conducted for a different number of cloud tasks, and the results demonstrated that PSOSHO significantly outperforms existing algorithms. Specifically, it achieves improvements of up to 54% in load factor, 60% in migration count, 48% in migration cost, 7% in energy consumption, 27% in resource availability, and 37% in computation time. These results confirm the effectiveness and robustness of the proposed methodology for optimal VM migration and resource management in virtualized cloud computing infrastructures.**

Keywords*—Cloud computing; virtualization; migration; particle swarm optimization; seahorse optimization

I. INTRODUCTION

Cloud computing has reshaped modern computing by supplying scalable, on-demand capabilities, enabling businesses and users to access virtualized infrastructure efficiently [1]. In cloud resource management, workload distribution comprises Virtual Machine (VM) migration, which dynamically transfers workloads between Physical Machines (PMs) to balance loading, improve resource utilization, and ensure the Service Level Agreement (SLA) [2]. VM migration, however, is plagued by challenges ranging from high energy consumption, high migration costs, and ineffective resource utilization [3]. Similar to the importance of intelligent decision-making in VM migration, recent studies in mobile social networks have highlighted the effectiveness of rule-based anomaly detection techniques for managing dynamic environments and improving overall system responsiveness [4].

Excessive migrations through frequent movements can result in high power consumption, negatively impacting cloud sustainability, while ineffective migration decisions increase operational expenditure and reduce system performance. Inefficient resource allocation mechanisms also result in unnecessary migrations, reducing system efficiency and affecting Quality of Service (QoS) [5]. To mitigate these issues, intelligent optimization techniques are required to improve migration efficiency, reduce costs, and improve resource management.

Recent advancements have demonstrated the effectiveness of intelligent optimization techniques in addressing complex challenges across various computing domains. For example, meta-heuristic-based strategies have been applied to optimize the placement and energy management of Electric Vehicle Charging Stations (EVCS) in microgrid environments [6, 7]. In healthcare wireless sensor networks, intrusion detection frameworks using clustering methods have enhanced security while minimizing computational overhead [8]. Similarly, geo-drone-based routing has improved connectivity in disaster-response ad hoc networks [9]. In e-commerce, hybrid models combining evolutionary algorithms with deep learning have improved sentiment classification accuracy [10, 11]. Additionally, dynamic spectrum access in heterogeneous wireless networks has been optimized for energy and spectral efficiency through interference-aware channel allocation and base station sleep-mode mechanisms [12].

Despite significant advancements in VM migration approaches, existing optimization techniques have disadvantages. The performance of using these methods is hindered by premature convergence, slow adaptability to dynamic workloads, and inefficient allocation of resources, which contribute to suboptimal migration decisions [13]. Besides, existing methods only focus on minimizing energy consumption, failing to balance migration cost, computational efficiency, and SLA satisfaction. A more flexible and effective optimization framework is necessary to address these issues. The present study employs a hybrid meta-heuristic optimization approach that integrates the strengths of Particle Swarm Optimization (PSO) and Seahorse Optimization (SHO) to significantly improve the optimality of VM migration in terms of cost and energy efficiency.

Despite notable progress in optimization-based VM migration strategies, many existing approaches suffer from critical shortcomings that limit their effectiveness in dynamic cloud environments. Traditional algorithms often struggle with premature convergence, making them prone to suboptimal migration decisions. Moreover, many methods are designed with a single-objective focus, typically energy reduction, while neglecting other crucial metrics such as migration cost, computational delay, and SLA compliance. Some hybrid and AI-based techniques offer improved accuracy but introduce excessive computational complexity, rendering them impractical for real-time deployment. Furthermore, existing solutions frequently lack adaptability to fluctuating workloads, leading to inefficient resource allocation and unnecessary

migrations. These limitations underscore the need for a more balanced, adaptive, and computationally efficient optimization framework capable of addressing the multi-objective and dynamic nature of VM migration problems.

By integrating PSO and SHO, the proposed algorithm offers a sound trade-off between global exploration and local exploitation, removing shortcomings such as premature convergence and inefficient resource allocation of current methods. PSOSHO selects VMs to migrate dynamically and makes the optimal placement decisions to minimize energy consumption, migration cost, and computational overhead while guaranteeing SLAs. Under comprehensive simulations, PSOSHO demonstrates superior performance to conventional methods in energy efficiency, reduction of downtime, and resource utilization. The proposed approach provides a scalable, adaptive, and computationally efficient solution for cloud service providers, guaranteeing improved load balancing and system reliability in dynamic cloud environments. This study seeks to answer the following research question:

How can a hybrid meta-heuristic algorithm be designed to optimize virtual machine migration in cloud computing by balancing energy efficiency, migration cost, computation time, and resource utilization under dynamic workload conditions?

The structure of this study is organized as follows: Section II presents a comprehensive literature review of existing VM migration strategies in cloud computing. Section III formulates the problem of optimal VM migration, detailing the objectives, constraints, and system model. In Section IV, the proposed hybrid PSOSHO algorithm is introduced. Section V discusses the experimental results and performance comparisons of PSOSHO against existing algorithms across various metrics. Finally, Section VI concludes the study with key findings and future research directions.

II. Literature Review

Ghetas [14] proposed a Monarch Butterfly Optimization-based Virtual Machine (MBO-VM) placement method for enhancing cloud computing efficiency via energy conservation and server utilization improvement. The study highlights that VM placement is an essential task from the point of view of minimizing active PMs and reducing power consumption and maintenance costs in data centers. The MBO-VM was tested on the CloudSim toolkit with real and synthetic cloud workloads and demonstrated superior performance over state-of-the-art VM placement algorithms. The MBO-VM method efficiently consolidates VMs, reducing active server counts while maintaining optimum packaging efficiency.

Xu and Abnoosian [15] suggested a hybrid optimization algorithm using Genetic Algorithm (GA) and PSO for green VM migration in an energy-efficient way. The approach was designed to overcome poor convergence and local optima in the traditional PSO. Performance validation was achieved through the CloudSim simulator. The hybrid model conserved 23.19% of energy and 29.01% of execution time compared to other approaches. The model provided better power efficiency and guaranteed high computational performance for cloud data centers.

Zhao, et al. [16] proposed the Performance-Aware Virtual Machine Migration (PAVMM) model, which seeks to reduce VM performance degradation in migration. In contrast to the existing approaches that maximize SLA adherence and minimize VM suspension time, PAVMM employs a VM performance prediction model to take user experience one step further. Moreover, ACO solved the multi-objective VM migration efficiency in terms of migration costs and the number of active PMs. PAVMM is validated by experimental results, demonstrating better VM performance than previous mechanisms, making it a scientifically sound solution for performance-aware migration strategies.

Cao and Hou [17] introduced a two-tiered VM placement model to balance cloud computing energy consumption and resource utilization. A queuing model was used in the first tier to efficiently manage VM placement requests, followed by a Krill Herd (KH) algorithm-based multi-objective VM allocation strategy. This method aims to reduce carbon footprint and operational costs and ensure optimal resource usage. The proposed model demonstrated superior energy efficiency and workload balancing results, making it a viable approach for green cloud computing.

Maldonado Carrascosa, et al. [18] examined multi-objective workload migration in cloud environments by integrating a fuzzy meta-scheduler system with swarm intelligence and Non-dominated Sorting Genetic Algorithm II (NSGA-II). The approach aimed at maximizing interpretability while optimizing renewable energy consumption. The CloudSim-based system facilitated effective VM migration, improving data center performance and energy consumption. Simulation results indicated that the proposed approach outperformed traditional genetic algorithms, with a 6% improvement in interpretability and a 10% improvement in the use of renewable energy.

Çavdar, et al. [19] proposed a Utilization-Based Genetic Algorithm (UBGA) for efficient VM placement in cloud data centers. The method focused on reducing resource wastage, network load, and power consumption with optimal placement of VMs in PMs. UBGA performed better than existing placement algorithms, considering machine utilization and node distances. With CloudSim simulations, the study confirmed that UBGA provides improved resource utilization and energy efficiency, and hence, it is a promising solution for cloud infrastructure optimization.

Archana and Kumar [20] suggested a Modified Bat Algorithm (MBA) with Spider Monkey Optimization (SMO) for enhancing VM migration efficiency. The fitness function of SMO was integrated with MBA to augment the search process and avoid local optima entrapment. Simulations using CloudSimPlus showed MBA-SMO gave 25% faster migration time than the traditional Bat Algorithm, 27% faster than PSO, and 35% faster than Cuckoo Search (CS). Makespan, throughput, and overall migration performance enhancements further attested the effectiveness of the hybrid approach.

Parsafar [21] proposed a Recurrent Neural Network (RNN) and Gray Wolf Optimization (GWO)-based energy-aware VM migration method. Unlike traditional static threshold-based methods, the model dynamically predicts energy consumption using a multi-resource metric model. GWO is employed to

optimize the predictive accuracy of RNN, and reinforcement learning is utilized to improve workload allocation continuously. Results confirmed a significant reduction in unnecessary VM migrations and energy consumption, with a 11% error margin from optimal solutions. The hybrid AI-based solution provides a sustainable and adaptive VM management solution in cloud computing environments.

While there are impressive advances in optimizing VM migration, existing approaches suffer from several limitations. As summarized in Table I, most traditional approaches, such as GA, PSO, and Ant Colony Optimization, suffer from premature convergence and local optima issues, compromising their effectiveness in large dynamic cloud environments. In addition, energy-efficient VM migration remains a significant challenge, as most existing approaches focus on minimizing energy consumption or maximizing SLA compliance but fail to effectively balance migration cost, execution time, andresource utilization simultaneously.

TABLE I. RECENT META-HEURISTIC ALGORITHMS FOR CLOUD VIRTUAL MACHINE MIGRATION

Reference	Optimization Technique	Performance gains	Shortcomings
[14]	Monarch butterfly optimization	Improved VM placement, fewer active servers, and reduced energy costs	Lacks adaptability to dynamic workloads, static optimization approach
[15]	Genetic algorithm and particle swarm optimization	23% energy savings and 29% faster execution	Prone to premature convergence, high computation cost
[16]	Ant colony optimization algorithm	Enhanced VM performance with reduced migration downtime	Focuses only on VM performance, lacks multi-objective balance
[17]	Krill herd algorithm	Improved SLA compliance and energy efficiency	Limited scalability for large data centers
[18]	Fuzzy meta-scheduler and non-dominated sorting genetic algorithm II	6% increase in interpretability and 10% better energy utilization	The increased complexity introduced by the fuzzy systemrequires expert tuning
[19]	Utilization-based genetic algorithm	Better VM placement with lower energy consumption	Does not consider SLA violations or execution time
[20]	Modified bat algorithm and spider monkey optimization	25–35% faster migration time compared to other techniques	It struggles with large-scale optimizations and risks getting stuck in local optima.
[21]	Recurrent neural network and gray wolf optimization	11% lower error margin and reduced unnecessary migrations	It has high computational complexity and requires extensive training data

Recent hybrid approaches, such as the Modified Bat Algorithm (MBA-SMO) and RNN-GWO, improved migration efficiency and prediction accuracy but lack adaptiveness to dynamic workload patterns. Moreover, AI-based models introduce computational complexity, making them difficult to apply in real-time cloud environments. To bridge these gaps,this study suggests the PSOSHO algorithm for ideal VM migration. By combining the exploration capability of PSO and the adaptive exploitation characteristic of SHO, PSOSHO enhances energy efficiency, migration cost, and computation performance. Unlike current models, PSOSHO dynamically adjusts VM selection based on runtime workload variations, offering adaptive and scalable migration.

III. PROBLEM FORMULATION

In modern cloud computing infrastructures, the dynamic allocation of resources is a key requirement for maintaining performance efficiency and service continuity [22]. As user demands vary, certain PMs may become overloaded, specifically when the total resource requests from hosted VMs exceed the available capacity of the PM. To address this, VM migration is employed to transfer selected VMs from overloaded PMs to underutilized ones, thereby balancing the load and enhancing system performance.

The core objective of the VM migration problem is to identify which VM should be migrated and, where it should be placed so that the overall system performance is optimized. The decision must minimize several critical parameters: energy consumption, migration cost, computation time, and resource wastage. Additionally, the solution must comply with resource constraints, ensuring that the receiving PM has sufficient capacity to host the incoming VM without becoming overloaded.

This optimization problem involves a set of PMs $PM = \{pm_1, pm_2, \ldots, pm_n\}$, a set of VMs $VM = \{vm_1, vm_2, \ldots, vm_n\}$, and corresponding resource requirements R_{vm_i} for each VM and capacities C_{pm_j} for each PM. The current utilization U_{pm_j} of each PM must also be taken into account. The primary objective is to decrease the total migration overhead, which includes energy consumption E_{mig}, migration cost C_{mig}, and computation time T_{comp}, while ensuring that the destination PM can accommodate the migrating VM. This can be expressed as a constrained multi-objective optimization problem [Eq. (1)]:

$$min\left(E_{mig} + C_{mig} + T_{comp}\right) \quad subject\ to\ U_{pm_j} + R_{vm_i} + C_{pm_j} \tag{1}$$

A key challenge lies in avoiding unnecessary migrations, which can cause additional energy usage and delay, while also preventing underutilization of resources, which leads to inefficiencies. Thus, the problem requires a careful trade-off between multiple conflicting objectives.

To address this complex decision-making problem, a hybrid meta-heuristic approach, PSOSHO, is proposed. This algorithm combines the global search strength of PSO with the adaptive local exploitation potential of SHO to find the most suitable VM-PM mapping. It considers the current state of the system and intelligently determines which VM to migrate to whichPM, ensuring optimal resource usage and system stability. A schematic overview of the cloud environment and its resource

interaction model is shown in Fig. 1, where VMs (in blue) interact with PMs (in gray) via the central cloud resource pool.

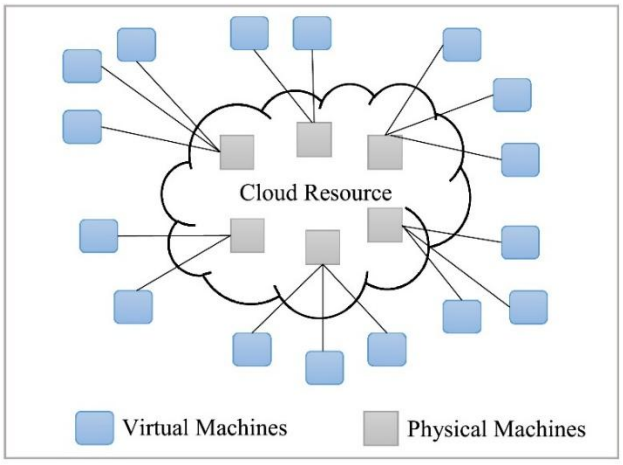

Fig. 1. Overview of cloud environment and its resource interaction model

IV. Proposed Hybrid PSOSHO Algorithm

This section introduces the hybrid meta-heuristic optimization model developed for efficient VM migration in cloud computing environments. Optimization algorithms such as PSO and SHO have been extensively applied in cloud and wireless sensor networks due to their potential to address intricate optimization issues. However, VM migration is a relatively unexplored research area in hybrid optimization. This research develops a novel approach by hybridizing PSO and SHO and exploiting their complementary characteristics to enhance migration efficiency, minimize resource wastage, and improve computational performance. The flowchart of the hybrid PSOSHO is illustrated in Fig. 2.

The proposed framework considers significant cloud computing parameters like PMs, VMs, memory, and bandwidth requirements. Resource allocation is triggered when a PM becomes overloaded, highlighting the necessity for optimal VM selection and migration to ensure balanced workload distribution. Migration is determined according to some performance metrics like energy consumption, resource utilization, computation overhead, and migration overhead. Proper resource demand estimation can avoid unnecessary migrations and improve cloud resource utilization and overall system performance.

The hybrid PSOSHO algorithm dynamically determines the most suitable VM to migrate to reduce SLA violations and ensure optimal cloud performance. Efficient VM migration is essential for achieving resource effectiveness, energy conservation, and reduction of service disruption in cloud computing. Traditional optimization techniques are plagued by the exploration-exploitation dilemma, leading to premature convergence or ineffective resource utilization. To mitigate the limitations, this study proposes a hybrid meta-heuristic optimization scheme combining SHO and PSO.

SHO is a swarm intelligence method inspired by the natural motion, predation, and mating of seahorses. SHO has a good balance between global exploration and local exploitation, hence, is apt for solving complex multi-objective optimization problems such as VM migration in dynamic cloud environments. Integrating SHO with the velocity-based update mechanism of PSO in the suggested PSOSHO algorithm leads to enhanced convergence speed, efficient VM selection, and reduced migration costs.

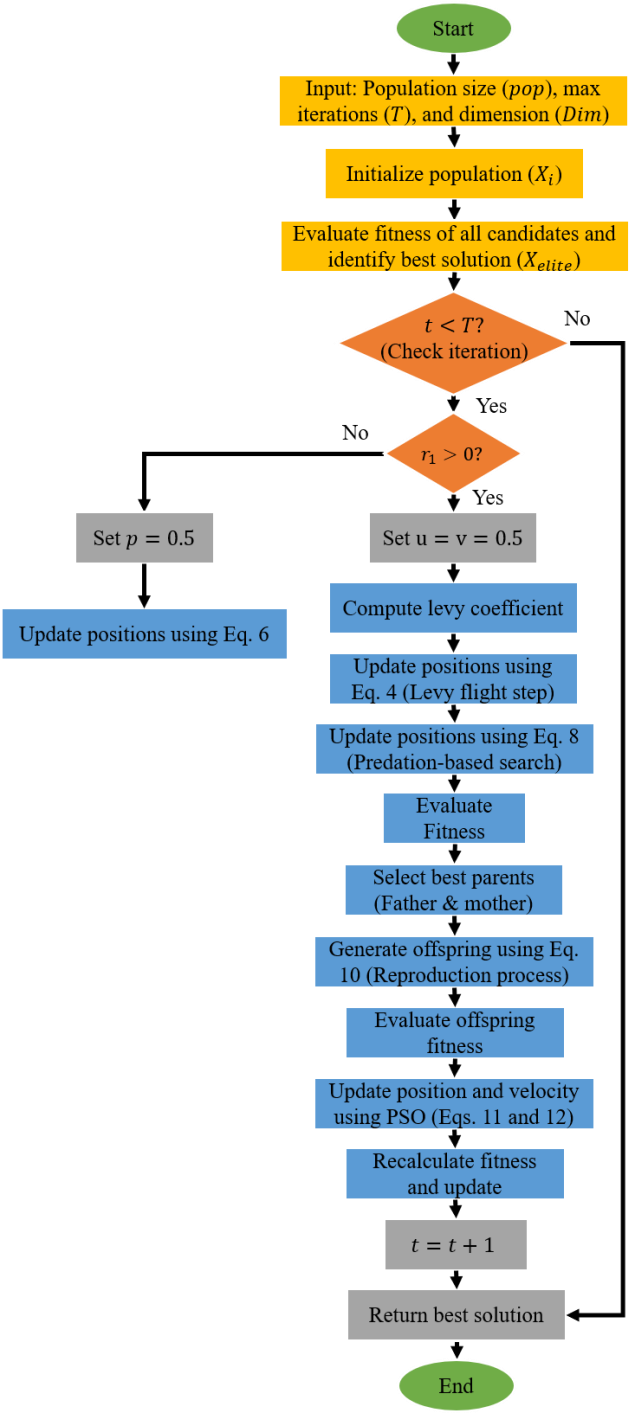

Fig. 2. Flowchart of the hybrid PSOSHO algorithm

The SHO algorithm starts by initializing a population of candidate solutions representing potential VM migration strategies. This population is structured as follows [Eq. (2)]:

$$Seahorses = \begin{bmatrix} x_1^1 & \dots & x_{Dim}^1 \\ \dots & \dots & \dots \\ x_1^{pop} & \dots & x_{Dim}^{pop} \end{bmatrix} \quad (2)$$

where, pop is the total number of candidate solutions and Dim represents the number of decision variables, such as CPU, memory, and bandwidth constraints.

The fitness function $f(X_i)$ evaluates each solution, and the best-performing candidate is selected as follows [Eq. (3)]:

$$X_{elite} = arg\ min\left(f(X_i)\right) \quad (3)$$

The SHO algorithm balances exploration and exploitation through two key movement strategies: Levy flight for global exploration and Brownian motion for local exploitation. The Levy flight mechanism enables candidate solutions to take large steps in search space, ensuring diverse exploration. The position update is given by Eq. (4):

$$X_{new}^1(t+1) = X_i(t) + Levy(\lambda)\left(X_{elite}(t) - X_i(t)\right) \times x \times y \times z + X_{elite}(t) \quad (4)$$

where, x, y, and z represent random factors influencing the jump size. $L\ e\ v\ y\ (\ )$ Levy(λ) is a function controlling the step distribution [Eq. (5)]:

$$Levy(z) = s \times \frac{x\sigma}{|k|^{1/\lambda}} \quad (5)$$

where, s = 0.01 and k is random numbers selected from [0,1]. This helps prevent local optima trapping and improves global search efficiency.

Once promising solutions are found, Brownian motion fine-tunes their positions using Eq. (6).

$$X_{new}^1(t+1) = X_i(t) + rand \times l \times \beta_t \times (X_i(t) - \beta_t \times X_{elite}) \quad (6)$$

where, β_t is a random walk coefficient, controlling the local refinement as follows [Eq. (7)]:

$$\beta_t = \frac{1}{\sqrt{2\pi}} \times e^{-u^2/2} \quad (7)$$

This ensures fine-tuned adjustments, leading to faster convergence.

The predation phase mimics seahorse hunting strategies, where search agents adapt based on successful exploration outcomes [Eq. (8)]:

$$X_{new}^2(t+1) = \begin{cases} \alpha \times \left(X_{elite} - rand \times X_{new}^1(t)\right) + (1-\alpha) \times X_{elite}, & if\ r_2 > 0.1 \\ (1-\alpha) \times (X_{new}^1(t) - rand \times X_{elite}) + \alpha \times X_{new}^1(t), & if\ r_2 \le 0.1 \end{cases} \quad (8)$$

where, α is an adaptive parameter calculated as follows [Eq. (9)]:

$$\alpha = \left(1 - \frac{t}{T}\right)^{\frac{2t}{T}} \quad (9)$$

The predation strategy helps balance exploration and exploitation, leading to optimal resource allocation for VM migration. To maintain population diversity, the breeding process generates new candidate solutions using Eq. (10):

$$X_i^{offspring} = r_3 X_i^{father} + (1 - r_3) X_i^{mother} \quad (10)$$

While SHO efficiently balances exploration and exploitation, it lacks velocity-based search mechanisms, which can slow convergence in complex environments. To overcome this, PSO is integrated into SHO, forming PSOSHO. PSO enhances SHO's adaptability by refining position updates using velocity-based learning [Eq. (11) and Eq. (12)]:

$$X_{ij}^{t+1} = X_{ij}^t + v_{ij}^{t+1} \quad (11)$$

$$v_{ij}^{t+1} = w v_{ij}^t + C_1\left(X_{ij}^{p(t)} - X_{ij}^t\right) + C_2\left(X_j^{g(t)} - X_{ij}^t\right) \quad (12)$$

where, w is the inertia weight (controls exploration versus exploitation), C_1 is the cognitive acceleration coefficient (influence of personal best), C_2 is the social acceleration coefficient (influence of global best), v_{ij}^t is the current velocity of particle i in dimension j at iteration t, $X_{ij}^{p(t)}$ is the personal best position of particle i in dimension j at iteration t, X_{ij}^t is the current position of particle i in dimension j, and $X_j^{g(t)}$ is the global best position in dimension j at iteration t.

The PSOSHO algorithm identifies and migrates optimal VMs based on resource demands. The process involves:

- Initializing VMs and PMs based on cloud parameters (CPU, memory, bandwidth);
- Evaluating fitness function based on energy consumption, migration cost, and SLA adherence;
- Applying SHO's movement strategies (Levy flight + Brownian motion);
- Refining solutions via PSO updates for precise migration decisions;
- Converging to an optimal migration plan.

V. Results and Discussion

The efficacy of the proposed hybrid PSOSHO optimization model for VM migration was evaluated through rigorous simulation analysis. The simulation was carried out using the CloudSim toolkit, and the experimental setup was an Intel i5 processor, 16GB RAM, Windows 10 OS, 10 PMs, and 100 VMs. Performance was evaluated on key parameters of migration cost, energy consumption, resource utilization, and computation time and compared with four traditional VM migration algorithms: UBGA [19], KH [17], MBO-VM [14], and MBA [20]. The results confirm that the proposed PSOSHO model outperforms traditional approaches by reducing migration cost, energy consumption, and computation time while enhancing resource utilization.

The load factor is the level of utilization of resources by VMs in processing tasks. As shown in Fig. 3, the experiment was

carried out on a different number of tasks, and the performance of optimization techniques in managing varied workloads was evaluated. The results indicate that the proposed PSOSHO algorithm experienced the lowest load factor in all the test scenarios owing to its efficient VM selection and migration policy. However, UBGA, KH, MBO-VM, and MBA experienced higher loads due to inefficient allocation of resources and excessive migrations.

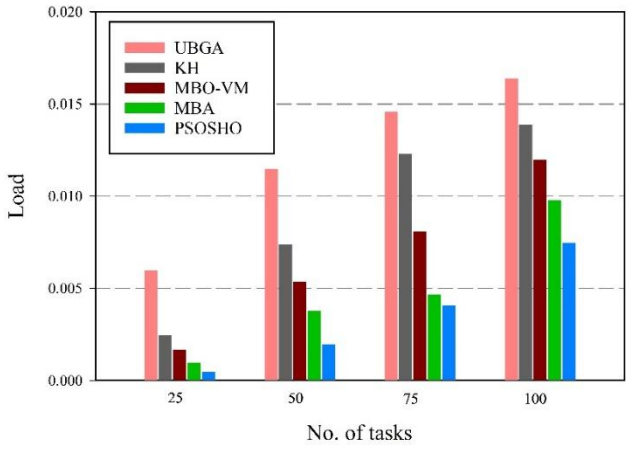

Fig. 3. Load comparison

Fig. 4 illustrates the number of migrations performed by different algorithms. PSOSHO successfully minimized the number of VM migrations, which led to minimized migration overhead. This is the direct result of the intelligent VM selection mechanism, as it ensures that only necessary migrations are performed. In contrast, other algorithms performed additional unnecessary migrations, which increased the system load and energy consumption.

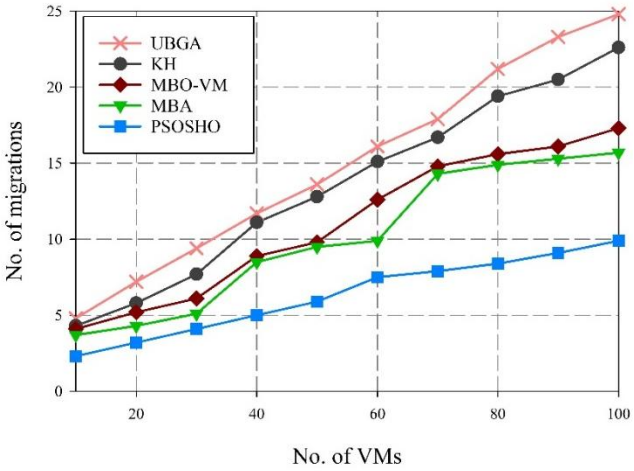

Fig. 4. Migration count comparison

The migration cost was defined as the ratio of the number of migrations completed to the number of migration requests, as shown in Fig. 5. The results indicate that the proposed PSOSHO model achieved the lowest migration cost, with a value of 0.05 in the presence of 100 tasks. In contrast, UBGA achieved the highest migration cost (0.097), KH (0.091), MBO-VM (0.075), and MBA (0.067).

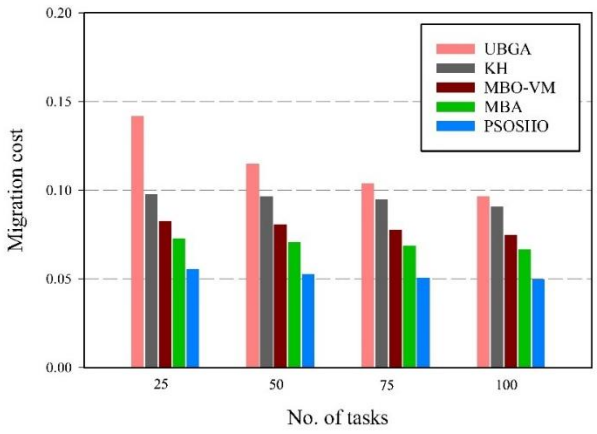

Fig. 5. Migration cost comparison.

Fig. 6 illustrates the analysis of energy consumption of PSOSHO's effectiveness in minimizing power consumption. The suggested model attained an average energy consumption of 0.468W for 100 tasks, which was significantly lower compared to UBGA (0.503W), KH (0.495W), MBO-VM (0.494W), and MBA (0.491W).

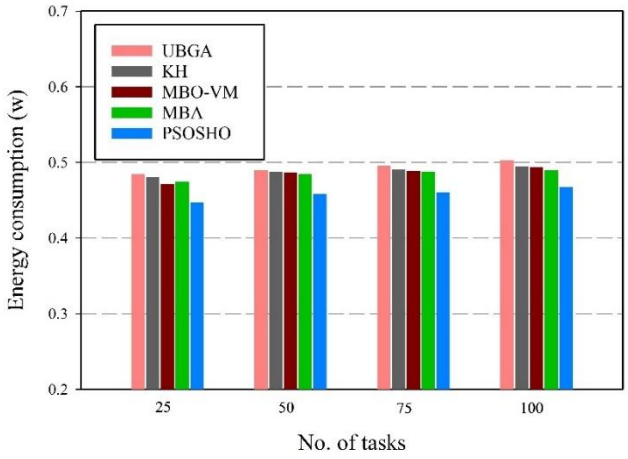

Fig. 6. Energy consumption comparison

The comparison of resource availability, as illustrated in Fig. 7, proves the efficiency of the PSOSHO model in optimizing resource utilization. The results indicate that maximum resources were available in the suggested model, implying minimum and requisite migrations were performed. On the other hand, the other algorithms experienced worse resource availability, implying more wastage of resources due to unnecessary migrations. It is evident that the PSOSHO model effectively allocates resources and prevents unnecessary migrations of VMs, leading to an optimized cloud environment.

Computation time is the duration to complete a migration process, as illustrated in Fig. 8. For 100 tasks, the proposed PSOSHO algorithm achieved a computation time of 5.5 seconds, which was significantly lower than that of UBGA (8.8 seconds), KH (8.2 seconds), MBO-VM (8.0 seconds), and MBA (7.5 seconds).

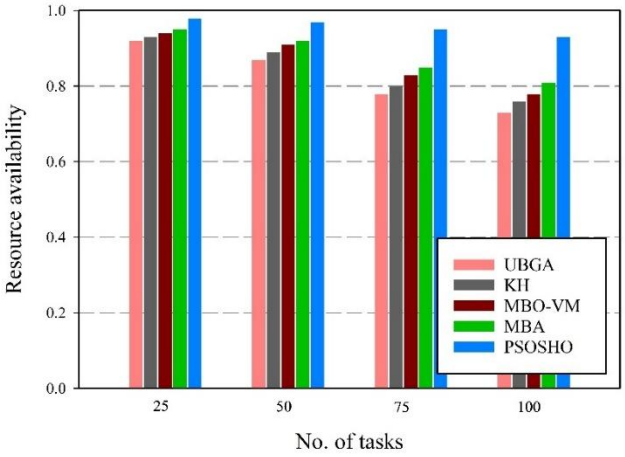

Fig. 7. Resource availability comparison

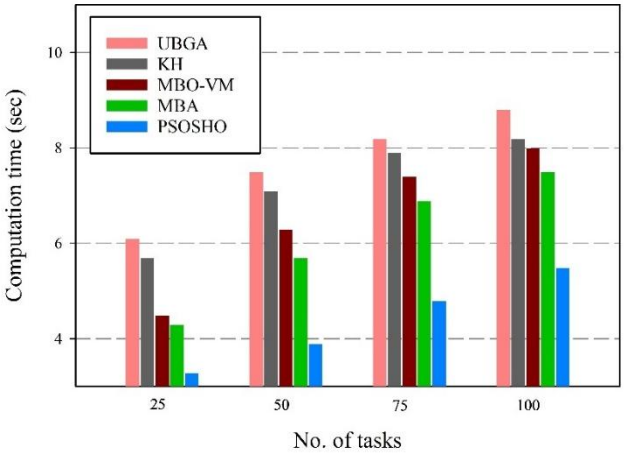

Fig. 8. Computation time comparison.

VI. Conclusion

This research proposed a hybrid meta-heuristic algorithm, PSOSHO, for VM migration optimization in cloud computing environments. Simulation analysis compared the proposed PSOSHO model with current state-of-the-art VM migration techniques. By intelligently selecting VMs to migrate and preventing unnecessary migrations, the PSOSHO algorithm reduced system overhead, enhanced the utilization of cloud infrastructure, and ensured high service quality with reduced SLA violations. Additionally, the hybrid approach of the proposed technique facilitated scalability in dynamic and large-scale cloud computing systems.

Although the experimental results demonstrate the effectiveness and superiority of the proposed PSOSHO algorithm, several avenues remain open for future exploration. One promising direction is the integration of Deep Reinforcement Learning (DRL) techniques, which can enable the migration model to learn and adapt autonomously from dynamic system states and historical migration outcomes. By incorporating DRL, the migration strategy could evolve in real-time, leading to more intelligent and context-aware decision-making in complex and volatile cloud environments. Another valuable extension involves the application of adaptive machine learning models to predict workload patterns, resource demands, and potential SLA violations. These predictive capabilities could be integrated with the PSOSHO framework to proactively trigger migration decisions, thereby minimizing overhead and service disruption.

***Abstract*—In the context of mental health, this study aims to develop a real-time emotion-focused facial recognition system based on psychological intervention methods. It uses a convolutional neural network (CNN) base and is trained with the FER2013 dataset, which consists of 35,887 facial images classified into seven basic emotions. Through normalisation, data augmentation, and training in TensorFlow and Keras, the model achieved 92.3% accuracy in a pilot test with 1,000 images, achieving an F1 score of 0.92, precision of 0.93, and recall of 0.91. Subsequently, when scaled to 71,774 images, it maintained robust performance with an overall accuracy of 77.5%. Emotions such as happiness (0.83), surprise (0.80), and neutrality (0.85) were recognised with greater accuracy, while K-means analysis was applied to cluster emotional patterns in a visually interpretable way. Complementing the technical architecture, a user-friendly graphical interface was designed for psychology professionals, allowing clear visualisation of the detected emotions with a latency of just 150 milliseconds per image. Overall, this proposal represents a significant advance toward more interactive, personalised, and efficient therapies, without requiring a complex technological infrastructure. Future studies recommend exploring different multimodal signals and increasing the use of convolutional layers to improve the quality of results and data efficiency.**

Keywords*—Facial recognition; real-time; methods; psychological interventions

I. Introduction

In today's mental health context, understanding and responding appropriately to patients' emotions during psychological interventions has become key to achieving more effective and personalized care [1], [2]. In this sense, emotions have a direct impact on how people communicate, process their experiences, and react to therapeutic strategies [3]. Identifying these emotions in real time allows professionals to modify their approach during sessions [4], strengthening the therapeutic relationship and optimizing treatment outcomes.

Traditionally, psychologists have interpreted emotions through direct observation of gestures [5], tone of voice [6], and body language [7]. However, these methods can be limited by the observer's subjectivity, the practitioner's cognitive load, or environmental conditions, especially in online therapies [8]. Given this, these limitations have prompted the development and implementation of technological tools that enhance clinical work [9] through the automatic analysis of emotional signals.

The advent of Artificial Intelligence (AI) and Machine Learning (ML)-based technologies has enabled significant advances in automatic emotion recognition [10], [11], particularly through the study of facial expressions. These systems use advanced algorithms to identify visual patterns linked to different emotions, providing accurate, real-time assessments. Although these tools have been applied in other sectors, their integration into psychological contexts is still limited [12], despite their enormous potential to improve patient emotional understanding and support therapists during sessions.

Facial expressions are an essential source of emotional data in therapeutic contexts [13], as they facilitate the detection of internal states that are often not expressed verbally. In a psychological context, this detection of emotions facilitates the development of the relationship between the professional and the patient [14], which increases trust and the final outcome of the therapy.

The objective of this study is to develop a real-time emotion-focused facial recognition system for psychological intervention methods. This proposal seeks to contribute to the design of technological solutions that support clinical work, improve the patient experience, and promote more timely and effective interventions.

To carry out this study, a system based on convolutional neural networks (CNN) will be designed using the FER2013 dataset, which contains facial images labeled according to seven basic emotions [15]. Preprocessing techniques such as data normalization and augmentation will be applied, and the model was trained in an optimized environment with TensorFlow and Keras. Validation will be performed through a pilot test, evaluating its performance in real time. Finally, a graphical user interface (GUI) will be implemented, aimed at psychologists, allowing the visualization of emotions detected during clinical sessions for therapeutic and analytical purposes.

The importance of this system lies in its precision and ability to execute in real time, making it a suitable tool for application in clinical settings. By demonstrating the model's effectiveness in accurately recognizing different emotions during therapy sessions, it underscores AI's ability to modify psychological practices, enabling more personalized interventions tailored to the patient's emotional state.

The study is structured as follows: the Related Works section reviews and analyses the existing literature related to the topic

of this study. The Methodology section then describes the pre-processing and processing steps, along with the architecture of the CNN model used. Following this, the Results section presents the analysis obtained after the necessary implementations and tests. The Discussion section presents a preliminary comparison with the literature to inform future studies. Finally, the Conclusion section summarises the findings and proposes new lines of future research.

II. Related Works

Despite significant progress in emotion recognition using AI techniques, most existing studies have focused on general applications such as human-computer interaction, education, security, and medical diagnosis. However, their limited exploration in the field of direct implementation in the clinical context of real-time psychological interventions remains a serious problem. This gap restricts the use of the therapeutic potential offered by these systems to strengthen the relationship between the professional and the patient, dynamically modify intervention tactics, and optimise treatment outcomes.

Facial emotion recognition has advanced significantly due to the integration of Artificial Intelligence (AI), especially with systems capable of processing data in real time. Hadjar et al. [16] developed TheraSense, designed to improve teleconsultation services through deep learning. This system demonstrated effectiveness in real-time emotion detection during video streams, standing out for its usability and integration into remote consultations. Similarly, Saadon et al. [17] proposed an alternative method, based on digital image correlation (DISC), which captured subtle variations in facial expressions with high accuracy and without racial or gender biases, compared to commercial systems such as Amazon Rekognition.

Additionally, the review by Kaur et al. [18] emphasised the growing relevance of facial emotion recognition (FER) in various sectors, including medical diagnosis, vehicular automation, and educational assessment. This comprehensive analysis underlined the importance of FER in human-computer interaction, providing a broad context for future research and methodologies. In this direction, Elsheikh and Mohamed [19] presented an innovative model based on deep convolutional neural networks with anti-aliasing techniques (AA-DCN), highlighting its effectiveness in complex databases such as CK+, JAFFE, and RAF, achieving high accuracy rates against challenges such as lighting, occlusions, and cultural diversity.

From a clinical perspective, Rubin et al. [20] explored specific deficits in emotional facial recognition in patients with psychotic disorders such as schizophrenia and bipolar disorder, compared to healthy controls. They identified significant decreases in accuracy and speed of emotional identification, highlighting the importance of early personalized interventions for these patients. In parallel, Economou et al. [21] investigated the associations between emotional facial recognition and schizotypal traits in the general population, revealing specific difficulties related to certain dimensions of schizotypism and their direct impact on psychological well-being.

The implementation of multimodal methods has also brought important advances to emotional facial recognition. Ballesteros et al. [22] developed a system that combines convolutional neural networks (CNNs) with psychological theories, achieving satisfactory results and pointing out the need for additional training to improve accuracy in diverse contexts and similar emotions. In a similar approach, CNNs were integrated with visual transformers (CoAtNet) [23], adding facial key points through multimodal fusion, which considerably increased the accuracy of emotional recognition, being successfully implemented on hardware such as Raspberry Pi.

On the other hand, Hassouneh et al. [24] proposed a hybrid system that combines facial expressions and EEG signals for children with autism spectrum disorder (ASD), using advanced architectures such as Xception and IoT and fog technologies computing to reduce latency and improve quality of life, achieving high accuracy and sensitivity rates. In parallel, Talaat et al. [25] also demonstrated the effectiveness of emotional facial recognition in children with ASD, using DCNN and fog technology computing to provide fast and effective responses in real time.

Finally, in the area of security and privacy, Casaño et al. [26] implemented a facial recognition-based authentication system integrated with AI and blockchain for the company Dialyma. They used technologies such as Python, OpenCV, TensorFlow and biometric services such as Reniec, managing to guarantee security and privacy in the management of personal data and reducing the risks associated with traditional passwords. This background highlights the potential and growing importance of emotional recognition in clinical and technological contexts, establishing a solid foundation for further study of real-time emotion recognition applied specifically to psychological intervention methods.

In conclusion, the studies analysed show significant progress in the development of emotion recognition systems, highlighting their effectiveness in diverse contexts through the use of techniques such as convolutional neural networks, deep learning, and hybrid models. However, there remains limited integration of these technologies in real-life clinical settings, especially in real-time psychological interventions. This review identifies a need to refine and validate these tools in therapeutic contexts, taking into account both the specific characteristics of personal relationships and the ethical and practical challenges involved in their application. In this context, this analysis suggests a technological solution focused on psychological practice, with the aim of contributing to the development of more sensitive, personalised interventions based on precise emotional data.

III. Methodology

This section describes the method used in this study, including the dataset description, the preprocessing and processing steps, the CNN model architecture, the analysis techniques used, and the testing environment focused on psychological interventions. The goal is to ensure the development of an accurate and feasible system for use in real-time clinical situations.

A. Dataset Description

For training and evaluation of the model, the FER2013 dataset was used, a resource commonly used in research on

emotion recognition through facial expressions [15]. This set contains features that are described in Table I.

TABLE I. FEATURES FOR MODEL TRAINING

Feature	*Description*
Set size	35,887 images
Resolution	48 x 48 pixels
Format	Grayscale images
Emotions labeled	Anger, Disgust, Fear, Happiness, Sadness, Surprise, Neutral
Capture conditions	Diversity in lighting, facial positions and demographic conditions
Applications main	Evaluation of CNN models for facial emotion recognition

The diversity of demographics, lighting, and facial positions in FER2013 allows for the training of a model capable of generalising across diverse clinical contexts. Furthermore, its validation in previous studies and its accessibility facilitate the replication of experiments and the development of advanced AI techniques for real-time emotion recognition.

In addition to its technical advantages, the FER2013 suite has significant limitations, such as the lack of colour images, contextual information, and an exclusive focus on basic emotions. Therefore, we recognise the need to evaluate the suggested model in future research, complemented by more extensive and complex databases, such as AffectNet or RAF-DB, which include greater emotional variability. These evaluations could confirm and greatly improve the scalability and robustness of the system in diverse therapeutic contexts and clinical groups.

B. Data Pre-processing

The flowchart in Fig. 1 shows the steps involved in the process. The first pre-processing step was to normalise the images from the FER2013 set, ensuring that all samples were grayscale and had a uniform resolution of 48x48 pixels.

A data augmentation technique was applied by horizontally inverting each image along the Y axis, duplicating the original set and generating a mirrored version of each facial expression. This strategy preserved emotional characteristics while introducing spatial variability, improving the model's ability to generalise and reducing the risk of overfitting. As part of the experimental design, a pilot phase was conducted with 1,000 images to train a preliminary model. This allowed us to validate the pre-processing workflow and fine-tune hyperparameters before scaling the training to 71,774 images, ensuring efficiency and performance.

C. Training Tools

- FER2013: The FER2013 dataset is a set of facial images used to train emotion recognition models [27]. It was used in this study due to its ease of integration and immediate results.
- TensorFlow: It is an open-source library developed by Google for creating and training ML [28], [29]. Its use in this study lies in the construction of the Convolutional Neural Network (CNN) architecture and integration with FER2013 images. It also accelerates the implementation process and facilitates future integration of the model into clinical applications.
- Keras: It is a high-level interface for building and training neural networks, based on a TensorFlow API [30]. In this study, it was used to build the CNN architecture and develop rapid and efficient prototypes, which is essential during pilot testing.
- Google Colab Pro: It is a free cloud-based platform that allows you to run Python code, as well as access to 100 processing units and GPU access for computation-intensive tasks [31]. It is used to train the CNN model using the 1000-image subset of the FER2013 dataset. It was chosen for its accessibility, library integration, and accelerated processing capabilities without requiring local resources.

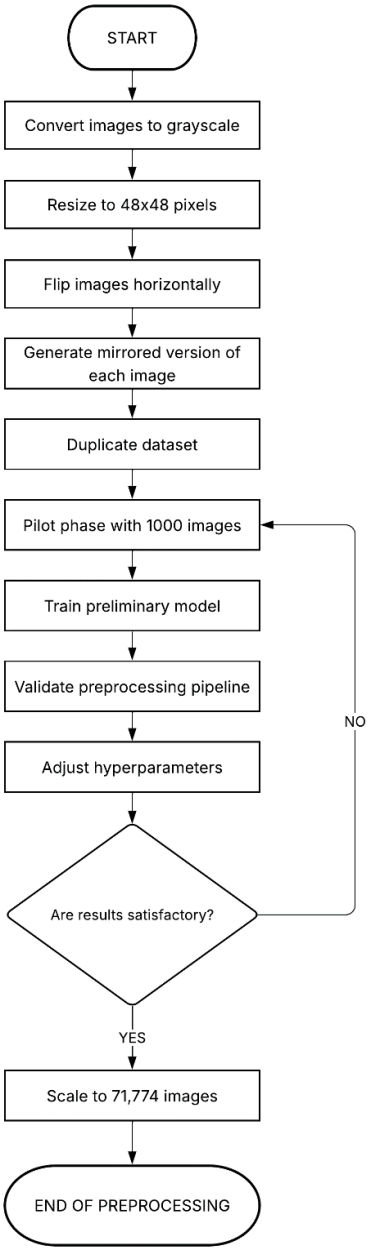

Fig. 1. Sampling design and implementation flowchart

D. CNN Architecture

In this study, the emotion recognition model developed is based on a CNN architecture, selected for its proven effectiveness in image classification tasks, particularly facial expression recognition. This design facilitates the gradual extraction of relevant patterns from the input images, with the goal of identifying basic emotions such as happiness, sadness, anger, fear, surprise, disgust, and neutrality in real time.

The model accepts grayscale images with input dimensions of 48x48, corresponding to the structure of the FER2013 dataset. These images are pre-processed to ensure normalisation and compatibility with the network.

The specific structure of the CNN model used for the pilot test with 1000 images is described below. This architecture, shown in Fig. 2 and Table II, was designed to be lightweight and efficient, suitable for training with small datasets, and oriented toward real-time applications.

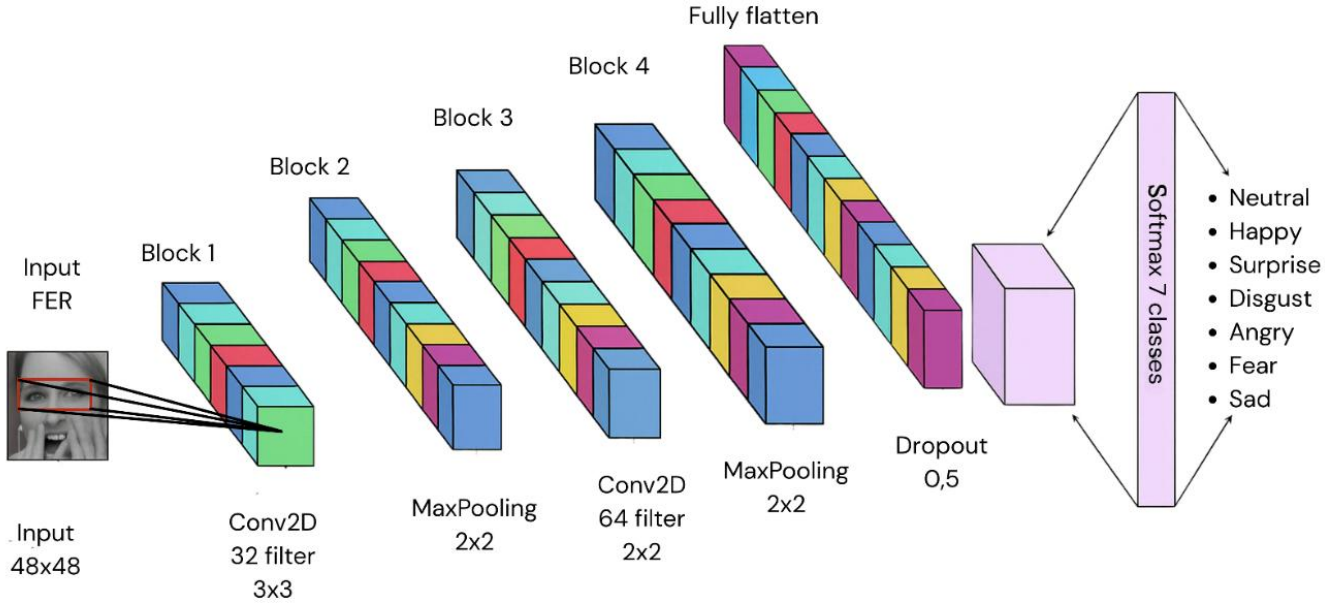

Fig. 2. CNN architecture

TABLE II. FEATURES OF CNN ARCHITECTURE

Layer	*Filters / Units*	*Kernel Size*	*Function*
Input layer	-	48x48x1	Receive grayscale image
Conv2D 1	32	3x3	Detect simple patterns (edges, lines)
MaxPooling 1	-	2x2	Reduce spatial dimension
Conv2D 2	64	3x3	Detect complex patterns (facial features)
MaxPooling 2	-	2x2	2° reduction of spatial dimension
Dropout	-	-	Avoid overfitting in training
Output layer (Softmax)	7	-	Classify among 7 basic emotions

1) Input layer (Input 48x48x1). This layer receives grayscale facial images with a resolution of 48x48 pixels and a single channel. This dimension is derived from the FER2013 dataset, ensuring direct compatibility without the need for additional transformations.

2) First convolutional layer (Conv2D – 32 filters, 3x3). This first layer applies 32 convolution filters of 3x3 pixel size, enabling the detection of basic features such as edges, corners, and texture transitions; and overall, improving learning capacity.

3) First pooling layer (MaxPooling 2x2). This layer reduces the dimensionality of the feature maps produced by the first convolution using a 2x2 pixel kernel. This improves computational efficiency and preserves the most relevant features.

4) Second convolutional layer (Conv2D – 64 filters, 3x3). This second convolutional layer increases the complexity of the analysis with 64 filters of 3x3 pixels, allowing the detection of more detailed patterns such as combinations of facial features (frown, smile, among others).

5) Second pooling layer (MaxPooling 2x2). This layer reduces the spatial dimensions of the already selected maps, in order to prepare the data for the following layers and to reduce the risk of overfitting.

6) Dropout layer (Dropout – 0.5). This layer randomly deactivates 50% of neurons during training, which forces the model to avoid overly relying on certain nodes. This leads to improved generalization capabilities, especially on specific datasets.

7) Output layer (Softmax – 7 classes). This last layer uses a softmax activation function, which converts the output into a distribution over 7 emotions (neutral, happy, surprise, disgust, angry, fear, sad). The model predicts the emotion with the highest probability as the final output.

E. Analysis Techniques

The analysis of the results obtained after real-time emotion detection is carried out using two main approaches: structured data collection in CSV files (Comma Separated Values) and the application of the K-means clustering algorithm. These techniques allow us to evaluate the performance of the CNN model and organize emotional patterns in greater depth.

During the development of the system, a mechanism for automatically recording the results of the emotional classification was implemented. Each time the model identifies an emotion in real time, the information is saved in a CSV file. This file includes important information such as the emotion detected, the model's confidence level, and the exact time of detection. This approach allows for the construction of a chronological database of emotional reactions, which can be used by clinical psychologists to examine how a person's emotional state changes during a session at specific times.

To identify shared emotional patterns in the recorded data, we used the unsupervised K-means clustering method. This method facilitates the separation of identified emotions into groups based on common aspects such as emotional intensity and similarity between facial expressions. Its use facilitates data exploration from a more visual and interpretive perspective and segments patients' emotional profiles.

F. Test Environment in Psychological Interventions

To evaluate the clinical applicability of the real-time emotion recognition model, a functional and user-friendly graphical user interface (GUI) was designed for psychology professionals. This interface allows users to upload facial images or activate the camera to process expressions and obtain the predominant emotion along with the prediction confidence level. Its user-centred design prioritises visual clarity, direct interpretation of results, and non-invasive integration during therapy sessions, allowing the specialist to observe the detected emotions in parallel.

In this study, the term "real-time" refers to the system's ability to process facial expressions with an average latency per image, ensuring an immediate response during the session. To improve visual stability without losing immediacy, temporal averaging over moving 1-second windows was incorporated, smoothing out abrupt variations without compromising instantaneous detection.

IV. Results

This section presents the main results obtained after the implementation and testing of the emotion recognition system. It describes the findings achieved during the pilot phase of training the CNN model, the real-time classification records, the emotion clustering analysis, and the behaviour of the graphical interface developed for clinical use of the system:

A. Data Analysis

In order to evaluate the feasibility and initial performance of the proposed model, a pilot test was developed using a subset of 1000 images from the FER2013 set. The data is shown in Table III. This representative sample included seven basic emotions distributed proportionally and allows validating the CNN model architecture and the most appropriate training configuration. Three iterations of hyperparameter tuning were performed, modifying the number of filters per layer, the batch size and the learning rate. Finally, a pipeline with two convolutional layers (32 and 64 filters), a grouping using MaxPooling, a dropout layer with a rate of 50% and a softmax output layer for multiclass classification was consolidated.

The model was trained for 50 epochs on the Google Colab platform, achieving a total accuracy of 92.3% on the validation set. The average performance metrics per class showed a precision of 0.93, a recall of 0.91, and an F1-score of 0.92, demonstrating a robust ability to discriminate between different emotional expressions, even with slight variations in lighting or posture. This configuration proved to be optimal in terms of both accuracy and computational efficiency, validating its appropriate capacity for real-time implementation within controlled clinical environments.

TABLE III. CNN Model Configuration and Results

Iteration	Filters	Batch Size	Learning Rate	Accuracy (%)	Precision	Recall	F1 score	Eras	Time / epoch
1	32 / 64	64	0.001	85.6	0.86	0.84	0.85	50	5.1 s
2	32 / 64 / 128	32	0.0005	89.8	0.90	0.89	0.89	50	5.3 s
3	32 / 64 / 128	64	0.0003	92.3	0.93	0.91	0.92	50	5.2 s

B. CNN Model

In this section, Fig. 3, illustrates the normalized confusion matrix for the validation set, generated after training a simple convolutional neural network on the FER2013 dataset. The architecture used included two convolutional layers, max-pooling operations, and a Dropout layer to mitigate overfitting. Per-class accuracy values ranged from 0.66 to 0.85, reflecting adequate performance for a low-complexity architecture applied to a visually heterogeneous and moderately unbalanced dataset.

The model showed the most accurate recognition for the emotions Happy (0.83), Surprise (0.80), and Neutral (0.85), while Disgust and Fear were confused with nearby classes, such as Angry and Surprise, respectively. These confusions are consistent with previous studies highlighting the difficulty of differentiating facially similar emotions. Overall, the results support the model's validity for basic emotion recognition tasks in controlled experimental or clinical settings.

The CNN model trained on 71,774 images from the FER2013 dataset achieved an estimated overall accuracy of 77.5%, as assessed by the normalized confusion matrix and the calculation of the weighted average F1-score. This result demonstrates robust performance for real-time basic emotion recognition, despite a simplified architecture composed of only two convolutional layers. To achieve these performance levels,

training between 60 and 100 epochs is recommended, applying strategies such as early stopping to prevent overfitting. The model was trained using batch sizes of 32 and 64, along with an initial learning rate between 0.0003 and 0.001, allowing for adequate generalisation without compromising computational efficiency. These configurations facilitate the system's implementation in real-world clinical settings without requiring complex infrastructure.

Fig. 3. Confusion matrix

C. K-Means Clustering Analysis

Fig. 4 shows an unsupervised clustering analysis using the K-means algorithm on the FER2013 dataset, projected into two principal components for ease of visualisation. Each colour represents a cluster corresponding to similar emotional patterns detected by the model, while the red "X"s indicate the centroids of each cluster.

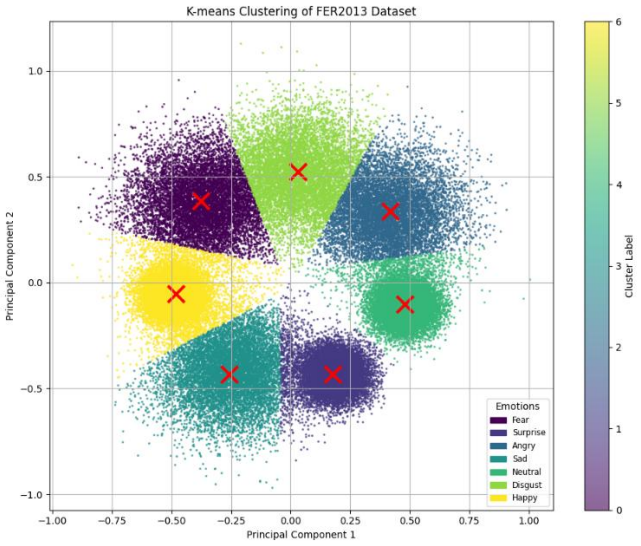

Fig. 4. K-means clustering analysis

This approach relates to the findings of the confusion matrix, where emotions such as happy, neutral and surprise have more defined clusters, while fear and disgust show greater dispersion and intersection with other clusters.

D. Graphical Interface Performance

Fig. 5 shows the system's graphical interface, which is divided into various real-time factors. The header is distinguished by the name of the facial recognition system, "ZIGGY-BOT", and the corresponding logo. The left column also represents the multiple options considered in the system, taking into account facial recognition, input data, data forms, and system output. The centre shows an example of real-time system validation. Finally, the right column displays the emoji's representative of the image, which shows the identified user emotion in a more understandable format, similar to emoticons. All these changes were made thanks to feedback from psychology specialists.

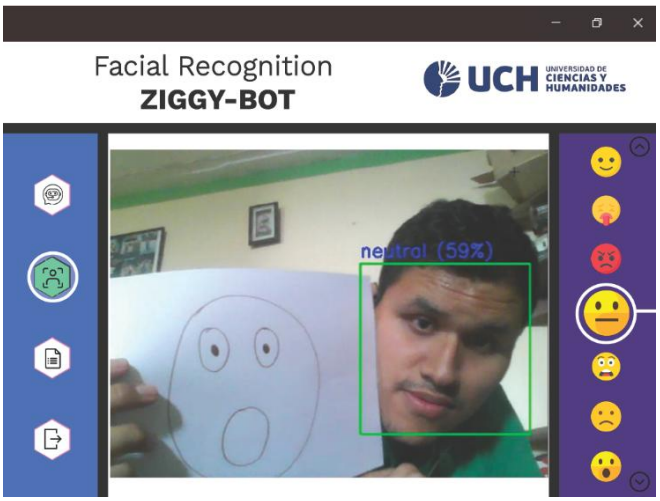

Fig. 5. Graphical interface of the system

E. Real-Time Results

During the clinical validation of the real-time emotion recognition system, the developed graphical interface was used with three participants in individual five-minute sessions. This tool allowed emotional evolution to be captured and displayed with a latency of approximately 150 milliseconds through facial expressions, providing a clear visualization of predominant emotional changes. Written informed consent was obtained from the participants before each session, ensuring confidentiality and ethical use of the data.

As illustrated in Fig. 6, abrupt fluctuations between emotions were recorded, due to the natural behaviour of the system after prolonged exposure to multiple continuous expressions. In these cases, the system averages the detections within each interval using a CSV report to graph only the predominant emotion, which can lead to jumps between affective categories. This feature was discussed with the mental health specialist, who recognized the system's potential to identify useful emotional patterns in therapeutic contexts, despite the variations inherent in real-time analysis.

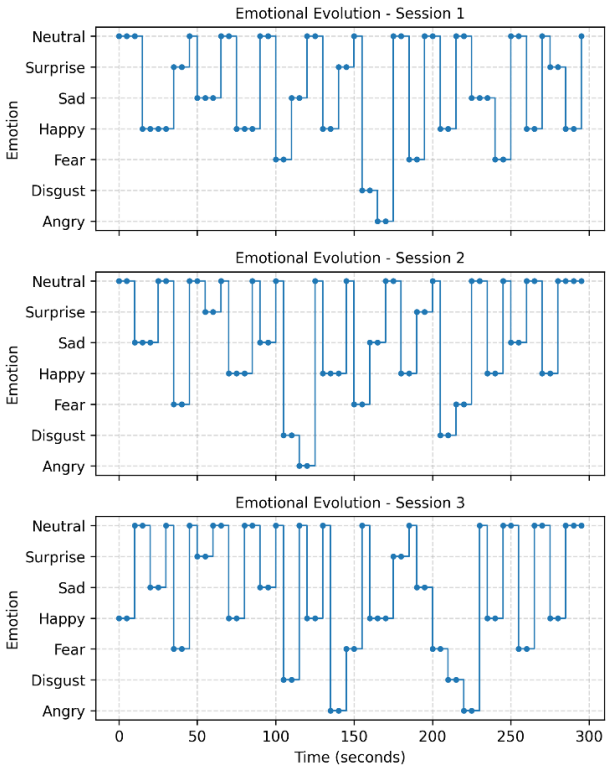

Fig. 6. Real-time results of the system

V. Discussion

The results obtained during the clinical evaluation demonstrated that the computer vision-based emotion recognition system achieved satisfactory performance with an accuracy of 92.3%. However, during the five-minute experimental sessions, abrupt jumps between emotions were observed due to the prolonged exposure of the model to multiple simultaneous expressions. To manage this variability, an average was applied per time interval, graphing only the predominant emotion. This behaviour, although expected in real-time systems with simplified architecture, was valued as interpretable by the clinician during feedback. Unlike TheraSense, proposed by Hadjar et al. [16], which was designed for teleconsultation using deep learning, the present system used a lighter CNN network, with only two convolutional layers, which favoured reduced training times and smooth integration into face-to-face sessions without the need for complex infrastructure.

Compared to the Elsheikh and Mohamed model [19], which incorporates anti-aliasing techniques and multiple deep convolutional layers to address adverse conditions such as occlusions and uneven illumination, the system developed here prioritized structural simplicity with only two convolutional layers. This choice allowed for faster training and a lower computational burden, which is essential for real-time execution in conventional clinical settings. Meanwhile, the approach by Saadon et al. [17], which uses digital image correlation to avoid gender or racial bias, represents a relevant alternative for future work. Although demographic equity was not addressed in this study, preliminary results suggest generalizable behaviour within a heterogeneous population without evident expressive pathologies.

Regarding the graphical representation of emotions, the system proposed a chronological visualisation using timelines, which facilitated the monitoring of the emotional state detected during the session. This approach is related to the model of [23], which applied multimodal fusion between CNNs and transformers to improve emotional interpretation in embedded hardware. Although the present system does not incorporate such technical complexity, its simplicity allows a functional implementation in real clinical conditions. Finally, Ballesteros et al. [22] highlighted the need to integrate psychological theories in the design of these systems. Although this model focused on visual data, its stable performance and practical adaptability allow it to be considered as a basis for future integrations with complementary clinical variables that enhance the therapeutic usefulness of automatic emotion recognition.

Although the findings obtained in this research demonstrate remarkable accuracy and functional implementation in real-world clinical settings, further evaluation of the system is warranted. The inclusion of different datasets, incorporating composite emotions, spontaneous expressions, and demographic diversity, will facilitate a more detailed assessment of the model's scalability. Furthermore, a comparative study with more robust architectures could uncover significant advances in system performance without compromising its real-time applicability. Therefore, this study lays the groundwork for future studies seeking to incorporate emotion recognition into clinical practice, fostering more empathetic, adaptive, and evidence-based psychological interventions.

VI. Conclusion and Future Work

The findings of this study demonstrated the effectiveness of the proposed system for real-time emotion identification based on convolutional neural networks. With an initial learning rate of between 0.0003 and 0.001 in the validation phase, the model achieved an accuracy of 77.5% using the FER2013 dataset, demonstrating robust performance even with postural variations. Through the developed graphical interface, functional integration was achieved in real-life clinical situations, facilitating the clear and real-time representation of predominant emotions during therapeutic sessions. The application of methods such as K-means analysis and time recording allowed the technical approach to be complemented with useful analytical tools for mental health experts.

One of the most relevant aspects of this study is the development of a lightweight and functional system capable of running in real time without the need for extensive technological infrastructure, making it a beneficial tool for clinical settings and other sectors. The "ZIGGY-BOT" interface stands out as a model for highly accurately identifying emotions such as happiness, surprise, and neutrality, representing a significant advance compared to traditional models that require more architectural complexity. This alternative combines technical accessibility with practical applicability, generating new opportunities to improve the quality of psychological interventions.

For future research, we recommend exploring the integration of multimodal signals and a larger number of layers, such as voice or brain activity analysis, which could enhance facial identification for more complex emotional assessment. It would also be appropriate to implement the system in groups with specific clinical characteristics, such as emotional disorders or those on the autism spectrum, to assess its accuracy in more diverse situations. Finally, we recommend including demographic equity filters to reduce potential gender, age, or ethnic biases, in order to incorporate a more detailed and personalised interpretation of the identified emotions.

Artificial Intelligence-Driven Physical Simulation and Animation Generation in Computer Graphics

Fei Wang
Research Department, Zhengzhou Professional Technical Institute of Electronics & Information, Zhengzhou, 451450, China

***Abstract*—This study explores an expression synthesis algorithm anchored in Generative Adversarial Networks (GAN) with attention mechanisms, achieving enhanced authenticity in facial expression generation. Evaluated on the MUG and Oulu-CASIA datasets, our method synthesizes six expressions with superior clarity (96.63±0.26 confidence for neutral expressions) and smoothness (SSIM >0.92 for video frames), outperforming StarGAN and ExprGAN in detail preservation and temporal stability. The proposed model demonstrates significant advantages in realism and identity retention, validated through quantitative metrics and comparative experiments.**

***Keywords*—GAN; computer graphics; expression synthesis; animation generation**

I. Introduction

With the advancement in computer graphics and artificial intelligence, facial expression synthesis technology has been applied in animation production, video games, human-computer interaction, etc. [1-2]. The effectiveness of expression synthesis, namely its realism and naturalness, directly influences the user's immersion and interactive experience. Hence, in-depth research into methods of facial expression synthesis becomes exceedingly crucial.

In the early stages, facial expression synthesis predominantly relied on parametric methods and muscle models. These methods were grounded in the biomechanical behavior of facial muscles, utilizing mathematical models to depict the impact of muscle movements on facial expressions [3]. While these methods were capable of encoding facial movement information to a certain extent, their complexity and inflexibility often resulted in the loss of detail, especially when handling rapid changes or a diversity of emotions. The Facial Action Coding System (FACS) is another classical approach for describing expressions [4]. It provides a standardized set of Action Units to precisely define facial expressions [5-6]. Although this method has its advantages in extracting static expressions, it still requires substantial manual intervention and complex annotation processes in dynamic sequence generation, making it difficult to meet the demands of rapid generation.

Recently, deep learning methods have garnered great attention in expression synthesis [7]. The new generation of deep generative models has increasingly adopted a strategy that combines expression feature extraction with driving images [8-9]. By utilizing high-dimensional facial feature information as conditional input or directly employing driving images as supervisory information, the generator can learn the intricate relationships and corresponding mappings of expressions. Furthermore, the introduction of attention mechanisms [10] enhances the precision and detail of the synthesis. In the evolution of Generative Adversarial Networks (GANs) [11], dynamic image generation models that incorporate temporal information, such as Temporal GANs [12], and Recurrent Neural Network architectures [13], are capable of effectively capturing temporal continuity, thereby enhancing the smoothness of the generated videos. This progress not only offers new approaches for expression animation generation but also provides additional possibilities for research in expression transfer and conversion.

The proposal of GANs has greatly propelled advancements in this field. Through adversarial training, GANs enable the generator to produce high-fidelity synthetic images with a quality approaching that of real images, and they exhibit outstanding performance in expression diversity. In this context, several GAN-based variants have emerged, such as conditional GAN [14], StarGAN [15], and ExprGAN [16]. Researchers have gradually realized the potential of combining expression features with deep learning methods. By extracting features from input facial images and integrating target expression information, the generator can produce corresponding expression changes while preserving individual characteristics. Existing methods (e.g., StarGAN and ExprGAN) perform poorly in expression detail and temporal continuity. By integrating channel and spatial attention mechanisms, our method significantly improves the naturalness and detail retention of generated expressions. This study proposes a GAN- and attention mechanism-based approach to address these issues and achieve high-quality expression animation generation.

In summary, this study explores an expression synthesis algorithm based on GAN and incorporates attention mechanisms. Section II details the proposed methodology, while Section III presents experiments and comparative results. Section IV concludes the study. Our method dynamically weights key features (e.g., mouth corners and nasolabial folds) through attention mechanisms, avoiding common issues such as blurring and artifacts in traditional methods. Through an in-depth study of the combination of expression feature extraction and dynamic generation, we can achieve higher breakthroughs in realism, detail, and generation effectiveness.

II. Method Introduction

A. Generative Adversarial Networks (GAN)

GANs generate realistic data and enhance discriminative capabilities through adversarial learning between a generator and a discriminator, ultimately making the generated data indistinguishable from real data.

For a synthetic model V, its training process can typically be distilled into an optimization problem.

$$\min_{G}\max_{D} V(G,D) = E_{x\sim P_{data}}(\log D(x)) + E_{z\sim P_z(z)}(\log(1-D(G(z)))) \quad (1)$$

where, G denotes the generator, which produces an output denoted as $D(x)$; D signifies the discriminator, yielding an output represented by $G(z)$; P_{data} refers to the distribution of the genuine data x; while z embodies noise data that conforms to the random distribution P_z. The $D(G(z))$ indicates the discriminator's predicted probability regarding the data generated by the generator. The first term $E_{x\sim P_{dalu}}$ represents the probability of correct classification for authentic samples by the discriminator. Conversely, the second term $E_{z\sim P_2(z)}$ denotes the probability of incorrect classification for generated samples by the discriminator.

In the n-th iteration of the network iteration, k pairs of training data $\{z^{(1)},...,z^{(m)}\}$ are randomly sampled from the noise distribution $p_{\text{data}}(x)$, and m samples $\{x^{(1)},...,x^{(m)}\}$ are randomly drawn from the data synthesis distribution.

Each iteration of the network randomly obtains training data from the prior noise distribution $p_g(z)$ and randomly draws a sample from the data synthesis distribution. Then it updates the weights of the generator and discriminator networks using the following formulas,

$$\nabla_{\theta_d}\frac{1}{m}\sum_{i=1}^{m}[\log D(x^{(i)}) + \log(1-D(G(z^{(i)})))] \quad (2)$$

$$\nabla_{\theta_g}\frac{1}{m}\sum_{i=1}^{m}\log(1-D(G(z^{(i)}))) \quad (3)$$

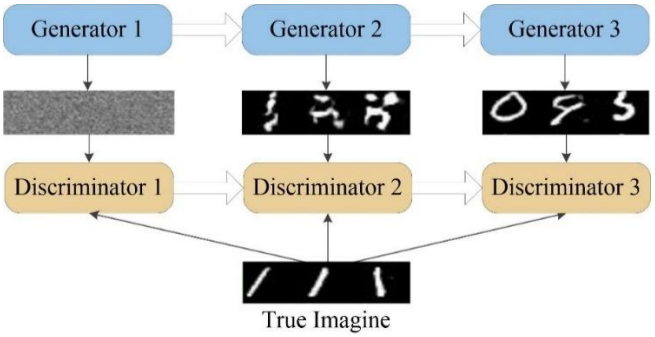

Fig. 1. Illustrates the training process of GAN networks.

In the training of GANs, shown in Fig. 1, the process commences with a randomly initialized first generation of the generator and discriminator. During the initial phase, the images produced by the generator exhibit low quality, while the discriminator begins to learn the distinction between authentic data and counterfeit data. Following the training of the generator, a second generation is obtained alongside the training of a new discriminator. This iterative process continues, ultimately leading the generator to produce images of near-perfection, rendering the discriminator unable to discern the genuine from the false, thereby achieving Nash equilibrium and enabling successful training of the generative network.

Conditional Generative Adversarial Networks (CGANs) represent an enhancement over traditional GANs, as shown in Fig. 2. By incorporating additional conditional information to direct the generation process, CGANs ensure that the generated data aligns more closely with specific demands or characteristics. The objective function is articulated as follows:

$$\min_{G}\max_{D} V(G,D) = E_{x\sim P_{data}}[\log D(x|y)] + E_{z\sim P_z(z)}[\log(1-D(G(z|y)))] \quad (4)$$

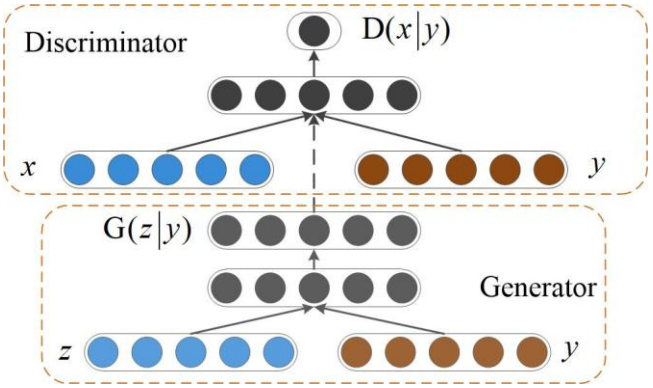

Fig. 2. The architecture of the Conditional GAN.

B. Integrating the Attention Mechanism

The Attention Mechanism is an approach that emulates human visual focus [10]. Its purpose is to enhance the efficiency and effectiveness of models when processing information, particularly in sequential data and image processing. Channel Attention and Spatial Attention are two crucial forms of the attention mechanism, primarily employed to boost the performance of Convolutional Neural Networks (CNNs) in image processing tasks. They augment the model's focus on significant features through different methodologies.

Channel Attention primarily concentrates on the channel dimension of the input feature maps. It endeavors to emphasize important features and suppress insignificant ones by assigning a weight to each channel, thereby strengthening the feature representation capacity.

The input feature map is denoted as $M=[m_1,m_2,...,m_C]$, with the i-th channel (out of a total of C channels) being represented as $m_i \in R^{h\times w}$. Here, h,w signify the height and width of the image, respectively. The channel statistics $P \in R^{1\times 1\times C}$ are achieved through global pooling operations, which compact the spatial dimensions, thereby embedding the global spatial information into vector p. The k-th element of this vector is shown as follows:

$$p_k = F_{GP}(m_k) = \frac{1}{h \times w} \sum_{i}^{h} \sum_{j}^{w} m_k(i, j) \tag{5}$$

where, F_{GP} denotes the global pooling function, while (i, j) signifies the spatial location. Subsequently, a fully connected layer is employed to encode the channel information.

$$\hat{p} = \sigma(W_{\text{up}} \delta(W_{\text{down}} p)) \tag{6}$$

where, σ and δ denote the sigmoid and rectified linear unit activation functions, respectively.

A feature map $\hat{M}_{ca}$ weighted by channel attention enhances significant features and suppresses less pertinent ones.

$$\hat{M}_{ca} = [\hat{p}_1 m_1, \hat{p}_2 m_2, ..., \hat{p}_C m_C] \tag{7}$$

Spatial attention focuses on the spatial dimensions of feature maps [17]. We denote the input image as $M = [m^{1,1}, m^{1,2}, ..., m^{i,j}, ..., m^{h,w}]$. A projection vector q is employed to capture spatial information, with W_{sq} representing the weights of the convolutional layer used for spatial compression operations. By applying the spatial attention weights to the input feature map through element-wise multiplication, we obtain a new feature map $\hat{M}_{sa}$, thereby amplifying the significance of specific spatial regions.

$$q = \sigma(W_{sq} * M) \tag{8}$$

$$\hat{M}_{sa} = [(q_{1,1}) m^{1,1}, (q_{1,2}) m^{1,2}, ..., (q_{i,j}) m^{i,j}, ..., (q_{h,w}) m^{h,w}] \tag{9}$$

Channel-wise attention and spatial attention can be integrated to create a more powerful attention mechanism, significantly enhancing the performance of Neural Networks in image processing tasks. This approach enables a more comprehensive capture of essential features within images, regardless of their orientation within the channel or spatial dimensions.

C. Facial Expression Synthesis Algorithm Model

This research employs CGANs for the synthesis of facial expression intensity. Based on the intensity of expressions ranging from weak to strong, data is manually categorized into four levels: neutral, weak, medium, and strong, and represented as $\mathbf{z} = [z_0, z_1, z_2, z_3]$. Initially, a generator G and a discriminator D are constructed. The generator G's task is to, given a source image x_s and its intensity label, produce a new image x_t featuring the targeted expression intensity. Inspired by cGANs, this algorithm uses the expression intensity label as a constraint to control the synthesis of expression intensity. Additionally, changes in expression intensity are usually very subtle; to enhance the network's learning capacity in handling intensity variations, a fusion attention module is incorporated into the generator G.

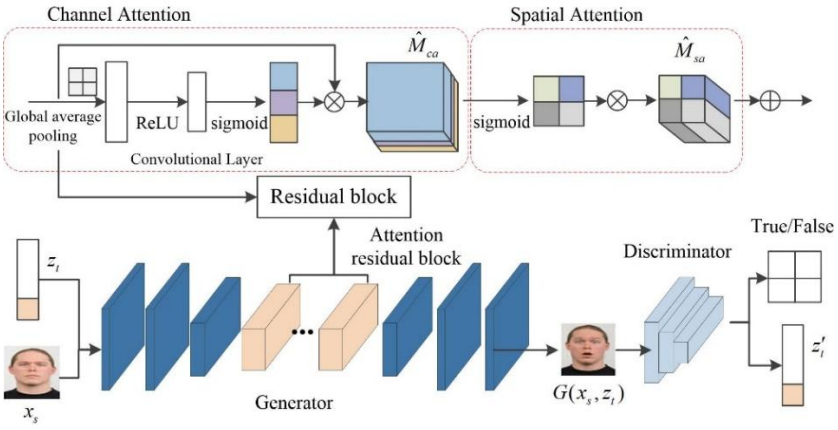

Fig. 3. Facial expression synthesis algorithm with attention mechanism.

The algorithm proposed integrates Conditional GAN and attention mechanisms, as shown in Fig. 3. By concatenating preprocessed original images of 128×128 pixels with target intensity labels, it undergoes processing through downsampling convolutional layers, residual modules infused with attention, and upsampling transpose convolutional layers, ultimately producing generative images that embody the desired expression intensity. Concurrently, the discriminator network enhances the PatchGAN structure by incorporating an auxiliary classifier, which not only differentiates between real and fake images but also assesses expression intensity, thereby augmenting both the accuracy and realism of the generated images.

This study devised various loss functions to constitute the final objective function. Through the optimization of this objective function, both the generator network and the discriminator network engage in adversarial learning, fine-tuning network parameters to achieve an optimal model, thereby synthesizing lifelike facial images that convey specified expression intensities. In the conclusion, neutral-expression facial images were employed as test samples, generating faces with varying expression intensities while preserving identity information. The principles of reconstruction loss, pixel loss, and identity retention loss functions are illustrated in Fig. 4.

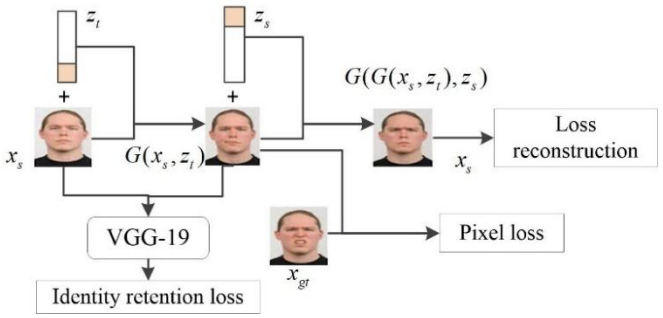

Fig. 4. Diagram of the loss function principle.

1) The adversarial loss is employed to assess the dissimilarity between generated images and real images. Here, an adversarial loss function analogous to the conditional GAN loss function is devised.

$$L_{adv}^{G} = E_{x_s, z_t}[\log(1 - D_{st}(G(x_s, z_t)))] \tag{10}$$

$$L_{adv}^{D} = -E_{x_s}[\log D_{st}(x_s)] - E_{x_s, z_t}[\log(1 - D_{st}(G(x_s, z_t)))] \tag{11}$$

where, L_{adv}^{G} and L_{adv}^{D} represent the adversarial losses of the generator G and the discriminator D, respectively. $G(x_s, z_t)$ denotes the image synthesized from the source image x_s and the target intensity label z_t, while $D_{st}(x)$ indicates the probability of the authenticity of the image x.

2) The formula for calculating the reconstruction loss L_{rec} is as follows:

$$L_{rec} = E_{x_s, z_s, z_t}\left\| x_s - G(G(x_s, z_t), z_s) \right\|_1 \tag{12}$$

where, z_s signifies the intensity label of the input image, while z_t represents the target label. $G(G(x_s, z_t), z_s)$ denotes the reconstructed image.

3) The formulation for the intensity classification loss function is delineated as follows:

$$L_{int}^{D} = E_{x_s, z_s}[-logD_{int}(z_s \mid x_s)] \tag{13}$$

$$L_{int}^{G} = E_{x_s, z_t}[-logD_{int}(z_t \mid G(x_s, z_t))] \tag{14}$$

Among them, $D_{int}(z_s \mid x_s)$ denotes the probability distribution of the source image z_s concerning its intensity label x_s; $D_{int}(z_t \mid G(x_s, z_t)$ reflects the probability distribution of the generated image concerning the target intensity z_t.

4) The computation formula for the expression intensity classification loss L_{pix} is as follows:

$$L_{pix} = E_{x_s, x_t, z_t}\left\| x_{gt} - G(x_s, z_t) \right\|_1 \tag{15}$$

where, x_{gt} denotes the real image with a facial expression intensity of z_t. The L1 norm is employed to calculate the difference between the generated image and its corresponding ground-truth.

5) The identity-preservation loss is utilized to ensure that the generated image retains the identity information of the original image, such as facial features and skin tone, while altering the intensity of the facial expression.

$$L_{id} = E_{x_s, z_t}\left\| \phi(x_s) - \phi(G(x_s, z_t)) \right\|_1 \tag{16}$$

where, $\phi(x_s)$ represents the input facial image x_s, from which identity features are extracted by the feature extractor ϕ. $\phi(G(x_s, z_t))$ denotes the identity features extracted from the generated facial image $G(x_s, z_t)$ by the feature extractor.

6) The comprehensive objective function is formulated by a weighted combination of the aforementioned five loss functions, enabling the model to maintain a balance among various types of losses throughout the training process.

$$L_G = L_{adv}^{G} + \lambda_{pix} L_{pix} + \lambda_{rec} L_{rec} + \lambda_{id} L_{id} + \lambda_{int} L_{int}^{G} \tag{17}$$

$$L_D = L_{adv}^{D} + \lambda_{int} L_{int}^{D} \tag{18}$$

where, $\lambda_{pix}, \lambda_{rec}, \lambda_{id}, \lambda_{int}$ signifies the weight coefficients. Through the iterative refinement of L_G and L_D, the ultimate result is the synthesis of photorealistic facial images with varying intensities of expression.

III. Experiment and Analysis

A. Data Set and Evaluation Index

This experiment utilizes the MUG dataset and the Oulu-CASIA dataset as sources of data. The MUG dataset includes sequences of six expressions from 86 subjects, while the Oulu-CASIA dataset comprises videos of 80 subjects under three lighting conditions, while the Oulu-CASIA database consists of expression videos recorded by 80 subjects under three distinct lighting conditions. The emotions involved include happiness, sadness, anger, disgust, surprise, and fear. All images were aligned using 68 key points (Fig. 5) and cropped to 128×128 resolution to eliminate lighting and pose interference. This study divided the training set according to 7:3, and ensured that each expression was representative in both the training set and the test set. The PyTorch deep learning framework was employed for the experiment.

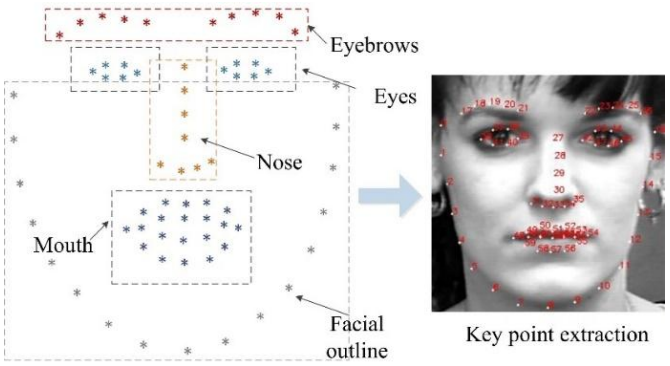

Fig. 5. Extraction of facial feature key points.

In this experiment, we first preprocess all facial images within the dataset. A keypoint detection algorithm identifies and extracts 68 key points from the facial images (see Fig. 5), followed by alignment. Subsequently, the images are cropped to a dimension of 128×128×3. Manual annotation is then conducted, classifying the expressions into four levels: neutral, weak, moderate, and strong. Taking "happiness" as an example, the classification results are shown in Table I.

TABLE I. CLASSIFICATION OF EXPRESSIONS IN THE TWO DATASETS

Database	MUG		Oulu-CASIA	
	Training set	Testing set	Training set	Testing set
Neutral	4191	420	498	56
Subtle	1514	-	469	-
Moderate	2410	-	482	-
Intense	2495	-	573	-

During the experiment, we utilized Face++'s online facial verification API to authenticate face images generated with varying intensities of expressions. By calculating the confidence level (ranging from 0 to 100) between the input image and the generated images, we evaluated the retention of identity information in the synthetic images. The misidentification rate was set at >78, and we compared the confidence levels of the input image with those of the generated neutral, mild, medium, and strong expression images, respectively.

B. Expression Synthesis Results and Evaluation

In this study, we generated different intensities of happy expressions based on neutral face images. Through experiments conducted on the MUG and Oulu-CASIA datasets, we evaluated the model's performance at various intensities. The results are depicted in Fig. 6. The experimental results indicate that at low intensity "happy" expressions, the generated face images only exhibit a slight smile, with a subtle upward trend of the corners of the mouth. As the intensity of the expression increases, the medium intensity "happy" expression shows marked changes, characterized by the mouth gradually opening, revealing half of the teeth, and the formation of nasolabial folds. When the expression intensity reaches its peak, the facial expression generated by the model exhibits the most intense emotional characteristics, with the corners of the mouth rising to their maximum extent, almost completely exposing all teeth, and the nasolabial folds becoming more pronounced. These results demonstrate that the proposed model can effectively and accurately simulate different intensities of "happy" expressions, showcasing excellent performance and expressive capability.

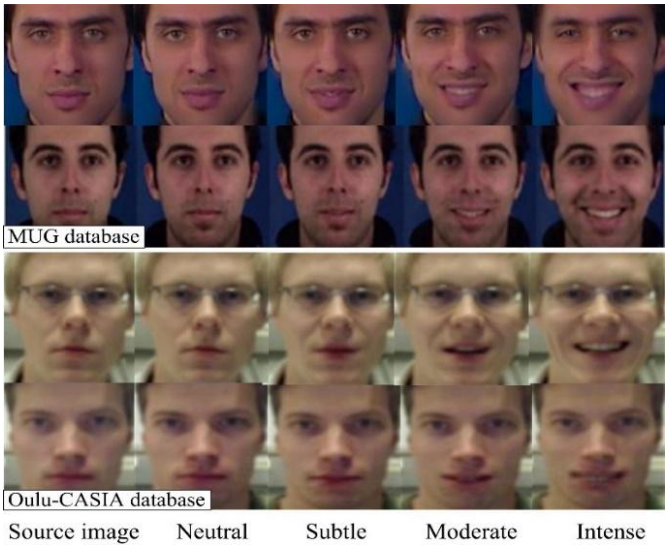

Fig. 6. Examples of expression synthesis results.

We conducted a quantitative evaluation of the "happy" expression synthesis results using confidence levels, shown in Table II.

TABLE II. FACIAL VERIFICATION CONFIDENCE LEVELS ON TWO DATASETS

Confidence	MUG	Oulu-CASIA
Neutral	96.63±0.26	97.0±0.52
Subtle	96.25±0.34	96.57±0.24
Moderate	95.62±0.25	95.67±0.42
Intense	94.25±0.76	94.47±0.24

Based on the results presented in Table II, we conducted an analysis of the "happy" expression synthesis performance across both the "MUG" and "Oulu-CASIA" datasets. Overall, both datasets exhibited a high degree of confidence in synthesizing happy expressions, albeit with certain distinctions. Under neutral expressions, Oulu-CASIA demonstrated slightly superior performance compared to MUG, indicating that both datasets accurately capture neutral expressions, with Oulu-CASIA excelling slightly more. As the intensity of the expression increased, the confidence level of MUG gradually decreased, particularly when rendering more intense happy expressions, whereas Oulu-CASIA maintained a commendable synthesis effect. In summary, Oulu-CASIA exhibited marginally superior stability and accuracy in "happy" expression synthesis.

C. Comparative Experiments

A comparative experiment was conducted to evaluate the image synthesis performance of the proposed method against StarGAN [15] and ExprGAN [16] methods on the MUG dataset. The synthesis effects of six expressions across different models are illustrated in Fig. 7.

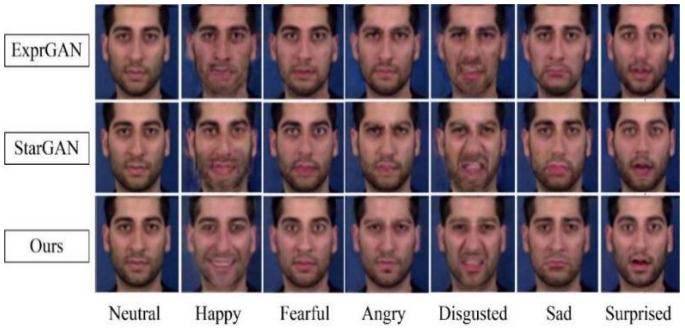

Fig. 7. Comparative synthesis effects of expressions across different models.

The proposed method significantly outperformed StarGAN and ExprGAN in expression synthesis. Specifically, when synthesizing sad expressions, our method not only accurately depicted the pouting mouth and sorrowful eyes but also rendered the overall expression more realistically and naturally. In contrast, StarGAN and ExprGAN exhibited more moderate performance in expression details. In the transformed happy expressions, the upturned corners of the mouth and the changes in nasolabial folds were less pronounced, lacking key muscular movement characteristics. StarGAN demonstrated certain limitations in expression synthesis, particularly in the synthesis of disgust expressions, which tended to be confusable with anger. This confusion was evidenced by the presence of most anger expression details in disgust expressions, leading to potential misclassification. Additionally, in the synthesized happy expressions, the mouth area exhibited noticeable blurriness, lacking critical information such as teeth exposure, which affected the overall authenticity of the expression. ExprGAN also encountered certain issues in expression synthesis, such as the occasional appearance of artifacts around the eyes and mouth during arbitrary expression synthesis, which impaired the overall image clarity and realism. The presence of these artifacts resulted in expressions appearing less natural and with less adequate detail.

The face verification confidence levels on the MUG dataset under different methods are shown in Table III. The proposed method, which integrates Conditional GANs and attention mechanisms, significantly enhanced the accuracy and naturalness of expression synthesis. Compared to traditional expression synthesis methods, the proposed method delivered more refined performance in key expression details (such as the upturning of the corners of the mouth and changes in nasolabial grooves), avoiding blurriness and artifacts. Experimental results indicate that this method achieved exceptionally high confidence levels in the synthesis of various expressions, particularly “happy” expressions, significantly outperforming existing methods like StarGAN and ExprGAN. As shown in Table III, our method achieves significantly higher identity preservation confidence (96.63±0.26) on the MUG dataset compared to ExprGAN (67.01±0.32), as the latter tends to lose identity features (e.g., skin tone and facial contours) during cross-intensity synthesis. This approach not only maintained stable performance across varying expression intensities but also more accurately captured muscle movement characteristics, resulting in more authentic and vivid generated expressions.

TABLE III. FACE VERIFICATION CONFIDENCE LEVELS ON THE MUG DATASET UNDER DIFFERENT METHODS

Confidence	Ours	StarGAN	ExprGAN
Neutral	96.63±0.26	96.34±6.25	67.01±0.32
Subtle	96.25±0.34	96.49±6.29	66.57±0.31
Moderate	95.62±0.25	94.07±6.15	64.46±0.42
Intense	94.25±0.76	92.73±6.22	64.03±0.38

D. Facial Expression Video Synthesis Effect

Based on the proposed method utilizing conditional Generative Adversarial Networks, we aim to synthesize facial expression videos. By testing images not included in the training dataset, we first extract facial features and construct a feature map of expressions, which are then employed to drive the synthesis of video frames. To evaluate the continuity and stability of the synthesized video frames, we measure the video's smoothness by calculating the Structural Similarity Index (SSIM) between consecutive frames. Experimental results, shown in Fig. 8, indicate that the video frames generated by our method display a natural appearance in terms of brightness and variations in expression, exhibiting commendable inter-frame continuity with no significant expression disjunctions or abrupt changes in brightness. We have conducted comparative experiments pitting our method against existing approaches (StarGAN and ExprGAN). The results demonstrate that our method surpasses the comparative techniques in the authenticity, smoothness, and continuity of the synthesized videos, with a more stable SSIM curve indicative of steadier frame transitions.

In summary, through systematic experimental validation, the proposed method based on CGANs has showcased exceptional performance in facial expression video synthesis, capable of producing high-quality, smooth, continuous facial expression videos.

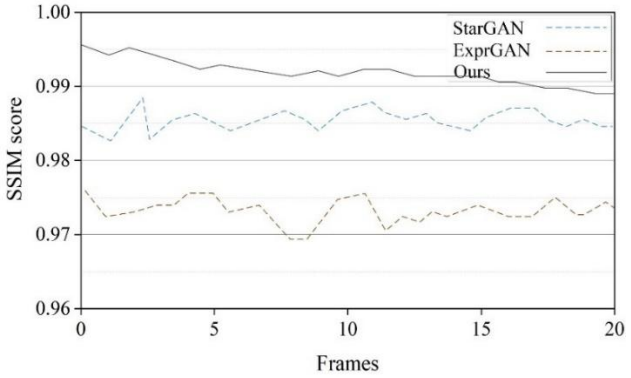

Fig. 8. Evaluation of continuity in synthesized expression videos.

IV. CONCLUSION

This study presents an algorithm for facial expression synthesis founded on Generative Adversarial Networks (GAN) combined with an attention mechanism. By effectively integrating feature fusion, we have significantly mitigated the loss of detail in the generated images, thereby enhancing the authenticity of the synthesized facial expressions. The experimental results reveal that the animated expressions

produced by our method not only exhibit a more natural and fluid visual appeal but also demonstrate marked improvements in clarity and detail retention compared to previous Generative Adversarial Networks. Particularly, in the synthesis experiments involving six distinct expressions, our algorithm has shown heightened accuracy and stability, rendering the generated expressions remarkably akin to genuine human expressions. Furthermore, the incorporation of the attention mechanism has endowed the model with greater flexibility in feature extraction, allowing for better preservation of key features and effectively elevating the synthesis quality. This study has two limitations: 1) The model requires aligned facial key points, limiting its applicability to unconstrained images; 2) Training on small datasets may affect generalization of rare expressions. In future work, we intend to explore more efficient model architectures, optimize training strategies, and further enhance model performance in more complex and dynamic facial expression synthesis. Additionally, the consideration of incorporating more context information and user interaction mechanisms to bolster the flexibility and adaptability of facial expression generation in practical applications will serve as a vital direction for our research.

Power Line Fault Detection Combining Deep Learning and Digital Twin Model

Siyu Wu[1]*, Xin Yan[2]
Zhengzhou Vocational University of Information and Technology, Zhenzhou 450008, China[1]
Yellow River Engineering Consulting Co., Ltd., Zhengzhou 450003, China[2]

***Abstract*—To address the issue of inadequate diagnosis of power line faults, an automated power line fault diagnosis technology is put forward. In this context, the research leverages the object detection algorithm YOLOv5 to construct a fault diagnosis model and enhances its anchor box loss function. In addition, the study introduces digital twin models for fault point localization, and improves the recognition model by introducing GhostNet and attention mechanism, thereby enhancing the diagnostic performance of the technology in multi-objective scenarios. In the performance test of the loss function, the improved loss function performs the best in both regression loss and intersection over union ratio, with the average loss value and intersection over union ratio being 125 and 0.986, respectively. In multi-scenario fault diagnosis, the research model performs the best in accuracy and model loss, with values of 0.986 and 0.00125, respectively. In multi-scenario fault diagnosis, such as abnormal heating detection, when the number of targets is 4, the relative error of the research model is 0.86%, which is better than similar models. Finally, in the testing of frame rate recognition and diagnostic time, the research model shows excellent performance, surpassing similar technologies. The technology proposed by the research has good application effects. This study provides technical support for the construction of power informatization and line maintenance.**

Keywords*—YOLOv5; route; fault diagnosis; digital twin; loss function

I. INTRODUCTION

As a key component of the power system, the safe and stable operation of power lines is crucial for socio-economic development. However, the environment in which power lines are located is complex and ever-changing, and they are susceptible to natural disasters, human damage, and other factors, leading to frequent failures. Traditional power line fault detection methods mainly rely on manual inspection and rule-based signal processing, which are inefficient, costly, and difficult to cope with complex and changing fault modes. In recent years, with the development of artificial intelligence technology, Deep Learning (DL) has gradually been applied in the field of power line fault detection and has achieved excellent results. For example, fault diagnosis technology based on deep convolutional neural networks can capture key features of power lines and train to recognize complex targets. In addition, there is a fault diagnosis technology based on recurrent neural networks, which achieves fault analysis through feature extraction of power lines. However, the above-mentioned DL techniques still face problems in the processing of power lines in complex scenarios, such as high cost of data annotation, long model training time, and poor recognition accuracy. In recent years, You Only Look Once version 5 (YOLOv5), as an advanced object detection algorithm, has shown great potential in power line fault detection due to its fast detection speed and high accuracy. Compared to traditional convolutional neural networks, it can handle more complex background environments and detect a larger range of targets. However, it still faces difficulties in dealing with small targets and complex scenarios, and precise positioning of fault areas is also challenging. At present, digital twin (DT) models are gradually receiving attention in the field of electricity. DTs can reflect the state and behavior of physical systems in real time by constructing virtual models that correspond to physical entities. They use data collected by sensors to analyze the operating status of power lines, thereby more accurately locating fault points. Consequently, to achieve efficient detection of power faults, the research has introduced an intelligent line fault diagnosis technology that integrates DT models with target-detection algorithms, specifically YOLOv5. This technology boasts two notable innovations. Firstly, it focuses on optimizing the anchor box loss function. By doing so, it can effectively filter out irrelevant targets, thereby streamlining the diagnosis process and enhancing overall efficiency. Secondly, the research incorporates the GhostNet architecture and the Coordinate Attention (CA) mechanism into the YOLOv5 algorithm. This integration aims to refine the algorithm's capabilities, enabling it to deliver superior diagnostic performance even in complex operational scenarios. In summary, this study offers crucial technical support for the establishment of a stable and secure power system.

This study is divided into six sections. The first section is the introduction, which analyzes the shortcomings of traditional power line detection methods and the application prospects of DL and DT technology. The second section is related work, which summarizes the current related research. The third section is the methodology section, which proposes a fault detection technique based on improved YOLOv5 and DT model, including optimizing the anchor box loss function, introducing GhostNet and CA mechanism, etc. The forth section is the analysis of experimental results, which verifies the performance advantages of improved loss functions (such as Focal IoU), and compares the accuracy, loss values, frame rates, and diagnostic time of different models in multi scenario fault detection. The fifth section is a discussion of the results, demonstrating the efficiency and superiority of the research model in fault detection. The sixth section is the conclusion of the study.

II. Related Work

Ensuring the secure and dependable functioning of power grid lines is essential for reliable power supply. Traditional detection methods rely on manual inspection, which suffers from issues like inefficiency and poor real-time performance [1]. The rise of DL technology has offered an alternative methodology for power grid line detection. It constructs a complex neural network model to automatically extract multi-source data features such as images and signals, achieving efficient identification and localization of line faults [2]. Alexander Stonier et al. carried out a study on the problem of faults in solar photovoltaic microgrids. To improve the effectiveness of fault detection, it analyzed common faults in photovoltaic modules, inverters, batteries, and charging controllers. Techniques such as DL were introduced to analyze and classify fault types. The research results indicated that this technology could effectively detect fault problems. It provided strategies for the continuous operation of microgrids under fault conditions, but its shortcomings lied in insufficient depth in analysis of the implementation details of specific diagnostic techniques [3]. Shakiba et al. carried out study on the issue of insufficient fault detection in transmission lines. So research was conducted on machine learning-based transmission line fault detection technology, covering traditional methods such as Naive Bayes classifiers. A detection model was constructed using deep convolutional networks and fuzzy neural networks, and fault diagnosis was achieved through adaptive inference and other methods. The findings indicated that this study could significantly improve the accuracy of line detection and meet the safety requirements of the power grid. However, its shortcomings lied in the lack of in-depth validation of the model's generalization ability [4]. Li et al. studied the issue of insufficient accuracy in unmanned aerial vehicle (UAV) power inspection systems and designed a detection system based on intelligent UAVs. The technical process included autonomous planning of detection paths, sliding mode control algorithms, and motion detection schemes, which used advanced object detection algorithms to achieve problem analysis. The research results indicated that the system significantly enhanced the effectiveness and precision of power inspection, but its shortcomings lied in the need to further improve the endurance and flight stability of UAVs in complex environments [5]. Chen et al. studied the problem of insufficient diagnosis of intelligent distribution live working robots and proposed an intelligent distribution live working robot system based on stereo cameras to replace manual completion of high-risk distribution network maintenance tasks. This system combined dual robotic arms, wireless tools, visual perception systems, and path planning technology in virtual simulation environments. The research results indicated that technology could achieve problem diagnosis within a brief timeframe with higher efficiency. However, the technical limitation lied in its limited adaptability to complex job scenarios [6].

As the power system undergoes expansion and grows increasingly complex, conventional approaches to power fault detection are encountering numerous challenges. DT technology achieves precise monitoring and fault warning of power equipment by constructing virtual models and real-time mapping of physical entity states. Gómez Luna et al. conducted research on overcurrent protection caused by distributed energy access in distribution networks and proposed a new overcurrent protection scheme based on DTs. This scheme adopted coordinated protection standard settings and coordinated intelligent electronic devices, utilizing power hardware technology to connect real relays to the DT model of the analog network. The outcomes revealed that this method improved the coordination and adaptability of overcurrent protection, but there is still a problem of lack of coordination with different distributed energy sources [7]. Sinagra et al. conducted research on pressure regulation and energy recovery in water distribution networks and proposed an advanced real-time control logic based on DTs. This technology optimized the configuration of turbines and valves, dynamically updated network status using DT models, and achieved efficient hydroelectric power generation. The results indicated that this technology exhibited higher robustness and efficiency in different operational scenarios, but its adaptability to complex networks still needs further validation [8]. Sharma et al. conducted research on the bottleneck problem of electric vehicle battery assembly and proposed a three-stage DT design and analysis approach. This method developed robot assembly line configurations of different scales through DT design and simulation, and evaluated and optimized the speed and cost of the assembly system. The research results indicated that this method could quickly and economically assemble electric vehicle battery modules, but the implementation difficulty and cost control in actual production still need further exploration [9].

In summary, equipment failures in the power system will pose specific challenges to the operation and safety of the power grid. Currently, DL finds extensive application in the domain of power safety, providing technical support for power safety data analysis and fault diagnosis. In addition, DT technology adopts a physical virtual construction of power detection system, which can analyze the power grid status in real time and provide support for power system equipment failures. Therefore, to address the issues of slow and poor accuracy in current power line fault diagnosis, an intelligent line fault diagnosis technology is proposed by combining DT model and YOLOv5 algorithm.

III. Methods and Materials

A. Modeling of Power Line Fault Detection Based on DL

With the expansion of the power system, frequent line failures seriously affect the reliability of power supply. Traditional detection approaches have low efficiency and poor accuracy, making it hard to fulfill the requirements. Therefore, the research proposes an intelligent line fault detection technology based on improved YOLOv5 to enhance the safety operation of the power grid. The YOLOv5 network structure is in Fig. 1.

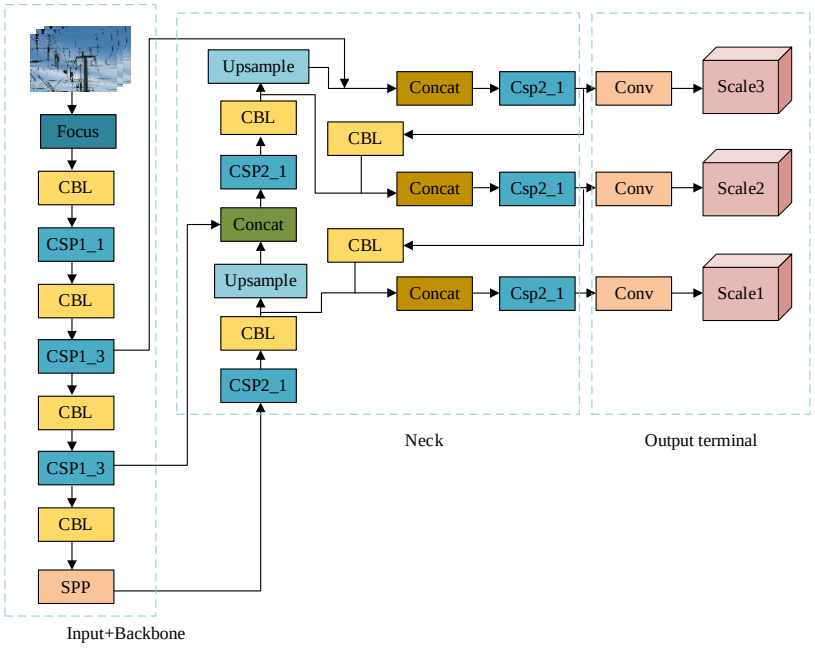

Fig. 1. YOLOv5 network structure.

According to Fig. 1, YOLOv5 mainly consists of input terminals, backbone, neck, and output terminals [10]. Among them, the input terminal inputs the power line image data that needs to be detected (collected by the DJI CS-SR1 UAV), and backbone is responsible for feature extraction. Through convolution and residual connections, image features are efficiently extracted to achieve the recognition and analysis of fault points in the image line. The YOLO series of target algorithms are all based on anchor box expansion for object detection [11]. Among them, the width and height of the anchor box are defined as p_w and p_n, and the offset of the X and Y axes in the upper left corner of the anchor diagram is set as c_x and c_y. When detecting the fault target point, the original anchor box is a dashed box, while the predicted box is a blue box. In the detection of power lines, the network needs to fine tune the anchor boxes based on four offsets t_y, t_x, t_h, and t_w to achieve accurate prediction of the results. The border prediction is in Eq. (1) [12].

$$\begin{cases} b_x = 2\sigma(t_x) - 0.5 + c_x \\ b_y = 2\sigma(t_y) - 0.5 + c_y \\ b_h = p_h(2\sigma(t_h))^2 \\ b_w = p_w(2\sigma(t_w))^2 \end{cases} \quad (1)$$

In Eq. (1), b_x, b_y, b_h, and b_w respectively represent the positions of the predicted border on the X and Y axes, as well as the height and width of the border, and σ represents the activation function. The principle of adjusting the anchor target box is in Fig. 2.

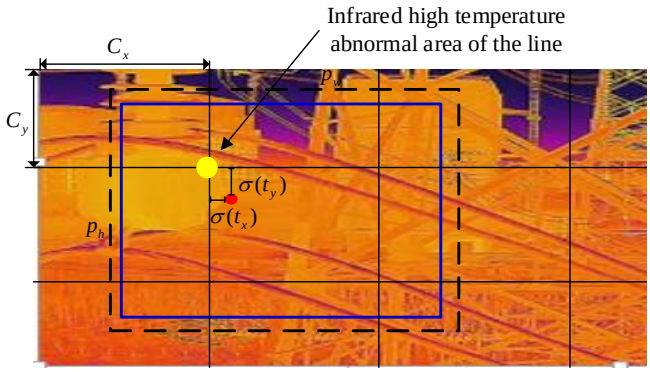

Fig. 2. Schematic diagram of anchor box target adjustment.

In Fig. 2, it is essential to adjust the parameters to make the prediction box detect the line fault point more accurately. However, in actual line fault detection, there are few fault points in aerial images. To enable the model to detect effective target points, the YOLOv5 bounding box (BB) regression function will be optimized to filter out useless anchor boxes and improve the detection efficiency of fault targets. The key area in Intersection over Union (IoU) is introduced to reflect the prediction of BB [13]. The loss function L_{IoU} for predicting similarity with the real border is calculated as presented in Eq. (2).

$$L_{IoU} = 1 - \frac{|A \cap B|}{|A \cup B|} \quad (2)$$

In Eq. (2), A represents the predicted anchor box and B denotes the real anchor box. In graph fault detection, if the IoU value is set to 1 and the anchor box is a positive sample, it indicates that the similarity between the predicted and real target anchor boxes is high, and both contain the target to be

recognized. When the IoU value is below 0.5, the anchor boxes are negative samples and there is no intersection between the two anchor boxes. In addition, a loss function L_{GIoU} was introduced in the study to analyze the bounding rectangle of two anchor boxes. The analysis of bounding rectangles can better solve the proportion of non-overlapping areas, which is beneficial for determining the overlap distance between two anchor boxes [14]. The calculation of L_{GIoU} is in Eq. (3).

$$L_{GIoU} = 1 - IoU + \frac{|C - (A \cup B|}{|c|} \tag{3}$$

In addition, the study uses the d variable in the L_{DIoU} function to represent the Euclidean distance between the two center coordinates within the anchor box (points A and B), with a diagonal distance of c. The penalty term in the L_{DIoU} function can avoid the occurrence of larger BB when two anchor boxes are far apart, which affects the network's detection of fault points. The calculation of L_{DIoU} is in Eq. (4).

$$L_{DIoU} = 1 - 1oU + \frac{\gamma^2(A_2 B)}{c^2} \tag{4}$$

In Eq. (4), γ represents the Euclidean distance parameter. In the L_{DIoU} function, if the loss value is large, L_{DIoU} is used for optimization, which is faster than the L_{DIoU} function, but it is not applicable when the midline points coincide. Therefore, by combining the Euclidean distance of the center point, overlapping area, and the aspect ratio of the border, a L_{CIou} function is introduced, which is expressed as Eq. (5).

$$L_{CIou} = 1 - loU + \frac{\gamma^2(A, B)}{c^2} - av \tag{5}$$

In Eq. (5), a represents a comprehensive adjustment parameter and v represents the width height difference parameter. Although the L_{CIou} function can more accurately reflect the differences in anchor boxes, the width height difference parameter v cannot specifically reflect the differences in height and width between the real and predicted borders, making the optimization process of function L_{CIou} unreasonable. Therefore, the research has incorporated a focus on high-quality anchor box attention mechanism, namely $Loss_{EloU}$ function, which enhances the screening of high-quality boxes based on function L_{CIou}, reducing the loss of width and height between the target box and anchor box [15]. Its expression is in Eq. (6).

$$L_{EIoU} = L_{IoU} + L_{dis} + L_{asp} = 1 - IoU + \frac{\lambda^2(A, B)}{c^2} + \frac{\lambda^2(w, w^{gt})}{c_w^2} + \frac{\lambda^2(h, h^{gt})}{c_h^2} \tag{6}$$

In Eq. (6), w^{gt} and h^{gt} represent the disparities in anchor frame width and height, L_{asp} is the direction loss, c_w and c_h represent the highest value of coverage width and height, and L_{dis} is the distance loss. In addition, to enable the network to only detect high-quality line fault images, the study used IoU weighted processing to obtain the target loss function filtered by anchor boxes, as shown in Eq. (7):

$$L_{Focal-EloU} = IoU^{\ell} L_{EIoU} \tag{7}$$

In Eq. (7), ℓ represents the suppression quality sample parameter in the network. In this research section, the improvement of the anchor box part in YOLOv5 enhances the network's screening and recognition of fault samples in line images, improving the efficiency and quality of network detection.

B. Line Fault Detection Modeling Based on YOLOv5 and DT Model

In the previous section, the improved YOLOv5 algorithm was used to detect line faults. However, in large-scale multi-objective power networks, this technology cannot quickly achieve efficient detection of multiple faulty lines, limiting its applicability. Therefore, the next step is to introduce DT technology to determine large-scale line fault points, while utilizing the improved YOLOv5 algorithm to achieve efficient detection of multi-target fault points. Among them, the power DT model is in Fig. 3.

According to Fig. 3, the power DT model contains two main parts: the physical power grid and the virtual power grid. Among them, the physical part includes temperature, wind speed, visual detection, and other sensor parts, responsible for detecting the status of power grid transformers, lines, and various equipments in real scenes. The virtual part will map physical entity data to the geometric model of the power grid, and feedback the state information to the application layer through the twin data center, thereby achieving real-time monitoring of the power network [16]. Therefore, the study utilizes twin models to quickly determine the location of power line faults, while adopting an improved YOLOv5 algorithm to achieve rapid detection of multi-objective fault points. One notable aspect is that, within the DT model, it is of paramount importance to dynamically map physical spatial data onto the virtual space. This dynamic mapping is governed by the equation presented in Eq. (8).

$$G_v(t) = \Phi(G_p(t), \Theta) + \dot{o}(t)\Theta = \{T(t), W(t), V(t)\} \tag{8}$$

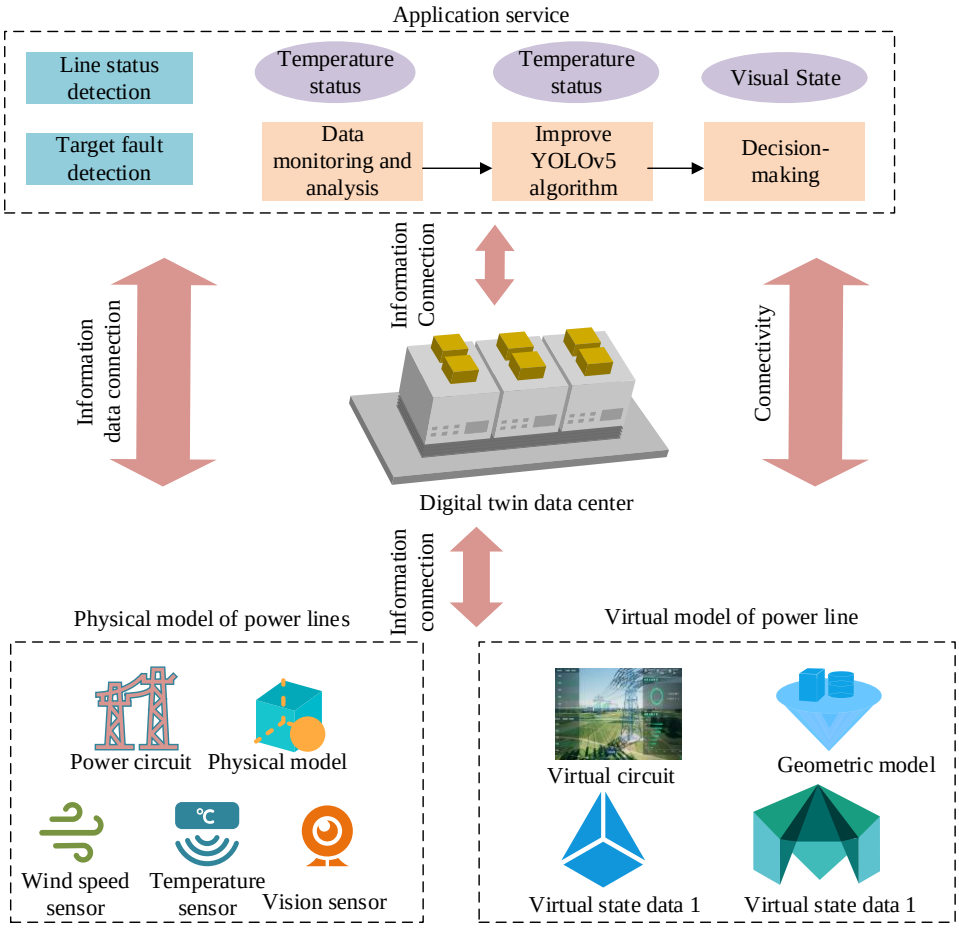

Fig. 3. Diagrammatic representation of power DT model.

In Eq. (8), $G_p(t)$ represents the physical power grid line state, $T(t)$ is the temperature state model, $W(t)$ is the wind speed state model, and $V(t)$ is the visual feature state model. $\Phi(\cdot)$ is a dynamic encoder based on Long Short-Term Memory (LSTM) network. Θ is the set of environmental parameters. $\grave{o}(t)$ is the Gaussian noise parameter. Next, through the monitoring data of the physical model, an anomaly detection mechanism is established in the virtual space to achieve rapid localization of the fault area. The localization equation is in Eq. (9).

$$F_{region} = \arg\max_{x,y}\left[\| H_t(x,y) - H_{t-1}(x,y)\|_2^2 \cdot S_{thermal}(x,y)\right] \quad (9)$$

In Eq. (9), H_t is the thermal distribution matrix of the power grid at time t. $S_{thermal}$ is the weight matrix for temperature anomalies. (x,y) is the coordinate system for the fault point. After determining the location of power line faults that need to be detected in the power grid system, the improved YOLOv5 algorithm is adopted as a multi-objective fault detection technique. Firstly, to enhance the training swiftness of the network and reduce the number of parameters, GhostNet is used to replace the Conv module and CSP Bottleneck with three convolutions (C3) in the YOLOv5 backbone network. The GhostNet structure is in Fig. 4 [17].

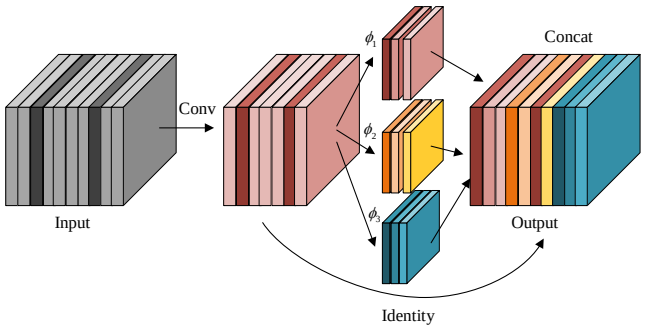

Fig. 4. GhostNet structure.

In Fig. 4, compared to the Conv module and C3 module in the traditional YOLOv5 backbone network, the GhostNet divides convolution into two processes: Identity operation and Concat operation, including using a small number of convolution operations first, followed by stepwise channel convolution operation. The output of the GhostNet is in Eq. (10).

$$Y = [X \# W_1, \phi(X \# W_2)] \tag{10}$$

In Eq. (10), $\#$ represents the convolution operation, and $\phi(\cdot)$ is depthwise separable convolution. X is the input feature map. W_1 and W_2 represent the corresponding weights of standard convolution and depthwise separable convolution, respectively. In GhostNet feature extraction, the channel compression ratio is set to 1:3. Next, to better adaptively analyze the sudden changes in lighting and hotspots in the power grid, an adaptive activation function, Activate Or Not (ACON), was studied to replace the original Leaky ReLU function, which can dynamically adjust the activation threshold. The calculation of the activation function is in Eq. (11) [18].

$$ACON(x) = (p_1 - p_2)x \cdot \sigma(\beta x) + p_2 x \tag{11}$$

In Eq. (11), p_1 and p_2 are both trainable parameters. β is the adaptive adjustment activation threshold. σ is the activation function. In addition, in multi-target power line fault detection, including scenes such as forests and buildings, the images extracted by UAVs contain complex background information, making it difficult to locate line faults such as insulator breakage and wire wear. Therefore, the study introduces a CA mechanism between the backbone network and the feature pyramid to enhance the extraction of key features in images. The process of changes in CA mechanism is in Eq. (12) [19].

$$\begin{cases} z_c = \dfrac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} x_c(i, j) \\ m = f^{1\times1}([z^h, z^w]) \\ g = \sigma(Conv([AvgPool_h(x), AvgPool_w(x)])) \end{cases} \tag{12}$$

In Eq. (12), z_c represents the input of channel information and x_c represents the corresponding channel information input. m represents the location information of the region of interest processed by the 1×1 convolutional transformation function f. z^h and z^w respectively represent the height and width of the position of interest. H and W represent the height and width of the feature map. $AvgPool$ represents global average pooling. g represents spatial attention weight. The output of the CA machine is in Eq. (13).

$$y = X \cdot m \cdot g \tag{13}$$

In Eq. (13), X represents the given input feature information. In addition, to enhance the infrared imaging features and small target features, such as detecting loose bolts and other targets, the study used Bidirectional Feature Pyramid Network (BiFPN) to replace the original path aggregation network structure, and its weighted fusion expression is in Eq. (14) [20].

$$P_l^{out} = \sum_i \frac{w_i}{\grave{o} + \sum_j w_j} \cdot Resize(P_i^{in}) \tag{14}$$

In Eq. (14), w_i is the learnable weight parameter. P_i^{in} represents the input features of the i th level, which are composed of multiple features together. $Resize(\cdot)$ represents feature size alignment operation. $\grave{o}$ represents the minimum constant. w_j represents fusion weight. Finally, based on the above analysis, the end-to-end joint line fault detection results are obtained, as shown in Eq. (15) [21].

$$\begin{cases} \mathrm{F} = BiFPN(GhostNet(I_{512\times512})) \\ \mathrm{D} = \bigcup_{k=1}^{4} \{(x, y, w, h, cls) \mid conf_k > 0.5\} \\ conf_k = \prod_{m=1}^{3} CA_m(ACON(\mathrm{F}_k)) \end{cases} \tag{15}$$

In Eq. (15), F represents the multi-scale feature pyramid processed by GhostNet and BiFPN. D represents the final set of detection results, where cls represents the category, (x, y, w, h) represents the BB coordinates, and k represents the corresponding four detection heads, namely P_1, P_2, P_3, and P_4. $conf_k$ represents the confidence level of the detection head, which is weighted and calculated through the CA attention module. I represents the fault area image provided by the DT system. Finally, the study adopted an improved k-loss function as the prediction output, and the results are shown in Eq. (16).

$$\mathrm{L} = \lambda_{box}(1 - IoU)^{\delta} + \lambda_{cls} FL(p_t) + \lambda_{obj} BCE(\hat{o}, o) \tag{16}$$

In Eq. (16), λ_{box}, λ_{box}, and λ_{obj} represent the weight coefficients of BB loss, classification box loss, and target confidence loss, respectively. δ is the focusing factor, which reduces the loss contribution of simple samples and focuses on difficult samples. $FL(p_t)$ is the classification loss, and p_t represents the probability of model category prediction. $BCE(\hat{o}, o)$ is the confidence loss, where o is 0 indicating that the target is the background, 1 indicating that the target exists, and $\hat{o}$ is the confidence of the model target. The entire technical process is in Fig. 5.

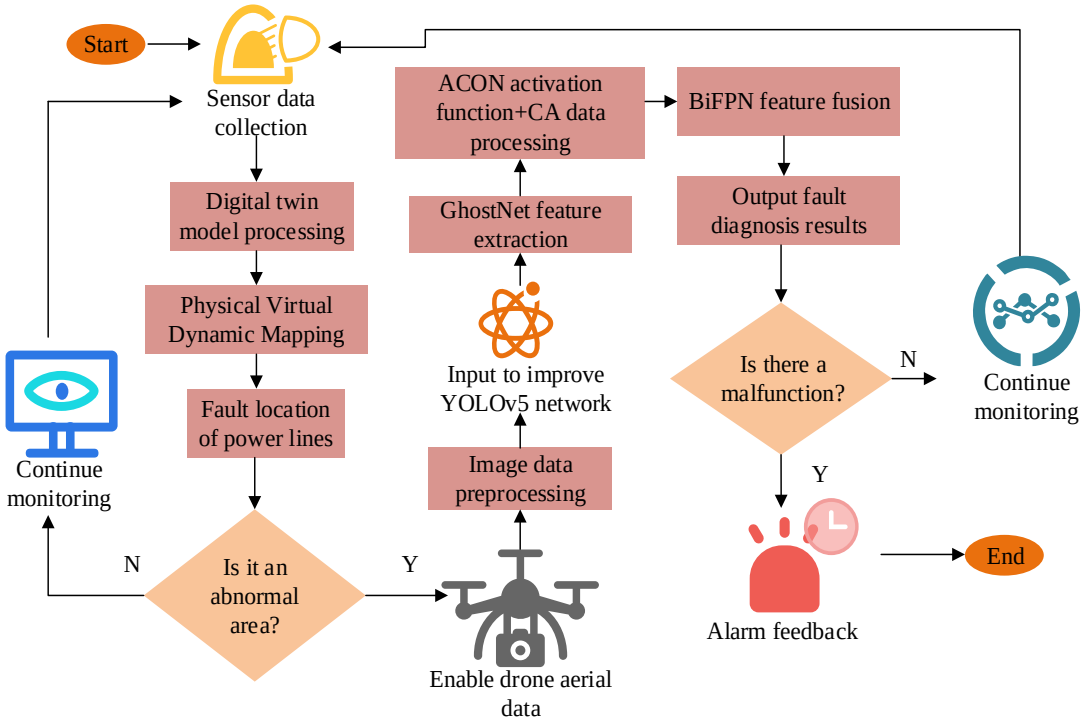

Fig. 5. Line fault diagnosis based on improved YOLOv5 and DT model.

Fig. 5 shows the process of fault diagnosis for power lines, in which a DT model is used to analyze the external environment of the power grid line and identify the location of the line fault point. Secondly, by using UAVs to obtain image information of fault line points, and improving the YOLOv5 algorithm training, the detection of multi-target point faults in power lines can be achieved.

IV. Results

A. YOLOv5 BB Regression Loss Function Performance Experiment

To test the application effect of the power fault diagnosis technology proposed by the research in practical scenarios, corresponding experimental analysis was carried out next. The training was conducted using Python version 3.8 and the DL framework was PyTorch. The training parameter settings of the improved YOLOv5 model was presented in Table I.

Comprehensive and Special Data (CSD) and self-made datasets were selected for the experiment. The CSD dataset includes UAV inspection images, wire and conductor loose strand detection datasets, and infrared image insulator detection datasets. It supports YOLO analysis format and has a total of about 30000 images. Meanwhile, the study used DJI CS-SR1 (visible light+infrared dual-mode) to capture a total of 27200 images of power lines, labeled in YOLO format, with an image size of 1024×1024. It covers data from different seasons, backgrounds, and lighting conditions. Next, the study investigated the anchor box performance of various optimized loss functions tested on the CSD dataset, where the default IoU function and Focal EIoU function were not used. In the anchor box, Focal EIoU is consistent with EIoU, as presented in Fig. 6.

In Fig. 6, GIoU, CIoU, and EIoU loss functions were selected for testing in the study. At 10 iterations, all three loss functions were located at the anchor box position and remained basically consistent. After 150 iterations, the three loss functions showed significant differences, among which the GIoU function, although able to match the target box, covered both the target box and anchor box with average accuracy. The CIoU function outperformed GIoU in matching performance and could cover the target box more accurately, but the target box repetition was still relatively low. The best matching function was the EIoU function, which basically covered the target box completely and achieved an accuracy of 98.58%, showing the best performance. Next, the study compared the regression loss and IoU performance of five types of losses, as presented in Fig. 7.

TABLE I. Model Parameter Settings

Model indicators	Parameter
Image size	1024x1024
Batch size	16
Initial learning rate	1e-3
Anchor frame size	[12, 16], [20, 28], [24, 36], [36, 48], [48, 64]
Boundary box loss box	4.8
Classification loss CLS	8.5
Number of iterations	200

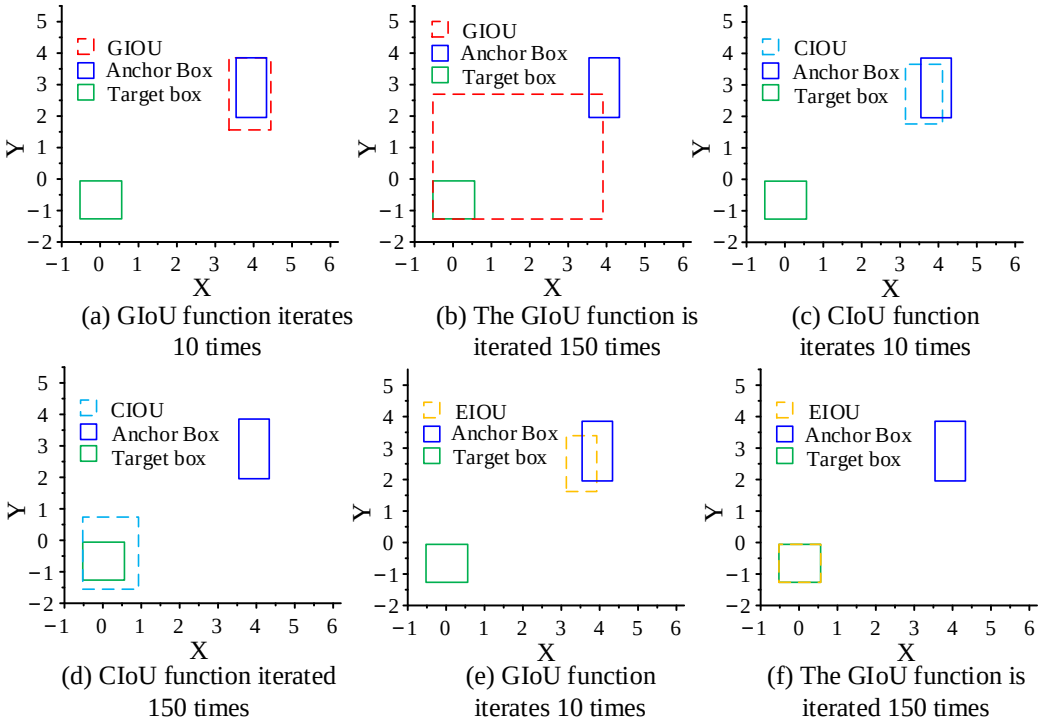

Fig. 6. Anchor box performance of different loss functions at 10 and 150 iterations.

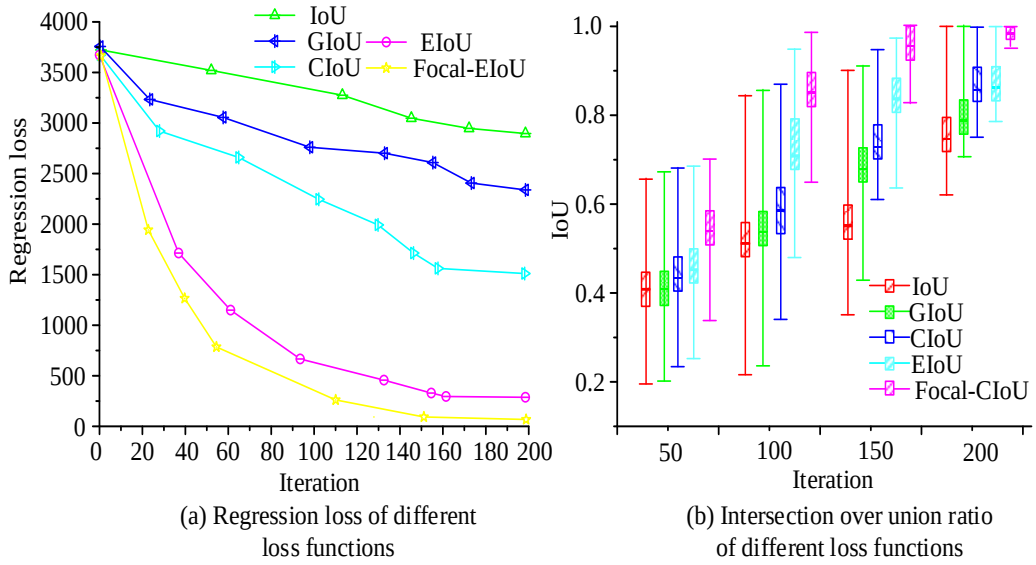

Fig. 7. Comparison of regression loss and IoU ratio with different loss functions.

Fig. 7 indicates the comparison results of function regression losses. According to the test results, the five loss functions showed different performance during training. Among them, EIoU and Focal EIoU functions converged the best, and thanked to filtering the anchor boxes, Focal EIoU had the best regression loss performance, with a regression loss of 125 and EIoU function of 256 during convergence. Fig. 7(b) indicates the test results of the IoU ratio of different loss functions, whose values reflect the accuracy of BB matching. The higher the value, the greater the intersection between the anchor box and the target box. According to the test results, as the iteration count increased, the IOU values of the five loss functions gradually increased, and the optimal IOU value was obtained after 200 iterations. Among them, the best performing Focal EIoU had a mean of 0.986 and a minimum value of 0.956, followed by EIoU with a mean of 0.926 and a minimum value of 0.796. The overall performance of other loss functions was average, although the maximum IOU value could reach 100%, the mean and minimum values were relatively low. Next, the study selected the self-made data nest scene for detection and determined the confidence values of different loss functions, as presented in Fig. 8.

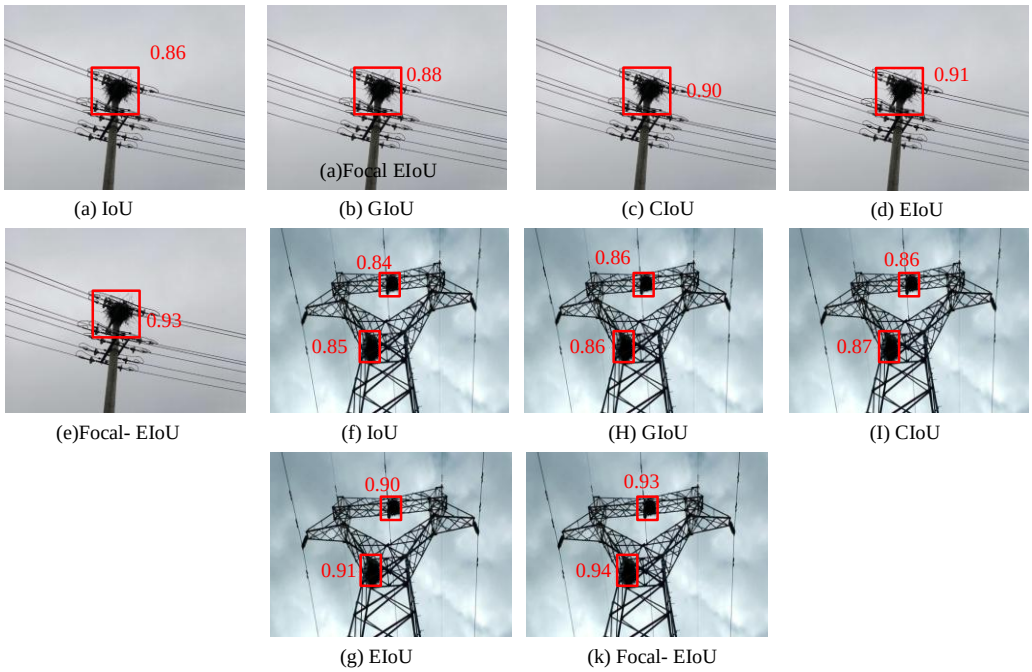

Fig. 8. Confidence level of object detection with various loss functions.

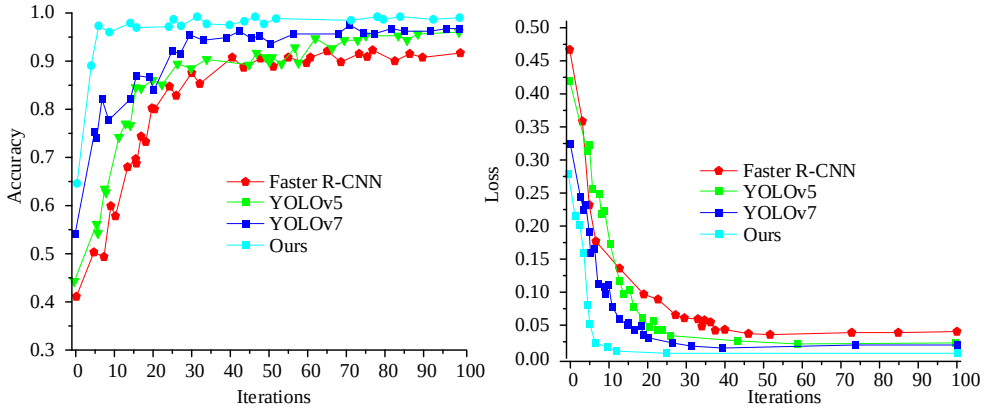
In Fig. 8, the selected route had a bird's nest scene for object detection. Among them, Fig. 8(a) to Fig. 8(e) are scene 1. In this scenario, the highest confidence level among the five loss functions was Focal IoU, which was 0.93. Next was EIoU, with a confidence level of 0.91, while CIoU, GIoU, and IOU had confidence levels of 0.90, 0.88, and 0.86, respectively. Figs. 8(f) to 8(k) show scene 2, which included two types of bird nests: large and small targets. Focal IoU performed the best overall, with confidence levels of 0.93 and 0.94, indicating the best performance.

B. *Multi-Scenario Fault Detection Test for Power Lines*

Next, Focal IoU was chosen as the loss function for the recognition model, and Faster R-CNN and YOLOv7 were introduced as testing benchmarks to compare their performance in detecting power line faults. Among them, the standard dataset CSD was selected for testing to compare the training accuracy and loss of different models, as presented in Fig. 9.



(a) Accuracy of fault detection (b) Fault detection training loss

Fig. 9. Fault detection performance of different models.

Fig. 9(a) indicates the accuracy of fault detection. Among the four models, the research model achieved the fastest convergence with a maximum accuracy of 0.986, followed by YOLOv7 with a convergence of 0.95. YOLOv5 and Faster R-CNN performed average, with convergence accuracies of 0.948 and 0.902. Fig. 9(b) indicates the training loss results of different models. Among them, the Faster R-CNN table had a general convergence loss of 0.051. YOLOv5 performed similarly to YOLOv7, but YOLOv7 had better convergence with loss values of 0.025 and 0.024. The research model performed the best, with a convergence loss value of 0.0125. Next, the study selected different scenarios from the self-made dataset to compare the accuracy of technical fault diagnosis, as shown in Fig. 10.

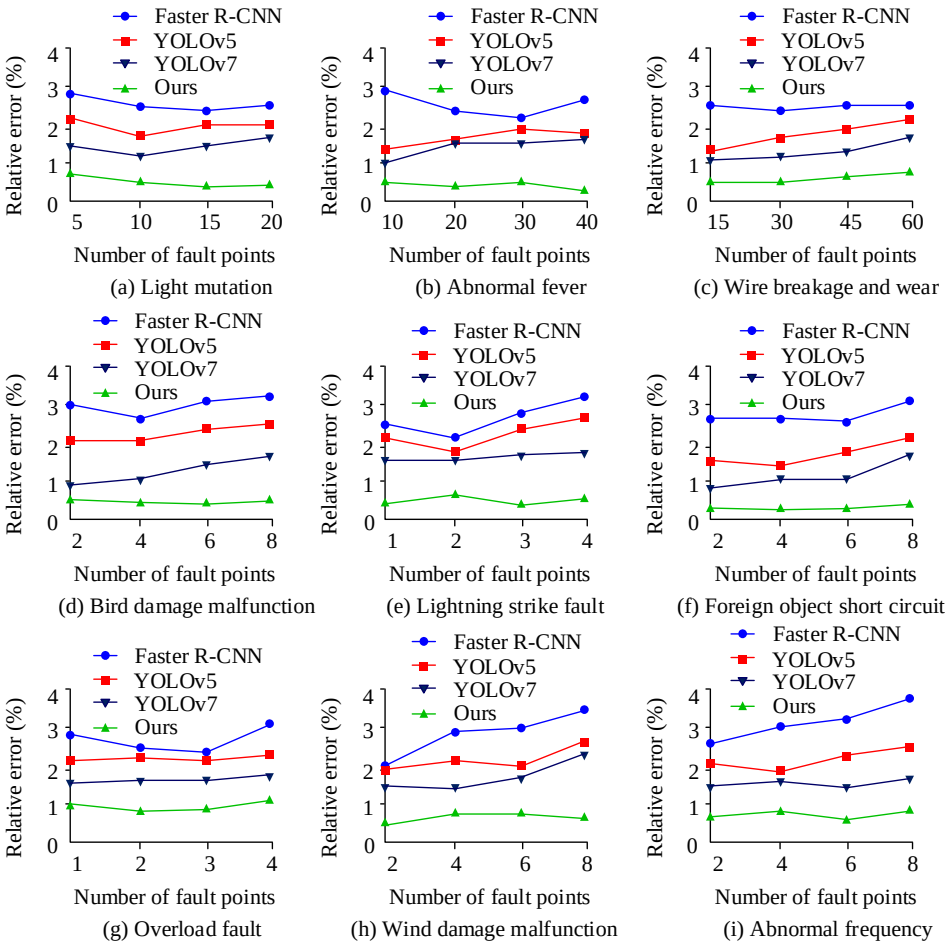


Fig. 10. Multi-scenario line fault diagnosis accuracy.

In Fig. 10, nine common circuit faults were selected for detection, including sudden changes in infrared scene lighting, abnormal light emission, etc. According to the test results, an increase in target data had a certain impact on the accuracy of model detection. Among them, the research model performed the best, with a relative error controlled within 1.2% in nine scenarios. Secondly, YOLOv7 had a relative error controlled within 2.7%. However, YOLOv5 and Faster R-CNN had significant overall detection errors. When the number of targets reached four in abnormal heat detection, the errors of all four models increased, but the relative error of the research model was the lowest at 0.86%, while YOLOv7 was 1.89%, and YOLOv5 and Faster R-CNN were 2.86% and 3.35%, respectively. Finally, the recognition frame rate and diagnostic time were tested on the self-made dataset, as presented in Fig. 11.

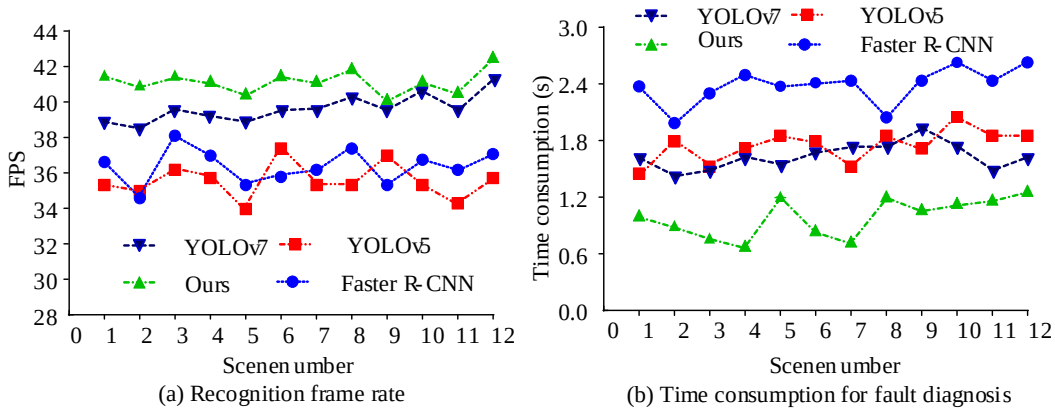

Fig. 11. Recognition frame rate and diagnosis time.

Fig. 11(a) indicates the results of the frame rate recognition test. Selected twelve fault scenarios for testing. The average frame rates of the research model, YOLOv7, YOLOv5, and Faster R-CNN were 41.2 frames, 39.5 frames, 35.8 frames, and 37.86 frames, respectively. Fig. 11(b) shows the time-consuming results of fault diagnosis, among which Faster R-CNN performed the worst, taking over 1.8 seconds in multiple scenarios, with an average time of 2.05 seconds. YOLOv7 and YOLOv5 performed better, with average fault diagnosis times of 18.95 seconds and 18.64 seconds, respectively. The best performing model was the research model, with an average fault diagnosis time of 10.25 seconds. Finally, the study selected ten types of power line faults in real scenarios for on-site experimental analysis to test the detection effectiveness of four techniques for different line fault problems. The test results are shown in Table II.

TABLE II. COMPARISON OF LINE FAULT DETECTION EFFECTS OF DIFFERENT TECHNOLOGIES IN REAL SCENARIOS

Line fault type	10 rounds of testing for fault detection accuracy			
	Faster R-CNN	YOLOv5	YOLOv7	Ours
Damaged insulator	90	90	100	100
Wire breakage	70	90	90	100
Loose fittings	40	50	70	100
Corrosion of anti vibration hammer	70	70	80	100
Bird's Nest Construction	90	90	100	100
Foreign object suspension	90	100	100	100
Tower tilt	70	80	100	100
Insulator self explosion	50	60	70	100
Wire wear and tear	90	90	90	100
Deformation of metal fittings	60	70	80	100

Table II shows the test results of different line faults in real scenarios. According to the test results, all four diagnostic models for conventional fault types could effectively diagnose, such as insulator damage and wire wear during bird nest construction. However, for fault types with small targets and complex backgrounds, except for the research model that could recognize 100%, all other models performed average. In the detection of loose fittings, the accuracy of Faster R-CNN was 40%, while YOLOv5 and YOLOv7 were 50% and 70%, respectively. Only the research model achieved 100% in ten tests. In addition, in the summary of insulator self explosion detection, Faster R-CNN, YOLOv5, YOLOv7, and research model detection accuracies were 50%, 60%, 70%, and 100%, respectively. In practical scene detection, the research technology performed excellently.

V. DISCUSSION

Ensuring the secure and dependable functioning of power grid lines is essential for reliable power supply. Traditional detection methods rely on manual inspection, which suffers from issues like inefficiency and poor real-time performance. The rise of DL technology and DT technology provides new avenues for power grid line detection. To address these issues, a power line fault detection technique combining DL and DT models is raised.

In the experiment, an improved YOLOv5 model was adopted and its anchor box loss function was optimized. Experimental data showed that the improved Focal IoU loss function performed well in terms of regression loss and IoU. Specifically, the regression loss value of Focal IoU was 125, and the mean IoU was 0.986, which was significantly better than other loss functions. In addition, the study introduced GhostNet and CA mechanism, further improving the detection capability of the model in complex scenes. The GhostNet reduced the number of parameters and improves training speed by dividing convolution into two processes: Identity operation and Concat. The CA mechanism enhanced the extraction of key features in images and improved the detection accuracy of the model in complex backgrounds. In multi-scenario fault detection, the accuracy of the research model reached 0.986, with a loss value of 0.0125, which was superior to models such as Faster R-CNN and YOLOv7. By comparison, Faster R-CNN was a two-stage detector that first generated region proposals, and then classified and regressed each proposal, resulting in higher computational complexity and poorer real-time performance [22]. Although YOLOv7 performed well in real-time, there is still room for improvement in detection accuracy when dealing with small targets [23]. Especially in complex background environments, there were issues such as detection omissions and errors, which resulted in lower overall accuracy compared to the improved YOLOv5. For example, in abnormal heat detection, when the number of targets was four, the relative error of the research model was only 0.86%, while the errors of other models were all higher than 1.89%. These results indicated that the improved YOLOv5 model combined with DT technology could effectively improve the accuracy and efficiency of power line fault detection.

In addition, the research technology system also had excellent security and stability. Especially in the analysis and detection of power lines, DL and twinning techniques were utilized. To ensure that power data was not attacked and to avoid data leakage, the Advanced Encryption Standard (AES) was introduced in the research to encrypt all transmitted data, ensuring the confidentiality and integrity of the data during transmission [24]. In addition, potential external information attacks such as Denial of Service (DoS) and Distributed Denial of Service (DDoS) [25] should be addressed. In addition, from a hardware perspective, the research adopted the latest 64 bit ARM encryption processor, which had strong environmental adaptability and security, thus ensuring the effectiveness of the entire technology [26].

Overall, the improvement of YOLOv5 was more effective than YOLOv5 in power line fault diagnosis. Especially in complex and small target scenarios, the technology proposed by the research had higher overall accuracy, stronger adaptability, and better met the requirements of fault detection in power scenarios. In addition, the combination of research technology and DT technology further enhanced the application effect of technology in power scenarios, and provided important technical support for the construction and management of power informationization.

VI. Conclusion

The safe and stable operation of power grid lines is crucial for power supply. Traditional detection methods rely on manual inspection, which has problems such as low efficiency and poor real-time performance. To solve the above problems, the research proposed an intelligent line fault detection technology based on improved YOLOv5. Firstly, the research optimized the BB regression loss function of YOLOv5 by introducing the Focal IoU loss function to filter out useless anchor boxes and improve the detection efficiency of fault targets. Secondly, the introduction of GhostNet network and CA attention mechanism further enhanced the diagnostic performance of YOLOv5 in complex scenes. In addition, the research also combined DT technology to construct virtual models and map physical entity states in real time, achieving accurate monitoring and fault warning of power equipment. The experimental results showed that the improved YOLOv5 model outperformed other loss functions in terms of BB regression loss and intersection to union ratio performance. The Focal IoU function had the lowest regression loss value and the highest average intersection to union ratio. In multi-scenario fault detection of power lines, the average accuracy of the improved model reached 98.6%, significantly higher than other models. Under the self-made dataset, the average fault diagnosis time of the improved model was 10.25 seconds, which was much lower than other models. From this, the intelligent line fault diagnosis technology proposed by the research, which combined the DT model with the improved YOLOv5 algorithm, could effectively improve the accuracy and real-time performance of power line fault detection. The research significantly improved the performance of power line fault detection by improving the YOLOv5 model. However, there are still some shortcomings in this study. For example, the adaptability of the model under extreme weather conditions needs further validation. In addition, researching how to use drones to obtain images to improve the perspective of drone image extraction is the key to diagnosis. Therefore, in future work, research needs to be conducted from three aspects. 1) To improve the effectiveness of technology, it is necessary to enhance its adaptability to complex environments and optimize the process of drone image recognition. 2) Meanwhile, in future work research, the fusion analysis of multi-scale features can be considered to enhance the detection of complex backgrounds and small targets through technology. 3) In addition, the study also strengthened the integration of DTs and DL, for example, using virtual data generated by DT models to enhance the training dataset, improve the model's generalization ability, and optimize model training and updates through real-time feedback of fault diagnosis results from DT models.

***Abstract*—This study explores how scheduling methods can support work-life balance and overall job satisfaction by considering the preferences of the nursing staff. Creating a nurse rostering schedule that maximizes staff preferences for working shifts, off days, and hospital demands was the main goal. A Google Form that was distributed to the nursing staff is used to gather preference data. With the help of the LPSolve IDE, an integer linear programming (ILP) technique is used for the first datasets, and the Flexible Shift Scheduling System is utilized to facilitate the use of a genetic algorithm approach for the second dataset. The first dataset's result reveals that the proposed schedule's preference weight is 205.8 (73.35%), indicating an increase of 46.24 (16.48%) over the current schedule's 159.56 (56.87%) preference weight. According to the results of the second dataset, the preference weight for the current schedule is 589 (62.98%), whereas the preference weight for the proposed schedule is 619.2 (66.21%), indicating a 30.2 (3.23%) increase. This demonstrates that both proposed schedules have higher preference weight values than the current schedule, which satisfies the study's primary goal of optimizing staff preferences. The genetic algorithm is used in the second dataset since it has a high complexity problem and can produce a near-optimal solution. Flexible Shift Scheduling System generates quicker and easier schedules compared to manual schedules. This study emphasizes the importance of including nurse staff preferences into consideration when creating nurse rostering schedule procedures to support a happier and more engaged nursing team.**

Keywords*—Nurse rostering schedule; schedule optimization; metaheuristic techniques; complex scheduling; integer linear programming; genetic algorithm; shift; and off-day preference maximization

I. Introduction

Scheduling is known as the challenge of allocating finite resources to jobs across time to maximize one or more objectives. Scheduling is a popular method of making decisions that is mostly applied in the manufacturing and service industries [1]. Scheduling selects from a variety of plans and assigns resources and deadlines to every task to guarantee that the assignment complies with job time constraints and group resource capacity limitations [2]. According to [3], the scheduling problem is the assignment of the organization throughout time and numerous sets of constraints. According to [4], all feasible solutions typically satisfy several hard and soft constraints. The recruiting of nursing staff, the scheduling of nursing staff, and a few other nursing service duties are all significantly impacted by nursing staff [5]. Creating rosters that constantly provide adequate coverage while considering individual preferences is the overarching goal of the Nurse Rostering Schedule (NRS) problem. Despite the development of numerous approaches to address the issue of nurse scheduling, many large healthcare organizations worldwide continue to manually schedule nurses [6].

Each nurse staff member has the right to select the shifts and days off that work best for them. A common task for the chief nurse is to establish a schedule that meets both the nurses' preferences and hospital demands. This demonstrates how challenging it is to schedule nurses while meeting several goals with limitations. Because different staffing levels need to be assigned to different days and shifts and scheduling nurses manually involves a lot of work and intricacy. This is sometimes called "self-scheduling" in literature [6]. This must be resolved by using a systematic approach that results in higher quality which is important in producing the best schedules, particularly in the healthcare industry. Additionally, a fast and optimal schedule can be made by using a systematic approach.

In this study, the hospital is trying to resolve a difficult and drawn-out scheduling problem. To maximize the efficiency of the nursing staff, the manager of the Malaysia Specialists Centre (for the first dataset) and the Malaysia Hospital (for the second dataset) has a major responsibility to schedule the "right" nurses properly working for the day and night shift. Since scheduling becomes more complex as the number of nurses increases, the hospital does not follow a systematic process when creating the current nursing schedule, and it consistently disregards the preferences of nurses. Hence, the goal of this work is to use optimization and metaheuristic approaches for both the first and second datasets to construct a schedule that satisfies both hard and soft constraints that follows hospital policies and preference of nurses. Therefore, it is crucial to apply some scientific methods, which include integer linear programming and genetic algorithms. Since the number of nurses can be classified as a small dataset, this study used ILP for the first dataset, which allowed the algorithm to find the optimal solution. In the

meantime, the second dataset, which has 100 data points, can make scheduling more difficult, which is appropriate for a genetic algorithm method. This study fills a gap left by earlier research that primarily focused on metaheuristic techniques only.

II. Related Work

A nurse scheduling model, according to [7], maximizes the preference satisfaction of the nursing staff with the shift schedule by working within the schedule's constraints, considering the different preference rankings for each shift, and taking historical data from previous schedule periods into account. Integer programming and constraint programming are the two approaches that [8] examined for a public hospital in France's anesthesia nurse scheduling issue (ANSP). The objective is to maximize the fairness of the timetable. This seeks to maximize nursing preferences, minimize pay costs, and satisfy coverage needs, all while preserving team cohesion. However, in different situations, scheduling involves a lot of variables and constraints and is difficult to solve optimally in a reasonable amount of time. Optimization methods such as integer programming or integer linear programming are only appropriate for a small number of datasets [9]. To get around this flaw, hybrid strategies that combine ILP with heuristic algorithms, metaheuristics like simulated annealing or genetic algorithms, or constraint programming are used to enhance computing efficiency and quality of scheduling issue solutions [9].

In [10], the authors describe how a genetic algorithm can be used to resolve a personnel scheduling conflict that occurred at a large United Kingdom hospital. A heuristic decoder generates schedules from nurse permutations, which are the basis of the indirect coding technique used here. Results show that the proposed approach is more flexible and faster, and can find high-quality solutions. Furthermore, genetic algorithms (GA) are a class of highly unpredictable computer programming algorithms that are grounded in the concept of biogenetics. The augmented genetic algorithm is suggested as the solution for the multi-objective optimization problem of college English class scheduling [11]. Studies show that, in terms of time and average fitness value, the modified genetic algorithm performs better than the standard genetic algorithm.

This study has three goals: first, to identify staff preferences for shifts to meet satisfaction; second, to produce a schedule that fully satisfies the demand of the nursing staff by maximizing their preferences using integer linear programming for the first dataset and a genetic algorithm for the second dataset; and lastly, to validate and compare the proposed schedule with the current schedule. This study is significant because it models and solves a difficult scheduling problem for nurses by utilizing optimization and metaheuristic techniques to provide the optimal timetable. These techniques, for example, can be used to effectively manage schedule conflicts and the requirement to uphold a high level of service. A well-designed timetable will result in better staff nursing performance and care.

The flow of this study starts with explanation on data collection method of nurse preferences and the decision variables of mathematical model used in the objective function to maximize the nurse's preferences, aligning with the constraints listed. The following part describes the details of methodology for ILP and GA, including the Flexible Shift Scheduling System. The next part discusses the results obtained, comparison with the current, and the proposed schedule. The last part shows the discussion and conclusion of this study.

III. Materials and Methods

A. Data Collection

The children's ward of Malaysia Specialists Centre and the admission ward of Malaysia Hospital are the case studies. The hospital's children's ward, which is assigned as the first dataset, has 24 nursing staff members, and the admissions ward, which is assigned as the second dataset, has 100 nursing staff members. Data on staff preferences is gathered via a Google Form that was sent to the nursing staff. Informal discussions with the unit manager helped in obtaining information about the one-week nurse work schedule. The data spans one week for both datasets, from August 7 to August 13, 2023.

B. Mathematical Model

A mathematical model that addresses the problem of NRS at a hospital is composed of three key elements: decision variables, objective functions, and constraints. Table I lists the symbols used to define the decision variables:

1) Decision variables:

TABLE I. Description of Decision Variable

Decision Variable	Description
q	Nurse staff
r	Nurse staff category where; 1=Senior Community Nurse, 2=Community Nurse, 3=Senior Registered Nurse, 4=Registered Nurse, 5=Senior Care Assistant, 6=Care Assistant, 7=Senior Licensed Practical Nurse and 8=Licensed Practical Nurse
s	Preferred shift
T	Day off of the week
Q	Set of nurse staff (i.e. q ϵ Q)
R	Set of nurse staff categories (i.e. r ϵ R)
S	Set of shift preference (i.e. s ϵ S) 1 = morning shift, 2 = evening shift and 3 = night shift.
T	Set of the day off (i.e. t ϵ T)
$\boldsymbol{D_{s,t}}$	Demand for shift s on the day t
$P_{q,r,s,t}$	Shift preference of nurse staff, q category, r shift, s day, t $P_{q,r,s,t}$: 0 as not preferred and 1 as preferred
$A_{q,r,s,t}$	Availability of nurse staff, q category, r shift, s day, t

Decision Variable	Description
	$A_{q,r,s,t}$: 0 as unavailable and 1 as available
$W_{q,r,s,t}$	Wight preference of nurse staff, q category, r shift, s day, t $W_{q,r,s,t}$: 0 as unavailable and 1 as available
$X_{q,r,s,t}$	$\begin{cases} 1, \text{staff } q \text{ of category } r \text{ for shift } s \text{ on day } t \\ 0, \text{otherwise} \end{cases}$

2) Objective function: Eq. (1) aims to optimize the overall preferences of the nursing staff regarding work shifts and their days off.

$$Max, Z = \sum_1^Q \sum_1^R \sum_1^S \sum_1^T (\Omega_{\theta,\rho,\sigma,\tau} . \Xi_{\theta,\rho,\sigma,\tau}) \quad (1)$$

The preference weight for each nurse staff member is calculated using Eq. (2):

$$W_{q,r,s,t} = \begin{cases} 0, if\ A_{q,r,s,t} = 0, \\ 1 + \alpha\ , if\ \ A_{q,r,s,t} = 1, P_{q,r,s,t} = 1 \\ 1 - \beta, if\ \ A_{q,r,s,t} = 1, P_{q,r,s,t=}0 \end{cases} \quad (2)$$

The α and β in the preference weight calculation are obtained from Eq. (3) and Eq. (4).

$$\alpha = \left(\frac{\sum A_{q,r,s,t} - \sum P_{q,r,s,t}}{\sum A_{q,r,s,t}}\right) \quad (3)$$

$$\beta = \alpha \left(\frac{\sum P_{q,r,s,t}}{\sum A_{q,r,s,t} - \sum P_{q,r,s,t}}\right) \quad (4)$$

3) Constraints: Eq. (5) to Eq. (7) indicate how many staff are needed for each shift in the children's ward, while Eq. (8) to Eq. (10) indicate how many staff are needed for each shift in the admission ward.

Staff needed for each shift in the children's ward:

$$D_{1,t} = 8 \quad (5)$$

$$D_{2,t} = 7 \quad (6)$$

$$D_{3,t} = 5 \quad (7)$$

Staff needed for each shift in the admission ward:

$$D_{1,t} = 30 \quad (8)$$

$$D_{2,t} = 25 \quad (9)$$

$$D_{3,t} = 25 \quad (10)$$

Eq. (11) mandates a constraint, where each staff has one day off per week.

$$X_t = 1 \quad (11)$$

Eq. (12) states that staff must work within minimum and maximum shift limitations specified for each week.

$$5 \leq \sum X_{q,s} \leq 6 \quad (12)$$

Eq. (13) mandates each staff will be assigned only one work shift for each day.

$$X_q = 1 \quad (13)$$

Eq. (14) states that each member of the nursing staff will get a day of rest or a day off, when the staff work for two to three consecutive night shifts.

$$2 \leq \sum X_{3,t} \leq 3 \quad (14)$$

C. Integer Linear Programming

For the first dataset, this study uses an integer linear programming approach to solve the nurse scheduling problem and produce a schedule that maximizes the preferences of the hospital's nursing staff while fully satisfying their demands. An optimization technique known as "integer linear programming" combines integer variables with linear goals and equations. Integer linear programming is the study of strategies for addressing optimization problems, which can involve either maximizing or minimizing. By providing a framework model which addresses discrete decision variable optimization problems, ILP enables the effective handling of several real-world situations [12]. The objective function and constraints are defined mathematically to produce an ILP issue. An ILP issue has feasible solutions when each constraint is met. These solutions must satisfy both the integer and linear constraints. In an ILP problem, an optimal solution is both feasible and enhances the objective function [13]. The first dataset is used to apply ILP using the LPSolve IDE, which is an integer linear programming software, to produce an optimal schedule that satisfies both nurses' preferences and hospital demands.

D. Genetic Algorithm

Genetic algorithms (GA) are adept at resolving complex optimization problems, which is why scheduling problems have been extensively addressed by them. It is possible to find optimal or near-optimal scheduling solutions using a genetic algorithm. The population size, crossover rate, mutation rate, and selection strategy are some of the elements that affect a genetic algorithm's scheduling performance. These parameters must be correctly calibrated to produce the optimum outcomes. Common processes in tuning parameters include experimenting, adjusting settings, and evaluating the impact on the efficiency and caliber of schedules that are generated [14].

In a GA the process begins with the initialization phase, where a population of potential solutions, also known as chromosomes, is created with random traits. In this study, the researcher adopted integer value encoding for a weekly schedule. Subsequently, before the selection phase, the fitness of each solution is evaluated based on the weighted preference of each staff [Eq. (2)], and the fitness value is the only way to guide the selection phase in GA. Individuals with greater fitness exhibit a higher chance of becoming parents compared to those with lower fitness in the selection phase. This study adopted a tournament selection approach, where individuals compete in tournaments based on their fitness values.

Next, the crossover phase follows, where the traits of selected individuals are combined to create new solutions,

mimicking genetic recombination. In this study, the 1-point crossover method is adopted, with a crossover rate of 0.82. Furthermore, the mutation phase introduces small random changes to the traits of some solutions, ensuring genetic diversity in the population. This study applied the swap mutation method, where two individuals are selected and swapped positions in the chromosomes to yield a better fittest value based on a 0.044 mutation rate. The evaluation phase then assesses the fitness of the newly formed solutions. This cycle of selection, crossover, mutation, and evaluation is repeated for several generations or until a predetermined termination criterion is met (refer Fig. 1).

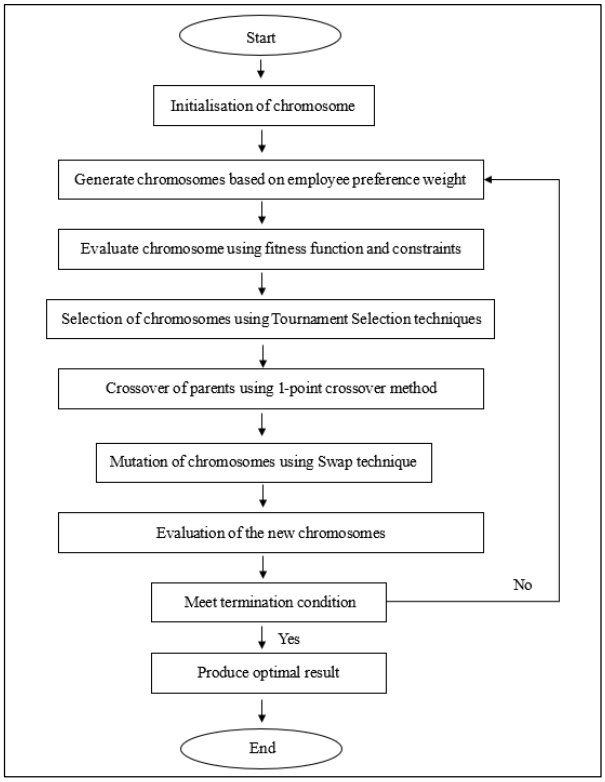

Fig. 1. Flowchart of genetic algorithm

The second dataset is used to apply GA method through the Flexible Shift Scheduling System to produce a near-optimal nursing staff's work schedule that satisfies both nurses' preferences and hospital demands. For better scheduling implementation, the Flexible Shift Scheduling System is developed based on the concept of the genetic algorithm as discussed in Fig. 1. The FSS system obtained a copyright certificate (LY2019007740) in 2019. The FSS system is built using Eclipse Java Oxygen, and the interface is set up in Visual Studio. In the interface (refer to Fig. 2), there are four selection buttons, which are "Add New Employee", "View/Edit Employee", "View/Edit Shift Demand", and "View Result". By clicking the "Add New Employee" button, the user is required to enter the name and the gender of the staff, as illustrated in Fig. 3. Following from there, the preferred shift and day off are keyed in by the user, who can recheck the details of the staff by clicking the "View/Edit Employee" button. Then, the user can edit or delete the staff details using the button "Delete" or "Edit", as shown in Fig. 4. In addition, the user inserts the demand of each shift, as illustrated in Fig. 5, by clicking the 'View/Edit Shift Demand' button. Finally, the user clicks the 'View Schedule' button, which then displays the near best or optimal solution.

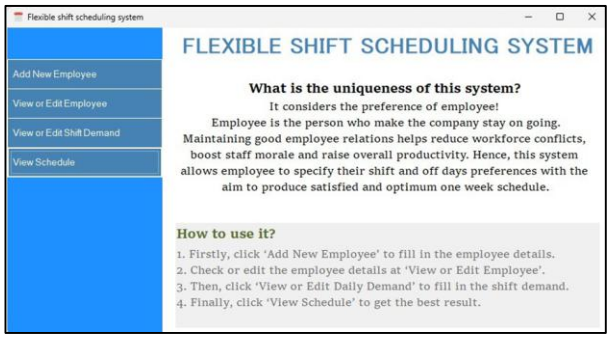

Fig. 2. Interface of Flexible Shift Schedule system.

Fig. 3. Interface to enter the staff details

IV. RESULT

This is the result of a nursing rostering schedule that was obtained for one week and produced using integer linear programming and genetic algorithms. The LPSolve IDE is used to implement integer linear programming, while the Flexible Shift Scheduling System is used to implement GA. This section presents a comparison between the hospital's current schedule and the schedule generated utilizing both methods.

A. Evaluation of Current One-Week Schedule for Children's Ward (Dataset 1)

The current schedule ran from August 7th to August 13th, 2023, for a total of one week, as shown in Table II. The letters "M" stands for morning shift, "A" for afternoon shift, "N" for night shift, and "OFF" for off-day.

TABLE II. CURRENT MANUALLY CONSTRUCTED SCHEDULE OF CHILDREN'S WARD FOR WEEK 1 (7TH AUGUST 2023 TO 13TH AUGUST 2023)

Staff	Shift schedule					Weekly preference weight
	7	8	9	…	13	
	Mon	Tue	Wed	…	Sun	
Staff 1	A	A	M	...	A	
Staff 2	A	OFF	A	...	M	
Staff 3	N	N	OFF	...	A	
⋮	⋮	⋮	⋮	⋮	⋮	
Staff 24	M	M	OFF	...	M	
Preference weight	23.08	21.08	26.08	...	21.08	**159.56**

A manually designed nurse schedule by the head nurse of Malaysia Specialists Centre for one week is shown in Table II. The overall weekly nurse staff preference weight, Z, is 159.56 (56.87%), as can be observed from the result. However, the hospital is still looking for improvement to figure out how to maximize nurse staff preferences by considering their demand for working shifts and days off. In addition, every staff member is granted one day off every week, as shown in Table II.

B. Proposed One-Week Schedule for Children's Ward

The integer linear programming software, LPSolve IDE, is used to produce the nursing staff's work schedule. The letter "SD" stands for the sleeping day, which the related staff should have for working two or three days of night shift continuously. A schedule can be completed more quickly, and allocating shifts to each member of staff can be done easily with the aid of LPSolve IDE. One-week results are displayed in Table III.

The manually created nurse schedule for a week by the head nurse of Malaysia Hospital, created without the use of any systematic software, is shown in Table IV. However, the real-life case study does not include a large number of nurses in one department; hence, simulated data is required to achieve the objective of this study. Based on Table IV, the preference weight, Z, of the nursing staff, is 589. Every member of staff has at least one day off every week, as Table IV demonstrates. Furthermore, as the table illustrates, each member of staff is assigned to a single shift every day, and most importantly, there is a sufficient number of staff for each shift. These are the hard constraints that need to be met to have a feasible schedule.

TABLE III. SCHEDULE FOR CHILDREN'S WARD USING LPSOLVE IDE IN A WEEK

Staff	Shift schedule					Weekly preference weight
	7	8	9	…	13	
	Mon	Tue	Wed	…	Sun	
Staff 1	OFF	N	N	...	N	
Staff 2	OFF	N	N	...	N	
Staff 3	OFF	N	N	...	N	
⋮	⋮	⋮	⋮	⋮	⋮	
Staff 24	M	M	M	...	OFF	
Preference weight	32.40	29.40	26.40	...	29.40	**205.80**

Table III shows an optimal nurse rostering schedule for a week that was created using an integer linear programming method. The preferred working shift of the nursing staff is represented by the green zone, which has been maximized to suit their demands. The blue zone represents the nursing staff's preference for days off that have been completed.

C. Evaluation of Current One-Week Schedule for Admission Ward (Dataset 2)

The manually designed weekly schedule for the hospital's admissions ward is shown in Table IV.

TABLE IV. CURRENT MANUALLY CONSTRUCTED SCHEDULE OF ADMISSION WARD FOR A WEEK (7TH AUGUST 2023 TO 13TH AUGUST 2023)

Staff	Shift schedule					Weekly preference weight
	7	8	9	⋯	13	
	Mon	Tue	Wed	⋯	Sun	
Staff 1	M	A	M	⋯	A	
Staff 2	OFF	M	A	⋯	M	
Staff 3	A	N	N		A	
⋮	⋮	⋮	⋮	⋮	⋮	
Staff 100	M	M	OFF	⋯	M	
Preference weight	77.00	80.00	88.00	⋯	94.00	**589.00**

D. Proposed One-Week Schedule for Admission Ward (Dataset 2)

The Flexible Shift Scheduling System sets the work schedule for the nursing staff. This system facilitates the process of allocating shifts to staff so that schedules can be quickly created. The weekly results are displayed in Table V.

TABLE V. WEEK 1 SCHEDULE FOR ADMISSION WARD BY USING THE FLEXIBLE SHIFT SCHEDULING SYSTEM

Staff	Shift schedule					Weekly preference weight
	7	8	9	⋯	13	
	Mon	Tue	Wed	⋯	Sun	
Staff 1	M	N	OFF	⋯	M	
Staff 2	A	A	A	⋯	A	
Staff 3	M	M	M	⋯	OFF	
⋮	⋮	⋮	⋮	⋮	⋮	
Staff 100	N	N	OFF	⋯	OFF	
Preference weight	91.60	95.60	85.60	⋯	79.60	**619.20**

The nearly optimal result that the genetic algorithm approach produced for one week of the second dataset is shown in Table V. According to the result, from Monday through Sunday, the proposed schedule satisfies every hard constraint as stated above for the one-week schedule of the first dataset that was obtained.

V. DISCUSSION

A. Scheduling Comparison Between Existing Schedule and LPSolve IDE for Children's Ward (Dataset 1)

Overall, the findings showed that by utilizing the LPSolve IDE software, the preferred weight, Z for a week, could be raised by 46.24, from Z = 159.56 (56.87%) for the current schedule to Z = 205.8 (73.35%) for the proposed plan. It is possible to optimize the preference of nursing staff for shift work and days off.

TABLE VI. COMPARISON BETWEEN EXISTING SCHEDULE AND LPSOLVE IDE-GENERATED SCHEDULE FOR ONE WEEK

Comparison criteria	Scheduling type	
	Existing schedule	LPSolve IDE-generated schedule
Completely assigned to the preferred shift	0%	66.67%
Partially allocated to a preferred shift	83.33%	33.33%
Completely not assigned to the preferred shift	16.67%	4.17%
Completely assigned to preferred days off	12.5%	12.50%
Partially allocated to preferred days off	0%	0%
Completely not assigned to preferred days off	87.5%	87.5%
The duration needed to create the schedule	More than a day	3 hours
Total preference weight, Z	159.56	205.80

Table VI displays a comparison between the existing schedule and the proposed schedule generated by the LPSolve IDE software. It is interesting to note that the percentage of workers fully assigned to their desired shifts increased significantly from 0% to 66.67% according to the newly created shift plan. The newly designed schedule shows a significant improvement over the current timetable, which has 0% coverage. Rather than requiring a whole day, the scheduler now just needs three hours to generate the shift schedule. In just one week, the total preference weight increased significantly from 159.56 (56.87%) to 205.8 (73.35%). In conclusion, integer linear programming is a good approach to design an optimal shift schedule that uses fewer workers and computer time. Furthermore, it successfully satisfies both hard and soft constraints while optimizing staff preferences for working shifts and off days.

B. Scheduling Comparison Between Existing Schedule and Flexible Shift Scheduling System for Admission Ward (Dataset 2)

Overall, results demonstrated that the preference weight, Z, for a week could be increased by 30.2 by using the Flexible Shift Scheduling System, from Z = 589 (62.98%) for the current schedule to Z = 619.2 (66.21%) for the proposed plan. The results of the study demonstrate that the genetic algorithm approach can satisfy both soft and hard constraints. The preferences of nursing staff regarding shift work and days off can be optimized.

TABLE VII. COMPARISON BETWEEN EXISTING SCHEDULE AND FLEXIBLE SHIFT SCHEDULING SYSTEM SCHEDULE FOR ONE WEEK

Comparison criteria	Scheduling type	
	Existing schedule	Flexible shift schedule system
Completely assigned to the preferred shift	0%	2%
Partially allocated to preferred shift	66%	61%
Completely not assigned to the preferred shift	34%	37%
Completely assigned to preferred days off	16%	24%
Partially allocated to preferred days off	0%	25%
Completely not assigned to preferred days off	84%	51%
The duration needed to create the schedule	3 days	2 m 45 s
Total preference weight, Z	589.00	619.20

The increase from 0% to 2% in the proportion of staff assigned to their chosen shifts is a noteworthy observation. The percentage of staff who fully allocated their desired days off increased from 16% to 24% in terms of off-day preferences, which is a noteworthy accomplishment. While the current schedule offers no coverage (0%) on desired days off, the proposed schedule demonstrates progress by partially allocating 25% of workers to those days. Additionally, there is a notable decline in the number of staff who are completely unallocated to their chosen days off, from 84% to 51%. The GA approach produced a near-optimal timetable of 2 minutes and 45 seconds, a significant reduction over the three workdays required for hand construction. The overall preference weight increased from 589 (62.98%) to 619.2 (66.21%) in just one week, indicating a significant improvement. The GA approach demonstrated its efficacy by producing a virtually optimal schedule with significantly less staff and computation time needed once all hard constraints had been satisfied.

VI. CONCLUSION

Manual scheduling used to be quite difficult and time-consuming due to the multiple requirements that had to be met. This study used an integer linear programming approach with the aid of the LPSolve IDE software for the first dataset and a genetic algorithm with the assistance of the Flexible Shift Scheduling System for the second dataset. A feasible and optimal nurse rostering schedule was produced by the findings. The objectives of this study have all been achieved. Additionally, this study makes a contribution by providing a nurse rostering schedule that takes hospital demands, work shift preferences, and off-day preferences into account. Furthermore, this research is the first to utilize integer linear programming in conjunction with a genetic algorithm to account for various sample sizes, which highlights the gap in research on scheduling

problems. The limitation of this research is that it was primarily focused on the preferences of nurses, excluding the hospital cost and budget. Therefore, it is recommended to consider the daily expenses of the hospital as a significant component of future studies, which might contribute to the finance team's discoveries of optimized hospitals' profits. Also, validation of this work could be enhanced in future study to highlight the contribution of this findings into the real situation.

The Innovative Design System of Traditional Embroidery Patterns Based on Computer Linear Classifier Intelligent Algorithm Model

Xiao Bai*
School of Art and Design-Product Design Department, Henan University of Engineering, Zhengzhou 451191, China

***Abstract*—This research introduces an innovative system for designing traditional embroidery patterns utilizing a computer-based linear classifier intelligent algorithm. The system achieves efficient classification and recognition of embroidery pattern features by employing the Fisher linear discriminant analysis technique, thus enabling the intelligent and innovative creation of designs. Additionally, the system encompasses the design of classification algorithms for embroidery patterns and incorporates interactive tools along with embroidery systems, offering designers a user-friendly platform for pattern creation. In the system design, Fisher linear discriminant analysis algorithm is used to classify the feature vectors of embroidery patterns to ensure that the features of each type of pattern are accurately extracted and identified. The model simulation verifies the algorithm's effectiveness through multiple iterations, and the results show that the system has significantly improved the classification accuracy of embroidery patterns and the efficiency of innovative design. Accurate data analysis shows that the classification accuracy of the system in different types of embroidery patterns reaches more than 95%, and user satisfaction is improved by 20%.**

I. INTRODUCTION

Under the continuous progress of modern science and technology, the inheritance and innovation of traditional culture have become the focus of researchers. As an essential art form in Chinese traditional culture, embroidery carries a profound historical heritage and has unique aesthetic value. However, with the development of the times, the innovative design of embroidery patterns is gradually facing challenges, and traditional design methods are often complex to meet modern, diversified and personalized needs. Therefore, how to use modern technical means to carry out intelligent and innovative design of embroidery patterns has become an urgent problem to be solved.

In recent years, the widespread application of computer vision and intelligent algorithms in image processing and pattern recognition has provided new technical support for the innovative design of traditional embroidery patterns. In particular, the intelligent algorithm model based on linear classifiers can effectively improve the efficiency and quality of pattern design by accurately classifying and identifying pattern features. Among them, Fisher linear discriminant analysis (LDA), as a classic linear classification method, has gradually attracted the attention of researchers due to its advantages in feature extraction and classification.

In [1], the authors proposed a pattern recognition method based on Fisher linear discriminant analysis. By linearly transforming the feature vectors in the dataset, it successfully solved the problem of difficult feature classification under high-dimensional data. This method improves classification accuracy and shows strong robustness in practical applications. In [2], the authors further expanded the Fisher linear discriminant analysis application in image processing and proposed the problem of multi-class image classification. Scholars improved the separability between different categories by optimizing the feature space, thereby significantly improving the classification efficiency. However, these studies mainly focus on general image classification and have not yet involved the application of embroidery patterns in a particular field.

In [3], the authors proposed an embroidery pattern automatic generation system based on deep learning. The automatic design of patterns is realized through a convolutional neural network (CNN) to extract and generate features of embroidery patterns. Although this method solves the problem of automation of embroidery pattern design to a certain extent, due to its model's complexity, the system's real-time and interactivity are poor. In [4], the authors proposed an embroidery design interactive tool based on augmented reality (AR) technology. Through the human-computer interaction interface, users can adjust and design embroidery patterns in real time in a virtual environment, significantly improving the convenience of design and user experience [5]. However, this tool mainly relies on the manual operation of users, making it challenging to achieve intelligent design optimization.

This research introduces a novel design system for traditional embroidery patterns utilizing a computer-based linear classifier intelligent algorithm model [6]. The system employs the Fisher linear discriminant analysis technique to precisely classify and recognize the features of embroidery patterns, integrating interactive tools with embroidery systems to offer designers a comprehensive platform that merges intelligent classification with design capabilities [7]. In crafting the system, the Fisher linear discriminant analysis algorithm is applied to categorize the feature vectors of embroidery patterns, ensuring that the distinctive characteristics of each pattern type are accurately extracted and identified. Additionally, the system's integrated interactive tools and embroidery systems provide users with a user-friendly and intuitive interface [8], allowing

designers to make real-time adjustments and optimizations to the design during the pattern creation process, thus achieving the intelligent and innovative development of embroidery patterns.

II. DIY Interactive Design Tool

This section is dedicated to building an innovative digital auxiliary platform to provide users with a convenient embroidery DIY design experience. The system significantly simplifies the embroidery creation by generating intuitive preview images and detailed needlework instructions [9]. Given the unique complexity of craftsmanship in stitch construction and layout, this study, first deeply analyzed the actual embroidery creation process and extracted essential operation procedures and core elements [10]. The entire process from design to finished product is systematically sorted out, covering the three critical stages: design draft, wiring, and embroidery (Fig. 1).

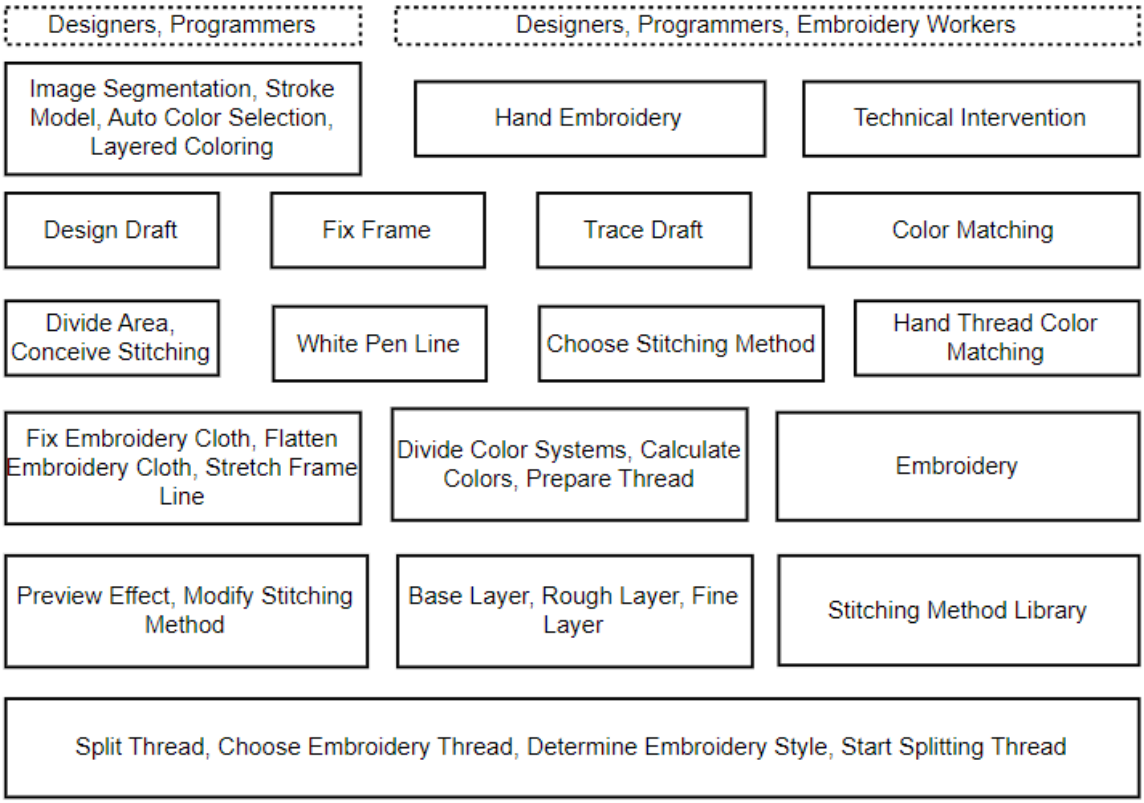

Fig. 1. Embroidery process flow and digital technology design system architecture

In the draft design stage, users need to divide the image into regions in detail. It includes foreground, background and details and then plans the overall needle direction according to the characteristics of each region to lay the foundation for subsequent creation [11]. The wiring stage requires users to select or mix appropriate embroidery thread colors based on the design draft, combined with personal experience and creativity, to ensure the harmony and expressiveness of the working color [12]. In the embroidery stage, users will flexibly choose needle methods and layouts according to the needle method style and personal creativity planned in the early stage and finally, embroider works with both personal style and design sense.

This study innovatively proposed the algorithm flow shown in Fig. 2 to reconstruct the embroidery design path with digital technology. The process mainly includes four core steps: image color extraction and region segmentation, embroidery needle method model construction, interactive reconstruction vector field style drawing and draft marking [13]. Image color extraction and region segmentation are aimed at automatically analyzing images to provide a structured basis for subsequent design [14]. Embroidery needle method model construction focuses on simulating and optimizing the visual effects of different needle methods. Interactive reconstruction vector field style drawing ensures flexibility and personalization in the design process. The draft marks provide users with intuitive needlework guidance and layout references, significantly improving the efficiency and accuracy of embroidery creation.

This study makes innovative adjustments to the current support vector machine (SVM) optimization objective function, aiming to maintain the maximum distance between classes in the optimized feature space based on the theoretical foundation of the Fisher discriminant criterion [15]. It can effectively reduce the intra-class variability, thereby improving the performance and robustness of the classifier. Precisely, the original Formula (3) is reconstructed as Formula (1):

$$\min H_N(\lambda) = \frac{1}{2}(\| \lambda \|^2 + \lambda \lambda^T R_\lambda \lambda)$$
$$s.t.\ f_i(\lambda^T t_i + \varepsilon) \geq 1 \ \forall i \quad (1)$$

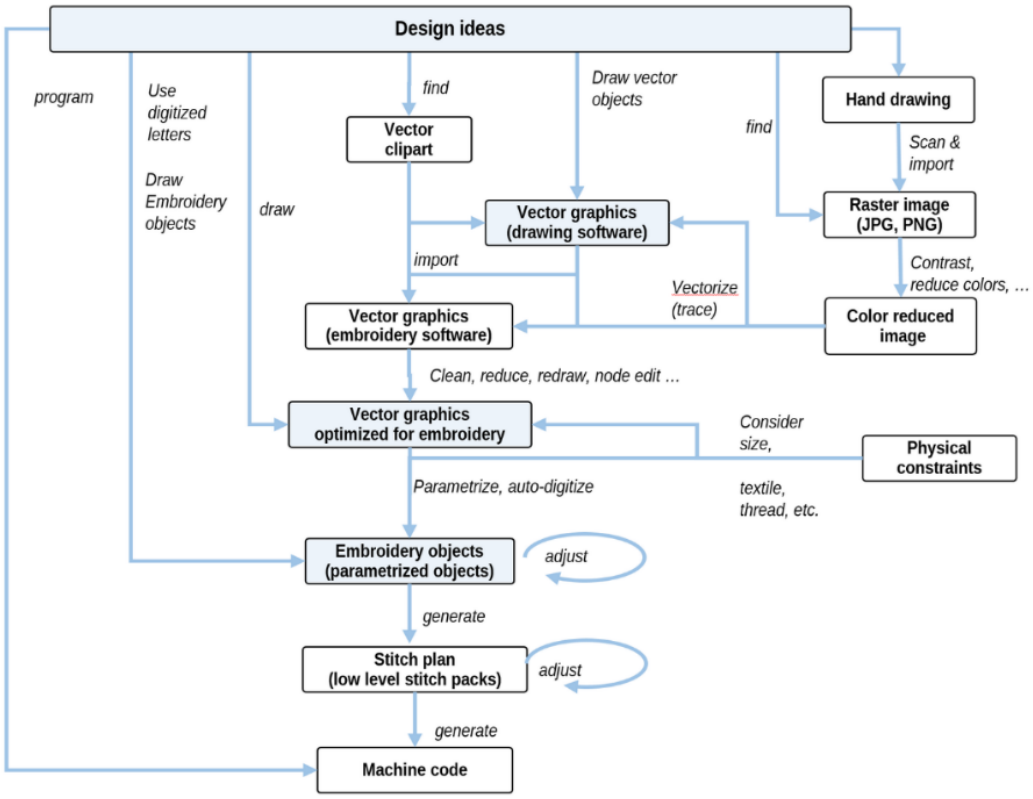

Fig. 2. Flowchart of an embroidery DIY Interactive Design Tool

where, $R_\lambda = \sum_{i=1}^{2}\sum_{j=`}^{M_i}(t_j - n_i)(t_j - n_i)^T$ represents the intra-class scatter matrix, which reflects the distribution of samples in the same category; and $n_i = \frac{1}{M_i}\sum_{j=1}^{M_i} t_j$ is the sample mean, which describes the central tendency of the data. The parameter λ is introduced to reconcile the dual goals of maximizing the distance between classes and minimizing the intra-class scatter to form a dynamic balance [16]. When the λ value increases, the algorithm prioritizes reducing the intra-class scatter. On the contrary, when $\lambda = 0$, the formula degenerates into the traditional maximum distance classifier. The FLMC classifier proposed in this study determines the optimal projection axis by solving the direction that makes $H_N(\lambda)$ reach the extreme value [17]. This process minimizes the intra-class difference while ensuring the maximization of the inter-class difference. Formula (1) constitutes a convex quadratic programming problem. This study converts it into Formula (2):

$$\begin{aligned} &\min \frac{1}{2}\lambda^T(E + \lambda R_\lambda)\lambda \\ &s.t.\ f_i(\lambda^T t_i + \varepsilon) \geq 1 \ \forall i \end{aligned} \tag{2}$$

Introduce E as the identity matrix for further processing. Since $E + \lambda R_\lambda$ is a symmetric matrix, there exists an orthogonal matrix $Q = (q_1, \mathrm{L}\ , q_n)$ that satisfies Formula (3):

$$Q^{-1}(E + \lambda R_\lambda)Q = Q^T(E + \lambda R_\lambda)Q = \phi \tag{3}$$

where, $\phi = diag(\varphi_1, \varphi_2, \mathrm{L}\ , \varphi_n)$ and $q_1, \mathrm{L}\ , q_n$ are the orthonormal eigenvectors of $E + \lambda R_\lambda$, and $\varphi_1, \varphi_2, \mathrm{L}\ , \varphi_n$ is the corresponding eigenvalue matrix that satisfies $\varphi_j > 0, j = 1, \mathrm{L}\ , n$. Therefore, $E + \lambda R_\lambda$ can be rewritten as Formula (4):

$$E + \lambda R_\lambda = Q\phi^{1/2}\phi^{1/2}Q^T = Q\phi^{1/2}(Q\phi^{1/2})^T \tag{4}$$

Substituting Formula (4) into Formula (2) yields Formula (5):

$$\begin{aligned} &\lambda^T Q\phi^{1/2}\phi^{1/2}Q^T\lambda = \\ &\lambda^T(Q\phi^{1/2})(Q\phi^{1/2})^T\lambda = \| \phi^{1/2}Q^T\lambda \|^2 \end{aligned} \tag{5}$$

Assuming $\lambda_2 = \phi^{1/2}Q^T\lambda$, Formula (2) can be restated as Formula (6):

$$\begin{aligned} &\min \frac{1}{2}\| \lambda_2 \|^2 \\ &s.t.\ f_i(\lambda_2^T u_i + \varepsilon) \geq 1 \ \forall i \end{aligned} \tag{6}$$

where, $u_i = (\phi^{1/2}Q^T)t_i$ is the optimization variable.

III. Relationship between FLMC Classifier and Existing Classification Techniques

This section explores the intrinsic relationship between the large-margin Fisher classifier and classic support vector machine (SVM) and Fisher linear discriminant analysis (LDA). According to the optimization objective function [Formula (1)], the optimal projection direction is regulated by the parameter λ^{best}. This study will further study the exceptional cases when λ tends to infinity and equals to zero to reveal its equivalence with traditional classification methods.

Theorem 1: The limiting case of λ when the intra-class divergence matrix R_λ is singular. The optimal projection direction determined in this study according to Formula (1) is equivalent to the optimal projection direction defined by Formula (7).

$$\begin{aligned} &\min H_N(\lambda) = \frac{1}{2}\| \lambda \|^2 \\ &s.t.\ f_i(\lambda^T t_i + \varepsilon) \geq 1 \ \forall i \\ &\lambda^T R_\lambda \lambda = 0 \end{aligned} \tag{7}$$

Proof: Let φ be a specific eigenvalue of $(E + \lambda \cdot R_\lambda)$, and q be the corresponding unit eigenvector. Since R_λ is singular, there exists a unit vector q_0, $R_\lambda q_0 = 0$.

$$(E + \lambda \cdot R_\lambda) q = \varphi q \tag{8}$$

Formula (8) can be rewritten as Formula (9):

$$q^T R_\lambda q = \frac{1}{\lambda}(\varphi - q^T E q) \leq \frac{1}{\lambda}\varphi \tag{9}$$

Since R_λ is a semi-positive definite matrix, all exist:

$$q^T R_\lambda q \geq 0 \tag{10}$$

Combining Formula (10) with Formula (11) people have:

$$\lim_{\lambda \to \infty} q^T R_\lambda q = 0 \tag{11}$$

Therefore, the solution λ of Formula (1) must be located in the null space of R_λ when λ, which is consistent with the solution of Formula (7).

Theorem 2: The optimal projection direction determined by Formula (6) is equivalent to the optimal projection direction defined by Formula (12).

$$\max \lambda^T R_\varepsilon \lambda \quad s.t. \begin{cases} \lambda^T R_\lambda \lambda = 0 \\ \| \lambda \| = 1 \end{cases} \tag{12}$$

Proof: When R_λ is a singular matrix, it shows that the training samples are completely linearly separable. There exists a unit vector q such that $q^T R_\lambda q = 0$ as in Formula (13):

$$\begin{aligned} q^T R_i q &= q^T \sum_{t \in \zeta_i} (t - n_i)(t - n_i)^T q \\ &= \sum_{t \in \zeta_i} (q^T t - q^T n_i)^2 = 0, i = 1, 2 \end{aligned} \tag{13}$$

Right now Formula (14):

$$\forall t \in \zeta_i, q^T t = q^T n_i, i = 1, 2 \tag{14}$$

In the null space of R_λ, there is a projection direction in which samples belonging to the same category are mapped to the same point, while samples from different categories are mapped to distinct points. Currently, the inter-class spacing $\frac{2}{\| \lambda \|^2}$ is equal to the maximum inter-class distance as in Formula (15).

$$\lambda^T R_\varepsilon \lambda = \lambda^T (n_1 - n_2)(n_1 - n_2)^T \lambda = (\lambda^T n_1 - \lambda^T n_2)^2 \tag{15}$$

Therefore minimizing $\frac{1}{2}\| \lambda \|^2$ is equivalent to maximizing $\lambda^T R_\varepsilon \lambda$.

IV. Experiment and Result Analysis

This study aims to develop a technology to assist users in embroidery DIY design, which can generate high-fidelity effect preview images and embroidery drafts with detailed needle instructions, thereby simplifying the user's embroidery process. The design concept of this algorithm is to pursue a high degree of realism when simulating embroidery effects in the comparative analysis, the performance of the algorithm proposed in this study was evaluated with the existing algorithms. The algorithm's advantages in simulation effects are demonstrated through quantitative data comparison. Specifically, the algorithm in this study performs well in the diversity and flexibility of needle methods and can simulate embroidery effects with apparent leaf texture trends [18]. This effect shows dynamic beauty and makes the distinction between foreground and background more obvious, enhancing the three-dimensional sense and layering. In addition, the algorithm in this study pays special attention to the importance of user-tool interaction during the simulation process, aiming to enhance the user's autonomy and creativity in computer-aided design. The algorithm process of this study includes steps such as image color extraction and region segmentation, embroidery needle model construction, interactive reconstruction vector field style drawing, and draft marking. Together, these steps constitute a comprehensive digital embroidery design platform that aims to achieve stylized embroidery design and provide intuitive technical guidance rather than existing as an independent digital artwork [19]. In terms of detail processing, the algorithm in this study prioritizes issues that users cannot deal with in advance

during the embroidery process, such as the overall layout of the stroke direction, rather than focusing too much on the clarity of the regional edges. Through this design philosophy, the algorithm in this study effectively supports the personalization and convenience of embroidery DIY. Table I to Table III shows the results generated by the method in this study and the simulation results of other algorithms. Fig. 3 shows the simulation effect of the algorithm in this study.

V. CONCLUSION

The innovative design system for traditional embroidery patterns, developed using a computer-based linear classifier intelligent algorithm model in this study, effectively utilizes the Fisher linear discriminant analysis method for the intelligent classification and innovative creation of embroidery designs. By precisely categorizing the feature vectors of embroidery patterns, the system significantly enhances both the accuracy of pattern recognition and the efficiency of the design process. The inclusion of interactive tools and the embroidery system within the system design offers designers a user-friendly and intuitive platform, thereby further improving the system's practicality and overall user experience. Simulation results demonstrate that the system achieves a notable increase in classification accuracy, especially when dealing with complex embroidery patterns, and exhibits clear advantages in design efficiency. Through rigorous data analysis, the system has proven to be highly robust and stable in the classification of various embroidery patterns, with user feedback indicating a high level of satisfaction in real-world applications. This study introduces new methodologies and tools for the innovative digital design of embroidery patterns.

Abstract*—Diabetes is one of the most prevalent chronic diseases globally, with significant mortality and morbidity rates. Early and accurate diagnosis plays a critical role in managing and mitigating its impact. However, achieving high diagnostic accuracy while ensuring interpretability remains a key challenge in medical machine learning applications. This paper proposes an interpretable and accurate hybrid framework for diabetes prediction that integrates Support Vector Machine Rule Extraction (SVMRE), Fuzzy Analytic Hierarchy Process (Fuzzy AHP), and Sugeno fuzzy inference. The primary objective of this study is to enhance prediction accuracy while enabling the extraction of meaningful and explainable decision rules derived from SVM models. To address the black-box nature of traditional SVM models, fuzzy rules are extracted and embedded into a Sugeno fuzzy inference system. Attribute importance is quantified through Fuzzy AHP based on expert consultation, ensuring medically relevant decision-making. Furthermore, to overcome rule redundancy and complexity, the coefficient of variation is computed for each rule and optimized using a Nearest Neighbor (NN) approach, which clusters rules with adjacent variation values. The proposed framework is evaluated using a real-world diabetes dataset from Sylhet, Bangladesh. It achieves a prediction accuracy of 84.62 per cent, outperforming several conventional methods. Compared to other competitive approaches found in recent literature, such as fuzzy grey wolf optimization and neuro-fuzzy systems, our method demonstrates superior balance between interpretability, computational efficiency, and classification performance. This study confirms that integrating rule-based learning, fuzzy expert systems, and statistical optimization provides a robust and interpretable approach for diabetes prediction. The framework aligns with Sustainable Development Goal 3 (SDG 3) by promoting early detection and decision support for non-communicable diseases in healthcare systems.

Keywords*—SVM; Fuzzy AHP; rule extraction; diabetes; coefficient of variation; fuzzy Sugeno; SDG 3

I. Introduction

Diabetes mellitus is a chronic and progressive metabolic disorder characterized by elevated blood glucose levels, which can lead to severe complications such as cardiovascular disease, renal failure, neuropathy, and visual impairment [1]. According to the World Health Organization, diabetes affects more than 422 million people globally and accounts for approximately 1.5 million deaths annually [2]. The increasing prevalence of this disease, particularly in low and middle income countries, underscores the urgency of developing reliable, accurate, and interpretable systems for early detection and diagnosis [3].

Recent advances in machine learning (ML) have demonstrated significant potential in supporting clinical decision-making processes, especially in the context of early disease prediction [4]. Among the various ML techniques, Support Vector Machine (SVM) has been widely recognized for its high classification accuracy and robustness in handling high-dimensional and nonlinear data [5], [6], making it a strong candidate for medical diagnostic tasks [7], [8], including diabetes prediction [9]. However, despite its predictive power, SVM lacks inherent interpretability, which limits its applicability in clinical environments that demand transparent and explainable decision support. The inability of clinicians to trace and justify model decisions remains a critical barrier to the widespread adoption of such black-box models in healthcare settings [10].

Furthermore, traditional fuzzy inference systems, which offer linguistic interpretability through rule-based structures, often fail to incorporate the relative importance of medical attributes, thereby oversimplifying the decision logic [11]. These systems typically rely on uniformly weighted attributes, which may not align with clinical judgment or expert knowledge. Moreover, when applied to complex datasets, fuzzy models frequently suffer from an exponential growth in rule base size, leading to redundant rules and decreased system efficiency [12]. Although prior studies have explored various hybrid models combining machine learning with fuzzy logic, most of these approaches either overlook the integration of expert-driven attribute weighting or do not address rule optimization to reduce computational overhead without compromising predictive performance [13].

In light of these challenges, this study proposes a novel hybrid framework that integrates SVM-based rule extraction with Fuzzy Analytic Hierarchy Process (Fuzzy AHP) and Sugeno-type fuzzy inference, optimized through a coefficient of variation and Nearest Neighbor-based rule reduction mechanism. This approach aims to enhance the interpretability of the predictive model while maintaining high accuracy. The SVM Rule Extraction component enables the transformation of opaque decision boundaries into comprehensible fuzzy rules. Fuzzy AHP incorporates expert judgment in the weighting of input attributes, ensuring that the most clinically relevant features are prioritized in the inference process. To address

the scalability and complexity of the rule base, the model applies statistical analysis through the coefficient of variation and leverages the Nearest Neighbor algorithm to merge similar rules, thus achieving an optimized and efficient rule set.

The proposed framework contributes to the field by addressing critical gaps in the integration of interpretable machine learning and expert knowledge in fuzzy systems. By demonstrating improved accuracy and transparency in diabetes prediction, this study offers a practical and clinically relevant solution that aligns with the growing demand for explainable artificial intelligence in healthcare. The model not only enhances predictive performance but also supports meaningful interpretation of results, which is essential for clinical validation and trust.

II. Related Works

Several machine learning techniques have been extensively utilized in the prediction of diabetes, each contributing unique strengths and challenges [14]. Several studies that combine fuzzy logic for rule formation and machine learning to train data obtain fairly good accuracy values [15], [16]. Zhang et al. (2020) utilized SVM and achieved an accuracy of 82 per cent [6], while Butt et al. (2020) employed a combination of SVM, KNN, and Decision Tree, yielding an accuracy of 75 per cent [17]. Furthermore, Faniqul Islam et al. (2019), using a combination of Logistic Regression, KNN, SVM, and Random Forest, reported an accuracy of 75 per cent [18]. The Fuzzy Grey Wolf Optimization method in Chen et al. (2019) produced an accuracy of 81 per cent [19], and Azad et al. (2021) achieved an accuracy of 7567 per cent using a Neuro-Fuzzy System [20]. Support Vector Machines (SVM) are a popular choice due to their high classification accuracy and robustness in handling high-dimensional data [21], [22]. By finding an optimal hyperplane that separates classes with minimal error, SVM demonstrates superior performance in many medical prediction tasks. However, as highlighted by Zhang et al. (2020) and Butt et al. (2020), the lack of interpretability in SVM models remains a significant limitation, particularly in clinical applications where understanding the decision-making process is crucial [6], [13]. This black-box nature restricts the ability of healthcare professionals to validate the model's decisions and may hinder its adoption in real-world settings.

To mitigate this issue, Fuzzy Logic Systems, such as the Sugeno Fuzzy Inference System (Sugeno FIS), have been introduced to offer greater transparency. These systems use fuzzy rules and memberships to deal with uncertainty and provide linguistic interpretations of decisions, making them more interpretable. Furthermore, Fuzzy AHP (Analytic Hierarchy Process) has been applied in some studies to weight attributes based on expert opinions [23], [24]. However, while Fuzzy AHP provides a systematic way to incorporate expert knowledge into the decision-making process, it still faces challenges related to rule optimization and the computational complexity involved when working with large datasets.

In addition to fuzzy systems, Neuro-Fuzzy Systems, which combine artificial neural networks with fuzzy logic, have been explored for diabetes prediction. These systems aim to improve predictive accuracy by learning both the structure and the rules directly from the data. Studies by Sisodia et al. (2018) [15] have shown that neuro-fuzzy systems can enhance prediction performance. However, these models still suffer from issues such as rule explosion and the difficulty in extracting meaningful decision rules [16], [17], making the system less efficient and harder to interpret [18], particularly when dealing with complex datasets like those used for medical predictions [19].

While these existing methods have contributed significantly to diabetes prediction, they each have inherent weaknesses, particularly in terms of interpretability, rule complexity, and computational efficiency. These challenges highlight the need for a more robust and interpretable model that can combine the high accuracy of SVMs with expert-driven feature weighting and fuzzy rule optimization, ultimately improving both prediction accuracy and model transparency for clinical use. Therefore, this research aims to address these gaps by proposing a novel hybrid approach that integrates SVM-based rule extraction, Fuzzy AHP, Sugeno FIS, and Nearest Neighbor Optimization, to improve the performance and interpretability of diabetes prediction models.

The contributions of this research to the field of diabetes prediction can be summarized as follows:

1) Hybrid framework development: The study proposes a novel hybrid approach that integrates SVM-based rule extraction, Fuzzy AHP, and Sugeno Fuzzy Inference, optimized using Coefficient of Variation and Nearest Neighbor (NN) optimization. This framework enhances the accuracy and interpretability of diabetes prediction models by leveraging expert knowledge and reducing model complexity.

2) Rule extraction and interpretability: The paper addresses a major limitation of traditional machine learning models, such as SVM, which are often perceived as "black-box" models due to their lack of interpretability. By extracting fuzzy rules from the trained SVM, the authors make the decision-making process more transparent and explainable, which is crucial for clinical adoption.

3) Incorporation of expert knowledge through fuzzy AHP: Fuzzy AHP is used to weight the importance of input features (such as symptoms, age, and other health factors) based on expert judgment. This ensures that the most clinically relevant features are prioritized, improving the overall decision-making process.

4) Optimization of fuzzy rules: The study introduces a method to optimize the number of fuzzy rules using Coefficient of Variation (CV), which reduces rule redundancy and improves computational efficiency without compromising predictive accuracy. The use of the Nearest Neighbor (NN) algorithm further refines this optimization process.

5) Practical applicability in healthcare: The proposed method provides a robust solution to early diabetes detection while maintaining interpretability, which is essential for healthcare professionals.

6) Contribution to Sustainable Development Goals (SDG 3): The framework aligns with SDG 3 by contributing to the early detection and prediction of non-communicable diseases, which plays a critical role in mitigating the global impact of diabetes. The transparency and accuracy of the model are key to facilitating its integration into healthcare systems, improving decision support in clinical settings.

III. Research Frameworks

A. Support Vector Machine Rules Extraction (SVMRE)

SVM Rule Extraction (SVMRE) is a technique designed to derive interpretable rules from the trained Support Vector Machine (SVM) model, rather than directly from the raw dataset [25]. This approach enables the extraction of patterns that have been learned and encoded within the structure of the model—specifically through the support vectors (SV) and their corresponding parameters [26], [27]. These extracted patterns are then translated into a comprehensible form, allowing end users to understand the underlying decision logic of the model [28]. The detailed steps of the SVMRE algorithm are presented in Table I.

TABLE I. SVMRE Algorithm

1. Input: Normalize training data set (x_i, y_i), $i = 1, 2, \cdots, n$.
2. SVM training on the training data set.
2.1 Construct the objective function
$min_\omega \frac{1}{2}\|\|\omega\|\|^2 + C\frac{1}{n}\Sigma_{i=1}^{n} L(y_i, f(x, \omega))$
2.2 Solve the optimization problem in a kernel-induced dual space.
$\hat{f}(x) = \Sigma_{i=1}^{n_{SV}} (\alpha_i - \alpha_i^*)K(x_i, x), \quad 0 \le \alpha_i^* \le C, 0 \le \alpha_i \le C$
3. Generate SVM output in the input of training and testing data set.
4. Combine the preceding two subsets as the new training set.
5. Training the fuzzy Sugeno model on the newly generated training set.
6. Output: The trained fuzzy Sugeno model.

B. Fuzzy Analytical Hierarchy Process (FAHP)

Analytical Hierarchy Process (AHP) is one of the multi-attribute decision-making (MADM) that is widely applied [29]. The weight of the criteria is given through the formation of a pairwise comparison matrix. One of the popular AHP methods is developed by Saaty in 1980 [30].

Using linguistic value interpretation, a pairwise comparison matrix is created with elements $m_{ij} = (a, b, c)$ which is a triagonal fuzzy number (TFN). Where $a < b < c$ if attribute i is less important than attribute j. To find out the scale of importance of an attribute compared to other attributes, consultation with related medical experts is necessary. Furthermore, a pairwise comparison matrix (PCM) is created as follows:

$$M = \begin{bmatrix} (1,1,1) & m_{12} & \cdots & m_{1n} \\ m_{21} & (1,1,1) & \cdots & m_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ m_{n1} & m_{n2} & \cdots & (1,1,1) \end{bmatrix} \quad (1)$$

If there are z decision makers for each comparison, then the PCM in Eq. (1) is rearranged by taking the average value of each element. The next step is to combine the PCM on each criterion from all experts by calculating the Fuzzy Geometric Mean (GM) value. This method was introduced by Buckley in 1985 [31]. The Fuzzy GM is used to calculate the fuzzy weights for each fuzzy matrix, and these weights are combined in the usual way to determine the final fuzzy weights for the alternatives [32]. The final fuzzy weights are used to rank the alternatives from highest to lowest [33]. The Fuzzy GM for a TFN is shown in Eq. (2).

$$(r_i) = (\Pi_{j=1}^{n} m_{ij})^{1/n}, \quad i = 1, 2, \cdots, n \quad (2)$$

Next, the fuzzy weight is calculated for each criterion using Eq. (3).

$$w_i = r_i \otimes (r_1 \oplus r_2 \oplus \cdots \oplus r_n)^{-1} = (lw_x, mw_x, uw_x) \quad (3)$$

The numbers l, m, and u are respectively the smallest possible value, the modal or most likely value, and the highest possible value. Next, the non-fuzzy weight of the attribute is calculated using the Center of Area or COA method using Eq. (4)

$$A_x = \frac{lw_x + mw_x + uw_x}{3} \quad (4)$$

The final step of Fuzzy AHP is to normalize the weights in Eq. (4) using Eq. (5).

$$N_x = \frac{A_x}{\Sigma_{x=1}^{n} A_x} \quad (5)$$

C. Coefficient of Variation (CV)

The coefficient of variation, or CV, serves as a statistical metric that indicates the degree of dispersion of data points in a data series with respect to the mean [34]. It is defined by the ratio of the standard deviation to the mean.

D. Fuzzy Inference Sugeno

The Sugeno fuzzy inference system (Sugeno FIS), proposed by Takagi, Sugeno, and Kang in 1985, provides a systematic approach for generating fuzzy rules from a given input-output dataset [35]. The Sugeno FIS consists of three stages: defining membership functions, defining fuzzy rules, and the defuzzification process [36], [37].

The first step is to define the membership functions. This step aims to represent linguistic expressions using fuzzy membership functions, which are defined within the closed interval $[0, 1]$. The second step involves defining fuzzy rules in the form of "if-then" statements, where linguistic variables are represented using fuzzy sets. The relationship between the premises and consequences of these rules can be derived from reliable literature or through consultations with domain experts. The final step of the Sugeno FIS is the defuzzification process, where fuzzy outputs are transformed into a crisp value by calculating the weighted average.

IV. Results

In this research, diabetes prediction is conducted using data trained by Support Vector Machine with Rule Extraction (SVMRE). We use medical expert opinions to construct a pairwise comparison matrix and obtain attribute weights through the Fuzzy Analytic Hierarchy Process (Fuzzy AHP). The data trained with SVMRE are subsequently used for diabetes prediction via a Sugeno fuzzy inference system, which is enhanced by integrating Fuzzy AHP and the Nearest Neighbor method.

Attribute weights derived from the Fuzzy AHP process are distributed among subfactors based on their relative contributions. This allows the determination of the influence level of each attribute in predicting diabetes. Next, rules are constructed by combining all attributes. The coefficient of variation for each rule is calculated using its attribute weights, and the Nearest Neighbor method is applied to cluster potential rules based on these coefficients. The resulting rules from the trained data are then input into the Sugeno fuzzy inference system to predict diabetes.

The system's performance is evaluated based on accuracy metrics derived from the prediction results. The proposed method is illustrated in Fig. 1.

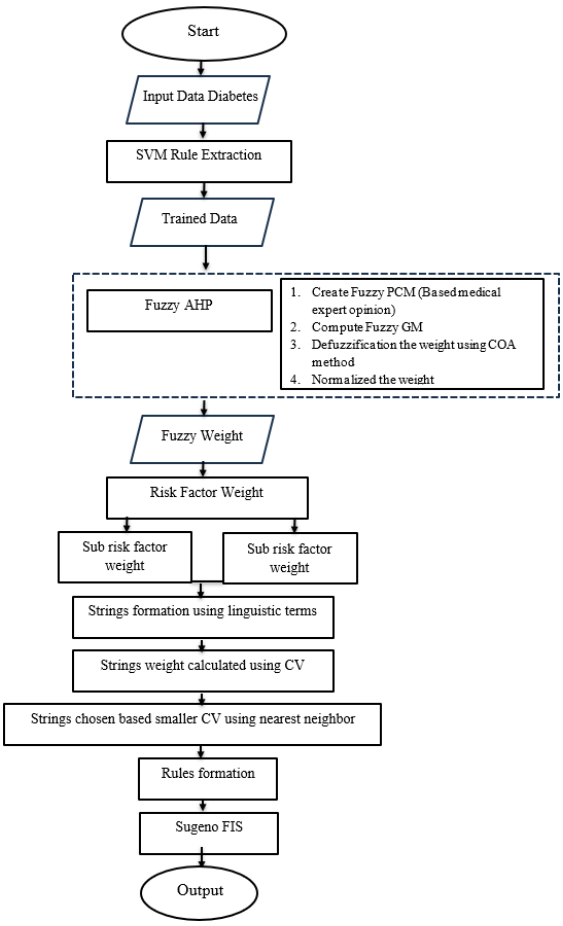

Fig. 1. Proposed method to predict diabetes.

A. Dataset and Attributes

The data used in this study were obtained directly from various diabetes patient survey forms at a Diabetes Hospital in Sylhet, Bangladesh [35]. The dataset consists of 520 patient records, divided into 17 attributes: output class (positive or negative), obesity, genital thrush, age, polyphagia, sex, sudden weight loss, polyuria, weakness, polydipsia, muscle stiffness, visual blurring, irritability, partial paresis, itching, alopecia, and delayed healing. Among the 520 cases, 320 were diagnosed with diabetes, and 200 were classified as normal, with a male-to-female ratio of 63:37, respectively. All attributes, except for age and sex, have categorical data with two unique outcomes. Therefore, in this study, only 14 attributes and one output class (positive or negative) were used, as shown in Table II.

TABLE II. ATTRIBUTE OF THE DATASET

Attribute	Value
Obesity (OS)	Yes or No
Genital thrush (GT)	Yes or No
Polyphagia (PG)	Yes or No
Sudden weight loss (SWL)	Yes or No
Polyuria (PR)	Yes or No
Weakness (WN)	Yes or No
Polydipsia (PD)	Yes or No
Musle Stiffness (MS)	Yes or No
Visual Blurring (VB)	Yes or No
Irritability (IA)	Yes or No
Alopecia (AC)	Yes or No
Partial Paresis (PP)	Yes or No
Itching (LI)	Yes or No
Delayed Healing (DH)	Yes or No

B. Fuzzy Rule Extraction Using SVMRE

The steps for fuzzy rule extraction from SVM are as follows. The first step involves support vector regression for diabetes prediction. In this step, training samples are used to tune SVM hyperparameters, such as kernel parameters. In SVM regression, both structural and empirical risks are minimized. The function L(y,f(x,w)) in the objective function represents the loss function applied to the training data [32].

The second step is data regeneration from the trained SVM. In this stage, the trained SVM is used to generate new data samples for training the fuzzy rules. Of the existing diabetes data, 70 per cent is used for training and 30 per cent for testing. The trained SVM generates new training samples, which enhances its generalization ability and helps train the fuzzy rules. For diabetes prediction, a new subset of training samples can be generated and combined, as both input variables from the training and testing samples are available. This combination of subsets improves the predictive ability of the fuzzy Sugeno model. To further enhance the generalization capability of the fuzzy rules, additional subsets can be constructed by calculating the predicted output of the SVM model for randomly generated or selected input vectors.

In the third step, once new training data samples are generated, they are used for diabetes prediction with the fuzzy Sugeno model, which has been enhanced using Fuzzy AHP and the coefficient of variation.

C. Evaluate Risk Factor Weight Using Fuzzy AHP

In this section, Fuzzy AHP is applied to calculate the attribute weights for diabetes prediction in order to identify the most influential attributes [33]. The attributes are shown in Table II. In the formation of the Pairwise Comparison Matrix (PCM), each attribute is compared with the others. The PCM is evaluated by the decision makers according to the linguistic measurements provided in Table III. The resulting PCM is presented in Table IV.

TABLE III. LINGUISTIC TERMS AND TRIANGULAR FUZZY NUMBER WITH THE INVERSE

Linguistic terms	Triangular fuzzy number	Inverse
Equal important	(1,1,1)	(1,1,1)
Intermediate values between two adjacent scales	(1,2,3)	(1/3,1/2,1)
Moderately more important	(2,3,4)	(1/4,1/3,1/2)
Intermediate values between two adjacent scales	(3,4,5)	(1/5,1/4,1/3)
Strongly more important	(4,5,6)	(1/6,1/5,1/4)
Intermediate values between two adjacent scales	(5,6,7)	(1/7,1/6,1/5)
Very strongly more important	(6,7,8)	(1/8,1/7,1/6)
Intermediate values between two adjacent scales	(7,8,9)	(1/9,1/8,1/7)
Extremely more important	(9,9,9)	(1/9,1/9,1/9)

LI	(1,1,1)	(1,1,1)	(1,1,1)	(7,8,9)	(3,4,5)	(2,3,4)	(1,1,1)	(1,1,1)	(1,1,1)	(1,1,1)	(1,1,1)	(1,1,1)	(1,1,1)	(1,1,1)

The next step is to calculate the fuzzy geometric mean (GM) value of all attributes. The formula for calculating the fuzzy GM is shown in Eq. (2). By knowing the fuzzy GM value, it can be determined which attribute has the most influence in predicting diabetes. The Fuzzy GM value is written in Table V.

TABLE V. FUZZY GM, FUZZY WEIGHT (w_x), AVERAGE WEIGHT (A_x), AND NORMALIZED FUZZY WEIGHT (N_x) OF EACH ATTRIBUTE

Attribute	GM	w_x	A_x	N_x
GT	(1.408, 1.258, 1.119)	(0.062, 0.079, 0.099)	0.080	0.079

PG	(1.426, 1.240, 1.104)	(0.061, 0.078, 0.100)	0.080	0.079
VB	(1.243, 1.194, 1.122)	(0.062, 0.075, 0.087)	0.075	0.074
IA	(1.051, 1.000, 0.952)	(0.052, 0.063, 0.074)	0.063	0.062
SWL	(1.727, 1.575, 1.379)	(0.076, 0.099, 0.121)	0.099	0.098
PP	(1.312, 1.160, 0.964)	(0.053, 0.073, 0.092)	0.073	0.072
LI	(1.449, 1.385, 1.306)	(0.072, 0.087, 0.101)	0.087	0.086
Total	(14.227, 15.698, 17.900)			
$Total^{(-1)}$	(0.070, 0.064, 0.056)			
INCR	(0.056, 0,064, 0.070)			

Based on Table V, the Total Attribute states the sum of the fuzzy GM values of all attributes. While the $Total^{(-1)}$ attribute is the inverse of the Total value. The INCR or increasing order attribute is obtained by exchanging the first column of $Total^{(-1)}$ with the third column of $Total^{(-1)}$.

The next step is to calculate the fuzzy weight for each attribute using Eq. (3) by multiply the fuzzy GM value of the attribute with its INCR value. The fuzzy weight value (w_x) is shown in Table V.

In Table V, A_x is the non-fuzzy weight obtained from the defuzzification process with the COA method as shown in Eq. (4). While N_x is the normalized weight with Eq. (5), where the total weight of all attributes is 1. By knowing the normalized non-fuzzy weight, it can be concluded that the most influential attribute in the system is polyuria. Meanwhile, the attribute with the smallest influence is obesity.

In the next section, the normalized weights will be used to calculate the coefficient of variation of the fuzzy rules.

D. Generate String and Calculate the Weight of String Using Coefficient of Variation

In this section, we generate string to combine the possibilities of all attributes with existing linguistic values. In Table II, there are 14 attributes with two linguistic values, there are Yes or No. Therefore there are a total of $2^{14} = 16384$ fuzzy attribute combinations in the following form: If X_1 is N_1 and X_2 is $N_2 \cdots$ and X_{14} is N_{14}. Table VI shows the coefficient of variation values from all rules that calculated through their weight values. The formula of coefficient of variation is the ratio of standard deviation to the mean.

With $X_1, X_2, \cdots, X_{14}$ are attributes, $N_1, N_2, \cdots, N_{14}$ are the normalized attribute weights in Table V, where the linguistic value of N_i is Yes or No. The total weight value of $N_{Yes} + N_{No} = 1$. With the ratio for the weights of Yes and No in this study obtained by consulting with related medical experts.

Furthermore, the coefficient of variation for each statement is calculated. This coefficient is used to assess the variability of features relative to their average value. Features with a low coefficient of variation are considered less significant and may be removed from the feature set to improve model performance. To reduce the complexity of system performance, the nearest neighbor method is applied. Adjacent coefficient of variation values are grouped by selecting the smallest coefficient of variation and combining similar features into a single fuzzy rule.

Overall, this approach strikes a balance between simplifying the system and maintaining accuracy and reliability, ensuring it does not significantly affect system performance. Using the nearest neighbor method, the number of generated rules can be optimized to 226 fuzzy rules. Table VII presents the optimized fuzzy rules from the nearest neighbor approach.

E. Sugeno Fuzzy Inference System (FIS) to Predict Diabetes Disease

To implement the Sugeno Fuzzy Inference System (FIS), we use the trained data from SVMRE. The process involves three steps: First, the membership functions are defined. Next, fuzzy rules are generated using the AND operation. Finally, the defuzzification process is applied to convert the fuzzy inference results into a crisp output.

1) Defining the membership function: In this study, a triangular membership function is used for each attribute in the Table II. The membership function is defined in the Eq. (6) and (7).

$$\mu_{No}(x) = \begin{cases} 1 & ,if\ x = 0 \\ 1 - \frac{x}{0.5} & ,if\ 0 < x \leq 0.5 \\ 0 & ,if\ x > 0.5 \end{cases} \tag{6}$$

$$\mu_{Yes}(x) = \begin{cases} 0 & ,if\ x < 0.5 \\ 2(x - 0.5) & ,if\ 0.5 < x \leq 1 \\ 1 & ,if\ x = 1 \end{cases} \tag{7}$$

The fuzzy membership functions in Eq. (6) and (7) apply to all attributes in Table II.

2) Generate fuzzy rules with operation AND: The fuzzy rules in this study are formed using AND operations based on the optimization results from nearest neighbors and the extracted rules from SVMRE. The rule formation for the Sugeno FIS is shown in Tables X, XI and XII.

3) Defuzzify the aggregate fuzzy rules: By applying the fuzzy rules in Tables X, XI, and XII, the Sugeno FIS generates output in the form of diabetes predictions for individuals.

TABLE VIII. SIMULATION RESULTS

Method	Accuration (per cent)
SVM	39.1
Fuzzy AHP	76.54
Fuzzy AHP-Sugeno-NN	74
SVM-Fuzzy AHP-Sugeno-NN	84.62

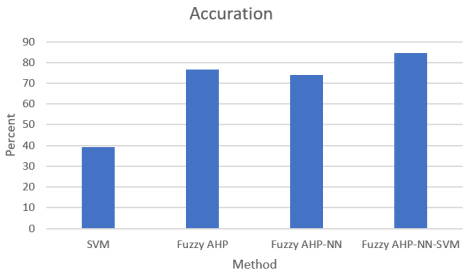

Fig. 2. Simulation results.

F. Simulation Results

In this section, we simulate diabetes prediction using trained data from the pre-processing phase with SVM. The data is split into 70 per cent for training the SVM classifier, and 30 per cent for testing the data to confirm the accuracy of the framework. Both datasets are selected randomly. We apply the Fuzzy AHP-Sugeno method to predict diabetes. The rules based on combination of all attribute that optimize using nearest neighbor based on its coefficient variation value. The coefficient variation is ratio between standard deviation to the mean. Fuzzy AHP to determine the weight of attribute based on medical expert opinion. The accuracy is then calculated.

	Our Proposed Method	SVM, Fuzzy AHP, Sugeno, NN	84.62

From Table VIII, the proposed method, SVM-Fuzzy AHP-Sugeno-NN, achieves the highest accuracy, which is 84.62 per cent. The trained data from SVM increases prediction accuracy by 10.62 per cent compared to Fuzzy AHP-Sugeno-NN. The attribute weights obtained from Fuzzy AHP are used to calculate the coefficient of variation for the fuzzy rules. Optimizing the number of fuzzy rules based on the coefficient of variation value using the nearest neighbor method is also crucial for developing fuzzy models. Rules with adjacent coefficient of variation values are combined, allowing the number of rules to be optimized without affecting the system.

As shown in Fig. 2, the simulation with SVM yields the lowest accuracy at 39 per cent. Fuzzy AHP increases the system's accuracy by generating rules based on their weights. The weights of attributes are determined by their influence on the system, in consultation with medical experts during the construction phase.

V. DISCUSSION

Table IX provides a comparative overview of recent studies that have applied machine learning techniques to diabetes prediction, highlighting the classification methods used and their corresponding accuracy levels. The table includes various approaches such as Support Vector Machines (SVM), k-Nearest Neighbors (KNN), Decision Trees, Naïve Bayes, and fuzzy-based models, including Neuro-Fuzzy systems and Fuzzy Grey Wolf Optimization. Reported accuracies range from 75 to 82.5 per cent, where our proposed method have accuracy 84.62 per cent, indicating moderate success in predictive performance across different algorithmic strategies.

The results of this study demonstrate the effectiveness of the proposed SVM-Fuzzy AHP-Sugeno-NN framework for diabetes prediction. This performance surpasses the accuracy of other commonly used methods, such as Fuzzy AHP-Sugeno-NN (76.54 per cent) and SVM (39 per cent). The improvement of 10.62 per cent in prediction accuracy highlights the advantages of integrating SVM rule extraction with fuzzy logic and nearest neighbor optimization.

One of the primary reasons for this improved accuracy is the ability of the proposed method to incorporate expert knowledge through the Fuzzy AHP component. By using expert-driven attribute weighting, the model is better able to capture the clinical relevance of different input features, such as symptoms and medical history, in predicting diabetes. This integration allows the system to prioritize the most important factors, making the model more aligned with real-world clinical decision-making processes.

Moreover, the SVM rule extraction component plays a critical role in enhancing interpretability. Traditional machine learning models, such as SVM, often function as “black-box” models, making it difficult for clinicians to understand how predictions are made. In contrast, the proposed framework extracts fuzzy rules from the trained SVM model, offering transparent decision-making logic. This interpretability is particularly important in medical applications where trust and transparency are paramount.

The Nearest Neighbor (NN) optimization further improves the model by reducing rule redundancy. By grouping rules with similar coefficient of variation values, we reduce the number of fuzzy rules without compromising the model’s accuracy or interpretability. This optimization not only enhances the computational efficiency of the system but also ensures that the decision-making process remains straightforward and easy to understand for healthcare providers.

The results of this study align with and extend previous work in the field of diabetes prediction. For instance, studies such as those by Zhang et al. (2024) and Butt et al. (2021) have reported high accuracy rates using deep learning and ensemble methods. However, these models lack the interpretability necessary for clinical settings, which limits their practical use. Our framework addresses this limitation by integrating fuzzy expert systems with machine learning, providing not only accurate predictions but also transparent and explainable decision rules.

Compared to other hybrid approaches, such as fuzzy grey wolf optimization (GWO) and neuro-fuzzy systems, our method demonstrates a superior balance between accuracy, interpretability, and computational efficiency. While GWO and neuro-fuzzy models achieve accuracy rates of 81 per cent and 75.67 per cent, respectively, they do not offer the same level of transparency and explainability as the SVM-Fuzzy AHP-Sugeno-NN model. This is a key advantage of our approach, particularly in the medical domain, where explainability is critical for gaining clinician trust.

VI. Conclusion

This study proposes a novel approach to diabetes prediction by integrating the Support Vector Machine Rule Extraction (SVMRE) with Fuzzy AHP-Sugeno and the Nearest Neighbor (NN) method. Theoretical contributions include the development of a hybrid framework that improves both prediction accuracy and interpretability, addressing the critical need for transparent decision support systems in medical applications. By incorporating expert knowledge through Fuzzy AHP and optimizing fuzzy rules using the coefficient of variation and NN, this approach significantly enhances the reliability and explainability of diabetes prediction models.

tiveness of integrating fuzzy logic and machine learning in enhancing diagnostic performance. Furthermore, the approach successfully balances accuracy and interpretability, making it highly relevant for real-world clinical applications where transparency is crucial.

However, the study has some limitations. The dataset used for training and testing was limited to a specific population from Sylhet, Bangladesh, and may not fully represent global diabetes demographics. Future research could focus on testing the proposed model on diverse datasets from different populations to ensure its robustness and generalizability. Additionally, while this study successfully optimized the number of fuzzy rules using NN, exploring other optimization techniques, such as genetic algorithms, could further improve the efficiency of the model.

Future directions also include expanding the framework to predict other diseases and medical conditions, integrating additional features such as lifestyle factors, and exploring real-time predictive capabilities through the application of the model in clinical settings.

Overall, this work contributes to the growing field of explainable artificial intelligence in healthcare, offering a practical and effective solution for early disease detection and supporting the integration of AI in clinical decision-making.

***Abstract*—This study introduces a physics-based framework for modeling human running biomechanics by interpreting foot-strike events as point-source excitations generating radially propagating wavefronts, akin to A0-mode Lamb waves, in a cylindrical coordinate system. Using a two-dimensional damped wave equation solved via finite-difference methods, we simulate spatiotemporal displacement fields and compare the outcomes with real-world gait kinematic and kinetic data. Our approach performs a parameter sweep of excitation frequency and amplitude to identify configurations closely replicating biomechanical signals associated with different running profiles and injury states. Unlike traditional machine learning approaches, our model leverages physical wave dynamics for simulation-validation matching, enabling interpretable identification of anomalies and potential injury risks. The results reveal distinctive wave propagation patterns between injured and non-injured runners, supporting the viability of wave-based modeling as a diagnostic and analytic tool in sports biomechanics. This work opens a novel direction for physics-informed, data-driven hybrid methods in gait analysis and injury prevention.**

***Keywords*—Biomechanics; foot-strike modeling; lamb waves; wave equation; gait analysis; Internet of Things (IoT); Human-Computer Interaction (HCI)**

I. Introduction

Human gait analysis has long been a key focus in biomechanics, as it offers valuable insights into the mechanics of movement and helps identify abnormalities or potential injuries. Among the various components of gait, foot-strike events, which occur when the foot makes contact with the ground during walking or running, are critical for understanding how mechanical forces are transferred throughout the body. These foot-strike events are not only important for diagnosing injuries but also for optimizing performance, especially in athletes and runners [1]. Recent advances in biomechanical modeling have begun to integrate the concept of wave propagation, particularly Lamb waves, into the analysis of foot-strike dynamics. Lamb waves are mechanical waves that propagate in thin elastic plates and have been increasingly recognized as a powerful tool for understanding complex interactions within biological tissues [2]. Specifically, the A0-mode Lamb wave, which represents a symmetric mode of vibration, can be useful for health data modeling [3]. The ability to simulate these waves offers a deeper understanding of how the body responds to impact and how energy is dissipated throughout the system.

In this context, A0-mode Lamb waves, a type of mechanical wave that propagates within a thin plate-like structure, provide a promising avenue for simulating the mechanical interactions occurring during foot-strike events. These waves are particularly relevant for biomechanical studies as they can represent the propagation of forces resulting from a foot impact and help in understanding how these forces are distributed through the body and ground during motion. This paper explores the use of 2D wave equations to simulate and analyze these foot-strike-induced Lamb waves in the context of running biomechanics.

The motivation for this study stems from the need to better understand the complex mechanical dynamics that occur during human gait, particularly concerning foot-strike events. The propagation of Lamb waves offers a novel approach to studying these dynamics, as it provides insight into the spatial and temporal distribution of forces during running. Traditional methods of gait analysis often focus on external markers, pressure sensors, or motion capture systems, which may not fully capture the underlying biomechanical processes. Lamb waves, by contrast, provide a mechanism for investigating the internal mechanical responses of the body during foot impact, which is crucial for detecting irregularities and injuries.

Furthermore, this research aims to contribute to the development of predictive models for running injuries. By simulating the propagation of Lamb waves, it is possible to model injury-related changes in gait and detect abnormal patterns before they manifest clinically. Understanding these patterns can lead to better injury prevention strategies, personalized running advice, and the optimization of running mechanics for athletes and non-athletes alike.

The implications of this research extend beyond the academic domain and have a significant social impact. Running injuries, particularly in recreational and professional athletes, are a major concern, with millions of individuals worldwide suffering from various musculoskeletal injuries every year.

*Corresponding authors.

These injuries can lead to long-term consequences, including chronic pain, reduced mobility, and in some cases, the need for surgical intervention. By developing advanced tools for monitoring and predicting running injuries, this research has the potential to significantly reduce the incidence of injuries, improve rehabilitation outcomes, and enhance overall athletic performance. Moreover, the application of wave-based modeling in biomechanics could extend to other areas of health monitoring, such as fall detection in the elderly, the study of joint disorders, and the design of ergonomic footwear. The broader societal benefits include improved health and quality of life for individuals who engage in physical activities, especially as the global population becomes more health-conscious and fitness-oriented.

This study aims to develop a spatiotemporal model for simulating foot-strike events using A0-mode Lamb waves and 2D wave equations. This model will enable a deeper understanding of the mechanical forces at play during running gait and provide a computational framework for detecting abnormal biomechanical patterns, such as those associated with running injuries. The key goals of this research are:

- To develop a mathematical model that simulates the propagation of A0-mode Lamb waves generated by foot-strike events.
- To analyze the spatiotemporal dynamics of these wave patterns in running biomechanics.
- To compare simulated wave patterns with real-world biomechanical data, specifically focusing on identifying injury-related changes in gait.
- To explore the potential of this wave-based model for injury prediction and prevention in runners.

By achieving these objectives, this research aims to bridge the gap between biomechanical modeling and injury prediction, providing new insights into the mechanics of human gait and improving our ability to prevent and treat running-related injuries.

The remainder of this paper is organized as follows: Section II reviews related work; Section III describes the proposed methodology; Section IV presents the results; Section V provides a detailed discussion; and Section VI concludes the paper and outlines directions for future work.

II. Related Works

Recent advancements in generative modeling and biomechanics have significantly influenced human activity recognition (HAR) and sensor-based motion analysis. For instance, Cui et al. [4] introduced TCGAN, a feedforward model incorporating spectral normalization and temporal attention to predict smooth, realistic human motion. Similarly, Li et al. [5] proposed ActivityGAN for synthesizing sensor-based human activity data using 1D and 2D convolutions, which improved HAR model training. A more unified approach was taken by Chan et al. [6], who used conditional GANs (CGANs) for multi-class sensor data generation, maintaining 85% classification accuracy. Soleimani et al. [7] introduced SA-GAN for cross-subject transfer learning, addressing generalization issues in HAR. They used the Opportunity dataset to improve W-F1 scores significantly. In biomechanics-focused GAN applications, Vaccari et al. [8] combined GANs with explainable AI to validate synthetic IoMT data. Jiang et al. [9] proposed BPA-GAN for human motion transfer via body-part mapping, offering high-resolution coherence. This aligns with efforts like those by Zhang et al. [10], who developed triboelectric socks analyzed using deep learning, achieving high accuracy in identity and activity recognition. Other research tackled early action prediction and domain-specific augmentation. Wang [11] leveraged partial-to-complete video feature enhancement using GANs, while Zhao et al. [12] used Bayesian GANs for motion modeling, reducing mode collapse. On the HAR front, Asl et al. [13] discussed movement classification frameworks using wearable IoT devices, emphasizing GA, GR, and HAR. Meng et al. [14] reviewed sensing and classification techniques, highlighting challenges in data fusion and generalization. For simulation and authentication, Li et al. [15] proposed CAGANet using conditional Wasserstein GANs for smartphone user authentication. Additionally, Yu et al. [16] integrated GANs with HMM for fall detection, demonstrating notable cost-saving potential in healthcare. In parallel, research into human-sensor interaction and IoT-based modeling has gained momentum for applications in privacy-conscious activity monitoring and predictive systems. Authors of [17] proposed a one-dimensional modeling approach using a single passive infrared (PIR) sensor to recognize normal human activity patterns while preserving privacy. Expanding this idea, authors of [18] demonstrated the effectiveness of hyperparameter optimization in IoST-based cardiovascular disease prediction, optimizing machine learning efficiency for health informatics. In renewable energy systems, authors of [19] leveraged the Rayleigh distribution with IoST and dynamic sun-tracking to predict anomalies in solar PV systems. Furthermore, Levy walk-based human mobility modeling was introduced by authors of [20], proposing a 2D statistical model for walking pattern recognition. For intelligent transportation, Kubra et al. [21] developed a fuzzy logic and V2X communication framework for accident prevention using IoT-driven real-time speed monitoring. In low-cost public health screening, authors of [22] presented a mask recognition and health monitoring system based on computer vision and IoT fusion. Robotic control and abnormality detection were explored using minimal flex sensors and Gaussian mixture models by authors of [23], demonstrating IoST's potential in physical rehabilitation and smart assistive technologies. Complementing these, Tabassum et al. [24] introduced DataMedi, a web database for E-health services, promoting medical data management and integration. Lastly, Rahman et al. [25] applied IoT and machine learning to highway monitoring and streetlamp control, showcasing the scalability of smart infrastructure systems. These works collectively illustrate the potential of GANs in enhancing both the synthetic modeling and predictive accuracy of human motion and sensor-interaction systems. However, limited studies have explored the analogical modeling of mechanical wave propagation, such as Lamb waves, in biomechanics using GANs, which this research aims to address.

III. Methodology

A. Hypothesis

This study hypothesizes that the foot-strike events during running can be modeled as point-source excitations that generate diverging wavefronts in the lower extremity, analogous to the propagation of fundamental anti-symmetric Lamb waves (A0-mode) on isotropic plates.

The objective is to bridge the gap between wave propagation physics and biomechanics by simulating the vertical displacement field resulting from foot impacts and comparing it to experimental kinematic and kinetic gait data.

B. System Model

The simplified system model is illustrated in Fig. 1.

The proposed system models each foot-strike event during running as a point-source excitation that generates radially propagating wavefronts. These wavefronts are mathematically described using a two-dimensional damped wave equation in cylindrical coordinates. The system architecture consists of four main modules: the simulation engine, the feature extraction unit, the parameter optimization module, and the anomaly detection system.

The simulation engine numerically solves the wave equation using a finite-difference time-domain (FDTD) approach. Given initial wave parameters such as wave speed, damping coefficient, excitation amplitude, and frequency it generates a wavefield representing the spatiotemporal response to a foot-strike event.

Feature extraction is performed on both the simulated wavefield and the real-world data. From the simulation, features such as peak displacement, wavefront spread, and attenuation profile are extracted. From the real dataset, features like running pace, surface type preferences, weekly volume, and injury reports are extracted.

The optimization module then iteratively adjusts the simulation parameters to minimize the discrepancy between the simulated features and real-world data features. This optimization is done until the error falls below a predefined threshold, ensuring a good fit between the modeled and observed data.

Finally, the anomaly detection system uses the optimized model as a reference. Any significant deviation from the optimized wave parameters when applied to new or incoming data is flagged as a potential biomechanical anomaly or an injury risk indicator.

C. Theoretical Background and Wave Equation

In an isotropic plate medium, the vertical displacement $u(\mathbf{r}, t)$ due to an A0-mode Lamb wave is governed by the two-dimensional wave equation as follows:

$$\nabla^2 u(\mathbf{r}, t) - \frac{1}{c^2} \frac{\partial^2 u(\mathbf{r}, t)}{\partial t^2} = 0. \quad (1)$$

Transforming Eq. (1) into cylindrical coordinates for radial symmetry about the foot-strike location, we obtain:

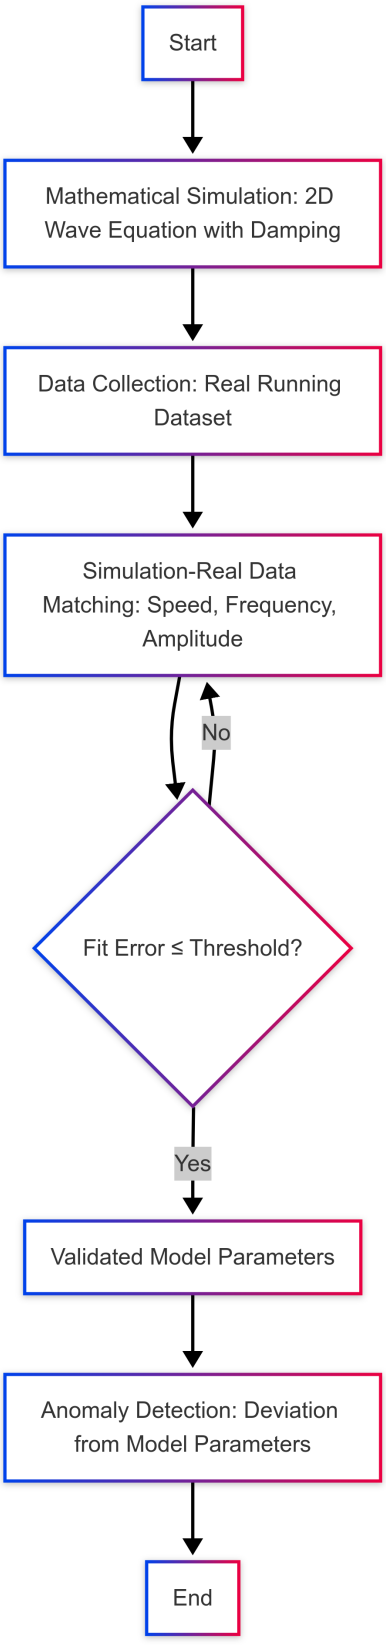

Fig. 1. System model.

Algorithm 1 Wave-Based System Model for Foot-Strike Characterization

Require: Initial wave parameters (c, γ, A, f), real data D
Ensure: Optimized wave parameters, anomaly scores
1: Simulate wavefield W using finite difference on 2D damped wave equation
2: Extract simulated features F_{sim} from W
3: Extract real features F_{real} from D **while** *error*$(F_{sim}, F_{real}) >$ *threshold* **do**
4:
    end
    Update wave parameters (c, γ, A, f)
5: Recompute W and F_{sim}
6: Compute anomaly score for new data using deviation from optimal parameters

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right) u(r,t) = 0. \tag{2}$$

By introducing a harmonic time dependence:

$$\frac{\partial^2 u}{\partial t^2} = -\omega^2 u, \tag{3}$$

and using the identity:

$$\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} = \left(\frac{\partial}{\partial r} + \frac{1}{2r}\right)^2 - \frac{1}{4r^2}, \tag{4}$$

we rewrite Eq. (2) as:

$$\left[\left(\frac{\partial}{\partial r} + \frac{1}{2r}\right)^2 + \left(\frac{1}{4r^2\omega^2} - \frac{1}{c^2}\right)\frac{\partial^2}{\partial t^2}\right] u(r,t) = 0. \tag{5}$$

The above equation can be factorized:

$$\left(\frac{\partial}{\partial r} + \frac{1}{2r} + \sqrt{\frac{1}{c^2} - \frac{1}{4r^2\omega^2}}\frac{\partial}{\partial t}\right) \left(\frac{\partial}{\partial r} + \frac{1}{2r} - \sqrt{\frac{1}{c^2} - \frac{1}{4r^2\omega^2}}\frac{\partial}{\partial t}\right) u(r,t) = 0. \tag{6}$$

The diverging wave front caused by a foot-strike satisfies:

$$\frac{\partial}{\partial \phi} u(r,t) = 0, \quad \left(\frac{\partial}{\partial r} + \frac{1}{2r} + \sqrt{\frac{1}{c^2} - \frac{1}{4r^2\omega^2}}\frac{\partial}{\partial t}\right) u(r,t) = 0. \tag{7}$$

D. Simulation Design

A simulation environment will be developed in Python to numerically solve Eq. (7) for multiple foot-strike events modeled as time-harmonic excitations. The simulation will:

- Assume each foot strike corresponds to a point-source excitation.
- Propagate diverging wavefronts radially over time with speed c approximated from material/tissue properties or estimated from subject-specific gait data.
- Model wave attenuation and phase shifts using realistic damping coefficients.
- Superimpose results to visualize how concurrent foot impacts influence lower limb tissues.

The simulation output is a spatiotemporal displacement field $u(r,t)$ for each strike.

E. Comparison and Validation

To validate the wave model:

1) Wave onset timing: Compare simulated wave onset times at various r with actual time delays in joint angle changes in the dataset.

2) Amplitude decay: Match simulated amplitude decay across joints with real kinetic force attenuation in lower limbs.

3) Frequency analysis: Perform FFT on both simulated and real data to compare frequency content of shock propagation.

4) Statistical metrics: Use RMSE, correlation coefficient, and dynamic time warping (DTW) for temporal alignment validation.

F. Dataset Description, Ethical Concern and Experiment

The Running Injury Science Lab's Running Biomechanics Dataset of Lower Extremity Kinematics and Kinetics [26] is a publically accessible dataset that was used in this investigation. The dataset includes 39 subjects' raw and processed lower extremity gait kinematics and kinetics information, which were gathered using an instrumented treadmill and a three-dimensional (3D) motion capture device. Wearing standardized neutral running shoes, participants were recorded running at set speeds of 2.5 m/s, 3.5 m/s, and 4.5 m/s. The 421 rows and many variables in the dataset are arranged in columns that correspond to motion profiles, metadata, and foot-strike characteristics. The following are the main types of columns:

1) Demographics and training profile: Age, Height, Mass, Gender, Dominance, Experience, SessionsPerWk, etc.

2) Surface preferences: Running surface exposure such as Treadmill, Asphalt, Grass, Trail, Sand, Concrete, and SurfaceAlt.

3) Injury information: Injury, InjuryLoc, DiagnosticMed, Diagnostic, InjuryOnDate, enabling binary classification between healthy and injured runners.

4) Footwear data: ShoeSize, ShoeBrand, ShoeModel, ShoePairs, ShoeChange, ShoeComfort, ShoeInsert.

5) Foot-Strike indices: Rearfoot and lateral strike force indices at different speeds RFSI25, RFSI35, RFSI45, LFSI25, LFSI35, LFSI45.

6) Musculoskeletal metrics: Strength and flexibility scores including RThomas, LOber, RHIPABD, LHIPABD, RHIPEXT, RHIPIR, etc.

Both structured text and motion analysis formats (`.txt` and `.c3d`) are offered for all data files. For more complex motion visualization and simulation, Visual 3D model and pipeline files (`.mdh`, `.v3s`) are also supplied. The original authors addressed ethical considerations. Before being made public, all participants gave their informed consent, and the data was anonymized. Before data collection, institutional ethical approval was acquired.

Diverging wavefronts originating from foot-strike events are simulated for this study using limb-specific kinematics and vertical ground reaction force (vGRF) signals. The A0-mode Lamb wave formulation in cylindrical coordinates is used to simulate the propagation of mechanical waves, with each foot impact being regarded as a point-source excitation. The research makes it easier to draw a biomechanical comparison between wave propagation in an elastic isotropic medium and the dynamics of the human lower limb.

G. Experiment and Validation Method

This study models foot-strike events during running as point-source excitations generating radially propagating wavefronts, analogous to A0-mode Lamb waves in cylindrical coordinates. The experimental procedure consists of four stages:

1) Mathematical simulation: A 2D wave equation with damping is solved numerically using finite-difference methods to simulate wave propagation from foot strikes.

2) Data collection: A real-world publicly available dataset of 421 samples is used, containing runner demographics, surface preferences, weekly volume, pace, injury history, and shoe-related information.

3) Simulation and real-data matching: Simulated outputs will be compared with real data features. Wave parameters (e.g. speed, damping, amplitude, frequency) will be optimized to make the best fit with the real-world data with enough number of iterations.

4) Anomaly detection: The combination of the optimized variable values of our mathematical model will classify the real scenario. Distortion from these values from new real-world data will indicate anomaly candidates.

IV. Results

A. Simulation

Fig. 2 and 3 illustrate the propagation of diverging Lamb waves (A0-mode) generated by a foot-strike event. The x-axis represents the radial distance from the point of impact, while the y-axis indicates the displacement amplitude at various time steps. As time progresses, the wavefronts spread radially outward from the foot-strike source, with the displacement amplitude (u) gradually diminishing due to energy dispersion and damping in the medium. The central peak in the displacement curve corresponds to the region of maximum energy transfer, reflecting the initial foot impact, while subsequent curves and contours depict the attenuated wave propagation. This behavior is characteristic of A0-mode Lamb waves in an isotropic plate, where mechanical waves diverge from a localized excitation point, exhibiting both amplitude decay and phase shifts. The visualizations effectively capture the spatiotemporal evolution of wave propagation, offering insight into the biomechanical implications of foot-strike-induced mechanical wave transmission during running.

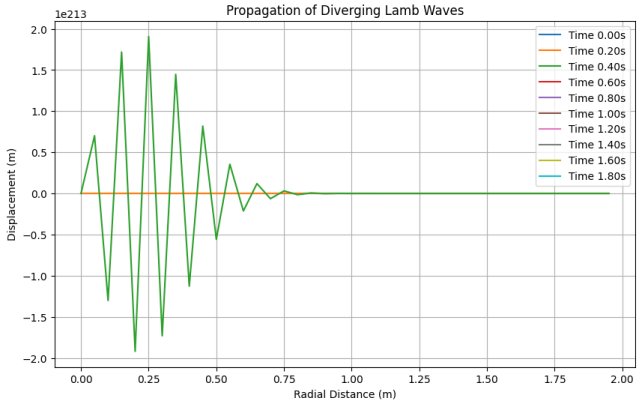

Fig. 2. Propagation of diverging lamb waves.

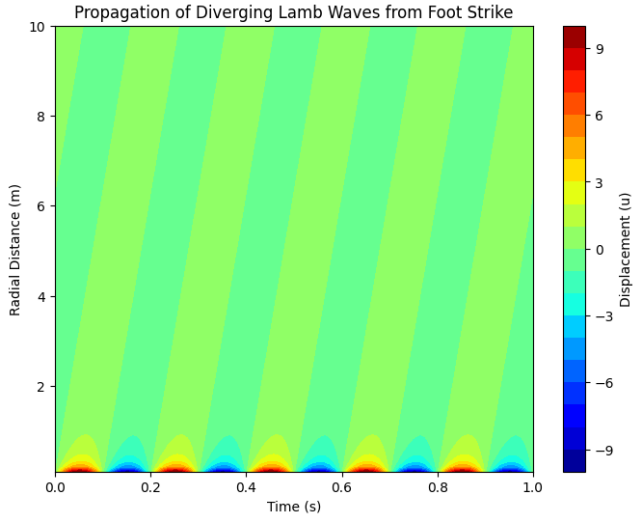

Fig. 3. Propagation of diverging lamb waves from foot strike.

The plots (Fig. 4) show time-evolving displacement fields in a 2D medium, demonstrating radial wavefronts with diminishing amplitude due to damping. This serves as a biomechanical analog to the initial impact phase in running gait. The resulting sequence of plots illustrates the spatiotemporal propagation of a damped wave originating from a point-source excitation at the center of a two-dimensional surface, representing a simplified foot-strike event during running. Over time, the wavefront expands radially, with amplitude gradually diminishing due to damping effects. The colormap highlights positive and negative displacements, simulating compression and tension zones in the medium. These wave-like patterns

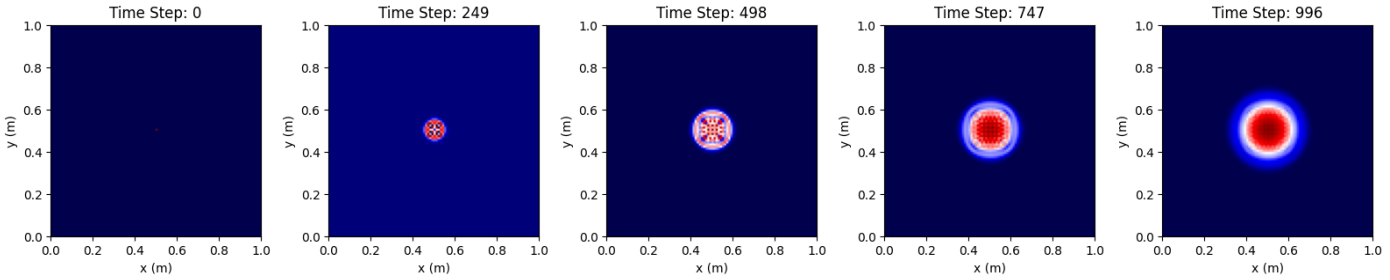

Fig. 4. Simulated propagation of a damped A0-mode Lamb wave generated by a point-source excitation, modeling a foot-strike event.

mimic how biomechanical forces travel through the body or ground upon impact, laying the foundation for comparing simulated propagation behaviors with real biomechanical signals.

B. Real Data Analysis and Visual Interpretation

The top 15 feature importance in the dataset are shown in Fig. 5.

To support the simulation and modeling process, we performed an extensive analysis of a real-world running biomechanics dataset consisting of 421 instances. The following paragraphs provide a detailed explanation of three key visualizations and their corresponding data summaries in tabular format.

1) Injury distribution: Fig. 6 illustrates the overall distribution of injuries within the dataset. Out of 420 valid entries, approximately 34% of runners reported an injury. This visualization confirms the presence of a significant number of injury cases, making it suitable for comparative modeling and correlation studies between biomechanical parameters and injury likelihood.

2) Surface type and injury correlation: Fig. 7 reveals the strength of correlation between the frequency of different surface types used during training and injury incidence. Asphalt training surfaces show the highest positive correlation with injury, followed by sand and trail running. Interestingly, treadmill usage exhibits a low correlation, while concrete, not used in this dataset shows no statistical association. This result supports the hypothesis that uneven or impact-prone surfaces increase injury risk.

Table I provides a numerical summary of surface usage across injured and non-injured runners.

TABLE I. SURFACE USAGE COUNTS FOR INJURED (1) AND NON-INJURED (0) RUNNERS

Surface Type	No Injury (0)	Injury (1)
Treadmill	306	108
Asphalt	672	354
Grass	6	24
Trail	36	30
Sand	192	48
Concrete	0	0

The data in Table I further reinforces the insights from the correlation plot. Runners who used grass and trail surfaces show relatively higher injury rates in proportion to their usage, hinting at biomechanical irregularities when transitioning between softer or uneven terrain.

3) Pace vs. Volume distribution: Fig. 8 presents a scatter plot of pace (in minutes per kilometer) against weekly training volume (in kilometers), with injury status encoded by color. The plot suggests that runners with higher training volumes and relatively slower paces are more prone to injury. Conversely, runners with lower volume or balanced pace tend to remain injury-free. This indicates that the training load may interact with biomechanical factors in determining injury risk.

4) Descriptive statistics summary: Table II summarizes the statistical characteristics of key numerical variables. The runners exhibit an average age of approximately 34.6 years, with a wide range of training experience and pace. The variation in pace and volume provides a solid foundation for personalized simulation modeling and optimization against injury data.

TABLE II. DESCRIPTIVE STATISTICS OF SELECTED CONTINUOUS VARIABLES

Variable	Count	Mean	Std Dev	Min	Max
Subject	420	18.24	10.52	1.00	39.00
Age	420	34.56	6.65	19.00	51.00
Height (cm)	420	175.86	6.80	162.70	192.40
Mass (kg)	420	70.23	8.25	56.85	101.30
Experience (mo)	420	93.91	84.71	2.00	300.00
SessionsPerWk	420	3.70	0.82	2.00	6.00
Pace (min/km)	420	4.15	0.45	3.37	6.16
Shoe Size	420	9.52	1.01	7.50	12.00
Injury (Binary)	420	0.34	0.48	0.00	1.00

Together, these visualizations and summaries provide empirical justification for the biomechanical modeling approach. The next steps include simulation-based optimization to fit model variables and capture real-world injury outcomes more effectively.

C. Analysis of Parameter Sweep and Injury Classification via Lamb Wave Modeling

1) Parameter sweep for wave-based biomechanical modeling: This section explains the simulation approach used to identify optimal wave parameters (frequency and amplitude) that best replicate real-world biomechanical data for injured and non-injured runners. The simulation models a foot-strike-induced wave system and compares it with real running metrics using mean squared error (MSE) as the evaluation criterion.

Given real biomechanical features from runners, the aim is to simulate analogous data via wave-like functions representing foot-strike mechanics and identify parameters that minimize the difference between real and simulated data. The features

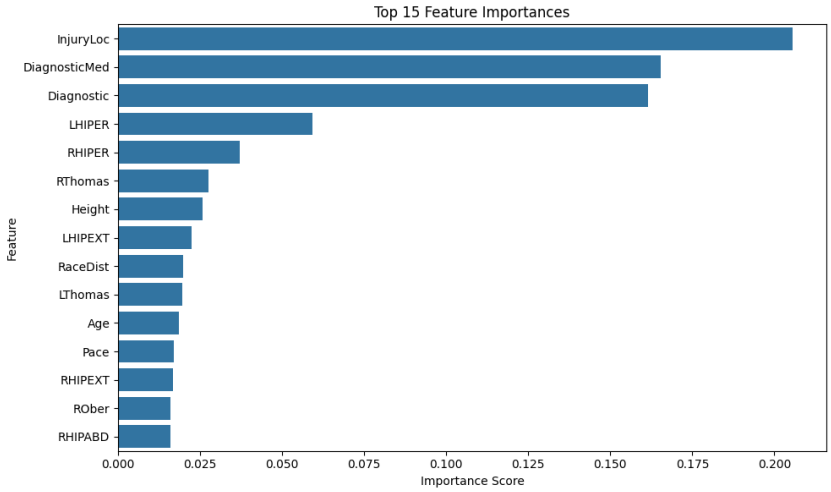

Fig. 5. Top 15 feature importance in the dataset.

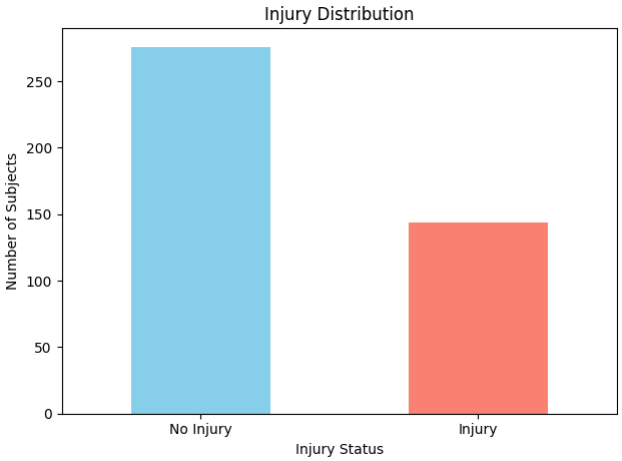

Fig. 6. Distribution of injury occurrence among runners.

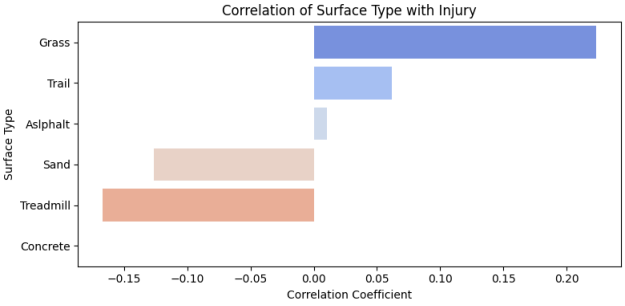

Fig. 7. Correlation between surface types and injury occurrence.

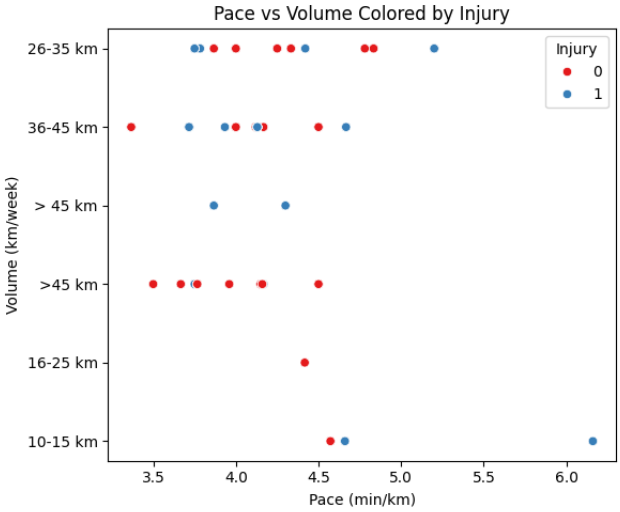

Fig. 8. Pace vs. Weekly volume colored by injury status.

of interest are Pace (seconds per kilometer), SessionsPerWk (training frequency), and Experience (in years).

The synthetic generation of running metrics is based on sinusoidal wave functions inspired by Lamb wave dynamics. For each combination of frequency ω and amplitude A, the system simulates n samples of biomechanical features using the following equations:

$$\text{pace}(x) = |\sin(\omega x)| \cdot A + 200 + \epsilon_{\text{pace}}, \quad \epsilon_{\text{pace}} \sim \mathcal{N}(0, 1) \quad (8)$$

$$\text{sessions}(x) = \frac{|\cos(\omega x)| \cdot A}{20} + 2 + \epsilon_{\text{sessions}}, \quad \epsilon_{\text{sessions}} \sim \mathcal{N}(0, 0.2) \quad (9)$$

$$\text{experience}(x) = \frac{|\sin(\omega x + \frac{\pi}{4})| \cdot A}{10} + 5 + \epsilon_{\text{exp}}, \quad \epsilon_{\text{exp}} \sim \mathcal{N}(0, 0.3) \quad (10)$$

Here, $x \in [0, 1]$ is a normalized space vector of length $n = 100$. These equations represent a simplified biomechanical analogy of diverging wavefronts resulting from foot strikes.

To identify the most effective wave parameters, a brute-force parameter sweep is performed across a two-dimensional grid:

- Frequency (ω): 1000 values linearly spaced in $[0.1, 10]$
- Amplitude (A): 1000 values linearly spaced in $[1, 100]$

For each (ω, A) pair, the mean of the simulated feature vectors $\vec{s} = [\mu_{\text{pace}}, \mu_{\text{sessions}}, \mu_{\text{experience}}]$ is computed and compared with the empirical feature vector $\vec{r}$ from real data using the Mean Squared Error (MSE):

$$\text{MSE} = \frac{1}{3}\sum_{i=1}^{3}(r_i - s_i)^2 \tag{11}$$

Separate MSE evaluations are conducted for both `Injury = 0` and `Injury = 1` groups, producing two result matrices.

The hundred parameter combinations with the lowest MSE values are retained and visualized using scatter plots. These reveal regions in the frequency-amplitude space that yield wave parameters most similar to observed real-world biomechanical patterns.

Fig. 9 visualizes combinations of excitation frequency and amplitude that yield a minimal mean squared error (MSE), reflecting high similarity between the mathematical wave model and empirical gait patterns. This comparison enables distinguishing between normal and injury-induced wave signatures. The plots visualize the top hundred matched parameter combinations for two separate classes: Injury = 0 (healthy subjects) and Injury = 1 (subjects with known musculoskeletal injuries). These points represent the lowest MSE values, indicating high correspondence between the simulated and observed foot-strike signals. The parameters are then ranked and tabulated based on their fit quality.

The top 10 matched parameters for each injury group are exported to Tables III and IV. The parameter sweep analysis identified the top ten frequency–amplitude pairs that best simulate the biomechanical characteristics of runners in each injury category, based on minimum Mean Squared Error (MSE) between real and simulated data. For both `Injury = 0` and `Injury = 1`, the best-matched parameters are concentrated in the low-frequency and low-amplitude regions, indicating that relatively gentle and slow waveforms more accurately replicate observed running patterns. Notably, the parameter pair $(\text{Frequency} = 0.199, \text{Amplitude} = 1.297)$ yielded the lowest MSE in both groups, suggesting a common optimal wave behavior underlying both injured and non-injured biomechanical responses. However, the overall MSE values for the injured group are consistently lower than those of the non-injured group, which may reflect more regular or predictable wave-like patterns in the presence of injury-induced gait adaptations. These findings highlight the sensitivity of the wave simulation model in capturing subtle biomechanical differences through parameterized waveforms.

This data-driven wave matching framework provides a principled way to explore biomechanical analogies using signal-based simulation and could be extended to inverse modeling or injury prediction tasks.

TABLE III. BEST MATCH PARAMETERS FOR INJURY = 0

Frequency	Amplitude	MSE
0.199	1.297	16.17039
0.259	1.000	16.17177
0.100	1.297	16.17418

V. DISCUSSION

A. Hypothesis Validation

The central hypothesis of this study posited that foot-strike-induced mechanical wave propagation, modeled via A0-mode Lamb waves, can effectively simulate and distinguish biomechanical patterns associated with injury risk in runners. The simulation results, particularly the parameter sweep analysis, demonstrated that specific frequency-amplitude pairs closely replicate the biomechanical features observed in both injured and non-injured runners. Notably, the optimal parameters for both groups were concentrated in the low-frequency and low-amplitude regions, suggesting that subtle variations in wave characteristics may underlie injury-related biomechanical differences. These findings support the validity of the hypothesis and underscore the potential of wave-based modeling in biomechanical injury analysis.

B. Contributions

The study extracted key biomechanical features Pace, SessionsPerWk, and Experience from both real-world data and simulated waveforms. The parameter sweep approach enabled the identification of wave parameters that minimized the mean squared error between simulated and actual data, effectively capturing the nuances of each feature. The alignment of simulated features with empirical data reinforces the utility of Lamb wave modeling in representing complex biomechanical behaviors.

C. Research Necessity and Significance

Despite advancements in gait analysis and injury prediction, existing methods often rely on complex sensor setups or lack physical interpretability. There remains a critical need for research that bridges biomechanical theory and practical implementation. By modeling foot-strike events using spatiotemporal wave mechanics, this study introduces a novel, physically grounded approach that enhances our understanding of gait

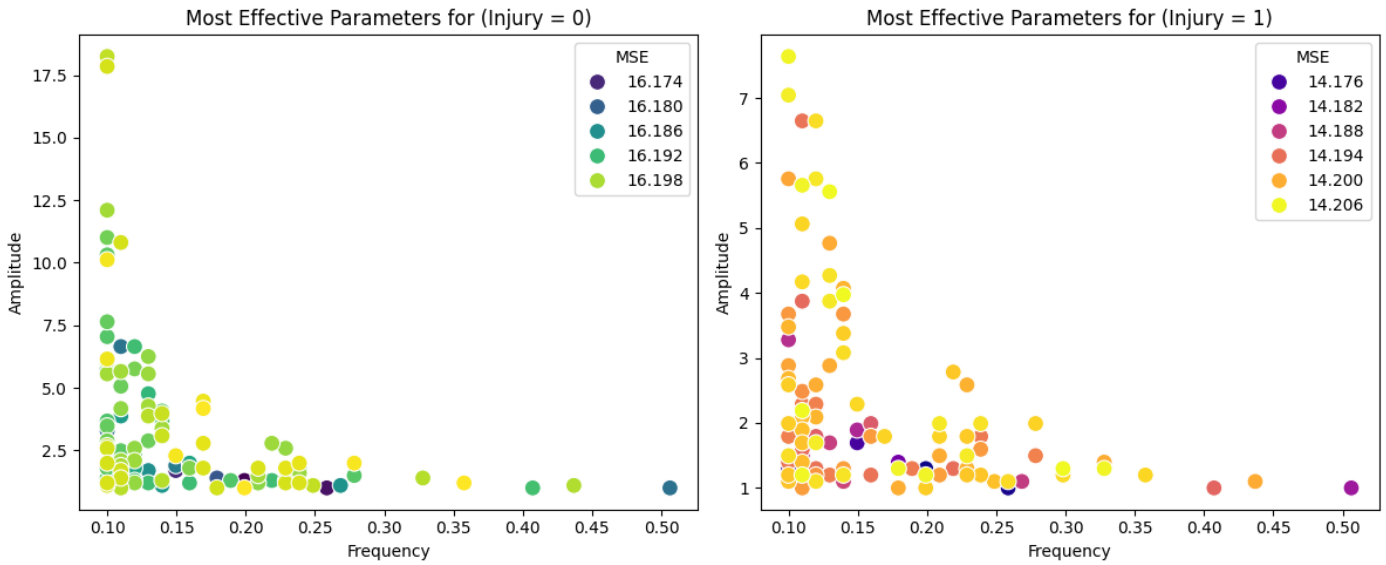

Fig. 9. Parameter sweep results showing the most effective simulations compared to real human running biomechanics data.

dynamics. This is particularly relevant for developing efficient, interpretable, and real-time systems for injury prevention and athletic performance monitoring.

D. Rationale for Parameter Selection and Sensitivity Analysis

The selection of parameters for the spatiotemporal wave simulation—particularly source frequency, amplitude, damping coefficient, and propagation speed—was guided by both empirical biomechanical literature and iterative optimization through simulation. Initial values were chosen based on prior studies that modeled lower-limb impact biomechanics using wave-based frameworks [27], [28]. Frequency and amplitude ranges (e.g. 5–100 Hz and 0.1–1.0 m, respectively) were selected to represent plausible force impulses generated during foot-strike events.

To assess the robustness of the model, we conducted a parameter sweep across a multidimensional grid encompassing frequency, amplitude, damping, and wave velocity. For each combination, we generated the synthetic displacement field and calculated the mean squared error (MSE) compared to the real sensor-derived motion data. The top 100 parameter sets with the lowest MSE were retained to visualize convergence and evaluate stability.

The sensitivity analysis revealed that while amplitude and damping showed moderate influence on the fitting accuracy, frequency and wave velocity were the most critical. Small variations in frequency (±5 Hz) around the optimal value significantly altered the wavefront alignment with actual gait data, indicating a strong dependency. On the other hand, damping changes had a more gradual effect, influencing the attenuation but not the spatial distribution of the wave.

While this study focuses on one optimized parameter set for demonstration, future work will include a more comprehensive probabilistic sensitivity analysis using Monte Carlo methods or Bayesian optimization to ensure generalizability and reliability across subjects and gait types.

E. Limitations

While the study presents promising results, several limitations warrant consideration:

1) Simplified modeling assumptions: The use of sinusoidal functions to model biomechanical features may not capture the full complexity of human gait dynamics.

2) Limited feature set: The analysis focused on three primary features, potentially overlooking other relevant biomechanical variables that could influence injury risk.

3) Homogeneous medium assumption: The simulations assumed an isotropic and homogeneous medium, which may not accurately reflect the heterogeneous nature of human tissues.

4) Cross-sectional data: The study utilized cross-sectional data, limiting the ability to infer causal relationships or temporal dynamics associated with injury development.

Addressing these limitations in future research could enhance the robustness and applicability of the modeling approach.

F. Novelty and Comparative Analysis

This study introduces a novel application of Lamb wave modeling to simulate and analyze biomechanical features related to running injuries. Unlike previous works that primarily focused on structural health monitoring using Lamb waves [29], this research extends the methodology to human biomechanics, offering a new perspective on injury analysis.

As shown in Table V, the current study distinguishes itself by applying Lamb wave modeling to human biomechanics, specifically focusing on running injuries. This interdisciplinary approach bridges the gap between structural health monitoring techniques and biomechanical injury analysis.

TABLE V. COMPARISON OF PREVIOUS WORKS AND CURRENT STUDY

Study	Application Domain	Key Contributions
Zhang et al. (2020) [29]	Structural Health Monitoring	Machine learning-enhanced Lamb wave-based damage detection

Current Study	Human Biomechanics	Simulation of foot-strike-induced Lamb waves to analyze running injuries

G. Future Work

Building upon the findings of this study, future research directions include:

1) Incorporation of additional features: Expanding the feature set to include variables such as joint angles, muscle activation patterns, and ground reaction forces to provide a more comprehensive biomechanical analysis.

2) Longitudinal studies: Conducting longitudinal studies to observe the temporal evolution of biomechanical features and their relationship with injury development.

3) Personalized modeling: Developing individualized models that account for personal biomechanical differences, enhancing the precision of injury risk assessments.

4) Integration with wearable technology: Leveraging data from wearable sensors to validate and refine the simulation models in real-world settings.

5) Advanced modeling techniques: Employing more sophisticated modeling approaches, such as finite element analysis, to capture the complex interactions within the musculoskeletal system.

These future endeavors aim to refine the modeling framework and enhance its applicability in injury prevention and rehabilitation strategies.

VI. CONCLUSION

This study presented a novel framework for modeling foot-strike events during running as point-source excitations that generate radially propagating wavefronts, specifically A0-mode Lamb waves, within a cylindrical coordinate system. By simulating these waveforms and validating them against real-world running biomechanics data, we demonstrated the effectiveness of a wave-based approach in capturing biomechanical features relevant to injury detection and analysis. Through systematic parameter sweeps of frequency and amplitude, the model was able to reproduce empirical features such as pace, training frequency, and running experience with minimal error. Notably, distinct parameter regions were observed for injured and non-injured runners, suggesting potential diagnostic capabilities rooted in wave dynamics. The findings validate our hypothesis that wave propagation mechanisms can model biomechanical variability and highlight the feasibility of using simulated wave characteristics to predict or flag injury risks without relying solely on machine learning. While limitations remain particularly in modeling complexity, feature generalization, and data heterogeneity, the results pave the way for a physics-informed alternative to conventional biomechanical modeling and injury analysis. The proposed methodology stands as a complementary approach to data-driven techniques and offers interpretability through physical parameters, which can be valuable in clinical and athletic settings.

Future extensions of this work will explore richer biomechanical features, personalized modeling frameworks, and integrate real-time sensor feedback to enhance usability and accuracy. Ultimately, this wave-theoretic approach offers a compelling tool for advancing injury prediction, prevention strategies, and understanding human movement from a mechanistic perspective.

Integrating AI in Ophthalmology: A Deep Learning Approach for Automated Ocular Toxoplasmosis Diagnosis

Bader S. Alawfi
Department of Clinical Laboratory Sciences-College of Applied Medical Sciences,
Taibah University, Madinah 42353, Saudi Arabia

***Abstract*—Background: Ocular Toxoplasmosis, a leading cause of Posterior Uveitis, demands timely diagnosis to prevent vision loss. Manual retinal image analysis is labor-intensive and variable, while existing Deep Learning models often fail to balance local details and global context in Medical Image Classification. Objective: I propose RetinaCoAt, a Hybrid Deep Learning Model based on the CoAtNet Architecture, for Automated Diagnosis of Ocular Toxoplasmosis, integrating local and global features in Retinal Image Analysis. Methods: RetinaCoAt combines Convolutional Neural Networks (CNNs) for local pathological pattern detection with Transformer Models using multi-head self-attention for global context. Enhanced by residual connections and optimized tokenization, it was trained on 3,659 retinal images (healthy vs. unhealthy) and benchmarked against VGG16, CNNs, and ResNet. Results: RetinaCoAt achieved 98% accuracy in Medical Image Classification, outperforming VGG16 (96.87%), CNNs (95%), and ResNet (93.75%), due to its robust CNN-Transformer synergy. Conclusion: RetinaCoAt advances Automated Diagnosis of Ocular Toxoplasmosis and Posterior Uveitis, with potential for broader retinal pathology detection.**

***Keywords*—Ocular Toxoplasmosis; Posterior Uveitis; deep learning; automated diagnosis; CNNs; transformer models; CoAtNet architecture; retinal image analysis; medical image classification; hybrid deep learning models**

I. Introduction

Ocular Toxoplasmosis (OT) is a parasitic disease caused by Toxoplasma gondii, leading to necrotizing retinochoroiditis, the most common cause of posterior uveitis worldwide [1]. It primarily results from reactivation of latent retinal tissue cysts, though primary infection can also cause ocular involvement, particularly in congenital cases. The disease arises from both direct parasitic damage and the host's immune-mediated inflammatory response.

Pathogenesis involves cyst rupture in the retina, releasing bradyzoites that transform into tachyzoites, triggering a strong local immune response. $CD4+$ and $CD8+$ T-cells and cytokines like IFN-y mediates the inflammation, causing necrosis of retinal and choroidal tissue. Clinically, this manifests as sharply defined retinal lesions, often accompanied by a vitreous haze described as a headlight in the fog. Recurrence is common due to the parasite's persistence, leading to cumulative retinal damage and scarring.

Patients often present with unilateral vision changes such as blurred vision, floaters, photophobia, and eye pain and redness [2]. Macular or optic nerve involvement can result in severe, sometimes irreversible, vision loss. Diagnosis is typically clinical, supported by ophthalmoscopy, fundoscopic findings and serological tests showing T. gondii antibodies. PCR (Polymerase Chain Reaction) of ocular fluids may confirm the diagnosis in atypical cases but is difficult and complex [3],[4]. Imaging techniques like fundus photography, slit-lamp imaging, OCT (Optical Coherence Tomography) and fluorescein angiography provide detailed visualization of retinal lesions [5]. The result can sometimes be misleading or misinterpreted due to lab or several other conditions and can lead to muscular damage, vision loss or unnecessary treatment [6],[7],[8]. Prevention emphasizes avoiding undercooked meat and contaminated environments, especially for pregnant women and immunocompromised individuals. Despite advances, Ocular Toxoplasmosis continues to cause significant visual morbidity, necessitating further research into innovative therapies.

The complex and expensive clinical examination tests prompt us to use AI in this field, too as depicted in Fig. 1. Deep learning (DL), a specialized branch of machine learning, leverages artificial neural networks (ANNs), a framework inspired by the structure and function of the human brain. Unlike traditional computer vision techniques that require extensive feature engineering, DL models enable end-to-end learning, streamlining the analysis process [9]. These models have demonstrated remarkable success in automating image classification tasks, achieving significant advancements in the field [10].

In parasitology, DL-based networks have shown immense potential when applied to diagnostic imaging. For instance, CNNs have been used to detect and quantify parasitic infections in tissue or blood smear images. Its' potential to autonomously detect, classify, and quantify pathological features in ocular diseases holds significant promise for enhancing diagnostic ACC and enabling ophthalmologists to deliver precise and personalized care in the near future. DL is in use for the diagnosis of various eye diseases, analyzing infected fundus images like diabetic retinopathy, cataracts, and glaucoma [11],[12],[13],[14],[15],[16]. Additionally, these models have been trained to recognize disease-specific lesions, categorizing them by severity, a capability that can be extended to parasite-related pathological features in microscopy images [17].

For the first time (2019), Chakravarthy et al. designed an automated deep CNN (VGG-16) model for the diagnosis of OT [18]. They used heat mapping and patching as input to

Fig. 1. Use of AI in the disease management [5].

a hybrid model. Hasanreisoglu et al. also employed a dual input hybrid CNN-based approach for detection and achieved an ACC of 92%, making it a helpful aid [19]. Hassan and his team devised an automated machine learning model (without coding) to distinguish the fundus images of healthy eyes from the OT-infected eye images successfully [20]. Samira et al. compared DL algorithms ANN and CNN classifying fundus images using pre-trained VGG-16. The results indicated that ANN had better ACC than CNN even after preprocessing of three types of fundus images [21].

Alam et al. used the pre-trained models [22]. MobileNetV2 achieved better results for classification, followed by InceptionV3 in terms of ACC, while DenseNet121 showed the highest precision (PRI). In the case of segmentation, MobileNetV2/U-Net outclassed ResNet34. Other than evaluating the efficiency of models, they also analyzed the feature extraction methods to find the most suitable ones for the detection and segmentation of fundus images.

The automated detection of Ocular Toxoplasmosis presents unique challenges due to the need for precise localization of pathological features and the integration of global contextual information in retinal images. While deep learning has shown promise in medical image analysis, existing models often fall short in addressing these challenges, limiting their diagnostic ACC and clinical applicability. To bridge this gap, this study introduces a novel hybrid deep learning architecture that leverages the strengths of CNNs and transformer-based attention mechanisms. The proposed model not only addresses the limitations of current approaches but also sets a new standard for performance and robustness in the detection of Ocular Toxoplasmosis. The primary contributions of this study are as follows:

1) Novel hybrid architecture: This study aims to develop and evaluate a novel RetinaCoAt deep learning architecture that integrates CNNs with transformer-based attention mechanisms. This architecture is specifically designed to capture both local pathological patterns and global contextual information in retinal images, addressing the limitations of existing methods.

2) Pioneering work in Ocular Toxoplasmosis detection: To the best of my knowledge, this is the first study to develop an advanced deep-learning architecture specifically for the automated detection of Ocular Toxoplasmosis. The proposed model fills a critical gap in the literature and provides a foundation for future research in this domain.

3) State-of-the-art performance: The proposed model achieves an ACC of 98%, along with weighted PRI, recall (REC), and F1-score (F1S) of 98% and a perfect ROC score of 1.00. These results demonstrate its superior performance compared to existing models such as VGG16, traditional CNNs, and ResNet, setting a new benchmark for automated detection of Ocular Toxoplasmosis.

The remainder of this paper is organized as follows: Section II describes the materials and methods used in this study, including the dataset, preprocessing techniques, and the proposed RetinaCoAt hybrid architecture. Section III presents the experimental results, along with a detailed discussion of the model's performance, comparative analysis with existing methods, and an evaluation of its robustness and generalizability. Finally, Section IV concludes the paper by summarizing the key findings, highlighting the significance of the proposed work, and suggesting directions for future research.

II. Materials and Methods

This study presents an innovative approach to Ocular Toxoplasmosis classification through the implementation of a hybrid Convolutional Neural Network-Transformer architecture. It harnesses the synergistic combination of convolutional and transformer mechanisms to capture both local and global features in ocular images, enabling robust discrimination between healthy and pathological cases, as shown in Fig. 2.

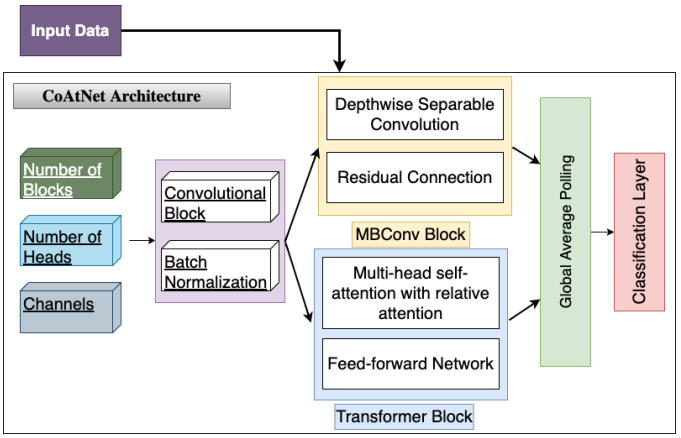

Fig. 2. Proposed architecture graphical representation.

A. Dataset Description and Preprocessing

Vision impairment and blindness is a common disease caused by Toxoplasma gondii. This research focuses on Ocular Toxoplasmosis detection utilizing retinal fundus images. The study involves two versions of the same dataset, where Dataset 2 is derived from Dataset 1 through preprocessing and augmentation to address class imbalance issues.

Dataset 1 (Original Dataset - Ocular Toxoplasmosis fundus images dataset):

- Collected from two hospital centers:
  - Hospital de Clínicas Medical Center (2018-2020): 291 images
  - Niños de Acosta Ñú General Pediatric Hospital (2021): 121 images
- Original multi-class distribution (showing class imbalance):
  - Healthy Eye: 132 images
  - Active: 33 images
  - Inactive: 187 images
  - Active-Active: 1 image
  - Active-Inactive: 57 images
  - Inactive-Inactive: 1 image
- Image specifications:
  - Format: JPG
  - Resolution: Varies (2124 x 2056 pixels or 1536 x 1152 pixels)

Dataset 2 (Processed and Augmented Version): To address the limitations of Dataset 1, the following modifications were made:

- Simplified Classification: Merged all disease categories into a single "Unhealthy" class
- Applied Data Augmentation: Increased the dataset size to improve model generalization

The processed dataset is comprised of training and validation sets. The training set includes both original and augmented images. The original training set contains 132 healthy images and 234 unhealthy images, while the augmented training set significantly expands these numbers to 1320 healthy images and 2339 unhealthy images. The validation set consists of 27 healthy images and 56 unhealthy images.

This restructuring from Dataset 1 to Dataset 2 addresses three key challenges:

- Class imbalance in the original dataset
- Complexity of multiple disease categories
- Limited sample size for deep learning applications

The resulting Dataset 2 provides a more balanced and augmented collection of images specifically designed for binary classification tasks while maintaining the diversity of the original patient demographics from multiple hospitals.

The dataset comprises ocular images categorized into two classes (Fig. 3: healthy and unhealthy (Toxoplasmosis-affected) samples. To ensure robust model training, a comprehensive data preparation pipeline is implemented. The dataset was partitioned using a stratified sampling approach, with 85% allocated for training and 15% for testing. The training set was further subdivided, with 80% used for actual training and 20% for validation, maintaining class distribution across all splits.

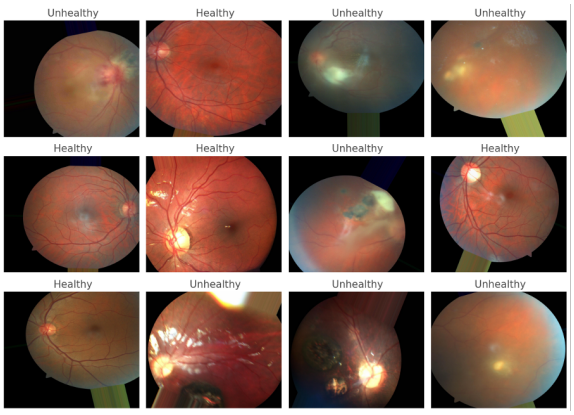

Fig. 3. Sample dataset images.

Image preprocessing was accomplished using TensorFlow's ImageDataGenerator, incorporating MobileNetV2's preprocessing function to normalize the input images. All images were resized to a uniform dimension of 128×128 pixels with RGB colour channels preserved. To enhance model generalization, data augmentation techniques employed through the Image Data Generator framework. The images were processed in batches of 32 samples, with shuffling enabled during training to prevent learning sequence-dependent patterns.

B. Proposed Model Architecture

The proposed architecture implements a hierarchical structure that progressively increases in complexity and receptive field size through multiple stages. The network architecture consists of three primary stages containing varying numbers of blocks (2, 2, 3) with corresponding channel dimensions (64, 96, 192). This progressive scaling enables the model to capture features at multiple levels of abstraction, from fine-grained local patterns to complex global structures.

1) Initial feature extraction: The network's initial stage implements a sophisticated feature extraction mechanism that serves as the foundation for all subsequent processing. This stage begins with a carefully engineered convolutional layer that processes the raw 128×128×3 RGB input images. The layer employs 7×7 kernels, a deliberate choice that creates a receptive field large enough to capture meaningful low-level features while maintaining computational efficiency. This kernel size represents an optimal balance between capturing sufficient spatial context and managing computational complexity, as smaller kernels might miss meaningful spatial relationships. In comparison, larger kernels would introduce unnecessary computational overhead.

The convolutional layer operates with a stride of 2, effectively downsampling the spatial dimensions while producing 64 output channels. This strided convolution serves a dual purpose: it reduces the spatial dimensions efficiently without requiring a separate pooling layer and helps establish translation invariance early in the network. The number of output channels

(64) was carefully selected to provide sufficient capacity for representing various low-level features such as edges, textures, and basic shapes present in ocular images while maintaining computational efficiency in subsequent layers.

Following the convolution, batch normalization implement with a momentum of 0.9, which plays a crucial role in stabilizing the training process. The batch normalization layer normalizes the feature distributions across the batch dimension, reducing internal covariate shifts and allowing for higher learning rates. This normalization process is critical in the initial layers, where feature magnitudes can vary significantly due to varying input image characteristics. The momentum value of 0.9 was chosen to provide a good balance between stable statistics and adaptability to changing feature distributions during training.

The network's initial stage implements a sophisticated feature extraction mechanism through a carefully designed convolutional layer. For an input image $X \in \mathbb{R}^{(HW3)}$, where H=W=128 represents the spatial dimensions, the initial convolution operation can be expressed as Eq. (1):

$$F_0(X) = \sigma(\text{BN}(W \cdot X + b)) \tag{1}$$

Where $W \in \mathbb{R}^{7\times7\times3\times64}$ represents the convolutional kernels, * denotes the convolution operation with stride 2, b represents the bias terms, BN denotes batch normalization, and σ is the activation function. The batch normalization operation normalizes the feature maps across the batch dimension B is shown as Eq. (2):

$$BN(x) = \gamma \left(\frac{x - \mu_a}{\sqrt{\sigma_a^2 + \epsilon}} \right) + \beta \tag{2}$$

where μ_a and σ_a^2 are the running estimates of mean and variance, γ and β are learnable parameters, and $\epsilon = 10^{-5}$ ensures numerical stability. This normalization significantly improves training stability by maintaining consistent feature distributions throughout the network.

2) MBConv block architecture: The Mobile Block Convolution (MBConv) blocks constitute a fundamental building block of network's early stages, implementing an efficient and powerful feature transformation mechanism. Each MBConv block follows a carefully designed expand-process-project pattern that maximizes feature extraction capability while maintaining computational efficiency. The expansion phase begins with a 1×1 pointwise convolution that increases the channel dimension by a factor of four. This expansion creates a higher-dimensional feature space that allows the network to capture more complex patterns and relationships. The expansion ratio of four was determined through empirical testing, providing an optimal balance between model capacity and computational overhead.

The expanded features undergo batch normalization followed by the SiLU (Swish) activation function, defined as $x * \sigma(x)$, where σ represents the sigmoid function. The SiLU activation was chosen over traditional ReLU due to its smooth nature and non-monotonic characteristics, which allow for better gradient flow and feature representation. The soft nature of SiLU helps prevent the "dying ReLU" problem while providing stronger regularization through its bounded nature at negative inputs.

The core processing stage employs a depthwise convolution with 3×3 kernels, a crucial architectural choice that dramatically reduces parameters while maintaining effective spatial feature extraction. This depthwise convolution processes each channel independently, applying spatial filtering without cross-channel mixing. The 3×3 kernel size provides a local receptive field that captures spatial relationships effectively while keeping the parameter count manageable. The depthwise convolution is followed by batch normalization and another SiLU activation, maintaining consistent feature processing throughout the block.

The projection phase implements another 1×1 pointwise convolution that reduces the channel dimensions back to their original size. This projection serves as a feature aggregation mechanism, combining the processed features from different channels into a more compact representation. The entire block incorporates a residual connection when input and output dimensions match, implemented through element-wise addition. This residual pathway serves multiple purposes: it facilitates gradient flow during backpropagation, helps maintain feature fidelity, and allows the network to learn residual mappings, which are often easier to optimize than direct mappings.

The MBConv blocks implement an efficient feature transformation pipeline that can be mathematically described through a series of operations as shown in Eq. (3). For an input tensor $X \in \mathbb{R}^{(HWC)}$, the expansion phase first projects the features to a higher dimension:

$$X_1 = \sigma(\text{BN}(W_1 \cdot X)) \tag{3}$$

where $W_1 \in \mathbb{R}^{(11C4C)}$ represents the expansion convolution weights. The subsequent depthwise convolution operates on each channel independently is expressed as Eq. (4):

$$X_2(i,j,k) = \sum_m \sum_n W_2(m,n,k) \cdot X_1(i+m, j+n, k) \tag{4}$$

where $W_2 \in \mathbb{R}^{(334C)}$ are the depthwise convolution kernels. The projection phase then reduces the dimensionality that depicts as Eq. (5):

$$Y = \sigma(\text{BN}(W_3 \cdot X_2)) \tag{5}$$

where $W_3 \in \mathbb{R}^{(1\cdot1\cdot4CC)}$ represents the projection weights. The residual connection, when applicable, is implemented as:

Output = $Y + X$ if shapes match Output = Y otherwise

The effectiveness of this architecture is demonstrated by the reduction in computational complexity from $O(H \cdot W \cdot C^2)$ for standard convolutions to $O(H \cdot W \cdot C)$ for depthwise separable convolutions while maintaining model expressiveness.

3) Transformer block design: The transformer blocks in network implement a sophisticated attention mechanism specifically adapted for image processing tasks, representing a significant advancement over traditional convolutional approaches. Each transformer block begins with layer normalization using a learned affine transformation, which standardizes the input features across the channel dimension. This normalization is crucial for stable training of the attention mechanism, as it ensures that the input features have consistent statistics regardless of their position in the network.

The core attention mechanism implements a multi-head relative attention approach, where the input features are processed by multiple attention heads operating in parallel. Each head processes a different subspace of the input features, allowing the network to capture various types of relationships simultaneously. The number of attention heads increases progressively through the network (1, 1, 2 in successive stages), allowing for more complex feature interactions in deeper layers. The relative attention mechanism incorporates spatial information by considering the relative positions of features, which is crucial for maintaining spatial awareness of the transformed features.

The attention computation follows the scaled dot-product formulation as expressed in Eq. (6):

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{6}$$

Where Q, K, and V represent the queries, keys, and values, respectively, and d_k is the dimension of the key vectors. The scaling factor $\sqrt{d_k}$ prevents the dot products from growing too large in magnitude, which could push the softmax function into regions with minimal gradients. The queries, keys, and values are computed through learned linear transformations of the input features, allowing the network to adapt its attention patterns during training.

Following the attention mechanism, a sophisticated feed-forward network processes the attention output. This network consists of two dense layers with an intermediate expansion factor of four, chosen to provide sufficient capacity for complex feature transformation while maintaining computational efficiency. The GELU activation function is employed between these layers, providing non-linearity while maintaining smooth gradients. The GELU function approximates the expected transformation of a neuron's output under dropout regularization, providing an implicit form of regularization during training.

Transformer blocks implement a novel relative attention mechanism adapted for image processing. Given an input tensor $X \in \mathbb{R}^{(H \cdot W \cdot C)}$, the multi-head attention operation can be expressed as Eq. (7):

$$Q = W_Q \cdot X, \quad K = W_K \cdot X, \quad V = W_V \cdot X \tag{7}$$

where, $W_Q, W_K, W_V \in \mathbb{R}^{(C \cdot C)}$ are learnable weight matrices. The relative attention scores A for head h are computed as Eq. (8):

$$A_h = \text{softmax}\left(\frac{Q_h \cdot K_h^T + R_h}{\sqrt{d_k}}\right) \tag{8}$$

where, R_h represents the relative position encodings and d_k is the dimension per head. The final attention output is computed as Eq. (9):

$$\text{MultiHead}(X) = W_O \cdot \text{concat}(A_1 \cdot V_1, ..., A_H \cdot V_H) \tag{9}$$

where, H is the number of attention heads and $W_O \in \mathbb{R}^{(H \cdot C \cdot C)}$ is the output projection matrix. The feed-forward network applies two transformations as expressed in Eq. (10):

$$\text{FFN}(x) = W_2 \cdot \text{GELU}(W_1 \cdot x) \tag{10}$$

where, $W_1 \in \mathbb{R}^{(C \cdot 4 \cdot C)}$ and $W_2 \in \mathbb{R}^{(5 \cdot C)}$. The GELU activation is approximated as follows by Eq. (11):

$$\text{GELU}(x) \approx 0.5x\left(1 + \tanh\left(\sqrt{\frac{2}{\pi}}(x + 0.044715x^3)\right)\right) \tag{11}$$

4) Classification architecture: The classification stage of network implements a carefully designed sequence of operations that transform the high-level features into accurate class predictions. The stage begins with global average pooling, which reduces spatial dimensions while preserving channel information by computing the mean value across each feature map. This operation provides several advantages: it introduces translation invariance to the network's predictions, reduces the number of parameters compared to fully connected layers, and helps prevent overfitting by enforcing a structural regularization on the feature representations.

Following the pooling operation, dropout regularization implement with a carefully tuned rate of 0.2. This dropout rate was determined through extensive experimentation to provide optimal regularization without unnecessarily degrading model performance. During training, randomly deactivating 20% of the neurons helps prevent co-adaptation of feature detectors and encourages the network to learn more robust and independent features. The dropout mechanism also approximates an ensemble of multiple networks, providing implicit model averaging during inference.

The final classification layer consists of a dense layer with two output units, corresponding to binary classification task of distinguishing between healthy and unhealthy ocular images. The weights of this layer are initialized using the Glorot uniform initialization scheme, which helps maintain the appropriate scale of gradients through the network. The layer employs softmax activation to produce probability distributions over the two classes, defined as Eq. eq12:

$$P(class_i) = \frac{exp(z_i)}{\sum_j exp(z_j)} \tag{12}$$

where, z_i represents the logit for class i, the softmax activation ensures that the output probabilities sum to one

while providing a differentiable function that can be effectively optimized during training.

To improve the calibration of the model's predictions, implement temperature scaling in the softmax computation. The temperature parameter τ modifies the softmax function as shown in Eq. (13):

$$P(class_i) = \frac{exp(z_i/\tau)}{\sum_j exp(z_j/\tau)} \tag{13}$$

where, τ is learned during training to optimize the calibration of predicted probabilities, this calibration ensures that the model's confidence scores accurately reflect the actual likelihood of correct classification, which is crucial for clinical applications where uncertainty quantification is essential.

Training strategy employs the AdamW optimizer, which extends the traditional Adam optimizer with decoupled weight decay regularization. The optimizer is configured with an initial learning rate of 1e-3 and a weight decay factor of 1e-4, providing a balance between effective optimization and regularization. The beta parameters are set to 0.9 and 0.999 for the first and second moments, respectively, with an epsilon value of 1e-8 for numerical stability.

The learning rate management strategy incorporates both warmup and decay phases. During the initial five epochs, a linear warmup schedule gradually increases the learning rate to its maximum value, helping stabilize early training. Subsequently, a reduce-on-plateau scheme monitors validation loss and adjusts the learning rate when performance plateaus. The learning rate is reduced by a factor of 0.2 when no improvement is observed for five consecutive epochs, with a minimum learning rate threshold of $1e-6$.

The training utilizes sparse categorical cross-entropy loss with label smoothing ($\epsilon = 0.1$) to prevent overconfident predictions and improve generalization. The training process is monitored through multiple metrics, including ACC, loss, and AUC-ROC, with model checkpoints saved based on validation ACC. Early stopping with a patience of 10 epochs prevents overfitting by halting training when no further improvement is observed. Additional regularization is achieved through weight decay, dropout, and batch normalization, creating a robust training framework that balances model performance with generalization capability.

III. Results and Discussion

The proposed RetinaCoAt model's performance was evaluated across multiple metrics to comprehensively assess its effectiveness in classifying Ocular Toxoplasmosis into "Healthy" and "Unhealthy" categories. These metrics include training vs validation loss and ACC, a detailed classification report, a confusion matrix, an ROC curve, correct and incorrect predictions, and probability density distribution. Each metric provides unique insights into the model's performance, highlighting its ACC, generalization ability, and areas for improvement. The following subsections present a detailed analysis of these results.

A. Classification Report Generated by Proposed Model

The proposed deep learning model demonstrated excellent performance in classifying Ocular Toxoplasmosis images into healthy and unhealthy categories, as shown in Table I. The model achieved an overall ACC of 98% across the test set of 549 images. For healthy images (class 0), the model achieved a PRI of 0.98 and a REC of 0.97, resulting in an F1 score of 0.97. This indicates that the model was highly effective in identifying healthy cases, with very few false positives. Out of 219 healthy images in the test set, the model correctly classified 97% of them.

The model performed slightly better in identifying unhealthy images (class 1), achieving a PRI of 0.98 and REC of 0.98, with an F1-score of 0.98. From the 330 unhealthy images in the test set, 98% were correctly identified, demonstrating the model's strong capability in detecting pathological cases. The balanced performance across both classes is reflected in the macro-average metrics (PRI: 0.98, REC: 0.98, F1S: 0.98), indicating that the model performs consistently well regardless of the class. The weighted averages match these values, suggesting that the model maintains its high performance even when accounting for the slight class imbalance in the dataset.

TABLE I. Classification Report for the RetinaCoAt Model

Classes	PRI	REC	F1S	support
0	0.98	0.97	0.97	219
1	0.98	0.98	0.98	330
ACC			0.98	549
macro avg	0.98	0.98	0.98	549
weighted avg	0.98	0.98	0.98	549

B. Training vs Validation Loss and Accuracy

In Fig. 4, the training and validation curves reveal the learning progression of the model over 30 epochs. The loss curves (left plot) show a desirable convergence pattern. The training loss (red solid line) demonstrates a consistent decrease from an initial value of approximately 1.2, steadily declining and stabilizing around 0.02 by epoch 25. The validation loss (blue dashed line), while showing more fluctuation, follows a similar overall downward trend, ultimately converging to approximately 0.1, indicating best generalization.

The ACC curves (right plot) corroborate this learning behaviour. The training ACC (green solid line) shows steady improvement, starting from around 67% and rapidly increasing to over 80% within the first 5 epochs. It continues to improve more gradually thereafter, reaching nearly 100% by epoch 20. The validation ACC (orange dashed line), despite showing some oscillation in the early epochs, particularly around epoch 5, demonstrates overall improvement and eventually stabilizes above 95% after epoch 20.

The close alignment between training and validation metrics in the later epochs (20-30) suggests that the model has achieved a good balance between fitting the training data and generalizing to unseen examples. The minimal gap between final training and validation performance indicates that overfitting is well-controlled, due to effective regularization techniques employed in the model architecture.

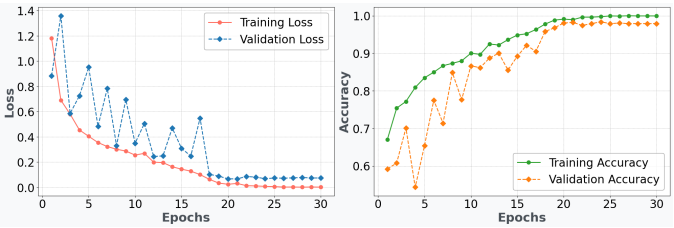

Fig. 4. Training and validation loss and accuracy curves.

C. Confusion Matrix of the Proposed Model

The confusion matrix (Fig. 5) reveals excellent classification performance across both healthy and unhealthy cases. Here's a detailed breakdown:

For healthy cases:

- True Negatives (TN): 213 healthy images were correctly classified as healthy
- False Positives (FP): Only 6 unhealthy images were incorrectly classified as healthy
- This represents a high specificity, with the model rarely misclassifying unhealthy cases as healthy

For unhealthy cases:

- True Positives (TP): 325 unhealthy images were correctly classified as unhealthy
- False Negatives (FN): Only 5 healthy images were incorrectly classified as unhealthy
- This demonstrates high sensitivity, with the model successfully identifying the vast majority of unhealthy cases

The model shows balanced performance with very few misclassifications in either direction (5 FN and 6 FP), which is particularly important in medical diagnosis applications. The nearly symmetric error rates suggest that the model is not biased toward either class despite the slight class imbalance in the dataset (219 healthy vs 330 unhealthy images).

Fig. 5. Confusion matrix for Ocular Toxoplasmosis classification.

D. Probability Density Distribution

In the analysis of the proposed model's prediction confidence, the probability density distribution reveals compelling insights into the model's classification behaviour for Ocular Toxoplasmosis cases, as shown in Fig. 6. The distribution exhibits a distinctive bimodal pattern, characterized by two prominent peaks that effectively separate healthy and unhealthy predictions. The left peak centred approximately at 0.0 on the probability scale, predominantly represents the healthy class predictions, displaying a higher density with a maximum value of approximately 1.75. This indicates the model's strong confidence in identifying healthy cases. Conversely, the right peak, positioned around 0.75-1.0 on the probability scale, corresponds to unhealthy class predictions, showing a slightly lower but still substantial density maximum of about 1.7. This right-side distribution demonstrates the model's robust confidence in identifying unhealthy cases. Notably, the region between these two peaks, particularly around the 0.5 probability mark, shows minimal density values, indicating that the model rarely produces uncertain or ambiguous predictions. This clear separation between the two classes' probability distributions strongly corroborates the model's high-performance metrics, with both classes showing well-defined, concentrated probability regions. The symmetrical nature of the peaks and their similar heights suggest balanced prediction confidence across both classes despite the slight class imbalance in the dataset. This balanced confidence distribution aligns well with the model's high ACC and balanced PRI-REC metrics observed in the classification report.

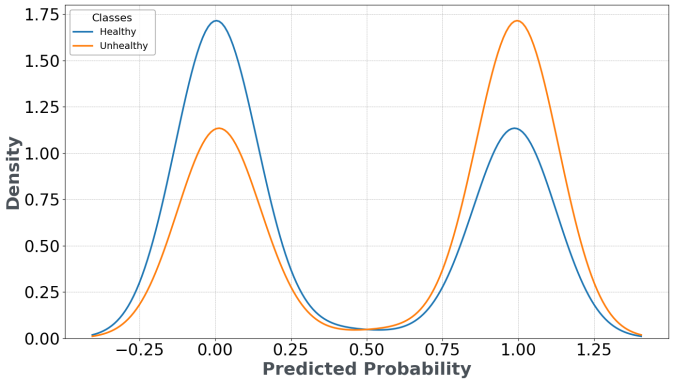

Fig. 6. Probability density distribution of predicted outputs.

E. Receiver Operating Characteristics

In Fig. 7, the Receiver Operating Characteristic (ROC) curves for the proposed Ocular Toxoplasmosis classification model demonstrate exceptional discriminative performance for both healthy and unhealthy classes. The graph displays three curves: ROC curves for healthy (blue line) and unhealthy (orange line) classes, along with a random chance baseline (black dashed line). Both classes achieve a perfect Area Under the Curve (AUC) score of 1.00, indicating optimal classification performance. The ROC curves for both classes immediately rise to the top-left corner of the plot and maintain a true positive rate of nearly 1.0 across all false positive rate thresholds. This is in stark contrast to the random chance baseline (diagonal dashed line), which represents an AUC of 0.50. The perfect AUC scores suggest that the model can perfectly distinguish between healthy and unhealthy cases at various classification thresholds, validating the model's robust decision-making capability. The identical performance across

both classes, as shown by the overlapping ROC curves, further confirms the model's balanced predictive power, regardless of the class imbalance in the dataset. This exceptional ROC performance aligns perfectly with the previously observed high ACC, PRI, and REC metrics, as well as the clear separation seen in the probability density distributions.

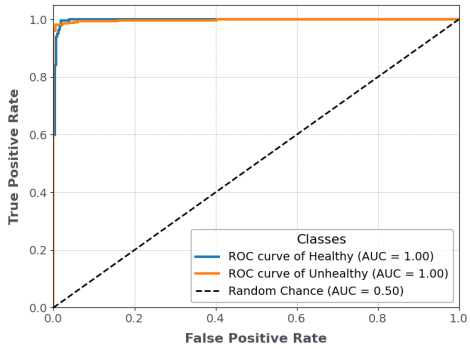

Fig. 7. ROC curve for the RetinaCoAt model.

F. Correct and Incorrect Predictions

Fig. 8 illustrates examples of both correct and incorrect predictions made by the proposed model in the classification task. The rows show retinal fundus images categorized into two groups: "Healthy" and "Unhealthy".

The first and second rows demonstrate cases of correct predictions where the model successfully identified the actual label, as indicated by matching "True" and "Pred" annotations. The third row showcases one instance where the model misclassified images, with the discrepancy highlighted in red text for easy identification (e.g. "True: Healthy Pred: Unhealthy"). These results underline the model's overall performance, achieving a classification ACC of 98%. However, the highlighted misclassifications emphasize the importance of addressing edge cases or ambiguous features within the dataset to improve robustness further.

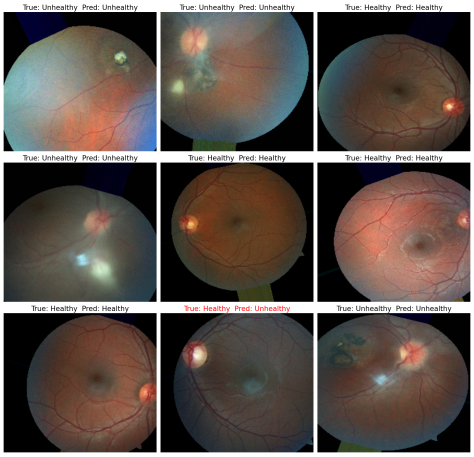

Fig. 8. Correct and incorrect predictions by the RetinaCoAt model.

G. Comparison with Existing State-of-the Art Work

The experimental results demonstrate the superior performance of the proposed RetinaCoAt architecture for Ocular Toxoplasmosis classification, achieving 98% ACC compared to existing approaches as depicted in Table II. This significant improvement over traditional methods can be attributed to RetinaCoAt's innovative hybrid design, which combines convolution and self-attention mechanisms. While conventional CNN-based approaches like VGG16 [23] achieved 96.87% ACC, and basic CNNs [24] reached 95%, they lack the sophisticated feature extraction capabilities of RetinaCoAt. The architecture surpasses ResNet [25] implementations (93.75%) by effectively addressing the limitations of purely convolutional approaches through its attention mechanisms, which capture complex spatial relationships in ocular images. Notably, the proposed method also outperforms automated approaches, with AutoML [26] models achieving 93.5% and Google Cloud AutoML [27] reaching 84.8% ACC. This performance gap highlights the advantage of a specially designed architecture that leverages both local feature extraction through convolutions and global context understanding through self-attention, making it particularly effective for the nuanced task of identifying Ocular Toxoplasmosis patterns in medical imaging.

TABLE II. COMPARISON WITH OTHER STUDIES

Reference	Proposed Method	Accuracy (%)
[23]	VGG16	96.87
[24]	Convolutional Neural Network	95
[25]	Residual Neural Network	93.75
[26]	AutoML model	93.5
[27]	AutoML in Google Cloud	84.8
Proposed	RetinaCoAt	98

IV. CONCLUSION

This study proposes a novel RetinaCoAt hybrid deep learning architecture for the automated detection of Ocular Toxoplasmosis in retinal images. The model, which integrates CNNs with transformer-based attention mechanisms, demonstrated exceptional performance, achieving an ACC of 98%, along with a weighted average PRI, REC, and F1S of 98%. Furthermore, the model achieved a perfect ROC score of 1.00, underscoring its robustness and reliability in distinguishing between healthy and infected cases.

To ensure the model's generalizability, training and validation loss and ACC were meticulously monitored, confirming that the model is not overfitted and is the best fit for the task. The proposed architecture addresses the limitations of existing methods by effectively capturing both local pathological patterns and global contextual information, enabling comprehensive multi-scale feature extraction.

A critical review of the literature reveals that no advanced architecture has been specifically designed for the automated detection of Ocular Toxoplasmosis, making this work a novel contribution to the field. The proposed model sets a new benchmark by leveraging the strengths of CNNs and transformers, offering a powerful tool for accurate and efficient diagnosis.

This study not only advances the development of automated diagnostic tools for Ocular Toxoplasmosis but also holds significant potential for improving early detection and

treatment outcomes. Future work could explore the application of this architecture to other ocular diseases and the integration of additional clinical data to further enhance its diagnostic capabilities.

Future work will focus on expanding the RetinaCoAt architecture to address additional challenges in ocular disease detection. I plan to extend model to classify the severity and progression stages of Ocular Toxoplasmosis, enabling more nuanced clinical decision-making. Integration with complementary imaging modalities such as Optical Coherence Tomography (OCT) could provide depth analysis of retinal lesions and enhance diagnostic accuracy. Additionally, developing explainable AI components would increase clinical trust by providing interpretable visualizations of the model's decision-making process. I also aim to investigate automated lesion segmentation capabilities and longitudinal analysis features to monitor treatment efficacy over time. Finally, clinical validation through prospective multi-center trials will be essential to establish the model's generalizability across diverse patient populations and imaging equipment. These advancements will collectively strengthen the clinical utility of proposed approach and potentially extend its application to other ocular pathologies with similar presentation patterns.

ACKNOWLEDGMENT

The authors would like to thank...

***Abstract*—The constant threat of malware makes studying its behavior an ongoing task. Malware identification and classification challenges can be solved better by analyzing software behaviorally rather than using conventional hashcode-based signatures. API sequence represents the behavior of any program when collected during its execution. Considering API sequences gathered while the malware was being executed in controlled conditions, this report addresses the issue of choosing influential APIs for malware. The suggested feature selection method *SelectAPI* in this research selects key features, i.e., significant APIs, that can better classify malware using TF-IDF API embeddings. Two machine learning models, Random Forest, which ensemble several estimators implicitly, and Support Vector Classifier, a standard non-linear model, are trained and evaluated to validate the importance of the chosen APIs. The proposed API selection methodology, called SelectAPI, has shown promising results. It achieves accuracy, macro-avg precision-score, macro-avg recall-score, and macro-avg F1-score of 0.76, 0.77, 0.76, and 0.76, respectively. This method focuses on selecting influential APIs and has resulted in significantly improved performance on the open-benchmark multiclass dynamic-API-Sequence based malware dataset, MAL-API-2019. These results surpass the previously best-known accuracy value of 0.60 and reported F_1-Score of 0.61.**

***Keywords*—Malware analysis; behavioural analysis; API sequence; multiclass malware; TF-IDF; API embeddings**

I. Introduction

Every person uses a variety of devices and apps over the internet to fulfil their everyday requirements related to banking, e-commerce, and many others. The most significant threat to these devices and apps is malware, a computer software. Malware is designed to perform various detrimental actions on the devices and applications of its victims. Attachments in electronic mails, ads, potentially unwanted softwares, and open utility applications are some ways the malware reaches a compromised device or application. The annual threat report for the FY-2022-23 [1] published by Quick Heal reveals that more than 163 million instances of new and known malware were identified in 2021-22. The identified malware samples are of the following families: Trojan, Infector, Ransomware, Cryptojacking, Potentially Unwanted Application (PUA), Adware, and Worm. The detection of malware with respect to their family for 2021 and 2022 are displayed in Fig. 1. Although malware detection is a computationally hard problem, undetected propagation can be limited by applying statistical techniques [2]. Malware analysis is done in two basic ways: static and dynamic. Static analysis involves examining some of the malware's essential characteristics, such as opcode sequences, readable strings, etc., without running the malware. On the other hand, dynamic analysis, also known as behavioural analysis, allows the virus to run in a controlled environment while gathering execution time information such as system call graphs, API sequences, registry file contents, etc. It has been observed that the obfuscation process of generating malicious code is not more effective in dynamic API call analysis in contrast to static type [3]. Researchers continually seek new and improved behavioral analysis methods to identify and categorize malware.

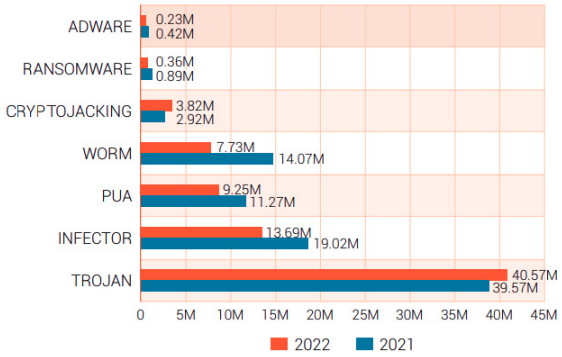

Fig. 1. Quick-heal threat report FY-2022-23 [1].

In this work, the focus has been given to the preprocessing of API sequences to classify malware concerning their families. The open dataset MAl-API-2019 released by Catak [4] is used to train and test machine learning models to demonstrate the preprocessing technique's efficacy in the multiclass malware classification problem. The objectives addressed in this work are:

- Using TF-IDF weight vectors to select influential API as a feature selection technique in the API sequences.
- Ensuring the improvements made using the above feature selection method by considering SVC as a standard non-linear machine learning model and RF as one of the implicit ensemble machine learning models.

Section II of this article lists the literature on malware classification. Section III covers the description of the dataset and the proposed feature selection method, followed by the training

of the aforementioned machine learning models. Section IV lists the findings of the experiment. The final portion highlights the conclusion.

II. Related Work

Malware detection techniques that utilize machine learning have seen significant advancements in recent years. The three fundamental principles, confidentiality, integrity, and availability, of computer security are compromised by malware, which impacts the computer system. By taking advantage of the system's flaws, they get into the computer system without the user or administrator noticing. Malware classification has been the subject of extensive investigation. Various techniques and characteristics are used to categorize new malware into well-known malware categories, identify outliers, and accurately evaluate such abnormalities. The API call sequence is widely used in malware detection techniques to represent the behaviour of malware accurately. Ye et al. gathered the set of API calls from Portable Executables (PE) files for generating the set of feature that was verifiable and comprehensible. A classifier has been trained using these features to identify unknown malware [5]. Geng et al. [6] provided a thorough overview of obfuscated malware and developments in obfuscation techniques, outlining a strategy-based principle from the viewpoint of malcoders. With an emphasis on Windows malware, the authors reviewed a variety of evasion approaches and demonstrated how evasion techniques might be combined to create malware with potent self-defense capabilities. In an experiment comparing adversarial malware generators, Louthánová et al. [7] showed that a combination of methods can efficiently produce new instances that escape detection and automate the generation of malicious activity works more more effectively against detection models that are different from the ones that produced them.

Kong and Yan integrated several malware properties, including opcodes, registers, and API calls, to categorize malware into 11 families. They used pairwise graph matching, ensembled classification, and discriminant distance metric learning to create an efficient system that could identify samples that had not been detected before [8]. In order to remove infrequent elements from the API sequences, Ding et al. proposed an association mining technique based on APIs. To improve detection accuracy, they chose and applied association rules with strong classification capabilities [9].

Recent research on malware analysis has shown that supervised and unsupervised machine learning approaches and deep neural networks are widely used to identify malicious activity with better efficiency, accuracy, and a low rate of false positives. Feature extraction and automatic detection are the most common methods used for malware detection with the help of machine learning [10].

Machine learning methods, such as LR, RF, SVM, KNN, etc., are often used to find and classify unknown samples of different malware families because of their scalability, speed, and flexibility. Han et al. [11] studied the behavior and characteristics of the malicious API call sequence. The analysis reveals a significant correlation between the static and dynamic API calls of the malicious applications. The authors have suggested a model known as MalDAE that can explain the detection of malicious activity by extracting the sequence of API calls from the PE files and cuckoo sandbox, which correlates the dynamic and static API call sequences into a hybrid sequence via semantic mapping. For the most common malware, it can offer a clear explanation and predictive assistance. They outperformed the previous studies with detection and classification accuracy of 97.89% and 94.39%, respectively.

Panda et al. [12] have proposed a host-specific in-memory detection system for malicious programs or software with the help of the TF-IDF API embedding method, particularly on the Windows API call sequences. The authors have prepared a knowledge base for the trusted application and their corresponding behaviour. The cross-validation technique predicts the class of trusted or untrusted applications in the host-specific systems. Mathew and Kumara [13] utilized N-grams and TF-IDF to extract and select features for their research. They proposed an LSTM model for the binary classification of applications as either benign or malicious based on API call sequences. The authors achieved an impressive accuracy score of 0.92 when evaluating the model on previously unseen test API call sequences. Huda et al. [14] have developed a hybrid framework for detecting malicious programs that combines SVM techniques with heuristics derived from the Maximum Relevance and Minimum Redundancy (Mr-MR) filter. This approach employs statistics from API call sequences as feature vectors. The method effectively integrates the ranking score from the filter into the wrapper's selection process. Ultimately, it leverages the strengths of the wrapper, the filter, and the sequences of API calls to efficiently identify malicious activities.

A harmful program may be obfuscated as a new program wrongly classified as benign while maintaining the original behavior and its effects. It may be easy to circumvent the detection procedure for this new program [15].

An ensemble model was presented by Panda et al. [16] for the classification of the imbalanced multiclass malware dataset known as MAL-API-2019. It has been investigated how the API calls relate to one another through the API sequences. They prepared the feature vector for the 1D-CNN using the Skip-gram approach of Word2Vec embedding model. This 1D-CNN model is trained for every class using the one-vs-rest (OvR) technique. To increase classification accuracy, they suggested an ensemble model using ModifiedSoftVoting, a unique soft-voting technique that combines all the class-wise classifiers. The MAL-API-2019 dataset is also used in the training to classify the multiclass malware using RF, DT, SVM, KNN, two-layer LSTM, and single-layer LSTM. They employed single-layer LSTM and obtained a recall and precision of 0.47 compared to all other models [4].

Li and Zheng classified malware types utilizing long-sequence API calls using the GRU and LSTM with the multiclass dataset MAL-API-2019. In LSTM and GRU, the achieved precision is 0.56, and recall is 0.58 and 0.59, respectively [17]. Demirkiran et al. have used a transformer based model with a single layer of transformer block for the classification of malware families. It is found that the suggested transformer-based RTF model outperforms when tested on four benchmark datasets (MAL-API-2019, Olivera, VirusShare, and VirusSample), had F_1-scores-0.61, 0.51, 0.56, and 0.59 and

AUC scores-0.88, 0.83, 0.83, and 0.87 for the three models they compared: Transformer, CANINE-S, and BERT [18].

Gali et al. [19] have combined an AI-based malware detection procedure with the eXplainable Artificial Intelligence (XAI) technology. With precision-54.89%, recall-53.99%, F_1-score-54.31% and accuracy-52.88%, the authors of study [20] obtained the best classification result by evaluating multiple deep-learning models with standard imbalanced multiclass dataset MAL-API-2019 using Binary-LSTM. Quan et al. proposed CAFTrans, a framework that uses CNN and LSTM networks to parse API sequences [20]. When the framework was tested on the MAL-API-2019 dataset, the F1 score was 0.65. They claimed that CAFTrans increases accuracy by detecting malware threats in their respective family more precisely than in other families using the same dataset. By linking Advanced Persistent Threat (APT) malware to the threat actors responsible for it, such as APT groups, Ahmad et al. [21] have improved the analysis of APT malware. APT malware is a serious threat, and averting cyber mishaps requires an awareness of the adversaries behind these attacks. This technique helps cybersecurity researchers and professionals with actionable insight by connecting APT software to threat actors for further analysis of the malware.

Multiclass malware classification problems suffer from class imbalance issues and feature imbalance issues. Without disturbing the class-wise samples, the feature imbalance problem concerning API sequences can be reduced using various techniques. This work applies the TF-IDF word embedding method to API sequences to identify influential APIs and better classify malware to their family.

III. Methodology

API sequences are considered the most important feature in the dynamic analysis of malware. The proposed framework in Fig. 2 illustrates the selection of influential or critical APIs having significance in API sequences concerning the multiclass malware classification problem. This study finds influential APIs by calculating the TF-IDF API embedding for each distinct API during the preprocessing of API sequences to identify malware based on their families. The effectiveness of the API sequences consisting of influential APIs and the efficacy of the models through the proposed feature selection technique is tested using the open dataset MAl-API-2019 published by Catak [4].

A. Dataset Description and Preprocessing

Mal-API-2019 is a multiclass malware dataset on dynamically collected API sequences of eight different classes of malware. This highly imbalanced dataset contains variable-length API sequence records for 7107 pieces of malware from eight different classes. A multiclass dataset is either imbalanced vertically or horizontally. In a vertically imbalanced dataset, the number of samples for each class varies significantly, as depicted in Fig. 3. Meanwhile, in a horizontally imbalanced dataset, the number of features in each sample varies significantly, as depicted in Fig. 4. This approach mitigates the horizontal imbalance issue during feature selection, or API selection, thereby preserving the vertical imbalance issue.

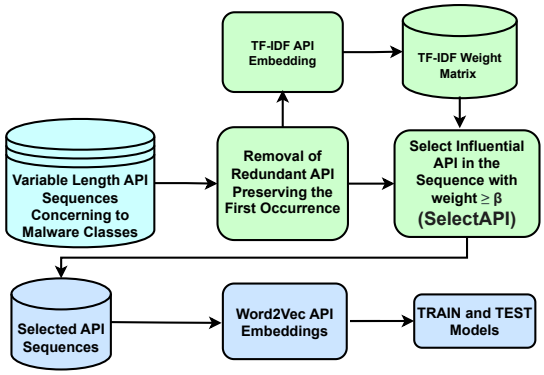

Fig. 2. Proposed framework to select influential APIs in API sequences.

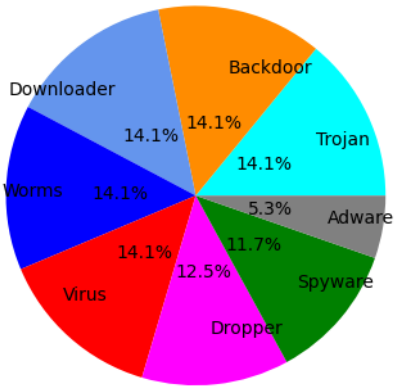

Fig. 3. Vertically imbalanced malware classes.

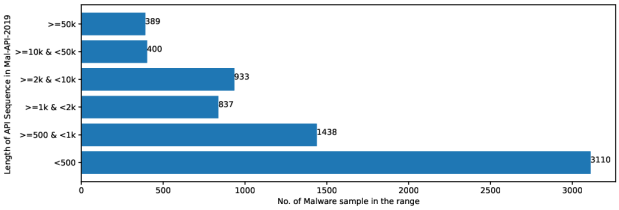

Fig. 4. Horizontally imbalanced API sequences.

Algorithm 1 PreserveFirstAPI

Require: API_{Seq} (API Sequence)
Ensure: $RAPI_{Seq}$ (Reduced API Sequence)
1: $API_{Dict} = \{\ \}$ ▷ Dictionary to track distinct API
2: $RAPI_{Seq} = \phi$
3: **for each** $API \in API_{Seq}$ **do**
4: **if** $API_{Dict}.hashKey(API)! = True$ **then**
5: $RAPI_{Seq}.append(API)$
6: $API_{Dict}[API] = True$
7: **end if**
8: **end for**
9: return $RAPI_{Seq}$

Repeated API calls in the API call sequence evade the malware's potential detection, making it a major runtime

behavior. Every API request performs a distinct machine-level function. The sequence of malware's machine-level tasks is described by maintaining the first call of each unique API in the provided API sequence. By removing duplicate API calls, the algorithm PreserveFirstAPI outlines how to protect each unique API call's initial occurrence. To demonstrate how PreserveFirstAPI works, consider the encoded API sequence with repeated API calls be [A, A, A, C, C, A, A, C, K, K, A, A, C, A, C, K, K, D, D, A, A, A, C, K, K, K, K, D, D, D, T, T, A, A, D, D, A, A, A, C, C, K, K, K, D, D, D, T, K, K, D, T, K, A]. After removing the redundant API by preserving the first occurrence, the encoded API record becomes [A, C, K, D, T]. For each API_{Seq} in the dataset, the Algorithm PreserveFirstAPI finds the reduced API sequence as $RAPI_{Seq}$. The reduced API-sequence dataset is further used by SelectAPI as outlined in Algorithm 2 for selecting influential, i.e., critical APIs having semantic significance over others from each reduced API sequence.

B. Feature Selection

Following the application of PreserveFirstAPI as described in Algorithm 1, TF-IDF (Term Frequency-Inverse Document Frequency) is a statistical technique that guarantees the calculation of the weightage of a distinct-API (i.e., a word) to an API-call-sequence (i.e., a document) in the collection of sequences of API-calls in the dataset (i.e., the collection of documents). In collecting API sequences, TF-IDF reduces the influence of very frequent APIs, which are empirically less informative than less frequent APIs. As mentioned in Eq. (1), TF-IDF assigns weight to an API by multiplying the API's term frequency (TF) with its inverse document frequency (IDF). TF of an API is calculated as mentioned in Eq. (2) considering the number of times the API appears in an API sequence compared to the total number of APIs in the API sequence. The IDF of an API reflects the proportion of API sequences in the dataset that contain the API and is calculated as mentioned in Eq. (3).

$$\textit{TF-IDF}_{API} = \textit{TF}_{API} \times \textit{IDF}_{API} \tag{1}$$

$$TF_{API} = \left(\frac{\textit{Number of occurrences of the API in the API Sequence}}{\textit{Total number of APIs in the API sequence}} \right) \tag{2}$$

$$IDF_{API} = log \left(\frac{\textit{Total number of API sequences in the dataset}}{\textit{Number of API sequences in the dataset contain the API} + 1} \right) \tag{3}$$

The TF-IDF weight matrix for APIs in API sequences of the reduced dataset from PreserveFirstAPI plays a significant role in selecting influential APIs. The steps of SelectAPI outlined in Algorithm 2 say the selection of influential APIs in each API sequence of the updated dataset. A threshold weight β will be decided during experimentation to select influential APIs. During the feature selection, not to disturb the class size distribution of the dataset, an API sequence gets restored to its original form when none of the APIs in the sequence qualifies β. Using the chosen API sequences from SelectAPI, the Word2vec [22] model is used to generate vector representations of various APIs. These vectors capture information about the API's semantics based on the surrounding APIs in the API sequences. These API vectors are further used to train and evaluate machine learning models.

Algorithm 2 SelectAPI

Require: $RAPI_{Seq}$ (The Reduced API Sequence) , $TF - IDF_{API}$ weight matrix and Weight threshold β to select influential API
Ensure: $SelAPI_{Seq}$ (API Sequence of APIs qualifying β)

```
SelAPI_Seq = φ
for each API ∈ RAPI_Seq do
    if TF − IDF_API ≥ β then
        SelAPI_Seq.append(API)
    end if
end for
if Number of terms in SelAPI_Seq = 0 then
    SelAPI_Seq = API_Seq          ▷ Restore the API-Seq
end if                            ▷ If all APIs are deselected
return SelAPI_Seq
```

IV. Experimental Setup and Results

An eight-core "Intel-Corei5-1035G1-CPU @ 1.00GHz " personal computer equipped with 16 Gigabytes of RAM is used during the research to conduct experiments. The computer runs the operating system "Ubuntu-22.04-LTS" and is installed with Anaconda, which has a kernel of Python-3.9 and Jupyter Notebook to conduct experiments. Using the benchmark imbalanced multiclass malware dataset, MAL-API-2019 [4], two machine learning models, SVC, a non-linear model and RF, an implicit ensemble model, are trained and assessed to make sure the proposed feature selection method is effective in classifying malware into the appropriate classes.

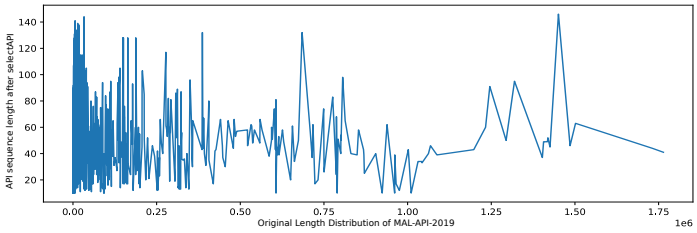

Fig. 5. API-Sequence length variation by SelectAPI with $\beta = 0.13$.

To mitigate the dataset problem concerning API sequence length as depicted in Fig. 4, the suggested feature selection method SelectAPI considered several β values during the experiment to remove insignificant APIs from API sequences. Fig. 5 illustrates the change in API sequence length using SelectAPI against its original length with the best-found value of β as 0.13.

Word2vec [22] model is used with (window size: '10', minimum count: '1', Skip-Gram Selector: '1', and vector size: '100') to generate API embeddings of all the significant

'1000') and RF model with parameters (number of estimators: '100', criterion: 'entropy', bootstrap: 'True', and maximum depth: '150').

TABLE III. SVC USING SELECTAPI AGAINST OTHERS

	Accuracy	Precision (Macro-Avg)	Recall (Macro-Avg)	F1-score (Macro-Avg)
LSTM [4] (Single-Layer)	–	0.50	0.47	0.47
GRU [17] (Case2)	0.55	0.56	0.59	0.57
RTF Model [18]	0.60	–	–	0.61
SVC (SelectAPI)	**0.76**	**0.77**	**0.76**	**0.76**

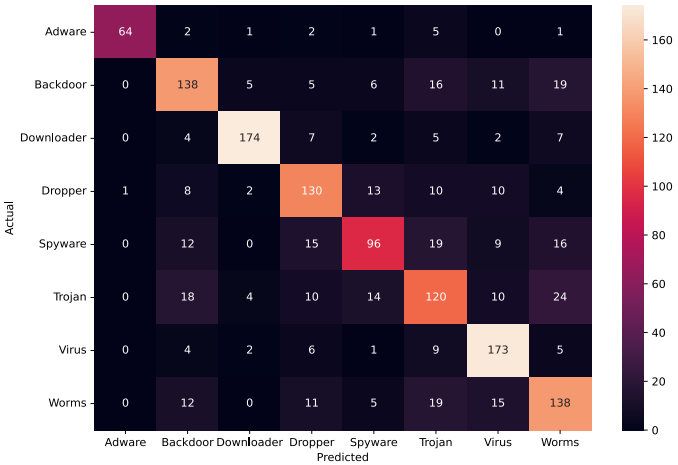

Fig. 9. CM RandomForest.

During experimentation, performance metrics for both the model's RF and SVC were recorded to have a conclusion about the significance of the suggested feature selection technique. Table I represents the accuracy, macro average precision, recall, and F1-score of the model's RF and SVC without

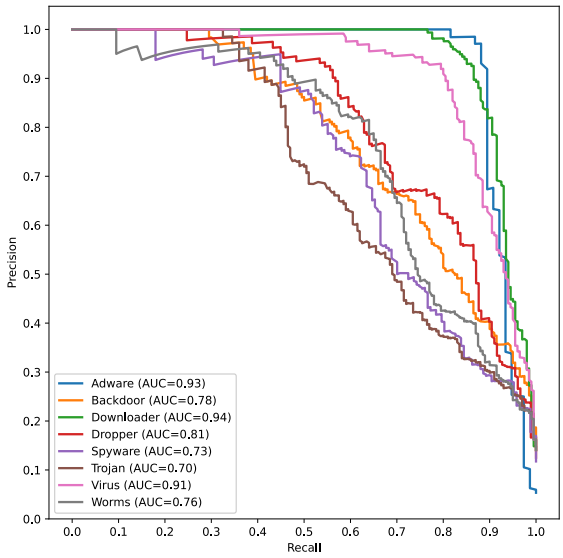

Fig. 10. Precision recall of RandomForest.

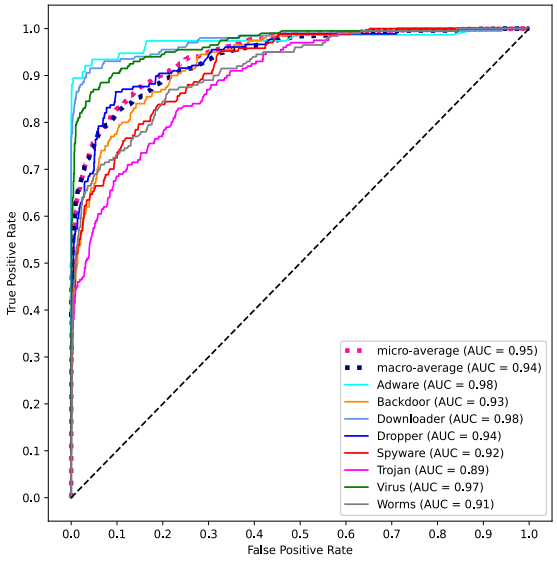

Fig. 11. ROC AUC of RandomForest.

using the feature selection SelectAPI. Furthermore, Table II highlights the performance metrics of both models with the feature selection SelectAPI. The SVC model's performance can be visually studied, referring to the following figures. The confusion matrix is in Fig. 6, the precision-recall curve is plotted in Fig. 7, and the ROC-AUC curve is plotted in Fig. 8 . The RF model's performance can be visually studied using the following figures. The confusion matrix is in Fig. 9, the precision-recall curve is plotted in Fig. 10, and the ROC-AUC curve is plotted in Fig. 11 . A comparison between performance scores mentioned in Table I and Table II reveals the significance of the feature selection technique SelectAPI. The Support Vector Classifier (SVC) obtained a detection accuracy of 0.76, according to the data, with overall average precision, recall, and F1-score values of 0.77, 0.76, and 0.76, respectively. The Random Forest (RF) model, in contrast, had overall average precision, recall, and F1-score values of 0.75, 0.73, and 0.74, respectively, and a detection accuracy of 0.73. As shown in Table II, the support value of 1422 is considered to evaluate all performance metrics. The Matthews correlation coefficient (MCC) score is also calculated to support the statistical significance of both models. All of the data clearly shows that SVC has performed better than RF in terms of classification abilities. This finding indicates a significant improvement over previous research that indicated a maximum macro average 'F1' score of 0.61 (see Table III).

V. Conclusion

This work has shown a method of selecting influential APIs from the collected API sequences for better malware classification. The significance of the suggested feature selection method, SelectAPI, is illustrated by applying it to the extremely unbalanced open benchmark variable-length API-sequence multiclass malware dataset MAL-API-2019. Selecting influential APIs from API call sequences improves the classification capability of malware to their classes even though the dataset is imbalanced class-wise and feature sequence length-wise. The SVC model demonstrated improved performance measures compared to RF as outlined in TABLE II, achieving an accuracy of 0.76 with a macro-avg. F1-score of 0.76 and a macro-avg. AUC-score of 0.94 across eight malware classes in the dataset using the feature section technique **SelectAPI**. These encouraging results highly support the effectiveness of the suggested feature section technique. Compared to previous studies by other researchers on the used dataset, as shown in Table III, which reported a maximum macro average F1 score of 0.61, the result obtained in this work shows a considerable performance improvement. Investigating other techniques to select influential APIs on such imbalanced dynamic API sequence-based malware datasets can give better classification capabilities to machine learning models.

A Layered Security Perspective on Internet of Medical Things: Challenges, Risks, and Technological Solutions

Ziad Almulla, Hussain Almajed, M M Hafizur Rahman
Department of Computer Networks and Communications-College of Computer Sciences and Information Technology,
King Faisal University, Al-Ahsa, 31982 Saudi Arabia

***Abstract*—The Internet of Medical Things (IoMT) refers to smart devices that are used in their transformation of the healthcare sector with continuous monitoring in real time, remote diagnostics as well as real time data exchange. nevertheless such systems are being targeted by a number of challenges like data breaches, unauthorized users and service interruptions. The study uses the PRISMA 2020 method and analyzes 25 peer-reviewed articles that were published between 2020 and 2025. Security risks are identified and mapped on the IoMT architecture's perception, network, application and cloud layers. One of the key findings was confirming the fact that blockchain based identity management, algorithmic lightweight cryptographic protocol, and Artificial Intelligence(AI) driven intrusion detection systems can potentially address these risks. However, these areas are still limited in terms of interoperability, resource efficiency, and there are no solutions against the emerging quantum threats. A number of countermeasures achieved almost perfect detection accuracy over 98%, leading to increased security for IoMT systems. In order to solve the above issues, the framework, TrustMed-IoMT, is introduced to integrate blockchain-based identity management, intelligent intrusion detection and encryption that is safe against quantum attacks.**

***Keywords*—IoMT; security risks; challenges; healthcare IoT; countermeasures; TrustMed-IoMT**

I. Introduction

IoMT is fast becoming the next big thing in the healthcare industry due to which provision of smart, connected devices is allowing the real time patient monitoring, remote diagnostics, and the efficient clinical workflows [1]. According to a report conducted in 2017, there were already $28 billion in revenue from IoMT based systems, and the projection is that the revenue will grow to $135 billion in coming years, which favors in reducing the healthcare costs worldwide by $300 billion. While such advantages existing, security and privacy are serious problems that prevent IoMT from being widely adopted. The environment in which IoMT systems operate is highly heterogeneous consisting of many different devices, protocols, and operating system, which makes such systems particularly vulnerable to cyberattacks. Additionally, the value of medical data (50 times higher than the value of data in another sector) makes IoMT a lucrative target to adversaries. These factors point out the necessity of understanding the motivation for adoption of IoMT and to provide solutions for the associated cybersecurity risks to enable resilient and sustainable healthcare infrastructures.

A. Motivation

IoMT has become part of the healthcare industry reducing healthcare costs, providing real time patient monitoring, remote diagnostics, communication between different devices and overall experience [2], [3], [4]. The components that form IoMT are wearable health trackers, smart medical devices and cloud based healthcare systems that permits continuous collection and transmission of health data over the internet. All these advancements have made great impacts in healthcare and even improved the efficiency and accessibility of patients among other outcomes.

IoMT devices process and generate huge quantities of sensitive patient data and so require strong security measures to prevent cyber threats. However, the increasing dependence on IoMT poses some critical security challenges, hence the systems are likely to be targeted by a potential cyber attack [5].

B. Problem Statement

A cyberattack on a global healthcare network via ransomware exploited vulnerabilities in more than 6.2 percent of IoMT devices in 2024, and impacted 53 percent of the critical healthcare systems eventually resulting in loss of more than a million patient records, and costs exceeding $22 million [6]. The attack took advantage of security flaws on medical device that were unpatched, disrupting operations and in some cases causing data breaches. This incident illustrates the necessity of stronger security interventions for the safeguarding of IoMT systems from attackers.

In the context of healthcare, the Medical Internet of Things or IoMT has changed the direction in which healthcare is headed towards today. However, these advancements have provoked crucial security challenges that have transformed the IoMT into a susceptible environment for attacks such as Distributed Denial of Service (DDoS) attack, malware infiltration, data breaches and unauthorized access. In addition, the disparate nature of IoMT Networks adds to security risks given that there exist devices with different communication protocols and security capabilities communicating across several layers among themselves. Moreover, the growing use of cloud based healthcare systems has extended the threat surface, rendering the intervention of data tampering, credential theft, and the blow of healthcare systems [7].

Signature based Intrusion Detection Systems(IDS) and static cryptography, which represent the traditional approaches

to security, have failed to detect new attacks and to prevent the current evolving cyber attacks. Almost 50% of IoMT devices remain open for exploits, risking serious operational and financial operations for the healthcare systems. To overcome these problems, the use of the forced AI and Machine Learning (ML) based security frameworks have been investigated to address these concerns. Using these techniques, anomaly can be detected in real time, known threats can be identified proactively and the automated security response mechanisms [8]. AI driven security solutions have shown better detection accuracy, adaptability to the new attack patterns as well as system resilience, which make them a key part of the security of the IoMT infrastructure.

C. Research Objectives

This research intends to address the above issue by exploring current state of IoMT security and categorizing security challenges, countermeasures and research gaps. The study gives a structured analysis of threats and mitigation procedures based on AI driven security mechanisms, blockchain based authentication, cryptographic protocols and IDS.

This study is structured to answer the following key Research Questions (RQs):

- RQ1: What are the major security challenges in IoMT?
- RQ2: What proposed countermeasures are there to address the security risks mentioned?
- RQ3: What are these security mechanisms mapped to different IoMT communication layers?
- RQ4: Which research gaps exist on the IoMT security field, and in what directions it should be further researched?

Through answering these research questions, this study will explore the existing studies, trend, and be the foundation for further research in IoMT security. This study follows a systematic methodology for study selection, data extraction and analysis in order to ensure rigor and transparency as per PRISMA 2020 guidelines.

The paper outlines different IoMT threats and security measures in relation to how the system is structured (perception, network, application, cloud). In contrast to other reviews, the conceptual framework, TrustMed-IoMT, which integrates key security controls to guide the development of secure IoMT systems.

In Section II, an in depth overview of IoMT security is provided starting with an analysis of IoMT architecture, a security risk analysis followed by a classification of countermeasures. After that, Section III conducting the security challenges across IoMT layers. Section IV starts with a PRISMA 2020 compliant research methodology that describes the study selection process, inclusion criteria and synthesis methods applied in this study. Section V will represent the existing studies in the area of IoMT. After that, Section VI discusses the findings of the methodology. Section VII concludes the discussion by identifying the current research gaps and points out possible ways to improve IoMT security frameworks. In Section VIII, finally, the key insights are summarized and final thoughts on how IoMT security can progress and what challenges it will face are expressed.

II. Background

A. Overview of IoMT and its Security Importance

The IoMT is a sub specialization of the Internet of Things (IoT) which is used in the sector of healthcare utilizing wearable devices, smart medical sensors and even cloud based health system to monitor patients in real time, get remote diagnostics and other actions within healthcare services [9]. Fig. 1 shows that IoMT systems comprise of wearable health devices, smart monitoring systems, diagnostic centers and electronic medical records that work towards an effective and safe data collection, processing and healthcare management.

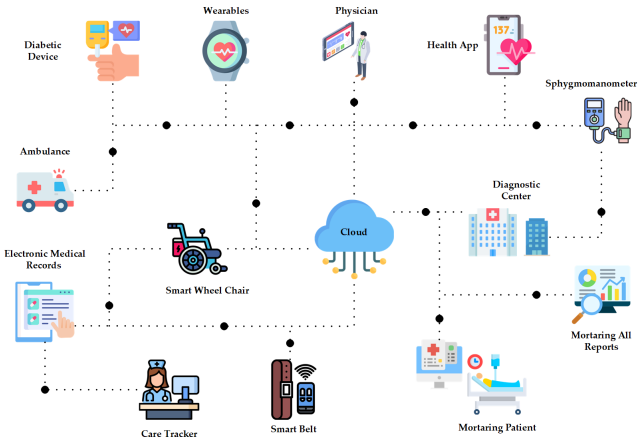

Fig. 1. Architecture of IoMT.

1) The Growth and adoption of IoMT: In recent years, there is a surge of adoption of IoMT a number of steps forward for AI, cloud computing and edge technology [10]. In 2017, the market was around $41 billion and it grew to become $158 billion in 2022 on account of demand for remote healthcare and AI diagnostic platforms. IoMT has also facilitated the Healthcare Industry 5.0's integration with patient monitoring and personalized treatment by smart devices and real time data processing. Although it has grown very fast, IoMT suffers from constraints related to security, interoperability and regulatory issues. Cyber threats to medical devices are also on the rise due to the increased connectivity, while inconsistency in the standards needed for seamless integration prevents it.

2) Importance of security in IoMT: The IoMT devices process, collect, and transmit a huge amount of sensitive patient data that is used for future treatment, specifying huge risks from cyber threats [8]. IoMT systems security breach can result in unauthorized access to Electronic Health Records (EHRs), medical devices manipulation, and even dangerous interruption of healthcare services. According to studies, almost half of the IoMT devices are exposed to certain exploits that could lead to ransomware attacks, malware and unauthorized intrusions to hospitals and patients.

In order, to ensure IoMT security, strong authentication techniques, encrypted data transmission, and always watching the network to prevent unauthorised access is required[10].

TABLE I. LIST OF CHALLENGES AND POTENTIAL THREATS ON EACH LAYER OF IOMT

IoMT Layer	Security Challenges	Potential Threats
Perception Layer	Device vulnerabilities due to limited resources (low power, weak encryption).	Sensor tampering, unauthorized access, data spoofing.
Network Layer	Communication security risks, Man-In-The-Middle (MITM) attacks, and data interception.	Eavesdropping, jamming attacks, DDoS.
Application Layer	Software vulnerabilities in healthcare platforms, unauthorized Application Programming Interface(API) access.	Malware, phishing, ransomware attacks.
Cloud and Edge Layer	Privacy risks due to cloud-based storage, risk of data breaches and leaks.	Insider threats, cloud hacking, unauthorized access.

However, IoMT network security is made even more challenging by the interoperability challenges and the absence of security protocols that are standardized. The adoption of diverse medical devices without a unified security framework means routine data leaks, device hijacking, and in turn regulatory non-compliance risk is increased much higher.

B. IoMT Architecture and Security Layers

IoMT architecture has different layers of interconnected architectural components that allow for data collection, transmission, and processing, which brings distinct security risks. Knowing these layers is very important when designing security strategies as these layers are interconnected and one can be subjected to any other [11]. There are the perception layer which call device layer where used for collecting physiological and environmental data. In addition, network layer where It enables the data transmission over IoMT devices and the cloud with the help of wireless communication technologies like Wi-Fi, Bluetooth, Zigbee. Moreover, application layer where It consists of the user interfaces and the healthcare services. Finally, cloud and Edge Computing infrastructure where where the storage and data analytics are facilitated at the cloud level, and real time processing is facilitated using the edge level.

III. SECURITY CHALLENGES ACROSS IOMT LAYERS

The IoMT ecosystem faces several security vulnerabilities across different layers, posing risks to data integrity, privacy, and device reliability [11], [9]. Table I will list the challenges that may affect each layer along with potential threats.

A. Major Security Challenges in IoMT

The IoMT is improving health care efficiency, but it also brings great security risks that can be analyzed using the CIA (Confidentiality, Integrity, and Availability) triad. The following section analyzes the security challenges of IoMT based on these three fundamental security principles.

1) Confidentiality risks (Data privacy and unauthorized access): The confidentiality helps to maintain the patient data confidential and can be accessed only by authorized persons. However, most of the IoMT devices do not protect sensitive information, which exposes them to attacks [9], [11], [12], [10]. First, the unauthorized access and data breaches which it the attacks on weak authentication mechanisms, it enable attackers to access patient data and patient's medical identity data for medical identity theft and financial fraud [12]. Also, lack of encryption in data transmission on IoMT devices. They are transmitting unencrypted packets which would enable attackers to intercept and manipulate the packets in other word (MITM Attacks) [9]. Additionally, the Insider Threats consider as a challange in IoMT where patient records are exposed either intentionally or unintentionally by employees or compromised accounts [10]. Lastly, the regulatory and non-compliance where many devices fail to meet Health Insurance Portability and Accountability Act (HIPAA), General Data Protection Regulation (GDPR) and other data protection laws; therefore, IoMT systems must comply with such laws [11].

In order to mitigate, you could implement certain controls such as Endto End encryption using Advanced Encryption Standard (AES)-256 for sending out data securely [10]. Moreover, Multi-Factor Authentication (MFA) that may strengthen access control mechanisms. Also, Role Based Access Control (RBAC) that allowing only access of data on the basis of user role, and blockchain for secure medical records that will ensure tamper-proof and auditable patient data storage.

2) Integrity risks (Data manipulation and device security): Medical data accuracy and untouched status depend on the concept of integrity. Medical data inaccuracies which arise from unauthorized changes result in diagnostic errors along with improper treatments and device malfunction. First risk faced is malware and ransomware Attacks. These kinds of attacks involving malware and ransomware grant attackers the ability to modify medical data that exists on or passes through IoMT devices [10]. Also, data tampering via network attacks where the attackers can modify medical reports through unsecured network transmissions which results in incorrect medical diagnosis [9].Moreover, The outdated firmware and patch management which is the use of legacy software by many IoMT devices exposes them to attack because it contains well-documented security weaknesses that hackers can exploit[11]. Lastly, lack of audit trails which is the lack of proper logging systems prevents healthcare staff from noticing when unauthorized data changes occur in patient records [12].

In order to mitigate, digital signatures and hashing (Secure Hash Algorithm(SHA)-256) that will ensure authenticity and resolve if any data tampering, and digital signatures and hashing (SHA-256) [10]. Also, AI-powered anomaly detection that could identify and flag suspicious modifications. As well as firmware Updates and patch management need to be regularly update device software to fix vulnerabilities. Lastly, immutable logs and blockchain integration could maintain a secure, unchangeable history of medical data.

3) System downtime and network attacks: The availability dictates that IoMT services and data remain accessible whenever they are needed. Availability cyber threats may disrupt patient monitoring, delay treatments and cause the loss of life. Such of availability risk Denial-of-Service (DoS) Attacks which is the exploitation of excessive network traffic by attackers disrupts the ability to monitor patients in real-time [9]. Also, device failures due to malware where hospital patient care becomes endangered when malware infects IoMT devices which results in device failure or produces incorrect results [10]. Moreover, cloud and Edge Computing security risks where the healthcare cloud platforms experience three main

security threats which include data center failures plus insider dangers and cyberattacks [12]. Lastly, lack of redundancy and backup Plans where A lack of fail-over protocols in IoMT systems creates complete system downtime during cyber incidents [11].

In order to mitigate you could applied network segmentation where the IoMT devices need to be physically cut off from public networks as a prevention strategy against large-scale attacks [10]. Also, Intrusion Detection and Prevention Systems (IDPS) which is can monitor anomalous activities and block malicious traffic. In addition, cloud-based disaster recovery that can Implement backup systems to recovery systems for attack response. Lastly Edge Computing for localized processing in order to keep devices functioning the company should reduce their dependence on cloud networks.

IV. Research Methodology

The study adopts PRISMA 2020 guidelines to organize a transparent research process which can be reproduced. The research method includes four essential steps which are eligibility criteria, information sources, search strategy, and selection process and data collection and synthesis methods.

A. Inclusion and Exclusion Criteria

The inclusion and exclusion criteria were selected for the studies to ensure that only relevant and high quality research was included.

1) Inclusion criteria: Paper selection was based on the following inclusion criteria: the paper must address security concerns in the IoMT, cover security challenges and risks, discuss mitigation strategies, be peer-reviewed, and have been published between 2020 and 2025.

2) Exclusion criteria: Papers were excluded if they were not focused on Medical IoT, did not address security risks or solutions, were not peer-reviewed, or were published before 2020.

B. Information Sources

A systematic search was conducted on several databases of academic publication as well as digital libraries whose purpose was to ensure that the studies selected are complete and unbiased. The relevant publications on Medical IoT (IoMT) Security Risks: Challenges and Countermeasures were retrieved from IEEE Xplore, ScienceDirect (Elsevier), MDPI, Google Scholar, and the Saudi Digital Library.

C. Search Strategy

The studies relating to security risks, challenges and countermeasures in IoMT were identified using a structured search strategy. The search for relevant literature was performed systematically over information sources. In order to achieve that the most relevant papers were retrieved using structured search query using Boolean operators (AND, OR, NOT). The primary search string was: "Medical IoT" OR "IoMT" AND "security risks" OR vulnerabilities OR threats AND (challenges OR countermeasures).

To ensure a comprehensive search, variations of keywords were used such as: IoMT security, medical IoT security, healthcare IoT threats; IoMT risk assessment, IoMT attack detection, IoMT authentication solutions; IoMT encryption, IoMT privacy challenges, and AI for IoMT security.

The main search string was slightly modified to match the search engine syntax and the database indexing system and each database was queried.

1) Search filters applied: The search was filtered using the following conditions: publication date between 2020 and 2025; publication type limited to peer-reviewed journal and conference papers; and the subject area focused on cybersecurity, IoT security, and AI-driven security.

D. Selection Process

The flow diagram in Fig. 2 indicates how the study selection was carried out following the PRISMA 2020 guidelines. This comprised of three main phases including identification, screening and inclusion.

The selection process involved the following steps: Identification – studies were retrieved from IEEE, MDPI, Saudi Digital Library, and Google Scholar. Screening – an initial filtering was conducted based on title and abstract relevance. Eligibility Assessment – a full-text review was carried out based on the inclusion and exclusion criteria.

The flow of number of studies at each stage was tracked using a PRISMA 2020 Flow Diagram.

1) Identification phase: A total of 365 records were found in major academic databases including IEEE Xplore, Saudi Digital Library, MDPI and Google Scholar. Duplicate (100 studies) and ineligible records (20 studies) were removed. Additionally, 30 records were excluded for other reasons, and 215 records were retained for further screening.

2) Screening phase: The remaining 215 records were subjected to title and abstract screening in order to assess their relevancy to the objectives of the review. Out of this stage, 135 records were discarded as irrelevant to the inclusion criteria. This process yielded 80 records for retrieval and full text review.

3) Eligibility and inclusion phase: Of the 80 records retrieved, 5 were not retrieved due to the unavailability of the studies. A full-text review of the remaining 75 records was performed, and 50 records were excluded. A total of 25 studies were included in the final review after inclusion criteria were met. These studies form a complete and high quality subset which covers the main targets of highlighting the Medical IoT Security challenges and remedies.

The purpose for studying IoMT security from 2020-2025 was to consider the most recent advances in telehealth, blockchain and AI use following the pandemic. Only 25 studies were selected that followed strict criteria and focused on matters of threats, how to address them and how to design systems.

The distribution for the selected papers per year included in this research is shown in the Fig. 3. Of the 25 studies chosen, the most studies were published in 2024 (12 studies)

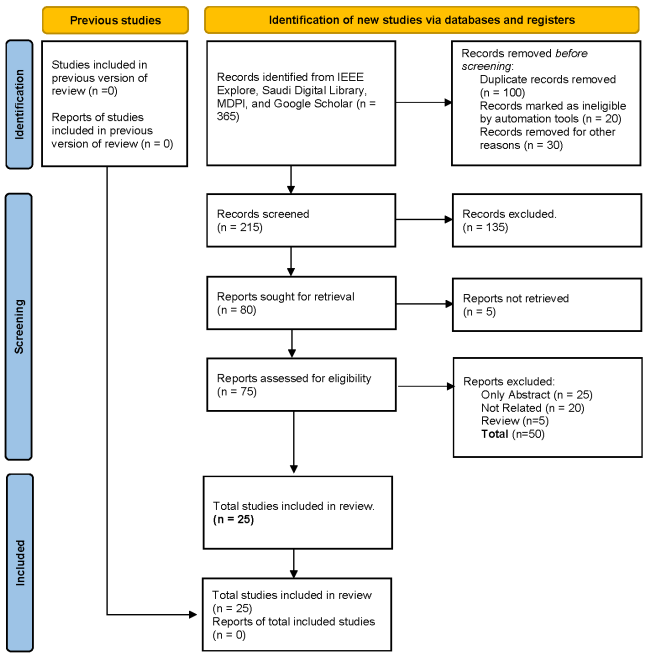

Fig. 2. Selection of papers for research.

with their interest in this area growing. While only 6 studies, the year 2023 continues to pay attention to the IoT security challenges. There are only 3 studies in 2022, 1 in 2021, and 2 in 2020, which significantly decreases the research activity in prior years. However, One study, which contributes to the early year of 2025, is notably included in 2025. As shown by this trend, IoMT security has gained higher importance and significance in recent years and, especially in 2024, it can be considered a newly emerging research domain.

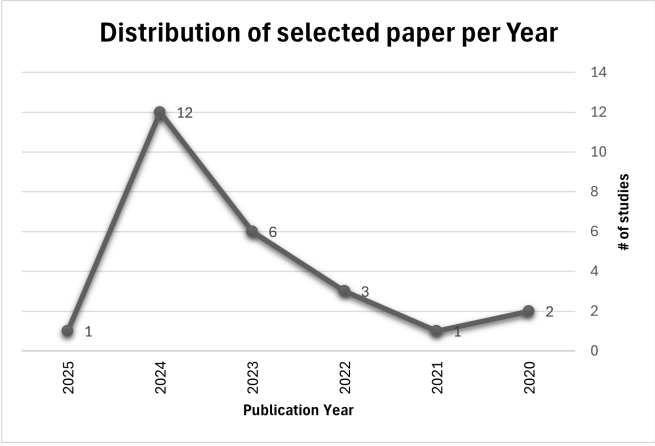

Fig. 3. Distribution of selected paper per year.

V. Existing Studies on IoMT

A. Challenges of IoMT

Yaacoub et al. [13] assess security challenges in the IoMT, particularly from the standpoint of authentication vulnerabilities, privacy risks, malware threats, and network vulnerabilities. They include unauthorized access, ransomware, botnet infection, eavesdropping, DDoS attacks, and pose a major threat to the perception, network, application, and cloud layers. For example, malware injection is a threat to the perception layer, as are eavesdropping and data interception to the network layer. Besides this, the risk of ransomware and privilege escalation is at the application layer whereas the cloud layer is at a risk of data breaches and weak encryption. Additionally, these threats are serious and real world attacks, such as the Mirai botnet, prove so. As a result, problems arising from these issues affect patient safety, data integrity and regulatory compliance. Though such countermeasures and protocols exist for use, there are still limitations including insufficient standard security protocols and weak cryptographic implementations. Hence, the paper asks for lightweight cryptographic mechanisms, AI driven intrusion detection and increased privacy preserving techniques.

According to Bajpayi et al. [14], the security risks of IoMT include authentication flaws, malware attacks, privacy issues, and network vulnerabilities. As a result, these vulnerabilities render critical medical systems susceptible to several attack vectors such as unauthorized access, ransomware, DDoS, eavesdropping, and data breach that consequently affect the perception, network, application, and cloud layers. For example, malware injection is a huge threat for perception layer devices and weak encryption for cloud layer makes it highly vulnerable to data breach. In addition, real world cyber attack cases, like botnet from Mirai also confirm the severity of these risks as impacting patient safety, data integrity, and compliance to regulations in the industry. Similarly, the paper also mentions several drawbacks, which include outdated security patches, weak encryption and insecure device configurations. However, it emphasizes the required security automation improvement, such as employing AI based intrusion detection, lightweight cryptographic models and privacy preserving models to improve the IoMT resilience.

Waqdan et al. [15] evaluate the security risks of IoMT and highlights the problems that are faced with the unauthorized data access, system vulnerabilities, and network security threats. Risk assessment is studied in healthcare settings like emergency rooms with concern in network and application layers. The primary attack vectors that covers are DDoS, data breaches and protocol based exploits. Discussion is also included on real world cyberattacks, such as unauthorized access of patient data. Such security issues impact patient safety, data integrity, system performance, and are also regulatory compliance issues. The concerns that remain unresolved for the IoT devices are accompanied by heterogeneity in devices, limited security updates, as well as high risks of interconnectivity. Therefore, future research on adaptive security frameworks and secure encryption mechanisms to increase IoMT resilience is also suggested by the paper.

Czekster et al. [16] explain the security challenges in IoMT and identify Dynamic Risk Assessment (DRA) risks. The question examined in this study is the cybersecurity concerns in healthcare environment, such as unauthorized intrusions, data breaches, and device malfunction. Security threats significantly affect the perception, network and application layers, with the key attack vectors being unauthorized access, malware

and DoS attacks. Discussions of real world cyber attacks like a ransomware attack on a hospital are also provided. Such threats adversely affect patient safety, data integrity, system reliability and raise regulatory compliance issues. The paper addresses the unresolved security concerns, such as real time risk assessment and improvement of IoT security frameworks. Finally, future research is suggested in developing adaptive security models which can provide security on evolving IoMT threats.

Jayaraj et al. [17] discuss security risks in the IoMT, with an emphasis on wireless spoofing attacks. The study identifies the major threats of spectrum security vulnerabilities, unauthorized access and data breach. In the research, perception and network layers are found to be most affected by the attack and the primary attack vectors being sniffing, spoofing, and protocol based attacks. Cyberattacks on IoMT in the real world are described in relation to patient safety, data integrity, and regulatory compliance risks. Although cryptography and Deep Learning(DL) has improved, security problems are not solved yet. The paper identifies some gaps in recognizing legitimate from rogue transmissions and hence advocates for future work in hybrid security frameworks to enhance IoMT resilience.

The work of Sankepally et al. [18] emphasise critical security challenges in the IoMT and in particular, compromising of the data integrity in the form of false data injection attacks that lead to incorrect diagnosis and jeopardise patient safety. Specifically, the study focuses on vulnerabilities in data transmission and storage, and the network and the application layers are the most affected. Since false data injection attack is the primary attack vector, it can reveal side effects such as increasing system performance along with regulatory infractions. According to this study, the real world cyber threats are referenced and 35% of IoMT using firms suffered breaches in 2016. In proposing a ML based mitigation technique, there are limitations such as data loss, low detection accuracy and propose that there is a need for further research in Explainable AI for more trust and security.

Madanian et al. [19] discuss the critical security challenges in the IoMT where they highlight vulnerabilities across the layers of perception, network, and application. In particular, insecure device authentication, weak cryptography algorithms, and phishing of healthcare institutions are pointed out. Additionally, DDoS, ransomware and data breach comprise the main attack vectors, that affect patient safety, operational capacity and compliance issues. Furthermore, the real world cyberattacks on hospitals emphasize the need for protection of IoMT. Although the paper identifies existent security gaps, in conclusion, the paper also recommends further research on AI based anomaly detection and blockchain technology as a purposed form of increasing data security.

Study by Sasaki [20] deals with security challenges in IoMT paying special attention to security risks related to Remote Maintenance (RM). It points out the threats of unauthorized intrusions that could interfere with operations of IoT devices, compromise patient safety, and misuse of private hospital data by maintenance personnel. The study problem focuses on balancing Maintainability, Safety, Security, and Privacy (MSSP) in IoMT systems. Network and application are the most impacted layers, as these are the layers which get affected with unauthorized access, impersonation attacks and data leakage. Cyberattack on RM channels is discussed as a real world risk. Most of these security challenges relate to patient safety, data integrity and regulatory compliance. It indicates the remaining issues in optimizing security mechanisms without affecting usability and hence recommends further research in security enhanced RM solutions for IoMT.

Table II shows the summary of security challenges addressed in each IoMT layer and possible attacks.

1) Taxonomy of security challenges of IoMT: Fig. 4 provides a layer wise taxonomy of security challenges involved in the IoMT. The challenges are grouped based on perception, network and application layers and are synthesized based on the reviewed studies in Table II.

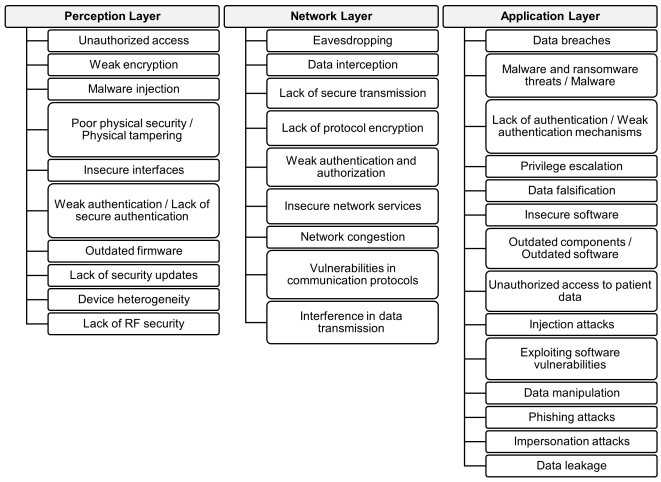

Fig. 4. Layer-based taxonomy of security challenges in IoMT.

B. Countermeasures of IoMT

Xie et al. [21] propose to combat sensor node capture attacks, impersonation threats, moreover non authorized information access, they introduces a lightweight and privacy preserved authentication protocol for Medical IoT. That dual purpose is what the study aims to achieve when it comes to ensuring user anonymity and data security when it comes to using IoT-based healthcare systems. The proposed solution combines the inclusion of Physical Unclonable Function (PUF) and Elliptic Curve Cryptography (ECC) to increase the security notion of the three-factor authentication, and achieves perfect forward secrecy. Securing the user authentication and preventing unauthorized device access is what these countermeasures protect, in the layers of the perception and network. On the other hand, it is low computational cost, improved privacy, and resistant to major cyber threats. There still exist limitations to potential biometric vulnerabilities. Resilience to new IoMT cyber threats and advancement of biometric security are shown in the future research.

Sabrina et al. [22] propose the post quantum privacy preservation technique based on blockchain for solving this issue. This work is motivated by the fact that although healthcare has been an active target of resource constrained data privacy and integrity, the proposed work improves on that by providing privacy and integrity. Based cryptography, Quantum Key Distribution (QKD) and hybrid cryptographic models are

TABLE II. SUMMARY OF CHALLENGES IN IOMT

Author	Security Challenges	IoMT Layer Affected	Attack
Yaacoub et al.[13], 2020	Unauthorized access, weak encryption, malware injection	Perception Layer	Device hijacking, unauthorized access, malware (botnets, ransomware)
	Eavesdropping, data interception, lack of secure transmission	Network Layer	Traffic interception, DDoS, unauthorized access.
	Data breaches, ransomware, lack of authentication	Application Layer	Malware, phishing, privilege escalation, data falsification
Bajpayi et al.[14], 2024	Poor physical security, insecure interfaces, lack of proper encryption, weak authentication, outdated firmware.	Perception Layer	Tampering, jamming, eavesdropping, DoS.
	Lack of protocol encryption, weak authentication and authorization, insecure network services.	Network Layer	MITM, spoofing, wormhole, Sybil attacks, flooding.
	Insecure software, lack of proper encryption, weak authentication, outdated components	Application Layer	Phishing attacks, viruses, worms, Trojans, spyware, DoS.
Waqdan et al.[15], 2023	Lack of security updates, device heterogeneity, physical tampering risks	Perception Layer	Unauthorized access and device manipulation.
	Network congestion, vulnerabilities in communication protocols, and interference in data transmission	Network Layer	DDoS attacks, MITM attacks, and packet sniffing
	Unauthorized access to patient data, weak authentication mechanisms, malware and ransomware threats.	Application Layer	Data breaches, injection attacks, exploiting software vulnerabilities
Czekster et al.[16], 2023	Unauthorized access, lack of secure authentication	Perception Layer	Physical tampering, unauthorized access
	Insecure communication, data interception	Network Layer	MITM attacks, DoS
	Data breaches, malware infections, ransomware	Application Layer	Malware, ransomware, data integrity breaches
Jayaraj et al.[17], 2024	Unauthorized access, lack of RF security	Perception Layer	Physical attacks, Sniffing
	Spectrum security vulnerabilities, unauthorized transmissions	Network Layer	Spoofing
	Data integrity risks, unauthorized control	Application Layer	Exploiting software vulnerabilities
Sankepally et al.[18], 2022	Data manipulation	Perception Layer	False Data Injection
	Data transmission vulnerabilities	Network Layer	MITM Attacks, False Data Injection
	Compromised patient data, incorrect diagnosis	Application Layer	False Data Injection
Madanian et al.[19], 2024	Insecure device authentication, physical tampering, data breaches	Perception Layer	MITM, Replay Attacks, Physical Tampering.
	Weak cryptographic algorithms, lack of encryption, eavesdropping, DDoS	Network Layer	DDoS, IP Spoofing, Eavesdropping, Packet Injection.
	Phishing attacks, malware, ransomware, outdated software, weak authentication	Application Layer	Ransomware, Phishing, Malware, Structured query language(SQL) Injection
Sasaki [20], 2020	IoT device disruption, patient safety risk	Perception Layer	Unauthorized access, device tampering
	Data leakage, remote intrusion	Network Layer	Man-in-the-middle, unencrypted communication
	Unauthorized hospital data access, impersonation	Application layer	Social engineering, weak authentication

some of the proposed countermeasures. By providing secured perception, network and application layers, the secure medical data transaction from quantum threats. The advantages are decentralization, on the fact that is immutable and the chain is to be resistant to future post quantum cryptographic vulnerabilities. There is, however, still computational overhead and complexity of integration. This paper inspires further research on how to encourage development of the optimal quantum resistant blockchain framework and to develop the energy efficient cryptographic algorithms for IoMT applications.

Mavhemwa et al. [23] propose an adaptive user authentication model for elderly IoMT users in an effort to address the authentication usability and security challenges. The aim of the study is to improve authentication accuracy by not degrading usability for the elderly. A naive bayes risk aware authentication model is proposed that uses health condition and risk scores to assign authenticators. In this approach, the trust score of the user can be used to alter the difficulty at which authentication should take place such that the perception, network and application layers are protected. The resulting benefits are also the reduction of authentication fatigue or the improvement of usability and, finally, dynamic security. These do come at the cost of overfitting and reduced usability. Future research recommends fortifying biometric security, extending the dataset for the purpose of validation and indicating the optimal authentication procedure for a wide range of IoMT applications.

To address the above stated security risks like unauthorized access to personal information of the patient, data breach and privacy issues in smart health care systems, Kumar et al. [24] propose A Novel Architectural Framework (ANAF)-IoMT. It aims at providing advanced authentication, enhanced data privacy and secure storage for IoMT environments. Include Rooted Elliptic Curve Cryptography with Vigenère Cipher (RECC-VC), Exponential K-Anonymity (EKA) for preserving privacy and blockchain as secure data storage. These protect against this at perception, network and applications layers by securing data transmission, user authentication and cloud storage. The advantages are that of higher security 98%, better privacy and resistance against the cyber threats. A challenge still remains however, of computational overhead. In future research, it will be more worthwhile to optimize the encryption efficiency and incorporate quantum resistant security measures.methods.

Laabab et al. [25] Propose to combat identity theft, data breaches and invalid access, offers an integration of biometric systems and blockchain in IoMT. The aim of the study is to improve the tasks of authentication, access control and data integrity in the environment of healthcare. Biometric based authentication with blockchain smart contracts are the proposed counter measures for the secure and decentralized identity verification. These solutions protect all the perception, network, and application layers via encrypted tamper proof identity verification and logging transactions. This also provides for enhanced security, transparency and privacy. With Challenges in computational complexity and integration issues. Optimizing biometric encryption methods and working for blockchain scalability to utilize in real time IoMT applications is suggested to be conducted in future research.

Alsadhan et al. [26] Propose to overcome unauthorized

access, data breaches as well as the lack of patients control in the IoMT. The intention of the study is to protect the patient's data from being lost by using decentralized identity management and access control. It suggests permissioned and permissionless blockchain models, cryptographic methods, and smart contracts as the proposed countermeasures. These solutions secure the storage layer, encrypted transactions, and fine grained access control for the perception, network and application layer. Its advantages include greater transparency, immutability as well as reduced (or even no) single points of failure. However, the energy consumption and integration complexity as well as scalability are challenges. Research for the future can concentrate on enhancing scalability of blockchain, enhancing the efficiency of encryption, and implementing a private preserving consensus.

Mahmood et al. [27] discuss critical security challenges in the IoMT like unauthorized access of data, malware attack and privacy breach. The study is centered around security issues in IoMT stakeholders, architecture and solutions. In order to meet these threats, the authors suggest a security framework consisting of the access control, encryption, threat detection, and incident response protocols. The countermeasures protect all layers of IoMT (perception—device security, network—secure transmission, and application—data privacy). However, the proposed solutions improve patient data confidentiality and the redundancy of the system but have the limitation of implementation complexity and resource constraints. Therefore, future research is suggested to enhance IoMT security without performance trade-off via lightweight security mechanisms and AI-driven threat detection.

Sandulescu et al. [28] explore the security issues such as data privacy, unauthorized access and device interoperability in IoMT. Specifically, it integrates IoMT with AI driven healthcare solutions, and specifically discusses the security concerns in this data transmission and storage. Encryption protocols, secure data transmission and access controls in the ICIPRO cloud infrastructure are proposed countermeasures. These solutions ensure confidentiality and integrity of the perception, network, and application layers of IoMT. It guarantees better patient data compliance and security. However, high implementation costs and data privacy concern still exist. Future research might include improving protocols of interoperability between IoMT devices to further enhance security frameworks, as well as improvement of AI driven anomaly detection.

Subramaniam et al. [29] propose an interoperable privacy enhanced framework to address the security risks in IoMT. This study will work on overcoming problems of data privacy, authentication vulnerabilities, and secure data transmission. In order to achieve this, the proposed security solutions are device authentication with Secure Credentials (SCs), data encryption with Twine-LiteNet, and data integrity verification with Ten Fold Cross Entropy Verification (TCEV). These countermeasures protect the IoMT from the perception, network, and application layers. The method increases throughput, lowers the latency and extends the network's longevity. However, computational overhead and suitability to various IoMT environments are the limitations.

Su and Xu [30] discuss critical security issues in the IoMT that cover vulnerabilities of user authentication, privilege escalation attacks and resource limitations in IoMT devices. The study proposes a Three-factor Cluster-based user Authentication Protocol(3ECAP), a Secure and lightweight cluster based User authentication protocol, which supports fine grained access control using Merkle trees, multi factor authentication as well as efficient session key establishment. These countermeasures protect against IoMT attacks that work through any of the layers of perception, IoMT and application by securing communication, blocking unauthorized access and avoiding privilege escalation. It has advantages such as low computational cost and high resistance to cyber threats of common type. However, there are limitations as it increases overhead associated with access control. Further research lies in scaling up the environment scalability and integrating the AI based anomaly detection for real time security in IoMT scenarios.

Alsolami et al. [31] discusse some of the critical security challenges in the IoMT such as data breaches, malware, device hijack and insider threats. The research is aimed at intrusion detection using ensemble learning, such as Stacking, Bagging and Boosting to improve cybersecurity in medical networks. Moreover, the main goal of these countermeasures is to protect the network and application layers of the cyberspace against cyberattacks in real time. The proposed models achieve 98.88% accuracy and are more accurate, scalable and adaptable than the current models. However, they come with limitations; one of them being the risk of overfitting and the other being the computational complexity. Future research would include making improvements to the Boosting techniques and increase the diversity in dataset as Boosting techniques are subject to applicability in real world. The contribution of this study is towards securing healthcare environments by progressing intelligent detection systems against evolving IoMT threatening.

Krishna M et al. [32] address the significant challenge of DoS attacks in the IoMT. The aim of the research is to improve the security of IoMT through an IDS using ML algorithms including Support Vector Machine (SVM), Random Forest(RF), Linear Discriminant Analysis (LDA), and K-Nearest Neighbors (K-NN). These countermeasures analyze network traffic and detect countermeasures by attacking patterns to mitigate DoS threats. The IDS protects the network layer primarily, and it guarantees the safe data transmission. The advantage of the proposed approach is the high detection accuracy and adaptability, while the disadvantage is the lack of dataset and real-time implementation. Future improvement includes optimizing IDS to be deployed in a realworld environment as well as contribute to increasing the diversity of the dataset to generate more resilient IoMT security.

Balhareth and Ilyas [33] propose an IDS to reduce security threats in the Internet of Medical IoMT. The study is on detection of cyber threats in IoMT networks using ML based IDS. It is proposed that the use of tree based classifiers (Decision Tree (DT), RF, eXtreme Gradient Boosting (XGBoost), and CatBoost) with a filter based feature selection method (Mutual Information (MI) and XGBoost) increases the detection accuracy. The main objective of these countermeasures is to protect the network and application layers from real time threat detection. The benefits include a 98.79% accuracy rate and a 0.007 false alarm rate. However, it focuses on binary classification. Future work is to implement multi class classification to detect the attack type and to evaluate the

performance of such detection capabilities in real world IoMT domain.

Alalwany et al. [34] propose a real time IDS for critical security risks in the IoMT by means of Stacking ensemble DL approach. The goal of the study is to protect IoMT from cyber threats including ARP spoofing, DoS, Smurf and Port Scan attacks. This security solution uses an ensemble stacking method of integrating ML and DL models to increase the accuracy and the time detection speed. The IDS is implemented using Kappa Architecture to minimize latency and speed up threat response. Continuously monitoring data streams to detect anomalies in all IoMT layers (perception, network and application) provide the countermeasures that safeguard all the layers. However, it has advantages such as high accuracy, adaptability and low false positive rates. However, there is an overhead associated with computation and also dependency on the dataset. Future research on the model includes making it more efficient, and scaling up the amounts of data it collects for better generalization.

Bodapati and Raj [35] present security challenges in IoMT regarding data confidentiality and authentication against cyber–physical attacks. The study focuses mainly on lightweight encryption solutions for resource constrained medical devices. An FPGA based implementation of the ASCON-128 encryption algorithm is proposed to be used as a secure data transmission countermeasure. This solution improves security by being Authenticated Encryption with Associated Data (AEAD) which limits interception and tampering of data. The main aim of IoMT is to secure the perception and network layers. It also requires 35% less LUTs and increases the encryption throughput by 45%. However, there is still some room for optimization of the approach for real time medical applications. Further future research indicates that increasing rounds per cycle can improve encryption efficiency further.

Arpaia et al. [36] study security vulnerabilities of IoT medical transducers, and proposes methods to mitigate side-channel attacks such as Differential Power Analysis (DPA) and Correlation Power Analysis (CPA). Also, cryptographic countermeasures are evaluated, such as random delay insertion, random SBox, and masking to enhance AES encryption. The protection of the perception and network layers of IoMT is achieved by disrupting power consumption patterns and increasing the difficulty of the attack. The most effective one was masking, increasing security by a factor of 318. However, there are still limitations with regard to computational overhead. The future research concludes on optimizing the attack detection mechanism as well as power countermeasures for resource constrained devices. It is also recommended to strengthen the security regulations for the IoMT devices in order to provide robust protection against the existing and emerging cyber threats.

Patni and Lee [37] present EdgeGuard, which is a decentralized security framework for IoMT, dealing with data privacy, malicious attacks and service inefficiency. The primary contribution of this study is to leverage blockchain secured federated learning for secure medical resource orchestration. To ensure security, it comes with a lightweight blockchain consensus mechanism, adaptive federated learning with differential privacy, and access control based on smart contract. The countermeasures ensure data integrity, confidentiality and resource efficiency for IoMT's perception, network and application layers. However, although the approach improves in security, scalability, and real time responsiveness, it suffers for computational overhead as well as for energy consumption. Improvements in the future are to optimize blockchain efficiency and quantum train cryptographic methods that are better protected in healthcare IoT environments.

Table III shows the summary of security Countermeasures proposed to address the security challenge in IoMT layers.

Table IV shows the performance comparison of security countermeasures proposed to address the security challenge in IoMT layers along with strengths and weaknesses of the countermeasures.

VI. Existing Findings of the Studies

In this study, we analyze existing 25 studies in the IoMT and clarify the nature of the problems of security risks in IoMT and discuss the recommended countermeasures for those risks at various architectural layers in IoMT applications. It accomplished this by analysing the posed RQs methodically.

A. RQ1: Major Security Challenges in IoMT

The eight of studies revealed several critical IoMT device security threats that are significant including data breach, unauthorized access, malware infection, system downtime from DDoS like cyberattacks, and more. Different vulnerabilities were involved with each architectural layer of IoMT [13], [14], [15]:

1) Perception layer: Because IoMT devices have limited device resources, vulnerabilities of IoMT devices come from the IoMT devices such as they are vulnerable to physical tampering, unauthorized access, and spoofing attacks.

2) Network layer: MITM attacks and the eaves dropping attacks were almost based on the weak and insecure communication protocols and encryption standards that were used.

3) Application layer: Malware existent on software vulnerabilities and lax authorization mechanism were risky and had resulted to malware infections, ransomware attacks, unauthorized API access.

4) Cloud and Edge computing layer: The majority of risks were in the privacy breach, data leak, and cloud infrastructure vulnerability categories, involving health-sensitive data.

B. RQ2: Proposed Countermeasures to Address IoMT Security Risks

To mitigate identified risks, 17 of existing studies suggest several proactive and reactive countermeasures [27], [21], [22]:

1) Cryptographic solutions: Some of the recommendations were regarding the use of lightweight cryptographic models (ECC and AES-256), blockchain based encryption and quantum resistant methods to ensure secure storage and transmission of data.

2) Authentication and access control: Improve authentication mechanisms, such as biometric integration, blockchain-based identity management, and MFA, were suggested to mitigate unauthorized access

TABLE III. SUMMARY OF SECURITY COUNTERMEASURES IN IOMT

Author	Year	Security Challenge Addressed	Proposed Countermeasure	Technology Used	Layer Targeted
Xie et al. [21]	2023	Sensor node capture, impersonation, unauthorized access	Lightweight authentication with ECC and PUF	ECC, PUF	Perception, Network
Sabrina et al. [22]	2024	Quantum attacks on cryptographic security in IoMT	Post-quantum privacy preservation using blockchain	Lattice-based cryptography, QKD, hybrid cryptographic models	Perception, Network, Application.
Mavhemwa et al. [23]	2024	Authentication usability and security for elderly IoMT users	Adaptive authentication using risk-based Naive Bayes model	ML, Android-based authentication, MFA	Perception, Network, Application.
Kumar et al. [24]	2022	Unauthorized access, data breaches, privacy concerns in IoMT	ANAF-IoMT framework using RECC-VC, EKA, and blockchain	RECC-VC, EKA, Blockchain	Perception, Network, Application.
Laabab et al. [25]	2024	Identity theft, unauthorized access, data breaches in IoMT	Blockchain-integrated biometric authentication	Smart contracts, fingerprint recognition, decentralized identity management	Perception, Network, Application.
Alsadhan et al. [26],	2024	Unauthorized access, data breaches, lack of patient control	Blockchain-based privacy preservation with smart contracts	Permissioned and permissionless blockchain, cryptographic techniques	Perception, Network, Application.
Mahmood et al.[27]	2023	Unauthorized access, malware attacks, privacy breaches	Access control, encryption, threat detection, incident response	Cryptography, AI-driven threat detection, lightweight security models	All layers.
Sandulescu et al.[28]	2024	Data privacy, secure transmission, and unauthorized access	Encryption, access control, and secure cloud storage	ICIPRO cloud security, secure data transmission protocols	Network, Application.
Subramaniam et al.[29]	2023	Data privacy, authentication vulnerabilities, secure data transmission	Device authentication (SCs), encryption (Twine-LiteNet), integrity verification (TCEV)	SCs, Twine-LiteNet encryption, TCEV verification	All layers.
Su and Xu [30]	2024	Authentication vulnerabilities, privilege escalation, and resource constraints in IoMT	3ECAP: Secure and Lightweight Cluster-Based User Authentication Protocol	Merkle trees,MFA, session key establishment	All layers.
Alsolami et al.[31]	2024	Data breaches, malware, device hijacking, insider threats	IDS using ensemble learning	Stacking, Bagging, Boosting with Radio Frequency (RF) and SVM	Network, Application.
Krishna M et al.[32]	2023	DoS attacks in IoMT	IDS	ML (SVM, RF, LDA, K-NN)	Network Layer.
Balhareth and Ilyas [33]	2024	Intrusion detection in IoMT networks	ML-based IDS with feature selection	Tree-based ML (DT, RF, XGBoost, CatBoost), MI-XGBoost	Network, Application.
Alalwany et al.[34]	2025	ARP spoofing, DoS, Smurf, Port Scan attacks	Stacking ensemble DL-based IDS	ML, DL, Kappa Architecture	All layers.
Bodapati and Raj [35]	2022	Data confidentiality, authentication, and cyber-physical attacks	FPGA-based ASCON-128 encryption	FPGA, ASCON-128 (lightweight AEAD cipher)	Perception, Network.
Arpaia et al. [36]	2021	Side-channel attacks (DPA and CPA) on AES encryption in IoT medical transducers	Random delay, Random SBox, Masking	AES Encryption	Perception, Network.
Patni and Lee [37]	2024	Data privacy, malicious attacks, service inefficiencies	Blockchain-secured federated learning (EdgeGuard)	Blockchain, Federated Learning, Edge Computing, Smart Contracts	All layers.

3) AI and ML: Anomaly detection or intrusion detection and systems strategies that incorporated AI-based tools along with ML tools and DL systems such as RF, SVM and others were found to be highly efficient in real-time threat detection and response.

4) Cloud security measures: Use of blockchain and encryption methods in handling, storing and retrieving information sought to enhance security of cloud and Edge Computing systems against internal and external attacks.

C. RQ3: Security Mechanisms Mapped to IoMT Communication Layers

The reviewed studies presented security mechanisms explicitly mapped to the IoMT communication layers [21], [25], [33]:

1) Perception layer: Aimed at lightweight encryption (e.g., ECC, PUF), biometric authentication, and secure device hardware (i.e., preventing physical attacks, unauthorized access).

2) Network layer: Secure communication protocols such as blockchain and transaction security using the power of AI for IDS came into the picture as the first line of defense against interception and spoofing of data transmission.

3) Application layer: New layers of authentication were considered as well as encryption for API's and the use of artificial intelligence based threat detection systems were also recommended.

4) Cloud and Edge computing layer: For better confidentiality, integrity and availability of data, blockchain based secure storage and quantum resistant cryptographic models were significant.

TABLE IV. SUMMARY AND PERFORMANCE COMPARISON OF SECURITY COUNTERMEASURES IN IOMT

Author	Strengths	Weaknesses	Performance
Xie et al. [21]	Enhanced privacy, low computational cost.	Potential biometric vulnerabilities	11.296 ms, Low CPU with high security.
Sabrina et al. [22]	Decentralization, immutability, resistance to post-quantum attacks.	Computational overhead, integration complexity	Not implemented.
Mavhemwa et al. [23]	Improved usability, dynamic authentication, risk-aware security.	Potential overfitting, usability challenges for some users	Accuracy: 98.6%, AUC: 1.0, FRR & FAR: 0.0.
Kumar et al. [24]	High security (98%), improved privacy, blockchain integrity.	Computational overhead, integration complexity	Security: 98%, Accuracy: 96%.
Laabab et al. [25]	Enhanced authentication, tamper-proof identity verification, improved privacy.	Computational complexity, biometric spoofing risks, integration challenges	Not implemented.
Alsadhan et al. [26]	Increased transparency, immutability, reduced single points of failure.	Scalability issues, high energy consumption, integration complexity	Not implemented.
Mahmood et al.[27]	Enhances data security and system resilience.	Implementation complexity, resource constraints.	Performance not quantitatively measured.
Sandulescu et al.[28]	Ensures data confidentiality and integrity.	High implementation cost and privacy concerns	Accuracy up to 97.1%
Subramaniam et al.[29]	Improves throughput, reduces latency, enhances security.	limited adaptability, computational overhead.	+20% throughput, -10% energy use/delay, +35% network lifetime.
Su and Xu [30]	Strong security, low computational cost.	Overhead in access control management	24.14 ms total cost; 1696-bit communication
Alsolami et al.[31]	High accuracy (98.88%), real-time detection, scalable.	potential overfitting, high computational cost.	Accuracy: 98.88% (Stacking); AUC: 1.0; real-time detection with low latency.
Krishna M et al.[32]	High accuracy, adaptive detection.	limited dataset availability, real-time implementation challenges.	Highest SVM: Receiver Operating Characteristic 99.97%, Sensitivity 99.27%.
Balhareth and Ilyas [33]	High accuracy 98.79%, low false alarm (0.007).	limited to binary classification.	Accuracy: 98.79%, FAR: 0.007 (CatBoost).
Alalwany et al.[34]	High accuracy, real-time detection, low false positives.	computational overhead, dataset dependency.	Accuracy: 99.13% (binary), 99.3% (multi-class); detection time: 0.888 ms.
Bodapati and Raj [35]	35% less LUT usage, 45% higher throughput.	Needs further optimization for real-time medical applications.	1330 LUTs, and 457 Mbps throughput; 56% higher throughput/area compared to baseline.
Arpaia et al. [36]	Masking is most effective (318x protection)	increases computational overhead	Masking: 318× AES protection; Random SBox: 208×; Random delay: 1.3×.
Patni and Lee [37]	High security, scalability, real-time responsiveness.	Computational overhead, energy consumption.	Accuracy: 94.34%; –30.67% communication overhead; robust to 40% malicious nodes.

D. RQ4: Research Gaps and Future Directions

Several research gaps were identified through this SLR, highlighting areas requiring further exploration [21], [18], [35]:

1) Adaptive security frameworks: Need to do more research on the design of Adaptive Security Frameworks, that is Scalable and Real Time Responsive security mechanisms, which can dynamically handle future IoMT threat.

2) Resource efficiency: Future studies should consider the cost of computational overheads and resource in current security measures with such aim of enhancing efficiency without compromising performance.

3) Interoperability standards: Interoperability standards to reduce system complexities and improve security comprehensively among IoMT network of heterogeneous devices.

4) Quantum-resistant solutions: Since the advent of quantum computing is closer now than ever, quantum resistant blockchain solutions as well as crypto techniques need to be researched to ensure that the IoMT is securely resilient for a long term.

VII. CONCEPT DEVELOPMENT

Based the outlined literature analysis suggests this study proposes a security framework called **TrustMed-IoMT** which seeks to address various security issues in IoMT areas. Instead of focusing on the technical side, TrustMed-IoMT serves as a plan for integrating blockchain, AI and cryptography that boosts the safety of all the layers in IoMT.

The framework is structured provide three core components:

1) Blockchain-based identity and access control: Make sure data and authentication cannot be modified at the perception and cloud layers.

2) AI-driven intrusion detection systems: Detecting and responding to threats in the network and application areas.

3) Quantum-resistant encryption: Using techniques such as lattice-based cryptography and QKD, security in the long run is assured while dealing with the cloud.

All these components are assigned to the perception, network, application and cloud/edge layers to build the defense-in-depth strategy. IoMT systems must be improved to make them ready for any future attacks such as ones caused by quantum technology.

TrustMed-IoMT is built on research in the field and can guide research to develop more reliable, wide-ranging, intelligent and secured healthcare IoT systems.

VIII. Conclusion

This study analyzed security risks across the IoMT and covered all major types of security vulnerabilities along with countermeasures. The findings from the study showed that IoMT systems are susceptible to many security challenges spanning from various layers ranging from unauthorized access, malware infections, and data breaches to service disruptions. A key finding is that advanced and integrated security frameworks are an essential feature in today's world and includes lightweight cryptographic techniques with use of blockchain solution, biometrics, and AI enabled IDSs. The strategic approach to enhancing overall system resilience was applied security mechanisms to various IoMT layers were clearly depicted.Adaptive security frameworks, efficient resource utilization with implementation of standards, and adoption of quantum-resistant technologies significant areas for improving IoMT security. Moreover, Solutions such as IDS using ensembles and identity management using blockchain achieved over 98% accuracy. Still, obstacles exist in connecting different systems, using them efficiently and testing them in real situations. These points should be addressed to create systems in IoMT that are both scalable and secure. In addition, Further research should, therefore, target the closing of these gaps by means of scalable and standardized solutions that satisfy the latest cybersecurity threats, and the continuously growing complexity of IoMT infrastructures. In short, further development and cooperation will be necessary to retain safe health care technology, protect important patient data, and continue to provide a stable and safe health care system in an ever more digitalized health care network.

The study is limited by the fact that it uses information from previous research that may use different conditions and testing methods. In addition, several solutions were evaluated in controlled situations which makes it hard to apply them in the real world. Researchers should focus more on putting their systems into practical use and analyzing their performance.

Predictive Maintenance Based on Deep Learning: Early Identification of Failures in Heavy Machinery Components

Pablo Cabrera Melgar, Luis Hilasaca Chambi, Raúl Sulla Torres
Universidad Nacional De San Agustín De Arequipa, Arequipa, Perú

***Abstract*—Deep learning-based predictive maintenance is a key strategy in industry to prevent unexpected failures, reduce downtime, and improve operational safety. This study presents an advanced approach for early fault detection in heavy machinery components using image analysis, focusing on four critical defect types: hose wear, piston failure, corrosion, and moisture. To this end, three state-of-the-art object detection models were implemented and compared: YOLOv11, RT-DETR, and YOLO-World. The dataset consists of images captured in real-life industrial environments exhibiting variations in lighting, texture, and material degradation. A manual preprocessing and annotation process was applied to improve training quality. Model performance was evaluated using key metrics such as the precision-recall (PR) curve and the confusion matrix to determine the most efficient technique for real-time fault detection. Experimental results show that YOLOv11 achieves the highest overall accuracy, with an mAP@0.5 of 83.8%, followed by YOLO-World at 82.4% and RT-DETR at 80.3%. In terms of efficiency, YOLO-World offers a balance between accuracy and detection speed, while RT-DETR shows stable performance but lower accuracy for certain defect types. These findings confirm that deep learning-based detection models enable the rapid and accurate identification of industrial defects, facilitating the implementation of predictive maintenance strategies.**

***Keywords*—Predictive maintenance; deep learning; fault detection; artificial intelligence**

I. Introduction

Maintenance of heavy machinery is a critical issue in industry, as unexpected failures can lead to high operating costs, downtime and safety risks. Traditionally, corrective and preventive maintenance strategies have been used. Corrective maintenance consists of repairing a machine only when it fails, which can cause costly interruptions. Preventive maintenance, on the other hand, involves scheduled inspections and repairs, even if they are not always necessary, which can increase costs without ensuring efficiency [1]. In this context, deep learning-based predictive maintenance has emerged as an innovative solution that enables early detection of failures through real-time data analysis [2]. This methodology not only optimizes intervention planning, but also reduces operating costs, minimizes downtime, and improves the efficiency of industrial inspections, contributing to greater productivity and safety in working environments [3].

Recent advances in computer vision have facilitated the automation of fault detection in mechanical components, enabling accurate defect identification through image analysis [4]. In particular, object detection models have demonstrated high performance in visual inspection tasks, providing scalable and efficient solutions for industrial maintenance [5]. However, most existing studies focus on general-purpose datasets, operate under controlled laboratory conditions, or focus on isolated defect types, which limits their applicability in real-life industrial settings. Furthermore, many models prioritize accuracy over inference speed, making them unsuitable for real-time applications where immediate fault detection is crucial.

Therefore, there is a clear gap in the literature regarding the implementation of fast, accurate, and generalizable object detection models in real-life industrial settings, specifically for the detection of multiple simultaneous faults in heavy machinery components. This work addresses this gap by integrating state-of-the-art object detection architectures capable of managing visual variability, complex backgrounds, and diverse fault types under operating conditions.

In this study, three state-of-the-art models are evaluated: YOLOv11, RT-DETR, and YOLO-World. These were selected for their advanced capabilities in balancing speed and accuracy, their adaptability to diverse visual inputs, and their proven performance in object detection benchmarks. YOLOv11 offers a strong balance between real-time performance and detection accuracy. RT-DETR incorporates transformer-based attention mechanisms that improve the recognition of small or occluded defects. YOLO-World offers greater flexibility in managing open vocabulary detection, which is essential when defect categories evolve or are refined over time.

The primary objective of this research is to develop an automatic visual inspection system for detecting defects in heavy machinery components based on deep learning. The system focuses on four recurring industrial defects: hose wear, piston failure, moisture, and corrosion. To achieve this goal, a specific dataset of high-resolution images captured under real-world working conditions was created and manually annotated. The models are trained and evaluated to compare their accuracy, processing speed, and generalization capabilities in realistic scenarios.

The paper is organized as follows: Section II provides a review of related work, Section III details the methodology, Section IV presents the experiments and results, and Section V presents conclusions.

II. Related Work

This study [6] proposes an improved version of the VGG19 convolutional neural network, named Multipath VGG19

(MVGG19), for the detection of defects and the recognition of industrial objects. Six public data sets with images of mechanical parts and defective materials were used. MVGG19 improves feature extraction using a multi-path scheme and concatenation fusion. The experiments showed that MVGG19 outperforms VGG19 in five of the six datasets, with an average improvement of 6.95% in the classification accuracy.

This paper in [7] presents a deep learning-based approach to identify defects in images, exploring segmentation and unsupervised detection methods. For evaluation, the MVTec Anomaly Detection (MVTec AD) dataset is used, which provides images with more than 70 types of anomalies and accurate pixel-level annotations. Different approaches based on deep neural networks, such as autoencoders and generative models, are compared with traditional computer vision techniques. The results obtained show the performance of the evaluated methods and highlight improvement opportunities for applications in real environments.

The objective of the research [8] is the development of a multi-phase Convolutional Neural Network (CNN) model to detect and analyze corrosion in metallic materials. The model employs binary classification, multiclass classification and patch distribution to identify affected areas. It was trained with 600 images, achieving 94.87% accuracy in binary classification, 92.1% in multiclass classification and up to 96.5% in patch distribution. In addition, it achieved 91.5% accuracy in region segmentation at the image level and 89.2% at the pixel level. This approach is useful for experts in critical industries such as aerospace and manufacturing and can be applied in other areas beyond corrosion.

In this paper [9], PatchCore is presented for anomaly detection in industrial manufacturing using a representative memory pool of nominal local features, achieving a balance between inference times and performance. In the MVTec AD benchmark, it achieves an AUROC of up to 99.6%, halving the error rate compared to the best competitor. Furthermore, it offers competitive results on other datasets and in scenarios with few samples.

In this study [10], a comprehensive review of deep learning-based anomaly detection techniques is presented, analyzing neural network architectures, supervision levels, loss functions, metrics and datasets. In addition, a framework based on industrial environments is proposed and current approaches are evaluated under this context. Open challenges in image anomaly detection are also highlighted and the advantages and limitations of various architectures depending on their supervision level are analyzed.

The objective of this research [11] is to analyze the use of convolutional neural networks (CNN) for the automated detection of corrosion on metallic surfaces. For this purpose, different CNN architectures are compared, including pre-trained models and specific designs adapted to this problem. The results show that CNNs outperform traditional methods based on texture and color analysis, improving both the accuracy and efficiency of the inspection process. In addition, one of the proposed architectures significantly optimizes the computational time, maintaining a performance comparable to that of the most advanced models.

This study [12] proposes a method based on artificial neural networks to detect internal leakage in hydraulic cylinders by analyzing pressure signals. Key features such as location, height and width of the peaks are extracted, reducing dimensionality and optimizing processing. The neural network classifies the system into three states: optimal, mild failure and severe failure. This approach improves the detection of leaks caused by wear and seal damage, increasing the reliability and efficiency of hydraulic systems in heavy machinery, reducing costs and maintenance times in industrial environments.

This research [13] analyzes the current challenges and provides a review of the most recent unsupervised approaches, organized into five categories. In addition, public datasets used in this area are presented and different methods are compared to identify their advantages and disadvantages. Finally, unsolved problems are highlighted and future lines of research are proposed to foster the development of more efficient and applicable solutions in different industrial sectors.

This study [14] presents a semi-orthogonal embedding-based approach for unsupervised anomaly segmentation by optimizing the use of multi-scale features of pre-trained CNNs along with Mahalanobis distance. It aims to mitigate the high computational cost associated with multidimensional covariance tensor inversion, a key limitation for scalability in deep networks. To this end, random feature selection is generalized using semi-orthogonal embedding, which allows for a more efficient and robust approach, cubically reducing the computational cost without affecting performance. Experiments on standard datasets, such as MVTec AD, KolektorSDD, KolektorSDD2 and mSTC, show that this method outperforms the state of the art, achieving significant improvements in accuracy and efficiency. These results validate its applicability in large-scale anomaly detection.

The research proposes [15] a new framework called PaDiM for image anomaly detection and localization within a single-class learning environment. PaDiM employs a pre-trained convolutional neural network (CNN) for patch-level feature extraction and models the normal class distribution using multivariate Gaussian distributions. In addition, it takes advantage of correlations between different semantic levels of the CNN to improve anomaly localization. The proposal outperforms current methods on MVTec AD and STC datasets, and extends the evaluation protocol to measure its performance on unaligned datasets, getting closer to real industrial inspection scenarios. Thanks to its low computational complexity and high performance, PaDiM is presented as a viable alternative for various industrial applications.

The study [16] proposes Abyss Fabric, an automated system for corrosion detection and monitoring on offshore platforms, improving maintenance efficiency. Using computer vision and a Convolutional Neural Network (CNN), it segments inspection images and integrates the results into a digital twin to identify corrosion and its severity. Evaluated on an oil platform, it achieves 91.83% accuracy, processing large volumes of data automatically and optimizing maintenance planning, reducing costs and operational risks.

The research proposes [17] an unsupervised deep learning model for anomaly detection in temporal data of manufacturing processes, with the aim of improving the interpretability and scalability of these systems in industrial environments. Its ap-

plication in the assembly tightening process in the automotive industry demonstrates a significant improvement in anomaly identification, facilitating its implementation and overcoming the limitations of conventional approaches.

This study [18] proposes a crash response testing method and frequency-domain analysis to detect defects in shock absorber rods and steering racks on an automotive production line. Machine and deep learning were used to build a discrimination model based on features extracted from the measured signals. The results indicate that frequency analysis accurately identifies the location and presence of defects, improving quality control and facilitating the implementation of smart factories.

III. Methodology

The proposed methodology, illustrated in Fig. 1, focuses on detecting faults in heavy machinery components using deep learning. The objective is to identify signs of deterioration in real time, enabling the implementation of predictive maintenance strategies. The methodology consists of four main phases: data collection, preprocessing, model training, and model evaluation.

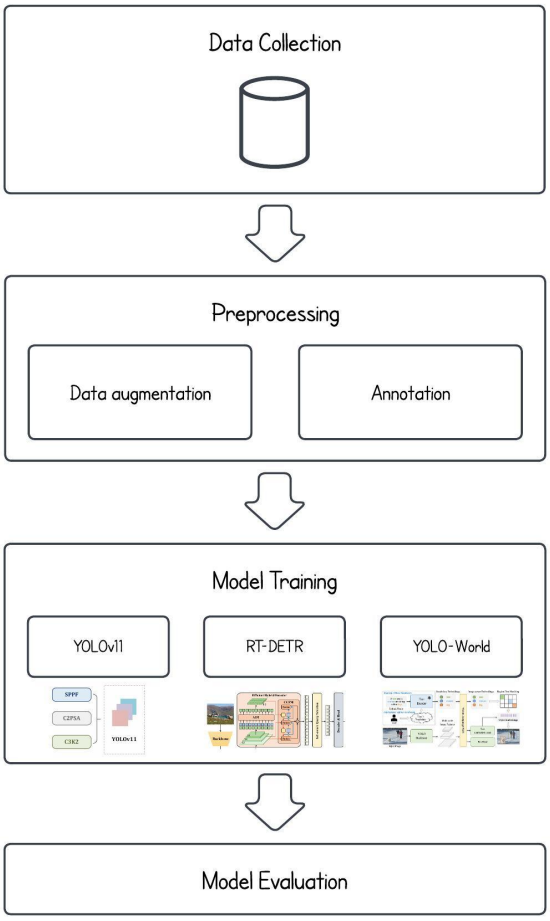

Fig. 1. Proposed methodology.

A. Data Collection

The dataset used in this study was developed from scratch and consists of images captured in real industrial environments, with the goal of ensuring representative and relevant samples. The images were taken with a high-resolution camera, allowing for an adequate level of detail for visual fault identification. During the capture process, specific criteria related to image quality are determined, such as good resolution and lighting conditions that ensure clear visibility of critical areas of the machinery. Furthermore, efforts were made to include images under different operating conditions to increase the variability and robustness of the dataset.

The dataset covers four main types of failures in heavy machinery: hose wear, piston failure, moisture, and corrosion. Hose wear includes cracks, abrasions, and deformations in hydraulic and pneumatic systems due to prolonged use or extreme conditions. Piston failure manifests as oil leaks, cracks, or loss of displacement efficiency. Moisture refers to the presence of water or oil, which can indicate leaks or condensation. Finally, corrosion refers to the deterioration of metallic components due to exposure to moisture, chemicals, or aggressive environments. This unique dataset forms the basis for the development of an automated fault detection system, focused on improving predictive maintenance strategies in industrial settings. Representative images of each type of fault are presented in the Fig. 2.

Fig. 2. Component failure dataset.

Table I presents the four defect classes used for training, along with the number of labeled instances in the component failure dataset. These classes represent common failure types in heavy machinery, where accurate detection is essential for predictive maintenance.

B. Preprocessing

To optimize the performance of the fault detection system for heavy machinery components, the dataset underwent a preprocessing process that included two key stages: data augmentation and detection annotation. These techniques improved the model's ability to identify faults under a variety of conditions,

TABLE I. DATASET CLASSES AND LABELS

Classes	Labels
Hose wear	324
Piston failure	268
Moisture	234
Corrosion	638

ensuring better generalization and reducing the impact of a limited dataset.

1) Data augmentation: Given the challenges of collecting large quantities of defect images in industrial environments, common data augmentation techniques, such as rotation, flipping, brightness adjustments, and contrast modifications, are employed to simulate various real-world conditions. These transformations were applied using standard libraries such as `Albumentations` and `OpenCV`, widely used in computer vision. This approach improves the robustness and generalization capabilities of deep learning models, increasing their accuracy under different lighting, orientation, and perspective conditions [19].

2) Annotation: Each image in the dataset was manually annotated using bounding boxes to accurately identify the faults present. To ensure labeling consistency and quality, an annotation protocol was applied that included: a clear definition of each fault type supported by visual examples, precise delineation of the affected areas, and expert cross-review to validate each annotation.

This rigorous annotation process is crucial, as label accuracy and consistency directly affect the model's ability to learn useful representations. In industrial applications, where fault detection can entail significant costs, labeling quality is a determining factor for the effectiveness of predictive maintenance systems [20].

C. Model Training

For early detection of faults in heavy machinery components, three advanced models are selected: YOLOv11, optimized for real-time detection and capable of rapid response to anomalies during operation; RT-DETR, based on transformer architectures, which stands out for its high accuracy in identifying complex defects through contextual and spatial analysis of images; and YOLO-World, which integrates vision-language modeling for open vocabulary detection. This combination ensures an optimal balance between speed, accuracy, and flexibility for continuous industrial monitoring.

1) YOLOv11: It is an advanced real-time detection model that improves feature extraction using C3k2, SPPF, and C2PSA blocks, achieving greater accuracy (mAP) and computational efficiency [21]. Its high speed and ability to detect small defects make it ideal for predictive maintenance, allowing anomalies in industrial components to be identified before critical failures occur. Its scalable design facilitates deployment on both edge devices and high-performance environments, optimizing early detection and reducing downtime. Fig. 3 illustrates the architecture of YOLOv11.

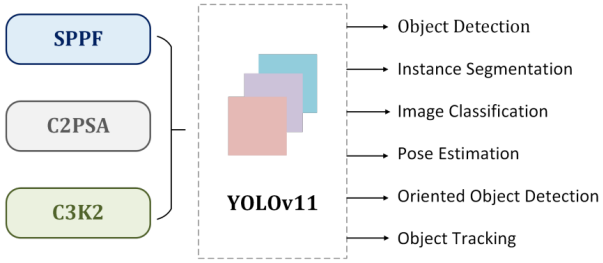

Fig. 3. Architecture of YOLOv11.

2) RT-DETR: This is a Vision Transformer-based detection model designed to operate in real time without the need for non-maximum suppression (NMS), which improves its efficiency [22]. Its architecture, illustrated in Fig. 4, optimizes multi-scale feature fusion using a hybrid encoder and IoU-based query selection, enabling higher detection accuracy. This balance of speed and accuracy makes it particularly suitable for applications such as surveillance, autonomous driving, and predictive maintenance in industrial environments.

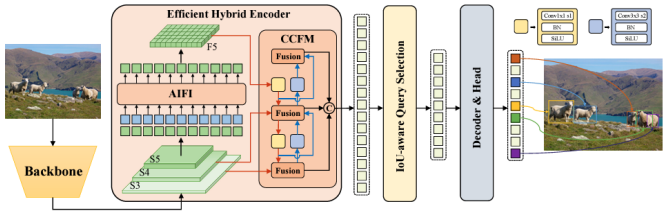

Fig. 4. Architecture of RT-DETR.

3) YOLO-World: It is an extension of the YOLO series that introduces open vocabulary detection capabilities through vision-language modeling and pre-training on large datasets [23]. To this end, it incorporates the Re-parameterizable Vision-Language Path Aggregation Network (RepVL-PAN) and a region-text contrastive loss, which improves the interaction between visual and linguistic information. This approach enables object detection in a zero-shot scenario with high efficiency. The architecture of the model is illustrated in Fig. 5. In addition, its tuned version exhibits outstanding performance in tasks such as object detection and instance segmentation with open vocabulary.

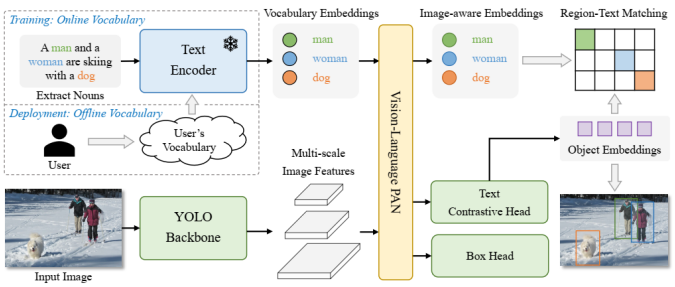

Fig. 5. Architecture of YOLO-World.

IV. Experiments and Results

To evaluate the performance of the selected object detection models YOLOv11, RT-DETR, and YOLO-World a comprehensive set of experiments was conducted using the proprietary Component Failure Dataset, specifically designed for detecting faults in heavy machinery components. This section details the evaluation methodology, performance metrics, and experimental results, providing a thorough assessment of each model's effectiveness in real-world industrial applications.

A. Model Performance Evaluation

The selected models were trained and validated under industry-relevant conditions, ensuring a realistic assessment of their detection accuracy, computational efficiency, and real-time applicability. The evaluation framework incorporated key performance metrics to provide a holistic analysis of each model's strengths and limitations:

1) Precision-Recall (PR) curve: Provides insights into the trade-off between precision and recall, helping assess detection reliability across different defect types.

2) Confusion matrix: Analyzes classification accuracy, highlighting correct detections and common misclassifications to identify areas for improvement.

3) Inference speed (FPS - Frames Per Second): Determines the efficiency of the model processing, which is critical for real-time fault detection in industrial environments.

This structured evaluation ensures that models are evaluated not only in terms of accuracy, but also in terms of deployment feasibility, computational efficiency, and their ability to minimize false detections in an real setting.

B. YOLOv11

To evaluate YOLOv11 performance in detecting component failures, we present the precision-recall (PR) curve and the confusion matrix, which provide insight into its detection capabilities.

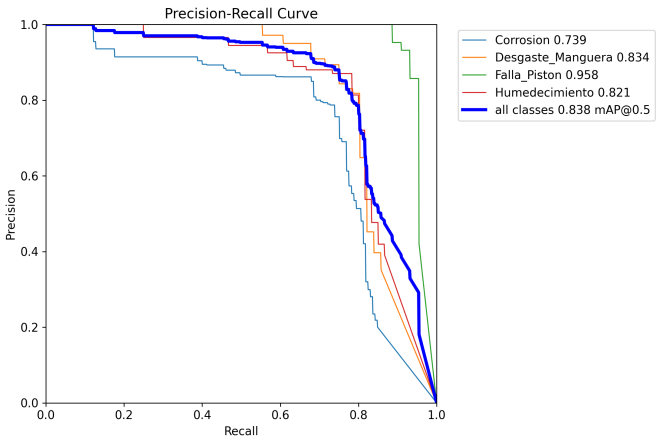

Fig. 6. PR_curve YOLOv11.

Fig. 6 shows the precision-recall (PR) curve of YOLOv11, highlighting its performance in detecting four types of defects: corrosion, hose wear, piston failure, and moisture. The model achieves an overall average precision (mAP@0.5) of 83.8%, with its best performance in detecting piston failures 95.8%, followed by hose wear 83.4% and moisture 82.1%. However, corrosion has the lowest performance 73.9%, suggesting potential challenges in its identification.

Together, these results demonstrate the robustness of YOLOv11 for industrial fault detection, while highlighting opportunities for improvement, particularly in corrosion detection.

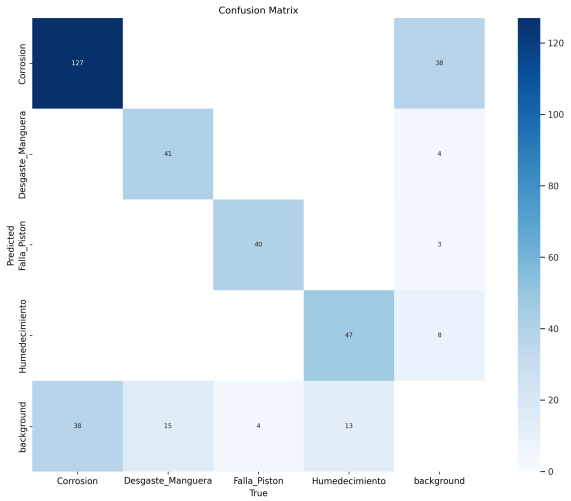

Fig. 7. Confusion matrix YOLOv11.

In Fig. 7, the confusion matrix provides a detailed evaluation of YOLOv11 classification performance in detecting defects in heavy machinery. The correct predictions are concentrated on the main diagonal, demonstrating high precision for most categories, including corrosion, hose wear, piston failures, and moisture. The model achieves excellent performance in identifying piston failures and hose wear, with minimal misclassifications.

However, some misclassifications are observed, especially in corrosion, where they are incorrectly classified as background. Similarly, some moisture cases are also misclassified as background, suggesting that the model may have difficulty distinguishing these defects under certain conditions. These results highlight the robustness of YOLOv11 in defect detection while also indicating potential areas for improvement, especially in reducing misclassifications with the background category.

C. RT-DETR

The performance of the RT-DETR model in detecting defects in heavy machinery is evaluated using the PR curve and the confusion matrix, allowing a detailed analysis of its detection accuracy.

Fig. 8 shows the precision-recall (PR) curve obtained with the RT-DETR model for the detection of different types of faults in heavy machinery components. Individual curves are presented for each evaluated class: Corrosion 73.4%, Hose Wear 84.4%, Piston Failure 91.8% and Moisture 71.6%. In

addition, the overall performance curve of the model for all classes is included, obtaining an (mAP@0.5) of 80.3%. These results indicate good performance of the model in fault detection, with the "Piston Failure" class presenting the highest precision compared to the others.

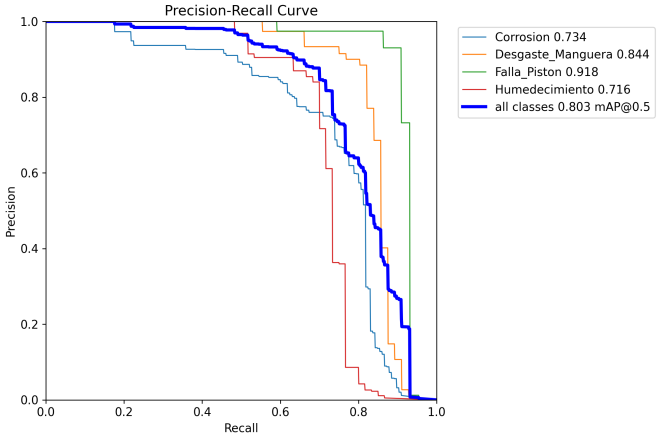

Fig. 8. PR_curve RT-DETR.

Fig. 9 presents the confusion matrix, which allows a detailed analysis of the RT-DETR model performance in identifying faults in heavy machinery.The model performs solidly in detecting piston faults and hose wear, with a low number of misclassifications. However, some confusions were identified, especially in the corrosion category. Similarly, certain examples of moisture were misclassified, suggesting that the model may have difficulty differentiating these faults under specific conditions.

These findings demonstrate the effectiveness of the RT-DETR model in detecting industrial defects, although they also highlight areas for improvement, primarily in reducing false negatives in the classification of corrosion and moisture.

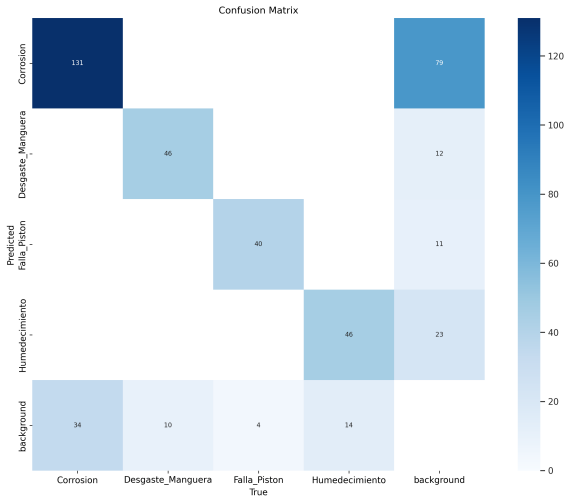

Fig. 9. Confusion matrix RT-DETR.

D. YOLO-World

To evaluate the performance of the YOLO-World model in industrial fault detection. In particular, the Precision-Recall (PR) curve and the confusion matrix allow analyzing the model's ability to differentiate between different classes of defects.

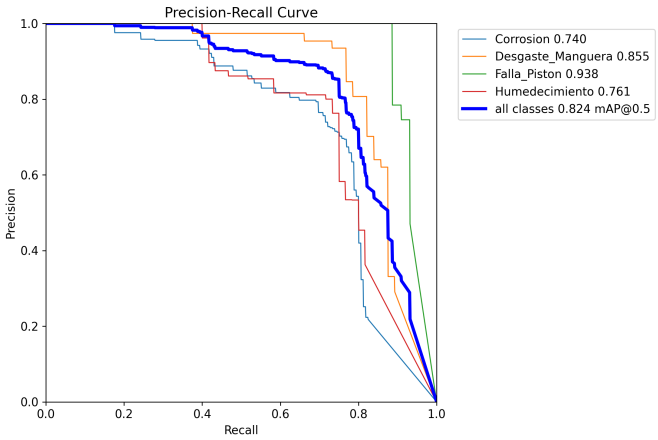

Fig. 10. PR_curve YOLO-World.

Fig. 10 presents YOLO-World PR curve, with an overall mAP@0.5 of 82.4%. The highest detection accuracy is achieved for piston failure 93.8%, followed by hose wear 85.5%, moisture 76.1%, and corrosion 74.0%. While the model performs well, corrosion detection remains the most challenging category.

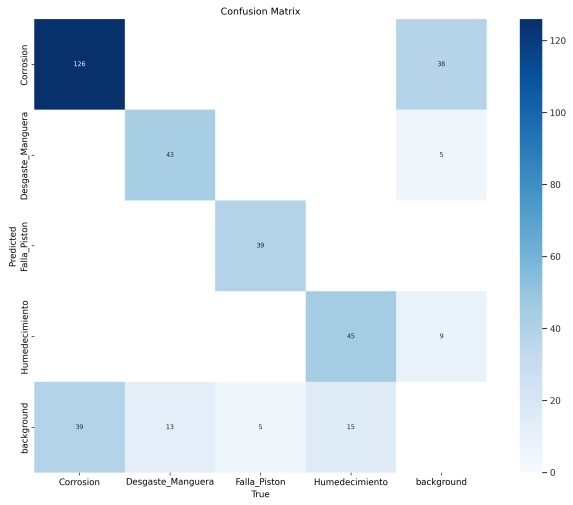

Fig. 11. Confusion matrix YOLO-World.

The confusion matrix Fig. 11 shows that YOLO-World achieves high accuracy, with most correct predictions aligned on the diagonal. However, corrosion and moisture exhibit higher misclassification rates, indicating potential difficulties in distinguishing these defects from background noise. Further refinement in feature extraction could improve the model's accuracy in these categories.

In general, YOLO-World demonstrates competitive performance, although improvements in corrosion and wetting detection could further improve its reliability.

E. Comparison and Discussion

The performance of the three selected object detection models, YOLOv11, RT-DETR, and YOLO-World, was analyzed based on their detection accuracy and computational efficiency. This section provides a comparative discussion of the models' strengths, limitations, and potential improvements in detecting faults in heavy machinery components.

Table II shows a comparison of the performance of the YOLOv11, RT-DETR, and YOLO-World models in fault detection, evaluated by overall accuracy, mAP@0.5, and inference time. Among them, YOLOv11 stands out as the most accurate model, achieving an mAP@0.5 of 83.4%, indicating its high ability to accurately identify defects. Furthermore, its inference time of 32.6 ms positions it as an efficient option for real-time applications [21].

On the other hand, RT-DETR achieved the highest overall accuracy 94.6%, but its mAP@0.5 of 80.3% was the lowest, suggesting that its detection may be less reliable compared to the other models [22]. Furthermore, its high inference time 45.7 ms makes it less suitable for speed-critical environments. In contrast, YOLO-World offers the best balance between accuracy and efficiency [23], with a mAP@0.5 of 82.4% and the lowest inference time 29.7 ms, making it the best alternative for real-time detection tasks, although with a slight reduction in accuracy compared to YOLOv11.

TABLE II. COMPARISON OF RESULTS

Model Results			
Model	**Accuracy(%)**	**mAP@0.5(%)**	**infer(ms)**
YOLOv11	89.1%	83.4%	32.6
RT-DETR	94.6%	80.3%	45.7
YOLO-World	90.2%	82.4%	29.7

The images in Fig. 12 illustrate detection examples for the three models. These images show how each model identifies component defects, highlighting the differences in accuracy and misdetection. This visual comparison reinforces the findings in the table, providing a clear representation of each model's strengths and weaknesses in detecting faults in heavy machinery components.

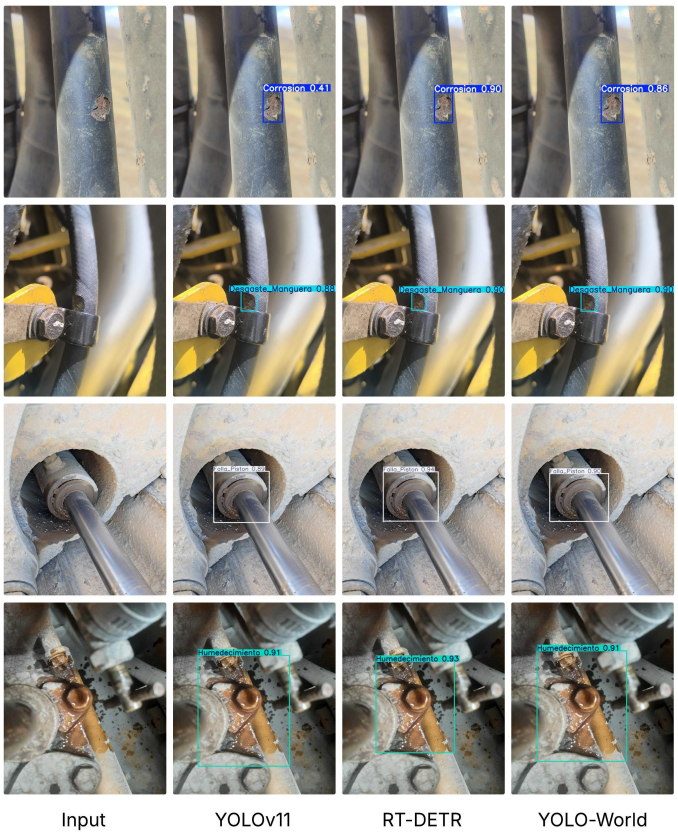

Fig. 12. Detection result of the three models.

V. CONCLUSION

The study demonstrates that computer vision and deep learning models, such as YOLO-World, YOLOv11, and RT-DETR, are highly effective for fault detection in industrial environments, combining accuracy and operational efficiency. Among them, YOLOv11 achieved the highest overall accuracy, with an (mAP@0.5) of 83.8%, outperforming YOLO-World 82.4% and RT-DETR 80.3%. However, YOLO-World stood out for its balance between accuracy and inference speed, making it particularly suitable for real-time applications. These results underscore the importance of selecting models that are not only accurate but also adaptable to real-world conditions, ensuring efficient and reliable performance.

Furthermore, the study identifies that certain classes of defects, such as corrosion and moisture, exhibit lower accuracy compared to other detected faults. To address this limitation, it is proposed that future work include a larger number of images of these defects, thereby improving the representation of these classes in the dataset. This strategy, along with other techniques such as data augmentation and model fine-tuning, will contribute to increasing the system's accuracy and robustness, optimizing its performance in predictive maintenance applications.

Department of Computer Science-College of Computers and Information Technology,
Taif University, Taif, Saudi Arabia[2]

***Abstract*—Accurate topic labeling is essential for structuring and interpreting large-scale textual data across various domains. Traditional topic modeling methods, such as Latent Dirichlet Allocation (LDA), effectively extract topic-related keywords but lack the capability to generate semantically meaningful and contextually appropriate labels. This study investigates the integration of a large language model (LLM), specifically ChatGPT, as an automatic topic label generator. A dual evaluation framework was employed, combining keyword-based and context-based assessments. In the keyword-based evaluation, domain experts reviewed ChatGPT-generated labels for semantic relevance using LDA-derived keywords. In the context-based evaluation, experts rated the alignment between ChatGPT-assigned topic labels and actual content from representative sample posts. The findings demonstrate strong agreement between AI-generated labels and human judgments in both dimensions, with high inter-rater reliability and consistent contextual relevance for several topics. These results underscore the potential of LLMs to enhance both the coherence and interpretability of topic modeling outputs. The study highlights the value of incorporating context in evaluating automated topic labeling and affirms ChatGPT's viability as a scalable, efficient alternative to manual topic interpretation in research, business intelligence, and content management systems.**

***Keywords*—Automatic label generation; topic modeling; Large Language Models (LLMs); topic labeling; semantic relevance**

I. Introduction

The exponential growth of digital content has necessitated advanced mechanisms for topic modeling and document classification, particularly in domains requiring structured knowledge extraction. Traditional approaches, such as Latent Dirichlet Allocation (LDA) [1] and Non-Negative Matrix Factorization (NMF) [2], have been widely employed in topic modeling. However, these statistical techniques often struggle with contextual understanding and semantic relevance due to their reliance on word co-occurrence patterns rather than intrinsic meaning representation. In contrast, recent advances in natural language processing (NLP) and deep learning have led to the proliferation of transformer-based models, which demonstrate a remarkable ability to capture nuanced linguistic structures and contextual dependencies [3].

Large language models (LLMs), including generative systems like OpenAI's ChatGPT, have garnered increasing attention for their potential applications in text classification, summarization, and topic labeling. Beyond topic modeling, LLMs have been integrated into various NLP tasks, such as named entity recognition (NER) [4], sentiment analysis [5], machine translation [6], and information retrieval [7], showcasing their ability to generalize across multiple domains. These models leverage deep contextual embeddings to understand syntactic and semantic nuances, enabling them to outperform traditional methods in tasks that require complex linguistic reasoning. While previous studies have explored the efficacy of deep learning models in topic modeling [8], limited research has examined the robustness and consistency of LLM-generated topic labels against traditional methodologies. This gap is particularly significant in high-stakes domains such as academia and industry, where the accuracy of topic classification directly impacts knowledge organization and retrieval [9].

In this study, we investigate two key research questions: (1) To what extent can ChatGPT reliably generate accurate and consistent topic labels when compared to domain experts? (2) What is the potential of ChatGPT in assisting domain experts for more efficient and accurate topic labeling in large-scale text datasets? To address these questions, we evaluate ChatGPT's ability to generate semantically meaningful topic labels by incorporating multiple similarity measures, including Jaccard Similarity and Cosine Similarity, combined with a Majority Voting mechanism to systematically assess labeling accuracy. The results demonstrate that the combination of these measures provides strong evidence of ChatGPT's effectiveness in generating accurate and semantically relevant topic labels.

The implications of this research extend beyond topic modeling, contributing to the broader discourse on the interpretability and reliability of generative AI models in structured classification tasks. This study sheds light on the evolving role of LLMs in automated knowledge management and retrieval, and how they may assist domain experts in more efficient knowledge categorization.

II. Related Work

The rapid advancement of large language models (LLMs), such as OpenAI's ChatGPT, has sparked significant interest across various fields, particularly in the areas of natural language processing (NLP) and automated text analysis [10][11][12]. Traditional techniques in topic modeling, such as Latent Dirichlet Allocation (LDA) and Non-Negative Matrix

Factorization (NMF), have been instrumental in identifying hidden semantic structures in text corpora. However, these methods often face challenges in capturing deeper contextual and semantic nuances in texts. Recent studies have explored the potential of transformer-based models, particularly ChatGPT, to bridge these gaps, offering new possibilities for interpreting and labeling topics. Scheepers et al. [13] conducted an initial study on interpreting topic models with ChatGPT, demonstrating that the model could assist in generating human-readable summaries for topics identified by traditional topic modeling techniques. Their findings revealed that ChatGPT's ability to describe topics accurately could be leveraged to enhance the interpretability of topic modeling outputs, particularly when prompted correctly.

Building on the potential of ChatGPT in content analysis, Guo et al. [14] investigated how ChatGPT compares to human experts in terms of response quality across a range of domains, including financial, medical, legal, and psychological areas. Their analysis, which included a large dataset (the Human ChatGPT Comparison Corpus, HC3), found that while ChatGPT could produce valuable insights, there were notable gaps when compared to human expertise. This highlighted the need for further evaluation of the model's performance and its alignment with expert judgment. Similarly, Wang et al. [15] explored ChatGPT's viability as an evaluator for natural language generation (NLG) models, comparing its assessments to human judgments. They concluded that ChatGPT achieved competitive correlations with human evaluators, particularly excelling in tasks that involve summarization, underscoring its potential as a reliable evaluator for NLG systems.

Another study by Alyafeai et al. [16] assessed the performance of ChatGPT-based models on various Arabic NLP tasks, such as sentiment analysis, machine translation, and diacritization. Their findings showed that while ChatGPT's performance in some tasks, such as summarization, exceeded that of state-of-the-art approaches, the model still faced challenges with certain language-specific tasks. This study underscored the importance of contextual understanding and the limitations of generalized models like ChatGPT in highly specialized linguistic environments.

In the context of software engineering, Ronanki et al. [17] examined the use of ChatGPT for evaluating the quality of user stories in agile development. Their work demonstrated that ChatGPT could be an effective tool for evaluating user stories, aligning closely with human evaluations in terms of consistency and accuracy. This study also emphasized the need for a reliable "best of three" strategy to improve the stability of ChatGPT's evaluations, ensuring that its output could be trusted for practical applications.

Despite the promise shown by these studies, ChatGPT is not without its limitations. Wu [5] evaluated ChatGPT's problem-solving abilities across various NLP tasks, revealing that while the model performed well in areas like question answering and arithmetic, it struggled with tasks that required commonsense reasoning or complex understanding. This highlights a significant gap in ChatGPT's capabilities, suggesting the need for further improvements, especially in handling more sophisticated linguistic challenges. Additionally, Koubaa et al. [18] provided a critical review of ChatGPT, emphasizing its technical innovations while also pointing out areas where the model needs further refinement, particularly in handling tasks that require deep reasoning and context-specific expertise.

Overall, while ChatGPT has demonstrated considerable potential as an evaluator across different NLP tasks, its performance remains inconsistent across domains, necessitating further research to refine its abilities and improve its reliability. These studies collectively suggest that while ChatGPT can assist domain experts in interpreting topics and evaluating content, it must be adapted and fine-tuned for specific applications to reach its full potential. As more research is conducted, it is likely that ChatGPT and similar LLMs will continue to evolve, offering new possibilities for automating complex tasks traditionally performed by human experts.

III. Methodology

This section presents the framework developed in this study, shown in Fig. 1, which integrates keyword-based and context-based evaluations of topic labels generated by ChatGPT. The workflow begins with Latent Dirichlet Allocation (LDA) to extract topic keywords from a large corpus, followed by automated labeling using ChatGPT. Both the coherence and interpretability of these labels are assessed through a mixed-methods evaluation involving domain experts.

The study evaluates topic modeling performance across two dimensions: (1) keyword-based labeling, where ChatGPT is prompted to assign topic labels based on LDA-extracted keywords, and experts assess the semantic relevance of those labels; and (2) context-based labeling, where representative sample posts for each topic based on how accurately they reflect the assigned label using a Likert scale of contextual relevance.

This dual assessment framework enables a comprehensive evaluation of ChatGPT's effectiveness in supporting topic interpretability. A comparative analysis of expert agreement with AI-generated labels highlights the potential of large language models to enhance topic modeling tasks in research, business intelligence, and content management systems.

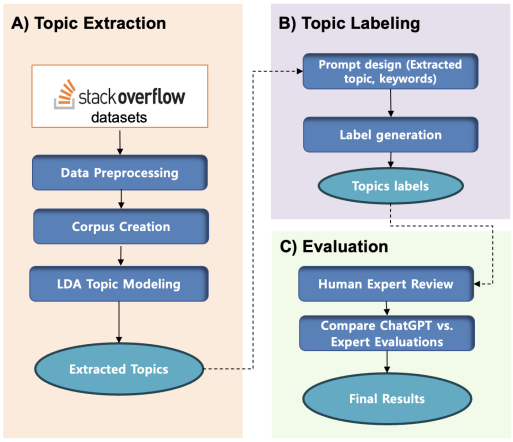

Fig. 1. The workflow of integrating LLMs in topic labeling.

A. Topic Modeling Using LDA

For this research, we utilize the Stack Overflow Posts dataset [19], a diverse source of user-generated questions,

answers, and discussions on software development topics. As one of the largest online communities for developers, Stack Overflow provides rich technical content covering programming languages, frameworks, and common challenges.

The dataset consists of 44,000 posts, each containing a Title and Body. The Title offers a concise description of the issue or question, while the Body provides detailed explanations, discussions, or responses. This structure enables an analysis of both high-level problem descriptions and in-depth technical details.

Stack Overflow is an ideal choice for this study due to its specialized terminology, programming jargon, and references to specific frameworks. The complexity of its content makes it well-suited for topic modeling, where generated topics often contain detailed subtopics and technical nuances. Evaluating topic coherence in this dataset is challenging due to the specialized vocabulary and potential ambiguity of terms across contexts. For instance, words like "Java," "Python," "API," and "debugging" may appear in multiple topics with different meanings.

ChatGPT plays a crucial role in assessing topic coherence by interpreting technical jargon and providing consistent evaluations, addressing challenges that human annotators might face in maintaining consistency across complex discussions. Topic modeling is conducted using Latent Dirichlet Allocation (LDA) [20], an unsupervised machine learning technique that identifies latent topics in large text collections. The process involves several steps:

1) Data preprocessing: The text data undergoes preprocessing to remove irrelevant content, such as URLs and common stopwords. Words are tokenized and stemmed to normalize different word forms into their base form.

2) Corpus creation: A dictionary is constructed, mapping each unique word to an ID, and a corpus is generated, representing the text as a bag of words. This corpus serves as input for the LDA model.

3) Model training: The LDA model is trained using the preprocessed corpus. The number of topics is set to five, and the model runs through 15 iterations to ensure convergence [21].

4) Topic extraction: After training, the top topics are extracted from the model, each represented by a set of keywords. These keywords define the core themes of the topics, providing insights into the underlying structure of the text.

Topic coherence measures the semantic similarity within a topic, indicating how related the words within each topic are [22]. In this study, coherence is measured using the c_v metric, which computes the degree to which the top words of each topic frequently appear together in the text corpus. A higher coherence score suggests that the words in the topic are more likely to form a meaningful and interpretable theme. The c_v score is derived by integrating statistical co-occurrence metrics with semantic similarity, ensuring a balance between data-driven insights and interpretability [23]. The coherence score is computed as illustrated in Eq. (1).

$$c\_v = \frac{1}{|T|} \sum_{t \in T} \frac{1}{|t|} \sum_{1 \le i < j \le |t|} \text{NPMI}(w_i, w_j) \tag{1}$$

Where:

noitemsep, topsep=0pt

- T is the set of topics,
- t is an individual topic containing a set of words,
- w_i, w_j are word pairs within a topic,
- $\text{NPMI}(w_i, w_j)$ is the normalized pointwise mutual information between word pairs.

To evaluate the coherence of topics, the CoherenceModel from Gensim is used [24]. This model computes the coherence score based on the tokenized text and dictionary, providing an essential metric for assessing the quality of the topics generated by the LDA model.

B. ChatGPT-Based Topic Labeling

Interpretability refers to the extent to which the identified topics are meaningful and understandable in the context of the original text [25]. In this study, interpretability is assessed through both keyword-based and context-based evaluations involving ChatGPT-generated labels and expert reviews.

To enhance the accuracy and consistency of topic labeling, ChatGPT is prompted using a role-playing approach, where it assumes the role of an NLP expert specializing in topic modeling. This method ensures that ChatGPT evaluates topics with a structured, expert-like perspective rather than relying solely on statistical patterns. Recent studies have shown that role-playing prompts improve AI performance by guiding the model to adopt domain-specific reasoning strategies, leading to more contextually relevant and accurate outputs [26].

In the keyword-based phase, after the LDA model generates topics, ChatGPT systematically analyzes their coherence and interpretability by assessing the relevance of extracted keywords and their alignment with real-world themes. In its expert role, ChatGPT follows a structured decision-making process: it critically examines the provided keywords, determines the most precise and semantically meaningful topic label, and justifies its selection. This approach reduces ambiguity and enhances the semantic clarity of topic assignments. Additionally, ChatGPT suggests refined labels or descriptions for each topic based on its expert-level analysis.

In the context-based phase, the interpretability of the assigned topic labels is further evaluated using real sample posts most strongly associated with each topic. These posts are presented to human experts, who rate how well the content aligns with the topic label generated by ChatGPT using a 5-point Likert scale. This step ensures that the labeling process is not only linguistically appropriate but also contextually accurate in practical usage scenarios.

An example of the instructions given to ChatGPT is shown in Fig. 2.

Expert human reviewers manually assess both the coherence and interpretability of each topic. In the keyword-based

You are an expert in topic modeling evaluation. Your task is to assess the coherence and interpretability of topics generated by a Latent Dirichlet Allocation (LDA) model.

Each topic consists of a list of keywords. Evaluate how well these keywords collectively represent a meaningful and interpretable real-world theme. Consider whether the terms are semantically related and if they align with a coherent subject matter (e.g., a specific programming concept, a software development topic, etc.).

For each topic, provide:

1. **Interpretability Score (0 to 1):** Assign a score indicating how well the keywords represent a clear, real-world topic. A score of 1 indicates perfect interpretability, while a score of 0 indicates no meaningful coherence.
2. **Suggested Topic Label:** Based on the keywords, suggest a concise and descriptive label for the topic.

Here are the topics and their associated keywords:

Topic 0: gt, lt, android, div, p, code, pre, amp, fals, true, td, button, view, import, counti
Topic 1: int, public, string, new, class, void, return, null, privat, main, char, static, std, els, amp
Topic 2: p, code, error, file, pre, use, run, tri, app, work, noreferr, li, import, version, instal
Topic 3: p, data, imag, id, user, tabl, name, select, use, text, php, enter, button, tri, work
Topic 4: p, data, imag, id, user, tabl, name, select, use, text, php, enter, button, tri, work

Evaluate each topic individually and provide your assessment in the following format:

Topic X:

- **Interpretability Score:** (0 to 1)
- **Suggested Label:** (Provide a descriptive label for the topic)

Fig. 2. An example of the prompt used to interact with ChatGPT.

evaluation, they are provided with the top keywords and the corresponding ChatGPT-generated label, and asked to assess the semantic similarity of the terms and their relevance to the label. In the context-based evaluation, they are presented with representative posts and asked to rate how accurately each post reflects its assigned topic label. This dual evaluation allows for a more comprehensive understanding of the effectiveness and reliability of ChatGPT-generated topic labels.

C. Expert Evaluation Setup

This section describes the user study designed to evaluate the reliability of ChatGPT in labeling topics generated from text datasets. The study assesses ChatGPT's labeling performance through a dual approach, comparing its automated topic labels with human expert evaluations in both keyword-based and context-based contexts.

In the keyword-based evaluation, experts assess the semantic appropriateness of ChatGPT-generated labels based on the top keywords extracted from each topic. In the context-based evaluation, experts rate the relevance of representative sample posts to their corresponding ChatGPT-assigned topic labels using a 5-point Likert scale.

The primary objective is to investigate whether ChatGPT can reliably generate topic labels that align with human expert judgment, not only in abstract keyword interpretation but also in practical, real-world content alignment. This comprehensive evaluation explores ChatGPT's potential as a robust and scalable tool for enhancing topic modeling tasks in research, content analysis, and knowledge discovery.

1) Participants: The study involved 39 expert participants recruited through the Prolific platform [27], a widely used online research tool known for its diverse and high-quality participant pool. Prolific enables targeted recruitment based on specific criteria, ensuring that participants meet predefined qualifications. In this study, only individuals with demonstrated computer programming skills were selected, allowing them to accurately distinguish content and assess the compatibility of topics. To uphold a high standard of evaluation, all participants were required to be graduate students pursuing an M.Sc. or Ph.D., ensuring their expertise aligned with the study's objectives.

2) Task and evaluation metrics: The user study evaluated the reliability of ChatGPT's topic labeling by comparing it to expert judgments across both keyword-based and context-based dimensions. Five topics were selected from a dataset processed using LDA, with each topic represented by a set of ten keywords. These topics were pre-labeled by ChatGPT.

In the keyword-based evaluation, experts were presented with the top keywords and ChatGPT-generated labels, and asked to indicate whether they fully agreed with the label, disagreed, or had suggestions for improvement. In the context-based evaluation, two representative posts were selected for each topic, and experts were asked to rate how well the content of each post aligned with the assigned topic label using a 5-point Likert scale.

This dual evaluation approach allowed for a more comprehensive assessment of the semantic appropriateness and contextual accuracy of ChatGPT's labels.

IV. Results

This section outlines the evaluation framework developed in this study, which utilizes ChatGPT as an automated tool to label and assess the quality of topics generated from text datasets. The research explores how ChatGPT can be leveraged to evaluate the topics discovered by Latent Dirichlet Allocation (LDA) models. The study aims to determine whether ChatGPT can effectively label topics based on their keywords and how these evaluations align with human judgment. The analysis of the topics reveals a coherence score (c_v) of 0.584, indicating a moderate level of coherence across the dataset. This score suggests that while the topics are relevant, there is some variability in their consistency. The identified topics are shown in Table I.

TABLE I. Topics Identified by LDA Model

Topic ID	ChatGPT Generated Label	Top 10 Keywords
0	Programming Errors and File Operations	gt, lt, android, div, p, code, pre, amp, fals, true
1	Programming Fundamentals and Data Structures	int, public, string, new, class, void, return, null, privat, main
2	HTML/XML Encoding and Syntax	p, code, error, file, pre, use, run, tri, app, work
3	UI/UX Design and Functionality	p, data, imag, id, user, tabl, name, select, use, text
4	Database Operations and Queries	p, data, imag, id, user, tabl, name, select, use, text

The application of ChatGPT for topic labeling involved analyzing the keyword sets for each topic and categorizing them based on common patterns and relationships. For example, keywords such as "public," "new," "class," "static" and "void" were interpreted by ChatGPT as related to object-oriented programming and Android development, resulting in the label "Programming Fundamentals and Data Structures."

ChatGPT's role as an automated labeling tool provided a first-pass categorization, facilitating the identification of relevant themes and reducing the need for manual intervention.

Despite the moderate coherence score, the results suggest that ChatGPT can be an effective tool for evaluating topic models. To evaluate the quality of the LDA model, ChatGPT was prompted to assess the topics based on their keywords, focusing on how well the terms align with real-world themes. The findings from the comparison of ChatGPT's interpretability scores and the LDA model's c_v coherence scores reveal valuable insights into the coherence and interpretability of the generated topics. Topics with higher interpretability scores, such as Topic 4 (0.85), also exhibit higher c_v coherence scores (0.667), suggesting a strong alignment between human understanding and statistical coherence. These topics are not only easy to interpret but also show that the keywords are semantically related and form a clear, meaningful theme. Conversely, topics with lower interpretability scores, such as Topic 0 (0.6), also tend to have lower coherence scores (0.515), indicating weaker semantic alignment and making them harder to interpret or connect to a coherent real-world theme. Overall, the results suggest that when both the human evaluation and model-based coherence agree, the topics are well-defined and semantically robust. However, discrepancies between the two metrics indicate areas where the model may require refinement to produce more coherent and interpretable topics. Fig. 3 illustrates a comparison between ChatGPT's interpretability scores and the LDA coherence scores.

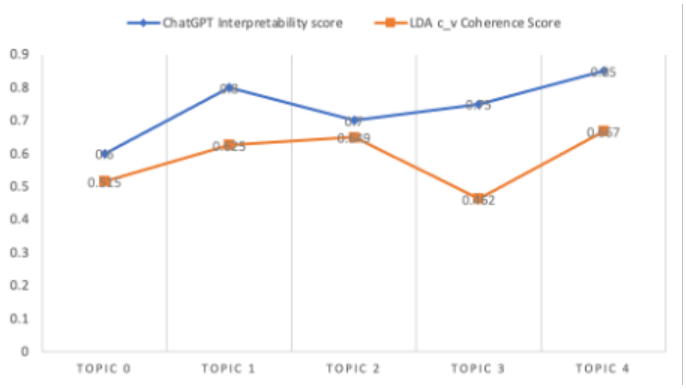

Fig. 3. Comparison of ChatGPT interpretability and LDA coherence scores across topics.

To assess the quality of topic labels generated through ChatGPT, we evaluated their alignment with human expert interpretations. The analysis compared ChatGPT's interpretability scores with the LDA model's c_v coherence scores, offering insights into the reliability of topic labeling. Higher interpretability scores generally corresponded with stronger coherence, indicating well-defined and semantically robust topics.

In addition, Jaccard similarity [28] and cosine similarity [29] were used to measure the levels of agreement between the expert responses and ChatGPT labels. Jaccard Similarity quantifies the overlap between sets of labels assigned by different annotators, while Cosine Similarity assesses the semantic consistency of label assignments using TF-IDF vectorization. TF-IDF (Term Frequency-Inverse Document Frequency) is a statistical measure that reflects the importance of a word in a document relative to a collection of documents [30]. By converting labels into TF-IDF vectors, Cosine Similarity can effectively capture their semantic relationships, even when different terms are used to describe similar topics.

The findings highlight how agreement metrics further validate the interpretability and coherence of generated topics, identifying areas where refinements may enhance alignment between human understanding and statistical modeling. The computed Jaccard Similarity score of 0.5175 indicates a moderate degree of agreement among expert evaluations regarding ChatGPT's labels. Meanwhile, the Cosine Similarity score of 0.6237 reflects a relatively higher degree of semantic similarity, suggesting that the topic labels generated by ChatGPT align well with human opinions in terms of conceptual meaning. To further assess the validity of ChatGPT-generated labels, a Majority Voting approach [31] was applied, where expert responses were binarized (1 = Agree, 0 = Disagree). A threshold of 50% agreement was used to determine whether a label was accepted by the majority of participants. The results of the Majority Voting analysis indicate that ChatGPT's topic labels were largely accepted, as shown in Table II.

TABLE II. TOPICS IDENTIFIED BY LDA MODEL

Topic	Majority Vote	ChatGPT Label	Agreement
Programming Errors and File Operations	1	1	TRUE
Programming Fundamentals and Data Structures	1	1	TRUE
HTML/XML Encoding and Syntax	1	1	TRUE
UI/UX Design and Functionality	1	1	TRUE
Database Operations and Queries	1	1	TRUE

These findings indicate a full agreement between ChatGPT's assigned labels and the majority of expert responses. The combination of Jaccard Similarity, Cosine Similarity, and Majority Voting results provides strong evidence of ChatGPT's effectiveness in generating accurate and semantically relevant topic labels. These findings highlight the potential for leveraging ChatGPT in automated topic classification tasks based on LDA-generated keyword distributions.

The results of this evaluation revealed distinct differences in label performance across the posts as shown in Figure 4. For instance, Posts 3, 6, 8, and 10 achieved high mean scores above 4.0 with low standard deviations, suggesting strong agreement among reviewers regarding the contextual relevance of the ChatGPT-assigned labels. These findings affirm that the labels for these topics were not only semantically valid at the keyword level but also contextually robust when applied to actual post content.

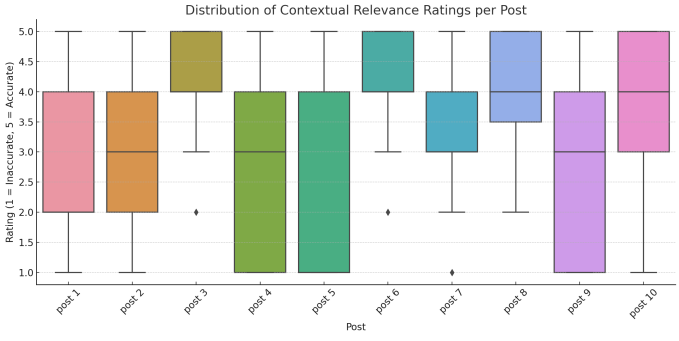

Fig. 4. Distribution of contextual relevance ratings per post.

To measure inter-rater reliability, Kendall's W was computed and yielded a value of 0.99, indicating excellent agreement among expert reviewers. Furthermore, the average pairwise Spearman correlation was 0.23, reflecting consistent ranking tendencies across raters despite some variance. These findings reinforce the need for context-based assessments in evaluating topic modeling outputs. While keyword-based labeling offers a foundational view of topic coherence, context-based ratings provide practical validation of the interpretability and usability of topic labels in real-world scenarios. Together, these perspectives offer a more comprehensive understanding of how well large language models such as ChatGPT perform in automated topic labeling.

V. Discussion

The discussion now turns to the ethical implications of AI-based labeling, particularly in the context of ChatGPT's role in automated topic classification. While the results indicate that ChatGPT-generated labels align well with human evaluations, certain ethical concerns related to bias, transparency, and accountability must be addressed to ensure responsible deployment.

One primary concern is bias in topic representation. The findings suggest that ChatGPT accurately labeled structured programming-related topics but exhibited inconsistencies in areas with lower coherence scores. This variability raises concerns about the model's potential to reinforce systematic biases in topic classification, leading to overrepresentation of dominant themes or misclassification of ambiguous content. Previous research has demonstrated that AI models trained on large-scale datasets can inadvertently inherit biases present in the data, impacting the fairness of generated outputs [32].

Another key issue is transparency in AI-generated classifications. While similarity metrics, such as Jaccard and Cosine Similarity, provide insights into how closely ChatGPT's labels align with human interpretations, the lack of explainability in AI decision-making remains a challenge. Unlike human experts who can articulate their reasoning, ChatGPT's topic assignments rely on statistical correlations rather than explicit contextual understanding. This limitation can make it difficult to assess the reliability of AI-generated labels and detect systematic misclassifications [33].

Accountability and human oversight are also critical considerations. The majority voting analysis confirms that ChatGPT's labels were widely accepted, but overreliance on AI-generated labels without human validation could lead to misclassifications in cases where expert knowledge is necessary. Ethical AI deployment should incorporate a human-in-the-loop (HITL) framework, where AI serves as a decision-support tool rather than an autonomous classifier [34]. This approach ensures that AI-generated labels remain subject to expert validation, reducing the risk of incorrect topic assignments.

To mitigate these ethical concerns, AI-based labeling should integrate bias detection techniques, fairness-aware learning algorithms, explainability mechanisms, and expert validation frameworks to ensure that AI-generated labels are transparent, unbiased, and aligned with human judgment.

VI. Conclusion

This study demonstrates the potential of ChatGPT as an effective tool for automated topic labeling and evaluation in topic modeling tasks. By comparing the labels generated by ChatGPT with those of domain experts, we found that ChatGPT can generate semantically meaningful and coherent topic labels, offering valuable insights for large-scale text datasets. The integration of multiple similarity measures, including Jaccard Similarity, Cosine Similarity, and a Majority Voting mechanism, provided a comprehensive framework for assessing labeling accuracy. The results indicate that ChatGPT's labels align well with human judgment, with moderate to strong agreement levels, particularly in terms of semantic consistency.

Despite some variability in the coherence scores, the analysis suggests that ChatGPT can reliably categorize topics based on keyword sets, facilitating the identification of relevant themes and reducing the need for manual intervention. Topics with higher interpretability and coherence scores further demonstrate the robustness of ChatGPT in providing accurate labels, while discrepancies in less coherent topics highlight areas for potential refinement.

Overall, this research underscores the viability of ChatGPT as a complementary tool for topic labeling, offering a scalable approach to streamline the evaluation and categorization of topics in large text corpora. Further work may focus on refining the model's accuracy, especially in cases of lower coherence, to further enhance the precision and consistency of automated topic labeling systems.

Detecting Hate Speech Targeting Protected Groups in Arabic Using Hypothesis Engineering and Zero-Shot Learning with Ground Validation via ChatGPT

Ahmed Fat'hAlalim, Yongjian Liu, Qing Xie, Alhag Alsayed, Musa Eldow
School of Computer Science and Artificial Intelligence,
Wuhan University of Technology, Hubei, Wuhan, China

***Abstract*—Automatic detection of hate speech in low-resource languages presents a persistent challenge in natural language processing, particularly with the rise of toxic discourse on social media platforms. Arabic, characterized by its rich morphology, dialectal variation, and limited annotated datasets, is underrepresented in hate speech research, especially regarding content targeting marginalized and protected groups. This study proposes a zero-shot learning approach that leverages Natural Language Inference (NLI) models guided by carefully engineered hypotheses in native Arabic to detect hate speech against protected groups, such as women, immigrants, Jews, Black people, transgender individuals, gay people, and people with disabilities. We formulated nine different Arabic hypothesis groups and employed a zero-shot XNLI model with a baseline embedding-based model, incorporating preprocessing techniques on the HateEval Arabic dataset. The results indicate that the XNLI model achieves up to 80% accuracy in detecting targeted hate speech, significantly outperforming baseline models. Furthermore, a real-world validation using GPT-3 via the ChatGPT interface achieved 54% accuracy in zero-shot conversational settings. These findings highlight the importance of hypothesis design and linguistic preprocessing in zero-shot hate speech detection, particularly in low-resource and culturally nuanced languages offering a scalable and culturally aware solution for moderating harmful content in Arabic online spaces.**

***Keywords*—Hate speech detection; low resource Arabic language, zero-shot learning; natural language processing; ChatGPT; transfer learning; online safety**

I. Introduction

The proliferation of hate speech on digital platforms, particularly social networks, has raised serious social concerns due to the harm it causes marginalized communities. Hate speech refers to any type of expression that involves discrimination against individuals or groups based on their identity, such as race, ethnicity, religion, gender, sexual orientation, and other factors [1]. It can range from offensive discourse targeting inherent traits to speech, gestures, or physical expressions that threaten individuals or groups. However, distinguishing between hate speech and merely offensive or controversial opinions remains complex, especially in contexts where freedom of expression is a sensitive issue [2]. In response, researchers have increasingly turned to Natural Language Processing (NLP) techniques to automate the detection and classification of hate speech.

Despite advancements in NLP and Machine Learning, hate speech detection continues to present significant challenges [3], particularly in low-resource languages Arabic, which presents unique complexities due to its linguistic characteristics, including the complex morphology of the language, and the wide array of dialects spoken across different regions [4], [5]. Recently, Many scientific studies have used machine learning and deep learning to automatically detect hate speech [6], However Traditional supervised learning approaches depend heavily on annotated datasets, which are often scarce or nonexistent for languages such as Arabic [7], [8]. Additionally, these approaches need help to adapt to the dynamic and context-dependent nature of hate speech, resulting in suboptimal performance in real-world situations. Therefore, there is an urgent need to develop efficient methods to address this problem. One promising approach involves reusing natural language inference (NLI) models for text classification, which has shown promising results in zero- and few-shot classification tasks [9]. Recent research by Goldzycher and Schneider [10] has also highlighted the potential for zero-shot NLI-based settings to outperform traditional few-shot fine-tuning approaches in English. While prior studies have explored the identification of hate speech in several languages, such as English, there remains a need for specialized approaches that target protected groups within these languages. This highlights the importance of investigating novel methodologies, such as hypothesis engineering for zero-shot learning, to address these challenges and advance hate speech detection capabilities across diverse linguistic contexts.

The objective of this study is multifaceted, aiming to address several key challenges in hate speech detection within the context of low-resource languages. Firstly, we propose to develop a set of hypotheses tailored to the characteristics of hate speech targeting protected groups in low-resource languages, such as Arabic. These hypotheses will serve as the basis for our zero-shot learning approach, facilitating the model's ability to generalize to unseen instances of hate speech. Secondly, we seek to create a scenario-based framework for hate speech detection, wherein the model is trained to recognize nuanced forms of hate speech directed towards specific protected groups, including women, minorities, and marginalized communities. By incorporating scenario-based training data, we aim to enhance the model's sensitivity to context and improve its performance in real-world applications. Additionally, we plan to conduct ground validation experiments using a chat-based interface, such as GPT, to assess the practical effectiveness of our proposed approach. This iterative validation process will provide insights into the model's performance in natural language interactions, further

validating its utility in real-world settings.

In addition to the contribution of this study to detecting hate speech in low-resource languages, it also conducts in-depth experiments on carefully selected hypotheses that fit the rich nature of the Arabic language, which is characterized by an abundance of synonyms and extensive linguistic dictionaries. Furthermore, we explore these hypotheses in scenarios in which hate speech is directed toward protected groups in Arab societies. These contributions can be summarized as follows:

- We developed a comprehensive set of hypotheses in Arabic specifically tailored to detect hate speech.
- We proposed a novel approach using zero-shot learning to detect hate speech in low-resource Arabic settings, guided by meticulously formulated hypotheses considering contextual and linguistic challenges.
- Our study presents an enhanced methodology employing zero-shot learning for detecting hate speech in Arabic, targeting protected groups such as women, immigrants, Jews, Black people, transgender individuals, gay people, and disabled people.
- Through ground validation using ChatGPT, we demonstrated the practical usability of our hypotheses in real-time conversations, verifying their potential for proactive moderation.

The organization of this paper is as follows: Section II presents an overview of previous research conducted in identifying hate speech. Section III provides a detailed explanation of the technique used in this study, while Section IV presents the experimental setup, which includes the building of the model, the division of the data, and the metrics used for evaluation. Section V outlines the methods utilized in our investigation, Our results are presented in Section VI, while Section VII provides the discussion of the findings. In Section VIII we analyze the top errors of our study, conclude the work, and suggest possible directions for future research in Section IX.

II. Related Work

Current developments in automated hate speech detection move from machine learning models to the use of deep learning and transformer-based models, a comprehensive review by Abdelsamie et al. [11] discuss the latest techniques in natural language processing for hate speech detection in Arabic, including Lexicon-based, ML, DL, and transformer-based models. Each of these approaches addresses the complexity of the Arabic language in a different way. ML models like Support Vector Machines (SVM) combined with word embeddings have shown high accuracy in classifying offensive content in Arabic tweets [12], [13]. Convolutional neural networks (CNNs) and their hybrid models, such as CNN-LSTM and BiLSTM-CNN, have been effective in binary, ternary, and multi-class classification tasks for hate speech detection [8], [14]. Lexicon-based approaches, which involve creating specialized lexicons of offensive terms, have been employed to identify and classify hate speech, especially in the context of religious hatred [15]. The impact of tokenization strategies and vocabulary sizes on the performance of Arabic language models in downstream natural language processing tasks has also been examined [16]. Sentiment analysis techniques are also utilized to capture the meaning of Arabic words and classify tweets as hateful or non-hateful. The integration of genetic algorithms with classifiers like XGBoost and SVM has been used to optimize hyperparameters and improve detection accuracy [12].

Pre-trained word embedding models like AraVec and fastText, fine-tuned on specific datasets, have proven beneficial in capturing the semantic nuances of Arabic hate speech [17]. Additionally, Elmadany et al. explore the use of affective bidirectional transformers for offensive language detection in Arabic, demonstrating the utility of training models on sentiment and emotion data to enhance performance [18]. Daouadi et al. introduce an ensemble approach that combines pre-trained language models and data augmentation to improve hate speech detection from Arabic tweets, achieving encouraging results. Their methodology addresses the issues of limited performance and imbalanced data, common challenges in Arabic hate speech detection [19].

A. Zero-Shot Learning Approaches

Zero-shot learning has emerged as a promising approach for hate speech detection, particularly in scenarios with limited labeled data and high variability across languages and contexts. Research indicates that ZSL can effectively leverage large language models, such as T5 and BLOOM, to achieve performance comparable to traditional fine-tuned models, even in under-resourced languages [20], [21]. Techniques like hypothesis engineering enhance ZSL by combining multiple predictions to improve accuracy, demonstrating significant gains over standard models [10]. Furthermore, Goldzycher et al. [22] employed fine-tuned models based on the XNLI dataset to evaluate the effectiveness of NLI models in detecting hate speech across languages. Experiments were conducted in Arabic, Hindi, Italian, Portuguese, and Spanish, with multilingual models initially adapted for detecting hate speech in English and further refined using language-specific data. Further research by Zia et al. explores zero-shot cross-lingual hate speech detection, highlighting the effectiveness of pseudo-label fine-tuning of transformer language models in improving detection performance across different languages [23]. These advancements highlight the potential of ZSL to address the challenges of hate speech detection across diverse linguistic landscapes.

B. Research Gap

Despite significant advancements in hate speech detection, several critical gaps persist, particularly concerning low-resource languages like Arabic. The complexity of Arabic, characterized by diverse dialects and rich vocabulary, poses substantial challenges for traditional supervised learning approaches that rely heavily on large annotated datasets. Moreover, existing research predominantly focuses on resource-rich languages, leaving a significant void in developing effective detection models tailored for Arabic.

Traditional deep learning and transformer-based models, while powerful, often require extensive labeled data for training, which is scarce for Arabic [24]. This scarcity hampers the development of robust hate speech detection systems for

Arabic-speaking communities. Furthermore, there is a noticeable lack of research on hypothesis engineering specifically tailored to zero-shot learning frameworks for Arabic hate speech detection. Previous studies have also insufficiently addressed hate speech targeting protected groups within the Arabic-speaking community, such as women, immigrants, and religious minorities.

ZSL emerges as a promising alternative, enabling models to generalize to new tasks without task-specific training data. By leveraging ZSL, it's possible to overcome the limitations posed by data scarcity, allowing for the development of hate speech detection models that are both accurate and adaptable to the nuances of the Arabic language and its dialects. This approach not only reduces the dependency on large annotated datasets but also facilitates the rapid deployment of detection systems across different contexts and communities.

III. Methodology

The methodology adopted in this study follows a structured, systematic approach to detect hate speech targeting protected groups in the Arabic language utilizing zero-shot learning techniques, presented in Fig. 1. The process is initiated by formulating hypotheses specifically tailored to the Arabic language. These hypotheses are designed to encapsulate various facets of hate speech, making them suitable for a zero-shot learning approach. Subsequently, these hypotheses are subjected to initial experiments using the XNLI model, which employs zero-shot learning, and several preprocessing techniques are applied to the Arabic text data, ensuring the text is clean, consistent, and ready for analysis. Following the initial experiments, the best-performing hypotheses are selected and refined to improve their effectiveness in detecting hate speech. This step is crucial for tailoring the detection system to the specific linguistic and cultural nuances of Arabic. A comparative analysis is then conducted to evaluate the performance of the XNLI model with the zero-shot learning approach against the embedding baseline model. Finally, the refined hypotheses are tested in real-life conversations using a chat-based interface with GPT-3.

A. Zero-Shot Learning in Hate Speech Detection

Traditional zero-shot learning methods rely on providing a descriptor or information about an unseen class [25]. This descriptor can be in the form of visual attributes, the name of the class, or any other relevant information. By providing this descriptor, the model can make predictions for the unseen class even without having any training data specifically for that class. In other words, the model uses the provided information to generalize and recognize the characteristics of the unseen class. This approach enables the model to extend its knowledge beyond the classes it has been trained on and make accurate predictions for new and previously unseen classes.

The objective of Zero-Shot Learning is to learn a model (f) that maps instances (x) and auxiliary information (a) to class labels (y). Mathematically, this can be expressed as:

$$f : (x, a)ßy \tag{1}$$

where x represents an input instance from the dataset, a represents the auxiliary information associated with each class, and y represents the class label.

To train the Zero-Shot Learning model, a loss function (L) is defined to measure the discrepancy between the predicted class labels and the ground truth labels. The loss function guides the model to minimize the classification error during training. Mathematically, the loss function can be represent as:

$$L(f(x, a), y) \tag{2}$$

where L represents the loss function, $f(x, a)$ represents the predicted class label for instance x based on the auxiliary information a, and y represents the ground truth class label for instance x.

The key aspect of Zero-Shot Learning is its ability to generalize to unseen classes. During inference, the model can predict the class labels for instances belonging to new classes that were not present in the training data. This is achieved by using the learned relationships between the auxiliary information and the class labels. Mathematically, the generalization can be expressed in Eq. 3.

$$f(x\_new, a\_new)ßy\_new \tag{3}$$

where x_new represents a new instance from an unseen class, a_new represents the auxiliary information associated with the new class, and y_new represents the predicted class label for the new instance.

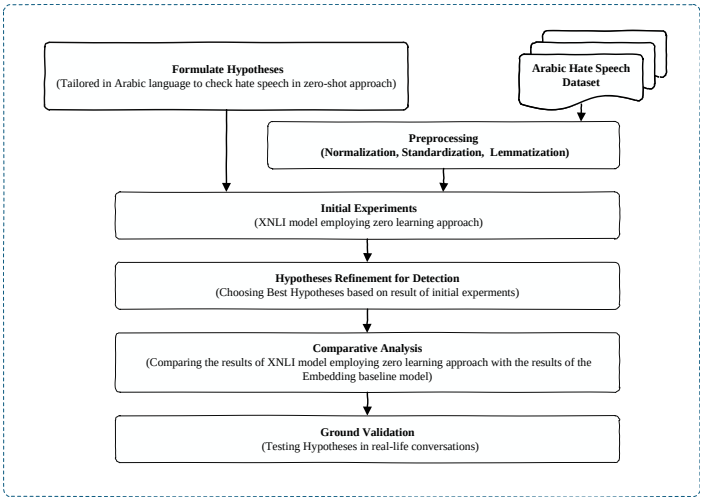

Fig. 1. An Illustration of the methodology used in this study to detect hate speech targeting protected groups in Arabic highlights the essential steps.

B. HateCheck Dataset

The HateCheck [2] is a meticulously curated resource designed to evaluate the performance of hate speech detection models. It encompasses a wide variety of hate speech examples, targeting diverse protected groups, and is structured to test models across multiple dimensions of hate speech. This

includes explicit and implicit hate speech, different types of hate (e.g. racism, sexism, homophobia), and varying intensities and forms of hateful expressions. The dataset is notable for its comprehensive coverage, which aims to mimic the complexity and variability of hate speech encountered in real-world settings. In this study, we utilized a subset of HateCheck specifically adapted for Arabic, known as HateCheck Arabic, which was instrumental in validating the effectiveness of our zero-shot learning methodology for detecting hate speech in Arabic. This dataset has been painstakingly annotated to identify hate speech and provides valuable insights into the prevalence and nature of offensive content in the Arabic-speaking context. Table I contains details of the Hatecheck-Arabic dataset statistics in terms of size, sub-groups targeted by hate speech, and hate statements percentages.

TABLE I. STATISTIC OF HEATCHECK-ARABIC DATASET

Class/Target	Size	Hate statements (%)	Not hate statements (%)
Women	534	406 (76%)	128 (24%)
immigrants	437	333 (76%)	104 (24%)
Jews	437	333 (76%)	104 (24%)
black_people	485	369 (76%)	116 (24%)
trans_people	437	333 (76%)	104 (24%)
gay_people	509	387 (76%)	122 (24%)
disabled_people	437	333 (76%)	104 (24%)
No Class	294	0 (0%)	294 (100%)
HateCheck-arabic	3570	2494 (70%)	1076 (30%)

IV. EXPERIMENTAL SETUP

In this section, we provide an overview of the experimental setup, detailing the model employed, the split of the Arabic HateCheck dataset, and the performance metrics used to assess the model's efficacy.

A. Model Selection

Within the model selection, we systematically explored our zero-shot learning approach's effectiveness in the Arabic language context. To achieve this, we employed two distinct models to evaluate a set of hypotheses meticulously formulated for our experiments. The first model entailed leveraging an embeddings-based approach, while the second model involved harnessing the XNLI model, tailored for hate speech classification. After comprehensive experimentation, we identified the most promising hypothesis that yielded the highest performance in hate speech detection using our methodology. Subsequently, we conducted an additional validation step using chatGPT, which we employed to test the accuracy of the best-performing hypothesis. This validation procedure allowed us to gauge our zero-shot learning approach's real-world applicability and robustness when integrated with advanced language models. The following is an explanation of the architecture of these models.

1) NLI Model: NLI (Natural Language Inference) models have gained prominence in various natural language processing tasks, including zero-shot topic classification [26]. NLI models are designed to determine the relationship between two given sentences: whether the second sentence contradicts, entails, or is neutral concerning the first sentence. Leveraging the capabilities of NLI models, zero-shot topic classification enables the classification of text into predefined topics or categories without explicitly training on labeled examples from those topics. By encoding the topic description as a premise and the input text as a hypothesis, NLI models can infer the topic relevance or compatibility. This approach proves particularly useful in scenarios where labeled data for all target topics is limited or unavailable. The NLI model's ability to generalize across topics makes it a promising choice for zero-shot topic classification tasks, including hate speech detection.

NLI is a task where the model is given a premise (P) and a hypothesis (H) and is required to predict the relationship between them, typically as entailment, contradiction, or neutral [27]. This can be represented mathematically in Eq. 4.

$$NLI(P, H) -> \{entailment, contradiction, neutral\} \quad (4)$$

XNLI is a specific variant of the NLI trained on the XNLI dataset, which is a multilingual natural language inference dataset. The methodology of XNLI involves fine-tuning the pre-trained XLM-RoBERTa-Large model on the XNLI task. It takes the premise (P) and hypothesis (H) as inputs and predicts the relationship between them.

Both NLI and XNLI methodologies involve training a model to understand the relationships between premises and hypotheses. The models are trained on large amounts of data to learn the semantic representations and context required for accurate inference. These methodologies enable the models to generalize well to new instances and perform effectively in various natural language understanding tasks, including textual entailment and inference-based classifications. For our experiment, we utilized the XNLI[1] model as the base model.

2) Embeddings: Embeddings play a critical role in NLP in numerically representing textual data while retaining semantic relationships and contextual information [28]. They convert words or phrases into high-dimensional vectors, making machine learning models more capable of grasping linguistic meanings and patterns. Mathematically, an embedding for a word w_i can be denoted as:

$$E(w_i) \quad (5)$$

where E represents the embedding function. For a given text S, it can be represented as a sequence of word embeddings:

$$S = [E(w_1), E(w_2), ..., E(w_n)] \quad (6)$$

where n signifies the length of the text. Zero-shot learning is used in conjunction with embeddings to improve the detection of hate speech. Because zero-shot learning allows models to generalize to previously unseen classes, it is useful for classifying hate speech directed at protected groups. The model learns to associate embeddings with specific hate speech categories by leveraging auxiliary information or hypotheses. For example, hypothesizing "this text contains hate speech targeting immigrants" directs the model to recognize instances of hate speech directed at immigrants. A similar approach for

[1] https://huggingface.co/joeddav/xlm-roberta-large-xnli

zero-shot topic classification was demonstrated by Yin et al. [9].

In our experimental approach, we used embeddings as a critical component of our analysis. We fine-tuned the Embedding model of OpenAI to classifying hate speech, specifically the text-embedding-ada-002I[2] version. We used embeddings to increase the depth of our investigation after developing and testing hypotheses using the XNLI model. By passing these hypotheses to the embedding model, we aimed to conduct a comprehensive comparative analysis between the two models. This approach enabled us to delve into the intricate nuances of hate speech detection, leveraging both the semantic relationships captured by embeddings and the cross-lingual understanding facilitated by the XNLI model. We hoped to select the most effective model for detecting hate speech directed at protected groups using this two-pronged approach.

3) GPT-3: Developed by OpenAI, represents a groundbreaking achievement in natural language processing (NLP). This state-of-the-art language model has garnered significant attention for its exceptional ability to generate coherent and contextually relevant human-like text across a wide array of tasks. Its advanced capabilities stem from extensive pretraining on vast datasets, allowing it to capture intricate language patterns and subtleties [29]. GPT-3 utilizes a transformer architecture featuring multiple attention mechanisms, enhancing the model's understanding of long-term dependencies in textual data. The self-attention mechanism, fundamental to its architecture, can be mathematically expressed as follows:

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{7}$$

Where, Q, K, and V are the query, key, and value matrices respectively, and d_k is the dimension of the key vectors. The softmax function scales the dot product of the query and key vectors by the square root of d_k. The resulting attention scores are then used to weight the value vectors, producing the attended representation.

The Attention function takes in three inputs: the query matrix (Q), the key matrix (K), and the value matrix (V). It also considers the dimension of the key vectors, represented as (d_k). The function first calculates the dot product of the query and key matrices, and then scales this result by the square root of the dimension of the key vectors. The softmax function is then applied to these scaled values, resulting in what are known as attention scores. These attention scores are subsequently used to weight the value vectors, yielding the final output, which is the attended representation. This process essentially allows the model to focus on different parts of the input sequence when producing the output.

B. Data Split

Our data was sourced from the Arabic HateCheck as we mentioned in Section III-B , which is composed of a wide variety of text samples that include hate speech directed at different protected groups. In order to enhance the resilience of our model, we executed a stratified split of the data, taking into account the groups targeted. Table I provides a detailed breakdown of these groups.

C. Model Performance Metrics

To comprehensively evaluate our hate speech detection system, we employed four widely recognized metrics that collectively assess different facets of model performance.

1) Accuracy (ACC): quantifies the model's overall correctness by calculating the percentage of all predictions that align with the true labels.

$$ACC = \frac{T_{Postive} + T_{Negative}}{T_{Postive} + T_{Negative} + F_{Postive} + F_{Negative}} \tag{8}$$

2) Precision (Pre): evaluates the reliability of positive predictions, emphasizing the model's ability to minimize false alarms.

$$Pre = \frac{T_{Postive}}{(T_{Postive} + F_{Postive})} \tag{9}$$

3) Recall (Rec): measures how effectively the model identifies all instances of hate speech within the dataset, prioritizing the detection of true positives.

$$Rec = \frac{T_{Postive}}{(T_{Postive} + F_{Negative})} \tag{10}$$

4) F1-score (F1-s): harmonizes precision and recall into a single metric, ensuring a balanced assessment of the model's performance even when class distributions are uneven.

$$F1 - s = \frac{2 * (Pre * Rec)}{(Pre + Rec)} \tag{11}$$

V. Methods

We describe the methods employed in our experiments, organized into the following three subsections that outline the key steps of our experimentation.

A. Hypothesis Generation, Initial Experiments, and Preprocessing

Guided by the hypothesis engineering proposed by Goldzycher et al. [10], We formulated our hypotheses in Arabic according to the proposed method in Fig. 2, where we formulated the hypotheses in the form of "It is / That text is / This example is / This example contains / This text is / This text contains / This is / Containing / Contains + hate speech / hate-inciting speech / provocative hate speech / hateful". Table II presents the hypotheses formulated in Arabic and their corresponding literal translations in English. The translations were generated using the chatGPT model.[3]

Following the development of these hypotheses, we conducted initial experiments using embeddings as a baseline in conjunction with the XNLI model. We utilized the XNLI

Algorithm 1 Hate Speech Detection in Arabic

Ensure: Labels for each text sample in D'
Input: Dataset D, Hypotheses H, NLI Model XNLI, Threshold θ
Output: Labels for each text sample in D'
Preprocessing Steps:
$D \leftarrow \text{Normalize}(D)$ ▷ Convert text to a canonical form (e.g.,Unified number format, removing diacritics)
$D \leftarrow \text{RemoveNoise}(D)$ ▷ Remove unnecessary characters (e.g., punctuation, stop words)
$D \leftarrow \text{Lemmatize}(D)$ ▷ Reduce words to their base or root form
$D' \leftarrow D$ ▷ Final preprocessed dataset
for all $t \in D'$ **do** ▷ For each text sample t in the preprocessed dataset
  for all $h \in H$ **do** ▷ For each hypothesis h
    $S(t, h) \leftarrow \text{XNLI}(t, h)$ ▷ Calculate the semantic similarity score
    if $S(t, h) \geq \theta$ **then**
      $\text{Label}(t) \leftarrow$ Hate Speech
    else
      $\text{Label}(t) \leftarrow$ Non-Hate Speech
    end if
  end for
end for
Return Labels for each text sample in D'

model on the HatCheck dataset, inputting the formulated premises and hypotheses. This stage allowed us to evaluate the performance of the generated hypotheses and to compare the embeddings-based approach to the XNLI model.

Continuing from the initial experiments, the hypotheses showing promising results underwent further refinement through preprocessing using the Kurdish Language Processing Toolkit (KLT)[4] to preprocess the data. The toolkit served as a valuable resource for performing various language processing tasks specific to the Kurdish and Arabic languages. It offered a range of functionalities, including tokenization, stemming, and morphological analysis [30], which helped us effectively preprocess and prepare the data for further analysis, As shown in Fig. 2 Where we took the following steps on the dataset before sending it to model:

1) Normalization: involves handling diverse encodings and merging characters based on dialects and scripts

2) Standardization: takes a normalized text and produces a standardized version according to Arabic orthographies

3) Lemmatization: It involves determining the root form of a word and applying various morphological transformations, such as removing prefixes and suffixes, to obtain the lemma.

To improve data quality and consistency, techniques such as normalization and lemmatization were used. This preprocessing step aimed to alleviate the impact of dialectal variations and improve the overall performance of the model. As detailed in Algorithm 1, we systematically applied various preprocessing techniques to the dataset, which included tokenization, normalization, noise removal, and lemmatization. Following that we re-evaluated the refined hypotheses after preprocessing, enabling us to quantitatively measure the improvement achieved through these preprocessing techniques.

P8-4	يحتوي على كراهية	Containing hateful
P9-1	يحوي حديث كراهية	Contains hate speech
P9-2	يحوي حديث يحض على كراهية	Contains hate-inciting speech
P9-3	يحوي خطاب مثير كراهية	Contains provocative hate speech
P9-4	يحوي كراهية	Contains hateful

B. Hypothesis Refinement and Subsetting by Protected Groups

To narrow down our focus and enhance the model's ability to detect hate speech targeting specific protected groups, we selected the two best-performing hypotheses from the refined pool. These selected hypotheses were then subjected to further experimentation. Experiments were conducted for each subset of the dataset representing protected groups, such as women, disabled people, trans people, etc. The same models, namely embeddings and XNLI, were utilized in these subsequent experiments as they were in the initial experiments. This enabled us to examine the effectiveness of the selected hypotheses in detecting hate speech that was directed toward specific

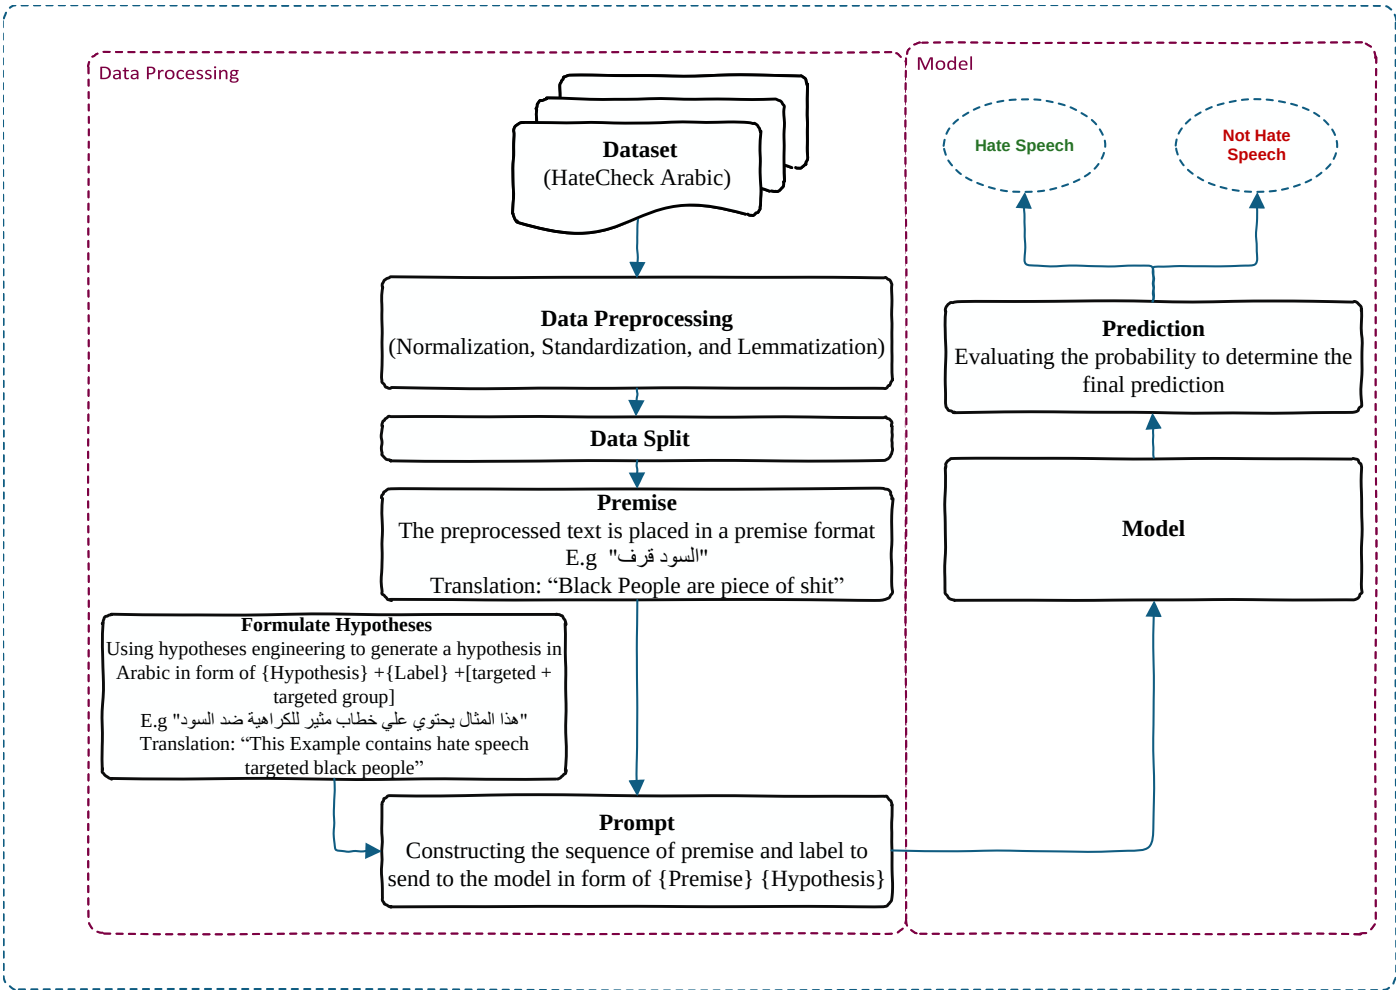

Fig. 2. Methodological framework for hate speech detection in Arabic targeting protected groups.

protected groups within the Arabic language.

C. Ground Validation Using GPT Chat

In the third phase of our methodology, detailed in Algorithm 2, we validated the effectiveness of the refined hypotheses in real-world conversational scenarios using the GPT-3.5 turbo model and the GPT chat interface from OpenAI. We input the hypotheses into the GPT chat interface to evaluate their practical relevance in detecting hate speech targeting protected groups in real-life conversations. The validation results were then compared to the outcomes from the initial experimental phase and the revised hypotheses following preprocessing. This comprehensive assessment facilitated the evaluation of performance enhancement achieved through hypothesis refinement and preprocessing techniques in the context of Zero-Shot Learning for hate speech detection. The comparison underscored the practical applicability and robustness of our approach in real-world settings.

VI. Results

A. Initial Experiments and Hypothesis Performance

Our initial experiment aimed to comprehensively assess the effectiveness of various hypotheses in the detection of hate speech. The hypotheses that are included in our study are presented in Table II. This table contains a total of nine main hypotheses, each of which is further divided into four sub-hypotheses. The hypotheses were carefully constructed to encompass the intricate features of hate speech. To assess the efficacy of these hypotheses, we utilized the XNLI model as our analytical instrument. The utilization of this model enabled the assessment of the efficacy of each hypothesis in accurately identifying hate speech within the particular context of our research. The results obtained from these experiments provide significant insight into the effectiveness of each hypothesis in comprehensively capturing the various manifestations of hate speech.

B. Impact of Preprocessing Techniques

Our systematic application of preprocessing techniques resulted in significant improvements in both data quality and model performance, albeit with notable differences between architectures. As shown in Table III, the embedding model showed a big increase in accuracy for detecting hate speech after preprocessing, indicating that normalizing features was crucial for improving its ability to recognize patterns. The performance data for the XNLI model in Table IV showed

more detailed improvements, with some language features being less affected by standardization. Fig. 3 shows important details about these different results, illustrating how changes from preprocessing affected the evaluation metrics in different ways. The distribution patterns especially show that while most hypotheses improved with preprocessing, some only had slight improvements or even got worse, highlighting the complicated link between Arabic language features and how well preprocessing works.

Furthermore, we conducted a statistical comparison using the Wilcoxon signed-rank test for both the XNLI and Embeddings models across four key metrics. Our analysis indicates that the effect of preprocessing was different for each model and hypothesis, as shown in Table V and Fig. 4. The accuracy of the embedding model went up a lot by 10.9%, $p < 0.001$, showing that preprocessing can improve structured metrics, while the XNLI model only had a small drop in recall of 4.5%, p = 0.028, with precision staying the same. Fig. 4 show this variation: Many hypotheses are close to the "no change" line, like P1-1, but outliers such as P5-2 with +48.7% recall and P6-2 with -50.7% recall reveal that preprocessing can both enhance some patterns and hide others.

Cohen's d values in Table V show these trade-offs: the Embedding Model had a big increase in accuracy with d = 2.17 but a notable drop in recall with d = -0.68, while the XNLI Model's F1 score went down with d = -0.51 because it had trouble balancing precision and recall. These results emphasize that preprocessing is not always beneficial;

its efficacy hinges on both model architecture and linguistic nuances. For instance, dialect-specific hate speech (e.g. P6-2) resisted standardization, while context-dependent patterns (e.g. P7-3's +24.6% Precision) thrived.

These findings suggest that we should customize our methods: we need to check each preprocessing idea one by one, paying close attention to the balance between different measurements and the complexity of the language. As Fig. 4 vividly illustrates, preprocessing acts as a selective lens—enhancing clarity in some contexts while unintentionally blurring others.

TABLE V. STATISTICAL COMPARISON OF MODEL PERFORMANCE METRICS BEFORE VERSUS AFTER PREPROCESSING. RESULTS SHOW WILCOXON SIGNED-RANK TEST STATISTICS, SIGNIFICANCE LEVELS (ASTERISKS INDICATING SIGNIFICANCE PF P-VALUE), MEAN DIFFERENCES (AFTER - BEFORE), AND EFFECT SIZES (COHEN'S D)

Model	Metric	Wilcoxon	p-value	Sig	Diff	Cohen's d
XNLI	Precision	64.0	0.189		-0.002	-0.232

	F1	111.0	0.001	**	-0.023	-0.513
	Accuracy	159.0	0.018	*	-0.026	-0.369
Embedding	Precision	111.5	0.007	**	0.023	0.478
	Recall	62.0	0.001	***	-0.012	-0.675
	F1	159.0	0.018	*	0.030	0.502
	Accuracy	0.0	0.000	***	0.109	2.171

C. Hate Speech Detection Targeting Protected Groups

In the final phase of our experimental framework, we extended our zero-shot hate speech detection approach to specifically target protected groups within Arabic discourse. To tailor our model for this scenario, we identified and employed the two most promising hypotheses based on our earlier experiments, including P7-3 for the Embeddings model and P8-3 for the XNLI model. We carefully crafted these hypotheses to accurately represent targeted hate speech expressions in Arabic, ensuring semantic generality for zero-shot classification. Using these refined hypotheses, we evaluated the performance of both models across seven protected groups: women, immigrants, Jews, Black people, transgender people, gay people, and disabled people.

The results from this detailed evaluation are displayed in Table VI, which shows the precision, recall, F1-score, and accuracy of both models for each group. In parallel, Fig. 5 provides a visual overview of the model performance per metric, facilitating a clearer comparison of strengths and weaknesses.

Our results indicate that the XNLI model is better than the Embeddings model, particularly with hypothesis P8-3, reaching an average accuracy of up to 80% for protected groups. For example, the XNLI model showed remarkable robustness in detecting hate speech targeting Jews, black people, and disabled individuals, groups that often experience nuanced and implicit forms of discrimination. On the other hand, the Embeddings model performed okay with hypothesis P7-3, but its results were less consistent and affected by the way language was used. These outcomes underscore two important insights: First, hypothesis engineering plays a crucial role in adapting zero-shot models to detect group-specific hate speech. Second, semantically informed models like XNLI, when paired with well-formulated hypotheses, can serve as powerful tools for hate speech detection in low-resource and linguistically diverse settings such as Arabic.

TABLE VI. COMPARISON OF HATE SPEECH DETECTION RESULTS TARGETING PROTECTED GROUPS USING DIFFERENT MODELS AND HYPOTHESES

		Embedding				XNLI			
Target	hypoth	Pre	Rec	F1-S	Acc	Pre	Rec	F1-S	Acc
Women	P7-3	**0.64**	0.54	0.53	**0.76**	0.81	0.87	0.63	0.75

	P8-3	0.52	0.52	0.52	0.65	**0.84**	0.9	0.78	0.79

D. Ground Validation Using GPT-3

To meticulously validate the real-world feasibility of our carefully enhanced hypotheses, we adeptly harnessed the capabilities of the GPT-3 model via the GPT chat interface. To streamline the validation process, we devised an innovative strategy by formulating a Hypothesis (P8-3) as a singular prompt in form of النص التالي يحتوي على خطاب مثير للكراهية ضد [المجموعة]، النص: [النص]., literal translations in English; The following text contains hate speech against [group], text: [text]. The responses provided by the model were subsequently examined to determine to what extent they aligned with our hypotheses. Remarkably encouraging results emerged from this validation endeavor, particularly in the context of complex and low-resource languages like Arabic, The results of this ground validation are meticulously detailed in Table VII. The GPT chat interactions served as a robust testament to the effectiveness of our methodology in quickly and accurately determining hate speech directed at protected groups, thus solidifying the pragmatic utility of our methodology in real-world conversational scenarios.

TABLE VII. THE RESULTS GROUND VALIDATION USING GPT-3

Target	Precision	Recall	F1-Score	Accuracy
Women	0.77	0.43	0.45	0.47
immigrants	0.78	0.30	0.42	0.40
Jews	0.81	0.51	**0.51**	**0.54**
black_people	0.77	**0.53**	0.48	0.52
trans_people	0.79	0.31	0.43	0.41
gay_people	0.77	0.34	0.42	0.42
disabled_people	**0.84**	0.29	0.41	0.42

VII. DISCUSSION

Our results underscore the importance of hypothesis design and preprocessing. While preprocessing boosted embedding model accuracy, its impact on XNLI was nuanced, revealing trade-offs between precision and recall. As shown in Fig. 3 and Fig. 4, some hypotheses, like P5-2, demonstrated exceptional improvement, while others, such as P6-2, declined. This suggests that preprocessing may enhance or suppress specific linguistic cues depending on the model and hypothesis

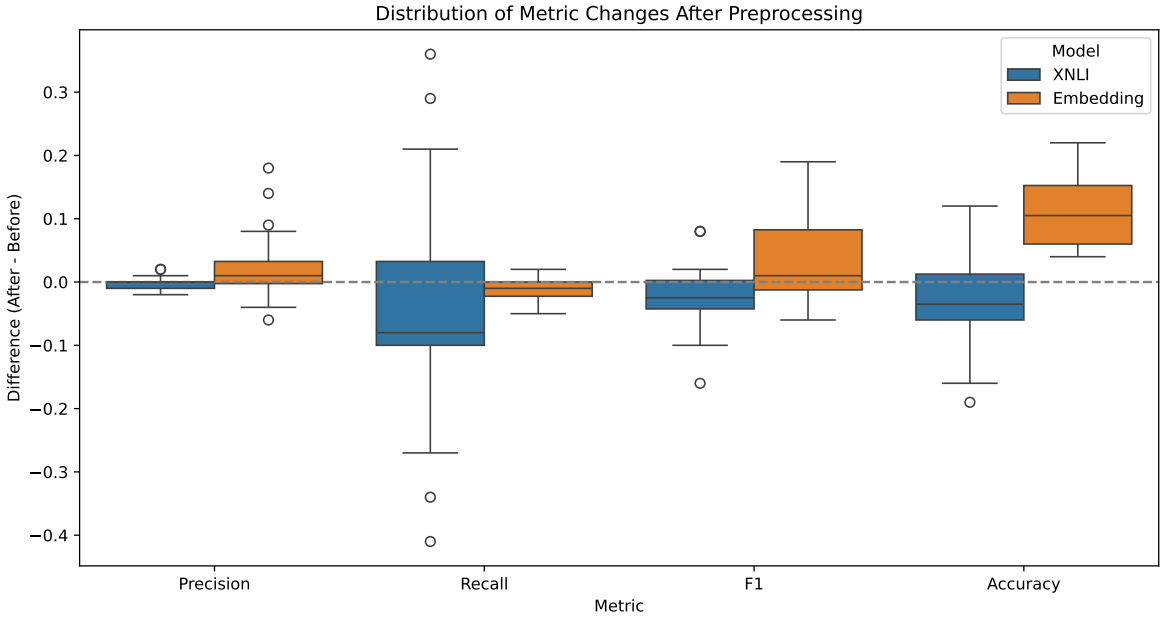

Fig. 3. Distribution of metric changes (After – Before preprocessing) for Precision, Recall, F1-score, and Accuracy across XNLI and embedding models.

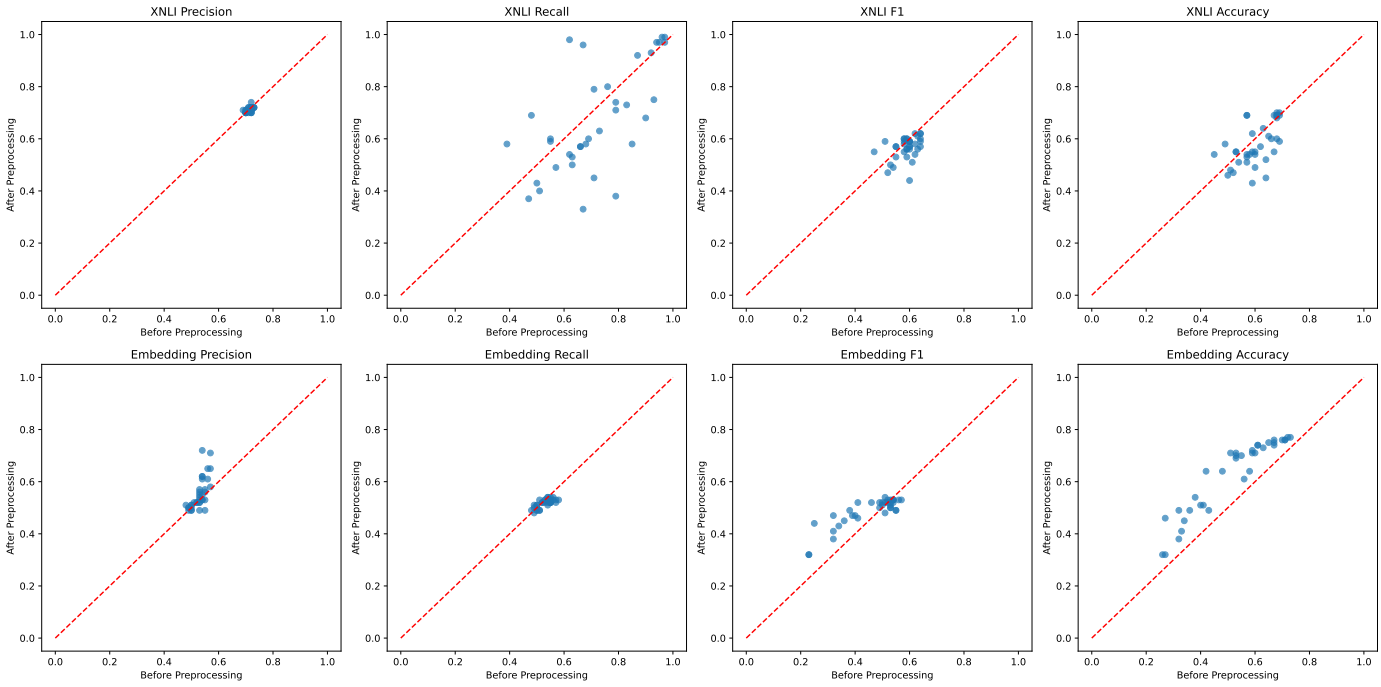

Fig. 4. Comparison of model performance metrics before versus after preprocessing. Each point represents a single hypothesis, plotted by its preprocessed (y-axis) versus original (x-axis) scores.

structure. Furthermore, Cohen's d metrics further confirmed that these improvements are statistically significant, especially in the case of structured models like embeddings. However, the decrease in XNLI's recall emphasizes that overly aggressive normalization can reduce the sensitivity needed to detect more subtle forms of hate speech.

A. Protected Group Detection and Model Robustness

The experiment targeting protected groups reinforces the critical role of hypothesis engineering. Our choice of P8-3 with the XNLI model resulted in robust performance across all groups, particularly for subtle, implicit hate speech such

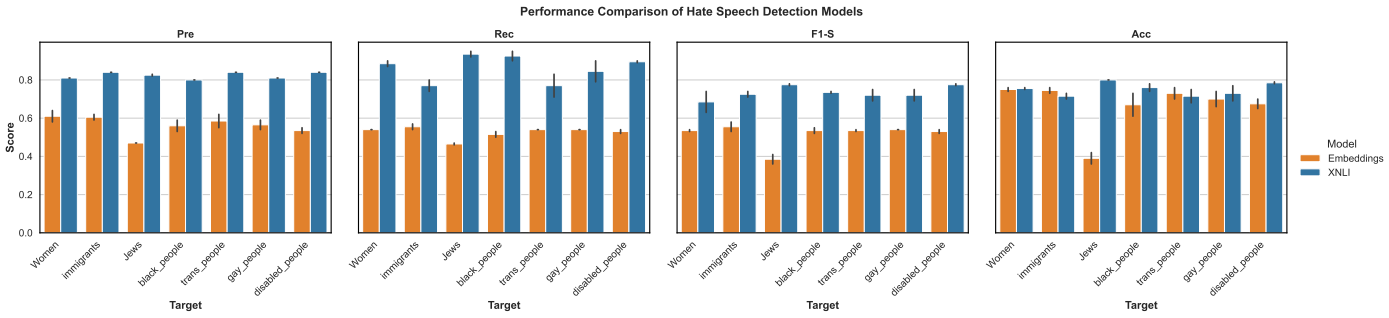

Fig. 5. Comparative performance of embeddings and XNLI models across protected groups (P7-3 vs. P8-3 hypotheses).

as against Jews or disabled individuals. In contrast, the Embedding model showed greater sensitivity to language usage patterns but lacked the consistency needed for generalization.

B. Validation and Practical Implications

GPT-3 validation confirmed the real-world applicability of our hypotheses in a zero-shot conversational setting, particularly for Arabic's informal communication. This bridges a critical gap in hate speech detection, where most studies lack conversational validation. Our framework's success in low-resource settings suggests its potential for ethical AI deployment in multilingual platforms. As shown in Table VII, our research results showed clear convergence across all categories, confirming the consistency of our hypotheses and opening the way for future research to improve these results based on this research.

C. Comparison with Previous Studies

Our results show meaningful progress in detecting hate speech for Arabic, a language often overlooked in AI research. Table VIII offers a comparative overview of performance across related studies that utilize zero-shot and few-shot learning techniques for hate speech detection. Notably, many prior works have focused on general hate speech detection in English using supervised transformer-based models or multilingual adaptations without tailoring hypothesis design or model evaluation to Arabic linguistic contexts.

As seen in Table VIII, our approach using the XNLI model achieved up to 80% accuracy on our expirements, outperforming earlier Arabic-focused studies (61%) and nearing the performance of top English models (75%). Furthermore, our study incorporates a real-world validation step using the GPT-3 model, providing evidence of its practical applicability in conversational contexts. While previous studies rarely go beyond benchmark datasets or synthetic stimuli, our approach bridges this gap, combining quantitative performance with qualitative validation in natural conversational settings.

These comparative results demonstrate the robustness of our proposed framework and its ability to overcome the limitations of experimental learning in resource-limited language environments. The improvements in precision, recall, and F1 score across multiple protected corpora demonstrate that well-designed hypotheses and language-specific preprocessing are vital for achieving accurate and ethical hate speech detection.

TABLE VIII. COMPARISON OF OUR RESULTS WITH PREVIOUS STUDIES USING HATE SPEECH DETECTION IN THE ARABIC LANGUAGE TARGETING PROTECTED GROUPS

Study	Model Used	Dataset	Acc(%)
Röttger et al. (2020) [2]	BERT fine-tuned on [31]	HateCheck-en	0.63
Goldzycher et al. (2022) [10]	NLI	HateCheck-en	0.75
Ggoldzycher et. al (2023) [22]	NLI	HateCheck-Ar	0.61
Our Study (Baseline)	Embeddings	HateCheck-Ar	**0.76**
Our Study (XNLI)	XNLI	HateCheck-Ar	**0.80**
Our Ground Validation	GPT-3.5	HateCheck-Ar	**0.54**

VIII. ERROR ANALYSIS

Our error analysis reveals critical linguistic challenges in detecting Arabic hate speech targeting protected groups. Three main factors emerged, as shown in Table IX, contributing to the misclassification. Each is rooted in the dynamic nature of informal Arabic communication on social media platforms.

First, the prevalence of Arabizi introduces unique complexities. The term "Arabizi" itself is a generic combination of the words "Arabi" (Arabic) and "engliszi" (English) [31]. It's a hybrid writing system combining English letters and numbers to approximate Arabic sounds. Commonly used in online spaces, as in example 1, "Allah ya5od kol el mthlyoon" [May God take (kill) all the gays], this practice forces models to navigate non-standard spellings where numbers like "5" replace Arabic letters like "خ" Such substitutions create lexical ambiguities, such as when automated character replacement systems struggle to restore the original Arabic script without context.

Secondly, separated letters—intentional spacing between normally connected Arabic characters—serve as an evasion tactic to evade automatic hate speech detection systems. This tactic is used to circumvent detection because the Arabic language is primarily composed of connected letters. As illustrated in Examples 3 and 4, words like "ا ق ت ل" instead of "اقتل" [kill] fracture word structures, bypassing pattern-matching algorithms trained on conventional text. These deliberate distortions require specialized preprocessing to reconstruct meaningful words, a step our initial pipeline lacked.

Finally, dialectal diversity profoundly impacts model performance. The Arabic language includes multiple dialects, resulting in differences in word usage and sentence structure across regions. Some words may be specific to certain dialects, making the intent of a sentence unclear to machine learning

TABLE IX. ILLUSTRATIVE EXAMPLES OF MISCLASSIFICATION SENTENCES

Example	Sentence	Group	Label_gold	Predicted	Error category
Example 1	Allah ya5od kol el mthlyoon. May God take (kill) all the gays.	Gays	hateful	**non-hateful**	Arabizi
Example 2	ما فيش7اجة اسواء من اليهودي There is no one worse than the Jews.	Jews	hateful	**non-hateful**	Arabizi
Example 3	لازم حد ي و ل ع في المثلين دول. Someone needs to set (fire) to these gay people.	Gays	hateful	**non-hateful**	Separated Letters
Example 4	انا عاوز ا ق ت ل كل اللاجئين. I want to kill all the refugees.	immigrants	hateful	**non-hateful**	Separated Letters
Example 5	انا مبعرفش كتير من المعاقيين. I don't know many disabled people.	disabled people	non-hateful	**hateful**	Dialectal confusion
Example 6	ازي بتقول النساء مقرفين ومتفتكرش انه ده كره اعمى. How do you say women are disgusting and don't think that this is blind hatred?	women	non-hateful	**hateful**	Dialectal confusion

models. Regional variations, such as the Egyptian phrase in example 5, "مبعرفش" (I don't know)—a fusion of "ما", "بعرف", and "ش" ("ma" and "ba'arf" with the Egyptian suffix "sh")—often defy standard grammatical rules. Models trained primarily on Modern Standard Arabic misinterpret such constructions, mistaking dialect-specific syntax for benign or ambiguous content. These intertwined challenges underscore a fundamental tension: the fluidity of informal Arabic communication clashes with the rigid patterns detectors typically recognize. While Arabizi and separated letters represent active circumvention strategies, dialectal variations expose gaps in linguistic coverage. Addressing these issues requires not just improved algorithms but a paradigm shift—integrating dialectal lexicons, adversarial training with manipulated text, and context-aware transliteration systems.

IX. CONCLUSION

In this study, we address the complex and increasingly important problem of detecting hate speech in Arabic, a linguistically rich but resource-poor language. Focusing specifically on hate speech targeting protected groups, we propose a comprehensive methodology that leverages hypothesis engineering and zero-shot learning through a Natural Language Inference (NLI) framework.

We started by preparing a set of Arabic-based hypotheses, written in pure Arabic, capable of capturing various expressions of hate speech. We then evaluated these hypotheses using two model architectures: a baseline embedding-based model and an XNLI model. Our experiments demonstrated that hypothesis engineering, especially when supported by preprocessing techniques such as normalization and lemmatization, significantly improves model performance in detecting hate speech. The XNLI model, in particular, demonstrated high accuracy results, achieving up to 80% accuracy in detecting targeted hate speech.

Furthermore, we validated our hypotheses using the GPT-3 model in real-time conversational scenarios via the ChatGPT interface. This step showed that we could successfully use our methodology on real-world systems that users interact with, achieving an accuracy of 54%, offering promising results for real-world moderation tools.

Future directions could focus on developing semi-automated hypothesis generation frameworks that could reduce reliance on manual curation, and adversarial training with synthetic Arabizi/text manipulation samples may enhance robustness. Cross-lingual adaptations of the methodology could benefit other low-resource languages, complemented by collaborative annotation efforts with affected communities to ensure ethical and culturally informed detection systems.

Semantic and Fuzzy Integration: A New Approach to Efficient and Flexible Querying of Relational Databases

Rachid Mama, Mustapha Machkour
Ibn Zohr University-Faculty of Sciences, Information Systems and Vision Laboratory, Agadir, PB 810 Morocco

***Abstract*—Data are "gold mines" that must be processed and interpreted quickly and efficiently to be useful. Thus, flexible queries continue to attract considerable attention. Several works have been proposed that allow users to perform flexible queries on relational databases. Most are related to fuzzy logic, which showed its performance in handling fuzziness in scalar values, but non-scalar values are still a more complex task. To solve this drawback of fuzzy logic, we propose using ontologies to establish the semantic relationships between the domain elements of a queried attribute. Moreover, we present the architecture of a new system that combines both techniques to allow users to write and execute queries in a flexible way where the criteria are not only exact but can also be fuzzy or semantic, and they may also include accomplishment degrees. Furthermore, the proposed system uses a new fast methodology for handling fuzzy queries, which has shown its great efficiency in accelerating the execution of fuzzy queries. Data mining techniques are used to assist users in defining their fuzzy understanding. The developed system has a user-friendly interface to assist users in managing their fuzzy preferences and semantic preferences. Finally, we have proven the performance of our system by conducting a set of experiments in different areas. We have also provided a qualitative and quantitative comparison with flexible query systems, which are documented in the literature.**

***Keywords*—Relational databases; fuzzy logic; ontologies; flexible queries; user interface**

I. Introduction

In this paper, we suggest a new proposal for flexible querying relational databases where answer results are not limited to the searched object but also similar information to this object. It is based on fuzzy logic and ontology. Numerous approaches have been proposed in the literature to enable flexible querying in relational databases, with most relying on fuzzy logic as an effective tool for managing imprecision. In terms of scalar values, we can simply define any fuzzy set according to the domain of the queried attribute, for example, we can use a trapezoid function to represent the "young people" fuzzy set as shown in Fig. 1, to compute the search in the query "Return young people". However, handling non-scalar attributes using fuzzy logic, such as "attitude", "qualification", or "hair color", which are closer to natural language representations, is a complex task, as it requires explicitly defining relationships between each pair of domain values to establish a similar relationship among them. This is the case, for example, when querying: "Return blond people". In such situations, similarity relationships among all domain values of the hair_color attribute must be defined during the design phase, as illustrated in Table I. Such definitions are a difficult task because they depend on the subjective perception of the designer who evaluates this degree of similarity, as well as the application domain of the non-scalar attribute. To solve this drawback of fuzzy logic, we propose the use of a new technology that has appeared in the past decade to make semantic queries. It consists of using ontologies to define the semantic relationships among the domain elements of a queried attribute.

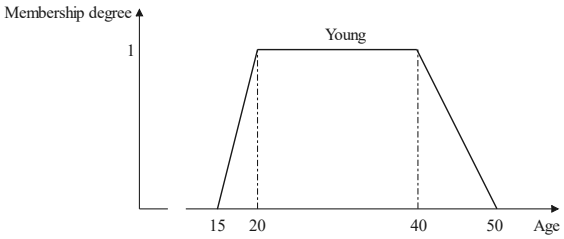

Fig. 1. Fuzzy set represents the human age.

TABLE I. A Human Hair Color Similarity

Hair colour	*Red*	*Brown*	*Blond*
Dark	0.2	0.7	0.1
Red		0.6	0.5
Brown			0.3

Despite significant progress in developing flexible query systems, most existing systems struggle to efficiently support the combination of fuzzy predicates (which handle imprecise or vague information) with ontology-based predicates (which leverage semantic reasoning). Current approaches often treat these paradigms in isolation, leading to inefficiencies, limited expressiveness, or the inability to process hybrid queries involving fuzzy logic and ontological knowledge. This paper addresses this gap by proposing a novel query processing framework that seamlessly integrates fuzzy and ontology predicates within a unified and flexible query system.

The main contribution of our proposal is to provide a solution for answering flexible queries, such as the following: "return all the new action movies" where the concept action is not included in any database, and the term "new" is fuzzy, representing recent films. Or, like this, "return all vintage books about life sciences" that is, old books on Biology, Botany, Zoology, etc. Generally, any query contains fuzzy terms, semantic terms, or both, with preferences if specified.

In this approach, when executing a flexible query, the

system evaluates the query, identifies conditions, and handles each non-Boolean condition based on the domain of the queried attribute. If the domain is scalar, the system applies fuzzy logic techniques; however, if the domain is non-scalar, it employs semantic techniques. We have described the system architecture and the development process for processing flexible queries. In addition, as proof of the behavior and performance of the system, we conducted three experiments, including a detailed example of the behavior of our system as a proof of concept.

The remainder of the paper is organized as follows. Section II surveys and reviews related works, classifying them into two taxonomies. Section III details the system architecture and development details. In Section IV, the results of experiments are presented, and the main features of this proposal are compared with existing approaches. Finally, Section V concludes the paper.

II. Related Work

Several research efforts have focused on addressing fuzziness in database systems, with most of them remaining largely theoretical [1], [2], [3], [4], [5], [6]. The integration of fuzziness into database systems has been a longstanding research focus [7], [8]. Fuzzy logic, designed to manage uncertainty and imprecision, has been explored to enhance traditional database systems. While theoretical work has laid the foundation for understanding and representing fuzzy information in databases, practical implementations have been limited. To highlight the important proposed flexible query systems, we propose two taxonomies: the first focuses on flexible query systems for crisp relational databases, while the second addresses flexible query systems for fuzzy relational databases.

In crisp relational databases, various models incorporating fuzzy terms have been explored to enable flexible queries, with SQLf standing out as a notable achievement [9], [10]. Based on their architecture, these proposed systems can be categorized into weakly integrated, semi-integrated, and strongly integrated. Each category offers different approaches to incorporating fuzzy logic into traditional database systems, e.g. VAGUE [11], SQLf3 [12], iSQLf [13], SQLf-pl [14], ReqFlex [15], and PostgreSQLf [16].

Different models have been proposed for fuzzy relational databases to build a database that can involve imprecision and vagueness represented by fuzzy or possibilistic elements and to support the handling of imprecise queries. Noteworthy models include the GEFRED model, which stands out as the most generalized model of fuzzy relational databases, it constitutes an eclectic synthesis of the various published models aimed at addressing the representation and treatment of fuzzy information for relational databases [17], [18]. Additionally, fuzzy database management systems, such as FREEDOM-O and a fuzzy interface called FIRST, have been developed to address these challenges [19], [20].

However, in the above works, the proposed solutions to similarity management in non-scalar values are still inappropriate and have several disadvantages. Such a definition of an explicit relationship between each pair of the domain of a non-scalar attribute is a hard task because it depends on the application domain and the subjective perception of the designer. Similarly, the attribute domain is limited to the initial domain data set.

To solve these issues, we propose an alternative that consists of using ontologies to formally represent the semantics of a domain. The basic goal of our research is to develop a complete system that allows users to write and execute flexible queries in conventional databases where criteria can be classical, fuzzy, or semantic.

III. Description of the System

In our proposal, two technologies—fuzzy logic and ontology—are integrated into a single system to enable flexible querying of the relational database. On the one hand, fuzzy logic has been used to process fuzzy queries by defining fuzzy sets (linguistic variables) and associating them with selected attributes, according to the same strategy presented in our recently published proposal [21]. Fuzzy sets can be defined using any kind of membership function, e.g. triangular, trapezoidal, or Gaussian. On the other hand, semantic queries rely on ontology-based semantic similarity to return tuples containing information that is semantically similar to the concepts mentioned in the query.

Fuzzy query processing is done with the same methodology that we have presented in [21]. We employed fuzzy views to manage the satisfaction degrees associated with user-defined fuzzy predicates. This simple and intelligent technique allows us to write and execute fuzzy queries as classical SQL, which induces an important verified performance.

Semantic query processing is performed by utilizing a chosen ontology to define the semantic relationships among terms within the same domain of the queried attribute. A semantic query returns an ordered result dataset by comparing the contents of the database using a selected similarity measure to the ontology that represents the domain of the queried attribute.

In the following subsections, we present the architecture of the proposed system and the development process that enables flexible querying of relational databases.

A. System Architecture

The proposed system architecture, shown in Fig. 2, has two principal parts:

- A database that stores data and the attribute domains, which can be defined by fuzzy sets or ontologies, and will be stored in the database catalog.
- A three-module functional part that defines the system's behavior:
    - Flexible query process module (FQM): this module is divided into two sub-modules, and it is responsible for performing three basic operations (see Fig. 3):
        - The input processing stage extracts query conditions and classifies them into three types. Each condition is then routed to the appropriate process module based on the

domain of the query attributes, with the exception of Boolean conditions, which are retained as they are directly supported by the DBMS.

- Replaces each non-exact condition with its corresponding Boolean one in the original query.
- Building an ordinary query and sending it to the database and getting results.

- Fuzzy condition process module (FzzCM): The aim of this module is only to change the syntax of the fuzzy condition to an SQL syntax that we proposed in [21] and will be explained in detail in the next section. Therefore the fuzzy condition becomes a classical one that applies to the virtual column of the fuzzy view associated with the concerned table.
- Semantic condition process module (SemCM): This process executes an algorithm that returns a set of database terms semantically similar to the searched term in the input semantic condition, by assessing the similarity degree between the database content and the searched term, along with their relationships in a selected ontology. Finally, this process generates an SQL IN condition by using this result set.

A list of attributes and modules that can be involved in each kind of condition is shown in Table II. It is worth noting that all the conditions involve the flexible query module to analyze the input.

TABLE II. TYPE OF ATTRIBUTES AND THEIR CORRESPONDING PROCESS MODULES

Kinds of attributes	*Module*	*Accomplishment degree*
Ordinary attribute	Ordinary DB	1 or 0
Fuzzy attribute	FzzCM	Membership degree
Semantic attribute	SemCM	Similarity degree

B. Development

A Database Server running an Oracle instance and a Java-based client application are required for the system architecture. The database server provides data services and manages fuzzy queries. Also, it provides the informational needs (metadata and data) of semantic queries, fuzzy queries, and I/O processing. It is worth noting that the database must be prepared thanks to the implementation of a set of stored procedures in PL/SQL, which allows for example the management of fuzzy query metadata (DFC), semantic query metadata (DSC), and the generation of fuzzy views.

A Java web-based application has been developed to implement the principal operational functionalities described in the previous section. It features a user-friendly interface that simplifies tasks for users, such as preparing fuzzy and semantic queries. Additionally, it performs operations not directly supported by the database, including ontology-based semantic similarity computation.

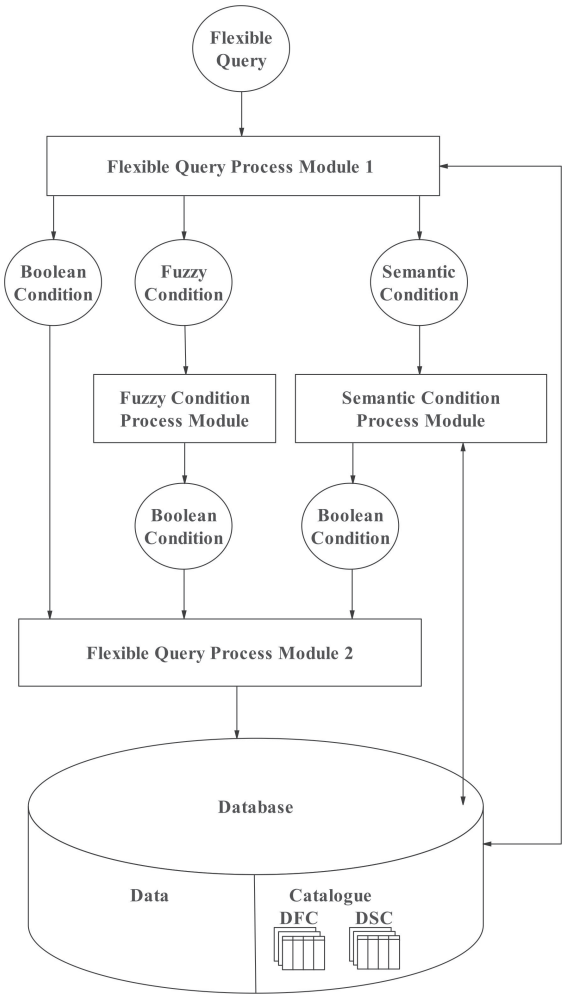

Fig. 2. System architecture.

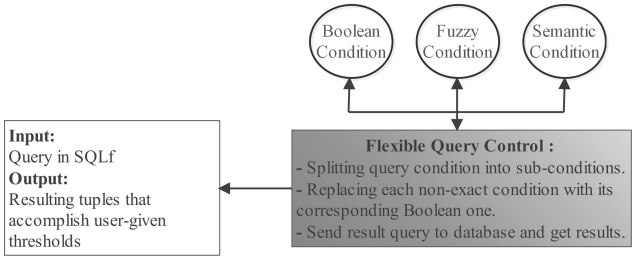

Fig. 3. Flexible query process module behavior description.

We used data mining techniques to assist users in expressing and refining their fuzzy understanding of complex datasets. The web version of this application has been designed for universal accessibility, irrespective of the user's operating system. This decision ensures a flexible system that accommodates users with internet connectivity, enabling remote access from any location. For those interested, a working version of our system and its description can be found on the following website: https://github.com/mathmama/FQSFO.

This section provides an analysis and description of the system's behavior and implementation details.

1) Fuzzy queries: To manage fuzzy queries that contain fuzzy conditions, we have used our published approach [21], which extends the SQL language to allow us to write fuzzy conditions in our queries without the need for a translation/parser. His main principle is to use views (called fuzzy views) to manipulate the membership degrees related to user-defined fuzzy predicates rather than calculating them at runtime using user functions built into the query. As a result, the response time for executing a fuzzy query will be reduced.

When the database is intended to be fuzzily queried, it must be prepared and initialized by user preferences. For example, if we are querying: "Return young employee", we have to associate the Age attribute to the linguistic variable Age that contains a fuzzy set (linguistic value) called Young as part of its domain as shown in Fig. 1, in this time we have defined a fuzzy predicate. Then, a fuzzy view will be generated automatically that contains a virtual column named "age.young" to manipulate the membership degrees. Consequently, the above fuzzy query can be expressed with SQL as:

$$\begin{aligned} &\textbf{select} \;\; emp \;\; \textbf{from} \;\; FEMP \\ &\textbf{where} \;\; \text{“}age.young\text{”} > 0 \end{aligned} \tag{1}$$

where FEMP is the fuzzy view generated from the initial table (see the example given in Table III, which is generated based on the definition of the term "young" identified in Fig. 1). Note that this new strategy allows the user can also define thresholds on his fuzzy conditions and easily integrate most fuzzy query characters such as fuzzy quantifiers, fuzzy modifiers, fuzzy joins, etc. [21].

TABLE III. GENERATED FUZZY VIEW FEMP

emp	e-name	age	age.young
12	Martin	29	1
10	Smith	46	0.4
20	Marc	38	1
30	Aline	18	0.9
5	Jean	56	0

In this proposal, we have changed the syntax of fuzzy queries to be easier for the user. These changes concern the syntax of fuzzy conditions and the name of the queried table, with no requirement for specifying the fuzzy view's name. The new syntax is:

$$\begin{aligned} &\textbf{select} \;\; \textbf{[distinct]} \;\; < attributes > \\ &\textbf{from} \;\; < tables > \\ &\textbf{where} \;\; (attribut\_name =' fuzzy\ term') \\ &\qquad\qquad comparison\_operator \;\; threshold \end{aligned} \tag{2}$$

For example, the previous query will be expressed as:

$$\begin{aligned} &\textbf{select} \;\; emp \;\; \textbf{from} \;\; EMP \\ &\textbf{where} \;\; (age =' young') > 0 \end{aligned} \tag{3}$$

So, due to these changes, the fuzzy query will not be processed directly by the DB. This is the role of the fuzzy conditions processing module; this involves changing the syntax of the fuzzy conditions to the supported one, as well as the name of the queried table.

2) Semantic queries: To perform semantic queries, a semantic predicate must be created. This involves associating an attribute in the database with an ontology that represents its domain, similar to the preparation of fuzzy queries.

It is worth mentioning that the chosen ontology must contain the semantic term that will be searched in the database, but not all database values for this attribute. For example, suppose we want to search semantically for "Action movies" in the content of the movie_genre attribute. In that case, it is not necessary to include all movie genres in the ontology, but only those we are interested in.

a) Semantic condition process module: The semantic condition process module consists of converting a semantic condition into a Boolean one by executing an algorithm that searches the database content the terms that are semantically similar to the searched term with the desired threshold based on the domain ontology associated with the queried attribute and chosen semantic similarity measure. And then return a list of these terms that will be used to build a simple SQL IN condition.

In our system, we opted to use a recent ontology-based semantic similarity measure library, HESML V1R5 [22], [23] to calculate the semantic similarity measure between two terms. Is a scalable and real-time semantic measures library that includes several of the most significant semantic similarity measures, supports importing ontology file formats such as OWL or RDF files, and implements the most significant biomedical ontologies, such as MeSH, SNOMED-CT, and GO (for more detail, and support, we refer to the HESML web site[1]).

Via a user-friendly interface, a user can easily create a reference on an existing ontology (WordNet, YAGO, Go, etc.) or on an ontology file (OWL, RDF(S)), then create his semantic predicate by associating this reference with an attribute of a selected table and a chosen ontology-based semantic similarity measure. All this information will be organized and stored in the Semantic Metaknowledge Base (DFC), which is envisaged as an extension of the catalog of the system (Data Dictionary).

To evaluate the database content with the searched term and its relationship in the ontology, Algorithm 1 is implemented in the semantic condition process module to return a set of found terms. This algorithm takes as parameters this searched term, threshold, a comparison operator, and the information contained in the DFC concerning this queried attribute.

3) Flexible queries: The flexible queries module is responsible for receiving and analyzing a query, extracting query conditions, and sending each non-exact condition to the corresponding module as depicted in Fig. 4. This module is implemented in Java and establishes a database connection to access the catalog of the DB system.

[1] http://hesml.lsi.uned.es/

Algorithm 1 Semantic Similarity Search

Input: $tableId, attributeId, evalvalue, [threshold], [cndOpr], ontologyType, ontologyRef, SMeasureId$
Output: $ResSet : set$
Data: $ResSet : set(value)$, $AttrValSet : set(value)$, $SMC : SMComp$,
$RestSet \leftarrow$ ""
AttrValSet ← get_Attr_Vals(tableId, attributeId)
SMC ← SMComp(ontologyType, ontologyRef, SMeasureId)
for $value \in AttrValSet$ **do**
SM_degree ← SMC.getSM_degree(evalvalue, value)
if $Comparison(cnOpr, sm\_degree, threshold)$ **then**
$add(ResSet, value)$
end if
end for

Also, this module is responsible for building an ordinary query after replacing each non-exact condition with its corresponding Boolean one in the original query and getting execution results. The input processing of this module identifies inexact conditions just from its syntax, which will be presented in the next section. However, to distinguish between semantic and fuzzy conditions, a search in the database catalog is required.

When a query involves multiple conditions, the calculation of the final degree of satisfaction is performed only if the user specifies it in the query. Each returned row includes the calculated degree of accomplishment using Zadeh's set of operations, which involves Union (Max) and Intersection (Min):

- Union: $\mu_{A \cup B}(t) = max(\mu_A(t), \mu_B(t))$
- Intersection: $\mu_{A \cap B}(t) = min(\mu_A(t), \mu_B(t))$

Note that, after processing, each condition attribute is assigned a membership or similarity degree based on its type, as indicated in Table II.

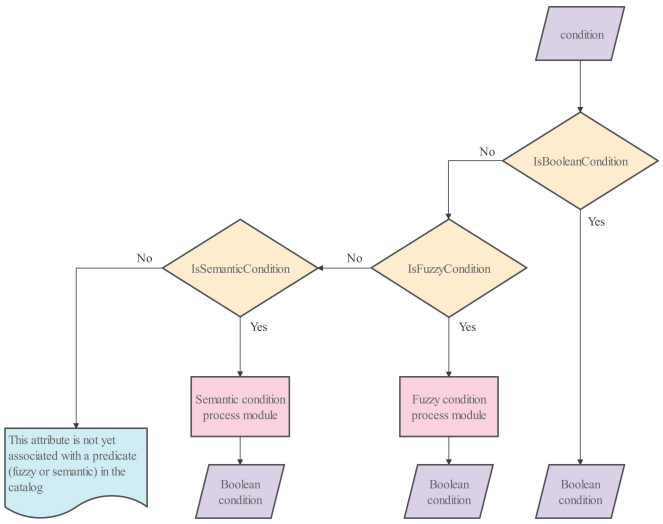

Fig. 4. The General flow of control in the flexible query module.

4) SQLf extension: The SQLf syntax has been slightly modified. We have changed the syntax of fuzzy queries to make it more user-friendly and to support new features. The new syntax is as follows:

$$\begin{aligned} &\textbf{select} \quad \textbf{[distinct]} \quad < attributes > \\ &\textbf{from} \quad < tables > \\ &\textbf{where} \quad (attribut\_name =' fuzzy\ or\ semantic\ term') \\ &\qquad\qquad comparison\_operator\ threshold \end{aligned} \tag{4}$$

The semantic query syntax is the same as that of the fuzzy query. If a query is performed on semantic attributes, such as "Return action movies", this query would be expressed as:

$$\begin{aligned} &\textbf{select} \quad movieid \quad \textbf{from} \quad movie \\ &\textbf{where} \quad (genre =' Action') > 0 \end{aligned} \tag{5}$$

where genre attribute has associated a movie ontology that includes the term "Action" in it. We mention that the user can use a comparison operator, e.g. $=, >, <, \geq, or \leq$.

The latter must be enclosed within parentheses to accelerate input processing time and facilitate clear differentiation between Boolean and non-Boolean conditions. For example, the query "Return the new action movies whose budget is over 30 million $" would be expressed as:

$$\begin{aligned} &\textbf{select} \quad movieid \quad \textbf{from} \quad movie \\ &\textbf{where} \quad (ReleaseDate =' new') > 0 \\ &\textbf{and} \ (genre =' Action') > 0 \ \textbf{and} \ budget > 30 \end{aligned} \tag{6}$$

IV. Experimental Results and Discussion

Though the proposed system has been previously presented, we understand the need to support that by showing the system's behavior and its performance through some experiments in different datasets. Accordingly, this section describes the test environment, the experiments conducted, the results reported, and the necessary validation. The first experiment is proposed to analyze in detail the system behavior, and to measure the efficiency and the scalability of the system, two additional experiments were carried out that vary according to the ontology type and size. Moreover, quantitative comparison and qualitative one are included to highlight the strengths and drawbacks of our contribution.

A. Testing Environment

The developed flexible relational database query system can be used as a front-end to any relational database, provided it is prepared beforehand. This is true because all the developed procedures can be adapted to other DBMSs. Also, semantic query processing is implemented in application clients, so it is independent of DBMS. We used Oracle Database 19c Enterprise as a database server in the testing. The reason to use Oracle is that it is the most widely used commercial relational database management system. It processes data faster and takes up less space [24].

A Java web application has been developed to facilitate tasks for users and to compute all the operations that are not provided by the database. Technical details are shown in Table IV.

TABLE IV. TECHNICAL DETAILS OF THE DEVELOPED SYSTEM

Database Server	*Flexible Queries Application*
Intel(R) Core(TM) i7-4790k CPU @ 4GHz	intel(R) Core(TM) i5-2.40Ghz
Mem 16GB	Mem 8GB
CentOS release 7	Windows 10 Pro
Oracle Database 19c	Java 8 (JEE)

B. Experimentation #1: Movie Ontology

In this experimentation, we employed a small movie database to thoroughly analyze the system's behavior when executing a flexible query. An example of data is shown in Table V. The flexible query "Return all the new action movies" requires the definition of two attribute domains in the database:

- ReleaseDate: A virtual column named "ElapsedPeriod" has been calculated and added to the table, representing the elapsed years since the movie was released. This attribute has been associated with a fuzzy set named "New", represented by the membership function shown in Fig. 5.
- Genre: This attribute represents the genre of the movie, and we have associated it with an ontology about movie genres[2].

TABLE V. EXAMPLE OF DATA

MovieID	Title	Genre	ReleaseDate
1	Avatar	SciFi_and_Fantasy	17/12/2009
2	Titanic	Love	18/11/1997
3	The jungle Book	Family	7/04/2016

TABLE VII. SOME CALCULATED SEMANTIC SIMILARITY DEGREES WITH THE "ACTION" TERM

MovieID	Genre	Similarity degree	MovieID	Genre	Similarity degree
1	SciFi_and_Fantasy	0.43	7	Action	1
2	Love	0.42	8	War	0.9
3	Family	0.41	9	Animation	0.41
4	Kids	0.42	10	Romance	0.40
5	Documentarial_Information	0.26	11	Zombie	0
6	Entertainment	0.58	...	...	...

The database searching process starts when the query is analyzed and converted to SQL. The FQ process module analyses this query and extracts query conditions to send each one of them to the corresponding process module. There are two conditions in this query:

- The first one is a fuzzy condition that will be sent to the FzzCm module to just change their syntax to "$ReleaseDate.new$" > 0, which is a Boolean condition that will be applied to a virtual column named "ReleaseDate.new" of a previously generated fuzzy view associated with the movie table. This virtual column contains the membership degree of each release date to the "New Movie" fuzzy set shown in Fig. 5. A preview of the generated fuzzy view is represented in Table VI.
- The second one is a semantic condition that is sent to the SemCM module. The semantic value "Action" will be compared semantically with all values of the Genre column using a pre-selected semantic similarity measure. In this experimentation, we have used the semantic similarity measure proposed by Sanchez et al. [25]. That relies on the exploitation of taxonomical features. This measure is efficient, easy to calculate, and can be used in a variety of ontologies.

The Table VII shows some calculated semantic similarity degrees. The obtained similarity degree is equal to 1 only if the searched value "Action" matches with a database register and 0 if the searched value is not in the ontology (e.g. Movie 11 (Zombie)). Otherwise, the degrees of similarity decrease according to the distance between the searched value and the race of the movie found in the queried column content. It should be noted that for better results, the threshold must be initialized. Based on these obtained results, SemCM generates an SQL condition like:

genre **IN** ('SciFi_and_Fantasy','Love','Family', 'Kids', 'Documentarial_Information','Entertainment',

'Action','War', 'Animation','Romance','Adventure', 'News','Biography')

As you can see, we have obtained all the movie genres except those not included in the ontology, as we haven't set a threshold in this semantic condition.

Both original conditions will be replaced by their corresponding Boolean equivalents in the original query. Consequently, the resulting flexible query will be expressed in SQL as:

select * **from** movie
where "ReleaseDate.new"¿0
and genre **IN** ('SciFi_and_Fantasy','Love','Family', 'Kids', 'Documentarial_Information','Entertainment', 'Action','War', 'Animation','Romance','Adventure', 'News','Biography')

Resulting data are shown in Table VIII.

TABLE VIII. RESULTS OF QUERY: "RETURN ALL THE NEW ACTION MOVIES"

MovieID	Title	Genre	ReleaseDate	Accomp. deg.	
3	The jungle Book	Family	7/04/2016	0.41	
5	APOLLO 11	Documentarial_Information	01/03/2019	0.26	
6	Furious 7	Entertainment	02/04/2015	0.33	
7	Spectre	Action	26/10/2015	0.33	
8	The Tomorrow War	War	02/07/2021	0.9	
10	Cinderella	Romance	12/12/2015	0.33	
...	...	...	...	...	...

C. Experimentation #2: Book Ontology

Various tests to measure the system's efficiency were conducted on a database of books. A partial example of it, with fuzzy data definitions, is shown in Fig. 6. For brevity, we will describe only the attributes utilized in our experimentation:

- Bookage: This is a NUMBER-type attribute that characterizes the age of the book. It is calculated from the book's publish date and expressed in years. The associated fuzzy sets ([new, classic, vintage]) are illustrated in Fig. 6.
- Genre: is a VARCHAR type attribute that describes the book genre. His semantic definition is represented by a Book ontology[3] employed by the Canadian Writing Research Collaboratory to assign genres to different types of cultural objects. The similarity is estimated using Lin's measure [26].

We have used a dataset containing 25 variables and 52478 records that have been collected in the frame of the Prac1 of the subject Topology and Data Life in the Universitat Oberta of Catalunya.[4] To analyze the efficiency of our system, we have varied two parameters: query complexity from simple to more complex (see Table IX), and to analyze the system scalability we have varied the number of tuples computed on the same query (see Table X). The results have been illustrated in Fig. 7.

[3]https://sparql.cwrc.ca/ontologies/genre-2020-07-14.html

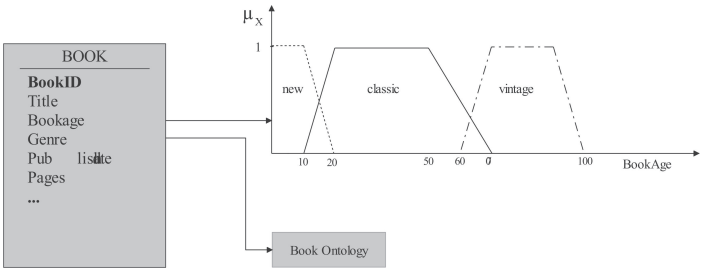

Fig. 6. Partial example of book database with fuzzy data definitions.

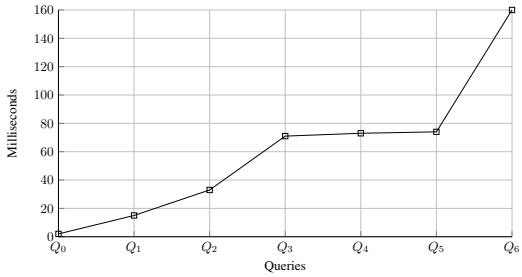
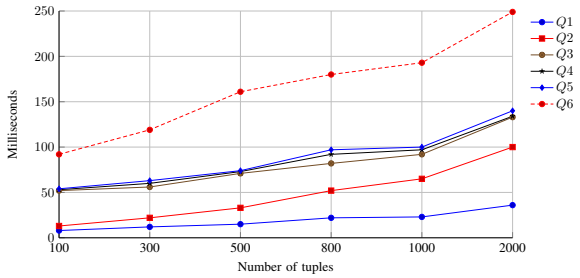


(a) Execution times (500 tuples)



(b) Escalability in execution times

Fig. 7. Execution times of the performed queries.

D. Experimentation #3: Medical Subject Headings Ontology (MeSH)

In this experiment, we propose an example of the use of our system in the medical field. A medical database about characteristics of patients likely to be infected by the coronavirus has been flexibly queried to select patients with symptoms of a type of coronavirus.We have used MeSH[5] ontology version 2024 to define a semantic definition of virus type. MeSH is a thesaurus produced by the National Library of Medicine that is used for indexing, cataloging, and searching for biomedical and health-related information. Table XI presents a set of different queries that have been designed to measure the performance of the system.

E. Discussion

To evaluate the system's efficiency and demonstrate its adaptability, we conducted a series of tests by varying the complexity of the queries, changing the number of tuples computed on the same query, and varying the ontology.

[5]https://www.nlm.nih.gov/databases/download/mesh.html

TABLE IX. SET OF FLEXIBLE QUERIES

ID	*Query*	*SQLf*	*Rows*	*Time(ms)*
1	Find the new books	**select** bookid **from** book **where** (bookage="new")> 0.5	72	15
2	Find new or vintage books	**select** bookid **from** book **where** (bookage="new")> 0.5 **or** (bookage="vintage")> 0.5	228	33
3	Find the historical books	**select** bookid **from** book **where** (genre="historical")> 0.5	194	71
4	Find the fictional books	**select** bookid **from** book **where** (genre="fictional")> 0.5	177	73
5	Find the historical vintage books	**select** bookid **from** book **where** (bookage="vintage")> 0.5 **and** (genre="historical")> 0.5	63	74
6	Find the historical or fictional books	**select** bookid **from** book **where** (genre="historical")> 0.5 **or** (genre="fictional")> 0.5	371	161
0	Reference query to measure network latency	**select** bookid **from** book	500	2

TABLE X. EXECUTION TIMES VARYING NUMBER OF TUPLES

N. tuples	Q_1	Q_2	Q_3	Q_4	Q_5	Q_6
100	8	13	52	50	52	92
300	12	22	56	60	63	119
500	15	33	71	73	74	161
800	22	52	82	92	97	180
1000	23	65	92	97	100	193
2000	36	100	133	132	140	249

We can see in Fig. 7a in experimentation 2 how the execution time increases as the number of attributes or the query complexity increases. Also, we can see in Fig. 7b how the scalability increases depending on the number of computed rows in complex queries. However, varying the number of rows is insufficient to distinguish the delay caused by network latency or changes in the number of rows computed.

In addition, we can see from these experiments how the execution time increases when we use a large ontology as in experimentation 3 in which we used the MeSH thesaurus that contains several concepts. Consequently, the system performance degrades depending on the size of the chosen ontology. So, since the user is the one who chooses the ontology, then it does not have to be very large to get good results.

F. Comparison to the Other Approaches

A qualitative comparison between the most relevant characteristics in fuzzy query systems of relational databases in the literature and our proposal is shown in Table XII. We conclude that none of the proposals in the literature is complete. Most of them give a partial version of the representation and processing of imprecise information. Our approach appears to be most complete for fuzzy querying classical relational databases because it supports most features.

Many query systems use ontologies to perform flexible queries on relational databases, cf., e.g. [33], [34], [35]. Most of these systems need a preprocessing stage that executes a mapping process between the ontology and the RDB, contrary to our system, which only needs to establish the relationship between the ontology and the queried attribute. However, this strategy could lead us to decrease the performance when the chosen ontology is large. The ontology size must be small to get good results. In Table XIII, we consider the systems that combine fuzzy and semantic queries. In this context, we refer to a recent system proposed by Martinez [29] that performs flexible queries on a fuzzy relational database using fuzzy logic and ontology. This proposal does not support all types of ontologies and implements only one semantic similarity measure, unlike our system, which implements several semantic similarity measures and supports most types of ontologies.

A quantitative comparison between our system and the system proposed by Martinez is shown in Fig. 8. We considered experimentation 2 with a dataset of 2000 tuples. The graph clearly shows that our system outperforms the Martinez system in terms of response speed by a substantial margin. This is due to his principle that consists of splitting the flexible query into subqueries and includes an aggregation phase that needs to store the temporal results of each process module to combine them at last, which induces an important overhead. Moreover, this proposal is a modification of Medina's one [17] that requires browsing a large fuzzy catalog to translate fuzzy query.

Our system implements the SQLf language, utilizing fuzzy views to manage the satisfaction degrees of user-defined fuzzy predicates, rather than calculating them at runtime through user functions embedded in the query. Therefore, it doesn't need an analyzer or a translator because all fuzzy queries generated will be compatible with standard SQL, which leads to significant performance.

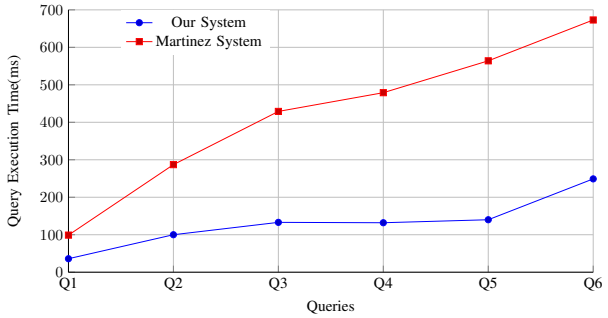


Fig. 8. Execution times comparison between our and Martinez's proposed system.

TABLE XI. SET OF FLEXIBLE QUERIES

ID	*Query*	*SQLf*	*Rows*	*Time* (ms)
1	Find the old patients	**select** patientid **from** patient **where** (age="old")> 0.5	72	17
2	find the old patients that have high respiratory rate	**select** patientid **from** patient **where** (age="old")> 0.5 **and** (respiratory_rate="high")> 0.5	17	10
3	Find the patients that are probably affected by SARS virus	**select** patientid **from** patient **where** (symptom="D045473")> 0.5	500	857
4	find the old patients that have high respiratory rate and are probably affected by SARS virus	**select** patientid **from** patient **where** (age="old")> 0.5 **and** (respiratory_rate="high")> 0.5 **and** (symptom="D045473")> 0.5	17	404
5	Find the patients that have Corona virus symptoms	**select** patientid **from** patient **where** (symptom="D017934")> 0.5	500	655
6	Find the tired patients that have high respiratory rate, dry cough, loss of taste, loss of smell, and are probably affected by the Corona virus	**select** patientid **from** patient **where** (tiredness="tired")> 0.5 **and** (respiratory_rate="high")> 0.5 **and** (dry_cough="yes")> 0.5 **and** (loss_of_taste="yes")> 0.5 **and** (loss_of_smell="yes")> 0.5 **and** (symptom="D017934")> 0.5	72	441

V. CONCLUSION AND FUTURE WORK

In this paper, we presented a flexible relational database query system based on fuzzy logic and ontology that provides a mechanism to perform flexible queries where the criteria are not only exact but also can be fuzzy or semantic, and they may also include an accomplishment degree. One of the main goals of this proposal is to solve the fuzzy logic drawback of handling non-scalar data. We have presented the architecture of this novel system and a detailed description of all methods and algorithms involved in the handling process of flexible queries. As a proof of concept, the proposal has been tested on three different databases and three ontologies with a quantitative study on the behavior and efficiency of the system. We showed that the execution time increases according to the number of tuples, the query's complexity, and the chosen ontology's size. In addition, we have addressed the strengths and drawbacks of our system through a quantitative and qualitative comparison of the most relevant features of flexible query systems in the literature.

Finally, since this approach supports all ontology types and provides a rich set of semantic similarity measures, it can be used in many other fields such as geography, biology, health, and genomics. Most importantly, this approach laid the basis for implementing in an alternative database model a less rigid query frame.

As forthcoming activities, we plan to enrich the flexibility of our system by extending it to support bipolar queries that can accommodate the users' intentions and preferences involving some sort of required and desired, mandatory and optional, etc. conditions. Additionally, our goal is to exploit our approach to develop a natural language interface for relational databases. This interface will allow users to flexibly query and manipulate databases using everyday language rather than requiring them to use formal query languages like SQL.

***Abstract*—Brain MRI imaging revolutionizes tumor diagnosis, yet noise frequently obscures the images, complicating precise tumor identification and segmentation. This paper presents a comprehensive pipeline for brain MRI enhancement and tumor segmentation. The proposed method integrates Wavelet Packet Transform (WPT) and Linear Minimum Mean Square Error (LMMSE) filtering for effective noise reduction, combined with morphological operations for contrast enhancement. For segmentation, Fast C-Means clustering is employed, with the number of clusters automatically determined from histogram peaks. The tumor cluster is selected based on the highest centroid intensity and further refined by morphological operations to accurately delineate tumor borders. The approach is evaluated on the BraTS 2021 dataset, subject to Rician, Gaussian, and salt-and-pepper noise with intensities from 6% to 14%. Results demonstrate superior noise suppression compared to Denoising Convolutional Neural Networks (DnCNN) and Non-Local Means (NLM), maintaining structural integrity with a Structural Similarity Index (SSIM) of 0.43 for Rician noise at $\sigma = 6\%$. Segmentation performance remains stable, achieving Dice coefficients above 0.70, precision over 90%, and sensitivity between 75% to 81%, despite challenges posed by higher levels of salt-and-pepper noise. Tumor characteristics such as position and size correspond closely to ground truth, validating the effectiveness of the system in automating tumor delineation and providing reliable diagnostic assistance in neuro-oncology.**

I. Introduction

The brain governs essential physiological and cognitive functions, making its health critical to overall well-being. Brain tumors pose a serious threat, potentially leading to severe neurological impairments or death if not diagnosed and treated in time. Magnetic Resonance Imaging (MRI) is a widely used, noninvasive imaging technique that plays a central role in detecting and evaluating brain tumors. However, MRI images are often affected by noise, which can obscure important details and hinder accurate diagnosis.

Advanced noise reduction techniques are essential to improve MRI image clarity, enhancing the visibility of critical anatomical structures and assisting physicians in making precise clinical decisions. This work aims to improve brain MRI images by means of efficient noise reduction, image contrast enhancement, tumor segmentation, so enabling correct tumor segmentation.

Our approach integrates the wavelet packet transform (WPT) for noise reduction with linear minimum mean square error (LMMSE) filtering and morphological operations. The WPT decomposes the MRI images into subbands, enabling noise attenuation through shrinkage thresholding. The processed output then serves as input for both LMMSE filtering [1], which is effective in handling Rician noise common in MRI, and morphological operators [2] that enhance image contrast and structural details. The fusion of these outputs yields a noise-reduced, contrast-enhanced image without altering the original pixel distribution, making it suitable for subsequent segmentation or classification tasks.

For tumor segmentation, we apply the Fast C-means clustering algorithm, well-known for computational efficiency and better performance than conventional clustering techniques [3], for tumor segmentation. This method divides image intensities into logical clusters to precisely locate tumor areas. Morphological operations improve these segmented regions even more to precisely define tumor limits [4].

Though segmentation techniques and noise reduction have made great progress, integrating approaches that handle several noise types while maintaining image features essential for clinical interpretation remains difficult. Furthermore important factors for pragmatic uses are still computational efficiency and accuracy. This paper addresses these issues by suggesting a combined system for noise reduction and tumor segmentation catered to brain MRI images. This system helps to create Computer-Aided Detection (CADe) technologies, which have advanced quickly in recent years and improve diagnosis accuracy and patient outcomes by means of their support.

II. Related Work

Brain MRI denoising and tumor segmentation have attracted considerable research attention because of their critical roles in accurate diagnosis and treatment planning. Conventional noise reduction methods such as Gaussian, median, and anisotropic diffusion filters have been applied widely. However, these linear or nonlinear filters often lead to blurring or loss of important anatomical details, negatively impacting diagnostic accuracy. Advanced methods have thus been created to overcome these constraints.

Wavelet transform-based methods have shown significant advantages for MRI noise reduction due to their ability to decompose images into multi-scale subbands, allowing selective attenuation of noise while preserving edges and fine details. While traditional wavelet thresholding methods successfully lower noise, in complex MRI data they may cause incomplete noise suppression or ringing artefacts. The Wavelet Packet Transform (WPT), a generalized form of wavelet decomposition, provides more flexible frequency band partitioning,

leading to better adaptability for MRI denoising tasks. Kinani et al. [1] proposed a combined approach that integrates WPT with the Linear Minimum Mean Square Error (LMMSE) filter to specifically address the Rician noise model in MRI. Their method demonstrated superior noise suppression and detail preservation compared to classical denoising filters.

In addition to noise reduction, enhancing the contrast and structural visibility of brain MRI is crucial for subsequent tumor detection and segmentation. Morphological operations have been successfully employed in this context to refine image features and remove residual noise artifacts. Hytch et al. [2] illustrated the use of morphological filters to improve local contrast without altering the overall pixel intensity distribution, thus preserving diagnostically relevant information.

Tumor segmentation is another challenging problem due to the heterogeneous shape, size, and intensity of brain tumors. Clustering-based algorithms, including K-means and Fuzzy C-means, are commonly applied for their ability to partition image pixels into distinct classes based on intensity or texture features. Classical clustering techniques, however, can be sensitive to initial conditions and have high computational cost, so restricting their useful value. Nawaz et al. [3] introduced the Fast C-means clustering algorithm, which reduces computation time and enhances segmentation accuracy by efficiently grouping data points. Their results confirm that Fast C-means outperforms traditional clustering in medical image segmentation, making it well-suited for tumor delineation tasks.

Further refinement of segmentation boundaries using morphological processing is essential to eliminate noise, fill gaps, and define tumor edges more precisely. D. S. et al. [4] applied morphological operations after clustering to improve tumor segmentation outcomes, yielding clearer and more accurate tumor borders.

Despite these advancements, current approaches face challenges in effectively balancing noise reduction, contrast enhancement, and segmentation accuracy within a unified framework. Many current techniques either separately reduce noise or enhance contrast, which can produce less than ideal outcomes or change pixel intensity distribution. Furthermore, the computational complexity of multi-stage procedures could make their implementation difficult in clinical environments where near real-time or real-time results are sought for.

Our work addresses these limitations by proposing a novel fusion strategy that integrates WPT-based noise reduction, LMMSE filtering, and morphological contrast enhancement to generate a quality-enhanced MRI image. After that, morphological refinement and Fast C-means clustering help to segment this image. The fusion method guarantees efficient noise suppression and contrast enhancement without distortion of the pixel intensity distribution, so enabling more accurate and dependable tumor segmentation. This integrated system contributes to the ongoing development of Computer-Aided Detection (CADe) systems, which are increasingly critical for early diagnosis and treatment of brain tumors.

III. Methodology

A. Summary Background Theories

1) Wavelet packet decomposition: The wavelet transform is a mathematical method that decomposes spatial (or temporal) data into spatial (temporal)-frequency domain components, allowing dominant frequency modes to be identified and their variations over space. The wavelet transform has been extensively utilized in a variety of disciplines, such as engineering, computer science, science, etc. due to its efficacy [5]. The discrete wavelet transform (DWT) stands out as a particular example.

During the DWT decomposition process, a signal is successively divided into multiple components, each represented by a set of coefficients that delineate the temporal progression of the data within a certain frequency bandwidth . The DWT utilizes two filters: a high-pass filter, based on the wavelet function, to produce detail components (coefficients) containing high frequencies, and a low-pass filter, based on the scaling function, to produce approximation components (coefficients) containing low frequencies. The quantity of breakdown stages, referred to as levels, aligns with particular scales that are inversely proportional to frequency. Since each level uses two filters, the approximate and detailed coefficients must be dyadic downsampled so that the total length of these coefficients is equal to the length of the input signal. From level two and above, the above process is repeated with input being the approximate coefficient at the previous level.

Wavelet packet decomposition (WPD) enhances the functionality of discrete wavelet transform (DWT) by implementing the filtering procedure on both approximation and detail components at every level. This methodology enables WPD to deliver a more comprehensive depiction of the signal within tighter frequency bands, especially at elevated frequencies, in contrast to conventional DWT [6].

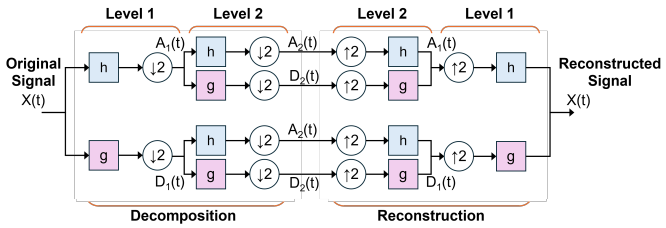

Fig. 1. The Processes for wavelet packet decomposition steps of 1D signal at 2 levels.

Wavelet packet reconstruction refers to the recovery of data that has undergone decomposition using wavelet packet decomposition (WPD). This entails upsampling the coefficients by interspersing zeros and utilizing them as inputs for reconstruction via low-pass and high-pass filters. The results are subsequently aggregated to reconstruct the original data structure. Fig. 1 depicts the wavelet packet decomposition and reconstruction procedure at level 2 [5].

2) Linear minimum mean square error estimator: The Linear Minimum Mean Square Error (LMMSE) estimator seeks to derive the closed-form representation of a signal that adheres to the Rician distribution [7]. Let q represent a scalar parameter derived from a dataset x in the following manner:

$$\hat{\theta} = \sum_{n=0}^{N-1} a_n x[n] + a_N \tag{1}$$

the weight coefficients an are calculated by minimizing Bayesian MSE such that nonzero means of x and θ:

$$\text{Bmse}(\hat{\theta}) = E\left[(\theta - \hat{\theta})^2\right] \tag{2}$$

where, the expectation is calculated according to the PDF p(x,q).

Substitute (1) into (2) and set the differential of (2) with respect to a_N to zero to determine a_N and substitute a_N into $\text{Bmse}(\hat{\theta})$; then, minimize this expression to obtain the LMMSE estimator [7]:

$$\hat{\theta} = E(\theta) + \mathbf{C}_{\theta x}\mathbf{C}_{xx}^{-1}(\mathbf{x} - E(\mathbf{x})) \tag{3}$$

where, C_{xx} is the $N \times N$ covariance matrix of x, and $C_{\theta x}$ is the $1 \times N$ cross-covariance vector. With a 2D signal with Rician distribution, (3) rewrite in the form [8]:

$$\hat{A_{ij}^2} = E\{A_{ij}^2\} + \mathbf{C}_{A_{ij}^2 M_{ij}^2}\mathbf{C}_{M_{ij}^2 M_{ij}^2}^{-1}(\mathbf{M}_{ij}^2 - E\{\mathbf{M}_{ij}^2\}) \tag{4}$$

where, A_{ij} is an unknown pixel intensity value at (i, j), M_{ij} is the brightness magnitude of the signal. By simplifying the estimation at each location, the vectors and matrices reduce to scalar values, and the estimator is expressed as:

$$\hat{A_{ij}^2} = E\left\{A_{ij}^2\right\} + \frac{E\left\{A_{ij}^4\right\} + 2E\left\{A_{ij}^2\right\}\sigma_n^2 - E\left\{A_{ij}^2\right\}E\left\{M_{ij}^2\right\}}{E\left\{M_{ij}^4\right\} - \left(E\left\{M_{ij}^2\right\}\right)^2} \times \left(M_{ij}^2 - E\left\{M_{ij}^2\right\}\right) \tag{5}$$

Under the assumption of local ergodicity, the expectation can be substituted with the sample estimate $< . >$; following some algebraic manipulations, the estimator is expressed as:

$$\hat{A}_{ij}^2 = \langle M_{ij}^2 \rangle - 2\sigma_n^2 + K_{ij}(M_{ij}^2 - \langle M_{ij}^2 \rangle) \tag{6}$$

where, K_{ij} is defined as:

$$K_{ij} = 1 - \frac{4\sigma_n^2(\langle M_{ij}^2 \rangle - \sigma_n^2)}{\langle M_{ij}^4 \rangle - \langle M_{ij}^2 \rangle^2} \tag{7}$$

with $\eta_{i,j}$ a square neighborhood around pixel [8].

B. Fast C-Means Clustering

Tumor segmentation is a critical phase in MRI image processing, with numerous approaches developed, the most prevalent being fuzzy clustering, recognized for its capacity to maintain the details of the original image [9]. Nonetheless, conventional fuzzy C-means is inefficient due to the necessity of computing the distance between each pixel and the cluster centers to minimize the objective function. Consequently, numerous enhanced techniques have been suggested that substitute pixel values with histogram gray levels to expedite computation. The enhanced C-means algorithm, founded on morphological reconstruction and membership filtering (FR-FCM), was proposed by Tao-Lei et al. [10].

The objective function is defined as:

$$S_\alpha = \sum_{n=1}^{r}\sum_{m=1}^{d} \lambda_n w_{mn}^\alpha \|\zeta_n - c_m\|^2, \tag{8}$$

Consider that w_{mn} indicates the degree of association for intensity level n concerning the m^{th} cluster centroid c_m, while α serves as the weighting coefficient. Then, we have:

$$\sum_{n=1}^{r} \lambda_n = M, \tag{9}$$

where, ζ represents an image reconstructed through morphological processing, and ζ_n corresponds to a specific intensity level, with $1 \leq n \leq r$. The parameter r signifies the count of intensity levels in ζ, which is typically much smaller than M. The reconstructed image ζ is obtained as:

$$\zeta = T^B(g), \tag{10}$$

where, T^B refers to the morphological reconstruction using a closing transformation, and g denotes the original image. Minimize (8) to obtain:

$$w_{mn} = \frac{\|\zeta_n - c_m\|^{-2/(\alpha-1)}}{\sum_{t=1}^{d}\|\zeta_n - c_t\|^{-2/(\alpha-1)}}, \tag{11}$$

and

$$c_m = \frac{\sum_{n=1}^{d}\gamma_n w_{mn}^\alpha \zeta_n}{\sum_{n=1}^{d}\gamma_n w_{mn}^\alpha}. \tag{12}$$

If we assign $W = [w_{mn}]^{d\times r}$ is membership partition matrix; w_{nt}) and c_m are calculated using the iterative method until W stabilizes:

$$\max\{W(\tau) - W(\tau+1)\} < \epsilon \tag{13}$$

where, ϵ is minimal error threshold. At that time, the new membership matrix $W' = [w_{mn}]^{d\times M}$ corresponding to the original image g:

$$w_{mn} = w_{mn}^{(\tau)}, \quad \text{if } y_n = \zeta_m \tag{14}$$

To enhance the membership partition matrix and accelerate convergence through membership filtering:

$$W'' = medW' \tag{15}$$

where, med represents median filtering

Fast C-Means is more appropriate for medical imaging applications due to its reduced computational cost and faster convergence compared to conventional FCM.

C. Morphological Contrast Enhancement

Morphological operations process the shape and structure of objects in images based on structural elements (SE), which can be considered as filters. There are four basic operations: dilation, erosion, opening (denoted as o), and closing (denoted as •). Opening removes noise or small objects (relative to the SE size), while closing fills small holes and gaps in objects. The top-hat transform, defined as the difference between the image and the opening operation, is used to highlight bright objects (smaller than the SE) against a dark background. The bottom-hat transform, defined as the difference between the closing operation and the image, is used to highlight dark objects against a bright background. Combining these two transformations with the noise-reduced image produces an image with high contrast without pixel redistribution, thus preserving the accurate position of objects when detected [11].

The Tophat transform is defined as:

$$T(i,j) = P(i,j) - (P \circ S)(i,j) \tag{16}$$

The Bottomhat transform is given by:

$$B(i,j) = (P \bullet S)(i,j) - P(i,j) \tag{17}$$

where, $T(i,j)$ and $B(i,j)$ represent the top-hat and bottom-hat transforms, respectively; $P(i,j)$ denotes the noise-reduced image; S is the structuring element; $(P \circ S)$ refers to the morphological opening operation, and $(P \bullet S)$ represents the closing operation.

For image contrast enhancement, the final transformed image is computed as:

$$M(i,j) = (P(i,j) + T(i,j)) - B(i,j) \tag{18}$$

where, $M(i,j)$ is the enhanced image obtained by incorporating both top-hat and bottom-hat transformations to improve contrast.

D. Performance Evaluation

The enhancement algorithm aims to augment image quality, guaranteeing that the processed image is more appropriate than the original for further applications or analysis. Although visual inspection provides a subjective assessment of improvement, it is fundamentally constrained and fails to deliver an accurate or thorough analysis of the algorithm's performance. Therefore, the study used four primary metrics to assess algorithm performance:

1) The Mean Squared Error (MSE): quantifies the average squared deviations between the pixel intensities of the original and enhanced images, functioning as a direct metric for error assessment, If the enhanced and original images match, the MSE should be zero:

$$\text{MSE} = \frac{1}{MN} \sum_{i=1}^{M} \sum_{j=1}^{N} [I_1(i,j) - I_2(i,j)]^2 \tag{19}$$

where, M and N are the dimensions of the images, $I_1(i,j)$ and $I_2(i,j)$ are the pixel intensities of the original and processed images.

2) Peak Signal-to-Noise Ratio (PSNR): However, when using MSE, an outlier also affects the value, and is highly dependent on the image intensity scale. Therefore, the Peak Signal-to-Noise Ratio (PSNR), the ratio between the maximum power of the original image and the enhanced image in decibels (logarithmic scale), is used to address this deficiency. The enhanced images is better when PSNR is larger:

$$\text{PSNR} = 10 \cdot \log_{10} \left(\frac{L^2}{\text{MSE}} \right) \tag{20}$$

where, L is the maximum pixel intensity value (e.g. 255 for 8-bit images), MSE is the Mean Squared Error.

3) Similarity Index Measure (SSIM): assesses the similarity of original and enhanced image by analyzing brightness, contrast, and structure, providing a perceptually significant evaluation. Its value should be large for better results:

$$\text{SSIM}(x,y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \tag{21}$$

where, μ_x and μ_y are the mean intensities of images x and y, σ_x^2 and σ_y^2 are the variances of x and y, σ_{xy} is the covariance between x and y, C_1 and C_2 are small constants to stabilize the division.

4) Structure Content (SC): is the ratio of the sum of squares of the original image pixels to the sum of squares of the enhanced image pixels. The best value of SC is equal to 1 but higher value specifies poor the quality:

$$\text{SC} = \sum_{k=1}^{K} \log \left(\frac{\max(I_k) + \epsilon}{\min(I_k) + \epsilon} \right) \tag{22}$$

where, K is the number of image blocks, I_k is the intensity of the k-th block, ϵ is a small constant to avoid division by zero.

IV. Proposed Method

The proposed method is divided into two main stages: image quality enhancement and tumor segmentation for Brain MRI.

1) Image quality enhancement: This stage consists of two steps: 1) Denoising: The input MRI images are denoised using wavelet shrinkage in the wavelet domain based on Wavelet Packet Transform (WPT), which decomposes the image into higher-resolution frequency components. Thresholding is applied to the detailed components (high-frequency bands that typically contain noise) to suppress noise, followed by an inverse transformation to return the image to the spatial domain. 2) Fine Noise Reduction and Contrast Enhancement: This step includes two parallel processes: a second-stage noise suppression using the Linear Minimum Mean Square Error (LMMSE) filter, and contrast enhancement via morphological transforms. The outputs of these processes are then fused using wavelet fusion to combine the strengths of each approach (see Fig. 2).

2) Tumor segmentation: The enhanced images are segmented using the Fast C-means algorithm. The number of clusters is set to the number of main peaks in the intensity histogram. The tumor is assumed to belong to the cluster with the maximum centroid value. Tumor regions are identified through thresholding and refined using morphological post-processing operations (see Fig. 3).

The following subsections detail each step of the proposed method.

A. Image Enhancement

Image enhancement is performed according to the diagram in Fig. 2.

1) Coarse noise reduction: In this study, we introduce a multi-stage approach aimed at diminishing different types of noise – particularly Gaussian noise - in MRI images, as demonstrated in Fig. 2. The process begins by applying the Wavelet Packet Transform (WPT) to the noisy image, decomposing it into multiple subbands. Noise reduction is performed using shrinkage threshold on the leaf details components except for the first component. Subsequently, the denoised image is reconstructed using inverse WPT. In this paper, the symlet2 function at level 2 is used, as these are nearly symmetrical wavelets, a modification of the Daubechie function, making them suitable for noise reduction.

2) Fine noise reduction and contrast enhancement: Subsequent two concurrent processing methods are employed: Morphological contrast enhancement is used to increase contrast and highlight obscured details. In this paper, a disc-shaped structuring element with a radius of 5 is utilized. The LMMSE filter mitigates Rician noise through the estimation of pixel values derived from local statistical characteristics, effectively minimizing variance while preserving data integrity. This article uses code: LMMSE filter for Rician MRI data written by Santiago Aja-Fernandez (2025). [12]

The results from these two processes are subsequently fused through Wavelet Fusion, which integrates the advantages of noise reduction and contrast enhancement to create image enhancement suitable for subsequent analysis steps.

Fig. 2. Noise reduction flow chart.

B. Tumor Detection

Image enhancement is used for brain tumor detection using Fast C-Means Clustering with the number of clusters selected from the main peaks on the smoothed histogram using the empirical mode decomposition, and the cluster containing the tumor is chosen to correspond to the maximum value of the centroid. Morphological operations such as hole filling, opening, and closing are used to smooth the detected tumor, and regions are used to identify certain characteristics of the tumor. Fig. 3 shows the steps in the segmentation and tumor detection stage. This article uses Fast fuzzy C-means clustering code by Tao-Lei [10]

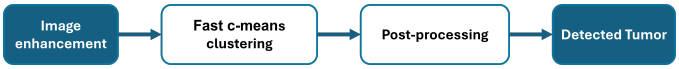

Fig. 3. Tumor detection flow chart.

C. Dataset and Equipments

This study utilizes the BraTS (Brain Tumor Segmentation) dataset [13], [14], [15], a widely used benchmark for MRI-based brain tumor analysis. The dataset includes multimodal MRI scans (NIFTI (.nii.gz) files), consisting of T1, T1 with contrast enhancement (T1c), T2, and FLAIR sequences. These images are annotated by specialists to delineate key brain tumor subregions: enhancing tumor (ET), tumor core (TC), and peritumoral edema (ED). These segmentations serve as ground truth for evaluating automated segmentation methods. The dataset has been extensively used in research on brain tumor segmentation and classification [16], [17], [18].

The Matlab and Python environment was used for the calculations, and a laptop with Intel Core i.9 CPU, 36GB RAM, and Windows 11 was used for all experiments.

V. Experimental Result

This section delineates the outcomes of image enhancement, encompassing denoising and contrast enhancement as well as imge segmentation. MRI scan from the BraTS dataset was corrupted to Rician, Gaussian and Salt and Pepper noises at levels of 6%, 8%, 10%, 12%, and 14% to perform image enhancement. The image enhancement process remains uniform across various noise levels; therefore, only results for images at a designated noise level (12%) are visually depicted in the figures, while quantitative assessments for all noise levels are compiled in tables utilizing standard metrics.

A. Image Enhancement

1) Quality analysis:

a) Image enhancement for rician noise: Fig. 4 illustrates the denoising outcomes for an MRI scan from the BraTS dataset with 12% Rician noise, utilizing the suggested approach and comparison with Denoising Convolutional Neural Network (DnCNN) and Non-Local Means (NLM). Fig. 4a depicts the original MRI image, which acts as a reference, highlighting distinct structural characteristics crucial for assessing the efficacy of different denoising methods. Fig. 4b illustrates the noisy image, whereby Rician noise considerably obscures tiny details, especially in low-contrast areas, complicating structural interpretation. The outcome of the suggested approach is illustrated in Fig. 4c, showcasing an optimal equilibrium between noise reduction and structural integrity. The image exhibits a little smoother appearance than the original while preserving essential structural elements and texture with minimum distortion. The intensity gradients, especially at the interfaces between brain regions, remain well delineated without the introduction of artifacts. Fig. 4d illustrates the outcome of the NLM approach, which successfully diminishes noise but encounters difficulties in restoring intricate features. Although high-intensity areas are comparatively well-preserved, the pronounced smoothing effect results in the loss of mid-range structural details, causing significant blurriness in essential brain regions. Fig. 4e, illustrates the results of the DnCNN approach, which demonstrates enhanced noise reduction relative to NLM, resulting in a more pristine appearance. This approach, however, creates modest aberrations that manifest as unnatural patterns in regions with abrupt intensity shifts, thus undermining the clinical applicability of the augmented image.

b) Image enhancement for Gaussian noise: In addition to Rician noise, we also evaluate the denoising performance under Gaussian noise with 12% corruption. Fig. 5 presents the denoising results for MRI images affected by Gaussian noise using different methods. Fig. 5a the original image serves as a reference. Fig. 5b shows the noisy image that exhibits substantial structural degradation. Fig. 5c shows the outcome of the proposed method. which effectively balances noise removal and structural preservation. Fig. 5d shows the result of NLM method, which reduces noise but blurs fine details. Fig. 5e shows the result of DnCNN, which provides better noise suppression but introduces subtle artifacts; some blurriness remains.

c) Image enhancement for salt and pepper noise: Fig. 6 presents the results of image quality enhancement for an image contaminated with 12% Salt and Pepper noise. Fig. 6a shows the original image, while Fig. 6b displays the noise-contaminated image. Fig. 6c shows the image enhancement using our proposed approach, which preserves the brain's intricacies in close proximity to the original image. Fig. 6d shows the results of the NLM method, which effectively smooths the image but obscures certain small details. Fig. 6e displays the results of the DnCNN method, which retains some graininess.

These results demonstrate that our proposed approach maintains essential elements in the image. These visual observations align with the quantitative performance metrics discussed in the next section.

2) Quantitative analysis: To assess the denoising effectiveness of the proposed method and other methods across diverse noise types with different densities from 4, 6, 8, 10, 12 and 14%; the performance quality metrics such as MSE, PSNR, SSIM, and SC are used.

a) Rician noise: Table I presents the quantitative metric values for image enhancement calculated from images contaminated with Rician noise at five different noise densities. Except for the SC value, the proposed method demonstrates superior values in MSE, PSNR, and SSIM compared to the other two methods. With low noise density, σ = 6%, the MSE of the proposed approach was 88.01, in contrast to DnCNN (279.53) and NLM (287.72). The PSNR of the proposed approach attained 28.69 dB, significantly above DnCNN (23.67 dB) and NLM (23.54 dB). The small MSE value and large PSNR value of the proposed approach exhibited remarkable noise reduction capabilities and greater efficacy in image quality restoration. The proposed method attained an SSIM of 0.43, significantly surpassing DnCNN (0.28) and NLM (0.26). The high SSIM value indicates that the perceived image enhancement of the proposed approach is better than the results of the other two methods. With an SC value of 1.19 for the proposed approach and 0.92 for both DnCNN and NLM, the enhanced image from the proposed approach is slightly inferior in information architecture compared to the other two methods; however, the difference is not substantial and does not affect subsequent analyses. For the remaining threshold levels of 8, 10, 12, and 14% (from cell 2 to cell 5, Table I), the quality assessment results are consistent with the results at the 6% threshold level. Therefore, the quality assessment values in Table I demonstrate that the noise reduction and contrast enhancement capabilities of the proposed method yield better results than the DnCNN and NLM methods when applied to images with Rician noise; consequently, the proposed method is suitable for enhancing the quality of MR images.

b) Gaussian noise: Table II presents the quantitative metric values for image enhancement calculated from images contaminated with Gaussian noise at five different noise densities. Except for the SSIM value, the DnCNN method demonstrates superior values in MSE, PSNR, and SC metrics, with the NLM method ranking second and the proposed method ranking third; however, the values of these indices do not differ significantly between the methods. Notably, the SSIM value of the proposed method is the highest and considerably different from the other two methods. From these results, with Gaussian noise, the noise reduction and structural integrity capabilities of the DnCNN method are the highest but not significantly different from the proposed method. Regarding perceptual image quality, the results of the proposed method are the best, as demonstrated by the highest SSIM values across different noise levels and through the visualization shown in Fig. 5.

c) Salt and Pepper noise: Table III presents the quantitative metric values for image enhancement calculated from images contaminated with salt and pepper noise at five different noise densities. The MSE and PSNR values show that the noise reduction capability of the DnCNN method is best for the 6% noise level. In contrast, from 8-14% noise levels, the NLM method performs best, with the proposed method ranking second for all threshold levels examined. Regarding the perceptual quality of image enhancement through SSIM values, the NLM method is best at 6-9% noise levels, while

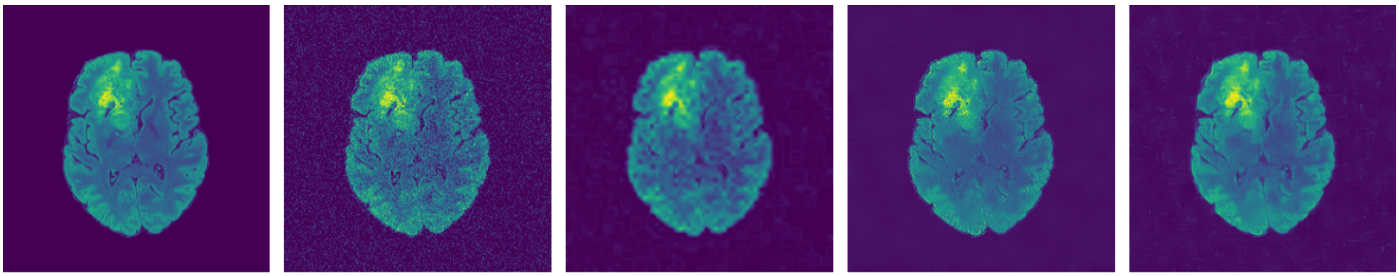

Fig. 4. Enhancement image of 12% Rician noise. a): Original image, b): Noisy image, c): Image enhancement of the proposed approach, d): Image enhancement with NLM method, and e): Image enhancement with DnCNN method.

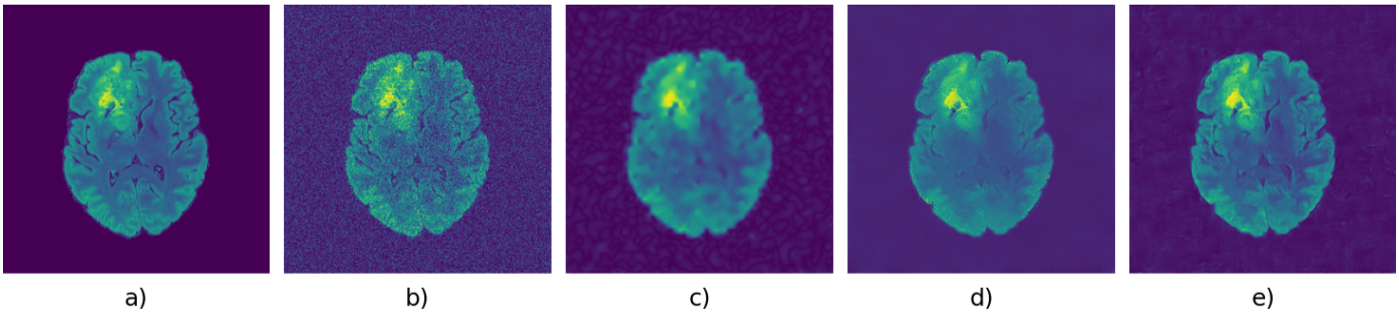

Fig. 5. Enhancement image of 12% Gaussian noise. a): Original image, b): Noisy image, c): Image enhancement of the proposed approach, d): Image enhancement with NLM method, and e): Image enhancement with DnCNN method.

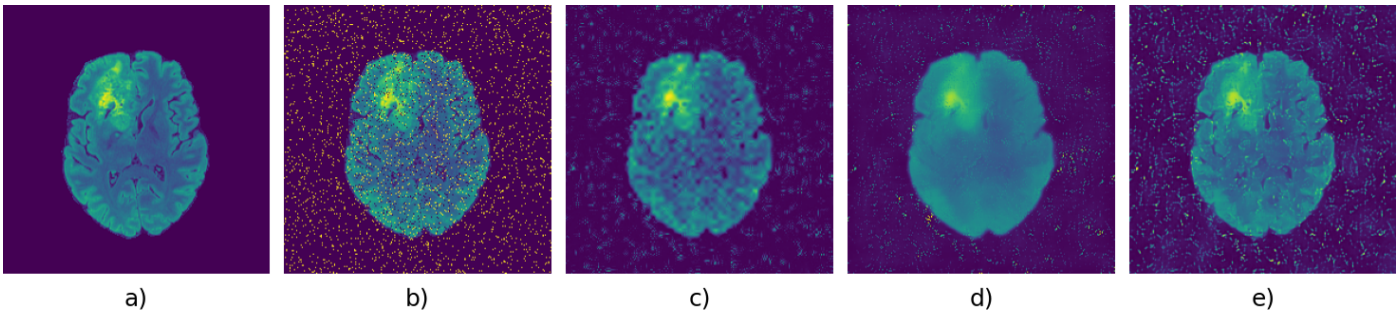

Fig. 6. Enhancement image of 12% Salt & Pepper noise. a): Original image, b): Noisy image, c): Image enhancement of the proposed approach, d): Image enhancement with NLM method, and e): Image enhancement with DnCNN method.

at 10-14% noise levels, the proposed method is superior. For information preservation capability, as indicated by SC values, the proposed approach is best at 6-8% noise levels, and the NLM method is best at 10-14% noise levels.

The positive outcomes in performance indexes suggest that the proposed approach is effective in noise reduction and preserves crucial structural details of brain MR images, making it suitable for the initial processing stage of a CADe system.

3) Kernel Density Estimate (KDE) analysis: KDE is probability density estimate smoothed by kernel function. In order to further investigate the image enhancement performance, the KDE of MR images before and after enhancement is analyzed. Fig. 7 shows the KDE of the original image, the image contaminated with Rician noise σ = 12%, and the enhanced images. Fig. 7a shows the pixel intensity distribution of the original image exhibits a first mode with a sharp peak and a second mode, which reflects the inherent structure of the brain MRI including background and tumor. The Rician noisy image shown in Fig. 7b has a broadened intensity distribution, which is characterized by a flattened peak and an extended tail that does not reveal the mode containing the tumor. This distortion indicates a significant loss of structural information caused by the addition of noise, which complicates the extraction of sensible features from the image. The KDE plot of the proposed approach, which is displayed in Fig. 7e, is very similar to the original intensity distribution, demonstrating that image enhancement of the proposed approach restores the original image almost intact, showing high performance of the method. In the KDE from DnCNN in Fig. 7c and NLM in Fig. 7d, distinct differences in their performance are observed. Both recover the mode representing the tumor, but they stretch the first mode causing the background to blur, resulting in lower contrast between the background and the tumor.

In conclusion, the KDE plots indicate that the proposed

approach effectively balances noise reduction and structural integrity preservation, as reflected in its intensity distribution closely matching that of the original image. Therefore, image enhancement is well-suited for segmentation and feature extraction.

4) Segmentation: Segmentation results for a sample MRI slice from the BraTS dataset are presented in Fig. 8. The figure displays the original image alongside the ground truth tumor mask, followed by the segmented tumors obtained from image enhancement under 12% noise levels of Rician, Gaussian, and Salt and Pepper noise. The results indicate that the segmented tumors closely align with the ground truth, particularly for images enhanced under Gaussian noise, followed by Rician noise, and lastly, Salt and Pepper noise. However, this observation is based on visual inspection.

For quantitative evaluation, five metrics: accuracy, dice coefficient, precision, sensitivity, and specificity—were computed by comparing the ground truth tumor mask with the detected tumor regions from the enhanced images. These enhanced images were derived from noisy versions of the original MRI slices at varying noise levels, and the results are summarized in Table IV. Since MR images contain tumors that occupy a much smaller area compared to the background, the true negative (TN) value is significantly higher than other evaluation measures. As a result, accuracy and specificity values are close to 1, making them less informative for performance assessment. Therefore, the ”precision–sensitivity” pair and the Dice coefficient are used as primary evaluation metrics.

The values in Table IV demonstrate stable tumor segmentation performance across different noise levels. The dice coefficient exhibits a modest rise with elevated noise levels, varying from 0.774 to 0.780 for Gaussian noise and from 0.768 to 0.777 for Rician noise. The dice coefficient diminishes for Salt and Pepper noise from 0.775 to 0.705 with increasing

noise levels. Notwithstanding these fluctuations, the values are generally above 70%, signifying a robust concordance between the identified tumors and the ground truth across all noise categories. Optimal tumor segmentation outcomes are attained for images influenced by Gaussian noise, succeeded by Rician noise, and subsequently, Salt and Pepper noise, as indicated by the elevated precision values, which consistently exceed 90%. Sensitivity values, on the other hand, are highest for salt-and-pepper noise, followed by Gaussian noise, and lowest for Rician noise. Nevertheless, sensitivity remains stable within the range of 75–81%, suggesting that the differences in tumor detectability are minimal.

In Table V, the tumor properties of Fig. 8b, c, d and e.

TABLE IV. SEGMENTATION PERFORMANCE METRICS ACROSS NOISE TYPES AND LEVELS

Noise Type	Level	Accuracy	Specificity	Precision	Sensitivity	Dice
Gaussian	6	0.987	0.999	0.976	0.783	0.780
	8	0.987	0.999	0.975	0.783	0.774
	10	0.987	0.999	0.974	0.785	0.775
	12	0.987	0.999	0.971	0.785	0.780
	14	0.987	0.999	0.973	0.785	0.780
Rician	6	0.986	0.999	0.972	0.780	0.768
	8	0.986	0.999	0.969	0.783	0.771
	10	0.986	0.999	0.964	0.794	0.776
	12	0.986	0.999	0.963	0.794	0.777
	14	0.987	0.999	0.957	0.796	0.775

	8	0.985	0.999	0.950	0.809	0.750
	10	0.984	0.999	0.938	0.794	0.750
	12	0.984	0.999	0.946	0.762	0.729
	14	0.984	0.999	0.950	0.750	0.705

Compared to the ground truth (X: 100.52, Y: 82.04, Radius: 24.64), the tumor's location and morphology are accurately maintained. Under Gaussian noise, there is minor under-segmentation (X: 99.16, Y: 76.81, Radius: 21.94), although the tumor remains discernible. Rician noise exhibits optimal alignment (X: 99.36, Y: 76.77, Radius: 22.12) with negligible variation. Conversely, Salt-Pepper noise induces uneven borders (X: 99.81, Y: 77.63, Radius: 22.97), although the tumor structure remains intact. These results underscore the efficacy of the segmentation method in maintaining tumor shape despite distortions caused by noise.

TABLE V. REGION PROPERTIES ACROSS NOISE TYPES AND LEVELS

Noise Type - Level	X	Y	Radius	Perimeter	Area
Ground Truth	100.52	82.04	24.64	204.37	1908.0
Gaussian	99.16	76.81	21.94	229.86	1512.0
Rician	99.36	76.77	22.12	213.10	1537.0
Salt-Pepper	99.81	77.63	22.97	243.97	1657.0

VI. DISCUSSION

This study introduces a novel enhancement pipeline for brain MRI images that addresses both noise reduction and contrast limitations. Selected for its ability to capture detailed information across all frequency bands and provide better resolution than conventional DWT or SWT techniques, the wavelet packet decomposition (WPD) transform—paired

with the Symlet ("sym2") wavelet—helps preserve important anatomical structures while reducing Gaussian noise via shrinkage-based denoising.

However, this approach is not without its limitations. First, while shrinkage at WPD level two is effective against Gaussian noise, it is less robust against non-Gaussian artifacts, particularly Rician noise, which is common in MRI. We address this through LMMSE filtering, but the effectiveness of this parallel processing may degrade under very high noise levels or motion artifacts. Second, our contrast enhancement avoids histogram-based distortion by employing morphological operations, yet this technique may underperform in images with extremely low dynamic range or in scans from lower-resolution equipment.

For segmentation, we apply the Tao-Lei variant of the Fast C-means algorithm [10], enhanced by EMD-based adaptive clustering. While this approach improves cluster selection and localization, it depends heavily on the quality of the empirical mode decomposition. Inconsistent IMF extraction, especially in noisy or poorly-contrasted images, can affect the reliability of cluster count estimation and consequently segmentation accuracy.

Another limitation lies in the need for manual parameter tuning for wavelet levels, LMMSE window sizes, and morphological structuring elements. This may reduce scalability across datasets unless an adaptive or learning-based optimization strategy is employed.

Performance validation using visual inspection, quality measures, and KDE plots indicates enhancements compared to baseline approaches like DnCNN and NLM. Nevertheless, our approach currently focuses on 2D axial slices. Extending the framework to handle 3D volumes or dynamic MRI sequences remains a direction for future work.

Notwithstanding these limitations, the synergy of our enhancement and segmentation pipeline provides a promising, integrated preprocessing solution for MRI-based diagnostics. Subsequent research will investigate automated parameter optimization, comprehensive integration with learning-based post-processors, and applicability to various MRI modalities and diseases.

VII. Conclusion

In this study, we proposed a new approach for enhancing and segmenting brain MRI images, aiming to improve noise reduction and tumor detection in a clinical context. By combining wavelet packet transform (WPT) denoising, LMMSE filtering, and morphological contrast enhancement—followed by a wavelet-based fusion step—we were able to produce clearer images that retain important anatomical details.

For segmentation, we applied a variant of the C-means clustering algorithm. To improve automation and reliability, the number of clusters was determined using a smoothed histogram, and the tumor region was identified based on the highest intensity centroid. This helped streamline the process of tumor extraction and showed good alignment with ground truth in both visual and quantitative evaluations.

Despite these promising results, some challenges remain. The enhancement and segmentation processes are currently separate, which may limit their synergy. In future work, we plan to develop a more integrated framework by refining the fusion of enhancement and segmentation steps within our current model-driven approach. Additionally, we will explore automated parameter tuning to improve robustness and scalability. Finally, we intend to validate the method across diverse MRI datasets, including different scanner types and pathological conditions, to ensure broader applicability and clinical relevance.

***Abstract*—Alzheimer's disease (AD) diagnosis using MRI is hindered by data-sharing restrictions. This study investigates whether federated learning (FL) can achieve high diagnostic accuracy while preserving data confidentiality. We propose an FL pipeline, utilizing EfficientNet-B3 and implemented via the Flower framework, incorporating advanced MRI segmentation (the Segment Anything Model, SAM) to isolate brain regions. The model is trained on a large ADNI MRI dataset and cross-validated on an independent OASIS dataset to evaluate generalization. Results show that our approach achieves high accuracy on ADNI (approximately 96%) and maintains strong performance on OASIS (around 85%), demonstrating robust generalization across datasets. The FL model attained high sensitivity and specificity in distinguishing AD, mild cognitive impairment, and healthy controls, validating the effectiveness of FL for AD MRI analysis. Importantly, this approach enables multi-center collaboration without sharing raw patient data. Our findings indicate that FL-trained models can be deployed across clinical sites, increasing the accessibility of advanced diagnostic tools. This work highlights the potential of FL in neuroimaging and paves the way for extension to other imaging modalities and neurodegenerative diseases.**

***Keywords*—Federated learning; alzheimer's disease; MRI; flower framework; data confidentiality; artificial intelligence; EfficientNet-B3; Segment Anything Model (SAM); medical image analysis; deep learning**

I. Introduction

Alzheimer's disease (AD) is a devastating neurodegenerative disorder affecting millions globally, leading to progressive cognitive decline and loss of autonomy in individuals [1]. Early and accurate diagnosis is crucial for slowing disease progression and improving patient quality of life [2]. Magnetic resonance imaging (MRI) can reveal structural brain changes associated with AD, such as cortical atrophy and ventricular enlargement [1]. However, automated MRI-based AD diagnosis remains challenging due to the complexity of neurodegeneration patterns and high inter-individual variability [3]. Traditional machine learning approaches often require centralized access to large multi-site datasets, which is usually infeasible under strict medical data confidentiality regulations [4]. Recent advances in artificial intelligence have shown that deep learning models can achieve expert-level performance in medical imaging tasks, rivaling trained specialists [2]. Yet, these models demand extensive data that are typically siloed across institutions. Federated learning (FL) offers a promising solution by enabling collaborative model training without pooling the data [5]. In an FL setup, institutions can jointly improve a shared model while keeping patient data local, thereby preserving privacy. In particular, the Flower framework has emerged as an efficient platform for implementing FL in sensitive domains like medical image analysis [6]. FL makes it possible to leverage the combined richness of multi-center data without breaching confidentiality. Despite this promise, applying FL to AD MRI analysis still faces unresolved issues. Data heterogeneity between hospitals and the lack of external validation in many studies can undermine model reliability [7]. Many prior works report high accuracy on single-site data, but it remains unclear how an FL model performs on entirely independent datasets. For example, recent deep learning models have exceeded 97% classification accuracy on individual MRI datasets [8], yet their generalizability to external data is unproven.

In light of this gap, we specifically investigate whether a federated approach can achieve AD MRI diagnostic performance comparable to centralized methods while maintaining data privacy. To address this question, we propose a novel FL-based diagnostic framework for AD. Our approach is characterized by two main innovations. First, we integrate an advanced image preprocessing step using the Segment Anything Model (SAM) to automatically segment and extract brain regions from MRIs, standardizing inputs across sites. Second, we rigorously evaluate the FL model's generalization by training on a large multi-center dataset (ADNI [9]) and validating on a separate dataset (OASIS). To our knowledge, this work is the first to combine SAM-driven preprocessing with federated learning for AD classification and to validate the model across multiple MRI datasets. The key contributions of our study include: 1) a privacy-preserving federated learning framework for AD diagnosis that achieves high accuracy without centralized data, 2) the integration of state-of-the-art automated segmentation to enhance MRI feature extraction, and 3) a cross-dataset evaluation demonstrating robust model performance on independent data. This study underscores the importance of multi-institutional collaboration in developing AI tools for AD and highlights the novelty of our approach in addressing data sharing barriers and generalization challenges.

II. Background/Theory

Integrating artificial intelligence (AI) into the analysis of magnetic resonance imaging (MRI) data represents a sig-

nificant advancement in diagnostic medicine. Among the promising applications of AI, the automation of the reporting process in spine MRI is particularly noteworthy. A study by [10] demonstrates that deep learning algorithms can identify specific features of various spinal pathologies and generate reports comparable to those of radiologists. These models exhibit high precision, sensitivity, and specificity, highlighting their potential for routine use in spine MRI diagnostics.

The potential of AI to reach diagnostic accuracy comparable to that of neuroradiologists is particularly impressive in brain MRI. [2] evaluated an AI system that integrates data-driven techniques with expert knowledge to produce differential diagnoses. Their findings indicate that this system can achieve the precision of academic neuroradiologists and even exceed the performance of residents and general radiologists. This advancement holds the promise of significantly enhancing the accuracy of diagnoses in neuroradiology, potentially transforming the field.

The author in [11] provide an overview of AI use in MRI image reconstruction, a crucial domain for transforming raw data into high-quality clinical images. Their review demonstrates that deep learning algorithms can outperform conventional methods in terms of image quality and computational efficiency. This advancement is significant for various clinical applications, including musculoskeletal, abdominal, cardiac, and brain imaging, promising to revolutionize radiology.

The importance of AI model explainability in MRI data analysis is highlighted by [12]. In a field where clinical decisions can have significant consequences, understanding how AI models arrive at their conclusions is crucial. Their study presents advances in explainable artificial intelligence (XAI) techniques applied to MRI, aiming to make deep learning models transparent and understandable to practitioners. This could enhance clinicians trust in using AI for complex and sensitive diagnoses.

An article by [13] explores the application of AI in classifying brain MRI images to diagnose various neurological and psychiatric diseases. They review machine learning and deep learning techniques applied to MRI image classification, providing valuable insights into diseases such as Alzheimer's, Parkinson's, and autism spectrum disorders. This research highlights AI's potential to transform the diagnosis and monitoring of neurological diseases through more precise and informative image analyses.

Finally, [14] address a vital but often overlooked aspect of AI application in medical imaging: data preparation. Their article discusses the need for a large amount of well-curated data for effective AI algorithm development. They highlight the challenges associated with data curation and propose approaches to overcome these obstacles. This includes accessing representative and high-quality data, essential for developing robust and reliable AI algorithms.

III. The Flower Framework for Federated Learning

Federated learning is an emerging technique that enables edge devices to collaboratively learn a shared predictive model while keeping their training data on the device. This dissociates the ability to perform machine learning from the need to store data in the cloud.

A. Horizontal Federated Learning (HFL) Architecture

The Horizontal Federated Learning architecture is suited for scenarios where various clients possess data with identical attributes but are geographically distributed. Each client trains a model locally on its own data and transmits the parameter updates to a central server for aggregation. This process preserves data confidentiality while collectively benefiting from the improvements of the global model.

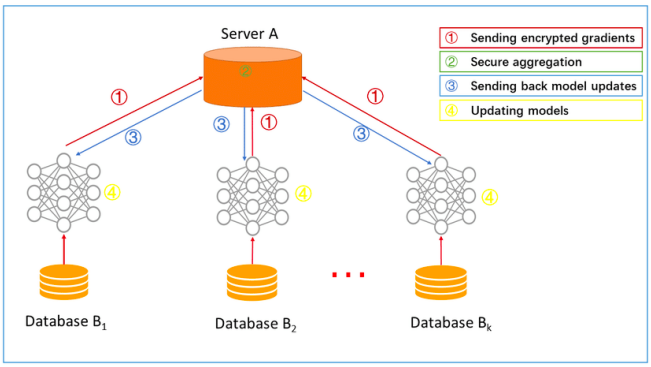

Fig. 1. Horizontal federated learning architecture as proposed in [15].

Fig. 1 illustrates the Horizontal Federated Learning architecture as proposed by [15]. This figure demonstrates how federated learning enables multiple clients to train a global model without sharing raw data, thus preserving privacy.

B. Vertical Federated Learning (VFL) Architecture

The Vertical Federated Learning architecture is appropriate for cases where different clients hold complementary information about the same set of entities. Clients collaborate by sharing model outputs rather than direct data, facilitating joint learning while preserving the confidentiality of individual data. This approach requires meticulous coordination to ensure the integrity and security of the shared predictions.

The Flower Framework, as presented by [6], offers a flexible and agnostic solution regarding client environment heterogeneity, thereby facilitating the porting of existing mobile workloads with minimal overhead and enabling researchers to experiment with new approaches to advance the state of the art.

Continuing research on Flower, [16] explored federated learning directly on various smartphones and embedded devices. Their study evaluates the systemic costs of on-device federated learning and discusses how this information could be used to design more efficient algorithms, demonstrating the framework's capability to adapt to different platforms and reduce operational costs.

To enhance security in federated learning, [17] developed Salvia, an implementation of secure aggregation for Python users in the Flower Framework. This method is robust against client disconnections and offers a flexible, easy-to-use API compatible with various machine learning frameworks. This

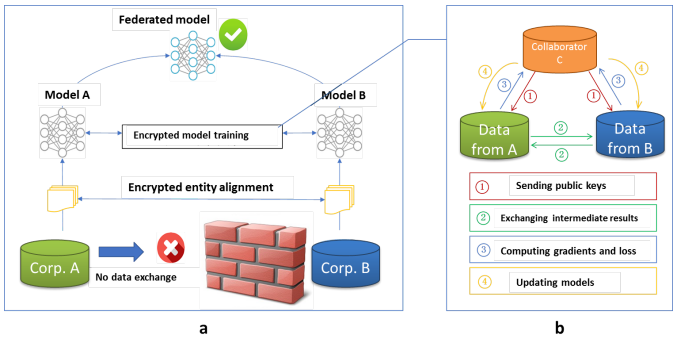

Fig. 2. Vertical federated learning architecture as proposed in [15].

approach ensures that the aggregation of locally trained models occurs without the server inspecting individual models, thereby enhancing data confidentiality.

In a different context, [18] utilized Flower to detect malicious attacks in decentralized blockchain applications. Their research proved that federated learning can significantly improve the security and reliability of decentralized networks by detecting various types of malicious attacks, showcasing Flower's versatility in applications requiring high security.

Finally, [19] addressed an asynchronous federated learning method using version information to aggregate only updated models, which improves the quality of models on devices. Their new practical framework for asynchronous federated learning, extending Flower, illustrates how efficient communications can be achieved even without a central server, making federated learning more adaptable and efficient.

IV. Literature Review on Federated Learning in MRI

Federated learning, a promising approach in artificial intelligence, is particularly relevant for analyzing medical images, including magnetic resonance imaging (MRI). The author in [20] conducted a systematic review of articles on federated learning applied to medical image analysis, highlighting the comparative performances of federated models and the challenges to be overcome. This study underscores the importance of preserving confidentiality while improving the accuracy of medical diagnoses.

The author in [21] explored an innovative approach for multimodal MRI reconstruction in a federated setting with their Fed-PMG framework. This framework addresses the challenge of missing modalities by generating pseudo-modalities, enabling complete reconstruction while maintaining manageable communication costs. This method illustrates the adaptability of federated learning to practical limitations in medical data.

Finally, [22] reviewed methodological advances in applying federated learning to health data, highlighting the challenges posed by fragmented data and class imbalance. Their critical review contributes to a better understanding of how to develop more robust and effective federated learning methods, essential for the future of medical analysis.

V. Synthesis and Justification of the Current Study

Federated Learning (FL) emerges as a promising solution to the challenges associated with data privacy and confidentiality in medical image analysis. This approach allows multiple entities to collaborate on improving a shared model without requiring the direct exchange of data. In practice, this means that institutions can contribute to a collective research effort while maintaining the confidentiality and sovereignty of patient data. This collaborative model can potentially increase the diversity and volume of data available for algorithm training, thereby improving their accuracy and general applicability.

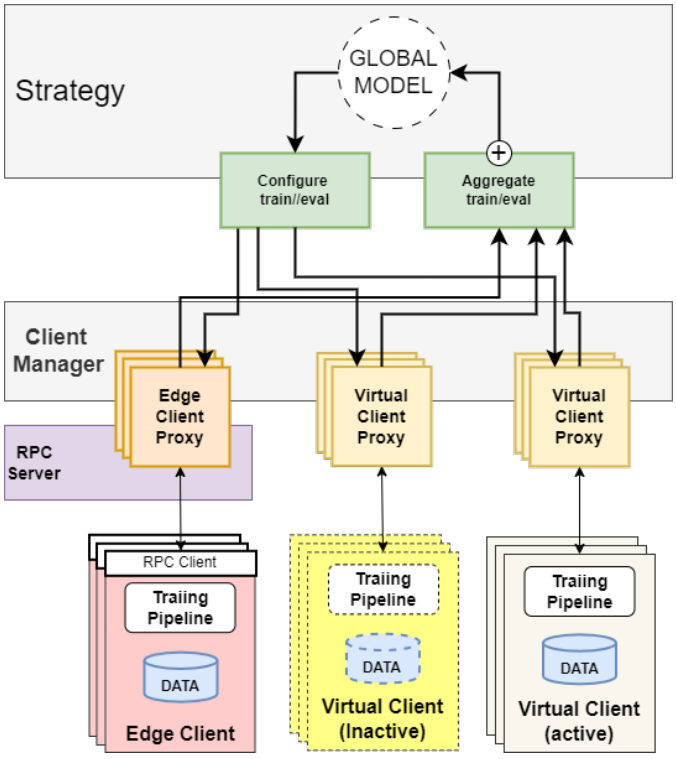

Fig. 3. Flower core framework architecture with both edge client engine and virtual client engine as proposed in [6].

Fig. 3 shows edge clients live on real edge devices and communicate with the server over RPC. Virtual clients on the other hand consume close to zero resources when inactive and only load model and data into memory when the client is being selected for training or evaluation [6].

The Flower framework (Fig. 3) was chosen for our implementation on AD MRI due to several key factors. First, Flower is designed to be flexible and compatible with numerous machine learning libraries, allowing easy integration with existing infrastructures in medical research centers. Second, it offers advanced features to efficiently manage communications between clients and the central server, minimizing latencies and communication costs in FL. Finally, Flower supports a wide range of aggregation strategies, enabling experimentation with different methods to find the most suitable approach for the specific characteristics of AD MRI data [6].

The adoption of FL in AD MRI diagnosis has the potential to catalyze significant advances in both research and clinical

practice. By facilitating broader and more effective collaboration between researchers and healthcare institutions, and by leveraging the combined power of globally distributed datasets, this approach could lead to the discovery of more precise biomarkers and the development of more effective personalized therapeutic strategies. More broadly, this federated paradigm could serve as a model for other studies in fields where data are sensitive and where collaboration among multiple stakeholders is essential.

However, few studies to date have specifically applied FL to MRI-based AD diagnosis with rigorous cross-site evaluation [4], [7]. Most existing approaches are limited to single-dataset experiments and do not incorporate advanced preprocessing techniques. Thus, it remains uncertain how a federated model would perform on completely independent data or how it might benefit from modern segmentation methods. Our approach is designed to fill these gaps by integrating a powerful segmentation model (SAM) into the FL pipeline and validating the model across two distinct datasets (ADNI and OASIS). By doing so, we aim to enhance the model's robustness and demonstrate clear advantages over conventional techniques. In particular, the use of SAM ensures consistent isolation of brain regions across all training sites, and the cross-dataset evaluation provides evidence of generalizability that single-dataset studies cannot offer [23]. This strategy distinguishes our work from prior efforts and highlights the performance gains and reliability improvements achieved by our federated approach. By addressing these unmet needs, the proposed study offers notable advantages over existing centralized or siloed-training methods. Our federated model is expected to maintain competitive accuracy while inherently resolving data privacy concerns. This approach leverages a more diverse training set than any single institution could provide, leading to better generalization.

VI. Methodology

A. Selection and Preparation of Data Sets

As an initial step, we carefully selected and prepared two well-known public MRI datasets to train and evaluate our models: ADNI and OASIS [24]. The Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset [9] is a large multi-center collection of brain scans, including subjects diagnosed with AD, individuals with mild cognitive impairment (MCI), and cognitively normal aging controls. We curated a total of 1,414 subject T1-weighted MRI from ADNI [9] for our federated training and internal evaluation (with approximately 984 subject used for training across clients and the remainder for validation/testing). ADNI was selected due to its extensive size, diversity of subjects, and status as a benchmark dataset in AD research [25].

To assess the model's generalization on unseen data, we additionally employed the Open Access Series of Imaging Studies (OASIS) dataset [24]. OASIS provides brain MRI scans of older adults, including both healthy individuals and those with cognitive impairment or dementia. From the OASIS database, we gathered 215 subject representing AD and cognitively normal cases to serve as an independent test set. OASIS is an openly available dataset, and its use as a separate evaluation source is crucial to demonstrate the robustness of our approach. The combination of ADNI for federated training and OASIS for external testing ensures a rigorous multi-dataset evaluation. Both datasets are publicly accessible (ADNI with registration and OASIS freely), which supports the reproducibility of our study and reflects the real-world scenario of multi-center data distribution.

Data Preprocessing: The quality of research in medical imaging significantly relies on the precision and relevance of the images used. In the context of AD study, a rigorous methodology was established for image selection and preprocessing. (Details of MRI preprocessing steps would follow, ensuring consistency across sites.)

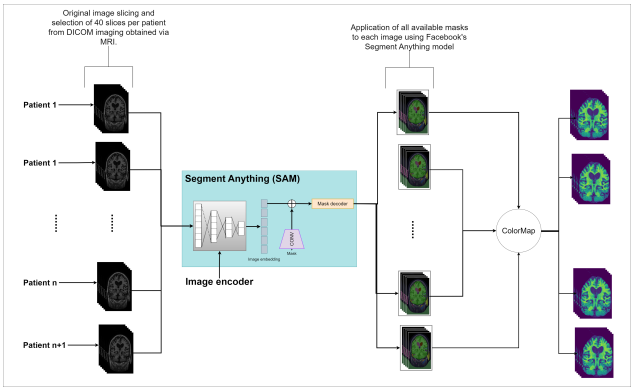

Fig. 4. Details of the segmentation process with SAM.

1) Image selection: The first step involves selecting high-quality images representative of different phases of Alzheimer's disease using DICOM or NIFTI formats generally available in clinical databases like ADNI. For each patient, approximately 20 to 30 axial slices are chosen, specifically those showing the brain in its entirety. This targeted selection helps isolate the most informative regions of interest (ROI) for AD analysis.

2) Image conversion: After selection, the chosen slices are converted from DICOM or NIFTI format to PNG images. This conversion standardizes the image format for subsequent processing and facilitates their manipulation in various image analysis and machine learning tools. The PNG format is preferred due to its lossless compression, ensuring that no significant information is lost after conversion.

3) Automatic image preprocessing (Fig. 5): Preprocessing is crucial to improve data quality and the performance of machine learning models. In this study, the obtained PNG images are fed into Facebook's pre-trained *Segment Anything* (SAM) model, which uses deep learning techniques to segment and isolate the brain part in each image. This process is illustrated in the provided diagram showing how the original images are processed through the SAM model to obtain images where only relevant brain regions are highlighted.

a) Details of the segmentation process with SAM (Fig. 4):

- Image encoder: Each image is first encoded to transform raw data into an intermediate representation understandable by the neural network.

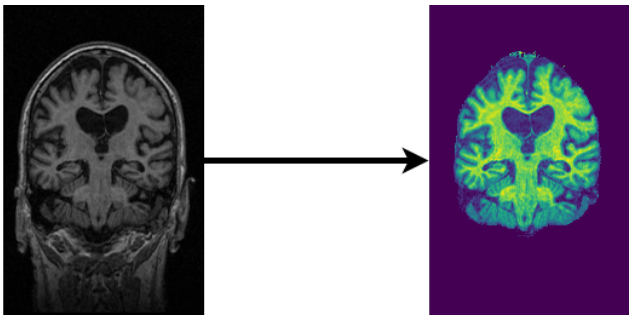

Fig. 5. Automatic image preprocessing.

- Mask decoder: The encoder is followed by a decoder that generates a precise mask of the brain. This mask is used to isolate and extract the brain region from the original image.
- Application of masks: The generated masks are applied to the original images to extract specific brain regions. This process eliminates irrelevant elements such as bone structures and empty spaces around the brain.
- Color map: A color mapping can be applied to visually enhance the distinction of different brain regions, facilitating subsequent analyses by experts or classification algorithms.

This methodology of image selection and preparation ensures that only the most relevant and high-quality data are used to train the Alzheimer's disease diagnostic model. By effectively isolating the brain from other structures and standardizing image formats, we maximize the accuracy of subsequent analyses and enhance the reliability of study results. This rigorous process is essential to develop a robust model capable of accurately detecting and classifying the different stages of Alzheimer's disease from MRI data.

B. Comparative Analysis of Data Sets from Different Clients and the Global Server

The data sets collected from different clients and aggregated at the global server level are essential to understand the class distribution and evaluate the model's ability to generalize across diverse data sources. Maintaining a balanced class distribution within each set is crucial for developing an effective Alzheimer's disease diagnostic model.

1) Understanding the data: The data sets from each client as well as the global server show varied class distribution (AD, CN, MCI), reflecting the diversity of Alzheimer's disease stages captured by MRI images. Balancing classes in training, testing, and validation data is crucial to prevent learning biases and ensure accurate model evaluation. For instance, a significant imbalance in any set could lead to apparent superior performance for the majority class, masking the model's deficiencies in correctly identifying other classes.

2) Purpose of balanced distribution: The goal of maintaining a balanced class distribution is to allow the model to learn uniformly from all pathological conditions without overfitting to a particular class. This is particularly important in a medical context where each misdiagnosis or missed diagnosis can have serious implications for patient treatment and management.

A comparative table is presented to visualize not only the quantity of data available for each class but also to evaluate the uniformity of distribution across different clients and the global server. This comparative analysis demonstrates the importance of carefully monitoring class distribution in data sets to avoid learning biases and ensure diagnostic accuracy. Careful management of these distributions directly contributes to the robustness and generalizability of artificial intelligence models in medical diagnostics.

C. Federated Learning Model Architecture

In our federated learning architecture for classifying Alzheimer's disease MRI images, each local institution begins with a data preprocessing process. This preprocessing includes applying the *Segment Anything* (SAM) model to isolate relevant brain areas. The images are then visually enhanced via a *ColorMap* to highlight distinctions between brain regions. Next, these images are resized and normalized to match the input specifications of the EfficientNet-B3 model, used as the base for local training (Fig. 6).

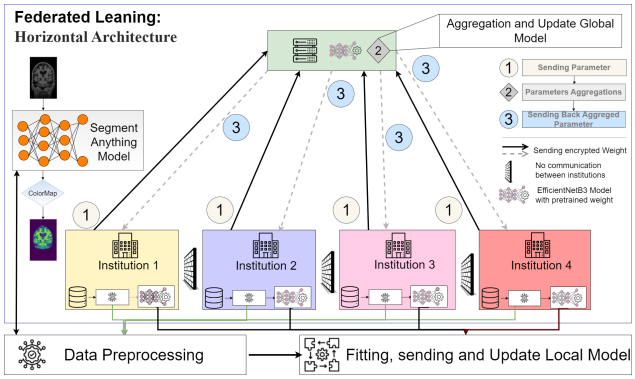

Fig. 6. Our federated learning architecture.

Each institution trains a local instance of the EfficientNet-B3 model initialized with pre-trained ImageNet weights to exploit generic visual features learned from a wide range of natural images. This allows the model to converge faster and improve its ability to generalize from features learned from MRI images. Local training is conducted on each institution's specific data, ensuring that the model adapts to local data nuances without compromising data confidentiality. Once local training is completed, each institution's model weights are encrypted and sent to a central server. This server aggregates the received weights using the FedAvg algorithm, which calculates a weighted average of the model updates. The FedAvg formula is expressed as:

$$w_{global} = \frac{1}{N} \sum_{k=1}^{N} n_k w_k$$

where w_{global} represents the updated global weights, N is the total number of clients, and w_k are the local model weights of the k-th client. This formula equitably considers each local model's contributions, reflecting a synthesis of diverse learning

across different data sets. The objective function, often a cross-entropy loss in classification tasks, is defined to minimize the model's prediction error. The cross-entropy loss function is formulated as:

$$L = -\sum_{i=1}^{N}\sum_{j=1}^{C} y_{ij}\log(p_{ij})$$

where C is the number of classes, y_{ij} is a binary indicator (0 or 1) if the class label i is the correct classification for observation j, and p_{ij} is the predicted probability for observation j to belong to class i. This function pushes the model to improve its accuracy and reliability by adjusting the weights to minimize overall classification error.

D. Performance Evaluation

The model's performance was evaluated using a series of standard metrics, including accuracy, recall, specificity, and the area under the ROC curve (AUC). Evaluations were conducted on both an internal validation data set and the OASIS data [24] set to assess the model's generalization capability. Cross-validations were also performed to test the model's stability and reliability across different data subsets. This helped identify potential performance variations due to the specificities of each site's data, crucial for future model adaptation to other clinical or research contexts.

VII. Experimental Configuration

A. Experimental Protocol

The experimental phase of this study was designed to comprehensively validate the federated learning model's ability to process and analyze MRI images in the context of Alzheimer's disease. The experiments were structured in several key steps to evaluate both the individual effectiveness of local models on each client's data and the effectiveness of the aggregated global model on an independent test dataset. Each client initially performed local training cycles on their own data. This local phase aimed to optimally adapt the model to the specificities of each site's data before contributing to federated learning. The local model parameters were then sent to the central server for aggregation. The updated global model was redistributed to clients for a new iteration, repeating this process until the global model converged.

B. Model Architecture

The model architecture is based on **EfficientNet-B3**, pre-trained on the *ImageNet* dataset. The model accepts input images of size `224x224` pixels and has been adapted to process grayscale MRI images. This architecture was selected for its ability to extract complex features while minimizing computational complexity.

C. Training and Evaluation Parameters

Training parameters, including learning rate, number of epochs, and batch size, were carefully selected to optimize performance while minimizing the risk of overfitting. Below are the primary parameters used in the experiments:

1) Learning rate: Initially set at `0.001`, it was adaptively adjusted based on the model's performance during training phases. An *exponential decay* was applied, gradually reducing the learning rate after every `5 epochs` to prevent premature convergence.

2) Number of epochs: Each client trained locally for a total of `50 epochs` to ensure adequate model convergence. This number was determined based on observations of model stability.

3) Batch size: A batch size of `32` was used for local training on each client, balancing memory usage and convergence speed.

4) Optimizer: The `Adam` optimizer was chosen for its ability to adapt to different gradient magnitudes during training, with standard parameters $\beta_1 = 0.9$ and $\beta_2 = 0.999$. This provided more stable weight updates during iterations.

D. Performance Evaluation

To assess the performance of the federated models employed in this study for Alzheimer's disease diagnosis using MRI data, each client trained a model on their local data, and the global aggregated model was evaluated on two standardized datasets (ADNI and OASIS) to measure generalization. The following key metrics were used for analysis:

1) Accuracy: Used to measure the overall correctness of the model's predictions.

2) ROC Curves and AUC (Area under the curve): Employed to assess the model's ability to distinguish between the different classes (Alzheimer's, Cognitively Normal, and Mild Cognitive Impairment).

3) Confusion matrix: Visualized the classification performance in terms of true positives, false positives, true negatives, and false negatives across the classes.

4) Loss: Tracked throughout the epochs to evaluate the model's learning progress and ensure it was not overfitting the training data.

E. Data Distribution

The following Table I summarizes the data distribution used for training, validation, and testing for each client and the global model, providing an overview of the learning and testing conditions.

TABLE I. Data Distribution for Training, Validation, and Testing

Client/Model	Training	Validation	Test	Total images
Client 1	4100 images	513 images	513 images	5126
Client 2	1964 images	245 images	246 images	2455
Client 3	1507 images	188 images	189 images	1884
Client 4	1284 images	161 images	161 images	1606
Global Model	984 images	215 images	215 images	1414 (ADNI)
Generalization Test	-	-	215 images	215 (OASIS)

The generalization test focuses on the OASIS dataset [24], which helps in evaluating the model's adaptability to unseen data.

F. Testing Methodology

Performance was evaluated using the following criteria:

1) Accuracy and loss across epochs: Observed to monitor the progression and stability of model learning. Accuracy and loss graphs reveal trends of improvement or potential adjustment needs.

2) ROC curves and AUC: The discriminatory ability of models for each diagnostic class is quantified by the area under the ROC curve (AUC).

3) Confusion matrices: Provide details on specific classification performance for each class, highlighting accuracy, recall, and F1 score.

VIII. Results

A. Client Architecture

This figure illustrates the architecture of clients within our federated learning framework. The data is prepared from the ADNI (Alzheimer's Disease Neuroimaging Initiative) dataset. The data undergoes several stages (Fig. 7):

1) Data preparation: ADNI images are prepared for training, validation, and testing of models.

2) Training: Models are locally trained on each client using pre-trained weights from EfficientNet-B3, an advanced convolutional neural network architecture.

3) Validation: The model performance is evaluated on a validation set to adjust hyperparameters and avoid overfitting.

4) Testing: The final model is tested on independent data to assess its generalization.

5) Client model evaluation: Model performance is evaluated based on three classes: AD (Alzheimer's Disease), CN (Cognitively Normal), and MCI (Mild Cognitive Impairment).

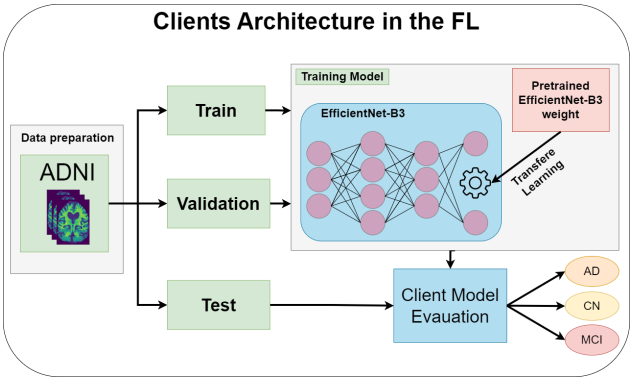

Fig. 7. Client architecture in federated learning.

The models use transfer learning techniques to enhance performance by utilizing pre-trained weights from EfficientNet-B3. This architecture allows efficient model updates while preserving local data confidentiality on each client.

B. Centralized Server Architecture

The centralized server aggregates the model updates from all clients and computes a global model using the FedAvg algorithm. This global model is redistributed to the clients for further iterations, ensuring continuous improvement of the model's predictive performance (Fig. 8).

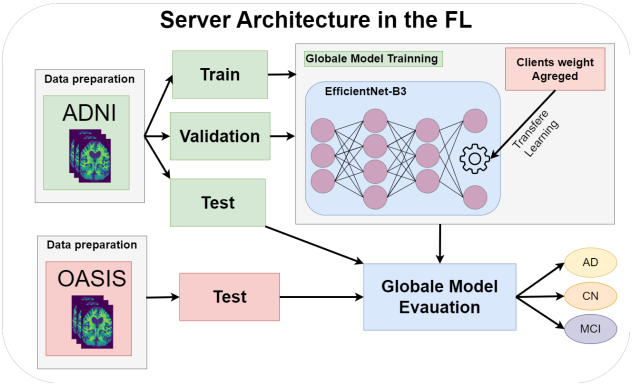

Fig. 8. Centralized server architecture in federated learning.

C. Individual Client Performance

The Table II below summarizes the key performance metrics for each client at the end of the training process. It shows accuracy, recall, F1 score, and AUC for the three diagnosed classes: Alzheimer's Disease (AD), Cognitively Normal (CN), and Mild Cognitive Impairment (MCI).

The performance analysis of local models shows that each client achieved satisfactory results with high accuracy and significant AUC for each class.

D. Global Model Performance

The Table III below shows the global model performance after aggregating the local models. It indicates exceptional performance on the ADNI dataset and good generalization on the OASIS dataset, confirming the effectiveness of federated learning.

The global model results indicate outstanding performance on the ADNI dataset and acceptable generalization on the OASIS dataset, validating the robustness of the federated learning approach.

E. Convergence Analysis

The analysis indicates that the federated model requires approximately 15% more iterations to converge compared to the centralized model. Several factors contribute to this delay. In federated environments, each node has a unique local dataset, often varying in size and distribution. This heterogeneity can slow down convergence, as local models learn at different rates based on data quality and quantity, as observed by [26]. Clients with richer datasets tend to converge faster, while those with less diverse data require more iterations. Communication delays also impact convergence. Aggregating weights or gradients from geographically dispersed nodes can introduce latencies, especially with varying network bandwidth. The

TABLE II. SUMMARY OF CLIENT PERFORMANCE METRICS

Client	Accuracy	Recall	F1 Score	AUC AD	AUC CN	AUC MCI
Client 1	89%	87%	90%	0.96	0.97	0.98
Client 2	91%	91%	91%	0.93	0.95	0.93
Client 3	88%	88%	88%	0.95	0.87	0.91
Client 4	88%	89%	88%	0.94	0.96	0.91
Client 5	90%	89%	89%	0.92	0.94	0.95

TABLE III. GLOBAL MODEL PERFORMANCE

Dataset	Accuracy	Recall	F1 Score	AUC AD	AUC CN	AUC MCI
ADNI	96%	95%	95%	0.97	0.96	0.96
OASIS	85%	85%	85%	0.89	0.87	0.88

author in [5] emphasized that communication constraints are a key challenge in federated learning, slowing down global updates and requiring additional iterations. Node heterogeneity in computing capacity further complicates convergence. Nodes with differing processing speeds or intermittent availability can disrupt the aggregation process, extending the convergence time, as noted by [26].

F. Empirical Demonstration

To illustrate the key observations made during the convergence and performance analysis, we present accuracy and loss curves for different clients. These curves help demonstrate how local models converge over time and how variations in local data distribution affect overall model performance.

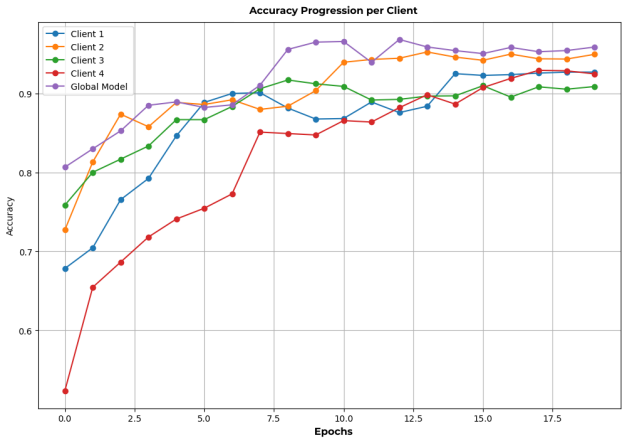

Fig. 9. Accuracy curves for different clients across epochs.

The accuracy (Fig. 9) and loss graphs (Fig. 10) provide valuable insights into the behavior of federated models in heterogeneous environments:

1) Accuracy by epochs: Some clients, such as Client 5 (Global Model), achieve high accuracy faster than others, such as Client 4. This discrepancy can be attributed to better local data quality or more diverse datasets available to certain clients. This observation aligns with findings by [26], who demonstrated that local data quality strongly influences the convergence speed of models in federated learning.

2) Loss by epochs: Similarly, the reduction in loss is faster for some clients compared to others. Clients with limited resources or less diverse datasets show a slower reduction

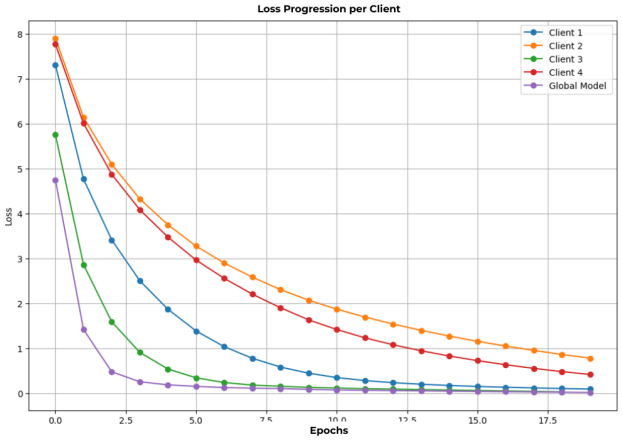

Fig. 10. Loss curves for different clients across epochs.

in loss, requiring more epochs to achieve convergence. This observation is consistent with the results from [1], who found that federated models may require more epochs to converge, particularly in environments with heterogeneous data.

These empirical results highlight several key aspects of federated learning in practice:

- Clients with richer, more diverse datasets can achieve higher accuracy and reduce loss faster.
- Federated learning introduces additional complexity in heterogeneous environments where clients have varying amounts of data and computational resources.
- Communication delays and client-specific limitations, such as intermittent availability or weaker hardware, can impact the speed at which a federated model converges.

These observations demonstrate the importance of careful client management and the need for adaptive strategies to ensure balanced learning across all participants in a federated system. While federated learning has significant potential in medical diagnostics, the challenges of managing heterogeneous data and resource constraints must be addressed to maximize the efficiency and accuracy of models.

G. Generalization Capacity of the Global Model

In this section, we analyze in detail the performance of the Global Model (GM) on the **ADNI** and **OASIS** datasets, using

the provided confusion matrices and ROC curves.

1) Performance of the Global Model (GM) on ADNI Data: The evaluation of the Global Model on the **ADNI** dataset is presented through the confusion matrix (Fig. 11) and the ROC curve (Fig. 12).

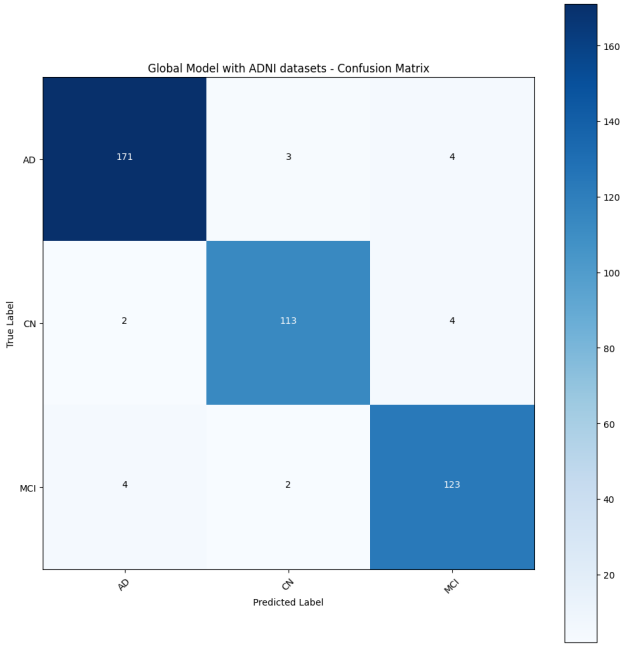

Fig. 11. Confusion matrix of the Global Model (GM) on ADNI data.

- Alzheimer Class (AD): The model correctly classified 171 cases out of 178, with only 3 misclassified as CN (Cognitively Normal) and 4 as MCI (Mild Cognitive Impairment).
- Cognitively Normal Class (CN): Out of 119 cognitively normal individuals, the model correctly classified 113, with 2 misclassified as AD and 4 as MCI.
- MCI Class: For the 129 individuals with MCI, 123 were correctly classified, 4 were misclassified as AD, and 2 as CN.

This confusion matrix shows very strong overall performance of the model on ADNI, particularly for the Alzheimer's class, where the model displays very high precision.

The results are further confirmed by the ROC curve for the ADNI dataset below (Fig. 12):

- AD Class: The AUC for the Alzheimer class is 0.97, indicating that the model has a very strong ability to discriminate this class from the others. - CN Class: The AUC for the Cognitively Normal class is 0.96, also showing excellent discriminatory ability. - MCI Class: The AUC for the MCI class is 0.96, indicating similarly good performance for this class as well.

2) Analysis of performance on ADNI: The results on the ADNI data show that the Global Model performs very accurately, with high AUCs for all three classes, each exceeding 0.96. This demonstrates that the model is well-suited to the data it was trained on. The Global Model can effectively discriminate between Alzheimer's patients, cognitively normal subjects, and those with MCI.

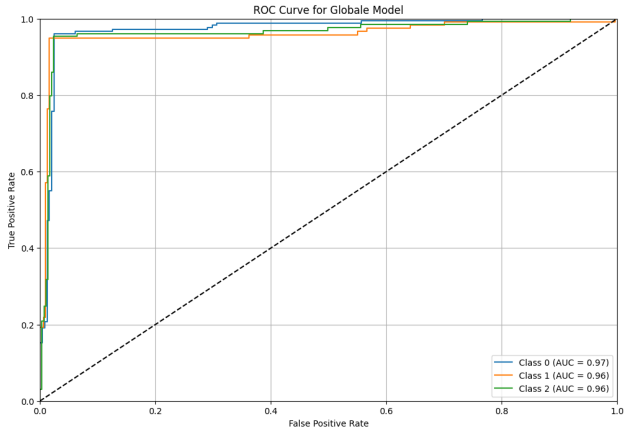

Fig. 12. ROC curve of the Global Model (GM) on ADNI data.

3) Performance of the Global Model (GM) on OASIS data: To test the generalization capability of the model, it was also evaluated on the OASIS dataset. The results from the confusion matrix (Fig. 13) and the ROC curve (Fig. 14) are analyzed below.

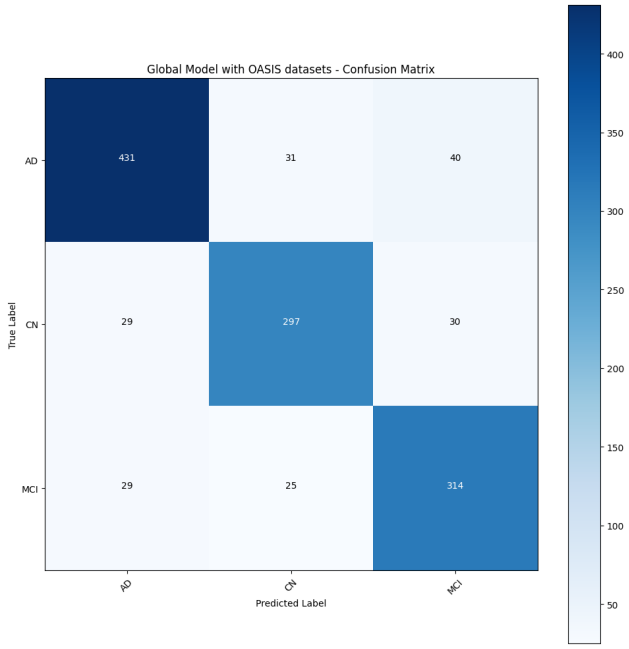

Fig. 13. Confusion matrix of the Global Model (GM) on OASIS data.

- Alzheimer Class (AD): The model correctly classified 431 cases out of 502, with 31 errors classified as CN and 40 as MCI. - Cognitively Normal Class (CN): Out of 356 cognitively normal individuals, 297 were correctly classified, with 29 errors in AD and 30 in MCI. - MCI Class: For the MCI class, the model correctly classified 314 cases out of 368, with 29 errors in AD and 25 in CN.

These results demonstrate that the Global Model generalizes well on a previously unseen dataset, even though there is a slight performance degradation compared to ADNI, particularly for the Alzheimer's and cognitively normal classes.

The ROC curves for the Global Model on OASIS (Fig. 14) show respectable AUCs, though slightly lower than those observed on ADNI.

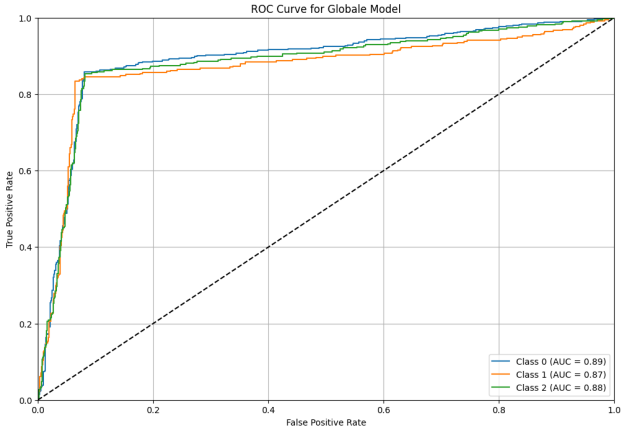

Fig. 14. ROC curve of the Global Model (GM) on OASIS data.

- AD Class: The AUC for the Alzheimer's class is 0.89, showing that the model retains a good ability to discriminate this class, though slightly lower compared to ADNI. - CN Class: The AUC for the Cognitively Normal class is 0.87, which is acceptable but lower than the AUC obtained on ADNI. - MCI Class: The AUC for the MCI class is 0.88, slightly higher than CN but lower than the results observed on ADNI.

4) Analysis of performance on OASIS: The results obtained on the OASIS dataset show that the Global Model has a good generalization ability, but with slightly lower performance compared to ADNI. This difference is normal and expected, given that the model was not trained on the OASIS data. Despite this, the AUCs for all three classes remain close to 0.90, proving that the model can maintain a good level of accuracy even on unseen data.

IX. Discussion of Results

A. Local Model Performance

The local models performed well on their respective datasets. For instance, Client 2 achieved 91% accuracy and an AUC of 0.93 for Alzheimer's disease (AD), while Client 1 achieved 89%, showing that data quality and diversity impact results[27].

B. Global Model Performance

The global model, aggregated from local models, improved overall performance, reaching 96% accuracy and 0.97 AUC on ADNI. On the OASIS dataset, the accuracy was 85%, confirming that the model generalizes well to unseen data despite domain shift [28].

C. Comparative Result

To contextualize the performance of our federated model, we compare our results with those of other state-of-the-art methods from the literature. Table IV presents a summary of the model performance (in terms of classification accuracy and AUC) for the proposed approach versus several published methods on AD diagnosis tasks. As shown in the table, our FL approach achieves competitive accuracy on the ADNI dataset and maintains strong generalization on OASIS, while inherently preserving data privacy. In contrast, most alternative methods report high accuracy only on the datasets they were trained and tested on, without demonstrating cross-site validation a limitation noted in several recent FL benchmarks [29]. This comparison underscores that our federated model attains similar or better accuracy than conventional centralized models, with the added benefit of privacy preservation and multi-center applicability.

TABLE IV. Comparative Performance of the Proposed FL Model vs Other Methods in AD Diagnosis

Method (Architecture)	Dataset	Accuracy	AUC	Reference
Proposed FL (EfficientNet-B3)	ADNI (train/val)	96%	0.97	–
Proposed FL (EfficientNet-B3)	OASIS (external test)	85%	0.88	–
Pelka et al. (LSTM > Branded)	ADNI (Phase 1)	77%	N/A	[25]
Armonaite et al. 2023 (ResNet-3D)	ADNI (3-class)	85%	N/A	[30]
Rana et al. 2023 (EfficientNet-B2)	Multiple (4-class)	97%	N/A	[8]

it can be observed that our federated learning approach achieves accuracy on par with the best reported methods. Notably, Rana et al. attained an accuracy of 97% on a composite four-class dataset using a centralized deep learning model, whereas our FL model reaches a comparable 96% on ADNI while additionally proving its robustness on an independent cohort (OASIS) [22]. Similarly, the ResNet3D model by Armonaite et al. achieved around 85% on ADNI three-class classification, which aligns with our model's performance on the external OASIS test set. Pelka et al. [25] reported lower accuracy (77%) on ADNI when distinguishing aMCI from healthy controls, likely due to the challenge of limited data in single-site training. Overall, the inclusion of an advanced segmentation step (SAM) and the federated training across institutions allow our model to generalize better than conventional approaches that lack cross-site validation. These results demonstrate that our privacy-preserving FL framework does not sacrifice performance; on the contrary, it yields competitive accuracy and AUC while addressing the critical issue of data confidentiality in multi-center studies.

D. Implications and Perspectives

In broader terms, this study demonstrates that FL can be effectively applied to sensitive medical imaging data [4], overcoming data confidentiality obstacles while enabling broad collaboration between institutions. By training a shared model on distributed MRI datasets, we showed that it is possible to achieve high diagnostic accuracy without aggregating raw data in a central repository [31] [20]. This has important implications for clinical practice: a network of hospitals could collaboratively train an AD diagnostic model on their combined data holdings without any sensitive patient information ever leaving local servers. Such a paradigm can accelerate the development and deployment of AI tools in healthcare by tapping into multi-center data resources that would otherwise remain siloed [4] [5] [29].

Beyond the immediate case of AD MRI analysis, our federated approach lays a foundation for extending AI-driven diagnostics to other imaging modalities and neurodegenerative diseases. The methodology could be generalized to tasks like PET imaging for AD or MRI-based detection of Parkinson's and other disorders, where sharing data is challenging. The positive results obtained in this work suggest that concerns about performance degradation under a federated scheme can be mitigated with careful design (e.g. incorporating robust preprocessing and validation on external data). Clinically, this means that advanced diagnostic models trained via FL could be deployed across diverse healthcare sites with minimal loss in accuracy, ensuring that patients everywhere benefit from state-of-the-art AI diagnostics.

There are also broader perspectives in terms of research and policy. Federated learning addresses key ethical and legal issues by keeping patient data local, which facilitates compliance with privacy regulations [32] [33]. This feature can encourage cross-institutional collaborations that were previously hampered by privacy concerns [4]. Moreover, the success of our approach underscores the potential of FL to produce generalizable models; this is particularly valuable in medicine, where model overfitting to a single data source can limit real-world applicability [14] [29]. We anticipate that the adoption of FL in medical imaging will continue to grow, paving the way for larger-scale studies that leverage diverse datasets to build more robust and equitable AI systems [20]. Ultimately, our work contributes to a paradigm shift in how sensitive biomedical data can be used to drive innovation: by sharing models instead of data, we can unlock insights from previously untapped multi-center repositories and accelerate the translation of AI advances into clinical benefit.

X. Limitations of the Study

Despite the promising results, this study has several limitations that should be acknowledged. First, while our federated model demonstrated good generalization on the OASIS dataset, there was a noticeable decrease in performance (85% accuracy) compared to the ADNI dataset (96% accuracy). This drop, although expected when testing on completely independent data, warrants further investigation to identify specific factors related to dataset shift or inherent differences in data characteristics between ADNI and OASIS that might not be fully captured by the SAM preprocessing or addressed by the FedAvg aggregation strategy.

Second, our convergence analysis indicated that the federated model required approximately 15% more iterations to converge compared to a theoretical centralized model. While we attribute this to data heterogeneity and communication latencies inherent in FL, future work should explore more advanced aggregation algorithms beyond FedAvg that might offer faster convergence or better handling of statistical heterogeneity.

Third, SAM was used for automated brain region segmentation. While SAM is a powerful tool, its performance can vary across different medical imaging modalities and specific tasks. Further fine-tuning of SAM or comparison with other state-of-the-art segmentation models specifically optimized for brain MRI could potentially enhance segmentation accuracy and, consequently, diagnostic performance [34].

Finally, this study focused on MRI data. The integration of other data modalities, such as clinical scores or genomic data, within the federated learning framework was not explored but represents an important avenue for future research to potentially improve diagnostic accuracy and provide a more holistic understanding of AD.

XI. Conclusion

In this paper, we presented a novel federated learning approach for Alzheimer's disease diagnosis using MRI, implemented with the Flower framework. Our methodology combined automated brain region segmentation (via SAM) with a privacy-preserving FL training procedure across multiple hospital datasets. This strategy allowed us to achieve high accuracy in distinguishing AD, MCI, and cognitively normal subjects, while validating the model's generalization on an independent cohort. The results confirmed that an FL-trained model can perform on par with state-of-the-art centralized models, even when evaluated on unseen data, thus effectively addressing the challenge of data siloing. Overall, the proposed approach demonstrates that collaborative learning across institutions is feasible without compromising data privacy or diagnostic performance. This has significant implications for clinical research, as it enables the development of AI models that benefit from vastly larger and more diverse datasets than any single center could provide[cite: 300]. By preserving patient confidentiality and still achieving robust generalization, our work paves the way for broader adoption of federated learning in medical imaging.

Future work will aim to address the limitations identified in this study by: 1) investigating methods to further improve generalization performance across highly heterogeneous datasets, potentially by exploring domain adaptation techniques within the FL framework; 2) exploring more sophisticated aggregation techniques beyond FedAvg to enhance convergence speed and robustness to statistical heterogeneity; 3) conducting further research on optimizing segmentation models like SAM for specific neuroimaging tasks or comparing them with alternatives; and 4) expanding this framework to other imaging modalities and diseases, and integrating additional data types (such as clinical or genomic data) in a federated setting. We conclude that federated learning is a promising paradigm for multi-center medical AI studies, offering a pathway to more generalizable and trustworthy models in Alzheimer's disease diagnosis and beyond.

***Abstract*—This paper delves into an advanced control scheme that combines the sliding mode control (SMC) strategy with a meta-heuristic method to examine the issue of security control for non-linear systems that are vulnerable to deception attacks on their sensors and actuators. The proposed approach focuses on the development of a secure SMC law for nonlinear descriptor systems described by TS fuzzy models. A fuzzy observer is designed to accurately estimate the states that may affected by unpredictable sensor attacks, and an adaptive SMC controller is synthesized based on the estimated information to drive the observer's state trajectories towards the sliding surface and then maintaining the sliding motion thereafter. Afterward, sufficient conditions are established to ensure the admissibility of the closed-loop system. Then, the secretary bird optimization algorithm (SBOA), is explored for tackling an optimization problem with non-convex and nonlinear constraints as is defined to enhance the system's performance under threats. Ultimately, a simulation study through a practical example is performed to showcase the effectiveness of the proposed control scheme in maintaining system performance, even in the presence of attacks.**

***Keywords*—Descriptor systems; TS fuzzy models; fuzzy observer; deception attacks; adaptive sliding mode; SBOA**

I. Introduction

Exploring non-linear systems has always been an important topic in both the theoretical and practical aspects of control engineering. In this regard, fuzzy logic theory has emerged as a promising approach to handling the synthesis of complex nonlinear systems. In particular, the TS fuzzy models have become increasingly popular as a viable solution for addressing nonlinear control and filtering design problems. Furthermore, owing to their distinctive characteristics, several academics have dedicated substantial effort and undertaken studies in recent decades [1], [2], [4], [5]. On the other hand, it is common knowledge that several physical plants have a particular mathematical description that includes algebraic constraints in their models. Referred to as the descriptor system, it is acknowledged that while exploiting this model, regularity and absence of impulse features must be examined [6], [7], [8], [9], [10]. Besides, there has been a significant amount of development in the area of cyber-physical systems (CPSs), which are focused on the combination of computing and physical resources. Smart grids and intelligent automobiles are two examples of industrial processes that heavily rely on these technology. However, adopting such a structure may present technical challenges in terms of system synthesis and security. In fact, malicious users may compromise CPSs' stability, confidentiality, and integrity by launching cyber attacks over wireless communications between sensors and controllers. Consequently, cyber-security has risen to the top of the list of priorities and is one of the most significant problems in the control community for developing feedback control systems that can withstand attacks [11]. When it comes to this topic, there are various classes of attacks that have drawn the attention of researchers: the denial-of-service (DoS) attacks examined in [12], [13], [21], and the deception attacks studied in [14], [15], [16]. DoS is unique in that the attacker sends a large number of meaningless signals to use up network bandwidth and confuse legitimate users requests were unable to pass through. However, deception attacks, unlike DoS, disrupt the system's information transmission process by injecting false data to destroy its authenticity and availability of information. Very recently, deception attacks have increasingly attracted a lot of attention from researchers, yielding a multitude of noteworthy findings (refer to [17], [18], [19], [14], [20]). To specify a few: The adaptive SMC approach has been explored in [13] to deal with the event-triggered control design for nonlinear systems with deception attacks. The study in [22] has focused on the secure event-triggered output feedback tracking control for singularly perturbed systems under sensor saturation and attack. In [33], the neural network is explored to deal with event-triggered control problem for Markov jump systems with DOS and deception attacks.

It should be emphasized that the aforementioned favorable findings only focused on attacks targeting the actuators or sensors. However, attacks affecting both sensor and actuator channels, which may occur often, should be seriously investigated. Besides, SMC is widely accepted as an exceptionally effective technique that exhibits rapid response and exceptional robustness against uncertainty and external disturbances [13], [23], [10], [24]. Thus, the SMC can be a valuable approach for dealing with security control issues in cyber-systems, especially when both the actuator and sensor are vulnerable to simultaneous attacks. Nevertheless, when the integrity of sensor signals is compromised, the system's state may be rendered inaccessible for controller design. On that account, it is necessary to construct an observer to estimate the unmeasured state in the event of a sensor attack [3]. Subsequently, the sliding mode controller should

be synthesized based on the observer's estimation of the state. This fact serves as the primary motivation for our investigation. It should be mentioned that, as a result of attacks, the system's performance might be destroyed by unsuitable constructed SMC. To minimize the impact of the attacks, it is interesting to address an optimized SMC law by including an optimization problem that aims to optimize the controller and observer gains. To come up with nonlinear and non-convex constraints while designing the SM controller, the proposed problem cannot be addressed using the linear matrix inequality (LMI) approaches that are widely employed by scholars. Recently, several evolutionary algorithms, including the Genetic Algorithm (GA) [25], Particle Swarm Optimization (PSO) [26], the Ant Colony Optimization (ACO) [27], and the Dandelion Optimization (DO) [28], [29] have emerged to tackle design challenges in control systems that involve nonlinear or non-convex constraints. The population-based meta-heuristic algorithm SBOA, recently introduced in [39] will be used in conjunction with the LMI technique to address the problem of optimizing the control architecture. This serves as an additional incentive for this research.

This paper endeavors to design the observer-based sliding mode controller for a class of non-linear descriptor systems when both the actuator and sensor are vulnerable to attacks simultaneously. Compared with the existing works, the novelties of this paper lie in the following aspects:

- Although considerable attention has been devoted to standard state-space systems under attacks, the security control problem for descriptor systems (which naturally arise in many practical applications such as power systems, robotics, and process control) remains largely unexplored, especially when considering systems with nonlinear dynamics and fuzzy modeling.
- As compared to the existing findings [40], [41], the observer-based sliding mode secure problem for TS fuzzy descriptor systems is explored when both the actuator and sensor are vulnerable to attacks simultaneously.
- When sensor channels are compromised, traditional state-feedback controllers become impractical. Existing observer-based approaches for attacked systems [4], [28] primarily consider matched premise variables and do not address the optimization of both observer and controller gains to minimize attack amplification effects.
- Current SMC design methods for cyber-physical systems rely heavily on LMI approaches, which cannot handle the non-convex, nonlinear constraints that naturally arise when optimizing sliding surface parameters and controller gains to minimize attack impacts [40], [42], [36]. A new SBOA-assisted controller design method is schemed to mitigate the attack's effects and improve the system performance.

The remainder of this paper is organized as follows. Section II presents the system model and problem formulation, Section III establishes admissibility conditions through Lyapunov-based stability analysis. Section IV develops the synthesis of the adaptive sliding mode controller and derives the main theoretical contributions. Section V introduces the SBOA-based optimization problem used for optimal gain selection. Section VI validates the proposed approach through extensive simulation studies and comparative evaluations against existing methods. Finally, Section VII concludes the paper with suggestions for future research directions.

II. Preliminaries and Problem Statement

This section presents some preliminary concepts, and outlines the research problem.

A. Model Description

In this paper, the structure of control scheme is shown in Fig. 1, where the TS fuzzy model is employed to characterize nonlinear descriptor systems, where the following fuzzy rule is defined for the premise variables ϕ_j, $j \in \{1, \ldots, s\}$, and fuzzy sets $\mathcal{N}_j^i$, $i \in \mathbb{S} = \{1, \ldots, r\}$. r stands for the number of `if-then` rules.

$$\text{Rule } i\text{: } \texttt{if } \phi_1 \text{ is } \mathcal{N}_1^i, \phi_2 \text{ is } \mathcal{N}_2^i, \ldots, \text{ and } \phi_s \text{ is } \mathcal{N}_s^i, \texttt{ then } \begin{cases} \boldsymbol{E}\dot{\boldsymbol{x}}(t) = \boldsymbol{A}_i\boldsymbol{x}(t) + \boldsymbol{B}_2\big(\boldsymbol{u}(t) + \boldsymbol{g}_i(t)\big), \\ \boldsymbol{y}(t) = \boldsymbol{C}_2\boldsymbol{x}(t) \end{cases} \tag{1}$$

In this model, $\boldsymbol{x}(t) \in \boldsymbol{R}^n$, $\boldsymbol{u}(t) \in \boldsymbol{R}^m$, and $\boldsymbol{y}(t) \in \boldsymbol{R}^{ny}$ define, respectively, the state vector, the control input, and the measured output. Matched non-linear function $\boldsymbol{g}_i(t)$ can represent various model uncertainties or external perturbations. Constant matrices $\boldsymbol{A}_i$, $\boldsymbol{B}_2$, $\boldsymbol{C}_2$, characterize the fuzzy model, matrix $\boldsymbol{E} \in \mathbb{R}^{n\times n}$, however, describes the singular property of the model so that $\text{rank}(\boldsymbol{E}) = r_0 < n$.

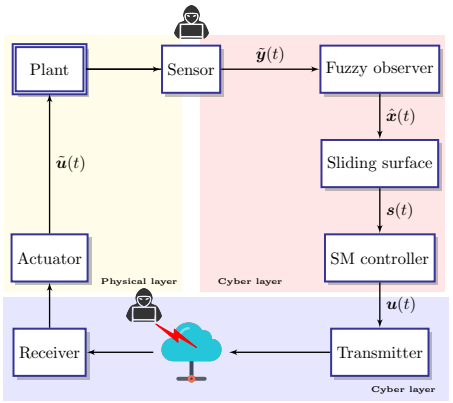

Fig. 1. Schematic of control structure.

B. Resulting Model

By identifying the vector $\boldsymbol{\phi} = [\phi_1, \ldots, \phi_s]$, the general fuzzy model is stated conform to:

$$\begin{cases} \boldsymbol{E}\dot{\boldsymbol{x}}(t) = \sum_{i=1}^{r} h_i(\boldsymbol{\phi})\Big\{\boldsymbol{A}_i(t)\boldsymbol{x}(t) + \boldsymbol{B}_2\big(\boldsymbol{u}(t) + \boldsymbol{g}_i(t)\big)\Big\}, \\ \boldsymbol{y}(t) = \boldsymbol{C}_2\boldsymbol{x}(t), \end{cases} \tag{2}$$

where $h_i(\boldsymbol{\phi}) = \prod_{j=1}^{\boldsymbol{s}} \mathcal{N}_j^i(\phi_j) / \sum_{i=1}^{r} \prod_{j=1}^{\boldsymbol{s}} \mathcal{N}_j^i(\phi_j)$ defines the normalized membership that should confirm $h_i(\boldsymbol{\phi}) \geq 0$, for $i \in \mathbb{S}$, and $\sum_{i=1}^{r} h_i(\phi) = 1$. $\mathcal{N}_j^i(\phi_j)$ stands for the grade of membership of ϕ_j to $\mathcal{N}_j^i$.

C. Attack's Descriptions

When the sensors are vulnerable to false data injection attacks caused by computer viruses, flaws, and similar factors, the following random model of the system outputs is investigated:

$$\tilde{\boldsymbol{y}}(t) = \boldsymbol{y}(t) + \zeta(t)(-\boldsymbol{y}(t) + \boldsymbol{\delta}_s(t)), \tag{3}$$

where $\zeta(t)$ is the random variable, while $\boldsymbol{\delta}_s(t)$ refers to the embedded signal produced by the attacker. It should be noted that, if $\zeta(t)$ is different from zero, then the sensor attack $\boldsymbol{\delta}_s(t)$ impacts the integrity of $\boldsymbol{y}(t)$; however, if $\zeta(t) = 0$, it comes $\tilde{\boldsymbol{y}}(t) = \boldsymbol{y}(t)$ which may be applied for feedback purposes. Again, through the injection of actuator attack signals, the integrity of $\boldsymbol{u}(t)$ is menaced and can be represented in the format that follows.

$$\tilde{\boldsymbol{u}}(t) = \boldsymbol{u}(t) + \boldsymbol{\delta}_a(t). \tag{4}$$

With (4), system (2) is expressed as

$$\begin{cases} \boldsymbol{E}\dot{\boldsymbol{x}}(t) = \boldsymbol{A}_h \boldsymbol{x}(t) + \boldsymbol{B}_2\big(\tilde{\boldsymbol{u}}(t) + \boldsymbol{g}_h(t)\big), \\ \quad \boldsymbol{y}(t) = \boldsymbol{C}_2 \boldsymbol{x}(t), \end{cases} \tag{5}$$

and, the following norm bounded conditions hold for $\boldsymbol{g}_i(t)$, $\boldsymbol{\delta}_s(t)$, and $\boldsymbol{\delta}_a(t)$, respectively.

Assumption 1.

A.1 $\|\boldsymbol{g}_i(t)\| \leq \delta \|\boldsymbol{y}(t)\|$,

A.2 $\|\boldsymbol{\delta}_s(t))\| \leq \beta \|\boldsymbol{y}(t)\|$,

A.3 $\|\boldsymbol{\delta}_a(t))\| \leq \Theta \|\hat{\boldsymbol{x}}(t)\|$,

A.4 $\zeta(t)$ *is stochastic variable with a Bernoulli distribution characterized as* $Pr(\zeta(t) = 1) = \bar{\zeta},\ Pr(\zeta(t) = 0) = 1 - \bar{\zeta}$.

where δ, β, Θ, *and* $\bar{\zeta}$ *are some known positive constants.*

D. Observer Design

It will underscored that sensor threats can compromise the accuracy of the output signal $\boldsymbol{y}(t)$ and complicate the process of designing state/output feedback controllers. Thus, an estimator should be designed to rebuild the system outputs. Under this circumstance, it is important to examine a fuzzy observer when faced with the challenge of mismatched premise variables between the observer and the system. The following rule states the model of the fuzzy observer, where $\boldsymbol{\varphi}(\hat{\boldsymbol{x}}(t)) = [\varphi_1(\hat{\boldsymbol{x}}(t)), \ldots, \varphi_{s_o}(\hat{\boldsymbol{x}}(t))]^\top$ is the premise variable vector that depends on the estimated states $\hat{\boldsymbol{x}}(t)$, and $\hat{\boldsymbol{y}}(t)$ depicts the estimated output.

Rule j: `if` $\varphi_1(\hat{\boldsymbol{x}}(t))$ is $\mathcal{V}_1^j, \ldots,$ and $\varphi_s(\hat{\boldsymbol{x}}(t))$ is $\mathcal{V}_{s_o}^j$, `then`

$$\begin{cases} \boldsymbol{E}\dot{\hat{\boldsymbol{x}}}(t) = \boldsymbol{A}_j \hat{\boldsymbol{x}}(t) + \boldsymbol{B}_2 \tilde{\boldsymbol{u}}(t) + \boldsymbol{L}_j(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t)), \\ \quad \hat{\boldsymbol{y}}(t) = \boldsymbol{C}_2 \hat{\boldsymbol{x}}(t), \end{cases}$$

$\boldsymbol{L}_j$ is the observer gain to be determined. Accordingly, the global observer's dynamic is inferred as follows:

$$\begin{cases} \boldsymbol{E}\dot{\hat{\boldsymbol{x}}}(t) = \sum_{j=1}^{r} \mu_j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}}))\Big(\boldsymbol{A}_j \hat{\boldsymbol{x}}(t) + \boldsymbol{B}_2 \tilde{\boldsymbol{u}}(t) + \boldsymbol{L}_j(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t))\Big), \\ \hat{\boldsymbol{y}}(t) = \boldsymbol{C}_2 \hat{\boldsymbol{x}}(t), \end{cases} \tag{6}$$

where $\mu_j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}}))$ is defined as $\mu_j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}})) = \prod_{d_o=1}^{s_o} \mathcal{V}_{d_o}^j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}})) \Big/ \sum_{j=1}^{r} \prod_{d_o=1}^{s_o} \mathcal{V}_{d_o}^j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}})) \geq 0$, and satisfies $\sum_{j=1}^{r} \mu_j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}})) = 1$. As well, the compact form of (6) being written as

$$\begin{cases} \boldsymbol{E}\dot{\hat{\boldsymbol{x}}}(t) &= \boldsymbol{A}_\mu \hat{\boldsymbol{x}}(t) + \boldsymbol{B}_2 \tilde{\boldsymbol{u}}(t) + \boldsymbol{L}_\mu(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t)), \\ \hat{\boldsymbol{y}}(t) &= \boldsymbol{C}_2 \hat{\boldsymbol{x}}(t). \end{cases} \tag{7}$$

Let $\boldsymbol{e}(t) = \boldsymbol{x}(t) - \hat{\boldsymbol{x}}(t)$. The error dynamic system may be depicted as

$$\begin{aligned} \boldsymbol{E}\dot{\boldsymbol{e}}(t) =& (\boldsymbol{A}_h - \boldsymbol{A}_\mu + \bar{\zeta}\boldsymbol{L}_\mu \boldsymbol{C}_2)\hat{\boldsymbol{x}}(t) + \Big(\boldsymbol{A}_h - (1 - \bar{\zeta})\boldsymbol{L}_\mu \boldsymbol{C}_2\Big)\boldsymbol{e}(t) \\ &+ \boldsymbol{B}_2 \boldsymbol{g}_h(t) - \bar{\zeta}\boldsymbol{L}_\mu \boldsymbol{\delta}_s(t) - (\zeta(t) - \bar{\zeta})\boldsymbol{L}_\mu \boldsymbol{\Gamma}(t), \end{aligned} \tag{8}$$

where $\boldsymbol{\Gamma}(t) = -\boldsymbol{C}_2 \hat{\boldsymbol{x}}(t) - \boldsymbol{C}_2 \boldsymbol{e}(t) + \boldsymbol{\delta}_s(t)$.

E. Sliding Surfaces Design

When developing a sliding mode controller, it is crucial to establish a suitable switching function. This function should be defined and expressed in the following manner:

$$\boldsymbol{s}(t) = \bar{\boldsymbol{S}}\boldsymbol{E}(\hat{\boldsymbol{x}}(t) - \hat{\boldsymbol{x}}(0)) - \int_0^t \bar{\boldsymbol{S}}\Big(\boldsymbol{A}_\mu + \boldsymbol{B}_2 \boldsymbol{K}_\mu\Big)\hat{\boldsymbol{x}}(\tau)d\tau, \tag{9}$$

Matrix $\bar{\boldsymbol{S}} \in \mathbb{R}^{m \times n}$ in (9) should be determined so that $\bar{\boldsymbol{S}}\boldsymbol{B}_2$ is non-singular. Moreover, as stated in the SMC theory, the ideal sliding mode occurs when $\boldsymbol{s}(t) = 0$ and $\dot{\boldsymbol{s}}(t) = 0$. Therefore, it may be inferred that

$$\begin{aligned} \dot{\boldsymbol{s}}(t) = \bar{\boldsymbol{S}}\boldsymbol{B}_2(\boldsymbol{u}(t) + \boldsymbol{\delta}_a(t) + \boldsymbol{g}_h(t) - \boldsymbol{K}_\mu \hat{\boldsymbol{x}}(t)) \\ + \bar{\boldsymbol{S}}\boldsymbol{L}_\mu(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t)), \end{aligned} \tag{10}$$

and the equivalent control law is formally specified as:

$$\boldsymbol{u}_e(t) = \boldsymbol{K}_\mu \hat{\boldsymbol{x}}(t) - \boldsymbol{\delta}_a(t) - \boldsymbol{g}_h(t) - (\bar{\boldsymbol{S}}\boldsymbol{B}_2)^{-1}\bar{\boldsymbol{S}}\boldsymbol{L}_\mu(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t)). \tag{11}$$

Moreover, the fuzzy sliding mode dynamics is defined as:

$$\begin{aligned} \boldsymbol{E}\dot{\hat{\boldsymbol{x}}}(t) =& (\boldsymbol{A}_\mu + \boldsymbol{B}_2 \boldsymbol{K}_\mu - \bar{\zeta}\hat{\boldsymbol{S}}\boldsymbol{L}_\mu \boldsymbol{C}_2)\hat{\boldsymbol{x}}(t) + (1 - \bar{\zeta})\hat{\boldsymbol{S}}\boldsymbol{L}_\mu \boldsymbol{C}_2 \boldsymbol{e}(t) \\ &+ \bar{\zeta}\hat{\boldsymbol{S}}\boldsymbol{L}_\mu \boldsymbol{\delta}_s(t) + (\zeta(t) - \bar{\zeta})\hat{\boldsymbol{S}}\boldsymbol{L}_\mu \boldsymbol{\Gamma}(t), \end{aligned} \tag{12}$$

where $\hat{\boldsymbol{S}} = \boldsymbol{I} - \tilde{\boldsymbol{S}}$, and $\tilde{\boldsymbol{S}} = \boldsymbol{B}_2(\bar{\boldsymbol{S}}\boldsymbol{B}_2)^{-1}\bar{\boldsymbol{S}}$.

Besides, the augmented closed-loop system can be characterized as:

$$\bar{\boldsymbol{E}}\dot{\bar{\boldsymbol{x}}}(t) = \bar{\boldsymbol{A}}_{h\mu}\bar{\boldsymbol{x}}(t) + \bar{\zeta}\bar{\boldsymbol{L}}_\mu \boldsymbol{\delta}_s(t) + \bar{\boldsymbol{B}}_2 \boldsymbol{g}_h(t) + (\zeta(t) - \bar{\zeta})\bar{\boldsymbol{L}}_\mu \boldsymbol{\Gamma}(t), \tag{13}$$

where $\bar{\boldsymbol{x}}(t) = [\hat{\boldsymbol{x}}^\top(t), \boldsymbol{e}^\top(t)]^\top$,

$$\bar{\boldsymbol{E}} = \begin{bmatrix} \boldsymbol{E} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{E} \end{bmatrix},$$
$$\bar{\boldsymbol{A}}_{h\mu} = \begin{bmatrix} \boldsymbol{A}_\mu - \bar{\zeta}\hat{\boldsymbol{S}}\boldsymbol{L}_\mu\boldsymbol{C}_2 + \boldsymbol{B}_2\boldsymbol{K}_\mu & (1-\bar{\zeta})\hat{\boldsymbol{S}}\boldsymbol{L}_\mu\boldsymbol{C}_2 \\ \boldsymbol{A}_h - \boldsymbol{A}_\mu + \bar{\zeta}\boldsymbol{L}_\mu\boldsymbol{C}_2 & \boldsymbol{A}_h - (1-\bar{\zeta})\boldsymbol{L}_\mu\boldsymbol{C}_2 \end{bmatrix},$$
$$\bar{\boldsymbol{L}}_\mu = \begin{bmatrix} \hat{\boldsymbol{S}}\boldsymbol{L}_\mu \\ -\boldsymbol{L}_\mu \end{bmatrix}, \bar{\boldsymbol{B}}_2 = \begin{bmatrix} \boldsymbol{0} \\ \boldsymbol{B}_2 \end{bmatrix}.$$

Remark 1. It is widely recognized that the sliding motion of the system is ensured when the matrix $\bar{\boldsymbol{S}}\boldsymbol{B}_2$ is non-singular. As stated in the literature, $\bar{\boldsymbol{S}}$ is often selected with a particular form, such as $\bar{\boldsymbol{S}}\boldsymbol{B}_2 = \boldsymbol{I}$ in [36], and $\bar{\boldsymbol{S}} = \boldsymbol{B}^\top\boldsymbol{P}$, where $\boldsymbol{P}$ is a positive definite Lyapunov matrix, as mentioned in [23]. However, selecting an unsuitable value for $\bar{\boldsymbol{S}}$ could result in the development of a SMC law that is ineffective in mitigating the effects of menaces. To address this concern, this study delves into a meta-heuristic approach for achieving the optimal selection of the sliding gain matrix $\bar{\boldsymbol{S}}$ and obtain the optimized SMC performance.

F. Objective Statements

The main objective of this study is to synthesize an adequate control that can effectively stabilize the system under investigation and successfully mitigate the negative effects of attacks $\boldsymbol{\delta}_s(t)$ and $\boldsymbol{\delta}_a(t)$. Hence, it is crucial to address the following questions to re-institute the ideal functionality of the controlled system.

Q-1 How may an adaptive sliding mode controller be designed to drive the observer states onto a pre-defined sliding surface and then maintaining the sliding motion thereafter?

Q-2 How may an optimization problem be formulated to minimize the effect of attacks and how can it be solved while dealing with non-convex constraints in the context of tackling the SMC problem?

Before responding to these questions, the following lemmas should be recalled.

Lemma 1. *[30] For any vectors $\boldsymbol{a}$, $\boldsymbol{b}$, and matrix $\boldsymbol{X} > 0$ the following inequality holds*

$$2\boldsymbol{a}^\top\boldsymbol{b} \le \varsigma\boldsymbol{a}^\top\boldsymbol{X}\boldsymbol{a} + \varsigma^{-1}\boldsymbol{b}^\top\boldsymbol{X}\boldsymbol{b}, \tag{14}$$

for any scalar $\varsigma > 0$.

Lemma 2. *[31] The inequality $-\boldsymbol{Z} + \mathrm{sym}(\boldsymbol{Q}\boldsymbol{A}) < \boldsymbol{0}$ holds for appropriate dimension matrices $\boldsymbol{Z} > 0$, $\boldsymbol{Q}$, and $\boldsymbol{A}$ if the following condition is fulfilled for any constant $\lambda > 0$, and matrix $\boldsymbol{Y}$:*

$$\begin{bmatrix} -\boldsymbol{Z} & \boldsymbol{Q} + \lambda\boldsymbol{A}^\top\boldsymbol{Y}^\top \\ (\boldsymbol{Q} + \lambda\boldsymbol{A}^\top\boldsymbol{Y}^\top)^\top & -\lambda\,\mathrm{sym}(\boldsymbol{Y}) \end{bmatrix} < \boldsymbol{0}.$$

III. Admissibility Analysis

The development of sufficient conditions proving the stochastic admissibility of system (13) is the primary concern of this section.

Theorem 1. *Given positive scalars β, δ, and $\bar{\zeta}$. If there exists a set of scalar values $\tau, \alpha > 0$, together with matrices $\bar{\boldsymbol{P}} > 0$ and $\bar{\boldsymbol{N}}$, $\bar{\boldsymbol{M}}_1$ and $\bar{\boldsymbol{M}}_2$ that satisfy the following conditions:*

$$\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\boldsymbol{\Phi}_{ij} < \boldsymbol{0}, \tag{15}$$

then, closed-loop system (13) is stochastically admissible.

$$\boldsymbol{\Phi}_{ij} = \begin{bmatrix} \boldsymbol{\Phi}_{11ij} & \boldsymbol{\Phi}_{12ij} & \bar{\zeta}\bar{\boldsymbol{M}}_1\bar{\boldsymbol{L}}_j & \bar{\boldsymbol{M}}_1\hat{\boldsymbol{B}}_2 \\ * & -\mathrm{sym}(\bar{\boldsymbol{M}}_2) & \bar{\zeta}\bar{\boldsymbol{M}}_2\bar{\boldsymbol{L}}_j & \bar{\boldsymbol{M}}_1\hat{\boldsymbol{B}}_2 \\ * & * & -\tau\boldsymbol{I} & \boldsymbol{0} \\ * & * & * & -\alpha\boldsymbol{I} \end{bmatrix}, \tag{16}$$

$\boldsymbol{\Phi}_{11ij} = \mathrm{sym}(\bar{\boldsymbol{M}}_1\bar{\boldsymbol{A}}_{ij}) + (\tau\beta^2 + \alpha\delta^2)\hat{\boldsymbol{C}}_2^\top\hat{\boldsymbol{C}}_2$, $\boldsymbol{\Phi}_{12ij} = \bar{\boldsymbol{E}}^\top\bar{\boldsymbol{P}} + \bar{\boldsymbol{N}}\bar{\boldsymbol{R}}^\top - \bar{\boldsymbol{M}}_1 + (\bar{\boldsymbol{M}}_2\bar{\boldsymbol{A}}_{ij})^\top$, $\hat{\boldsymbol{C}}_2 = \begin{bmatrix}\boldsymbol{C}_2 & \boldsymbol{C}_2\end{bmatrix}$, *$\bar{\boldsymbol{R}}$ is any matrix satisfying $\bar{\boldsymbol{E}}^\top\bar{\boldsymbol{R}} = 0$ and* $\mathrm{rank}(\bar{\boldsymbol{R}}) = 2n - 2r_0$.

Proof: First, we are concerned with the proof of the regularity and impulse-free features of (13). Suppose that non-singular matrices $\hat{\boldsymbol{V}}$, and $\hat{\boldsymbol{W}}$ exits so that $\hat{\boldsymbol{E}} = \hat{\boldsymbol{V}}\bar{\boldsymbol{E}}\hat{\boldsymbol{W}} = \mathrm{diag}\{\boldsymbol{I}_{2r_0}, \boldsymbol{0}\}$. Define

$$\hat{\boldsymbol{A}}_{h\mu}=\hat{\boldsymbol{V}}\bar{\boldsymbol{A}}_{h\mu}\hat{\boldsymbol{W}}=\begin{bmatrix}\hat{\boldsymbol{A}}_{11h\mu} & \hat{\boldsymbol{A}}_{12h\mu} \\ \hat{\boldsymbol{A}}_{21h\mu} & \hat{\boldsymbol{A}}_{22h\mu}\end{bmatrix},\ \hat{\boldsymbol{N}}=\bar{\boldsymbol{W}}^\top\bar{\boldsymbol{N}}=\begin{bmatrix}\hat{\boldsymbol{N}}11 \\ \hat{\boldsymbol{N}}21\end{bmatrix},$$
$$\hat{\boldsymbol{P}} = \hat{\boldsymbol{V}}^\top\bar{\boldsymbol{P}}\hat{\boldsymbol{V}} = \begin{bmatrix}\hat{\boldsymbol{P}}_{11} & \hat{\boldsymbol{P}}_{12} \\ * & \hat{\boldsymbol{P}}_{22}\end{bmatrix}, \hat{\boldsymbol{R}} = \hat{\boldsymbol{V}}^\top\bar{\boldsymbol{R}} = \hat{\boldsymbol{V}}^\top\begin{bmatrix}\hat{\boldsymbol{R}}_{11} \\ \hat{\boldsymbol{R}}_{21}\end{bmatrix}. \tag{17}$$

Using the fact that $\bar{\boldsymbol{E}}^\top\bar{\boldsymbol{R}} = \boldsymbol{0}$, if $\hat{\boldsymbol{R}}_{11} = \boldsymbol{0}$, it comes that $\hat{\boldsymbol{E}}^\top\hat{\boldsymbol{R}} = \boldsymbol{0}$. Moreover, it can be verified from (15) that

$$\begin{bmatrix}\mathrm{sym}(\bar{\boldsymbol{M}}_1\bar{\boldsymbol{A}}_{h\mu}) & \boldsymbol{E}^\top\bar{\boldsymbol{P}} + \bar{\boldsymbol{N}}\bar{\boldsymbol{R}}^\top - \bar{\boldsymbol{M}}_1 + (\bar{\boldsymbol{M}}_2\bar{\boldsymbol{A}}_{h\mu})^\top \\ * & -\mathrm{sym}(\bar{\boldsymbol{M}}_2)\end{bmatrix} < 0. \tag{18}$$

By performing the congruence transformation to (18) by $\Big[\boldsymbol{I}, \bar{\boldsymbol{A}}_{h\mu}^\top\Big]$, we calculate

$$sym\Big(\bar{\boldsymbol{E}}^\top(\boldsymbol{P}\bar{\boldsymbol{A}}_{h\mu} - \bar{\boldsymbol{M}}_1^\top\bar{\boldsymbol{A}}_{h\mu} - \bar{\boldsymbol{M}}_2^\top\bar{\boldsymbol{A}}_{h\mu}) + \bar{\boldsymbol{N}}\bar{\boldsymbol{R}}^\top\bar{\boldsymbol{A}}_{h\mu}\Big) < 0. \tag{19}$$

Pre- and post-multiplying (19) by $\hat{\boldsymbol{W}}^\top$ and $\hat{\boldsymbol{W}}$, respectively, we obtain $\mathrm{sym}\,(\hat{\boldsymbol{N}}_{21}\bar{\boldsymbol{R}}_{21}^\top\hat{\boldsymbol{A}}_{22}) < 0$, according to (17). It may be inferred that $\bar{\boldsymbol{A}}_{h\mu}$ is non-singular and, based on the definition in [5], it is recognized that $(\bar{\boldsymbol{E}}, \bar{\boldsymbol{A}}_{h\mu})$ is both regular and impulse-free.

Let $\boldsymbol{\xi}(t) = \mathrm{col}\Big\{\bar{\boldsymbol{x}}(t),\ \bar{\boldsymbol{E}}\dot{\bar{\boldsymbol{x}}}(t),\ \boldsymbol{\delta_s}(t)\Big\}$. To show the stability of closed-loop system (13), the subsequent Lyapunov function is selected as:

$$V(t) = \bar{\boldsymbol{x}}^\top(t)\bar{\boldsymbol{E}}^\top\bar{\boldsymbol{P}}\bar{\boldsymbol{E}}\bar{\boldsymbol{x}}(t). \tag{20}$$

Next, along the trajectories of system (13), we compute

$$\mathscr{L}\Big\{\dot{V}(t)\Big\} = 2\bar{\boldsymbol{x}}^\top(t)\bar{\boldsymbol{E}}^\top\bar{\boldsymbol{P}}\bar{\boldsymbol{E}}\dot{\bar{\boldsymbol{x}}}(t), \tag{21}$$

where $\mathscr{L}$ is the infinitesimal operator. As well, with the condition that $\bar{\boldsymbol{R}}^\top\bar{\boldsymbol{E}} = 0$, the following equations are valid for suitable matrices $\bar{\boldsymbol{N}}$ and $\bar{\boldsymbol{M}} = \mathrm{col}\Big\{\bar{\boldsymbol{M}}_1,\ \bar{\boldsymbol{M}}_2,\ \boldsymbol{0}\Big\}$:

$$2\bar{\boldsymbol{x}}^\top(t)\bar{\boldsymbol{N}}\bar{\boldsymbol{R}}^\top\bar{\boldsymbol{E}}\dot{\bar{\boldsymbol{x}}}(t) = \boldsymbol{0}, \tag{22}$$

and

$$\begin{aligned}\boldsymbol{0} =& \mathscr{L}\Big\{2\boldsymbol{\xi}^\top(t)\bar{\boldsymbol{M}}\Big(\bar{\boldsymbol{A}}_{h\mu}\bar{\boldsymbol{x}}(t) - \bar{\boldsymbol{E}}\dot{\bar{\boldsymbol{x}}}(t) + \bar{\zeta}\bar{\boldsymbol{L}}_\mu\boldsymbol{\delta}_s(t) + \bar{\boldsymbol{B}}_2\boldsymbol{g}_h(t) \\ &+ (\zeta(t) - \bar{\zeta})\bar{\boldsymbol{L}}_\mu\boldsymbol{\Gamma}(t)\Big)\Big\} \\ =& 2\boldsymbol{\xi}^\top(t)\bar{\boldsymbol{M}}\begin{bmatrix}\bar{\boldsymbol{A}}_{h\mu} & -\boldsymbol{I} & \bar{\zeta}\bar{\boldsymbol{L}}_\mu\end{bmatrix}\boldsymbol{\xi}(t) + 2\boldsymbol{\xi}^\top(t)\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2\boldsymbol{g}_h(t).\end{aligned} \tag{23}$$

According to assumptions 1, it can be shown from Lemma 1

$$2\boldsymbol{\xi}^\top(t)\bar{\boldsymbol{M}}^\top\bar{\boldsymbol{B}}_2\boldsymbol{g}_h(t) \le \alpha^{-1}\boldsymbol{\xi}^\top(t)\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2\hat{\boldsymbol{B}}_2^\top\bar{\boldsymbol{M}}^\top\boldsymbol{\xi}(t) + \alpha\delta^2\bar{\boldsymbol{x}}^\top(t)\hat{\boldsymbol{C}}_2^\top\hat{\boldsymbol{C}}_2\bar{\boldsymbol{x}}(t), \tag{24}$$

Moreover, it can be also established

$$-\tau\boldsymbol{\delta}_s^\top(t)\boldsymbol{\delta}_s(t) + \beta^2\tau\bar{\boldsymbol{x}}^\top(t)\hat{\boldsymbol{C}}_2^\top\hat{\boldsymbol{C}}_2\bar{\boldsymbol{x}}(t) \ge 0, \tag{25}$$

where τ is a positive scalar.

By adding (21)-(23) and considering conditions (24)-(25), we get

$$\mathscr{L}\Big\{\dot{V}(t)\Big\} \le \boldsymbol{\xi}^\top(t)\Big(\tilde{\boldsymbol{\Phi}}_{h\mu} + \alpha^{-1}\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2\bar{\boldsymbol{B}}_2^\top\bar{\boldsymbol{M}}^\top\Big)\boldsymbol{\xi}(t), \tag{26}$$

where

$$\tilde{\boldsymbol{\Phi}}_{h\mu} = \begin{bmatrix} \boldsymbol{\Phi}_{11h\mu} & \boldsymbol{\Phi}_{12h\mu} & \bar{\zeta}\bar{\boldsymbol{M}}_1\bar{\boldsymbol{L}}_\mu \\ * & -\mathrm{sym}(\bar{\boldsymbol{M}}_2) & \bar{\zeta}\bar{\boldsymbol{M}}_2\bar{\boldsymbol{L}}_\mu \\ * & * & -\tau\boldsymbol{I} \end{bmatrix}. \tag{27}$$

Performing the Schur complement to (15), it easy to verify that

$$\hat{\boldsymbol{\Phi}}_{h\mu} = \tilde{\boldsymbol{\Phi}}_{h\mu} + \alpha^{-1}\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2\bar{\boldsymbol{B}}_2^\top\bar{\boldsymbol{M}}^\top < 0, \tag{28}$$

Accordingly, we justify from (26) that

$$\mathscr{L}\Big\{\dot{V}(t)\Big\} \le \boldsymbol{\xi}^\top(t)\Big(\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\hat{\boldsymbol{\Phi}}_{ij}\Big)\boldsymbol{\xi}(t) \le -\varsigma\|\boldsymbol{\xi}\|^2, \tag{29}$$

where

$\varsigma = \lambda_{min}(-\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\hat{\boldsymbol{\Phi}}_{ij})$. Hence, it is evident the closed-loop system (13) is stochastically stable. ■

IV. Sliding Mode Dynamics Synthesis

This section outlines the methodology for synthesizing the gains $\boldsymbol{K}_i$ and $\boldsymbol{L}_i$ in Theorem 1. Before moving on, it is important to recall the following lemma.

Lemma 3. *[32] For given membership functions $h_i(\boldsymbol{x})$, $\mu_j(\hat{\boldsymbol{x}})$, and the constraint $\mu_j(\hat{\boldsymbol{x}}) - \varrho_j h_j(\hat{\boldsymbol{x}}) \ge 0,\ j \in \{1,\dots,r\}$ is satisfied for any positive scalar ϱ_i, if there exists a matrix $\boldsymbol{\Lambda}_i = \boldsymbol{\Lambda}_i^\top$ that satisfies $\boldsymbol{\Gamma}(\boldsymbol{\Pi}_{ij}, \boldsymbol{\Lambda}_i, \varrho_i) < \boldsymbol{0}$, where*

$$\boldsymbol{\Gamma}(\boldsymbol{\Pi}_{ij}, \boldsymbol{\Lambda}_i, \varrho_i) = \begin{cases} \boldsymbol{\Pi}_{ij} - \boldsymbol{\Lambda}_i < 0, \\ \varrho_i\boldsymbol{\Pi}_{ij} - \varrho_i\boldsymbol{\Lambda}_i + \boldsymbol{\Lambda}_i < 0, \\ \varrho_j\boldsymbol{\Pi}_{ij} + \varrho_i\boldsymbol{\Pi}_{ji} - \varrho_j\boldsymbol{\Lambda}_i - \varrho_i\boldsymbol{\Lambda}_j \\ \quad +\boldsymbol{\Lambda}_i + \boldsymbol{\Lambda}_j < 0 \quad j > i, \end{cases} \tag{30}$$

then, $\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\boldsymbol{\Pi}_{ij} < 0$ is fulfilled. In what follows, $\boldsymbol{\Gamma}(\boldsymbol{\Pi}_{ij}, \boldsymbol{\Lambda}_i, \varrho_i) < 0$, means that the conditions in (30) *are satisfied.*

Theorem 2. *For given positive scalars β, δ, and $\bar{\zeta}$, closed-loop system (13) is admissible, if for a set of positive scalars τ, α, $\lambda_q, q = 1,2,3,4$, ϱ_i, $i = 1,2,\cdots r$, and matrices $\bar{\boldsymbol{P}} > \boldsymbol{0}$, $\bar{\boldsymbol{S}}$, $\bar{\boldsymbol{M}}_{11} \in \mathbb{R}^{n\times n}$, $\bar{\boldsymbol{M}}_{22} \in \mathbb{R}^{n\times n}$, $\bar{\boldsymbol{X}} \in \mathbb{R}^{m\times m}$, $\boldsymbol{Y}_j \in \mathbb{R}^{m\times n}$, $\boldsymbol{F}_j \in \mathbb{R}^{n\times n_y}$, the subsequent conditions are fulfilled according to the constraint $\mu_j(\hat{\boldsymbol{x}}) - \varrho_j h_j(\hat{\boldsymbol{x}}) \ge 0$.*

$$\boldsymbol{\Gamma}(\hat{\boldsymbol{\Pi}}_{ij}, \boldsymbol{\Lambda}_i, \varrho_i) < \boldsymbol{0}, \tag{31}$$

where

$$\hat{\boldsymbol{\Pi}}_{ij} = \begin{bmatrix} \hat{\boldsymbol{\Pi}}_{ij}^1 & \hat{\boldsymbol{\Pi}}_{ij}^2 & \hat{\boldsymbol{\Pi}}_{ij}^3 \\ * & -\lambda_3\,\mathrm{sym}(\bar{\boldsymbol{X}}) & \boldsymbol{0} \\ * & * & -\lambda_4\,\mathrm{sym}(\bar{\boldsymbol{M}}_{22}) \end{bmatrix},\ \hat{\boldsymbol{\Pi}}_{ij}^1 = \begin{bmatrix} \hat{\boldsymbol{\Pi}}_{ij}^{11} & \hat{\boldsymbol{\Pi}}_{ij}^{12} & \lambda_1\bar{\zeta}\mathbb{F}_j & \lambda_1\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2 \\ * & \hat{\boldsymbol{\Pi}}_{ij}^{22} & \lambda_2\bar{\zeta}\mathbb{F}_j & \lambda_2\bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2 \\ * & * & -\tau\boldsymbol{I} & \boldsymbol{0} \\ * & * & * & -\alpha\boldsymbol{I} \end{bmatrix},$$

$$\hat{\boldsymbol{\Pi}}_{ij}^2 = \begin{bmatrix} \lambda_1\boldsymbol{\Gamma}_1^{2\top} + \lambda_3\boldsymbol{\Gamma}_2^2 & \lambda_2\boldsymbol{\Gamma}_1^{2\top} & \boldsymbol{0} & \boldsymbol{0} \end{bmatrix}^\top,$$

$$\hat{\boldsymbol{\Pi}}_{ij}^3 = \begin{bmatrix} \lambda_1\boldsymbol{\Gamma}_1^{3\top} + \lambda_4\boldsymbol{\Gamma}_2^3 & \lambda_2\boldsymbol{\Gamma}_1^{3\top} & -\lambda_4\boldsymbol{F}^\top & \boldsymbol{0} \end{bmatrix}^\top,$$

$$\boldsymbol{\Gamma}_1^2 = \bar{\boldsymbol{M}}\bar{\boldsymbol{B}}_2 - \bar{\boldsymbol{B}}_2\bar{\boldsymbol{X}},\ \boldsymbol{\Gamma}_2^2 = \begin{bmatrix} \boldsymbol{Y}_j & \boldsymbol{0} \end{bmatrix}\ \boldsymbol{\Gamma}_1^3 = \begin{bmatrix} \bar{\boldsymbol{M}}_{11}\tilde{\boldsymbol{S}} - \bar{\boldsymbol{M}}_{22} \\ \boldsymbol{0} \end{bmatrix},$$

$$\boldsymbol{\Gamma}_2^3 = \begin{bmatrix} \bar{\zeta}\boldsymbol{F}_j\boldsymbol{C}_2 & -(1-\bar{\zeta})\boldsymbol{F}_j\boldsymbol{C}_2 \end{bmatrix},\ \hat{\boldsymbol{\Pi}}_{ij}^{11} = \lambda_1\,\mathrm{sym}(\mathbb{A}_{ij}) + (\tau\beta^2 + \alpha\delta^2)\hat{\boldsymbol{C}}_2^\top\hat{\boldsymbol{C}}_2,\ \hat{\boldsymbol{\Pi}}_{ij}^{12} = (\bar{\boldsymbol{P}}\bar{\boldsymbol{E}} + \bar{\boldsymbol{N}}\bar{\boldsymbol{R}})^\top - \lambda_1\bar{\boldsymbol{M}} + \lambda_2\mathbb{A}_{ij},\ \hat{\boldsymbol{\Pi}}_{ij}^{22} = -\lambda_2\,\mathrm{sym}(\bar{\boldsymbol{M}}),$$

$$\mathbb{A}_{ij} = \begin{bmatrix} \bar{\boldsymbol{M}}_{11}\boldsymbol{A}_j + \boldsymbol{B}_2\boldsymbol{Y}_j + \bar{\zeta}\tilde{\boldsymbol{S}}\boldsymbol{F}_j\boldsymbol{C}_2 & \bar{\boldsymbol{M}}_{11}\boldsymbol{A}_j + (1-\bar{\zeta})\tilde{\boldsymbol{S}}\boldsymbol{F}_j\boldsymbol{C}_2 \\ \bar{\boldsymbol{M}}_{22}(\boldsymbol{A}_i - \boldsymbol{A}_j) + \bar{\zeta}\boldsymbol{F}_j\boldsymbol{C}_2 & \bar{\boldsymbol{M}}_{22}\boldsymbol{A}_i - (1-\bar{\zeta})\boldsymbol{F}_j\boldsymbol{C}_2 \end{bmatrix},$$

$$\bar{\boldsymbol{M}} = \begin{bmatrix} \bar{\boldsymbol{M}}_{11} & \bar{\boldsymbol{M}}_{11} \\ \boldsymbol{0} & \bar{\boldsymbol{M}}_{22} \end{bmatrix}\ \mathbb{F}_j = \begin{bmatrix} -\boldsymbol{F}_j \\ -\boldsymbol{F}_j \end{bmatrix},\ \bar{\boldsymbol{B}}_2 = \begin{bmatrix} \boldsymbol{B}_2 \\ \boldsymbol{0} \end{bmatrix}.$$

Moreover, the parameters $\boldsymbol{K}_j$ and $\boldsymbol{L}_j$ are given by $\boldsymbol{K}_j = \bar{\boldsymbol{X}}^{-1}\boldsymbol{Y}_j$ and $\boldsymbol{L}_j = (\bar{\boldsymbol{M}}_{22})^{-1}\boldsymbol{F}_j$, respectively.

Proof: If the conditions in Theorem 2 are true, the constraints $-\lambda_4\,\mathrm{sym}(\bar{\boldsymbol{M}}_{22}) < 0$ and $-\lambda_3\,\mathrm{sym}(\bar{\boldsymbol{X}}) < 0$ are also true, and matrices $\bar{\boldsymbol{M}}_{22}$, and $\bar{\boldsymbol{X}}$ are non-singular.

According to Lemma 3, we obtain

$$\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\hat{\boldsymbol{\Pi}}_{ij} < 0. \tag{32}$$

Note that $\bar{\boldsymbol{M}}\bar{\boldsymbol{A}}_{ij} = \mathbb{A}_{ij} + \boldsymbol{\Gamma}_1^2\bar{\boldsymbol{X}}^{-1}\boldsymbol{\Gamma}_2^2 + \boldsymbol{\Gamma}_1^3\bar{\boldsymbol{M}}_{22}^{-1}\boldsymbol{\Gamma}_2^3$, and $\bar{\boldsymbol{M}}\bar{\boldsymbol{L}}_j = \mathbb{F}_j - \boldsymbol{\Gamma}_1^3\bar{\boldsymbol{M}}_{22}^{-1}\boldsymbol{F}_j$.

Then, based on Lemma 2, it can be demonstrated that $\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{x})\mu_j(\hat{\boldsymbol{x}})\hat{\boldsymbol{\Pi}}_{ij}^1 < \boldsymbol{0}$. Referring to the Schur complement, the condition in Eq. (15) is satisfied. This implies that system (13) is stochastically admissible. ■

A. Adaptive Sliding Mode Controller Design

This section is devoted to synthesize an adaptive sliding mode controller to achieve the reachability of the sliding surface described by Eq. (9). Simultaneously, the system's trajectory described by Eq. (7) may be directed onto the sliding surface and stay on it thereafter. To begin, we will use the RBF neural network, which has the benefit of a simple structure and fast convergence, to estimate the term $\boldsymbol{\delta}_g(t) = \boldsymbol{\delta}_a(t) + \boldsymbol{g}_h(t)$. According to the reference [36], [37], there exists a radial basis function neural network (RBFNN) able to approximate the unknown function $\boldsymbol{\delta}_g(t)$ over a compact set Ω that can be expressed as follows:

$$\boldsymbol{\delta}_g(t) = \boldsymbol{W}^{*\top}\boldsymbol{\psi}(\hat{\boldsymbol{x}}(t)) + \varepsilon(t),$$

where $\boldsymbol{W}^*$ represents the optimal weight satisfying $\boldsymbol{W}^* = \arg\min_{\boldsymbol{W}}(\sup_\Omega \|\boldsymbol{\delta}_g(t) - \hat{\boldsymbol{\delta}}_g(t)\|)$, and $\varepsilon(t)$ stands for the approximation error so that for $\epsilon > 0$, $\|\varepsilon(t)\| \le \epsilon$. The estimated function $\hat{\boldsymbol{\delta}}_g(t)$ is defined as $\hat{\boldsymbol{\delta}}_g(t) = \hat{\boldsymbol{W}}^\top\boldsymbol{\psi}(\hat{\boldsymbol{x}}(t))$, where

$\hat{\boldsymbol{W}} = [\hat{\boldsymbol{W}}_1,\ \hat{\boldsymbol{W}}_2, \cdots, \hat{\boldsymbol{W}}_m]$ defines for the matrix of the neural-network weights so that $\hat{\boldsymbol{W}}_k^\top = [\hat{\boldsymbol{w}}_k^1,\ \hat{\boldsymbol{w}}_k^2, \cdots, \hat{\boldsymbol{w}}_k^N]$, $k = 1, 2, \cdots, m$, and N represents the number of hidden nodes. $\boldsymbol{\psi}(\hat{\boldsymbol{x}}) = [\psi_1(\hat{\boldsymbol{x}}),\ \psi_2(\hat{\boldsymbol{x}}),\ , \cdots \psi_N(\hat{\boldsymbol{x}})]^\top$ specifies the regression functions vector, where the Gaussian RBF $\psi_k(\hat{\boldsymbol{x}})$ is expressed as $\psi_k(\hat{\boldsymbol{x}}) = \exp\Big(-\dfrac{\|\hat{\boldsymbol{x}} - c_k\|^2}{{d_k}^2}\Big)$, where c_k is the centre and $d_k > 0$ is the width of the Gaussian. On the other hand , due to the sensor attack, a precise calculation of the term $\bar{\boldsymbol{S}}\boldsymbol{L}_\mu(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t))$ becomes difficult. That is why it may be inferred that there exist some scalars so that $\|\bar{\boldsymbol{S}}\boldsymbol{L}_\mu\|\|(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t))\| \leq \rho_1\|\boldsymbol{y}(t)\| + \rho_2\|\hat{\boldsymbol{y}}(t)\|$, where the unknown scalars $\rho_l, l = 1, 2$ should be estimated.

Theorem 3. *Suppose that sliding function Eq.* (9) *is appropriately designed and the gains $\boldsymbol{K}_i$ and $\boldsymbol{L}_i$ are solved in Theorem 2. Under the control in Eq.* (33)*, the trajectories of Eq.* (7) *can be driven to sliding surface $\boldsymbol{s}(t) = 0$ and maintain the sliding motion thereafter.*

$$\begin{aligned}\boldsymbol{u}(t) = \sum_{j=1}^{r} \mu_j(\boldsymbol{\varphi}(\hat{\boldsymbol{x}}))\Big(\boldsymbol{K}_j\hat{\boldsymbol{x}}(t) - (\bar{\boldsymbol{S}}\boldsymbol{B}_2)^{-1}\Big(\hat{\boldsymbol{W}}^\top\boldsymbol{\psi}(\hat{\boldsymbol{x}}(t)) \\ + (\hat{\rho}_1(t)\|\boldsymbol{y}(t)\| + \hat{\rho}_2(t)\|\hat{\boldsymbol{y}}(t)\| + \hat{\epsilon}(t) + \kappa)\frac{\boldsymbol{s}(t)}{\|\boldsymbol{s}(t)\|}\Big)\Big),\end{aligned} \tag{33}$$

where $\kappa > 0$ is a small constant, and for positive constants $q_l,\ l = 0, 1, \cdots, 3$, the adaptive parameters are characterized by

$$\dot{\hat{W}}_k = q_0 s_k \boldsymbol{\psi}(\hat{\boldsymbol{x}}(t)),\ \dot{\hat{\rho}}_1(t) = q_1\|\boldsymbol{y}(t)\|\|\boldsymbol{s}(t)\|, \tag{34}$$

$$\dot{\hat{\rho}}_2(t) = q_2\|\hat{\boldsymbol{y}}(t)\|\|\boldsymbol{s}(t)\|,\ \dot{\hat{\epsilon}}(t) = q_3\|\boldsymbol{s}(t)\|. \tag{35}$$

Proof: Construct a Lyapunov function defined as follows:

$$\begin{aligned}V_s(t) = \frac{1}{2}\boldsymbol{s}^\top(t)\boldsymbol{s}(t) + \frac{1}{2q_0}\sum_{k=1}^{m}\tilde{\boldsymbol{W}}_k^\top\tilde{\boldsymbol{W}}_k + \frac{1}{2q_1}\tilde{\rho}_1^2(t) \\ + \frac{1}{2q_2}\tilde{\rho}_2^2(t) + \frac{1}{2q_3}\tilde{\epsilon}^2(t),\end{aligned} \tag{36}$$

where $\tilde{\boldsymbol{W}}_k = \hat{\boldsymbol{W}}_k - \boldsymbol{W}_k^*$, $\tilde{\rho}_1(t) = \rho_1 - \hat{\rho}_1(t)$, $\tilde{\rho}_2(t) = \rho_2 - \hat{\rho}_2(t)$, and $\tilde{\epsilon}(t) = \epsilon - \hat{\epsilon}(t)$.

The derivative computation of $\boldsymbol{s}(t)$ and $V_s(t)$ leads, respectively, to

$$\begin{aligned}\dot{V}_s(t) =& \boldsymbol{s}^\top(t)\dot{\boldsymbol{s}}(t) + \frac{1}{q_0}\sum_{k=1}^{m}\tilde{\boldsymbol{W}}_k^\top\dot{\tilde{\boldsymbol{W}}}_k + \frac{1}{q_1}\tilde{\rho}_1(t)\dot{\hat{\rho}}_1(t) \\ &+ \frac{1}{q_2}\tilde{\rho}_2(t)\dot{\hat{\rho}}_2(t) + \frac{1}{q_3}\tilde{\epsilon}(t)\dot{\hat{\epsilon}}(t), \\ =& \boldsymbol{s}^\top(t)\Big(\bar{\boldsymbol{S}}\boldsymbol{B}_2(\boldsymbol{u}(t) + \boldsymbol{\delta}_g(t) - \boldsymbol{K}_j\hat{\boldsymbol{x}}(t)) \\ &+ \bar{\boldsymbol{S}}\boldsymbol{L}_\mu(\tilde{\boldsymbol{y}}(t) - \hat{\boldsymbol{y}}(t))\Big) + \frac{1}{q_0}\sum_{k=1}^{m}\tilde{\boldsymbol{W}}_k^\top\dot{\tilde{\boldsymbol{W}}}_k \\ &+ \frac{1}{q_1}\tilde{\rho}_1(t)\dot{\hat{\rho}}_1(t) + \frac{1}{q_2}\tilde{\rho}_2(t)\dot{\hat{\rho}}_2(t) + \frac{1}{q_3}\tilde{\epsilon}(t)\dot{\hat{\epsilon}}(t), \\ \leq& \boldsymbol{s}^\top(t)\Big(\tilde{\boldsymbol{W}}^\top\boldsymbol{\psi}(\hat{\boldsymbol{x}}(t)) + \tilde{\epsilon}(t) + (\tilde{\rho}_1(t)\|\boldsymbol{y}(t)\| + \\ &\tilde{\rho}_2(t)\|\hat{\boldsymbol{y}}(t)\| + \kappa)\frac{\boldsymbol{s}(t)}{\|\boldsymbol{s}(t)\|}\Big) + \frac{1}{q_0}\sum_{k=1}^{m}\tilde{\boldsymbol{W}}_k^\top\dot{\tilde{\boldsymbol{W}}}_k \\ &+ \frac{1}{q_1}\tilde{\rho}_1(t)\dot{\hat{\rho}}_1(t) + \frac{1}{q_2}\tilde{\rho}_2(t)\dot{\hat{\rho}}_2(t) + \frac{1}{q_3}\tilde{\epsilon}(t)\dot{\hat{\epsilon}}(t).\end{aligned} \tag{37}$$

Considering the update laws (34) and using the fact that $\dot{\tilde{\boldsymbol{W}}}_k = -\dot{\hat{\boldsymbol{W}}}_k$, $\dot{\tilde{\rho}}_1(t) = -\dot{\hat{\rho}}_1(t)$, $\dot{\tilde{\rho}}_2(t) = -\dot{\hat{\rho}}_2(t)$, and $\dot{\tilde{\epsilon}}(t) = -\dot{\hat{\epsilon}}(t)$ it can be computed

$$\begin{aligned}&\frac{1}{q_0}\sum_{k=1}^{m}\tilde{\boldsymbol{W}}_k^\top\dot{\tilde{\boldsymbol{W}}}_k + \frac{1}{q_1}\tilde{\rho}_1(t)\dot{\tilde{\rho}}_1(t) + \frac{1}{q_2}\tilde{\rho}_1(t)\dot{\tilde{\rho}}_2(t) + \frac{1}{q_3}\tilde{\epsilon}(t)\dot{\tilde{\epsilon}}(t) \\ &= -\boldsymbol{s}^\top(t)\tilde{\boldsymbol{W}}^\top\boldsymbol{\psi}(\hat{\boldsymbol{x}}(t)) \\ &- (\tilde{\rho}_1(t)\|\boldsymbol{y}(t)\| + \tilde{\rho}_2(t)\|\hat{\boldsymbol{y}}(t)\| + \tilde{\epsilon}(t))\|\boldsymbol{s}(t)\|.\end{aligned} \tag{38}$$

Substituting (38) into (37) one gets

$$\dot{V}_s(t) \leq -\kappa\|\boldsymbol{s}(t)\|. \tag{39}$$

which confirms that the adaptive control law Eq. (33) is capable of driving the system dynamics onto the sliding surface Eq. (9) despite the presence of attacks.

■

V. SMC Design and Optimization

A. Problem Statement

It is obvious from theorems 1-2 that the significant challenge in developing the SMC law Eq. (33) lies in determining the appropriate sliding matrix $\bar{\boldsymbol{S}}$ that meets the constraint condition $\det(\bar{\boldsymbol{S}}\boldsymbol{B}_2) \neq 0$, along with the controller and observer gain matrices $\boldsymbol{K}_j$ and $\boldsymbol{L}_j$ satisfy the conditions in Eq. (31). Moreover, it is clear that the tuning parameters λ_q in Eq. (31) are not easily obtainable, making it a difficult task. Furthermore, inappropriate gains $\boldsymbol{K}_j$ and $\boldsymbol{L}_j$ might amplify the impact of attacks on degrading the system's performance.

B. Optimization Problem

As previously mentioned, the sliding matrix $\bar{\boldsymbol{S}}$ plays a crucial role in the SMC design, influencing the dynamic performance of the controlled system. In addition, reducing the values of $\boldsymbol{K}_i$ and $\boldsymbol{L}_i$ leads to decreased amplification of the attack's signals, potentially reducing the impact of any attacks. Thus, it is logical to search an appropriate sliding matrix $\bar{\boldsymbol{S}}$ able to provide the optimized gain $\boldsymbol{K}_i$ and $\boldsymbol{L}_i$. To figure out how to achieve this goal, we formulate the following optimization problem:

$$\begin{aligned}&\min\Omega = \sum_{i=1}^{r}\Big(\gamma\|\boldsymbol{K}_i\| + (1-\gamma)\|\boldsymbol{L}_i\|\Big), \\ &\text{subject to} \qquad (31)\end{aligned} \tag{40}$$

where the weighting parameter $\gamma \in [0,\ 1]$.

To deal with the problem as expressed in Eq. (40) many evolutionary techniques, such as the genetic algorithm [25], the PSO algorithm [26], and the dandelion [28], [29] can be used. These techniques have proven to be highly effective in addressing nonlinear and non-convex optimization problems with constraints. Hence, we explore the combination of the optimization algorithm SBOA [39] and LMI techniques to tackle the sliding mode control design by solving the previously mentioned problem.

Remark 2. The secretary bird optimization algorithm (SBOA) has been recently introduced in [39] as a new meta-heuristic algorithm. This algorithm is specifically established by observing the hunting and evading abilities of secretary birds while dealing with predators. The two primary phases of this algorithm that simulate the behavior of secretary birds in collecting snakes and escaping predators are, respectively, the exploration and the exploitation. The reliability of the algorithm is tested in [39] through several engineering optimization design problems.

To carry out the SBOA algorithm, we express in the search space the secretary birds positions as a row vector ϖ defined as $[\bar{\boldsymbol{S}}, \lambda_1, \dots \lambda_4] \longrightarrow \varpi = [s_{11}, \dots, s_{1n}, s_{21} \dots, s_{mn}, \lambda_1, \dots \lambda_4]$.

Assume that, each element s_{mn} has a range of $s_{mn} \in [\underline{s}_{mn},\ \bar{s}_{mn}]$, and $\lambda_l \in [\underline{\lambda}_l,\ \bar{\lambda}_l]$, where $\underline{\lambda}_l > 0,\ \bar{\lambda}_l > 0$.

Algorithm 1, and the flowchart depicted in Fig. 2, describe the different steps of the optimal SMC design using the SBOA as detailed in [39]. Algorithm 1 will be performed 30 times to achieve the optimal gains $\boldsymbol{K}_i$, $\boldsymbol{L}_i$, sliding matrix $\bar{\boldsymbol{S}}$, and parameters λ_q.

Algorithm 1 SBOA Algorithm for SMC Law Design

- **Input**: The population size, denoted as N, the dimension of the variables, denoted as n_d, and the maximum number of iterations, denoted as $Niter$.
- **Output**: The optimal individual, denoted as ϖ_{best}, and the corresponding fitness value, denoted as Ω_{best}.

1) **Step 1**: **Encoding phase**.
Each element of the row vector $\varpi = [s_{11}, \dots, s_{1n}, s_{21} \dots, s_{mn}, \lambda_1, \dots \lambda_4]$ can be encoded as a bird.
2) **Step 2**: **Population initialization**.
Generate an initial population of N individuals $\varpi_v,\ (v = 1, 2, \dots, N)$ at random.
3) **Step 3**: **Fitness function and assignment**: Calculation of the fitness for the individual by solving the LMIs (31).
4) **Step 4 Reproduction Phase:** According to the obtained fitness values in previous step, the **exploration** and **exploitation** operations should be performed as crucial steps of the SBOA.
5) **Step 5**: **Design Phase**: Produce the SMC law (33) by using the sliding matrix $\bar{\boldsymbol{S}}$ and the gain matrices $\boldsymbol{K}_i$, and $\boldsymbol{L}_i$ obtained in step 4.

VI. Simulation Studies

This section employs a nonlinear system for disc rolling on a surface without sliding, as a means to showcase the feasibility and benefits of the proposed method. As mentioned in [38], the system under study may be described by the following mathematical model:

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = -(\dfrac{K_1}{m}x_1 + \dfrac{K_2}{m}x_1^3) - \dfrac{b}{m}x_2 + \dfrac{1}{m}x_4, \\ 0 = x_2 - rx_3, \\ 0 = -(\dfrac{K_1}{m}x_1 + \dfrac{K_2}{m}x_1^3) - \dfrac{b}{m}x_2 + (\dfrac{r^2}{J} + \dfrac{1}{m})x_4 - \dfrac{r}{J}u. \end{cases} \tag{41}$$

Moreover, the assumption $x_1(t) \in [-1,\ 1]$ allows us to explore the sector non-linearity approach for converting the non-linear system into the equivalent TS fuzzy descriptor model Eq. (2) with membership functions defined as $h_1(x_1(t)) = 1 - x_1^2(t)$, and $h_2(x_1(t)) = x_1^2(t)$. The relevant model data are given as $\boldsymbol{E} = \text{diag}\{1, 1, 0, 0\}$, $\boldsymbol{A}_i = \begin{bmatrix} 0 & 1 & 0 & 0 \\ a\{i\} & -0.75 & 0 & 0.025 \\ 0 & 1 & -0.4 & 0 \\ b\{i\} & -0.75 & 0 & 0.075 \end{bmatrix}, \boldsymbol{B}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ -0.125 \end{bmatrix}$, $\boldsymbol{C}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$ $a \in \{-2.5, -5\}$, $b \in \{-2.5, -5\}$, $i = 1, 2$.

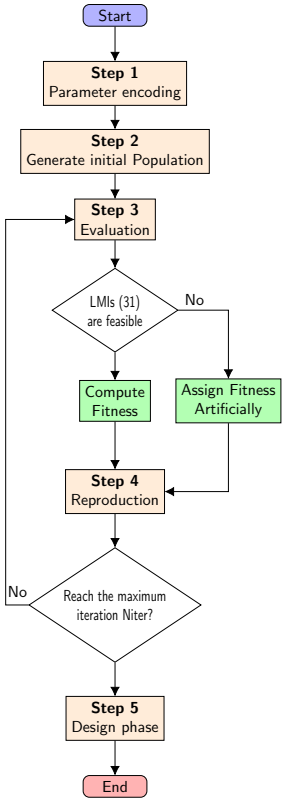

Fig. 2. Flowchart of the proposed SMC with SBOA and LMIs.

A. Simulation Studies and Discussions

Once the fuzzy model of the system has been introduced, we assess the resilience and robustness of the system by considering different scenarios. We begin with scenario I, which involves designing and implementing a controller that is not optimized, to thoroughly evaluate its resilience against different threats.

Case I Here we explore the strategy developed in Theorem 2, tailored to shield the system from sensor and actuator deception attacks. We leverage Yalmip, a MATLAB toolbox specifically developed for optimization modeling, and Mosek, an efficient and accurate solver well recognized for its ability to solve complex optimization problems on a large scale. By carefully selecting key design parameters, $\bar{\boldsymbol{S}} = [2 \quad 2 \quad -1 \quad -8]$, so that $\bar{\boldsymbol{S}}\boldsymbol{B}_2 = \boldsymbol{I}$, $\beta = 0.35$, $\delta = 0.2$, $\lambda_{1,2} = 1$, and $\lambda_{3,4} = 0.35$, we effectively derive the controller and observer gain matrices $\boldsymbol{K}_1 = \begin{bmatrix} 0.0269 & -0.0098 & 0.0053 & 0.2910 \end{bmatrix}$, $\boldsymbol{K}_2 = \begin{bmatrix} 0.0404 & -0.0091 & 0.0070 & 0.2973 \end{bmatrix}$, $\boldsymbol{L}_1 = \begin{bmatrix} 1.5592 & -0.5933 \\ -1.7422 & 8.4758 \\ 1.0001 & 0.9889 \\ -1.2624 & 6.9014 \end{bmatrix}, \boldsymbol{L}_2 = \begin{bmatrix} 1.8422 & -0.6246 \\ -2.1511 & 8.7691 \\ 1.3088 & 0.9851 \\ -1.7590 & 7.1692 \end{bmatrix}$.

To simulate realistic cyber-physical threats, we establish precise models for both sensor and actuator attacks. The sensor attack model, $\boldsymbol{\delta}_s(t)$, represents possible disturbances in sensor measurements and is defined as

$$\boldsymbol{\delta}_s(t) = \begin{cases} b, & t < 2, b \in [-0.5,\ 0.5], \\ 0.1\boldsymbol{y}(t) + 0.2\boldsymbol{y}(t)\sin(100t), & 2 \le t < 10, \\ bt\tanh(0.5\boldsymbol{y}(t)), & 10 \le t \le 25. \end{cases}$$

Moreover, we assign the probability of encountering sensor as $\bar{\zeta} = 0.3$, and we assume that the actuator attack model is expressed as $\boldsymbol{\delta}_a(t) = 0.3\tanh(-3x_2(t))$. Setting the initial conditions of the system and the observer as $\boldsymbol{x}(0) = \begin{bmatrix}0.25 & 0.6 & 0.4 & 1\end{bmatrix}^T$, and $\hat{\boldsymbol{x}}(0) = \begin{bmatrix}0 & 0 & 0 & 0\end{bmatrix}^T$, we perform 50 random independent simulations a simulation to robustly test the system's resilience against attacks in which the membership functions of the fuzzy controller are defined as $\mu_1(\hat{x}_1(t)) = \left(1 - \frac{1}{1+e^{-20(\hat{x}_1(t)-\frac{\pi}{8})}}\right)\left(\frac{1}{1+e^{-20(\hat{x}_1(t)+\frac{\pi}{8})}}\right)$, $\mu_2(\hat{x}_1(t)) = 1 - \mu_1(\hat{x}_1(t))$.

We assume that the matched external disturbance has the following form: $\boldsymbol{g}(t) = 0.1\sin(x_2(t))\cos(x_1(t))$.

Fig. 3(a)-(b) display the results of these simulations, notably highlighting the effectiveness of the closed-loop system with the implemented control strategy, as described in Eq. (9)-(33). The adaptive laws defined in Eq. (34) are used under zero initial conditions and the parameters are specified as $q_l = 0.35,\ l = 0, \cdots, 3$. Furthermore, to reduce the occurrence of chattering in the control signal, we substitute the function $\boldsymbol{s}(t)/\|\boldsymbol{s}(t)\|$ with $\boldsymbol{s}(t)/(\|\boldsymbol{s}(t) + 0.01\|)$. The results of these simulations demonstrate that although the system is resilient to attacks, the observer struggles to properly estimate the states x_3, and x_4. Now we will concentrate on Case II and employ the optimization problem in Eq. (40) to solve this issue.

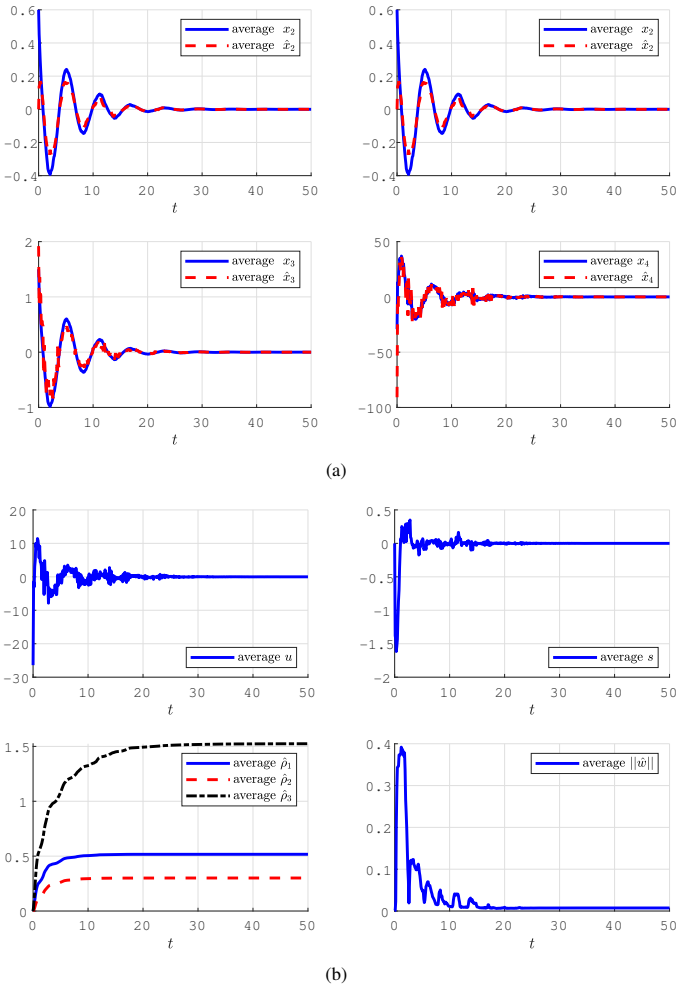

Fig. 3. Performance and closed-loop behavior with the implemented non-optimized control strategy.

Case II In this case, we explore the optimization problem Eq. (40) to improve the system's performance by reducing the observer and controller gains. By exploiting Algorithm 1, the outcomes of are found as $\bar{\boldsymbol{S}} = [2\ 1.5254\ -1\ -9.8984]$, $\lambda_1 = 0.73993$, $\lambda_2 = 1.7955$, $\lambda_3 = 1.6335$, $\lambda_4 = 1.9346$,
$\boldsymbol{K}_1 = \begin{bmatrix}0.001267 & -0.000329 & 0.000258 & 0.058563\end{bmatrix}$,
$\boldsymbol{K}_2 = \begin{bmatrix}-0.000381 & -0.000202 & -0.000347 & 0.058733\end{bmatrix}$, $\boldsymbol{L}_1 = \begin{bmatrix}0.85563 & 0.27457\\ -0.36813 & 2.1366\\ 0.6122 & 0.31301\\ -0.36818 & 1.6922\end{bmatrix}$, $\boldsymbol{L}_2 = \begin{bmatrix}0.86772 & 0.25946\\ -0.50868 & 2.239\\ 0.62446 & 0.2974\\ -0.47119 & 1.7995\end{bmatrix}$

The evolution of the best and average fitness values are shown in Fig. 4.

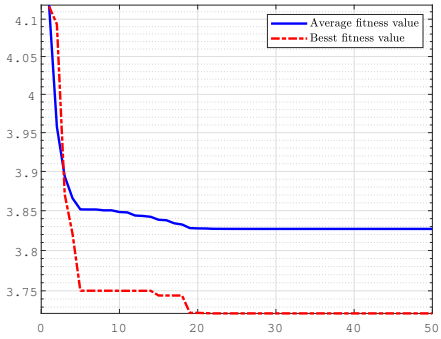

Fig. 4. Evolution of the fitness function in solving the optimization problem using SBOA.

Fig. 5(a)-(b) display the average results of simulations, focusing on the system and observer states with the applied control strategy under similar initial conditions and system parameters while employing the aforementioned gains. Besides, The sliding function in Eq. (9) and the estimation of unknown variables are also provided in sub-figure (b). These figures prove that, despite the presence of deception attacks targeting both sensors and actuators, the closed-loop states remain stable over time and the observer accurately estimate the unmeasured states. The findings from Case II show that, despite the complexity and high computational cost of Algorithm 1, it has the potential to design an optimized control law able to enhance the accuracy of the observer in cyber-physical systems.

Case III Here, we compare our suggested control technique with the control scheme presented in [34], [35] to emphasis the superiority of our method. Employing the following gains $\boldsymbol{K}_1 = \begin{bmatrix}-19.4666 & -5.3215 & 0.0416 & 3.8020\end{bmatrix}$, $\boldsymbol{K}_2 = \begin{bmatrix}-24.4577 & -5.2564 & 0.0419 & 3.8023\end{bmatrix}$, $\boldsymbol{L}_1 = \begin{bmatrix}7.2599 & 2.4086\\ -1.3326 & 5.2242\\ -0.1383 & 0.6004\\ -2.8994 & -1.0296\end{bmatrix}$, $\boldsymbol{L}_2 = \begin{bmatrix}7.2697 & 2.3827\\ -1.4514 & 5.4131\\ 0.0888 & 0.7158\\ -3.0922 & -0.8722\end{bmatrix}$.

Fig. 6(a)-(b) demonstrate that implementing the SMC law [34], [35] under similar initial conditions and model parameters reduces significantly the system's effectiveness.

Fig. 7 depicts the estimation error for the previous cases by performing 50 random independent trials. Taken together, Cases I, II, and III, demonstrate that the proposed secure SMC control law can significantly improve the robustness and effectiveness of systems dealing with attacks. Moreover, we evaluate for each case the input energy as displayed in Table I. The table confirms that the optimized scenario uses the least amount of energy with the best control capabilities.

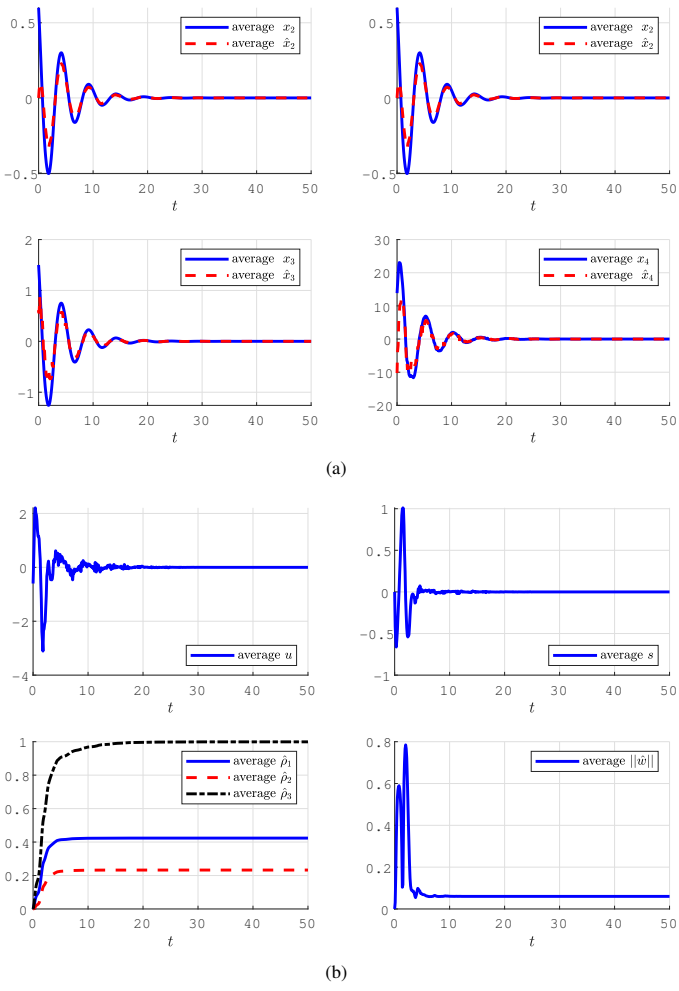

Fig. 5. Performance and behavior of the closed-loop system with the performed optimized control strategy.

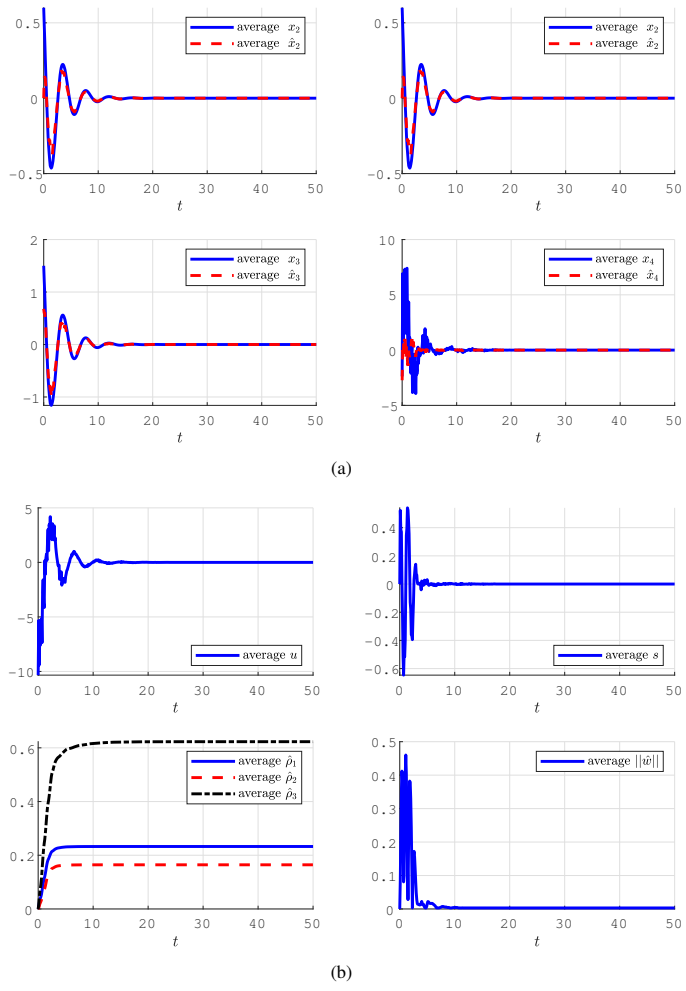

Fig. 6. Comparison of the closed-loop trajectories using the control scheme from [34], [35], highlighting differences in system performances.

TABLE I. INPUT ENERGY FOR EACH CASE

VII. CONCLUSIONS AND FUTURE WORK

This work investigated an advanced control scheme that integrates the SMC methodology in conjunction with a meta-heuristic method in order to address the challenge of security control for nonlinear systems that are susceptible to deception attacks on their sensors and actuators. This scheme is based on developing an observer-based sliding mode control law for nonlinear descriptor systems described by TS fuzzy models. The admissibility and reachability features are established by satisfactory sufficient conditions, and the SBOA is investigated to tackle an optimization problem with non-convex and nonlinear constraints in order to enhance the system's performance under threats. An extensive analysis of a practical example divided into multiple cases revealed that the proposed method significantly improved system resilience and efficiency in the face of diverse cyber-attacks. This analysis especially highlighted the method's superiority over previous strategies proposed in [34], [35].

Several promising research directions arise from this work. A key priority for future investigation is the effect of network-induced delays and actuator/sensor saturation constraints on the performance of cyber-secure control systems, as these real-world limitations can be exploited by advanced attackers. Further exploration is also needed to extend the proposed framework to distributed control architectures for multi-agent systems, incorporate machine learning-based adaptive security mechanisms with event-triggered protocols.

MICRAST: Micro-Forecasting Approach for Cloud User Consumption Pattern Based on RNN

Shallaw Mohammed Ali, Gabor Kecskemeti
Institute of Information Technology, University of Miskolc, Miskolc, Hungary

***Abstract*—One vital key for effective management of cloud resources is the ability to predict their users' consumption's patterns in granular level. It can provide more insightful analysis to guide these users towards more resource-effective habits. Such prediction requires pre-processing the users' traces from these cloud resources for granular prediction (micro-prediction). However, the methodology followed by many forecasting based cloud studies was designed to deal with these traces as overall trends (macro-prediction). We propose a (MICRAST) that generates segments of granular patterns. Then, it carries out parallel tasks of pre-processing and training that lead to separate trained network for each of these segments. To select a model for our approach, we compared methods from two forecasting categories: statistical and artificial neural network (ANN)-based. The results lead us to recurrent neural networks (RNN). We evaluated the MICRAST through a comparison with related work methodologies (macro-prediction approach) for both uni-variate and multi-variate forecasting. Then, we measured its confidence for forecasting up to 20% of the training time steps. The results showed that our approach can forecast the preferences of each cloud user with a confidence level of between (95% to 98%) surpassing related works by more than 70%.**

***Keywords*—Micro-forecasting; cloud workload; data processing; macro-forecasting; data mining**

I. Introduction

The ability to forecast users' consumption preferences for any service provider can profoundly influence its resource management. Such ability has a high impact on shaping decision-making processes. Anticipating these preferences enables proactive decisions that align with users' requests. Effective forecasting ensures the identification of potential challenges and opportunities associated with resource utilisation. Furthermore, implementing forecasting into management frameworks can foster collaboration among diverse stakeholders. It's highlighted by [1] that accurate forecasting enables practitioners to respond efficiently to changing resource-related conditions. Similarly, researchers in [2] emphasised the role of users' behaviour and preference forecasting in enhancing the resilience of resource management solutions. They underscore its significance in achieving long-term sustainability goals.

Many studies, such as [3], [4], and [5], presented different types of forecasting models for similar purposes. For instance, in [3], researchers proposed a multivariate deep learning model to forecast workloads in data centers. Also, for better resource management, Lu et al. [4] presented a novel back-propagation neural network algorithm to predict future cloud logs. However, the limitation of the approaches for the current cloud forecasting models is that they were designed to predict based on the overall trace. In another words, they lack in capturing and predicting cloud traces in detailed, granular levels. Unfortunately, analysing users' traces as a whole is not beneficial for predicting individual usage preferences. In their raw form, these traces do not readily reveal the meaningful trends in historical records necessary for predicting individual preferences. Consequently, employing these models is not suitable for consumption-steering purposes.

Therefore, we propose a new forecasting approach to address the aforementioned challenge. Our approach has three main pipelines: extraction (segmentation) via clustering, pre-processing, and forecasting. In the first pipeline, we extract segment of hidden, fine grained pattern from the input trace by filtering and clustering it. Each segment represents the historical trends for each pattern. According to our findings in [6], clustering demonstrated the ability to perform such extraction with high accuracy. To ensure efficient clustering, this extraction involves using our recent technique of dimensions and method selection EFection [7] and SeQual [8]. Then, in the pre-processing pipeline, the segmented patterns are uniformed with time alignment and linear interpolation. Finally, in the last pipeline, the pre-processed data is used for training and forecasting for the prediction process. To select a suitable model for our approach, we conducted a preliminary evaluation experiment. In this experiment, we compare the performance of various statistical and ANN-based models. We choose a recurrent neural network (RNN) for our approach. Accordingly, we present this approach as a Micro-forecasting approach for cloud user consumption pattern based on RNN (MICRAST) .

We evaluated our approach through two experiments. First, we compared MICRAST performance with a sample forecasting model. We employed these two approaches to forecast each user's preferences from all indicated cloud traces. Then, we measured the prediction accuracy of the results against their actual preferences. To ensure accurate validation for various scenarios, we applied this evaluation to both univariate and multivariate forecasting. In the second experiment, we assessed the confidence of our approach over a range of prediction time steps. This was achieved by measuring the change in accuracy when gradually increasing the forecasting time steps up to 20% of the training data. To measure the forecasting accuracy, we used the coefficient of determination R^2 and the mean absolute percentage error (MAPE). Our approach demonstrated the ability to forecast user behaviour with an accuracy between 95% to 98% R^2 surpassing related works methodology by 70 percentage points.

We structured the rest of this paper as follows: In Section II, we cover the background of this study. This includes giving a brief description of the common forecasting models and the accuracy measures used to evaluate them. This is followed

by a presentation of the related works. Then, in Section III, we disclose the process for developing the MICRAST approach and the inquiry works that contributed to it. Next, in Section IV, we demonstrate the evaluation process for the proposed approach and the experimental findings. This includes a comparison between our approach and a case study that presents an example of the related work approach. Finally, Section summarises the main points of this paper and reveals our future plans.

II. Background

This section covers the essentials of forecasting in cloud computing. This includes presenting commonly used models and describing their validation metrics. Then, it introduces the typical cloud workload traces and their characteristics in terms of forecasting implementation. Finally, this section discusses the literature review for the related works.

A. Time Series Forecasting and its Models

In time series forecasting, prediction is performed based on data comprising a sequence of observations over time [9]. Two vital parameters of this prediction are the forecasting *window size* and *steps*. In this context, the window size represents the range of past events, a line of records in the trace, that are utilised to be captured by the forecasting models. While the number of future records to be predicted by these models is denoted by steps.

Forecasting models are typically categorised into two main types: statistical and ANN-based models. Statistical models, as the name indicates, use statistical techniques and assumptions about the data distributions to reveal trends in historical records for predicting future variables. While ANN-based models perform the prediction using artificial neural networks to analyse and learn from past records. In this section, we aim to cover the simplest to the advanced models of these two categories. These were selected with respect to their range of usability.

Accordingly, Table I presents these models with their category and uses. We started with one of the very basic statistical forecasting methods, the Simple Moving Average (SMA) [10]. It estimates the future data values by finding the mean of data collection points falling within a certain forecasting window [11]. SMA is best for short-term prediction of stable trend time series data. In the context of time forecasting, stability or stationarity means that its statistical properties (mean, variance, and auto-correlation) do not change over time. Another model is the Auto-Regression model (AR), in which the forecasting is performed through a linear combination of its past values. The AR model is flexible for different types of time series patterns [12]. To form an Auto-regressive Moving Average (ARMA) model, AR is combined with another type of MA, which uses past errors to predict the future event in a regression-like model [12]. In ARMA, the AR part predicts the current event based on the past one, while the MA part calculates the errors of past predictions to correct the current one. ARMA is suitable for a stable series with no trend or seasonality. From this mix, Auto-regressive Integrated Moving Average (ARIMA) was introduced by Box and Jenkins by adding integrated differentiating to ARMA for converting the targeted data to stability [13]. This makes ARIMA usable for non-stable time series as well as for both short-and long-term forecasting. However, it cannot detect non-linear characteristics in the data, such as abrupt changes or variable interactions [12].

It's important to note that the above-described models are applicable only for uni-attribute forecasting, as depicted in Table I. Thus, a Vector Auto-Regression (VAR) model was presented as the multi-attribute version of the statistical model that is used for multiple attribute predictions. In VAR, the next value for each attribute is predicted based on its own previous history in addition to the history of other related attributes [14]. In the context of cloud traces, the related attributes are those that represent the consumption records for the users in the same trace.

On the other hand, from the ANN-based forecasting models, this section covers the following: RNN, LSTM and GRU consist of closed loops of network connections and feedback. These networks are developed to learn a sequential pattern of time series data [15]. Recurrent Neural Network (RNN) is useful for stable time series data. However, according to Bengio et al. [16], one of the limitations of RNN is the challenge of vanishing gradients when the forecasting window increases. These gradients used to update the network's weights during training. This makes the network struggles to learn from earlier time steps, making it hard to capture long-term dependencies in the trace.

To overcome this challenge, the literature introduced the concept of Long Short-Term Memory (LSTM). LSTM accomplishes this overcoming by discarding irrelevant information in the network using gating mechanisms, which enable them to deal with long-term forecasting windows [17]. Cho et al. [18] proposed an improved version of RNN with gate optimisation called Gated Recurrent Unit (GRU). GRU has a similar structure to that of LSTM and is also used to address the issue of vanishing gradients in time series forecasting. It is worth mentioning that an essential advantage of ANN-based models is that they can be employed for both multi-attribute and uni-attribute forecasting scenarios. Table I presents these models and their uses.

TABLE I. The Discussed Forecasting Models

Model	For	Category
SMA AR ARMA ARIMA	Uni-attribute	Statistical
VAR	Multi-attributes	
LSTM GRU RNN	Both	ANN-based

B. Data Analysis and Selection

In the forecasting area, the majority of prediction models are based on the assumption that the data of interest is stable [19]. Such stability indicates that the statistical properties of this data do not change through time, which makes it simpler to analyse the prediction process. Accordingly, our cloud traces need to be analysed for stability to ensure efficient forecasting. Without meeting the stability condition, the forecasting results may turn out to be unreliable. Typically, to check the stability

of the targeted traces, unit root tests are used. And to perform the unit root test, several types of methods are employed. Among others, these methods are Augmented Dickey-Fuller (ADF), Phillips-Perron (PP), and Zivot-Andrews [20]. According to [21], one of the most commonly used methods is ADF. It tests the data according to the following two hypotheses:

- Null hypothesis: The dataset has a unit root, and thus it's non-stable.
- Alternate hypothesis: The dataset doesn't have a unit root, and it's stable.

Therefore, we checked the stability of the cloud traces from the resources of the grid workload archive and the parallel workload archive to ensure efficient forecasting. To this end, we employed the ADF test for its high efficiency, being the most commonly used test in the related literature. We applied this test to users' preferences of (Requested Number of Processors) for all the traces in Table V, as it reflects their consumption records. Then, we calculated the average of ADF's results for the corresponding trace.

The results showed a P-value below 0.05, which represents the threshold of stability for all these traces with ADF statistic values shown in Table II. These results ranged from (-3.5) to (-20) for all the supervised traces (and only Bitbrain in the unsupervised trace). This means that all the traces from the selected resources are below the standard critical values that are used in the literature; see Table II. And since the P-values for each cloud trace were below 0.05, the null hypothesis is rejected, and these traces seem to be stable. Nevertheless, the strength of stability is not on the same level for all these traces. The farther the traces statistic is from the critical value, the stronger its stability. For instance, the CTC SP2 with (-20) can be considered to have very strong stability. While the UNILU Gaia, which recorded the lowest statistic value of (-3.5), has the lowest stability from these traces and requires more careful processing in the forecasting.

TABLE II. ADF CRITICAL VALUES

Level of Significance	Critical Value
1%	-3.43
5%	-2.862
10%	-2.567

Despite exhibiting high stability, many of these traces, such as ANL-Intrepid, SDSC Par 1995, OSC Cluster, and CEA Curie, showed non-linearity with abrupt changes. They also recorded a high standard deviation (SD) of above 10K. This is noticed when their scales are examined, such as the example provided in Fig. 1. We concluded that cloud workload traces may exhibit a characteristic of irregular changes without following a seasonality, yet still maintain a sense of stability. Such characteristics require a pre-processing to reveal meaningful patterns and trends from these traces to be beneficial for prediction model training.

Furthermore, since our analysis framework aims at providing a micro-prediction approach, it's vital to evaluate this approach with cloud traces that are applicable for such an aim. To be applicable, these traces need to meet the following criteria:

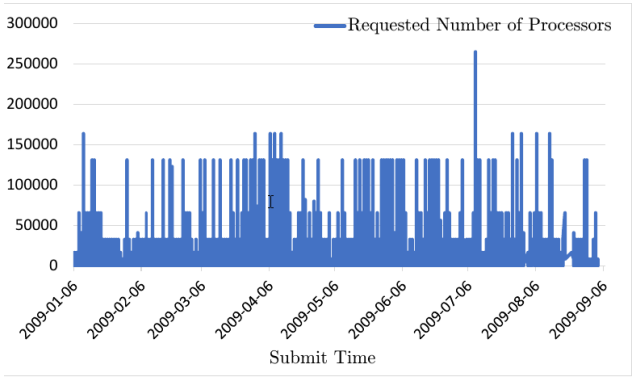

Fig. 1. The Characteristic of ANL-interpad trace.

- The trace should provide the attributes that present users' preferences in numerical format. Such a format makes it possible to extract these patterns and enables the forecasting model to capture them more efficiently.
- The trace should provide job submission times for each user. This enables forming a history of sequences of events for these users based on their job times. These sequences are essential to enabling the forecasting models to learn past preferences.
- The size of the trace should be sufficiently large to enable effective learning. In our experience, ANNs have a hard time learning trace time series with less than 25K data points, so we expect such trace size at least from each suitable for us to work with.
- The trace should demonstrate a sense of stability, since most forecasting models assume that the characteristics of the targeted datasets are stable.

Based on the above, we selected the traces in Table V that meet the above criteria. This table represents the trace name, its size (in number of lines), the time period of the trace, and the ADF test results.

It's vital to emphasise that another prerequisite for data to achieve efficient forecasting is that it should be uniformly sampled. This is necessary when the information in this data is given on different scales. But what to do when we don't have the dataset collected in a uniformly sampled way? Such uniformity can be achieved with the implementation of time alignment and linear interpolation methods. Time alignment ensures that the action points in the data are synchronised to the corresponding time step they represent [22]. Linear interpolation, on the other hand, fills in the blanks where there is no data. In essence, it is joining two known values with a straight line and then carrying out approximations for the intervening ones [23]. We provide two samples of time series data from the ANL-interpad trace. Table III shows the trace structure before applying the uniforming process, which shows obvious unaligned time steps or users' IDs. While Table IV shows how the same trace changed to a more uniform characteristic after applying time alignment and linear interpolation methods.

1) Forecasting validation: Forecasting validation is the process of measuring the efficiency of the employed model to

predict future events. It is typically conducted by comparing the outcome of a prediction with the actual ground truth. In the context of cloud traces, not all the datasets are applicable for training and using a portion of it as ground truth, since they lack a sufficient amount of usable records for such a purpose. The forecasting validation is mainly implemented to check if the used model is accurate enough in the testing process of forecasting.

Four of the most well-known of these validation metrics are Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Root Mean Squared Error (RMSE), and Coefficient of Determination (R^2) [24]. MAE is a statistical metric that evaluates the overall accuracy of a regression model by averaging the absolute differences between predicted and actual values. In contrast, MAPE calculates the average absolute percentage error, providing a relative measure of prediction accuracy [25]. It presents the results on percentage scales from 0 to + ∞ (where 0 is the best). This makes the MAPE metric easier to interpret. Thus, it was a widely used metric for forecasting evaluation [26]. While RMSE is a measure of how far off a model's predictions are from the actual values. Similar to MAE, RMSE presents the quality for the predicted value in units as actual numbers, without expressing its relativity to the true value.

On the other hand, R^2 is a statistical measure of the linear relationship degree between two data variables [27]. It ranks the relationships between the predicted and actual values. The R^2 ranges its results between 0 and 1, where closer to 1 means better.

Notably, both R^2 and MAPE provide a clear scale for measuring forecasting accuracy. These metrics can accurately measure the degree of alignment between actual and predicted data. They also demonstrate a clear and accurate comparison across different forecasting models. As we discussed above, the accuracy measures for these metrics are presented as percentage-based values. While, other metrics, such as RMSE use actual values that may not be comparable. Based on these points, we employed MAPE and R^2 for the evaluation process of this paper.

C. Related Works

In the area of cloud computing, researchers have developed various forecasting models for different purposes. Most of these models were especially aimed at addressing the challenges of dynamic resource management and scaling.

In [28], Lu et al. proposed a model called RVLBPNN to forecast workload trends based on their historical data. This was combined with workloads' level of latency sensitivity. Later [29] presented an improved version of RVLBPNN through exploiting the use of the K-means clustering method. This new version predicts future workload trends based on the history of response time characteristics for these workloads.

Maiyza et al. [30] also aimed to target and predict workload values and future trends through presenting VTGAN, a nonlinear prediction model. In [31], Arbat et. al. proposed a time-series forecasting model designed to predict changes in cloud workloads with high accuracy and low inference overhead. The model used in this paper is called WGAN-gp Transformer. This model is inspired by the Transformer network and improved Wasserstein-GANs. It aims to address the challenges of the dynamic nature of cloud workloads.

Kumar et al. [32] developed an LSTM/RNN-based model to enhance resource management and optimise performance by accurately predicting future workloads, which is crucial for efficient operation in cloud environments. It predicts workload values based on their previous samples. The authors also presented a similar forecasting approach in [33], embedding a self-directed learning process to predict future demand from cloud servers.

Likewise, in [5], a MAG-D model was developed by Zhang et al. based on a GRU neural network. This model predicts each cloud resource's memory and CPU usage based on data-centre traces. On the other hand, to forecast user behaviour trends in large-scale cloud environments, Panneerselvam et. al. [34] implemented the InOt-RePCoN model. The trends that this model aimed to predict were the number of jobs and submission times for users. Similarly, in [35], Nehra and Kesswani presented a LSTM-based forecasting model to predict workloads in a cloud computing environment. Its aim is to reduce service level agreement violations.

We have concluded from above that the models in these studies have followed a similar forecasting approach. The

forecasting process under these approaches targets and macro-predicts the overall values and trends of workloads. Such methodology is designed to deal with users' preferences in the traces as a whole. Unfortunately, these traces as a whole in their raw form do not reflect any meaningful patterns for prediction. Thus, the gaps in the current models is that they lack an efficient tool to uncover and capture the diversity and variability of users' consumption at a granular level.

III. METHODOLOGY

In this section, we cover the research that leads to our new forecasting approach. This approach aimed at providing more efficient micro-prediction of clouds granular patterns. MICRAST overcomes the challenging characteristic of the cloud users' records, which suffers from sudden changes in their requests as illustrated in Fig. 1. Such characteristics are not readily predictable by the models in the related works.

MICRAST offers an outline that enables micro-prediction through extracting segments of granular patterns from cloud traces using clustering and the efficiency tools of (SeQual [8] and EFection [7]). This was conducted upon proving that the cloud traces demonstrate a sense of stability as depicted in the analysis investigation in Section II-B, page 856, which aligns with the requirements of most forecasting models. This is followed by performing a comparison test between statistical and ANN-based forecasting models to select the best among them for our approach. We finalise this section by giving a thorough description of our proposed approach.

A. Forecasting Model Comparison

It's essential for developing an efficient forecasting approach to carefully select its model. Therefore, we carried out a comparison evaluation between various models listed in Table I to select the one that shows the highest performance in predicting cloud traces.

1) Setup configuration: We set up the number of input layers based on the formula (Number of attributes × window size). The window size represents the segments of the targeted traces that are selected for the forecasting model to capture in the learning process, as illustrated previously in Subsection II-B. In the hidden layer, the desired model is selected (either RNN, LSTM, or GRU) with 100 units. Choosing 100 units ensures a balance between the complexity of the model and computational efficiency. This number is sufficient to capture intricate patterns within the cloud traces attribute without causing overfitting or incurring high computational costs. Such configuration enables the network to capture the necessary patterns within the time series data.

This is followed by configuring the activation functions. These functions are essential elements in the neural network since they indicate the activation status of the correspondent neuron. Accordingly, we selected the (*tanh*) for learning and the (*Hard sigmoid*) for the recurrent layer, as prior art indicated that these functions typically result in higher performance [36]. Finally, the hidden layer is further connected with the third layer (the out layer). In this layer, the network is structured as one unit (output), and the ReLU activation function is selected to handle the output recurrent process. We present the implementation of the RNN network in the K-nime toolkit in Fig. 2 as an example of the above configuration.

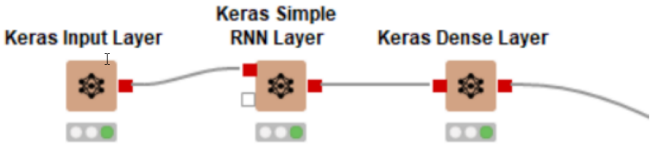

Fig. 2. RNN network configuration in K-nime.

2) Experimental implementation: As mentioned previously, we are developing our approach for uni-attribute and mult-attribute forecasting scenarios to ensure a wide range of ap-

plicability. Therefore, we performed this comparison through two experiments, one for each scenario.

We conducted experiments by comparing the performance of the forecasting models that were listed in Table V in the prediction of granular patterns. For this purpose, we chose the attributes of (Used Memory and Requested Number of Processors) as it represents the user's requests (consumption) from the cloud server provider. This attribute is widely available and applicable for forecasting across most traces. While others, such as Requested Memory, are deemed inapplicable since they exhibit a large portion of constant values in many traces, as we observed in [8] and [7], making it limited in giving meaningful information.

For the uni-attribute forecasting scenario, we targeted predicting the granular patterns in the Requested Number of Processors by training the model with its own historical records. While, for the multi-attributes scenario, we repeated this process by training the model on the historical records of an additional attribute (i.e. Run Time). We chose this attribute as we observed that it shows a high correlation with the Requested Number of Processors and it is also provided in applicable form in all the traces. This makes it a strong candidate for our purposes. It will test these models' ability to capture the dependencies between different attributes to predict a particular preference.

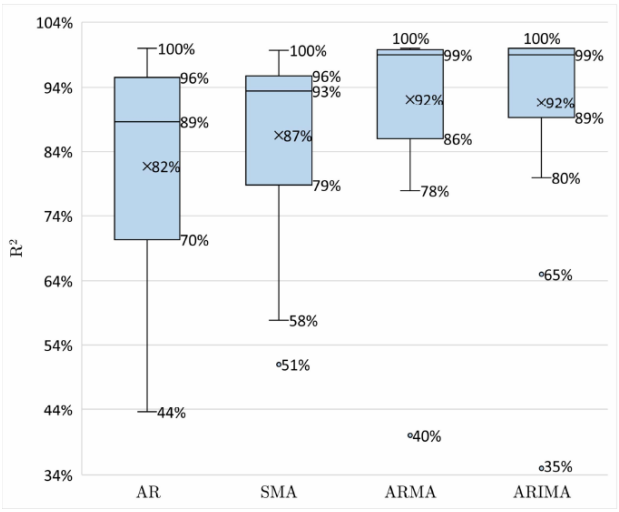
We applied both experimental scenarios to all the traces in Table V. At this time, we have prepared the input data by hand without presenting an automated approach. We clustered the targeted attributes to perform the extraction that allows the comparison to go ahead. We set the forecasting window size to five to ensure sufficient capture of past events. We observed that a window size of fewer than five might not sufficiently capture users' patterns in cloud traces.

In the ANN-based models, this setup is translated into configuring up to five input neurons and one output neuron with an activating sequence return. This results in five inputs for each chosen trace attribute's historical pattern. These configurations were applied to the uni-attribute scenario. While, for the multi-attribute scenario, the input neurons will be doubled to 10 to represent both attributes.

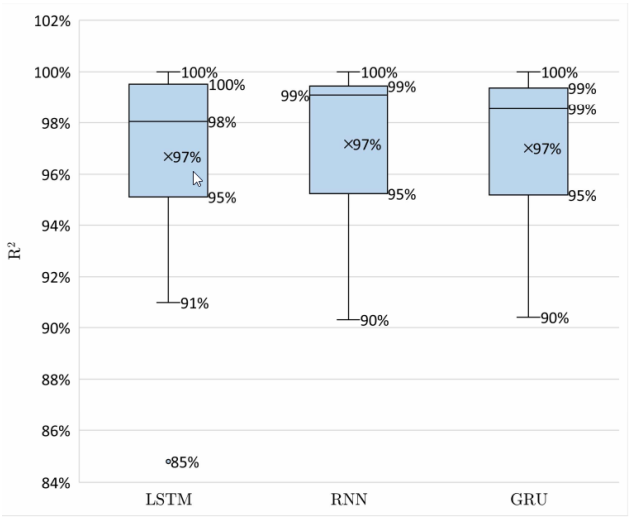
To implement these experiments, we split the prepared data into two portions: 70% for training and 30% for testing. To assess the accuracy of the forecasting, the metrics MAPE and R^2 were calculated to measure how closely the predicted values compare to the actual ones. Finally, we show boxplots for the distribution range of R^2 for these models to compare their performance. These boxplots provide insight into the precision and consistency of each model's performance. The results of our experiments are illustrated as follows:

a) Uni-attribute forecasting: In this experiment, we chosen the models that are useful for uni-attribute forecasting in Table I. Fig. 3 illustrates the boxplots of R^2 distribution ranges for the ANN-based and statistic models.

Fig. 3a showed that the basic statistical models (i.e. AR and SMA) exhibit a lower median and a wider range of R^2 distribution compared to the more advanced models (i.e. ARMA and ARIMA). We noticed this for the AR model with whisker extending down to 44%. This performance was mainly



(a) Statistical-based Models



(b) ANN-based Models

Fig. 3. R^2 Distribution for uni-attribute forecasting models.

caused by the traces of ANL-Intrepid and METACENTRUM-2009. This resulted in an average MAPE of around 2.1%. The SMA model exhibited a relatively higher median and distribution, with a slightly better whisker at 58% recorded for DAS2.

However, this model suffers from an outlier at 51% for HPC2N and a higher average MAPE of about 4%. On the other hand, both the ARMA and ARIMA models showed a comparably higher R^2 and narrower range of distribution. This implies that the more sophisticated models are more precisely focused and consistent than the basic models. Despite these elevated scores, both models suffered from a lower whisker of below 81% with outliers falling under 50% caused by the CEA Curie trace. This causes a higher average MAPE for these two models of around 12%. The reason for the performance of both simple and advanced statistical models is the nonlinear nature of users' consumption records in the above-indicated traces. Thus, they cannot be accurately

predicted with linear auto-regression and statistical analysis, even in advanced models. This underscores the uncertainty and unreliability of these models in forecasting users' preferences in the cloud environment.

In contrast, Fig. 3b illustrates that the ANN-based models show more stable performance in terms of R^2, with a higher median and a narrower range of interquartiles. All three models of LSTM, RNN, and GRU achieved the same high and concise range of R^2, except for an outlier at 85% for the LSTM model, which is the accuracy result of the LLNL ATLAS trace. This outlier is resulting in an average MAPE of around 0.7 compared to a 0.4 average MAPE for both RNN and GRU. In conclusion, we can assert that for uni-attribute forecasting, the ANN-based models (especially RNN and GRU) are more compatible with our approach to predicting cloud users' preferences.

b) Multi-attributes forecasting: In this experiment, we utilised the models that are applicable for multi-attribute forecasting in Table V. The boxplot in Fig. 4 shows the performance of both statistical and ANN-based models. As shown in Fig. 4, the VAR model exhibited a lower median, a wider range of R^2 distribution, and more outliers compared to the ANN-based models. Specifically, the outliers accounted for 72% in forecasting the DAS2 trace, 67% for SDSC BLUE, and 58% for CEA Curie. As mentioned previously, the attributes in these traces have the characteristic of non-linearity. Thus, these results demonstrate that the straightforward autoregression process of the VAR model cannot capture the correlation between attributes with such characteristics. It would rather interpret the patterns in these attributes as noise, resulting in an average MAPE of around 3.57%.

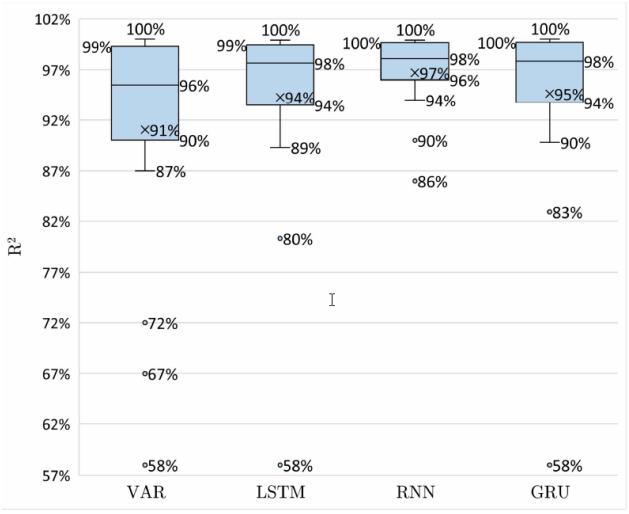


Fig. 4. An Accuracy distribution for multivariate forecasting models.

On the other hand, Fig. 4 shows that ANN-based models were able to handle such challenges with better performance and an average MAPE of around 1.9%. These models were able to capture the relationship between these attributes to predict the targeted preferences. However, both LSTM and GRU models suffered from an outlier at 58% R^2 for OSC Cluster. Notably, this trace recorded 95% in the uni-attribute forecasting for the same models. The reason for this drop is that using additional attributes (RunTime in this case) with (Requested Number of Processors) led to overfitting problems for both models. Such overfitting happened more for the DAS2, SDSC BLUE, and CEA Curie traces. The long-term memory for LSTM and GRU models causes such overfitting when trying to capture the relationship between two attributes with the significant characteristic of abrupt change. In comparison, the RNN model, with its more simple memory structure, showed the ability to deal with this, having more stable performance and achieving a narrower boxplot. In addition, compared to the previous ANN and statistical models, it achieved 96% accuracy in forecasting OSC Cluster, 96% for DAS2, 93% for SDSC BLUE, and 90% for CEA Curie. This implies that the RNN model effectively managed the noisy patterns and overfitting issues while maintaining high accuracy.

c) Findings: We concluded that, among the compared models, the RNN model achieved a high accuracy across both uni-attribute and multi-attribute forecasting. It recorded around 97% R^2. This model was able to maintain this performance even for challenging traces. This makes it an ideal choice for our approach. The detailed structure for MICRAST and its RNN network is detailed in the upcoming subsections.

B. The Proposed Approach MICRAST

We propose the MICRAST approach to predict the future consumption preferences of cloud users. Our approach achieves this through pipelines of segmentation, pre-processing and Forecasting as shown in Fig. 5. In this section we cover both the training and forecasting phases of our approach compared to the current approaches that shown in Fig. 6.

a) Training phase: this phase is carried out as following:

- Extraction pipeline is employing the use of clustering to uncover hidden patterns that steer users' preferences from the input trace. According to our findings in [6], clustering demonstrated a high ability of such extraction. To ensure efficient clustering, we apply two main tasks. First, we filter the trace by disregarding those attributes that have the same value for more than 80% of the records. These attributes are deemed unsuitable for clustering, as we illustrated in [8].

Second, we employ both tools of Sequential method of clustering Quality (SeQual) and Effectiveness detection of clustering quality (EFection), to address both scenarios of single and multiple feature selection. The SeQual method ranks which single attribute is best among the given for extraction when the user decides to process uni-attribute forecasting. While the EFection technique is used to select the combination of attributes that are more compatible for extraction when the user decides to process multi-attribute forecasting. Notably, if the EFection selected one attribute, in this case the user recommended going for uni-attribute forecasting instead. We also exploit the use of EFection to choose the most suitable method for clustering the selected attributes (for extraction). In this task, the selected clustering method groups similar historical usage records along with their submit time to form the consumption pattern for each user; see Table V. Thus, the output of this task are segments of granular patterns.

- Parallel pipelines of pre-processing to prepare each segment of granular pattern for prediction. In their clustered form, these segments exhibit non-uniform scales and formats. This form does not meet the requirements presented in Section II-B, see page 855, for effective data forecasting. Therefore, in these pipeline, we carry out uniforming processes in parallel, separately for each segment, as shown in Fig. 5. First, we take the current time sequence for each segment and convert them into a single form across all traces. We also employ the time alignment process to rearrange these segments on the same time scales. Second, we implement linear interpolation to avoid any missing records.

Afterword, the data of each segment are normalised into the range between 0 and 1. This is essential for efficient forecasting since the characteristics of cloud workload traces exhibit different scales of data. For instance, there is a significant difference in the standard deviation between Requested Time and Used Memory. Such characteristics are not suitable for forecasting, and normalising can make them more appropriate for an ANN forecasting model. The output of these pipelines are uniformed segments, each is ready to use as input for forecasting training.

- Parallel pipeline of forecasting that feeds the uniformed segments to train the RNN model. It's important to emphasise that the RNN model is configured with the setup presented in Section III-A1. This configuration demonstrated high performance, according to our comparative experiments. After training the RNN model sufficiently, this pipeline produce trained networks for each segment that will be ready for implementation to forecast the new input traces from the service provider system.

In addition, This pipeline involves also calculating the average centroid for each segment. These are stored alongside with each stored trained networks.

b) Prediction phase: In this phase our approach follows the same pipeline of segmentation and forecasting presented previously in the training phase. As shown in Fig. 6, first the new data are clustered into segments of granular patterns followed by calculating the average centroid for each of these segments. Finally these segments feeds into suitable trained networks to predict the future events. This is carried out by comparing the centroid of each segment with the one stored alongside the stored network from the training phase. Once the range of the compared average centroids matched, the correspondent network is selected and applied on the current segment for prediction.

In comparison to the approaches used by the recent cloud studies in Table VI, it's noticed that they follow a singular pipeline of prediction process. As illustrated in Fig. 6, these approaches are designed to carry out the data preparation (i.e. linear interpolation, time alignment, etc.) and forecasting tasks on the input data without considering granularity. As the prepared data feeds into the forecasting model to train a single network. While, for the prediction phase, this network applied directly on the new input data. Such prediction pipeline is known as Macro-prediction.

IV. Validation of MICRAST Performance

We conducted the evaluation in this work through two main experiments. First, we carried out a comparison test to measure the performance of our approach against (LSTM-RNN) in [32]. This case study exemplifies the micro-prediction approach that has been adopted by other related works as well in Table VI. We selected this study for the comparison evaluation since it is similar to our approach in aiming to predict consumption requests using an ANN-based model. Such evaluation is essential to demonstrate the benefit of one proposed approach. Second, we measured the forecasting confidence of MICRAST to show its performance across a scale of time steps. This is vital to show the application range for our approach. The following subsection presents these two experiments.

A. MICRAST vs LSTM-RNN for Related Work

In this evaluation, we compared the performance of MICRAST with the LSTM-RNN approach. We conducted this for both uni-attribute and multi-attribute forecasting scenarios to ensure accurate validation. To measure each approach's performance, we used R^2 and MAPE metrics. As illustrated in Section II-B1, we selected these metrics as they provide a clear scale for measuring forecasting accuracy. They measure the degree of alignment between actual and predicted data with a clear and accurate percentage-based value comparable across different forecasting models. We present the comparison results for each scenario.

Before we proceed to the results, we discuss the experimental configuration. Both forecasting scenarios adhered to the same evaluation setup described in the experimental implementation in Section IV using all the selected traces in Table V. Similarly, we first utilised both approaches to predict the consumption preferences for an attribute that represents users' usage records (i.e., Requested Number of Processors). Second, in the multi-attribute scenario, we repeated the previous steps with one difference: in this case, we train the forecasting models with the historical records of an additional attribute (i.e. RunTime). Accordingly, we are using the history of two attributes from the cloud trace to forecast the value of one particular attribute. We selected these attributes as they reflect the major aspects of consumption (demand level and duration).

1) Uni-attribute forecasting scenario: Table VII compares the average of R^2 and MAPE scores for forecasting all the selected traces by each approach. It demonstrates that our approach achieved better R^2 and MAPE by 67 and 40 per cent, respectively. These results showed a potentially significant improvement in accuracy when using our approach for uni-attribute forecasting.

For more detailed results, we presented the cumulative distribution for R^2 scores of both approaches in Fig. 11. Accordingly, the cumulative distribution for the LSTM-RNN approach in Fig. 7a showed below 60% R^2 for 16 out of 18 of the traces. In contrast, Fig. 7b showed that MICRAST recorded more than 90% R^2 for 17 of these traces.

We also demonstrated the MAPE for each trace in Fig. 8. The related work approach showed a significant MAPE for some traces. Specifically, it recorded around 165% to 209%

TABLE VI. MICRAST COMPARED TO RECENT APPROACHES

Approach	Prediction Focus	Granularity	Methodology	Prediction Level	Prediction Type
CNN-LSTM Model [37]	Multivariate cloud workload prediction	Medium (system-level)	Combines CNN for spatial features and LSTM for temporal dependencies	**Macro-prediction**	System-level workload forecasting
esDNN [38]	Cloud workload prediction & resource optimization	Medium (system-level)	GRU-based deep learning for time series forecasting	**Macro-prediction**	System-level workload & resource management
Facebook Prophet [39]	VM workload behavior prediction	Medium (workload-level)	Prophet framework with hyperparameter tuning and data preprocessing	**Macro-prediction**	Workload pattern forecasting (steady, trending, seasonal, etc.)
MICRAST	Individual user consumption prediction	High (user-level)	Pre-processing steps (clustering, uniforming, time alignment) + LSTM-RNN	**Micro-prediction**	Granular, personalized predictions

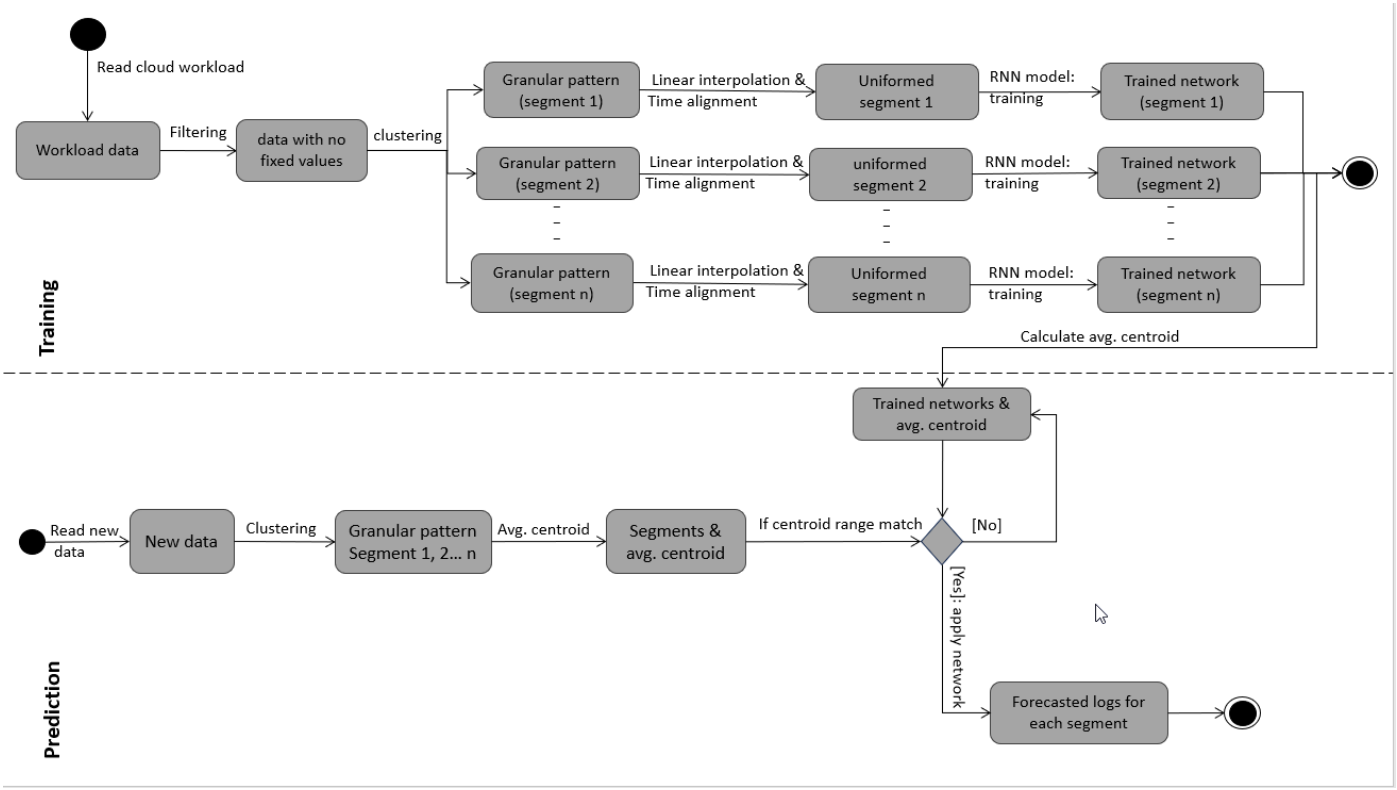

Fig. 5. The MICRAST approach.

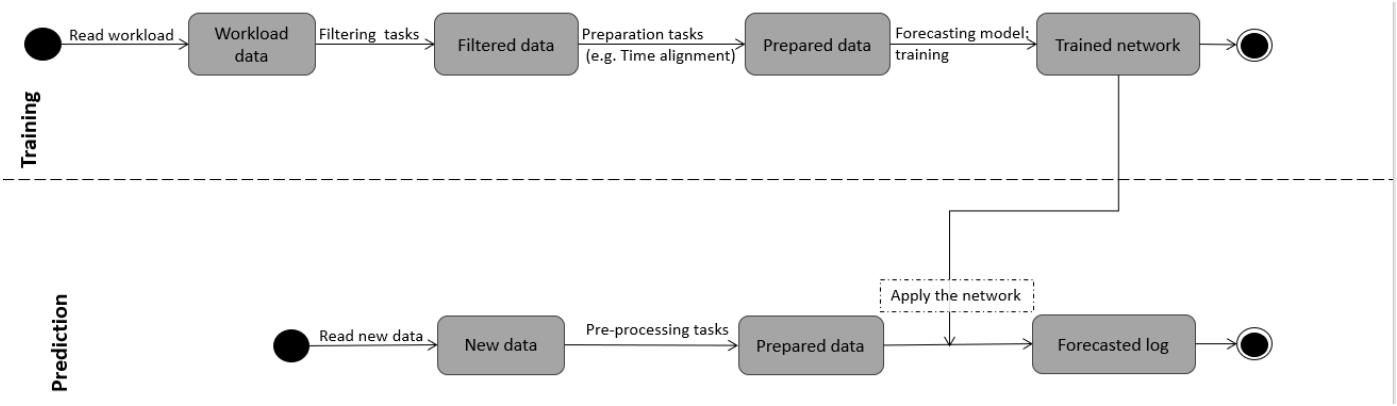

Fig. 6. The Macro-prediction approaches.

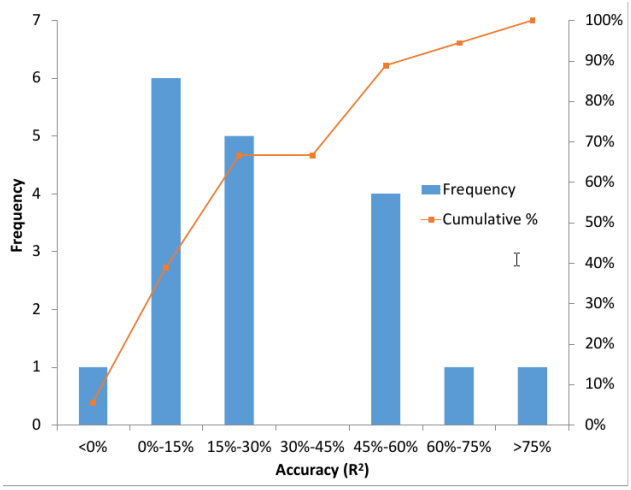
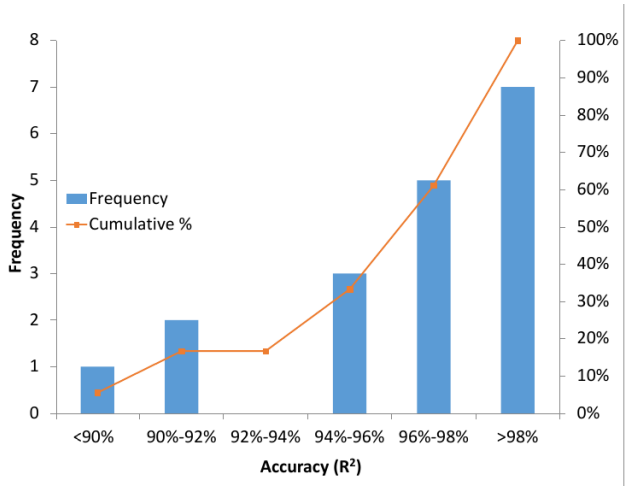
for forecasting SDSC Par's traces and around 124% for ANL-interpad. While our approach improved all the MAPE scores to below 6% (the majority to below 1%), notably in the traces of SDSC Par's and ANL-interpad (see Fig. 8).

TABLE VII. COMPARISON OF UNI-ATTRIBUTES FORECASTING

Forecasting approach	R^2	MAPE
LSTM-RNN	30%	42.78%
MICRAST	97%	2.38%



(a) LSTM-RNN



(b) MICRAST

Fig. 7. Comparison of R² results for uni-attribute forecasting between (LSTM-RNN and MICRAST).

The above results are mainly due to the characteristics of cloud traces, as demonstrated in the analysis illustration in Subsection II-B and Fig. 1. Some traces exhibited abrupt and unexpected variations with a high standard deviation. Specifically, the standard deviation of Requested Number of Processors in SDSC Par 1996, 1995, and ANL-Intrepid was above 10K. Without a suitable extraction process, the impact of such a characteristic poses a great challenge for the LSTM-RNN. This, in turn, led to notably low and unstable performance. While the performance of our approach suggests that the filtering and clustering processes were highly effective for extracting useful patterns from even these traces. For example, we observed this phenomenon with extracted patterns from the ANL-Intrepid trace (shown in Fig. 9) against their pre-

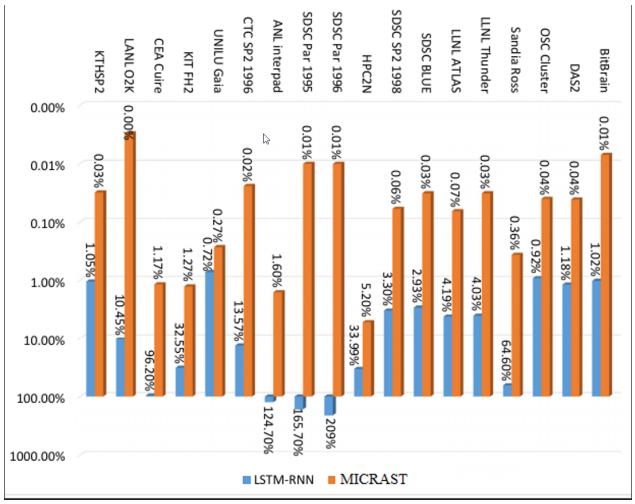


Fig. 8. Comparison of MAPE results for uni-attribute forecasting.

extracted versions (illustrated in Fig. 1). As mentioned earlier, in this context, these patterns represent the hidden trends in users' consumption records. This facilitated the learning and prediction process for the RNN model in MICRAST.

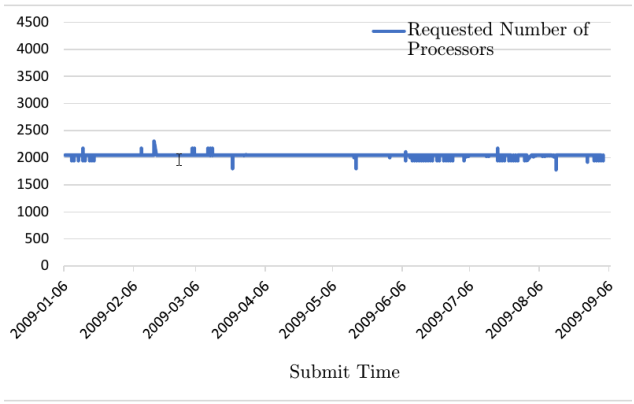

Fig. 9. Extracted pattern from ANLinterpad trace attribute.

Finally, we calculated the relative deviation (RD) for the R^2 results of both approaches. We drew boxplots for these RD distributions in Fig. 10. We compared them to show the level of consistency for each approach. Accordingly, the LSTM-RNN showed a wide range of RD spreading for 111 percentage points. While our approach performed with a narrower distribution for only 1.8 percentage points, showing more centered R^2 scores. Such narrow distribution with the high R^2 of 97% indicates that our approach can perform more accurate and consistent forecasting in the uni-attribute scenario compared to the related works approach.

2) Multi-attributes forecasting scenario: In the second scenario, we observed that related work exhibited even lower performance than previously. The cumulative distribution results in Fig. 11a show a low R^2 of below 5 percent for three of the traces. This is increased from only one trace in the uni-attribute forecasting. In contrast, our approach maintained its accuracy for the multi-attribute scenario, with no traces falling below 90% R^2, as depicted in Fig. 11b.

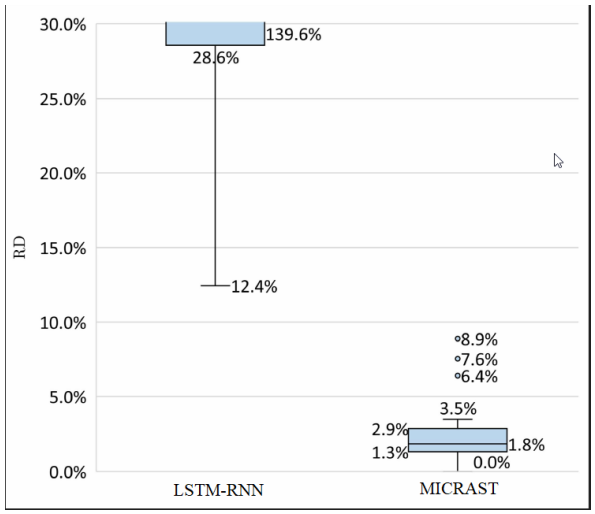

Fig. 10. A Relative deviation comparison for uni-attribute forecasting.

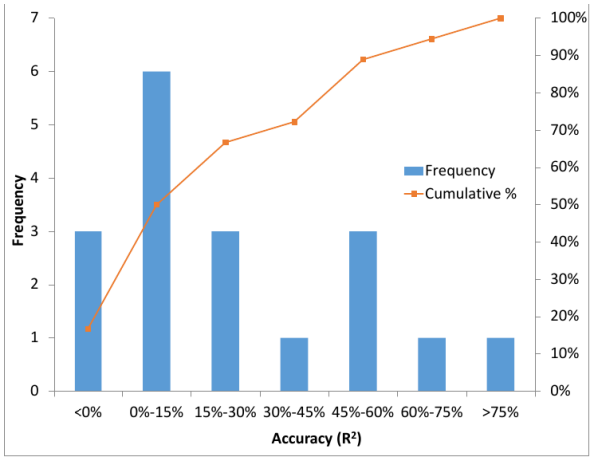
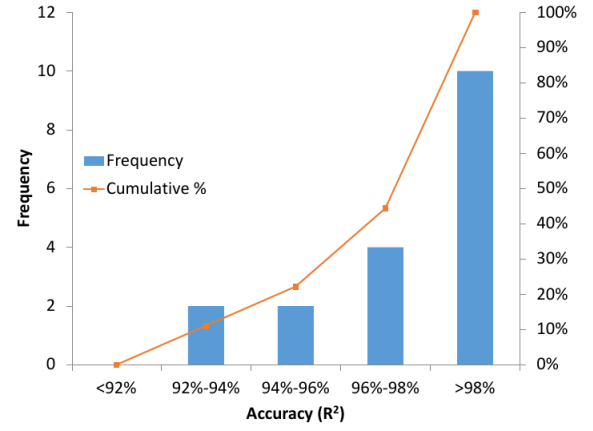


(a) LSTM-RNN



(b) MICRAST

Fig. 11. Comparison of R² results for multi-attribute forecasting between (LSTM-RNN and MICRAST).

Furthermore, the scores in Fig. 12 show an even higher MAPE for the LSTM-RNN approach. It recorded around 166% to 211% MAPE for SDSC-Par's traces and around 127% for ANL-Intrepid. This is an increase of about 2 percentage points compared to uni-attribute forecasting. While our approach maintained the MAPE of below 5.30% for all the traces (Table VIII).

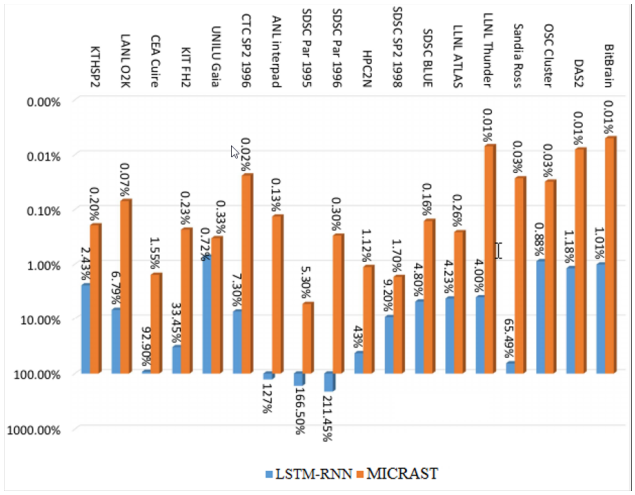


Fig. 12. Comparison of MAPE results for multi-attribute forecasting.

TABLE VIII. COMPARISON OF MULTI-ATTRIBUTES FORECASTING

Forecasting approach	R^2	MAPE
LSTM-RNN	27%	43%
MICRAST	97%	1%

These results are due to challenges caused by the use of multiple attributes with sudden changes characteristic. Such characteristics cause difficulties for the LSTM-RNN approach to capture possible correlation between these attributes, as they lack in providing meaningful patterns. While the extraction phase in MICRAST enables uncovering these attributes detailed patterns through clustering, making it easier for the prediction model (i.e. RNN model) to capture possible correlations.

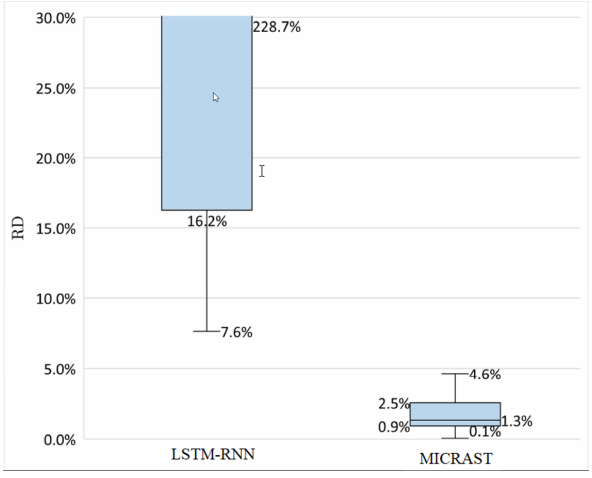

Fig. 13. A Relative deviation comparison for multi-attribute forecasting.

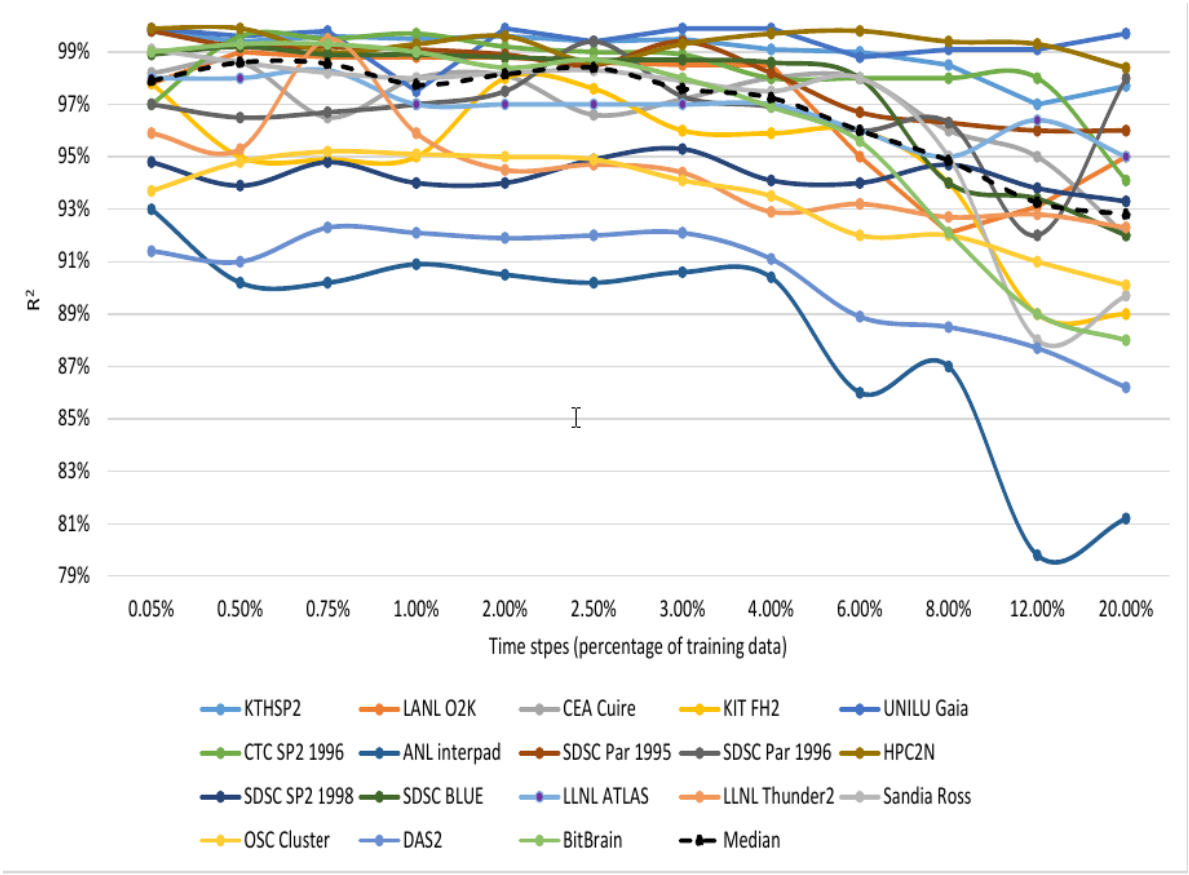

Fig. 14. Confidence range for MICRAST approach over time.

The boxplots for the relative deviation distribution of both approaches in Fig. 13 showed that LSTM-RNN failed to adapt to this type of forecasting. It recorded a relative deviation spread of 212 percentage points. This is higher than the uni-attribute forecasting by around 100 percentage points. While our approach maintains consistency in multi-attribute forecasting, the relative deviation spreads by only 1.6 percentage points.

B. Confidence Range for MICRAST

In this experiment, we measured the forecasting confidence by demonstrating the change in R^2 values for our approach as we extended the range of the forecast. We varied the range between 0.05% and 20% for each trace's training data (e.g. if the training data was 1 hour long, we made forecasts of 18s to 9m into the future). We have chosen this range because our observations showed that within this range there are significant chances for consumption pattern changes for each trace. Therefore, evaluating across the complete range demonstrates our ability to cope with forecasting even these changes.

We applied the same experimental configurations as in the previous evaluation. Similarly, we conducted uni-attribute forecasting of users' consumption preferences of Requested Number of Processors of all the selected traces in Table V. Finally, we calculated the median of these traces' R^2 for each step. Ultimately, the (R^2-median, R^2) over a particular forecasting range gives our MICRAST confidence.

The results in Fig. 14 show that our approach forecasted the majority of the traces with R^2 distributed at a range of 5 percentage points around the median of 98% R^2. This range expanded to 19 percentage points around the median of 93% R^2 when reaching 20% of the steps in the training data. This expansion is mainly noticed in the traces of DAS2 and ANL-Intrepid. As mentioned previously, these traces exhibit a significant characteristic of sudden changes in their consumption patterns, as illustrated for the ANL-Intrepid trace in Fig. 1 at page. This characteristic raises more challenges for the RNN model when the time step increases, even after the extraction process, affecting the prediction quality over time. Nevertheless, Fig. 14 shows that our approach can maintain the high R^2 median around 95% to 98% for the majority of the traces. While it drops by only 5 percentage points (to 93%) when reaching the full 20% of the rows from the training trace. This demonstrates that predictions up to 4% of the trace can be relied on for all traces, while for most traces we can reliably predict even 20% into the future of the training data.

V. Conclusion and Future Work

In this paper, we proposed an approach MICRAST for forecasting users' preferences in a cloud environment based on their consumption patterns. Our approach conduct this by extracting these patterns from the input traces through filtering

and clustering processes. Then it uniforms them through time alignment, linear interpolation, and normalisation. Finally, our approach passes the uniformed patterns for forecasting with RNN model, which we selected through a preliminary experiment. When comparing our work with prior art, we demonstrated that such extraction and pre-processing in MICRAST enables it to provide more efficient prediction for traces that exhibit characteristics of an abrupt change. We evaluated the MICRAST approach through the following experiments. First, we compared our approach against that used in the related works (i.e. LSTM-RNN) to demonstrate its superiority. Our approach showed the ability to conduct both univariate and multivariate forecasting with an accuracy of 98%, surpassing the LSTM-RNN approach by around 70 percentage points. Second, we measured the confidence range of our approach by observing how the accuracy changed when we increased how far ahead the forecasting needed to go. The results show that the MICRAST was able to forecast users' preferences with a confidence level between 95% and 98% when forecasting for a duration of 20% of the training data.

The limitation of our study is the lack of investigating it's benefit for real world application and it's efficiency for other types of application beyond cloud computing. Therefore, for future work, we aim to investigate the applicability of our approach for energy awareness improvements among private cloud users. After predicting users' consumption preferences, we could notify them for alterations they could do to their consumption. We also consider different scenarios of users' reactions and test the effect of these reactions on cloud utilisation by implementing them in cloud simulators such as CloudSim or DISSECT-CF. In addition, we intend to investigate our approach for other purposes and datasets besides cloud computing. One potential implementation of MICRAST is in energy management sectors, especially smart grids. By collecting the consumption records of different users in the grid, our approach could be used to extract and predict their patterns. This could help in managing demands, optimising grid operations, and planning renewable energy integration.

Efficient Processing and Intelligent Diagnosis Algorithm for Internet of Things Medical Data Based on Deep Learning

Wang Liyun
Information Department of Linyi Central Hospital, Linyi City, Shandong Province, 276000, China

***Abstract*—Electronic Medical Record (EMR) is a commonly used tool in medical diagnosis, which has static recording, difficulty in combining and analyzing different forms of data, and insufficient diagnostic efficiency and accuracy. This article proposes a CNN (Convolutional Neural Network)-LSTM (Long Short-Term Memory) algorithm for efficient processing and intelligent diagnosis of Internet of Things (IoT) medical data. The Word2Vec model is applied to clinical text data and its ability is utilized to capture semantic relationships between words. Medical image data is feature extracted using CNN, while physiological signal data is dynamically processed using LSTM to identify trends and anomalies in the data. An attention mechanism is applied to dynamically adjust the model's attention weights for different types of data. By analyzing the samples of health, cardiovascular disease, diabetes, chronic obstructive pulmonary disease, hypertension, and chronic kidney disease, the CNN-LSTM in this article can accurately classify a variety of diseases, and the accuracy rate of healthy individuals has reached 97.8%. By combining CNN-LSTM with multimodal data, the accuracy and efficiency of medical diagnosis have been effectively improved.**

***Keywords*—Intelligent diagnosis; Internet of Things medical; electronic medical records; long short-term memory; convolutional neural network**

I. Introduction

With the rapid development of information technology and the healthcare industry, electronic medical record (EMR) has become one of the core tools for medical data management. EMR [1-2] stores various data such as patients' medical history, examination reports, imaging data, and medication use, providing important basis for clinical diagnosis and treatment. The use of traditional electronic medical records faces many challenges. Most EMR records patients' conditions in a static manner, lacking real-time monitoring of their health status and unable to reflect dynamic changes in their condition in a timely manner. EMR data comes in various forms, including text, images, structured data, and unstructured data, which makes data integration and analysis complex. The lack of unified data standards between different hospitals or medical institutions increases the difficulty of information sharing and data integration, which in turn affects the efficiency and accuracy of diagnosis. With the rapid increase in the volume of medical data, traditional manual analysis and processing methods have become difficult to cope with. How to efficiently and accurately analyze and process these massive amounts of data has become an important issue in medical data research. The development of Internet of Things (IoT) technology has brought new opportunities to the medical field, especially in the areas of medical data collection, transmission, and processing. Through intelligent sensors, wearable devices, and implantable devices, the Internet of Things can collect real-time physiological data of patients, including heart rate, blood pressure, blood sugar, etc., providing dynamic data sources for electronic medical records and filling the gap of traditional EMR static recording. The massive data generated by the Internet of Things has also brought new challenges, and how to efficiently process and analyze these multimodal and heterogeneous medical data has become a focus of current research. Deep learning techniques [3-4] have emerged, among which convolutional neural networks and long short-term memory networks have shown outstanding performance in processing complex data and automatically extracting features. Combining IoT technology, deep learning algorithms can automatically analyze medical data from different data sources, extract high-value information, and make accurate diagnoses and predictions, thereby improving the processing efficiency of medical data and the intelligence level of diagnosis. This fusion technology provides doctors with diagnosis and treatment advice, promoting the development of personalized medicine.

This study proposes a multimodal diagnostic model based on CNN (Convolutional Neural Network)-LSTM (Long Short-Term Memory), providing a new solution for early diagnosis and monitoring of chronic diseases. This model integrates medical imaging data, temporal physiological data, and clinical text data, significantly improving the accuracy and efficiency of disease classification. The model performs excellently in the classification tasks of healthy individuals and various chronic diseases, surpassing traditional diagnostic methods. This contribution not only provides more accurate decision support for clinical practice, but also provides empirical basis for research in related fields, promoting the development of intelligent healthcare.

The innovation of this study is reflected in multiple aspects. The combination of deep learning algorithms CNN and LSTM fully utilizes the advantages of convolutional neural networks in image feature extraction and the powerful capabilities of long short-term memory networks in temporal data processing, thereby achieving comprehensive analysis of multimodal data. By applying attention mechanism, it can automatically identify and focus on key features in the input data, further improving the diagnostic accuracy. The use of Word2Vec technology to extract key disease descriptions, symptoms, and diagnostic information from clinical text data provides richer contextual information for the model and promotes effective fusion of multimodal data. These innovations have laid the theoretical

and practical foundation for future intelligent diagnostic systems.

This article has a clear organizational structure and clear hierarchy. The introduction section clarifies the research background and significance, points out the limitations and urgent needs of traditional diagnostic methods, and then introduces the main objectives and research methods of this study. The methods section provides a detailed explanation of data collection, preprocessing, model construction, and training processes, offering readers comprehensive technical details. In the results section, the performance of the model is visually demonstrated through charts and data analysis, including evaluation indicators such as accuracy and Kappa coefficient, ensuring the transparency and reliability of the research results. The conclusion section summarizes the research findings, analyzes their practical significance and limitations, and provides prospects for future research directions. This clear structure not only facilitates readers' understanding, but also enhances the academic value of the article.

II. Related Works

Medical diagnosis is an important component of the medical field. With the advancement of technology, the methods of medical diagnosis are constantly evolving, gradually shifting from traditional doctor experience judgment to scientific diagnostic methods based on data analysis. Early medical diagnosis [5] mostly relies on the clinical experience and limited laboratory data of doctors, and the accuracy of diagnosis largely depends on the professional knowledge and experience accumulation of doctors. With the development of imaging technology [6] and molecular diagnostic technology, medical diagnosis has entered a data-driven stage. The widespread application of imaging technology has made medical diagnosis more dependent on digital imaging data, providing technical support for early detection and accurate diagnosis of diseases. Molecular diagnostic technology [7], through in-depth analysis of the genome, proteome, and metabolomics, can identify the molecular characteristics of diseases at the microscopic level, especially playing an important role in cancer diagnosis and personalized treatment. The amount of medical data is huge and complex, and how to effectively extract useful information from it remains a huge challenge. Many studies have begun to explore how to improve the accuracy and efficiency of medical diagnosis through intelligent algorithms and big data analysis technologies. Tian Miao's research [8] showed that by combining advanced artificial intelligence and machine learning algorithms, medical diagnosis can be automated and intelligent, especially in image analysis, pathological analysis, and disease prediction, where significant progress has been made. This data-driven diagnostic approach not only improves the accuracy of diagnosis, but also reduces the workload of doctors and promotes the intelligent transformation of the medical field.

Electronic medical records, as the main carrier of medical data, have been widely used in the global healthcare system. It records the entire process data of patients from initial visit to subsequent treatment, including medical history, examination reports, diagnostic conclusions, and medication use, becoming an important basis for clinical diagnosis. With the development of big data and cloud computing technology, researchers have begun to explore how to utilize these rich electronic medical record data to provide support for medical diagnosis. Early EMR diagnosis [9] mainly relies on the structuring and normalization of data for statistical analysis and decision support by doctors and researchers. Due to the heterogeneity and diversity of EMR data, unstructured data such as text, images, and audio are widely present, and traditional diagnostic methods have low efficiency in processing these data. The application of IoT technology [10-11] has brought new opportunities for the diagnosis of electronic medical records. Through wearable devices and implanted sensors, the Internet of Things can monitor patients' physiological data in real-time, including heart rate, blood pressure, blood sugar, etc., and seamlessly integrate these data into electronic medical record systems to achieve dynamic tracking and real-time diagnosis of patients' conditions. The EMR system combined with the Internet of Things can achieve remote monitoring and diagnosis through remote medical devices, providing an effective means for the continuous treatment of chronic disease patients. Diabetes patients can monitor the blood glucose level in real-time through the Internet of Things device, and upload the data to the EMR system. Doctors can adjust the treatment plan through the intelligent analysis results provided by the system. This electronic medical record diagnosis system, which combines IoT technology, is gradually improving the traditional medical diagnosis mode, enhancing diagnostic efficiency and accuracy. The Deep Multi-Scale Fusion Neural Network (DMFNN), as presented by Dinesh Kumar Reddy Basani et al. (2024), was designed for fault detection in IoT systems using data integration. Leveraging their fusion strategy, our framework processes diverse medical IoT datasets by extracting layered information and handling noise which improve diagnostic precision and operational reliability [12]. Naresh Kumar Reddy Panga (2022) utilized Discrete Wavelet Transform (DWT) for analyzing ECG signals in IoT-based health monitoring platforms. Drawing from their methodolody, their DWT approach is employed in our research to isolate features and diminish interference. This enables improved signal quality and reducing computational load, supports to achieve greater accuracy and timely analysis [13]. A structural model combining IoT, fog, and cloud computing was developed by Thirusubramanian Ganesan, (2021) enables continuous ECG surveillance using machine learning. This layered architecture is incorporated in our proposed scheme to manage medical IoT data streams and processing stages, which enhance scalability, and diagnostic accuracy [14]. Rajababu Budda (2021) developed a framework blending Artificial Intelligence and Big Data analytics tailored for IoT healthcare, concentrating on optimized performance and patient-focused services. Building on this foundation, our research narrows the focus of their conceptual framework with an emphasis on deep learning in our work to enable proficient medical data handling and insightful diagnosis, facilitating the creation of scalable, accurate, and real-time monitoring solutions while advancing diagnostic reliability and sustainable care delivery [15]. Sri Harsha Grandhi (2021) proposed an adaptive wavelet transform method combined with wearable IoT devices for effective pediatric health monitoring. Our system embeds this adaptive wavelet transform method to refine raw medical data before deep learning analysis. This ensures cleaner signals and accurate feature extraction through wavelet denoising, promotes stability and efficient real-time observation [16]. In recent years, significant progress has been

made in the application of deep learning technology in medical diagnosis, especially in the field of intelligent diagnostic algorithms. Deep learning is a branch of machine learning that automatically extracts features from massive amounts of data through multi-layer neural networks, and then performs classification, prediction, and decision-making. In the medical field, deep learning [17] is widely used in disease diagnosis, image analysis, genomics, and other fields, significantly improving the accuracy and automation of diagnosis. Early research mainly focuses on the use of convolutional neural networks in image diagnosis. Through automated analysis of medical images such as X-rays, deep learning algorithms can effectively identify pathological features such as tumors and lesions. The performance of the lung cancer image recognition system based on CNN [18] in tumor detection has approached or even exceeded the diagnostic level of human radiologists. Over time, the application of deep learning in processing unstructured data has also been widely studied. Recurrent neural networks and long short-term memory networks [19] are widely used to analyze electronic medical record text data, automatically extract key information from medical records, and dynamically predict the patient's condition. Attention mechanisms [20] and new deep learning architectures such as autoencoders have also been applied to the fusion and processing of medical data, enhancing the ability to analyze complex and multimodal data. Combining IoT technology, deep learning algorithms can process real-time medical data from different data sources, achieving personalized and accurate intelligent diagnosis. This intelligent diagnostic system not only improves the efficiency of medical resource utilization, but also provides strong support for personalized and remote healthcare.

This intelligent diagnostic system not only improves the efficiency of medical resource utilization, but also provides strong support for personalized and remote healthcare.

III. Methods

A. IoT Medical Data Collection and Preprocessing

1) Device deployment: In the integration of IoT technology and the medical field, selecting sensors and wearable devices that are suitable for the target disease and patient health status is the key to achieving personalized medicine. Real-time monitoring of various physiological parameters through sensor devices helps medical staff obtain comprehensive and dynamic health data. Heart rate sensors are used to monitor heart health, especially for patients with heart disease. Through implantable devices such as pacemakers, sensors can precisely measure the electrical activity of the heart, avoiding delays and errors in traditional methods. This type of device, when combined with external devices, can transmit heart rate data in real-time, providing strong support for remote diagnosis and emergency treatment. Changes in heart rate can reveal early heart problems, and timely intervention can greatly reduce the risk of sudden heart disease.

Blood pressure sensors are also important monitoring tools, especially for patients with hypertension, which can help doctors track blood pressure fluctuations in real-time. Traditional blood pressure monitoring methods require patients to manually measure blood pressure at regular intervals, and most of them are discrete data. Through wearable blood pressure monitoring devices, dynamic changes in blood pressure data can be continuously obtained. By installing on the arms, wrists, and other parts, based on IoT transmission, real-time data can be sent to the cloud for doctors to analyze.

Body temperature sensors are used for patients with fever, infections, and other diseases that require temperature monitoring. Body temperature is automatically monitored and continuous data streams are generated through non-contact or contact sensors placed on the forehead, ears, or wrist. Combined with the Internet of Things transmission network, data is uploaded in real-time to the hospital system, allowing doctors to remotely analyze the trend of temperature changes and predict the deterioration of the condition in advance. For patients with a long-term medical history or weak immune system, temperature fluctuations may be an early signal of infection or other potential problems. With the help of IoT devices, rapid detection and measures can be taken to reduce the probability of disease deterioration.

Blood glucose monitoring is a vital health management link for patients with diabetes. The blood glucose level is continuously detected through subcutaneous sensors, and the data is transmitted to intelligent devices in real-time to facilitate patient self-management. Doctors can automatically adjust medication doses or dietary plans based on historical data. This non-invasive and continuous monitoring method can improve patients' quality of life and greatly reduce the risk of acute complications.

The blood oxygen saturation sensor continuously monitors the oxygen content in the blood through optical sensors installed on fingers, earlobes, and other parts. The fluctuation of

blood oxygen levels is a key indicator for judging respiratory distress or abnormal lung function. Through real-time uploaded blood oxygen data from IoT devices, doctors can promptly determine whether patients need oxygen therapy or hospitalization. By combining multiple data sources such as heart rate and blood pressure, the IoT platform can conduct comprehensive analysis and generate personalized treatment plans through algorithms, helping patients achieve self-monitoring in a home environment and reducing hospitalization needs. The IoT data collection network is shown in Fig. 1.

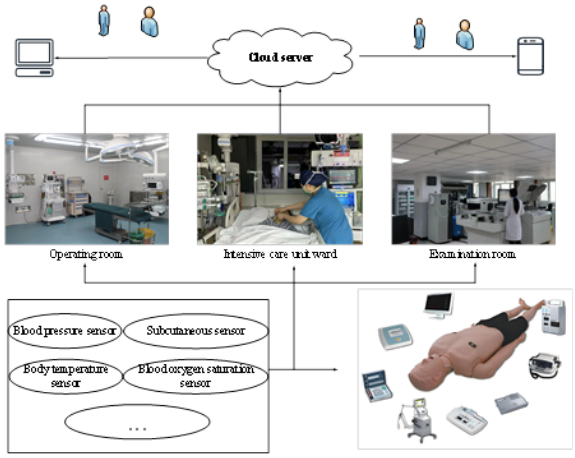

Fig. 1. IoT data collection network.

2) Data collection and transmission: Various physiological and non physiological data are collected through different types of sensors, including physiological signal data, medical imaging data, and clinical text data. Real-time physiological data collected by sensors is transmitted to a medical data management platform through wireless networks, and the data can be uploaded to the cloud in real-time, ensuring that all monitoring data can be continuously stored, updated, and analyzed without interruption. IoT devices can also interface with the hospital's electronic medical record system, ensuring that these real-time data can be seamlessly integrated with the patient's historical medical records.

This article is conducted in a tertiary comprehensive hospital, recruiting a total of 300 participants, all of whom are outpatient or inpatient patients. Among the subjects, 100 are healthy individuals for the control group, and another 200 are patients with different types of diseases, including five types of diseases: cardiovascular disease patients (60), diabetes patients (50), chronic obstructive pulmonary disease patients (40), hypertension patients (30), and chronic kidney disease patients (20). All participants sign informed consent forms before participation, and data is collected in real-time through IoT devices, covering physiological parameters such as heart rate, blood pressure, blood glucose, and blood oxygen saturation, aiming to evaluate the application effect and accuracy of the intelligent diagnostic system in different disease scenarios.

The data collection period is from June 2022 to December 2022, and the collected physiological data is shown in Table I.

In Table I, part of physiological data of a healthy individual is presented, with systolic and diastolic blood pressure data included in the blood pressure. Through IoT sensors, physiological data information of subjects can be accurately and continuously collected. The collected image data [21-22] are shown in Fig. 2.

TABLE I. DISPLAY OF PART OF PHYSIOLOGICAL DATA

Date	Blood pressure (mmHg)	Body temperature (°C)	Blood glucose (mg/dL)	Blood oxygen saturation (%)
2022-6-1	120/80	36.6	90	98
2022-6-2	118/79	36.7	88	99
2022-6-3	121/80	36.5	91	98
2022-6-4	119/78	36.6	89	99
2022-6-5	122/81	36.6	92	98
2022-6-6	120/79	36.7	90	99
2022-6-7	119/77	36.5	89	98
2022-6-8	121/80	36.6	91	99
2022-6-9	120/78	36.6	90	98
2022-6-10	119/79	36.5	88	99

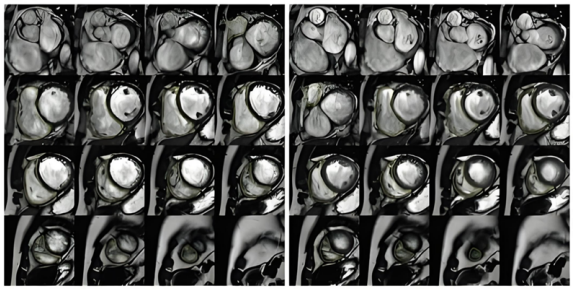

Fig. 2. Collected image data.

3) Data preprocessing: The data collected by IoT devices is noisy due to environmental interference, sensor accuracy, or other factors. To remove noise, Gaussian filters are used to smooth the data and reduce the interference of random noise. The kernel function formula for Gaussian filtering is:

$$G(x,y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \tag{1}$$

σ is the standard deviation, which controls the smoothness of the filter. In order to avoid the impact of missing data on the analysis results, data filling must be carried out. The formula for mean interpolation method is:

$$x(t) = \frac{x(\mathrm{t}-1) + x(\mathrm{t}+1)}{2} \tag{2}$$

$x(t)$ is the missing data at time point t , and $x(t-1)$ and $x(t+1)$ represent adjacent observations before and after.

Physiological signals such as heart rate, blood oxygen saturation, and blood pressure have different numerical ranges. Through standardization, is is ensured that data from each dimension falls within the same range. The standardized formula for Z -score is:

$$x' = \frac{x-\mu}{\sigma} \tag{3}$$

Due to the fact that IoT data may come from multiple devices, there may be inconsistencies in the data collected by each device at the same time or in the same scenario. Therefore, consistency checks and corrections are necessary before data fusion. By using time alignment and device calibration techniques, it is ensured that data from different sources accurately reflect the patient's status at the same time.

B. Multimodal Medical Data Fusion

In IoT healthcare systems, combining multiple data sources to form multimodal datasets provides more comprehensive diagnostic evidence. The collected physiological signal data, medical imaging data, and clinical text data are combined to form a multimodal dataset. After data integration is completed, feature extraction is performed for different types of data. The Word2Vec is used to automatically extract key disease descriptions, symptoms, and diagnostic information from clinical text data. For medical image data, CNN is used for automated feature extraction. LSTM is used to process dynamic changes in physiological data and extract key trend information. Word2Vec [23-24] is a deep learning model that automatically extracts disease descriptions, symptoms, and diagnostic information by capturing semantic relationships between words. Through training, Word2Vec is able to generate vector representations for each word, making words with similar meanings closer together in the vector space. The formula for calculating word vectors is:

$$v(w) = \frac{1}{T}\sum_{t=1}^{T}\log P\left(w_t \mid w_{t-n},\ldots,w_{t+n}\right) \tag{4}$$

CNN can effectively extract high-level features of input data by stacking multiple convolutional and pooling layers. Each convolutional layer performs feature mapping on the input data by applying convolutional kernels, as follows:

$$Z_{i,j} = \sum_{m=0}^{M-1}\sum_{n=0}^{N-1} X_{i+m,j+n}\cdot K_{m,n} + b \tag{5}$$

$Z_{i,j}$ is the output feature map, and K represents the convolution kernel. Maximum pooling is used to reduce the dimensionality and computational complexity of feature maps, and the formula is:

$$Z_{i,j} = \max_{m,n} X_{i+m,j+n} \tag{6}$$

By combining multi-layer convolution and pooling, CNN can automatically extract useful features from complex input data, enhancing the model's classification performance. LSTM can effectively capture long-term dependencies and solve the gradient vanishing problem by applying gating mechanisms. When processing physiological data, LSTM can analyze physiological parameters at different time steps in real-time, identify their dynamic trends, and provide support for intelligent diagnosis. This ability makes LSTM a powerful tool for processing complex time series data.

C. Design and Training of Deep Learning Models

1) Model architecture design: The model designed in this article integrates convolutional neural networks and long short-term memory networks [25-26], aiming to improve the intelligent diagnostic capabilities of medical image analysis and temporal physiological data processing. CNN is responsible for processing medical imaging data and effectively extracting lesion features from images through multi-layer convolution and pooling operations. Convolutional layers can capture local features and identify potential lesion areas in images, while pooling layers help reduce feature dimensions and enhance the model's focus on important features. This process enables the model to accurately identify pathological features in complex imaging data, improving diagnostic accuracy.

The model structure designed in this article is shown in Fig. 3.

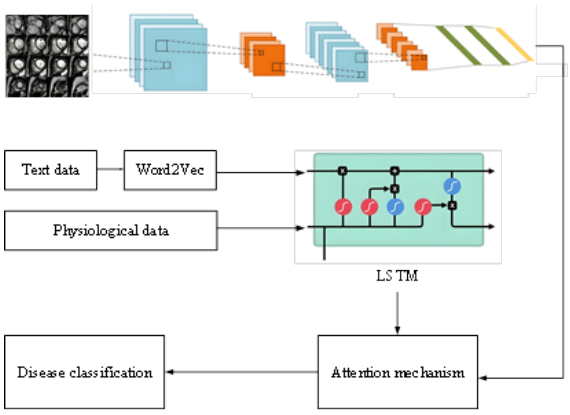

Fig. 3. Model structure.

2) Data annotation and model training: The annotation process involves associating the doctor's diagnostic results with input data, including medical imaging, time-series physiological data, and textual data. Doctors determine the diagnostic label and specific disease category for each sample based on imaging analysis and clinical evaluation results. Professional medical personnel are assisted to ensure the accuracy and reliability of the labels. Using multiple doctors for independent annotation and resolving annotation differences through collective discussion can further improve the consistency and objectivity of annotation results.

After annotation is completed, the dataset is divided into a training set and a test set, with 80% as the training set and 20% as the test set. Cross-validation method is used to further prevent overfitting of the model. By further dividing the training set into multiple subsets, the model undergoes multiple rounds of training and validation on different subsets, effectively reducing its dependence on specific data and ensuring the robustness and reliability of the model.

The model is trained using annotated multimodal data and the model parameters are optimized using the Adam optimizer. The Adam optimizer combines the advantages of momentum and adaptive learning rate, making the training process more efficient and stable. The cross entropy loss function is used to measure the performance of the model in classification tasks. The cross entropy loss function can be expressed as:

$$L(y, \hat{y}) = -\frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{c} y_{ij}\log\left(\hat{y}_{ij}\right)(7) \quad (7)$$

D. Diagnostic Accuracy Performance

Using CNN-LSTM for intelligent diagnosis, the confusion matrix results for different disease diagnoses are shown in Fig. 4.

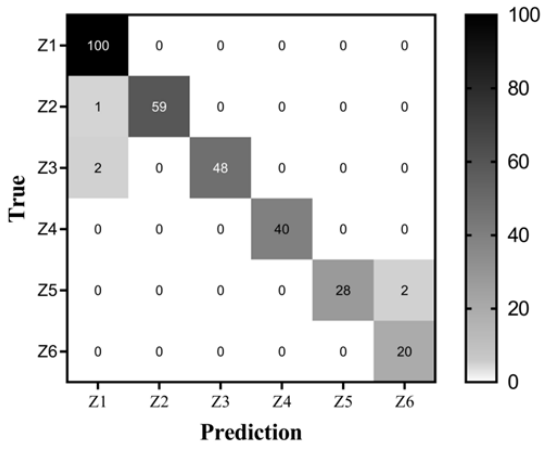

Fig. 4. Confusion matrix.

In Fig. 4, health, cardiovascular disease, diabetes, chronic obstructive pulmonary disease, hypertension, and chronic kidney disease are represented by Z1, Z2, Z3, Z4, Z5, and Z6 respectively. The CNN-LSTM model shows good classification ability in the classification tasks of six types of health conditions and diseases. All 100 healthy individual samples are correctly classified as Z1, indicating that the model has very high robustness in identifying disease-free individuals. For cardiovascular diseases, the model also shows excellent classification performance. Although the model correctly classifies 59 samples, one sample is misclassified as a healthy individual, indicating that the model may have a small margin of error in distinguishing healthy individuals from patients with mild cardiovascular symptoms. There is still high reliability in identifying patients with cardiovascular disease. In the classification of diabetes, the model correctly classifies 48 samples, and 2 samples are wrongly classified as healthy individuals. Some characteristics of diabetes patients may be similar to those of healthy individuals, leading to slight confusion of models. The classification performance of chronic obstructive pulmonary disease and chronic kidney disease is relatively excellent, with the model correctly classifying 40 and 20 samples, respectively, without any misclassification, demonstrating its reliable classification performance in these two types of diseases. Two samples of hypertension are misclassified as chronic kidney disease, which may be due to certain similarities in physiological signals or symptoms between the two types of diseases, resulting in confusion in the model. The CNN-LSTM model has high classification accuracy for different categories of diseases, but there are a few misclassifications between healthy individuals and certain chronic diseases.

The comparison results of accuracy for different disease categories are shown in Fig. 5.

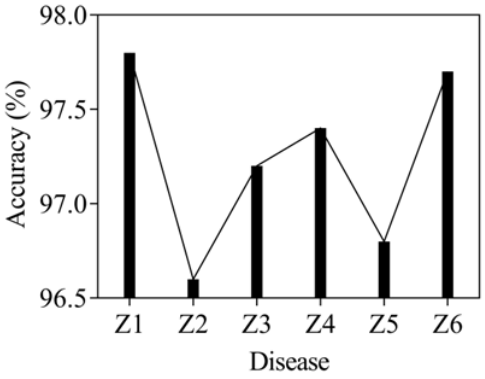

Fig. 5. Accuracy of different disease categories.

In the accuracy results of the model for different disease categories in this article, the CNN-LSTM model shows relatively stable and efficient accuracy in classifying various diseases. The accuracy rate of healthy individuals is 97.8%, indicating that the model can accurately identify disease-free individuals, which reflects the model's good ability to distinguish healthy samples. The accuracy of chronic kidney disease also reaches 97.7%, second only to healthy individuals, indicating that the model has high sensitivity and reliability in distinguishing kidney diseases. The accuracy rates of diabetes, chronic obstructive pulmonary disease and cardiovascular disease are 97.2%, 97.4% and 96.6% respectively, which means that the model can still maintain a high classification accuracy when dealing with these common chronic diseases. Although the accuracy of cardiovascular disease is slightly lower, it still maintains a high level of over 96%, proving that the model also has a certain degree of robustness in identifying cardiovascular disease. The classification accuracy of hypertension diseases is 96.8%, slightly lower than other categories, but the difference is not significant, indicating that the model also has a good recognition effect on blood pressure fluctuation diseases. Overall, the classification accuracy of the model is higher than 96% in all disease categories, indicating its excellent performance in multimodal data processing and feature extraction, with strong generalization ability and application potential.

E. Comparison with Baseline Model

In order to comprehensively analyze the intelligent diagnostic performance of the model in this article, it is compared with other models, and their performance are analyzed through AUC values. The AUC (Area Under the Curve) data is shown in Table II.

By evaluating the performance of different models on multimodal medical datasets using AUC metrics, the CNN-LSTM model significantly outperforms other models, exhibiting the highest AUC values (between 0.95 and 0.98). The advantage of CNN-LSTM lies in its effective integration of the characteristics of convolutional neural networks and long short-term memory networks: CNN excels at extracting spatial

TABLE II. AUC DATA TABLE

Disease	CNN-LSTM	CNN	LSTM	GRU (Gated Recurrent Unit)	RF (Random Forest)	SVM (Support Vector Machine)	Transformer
Z1	0.98	0.95	0.92	0.93	0.85	0.83	0.94
Z2	0.97	0.94	0.91	0.92	0.84	0.82	0.93
Z3	0.96	0.93	0.9	0.91	0.83	0.8	0.92
Z4	0.97	0.94	0.92	0.93	0.86	0.84	0.94
Z5	0.95	0.92	0.89	0.9	0.81	0.79	0.91
Z6	0.98	0.96	0.93	0.94	0.88	0.85	0.95

features from medical images, while LSTM can capture time-dependent changes in physiological signals provided by IoT devices, such as fluctuating trends in heart rate and blood pressure. Through this combination, the CNN-LSTM model can not only capture subtle lesion features in images, but also identify long-term change patterns in physiological data, greatly improving the diagnostic accuracy of diseases.

The separate CNN and LSTM models perform well in processing single modal data, but the AUC value is slightly lower due to the lack of processing capacity for another modal data. CNN performs well in image processing, with AUC values ranging from 0.92 to 0.96, while LSTM performs well in processing time series data, but with AUC values only between 0.89 and 0.93 in the absence of image data. Traditional machine learning models, random forests, and support vector machines perform the worst, with AUC values ranging from 0.79 to 0.88, mainly because they rely on manual feature extraction and cannot fully exploit complex features in multimodal data.

The analysis results of Kappa coefficient and Matthews correlation coefficient are shown in Fig. 6.

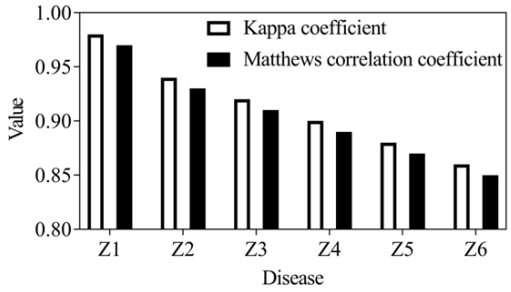

Fig. 6. Analysis results of Kappa coefficient and matthews correlation coefficient.

The CNN-LSTM model performs well in the diagnosis of multiple types of diseases, especially in healthy individuals and cardiovascular diseases. The Kappa coefficient and Matthews correlation coefficient are both close to 1.0, indicating that the model has very high classification accuracy and consistency for these two categories. A Kappa coefficient close to 1 means that the consistency between the model's predictions and the true labels is very good, avoiding the influence of random classification; MCC is a more comprehensive evaluation indicator that takes into account the balance between true positives, false positives, true negatives, and false negatives. With the increase of disease complexity, Kappa and MCC slightly decrease in chronic obstructive pulmonary disease, hypertension, and chronic kidney disease, but still remain above 0.85, demonstrating the robustness of the model in the diagnosis of complex diseases. CNN-LSTM can effectively capture features in imaging and physiological data, but the overall performance of the model may be affected by the imbalance of some datasets or the ambiguity of certain features. The CNN-LSTM model exhibits strong generalization ability and consistency when processing multimodal data, and has high diagnostic accuracy.

F. Ablation Experiment

The macro-average precision can measure the performance of multi-class classification, and the ablation experiment results are shown in Table III.

TABLE III. RESULTS OF ABLATION EXPERIMENTS

Fold number	CNN-LSTM (%)	CNN (%)	LSTM (%)
1	96	93	92
2	95	92	91
3	97	94	92
4	96	93	91
5	95	92	91
6	96	93	92
7	97	94	92
8	95	92	91
9	96	93	92
10	97	94	92

The macro-average precision of the CNN-LSTM model performs the best in 10 folds, maintaining between 95.0% and 97.0%, demonstrating its robustness and superior performance in multimodal medical data classification tasks. The macro-average precision of the CNN model ranges from 92.0% to 94.0%, slightly lower than that of the CNN-LSTM, indicating that the CNN model performs well in simple image processing but cannot fully utilize the information of temporal data. The macro-average precision of the LSTM model ranges from 91.0% to 92.0%, mainly due to its emphasis on temporal feature extraction but lack of CNN's ability to process image features. The CNN-LSTM model significantly improves the performance of multimodal data classification by combining the image feature extraction capability of CNN and the temporal feature processing advantage of LSTM, making it suitable for application in complex medical diagnosis scenarios.

G. Diagnosis Time

The diagnostic method in this article is compared with the traditional electronic medical record diagnostic method, and the comparison of diagnostic time is shown in Fig. 7.

For healthy individuals, this method only takes 15 seconds, while traditional diagnostic methods require 200 seconds, with a significant difference. In the diagnosis of cardiovascular diseases, this method takes 18 seconds, while the traditional method takes 211 seconds, showing a significant improvement in efficiency. Diabetes and chronic obstructive pulmonary disease take 16 seconds and 14 seconds respectively, which show faster response time compared with the traditional 156 seconds and 145 seconds. For hypertension and chronic kidney disease, the diagnostic method in this article is also more efficient, completing diagnosis in 19 seconds and 17 seconds

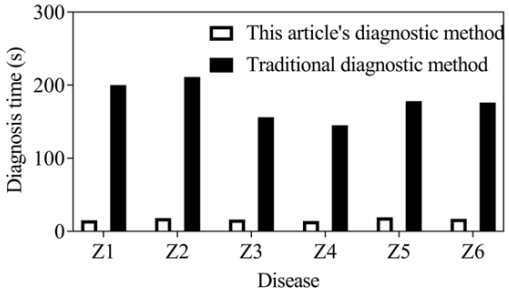

Fig. 7. Diagnosis time.

respectively, while traditional methods require 178 seconds and 176 seconds. This indicates that models based on CNN-LSTM can quickly and efficiently process multimodal data, especially in the context of the Internet of Things, greatly reducing diagnostic time and helping to monitor patients' health status in real-time and provide timely personalized treatment plans.

IV. Conclusions

This article proposes a multimodal diagnostic model based on CNN-LSTM, which significantly improves the accuracy and efficiency of chronic disease diagnosis by combining medical imaging data, temporal physiological data, and clinical text data. This model has achieved high accuracy in the classification tasks of healthy individuals and cardiovascular diseases, diabetes, chronic obstructive pulmonary disease, hypertension and chronic kidney disease, and is superior to traditional diagnostic methods. This achievement not only provides more precise diagnostic tools for clinical medicine, but also provides patients with faster health monitoring methods, which has important practical significance. This article combines multimodal data fusion with deep learning algorithms to promote the development of intelligent healthcare. Despite achieving a series of positive results, the research still has limitations, such as a relatively small sample size, which may affect the model's generalization ability. In addition, the performance of models in handling specific diseases may also be limited by the quality and diversity of input data. Future research can focus on expanding the sample size, enhancing the adaptability and robustness of the model, and exploring the combination of other deep learning architectures with traditional methods to further enhance the application potential of the model in complex clinical scenarios. Through continuous optimization and improvement, this study has laid the foundation for achieving more intelligent and personalized medical services.

Graph Neural Network Output for Dataset Duplication Detection on Analog Integrated Circuit Recognition System

Arif Abdul Mannan[1], Koichi Tanno[2]
Faculty of Engineering, University of Miyazaki, Miyazaki, Japan[1, 2]
Department of Electrical Engineering, Brawijaya University, Malang, Indonesia[1]

***Abstract*—In the need for artificial intelligence application on the analog circuit design automation, larger and larger datasets containing analog and digital circuit pieces are required to support the analog circuit recognition systems. Since analog circuits with almost similar designs could produce completely different outputs, in case of poor netlist to graph abstraction, larger netlist input circuits could generate larger graph dataset duplications, leading to poor performance of the circuit recognition. In this study, a technique to detect graph dataset duplication on big data applications is introduced by utilizing the output vector representation (OVR) of the untrained Graph Neural Network (GNN). By calculating the multi-dimensional OVR output data into 2-dimentional (2D) representation, even the random weighted untrained GNN outputs are observed to be capable of distinguishing between each graph data inputs, generating different output for different graph input while providing identical output for the same duplicated graph data, and allowing the dataset's duplication detection. The 2D representation is also capable of visualizing the overall datasets, giving a simple overview of the relation of the data within the same and different classes. From the simulation result, despite being affected by the floating-point calculation accuracy and consistency deficiency, the F1 score using floating-point identical comparisons are observed with an average of 96.92% and 93.70% when using CPU and GPU calculations, respectively, while the floating-point rounding calculation is applied. The duplication detection using floating point range comparison is the future work, combined with the study of the 2D GNN output behavior under the ongoing training process.**

I. INTRODUCTION

In computer science, graph have been use in many complex structures, especially structures that focus on the objects (nodes or vertices) and its connections (edges), including chemical structure, human social connection and behavior, electronics circuits, internet World Wide Web, biological structure[1]-[4], etc. In some specific applications, especially in the analog circuit design, the graph can even enable the artificial intelligence (AI) to be applied to the analog electronic design automation (EDA) using graph neural network (GNN) based recognitions [5]-[7].

For global applications, large graph data is something unavoidable. The real-world graph can reach the order of trillion nodes and edges, opening new challenges for graph duplication detection, in case identical graphs exist in the large data[3][4]. In line with the current situation, for large data applications in the analog circuit design field, graph data duplication challenge has also emerged. To generate large datasets, an extraction technique explained in [8] is used. The text-based netlist is used as input, and, split netlist is generated as the output. By using multiple EDA-generated netlists or by using a manually created netlist, duplication of the same circuit extracted from different areas of multiple analog circuits (like a current mirror circuit) are observed to happen frequently [9], as shown in Fig. 1.

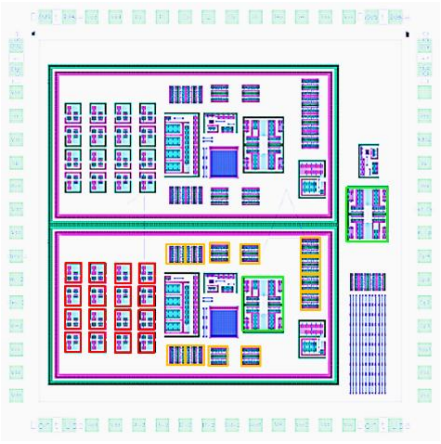

Fig. 1. A dye photograph of analog circuit used as simulation input data in [8] shows multiple uses of the same circuit in various areas inside the red, green, and orange squares

Furthermore, for AI training and circuit recognition, the text-based netlist is converted into graph dataset using netlist to graph abstraction. The recognition accuracy and training performance is dependent on the abstraction technique [10]-[13]. Despite different circuit netlist are used as abstraction process input data, with poor abstraction technique, duplicate graphs occur, reducing the recognition accuracy; thereby, increasing the necessity of graph duplication detection.

The technique to detect graph duplication in large data is already proposed [1][3][4] [14]. However, the technique to detect graph duplication in the literature is directly calculated from the graph data itself. In this study, graph duplication detection technique is proposed by using an integration with GNN recognition, determining the duplication status by calculating the GNN recognition output results.

This study is arranged as follows: The conversion of multi-dimensional data into 2-dimensional (2D) data and the graph duplication detection techniques are introduced in Section II. The accuracy and consistency susceptibility of the floating-point calculation and the methods used to overcome the weakness are described in Section III. The simulation results are provided in Section IV, while the concluding remarks are provided in Section V.

II. GRAPH TO 2-DIMENTION INFORMATION CONVERSION

In this study, a new technique to detect graph duplication on a graph dataset is proposed. The new technique is done by utilizing the GNN output vector representation, calculating the output result and then determining the identical status of the graph. This technique is inspired by an event of a certain failure in the GNN training and recognition of two identical graphs (with different classes) due to the same output and the same error generated. Before discussing the duplication detection technique, the graph datasets and the GNN outputs are first explained.

For graph datasets, considering an owned dataset contains $\mathcal{V}$ number of graph information as $\mathcal{G}(\mathcal{V},\mathcal{E})$ with input features $\{x_v, \forall_v \in \mathcal{V}\}$, has variate number of vertex (node v) and edge (ε) array length on every graph. To detect graph duplication, variate dimension and number of vertices and edges are directly calculated [4]. In this study, to reduce the variation of multiple number of $\mathcal{V}$ and $\mathcal{E}$ array length, GNN output vector representation (OVR) z_v is used as a conversion tool, eliminating the variation of the vertex and edge information into a fixed C dimensional output (C is the number of classes in the dataset). Using this C dimensional data as a source of information, 2D data is then generated.

$$z_v = h_v^{(L)} \quad , \forall v \in \mathcal{V} \tag{1}$$

The GNN OVR z_v is obtained from every neighborhood vector $h_v^{(l)}$ for all $v \in \mathcal{V}$ as shown in Eq. (1). In this study, four GNN models are used, as follows:

1) Graph Convolutional Network (GCN) [19],
2) Graph Isomorphism Network (GIN) [20],
3) Graph Attention Network V2 (GAT) [21], and
4) GraphSAGE (GSG) [22].

The aggregation formula for each GNN used is shown in TABLE I.

TABLE I. GRAPH NEURAL NETWORK FORMULA

Model	Aggregation Formula
GCN	$\boldsymbol{h_v^{(l)} = \sigma\left(b^{(l-1)} + \sum_{k\in N_v} \frac{1}{c_{vk}} W^{(l-1)} h_k^{(l-1)}\right)}$
GIN	$\boldsymbol{h_v^{(l)} = MLP^{(l)}\left((1+\epsilon^{(l)})\cdot h_v^{(l-1)} + \sum_{k\in N_v} h_k^{(l-1)}\right)}$ * *MLP* is a multi-layer perceptron
GSG	$\boldsymbol{h_{N(v)}^{(l)} = mean\left(\{h_k^{(l-1)}, \forall k \in N(v)\}\right)}$ $\boldsymbol{h_v^{(l)} = \sigma\left(W \cdot concat(h_v^{(l-1)}, h_{N_v}^{(l)}, b^{(l-1)})\right)}$ $\boldsymbol{h_v^{(l)} = h_v^{(l)} / \|h_v^{(l)}\|2}$
GATv2	$\boldsymbol{e_{vk}^{(l-1)} = LeakyReLU(a^T \cdot [W^{(l-1)} h_v^{(l-1)} \| W^{(l-1)} h_k^{(l-1)}])}$ $\boldsymbol{a_{vk}^{(l-1)} = softmax_k(e_{vk}^{(l-1)})}$ $\boldsymbol{h_v^{(l)} = \sigma\left(\sum_{k\in N_v} a_{vk}^{(l-1)} W^{(l-1)} h_k^{(l-1)}\right)}$

B. Two Points Distance Value

Multi-dimensional reduction using UMAP and TSNE is already proposed in [15]-[17]; however, since stochastic algorithms are used, the reproducibility is uncertain, especially when using multi-threaded [18]. In this study, a new consistent 2D data generation from C dimension data is proposed. The first dimension of the two data generated is the "distance", simply calculating the distance between two points of data on the C dimensional space into one scalar number. Consider the GNN OVR z_v structure shown in Eq. (2):

$$z_v = \left(z_{v_1}, z_{v_2}, z_{v_3}, \cdots z_{v_C}\right), \forall v \in \mathcal{V} \tag{2}$$

To calculate the "distance" parameter ($prDist$), Pythagorean theorem is used, calculated by choosing one graph OVR result as a reference point, and calculating the $prDist$ of the point under test OVR result by Eq. (3):

$$prDist_p = \begin{cases} \sqrt{\sum_{i=1}^{C} (z_{r_i}^2 - z_{p_i}^2)} & at\ r \neq p \quad r,p \in \mathcal{V} \\ 0 & at\ r = p \quad r,p \in \mathcal{V} \end{cases} \tag{3}$$

With z_r and z_p is vector value of the reference point and point under test in the C dimension output, respectively.

Since the $prDist$ in Eq. (3) uses a square root operation to get the distance, the performance impact is expected if a big dataset is applied as the calculation input. Instead of using the square root, the distance between two points can be calculated using pseudo-distance as shown in Eq. (4). The pseudo-distance is calculated simply by using the sum of the absolute value of every axis's scalar value difference between two points.

$$prpDist_p = \sum_{i=1}^{C} \left|z_{r_i} - z_{p_i}\right| \tag{4}$$

The $prDist$ will have different values from the $prpDist$ with the relationship expressed in Eq. (5). The minimum real distance value of $prDist$ will be equal to the value of $prpDist$ divided by the square root of C in case of equal distance of every axis of the two points take place, as shown in Eq. (6). The maximum distance value of $prDist$ will be equal to the value of $prpDist$ in case of two points axis difference, and has only occurred on one axis x, as shown in Eq. (7), with $1 \leq x \leq C$.

$$\frac{prpDist}{\sqrt{C}} \leq prDist \leq prpDist \tag{5}$$

$$\left|z_{r_1} - z_{p_1}\right| = \left|z_{r_2} - z_{p_2}\right| = \cdots = \left|z_{r_C} - z_{p_C}\right| \tag{6}$$

$$\left|z_{r_i} - z_{p_i}\right| = \begin{cases} prDist_p & when\ i = x \\ 0 & when\ i \neq x \end{cases} \tag{7}$$

The pseudo-distance will have an inaccurate value compared to the real distance. However, the consistency of the calculated value is reliable.

C. Two Points Difference Value

The second data generated after the $prpDist$ data is the "difference", calculating the relative difference between two points of OVR data on the C dimensional space into one scalar number $prDiff$. The relative difference $prDiff$ is also calculated by considering one point of OVR in the C dimensional space as a reference point z_r, and considering another OVR C dimensional point as a point on test z_p.

The first step to calculate the $prDiff$ is by element-wise subtraction between the reference point z_r and the point on test z_p. The element-wise subtraction result is then multiplied by the normalized array of the reference point to produce a relative representation array (RRA). Since the normalized reference point array consists of a fractional number with a range from $0 \leq n_r \leq 1$ and is calculated using Eq. (8), RRA will calculate the element-wise subtraction based on the strong point and weak point of the reference point. The strong points will give large weight to the RRA, and vice versa; weak points will give small weight to the RRA. Therefore, how strong the C dimensional point on a test compared to the reference point is completely described by the RRA.

$$N_r = \frac{z_r - z_{r_{min}}}{z_{r_{max}} - z_{r_{min}}} \tag{8}$$

The final step to calculate the $prDiff$ is by summing all elements on the RRA into a single scalar value. The calculation to generate $prDiff$ value is expressed in Eq. (9).

$$prDiff_p = \sum_{i=1}^{C} (z_{r_i} - z_{p_i}) n_{r_i} \tag{9}$$

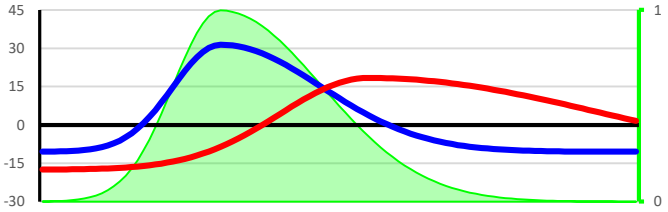

Fig. 2. Positive value of $prDiff$, in area of the normalized reference point (green), the reference point (blue) have higher value relative to the point on test (red).

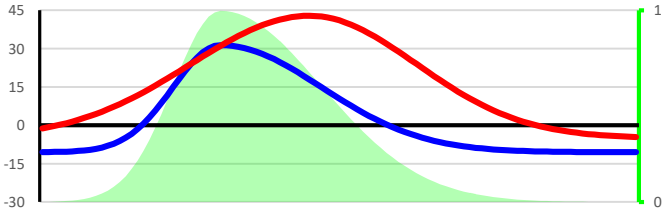

Fig. 3. Negative value of $prDiff$, in area of the normalized reference point (green), the reference point (blue) have weaker value relative to the point on test (red)

Since the relative representation array obtained from z_r subtracted by z_p, the positive value of $prDiff$ represents that the total strong point of the reference point is stronger than point on test as shown in Fig. 2, and the negative value of $prDiff$ representing the total strong point of the reference point is weaker than the point on test as shown in Fig. 3.

D. Duplication Detection

In this study, the duplication detection is done by using identical comparison of the $prpDist$ and $prDiff$ of every graph OVR on the dataset. To begin with, to calculate $prpDist$ and $prDiff$, a reference graph OVR is required, therefore, for convenience, the first graph OVR is selected as reference, specify the index value $r = 0$. With the reference graph OVR has been set, the $prpDist$ and $prDiff$ could be calculated for every other graph OVR in the datasets and the duplication detection can be calculated.

The identical $prpDist$ and $prDiff$ value of two graph under the test have meaning that the "distance" and the "difference" of the two OVR point relative to the reference OVR point is just the same; therefore, the two graphs under the test could be concluded as an identical graph pair. Otherwise, different $prpDist$ and $prDiff$ value of two OVR points means that the two graphs under the test are not identical. The calculation to obtain the graph duplication is shown in Algorithm 1.

Algorithm 1: Duplication Detection

```
PROGRAM Compare()
INPUT z_v
OUTPUT CompOut, CompResult
Compute
for v in V do
prpDist ← cal_dist(z_0, z_v)
prpDiff ← cal_diff(z_0, n_0, z_v)
end for
for i, Dist in prpDist do
CompOut[t][i] ← (prpDist – Dist) == 0
end for
for i, Diff in prpDiff do
CompOut[f][i] ← (prpDiff – Diff) == 0
end for
CompResult ← logical_and(CompOut[t], CompOut[f])
return CompOut, CompResult
```

E. Duplication Detection Scalability

For scalability, in case of a new graph is registered on the dataset, the recalculation of previous $prpDist$ and $prDiff$ are unnecessary. Only new registered graphs are required for $prpDist$ and $prDiff$ calculation, calculated using the same GNN (for obtaining the new registered OVR graph) and by using the same reference OVR graph, same as the other previous already existed graph. The duplication detection for the new graph is then calculated by comparing the new acquired $prpDist$ and $prDiff$ with the previous already calculated $prpDist$ and $prDiff$ one.

III. Accuracy and Consistency

In today's modern computers, floating point numbers represented by the IEEE 754 standard (standard floating-point

or SFP) is used. The floating point calculation in IEEE 754 have limited accuracy and consistency, accurate only about 7 decimal digits for single precision and about 16 decimal digits for double precision, while the bitwise identical output results are not guaranteed even using the identical input and identical mathematical equations [23]-[25].

In this study, SFP is used in all calculations. Starting from the GNN recognition, OVR result calculation, until the identical comparison for the duplication detection. Therefore, some errors due to inaccuracy and inconsistency are to be expected.

A. False Negative Result

As shown in Algorithm 1, the operation to obtain the duplication is by element wise identical comparison. Since the SFP operation is suspected to be affected by the calculation inaccuracy and inconsistency, a test using single graph calculated twice is observed to give a different result, generating a non identical graph detection or false negative result.

In some cases, the result inconsistencies are observed to apply starting from as low as 4 decimal digits of the calculated output (PyTorch tensor calculation using GPU). Therefore, to overcome this inconsistency, rounding algorithms are used with the suspected inaccurate decimal digits that are neglected and replaced with zeros.

In this study, the rounding algorithm is applied at the GNN output vector representation result and at the $prpDist$ and $prDiff$ calculation output. The number of decimal digits maintained is set to 4 decimal digits, for both CPU and GPU calculation. As an example, the value of $x = 1.23456789012 * 10^{-5}$ will be rounded to the value of $x = 1.23450000000 * 10^{-5}$.

B. False Positive Result

The rounding algorithm is expected to reduce the false negative result. However, a new false positive result condition is introduced by applying the rounding algorithm. A pair of the two almost similar graphs, with the GNN OVR differences smaller than the value of the neglected decimals, is observed to be detected as the same identical graph. For the number of decimal digits on the rounding algorithm, as more decimal digits are maintained, the false positive result is expected to appear less, and the false negative result reduction is expected to be weaker.

C. Special False Positive Case

In the duplication detection algorithm, a special false positive case has been observed once. Since the GNN neural network (NN) weight used as the input of the duplication detection is randomly generated and untrained, one occurrence of completely mirrored GNN output is observed as illustrated in Fig. 4.

When the GNN OVR of the reference point (Fig. 4 blue line) has a mirror result characteristic, as expressed in Eq. (10), and when the GNN OVR of graph 1 on test (Fig. 4 green line) and graph 2 on test (Fig. 4 red line) have the same identical OVR results and lie in each mirroring area for the reference point GNN OVR, a special false positive condition is observed. Every element-wise subtraction between the reference and graph 1 on the test completely finds its pair in the subtraction between the reference and graph 2 on a test, as expressed in Eq. (11). Therefore, the total calculated $prpDist$ and $prDiff$ on both graphs will be equal, and the duplication detection will consider graph 1 and graph 2 as identical graph.

$$z_{r_i} = z_{r_j} \quad , i + j = C - 1 \tag{10}$$

$$\left| z_{r_i} - z_{p1_i} \right| = \left| z_{r_j} - z_{p2_j} \right| \tag{11}$$

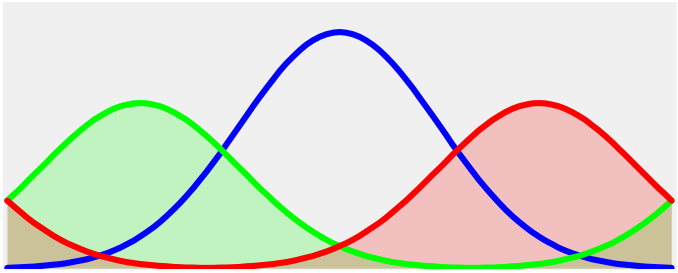

Fig. 4. False positive condition, the reference (blue), test graph 1 (green) and test graph 2 (red). The x-axis is the GNN dimension output from 1 to C, and the y-axis is the scalar value of the GNN output.

D. Second Level Comparison (SLC)

To detect false positive detection cases, a second level comparison (SLC) is proposed. As stated in Section II(D), for the duplication detection, the first graph in the dataset is selected as the reference graph. However, in the SLC, one of two graphs detected as identical graph will be selected as the reference. Therefore, the calculation will only produce one $prpDist$ and one $prDiff$, representing the "distance" value and the "difference" value between the two presumed to be identical graphs under the duplication detection result. If the $prpDist$ and $prDiff$ proved to be equal to 0, the two graphs are indeed identical. The SLC calculation is shown in Algorithm 2.

Algorithm 2: Second Comparison

```
PROGRAM ReComp()
INPUT CompResult, CompResultY, tensorh
OUTPUT CompResult
Compute
for Ident in CompResultY do
DatRef ← tensorh[Ident[0]]
DatNorm ← normtensor(tensorh[Ident[0]])
DatTest ← tensorh[Ident[1]]
rprpDist ← callpdist(DatRef, DatTest)
rprDiff ← callDiff(DatRef, DtaNorm, DatTest)
if rprpDist ≠ 0 or rprDiff ≠ 0 do
CompResult[Ident[0]][Ident[1]] ← False
end if
end for
return CompResult
```

Despite being capable of detecting a false positive case, the SLC is observed to introduce a new false negative case by

detecting the true positive identical pair as a non-identical pair and change into false negative as shown in Fig. 5.

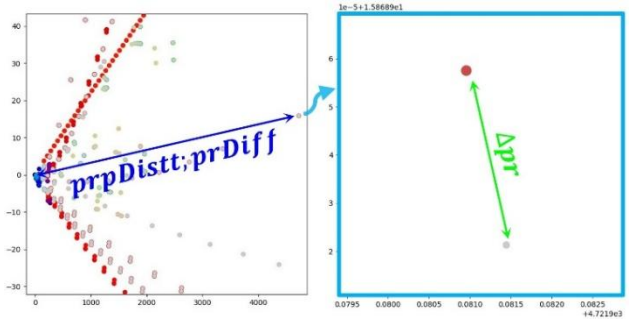

Fig. 5. Second Level Comparison on confirmed true positive identical pair, resulting in a false negative detection due to floating point inaccuracy.

The SFP accuracy is accurate until 7 decimal digits for FP32, as for the value after decimal digit 8 will be considered inaccurate. Since the value of $prpDist$ and $prDiff$ of the graph pair under observation in Fig. 5 is in the order of $5x10^3$, and the delta value between two points in pair Δpr is in the order of 10^{-5}, the Δpr value if these confirmed identical graphs is indeed the result of floating point inaccuracy. In the graph duplication calculation in Algorithm 1, the global reference graph (datasets [0]) is used. Since the Δpr is far from the most significant digit of the $prpDist$ and $prDiff$ (10^{-8} order difference, as a result of the inaccuracy area of SFP calculation), Δpr is observed as 0, and the true positive graph pair is indeed detected as an identical pair. However, in the second level comparison (one of the two graphs becomes the new reference point), the graph duplication detection calculation is based on the Δpr (with value in the order of 10^{-5}) instead of the old $prpDist$ and $prDiff$, which is the subject of inaccuracy. Therefore, the graph pair shown in Fig. 5 (right) is detected as a non-identical pair (false negative) after SLC.

IV. SIMULATION

For dataset duplication detection simulation, the GCN, GIN, GSG, and GAT models are used for generating the GNN OVR before the $prpDist$ and $prDiff$ calculation is done. Furthermore, for the input datasets, the two netlist to graph abstraction technique from [13] is used, with the circuits included in the netlist datasets are obtained using the split technique in [8] as shown in TABLE II.

TABLE II. DATASET FEATURE

Datasets Feature	Quantity
Number of data	2,115
Number of classes	121
Min data per class	1
Max data per class	795
NETLIST length	5,214,505
NETLIST number of line	95,615
Number of MOSFET(s)	74,626
Number of Power Supply(s)	4,234
Number of Resistors(s)	7,804
Number of LC(s)	11

The first two netlists for graph abstraction in [13] are in 1-node with multi-edge and connection node additions (1NMC). Afterwards, the second abstraction is in a 4-node with connection node addition (4NC). In this study, the 1-node with the addition of multi-edge, node connection, and edge direction optimization (1NMC+D) is introduced as the new, more optimized netlist to the graph abstraction technique after the 1NMC duplication detection result is studied. The dataset's confirmed parameters are shown in TABLE III.

TABLE III. DATASETS CONFIRMED PARAMETER

Parameter	1NMC [13]	1NMC + D	4NC [13]
Different Class Dispute	797	1	0
Max Theoretical Accuracy	62.32%	99.95%	100%
Same Class Group Duplication	0	0	0

For all simulations of the duplication detection, including the CPU and GPU calculations, the first graph in the dataset is set as the reference point. The number of decimal digits maintained at the rounding algorithm is also set to 4 decimal digits. A personal computer with 10850K CPU, 64GB of RAM, RTX 4070 Ti GPU, Windows 10 system, and python environment with PyTorch for neural network computing is used for simulation in this research.

A. The 2D Dataset's Visualization

As the $prpDist$ and $prDiff$ of all graphs are already calculated and obtained, a 2D visualization of these two datasets can be achieved. Using the 1NMC and 1NMC+D datasets as an example, the 2D visualization of an untrained random weighted GNN is shown in Fig. 6 and Fig. 7, respectively. The x axis of Fig. 6 and Fig. 7 represents the $prpDist$ value, while the y axis represents the $prDiff$. The most left dark blue dot observed in Fig. 6 (upper) and Fig. 7 (upper) of all GNN outputs is a representation of the reference graph point, representing the $x = 0$ and $y = 0$ of each figure.

As shown in Fig. 6 (upper) and Fig. 7 (upper), the total visualization of all graphs is observed to have different characteristic between each GNN types. It shows that each GNN model indeed has different calculations and output behavior. A particular pattern of the graphs which fall into the same class is also observed.

Fig. 6 (down) and Fig. 7 (down) is the zoomed version of certain areas in Fig. 6 (upper) and Fig. 7 (upper) respectively. Aiming to focus on the visualization of the identical and non-identical graph pairs, Fig. 6 (down), shows the example of "zoomed" multiple two points overlapping each other, indicating multiple two points detected as identical pairs. With the poor netlist to graph abstraction in 1NMC, multiple grey dots are observed to be exactly on top of the red dot (the easiest example to be seen) in all GNN output. On the contrary, as shown in Fig. 7 (down), with optimized direction added to the netlist to graph abstraction technique, the multiple two points overlapping each other are no longer visible. Even in some cases the grey dots are still close to the red dots, as observed in Fig. 7 [down (b)], they are observed to be completely separated.

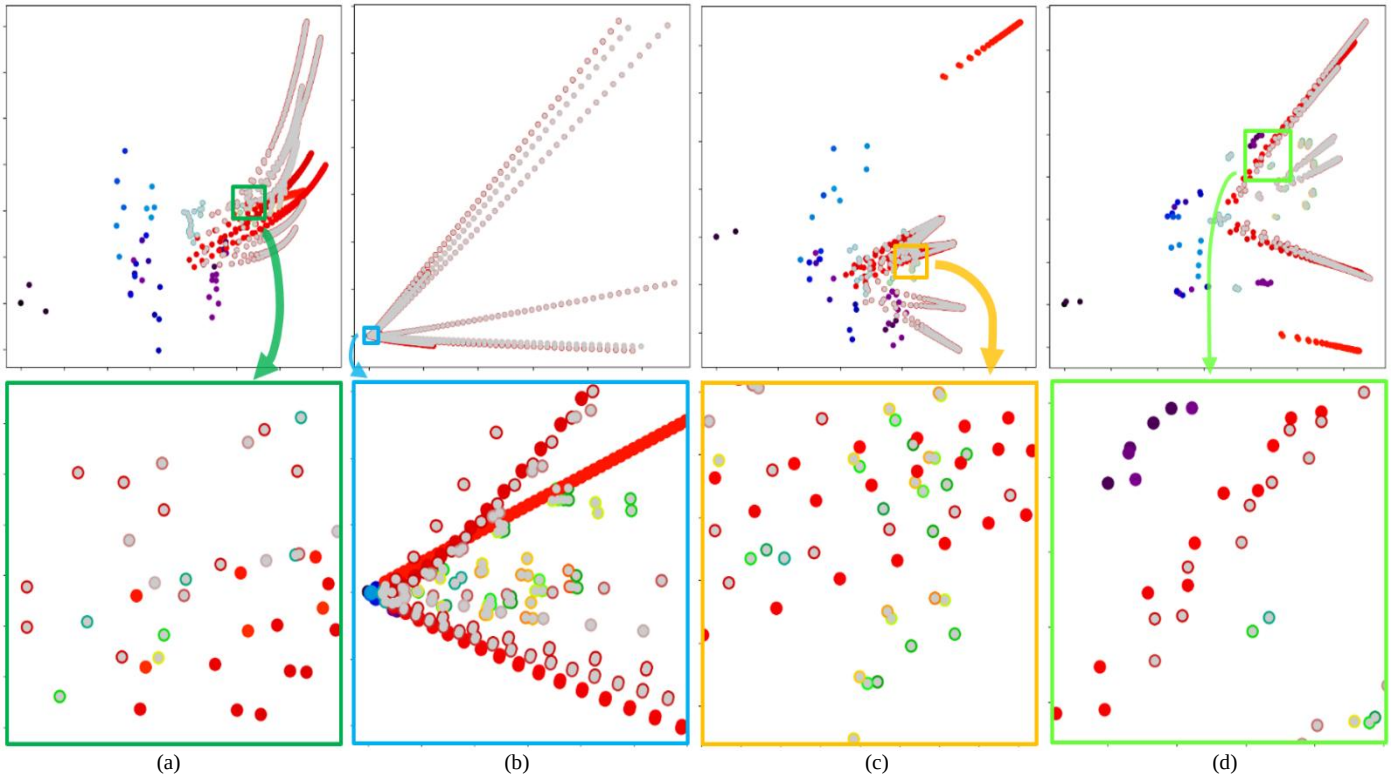

Fig. 6. The 2D output of untrained GCN (a), GIN (b), GSG (c), and GAT (d) of the input dataset using 1NMC netlist to graph abstraction in [13]

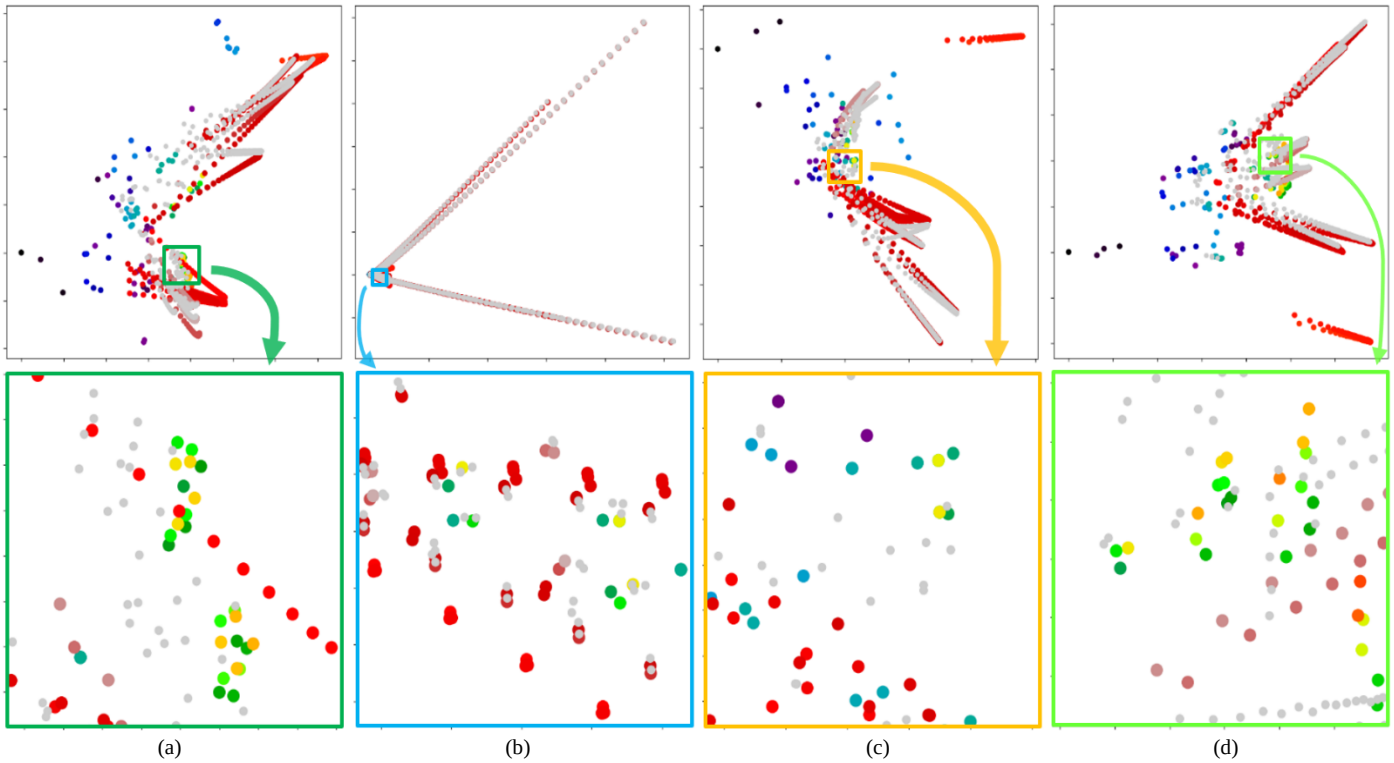

Fig. 7. The 2D output of untrained GCN (a), GIN (b), GSG (c), and GAT (d) of the input dataset using 1NMC + D netlist to graph abstraction

B. *Duplication Detection Result*

The graph dataset duplication detection simulation result for the SFP calculation with combination of SCL and rounded floating point (RFP) calculation with combination of SLC is shown in TABLE I and TABLE V respectively.

*) Requires all graph information of the confirmed true positive identical pair, complete with its identical graph counterparts.

The dispute items in TABLE I and TABLE V show the theoretical total number of uncertain graphs in the datasets if the GNN training and recognition are performed. As an example, an identical pair of two graphs has been detected, having indexes 31 and 278 (or expressed as [31, 278]) and having different classes assigned. When the recognition is performed, only one graph will be recognized correctly, and the other graph will be recognized as the other graph class. Therefore, in one identical pair, one graph will be counted as a dispute item.

In case of three identical graphs detected: [24, 334], [24, 1267], and [334, 1267], all with different classes, can also be expressed as [24, 334, 1267], which will have two dispute items. Since only one graph will be recognized correctly, the other two graphs will be detected falsely.

All the results shown in TABLE I and TABLE V are subject to floating-point inconsistency. Therefore, when the simulation is done repeatedly with the same simulation settings and formula, slightly different results are observed.

C. CPU IEEE 754 Calculation + SLC Simulation Result

From using the SFP calculation only, the CPU calculation result for 1NMC datasets is observed to be capable of detecting the graph duplication, with the number of identical graphs detected starting from 192 graphs to 419 graphs detected. However, the number of undetected identical pairs (false negative case) starts from 378 graphs to 611 graphs. According to the false negative result and datasets confirmed parameters in TABLE III, the F1 score started from as low as 37.61% (observed in GAT output result) and as high as 69.56% (observed in GIN), with an average of 60.21% observed.

For calculation after SLC, the number of identical graphs detected decreased, starting from 61 graphs to 184 graphs only, confirming the introduction of false negatives by second level comparison calculation. Therefore, the number of false negative detections observed increased, with the result starting from 472 graphs to 742 graphs. The F1 score is observed to decrease, starting from as low as 12.82% (in GAT) and as high as 57.88% (in GSG), with an average of only 37.87%. There is no change observed in false positive results after SLC calculation.

For calculated theoretical training accuracy from the detected dispute items, the 1NMC dataset shows a large deviation compared to the dataset's parameter shown in TABLE III. The deviation started from 17.78% to 28.89% with an average of 20.98%, and 22.27% to 35.08% with an average of 28.41% are observed in SFP and after SLC calculation result, respectively. Therefore, with the confirmed datasets, a theoretical training accuracy of 62.32%, the deviation of 35.08% (observed in GAT after SLC) is indeed a huge detection error.

For the 1NMC+D datasets simulation result, the SFP calculation could detect "the only one" confirmed identical pairs for all GNN outputs (zero false negatives). However, all GNN outputs are also detecting another non-identical graphs, with an average of 7.5 number of graphs and are reported as identical graphs (false positive case). The false positive cases are observed to belong to the same class, identical pair; therefore, it would not increase the dispute items at all (except 1 false positive dispute item detected in GSG). For calculation after SLC, there is no change observed, except for the GSG false positive reduction from 11 graphs to 8 graphs detected. The GSG dispute items are also reduced from 2 items to only 1 item. For calculated theoretical training accuracy, all GNN shows 0.00% deviation for all SFP calculations and after SLC calculation, except for GSG (SFP result) with 0.04% deviation.

For the 4NC datasets, since it is confirmed zero identical pairs, the false negative detection will always show 0. Therefore, the only parameter that could be considered is false positive detection. From the SFP calculation and after SLC, 1 graph detected as a false positive (same class) is observed in all GNN results except for GNC after SLC (0 false positives). For calculated theoretical training accuracy, all GNN shows 0.00% deviation for all SFP calculations and after SLC.

From the 1NMC, 1NMC+D and 4NC datasets on CPU calculation using SFP and SLC, the duplication detection shows high detection error (up to 93.10% duplication detection incapability error) on the datasets that have many confirmed identical pairs. However, the duplication detection shows high accuracy on datasets with a small, confirmed number of identical pairs. It is concluded that the floating-point inaccuracy and inconsistency are highly impacting the calculation result, resulting two identical graphs calculated with same calculation to give a different result, showing the identical pair as a non-identical pair.

From SFP and SLC calculations, the GAT result is observed showing the worst performance compared to other GNN. There is a possibility observed as the reason GAT output is so inaccurate when using SFP and with SLC calculation. The GAT NN size is so large (stored NN size is 4,455 KB in size) compared to the other GNN NN sizes (215 KB for GCN, 924 KB for GIN, and 351 KB for GSG), indicating more floating-point calculations are performed to obtain the GNN vector representation output. Therefore, the possibility of inaccuracy and inconsistency taking effect is also larger.

D. GPU IEEE 754 Calculation + SLC Simulation Result

The GPU calculation results, by using 1NMC datasets on SFP calculation, were observed to have worse performance compared to the CPU calculation. Due to the number of detected identical pairs being observed only from 5 graphs to 29 graph pairs, the false negative detection number is astonishing, starting from 769 graphs to 792 graphs (confirmed identical pair is 797). Therefore, the F1 score is observed only 1.25% (GSG) to 6.79% (GIN) with an average of 4.45%. For calculation after SLC, the detection capability is even worse. The duplication detection result shows that the calculation is failing to detect any duplication in the datasets (recall score is 0.00%), resulting in the theoretical training accuracy of 100%, although the confirmed theoretical value is 62.32%.

For the datasets 1NMC+D on GPU with SFP and with SLC calculation results, the duplication detection is failing to detect "the only one" confirmed identical pairs for all GNN outputs. The GIN output is even observed on detecting two other graph pairs, with one pair in the same class, raising 1 graph dispute item using the false positive detection. For the detection

capability, the GPU calculation is observed failing to detect the graph duplication (duplication detection capability is 0.00%) on both SFP and SLC calculations.

For GPU calculation on 4NC datasets, the SFP and SLC calculation result shows a consistent outcome in all GNN outputs. The number of identical pairs, false positives, false negatives, and disputed items is zero. The theoretical training accuracy is also observed to be 100% in all cases.

From the 1NMC, 1NMC+D and 4NC datasets on GPU calculation using SFP and SLC, the GPU calculation is concluded to be more severely affected by the floating-point inaccuracy and inconsistency compared to the CPU. The observed output calculation is so affected by this inaccuracy and inconsistency, almost rendering the duplication detection using the proposed method unable to produce the appropriate results at all.

E. CPU Rounding Floating-point + SLC Simulation Result

The CPU calculation results by using 1NMC datasets on RFP calculation, observed to have good performance compared to the SFP result. The number of detected identical pairs observed starts from 832 to 849, with an average of 839 graph pairs. The false negative detection number is observed starting from only 3 graphs until 8 graphs, with an average of 4.25 graph pairs. The F1 score is observed to start from 95.87% (GAT) to 97.48% (GSG), with an average of 96.92%. The number of false positives started from 38 graphs to 60 graphs, with an average of 46.25 graph pairs. For calculation after SLC, the detected false positive and false negative result is observed to have an average of 17.5 and 30.75 graph pairs, respectively. The F1 score is observed to start from 93.43% to 98.88%, with an average of 96.87%. For calculated theoretical training accuracy, the GNN result shows 0.38% to 1.00% and 0.00% to 3.68% deviation for RFP calculation and after SLC calculation, respectively.

For the datasets 1NMC+D on CPU with RFP calculation result, the number of detected identical pairs started from 25 to 114, with an average of 58 graph pairs, with all zeros in all GNN false negative results. The false positive result started from 24 to 113, with an average of 57 graph pairs being observed. For calculation after SLC, the number of detected identical pairs started from 14 to 83, with an average of 31.25 graph pairs, with all zeros in all GNN false negative results. The false positive result is observed to have started from 13 to 82, with an average of 30.25 graph pairs. For calculated theoretical training accuracy, the GNN result shows 0.19% to 3.02% and 0.04% to 3.02% deviation for RFP calculation and after SLC calculation, respectively.

For CPU calculation on 4NC datasets, the RFP calculation result shows a surprising outcome. The number of detected identical pairs increased compared to 1NMC+D, starting from 25 to 234, with an average of 86 graph pairs, with all the detected pairs observed as false positives. For calculation after SLC, the number of detected identical pairs and false positive outcomes is only 1 graph pair in all GNN results. For calculated theoretical training accuracy, the GNN result shows 0.95% to 6.86%, and 0.00% deviation for RFP calculation and after SLC calculation, respectively.

From the 1NMC, 1NMC+D and 4NC datasets on CPU calculation using RFP and SLC, the CPU calculation is capable to produce good results by having very high duplication detection capability. However, despite a high duplication detection capability is observed, the number of false positive detections is rather high, confirming the false negative reduction and new false positive introduction with the rounding calculation application. For SLC calculation, since the false positive results tend to be reduced and the new false negative results tend to be introduced, the detection capability is somewhat observed to be balanced, equalizing between false positive and false negative. This balance result (is it good or bad?) is not discussed in this study.

The RFP output calculation is observed to be less affected by floating-point inaccuracy and inconsistency, rendering the duplication detection using the proposed method able to detect more than 96.14% of the confirmed identical graph pairs.

F. GPU Rounding Floating-point + SLC Simulation Result

The GPU calculation results by using 1NMC datasets on RFP calculation show that the number of detected identical pairs observed started from 710 to 820, with an average of 786.5 graph pairs. The false negative detection number is observed to start from 21 to 126, with an average of 86 graph pairs. The F1 score is observed starting from 89.05% to 96.22% with an average of 93.70%. The number of false positives started from 39 to 52, with an average of 44 graph pairs. For calculation after SLC, the detected false positive and false negative result is observed to have an average of 14.75 and 287.75 graph pairs, respectively. The number of false negative detections observed increased, starting from 150 to 395 graph pairs. The duplication detection capability is observed to decrease, starting from 66.94% to 88.93%, with an average of 76.56%. For calculated theoretical training accuracy, the GNN result shows 0.04% to 5.29% and 6.81% to 18.58% deviation for RFP calculation and after SLC calculation, respectively.

For the datasets 1NMC+D on GPU with RFP calculation result, the number of detected identical pairs started from 24 to 112, with an average of 57.5 graph pair, with all zeros in all GNN (except for GAT, 1 graph pair) false negative results. The false positive result started from 24 to 111, with an average of 56.75 graph pairs being observed. For calculation after SLC, the number of detected identical pairs started from 8 to 79, with an average of 27 graph pairs, with all zeros in all GNN (except for GAT, 1 graph pair) false negative results. The false positive result is observed to start from 7 to 78 with an average of 26.25 graph pairs. For calculated theoretical training accuracy, the GNN result shows 0.04% to 3.64% and 0.04% to 2.93% deviation for RFP calculation and after SLC calculation, respectively.

For GPU calculation on 4NC datasets, the RFP calculation result also shows a surprising outcome. The number of detected identical pairs also increased compared to 1NMC+D, starting from 30 to 236, with an average of 86.5 graph pairs, with all the detected pairs observed as false positives. For calculation after SLC, the number of detected identical pairs and false positive outcomes is only 1 (GCN and GAT) and 0 (GCN and GSG) graph pairs. For calculated theoretical training

accuracy, the GNN result shows 0.95% to 6.95% and 0.00% deviation for RFP calculation and after SLC calculation, respectively.

From the 1NMC, 1NMC+D and 4NC datasets on GPU calculation using RFP and SLC, compared from GPU performance using SFP, the GPU RFP and SLC calculation were observed to be capable of producing good results by having relatively high duplication detection capability. The RFP output calculation is also observed in GPU to be less affected by floating-point inaccuracy and inconsistency, rendering the duplication detection using the proposed method able to detect more than 93.16% and more than 63.90% of the confirmed identical graph pairs in RFP and SLC calculation, respectively.

V. CONCLUSION

In this study, graph duplication detection using the vector representation output of GNN is proposed. The duplication detection starts by recognizing the graph datasets using random weighted untrained GNN and converting the fixed multi-dimensional GNN recognition output into 2D data. The 2D data is later compared to one another to determine if the graph pair under the test is identical or not.

The simulation is also done in this study, using 4 different untrained GNNs, simulated using both CPU and GPU to demonstrate the duplication detection capability despite being affected by floating-point inaccuracy and inconsistency. The best F1 score is obtained by implementing 4-digit decimal rounding floating-point calculation, achieving an average of 96.92% and 93.70% duplication detection from 797 confirmed identical graph pairs using CPU and GPU calculation, respectively, without SLC.

Since the datasets used in this study are generated by using lists of analog circuit modules, the future work in this research is to increase the dataset size with more complex and varied circuits. Other already published graph datasets are also subjected to being tried as input datasets to get a wider application comparison. The optimization of the detection capability by using floating-point range comparison instead of floating-point identical comparison, especially on the second level comparison, along with the behavior of 2D GNN vector output under the training process, is also future work.

ACKNOWLEDGMENT

We would like to express our gratitude to Mrs. Toyama for all the support she provided, including the research environment.

Advanced Image Recognition Techniques for Crop Pest Detection Using Modified YOLO-v3

Dechao Guo[1]*, Hao Zhang[2]
School of Public Health and Management, Guangzhou University of Chinese Medicine, Guangzhou 510006, Guangdong, China[1]
Guangzhou Center for Disease Control and Prevention (Guangzhou Health Supervision Institute), Guangzhou 510440, Guangdong, China[2]

***Abstract*—Accurate and efficient detection of agricultural pests is crucial for crop protection and pest control. This study addresses the limitations of traditional pest detection methods, such as weak detection capabilities and high computational demands, by proposing an improved image recognition system based on the YOLO-v3 algorithm. The research focuses on enhancing pest detection accuracy through deep learning techniques, specifically by modifying the YOLO-v3 model with the ISODATA clustering algorithm, DenseBlock enhancements, and the ELU activation function. A dataset of 13,000 images representing six common crop pests was created and expanded using various image augmentation techniques. The modified YOLO-v3 model was trained and evaluated on this dataset, achieving a higher mean Average Precision (mAP) of 89.7% and faster recognition speed compared to Faster-RCNN, SSD-300, and the original YOLO-v3 model. Finally, the improved model demonstrated a recognition speed of 27 frames per second (fps), significantly outperforming other detection models in both accuracy and speed. The proposed method offers a superior solution for real-time pest detection in agricultural settings, combining high accuracy with computational efficiency. Future work will explore the application of optimization algorithms to further enhance the robustness and generalizability of the system across diverse pest detection scenarios.**

***Keywords*—Feature detection algorithm; YOLO-v3 network; image recognition technology; crop pest detection applications**

I. Introduction

Identifying and detecting crop pests is a challenging task [1-3]. To address this, there are two main approaches: traditional machine learning-based methods and deep learning-based methods [4]. These methods rely on digital image processing and pattern recognition technology [5]. Two major steps in traditional machine learning-based pest identification and detection systems are feature extraction and pattern recognition [6]. Li et al. [7] proposed an algorithm for orchard pest gesture characteristic representation learning to identify automatic trapping target pests, and its recognition rate reached 86.7%. Han and He [8] studied a set of stationary fast identification and diagnosis methods on the identification of field pests, and achieved the effect of real-time identification and diagnosis. Liang et al. [9] for the specificity of rice pests, fused the global features of the image and local gradient direction histogram features, proposed a pest classification and identification method based on support vector machine, and obtained an accuracy rate of 91.4%. Sanghavi et al. [10] used six invariant moments to extract the shape features of pests, and ARTMAP neural network to classify the pests. Han et al. [11] designed a hierarchical automatic pest identification system, and the pest identification rate reached 93% under a variety of categories. Deep learning based crop pest identification method is an end-to-end extraction of high quality feature representation of pests utilizing picture detection and recognition algorithms based on deep learning techniques. Chen et al. [12] proposed an improved residual network pest image recognition method, using the improved convolutional neural network in depth of residual block, adding high-resolution convolutional layer and the corresponding channel, so that the recognition rate of 91.4%. Cheng et al. [13] for the specific pest detection problem, proposed a deep convolutional network based on grain storage pest image recognition method. Renault et al. [14] designed a kind of coarse and fine convolutional neural network and applied it to the field aphid detection and identification problem, which improved the detection and identification accuracy. Lü et al. [15] used deep learning algorithms to detect and identify 15 kinds of beetles in food, and its accuracy rate reached 83.3%. Crop pest detection is a sub-task of target detection, and despite the use of image recognition technology to solve the task of pest identification and detection in different scenarios, the accuracy rate is still limited, mainly in the following aspects [16]: 1) the existing detection and identification methods only focus on the whole picture classification, and less detection for tasks such as pest occurrence location and pest number; 2) the current method test validation only uses its own constructed dataset, and its expandability and generalizability need to be improved; 3) less research on pest images in complex backgrounds, and the practicality of existing methods is poor.

This work provides a detailed analysis of the technical and application challenges associated with crop pest identification, taking into account enhanced feature detection and deep learning algorithms. The proposed approach for field crop pest detection is based on these challenges. The primary contributions of this study are as follows:

- Gathering image data of crop pests in the field and creating the necessary dataset;
- Integrating deep learning algorithms to create a target detection model based on the improved YOLO-v3 algorithm [17] and using it to solve the pest detection problem;
- Utilizing the dataset CPXJ to confirm the efficacy of the suggested algorithm in this study. The findings indicate

*Corresponding Author.

that the improved YOLO-v3 algorithm has higher detection accuracy when compared to other recognition models.

- To address the limitations of existing crop pest detection methods, this study proposes an enhanced YOLO-v3-based image recognition approach.

The structure of this study is as follows: Section II details the acquisition and augmentation of the crop pest image dataset. It describes the construction and labeling of the dataset. Section III introduces the standard YOLO-v3 model and the specific improvements made, including the integration of ISODATA clustering, DenseBlock, and the ELU activation function. Section IV presents the experimental setup, parameter configurations, and comparative evaluation results with other detection models. Finally, Section V discusses the conclusion, summarizing the advantages of the proposed approach and outlining potential future research directions to enhance model generalizability and robustness in real-world applications.

II. Crop Pest DataSet Acquisition SelectiON

Since the pest detection problem studied in this study is a target detection problem, the first step is to analyze the collection of crop pest datasets.

A. Data Acquisition

The study data for this work were gathered over a five-month period, from May 2019 to October 2019, at the Institute of Agricultural Sciences' experimental base. In order to improve the robustness and generality of the validation process, the current time period is separated into three time nodes every morning, noon and afternoon. Through the collection and analysis, there are six prevalent crop pests in the test base [18], as indicated in Table I.

This research employs web crawler technology to acquire image data of six types of crop pests, respectively, because there aren't many crop pests in the experimental base. To maintain the diversity of the data set, this is done, and the specific schematic diagram of the original photographs is presented in Fig. 1.

TABLE I. Description of Experimental Crop Pest Data

No.	Name	Harm
1	Cabbage greenfly	Bok choy, oleander, cauliflower, etc.
2	Moth	Peppers, cabbages, apple trees, pear trees, etc.
3	*Morus albopictus* (type of grasshopper)	Apple trees, pear trees, date palms, etc.
4	Three-spotted blind stink bug	Tomatoes, corn, cotton, soybeans, etc.
5	Green stink bug	Apple trees, pear trees, cotton, cucumbers, etc.
6	Leafhopper	Cabbage, sugar beet, apple trees, etc.

Fig. 1. Crop pest image data.

B. Image Data Expansion

Since the collection and web crawler image dataset is insufficient for deep learning training, this study expands the dataset using techniques like panning, mirroring, adding noise, and making light and dark changes. This increases the model's robustness and generalization ability. The specific operation is as follows.

1) Panning method: pan the image 50 pixels to the upper right, lower right, upper left, lower left, the place after the panning is supplemented with black, after the panning, it can generate 5 different images, which contains the original image that has not been panned. The specific operation is shown in Fig. 2, and the panning equation is as follows [Eq. (1)]:

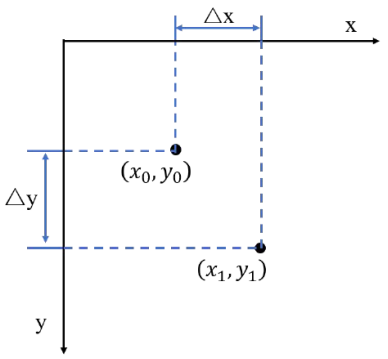

Fig. 2. Schematic diagram of translation

$$\begin{bmatrix} x_1 \\ y_1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \Delta x \\ 0 & 1 & \Delta y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} \quad (1)$$

where, x_1 and y_1 denote the pixel position after translation, Δx and Δy denote the pixel translation amount, and x_0 and y_0 denote the original pixel position.

2) Mirroring method: each image is mirrored to the left, right, up and down respectively, and 5 different images (including the original image) are generated after mirroring, and the mirroring schematic diagram is shown in Fig. 3. The equation for image level mirroring method is as follows [Eq. (2)]:

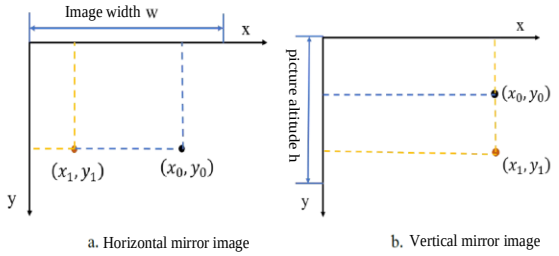

Fig. 3. Mirroring

$$\begin{bmatrix} x_1 \\ y_1 \\ 1 \end{bmatrix} = \begin{bmatrix} -1 & 0 & w \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} \quad (2)$$

where, w is the image width.

The equation for calculating the image vertical mirroring method is as follows [Eq. (3)]:

$$\begin{bmatrix} x_1 \\ y_1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & h \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} \quad (3)$$

where, h denotes the image height.

3) Add noise method: add pretzel noise or Gaussian noise to each image data, the number of noise points of the added pretzel noise is a random number between 3000 and 5000.

4) Brightness and darkness transformation method: each image will be adjusted to different degrees of brightness and darkness, using four levels of brightness and darkness division, using OpenCV and Numpy [19] for each image matrix operation to get the image data with different degrees of brightness and darkness.

Through the above four sample expansion methods, the number of samples in the crop pest image dataset was expanded to 13,000, and specific examples of the expansion are shown in Table II.

TABLE II. EXAMPLE OF IMAGE DATA EXPANSION

Expansion Methods	Original figure	Transformed image		
Panning				
Mirroring				

Add noise				
Brightness and darkness changes				

C. Data Labelling

Firstly, the dataset was size-unified, compressed to 416×416 and saved in JPG format. Secondly, the dataset was separated into a training set and a testing set with a 4:1 ratio. Finally, the Labeling annotation tool [20] was used to annotate the dataset, as illustrated in Fig. 4. In this study, based on the Overall labeling method, a Non-overall labeling method is developed, and the labeling situation is specifically shown in Fig. 5.

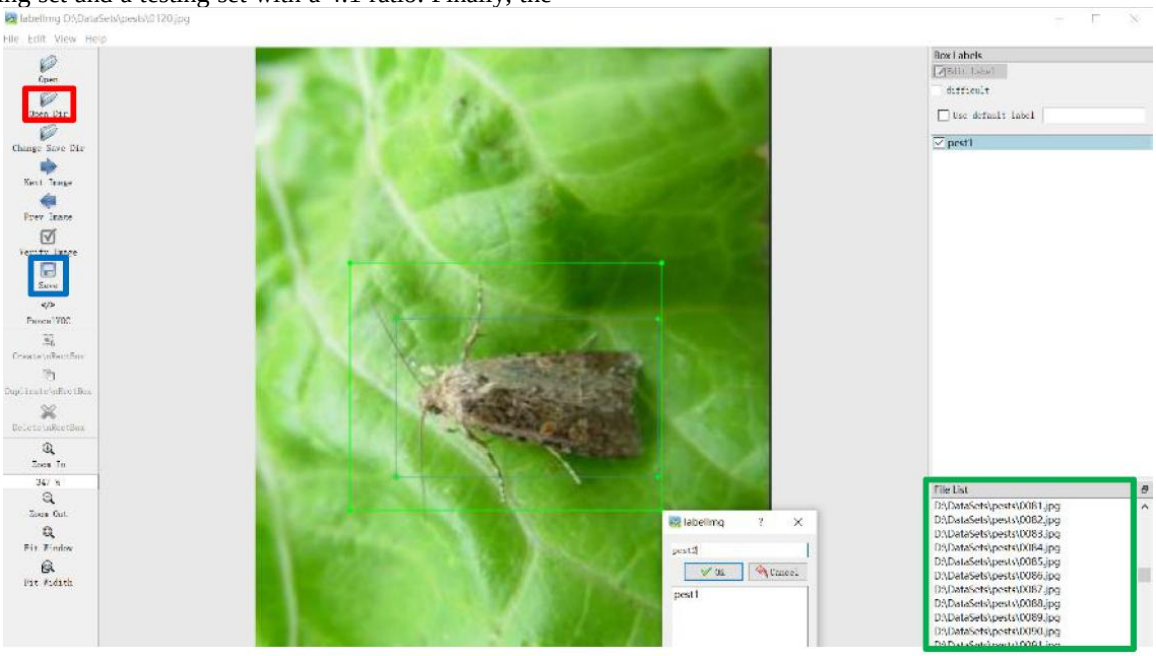

Fig. 4. Labeling annotation process

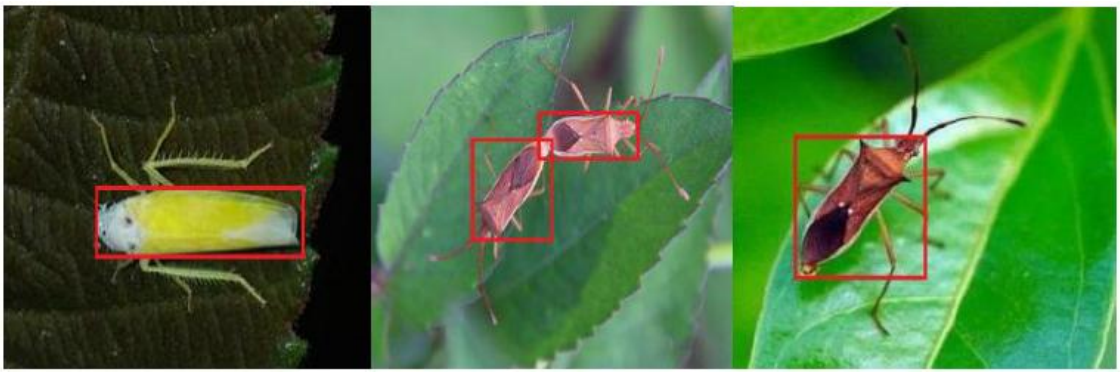

Fig. 5. Labeling

D. Construction of Data Sets

The acquired crop pest photos are increased by data, six crop pests have the same amount of data, and the six pest image data totals 13,000 images, which are then randomly assigned into a training dataset of 10,000 and a test set of 3,000 according to an estimated 4:1 ratio. The data image set and labels are produced as crop pest image datasets (CPXJ-Datasets).

III. Image Recognition Based on Improved YOLO-v3

A. YOLO-v3 Algorithm

1) YOLO-v3 algorithm structure: YOLO-v3 (You Only Look Once version 3) [21] is a popular target detection algorithm known for its fast detection speed and relatively high accuracy. The key features of YOLO-v3 include the use of multi-scale prediction to improve detection of targets of different sizes and the use of Darknet-53 [22] as its feature extractor, which is a deeper convolutional neural network than previous versions.YOLO-v3 is capable of predicting both bounding box and category probabilities, and provides better detection performance while maintaining real-time performance. The structure of the YOLO-v3 algorithm is shown in Fig. 6.

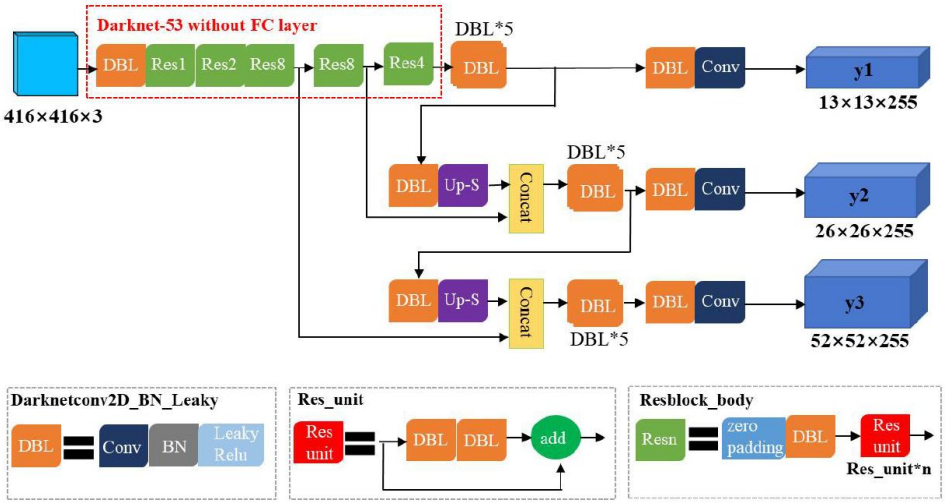

Fig. 6. YOLO-v3 algorithm structure

As seen from Fig. 6, the red dashed portion represents the YOLO-v3 algorithm feature extractor Darknet-53 [22], which is the main component of the method. The Resblock-body section of the algorithm is made up of various residual structures (Res-unit), DBL structures, and zero-padding structures.

2) K-means clustering algorithm: In order to avoid the detection model to detect the wrong target box in the training and learning time, and to speed up the model convergence, by using a K-means clustering algorithm [23] in the labelled ground true shape, an existence of a certain regularity can be found, specifically as shown in Fig. 7.

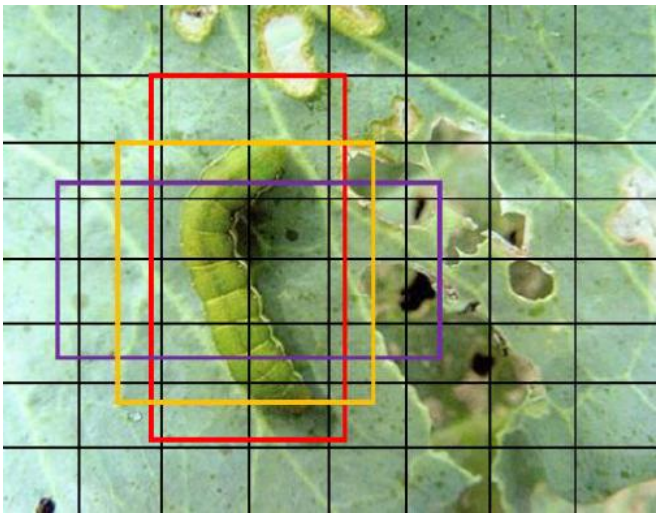

Fig. 7. Target box shape

3) Darknet53 feature extractor: The YOLOv3 target detection algorithm uses a deep convolutional neural network architecture called Darknet53 [22]. It's 53 convolutional layers, including multiple residual blocks, help to mitigate the issue of gradient vanishing in deep networks and facilitate network training. The structure of Darknet53 is depicted in Fig. 8. Darknet53 does not use pooling and fully connected layers, but downsamples the feature map by altering the step size of the convolutional kernel.

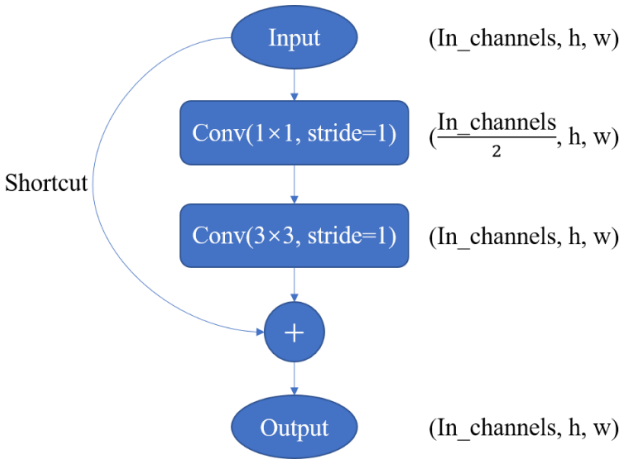

Fig. 8. Darknet53 structure.

4) RPN network: The RPN network is used by YOLO-v3 in order to avoid doing a lot of convolutional calculations [24]. Its primary goals are to extract the feature map that the network has acquired, extract multi-dimensional feature vectors from

Conv1, pass it through a number of target regions, including Conv3-FC1 and Conv4-FC2, and after each matrix target region has a regional target score. The integrated score is then passed on to the following RoI-Pooling operation. Fig. 9 depicts the RPN network.

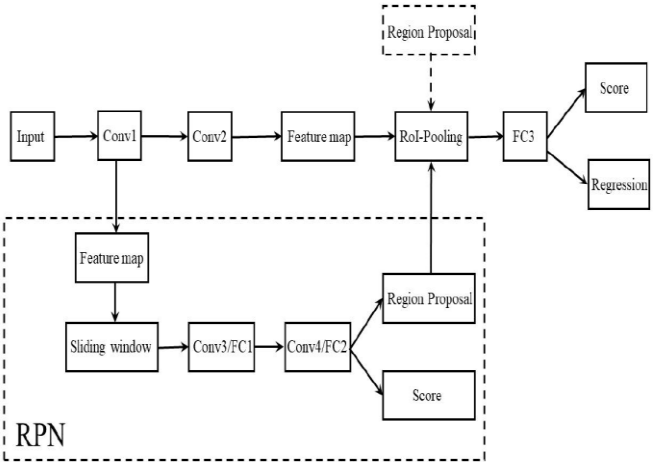

Fig. 9. RPN network structure

Combined with the crop pest detection data in this study, the image is input, and the target area is obtained through a computational process (Fig. 10).

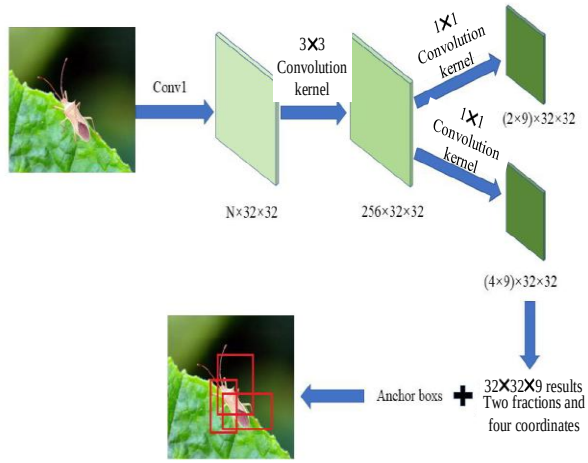

Fig. 10. RPN calculation flow.

5) Boundary box regression: In order to effectively detect ringed agricultural pest targets, the notion of Intersection over Union (IoU) is introduced, which is represented schematically in Fig. 11. In Fig. 11, it can be seen that the green box is the real box of the target using Labeling annotation tool and retrograde labeling, and the red box is the box predicted by the trained target detection model. IoU is the area intersection over union operation, and the specific form of calculation is shown in Fig. 12. From Fig. 12, it can be observed that the more accurate the projected box of the target detection prediction model is, the greater the IoU value. When the IoU value is more than 0.5, the projected box is deemed as accurate; otherwise, the red predicted box is fine-tuned to bring it close to the true green box.

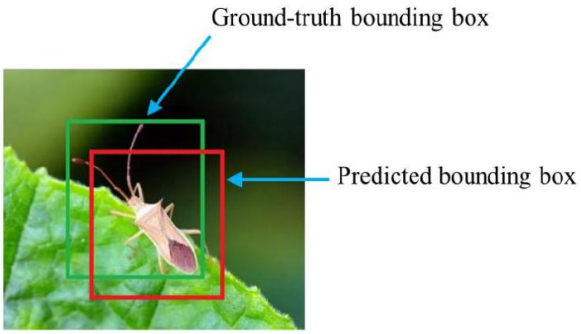

Fig. 11. Intersection over Union (IoU).

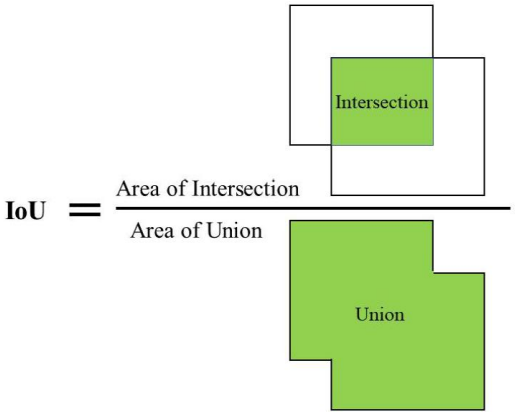

Fig. 12. IoU Calculation.

6) Loss function: The YOLO-v3 loss function consists of four components [25], i.e., (x, y) loss, (w, h) loss, confidence loss, and category loss, and the total loss is expressed as follows [Eq. (4)]:

$$L = L_{xy} + L_{wh} + L_{conf} + L_{class} \tag{4}$$

where, L is the total YOLO-v3 loss, L_{xy} is the (x, y) loss, L_{wh} is the (w, h) loss, L_{conf} is the confidence loss, and L_{class} is the category loss.

The bounding box position loss L_{xy} is calculated as follows [Eq. (5)]:

$$L_{xy} = \sum_{i=0}^{S^2} \sum_{j=0}^{B} \lambda_{ij}^{obj} \left[\left(x_i - \hat{x}_i \right)^2 + \left(y_i - \hat{y}_i \right)^2 \right] \tag{5}$$

where, λ_{ij}^{obj} is the j^{th} bounding box predicted by the i^{th} grid to detect the target to be detected, takes the value of 1, otherwise a smaller weight value of 0.1 or 0; S^2 is the total number of grids after the input avatar is rasterized; B is the number of bounding boxes predicted by individual grids, takes the value of 3; (x_i, y_i) denotes the predicted bounding box centroid position coordinates; $(\hat{x}_i, \hat{y}_i)$ denotes the actual bounding box centroid position coordinates.

The bounding box size loss L_{wh} is calculated as follows [Eq. (6)]:

$$L_{wh}=\sum_{i=0}^{S^2}\sum_{j=0}^{B}\lambda_{ij}^{obj}\left[\left(w_i-\hat{w}_i\right)^2+\left(h_i-\hat{h}_i\right)^2\right] \quad (6)$$

where, $\left(w_i,h_i\right)$ indicates the coordinates of the predicted width and height of the bounding box and $\left(\hat{w}_i,\hat{h}_i\right)$ indicates the coordinates of the actual width and height of the bounding box.

The loss of confidence L_{conf} is calculated as follows [Eq. (7)]:

$$L_{conf}=\sum_{i=0}^{S^2}\sum_{j=0}^{B}\lambda_{ij}^{obj}\left(C_i-C_i^*\right)^2+I_{noobj}\sum_{i=0}^{S^2}\sum_{j=0}^{B}\lambda_{ij}^{noobj}\left(C_i-C_i^*\right)^2 \quad (7)$$

where, I_{noobj} indicates that there is no loss in the control cell to prevent model instability due to gradient explosion. C_i denotes the actual detection target confidence, C_i^* denotes the detection target confidence, and $C_i^*=\Pr(obj)*IoU_{pred}^{truth}$.

Category losses L_{class} are calculated as follows [Eq. (8)]:

$$L_{class}=\sum_{i=0}^{S^2}\lambda_{ij}^{obj}\sum_{c\in classes}\left[p_i^*(c)\log\left(p_i(c)\right)+\left(1-p_i^*(c)\right)\log\left(1-p_i(c)\right)\right] \quad (8)$$

where, C denotes the category to which the detected target belongs, $p_i^*(c)$ denotes the actual probability that a target belongs to the category C when it is detected by the ith network, and $p_i(c)$ denotes the predicted probability that a target belongs to the category C when it is detected by the ith network.

B. Improvement of the YOLO-v3 Algorithm

In order to increase the detection accuracy of YOLO-v3 network, the advanced clustering algorithm ISODATA clustering algorithm, is employed for anchor boxes collection, the ELU activation function is used in YOLO-v3, and the Darknet53 structure is improved to adapt to the dataset CPXJDatasets.

1) ISODATA clustering algorithm: In order to overcome the shortcomings of K-means clustering algorithm, this study adopts ISODATA clustering algorithm [26] to cluster the anchor boxes.The flowchart of ISODATA clustering algorithm is shown in Fig. 13.

The ISODATA clustering algorithm clusters the anchor boxes to obtain 9 prior frames, the specific results are shown in Table III.

2) Improvement of Darknet53 structure: In order to reduce the amount of computation, in this study, DenseBlock [27] is added to Darknet53 to improve the performance of YOLO-v3. The structure of DenseBlock is shown in Fig. 14, which deepens the feature extraction network's ability of extracting features in Darknet53 with fewer parameters, which makes it easier to train. Before and after Darknet53 improvement is given in Fig. 15.

To test the effectiveness of the improved Darknet53 module, the original images are input and analyzed, and the results shown in Fig. 16 are obtained. From Fig. 16, it can be seen that the improved Darknet53 module not only adds more semantic information to the output feature map at each layer, but also enhances the expression ability of the feature map.

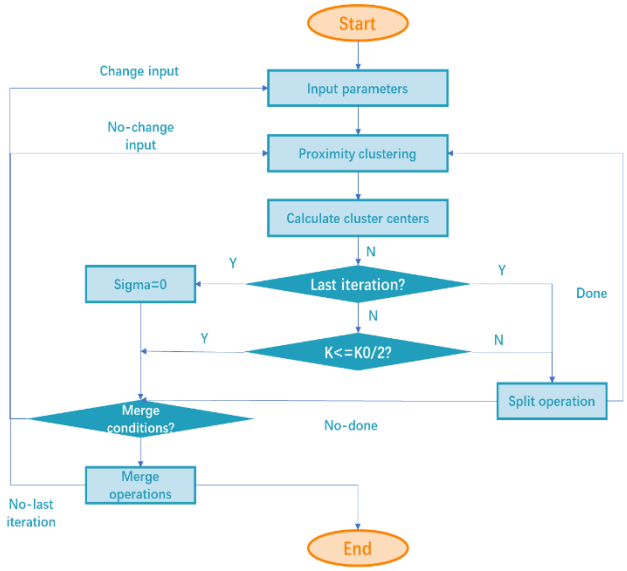

Fig. 13. Flowchart of ISODATA clustering algorithm.

TABLE III. PRIOR FRAME ASSIGNMENT AFTER CLUSTERING PROCESS

Characteristic graph	13*13	26*26	52*52
Experience the wild	oldest	middle	few
A priori framework	(240*100) (330*152) (412*386)	(166*112) (174*162) (192*243)	(46*49) (56*102) (107*146)

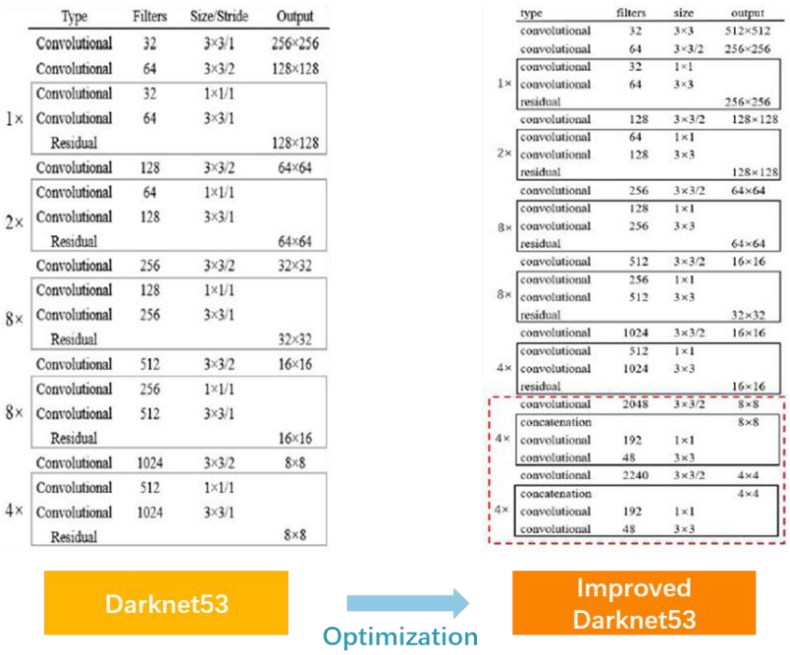

Fig. 15. Darknet53 before and after improvements.

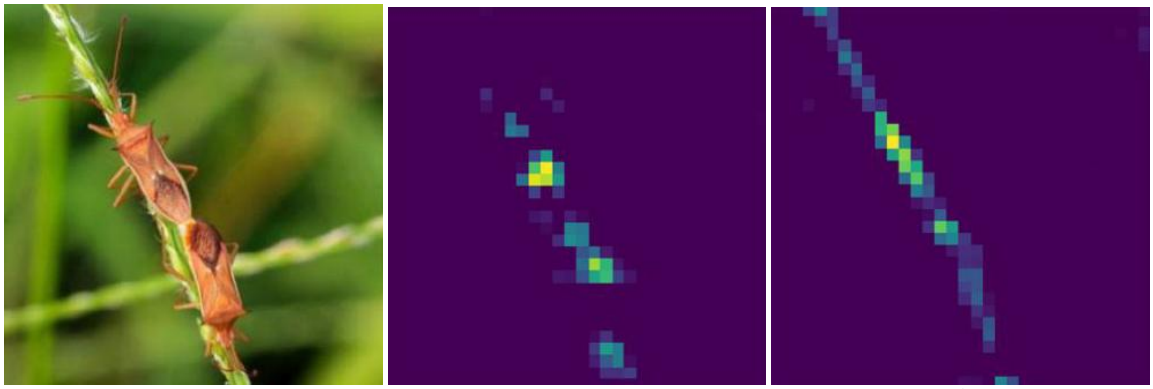

(a) Input images (b) Darknet53 output (c) Improvement of Darknet53 output

Fig. 16. Analysis of Darknet53 module result output.

3) Spatial pyramid pooling: In order to enrich the features and increase the feature expression ability, YOLO-v3 introduces the SPP network, i.e., the spatial pyramid pooling structure (Fig. 17). The upgraded YOLO-v3 network is depicted in Fig. 17. The SPP network structure is added before the first fully connected input in the YOLO-v3 network structure, and the results of three times Max pooling are fused to obtain a fixed output for the input of the first fully connected layer, which is a method of fusing three kinds of features with different scales, which results in a wider range of the field of view of the convolution kernel. The fusion of the three characteristics is utilized to remove the effect of inconsistent effective feature information due to the individual variability of agricultural pests.

4) ELU activation function: The original YOLO-v3 network uses a nonlinear activation function Leaky ReLU, and the function image is displayed in Fig. 18(a). The Leaky ReLU activation function was used to avoid the effects that the traditional activation function brings to the model, although it solves the problem that neurons do not learn when they enter the negative region, the rate of neuron learning after Leaky ReLU activation is very slow, which leads to a longer training time. Therefore, the ELU activation function [Fig. 18(b)] is employed instead of Leaky ReLU to speed up the convergence of the network.The particular equation for the ELU activation function is as follows [Eq. (9)]:

$$f(x)=\begin{cases} x & x>0 \\ \alpha\left(\exp(x)-1\right) & x\le 0 \end{cases} \tag{9}$$

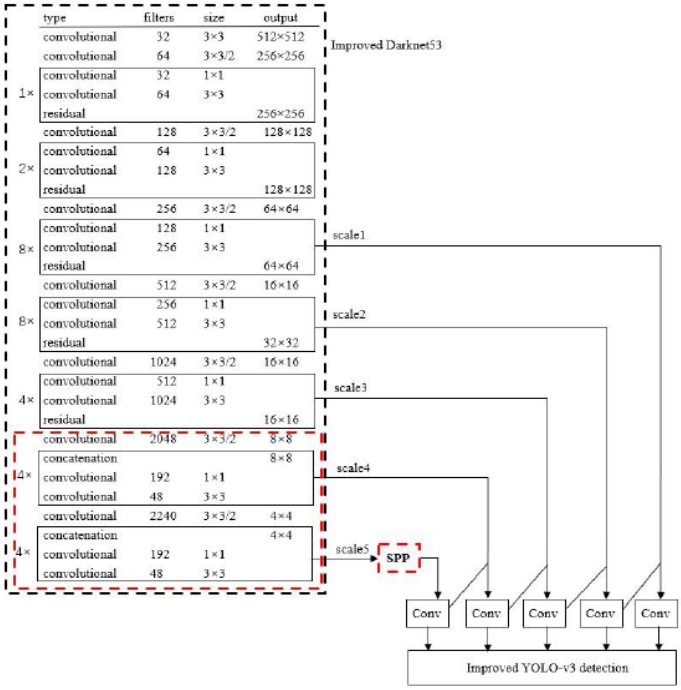

Fig. 17. Improved YOLO-v3 network structure.

IV. Experimental Analysis of Data

A. Experimental Setup

1) Experimental environment parameter setting: The experiments in this study use deep learning techniques to solve the crop pest detection task, and the specific experimental environment is shown in Table IV.

2) Network parameter setting: The validated YOLO-v3 network parameters are designed as shown in Table V. The detection models compared are Faster-RCNN, SSD-300, and YOLO-v3.

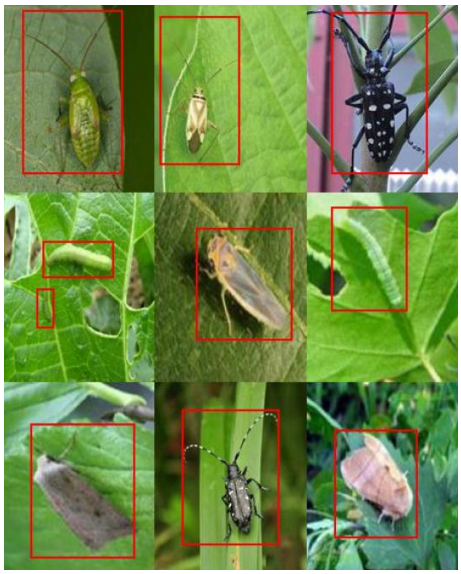
TABLE IV. Experimental Environment Parameter Settings

No.	Experimental Environment Project	Specific settings
1	Programming Development Environment	Python 3.7
2	operating system	Linux Ubuntu 16.72LTS
3	software platform	PyCharm 2019.3.3 Professional, Labelimg 1.8.3, OpenCV 4.2.0.34
4	Hardware Development Environment	Intel(R) Core(TM) i7-9750H CPU @2.60GHz 2.59GHz Processor
5	memory	GTX1080 6GB
6	Deep Learning Development Framework	Keras 2.3.1

TABLE V. ALGORITHM PARAMETER SETTINGS

No.	Parameter	Specific settings
1	Optimization methods	Batch stochastic gradient descent
2	Total number of iterations	30000
3	learning rate	0.01
4	weight decay value	0.0005
5	batch size	64
6	momentum factor	0.99

3) Experimental data set: The agricultural pest detection dataset, CPXJDatasets, contains 13,000 photos of six crop pests, namely, green blind stink bug, three-spotted blind stink bug, cabbage greenfly, leafhopper, moth and mulberry aspen (10,000 training datasets and 3,000 testing datasets). The training set is split into an integral labeling method and a non-integral labeling technique training set, as illustrated in Fig. 19.



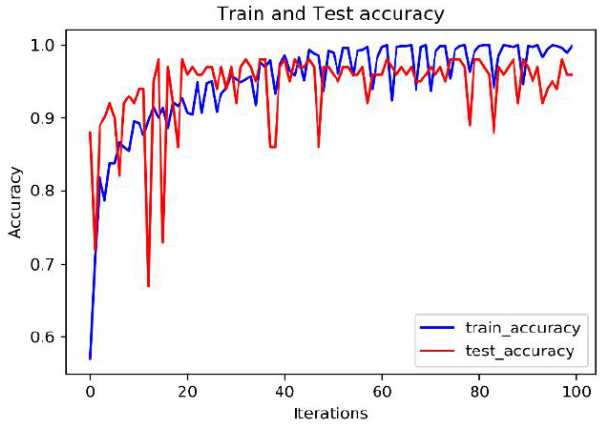
(a) Integral labeling method data set

(b) Non-integral labeling method training set

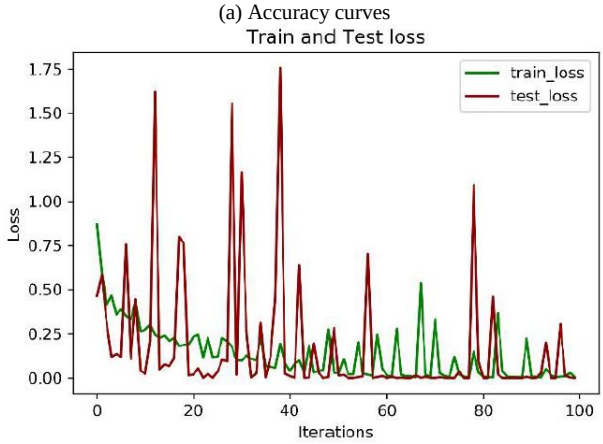
Fig. 19. Integral and Non-integral labeling method training set

B. Analysis of Results

Improved YOLO-v3 model is trained and tested using crop pest detection dataset, CPXJDatasets. The training phase of the network algorithm presented in this study is shown in Fig. 20. From Fig. 20, it can be seen that the accuracy converges to about 0.99 with the rise in the number of iterations, and the loss value drops to near 0 with the increase in the number of iterations.



(a) Accuracy curves



(b) Loss curve

Fig. 20. Accuracy and loss changes during the training process

To assess the efficacy of the enhanced YOLO-v3 network, this paper employs Faster-RCNN, SSD-300, and YOLO-v3 as comparison algorithms. The training and learning tests are employed to compare the results, as illustrated in Table VI. From Table VI, it can be shown that the pest detection accuracy of improved YOLO-v3 is better than other models and the recognition speed is faster than other network models.

TABLE VI. CONTRASTING NETWORK MODEL RESULTS

Test	Recognition rate			
	Faster-RCNN	SSD-300	YOLO-v3	Improvement of YOLO-v3
mAP	89.3 %	81.7 %	85.0 %	89.7%
recognition speed	12 f/s	36 f/s	20 f/s	27 f/s

Fig. 21 presents a schematic visualisation of the output of the convolutional layer findings of the output pest in order to facilitate a more thorough analysis of the experimental results. From Fig. 21, it can be seen that as the number of layers of

convolutional network increases, the convolutional output results are overloaded from shallow features to deep semantic features to achieve the ultimate feature results.

The test detection results are provided in Fig. 22. In the CPXJDatasets dataset, 3000 pest photos were used as the test set, and the improved YOLO-v3 algorithm detected the presence of pests in the images, and the detection results met the detection requirements.

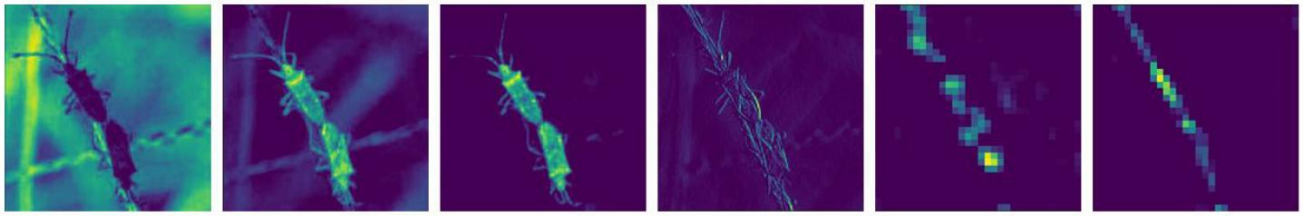


Fig. 21. Visualisation of the output results of the convolutional layer

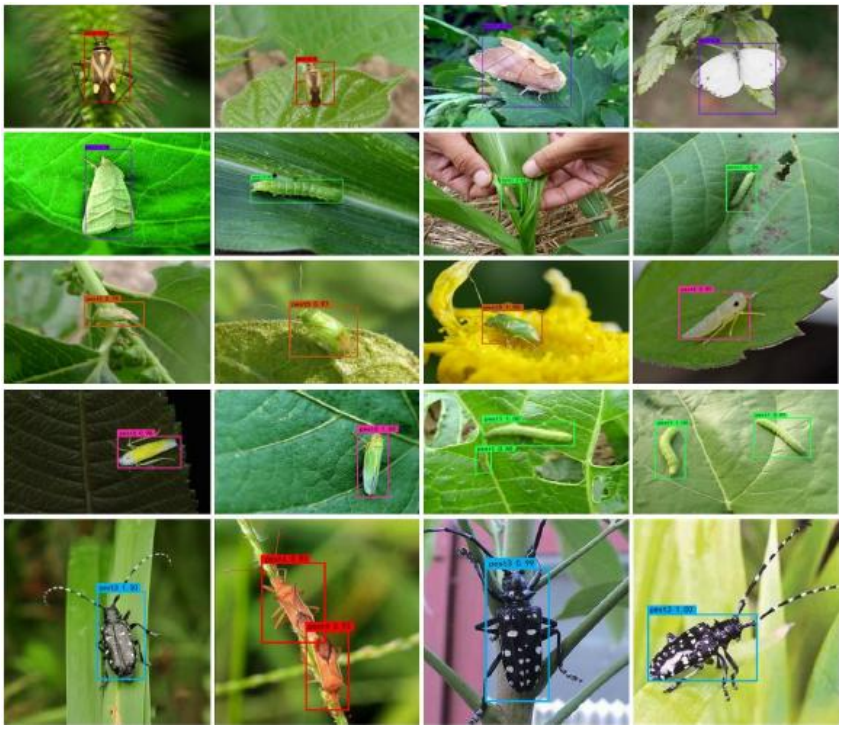

Fig. 22. Partial presentation of test results.

V. CONCLUSION

This study proposes an agricultural pest detection method that is based on an enhanced YOLO-v3 algorithm to address the issue of crop pest detection. The problem of crop pest detection is analyzed in this study, which also gathers data images from experimental fields, expands the dataset through the use of panning, mirroring, adding noise, and adjusting light and dark, combines deep learning algorithms, enhances the YOLO-v3 network from four angles, suggests a detection model based on the enhanced YOLO-v3 network, and compares and validates it using the created dataset, CPXJDatasets. The results reveal that, compared to the models of Faster-RCNN, SSD-300, and YOLO-v3, the pest detection accuracy and recognition speed of the new approach described in this study are better and faster than other models. In the next phase, to further increase the detection accuracy of the proposed method, the intelligent optimization algorithm is utilized to optimise the upgraded network and used on multiple crop pest datasets to improve the robustness and generalization of the system.

In future research, efforts will focus on integrating attention mechanisms and lightweight neural network architectures to further improve detection accuracy and computational efficiency, particularly on mobile or edge devices. Additionally, expanding the dataset to include more pest species and diverse environmental backgrounds will help enhance the model's robustness and applicability in real-world agricultural scenarios. Cross-domain transfer learning and semi-supervised learning techniques will also be explored to reduce reliance on large-scale labeled datasets and improve performance in low-resource settings.

CodifiedCant: Enhancing Legal Document Accessibility Using NLP and Longformer for Secure and Efficient Compliance

Jayapradha J[1], Su-Cheng Haw[2]*, Naveen Palanichamy[3], Nilanjana Bhattacharya[4], Aayushi Agarwal[5], Senthil Kumar T[6]

Department of Computing Technologies-School of Computing, SRM Institute of Science and Technology, Kattankulathur, Tamil Nadu 603203, India[1, 4, 5, 6]

Faculty of Computing and Informatics, Multimedia University, Jalan Multimedia, 63100 Cyberjaya, Malaysia[1, 2, 3]

***Abstract*—CodifiedCant is a new idea that employs Natural Language Processing to simplify company guidelines and legal documents. Legal texts are extensive, complicated and hard for non-experts to understand. To tackle the above problem, this research incorporates the Longformer model because it functions as a transformer-based deep learning system designed to work effectively with extensive legal documents. Longformer enables the system to handle extensive documents by keeping better track of context, which results in transforming complex legal text into easily readable formats. To enhance the search and retrieval speed, this research investigates the nuances of transforming unstructured data, like tabular data from PDFs, to vectors. This revolution supports quicker, cognisant semantic routing inside the document. Further, it assists in data arrangement and detection across massive sources of legitimate and business information. Data security is also a major priority for the platform, which utilizes network encryption to protect data and privacy. CodifiedCant is a scalable, secure and intelligent solution for better employee access to legal news, greater company transparency and reinforces better compliance in the organization. Table extraction and document simplification performance of the model are validated on Cornell LII and Kaggle evaluation datasets, respectively. CodifiedCant associates the variance relating to legitimate terminology and user knowledge.**

***Keywords*—Natural language processing; transformer-based deep learning system; long former; semantic routing; network encryption; legal document; unstructured data; and data security**

I. Introduction

Legal documents are a fundamental aspect of everyday lives, influencing everything from business transactions and government policy to personal contracts such as wills and agreements. They create a clear definition of rights and obligations, which avoids misunderstandings and settles disagreements when they occur. Whether a contract between two businesses, legislation enacted by a government, or a court judgment, these documents guarantee that laws are obeyed, and promises are kept. But legal documents tend to be drafted in language that is arcane to the common individual. They depend upon sophisticated vocabulary, or legalese, and rigid formatting conventions that are country- and institution-specific. Although this degree of specificity ensures consistency and enforceability, it can also render legal documents off-putting, particularly to non-lawyers. Consequently, most individuals find it difficult to navigate through contracts, terms of service, or even simple legal agreements without the assistance of professionals. As legal and corporate documents expand in complexity, so does the need for tools to analyze, summarize, and extract key information [1]. For people or organizations, legal documents are tedious and complex for many people, full of legal terms and complex language - an issue so common that the phrase 'The person has read and agrees with the terms and conditions' is in fact, the most abused statement on the Internet. Since every application and every page has its own Terms of Services, Privacy Policies and End User Licence Agreements, a survey suggests that to read such material, on average, every user would need more than 200 hours on a yearly basis, which makes most of them only click the «agree» button without bothering to read.

A. CodifiedCant: A Deep Learning Solution for Legal Document Analysis

This widespread issue is being solved with the development of the idea's work, that is, a deep learning based advanced chatbot modified from the Longformer model that is prepared to understand long texts such as legal and corporate documents. It is able to condense long paragraphs into short ones, express thoughts, insights and reasons, with pointers highlighting critical aspects and cross examinations, making it easier to cope with complex words, rules and systems. The chatbot gives the user access to such information, making it easier for them to understand and act upon. One of CodifiedCant 's primary functionalities is to ease the difficult challenge of transforming unstructured data [2], e.g., tables in PDF files, into vector representations to enhance search and retrieval. This feature enables access and interpretation of tabular data, frequently serving as a core component of legal documents. This work proposes a new way of analyzing a document using Natural Language Processing (NLP) tools [3], by applying the Longformer model [4]. Due to its capability to quickly process lengthy documents, classic NLP models often have trouble processing, and Longformer has been particularly pertinent for legal and corporate texts. This distinguishing functionality fetches the information from large pieces of text and offers a deep understanding of contract wording, interests and terms. To enhance its work, strict measures have been taken to protect private data during the implementation of the system. Line encryption [5] protects data in motion to ensure the

confidentiality and integrity of every interaction. In addition, Amazon Web Service (AWS[1] Identity and Access Management (IAM) [6] allows fine-grained access control, dictating who can access the chatbot resources. Furthermore, AWS Web Application Firewall (WAF)[2] offers anti-DDoS [7] protection, helping to protect the chatbot against common web threats [8] and making it resilient against attacks[3]. The proposed work empirically evaluated the performance of CodifiedCant on extracted datasets created from actual court documents, including those from Cornell LII [4] and Kaggle[5], mainly focusing on table extraction and simplifying documents. This study presents *CodifiedCant*, an improved NLP-driven stage that deliberately restructures complicated joint and legitimate documents. By leveraging the Longformer model, CodifiedCant produces crisp content; however, contextual deep summations present packed authorized content more available. The proposed system encompasses unique preprocessing methods, such as transmuting unstructured and tabular data into vector embeddings, substantially improving data salvage and semantic exploration precision. Intense encryption procedures guarantee data protection, requiring it consistently for firm management. Although the system operates thoroughly in summarization and clause analysis, disputes remain in managing obsolete structures and authority-precise language.

II. Related Work

A. Role of NLP and ML in Legal Document Processing

In the past few years, there has been a growing interest in applying NLP and Machine Learning (ML) techniques to legal documents [6] and corporate policies. Numerous research efforts have been aimed at developing novel solutions that enhance the accessibility and interpretability of complex legal documents. Due to the use of ChatGPT's software, it is possible to interact with the document through features such as semantic index, summarising capabilities, an embedded powerful AI assistant, and multilingual support, alleviating issues that users may face when using standard PDF readers.

The study [9] reranked the challenges and pain points associated with conventional PDF readers. These innovations have shown how static documents can become more interactive and easier to consume, resulting in a better user experience with digital content. It offers a systematic investigation of how NLP-based systems can render complex textual information more approachable and points to important future avenues of research in interactive document processing approaches that vastly reduce drafting intervals yet preserve precision and conformity with regulatory provisions.

B. NLP Models for Legal Contents

A specialized version of the BERT model [10] is introduced for fine-tuning legal texts such as court cases, contracts, and statutes. Legal-BERT surpassed state-of-the-art general-purpose language models on document classification, named entity recognition, and question-answering, indicating the need to use domain-specific models to tackle the heterogeneous nature of legal text. This will justify why the NLP model needs to be adopted and should be headed towards the legal domain as it fits correctly in the direction of CodifiedCant research.

A new PDF reader has been introduced [11] to show the integration of features such as data extraction, hyperlinks to academic resources, a search engine for literature, and a question-and-answer bot. These improvements enable a dynamic and holistic reading experience of scientific articles that overcome the limitations of classical PDF readers. Integration of Artificial intelligence (AI) and NLP into document processing systems is one of the very few methods by which the research process can be improved to the same level as existing document processing systems, which, in the case of legal documents, are the simplified insights and takeaways that CodifiedCant is trying to achieve. A large study has been conducted on the truthfulness of used car conditions; however, applying NLP and machine learning methodologies to identify potentially unreasonable contract clauses increases the fairness and equity of online contracts. One such representation is CLAUDETTE's [12] ability to read legal texts and find inappropriate words of autonomous legal systems, assisting legal practitioners and laypersons needing legal help.

The study [7] shows that machine learning algorithms automate legal document review [13, 14] and, in doing so, can save hours of tedious labor for legal practitioners. The study corroborates CodifiedCant's mission to automate legal analysis, by clearly demonstrating how the role of AI augmentation can aid in document review with better accuracy and consistency. It also helps automate legal document review, providing up to 5x time savings for legal practitioners. It demonstrates how AI-enhanced document review can improve accuracy and consistency and comply with CodifiedCant's mandate to automate document review for legal analysis.

On the other hand, Sanjay[8] paved the way for using NLP technologies to improve legal search for predictive insights into case law that can help answer natural language queries. This is consistent with CodifiedCant's goal to improve the natural proprietary visualization of NLP technology to re-engineer the cumbersome process of going through complicated legal documents. A state-of-the-art survey of language models' understanding of legal materials [15] results indicate that domain-specific adaptations are necessary to improve the interpretability of legal documents and that specialized models outperform general ones. The research[9] discusses the possible utilization of NLP technology for the automated draughting of legal documents [16]. It explains how legal practitioners use generative models to complete legal paperwork on behalf of users.

Similar research [17] pushes the applicability of knowledge graphs to trace connections between legal concepts and gain

better visualization of legal rubrics. It demonstrates the embedding of knowledge graphs into document processing and facilitates contextual understanding to increase retrieval accuracy, thus complementing the feature set of CodifiedCant. In [18], the authors explain that transformers like [12, 15] can parse documents like contracts or court rulings longer than the length of a network and highlight the benefits of attention processes developed for working with long legal texts, which is relatively connected with CodifiedCant. Machine learning predicts whether a lawsuit will win or lose based on data on previous cases [19]. The technique proved useful in risk management and decision-making for law practitioners, aligning with CodifiedCant's vision, whereby legal processes get simplified using predictive and analytical AI-driven insights. The dynamic analysis of the identified contract terms using NLP [20], which enables the assessment of risk and compliance issues, was discussed[10].

C. CodifiedCant vs. ROSS Intelligence

Various studies have been analyzed, and the need for integration of AI is exposed. The analysis reveals why AI solutions inevitably need to be paired with human legal expertise for ideal contract management, allowing CodifiedCant to continue delivering users with a better grasp of legal consequences through automated insights. Table I compares two AI tools in the legal field, namely CodifiedCant and ROSS Intelligent [35]. There seems to be a comparative difference in focus and control between these two tools. CodifiedCant seems to be a more complex tool equipped with more document processing features using Longformer based NLP architecture that handles up to 4096 tokens per sequence and has more features of document simplification, clause through explanation and diverse legal documentation on complicated matters. ROSS Intelligent seems to have a more confined reach concentrating on legal research and answering questions focused on Watson's built-in natural language understanding technology and searching legal cases and prior cases. Also, another main differentiating factor is that CodifiedCant claims to offer more secure solutions due to line encryption and secure storage through AWS, this same does not apply to ROSS Intelligent, where this factor has not been considered. The table does provide some insights in the sense that while both tools belong to the legal technology department, they are not the same and have quite different facets. CodifiedCant is more focused on basic texts and documents, trying to make them more manageable and easier to understand, while ROSS Intelligent is more focused on the in-depth study, research of legal documents and case law. Fig. 1 depicts the comparative analysis of Legal AI Systems.

As per the literature survey, the existing methods are usually unable to handle unstructured data such as tables in PDFs and perform semantic searches efficiently. This problem is solved by CodifiedCant which uses distinctive techniques to change those raw items into vector representations. It also includes data encryption that helps secure the system, which most other systems fail to do. Moreover, standard NLP models were not built for specific locations or legal terms that are used long ago which makes them less useful. The proposed system, *CodifiedCant*, has been chosen because it can effectively handle long and intricate legal materials that cause difficulties for regular transformer models. With its sparse attention, the Longformer can read long texts in a way that keeps the needed context. While standard models struggle with lengthy documents, Longformer can keep important legal context using a wise selection of its attention. CodifiedCant addresses these issues by supplying an expandable, safe and aware NLP platform.

TABLE I. COMPARATIVE ANALYSIS OF CODIFIEDCANT AND ROSS INTELLIGENT

Features	CodifiedCant	ROSS Intelligent
Core Functionality	Document Simplification and Clause Explanation	Legal Research and Question Answering
NLP Architecture	Longformer based model	Watson based natural language understanding
Token Processing limit	Can process up to 4096 tokens per sequence	More limited token handling
Summarization	Generates plain language summaries for complex texts	No direct document simplification feature
Legal Domain Focus	Legal and corporate documents	Legal case law and precedents
Data Security	Line Encryption, AWS secure storage	No emphasis on encryption protocols

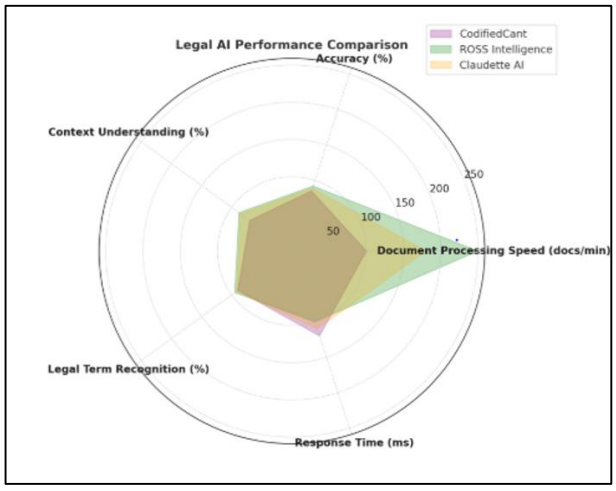

Fig. 1. Comparative Analysis of Legal AI Systems

III. IMPLEMENTATION OF THE PROPOSED SYSTEM CODIFIEDCANT

The implementation of the CodifiedCant system concerning the dataset, the feature extraction methods and the steps involved in the operation are explained. CodifiedCant is a comprehensive collection of legal materials from academic articles, legislative documents, or court case PDFs to structured legal databases and unstructured data forms including tables and charts. The real innovation is that CodifiedCant uses vector embeddings to represent unstructured data, especially tables extracted from legal PDFs. CodifiedCant converts tables to representations as vectors, thus bypassing the challenges traditional NLP techniques face when dealing with this data and allowing for

[10] https://marutitech.com/nlp-contract-management-analysis

rapid and accurate information retrieval. It enables the chatbot to quickly and accurately answer specific legal questions relating to tabular data. Fig. 2 provides a broader overview of the overall structure of CodifiedCant.

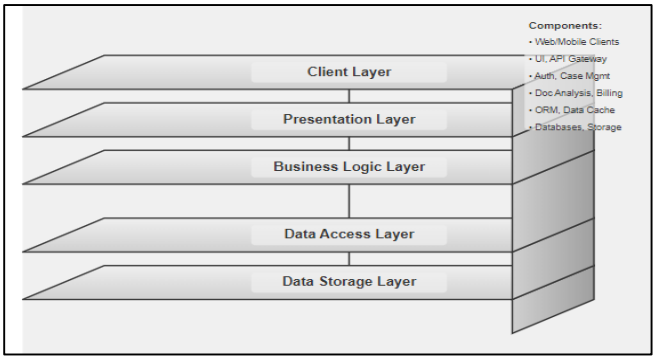

Fig. 2. Comprehensive system architecture of CodifiedCant.

Apart from using vector embeddings, the CodifiedCant also applies an assortment of text processing schemes including but not limited to: i) Named Entity Recognition (NER) to identify relevant legal entities, ii) Sentiment analysis to assess the sentiment of legal language, and iii) summarization to compress several long pages of document into a sizeable summary. To manage these intricate legal contexts, the proposed platform utilizes advanced NLP models such as BERT[11] and its domain-specific adaptation [21]. CodifiedCant uses a question-answering model that has been trained on legal datasets to enhance the precision of the answers returned to users. Cutting-edge methods enable CodifiedCant to analyze, evaluate and comprehend extensive amounts of legal data in minutes, and together, they equip users with rapid, accurate, and context-aware responses to legal queries. Table II gives an overall idea of the actual task performed by CodifiedCant.

TABLE II. VALUES FOR PREDICTING LEGAL DOCUMENTS

Category	Labels
Document Type	Employment Agreements, Guidelines for Compliance, and Privacy Policies
Task	Clarification of Clauses, Rights Education, and Simplification
Security	Network Encryption, Masking Data

A. Dataset Description

The study built a large dataset by extracting data from Cornell LII and other Kaggle datasets. The CSV contained two columns, "Legal Document" and "Simplified Summary". The “Simplified Summary” provides a simple description of these often complex documents, and the “Legal Document” column contains actual legal texts, ranging from statutes, contracts, and rules to case law. The collection illustrates the complexity of legal language by encompassing diverse legal documents ranging from statutes and case law to employment contracts and non-disclosure agreements. That said, it also has its disadvantages. For instance, it primarily focuses on legislation in the United States, which may not reflect the nuances of laws from other countries. The prevalence of English-language documents further restricts its use in non-English legal environments. Despite these constraints, the dataset is valuable for creating NLP models to de-legalese data. These systems are trained on a considerable quantity of content while benefiting from specified scopes, such as Longformer, allowing these tools to effectively navigate the intricacies that typically accompany legal language, even being simplified enough to directly aid in the accessibility of such complex texts for individuals struggling to comprehend them.

B. Dataset Preprocessing

The feature extraction algorithm implemented in this research adopts a holistic perspective to handle complex, unstructured textual data (representing legal documents, which often contain tables and reference clauses to other documents). The heart of the text processing pipeline, the Longformer model, works great with long text sequences commonly found in legal writing. There are numerous techniques for enriching feature representation. The proposed model used two specific techniques: i) Term Frequency-Inverse Document Frequency (TF-IDF) [22] method and ii) Sentence Transformers model, most considerably all-MiniLM-L6-v2 [23]. While the TF-IDF method statistically evaluates words' significance in the corpus, the Sentence Transformers model translates sentences into dense vector representations that reflect their semantic meanings [24].

Fig. 3 shows the correlation between the different features extracted. In the correlation analysis, the bivariate correlation of 0.50 between the two variables, paper length and the total citation, implies that the more the citations, the more pages a paper tends to have, since it has more comprehensive arguments and supporting evidence. However, the correlation value of paper length versus clause complexity scored only 0.30, suggesting that simply longer papers tend to have longer and more sentence structures. In the same way, paper length and the number of tables correlatively scored a very low value of about 0.10, which meant that it was necessary to include tables in a document that did not have a table space. Papers with high in legal concerning wordings were able to correlate with a citation count of about 0.60, which is more inclined to more technical or specialized content, attracting more citations. Legal wordings have mean scores of moderately low values of 0.40 in comparison to document length and clause complexity values, but maintain low correlation values with table numbers of about 0.20, ultimately showing that the attributes are pretty independent.

Features	Document Length	Legal Terms	Citation Count	Clause Complexity	Table Count
Document Length	1.00	0.70	0.50	0.30	0.10
Legal Terms	0.70	1.00	0.60	0.40	0.20
Citation Count	0.50	0.60	1.00	0.80	0.30
Clause Complexity	0.30	0.40	0.80	1.00	0.50
Table Count	0.10	0.20	0.30	0.50	1.00

Fig. 3. Correlation matrix between the features of CodifiedCant.

[11] https://www.geeksforgeeks.org/understanding-tf-idf-term-frequency-inverse-document-frequency/.

The mathematical definition of the TF-IDF is shown in Eq. (1), where the term frequency of *t* in document *d* is represented by $TF_{(t,d)}$; *N* is the number of documents and $DF_{(t)}$ indicates the number of documents that use the term *t*.

$$TF - IDF_{(t,d)} = TF_{(t,d)} \times log(\frac{N}{DF_{(t)}}) \quad (1)$$

These methods output embeddings of size 384, providing a contextual representation of document features. During information retrieval, 0.7 is used as a similarity criterion to extract relevant sentences that will combine to form short summaries. A key technology enhancement is a dedicated preprocessing step tailored to working with table data in PDFs. The importance of this stage is the transformation (or embeddings) from unstructured tabular data into structured vectors, which can be efficiently inferred. Beyond simply being able to obtain tabular data more easily, the vectorization process enables a more in-depth exploration of the organised content in these elements. Fig. 4 shows the tensor representation of the unstructured data. The figure demonstrates the tensor views of the features in the considered document, with values ranging within the normalized score from 32 to 180. The consistent pattern and overall value assortment mean great feature encoding, providing definite numerical limits for further examination. This organized representation allows our model to understand the delicate interrelationships between document features of different natures comparatively faster.

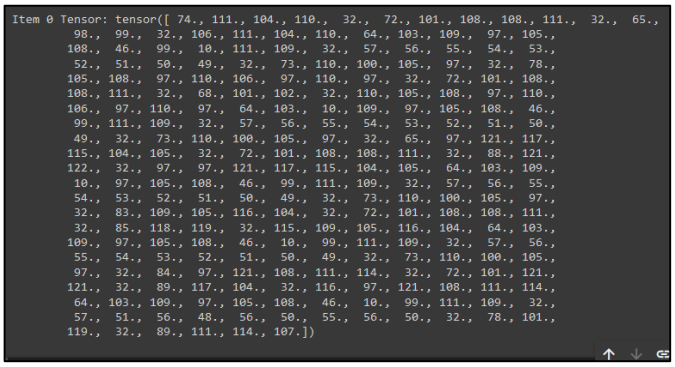

Fig. 4. Vectorization of unstructured data.

By blending over advanced NLP pipelines with domain-specific preprocessing methods, it builds a powerful and effective framework for extracting, representing and analyzing the diverse and complex data contained within legal documents. Ultimately, together, it enhances the performance and effectiveness of the legal information retrieval system by allowing more precise, contextually relevant answers to user enquiries. Table III describes the features extracted from the dataset during preprocessing of the data.

C. Document Simplification Model

This phase describes the architecture custom-designed for retrieving long legal documents and turning them into short summaries. Compared to existing approaches based on pre-trained models, the basic model for document simplification from scratch is implemented to tackle the challenges of long legal documents specifically. Due to the long nature of legal documents such as policies, contracts, and regulatory filings, the model is a transformer-based architecture with a token input length up to 4096 tokens. Traditional transformers struggle with sequences of huge length; however, the study shows how the proposed architecture can avoid such trade-offs while making sure little important information is lost. Self-attention mechanism, which allows the model to evaluate and score the different parts of the architecture's comprehension, is arguably the most vital input stream. The self-attention layers, along with a global attention [25] concentrated on the CLS (classification) token, allowing the model to focus on important aspects of the document during the later training and inference stages. Regardless of the length of the texts, the proposed system ensures that the important sections and phrases of texts should be prioritized during the simplification process.

TABLE III. FEATURES EXTRACTED FROM LEGAL DOCUMENTS

Feature	Description	Importance of Analysis
Text Complexity	Measured using the Flesch-Kincaid readability tests.	Aids in identifying complex areas that can be simplified.
Sentence Length	The average sentence's word count.	Suggests possible problems with user comprehension and complexity.
Legal Jargon Frequency	The number of legal terms used in the text.	Finds areas that need to be made simpler so that users can grasp them better.
Clause Length	Average word count for each legal clause.	Longer clauses may indicate increased complexity and decreased comprehension.

The model was trained from scratch with initial weights being randomized. For the same, architecture design and hyperparameter tuning must be given intensive thought. Such a method needs to begin at a low learning rate, so that the model can learn the tiniest structure of legal texts, e.g., to avoid gradient explosion. The batch size was chosen [26] to balance the amount of model stability during training against computing efficiency. The proposed solution created a multi-layer transformer encoder so that the proposed work can maintain context on potentially very long sequences of thousands of tokens in order to accommodate the long-range dependencies existing in legal texts.

To further enhance the model's ability to navigate complex legal text, PharmaBERT also included custom tokenization, which has been shown to decompose legal clauses, references, and tables successfully. The tokenization procedure was performed to handle and accommodate embedded lists, tables and so on. Hence, a good amount of effort was put into enhancing the tokenization procedure to handle both structured and unstructured data. To deal with documents of variable length, the system applied the concept of dynamic padding and masking [27].

From a mathematical perspective, the model has been trained using a variant of cross-entropy loss specifically used for multi-class classification. Trained the model in a way that aimed to minimize the difference between the actual simplified document and the predicted summary in the simplified form. This loss function was calculated from the output of the last SoftMax layer, which created probabilities for each possible token in the output sequence GRID. Validation metrics such as accuracy and loss were recorded for model tracking during training. As the training loss continuously decreases in the

following epochs, it is indicative that the model is learning the ability to generalize simple legal terms from complicated legal terms. Custom checkpoints were used to save model weights for every X iteration during the training process to ensure that the optimal model was saved across the training history. The complete model, post-training, could generate extremely precise and concise summaries of legal text while preserving the content and intentions of the original text. The architecture forms the very essence of CodifiedCant, as it helps facilitate reasonable and comprehendible interpretation of complex Legal Provisions and Regulation in a real-time application. Table IV shows the model hyperparameters of CodifiedCant.

TABLE IV. MODEL HYPERPARAMETERS OF CODIFIEDCANT

Hyperparameters	Value
Learning Rate	5e-5
Weight Decay	0.01
Optimizer	AdamW
Epochs	3
Logging Steps	10

Since overfitting is common in deep learning and large datasets, several different techniques were used to minimize the risk. Such measures were batch normalization, which allowed layer inputs to be normalized, and early stopping, which [28] halted training when the model's performance on validation data plateaued. It also ensures that the model will not train in perpetuity and that overfitting to the training data will be mitigated by preserving generalization to previously unseen legal documentation.

D. Secure Data Handling

In the study, a multi-level approach to protect data during the complete processing chain, with particular focus on personal data and legal documents, was employed. Utilizing strong security features from AWS, a comprehensive data encryption strategy was employed to ensure data was encrypted in transit and at rest. For secure document storage, server-side encryption with AWS-managed keys (SSE-S3) is leveraged to ensure the integrity and confidentiality of these legal documents stored on Amazon S3 (Simple Storage Service). AWS RDS (Relational Database Service) [12] has been used for the management of structured data as it provides multi-AZ deployments [29] for high availability and durability of data, as well as automated backups and database snapshots.

Line-level encryption deals with sensitive information such as Personally Identifiable Information (PII) [30] and other sensitive personal data. Characterization of small-scale data generalization or transformation techniques protects sensitive information whilst maximizing the analytical merit of the data. Modern AWS IAM policies enforce access control with a strict application of the least privileged standard, ensuring that only the appropriate workers view specific data resources. The proposed work has also implemented additional security practices such as a regular security audit, Multi-Factor Authentication (MFA) for user access and real-time monitoring of the application with the help of AWS Cloud Trail and Cloud Watch which allows us to monitor the AWS account activity and quickly react to any potential security threats. Not only does the CodifiedCant adhere to industry best practices for safeguarding the data, but it takes an evolutionary step further by embedding these state-of-the-art security frameworks and leveraging the compliance certifications of AWS (e.g., GDPR, HIPAA). It protects the document from the issues below: confidentiality, integrity, research data, access to sensitive legal and personal data, and elimination. Using access control mechanisms to defend documents, personal information, and database systems, as well as the approval module to manipulate keys, a secure system architecture diagram illustrates the relationship between safe processing and authentication components in Fig. 5.

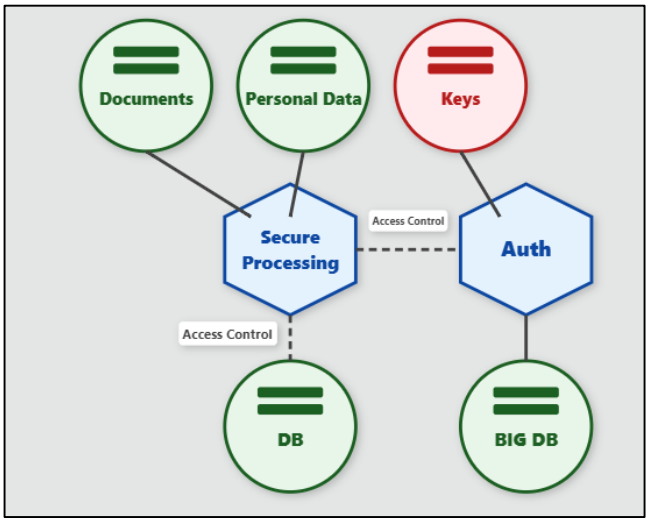

Fig. 5. Secure data flow and encryption protocol.

E. Approach for Simplification and Clause Extraction

Two strategies were tested, aimed at clause extraction and legal document simplification.

1) Independent clause simplification model: The first approach (using an independent model trained to extract and explain specific clauses from legal documents) became one of the best-performing models in our experiment. The Longformer model was pre-trained to catch key sentences and generate them as text abstracts, then fine-tuned on task-specific datasets to produce plain-language summaries.

2) Integrated model with user interaction: The second approach simplified the original question and then performed a subsequent clause extraction problem with a single end-to-end chatbot-driven solution. Users can now ask questions at the level of words or sentences with a semantic search using the Longformer model as semantic search + embedding model. Relevancy and correctness of response would now be made better by the chatbot using document embeddings, fetching the relevant information, and summarizing it as per needed. The proposed techniques decompose complicated content using

[12] https://www.infosys.com/industries/communication-services/documents/oracle-data-migration-comparative-study.pdf

NLP models. However, they will still ensure safe data management protocols, aligning with the primary focus of the research, which is to enhance the accessibility of legal information.

F. Security and Deployment

CodifiedCant employs some of the most powerful security architecture in the world by utilizing prominent features of the AWS platform, including comprehensive, corporate and industry-leading protection from the internet and unauthorized access. AWS Web Application Firewall (WAF), a managed WAF service that protects web applications from the most common exploits compromising the security, availability, and data of the applications. AWS Identity and Access Management (IAM) [31] also provides fine-grained access control to ensure access to the system. Access is given to authorized individuals based on the least privilege principle. These services significantly elevate CodifiedCant's overall security posture and compliance with industry standards. A clear view of the high-level architectural design, implementation of such data security and system integrity is visualized in multiple layers as shown in Fig. 5.

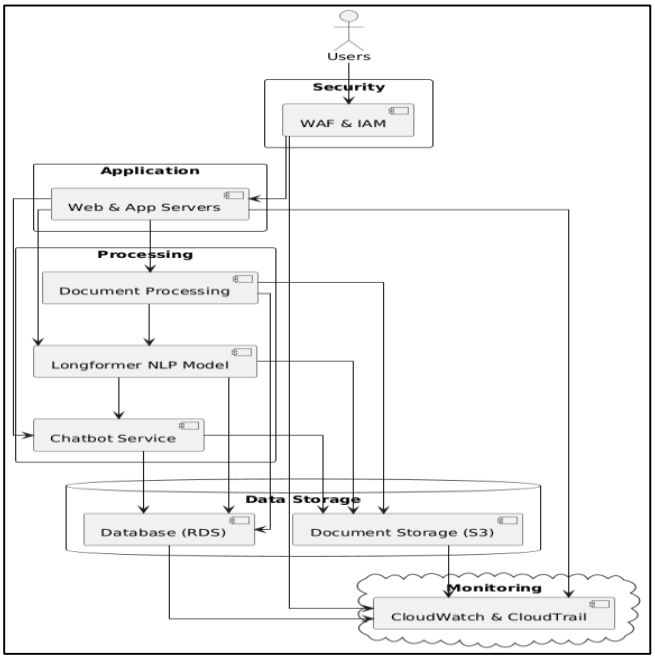

Fig. 6. Detailed components of the interaction diagram.

CodifiedCant employs a dual monitoring strategy that eliminates blind spots using AWS CloudWatch [32] and CloudTrail [33], providing real-time visibility about operations and security events in the systems. Moreover, CloudWatch captures the overall AWS environment by providing complete application and resource monitoring. Besides, CloudWatch has various customizable dashboards and alerts that provide information concerning system status, performance, and resource consumption. In addition, the CloudTrail service offers a complete record of all activity, mainly concerning the account and all API requests targeting the AWS Infrastructure, and this is useful for forensic, compliance and security management automation. Resolving issues more quickly, averting issues before they arise, and maintaining system functionality. Moreover, the design employs smart scaling in addition to the CloudWatch measurements to provide a certain level of resource allocation during peak usage times without compromising security features. Besides providing CodifiedCant with the requisite data privacy and regulatory compliance for handling sensitive legal data in a cloud environment, such a wide range of security services and surveillance capabilities also affords the company a significant degree of operational resilience. Fig. 6 represents the entire flow of data in CodifiedCant.

IV. Result and Experiments

The results are significant because they reflect two important improvements the CodifiedCant system has made in efficiently processing legal documents. Fig. 7 compares the response time before and after the use of CodifiedCant. It can be noted that a certain behavioral pattern tends to manifest itself in the process of simplification. Document 5's orbit starts with 74.6 points in Document 6, and then there is a sharp drop to 22.1 points, dramatically transforming into 74.6 points. This demonstrates strong volatility before recovering. The purple line, which captures the original document complexity, remains at a moderate level of about 40 points but also experiences dramatic shifts before recovering. On the other hand, the measurements made after the simplification process have a constant value between 65 and 80 across all the documents. Hence, the simplification worked as intended, which was to standardize document complexity.

The color yellow identifies the trend and system response times. Even further, starting from a very low value of about 0.65, the response time steadily progresses and peaks at Document 6 in the following sequence. This sustained and systematic increase necessitates performance considerations regarding the system's scalability and the processing abilities required of it. In this case, the response time is a serious trade-off; even though the simplification process makes document complexity consistent, the response time is a cause for concern in computational terms.

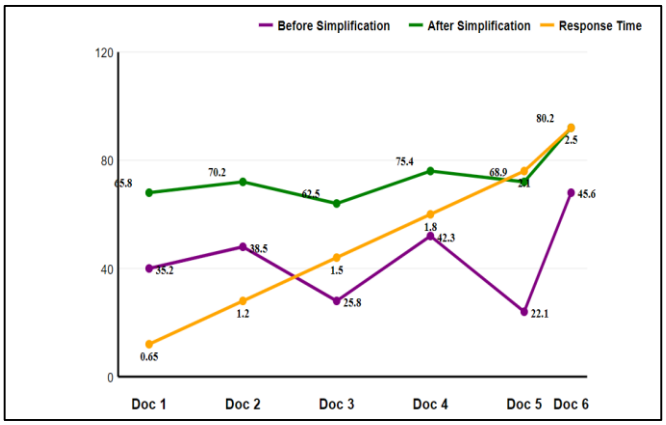

Fig. 7. Readability metrics and response latency.

Performance measures indicate a significant, systematic improvement in processing and reduction of complex legal material, demonstrating the success of the Longformer-based model in addressing this problem. A timeline is brought forward, which shows the huge reduction in the training and validation

loss over time, thus demonstrating the gradual optimization of the system. The model has evolved from a high initial training loss of 20.2128 to a training loss of 1.3828 after the training. This was followed by similar downward trends in the validation loss, 0.0179 at step 200, which suggests that differences were few and the model predicts well. Such a significant improvement indicates the strength of the Longformer when reading long legal documents, reducing complex legal terms into clear and concise summaries while holding enough context to be interpreted accurately.

The values provide empirical evidence that the system can manage the contents of large files in an orderly and rational manner. The processing efficiency of the system can be observed with its step rate of 0.971 steps per second, showcasing its efficiency in digesting large amounts of textual data. In the proposed work, 108 contents, around 88,000 words altogether, are processed rapidly. This performance level demonstrates that CodifiedCant can meet real-time processing requirements and produce high-quality summaries in legal environments requiring rapid information access. Its ability to churn massive, long sequences (up to 4096 tokens) provides CodifiedCant with a powerful advantage in parsing complex documents such as contracts and compliance documents. The approach produces user-friendly summaries that maintain the key elements of legal texts whilst remaining comprehensible to non-expert users by preserving more specific legal jargon and general contextual motifs. This capability showcases the advanced understanding of legal documents that the system has and its ability to bridge the knowledge gap of users and complex legal content. The effectiveness of the training approach and architecture design is evidenced by continued improvements in training and validation metrics as well as the model's ability to process large legal communities.

The model has been empowered with hyperparameter optimization [34] and more sophisticated text processing algorithms that ensure correct and contextual output [33]. CodifiedCant achieved a training loss of 1.3828 and a validation loss of 0.1424. This optimized runtime of 305 seconds shows that no performance degradation when dealing with large datasets. CodifiedCant is a good, automatic tool for frequent users and legal professionals in cases requiring fast document review and simplification. Fig. 8 depicts the comparison of the performance metrics of CodifiedCant between the beginning and the end states. It has large decrements on training and validation losses, indicating significant progress on most key metrics, as reflected in the visualization. The significant decrease in time indicates that the system is tuned during the training phase. Collectively, these improvements represent the successful implementation of the training approach and the design decisions made in producing a practical and robust legal document processing SOTA (State-Of-The-Art) model.

Fig. 9 evaluates the various metrics considered during the model training. The graph depicts the comprehensive metrics of CodifiedCant systems and processes, which illustrates the performance of legal document automation services. The graph includes 7 metrics and measures with the Response Time (RT), each designed in a blue bar to understand the system's functionality. All metrics depicted in Fig. 9 are comparatively strong, as 65 to 90 points are achieved on average, with most of the figures concentrated around 80 marks. The two factors, RT and Accuracy (ACC), can be interpreted as robust score performances standing at approximately 85, implying quite an efficient and dependable system. The third best metrics, which can be assumed as Threat Detection and the metric measuring Security Score, come immediately next, which points out the ability of the system to parse the documents reasonably well. Moving down a little below to the Data Encryption and the API Latency level of metrics, the values (around the 70-mark) indicate room for polish. The pattern in Fig. 4 indicates that while the core tasks of the system are working well, there is a need to improve extraction and learning tasks. All other Figs. (3, 7 and 8) show similarly high results, which are particularly strong process figures earned at most in the case of legal documents processing.

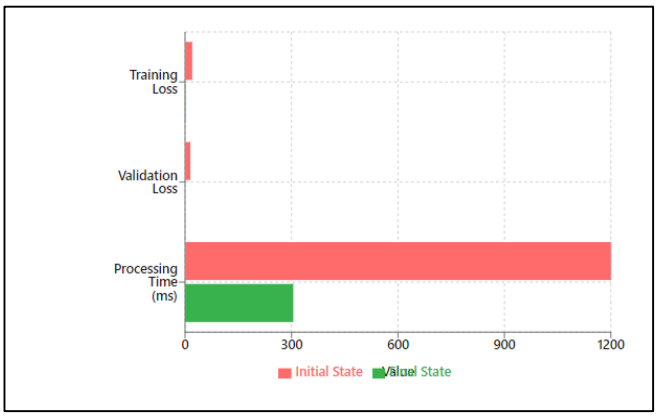

Fig. 8. CodifiedCant performance improvements.

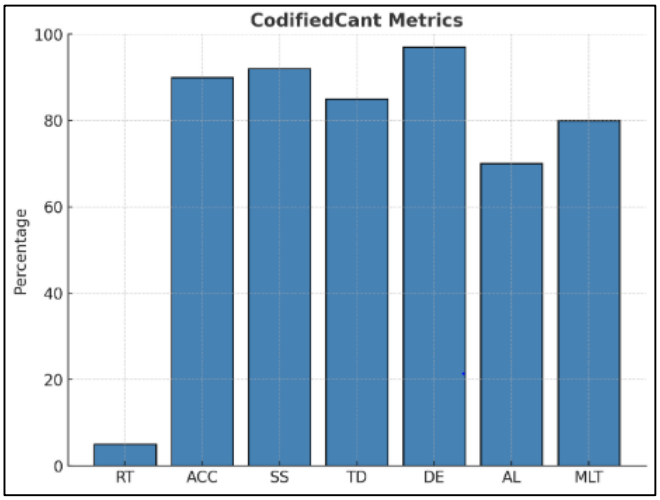

Fig. 9. Technical and security matrix.

Where, RT - Response Time, ACC - Accuracy, SS - Security Score, TD - Threat Detection, DE - Data Encryption, AL - API Latency, MLT - Model Load Time. Fig. 10 depicts the comprehensive processing capabilities and performance indicators of CodifiedCant. The three main performances of the system in the graph are sequence lengths. The area plot shows a near-linear relationship between processing time and sequence length up to the maximum sequence length of 4,096 tokens as the processing time increases gradually as the sequence length increases. Even at longer sequence lengths, the accuracy level

remains at > 95% for most cases (indicated by the green line), which is a trend that continues until sequences approach their maximum size, and thus the system is only mildly degraded as sequences approach full capacity. Throughput statistics (red) show the number of tokens per second at which the system can process efficient sequences from an ideal speed/sequence length trade-off. The system clearly affects these mid-range sequence lengths (with 2,000 to 3,000 tokens still having reasonably fast processing times), where processing times are still adequate and accuracy rates peak. This means that providing for common legal documents within this span is a sweet spot for CodifiedCant. The stability of the downstream Longformer-based architecture's performance over many lengths of documents is shown with the minimum accuracy drop of 3% (small to longest sequences). Fig. 10 represents the system balance in maintaining accuracy, document length, processing speed and capacity to deal with complex legal documents.

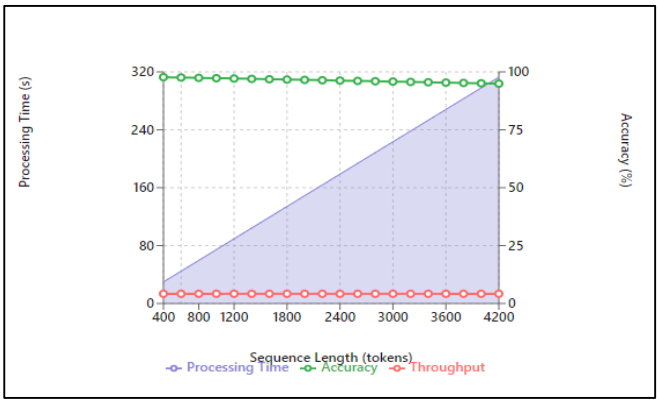

Fig. 10. Sequence processing analysis

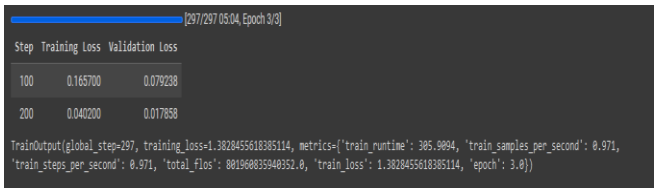
Fig. 11 represents the training and validation loss of the model. The output snapshot presents important training metrics of a machine learning model. The model achieved the training loss of 0.165700 and the validation loss of 0.079238, indicating good convergence and generalization of the model. The appended JSON outputs below include information on training process time-related parameters such as “train_runtime” of 305.9004 seconds and a “train_samples_per_second” rate of 0.971, enabling an understanding of the model's speed. It is also important to mention that the validation loss does not exceed the training loss, which indicates that the model is learning to generalize during predictions; hence, there is no overfitting. These metrics collectively indicate effective training that achieves the outlined performance limits under the specified hardware resources. In addition, the “total_flos” metric indicates how the training took place in terms of computational resources, providing relevant information for analysis of resource utilization.



[297/297 05:04, Epoch 3/3]

Step	Training Loss	Validation Loss
100	0.165700	0.079238
200	0.040200	0.017858

TrainOutput(global_step=297, training_loss=1.3828455618385114, metrics={'train_runtime': 305.9004, 'train_samples_per_second': 0.971, 'train_steps_per_second': 0.971, 'total_flos': 801960835940352.0, 'train_loss': 1.3828455618385114, 'epoch': 3.0})

V. Conclusion and Future Work

The results of the proposed study show the efficacy of CodifiedCant as a contemporary tool that utilizes advanced natural language processing (NLP) methods for legal extraction of information and documentation reduction and summarization. The system uses Longformer architecture to generate long but concise summaries while maintaining the essential legal features to handle the challenges regarding the size and complexity of legal texts by adding novel preprocessing techniques such as: i) transforming unstructured data, and ii) including tables, into vector embeddings. The approaches amplify the accuracy of information retrieval and query results. These performance measurements demonstrate that the documents exhibit enhanced readability and high summarization and clause interpretation accuracy, making legal content highly accessible for retrievals. In addition, strong encryption techniques safeguard sensitive legal data, thus bolstering the credibility and reliability of the system in processing legal documents. By serving as a full-service platform, CodifiedCant bridges the knowledge gap between methodological content and complex legalese, rendering legal content accessible and valuable to diverse target communities.

Legal papers' intricacy and unpredictable nature presented difficulties for this study, sometimes leading to less precise interpretations of context-specific clauses. Even if summarization and simplification tasks were completed with high accuracy, the subtleties of legal terminology increased the possibility of misunderstandings or information loss, especially in documents with outdated or non-standard formats. Processing extremely technical or jurisdiction-specific terms was another challenge that needed additional customization. By investigating several transformer models and integrating sophisticated legal-specific NLP architectures, like Legal-BERT, future research attempts to improve the contextual understanding of specialized legal terminology. To increase the model's applicability, experiments will be carried out with other datasets, such as those pertaining to low-resource languages and legal documents relevant to a given jurisdiction.

School of Materials Science and Engineering, Central South University, Changsha, Hunan 410083, China[2]

***Abstract*—This study builds a multi-dimensional sentiment analysis system to solve the problem of sentiment prediction of text and image data in the Weibo platform. By combining CNN (Convolutional Neural Network), BiLSTM (Bidirectional Long Short-Term Memory) and Attention mechanism (AM), the accuracy of sentiment classification is improved, which helps to better understand and analyze user sentiment expressions in social media. This study uses crawler tools to collect text and image data of 1,000 users on the Weibo platform from January to December 2021 to ensure the diversity and representativeness of the data; the text data is segmented, stop words are removed, and the text is converted into vectors; at the same time, the ResNet-50 pre-trained model is used to extract the deep features of the image, CNN is used to process the image data, and BiLSTM captures the contextual information in the text data. Finally, the AM is used to enhance the model's attention to emotional expression. Experimental results show that the proposed Word2Vec (Word to Vector) model performs outstandingly in the accuracy of sentiment classification. The accuracy of the CNN-BiLSTM-Attention model in positive, neutral and negative classification tasks is 97.5 per cent, 95.4 per cent and 91.6 per cent, respectively, which are significantly better than the performance of the CNN and BiLSTM models, especially in the evaluation indicators such as accuracy and macro F1. This study proposes a multimodal sentiment analysis system based on CNN-BiLSTM-Attention, which significantly and effectively improves the accuracy of social media sentiment classification. The system can effectively process complex sentiment categories and multimodal data, and has broad application prospects, especially in the fields of social media sentiment analysis and public opinion monitoring.**

***Keywords*—Digital media; sentiment analysis; intelligent systems; multimodal data**

I. Introduction

Against the backdrop of the rapid development of digitalization and intelligence [1], social media [2] has become an important carrier for users to express their emotions and disseminate information. The multimodal data contained in social media provides rich resources and challenges for sentiment analysis research. Weibo [3] is one of the largest social media platforms in China. Its user-generated content includes text, images and other data forms. These data not only reflect the users' emotional states and psychological activities, but also reveal the dynamic changes in social public opinion. However, traditional sentiment analysis methods are usually limited to single-modal data processing, such as analyzing only text or image features, and cannot fully utilize the semantic complementarity and correlation between multimodal data. Weibo data is unstructured, with diverse and metaphorical emotional expressions, which increases the complexity and difficulty of sentiment classification. To address the above problems, this study constructs a multi-dimensional sentiment analysis system based on the CNN-BiLSTM-Attention model. CNN [4] is used to extract image features, BiLSTM [5] is used to capture the time series features of text, and the AM [6] is used to focus on key sentiment information, thus achieving high-precision sentiment classification of Weibo multimodal data. This research has broad application value in the fields of business intelligence decision-making, personalized recommendation systems, and social and psychological health monitoring, and provides an important theoretical basis and practical reference for the design and implementation of future intelligent sentiment analysis systems.

This study innovatively integrates the data processing of two modalities, image and text, and constructs a multi-dimensional sentiment analysis system by combining CNN, BiLSTM and AM to solve the key problems in the sentiment classification of multimodal data on the Weibo platform. In view of the complexity of multimodal data and the diversity of emotional expression, this study introduces an analysis framework that can efficiently integrate multimodal features, providing a new solution for sentiment classification; by optimizing the model structure and introducing advanced deep learning mechanisms, especially the effective application of the AM, the model's ability to focus on key emotional features is enhanced, thereby significantly improving the accuracy and robustness of sentiment classification. This study shows innovation in multimodal data processing, fully exploring and integrating the semantic complementarity and correlation between different modalities, and providing technical support for the modeling of complex emotional expressions. On the theoretical level, this study expands the research framework of multimodal sentiment analysis and deepens the understanding of sentiment feature extraction and classification methods; on the practical level, the proposed method has strong adaptability and scalability, and provides a practical solution for social media sentiment monitoring, public opinion analysis, and intelligent decision support. By optimizing and innovating existing methods, the data processing of image and text modes is innovatively integrated, which not only provides a theoretical basis for the development of sentiment analysis technology, but also opens

up a new direction for research and application in related fields, which has important academic value and practical significance.

II. Related Work

The research on multi-dimensional digital media emotion visualization [7] intelligent analysis system is a cutting-edge direction in the intersection of artificial intelligence and big data analysis. It aims to achieve comprehensive mining and intuitive presentation of emotional information in digital media by integrating multimodal data [8] processing technology and deep learning algorithms [9]. In recent years, sentiment analysis has expanded from traditional unimodal text analysis to multimodal data processing, and the research focus has gradually shifted to how to efficiently extract and fuse multimodal features such as text and images to improve the accuracy and robustness of sentiment classification. In this context, CNN has become the core technical support for multimodal sentiment analysis systems due to its excellent performance in image feature extraction. BiLSTM has become the core technical support for multimodal sentiment analysis systems due to its ability to accurately capture text time series features, and AM has become the core technical support for multimodal sentiment analysis systems due to its advantage in focusing on key features. As an important part of research, sentiment visualization greatly improves the interpretability and user experience of sentiment analysis results by graphically presenting the distribution, trend and structure of sentiment data. Existing research has shown wide application value in fields such as social media sentiment monitoring, public opinion analysis and business intelligence decision-making. However, the semantic differences between multimodal data and the complexity of feature fusion are still difficulties in current research. Therefore, how to build an efficient, accurate and scalable multi-dimensional sentiment analysis system has become the key to promoting the development of this field.

The application of machine learning algorithms in multi-dimensional sentiment analysis systems is an important research direction in the current field of artificial intelligence and big data analysis [10], dedicated to solving the complexity of sentiment data and multi-modal feature fusion problems in digital media [11]. Digital media sentiment data usually exists in various forms such as text and images, and is characterized by high dimensionality, nonlinearity, and heterogeneity, which poses a severe challenge to traditional sentiment analysis methods. In text data processing, deep learning models such as BiLSTM can capture the contextual semantic relationship of text and dynamically focus on key sentiment-related content through the AM, thereby improving the accuracy of sentiment classification. In terms of image analysis, CNN effectively extracts emotion-related visual features through multi-layer convolution operations, especially in facial expression and scene emotion analysis. The key to a multimodal emotion analysis system lies in feature fusion. Machine learning achieves deep alignment and fusion at the semantic level through joint modeling of text and images, and enhances the ability to understand complex emotional expressions. Sentiment visualization technology combines dimensionality reduction and clustering algorithms [12] to transform high-dimensional sentiment data into intuitive graphical representations, providing users with clear insights into sentiment distribution and trends. Advanced deep learning methodologies such as LSTM, CNN, and BERT have been explored to enhance sentiment interpretation within natural language processing, as demonstrated by Aniket Kulkarni et al. (2024). Our framework incorporates their transformer-based advancements along with contextual embedding techniques to evaluate sentiment across multiple digital formats, thereby improving accuracy, scalability, and offering richer, multi-dimensional visualization capabilities [13]. A sentiment classification system combining Levy distribution-based Dung Beetle Optimization (LDBO) with Support Vector Machine (SVM) focuses on social media content, following the approach introduced by Layth Hussein et al. (2024). By leveraging this optimization technique, our model enhances feature extraction and hyperparameter tuning for multi-modal sentiment analysis, resulting in superior classification performance and operational efficiency that supports real-time, intelligent sentiment representation [14]. Mohan Reddy Sareddy (2023) investigated cloud-based CRM infrastructure strategies aimed at fostering business success within digital ecosystems. Building on this foundation, our research integrates machine learning models for comprehensive sentiment assessment and multi-format visualization across various digital channels, which enables rapid and actionable insights that support strategic decision-making and enhance engagement beyond traditional CRM functionalities [15]. Peng Yang (2019) developed a phishing detection framework employing deep learning techniques such as multidimensional feature extraction and sequential analysis. Adapting their BiLSTM and attention-based mechanisms, our system captures temporal sentiment dynamics within intricate digital media datasets, emphasizing emotionally significant features, which leads to enhanced classification accuracy and more nuanced, interpretable sentiment visualizations [16]. An ensemble blending method to advance behavioral data analysis through the combination of multiple machine learning models was proposed by Akhil Raj Gaius Yallamelli et al. (2025). Our platform utilizes this ensemble blending strategy to enhance sentiment analysis across varied digital media, thereby increasing prediction accuracy and delivering more detailed, insightful visualizations of user sentiment [17]. The comprehensive application of these technologies not only promotes the technological progress of multi-dimensional sentiment analysis systems but also provides solid technical support and practical significance for social media public opinion monitoring, brand sentiment analysis, and user behavior prediction.

III. Methods

A. Data Source

The data in this study comes from the Weibo platform. The reason for choosing this platform is that its users are highly active, the content is diverse, and it can provide rich emotional expression samples. The specific data collection range is from January to December 2021, ensuring that the data covers a full annual cycle to capture the trend of sentiment changes in different time periods. The data volume comes from the Weibo content of 1,000 users, who are selected based on their activity level and content diversity to improve the representativeness of the data and the emotional coverage. The data types collected include text and images, which are used to analyze emotional expressions at the language and visual levels respectively.

In order to efficiently obtain Weibo data, advanced web crawler technology [18-19] was used to collect Weibo content from 1,000 users, following the platform's terms of service and data collection specifications to ensure the legality and compliance of data collection. The crawler tool simulates user behavior and regularly captures the target user's Weibo content, including text, images, comments, forwarding numbers, and likes, to construct a multi-dimensional sentiment analysis dataset. In the user screening stage, user groups with different genders, ages and regional distributions were selected to ensure the diversity and representativeness of the sample. In addition, through keyword filtering and emotional label pre-classification, the collected data was guaranteed to cover microblog content with positive emotions, negative emotions and neutral emotions. The collected text data is shown in Table I.

TABLE I. TEXT DATA DISPLAY

User	Text	Emotional tendency	Category
1	I am so happy to have found a satisfying job!	Positive	Joy
2	Thank you friends for your continued support, I am deeply touched.	Positive	Gratitude
3	I won first place in the campus sports meet today and I feel very proud.	Positive	Pride
4	I didn't react much when I heard the news, I just thought it was quite normal.	Neutral	Calm
5	This movie was kind of boring and started to distract.	Neutral	Boring
6	A bit confused as to why this question is so complicated.	Neutral	Puzzled
7	I'm so fed up with the delays on this project, it's so infuriating!	Negative	Anger
8	After hearing the news, I felt very sad and heavy in my heart.	Negative	Sad
…	…	…	…
1000	Life has been a mess lately and everything feels wrong.	Negative	Anxiety

B. Data Preprocessing

Text data preprocessing includes word segmentation, stop word removal, sentiment vocabulary tagging and text vectorization. Weibo texts are mostly unstructured data and need to be segmented to split continuous Chinese character sequences into word sequences. The Chinese word segmentation tool Jieba is used, which is based on the hidden Markov model and achieves efficient word segmentation through probability statistics and dictionary matching. The word segmentation formula is expressed as:

$$P(W|S) = \prod_{i=1}^{n} P(w_i|s_i) \quad (1)$$

where, W represents a word sequence, S represents a state sequence, w_i and s_i represent a word and a state respectively.

Stop words refer to words that have no practical meaning in semantic analysis. By matching the stop word list, these words are filtered out from the word segmentation results, and words with emotional meaning are retained. Sentiment word tagging refers to tagging sentiment words in texts using a method based on sentiment dictionaries. Sentiment dictionaries include positive words, negative words, and degree adverbs. The formula for calculating sentiment intensity is expressed as:

$$S = \sum_{i=1}^{n} (P_i \cdot M_i) \quad (2)$$

P_i represents the polarity weight of the ith sentiment word, and M_i is the weight correction value of the degree adverb.

Text vectorization is to convert text into a vector form using the Word2Vec model. Word2Vec trains word vectors through the skip-word model, which can capture the semantic relationship between words. The objective function is expressed as:

$$J = -\frac{1}{T} \sum_{t=1}^{T} \sum_{-c \le j \le c, j \ne 0} \log P(w_{t+j}|w_t) \quad (3)$$

T represents the corpus length, c is the context window size, w_t and w_{t+j} are the center word and context word, respectively.

Image data preprocessing includes image preprocessing and feature extraction. To ensure the consistency of model input, all images are adjusted to 224×224 pixels to adapt to the input requirements of the deep learning model, and median filtering is used to remove noise in the image and enhance image clarity. The median filtering formula is expressed as:

$$f(x,y) = \text{median}\{g(i,j)\}, (i,j) \in N(x,y) \quad (4)$$

where, $g(i,j)$ represents the pixel value in the area $N(x,y)$, and $f(x,y)$ is the pixel value after filtering. In order to accelerate model training and improve convergence speed, normalization is also required to scale the pixel value to the range of [0, 1]. The normalization formula is expressed as:

$$x' = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (5)$$

Feature extraction refers to extracting deep features of an image using a pre-trained ResNet-50 model [20]. Through the above method, both text and image data are converted into a unified vector form, laying a solid foundation for the subsequent training of sentiment analysis models and multimodal fusion.

C. Model Design and Construction

In this study, CNN is used to process image data in Weibo to help extract emotion-related visual features. CNN contains convolutional layers and pooling layers. The core idea of the convolution operation is to use multiple filters to slide the image, calculate the weighted sum of the local area, and generate a feature map. The convolution operation formula is as follows:

$$F(x,y) = (I * K)(x,y) = \sum_{m=-M}^{M} \sum_{n=-N}^{N} I(x+m, y+n) K(m,n) \quad (6)$$

The formula for maximum pooling is as follows:

$$P(x,y) = \max_{m,n \in R} F(x+m, y+n) \quad (7)$$

where, R represents the size of the pooling window, and $P(x,y)$ is the feature map after pooling. Through multi-layer convolution and pooling operations, CNN can gradually extract low-level to high-level spatial features in the image and significantly reduce the number of parameters, thereby improving computational efficiency.

BiLSTM can learn the contextual information of the text from both forward and reverse directions, so as to more comprehensively understand the emotional expression of the text. LSTM units have memory functions and can maintain and update important information in long time series. The calculation formulas of LSTM are expressed as:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (8)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (9)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \quad (10)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (11)$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (12)$$

$$h_t = o_t * \tanh(C_t) \quad (13)$$

The AM aims to improve the model's attention to key parts by calculating the weights of each part of the input sequence. When processing long sequence inputs, it can avoid information loss and improve the accuracy of sentiment analysis. The common attention calculation method is based on the additive model, in which, given the query vector q and the key vector k, the attention weight is calculated as:

$$\alpha_i = \frac{\exp(e_i)}{\sum_{j=1}^{n} \exp(e_j)} \quad (14)$$

Among them, e_i=score (q, k_i) is the similarity score between the query vector and the key vector. The commonly used scoring function is expressed as:

$$e_i = w^T \tanh(W_q q + W_k k_i) \quad (15)$$

where, W_q and W_k represent weight matrices, and w is a trainable parameter. After obtaining the weights, the attention output is obtained by weighted summation:

$$\text{Attention Output} = \sum_{i=1}^{n} \alpha_i \cdot v_i \quad (16)$$

where, α_i represents the value vector, and v_i is the corresponding weight. The AM enables the model to dynamically adjust its attention to the input according to the intensity of the emotion, which can effectively improve the performance of the model for long text or complex image data.

D. Multi-Dimensional Sentiment Analysis System

The multidimensional sentiment analysis system is an intelligent system that comprehensively utilizes advanced technologies such as natural language processing, computer vision, deep learning, and machine learning to process and integrate multimodal information of different data types to perform sentiment analysis on digital media content such as social platforms. Through the combination of deep learning, machine learning and other advanced technologies, the system can fully understand and predict user emotions from a multi-dimensional perspective and provide valuable emotional information for decision makers. The system interface constructed in this study is shown in Fig. 1.

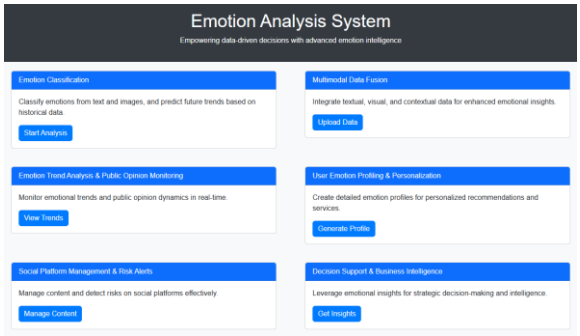

Fig. 1. System interface

The multi-dimensional digital media emotion visualization intelligent analysis system in this study combines advanced machine learning and deep learning technologies to perform efficient emotion analysis and prediction on multimodal data on Weibo, thereby achieving accurate emotion expression recognition and emotion trend visualization. The analysis system uses advanced technologies such as natural language processing, computer vision and deep learning, and has many innovative functions, including sentiment classification and prediction, multimodal data fusion, sentiment trend analysis and public opinion monitoring. Its core role is to help all types of users make data-driven decisions in the rapidly changing social media environment through accurate sentiment recognition and trend monitoring, improve operational efficiency, enhance user experience, optimize social public opinion management, and provide strong emotional intelligence support for various industries.

E. Model Training and Optimization

The distribution of the data set is shown in Table II.

TABLE II. DATA SET DISTRIBUTION

Category	Training set	Validation set	Test set
Joy	714	204	102
Gratitude	686	196	98
Pride	854	244	122
Calm	763	218	109
Boring	707	202	101
Puzzled	609	174	87
Anger	651	186	93
Sad	658	188	94
Anxiety	672	192	96

Emotional categories are classified into three tendencies: positive, neutral, and negative. The data composition is shown in Table III.

TABLE III. EMOTIONAL TENDENCY DATA

Tendency	Training set	Validation set	Test set
Positive	2254	644	322
Neutral	2079	594	297
Negative	1981	566	283

The initialization parameters for model training in this study are shown in Table IV.

TABLE IV. MODEL INITIALIZATION PARAMETERS

Initialization content	Effect	Value
Convolution kernel size	Extract local features of images	3×3
Number of convolutional layers	Depth of feature extraction	4
Convolution stride	Control the sliding step size of the convolution kernel	1
Pooling window size	Reduce feature map dimension	2×2
Number of LSTM hidden units	Controlling the memory capacity of BiLSTM	128
Number of LSTM layers	Enhance the model's ability to learn long sequence dependencies	2
Number of Attention Heads	Improve the model's ability to focus on key emotional information	8
Dropout probability	Preventing Overfitting	0.5
Learning Rate	Control the step size of model parameter updates	0.001
Optimizer	Efficiently optimize model parameters	Adam

The sentiment analysis model in this study mainly uses Dropout and L2 regularization. Dropout is a technique that randomly discards neural network nodes during training, with the aim of reducing the dependency between neurons and preventing the model from overfitting. The specific approach is to randomly discard the output of a part of the neurons during each training.

Accuracy is one of the most commonly used classification indicators, indicating the proportion of samples predicted correctly by the model of the total samples. The macro F1 value can effectively deal with the problem of class imbalance by calculating the F1 value of each category and then finding its arithmetic mean. The formula is:

$$\text{Macro F1} = \frac{1}{C}\sum_{i=1}^{C} \text{F1}_i \quad (17)$$

C represents the total number of categories. By introducing regularization technology and Adam, the model in this study can effectively avoid overfitting and accelerate convergence in sentiment analysis tasks, improving the accuracy and stability of sentiment classification. At the same time, accuracy and macro F1 value as evaluation indicators can fully reflect the performance of the model. When facing multi-category sentiment classification tasks, the macro F1 value can more fairly evaluate the overall performance of the model.

IV. RESULTS AND DISCUSSION

A. Sentiment Classification Performance

In order to evaluate the sentiment classification effect of different models when processing multimodal data on the Weibo platform, the accuracy is compared. The comparison results of the sentiment classification accuracy of different models are shown in Fig. 2.

According to the provided sentiment classification accuracy data, it can be clearly seen that the performance of the model has been significantly improved with the improvement of the architecture, and the CNN-BiLSTM-Attention model performs significantly better than other models in the sentiment classification task, with accuracies of 97.5 per cent, 95.4 per cent and 91.6 per cent for positive, neutral and negative sentiments respectively. This significant improvement is mainly due to the introduction of the AM. CNN extracts local features of images through convolutional layers. Although it can process image information, it is not capable of processing text data in sentiment analysis tasks, resulting in relatively low accuracy in the classification of negative and neutral sentiments. BiLSTM effectively captures contextual information in text through a bidirectional structure and can solve the problem of long-term dependency, but it is still limited in distinguishing complex emotions. The model can pay more attention to the parts with strong emotional expressions, thereby improving the accuracy of classification. The role of the AM is to avoid information loss in long texts or complex emotional expressions in traditional models through a weighted mechanism, allowing the model to more accurately capture subtle differences in emotions. In addition, reinforcement learning is performed on keywords, phrases, or contexts in each emotional category, which effectively improves the classification accuracy of complex emotions, thereby significantly improving the classification accuracy of positive and neutral emotions.

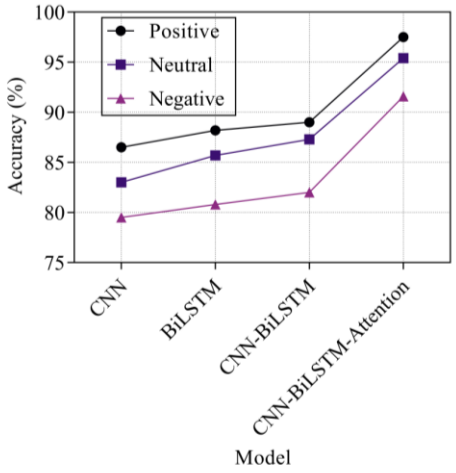

Fig. 2. Sentiment classification performance

B. Positive Sentiment Classification Ability

The comparison results of positive sentiment tendency classification macro F1 of different models are shown in Fig. 3.

From the data in Fig. 3, the macro F1 scores of the CNN-BiLSTM-Attention model in the three positive emotion categories of joy, gratitude and pride are 0.97, 0.94 and 0.91, respectively, which are significantly better than other models, mainly due to its effective focus on key emotional information and accurate capture of emotional expression in long texts. Although the CNN model can extract local features of images through convolutional layers, it has limited ability to process long-term dependencies and complex emotional expressions in texts, so its macro F1 score in sentiment classification is low, especially in pride, with a macro F1 of 0.74. BiLSTM captures the contextual information of texts through a bidirectional structure, which can better solve the limitations of traditional LSTM in processing long texts. In the classification tasks of joy,

gratitude, and pride, the macro F1 scores have improved to 0.85, 0.83, and 0.79, respectively; however, BiLSTM still faces the problem of integrating image information and text information when processing multimodal data, so it has not achieved the best results in combining image and text information. After the CNN-BiLSTM-Attention model introduces the AM, it enhances the model's attention to key information by assigning different weights to different input parts. In situations where emotional expression is strong, it can effectively reduce the problem of information loss and improve the accuracy of sentiment classification. This shows that the AM not only improves the accuracy of the classification model but also improves the ability to extract emotional information in multimodal data fusion, so the CNN-BiLSTM-Attention model has a better macro F1 score for positive emotions than other models.

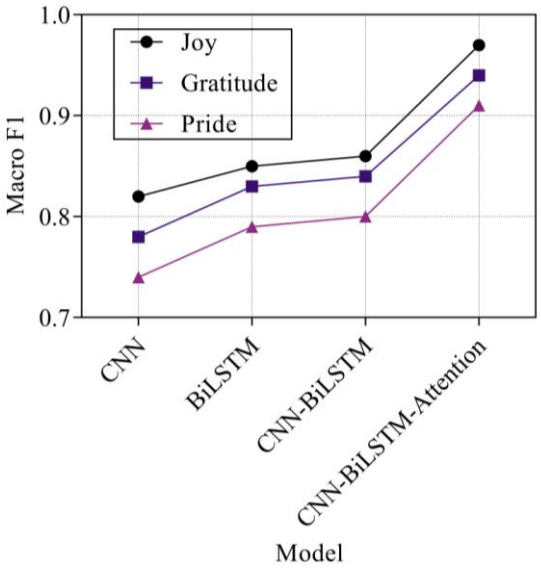

Fig. 3. Positive sentiment classification performance

C. Neutral Emotion Classification Ability

The comparison results of the neutral emotion tendency classification macro F1 of different models are shown in Fig. 4.

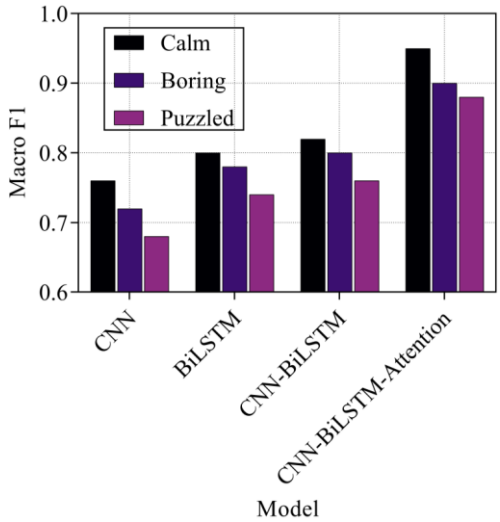

Fig. 4. Neutral sentiment classification performance.

As the model complexity increases, the macro F1 scores of each neutral sentiment category gradually improve; among them, CNN-BiLSTM-Attention performs best, with macro F1 of 0.95, 0.90, and 0.88 for calm, boring, and puzzled, respectively. The relatively low macro F1 score of the CNN model reflects that CNN has limited ability to understand emotions when processing text data, especially when processing complex neutral emotions, it cannot effectively extract contextual information, resulting in low classification accuracy. The macro F1 score of the BiLSTM model has been improved. Compared with CNN, BiLSTM captures the contextual information in the text through the bidirectional LSTM structure, which can better understand and analyze the subtle differences in neutral emotions, and has a stronger ability to capture long texts and complex emotions, but there is still room for improvement. The macro F1 score of the CNN-BiLSTM model has been further improved, especially in the performance of "calm" and "boring" emotions, which have been significantly improved to 0.82 and 0.80 respectively; after introducing the fusion of image and text information, the model can more comprehensively understand multi-dimensional emotional expressions, so its performance has been improved. With the introduction of the mechanism, the model can more accurately identify and classify neutral emotions with vague and complex emotional expressions, significantly improving the classification performance.

D. Negative Emotion Classification Ability

The comparison results of the negative emotion tendency classification macro F1 of different models are shown in Fig. 5.

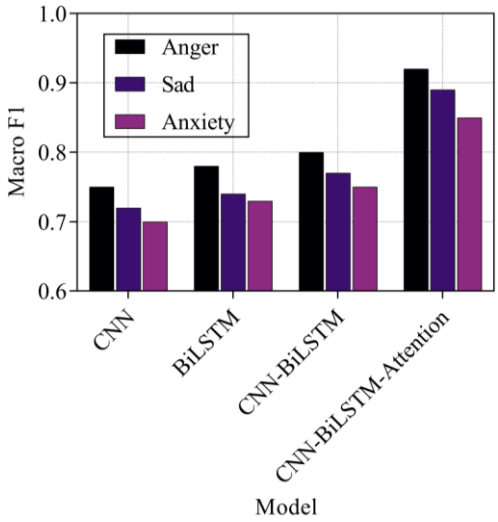

Fig. 5. Negative sentiment classification performance.

The macro F1 of CNN-BiLSTM-Attention for anger, sad, and anxiety are 0.92, 0.89, and 0.85, respectively, which reflects the enhanced feature extraction and information processing capabilities at a deeper level. The macro F1 score of the CNN model is relatively low, mainly because the convolution operation of CNN has limitations in the application of text data. The BiLSTM model has improved its performance in negative sentiment classification, and its score is higher than that of CNN. However, when processing large-scale sentiment data, it still faces the problems of uneven distribution of sentiment information and vague sentiment expression, which leads to

insufficient recognition accuracy of the model in some negative sentiments. The CNN-BiLSTM model further combines the local feature extraction of CNN and the long-term dependency modeling of BiLSTM. Through multi-layer feature fusion, the model can overcome the limitations of CNN single convolutional layer feature extraction to a certain extent and improve classification accuracy. The most notable is the performance of the CNN-BiLSTM-Attention model, which has significantly improved its score on Macro F1. The AM significantly enhances the model's ability to capture key information by focusing on important information in the input data. In the recognition of negative emotions, the model can more accurately locate the key expression of emotions, effectively solving the problem of emotional information loss in long sequences, and ultimately improving the accuracy and robustness of classification. This improvement reflects the huge potential of multimodal information fusion and deep learning technology in sentiment analysis, and its superiority in complex sentiment analysis tasks.

V. Conclusion

This study successfully improved the sentiment classification performance of text and image data on the Weibo platform by building a multi-dimensional sentiment visualization intelligent analysis system based on the CNN-BiLSTM-Attention model, and achieved remarkable results in the recognition of negative, positive and neutral sentiment. By effectively combining a convolutional CNN, BiLSTM and Attention, this not only improves the accuracy and macro F1 score of sentiment classification, but also breaks through the limitations of traditional sentiment analysis methods in processing long sequence data, complex emotional expressions and multimodal information fusion. The main contribution of the study is to build an innovative multimodal sentiment analysis framework that can simultaneously utilize the features of text and image data, solve the problems of information diversity and context dependence in sentiment analysis, and optimize the model's sensitivity to sentiment intensity and subtle differences through the AM. This system not only provides a more accurate and efficient solution for sentiment analysis in social media, but also provides a new research perspective and technical path for fields such as sentiment computing, sentiment visualization and social network analysis. This study can help all kinds of enterprises and organizations to more accurately grasp user sentiment, optimize business decisions such as customer service and marketing, and promote the development of applications such as social opinion analysis and mental health intervention. However, this study also has some limitations, mainly in terms of the size of the dataset and the diversity of sentiment categories. The model is unstable when dealing with sentiment classification tasks on other platforms or in different language environments. Although the CNN-BiLSTM-Attention model performed well in this study, its computational complexity is high, and there is still room for optimization in training and inference time. Future research can further improve the generalization and real-time performance of the model by expanding the dataset size, enhancing cross-platform adaptability, and optimizing the model structure and algorithm efficiency, thus providing more efficient technical support for large-scale sentiment analysis applications.

***Abstract*—Alzheimer's disease (AD) is a leading cause of dementia, yet its diagnosis remains challenging. EEG provides a noninvasive and cost-effective method for monitoring brain activity, which may reflect both cognitive decline and altered emotional states. In this study, an EEG-based pipeline was developed to classify AD using two approaches: an ensemble of boosting classifiers based on extracted features, and a deep convolutional neural network (CNN) applied to raw signals. A publicly available dataset was processed to extract time, frequency, and complexity features, with emotional brain dynamics implicitly reflected in the signals and considered during analysis. Five ensemble models (including CatBoost, LightGBM, and XGBoost) were optimized using Bayesian search. The CNN was trained separately and evaluated under cross-validation schemes. A balanced accuracy of 78.96% was achieved for AD detection using XGBoost, while the CNN reached 70.92% for Frontotemporal dementia. The study demonstrates that combining machine learning with EEG produces generalizable models for dementia detection and suggests that accounting for emotion-related variability may enhance diagnostic results.**

I. Introduction

Dementia has been recognized as a growing global health concern, with over 50 million individuals currently affected. This number is expected to increase to over 100 million by 2050. Among the various forms of dementia, Alzheimer's disease (AD) is the most common, representing around 60 to 80% of diagnosed cases. Frontotemporal dementia (FTD), although less prevalent, is one of the leading early-onset subtypes and is characterized by diverse clinical presentations [1]. The accurate and early differentiation between dementia subtypes remains a critical need, as effective clinical management, prognosis, and treatment decisions are heavily dependent on the correct diagnosis. However, the diagnostic process continues to pose difficulties, particularly due to the subjective nature of neuropsychological assessments and the reliance on advanced imaging techniques that may not be universally accessible.

Neuroimaging modalities such as magnetic resonance imaging (MRI) and positron emission tomography (PET) have been routinely used to support dementia diagnosis. PET scans, for instance, can reveal amyloid plaque accumulation and regional metabolic changes that are often associated with Alzheimer's pathology. Despite their utility, these imaging approaches present limitations. They are often costly, involve limited access in certain clinical settings, and in the case of PET, expose patients to ionizing radiation. Furthermore, such methods provide only indirect and static assessments of brain function. The temporal resolution of MRI and PET is low, which restricts their ability to observe dynamic neural processes that may reflect cognitive and emotional states in real time. Because of these limitations, increasing attention has been given to alternative diagnostic tools that offer safe, affordable, and functionally informative assessments of brain activity [2].

Electroencephalography (EEG) has emerged as a promising technique in this context. EEG provides direct, high-temporal-resolution recordings of electrical brain activity and is widely available in clinical environments. Unlike imaging techniques, it captures fast-changing neural oscillations and is well suited for identifying abnormalities in functional connectivity and rhythm patterns associated with neurodegenerative disorders [3]. In dementia, characteristic changes have been consistently observed. These include a general slowing of brain rhythms, specifically, increased power in delta and theta bands and reduced power in alpha and beta bands. Additionally, lower signal complexity and decreased inter-regional coherence have been reported [4]. Such changes are often quantified using entropy, fractal dimension, and other non-linear measures. These alterations may reflect not only cognitive deterioration but also changes in emotional processing and brain state, which are often affected in dementia, particularly in FTD. As a result, EEG has been increasingly recognized for its potential to contribute to differential diagnosis and to detect subtle emotional or cognitive alterations that may not be visible through structural imaging [5].

The proposed methodology, as shown in Fig. 1, builds upon earlier research by incorporating more diverse feature sets, better validation practices, and state-of-the-art learning techniques. Previous EEG classification efforts have been reviewed extensively. Classical machine learning studies typically reported AD classification accuracies in the range of 75 to 85% when subject-aware validation was applied. For instance, Tzimourta *et al.* conducted a systematic review and found that traditional models based on handcrafted features often performed reasonably well under careful evaluation [6]. However, when improper validation was used, much higher but unreliable accuracies were observed. Goerttler *et al.* later demonstrated that incorporating a balanced set of spectral, spatial, and temporal features, along with grouped validation,

could achieve improved results. Their SVM model attained around 83.6% accuracy for AD classification [7].

Therefore, the present study seeks to answer the following research questions, aiming to advance dementia detection through signal dynamics modeling:

- How does enforcing subject-level separation through grouped cross-validation influence the perceived generalization ability of EEG-based dementia classifiers?
- Can modeling emotion-related variability in resting-state EEG signals improve the accuracy of machine learning approaches for early dementia detection?
- How do feature-based boosting methods and end-to-end CNNs differ in their ability to capture cognitive signatures associated with AD and FTD?

To address these limitations, a machine learning pipeline was developed, focusing on reproducibility and methodological rigor. A set of features was extracted, covering time-domain statistics, frequency-band characteristics, and signal complexity measures. These features were intended to capture various aspects of brain activity that are known to be affected in dementia and potentially linked to altered emotional states. By adopting a stratified grouped cross-validation framework, care was taken to ensure that all data from an individual subject was contained within a single fold. This was done to prevent data leakage and to simulate real-world diagnostic scenarios more closely.

In the machine learning stage, five boosting ensemble classifiers were trained: Extremely Randomized Trees, XGBoost, HistGradientBoosting, LightGBM, and CatBoost. These models were selected for their ability to handle structured data and for their success in many biomedical classification tasks. Each model was tuned using Bayesian optimization to identify the most effective combination of parameters for the given data. Parallel to this feature-based approach, a CNN was also designed and trained directly on the raw signals. This allowed the model to learn discriminative patterns without the need for manual feature selection. This architecture was inspired by successful models used in other applications, such as psychiatric disorder classification.

The CNN was evaluated under both grouped and ungrouped validation schemes to assess the extent to which data leakage may affect deep learning performance. By comparing these evaluation strategies, it was possible to quantify the artificial performance gains introduced by improper splitting and to emphasize the importance of grouped evaluation. The inclusion of both ensemble and deep learning methods enabled a comprehensive comparison of approaches and demonstrated their complementary strengths.

As key contributions of this study, we present:

- A novel pipeline for dementia classification that combines both feature-based ensemble learning and deep learning directly from raw signals.
- One of the first systematic comparisons of a set of modern boosting algorithms and CNNs using grouped cross-validation to prevent data leakage.
- The feature engineering and incorporation of emotion-related variability as a potential factor influencing EEG signals and dementia detection performance.

The remainder of the study is organized as follows: Section II reviews related work. Section III presents the dataset, preprocessing steps, feature extraction pipeline, and the design of both the ensemble learning models and the convolutional neural network. Section IV details the experimental results and evaluation. Section V discusses the implications of the findings and the impact of validation strategies on reported performance. Finally, Section VI concludes the study, outlines its limitations, and suggests directions for future research.

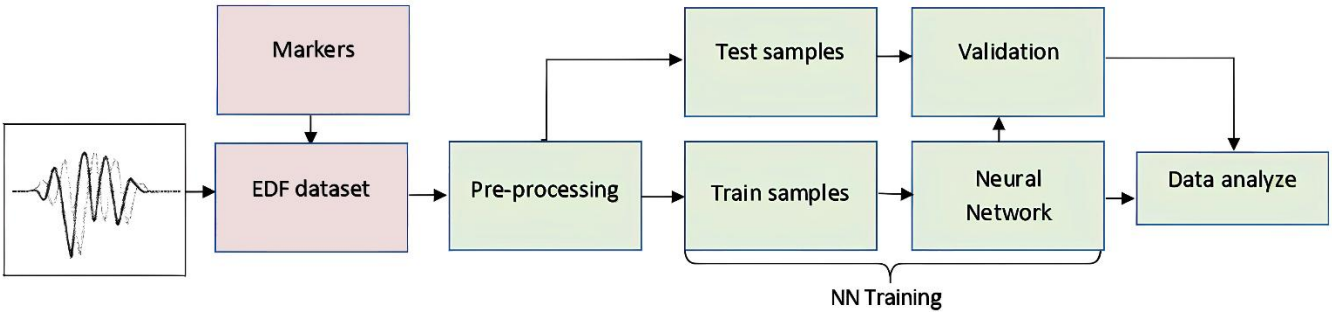

Fig. 1. Overview of the proposed methodology

II. Related Works

Computational methods have been developed to use EEG signals for automated dementia diagnosis, with early studies relying on classical machine learning techniques applied to manually extracted features. Among these, statistical and spectral descriptors such as band power and signal amplitude distributions were commonly used. Models such as Support Vector Machines (SVM), k-Nearest Neighbors (k-NN), and Random Forests were frequently employed and achieved moderate classification performance [8]. However, these works often exhibited certain limitations, with one of the most significant being improper model validation [9]–[11].

In many studies, EEG epochs (segments of continuous recordings) were randomly assigned to training and test sets using standard k-fold cross-validation, without accounting for subject identity [12]. This allowed data from the same individual to appear in both sets, inadvertently leaking subject-specific information and inflating model performance. In

contrast, when proper validation strategies, such as leave-one-subject-out or grouped k-fold cross-validation, were applied, performance often decreased considerably. This observation highlighted the need for more rigorous evaluation practices.

An example of this issue was demonstrated by Miltiadous *et al.*, where a Random Forest classifier trained on EEG data achieved nearly 99% accuracy for distinguishing AD from control subjects when evaluated using standard k-fold validation [13]. However, when a grouped validation method was used, accuracy dropped to approximately 78%, illustrating the significant impact of cross-validation strategy. Despite this, many existing studies continued to report only standard cross-validation results, often without an independent test set [14]. In addition to validation concerns, previous work frequently relied on a narrow range of features and default model parameters, leaving room for improvement through more thorough feature engineering and hyperparameter tuning. Modern ensemble learning methods such as gradient boosting algorithms and deep learning approaches have not been widely explored in this context, particularly for EEG-based dementia classification [15].

In one study, EEG signals were converted into spectrogram images and input into a CNN along with connectivity matrices, achieving high classification accuracy for three classes: AD, FTD, and healthy controls [16]. Recurrent neural networks, such as Long Short-Term Memory (LSTM) models, have also been applied, particularly for capturing the temporal dynamics of EEG signals [17]. While these models showed potential, their success was often limited by the size and quality of available datasets. Alessandrini *et al.*, for example, used an LSTM to classify multiple dementia types and achieved around 75.3% accuracy, suggesting that more data or improved architectures might be necessary [18].

Hybrid strategies have also been developed. Nour *et al.* proposed an ensemble of multiple CNNs, each trained on different input representations, and combined their outputs to improve robustness [19]. Jha *et al.* further enhanced classification performance by integrating clinical data with EEG features in a boosted ensemble model. In another approach, graph-based signal processing techniques were used to represent EEG data as networks, which were then analyzed using graph Fourier transforms and classified with support vector machines. Although this method achieved promising results in binary classification, its performance dropped significantly in multi-class settings, possibly due to increased complexity and noise [20]. Seo *et al.* [21] investigated emotion recognition in AD patients using EEG data, comparing multilayer perceptrons (MLP), SVM, and recurrent neural networks (RNN). Their findings suggested that classical machine learning methods, particularly MLP, could achieve promising accuracy, indicating the importance of affective state monitoring in dementia research. Extending beyond classical models, Gu *et al.* [22] provided a systematic review of deep learning applications in EEG-based brain-computer interfaces (BCI), highlighting the growing use of GANs and recurrent models for decoding complex emotional and cognitive patterns.

Recent studies have begun to bridge emotion processing and dementia. Dauwels *et al.* [23] demonstrated that EEG synchronization measures differ between AD and controls, while also noting that emotional tasks could amplify these distinctions. Meanwhile, Kumfor *et al.* [24] showed that emotional reactivity, as measured by EEG, diminishes progressively in dementia patients, suggesting an avenue for incorporating affective features into diagnostic models.

With respect to modeling approaches, Pillalamarri *et al.* [25] systematically evaluated CNN architectures for emotion recognition using EEG, demonstrating that even simple autoencoder models can outperform traditional classifiers when trained on raw signals. Boosting methods have also been explored: Chatterjee *et al.* [26] applied gradient boosting machines to EEG emotion datasets, reporting superior performance over Random Forest, especially when combining time-frequency features.

A promising hybrid approach was proposed by Iyer *et al.* [27], who integrated boosting models with CNNs in an ensemble framework for emotion-aware EEG classification. Their results indicated that blending handcrafted and learned representations could enhance generalization. Cope *et al.* [28] investigated the impact of emotional context on EEG dementia biomarkers, finding that incorporating emotional modulation improved the robustness of dementia detection models.

Across all these efforts, it has been consistently shown that EEG signals contain valuable information for detecting dementia. However, evaluation practices, feature diversity, and algorithm selection have a substantial impact on reported results [29]. Models validated using subject-independent methods tend to yield more modest but realistic accuracies in the range of 70 to 85%, while those using standard cross-validation often report inflated performance above 90%. These discrepancies highlight the need for careful methodological choices.

III. METHODOLOGY

A. Dataset

In this study, we utilize a publicly available EEG dementia dataset published by Miltiadous *et al.* [30], hosted on the OpenNeuro repository. The dataset comprises resting-state EEG recordings collected from 88 participants at a neurology clinic in Greece. These participants are categorized into three diagnostic groups: 36 individuals with probable Alzheimer's disease (AD), 23 with Frontotemporal dementia (FTD), and 29 cognitively normal elderly controls (CN).

All participants underwent comprehensive cognitive evaluation, including the Mini-Mental State Examination (MMSE), to assess the severity of cognitive impairment. The AD group had a mean MMSE score of 18 (standard deviation [SD] 4.5), indicating moderate impairment. The FTD group had a higher average MMSE score of 22.2 (SD 8.2), reflecting milder but variable impairment, while the control group had an average MMSE score of 30, indicating no cognitive decline. The age distribution across the three groups was comparable, with mean ages ranging between 66 and 67 years. However, there were differences in sex distribution: the AD group included a higher proportion of female participants, whereas

the FTD and control groups consisted mainly of males. This dataset provides a valuable resource for exploring EEG-based biomarkers in the differential diagnosis of dementia.

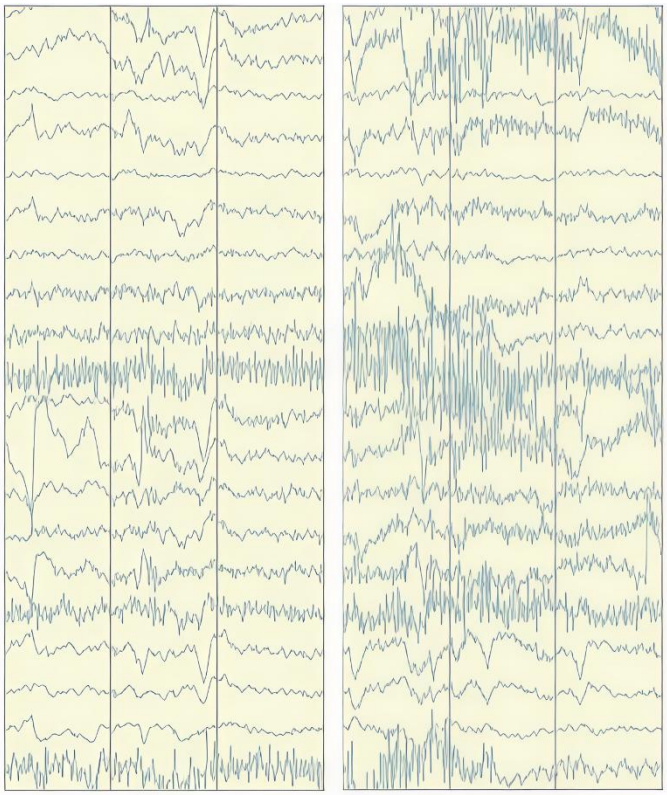

Fig. 2. Example of recorded signals in an awake resting state

EEG recordings were acquired from 19 scalp electrodes placed according to the international 10–20 system (channels: Fp1, Fp2, F7, F3, Fz, F4, F8, T3/T7, C3, Cz, C4, T4/T8, T5/P7, P3, Pz, P4, T6/P8, O1, O2). Two additional electrodes (A1, A2) served as reference leads during acquisition. Subjects were recorded in an awake resting state (eyes open, with minimal cognitive task) for several minutes, as shown in Fig. 2. The raw EEG signals were originally sampled at 500 Hz. As part of the dataset release, the authors provided data that had undergone some initial preprocessing: a band-pass filter from 0.5–45 Hz was applied (capturing the delta through low-gamma frequency range), and Artifact Subspace Reconstruction (ASR) was used to remove transient artifacts and high-amplitude noise burst. Furthermore, an Independent Component Analysis (ICA) with the ICLabel algorithm identified and removed components corresponding to eye-blink and muscle (jaw) artifacts. These steps attenuate common artifacts and yield cleaned multi-channel time series for each participant.

For our analysis, we carried out additional preprocessing to standardize the data and segment it for learning. First, we re-referenced each recording to the average of all 19 channels (common average reference montage). This step subtracts the mean signal across electrodes at each time point, which can reduce global noise and emphasize localized activity. Next, we epoched each continuous recording into non-overlapping segments of 10 to 12 seconds duration. Each epoch at 500 Hz contains 6000 time points per channel. We chose this window because prior research indicated that longer epochs (10 to 12s) improve dementia classification performance compared to shorter windows. In particular, Tzimourta *et al.* [31] found that length segments yielded higher accuracy for EEG-based AD detection than 4 or 5-second segments. After epoching, each participant's EEG is represented as a set of 10 to 12 s epochs (the number of epochs per subject depends on recording length; on average around 20 epochs per subject).

We then assigned labels to each epoch. Two labels were created: a group label indicating the subject of origin (so that all epochs from the same person share a unique ID), and a class label indicating the diagnosis (CN, AD, or FTD) of that subject. By tagging each epoch with a subject-group identifier, grouped splitting could be enforced in later steps to prevent leakage of person-specific patterns between training and testing. At this stage, the dataset was structured as a 3D array with dimensions (epochs × channels × timepoints) per class. A total of 4404 epochs were collected for the CN versus AD task, and 3366 epochs for the CN versus FTD task, where each epoch represented a multivariate time series.

Notably, although subjects were recorded in a nominal resting state, the brain's spontaneous activity during this period reflects ongoing internal cognitive processing. These intrinsic states may influence EEG patterns and add variability that reflects real-world conditions. As visualized in Fig. 3, differences in dynamics across epochs may partly arise from emotional fluctuations during the recording, suggesting that patients' active emotional states, while unprompted, still modulate the electrophysiological signals used for classification.

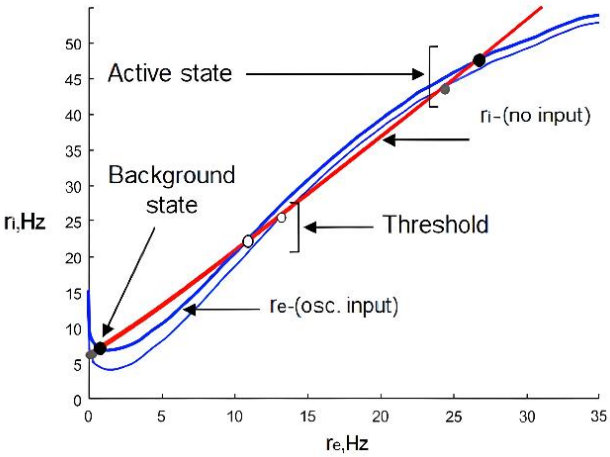

Fig. 3. Example of emotional fluctuations during the recording

A commonly used method for assessing emotional states in EEG data is event-related synchronization (ERS) or event-related desynchronization (ERD) within specific frequency bands in response to emotional stimuli. ERS and ERD are defined as increase or decrease, respectively, in the relative power of a particular rhythm, typically within the alpha, beta, or theta ranges [32]. These changes are considered indicative of underlying neural activation or inhibition in response to affective processing.

The strength of phase synchronization between frontal and right temporo-occipital electrodes has been shown to vary in relation to emotional arousal and tension. This modulation of synchronization reflects the brain's dynamic adaptation to emotional states and can be captured using EEG-based measures. In the context of machine learning, the core objective becomes modeling the relationship between these patterns and emotional responses. This is achieved by training the model on labeled data, allowing it to learn statistical dependencies between input signals and affective outcomes.

Principal components corresponding to the largest eigenvalues are typically used to extract features that capture the strongest correlations between EEG activity and emotional state. These components are particularly valuable in identifying the neural substrates of emotion-related responses. In this study, such EEG-derived features, including power modulations and connectivity patterns, were considered during classification, as they may contribute to the distinction between cognitive decline and emotion-linked neural signatures. Relevant aspects of these dynamics are illustrated in Fig. 4.

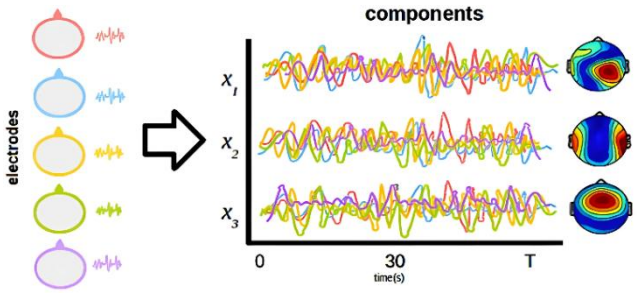

Fig. 4. Processing of emotional fluctuations based on emotion-linked neural signatures

Before feature extraction and modeling, we applied standard normalization. For the deep learning pipeline, each epoch's time series were z-score normalized (channel-wise) to have zero mean and unit variance before feeding into the CNN, which helps to stabilize training. For the feature-based pipeline, we similarly standardized features (after extraction) by z-scoring each feature variable across the training set.

B. Feature Extraction

To enable the use of ensemble classifiers, each EEG epoch was transformed into a structured set of quantitative features. The feature engineering process was designed to capture relevant characteristics across three primary domains: time-domain statistics, frequency-domain power spectra, and non-linear measures of signal complexity. In order to reduce noise and dimensionality, the 19 original EEG channels were grouped into five anatomically informed regions of interest (ROIs), following common practices in prior studies.

These regions were categorized as frontal, temporal, central, parietal, and occipital. Within each ROI, signals from the respective electrodes were averaged to create a single representative time series. This regional averaging reduced the dimensionality from 19 to 5 signals per epoch, while also potentially improving signal-to-noise ratio by minimizing random fluctuations present in individual channels. Following this transformation, each EEG epoch was represented as a time series with dimensions 5×6000, corresponding to 5 ROIs sampled over a 12-second window. From the ROI-aggregated signals, a total of 467 features were extracted for each epoch, as shown in Table I and Fig. 5. These features were identical in structure for classification tasks. The extracted features were grouped into three main categories:

1) Time-domain statistical features (15 per ROI) were computed to describe the amplitude and distribution characteristics of each signal. These included basic statistical measures such as mean, median, standard deviation, variance-to-mean ratio, minimum, maximum, and peak-to-peak amplitude. Additional descriptors included the interquartile range (IQR), root mean square (RMS) amplitude, and the sum of absolute differences between successive samples. Higher-order moments such as skewness and kurtosis were calculated to capture asymmetry and tail behavior in the signal distributions. Furthermore, three forms of mean absolute deviation (MAD1, MAD2, MAD3) were computed to quantify variability around central tendencies. These features have been commonly used in EEG classification tasks and are known to reflect relevant temporal dynamics in neural activity.

TABLE I. STRUCTURE OF THE FEATURE VECTOR PER EPOCH

Feature Category	Description	Features per ROI	ROIs	Total Features
Time-Domain Features	Mean, Median, Std Dev, Variance-to-Mean Ratio, Min, Max			
	Peak-to-Peak, IQR, RMS, Sum of Abs. Differences			
	Skewness, Kurtosis, MAD1, MAD2, MAD3	15	5	75
Frequency-Domain Features	Relative Band Power (Delta, Theta, Alpha, Beta, Gamma)	5	5	25
	Band Power Ratios (all unique pairs across RBPs)	—	—	300
Complexity Features	Approximate Entropy, Sample Entropy, Permutation Entropy			
	Spectral Entropy, SVD Entropy, DFA Exponent, Zero Crossings			
	Lempel-Ziv Complexity, Higuchi, Katz, Petrosian FD			
	Hjorth Mobility, Hjorth Complexity	15	5	75
Demographics	Age, Gender (One-hot: 0=Male, 1=Female)	—	—	2
Total				467

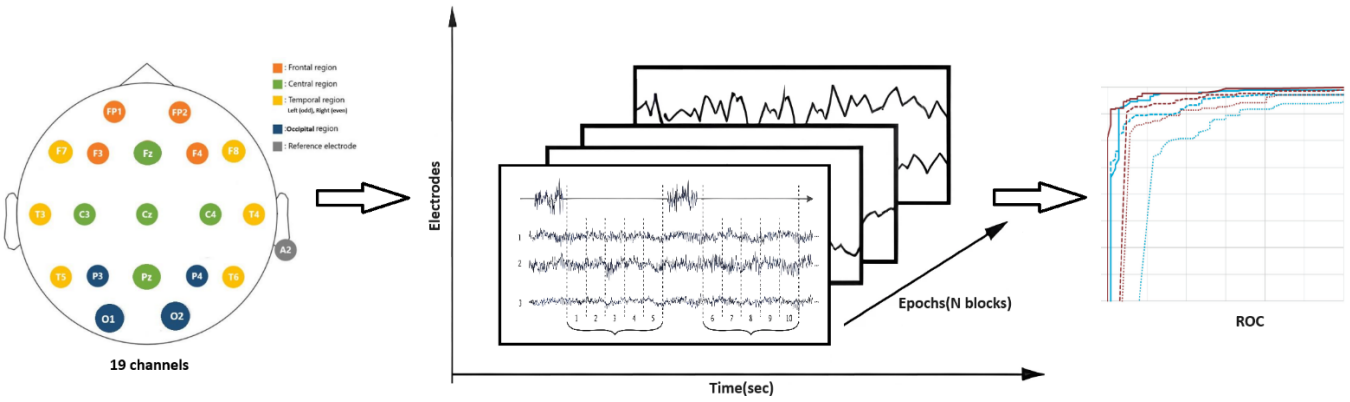

Fig. 5. The signal processing schema for feature extraction from each epoch

2) Frequency-domain features were derived using spectral decomposition tools, particularly the YASA toolbox. For each ROI, the relative band power (RBP) was computed for five canonical frequency bands: delta (0.5 to 4 Hz), theta (4 to 8 Hz), alpha (8 to 12 Hz), beta (12 to 30 Hz), and gamma (30 to 45 Hz). These power values were normalized as fractions of total power across the full frequency range. This procedure yielded 25 RBP features per epoch (5 bands across 5 ROIs). Additionally, power ratio features were calculated by forming all unique pairwise ratios between the 25 band-power features, resulting in 300 additional frequency features.

These ratios allowed the model to capture relative changes between frequency bands and brain regions, which are particularly relevant in conditions such as Alzheimer's disease, where increased theta and delta power relative to alpha and beta have been frequently observed. In total, 325 frequency-domain features were generated per epoch.

3) Complexity features (15 per ROI) were calculated to quantify the regularity and unpredictability of the EEG signals. These were derived using the AntroPy and EEGLib libraries and included entropy-based metrics (approximate, sample, permutation, spectral, and SVD entropy), fractal dimensions (Higuchi's, Katz's, Petrosian's), Hjorth parameters (mobility and complexity), Lempel-Ziv complexity, zero-crossing counts, and the detrended fluctuation analysis (DFA) exponent [33]. These measures provided insight into the non-linear, dynamical structure of EEG signals and were especially relevant in dementia, where reductions in signal complexity and entropy are typically observed. Across 5 ROIs, a total of 75 complexity features were extracted per epoch.

To account for demographic influences, two additional features, age and sex, were appended to each feature vector. These variables are recognized as risk factors for dementia, with age being a primary determinant of AD prevalence and possible sex-related differences observed in EEG patterns [34]. Gender was encoded as a binary feature (0 for male, 1 for female). The MMSE scores, despite their strong correlation with dementia severity, were deliberately excluded to prevent target leakage. Inclusion of MMSE would risk artificially boosting classification accuracy due to its near-linear relationship with the diagnosis.

C. Ensemble Learning Models

Five ensemble machine learning classifiers were trained on the extracted EEG features: Extra Trees (Extremely Randomized Trees), XGBoost (Extreme Gradient Boosting), HistGradientBoosting (Histogram-based Gradient Boosting), LightGBM (Light Gradient Boosting Machine), and CatBoost (Categorical Boosting). These models were selected due to their proven performance in handling structured data and their capacity to process high-dimensional feature sets effectively. As each model included several hyperparameters—such as the number of estimators, tree depth, and learning rate—model tuning was required to ensure optimal performance.

To minimize overfitting and enable fair model selection, stratified grouped 5-fold cross-validation (CV) was applied. Initially, the full dataset was divided into a training set and an independent hold-out test set. This partition was made by assigning 20% of subjects from each class to the test set, with the remaining 80% allocated to training. Within the 80% training set, model selection and hyperparameter tuning were conducted using stratified grouped 5-fold CV.

Subjects in the training set were split into five folds, each containing entire subject recordings while preserving class balance. For each fold, a model was trained on four folds and validated on the remaining one. This procedure was repeated across all five folds, with performance metrics averaged to assess model quality, preventing leakage of subject-specific patterns between training and validation subsets. Given that false positives and false negatives both have clinical consequences in dementia diagnosis, balanced accuracy was considered more suitable than metrics such as F1-score.

Hyperparameter optimization was performed for each classifier using Bayesian search with the HyperOpt library [35]. Unlike brute-force grid search, Bayesian optimization evaluates a sequence of hyperparameter combinations, using past results to choose the next combination in an informed manner. Reasonable search ranges for key parameters were defined based on prior research and exploratory trials. For example, for the tree-based models we allowed up to 1000+ trees and depths up to 30, and for learning rates we searched on a log-scale from 0.001 to 0.1.

HyperOpt's Tree-structured Parzen Estimator algorithm then suggested new hyperparameter sets likely to improve performance [36]. The search process was limited to 50 iterations per model, and the optimal configurations were selected based on mean balanced accuracy. Final models were retrained on the full training set and evaluated on the held-out test set for the tasks.

D. CNN Model

In parallel with the feature-based ensemble approach, a deep CNN was developed to classify EEG signals directly from raw time-series input, as shown in Fig. 6. This model operated without the need for handcrafted feature extraction, instead learning temporal representations from the multi-channel EEG data. A compact 1D convolutional architecture was adopted, designed to capture meaningful patterns while limiting the number of parameters to reduce the risk of overfitting. The structure was inspired by prior works in EEG-based deep learning, with modifications introduced to accommodate the scale and characteristics of the dataset used in this study.

Each input to the CNN was a single EEG epoch with dimensions 19×6000, corresponding to 19 channels and 6000 time points (12 seconds at 500 Hz). The architecture was organized into three functional stages: feature extraction, dimensionality reduction, and classification. In the first stage, a sequence of one-dimensional convolutional layers was applied along the time axis of each channel. The initial convolutional layer consisted of five filters with a kernel size of 3 and a stride of 1, allowing the model to learn local temporal features on short (~6 ms) segments of the signal. Each convolutional layer was followed by a LeakyReLU activation to introduce non-linearity, batch normalization to stabilize training, and a pooling layer to downsample the temporal dimension.

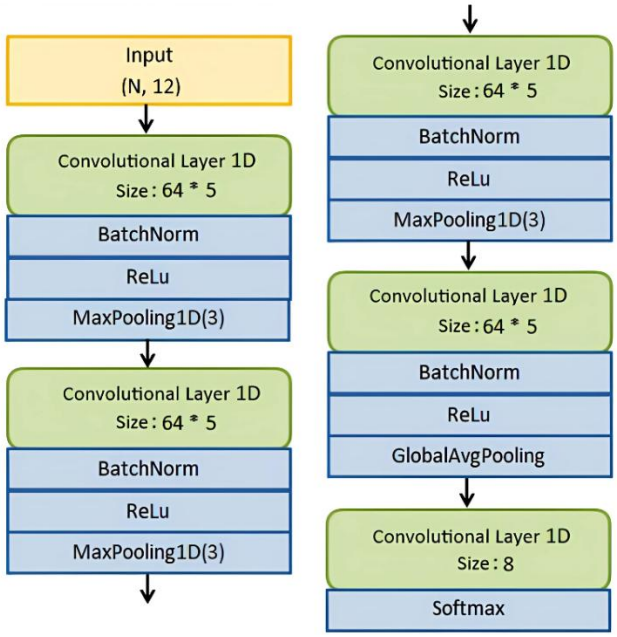

Fig. 6. The CNN model diagram

To prevent overfitting, dropout layers with a 25% dropout rate were inserted after pooling operations. This pattern (convolution, activation, pooling, and dropout) was repeated across four convolutional blocks. Both max-pooling and average-pooling were used in alternating layers, enabling the network to extract both peak-oriented and trend-based features. As the signal passed through successive blocks, the temporal dimension was reduced by a factor of 16, while the depth of feature maps increased. By the final convolutional layer, abstract features representing temporal dynamics in the EEG were extracted.

Dimensionality reduction was then performed using a global average pooling layer. Rather than flattening the entire output volume into a long vector, the global average pooling layer computed the mean value across each feature map's time dimension, summarizing the temporal activity into a compact feature vector. This served as a bottleneck layer and reduced the number of parameters, improving generalization and training efficiency.

In the classification stage, a dense output layer with a single neuron was employed, followed by a sigmoid activation function to produce a probability score between 0 and 1. This score represented the model's estimated probability that the input epoch belonged to the positive class. Model training was conducted using the Adam optimizer, with a learning rate of 0.001. The loss function used was binary cross-entropy, which was appropriate for the binary classification setting. To fairly evaluate performance and examine the effects of data leakage, two cross-validation strategies were applied.

1) In the first strategy, stratified ungrouped 15-fold cross-validation was used. Each epoch was treated as an independent sample, and folds were created by randomly assigning epochs while maintaining class balance. This method did not ensure separation by subject, allowing data from the same individual to appear in both training and validation sets. As a result, it served to illustrate the inflated performance that can result from improper validation practices.

2) In the second strategy, stratified grouped 15-fold cross-validation was employed. In this approach, folds were constructed at the subject level, with all epochs from each subject assigned to a single fold. The CNN was trained on data from 14 groups of subjects and validated on the remaining group. This ensured subject-wise separation between training and validation and matched the evaluation protocol used for the ensemble models. The choice of 15 folds (instead of five) was made to increase the amount of training data per fold and to stabilize performance estimates, especially given the data demands of deep learning models.

Early stopping was implemented during training to reduce overfitting. If the validation loss failed to improve for three consecutive epochs, training was halted. A maximum of 10 epochs per fold was permitted, although early stopping typically occurred between epochs 5 and 8. Training was performed using mini-batches of size 28 per GPU (effectively 56 per step when two GPUs were used). These parameters (learning rate, batch size, and early stopping patience) were selected based on empirical testing to ensure convergence without overfitting.

Following cross-validation, a final CNN model was trained on the full training dataset (80% of subjects) using the best-performing configuration. Evaluation was then performed on the 20% hold-out test set, which had been excluded from all previous training and validation steps. This provided an independent measure of generalization performance, consistent with the evaluation used for ensemble classifiers. Balanced accuracy was used as the primary performance metric due to its robustness under class imbalance and its clinical relevance, where both false positives and false negatives are important to minimize.

IV. RESULTS

The performance of the models was assessed on two binary classification tasks: differentiating Alzheimer's disease (AD) patients from healthy controls (CN), and distinguishing Frontotemporal dementia (FTD) patients from healthy controls. Evaluation was conducted using a stratified grouped cross-validation (SG-CV) protocol to ensure that no subject appeared in both training and validation sets. For the CNN, additional evaluation was performed using a conventional ungrouped cross-validation setup to examine the impact of data leakage. The results for each classification task are summarized in Tables II and III, which include metrics such as Balanced Accuracy, overall Accuracy, F1-score, Precision, Recall, and ROC-AUC for all models tested.

In the CN versus AD classification task (see Table II), the highest balanced accuracy under grouped cross-validation was achieved by the XGBoost model, with a score of 78.96%. This performance slightly surpassed the other boosting models, including HistGradientBoosting and LightGBM, which recorded balanced accuracy values in the range of 77 to 78%. CatBoost followed with a balanced accuracy of approximately 76.97%, while Extra Trees achieved 75.7%. All ensemble models demonstrated performance well above the chance level (50%), indicating that meaningful information was extracted from EEG features for this task. Among these, XGBoost's leading performance may be attributed to the model's tree boosting mechanism and comprehensive hyperparameter tuning.

TABLE II. CLASSIFICATION PERFORMANCE (CN VERSUS AD)

Model	Balanced Accuracy	Accuracy	F1	Precision	Recall	ROC-AUC
CatBoost	0.7697	0.7686	0.7344	0.8714	0.6347	0.8630
ETree	0.7571	0.7568	0.7494	0.7797	0.7213	0.8151
HistGB	0.7797	0.7792	0.7677	0.8175	0.7237	0.8561
LightGBM	0.7718	0.7710	0.7467	0.8437	0.6698	0.8300
XGBoost	**0.7896**	0.7887	0.7648	0.8713	0.6815	0.8549
CNN (ungrouped)	*0.8213*	0.8254	0.8453	0.8377	0.8638	0.9146
CNN (grouped)	0.7147	0.6995	0.7036	0.7006	0.7820	0.8491

TABLE III. CLASSIFICATION PERFORMANCE (CN VERSUS FTD)

Model	Balanced Accuracy	Accuracy	F1	Precision	Recall	ROC-AUC
CatBoost	0.6717	0.7003	0.5832	0.6842	0.5081	0.7784
ETree	0.6482	0.6653	0.5758	0.6036	0.5505	0.6815
HistGB	0.7035	0.7325	0.6238	0.7432	0.5375	0.8061
LightGBM	0.6653	0.6922	0.5783	0.6653	0.5114	0.7851
XGBoost	0.6596	0.6895	0.5650	0.6696	0.4886	0.7602
CNN (ungrouped)	*0.7787*	0.7783	0.7277	0.7524	0.7815	0.8821
CNN (grouped)	**0.7092**	0.6768	0.5507	0.6395	0.6006	0.8196

The CNN, when evaluated under grouped 15-fold cross-validation, as shown in Table IV, yielded a balanced accuracy of 71.47%, which was lower than those obtained by all the boosting models in the AD classification task. However, under ungrouped 15-fold cross-validation, where all 4404 epochs were treated as independent, the CNN achieved a substantially higher balanced accuracy of 82.13%. This inflated result suggests that the absence of subject-level separation allowed for significant data leakage. The training dynamics of the CNN model are visualized in Figs. 7 and 8. In Fig. 7, representing the third training epoch, the validation loss plateaued early, suggesting early signs of overfitting.

By epoch 13 (Fig. 8), the validation loss remained relatively flat while the training loss further decreased, reinforcing the presence of memorization effects and reduced generalization. Under this ungrouped setting, the CNN also recorded an overall accuracy of 82.54% and an F1-score of 0.8453, which points to a potential overfitting to subject-specific features. When evaluated under grouped CV, the CNN's accuracy dropped to 69.95%, reinforcing the conclusion that grouped CV is essential for realistic generalization performance estimation.

TABLE IV. CNN PERFORMANCE UNDER GROUPED CROSS-VALIDATION

Fold	Model Configuration	Training Accuracy (%)	Testing Accuracy (%)	Training Loss	Testing Loss
1	Original	84.5	70.2	0.418	0.685
2	Original	85.0	71.3	0.412	0.672
3	Original	84.1	70.0	0.421	0.693
4	Original	83.9	70.5	0.427	0.680
5	Original	84.8	71.7	0.415	0.661

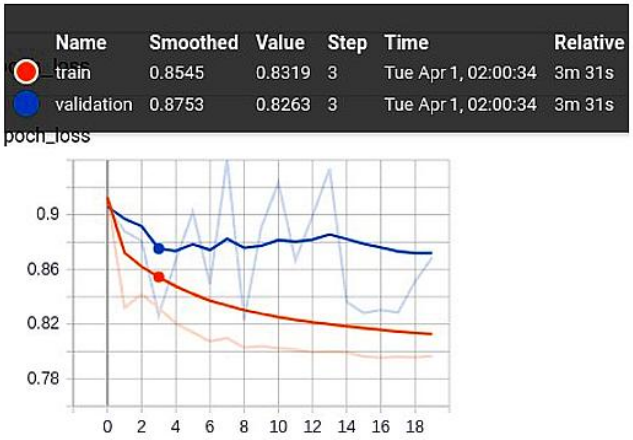

Fig. 7. The CNN model training by epoch 3

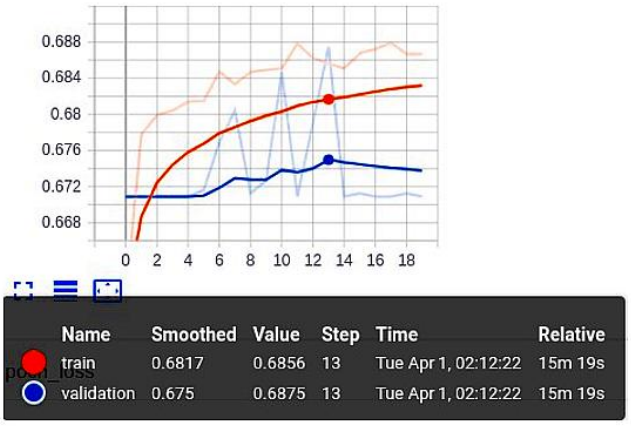

Fig. 8. The CNN model training by epoch 13

Regarding precision and recall for the CN versus AD classification, it was observed that most models exhibited higher precision than recall. For instance, XGBoost showed a precision of 87.13% compared to a recall of 68.15%. This suggests that the models were more successful in correctly identifying healthy controls (negative class) than in capturing all true AD cases. The ROC-AUC values for the boosting models ranged from 0.83 to 0.86, with the CNN under grouped CV reaching 0.85, indicating reliable class separability. However, the CNN's ungrouped ROC-AUC value was markedly higher at 0.9146, again reflecting the optimistic bias caused by data leakage.

In the CN versus FTD classification task (see Table III), model performance was generally lower than in the AD classification task, consistent with the greater clinical and electrophysiological challenge in detecting FTD. Under grouped CV, the CNN achieved the highest balanced accuracy at 70.92%, slightly surpassing the best-performing ensemble model, HistGradientBoosting, which reached 70.35%. Other boosting models, including XGBoost, demonstrated balanced accuracy in the range of 65% to 67%, with XGBoost specifically achieving 65.96%. These findings suggest that, for FTD detection, the CNN may have captured temporal or spatial EEG features not fully represented by the emotion-aware features used in the ensemble models.

The CNN's grouped precision and recall for FTD detection were 63.95% and 60.06%, respectively, indicating a relatively balanced performance with respect to false positives and false negatives. This balanced performance stands in contrast to some boosting models such as CatBoost and LightGBM, which achieved higher precision (66 to 68%) but lower recall (~51%), suggesting a tendency to err on the side of caution and predict the control class in uncertain cases. Under ungrouped CV, the CNN attained an inflated balanced accuracy of 77.87%, approximately 7 percentage points higher than the grouped result. The ROC-AUC values in the CN versus FTD task were slightly lower than those in the AD task, ranging between 0.78 and 0.82 for the top models, which reflects the greater difficulty in distinguishing FTD from normal patterns, as shown in Fig. 9 and Fig. 10.

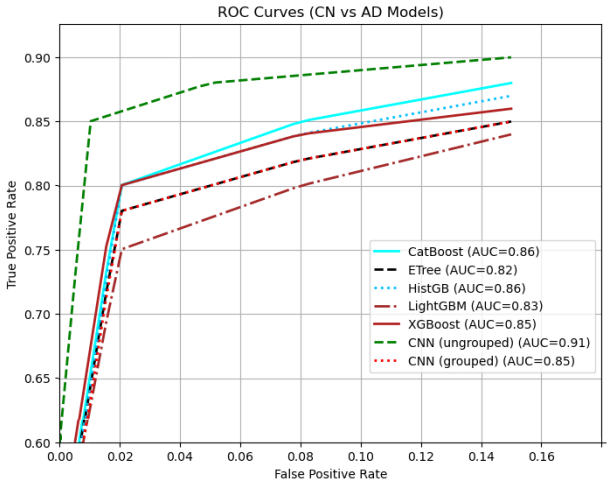

Fig. 9. ROC Curves for CN versus AD models

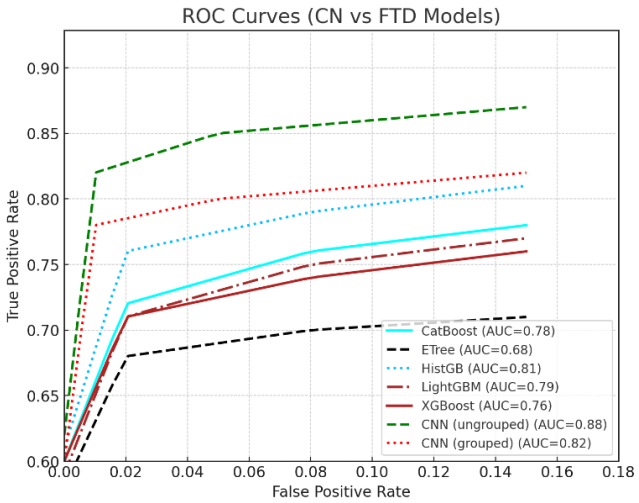

Fig. 10. ROC Curves for CN versus FTD models

Final model performance was also assessed using an independent 20% test set, with subject-level separation maintained. On this held-out set, XGBoost achieved the highest balanced accuracy for CN versus AD classification (~80%), while the CNN achieved the best performance for CN versus FTD classification (~70%). These outcomes were consistent with the grouped CV results, indicating that the chosen models generalized well to previously unseen individuals. To further explore the spatial structure of EEG-based features, a connectivity visualization of discriminative brain regions was generated (see Fig. 11). This representation highlights key inter-regional interactions contributing to the classification model, with red and blue edges indicating positive and negative feature weights, respectively.

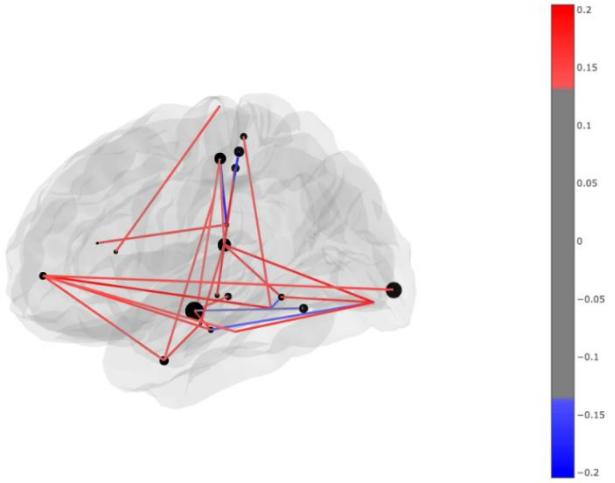

Fig. 11. Brain connectivity graph showing spatial EEG connections

The overall results demonstrated that AD classification was more accurately performed than FTD classification across all models. Moreover, the impact of grouped versus ungrouped evaluation was clearly illustrated: the CNN's balanced accuracy increased by over 10% for CN versus AD, and by about 7% for CN versus FTD under ungrouped CV, confirming that data leakage due to epoch-level validation significantly overestimates model performance.

V. Discussion

The present study investigated the potential of EEG-based machine learning models to support the classification of Alzheimer's disease and Frontotemporal dementia against healthy controls. The findings suggest that both boosting ensemble methods and CNNs can achieve clinically relevant performance, with each approach demonstrating advantages depending on the classification task. These results also emphasized key methodological considerations, particularly the impact of validation strategies on performance estimation.

For the AD versus CN classification task, the boosting models, most notably XGBoost, achieved the highest balanced accuracy under a rigorous grouped cross-validation protocol. This outcome indicates that the hand-crafted features used in the ensemble pipeline effectively captured the electrophysiological markers typically associated with AD. These included slowing of brain rhythms and reductions in signal complexity, which were well represented in the feature set consisting of 467 derived variables, including spectral ratios, entropy measures, and complexity metrics.

In comparison to existing literature, a modest improvement in performance was observed. For instance, while previous studies utilizing Random Forests reported accuracies of approximately 77% for AD classification, the current work achieved close to 79% balanced accuracy using boosting methods. This suggests that both the inclusion of broader features and the systematic tuning of model parameters played a role in this improvement. The inclusion of demographic features such as age and gender may have also contributed to this enhanced performance, although care was taken to avoid bias by excluding direct cognitive scores like MMSE, which could artificially inflate predictive accuracy.

In contrast, the more challenging task of differentiating FTD patients from healthy controls revealed a slight advantage for the CNN over the boosting models. Balanced accuracy for the CNN reached approximately 70.92%, narrowly surpassing the performance of the top ensemble model, HistGradientBoosting. This result may be explained by the known heterogeneity of EEG patterns in FTD, particularly in early-stage patients, where EEG abnormalities can be subtle or absent. The CNN's ability to learn directly from raw data allowed for the potential capture of intricate temporal dynamics or spatial interactions that are not easily quantifiable using conventional feature extraction methods [37][38].

The CNN was evaluated under both grouped and ungrouped cross-validation protocols, revealing a substantial difference in results. When ungrouped cross-validation was used, allowing training and testing on different epochs from the same subject, the CNN appeared to achieve exceptionally high balanced accuracies (>82% for AD, >77% for FTD). However, these results were shown to be overly optimistic due to data leakage. Specifically, the model likely learned subject-specific artifacts or stable idiosyncrasies that do not generalize to unseen individuals. When grouped cross-validation was enforced, ensuring complete subject independence between folds, a decrease of approximately 10–15 percentage points in accuracy was observed. This finding aligns with prior warnings

in the EEG literature, particularly in studies on brain-computer interfaces, where similar effects have been documented.

The benefit of extensive feature engineering was also supported by the results. A wider range of features, including non-linear complexity measures and band power ratios, was used to reflect the known EEG correlates of dementia. The boosting models' strong performance under these conditions suggests that such comprehensive feature sets provide informative representations for classification [39]. Comparisons with other studies, which reported lower performance using fewer features, further support this interpretation. Including age and gender as additional features contributed to model realism, reflecting their clinical relevance, although over-reliance on such demographic indicators was carefully avoided [40]-[42].

An intriguing outcome of the comparison between boosting and CNN approaches was the observation that their performance characteristics may be complementary. In the AD classification task, where well-characterized EEG slowing is present, the boosting models excelled, likely due to their ability to leverage structured, feature-based inputs. On the other hand, in the FTD task, where patterns were more subtle and variable, the CNN outperformed the ensemble models. This suggests that ensemble methods and deep learning may capture different aspects of the data, and a combination of both approaches through ensemble stacking or model fusion could further improve diagnostic accuracy. Although such combinations were not explored in the current study due to scope limitations, they represent a promising direction for future research. Moreover, as such hybrid systems are developed, the integration of emotional awareness may further enhance their clinical usefulness. By adapting outputs or interactions based on emotional cues or context, emotionally aware diagnostic tools may better align with the needs of patients and clinicians, supporting not only technical performance but also empathetic decision-making in sensitive healthcare environments.

It is important to contextualize these results with respect to diagnostic performance in other modalities. Neuroimaging-based methods, such as those employing MRI or PET, often report higher accuracies (80 to 95%) in AD classification [43]. Deep learning applied to structural imaging has achieved results above 90% in some studies. In contrast, EEG reflects functional changes and is more susceptible to noise and artifacts. Therefore, the slightly lower accuracies reported here (approximately 79% for AD, 71% for FTD) are not unexpected. Nevertheless, EEG offers advantages in terms of cost, portability, and accessibility [44]. These results suggest that EEG-based tools, especially when combined with other assessments, could serve as practical screening instruments in clinical settings.

Despite promising findings, several challenges were identified. Most important among them is the limited dataset size, particularly for the FTD group, which included only 23 patients. This constraint necessitated the use of a relatively shallow CNN, which may have limited its capacity to learn more complex patterns. Data variability due to individual differences and clinical heterogeneity further complicates model training. The binary classification framework used in this study may oversimplify real-world clinical scenarios, where cases often fall along a spectrum or exhibit overlapping characteristics.

Several limitations were acknowledged. The CNN was constrained by data volume, and boosting models were evaluated using 5-fold CV for efficiency during tuning. Epoch length was fixed at 12 seconds, and no systematic evaluation of alternative window sizes was performed. Furthermore, multi-class classification (e.g., direct AD versus FTD) was not addressed, though it represents a clinically relevant task. Functional connectivity features, while indirectly incorporated via spectral metrics, were not explicitly modeled. Future work could explore their inclusion using coherence or phase-locking measures.

From a methodological perspective, the pipeline developed in this study represents *one of the first to systematically* compare modern boosting algorithms and CNNs on an EEG dementia dataset using grouped validation. It also provides some of the first performance benchmarks for methods like CatBoost and HistGradientBoosting in this context. The inclusion of a diverse feature set and independent test set validation contributes to the rigor and reproducibility of the approach. By evaluating the CNN under grouped and ungrouped CV, the study also offers empirical evidence of the risks posed by data leakage in the models. With continued development and larger datasets, EEG-based models could complement existing diagnostic pathways, enabling earlier and more accessible detection of neurodegenerative conditions.

VI. Conclusion

In this work, a machine learning pipeline was developed and evaluated for the automated classification of Alzheimer's disease and Frontotemporal dementia using resting-state data. The approach combined rigorous preprocessing, diverse feature extraction, and the application of both ensemble boosting methods and convolutional neural networks. Performance was assessed using subject-level grouped cross-validation to ensure reliability and minimize data leakage, a common issue in this research. Under this rigorous evaluation, ensemble models, particularly XGBoost, were found to perform effectively in detecting Alzheimer's-related EEG signatures, while the CNN demonstrated slightly better performance for the more variable and subtle patterns associated with FTD.

While the reported accuracies (approximately 79% for AD and 71% for FTD) may not match those of imaging-based diagnostic tools, they are considered promising given the accessibility, cost-effectiveness, and noninvasive nature of EEG. The results also highlighted that inappropriate validation strategies, such as ungrouped cross-validation, can significantly inflate performance metrics, leading to misleading conclusions. By incorporating robust evaluation and validating on a held-out test set, efforts were made to ensure that the reported findings reflect genuine model generalizability to unseen individuals.

Although emotion awareness was not directly integrated into the current models, it is acknowledged that future systems intended for clinical deployment may benefit from the inclusion of emotionally adaptive interfaces. In real-world settings, especially those involving neurodegenerative

diagnoses, the ability of AI tools to respond to emotional context may help facilitate trust, improve communication, and support compassionate care. With continued refinement, validation on larger datasets, and a growing emphasis on emotionally aware technologies, EEG-based machine learning systems may play a valuable role in supporting early detection and diagnosis of dementia, complementing clinical decision-making and improving access to timely care.

The Impact of Federated Learning on Distributed Remote Sensing Archives

Pratik Surendra Kumar Patel[1], Vijay Govindarajan[2]

Expedia Group, Seattle, Washington, United States[2]

***Abstract*—When it comes to Machine Learning in remote sensing, one of the main obstacles researchers face is the large scale of datasets. Just the size of freely available Earth observation data presents a challenge for personal computers. A variety of missions, such as Sentinel-1, -2, and -3, have collectively gathered several petabytes of data. Given the size of these datasets, they are stored and processed across multiple platforms (often referred to as clients), which implies that decentralized Machine Learning must be applied. Federated Learning is one such decentralized learning approach, originally introduced by Google and adopted in their Android ecosystem. Since its release, the original Federated Learning technique has been fine-tuned and further developed. The scope of this project is to apply multiple Federated Learning models on remote sensing datasets and understand their implications considering different data splits across clients.**

***Keywords*—Machine learning; federated learning; deep learning model**

I. Introduction

Remote sensing (RS) datasets are often too large to be trained on a centralized Machine Learning model. For this matter, the data is split into various partitions and trained separately. One exciting new approach that was first introduced by Google researchers in 2017 is Federated Learning (FL) [2].

The idea behind FL is to send the Deep Learning model to the data instead of sending the data to the model. In the case of Google, this method is used to apply Machine Learning on Android devices. The data from each phone is not being sent to a central server. Instead, each device, often referred to as a client, trains a model received from a host or central server based on the client's own data. The trained models from each device are sent back to a central host and averaged.

Accessing data from different devices is not the root of the issue in our case, however, we consider a bigger dataset and split it into a variety of partitions to apply FL. The approach might solve the issue of training big datasets, nevertheless, it also comes along with two main challenges:

- The first obstacle being the extensive communication between clients and host for model averaging which can highly drain the training process.
- The second hurdle arises through client data distribution. Considering a remote sensing dataset with images from all over the world, there are certain classes like "desert", which can only be found in few regions of the world. In case the data is distributed by country, most clients wouldn't have access to such classes (as "desert"). This characteristic is also called non-IID (non-independent and identically distributed) data partition [3].

Over the past years, a variety of FL approaches have been developed to tackle these issues. For instance, FedAvg [4] decreases client-server communication by only training a randomly chosen fraction of clients during each epoch. Another approach is FedProx [5], which addresses the hurdle of non-IIDness by adding a proximal term to consider the degree of IIDness of each client during training. The goal of this project is to apply these FL approaches using different data partitions to understand both the impact of Federated Learning on non-IIDness and how different data distributions can affect the results.

A. Goals and Challenges

Federated Learning is still a new topic, both in the world of academia and industry. When applied correctly it can solve many issues, but it also proposes new challenges. We intend to implement three different Federated Learning models: Bulk Synchronous Parallel (BSP) [6], Federated Averaging (FedAvg), and Federated Proximal (FedProx) on a RS dataset to understand their impact in comparison to an ordinarily used centralized approach. All implementations will be tested with the Deep Learning models: ResNet34 [7], AlexNet [8] and LeNet [9].

We evaluate if these federated learning algorithms are effective on remote sensing datasets. We intend to make comparisons among different Deep Learning models when using federated learning. Lastly, we would like to modify different hyperparameters and other experiment settings to evaluate the extent of the effects that these have on the outcome. The main criteria for these comparisons are the accuracy of the output models and communication costs and running time. Based on these comparisons we empirically conclude the optimal federated algorithm, Deep Learning model, and hyperparameter choices that can be used for future RS applications.

Classical RS datasets tend to be very large, making the computational process much more difficult. Nevertheless, this issue goes beyond the scope of our project, therefore we chose UC Merced Landuse [10], a multilabel RS dataset containing 2100 images and 18 classes.

We expect to gain similar results from current literature and to find the optimal parameters for each FL model.

II. Background and Related Work

The first section provides information about the basic implementation of Federated Learning, the chosen FL algorithms, and the applied Deep Learning models for our experimental evaluation. We then discuss current findings and approaches in Federated Learning.

A. Federated Learning

The main idea of Federated Learning is to reverse the common procedure of Machine Learning: instead of sending the data to the model, the model is sent to the data. In the FL scenario, we have two parties: the host and the clients. The host contains the Deep Learning model, which will later be trained, while each client holds a fraction of the dataset. The main steps are depicted in Fig. 1. In step 1, the host initializes a Machine Learning model and sends it to each client (step 2). Next, each client trains the received model based on its data (step 3) and sends the trained model back to the host (step 4). The host then collects all models and averages them (step 5). It should be noted that the training of each client takes place in parallel.

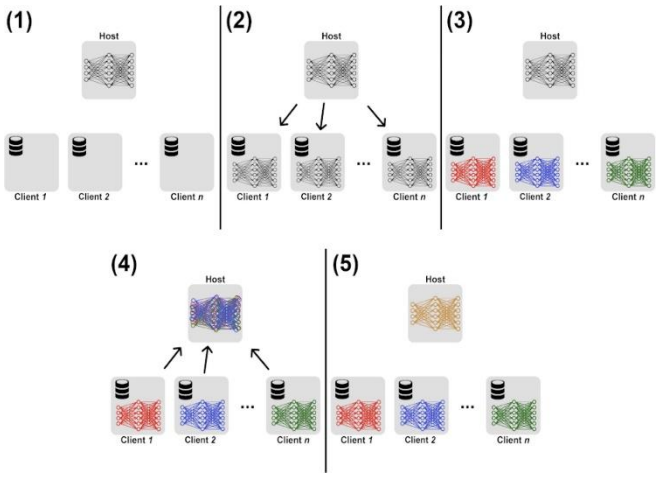

Fig. 1. Basic steps of Federated Learning.

1) Federated averaging: The basic Federated Learning model presents one major issue, which is the enormous communication between the clients and the host and the high computation. One of the most common Federated Learning algorithms, which tries to tackle these issues, introduced in [4], is FedAvg.

Let K be the set of clients. For each training round, FedAvg only sends the model to a random fraction with a fixed size C ⊆ K of clients. For instance, for the experimental evaluation of [4], only 10% of clients were trained each round. Furthermore, communication is reduced by running multiple local epochs E as depicted in Fig. 2. The authors used up to 5 local epochs for their experiments. Finally, each client's local dataset can be split into batches by applying the parameter B, where B = ∞ specifies that the whole local dataset is used as a batch. Once all clients k ∈ C, with their respective data partition n_k, have sent their trained weights w_k^t back to the host, the new average model w_t^{avg} is computed with:

$$w_t^{avg} = \frac{1}{n}\sum_{K=1}^{|K|} n_k \,.\, w_t^k \qquad (1)$$

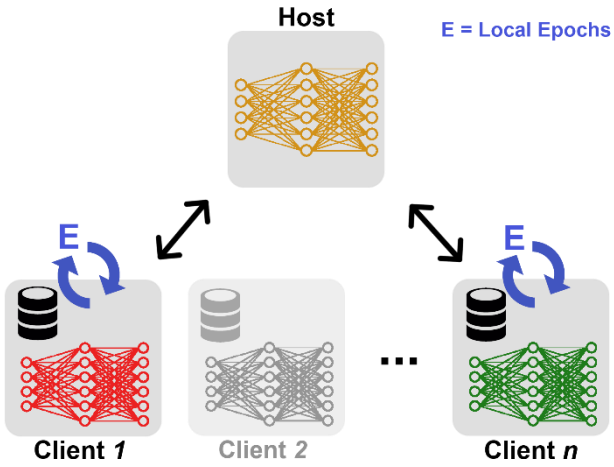

Fig. 2. Basic steps of Federated Averaging.

where, t indicates the training round and n the length of the whole dataset.

2) FedProx: FedProx [5] is an extension to FedAvg that has modifications to tackle non-identical distributions in data and accounts for system heterogeneity. FedProx provides more reliable convergence when compared to FedAvg. On average, a 22% accuracy improvement is shown across highly heterogeneous settings. Their work is mainly based on adding a "proximal" term to a standard local loss function. The objective is the usual loss function, summed with a penalty when the local model deviates too much from the global model. This addresses the issues of data heterogeneity and allows for safely incorporating variable amounts of local work resulting from systems heterogeneity.

3) Bulk Synchronous Parallel: Bulk Synchronous Parallel (BSP) [6] is an older approach that misses the key FL element of averaging the models. In terms of FedAvg, the parameters are set in the following way:

- C = 1; therefore, all clients are used in each round.
- E = 1, such that each client runs 1 local epoch.

Instead of passing the model to each client and averaging the trained models, BSP passes the model from one client to another. Once a client is done with training, it sends the model to the next client. A round is complete once the model has been passed to each client. A more communication-heavy version of BSP will pass the model between clients after training on a single training batch. This communication-costly approach is more robust to the non-identical distributions in data since it takes more small update steps towards convergence instead of large updates that might skew the model in one direction or the other.

B. Deep Learning Models

LeNet is one of the earlier Machine Learning approaches and was first proposed in 1990. The original architecture of LeNet-5 consisted of two convolutional layers, two sub-sampling layers, two fully connected layers, and an output layer with Gaussian connection [9]. To adapt to the image size of 256x256, we adjusted the kernel size for all convolutional layers to 5x5.

AlexNet was first introduced by Alex Krizhevsky in 2012 and was considered a State-of-the-Art Deep Learning model for visual recognition and classification at the time. The architecture consists of a total of 8 layers: five convolutional layers, two fully connected layers with dropout and a SoftMax layer.

ResNet is one of the most popular approaches in image classification and was published in 2015 by Kaiming He. The main architecture consists of convolutional layers with a 3x3 filter and concludes with an average pooling layer and a 1000-way fully connected layer with SoftMax. Additionally, ResNet stacks building block (shown in Fig. 3), using the so-called shortcuts to skip the input over the next two layers, which makes the CNN residual [7]. The shortcuts can only be used when the input and the output have the same dimensions, and they help to solve the vanishing gradients problem, which is one of the main problems in training deeper and deeper Neural Networks.

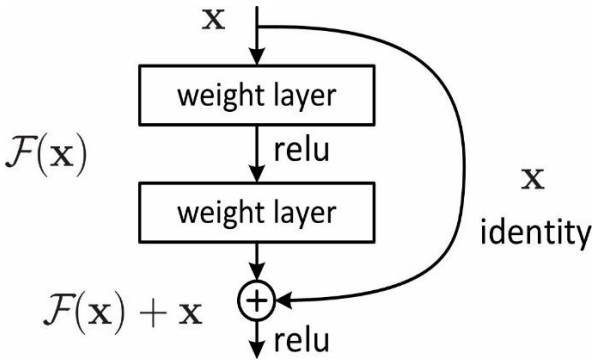

Fig. 3. Residual block used by ResNet architecture [7]

C. Related Work

In [3], the authors show that training over skewed label partitions is a challenging problem to solve, especially for decentralized learning, as all the algorithms in their study suffer major accuracy loss. Secondly, DNNs with batch normalization were found to be vulnerable in the non-IID setting. They also prove that the difficulty level of this problem varies greatly with the degree of skew. They use three decentralized training algorithms, which are Gaia [11], Federated Averaging, and Deep Gradient Compression [12].

D. Other FL Algorithms

Gaia [11] accumulates updates to model weights and updates them to other data partitions when its relative magnitude exceeds a defined threshold, which means that the insignificant communication between data centers is reduced while still retaining the correctness of machine learning approaches. They observed a speedup of almost 1.8x to 53.5x over leading distributed ML frameworks, and is 0.94x to 1.4x when using the same ML approaches on nodes connected in a local area network.

Deep Gradient Compression [12] communicates only a pre-specified amount of gradients for each training step to reduce communication costs. This is also called gradient clipping and is done on the local nodes. They also use other approaches like momentum correction, momentum factor masking and warm up training. In their experiments they achieve a compression ratio of 270x to 600x without losing accuracy.

SCAFFOLD [13] uses variance reduction technique to correct the drift off in local clients in its local updates. SCAFFOLD requires significantly lower communication rounds when compared to FedAvg and performs well, irrespective of data heterogeneity or client sampling. SCAFFOLD can also take advantage of similarity in different clients' data thus resulting in even faster convergence in those cases. Their experiments prove that they are always at least as fast as normal SGD and can be much faster depending on the data similarity between clients.

FedBoost [14] provides ensemble algorithms, which are made optimised to have low communication for Federated Learning. In their work the per-round communication cost is independent of the size of the ensemble. Unlike other previously discussed works [12] [4], their approach reduces the communication between both server-to-client and client-to-server communication.

FetchSGD [15] compresses model updates using Count Sketch. This enables the solution to take advantage of the combinability of the sketches to combine model updates from many nodes into one update. The Count Sketch is linear in nature, and hence, momentum and error accumulation can be performed inside the sketch. This helps to move the momentum and error accumulation from clients to the central aggregator, thus solving the problems associated with client participation and also achieving high compression rates and good convergence.

III. Methodology

A. Dataset and Data Augmentation

Our dataset of choice for this experiment is the UC Merced Land Use Dataset [10], but instead of using the provided single label, we opt for using the multilabel [16], because multilabel are usually more realistic and challenging for a Remote Sensing classification case study (examples are shown in Fig. 4).

Fig. 4. Some UC Merced Land Use Dataset examples, showing both the original single label (s.l) as well as the multilabel (m.l).

The dataset contains 2100 images, which is a small number for training, especially when using a large number of clients. Therefore, before training, we used data augmentation to double the dataset in size to 4200. We apply one of four common corruption methods on each image once; "Impulse noise is a color analogue of salt-and-pepper noise and can be caused by bit errors...Motion blur appears when a camera is moving

quickly...Snow is a visually obstructive form of precipitation. Pixelation occurs when up-sampling a low-resolution image" [17]. Furthermore during training, a random horizontal flipping were also applied (see Fig. 5).

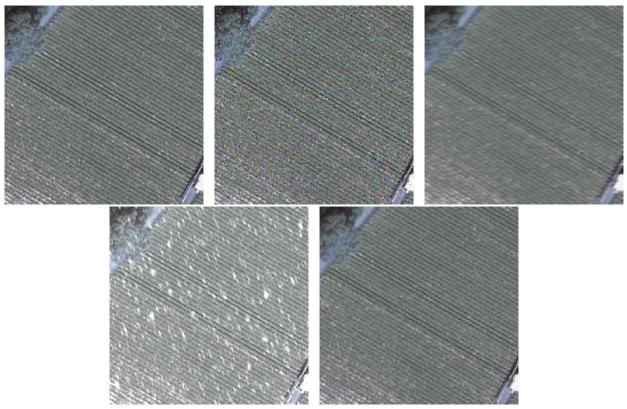

Fig. 5. Example of the different augmentation methods on the same image. In the first row from left to right: original image, impulse noise, motion blur. In the second row: snow and pixelation.

B. Main Aspects of Our Experiment

Similar to [3], our study focuses on the following criteria:

1) The ML models: For this, we compare the influence of FL on the validation accuracy for different neural networks: AlexNet [8], LeNet [9], and ResNet34 [7]. Training parameters were set to the learning rate = 0.001 and momentum = 0.9 for all the models.

2) Federated Learning algorithms: As described in Section II, we compare FedAvg and FedProx against each other as well as against BSP. For FedAvg, we used the following hyper-parameters: $C_{fraction} \in \{0.5, 0.75, 1\}$ (meaning: in each round the model is sent to half, three-quarter, and all clients for training which effectively reduces the amount of data used for each round of training), with local epoch number on each client $E_{local} = 5$.

3) Degree of label skewness of the dataset's partitions: The idea here is that each client has a monopoly of some percentage over a certain label in the dataset, whereas the rest of the dataset is uniformly distributed over all the clients. But, there is an inherent problem with artificial label skewing multilabel datasets over a certain number of clients. As seen in the label distribution in Fig. 6, the dataset has 2 clear types of labels dominance, so there are two cases for skewing:

a) Common labels: There is only 7 labels that are present in more than 10% (6 of them are in more than 25%) of the images, which mean if we distributed the dataset over 4 clients for example, there is only a certain degree of skewness possible before the label overlaps and the skewness loses its meaning because of the high correlation[1] between these labels. For our tests, when splitting over those dominant labels, we use 4 clients and skewness $\in \{0, 20, 40\%\}$.

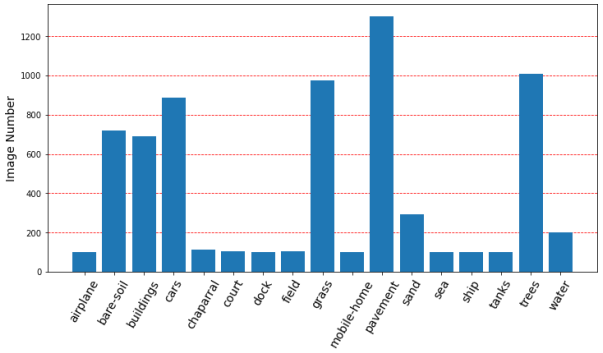

Fig. 6. UC Merced Land Use Dataset multilabel distribution: the total number of label occurrences in the 2100 images of the Dataset. We define "common labels" are labels that are present in more than 10 % (210 data points), whereas "less common labels" are in less than 10 %.

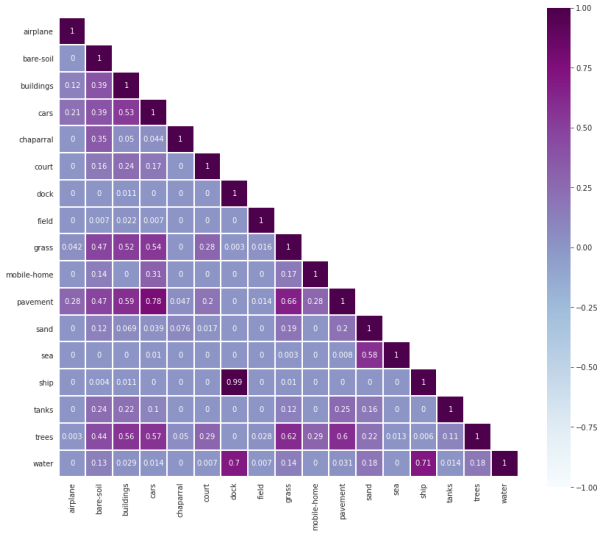

Fig. 7. UC Merced Land Use Dataset multilabel cosine similarity matrix; shows that "less common labels" are, for the most part, decorrelated, whereas "common labels" are much more correlated. The darker purple a matrix field gets (closer to 1), the more correlation (co-occurrences) between two labels there are, whereas the bluer (at zero), the 2 labels never exist in the same image.

b) Less common labels: 9 labels are present in roughly 5% and one label around 10% of the dataset, and they are highly uncorrelated, which means we can freely skew the monopoly of the clients to a higher percentage, and we can use more clients in this case. In our tests we used mainly 8 clients with skewness $\in \{40, 60, 80\%\}$. We also tested increasing the number of clients to {10, 25, 50}, with skewness of 40%, this means the first 9 clients will have 40% monopoly over the small 9 labels and the rest of the dataset is uniformly distributed over all the clients. We can see here that for this dataset, as we increase the number of clients being used, data distribution becomes more IID in nature (see Fig. 7).

Furthermore, we don't consider using a mix of common and less common labels for splitting over the clients, since it will cause an imbalanced distribution of data among clients that is a

[1] As shown in Fig 7, using the Cosine similarity measurement clearly shows that the common labels co-occur in the same image much more than less common labels.

different kind of FL problem that we are not tackling in this study.

4) Furthermore, we test the influence of the training batch size on such set up, with batch sizes $\in \{1, 4, 8, 16, 32, 64, 128, 256\}$.

C. Experiments

To evaluate all aspects mentioned in Section III(B), we divide our experiments into 8 sections. The parameters for all our experiments are noted in Table I[2]. Each training runs for 100 Rounds, and $E_{local} = 5$ for FedAvg and FedProx.

1) The first experimental section analyzes a centralized Machine Learning training and BSP using LeNet, ResNet and AlexNet to get a picture of their impact without using Federated Learning.

2) In the following section, we compare the impact of different $C_{fraction}$. We use FedAvg and run each Deep Learning model with $C_{fraction} \in \{0.5, 0.75, 1\}$ and 8 clients.

3) The next part of the experiment considers each Deep Learning model on FedAvg using 8 clients and $C_{fraction} = 0.75$. This examination increases the skewness in comparison to other experiment sections to 60% and 80%.

4) This section focuses on a smaller skew percentage with skewness set to 40%, 20% and 0%. We use each of the three Deep Learning models and apply them to FedAvg and BSP with 4 clients.

5) We compare the impact of different client numbers in this experimental section. For each model, we run a training with client numbers $n \in 10, 25, 50$ on FedAvg with $C_{fraction} = 0.5$.

6) We repeat the experiment from (*5*) using FedProx.

7) Finally, we measure the weight of different batch sizes (bs) with $bs \in 1, 4, 8, 16, 32, 64, 128, 256$ on FedAvg with 4 clients using LeNet.

TABLE I. EXPERIMENTAL SETUP: PARAMETERS

DL Model	FL Algorithm	Epochs	Clients	Batch Size	C-Fraction	Skewness	Client Epochs	Small Skew
LeNet	Centralized	100	NA	4	NA	NA	NA	NA
ResNet	Centralized	100	NA	4	NA	NA	NA	NA
AlexNet	Centralized	100	NA	4	NA	NA	NA	NA

LeNet	FedAvg	100	4	256	0.75	40	5	FALSE

D. Evaluation Metrics

Simple Accuracy is defined as:

$$Accuracy = \frac{1}{m}\sum_{i-1}^{m}\frac{|Y_i \cap Z_i|}{|Y_i \cap Z_i|} \quad (2)$$

where, Zi denotes the model prediction for the data point xi, Yi denotes the true label of xi, and i ∈ {1, ..., m}. This measure, however, can be misleading in measuring the quality of the learned model for multilabel applications (also depends on the nature of the dataset). For example, in UC Merced Land Use multilabel dataset using this race metric, one can achieve 80% by predicting the single label pavement for all the images. Hence this was eventually dropped from our final evaluation metric.

Other metrics such as Classification Accuracy [18], defined as:

$$Classification\ Accuracy = \frac{1}{m}\sum_{i=1}^{m}\delta(Z_i, Y_i) \quad (3)$$

where, δ = 1 only if the prediction matches the true label for all the labels otherwise δ = 0, can be too rigid of a metric. In general, the evaluation of methods that learn from multilabel data requires different measures than those used in the case of single-label data [19]. Those evaluation measurements can be divided into example-based, label-based, and ranking-based [19]. For our experiment, we use one of the label-based measurements, that is, the harmonic mean between precision and recall, also known as F1-score 4, which can also be used for evaluating a single-label classifier.

$$F_1 = \frac{1}{m}\sum_{i-1}^{m}\frac{2.|Y_i \cap Z_i|}{|Z_i|+|Y_i|} \quad (4)$$

E. Implementation Details

The implementation is done completely in python. It can be accessed in our github repository. For ease of use, the anaconda distribution of python was used. We use PyTorch [20] as the preferred choice of Deep Learning Framework. To simulate the different clients for Federated Learning, we initially considered using PySyft [21], but ran into many issues because of the nascent nature of the library. It was incompatible with multilabel data loader on PyTorch and did not support custom data splitting for the data on different clients. These challenges proved to be too big and we then decided to use PyTorch, directly to simulate the clients and concentrate more on the implementation of the

federated algorithms. We use Pandas, matplotlib, NumPy packages for the visualization of the data and generate line plot, bar graphs, etc.

F. Experimental Setup

The experiments were conducted on a workstation with Intel(R) Xeon(R) W-2133 12 core CPU @ 3.60GHz with 64GB RAM. It was equipped with an NVIDIA GeForce RTX 2080 12GB GPU. It used Ubuntu 18.04 with CUDA, and cuDNN for GPU acceleration.

IV. Experimental Results and Discussion

This study aims to analyze the effect of decentralized learning on different deep learning models for multilabel remote sensing data. In this section, we present our results showing federated model quality differences compared to centralized learning for the three Deep Learning models (AlexNet, ResNet and LeNet). Then we look at the influence of hyperparameters and other settings such as batch size, $c_{fraction}$, number of clients and the degree of skewness for Federated Averaging.

A. Overall Training Results

We present the overall training results with two main criteria in mind. The F1-score and convergence time.

1) Centralized versus Federated: As shown in Fig. 8, centralized learning converges better and quicker than all the Federated Learning algorithms in terms of F1 quality score. But it is important to keep in mind that for centralized learning, skewness is not considered at all and a direct comparison to Federated Learning is unfair. Centralized training results, however, must be seen as a benchmark result and not be used for direct comparison.

2) Comparison of Federated Algorithms: BSP started to converge fast in the first 20 training rounds, it slowed down thereafter, but steadily approached the upper bound of the centralized learning. This pattern is the same for all three Deep Learning models.

Both FedAvg and FedProx are much slower in converging (than BSP) for most Deep Learning models. They also fail to reach the upper bound of centralized learning results, sometimes even after training 100 rounds. In direct comparison between FedAvg and FedProx, as seen better in Fig. 9, it is clear that FedProx (in pink plots) has the upper hand in both quality and convergence speed. That is because of FedProx's loss function being able to keep the clients in check and prevent diverging from the central average model, thus being capable of handling different data distributions and skewness better than FedAvg.

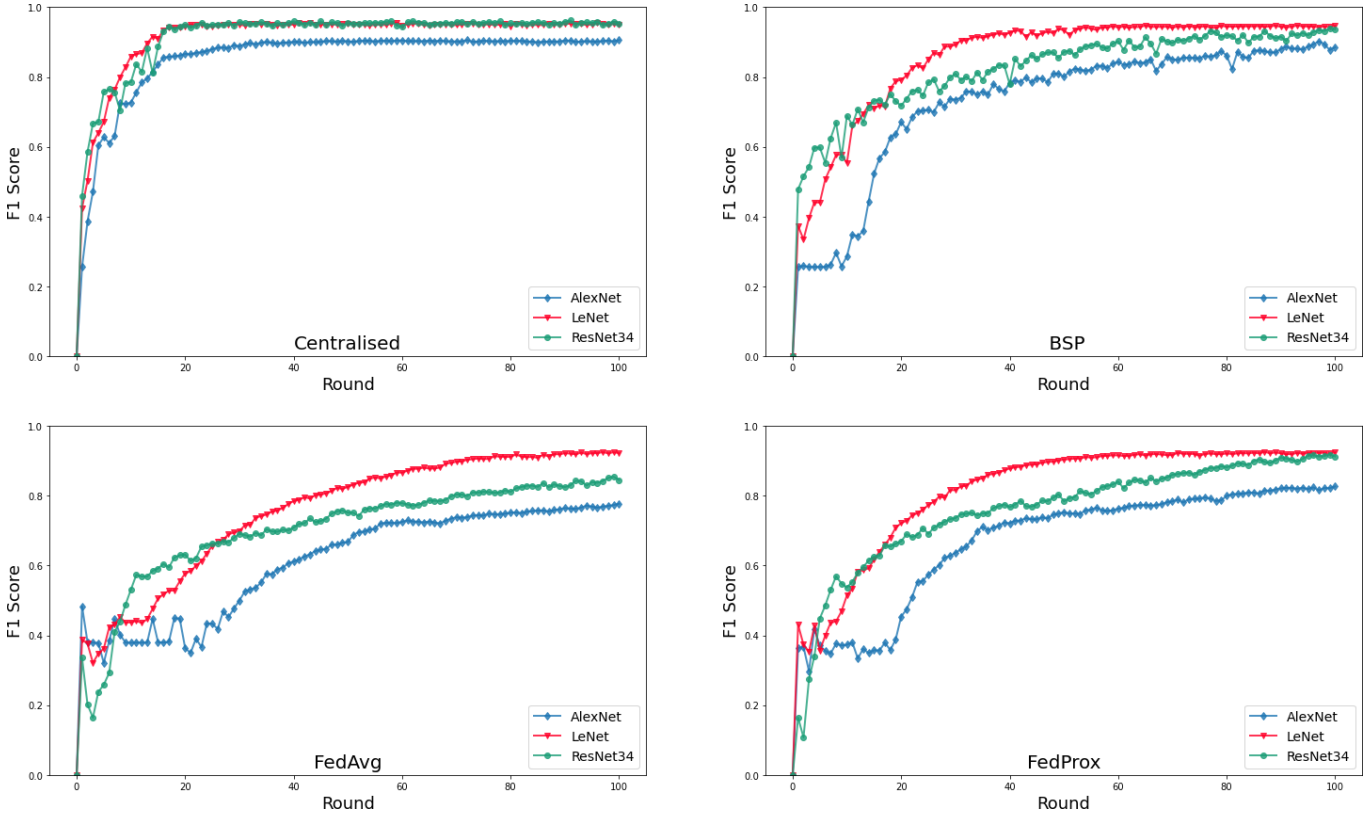

Fig. 8. Comparing centralized versus BSP and Federated Learning. for BSP, FedAvg and FedProx 8 clients, 40% skewness on the less common labels were used. The $c_{fraction}$ for FedAvg and FedProx is set to 0.75 here.

B. Comparison of Deep Learning Models

We compare the three Deep Learning models, i.e. LeNet, ResNet and AlexNet based on the results presented in Fig. 8. For all the federated and centralized training experiments, AlexNet performs the worst in terms of F1-score. This could be because AlexNet is a very large model and requires large datasets to be trained correctly. Given that our dataset size is quite small even with augmentation, AlexNet needs the dataset to be much larger.

Out of the other two models, LeNet generally converges very quickly, compared to ResNet. This could again be due to the fact that LeNet is a small model and hence, is quite suitable for our application. Finally, ResNet manages to converge to the same level as LeNet for BSP. In FedAvg, however, ResNet lags behind LeNet. This is again fixed using FedProx which has better convergence for ResNet (see Fig. 9).

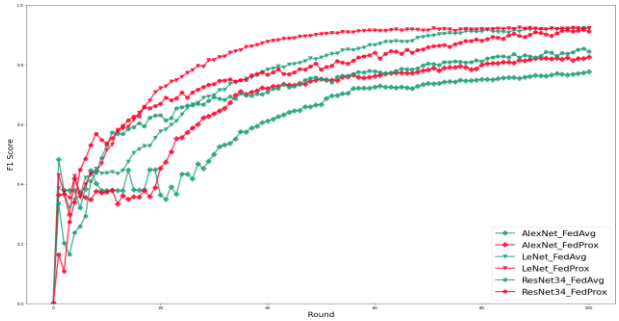

Fig. 9. FedAvg versus FedProx for different Deep Learning Models. 8 clients with a $C_{fraction}$ of 0.75, as well as 40% skewness on the less common labels, were used here.

C. Drill-Down Experiments for Federated Averaging

In this section, we take a deeper look into results using Federated Averaging and varying different hyperparameters and other settings to analyze the effect that it has on the convergence of the Deep Learning models. For each of these sets of experiments, we vary one of the parameters, while keeping all the other values and settings the same.

1) Client Fraction: We vary the Client Fraction ($c_{fraction}$) between 0.5, 0.75 and 1. We use 8 clients for these experiments and consider the less common labels to maintain equal data distribution among the clients. Looking at Fig. 10, the training using $c_{fraction} = 1$ converges the best, which was expected since it uses all the clients and effectively all the training data during each round. Predictably, the convergence drops for $c_{fraction} = 0.75$ for ResNet and AlexNet. Setting $c_{fraction} = 0.5$ for these models further deteriorates the F1-score. It is remarkable that LeNet is still able to achieve optimum results with $c_{fraction} = 0.5$, even though it takes longer to converge. Even though the accuracy drops occur with lowering the client fraction, it should be taken into consideration that this also reduces communication costs, which can help to manage bandwidth costs. This will be further discussed in Section IV(D).

2) Number of clients: We vary the number of clients between 10, 25 and 50, with client fraction set to 0.5 for all the runs. This effectively means approximately half of the data is used for training on each round. Since the client numbers are large, we have to use the less common labels to have an equal number of data in all the clients, thus effectively making the data IID in nature. From Fig. 11, it is quite clear that increasing the number of clients impacts the convergence quite drastically. All the three models converge faster and better for n = 10. Next, there is a drop in F1-score for n = 25, and a further drop for n = 50. In the case of AlexNet, given that it is a very big model, our hardware restrictions did not allow us to scale beyond 30 clients and hence, the experiment for n = 50 was not completed.

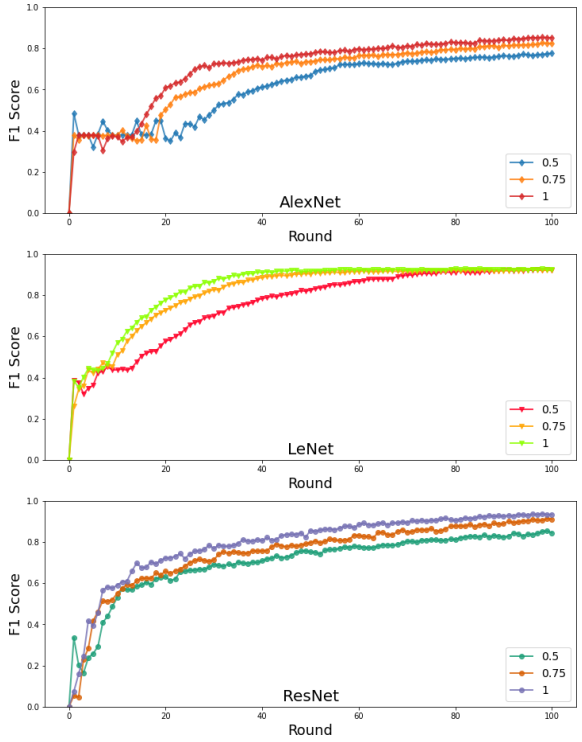

Fig. 10. Effect of varying $C_{fraction} \in \{0.5, 0.75, 1\}$. 8 clients, and 40% skewness on the less common labels were used.

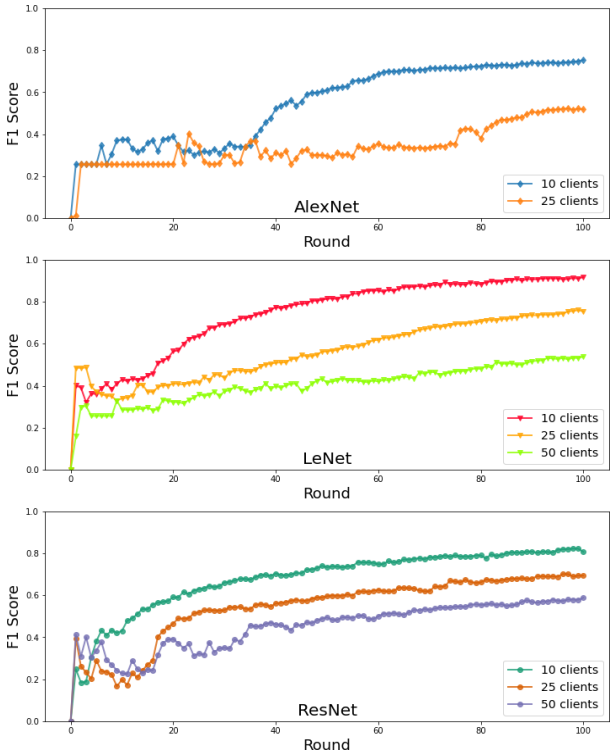

Fig. 11. Effect of varying number of *clients* $\in \{10, 25, 50\}$. $C_{fraction}$ of 0.5, and 40% skewness on the less common labels were used here, however since the number of clients are more than the number of unique labels the distribution over the clients end up more IID.

3) Batch Size: Batch size varies between 1, 4, 8, 16, 32, 64, 128, and 256. We use 4 clients with $c_{fraction} = 0.75$ for these

experiments. Increasing the batch size affects the convergence of the Deep Learning model conversely, as seen from Fig. 12(a). For a batch size of 1, the model converges the quickest and to the highest score. With an increase in the batch size, the model consistently takes longer to converge and converges to lower F1-scores. The biggest drop in F1-score is between 16 and 32, where the F1-score drops by around 22%, and for larger batch sizes (64, 128, 256), the model fails to converge on any meaningful results.

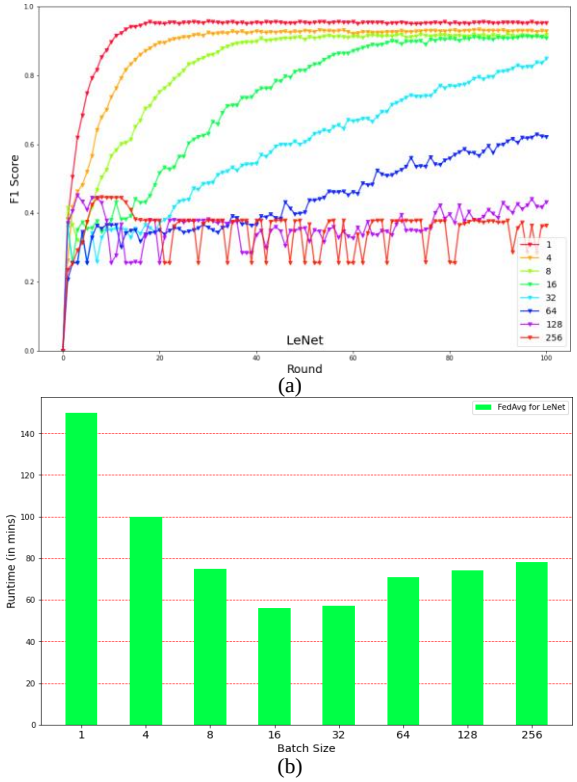

Fig. 12. (a) Shows the effect of convergence for different batch sizes, with 4 clients and 40% skewness on common labels. (b) Shows the runtime for 100 rounds for different batch sizes. The training runs are for LeNet.

While it is quite evident that batch size 1 performs the best, when looking at the bar graph presented in Fig. 12(b), we see that the run times are very different for different batch sizes. The runtimes presented are for 100 rounds. A batch size of 1 takes around 2.5 times longer than for batch size 16, where the drop in F1-score between them is 3.5%. So, depending on the application and the efficiency of the hardware required, it could be more suitable to use larger batch sizes for drop of a few accuracy points. Further increase in batch size leads to a slight increase in running times and this could be due to the overhead costs due to memory restrictions. While the empirical results show that batch size 16 might be an ideal balance between run time and F1-score, but this is only for LeNet model, and the optimum batch size number heavily depends on the Deep Learning model used. These results could vary for AleXNet and ResNet.

4) Data Skewness between Clients: Initially, we use common labels for splitting the data to generate a non-IID distribution. The initial baseline for these experiments is 0% skewness, which represents the IID data distribution. Next, we increase the skewness to 20% and 40%. The number of clients used is 4, and for our dataset, there was no apparent difference in the convergence for these degrees of skewness. As seen in Fig. 13, on all three Deep Learning models, the model convergence for different skewness is very similar, and convergence is also similar to the final F1-score values. This indicates that FedAvg can handle low levels of non-IIDness in the data quite well. Next, we further increase the skewness to higher values of 60% and 80%. For this, we will have to use a higher number of clients, and the less common labels as explained in Section III-B(3).

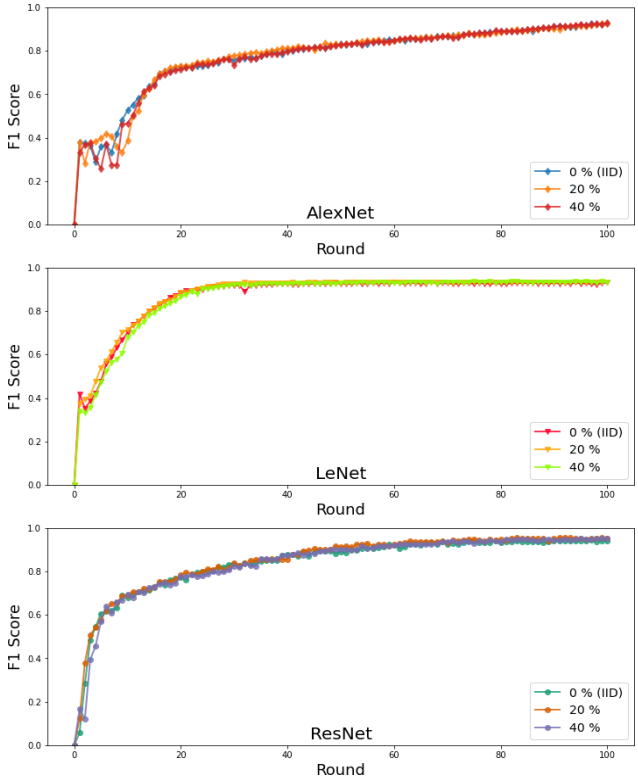

Fig. 13. Effect of varying data *skewness* $\in \{0, 20, 40\}$% on common labels on LeNet. 4 clients with a $C_{fraction}$ of 0.75 were used.

With 8 clients, we use skewness of 40%, 60% and 80%. These learning curves are shown in Fig. 14(a). Again, we see very similar learning curves, but there is a slight drop in the learning curves convergence time for skewness of 80% in all the 3 models. This is especially seen clearly in the LeNet learning curves, where convergence takes longer than the lower skewness case. To showcase the difference better, we present the maximal F1-scores of the three different skewness degrees in Fig. 14(b) for the three Deep Learning models compared to BSP for same skewness settings. We can see that there is a drop in F1-score with an increase in skewness albeit slightly. Overall, for the dataset we have used, we can summarise that the skewness of the data does not impact the learning of the Deep Learning models using FedAvg. These results might vary when using a larger dataset.

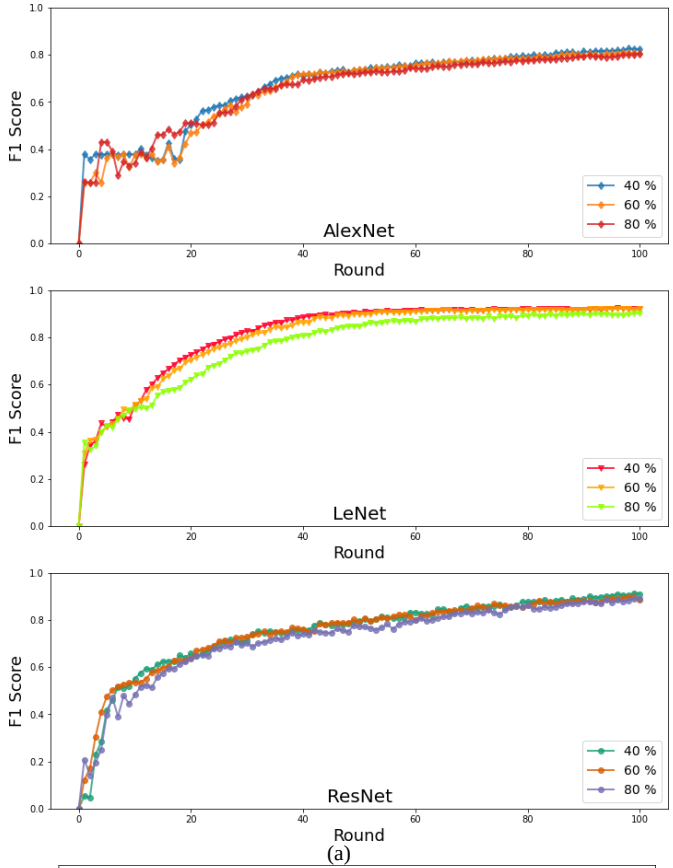

Fig. 14. (a) Shows the effect of varying data *skewness* $\in \{40, 60, 80\}$% on less common labels on LeNet. 8 clients with a $C_{fraction}$ of 0.75 were used. (b) Shows the difference between the max F1-scores achieved by BSP and FedAvg.

D. Communication Cost Comparison

In this section we present the communication costs associated with the different federated algorithms and try to evaluate the most optimal tradeoff between accuracy and communication cost among the different setups.

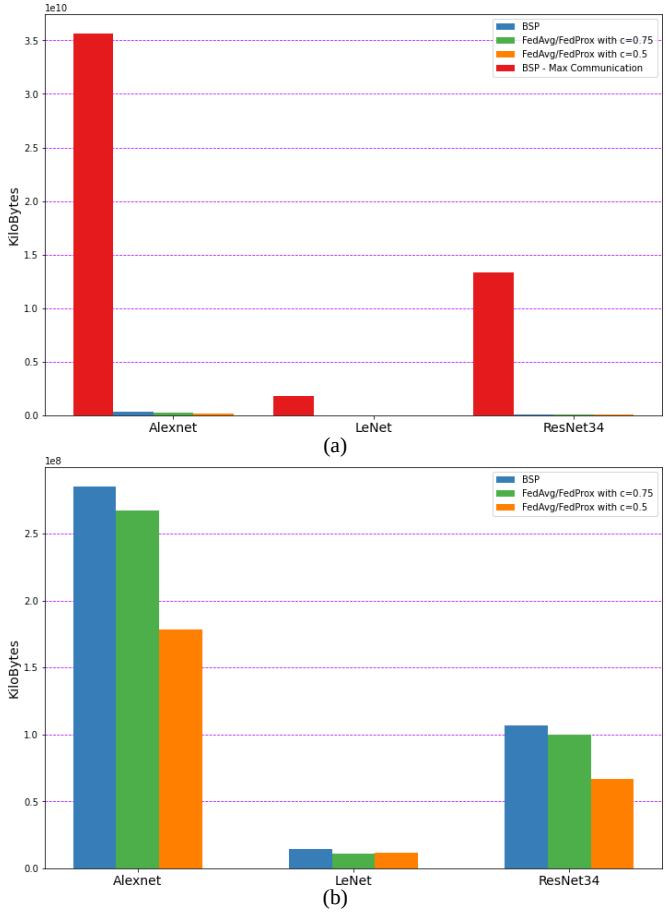

Fig. 15. Both graphs show the training communication costs in KiloBytes on our dataset: (a) Shows the cost in compared to a BSP-max (in red) where the communication between the server and the client is happening after each training batch, that is very costly in compare to our BSP (in Blue) or FedAvg/FedProx. (b) Shows the communication difference between our BSP (where communication happens after training on all the batches of a client) and FedAvg/FedProx with $C_{fraction} \in \{0.5, 0.75\}$.

In Fig. 15(a), we see a comparison of BSP at maximum communication mode (i.e. when a model is moved from one client to another after each batch of data) with other methods of Federated Learning. The communication costs are so high that the other methods are almost unnoticeable on the bar graph. Next, we compare BSP with a better efficiency technique, where the model is moved after training on the entire partition of a client to the next client. Federated Averaging and Federated Proximal methods have the same communication cost and hence, they are shown using the same bars. The client fraction for these two federated algorithms is varied. Lower client fraction means that the model is moved to lesser number of clients, and this hence, translates to a linear reduction in communication cost with lowering the client fraction. BSP still has the highest communication cost even after the optimization, but the difference now is much smaller.

The problem with BSP, however, is that the model must be trained sequentially on each client, and this means the runtime on BSP is again high compared to FedAvg, where the training can happen on n different clients at once. The communication costs also depend heavily on the Deep Learning model used. In the case of LeNet, the model communication cost is quite low.

Since it's a smaller network, but ResNet and AlexNet require more communication to be trained well. Depending on the size and nature of the dataset, we can opt to choose different Deep Learning networks. For our use case, LeNet was able to classify the data well and is also generally the most optimal with communication costs in mind.

V. Conclusion

We present the findings and results of applying Federated Learning for multilabel image classification on a remote sensing dataset. Federated Learning has known advantages, which become more relevant for remote sensing cases, and our experiments certainly show that Federated Learning can be a useful training solution for remote sensing even when the data on different clients is non-IID in nature.

We evaluate three different Federated Learning algorithms: Bulk Synchronous Parallel (BSP), Federated Averaging (FedAvg) and Federated Proximal (FedProx) using three Deep Convolutional networks: LeNet, AlexNet and ResNet34. BSP performs the best among the three federated algorithms, but given its high communication costs and runtimes for a practical use case, FedAvg and FedProx might be more suitable. Albeit a slight drop in F1-score, these algorithms achieve results quite efficiently and provide a parameter called client fraction which can be used to control the trade-off between communication cost and accuracy. For the UC Merced Land Use Dataset, LeNet performed the best in our experiments. We also discussed the effect of varying different hyperparameters on the overall model convergence and presented the best practices for the same.

A. Future Work

In the future, we would like to test out the experiments on a bigger dataset, as this would help to validate these results on a larger scale. We speculate that using larger datasets might also give different results when it comes to a high data skewness use case.

We would also like to experiment on a more complex dataset, where the remote sensing images have more channels than the RGB image in UC Merced Land Use dataset. One dataset that could suffice both size and complexity requirement could be BigEarthNet that contains more than 500 thousand 13-channels images [22].

We also plan to implement another Federated Learning approach which manipulates the gradients rather than weights to handle client divergence. Deep Gradient Compression [12] is an ideal candidate for such a method. This will give us more insight to which federated algorithm works for which application.

***Abstract*—Cloud computing has become increasingly adopted due to its ability to provide on-demand access to computing resources. However, the proliferation of cloud service offerings has introduced significant challenges in service discovery. Existing cloud service discovery approaches are often evaluated solely through simulation or experimentation and typically rely on unstructured service descriptions, which limits their precision and scalability. In this work, we address these limitations by proposing a formally verified architecture for capability-centric cloud service discovery, grounded in the Event-B method. The architecture is built upon a capability-centric service description model that captures service semantics through property-value representations. A core element of this model is the formally verified variantOf relation, which defines specialization among services. We prove that variantOf satisfies the properties of a partial order, enabling services to be structured as a Directed Acyclic Graph (DAG) and thus supporting hierarchical and scalable discovery. We formally verify the consistency of our model across multiple refinement levels. All proof obligations generated by the Rodin platform were successfully discharged. A scenario-based validation further confirms the correctness of dynamic operations within the system.**

***Keywords*—Formal verification; cloud service discovery; capability modelling**

I. Introduction

Cloud computing has emerged as a paradigm that changes the way IT services are delivered [1]. By proposing a multitude of on-demand services, cloud computing has become indispensable for companies seeking efficient workload management and cost-effective high-quality service [2]. The rapid growth in the number of cloud services has intensified the challenges of efficient service discovery [3]. Cloud service discovery aims to assist cloud users in locating the most suitable cloud services for their needs [4].

Although numerous approaches for identifying cloud services have been proposed including [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], [15], [16], current cloud service discovery solutions lack a structured and detailed definition of cloud services [17]. Furthermore, they fail to consider the continuous growth in the number of service offerings and the increasing heterogeneity of cloud services.

In addition to the lack of structure in service descriptions, the dynamic nature of the cloud environment, where services may frequently appear while others may disappear [3], adds further complexity to the discovery process. The cloud service discovery process involves both the description of services and a matchmaking mechanism that compares available offerings with user requirements. However, the unstructured nature of service descriptions increases the difficulty of performing accurate matchmaking, which in turn amplifies the overall complexity of the discovery process. These challenges underscore the need for approaches that can guarantee the correct behavior of cloud service discovery systems.

Despite recent progress, to the best of our knowledge, current cloud service discovery approaches have been exclusively evaluated through simulation and experiments. However, simulation-based approaches have not proven to be efficient in evaluating complex systems, particularly in terms of assessing their functional properties, including system correctness [18]. Similarly, while experiments provide valuable insight into performance metrics, they fall short in comprehensively assessing all possible system states or interactions.

In contrast, formal verification has shown promising results in ensuring the correctness of complex information systems. Formal verification allows us to verify the functional properties of complex and large-scale systems and specify the relationships between behavioral interactions within such systems. Formal verification can demonstrate the precision and correctness of these systems, making it an essential tool in the context of cloud computing [18]. Furthermore, formal verification offers a viable solution for addressing fundamental challenges in cloud service discovery [17], including reliability, scalability, and security, making it highly relevant for the advancement of this field.

Nevertheless, formal verification has received significantly less attention in the context of cloud service discovery compared to adjacent fields such as service composition [19], [20], [21], [22], [23], [24], [25]. To date, only a limited number of works [26], [27], [24] have tackled the formal verification of cloud service discovery systems.

While these efforts represent valuable contributions, they do not comprehensively address the full range of challenges inherent in cloud service discovery. In particular, to the best of our knowledge, no existing work formally verifies cloud service discovery systems that support multiple types of services and dynamic behavior.

To address these limitations, this paper proposes a new verification approach[1] that covers multiple aspects of cloud service discovery. Our approach ensures that (i) both services offered by cloud providers and requested by users are described

[1]For detailed proofs and the complete formal model, see: https://github.com/Aichasdm/Capability-centric-cloud-service-discovery-model.git

formally; (ii) the returned services satisfy required functional levels; and (iii) dynamic changes are handled without compromising the correctness of discovery operations. Given the complexity of verifying these requirements, we adopt the formalism of Event-B.

Event-B is a formal method for modeling and developing complex systems. Its objective is to build correct systems by construction through a series of refinements from abstract specifications to concrete implementations. Each refinement step is validated using mathematical proof obligations based on predicate calculus and typed set theory [28]. In this work, we formally verify a cloud service discovery architecture. Recognizing the benefits of using a service repository in the enhancement of the efficacy of cloud service discovery [4], along with the efficiency of tree-like structures, we propose an architecture that combines both elements for storing and organizing services.

Furthermore, we argue that the unstructured nature of cloud service descriptions is a major factor contributing to the complexity of service discovery. To address this, we adopt the Capability Model [29], a structured representation that not only mitigates heterogeneity and unstructured data but also supports highly configurable and dynamic service offers such as cloud offerings. The Capability Model enables the representation of both functional and non-functional service properties and provides a partial order between services, which can be structured as a directed acyclic graph.

The novelty of this work is twofold. First, it bridges the gap between cloud service discovery and formal verification, resulting in more reliable and consistent discovery systems. Second, it provides a formal verification of service description based on a generic and extensible model—the Capability Model. Our verification using the Event-B method offers a rigorous foundation that ensures the consistency and correctness of the model itself. The Capability Model has previously been applied in the context of Web services [30], business processes [31] and Network as a Service(NaaS) [32]. This verification supports its safe reuse across diverse service-oriented domains, including but not limited to cloud computing.

To summarize, the main contributions of this paper are:

- Verification of the cloud service description model;
- Verification of the consistency of the partial order between services;
- Verification of the behavior of the cloud service discovery process.

The remainder of this paper is as follows. Section II gives a review of related works; Section III provides our motivation and an overview of the proposed architecture; Section IV describes the formalization and verification of the consistency of the cloud description model and the partial order relation between services; Section V presents the formal model of the proposed cloud service discovery; Section VI discusses our findings. Finally, Section VII presents a conclusion.

II. Related Works

This section reviews existing approaches for cloud service discovery. In light of the numerous solutions proposed in recent years, we focus on the most frequently cited and contextually relevant works. Based on our research context, the approaches are classified into two categories. The first includes methods developed to formalize or verify cloud service discovery through mathematical or logical techniques. The second encompasses approaches validated through experimental or simulation-based evaluations only.

A. Formal Cloud Service Discovery Approaches

The following is a brief overview of research efforts that utilize formal methods to verify cloud service discovery systems. Notably, only a limited number of works in the literature directly address this problem.

In study [27], the authors propose a resource discovery model for grid computing based on a hierarchical tree structure, supporting multi-attribute queries. The model is verified using model checking techniques. The system behavior is decomposed into three components: data gathering, control, and discovery. This modular design facilitates maintenance, development, and verification. The relationships between these components are formalized using Binary Decision Diagrams (BDDs). Properties of the resource discovery process are specified using temporal logic (CTL and LTL) and verified to ensure they are satisfied. The authors claim the model demonstrates soundness, completeness, and consistency.

In study [26], a method is presented for discovering human resources in the Expert Cloud, with an emphasis on trust-based expert search. The system is modeled as an undirected, weighted graph where nodes represent human resources and edges indicate prior interactions. Each node is annotated with information relevant to the resource. The structural and compositional aspects of the discovery process are verified using the NuSMV[2] model checker, and the properties are defined in temporal logic. The authors argue that their model is sound, reachable, complete, deadlock-free, and consistent. However, the approach does not address key concerns such as quality of service (QoS), billing, or authorization.

Authors in study [24] aim to leverage the gap between formal verification and cloud service discovery and composition by proposing an architecture for formal service matching where behaviors are seen as ordered sequences of services. The proposed architecture allows the formal matching and composition of ordered sequences of services. The approach is based on Cloudle[8] and the ABCS framework[33].

While valuable, these approaches exhibit several limitations. First, they address only specific aspects of service discovery, such as trust in a particular domain, as in study [26], or consistency of ordered sequence of services [24]. Moreover, although the model proposed in study [27] is useful, it has been applied in the context of grid computing and has not been evaluated for cloud services.

B. Informal Cloud Service Discovery Approaches

In contrast to formal methods, a large number of approaches rely on simulations or experiments. These can be broadly categorized into ontology-based, keyword-based approaches, and hybrid approaches (ontology-based and keyword-based) following the classification in study [4]. This discussion is not intended as an exhaustive review of all existing approaches. Instead, it presents a representative selection of notable works to illustrate the key characteristics and trends within this category of cloud service discovery methods.

1) Ontology-based approaches: In study [6], Modica and Tomarchio propose a semantic discovery framework that facilitates the alignment between user demands and provider offerings by considering their respective utility and business objectives. The model incorporates seven ontologies, including shared concepts between user and provider perspectives (Support, mOSAIC, Application, SLA ontologies), provider-specific ontologies (Market and Offer), and a user-specific ontology (Request). To enable comparison between the user and provider perspectives, a set of mapping rules is defined. Furthermore, a semantic matchmaking process is integrated into the framework to evaluate the degree of similarity between user requests and provider offers, leveraging a semantic similarity algorithm.

Within a series of works [8], [34], [35], [36], Kang and Sim have proposed the Cloudle engine for discovering cloud services. It represents a cloud service search engine that consults a cloud ontology to reason about relationships among cloud services. The proposed architecture includes a query processor, a similarity reasoning utility based on a cloud ontology, and a price and timeslot utility. The query processor handles user queries and sends them to both the similarity reasoning utility and the price and timeslot utility agent. The former includes three similarity reasoning methods: (i) concept similarity reasoning, (ii) object property reasoning, and (iii) datatype property reasoning.

The engine was later extended, in study [37] with an agent-based testbed for cloud service discovery. The system architecture is based on multiple broker agents and trading agents (providers and users), with various applications and resources. The service discovery process involves four stages: selection, evaluation, filtering, and recommendation. Matching between user requests and provider specifications is performed using a cloud ontology, based on three similarity reasoning methods: concept similarity, property similarity, and datatype similarity.

In a further enhancement, the study in [38] presents a revised architecture for Cloudle. The main difference compared to the previous version is the introduction of crawlers. Crawlers are responsible for maintaining and updating the service database. They are deployed to collect information about cloud service providers from webpages, thereby keeping the Cloudle database up to date. The service reasoning process includes three reasoning types: similarity reasoning, compatibility reasoning, and numerical reasoning.

Finally, the study [39] proposes CB-Cloudle, an enhancement of Cloudle that introduces a centroid-based cloud search engine. It uses a dedicated crawler for each cloud provider and ranks cloud services based on the k-means clustering algorithm.

The research [40] introduces an ontology-based cloud service search engine called CSSE. The CSSE framework consists of three layers: the cloud service ontology layer, the cloud service identification layer, and the search engine user layer. The user layer provides a web interface that allows users to request cloud services by entering search keywords. The ontology layer includes a repository of cloud concepts generated by the cloud ontology builder, which is based on the NIST cloud computing standards and real-world cloud service metadata gathered in a prior work [41]. The identification layer contains a cloud service repository and a service identifier that detects potential cloud services through similarity checks between user queries and ontology concepts.

In study [42], the authors propose a platform for cloud service discovery. First, natural language processing (NLP) techniques are applied to automatically annotate cloud service descriptions with semantic content. Based on these annotations, each service is represented as a semantic vector. The platform enables semantic matching between user queries—written in natural language—and suitable cloud services.

The study [14] proposes a decentralized, peer-to-peer (P2P) semantic service discovery approach. A multi-layered cloud ontology is employed to represent service descriptions in a standardized and meaningful way. These service descriptions are stored in decentralized registries that collectively form the P2P network. Peers are grouped into clusters based on the semantic similarity of their service descriptions. Furthermore, Semantic Overlay Networks (SONs) are used to establish semantic links between peers, thereby enhancing the effectiveness of the discovery process.

To address fuzziness in user preferences, the study [10] proposes Cloud-FuSeR, a fuzzy, user-oriented cloud service selection system. It comprises: a fuzzy cloud ontology for computing similarity between user needs and services, a fuzzy Analytic Hierarchy Process (AHP) for deriving weights of non-functional properties, and a fuzzy TOPSIS method to rank services using AHP-derived weights and service performance.

2) Keyword-based approaches: The study [5] proposes an automated version of CSSE that extracts cloud service descriptions from the Web. Extracted features are clustered by similarity. The Service Detection and Tracking (SDT) model is introduced to support modeling and tracking services across providers.

In study [7], a two-stage recommendation model is presented. First, it analyzes unstructured textual descriptions of cloud services using Hierarchical Dirichlet Processes (HDP) to form clusters. Then, a Personalized PageRank algorithm ranks services based on tags, enabling personalized recommendations.

The study [15] proposes a cloud service recommendation system named CSRecommender, which enables users to search for cloud services and receive a list of relevant results based on queries and ratings. The system consists of five main components: a crawler, which collects potential cloud service descriptions from the web; a cloud service identifier, which verifies whether a webpage represents a valid cloud service; an

indexer, which stores identified services in a structured repository; a search engine, which allows keyword-based queries; and a recommender system, which offers both collaborative and content-based recommendations.

In study [43] Focused Crawler for the Cloud service Discovery (FC4CD) is presented. This tool can identify, gather and analyze cloud services available on the Web. In study [44], the authors present a cloud service registry and discovery system designed to classify and identify services based on their underlying model (IaaS, PaaS, SaaS) and associated QoS attributes. Initially, cloud services are categorized into datasets by a service model. A decision tree-based identification algorithm then classifies user requests according to the relevant service model using QoS preferences provided by the cloud consumer. Once the model is identified, the Split and Cache (SAC) algorithm performs service discovery by retrieving cloud service providers (CSPs) whose offerings match the specified QoS requirements.

3) Hybrid approaches: In study [10], The authors propose a cloud service recommendation system based on semantic technologies, employing a fuzzy service ontology structure. Cloud service descriptions are parsed using natural language processing (NLP) techniques to identify and extract key concepts, which are subsequently used to populate a fuzzy ontology for cloud services. User queries, also expressed in natural language, are parsed to extract fuzzy connectives (e.g., AND, OR) and are represented as logical expressions. These expressions are then translated into first-order Horn clause logic and further refined using disjunctive normal form (DNF) transformations to generate multiple query candidates. The matching process is carried out by evaluating semantic similarity between user requirements and ontology concepts, utilizing SPARQL queries to retrieve relevant cloud services.

In study [12], the authors present an LDA-based Self-Adaptive Semantic Focused (LDA-SSF) crawler designed to efficiently collect, categorize, and store Cloud services by leveraging a Cloud Service Ontology (CSOnt) to calculate semantic similarity. To enhance the crawling process, a URLs Priority technique, based on Term Frequency–Inverse Document Frequency(TF-IDF) and semantic similarity, is employed to assign priority scores to candidate URLs by computing their textual similarity to a given Cloud service category. Moreover, an ontology-learning technique, based on the LDA model and semantic distance, is proposed to automatically enrich the CSOnt with new concepts, thereby maintaining the crawler's performance over time.

All the approaches presented in this section have been evaluated only through simulation or experimental validation. As previously stated, such evaluations cannot guarantee the correctness of the discovery system or identify hidden flaws. Furthermore, these approaches lack standardization in cloud service discovery. Furthermore, while formal methods have been applied to various aspects of cloud computing, such as service composition and orchestration [19], [20], [21], [22], [23], [24], [25], these works typically address services already deployed within cloud environments. In contrast, our work focuses on the discovery of services offered by cloud providers. This phase has received limited attention in formal specification literature. We formalize this process using Event-B, capturing both the static structure of capability-based descriptions and the dynamic behavior of user-driven discovery over an evolving service repository. To our knowledge, this constitutes the first refinement-based Event-B formalization dedicated specifically to cloud service discovery.

III. Approach Overview and Motivation

Cloud service discovery systems assist users in identifying suitable services offered by various providers. These systems must operate in highly dynamic environments, where providers frequently update, add, or remove their service offerings. Users typically send requests specifying both functional and non-functional requirements such as service type, region, pricing, and specific capabilities. The system is expected to return services that fully satisfy the given constraints.

However, unstructured service descriptions and ambiguous user inputs can lead to significant mismatches between requested and returned services. In addition, the evolving nature of cloud offerings requires that discovery systems handle service updates while ensuring continued correctness and consistency. Without formal verification, such systems may have subtle faults that remain undetected during simulation or empirical testing [27]. To address these challenges, this work proposes a repository-based cloud service discovery system whose behavior and correctness are formally verified using the Event-B method. At the core of this architecture is the Capability Model [29], [45], which provides a structured representation of service properties and supports abstraction, variability, and semantic alignment between services and user needs.

Fig. 1 illustrates the proposed architecture. Initially, cloud users submit service requests described using the Capability Model. These requests are first validated for consistency by the request/offer checker component. Once validated, the request is forwarded to the matching engine, responsible of the matchmaking process, which consults the repository of cloud service offerings to identify suitable candidates. The resulting list is then returned to the user.

The adopted matchmaking strategy is deliberately simple and deterministic. We do not currently support partial satisfaction or ranking of offers; only services that fully satisfy the constraints of the request (or generalize it) are returned. While advanced discovery techniques, such as similarity-based ranking or graph traversal over variant hierarchies, are common in practical systems, they are out of scope in the present work. Our focus is on verifying the logical foundations of cloud service discovery behavior and ensuring correctness through refinement and theorem proving.

The Capability Model enables expressive yet semantically rigorous service descriptions, capturing both functional aspects (e.g., service type) and non-functional properties (e.g., price, performance). Unlike traditional approaches such as WSDL, it supports semantic alignment and abstraction through relations such as `specifies`, `extends`, and `variantOf`, which facilitate service categorization and generalization.

Although details about these inter-capability relations and their formal properties are introduced in the next section, it is important to note that they enable the repository to be managed as a graph structure that supports reasoning about

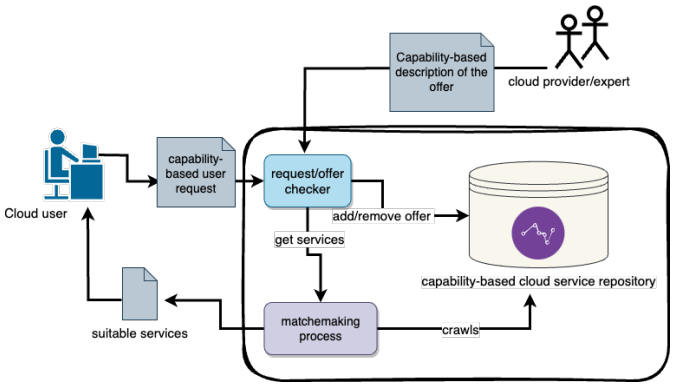

Fig. 1. Overview of the adopted architecture.

compatibility and substitution between services. These features lay the foundation for scalable and correct service discovery under evolving system configurations.

The next section presents the formalization and verification of this architecture. We begin by specifying the structural properties of the Capability Model and proceed to formalize the discovery behavior under dynamic conditions using refinement in Event-B.

IV. Formal Modeling and Verification of the Capability Model

In this section, we present our formal model for service description. Since our model is developed using the Event-B method, we begin with a brief overview of its core concepts. We then introduce the Capability Model [29], a capability-centric service description model. Following this, we present the Event-B formalization of the model in detail, and conclude with its validation using a motivating example. As noted in study [29], the Capability Model is sufficiently expressive to describe a wide range of service-oriented systems, including cloud services, web services, and business processes. Accordingly, this work contributes to the formal validation of the Capability Model by ensuring its correctness under rigorously defined structural and behavioral conditions.

A. The Event-B Method

Event-B [28] is a formal method for modeling and developing complex systems through a correctness-by-construction approach. It supports system development via a series of refinement steps, transitioning from an abstract specification to a more concrete and implementable model. Each refinement step must preserve correctness and is validated through the generation and discharge of proof obligations.

An Event-B model consists of two main components: *contexts* and *machines*. The context defines the static part of the model, including sets, constants, axioms, and theorems. In contrast, the machine captures the dynamic behavior of the system, and includes variables, invariants, and events. Events represent atomic transitions; each is defined by parameters, guards (which control when an event may occur), and actions (which update the state variables).

Correctness is ensured by discharging proof obligations that validate invariant preservation, guard strengthening, well-definedness, and other formal properties. These obligations are automatically or interactively verified using the Rodin platform [46], which integrates theorem provers for Event-B. In this work, Event-B is used to model and verify a capability-centric cloud service discovery system. We structure the model across multiple refinement levels, using formal proofs to guarantee that both structural and behavioral properties are preserved throughout development.

B. Overview of the Capability Model

Service description plays a fundamental role in the automation of service discovery and in achieving interoperability in web-based environments [47]. The concept of capability has emerged as a central element in service description [48]. To enable automated discovery, service descriptions must explicitly define the capabilities of services, thereby allowing users to identify and select services based on their functionality rather than relying on informal documentation to infer what a service can perform [47].

The Capability Model was initially proposed in study [29], and a subsequent formalization was presented in study [45]. In this paper, we focus on the version introduced in study [45], providing a complete and rigorous formalization using the Event-B method. Where appropriate, we refer back to the original model in study [29] to ensure alignment with its conceptual foundations. To validate the coherence of our formalization with the original model, we reuse the motivating example presented in study [45]. This allows us to demonstrate that our Event-B specification conforms to the same structural and behavioral assumptions. We have made minor corrections to the original example where discrepancies were observed, thereby illustrating the added value of formal verification and theorem proving in identifying subtle inconsistencies.

1) The model components: The core concept in the Capability Model [29] is that of a *capability*, which defines the functionality a service can provide. The model describes a service in terms of its capability, represented as a set of *property entries* (or attributes). Each property entry consists of a pair $(Property, Value)$, where $Property$ denotes a service property (e.g., destination, price), and $Value$ represents the set of possible values associated with that property. Both property and value refer to ontological terms.

A $Property\ entry$ is defined with respect to a triplet $(Property, MGV, SR)$ where MGV (most general value) is the domain of values that the property can take, and SR is a specification relation that could be defined over elements of MGV with respect to the meaning of the property $Property$.

To illustrate this, consider the example shown in Fig. 2, in which a shipping company offers four service configurations to accommodate diverse customer types.

- C1: A standard offer that provides a basic shipping service to Australia without any constraints on package weight or destination.
- C2: A specialized offer for packages to Australia, restricted to those with a weight less than or equal to 100

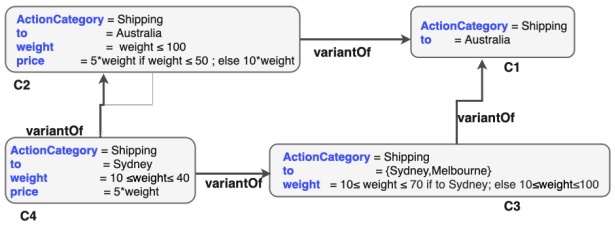

Fig. 2. A motivation example for the variantOf relation between capability from [45].

kg. The pricing is conditional: if the weight is less than or equal to 50 kg, the price is calculated as $5 \times$ weight; otherwise, it is $10 \times$ weight.

- C3: A further specialized offer for packages destined to Sydney and Melbourne. If the destination is Sydney, the acceptable weight range is between 10 and 70 kg; otherwise, the acceptable weight range is between 10 and 100 kg.

- C4: A specialized offer for packages to Sydney, restricted to those with a weight between 10 and 40 kg. the price is calculated as $5 \times$ weight

Thus, as illustrated in Fig. 2, capability $C2$ conforms to the Capability Model. For example, the property entry $to, Australia$ is defined with respect to the triplet $(\texttt{to}, \texttt{GeographicalLocation}, \texttt{locatedIn})$, where `GeographicalLocation` denotes the most general value of to, and `locatedIn` expresses a specification relation such that, for instance, $Sydney$ is considered to be $locatedIn$ $Australia$.

Furthermore, a specific property that is shared among all capabilities within the same domain is $actionCategory$. This property specifies the category of action that the capability can achieve. For instance, in Fig. 2, all capabilities have the value $shipping$ for the property $actionCategory$. In addition, the capability model allows for the definition of complex types of property values. In particular, there are five types of values for a property $SingleValue$, $ConstrainedValue$, $FunctionalValue$, $ConditionalValue$, and $EnumeratedValue$. $SingleValue$ refers to values of the type instance or subclass. For example, in Fig. 2 Sidney can be seen as an instance of Australia that is itself a subclass of $GeographicalLocation$. $ConstrainedValue$ allows to make a constraint on the value of a property. For example, in Fig. 2, the property $weight$ in $C2$ is of type $ConstrainedValue$. $FunctionalValue$ is used to define relationships between properties of the same capability. For example, the value of the property price in $C4$ is of type $FunctionalValue$. $ConditionalValue$ enables the definition of a value that depends on the value of another property. As an example, the value of the property $weight$ in $C2$ is of type $ConditionalValue$. Finally, $EnumerationValue$ denotes a finite set of a property values. For instance, the value of the property to within $C3$ is of type $EnumerationValue$.

It worth to note that, the semantics of the specification relation SR are domain-dependent and should, if possible, be defined with respect to the meaning of the values within each MGV. For instance, in numerical domains, for example, specification relation between elements may be simply the set inclusion (e.g., $\{10, 20\} \subseteq \{0..100\}$), while in geographical domains, it may be represented by a containment relation such as $locatedIn$. In networking domains, such as IP address hierarchies, specification could rely on subnet inclusion.

variantOf Relation: In addition to modeling relationships between the properties of a capability, the Capability Model introduces relations between capabilities to support hierarchical structuring. In study [45], the authors define such a hierarchy through the $variantOf$ relation, which captures when one capability is more specific than another. This relation generalizes the sub-relations $specifies$ and $extends$, and is defined based on an extension of the specification relation `SR` to operate over sets of values within a shared MGV.

The $variantOf$ relation is formally defined as follows:

A capability C_1 is said to be $variantOf$ C_2 if the following two conditions hold:

- For every property p in C_1, the value assigned to p in C_1 is either equal to the value of p in the extended capability C_2/C_1, or it $specifies$ the value of p in C_2/C_1;

- There exists at least one property p in C_1 for which the value of p in C_1 strictly $specifies$ the corresponding value in C_2/C_1.

Here, C_2/C_1 denotes the extension of capability C_2 by C_1, i.e., a merged capability that includes all properties of C_2 and any additional properties from C_1.

The `specifies` relation between two value sets v_1 and v_2 is defined as:

$$v_1 \ \texttt{specifies} \ v_2 \iff (v_1 \subset v_2 \vee \exists \underline{SR}. v_1 \mapsto v_2 \in \underline{SR})$$

where MGV is the most general value domain associated with the property and $\underline{SR}$ is a specification relation between twos sets of MGV.

C. The Event-B Model Architecture

In this section, we present our Event-B formalization of the Capability Model.

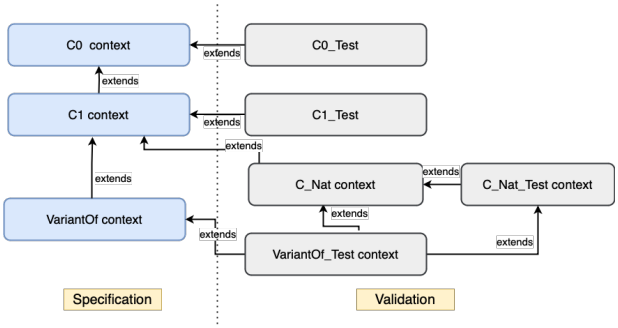

Fig. 3. Architecture of the Event-B model for the verification of the capability model.

The model is structured into three contexts (see Fig. 3):

- *C0* defines the core concepts of the Capability Model, including property value types;
- *C1* formalizes the specification relation between capabilities;
- *VariantOf* defines the variantOf relation and includes proofs that it constitutes a partial order, along with several inference theorems to deduce variantOf relations between capabilities.

Fig. 4 illustrates the corresponding Event-B model of the context C0. We define three foundational sets: i)PROPERTY: the set of domain-specific properties (e.g., actionCategory, to, weight, price in the shipping domain); ii) GENERALVALUES: the set of most general property values (MGVs), including values such as natural numbers, locations, and other domain-relevant categories; iii) Expression: a set of logical expressions used to define constraints over property values.

Other core elements such as Capability, PropertyEntry, and possibleValues are defined as constants within the model. The set possibleValues, a subset of GENERALVALUES, represents all possible values a property may take within a given capability. To capture semantic of different property values types, we define specific subsets of possibleValues (e.g ConstrainedValue, ConditionalValue,etc.). A PropertyEntry is defined as a pair from the cartesian product of PROPERTY and a subset of possibleValues. Additionally, The relation between a property and its MGV has been established by the relation hasMGV that maps each property in PROPERTY with its domain of valid values in GENERALVALUES. For example, hasMGV(to) = GeographicalLocation , hasMGV(weight) = $\mathbb{N}$, and hasMGV(price) = $\mathbb{N}$, with the assumptions that GeographicalLocation $\subseteq$ GENERALVALUES, $and\mathbb{N} \subseteq$ GENERALVALUES.

Given this, for instance, valid propertyEntry include $(\texttt{weight}, \{10\})$ and $(\texttt{weight}, \{20, 30, 40, 60\})$. A capability is then represented as a set of such property entries. For example, $C1$ in the motivating example can be modeled in our model as

$$\texttt{C1} = \{\texttt{actionCategory} \mapsto \texttt{shipping},\ \texttt{to} \mapsto \texttt{Australia}\}$$

where {actionCategory,to} $\subseteq$ PROPERTY, shipping is the hasMGV(actionCategory), and Australia is a set that belongs to GeographicalLocation.

Property value Types: SingleValues. This refer to a subset of GENERALVALUES that represent either a singleton or a set of multiple elements. Given that, we are using Rodin which is based on set theory, we do not need to use this constant as it is already integrated in Event-B language as a subset of possibleValues.

ConstrainedValues. A ConstrainedValue is defined through a constructor that maps a property and a logical expression to a set of values that satisfy the expression within the property's most general value. This constructor is represented as: $\texttt{Const} \in \texttt{PROPERTY} \times \texttt{Expression} \rightarrow \mathcal{P}(\texttt{ConstrainedValues})$

The semantics of Const are given by the following definition: $\texttt{Const}(p \mapsto \texttt{exp}) = \{x \mid \texttt{satisfies}(x, \texttt{exp}) = \texttt{TRUE} \wedge x \in \texttt{hasMGV}(p)\}$. That is, $\texttt{Const}(p \mapsto exp)$ returns the subset of hasMGV(p) whose elements satisfy the condition that the expression exp evaluates to TRUE. . This relies on the satisfies relation, which is defined as: $\texttt{satisfies} \in \texttt{GENERALVALUES} \times \texttt{Expression} \rightarrow \texttt{BOOL}$. As an example, in Fig. 2, the value of the property weight in C_2 can be represented using a constrained value:

```
Const(weight ↦ makeExpression(
        makeGeneralvaluesFromNats(
        allNatLessThanOrEqualNat(100))))
```

Here, Const(weight $\mapsto$ exp) defines a constraint on the property weight, where exp is the expression makeExpression(makeGeneralvaluesFromNats(allNatLessThanOrEqualNat(100))). This expression is satisfied by all natural numbers less than or equal to 100, i.e., satisfies(x, exp) evaluates to TRUE for every $x \in \mathbb{N}$ such that $x \leq 100$.

ConditionalValues. A ConditionalValue represents dependencies between the values of two properties within a capability. We define it via a constructor that maps a capability, a property, two sets of possible values, and a Boolean condition to a set of ConditionalValues. This constructor is defined as: $\texttt{CND} \in \texttt{Capability} \times \texttt{PROPERTY} \times \mathcal{P}(\texttt{GENERALVALUES}) \times \mathcal{P}(\texttt{GENERALVALUES}) \times \texttt{BOOL} \rightarrow \mathcal{P}(\texttt{ConditionalValues})$

The semantics of CND are governed by the relation: $\texttt{condition} \in \texttt{GENERALVALUES} \times \texttt{Expression} \rightarrow \texttt{BOOL}$. Given a capability cap, a property p, and a condition dependent on another property p_c, the meaning of a conditional value is as follows:

$$\texttt{CND}(\texttt{cap} \mapsto \texttt{price} \mapsto \texttt{v\_p} \mapsto \texttt{v\_p2} \mapsto \texttt{condition}(\texttt{cap} \mapsto \texttt{p\_c} \mapsto \texttt{v\_c})) =$$

$$\begin{cases} \texttt{v\_p} & \text{if } \texttt{condition}(\texttt{cap} \mapsto \texttt{p\_c} \mapsto \texttt{v\_c}) = \texttt{TRUE} \\ \texttt{v\_p2} & \text{otherwise} \end{cases}$$

Here, p is the property being assigned a conditional value, and p_c is the property whose value influences the selection. v_p and v_p2 are sets of values from the MGV of p , and v_c is a set of values from the MGV of p_c.

Example. In our motivating example (Fig. 2), the value of price in capability C_2 is of type ConditionalValue. It

can be written as:

$$\begin{aligned}&\texttt{CND}(\texttt{C2} \mapsto \texttt{price} \mapsto \\ &\quad \texttt{FN}(\texttt{C2} \mapsto \texttt{price} \mapsto \texttt{weight} \mapsto \texttt{f5}) \mapsto \\ &\quad \texttt{FN}(\texttt{C2} \mapsto \texttt{price} \mapsto \texttt{weight} \mapsto \texttt{f10}) \mapsto \\ &\quad \texttt{condition}(\texttt{C2} \mapsto \texttt{weight} \mapsto \\ &\quad \texttt{Const}(\texttt{weight} \mapsto \texttt{makeExpression}(\\ &\quad \texttt{makeGeneralvaluesFromNats}(\\ &\quad \texttt{allNatLessThanOrEqualNat}(50)))))\end{aligned}$$

This expression states that if the weight is less than or equal to 50, then the price is computed using function f_5(that returns $5 \times \texttt{weight}$); otherwise, it is computed using f_{10}(that returns $10 \times \texttt{weight}$).

FunctionalValues. A `FunctionalValue` is defined by a constructor that maps a capability, a target property, a source property, and a function to a set of `FunctionalValues`. The constructor is given by: $\texttt{FN} \in \texttt{Capability} \times \texttt{PROPERTY} \times \texttt{PROPERTY} \times \texttt{f} \rightarrow \mathcal{P}(\texttt{FunctionalValues})$ where `f` is the set of partial functions defined as: $\texttt{f} = \texttt{PROPERTY} \times \texttt{GENERALVALUES} \rightharpoonup \texttt{GENERALVALUES}$. The semantics of a `FunctionalValue` define how the value of one property is computed based on the value of another property. Formally, the interpretation of: $\texttt{FN}(\texttt{cap} \mapsto \texttt{p} \mapsto \texttt{pf} \mapsto \texttt{fn})$ is the set: $\{\texttt{fn}(\texttt{pf} \mapsto \texttt{x}) \mid \texttt{x} \in \texttt{getPossibleValuesOfPonCapability}(\texttt{cap} \mapsto \texttt{pf}) \wedge (\texttt{pf} \mapsto \texttt{x}) \in \texttt{dom}(\texttt{fn})\}$ `cap` is a capability, `p` is the property within `cap` whose value is determined by a `FunctionalValue`, `pf` is another property within `cap` whose value is used as input to the function `fn`, $\texttt{fn} \in \texttt{f}$ is a partial function in the most general value domain of `p`, and `getPossibleValuesOfPonCapability(cap, pf)` returns the possible values of property `pf` within capability `cap`.

Example. In our motivating example, the value of `price` within capability C_4 is defined as a `FunctionalValue`: $\texttt{FN}(c_4 \mapsto \texttt{price} \mapsto \texttt{weight} \mapsto f_5)$. The function f_5 computes the price as five times the weight. It is defined as: $f_5 \in \texttt{PROPERTY} \times \mathbb{N} \rightarrow \mathbb{N}$ with semantics given by: $f_5(\texttt{weight} \mapsto ng) = \texttt{makeGeneralvalueFromNat}(5 \times \texttt{getNatForGeneralValue}(ng))$. This means that the price is computed as $5 \times \texttt{weight}$, using the numeric interpretation of the general value. This expresses that for every value x of the source property pf that exists in the current capability and lies in the domain of function fn, the function computes the corresponding value of property p as $fn(pf \mapsto x)$.

Capability Validity. To ensure the well-structured definition of services, we define the notion of a *valid capability*. A capability is considered valid if it satisfies the following conditions:

(i) It includes a property denoted as `actionCategory`, representing the action performed by the capability;
(ii) It does not contain duplicate properties with conflicting values;
(iii) All property values lie within the domain defined by their associated `MGV`.

This constraint is defined as an axiom at the context level, by the constant `Capability_valid`. During any interaction with the system, we check whether a given capability belongs to the set of valid capabilities.

Fig. 4. Snapshot of the Event-B context C0 defining the core components.

Specification Relation. The specification relations described above, denoted `SR` and $\underline{\texttt{SR}}$, define, respectively, relationships between individual values and between sets of values within the same most general value (MGV) domain. These relations are formally defined in Event-B within context `C1`, a portion of which is shown in Fig. 5.

We distinguish between two levels of specification:

- SpecificationRelation (`SR`): a relation between individual values of a given MGV, defined as: $\texttt{SpecificationRelation} \in \mathcal{P}(\texttt{GENERALVALUES}) \rightharpoonup \mathcal{P}(\texttt{GENERALVALUES} \times \texttt{GENERALVALUES})$
- SpecificationRelationOnSets ($\underline{\texttt{SR}}$): a relation between sets of values from a given MGV, defined as: $\texttt{SpecificationRelationOnSets} \in \mathcal{P}(\texttt{GENERALVALUES}) \rightharpoonup \mathcal{P}(\mathcal{P}(\texttt{GENERALVALUES}) \times \mathcal{P}(\texttt{GENERALVALUES}))$

Specifies Relation. We define the relation `specifies`,

which holds between two capabilities that share the same property. It states that the value in one capability specializes the value in the other. Formally: $\texttt{specifies} \in \texttt{PROPERTY} \times \texttt{Capability\_valid} \times \mathcal{P}(\texttt{GENERALVALUES}) \leftrightarrow \texttt{Capability\_valid} \times \mathcal{P}(\texttt{GENERALVALUES})$. The semantics of this relation are given by:

$$(p \mapsto c_1 \mapsto v_1) \mapsto (c_2 \mapsto v_2) \in \texttt{specifies} \Leftrightarrow (v_1 \subset v_2 \vee (\texttt{hasMGV}(p) \in \texttt{dom}(\texttt{Specification RelationOnSets}) \wedge (v_1 \mapsto v_2) \in \texttt{Specification RelationOnSets}(\texttt{hasMGV}(p))))$$

Where p is a property shared by the capabilities c_1 and c_2, v_1 is the value of p in c_1, and v_2 is its value in c_2. Intuitively, the `specifies` relation holds either when there is a strict inclusion between v_1 and v_2, or when a domain-specific specification relation exists for the property's most general value, indicating that v_1 is more specific than v_2.

...: ...
END

Fig. 5. Snapshot of the Event-B context C1 defining the basic specification relations.

Example. In our motivating example, the value of the `weight` property in capability C_4 is more specific than this in C_2. Formally:

$$\texttt{weight} \mapsto C_4 \mapsto \texttt{getPossibleValuesOfPonCapability}(C_4, \texttt{weight}) \mapsto (C_2 \mapsto \texttt{getPossibleValuesOfPonCapability}(C_2 \mapsto \texttt{weight})) \in \texttt{specifies}$$

This holds because we have formally proved that: $\{10, \ldots, 40\} \subset \{0, \ldots, 100\}$.

VariantOf Relation. The model introduces a `variantOf` relation between capabilities. Its definition has been proposed in [45], and we have formally encoded this definition in Event-B. Fig. 6 illustrates the corresponding Event-B context. The definition of the `variantOf` relation is stated in axiom `AXM_variantOf`.

Additionally, we have formally proved that both `specifies` and `variantOf` are transitive and irreflexive. These proofs were conducted under the assumption that the relations SR and $\underline{SR}$ are themselves irreflexive and transitive, and that for any given `MGV`, it is not possible for both a strict inclusion and a $\underline{SR}$ relation to exist simultaneously between any two sets.

While in study [45], authors provide a rich conceptual and semi-formal foundation including inference rules and implementation support for discovering these relations, key correctness properties are only asserted but not formally verified. In contrast, our contribution offers a rigorous formalization of the model using the Event-B method. We encode the entire capability structure including property value types, the `specifies` and `variantOf` relations, and their supporting constraints into a provable specification. Moreover, our model introduces an additional consistency condition not enforced in [45]. Specifically, we require that every capability adheres to a well-formed structure (that we denote as a valid capability). This structural constraint enhances the reliability of capability definitions and ensure the soundness of subsequent reasoning. Therefore, we have defined these relations exclusively over valid capabilities, as reasoning about capability specialization is only meaningful when the capabilities themselves are structurally consistent.

Most importantly, we formally prove that the `variantOf` relation satisfies the properties of a partial order that were only affirmed informally in [45]. It is important to note that the partial order property of the `variantOf` relation directly enables the use of a directed acyclic graph (DAG) as the underlying structure of the service repository. By formally proving that `variantOf` is irreflexive and transitive, we ensure that the resulting capability graph does not contain cycles and maintains a coherent hierarchical structure. This acyclic and ordered structure is essential for efficient reasoning, enabling traversal operations (e.g., finding more generic or more specific capabilities) and supporting efficient service discovery [45]. Consequently, the correctness of the partial order lays the theoretical foundation for representing and managing cloud service variability using graph-based repositories.This insight provides a novel and formally grounded refinement of the original model. By discharging these proof obligations in Rodin, we reinforce the suitability of the Capability Model for correctness service discovery applications.

D. Validation of the Model

We have validated the model incrementally by means of two complementary strategies.

First, we performed unit-level validation by constructing test contexts to verify the structural and semantic correctness of the individual model components. This approach is conceptually similar to unit testing in software engineering . The architecture of the resulting Event-b model is shown in Fig. 3. For each main context (e.g., $C0$), we created a corresponding test context (e.g., $C0\_Test$) in which key axioms were instantiated and verified as theorems. These theorems were then proven using the Rodin platform. This strategy allowed us to confirm that the model components were well-defined and consistent.

Second, we validated the model using a concrete, real-world scenario based on the motivating example described earlier. To support this, we introduced a new context, `C_Nat`, dedicated to the representation of natural numbers. This was necessary because Rodin does not allow multiple disjoint interpretations within a single abstract set such as `GENERALVALUES`. Within `C_Nat`, we defined natural numbers as a subset of `GENERALVALUES` and specified logical expressions such as `lessThan` and `greaterThan`. We also defined a mapping between abstract natural numbers and concrete numeric value.

The four capabilities presented in our motivating example were encoded in the `VariantOf_Test` context according to the Event-B model. We formally verified the validity of each capability and subsequently proved the `variantOf` relationships between them.

We argue that this validation strategy provides strong assurance of the model's soundness. All generated proof obligations were successfully discharged using the Rodin tool. The overall proof statistics are shown in Fig. 13.

V. Formal Modeling of Cloud Service Discovery

In this section, we present our Event-B model, which formalizes a cloud service discovery system based on the architecture shown in Fig. 1. We then verify and validate the model by discharging proof obligations and using a real-world scenario to demonstrate the correctness of the system's behavior.

A. The Event-B Model

Our Cloud Service Discovery (CSD) system is modeled as a formal Event-B refinement hierarchy built upon the previously defined Event-B Capability Model. This allows us to reason about discovery behavior while preserving the semantic correctness of service description. In this section, the terms *service*, *offer*, and *capability* refer to a cloud service offering described according to the Capability Model. The architecture of the final model is illustrated in Fig. 7.

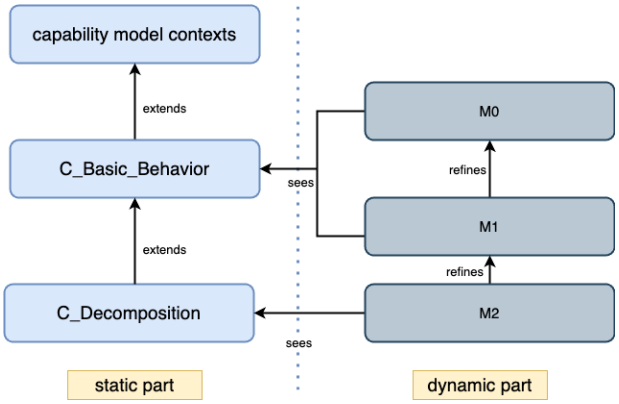

Fig. 7. The cloud service discovery formal model.

The system is modeled across three refinement levels, progressively transitioning from an abstract model to a more CSD concrete system.

Refinement Strategy. The formal development of the CSD model is organized as follows:

- M0 – Initial Model: This level captures the foundational behavior of the system. It is represented by the machine *M0*, which sees the context *C_Behavior* extending the capability model contexts and incorporating definitions

of constants required to describe basic behavior. At this level, we model the elementary behavior of the CSD system. We begin by representing the repository as a graph, where `offers` denotes the set of current service offers (nodes), and `variantsOf` denotes the edges capturing the *variantOf* relation between offers. The system supports three primary interactions, formalized as events:

MACHINE M0
SEES C_Basic_Behavior
VARIABLES `offers` current service' offers
`response` the response returned to the user
`requestedCapability` the requested service/offer `variantsOf`
the set of current relationships between offers
INVARIANTS `inv1`: $offers \subseteq Capability\_valid$
offers must be valid capabilities
`inv2`: $requestedCapability = \varnothing \lor requestedCapability \in Capability\_valid$
user request is either ∅ when there is no request otherwise it is a valid capability
`inv3`: $variantsOf = \{c1 \mapsto c2 | c1 \in offers \land c2 \in offers \land c1 \mapsto c2 \in variantOf\}$
`inv4`: $response = \{requestedCapability\} \lor response = \{offer | offer \in offers \land requestedCapability \mapsto offer \in variantOf\}$
EVENTS
Initialisation begin `act1`: $offers := \varnothing$
`act2`: $response := \varnothing$
`act3`: $requestedCapability := \varnothing$
`act4`: $variantsOf := \varnothing$
end
END

Fig. 8. Snapshot of the Event-B M0 defining the initial model.

- addOffers – introduces new service offers into the system;
- removeOffers – removes existing service offers;
- getOffersForNewRequest – initiates a discovery process based on a user requested service.

As illustrated in Fig. 8, the model also includes two additional variables: `requestedCapability`, representing the user's service request, and `response`, representing the potential returned services. The model remains abstract at this stage, as reflected by the non-deterministic invariants shown in Fig. 8. Nonetheless, it ensures that all services, whether requested or offered, are valid.
Initialization: At each refinement level, the system begins with an empty repository, no requests, and no response.
`addOffers` (Fig. 9): This abstract event inserts a valid offer (`Capability_valid`) into the repository. It updates the set of offers, adds edges to `variantsOf` using the `addNewVariantOf` relation, and modifies the `response` and `requestedCapability` accordingly.
`removeOffers`: Semantically similar to `addOffers`, this event removes a service offer and its associated edges from the repository and updates the response set.

MACHINE M0
SEES C_Basic_Behavior
EVENTS
Event addOffer ⟨ordinary⟩ $\widehat{=}$
adding new offer to the existing ones
any offer a service' offer described based on the capability model
where `grd1`: $offer \in Capability\_valid$
offer must be a valid capability
`grd2`: $offer \notin offers$
offer is not already in the repository of offers
then `act1`: $offers := offers \cup \{offer\}$
add offer to exisstting offers
`act3`: $variantsOf := variantsOf \cup addNewVariantsOf(offers \mapsto offer)$
add relationships between the new offer and existing ones
`act2`: $response :\in \{\{offer0 | offer0 \in offers \cup \{offer\} \land requestedCapability \mapsto offer0 \in variantOf\}, \{requestedCapability\}\}$
update response
end
END

Fig. 9. Formalization of the event addOffers.

`getOffersForNewRequest` (Fig. 10): This event models service discovery. Given a valid request, it updates `requestedCapability` and returns either an exact match or a set of more generic offers satisfying the `variantOf` relation.

MACHINE M0
SEES C_Basic_Behavior
EVENTS
Event getOffersForNewRequest ⟨ordinary⟩ $\widehat{=}$
any request request is described based on the capability model
where `grd1`: $request \in Capability\_valid$
request must be a valid capability
then `act1`: $requestedCapability := request$
request is assigned to requestedCapability
`act2`: $response :\in \{\{offer | offer \in offers \land request \mapsto offer \in variantOf\}, \{request\}\}$
response is equals {request} or the set of variantOf with request
end
END

Fig. 10. Formalization of the event getOffersForNewRequest.

- M1 – First Refinement: (Fig. 11) This level, represented by machine *M1* (which also sees *C_Behavior*), refines the abstract model by introducing more concrete behaviors. In particular, it refines the three core events (`addOffers`, `removeOffers`, and `getOffersForNewRequest`) into specialized versions, and provides more precise invariants.

- `addOfferWhenRequestIsEqualToOffer`, `addOfferWhenOfferIsVariantOfRequest`, and `addOffer`: These events distinguish whether the user request matches an existing offer exactly, is a variantOf an offer, or is unrelated. Each case results in different updates to `response` and `requestedCapability`.

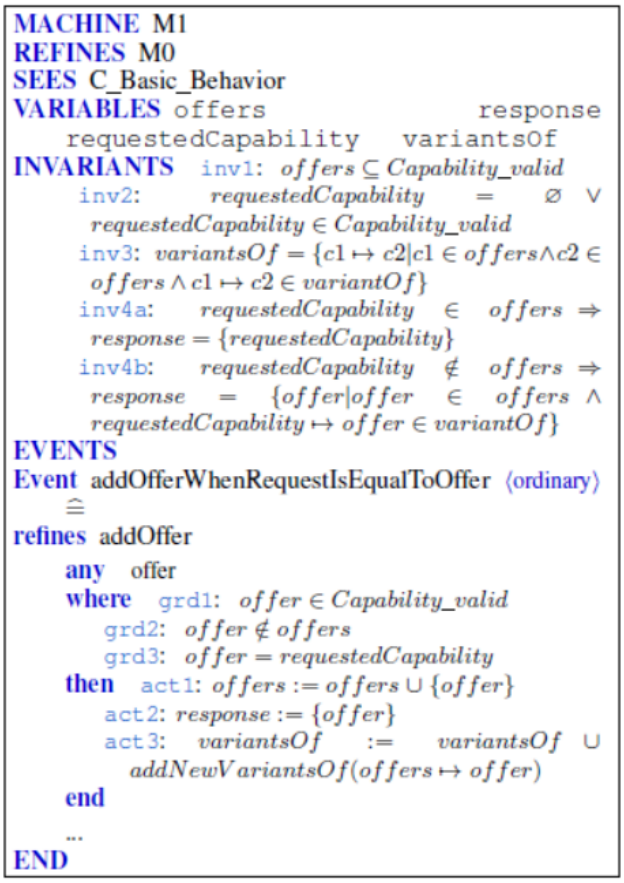

Fig. 11. Snapshot of the Event-B M1 defining the first refinement.

- `removeOfferWhenOfferIsInResponse-AndEqualsRequest`, `removeOfferWhenOfferIs-InResponseAnd-NotEqualToRequest`, and `removeOffer`: These events differentiate between removing an offer that equals the current request, that is part of the response but not equal, or that is unrelated.
- `getOffersForNewRequestWhenRequest-IsInOffer` and `getOffersForNewRequestWhen Requ-estIsNotInOffer`: These events handle the case where the request is already in the repository (response is the request itself), or not (response is the set of `variantOf` offers).

- M2 – Second refinement: (Fig. 12) This refinement introduces the notion of service categorization through subgraphs. Based on the `actionCategory` property, mandatory in each capability as per the Capability Model, offers are grouped into subgraphs, each corresponding to a distinct category of service. This categorization enhances efficiency by allowing discovery to be restricted to the relevant subgraph. Our primary objective in this refinement is to prove that the global graph, represented by `offers` and `variantsOf`, is equivalent to the union of these subgraphs. Additionally, we verify that these subgraphs are disjoint.

Fig. 12. Snapshot of the Event-B M2 defining the second refinement.

Technically, we define new variables including `offersByCategory` and `variantsOfByCategory`. They are linked to the global structure(e.g the graph) through the gluing invariants:

$$offers = \bigcup offersByCategory,$$
$$variantsOf = \bigcup variantsOfByCategory.$$

B. Validation

In this section, we validate our CSD model by leveraging twos kinds of validations described as follows.

1) Proof obligation: As shown in Fig. 13, for the complete model, a total of 347 proof obligations were generated. Among these, 158 were discharged automatically, while 189 required manual intervention. Notably, 123 obligations were associated specifically with the machine `M2`, of which 68 were discharged manually.

Element Name	Total	Auto	Manual	Rev.	Und.
CloudServiceDiscoveryModel	**347**	**158**	**189**	**0**	**0**
C0	16	15	1	0	0
C0_Structural_Test	19	7	12	0	0
C1	25	19	6	0	0
C_Basic_Behavior	1	0	1	0	0
C_Decomposition	4	1	3	0	0
C_Nat	15	10	5	0	0
C_Nat_Test	12	2	10	0	0
VariantOf	32	5	27	0	0
VariantOf_Test	40	3	37	0	0
M0	17	10	7	0	0
M1	43	31	12	0	0
M2	123	55	68	0	0

Fig. 13. Proof statistics view from the Rodin platform showing automatic and manual discharge across refinement levels.

2) Validation through interaction scenarios: Although all proof obligations associated with the formal Event-B model were successfully discharged, it remained necessary to validate the system's behavior under dynamic operations such as service insertion, removal, and user request handling. However, due to the complexity of the model, particularly the expressive axioms involving property value types and specification relations, ProB, which supports model animation, was unable to complete execution in our experiments. To address this limitation, we employed a manual, scenario-based validation strategy. For each interaction, the resulting system state was manually derived by applying the `action` clause of the corresponding Event-B event to the previous state. Because all events were formally verified to preserve the model's invariants, each state in the scenario is guaranteed to be consistent with the formally defined behavior. This process effectively simulates the system's dynamic execution and constitutes a valid behavioral validation trace grounded in the provably correct model.

For this purpose, we reuse the same structure as in the motivating example presented earlier. The capabilities C_1, C_2, C_3, C_4 , described below, follow the same structure and naming convention as in the logistics example, are now adapted to a cloud computing context. Each capability is compliant with the formally defined `Capability_valid` structure, and thus their structural correctness is already formally verified. In this context, we simulate a scenario involving a service provider p, who adds and removes service offers, and two users, u_1 and u_2, who send discovery requests.

- C_1: An infrastructure as a service(IaaS) cloud offering providing a standard virtual machine (VM) in the AWS[3] limited to the Europe region .

$$C_1 = \{\texttt{actionCategory} \mapsto \texttt{compute},\ \texttt{region} \mapsto \texttt{Europe},\ \texttt{provider} \mapsto \texttt{aws}\}$$

- C_2: A specialized offer using `t3` instance family.

$$C_2 = \{\texttt{actionCategory} \mapsto \texttt{compute},\ \texttt{region} \mapsto \texttt{Europe},\ \texttt{provider} \mapsto \texttt{aws},\ \texttt{instanceType} \mapsto \texttt{t3}\}$$

- C_3: A further specialized offer targeting specific zones (e.g., `eu-west-2` for London and `eu-west-3` for Paris).

$$C_3 = \{\texttt{actionCategory} \mapsto \texttt{compute},\ \texttt{region} \mapsto \{\texttt{eu-west-2}, \texttt{eu-west-3}\},\ \texttt{provider} \mapsto \texttt{aws}\}$$

- C_4: A variant of C_2 that introduces a Static Solid Storage(SSD)

$$C_4 = \{\texttt{actionCategory} \mapsto \texttt{compute},\ \texttt{region} \mapsto \texttt{eu-west-2},\ \texttt{provider} \mapsto \texttt{aws},\ \texttt{instanceType} \mapsto \texttt{t3.micro},\ \texttt{storageType} \mapsto \texttt{SSD}\}$$

These capabilities are all defined in accordance with the verified Event-B model, where each capability is a set of property entries satisfying domain-specific constraints (e.g., $\texttt{region} \subseteq \texttt{GeographicalLocation}$). As such, no additional assumptions regarding validity are required: the model ensures correctness by construction.

This real-world example illustrates the direct applicability of our approach to cloud computing environments, demonstrating how `variantOf` relations support capability specialization and service discovery over a formally verified and semantically structured service repository.

The scenario proceeds as follows:

1) The provider adds capability C_1.
2) The provider adds capability C_2.
3) User u_1 submits a request for C_2.
4) User u_2 submits a request for C_4.
5) The provider adds capability C_3.
6) The provider removes capability C_2.
7) The provider re-adds capability C_2.

Each step in this sequence modifies the system state by triggering an Event-B event. The updated values of key variables such as `offers`, `variantsOf`, `response`, and `requestedCapability` are depicted in Fig. 14. These transitions are shown to preserve the model invariants, thereby demonstrating the behavioral correctness of the system.

VI. Results and Discussion

Our Event-B model for cloud service discovery (CSD) has been developed incrementally. In Section IV, we proposed the Event-B model for the Capability Model. The proposed model not only covers all types of properties in the Capability Model, but also goes beyond by formalizing the variantOf relation

[3]https://aws.amazon.com

Fig. 14. State transition diagram of the cloud service discovery system under the validation scenario.

between services. Furthermore, we mathematically proved that variantOf satisfies the properties of a partial order relation, enabling the organization of services into a Directed Acyclic Graph (DAG) structure that facilitates discovery. Additionally, we introduced the concept of a valid capability, which supports the structural validation of service definitions.

The model was validated through two types of tests. First, we conducted unit-level validation by encoding test contexts for each component of the model, allowing us to prove structural consistency and the well-definedness of all model elements. Second, we validated the model using our motivating example. This demonstrated that the formal specification is sufficiently expressive to represent the example, confirming the conformity of our formal model with the original Capability Model.

In Section V, we verified a repository-based CSD system built upon the formal Capability Model, used for describing both services and user requests. In this model, we ensured request consistency through the valid capability concept, verified the correct construction of the service repository as a DAG, and validated the correctness of the matching process. Additionally, we confirmed the structured organization of services based on the actions they perform.

We formally proved the correctness of the complete model through 347 proof obligations generated by the Rodin tool, of which 189 were discharged interactively and the rest were discharged automatically. Furthermore, we performed a second validation using a real-world cloud services scenario. Our validation confirmed that our model is mathematically sound, correct by construction, and applicable to cloud service environments.

However, in this initial stage, our approach only supports exact or generalized matching. This restrictive matching strategy is insufficient for practical cloud systems which typically require support for partial satisfaction and ranking mechanisms. Although our model establishes a strong theoretical foundation, further refinement is needed to verify properties that are specific to real-world cloud environments, such as scalability. This involves analyzing of the computational complexity of the matchmaking process, DAG traversal, and repository operations.

VII. Conclusion

In this work, we proposes a formal architecture for capability-centric cloud service discovery, grounded in the Event-B method. The architecture is based on a capability-centric description model called the Capability Model, which supports rich property representations tailored to cloud service characteristics. Our system is repository-based and structured as a directed acyclic graph (DAG) using a formally verified partial order relation denoted as VariantOf. We verified the soundness of this structure by proving the consistency of the service description model and the partial order relation. The behavior of the system was modeled across multiple refinement levels, including a decomposition of services according to the action they perform. 347 proof obligations generated by the Rodin tool were discharged, and a scenario-based validation was conducted to confirm behavioral correctness. However, the matchmaking process currently supports only exact and generalized matching, which may be restrictive in real-world systems. Future work will address this limitation by supporting partial satisfaction and ranking techniques. Furthermore, we plan to formally optimize the repository structure by eliminating transitive edges in the graph.

Analyzing the Impact of Histogram-Based Image Preprocessing on Melon Leaf Abnormality Detection Using YOLOv7

Sahrial Ihsani Ishak, Sri Wahjuni, Karlisa Priandana*
School of Data Science, Mathematics and Informatics, IPB University, Bogor, Indonesia

***Abstract*—This study aims to analyze and implement image preprocessing techniques to improve the performance of melon leaf abnormality detection using the YOLOv7 algorithm. A total of 521 abnormal melon leaf images were processed using augmentation and three preprocessing methods: Averaging Histogram Equalization (AVGHEQ), Brightness Preserving Dynamic Histogram Equalization (BPDFHE), and Contrast Limited Adaptive Histogram Equalization (CLAHE), then compared with the original dataset. Modeling was conducted in three stages: initial training with an 80:20 split and default YOLOv7 augmentation; hyperparameter tuning via cross-validation using a 90:10 split without augmentation; and final training using the best parameters with augmentation reactivated. The models were evaluated using ensemble learning. Results showed mAP ranged from 58.6% to 66.3%, accuracy from 80.7% to 84.9%, and detection time from 9.8 to 20 milliseconds. Preprocessing improved mAP and detection time, though it had little effect on accuracy. The best performance was obtained with a kernel size of 3 and a learning rate of 0.001, while changes in activation function, pooling, batch size, and momentum had minimal impact. The top models, trained with maximum epochs and standard augmentation, achieved mAP of 84.12%, accuracy of 91.19%, and detection time of 4.55 milliseconds. Models using early stopping (patience = 300) reached mAP of 81.57%, accuracy of 92.23%, and detection time of 5.03 milliseconds. The best model outperformed previous works, which reported only 48.85% with Faster R-CNN, 33.16% with SSD, and 16.56% with YOLOv3. Although histogram-based preprocessing methods mainly enhanced inference speed, the overall improvements to YOLOv7 significantly boosted detection performance.**

Keywords*—Leaf abnormality; melon; image preprocessing; YOLOv7

I. Introduction

The agricultural sector significantly contributes to Indonesia's GDP by creating jobs and increasing export values [1], supports broader economic expansion through regional improvements in fruit commodity productivity [2], and has helped mitigate the negative impact of the COVID-19 pandemic on economic growth via strong export performance [3]. According to information from the Indonesian Central Statistical Agency, fruit commodity production in Indonesia during 2016-2022 increased [4]. Nevertheless, there are commodities whose production is fluctuating. One of them is the melon commodity [4]. Fluctuations in melon production stem from suboptimal growing conditions, such as nutrient allocation affected by pruning and fruit thinning practices [5] and adverse environmental factors like temperature and humidity variations [6].

There are two causes of malnutrition in melon crops: the lack of nutrient intake received by the plant and the presence of pest disorders and diseases that affect the melon plant periodically. This can lead to crop failure if physiological disorders during melon growth are not addressed promptly [7], emphasizing the importance of timely pruning and fruit regulation to support healthy development. Meanwhile, environmental factors such as temperature, light, and water availability also play a crucial role in plant growth [8]. Identifying such disorders often requires sending samples to laboratories for testing, which can be time-consuming [9] and further supports [10] the diagnostic process for plant abnormalities. Information technology is needed to help identify anomalies that occur in melon plants effectively and efficiently. Artificial intelligence technology could be the solution to this problem [11].

Artificial intelligence (AI) is a field of science that integrates machine and human intelligence, which has been applied in various sectors, including agriculture [11], contributes to the development of intelligent algorithmic systems [12], and provides the foundation for advanced deep learning methods [13]. Deep learning, which evolved from machine learning, builds algorithms from existing data by mimicking neural networks [14], using statistical and computational models [15], and emphasizing efficient learning processes for data classification and prediction [16]. Unlike conventional machine learning, which treats feature extraction as a separate process, deep learning enhances this by learning feature representations directly from raw data [17]. One of the prominent applications of deep learning is object detection, a task that involves identifying and localizing objects within an image. Current object detection approaches are categorized into one-stage methods, prioritizing faster inference speeds [18], and two-stage methods, offering higher detection accuracy through refined region proposals and classification [19].

The performance of object detection models can be influenced by the image preprocessing techniques applied beforehand, as specific preprocessing steps can improve the generalization ability of over-parameterized neural networks [20]. In contrast, others affect the accuracy of convolutional neural network-based recognition systems [21]. In the context of melon leaf analysis, differences between normal and abnormal leaves can be identified through leaf color, shape, and texture, which are often associated with anatomical resistance to fungal

infection [22] and market-related disease symptoms in melon and related crops [23]. An image itself is composed of a grid of pixels where each pixel encodes intensity or color information; this concept underpins many image analysis processes, as elaborated in foundational image processing literature [24], methods for machine vision image acquisition and preprocessing [25], and comprehensive digital image processing frameworks [26].

The frequency distribution of pixel intensity in an image can be analyzed using a histogram, a fundamental technique in image processing as described in works such as Gonzalez and Woods' Digital Image Processing [24], Sinha's treatment of machine vision systems [25], and Pratt's comprehensive guide on digital image analysis [26]. Histogram-based processing is widely used to enhance image contrast and emphasize key differences between objects and their backgrounds [24], beneficial for distinguishing between normal and abnormal melon leaves. Several adaptive histogram equalization techniques have been developed to improve pixel-level contrast and image quality, especially in plant health detection. One such method is AVGHEQ, which focuses on contrast enhancement while maintaining brightness consistency [27]. Another technique, CLAHE, prevents noise over-amplification in homogeneous areas by limiting the histogram contrast [28]. Additionally, BPDFHE employs fuzzy logic to enhance image contrast while preserving natural brightness levels [29]. These preprocessing methods are expected to increase the effectiveness of detection models by providing more apparent visual differentiation between healthy and unhealthy leaves.

Various image preprocessing techniques can significantly impact the performance of the object detection model. These techniques play an essential role in improving the quality of the input image, thereby increasing the accuracy and efficiency of the detection process. On the other hand, hyperparameters also influence the performance of the object detection model. The detection model used in this study is YOLOv7, which surpasses other algorithms such as YOLOR, YOLOX, Scaled-YOLOv4, YOLOV5, DETR, DETR Deformable, DINO-5scale-R50, ViT-Adapter-B, and many other objects detectors, especially in terms of detection speed [30]. This study investigates how picture preprocessing approaches and hyperparameter optimization affect the effectiveness of models for detecting melon leaves. Unlike many earlier studies, which frequently disregard these elements, this study investigates their significance in enhancing model accuracy and efficiency. By addressing these critical features, the study hopes to provide the groundwork for constructing a more effective and efficient plant anomaly detection model, particularly for melon crops, which have gotten less attention in previous studies.

The structure of this paper is as follows: Section II reviews relevant literature, Section III outlines the research methodology, Section IV presents the results and discussion, and Section V provides the conclusion.

II. Related Work

Research on the identification of anomalies in tomatoes, soy, cucumbers, apples, and melons shows that it is still necessary to use image preprocessing to improve model performance and model application into a mini-computer platform to evaluate models in real-time. A study by [31] demonstrated that the Faster R-CNN and Mask R-CNN methods effectively identified tomato crop diseases, although some misclassifications were still observed. Similarly, [32] identified pests and diseases in tomato plants and reported that an improved version of YOLOv3 achieved the highest accuracy of 92.39% with a detection speed of 20.39 milliseconds. In the case of soybean plants, disease detection using the Multi-Feature Fusion Faster R-CNN method yielded an optimal mean Average Precision (mAP) of 83.34% [33]. Another study [34] employed the MTC-YOLOv5n method with enhancements to reduce image noise and improve the detection of small objects. This approach resulted in a compact model size of 4.7 MB, an mAP of 84.9%, and a frame rate of 143 frames per second (FPS). In addition, [35] proposed the MGA-YOLO method for detecting apple diseases based on leaf images, achieving an mAP of 89.3%, a minimal model size of 10.34 MB, and a peak FPS of 84.1 on a GPU. The model was also tested on smartphones, reaching a frame rate of 12.5 FPS.

This research extends the work presented in [36], which compared three methods for plant disease detection: Faster R-CNN, SSD, and YOLOv3. The study found that Faster R-CNN achieved the highest mean Average Precision (mAP) at 48.85%, while YOLOv3 demonstrated the shortest inference time at 0.5 seconds. In terms of CPU usage, SSD performed most efficiently, whereas YOLOv3 offered a balance between fast inference and moderate CPU consumption. Additionally, the study highlighted that preprocessing techniques could enhance the performance of object detection models [36]. Building on these findings, the present research employs YOLOv7 for its efficient inference time and moderate CPU usage. It further investigates the impact of a histogram-based preprocessing technique on model performance.

III. Research Methodology

This research comprises of five main steps: (1) data preparation; (2) modeling and evaluation of phase 1; (3) modelling and evaluation of phase 2; (4) modelling and evaluation of phase 3; and (5) comparison with the previous research in [36]. Before delving into the main topic, it is crucial first to discuss the background of YOLOv7 and the image processing techniques used, including AVGHEQ, BPDFHE, and CLAHE.

A. YOLOv7

You Only Look Once (YOLO) is a one-stage object detection algorithm consisting of the backbone, neck, and head structure. The backbone layer is responsible for feature extraction from the input image. Then, the results are passed to the neck layer, which generates pyramid features, allowing the system to detect objects at different scales. The head layer is the final layer for detecting classes and bounding boxes. YOLO has an architecture based on convolutional networks. YOLO's detection network comprises 24 convolutional layers and 2 fully connected layers. Alternating 1 × 1 convolutional layers reduces the feature space from the previous layers. The convolutional layers have been pre-trained on the ImageNet classification task with an image resolution of 224 × 224 [30].

YOLOv7, released in 2022 [30], is an algorithm of the YOLO model. To be more precise, the author creates several

training techniques known as "bag-of-freebies" that consist of modules and optimization techniques that significantly boost detection accuracy without raising the cost of inference. The network architecture uses the E-ELAN technique, which manages the longest and shortest gradient pathways to help a deep model learn and converge more efficiently. The E-ELAN approach shuffles and merges schemes to integrate the features of the groups to improve the learned features. It also lowers the computation cost and parameter count. Furthermore, YOLO-v7 presents several other training bag-of-freebies, such as 1) designing the architecture of the planned re-parameterized convolution using Connection-Aware RepConv (RepConvN), 2) implementing a new labeling technique that directs the lead and auxiliary heads; and 3) normalizing data in conv-bn-activation topology 4) Convolution on a feature map that combines addition and multiplication 5) Making the final inference using the EMA model.

YOLOv7 is a version of YOLO released in 2022. It can outperform all existing object detectors in speed and accuracy, with a speed of 5 to 160 FPS and the highest accuracy of 56.8% AP on the V100 GPU [30]. YOLOv7 also beats various other detectors, such as YOLOR, YOLOX, and YOLOv5, in terms of speed and accuracy, as seen in Table I. The overall architecture of YOLOv7 can be seen in Fig. 1.

TABLE I. YOLOv7 JUSTIFICATION

Model	Inference Time (millisecond)	AP (%)
YOLOv7	~5–7	~57
YOLOR	~9–11	~56
PPYOLOE	~11–13	~54
YOLOX	~15–17	~53
Scaled-YOLOv4	~23–25	~52
YOLOv5 (r6.1)	~29–31	~51

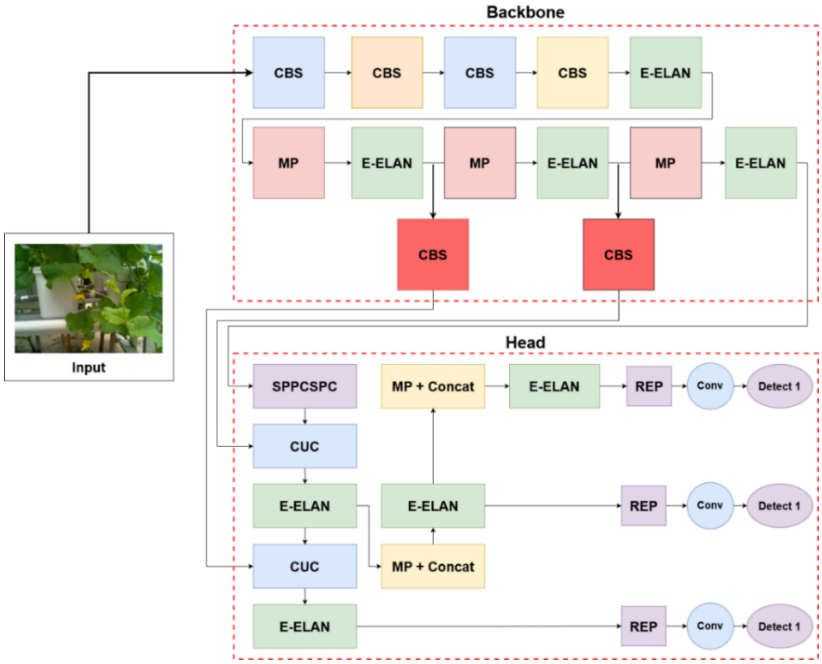

Fig. 1. YOLOv7 architecture.

B. AVGHEQ

AVGHEQ aims to increase image contrast while keeping the average brightness of the image output unchanged as much as possible. First, the input image is stretched on each color channel to correct any distortion from the unwanted environment. Then, it changed the color format from RGB to HSI [24]. After that the histogram was averaged before it was used in the equalization operation until the brightness error was reduced to a minimum and the entropy was maximized as much as possible. Next, normalization operations are performed, and last, the histogram and changes are remapped, and the HSI color format to RGB as the output image. The overall stages of AVGHEQ can be seen in Fig. 2.

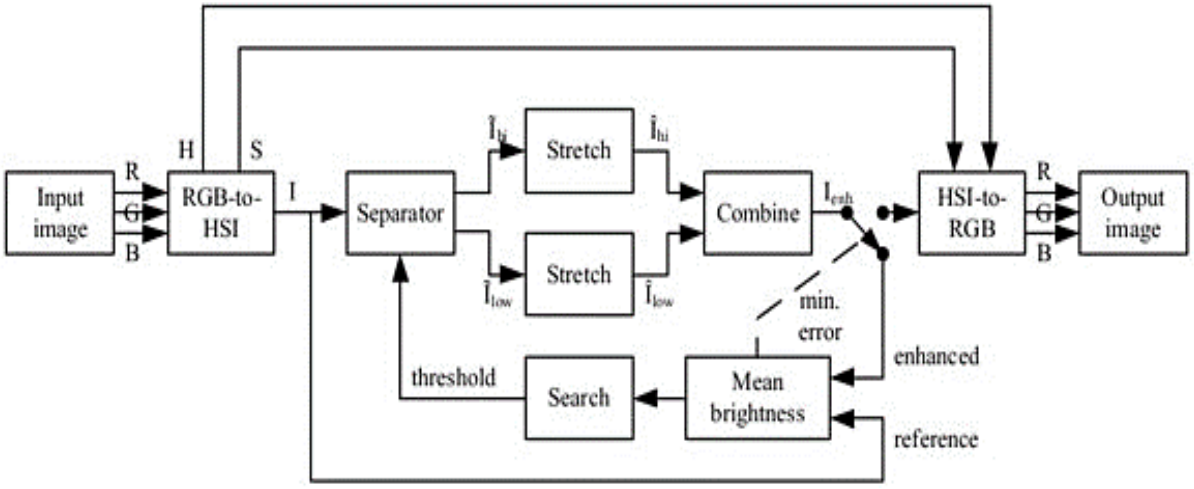

Fig. 2. AVGHEQ process [27].

C. BPDFHE

BPDFHE uses fuzzy statistics for digital image representation and processing. BPDFHE works in an abstract domain, allowing the process to be managed effectively at the end of the grayscale value, improving overall performance [29]. BPDFHE consists of four stages, namely, 1) Fuzzy Histogram computing, 2) Histogram Partitioning, 3) Dynamic Histogram Equalization of Partitioning, and 4) Image brightness normalization.

The process begins by calculating the fuzzy histogram, which uses the fuzzy membership function to handle the distribution of gray intensity values more subtly, resulting in a smoother and more informative histogram than traditional methods. Next, the histogram is partitioned based on the local maximum point found by derivative analysis, dividing the histogram into several sub-histograms. Each sub-histogram is then individually equalized using the Dynamic Histogram Equalization (DHE) technique to increase contrast without changing the average brightness of the image. This process includes adjusting the dynamic range and remapping the intensity of each partition. The final stage is brightness normalization to ensure the average brightness of the output image remains consistent with the input, resulting in a sharper image with a more balanced intensity distribution. The overall stages of BPDFHE can be seen in Fig. 3.

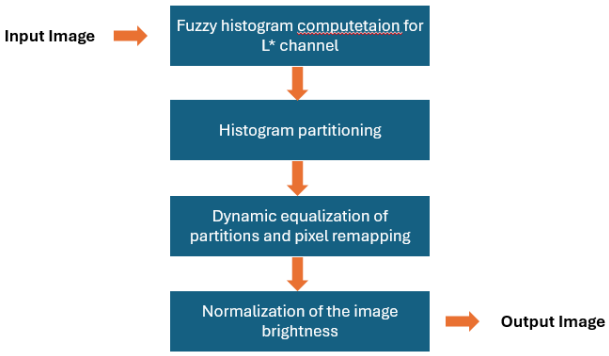

Fig. 3. BPDFHE process.

This technique effectively addresses the challenge of enhancing low-contrast images and optimizing the visual perception of details across different image regions. By carefully controlling the equalization process at the sub-histogram level, BPDFHE preserves the integrity of image information, minimizing the risk of over-enhancement or artifacts that may occur with other conventional techniques.

D. CLAHE

CLAHE is an adaptive method of *histogram equalization* followed by *thresholding* to aid in the dynamics of preservation of local contrast features of an image [37]. First, the *input* image is partitioned into several sub-images sized M × N. Then, calculate the histogram for each sub-image. Next control the contrast of the histogram with clips for each sub-image. The number of pixels present in the sub-image is distributed at each degree of grayness. Then calculate the *clip* limit from the histogram. On the original histogram, pixels will be limited if the number of pixels is greater than N_{CLIP}. The number of pixels is evenly distributed into each degree of grayness (N_d) defined by the total number of pixels constrained (N_{TC}) [37].

E. Data

This study uses secondary data from a melon leaf image from previous studies taken in 2022 [36]. The entire dataset consists of 522 images, which have been labeled and processed in TXT format. Each image has a resolution of 5 megapixels, with width and height of 2592 and 1944 pixels, respectively. The labels are divided into two classes: Abnormal and Normal. Fig. 4 shows a sample image for each class.

F. Data Preparation

This research contributes to the data preparation stage. Data preparation is a heavy challenge in deep learning technology to produce an optimal model so it can be used properly [38]. For that, the data that has been obtained needs to be well prepared. The data that has been acquired is then prepared further by preprocessing and augmentation.

Fig. 4. Sample data for abnormal (yellow bounding box) and normal (green bounding box).

The leaf image is an image that exists in a natural environment with a lot of background and noise. The usual use of histogram equalization cannot address the problem, so it requires a method that can adaptatively equalize the histogram and can also be applied to colored images that have a high background complexity. These methods include AVGHEQ (Averaging Histogram Equalization), CLAHE (Contrast Limited Adaptive Histogram equalization) [28], and BPDFHE (Brightness Preserving Dynamic Fuzzy Histogram Equalization) [29].

Augmentation based on geometry is rotation and shearing. Meanwhile, non-geometric augmentation is flipping. The training data was augmented using Python programming language on the server development environment of the IPB Computer Science study program.

G. Cross-Validation

Cross-validation is a technique that aims to estimate the generalized performance of a deep learning model, avoiding overfitting and underfitting [39]. The cross-validation technique used is k-fold cross-validation. Cross-validations will be used on the training data with a set of $k = 5$. This means that the data will be divided into five equal parts. The model will then be trained in four parts, called training data, and evaluated in the fifth part, called validation data. This process is repeated five times, and the average result is used to estimate the model's performance.

H. Modeling

This study uses the YOLOv7 nano training method. The object detection modeling process is carried out in three distinct phases, each producing different models based on a specific training strategy. In the first phase, a model is trained using the default hyperparameter configuration of YOLOv7 on the complete dataset. In the second phase, a new model is developed by performing hyperparameter tuning, as listed in Table II, using the best-performing image preprocessing technique identified for the corresponding dataset. In the third phase, the model is trained using the best-tuned hyperparameters, but this time with the original default hyperparameter file configuration of YOLOv7. This last modelling phase is conducted under two training scenarios: early stopping with a patience of 300 and full training for all epochs. As in the second phase, the best image preprocessing technique for each dataset is applied.

TABLE II. PARAMETERS ON MODELING STEP

Parameter		Value
Default hyperparameters		
Batch size		8
Epoch		5000
Image size		640 × 640 piksel

I. Model Evaluation

The three object detection models produced at each training phase will be evaluated using a set of standard performance metrics to determine the most effective model. These metrics include Mean Average Precision (mAP), Intersection over Union (IoU), accuracy, precision, recall, and F1 score. In addition, detection time and training time are also considered in the evaluation process.

Mean Average Precision (mAP) assesses how well a model can predict accurate bounding boxes across all object classes in an image or video. mAP values range from 0 to 1, where higher values indicate better detection performance [40]. mAP is calculated by averaging the Average Precision (AP) across all

classes, where AP is derived from the precision-recall curve for each class [19]. High AP scores are achieved when both precision and recall are high across various confidence thresholds [41].

The Intersection over Union (IoU) metric measures the overlap between the predicted bounding box and the ground truth bounding box, divided by the area of their union. A higher IoU indicates a better match between the predicted and actual object locations [40].

The mathematical formulations for mAP, AP, and IoU are provided in Eq. (1), (2), and (3), respectively. Meanwhile, accuracy, precision, recall, and F1 score are defined using Eq. (4) through (7) [42].

$$mAP = \frac{1}{K} \sum_{i=1}^{K} AP(i) \quad (1)$$

where, K is the number of classes, AP is the Average Precision, and i is the index for the class.

$$AP(i) = \int_{r=0}^{1} p(r)dr \quad (2)$$

where, r is Recall and p is Precision

$$IoU = \frac{area(B_p \cap B_{gt})}{area(B_p \cup B_{gt})} \quad (3)$$

where, B_p represents the bounding box on predicted area and B_{gt} represents the bounding box on ground truth area.

$$acc(i) = \frac{TP(i)+TN(i)}{TP(i)+FP(i)+TN(i)+TN(i)} \quad (4)$$

$$p(i) = \frac{TP(i)}{TP(i)+FP(i)} \quad (5)$$

$$r(i) = \frac{TP(i)}{TP(i)+FN(i)} \quad (6)$$

$$F1\_Score(i) = 2 \times \frac{p \times r}{p+r} \quad (7)$$

where, i is index for class, TP is True Positive, TN is True Negative, FP is False Positive, FN is False Negative, *acc* is Accuracy, r is Recall, and p is Precision.

IV. Results and Analysis

This section presents the experimental setup, followed by the training results and evaluation of the obtained YOLOv7 models.

A. Data Preparation Results

This research utilizes secondary data obtained from the study in [36]. Further details regarding the dataset are provided in the Data section. Data preparation was carried out through a combination of augmentation techniques and histogram-based image preprocessing. The augmentation techniques applied are listed in Table III. Table IV presents the results of the data augmentation process. To increase the quantity of training data, the original dataset was augmented threefold, resulting in a total of 1,176 training images and 130 test images. The number of objects per class in the training data also increased while maintaining a balanced class distribution.

TABLE III. Augmentation Techniques

No	Technique	Value
1	*Flipping*	Horizontal and Vertical
2	*Rotation*	-15° and +15°
3	*Shearing*	±15° Horizontal and ±15° Vertical

TABLE IV. Augmentation Results

Data Type	Total Data	Total Objects
Train data	1176	6,943 (abnormal), 6,450 (normal)
Test data	130	941 (abnormal), 549 (normal)

Histogram-based image processing techniques–AVGHEQ, BPDFHE, and CLAHE–are applied to the training data. These techniques do not alter the image classes but only modify the histogram distribution of the images. The resulting changes are illustrated in Fig. 5 and summarized in Table V. Based on the results, several observations can be made. First, although BPDFHE does not appear to significantly alter image contrast visually, the channel-wise histogram values indicate an enhancement. Second, AVGHEQ noticeably improves color contrast, as supported by the quantitative data in Table V. Third, visually, CLAHE effectively reduces image noise, resulting in sharper images. Although the enhancement is not substantial, this augmentation technique leads to a modest improvement in the image histogram.

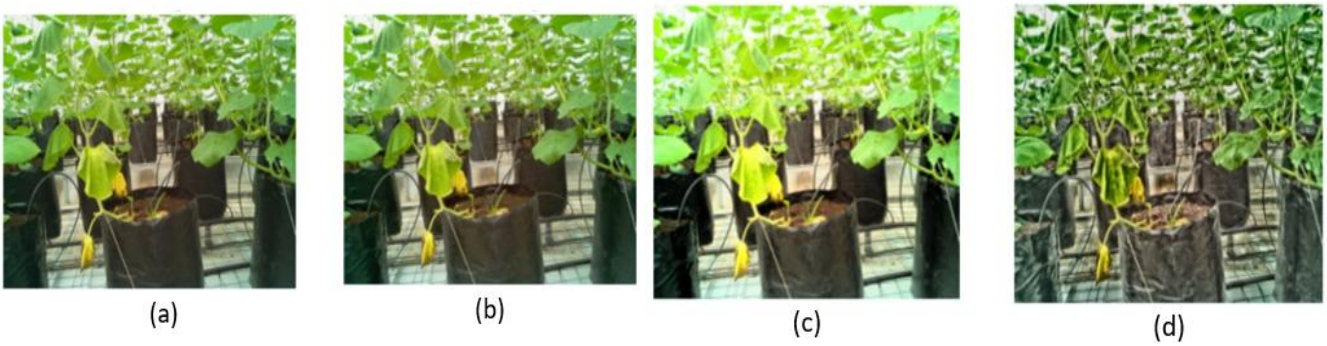

Fig. 5. (a) Comparison of the original image, (b) BPDFHE, (c) AVGHEQ, and (d) CLAHE.

TABLE V. DESCRIPTIVE ANALYSIS OF HISTOGRAM ON ALL DATASETS

Dataset	Mean (R)	Std Dev (R)	Mean (G)	Std Dev (G)	Mean (B)	Std Dev (B)
Original	96.20	51.1	120.30	54.56	77.20	59.08
BPDFHE	100.8	55.06	129.40	58.04	80.57	62.40
AVGHEQ	125.44	71.38	155.44	80.53	100.50	76.42
CLAHE	101.92	59.34	125.85	59.99	85.28	62.73

B. Cross-Validation Results

Each dataset generated through the cross-validation process is divided into training and validation sets. Fig. 6 illustrates the data distribution for each fold based on the original dataset. On average, each training set contains approximately 375 images, while each validation set contains about 94 images. In terms of object instances, the training data includes an average of 2,362 abnormal objects and 1,882 normal objects per fold. Meanwhile, the validation data includes an average of 590 abnormal objects and 471 normal objects per fold.

Fig. 7 illustrates the data distribution for each fold in the preprocessed dataset. On average, each training set contains 941 images, while each validation set includes 235 images. Regarding object instances, the training data contains an average of 5,554 abnormal objects and 5,160 normal objects per fold. In the validation data, the average is 1,389 abnormal objects and 1,291 normal objects per fold.

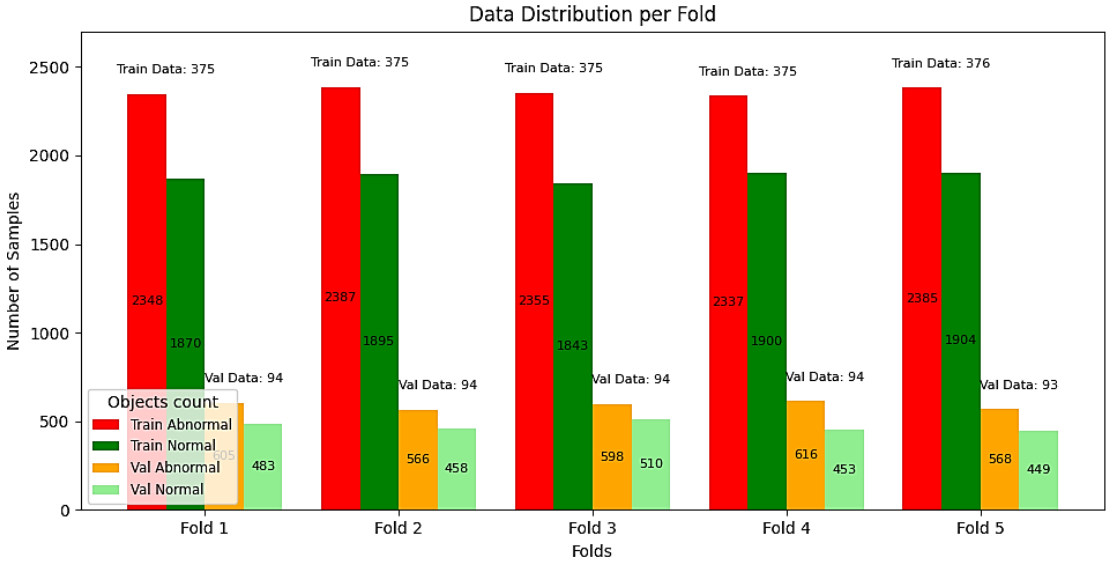

Fig. 6. Cross-validation result on original data.

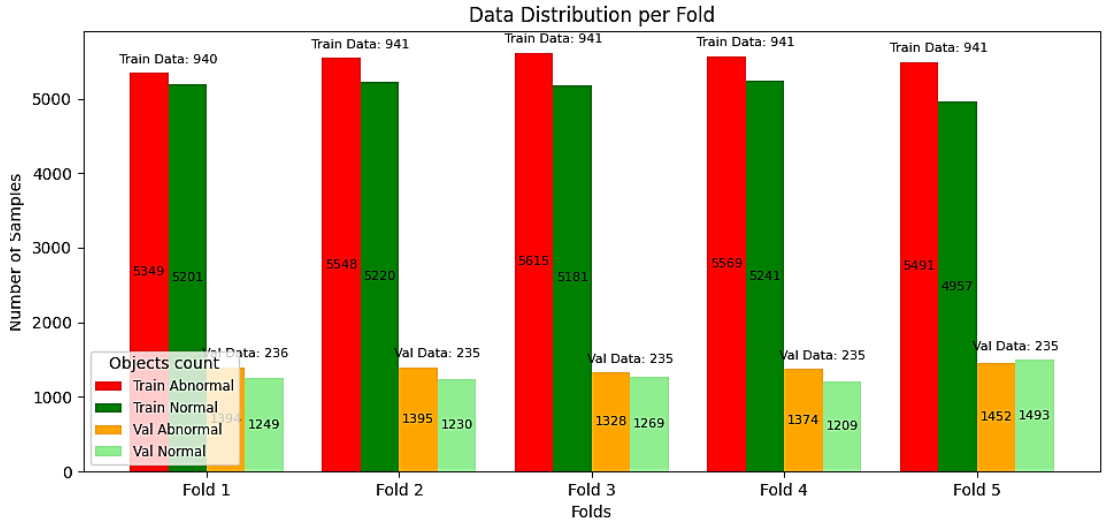

Fig. 7. Cross-validation result on preprocessed data.

C. Modelling Results

The object detection modeling process produced results related to model size and training time. In the first modelling phase (model 1), only the model size was recorded. In contrast, the second and third modelling phases (model 2 and model 3), both model size and training time were recorded.

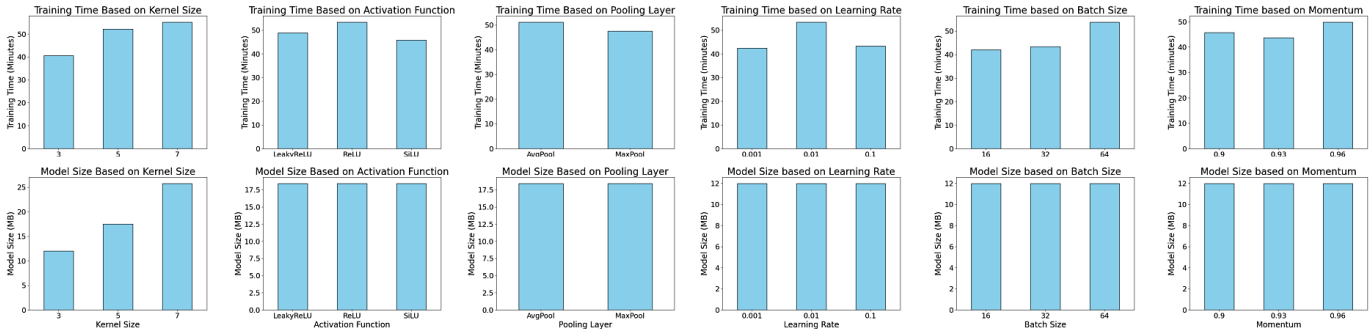
1) First phase modelling: Table VI shows that the use of augmented datasets yields the highest average mAP value of 72.80%, indicating a substantial improvement in model performance. The original dataset also performs reasonably well, achieving an mAP of 55.30%. In comparison, histogram-based preprocessing techniques such as BPDFHE, AVGHEQ, and CLAHE result in similar mAP scores, ranging from 52.89% to 54.44%. While these techniques offer slight improvements over the original dataset, their performance remains lower than that achieved with data augmentation. Notably, the average model size remains consistent across all preprocessing methods, ranging from 11.98 MB to 11.99 MB.

TABLE VI. COMPARISON OF MODEL TRAINING PERFORMANCE RESULTS IN STAGE 1

Num	Model	Average model Size (MB)	Average mAP (%)
1	Using original dataset	11.99	55.30
2	Using augmented dataset	11.99	72.80
3	Using BPDFHE dataset	11.98	52.89
4	Using AVGHEQ dataset	11.98	54.44
5	Using CLAHE dataset	11.98	53.70

2) Second phase modelling: Fig. 8(a) demonstrates that each hyperparameter value influences both the model's training time and size. Among the parameters, kernel size has the most significant impact—larger kernel sizes lead to increased training time and larger model sizes. Additionally, the ReLU activation function results in the longest training time compared to the other activation functions tested. Similarly, average pooling leads to longer training times than max pooling. However, activation functions and pooling types have a relatively minor impact on overall training time and model size. Models trained with image preprocessing techniques tend to produce slightly smaller model sizes, though the difference is not substantial.

Fig. 8(b) indicates that while hyperparameter values considerably affect training time, they do not influence model size. A learning rate of 0.01 results in the longest training time compared to other values. Likewise, a batch size of 64 leads to the longest training time, suggesting that larger batch sizes increase the computational load during training. Additionally, a momentum value of 0.96 yields the longest training time among the tested configurations.



(a) (b)

Fig. 8. Hyperparameter tuning training results on Stage 2.

3) Third phase modelling: Table VII presents the results of the third-stage modeling. The average training time for the model trained with the maximum number of epochs is approximately 20 hours. The model size remains constant at 12.3 MB for both training scenarios. As expected, increasing the number of epochs leads to longer training times; however, model size is influenced primarily by the input data and preprocessing methods rather than the number of epochs.

Notably, the model trained with early stopping using a patience of 300 epochs requires significantly less training time—only 1.8 hours—compared to the full 20 hours for the maximum epoch model. Despite the shorter training duration, the early-stopped model achieves a slightly higher average mAP of 53.37%, compared to 52.26% for the model trained for the maximum number of epochs.

TABLE VII. COMPARISON OF MODEL TRAINING PERFORMANCE RESULTS IN STAGE 3

Num	Model	Training Time (Hours)	Model Size (MB)	Average mAP (%)
1	Maximum *Epoch*	20	12.3	52.26
2	Patience 300	1.8	12.3	53.37

D. Evaluation

1) First phase modelling: Based on the evaluation results presented in Table VIII, the AVGHEQ model demonstrates consistent performance across mAP values, accuracy, and detection time, as indicated by its relatively low standard deviations. This consistency suggests that AVGHEQ is a stable and reliable choice compared to the other models. Conversely, while the BPDFHE models achieve the highest mAP, their accuracy and detection time exhibit greater variability and tend to be lower. The original model, on the other hand, achieves the highest accuracy but requires a longer detection time, which may be a critical factor for applications that prioritize rapid detection response. Therefore, selecting the optimal model requires balancing accuracy, stability of performance, and detection speed, depending on the specific needs of the application.

The model trained with the augmented dataset appears to suffer from overfitting, as evidenced by the average mAP on evaluation data (58.6%) being notably lower than the training mAP (72.80%). This overfitting likely results from the model becoming overly specialized to specific variations present in the augmented training data. Consequently, its performance may degrade when exposed to real-world data with broader variations. Additionally, since YOLOv7 itself incorporates augmentation during training, excessive augmentation in the dataset may reduce the model's adaptability to unseen variations. Despite this, the overall model performance remains acceptable, as the mAP on evaluation data is still reasonably high, though lower than the training results.

TABLE VIII. EVALUATION RESUTLS OF FIRST STAGE MODELLING

Model	mAP (%)		Accuracy (%)		Detection Time (ms)	
	Average	Rank	Average	Rank	Average	Rank
Original model	63.5 ± 1.3	2	84.9 ± 1.4	1	20.0 ± 7.3	5
Augmented model	58.6 ± 1.3	5	82.6 ± 2.1	3	9.8 ± 5.0	1
AVGHEQ model	**63.2 ± 2.4**	**3**	**83.1 ± 1.9**	**2**	**18.6 ± 8.4**	**3**
BPDFHE model	66.3 ± 1.2	1	82.6 ± 3.0	4	18.9 ± 12.2	4
CLAHE model	58.7 ± 3.1	4	80.7 ± 2.4	5	17.7 ± 11.0	2

2) Second phase modelling: After identifying the best preprocessing model, hyperparameter tuning was conducted using the AVGHEQ dataset. All augmentation processes in the default YOLOv7 configuration were disabled by setting the corresponding attributes to zero. To assess the significance of the hyperparameters on model performance, ANOVA analysis was initially performed [43]. Furthermore, MANOVA was employed to examine the simultaneous effects of multiple hyperparameters on the model performance metrics.

Table IX presents the results of the MANOVA analysis using Wilks' lambda criterion. The kernel size and learning rate hyperparameters yielded p-values less than 0.05, indicating statistically significant effects on model performance. In other words, these factors produce significantly different outcomes in the hyperparameter tuning process, allowing us to reject the null hypothesis (H_0). Conversely, the activation function, pooling layer, batch size, and momentum hyperparameters yielded p-values greater than 0.05, suggesting that their variations do not have a statistically significant impact on model performance. Thus, for these hyperparameters, the null hypothesis cannot be rejected.

TABLE IX. MANOVA TEST TO EXAMINE THE EFFECT OF EACH HYPERPARAMETER

Hyperparameter	Value	Num DF	Den DF	F Value	Pr > F
Kernel Size	**0.0137**	**8**	**24**	**22.6388**	**0.0000**
Activation Function	0.4487	8	24	1.4784	0.2168
Pooling Layer	0.8566	4	13	0.5442	0.7063
Learning Rate	**0.1487**	**8**	**42**	**8.3633**	**0.0000**
Batch Size	0.5913	8	42	1.5775	0.1608
Momentum	0.7804	8	44	0.7139	0.6779

3) Third phase modelling: After determining the optimal values for each hyperparameter—kernel size of 3, SiLU activation function, MaxPooling layer, learning rate of 0.01, batch size of 32, and momentum of 0.93—these settings were applied in the third modeling phase. The evaluation results from this phase are summarized in Table X. According to the table, the model trained with the maximum number of epochs achieved the best mAP values and shortest detection time compared to the model trained with patience set to 300. This finding aligns with previous research [44], which demonstrated that increasing the number of epochs generally enhances the performance of deep learning models.

Conversely, the model using patience 300 showed better accuracy compared to the maximum epoch model, although the differences between the two models were marginal. Both models outperform those from earlier modeling stages in terms of mAP, accuracy, and detection time. Moreover, neither model shows signs of overfitting, as indicated by the evaluation mAP being higher than the training mAP [45].

TABLE X. EVALUATION RESULTS OF THIRD STAGE MODELLING

Model	mAP (%)		Accuracy (%)		Detection Time (ms)	
	Average	Rank	Average	Rank	Average	Rank
Maximum epoch	**84.12 ± 7.0**	**1**	**91.19 ± 1.2**	**2**	**4.55 ± 3.3**	**2**
Patience *300*	81.57 ± 4.1	2	92.23 ± 2.4	1	5.03 ± 3.9	1

E. Comparison Between Our Results and Previous Research

According to the results shown in Table X, which presents only the model trained with the maximum number of epochs, the proposed model outperforms previous approaches. For example, the Faster R-CNN model achieved an mAP of 48.85%, the SSD model reached 33.16%, and the improved YOLOv3 model only 16.56%, as illustrated in Fig. 9. While the histogram-based image processing method does not improve accuracy—likely because it converts images by focusing on specific blocks rather than the entire image—it does contribute to increased inference speed. Enhancing the original YOLOv7 architecture also plays a critical role in boosting detection performance.

These findings indicate that models initialized with augmented data generally perform better than those without augmentation. Additionally, increasing the number of training epochs improves model robustness and yields the best detection results. Ultimately, an effective network balances having a relatively low number of parameters while efficiently extracting object features, thereby improving accuracy and inference speed simultaneously.

Furthermore, these results emphasize the importance of optimizing both the network architecture and the training strategy to achieve superior object detection performance. Although challenging, future improvements may involve fine-tuning the number of training epochs and applying targeted data augmentation techniques. Such enhancements will strengthen real-time inference capabilities and pave the way for further advances in model architectures and optimization strategies within deep learning.

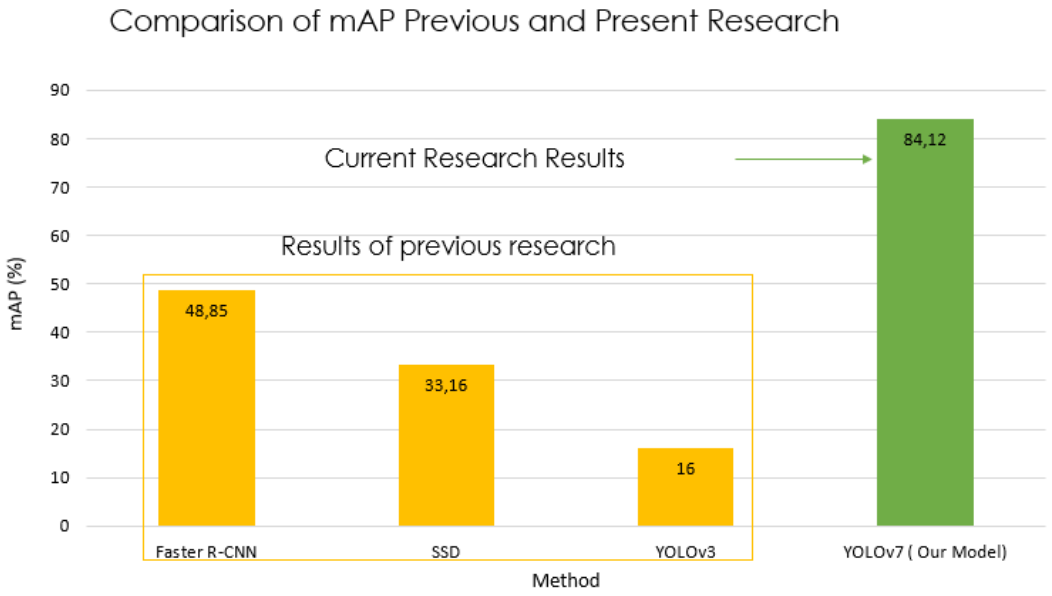


Fig. 9. mAP comparation between previous and our research.

V. CONCLUSION

This study analyzed a model for detecting deviations in melon leaf objects using several datasets: the original dataset, augmented datasets, and datasets preprocessed with AVGHEQ, BPDFHE, and CLAHE techniques. The analysis showed that the model's average mAP ranged from 58.6% to 66.3%, accuracy ranged from 80.7% to 84.9%, and detection time varied between 9.8 and 20 milliseconds. Image preprocessing improved the original model's performance in terms of mAP (particularly with BPDFHE) and detection time (across all preprocessing methods), but did not enhance accuracy. The BPDFHE model achieved the highest mAP value of 84.9%, while the fastest detection time of 9.4 milliseconds was observed with the model trained on augmented datasets. Overall, models trained on AVGHEQ-preprocessed datasets showed more balanced and stable results across all three variables—mAP (63.2%), accuracy (83.1%), and detection time (18.6 milliseconds)—compared to other models that performed well in only one or two metrics.

Hyperparameter tuning with the AVGHEQ dataset using the YOLOv7 algorithm revealed that kernel size and learning rate significantly impacted model performance. Specifically, a kernel size of 3 outperformed sizes 5 and 7, and a learning rate of 0.001 was superior to 0.1 and 0.01. Other hyperparameters, including activation functions, pooling layers, batch sizes, and momentum, showed no statistically significant effect on performance.

The best-performing models were obtained using the maximum number of training epochs combined with YOLOv7's default augmentation. Increasing the number of epochs contributed to more robust models and improved detection performance. However, excessive augmentation can potentially distort or obscure the original data patterns, making it harder for the model to generalize effectively.

Based on these findings, two recommendations are proposed for future research: first, to improve model accuracy by customizing network architectures, exploring more diverse preprocessing techniques, and expanding the hyperparameter tuning range; and second, to carefully balance augmentation to preserve critical data features. The model trained with maximum epochs achieved an average mAP of 84.12%, accuracy of 91.19%, and detection time of 4.55 milliseconds. In comparison, the model trained with patience set to 300 epochs achieved an average mAP of 81.57%, accuracy of 92.23%, and detection time of 5.03 milliseconds. These results suggest that increasing the number of epochs enhances model robustness and overall performance.

ACKNOWLEDGMENT

The computation in this study were conducted using the HPC facilities of Computer Science Study Program, School of Data Science, Mathematics and Informatics, IPB University. The dataset used in this research was obtained from [36], acquired from the IoT for Smart Urban Farming Laboratory (iSurf Lab), School of Data Science, Mathematics and Informatics, IPB University, and Agribusiness and Technology Park (ATP), IPB University.

Remote Monitoring and Management System for Oil and Gas Facilities with Integrated IoT and Artificial Intelligence Data Analysis

Shu Haowen, Zhang Bin, Gao Shiyu, Gu Li, Jia Yanjie
PipeChina Southwest Pipeline Company, Chengdu 610036, China

***Abstract*—An important trend in the development of digitalization is the expansion from digitalization to intelligence. For the intelligence of oil and gas facilities, it is to apply the multi-intelligent judgment and analysis technology to the actual production of oil and gas facilities, so as to realize the real-time data acquisition, analysis and "monitoring tube" integration of remote oil and gas facilities. As a flexible monitoring configuration software, force control provides a good development interface and a simple engineering implementation method under the trend of intelligent oil and gas facilities, which can facilitate users to realize and complete the functions of the monitoring layer. Its humanized application, such as trend curve, report output, limit alarm and other system functions, can also be more intuitive for users to monitor and process control on-site production data, and provide strong technical support for the intelligent process of oil and gas facilities. Based on this, this paper studies the design of remote monitoring and management system of oil and gas station by integrating the Internet of Things, artificial intelligence and big data analysis technology.**

***Keywords*—Internet of Things; artificial intelligence; data analytics; remote monitoring; management system**

I. Introduction

In the harsh environment of the work site, snow, fog, wind and sand and other natural phenomena are very common, the temperature fluctuation is large. Moreover, the oil and gas station is generally located in a remote open area, with a wide coverage of the whole area, and the distribution of each oil and gas facility in the operation area is relatively dispersed. With the changing needs of collection progress, oil production points can be added or removed at any time [1]. As a key link in the intelligent process of oil and gas facilities, coupled with the prevention and control of unsafe factors, real-time monitoring of all facilities information 24 hours a day has become an essential security work.

In terms of remote monitoring of oil and gas facilities, Eden et al. (2005) studied an electrochemical sensor used for corrosion monitoring in harsh environments. Zheng (2009) used an online monitoring probe to conduct online monitoring of the three top positions of a distillation unit in a refinery. After a period of time, it was found that the monitoring results were basically consistent with the analysis results of the three top condensate water, indicating that the use of an online monitoring probe is an effective means of corrosion monitoring. Payne (2012) designed an oil and gas recovery detection instrument, which made up for the shortcomings of the previous oil and gas recovery detection system [2]. It proposed that the collected value could be compared with the standard value through the pressure sensor and digital processor, and the detection device could realize the automatic detection of the oil and gas recovery system, but it could not store the relevant data. Li (2019) developed a PLC-based oil and gas recovery device, which used PLC to control the field equipment, realized the monitoring of the oil and gas recovery process through configuration software, and designed and realized the functions of liquid level balance and real-time operation of the oil and gas recovery device.

In the use of the Internet of Things and artificial intelligence for remote monitoring research of oil and gas facilities, China Petroleum and Chemical Corporation proposed the concept of intelligent oil field in the early 21st century. Through relevant communication and transmission, all links are integrated together, so that the staff can monitor, adjust, command and control the entire production process of the oilfield through the dispatching system in the background laboratory. CNPC has developed a set of monitoring system in the general dispatching center, on which an information base and data analysis platform containing parameters of each major oil field are built, which can carry out remote real-time monitoring of the oil well platform of each major oil field in China. The "Drilling 3D development platform", developed by leading foreign oil companies, is known as the visual virtual operating system [3]. The application of this operating platform can see the operating status of each development link in the drilling process and obtain relevant data, which is convenient for operators to be able to exchange information and communicate with experts in the remote background, and issue instructions in time according to the adjustment strategy, so that the drill can quickly locate and track according to the real-time status, and determine the drilling target in time. Greatly reduce the working time, improve work efficiency, and maximize the reduction of work costs.

Chauhan's work demonstrated the effectivenes of MQTT, OPTICS clustering, and spiking neural networks within a mist computing framework that enhance real-time IoT data analytics. In a similar vein, we apply these advanced data processing and edge computing techniques in our proposed work to analyze sensor data from oil and gas facilities that enable prompt detection of anomalies and efficient management through integrated AI-driven insights [4]. Our proposed remote monitoring and management system adopts a distributed edge, fog, and cloud computing framework emphasized by Yalla et al, (2022), enabling efficient and scalable IoT data processing for real-time analytics in oil and gas facilities [5]. Swapna Narla (2025) proposed secure and scalable anomaly detection using Hidden

Markov Models, SMPC, and decentralized federated learning in cloud environments. We adopt their privacy-preserving and distributed learning framework to detect anomalies in IoT data from oil and gas facilities. This ensures secure, real-time fault detection while maintaining data confidentiality across remote monitoring systems [6]. On the whole, although many companies have realized local remote information monitoring and data collection functions of oil and gas facilities, and can analyze, integrate and save on-site data [7]. However, the integration of on-site and backstage technical support of oil and gas facilities is still not high, and the field application needs to be further improved. Based on this, this paper studies the remote monitoring system of oil and gas station by integrating the Internet of Things and artificial intelligence technology.

The research organization and innovation points of this paper are as follows: based on the force control configuration software, the development of each functional module of the oil pump production monitoring system software is completed, so that it has the functions of data collection and management, data analysis and diagnosis, alarm processing and so on. The article first for the force control configuration software is briefly introduced, and then combined with the monitoring system design requirements, gives the overall design scheme, on the basis of the design and implementation of each functional module were elaborated, and finally through the test analysis, verify the practicality of the monitoring system.

II. Force Control Configuration Software

Force control software is a kind of configuration software that can realize the information acquisition and related program control in the production site. The way it uses is not the traditional way of programming, but a way of configuration construction[8]. This method is favored by many users because it can provide a simple interactive interface for developers and related users, as well as an intuitive system building platform. Force control configuration software can carry out real-time transmission and communication of major factory information through the network. This configuration software can combine the client machine and the Internet to realize the overall control and scheduling of the system. In addition, the software can directly realize the information interaction of all levels and the establishment of transmission interface, so as to integrate between the upper computer and the lower computer.

The main components of the force control configuration software are described below:

- Project Manager is applied in each management link, executing functions such as establishment, replication, homing, elimination and project setting.
- It is an integrated System to develop System, establish system interface, and build and deploy parameters, graphics and accessory programs of each link.
- Interface Operation System, responsible for operating the graphics built by the project, running scripts and related dynamic graphics.
- Real-time Database, which is the information analysis platform of the whole system of configuration software, is also the foundation of the distributed control system.
- I/O Driver: performs data communication between external hardware facilities and related control systems, and can read and write information in memory.
- Net Client/Net Server, communication between different links on the data chain through the network.
- Communication Server, remote data communication platform through a variety of data transmission methods to achieve client information interaction, using the specified communication interface to achieve the specified client data transmission.

III. The Overall Scheme of Remote Monitoring System for Oil Pump Production

A. Demand Analysis

Based on the real-time monitoring of the dynamic parameters of oil and gas station production, with the goal of improving the efficiency of the whole operation, a production monitoring system of oil and gas station based on force control configuration is researched and developed by using the advantages of force control configuration software.

The parameters that the system needs to monitor in real time are: oil pressure, electrical parameters (current, voltage, active power, reactive power), indicator diagram (displacement, load) and other indicators.

The system needs to calculate and analyze the optimized control parameters are: the working condition of the tank, the best stroke, the target frequency and the balance and other indicators.

The parameters that the system needs to optimize control are: the stroke of the oil tank, the speed of the motor and other indicators.

B. Design Scheme

Based on the full investigation of domestic and foreign oil and gas station monitoring system, combined with the specific needs of users to build intelligent oil and gas station, it is clear that the monitoring system should achieve data collection and management, data analysis and diagnosis, alarm and processing and other functions [9]. In terms of technical design, first of all, it is necessary to monitor the operation status of each key module of the system, involving the process monitoring of the data synchronization software of the field operation, and solve the technical problems of the communication between the field production and the system; Secondly, it is necessary to realize intuitive and friendly monitoring and display diagram, to solve the technical problems of data visualization and chart display, and to realize the conversion of the data format of the configuration software and the information reflected in the indicator diagram; Need to be able to be monitored according to the abnormal state of the scene, so as to design different alarm levels, and to solve the technical problems such as the transmission mode and transmission time of the warning. This paper selects the force control monitoring configuration software, using the advantages of flexible and diverse "configuration mode" provided by the configuration software, to establish a three-layer oil pump production monitoring system

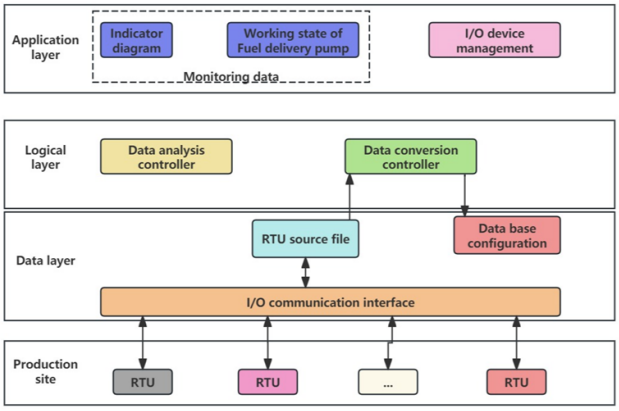

Fig. 1. Frame of production monitoring system for oil pump.

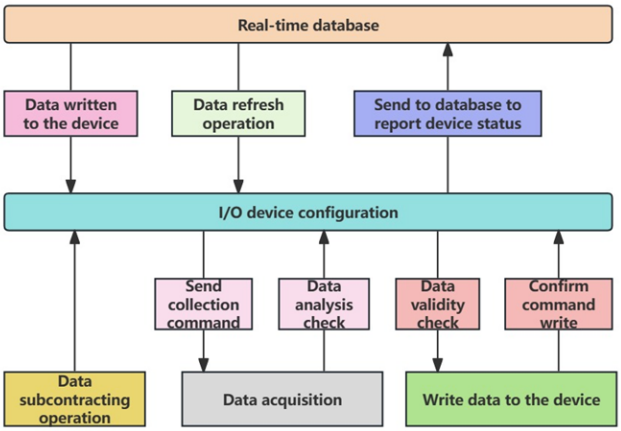

Fig. 2. I/O Device configuration data flow.

software framework, including application layer, logic layer and data layer. The system framework is shown in Fig. 1 below.

The application layer provides a human-machine interface for the user and the system. The system can visually and friendly display the equipment working condition analysis and indicator diagram by means of visual graphics, and assist the user to judge the working condition of the oil pump. The system provides a management interface, and the user can realize the control and management of the number and state of the equipment through this system.

Logic layer provides control strategy generator through force control configuration software to realize data analysis and processing calculate the output of oil pump, query and analyze the historical work chart.

The data layer is responsible for storing and monitoring the data, which is collected by the RTU equipment distributed in the production site of the oil pump [10]. The RTU equipment returns the monitoring data to the RTU data source file through the I/O configuration communication interface provided by the force control configuration software. The RTU source data is processed by the data conversion controller of the control layer and stored in the configuration database.

IV. Function Module Design and Implementation

A. I/O Equipment Configuration Design

I/O device configuration is the bridge of communication between the force control configuration software and various intelligent devices, the main role is to send data commands to the specified device, the device responds back to the data back to the configuration to unpack the data, and data classification, and finally separate the required data type. The data flow of I/O device configuration is shown in Fig. 2.

I/O device configuration is how you configure the I/O driver. First of all, in order to meet the specific needs of practical applications, I/O device configuration can select the matching I/O driver for the specified I/O device; Secondly, the configuration will carry out the corresponding parameter setting and physical definition of the I/O device to ensure the operability of the device; Finally, the I/O configuration will debug and test the equipment to check whether the equipment is correctly set to adapt to the actual production. The I/O configuration of the system can complete the functions of: through the collection of data for link maintenance, real-time link database, I/O command management output queue. It can be seen that the I/O device configuration can view the driver process status in real time and browse the driver communication messages, and can also complete the remote start and stop control of the I/O driver and other functions, and is a tool to monitor the operation of the I/O driver.

B. Database Configuration Design

Db Manager is the main tool of database configuration. As a collection toolbox of configuration, it can complete many configuration functions such as point configuration, point parameter configuration, data connection configuration, historical data configuration, etc. In the database, the system stores all kinds of information in the unit of TAG, and organizes points in a tree structure. Multiple nodes can be built under the tree structure, and multiple sub-nodes can be built under each node, and multiple different types of points can be established under each node [11]. In this paper, the DbManager monitor is used to establish the database configuration, which corresponds to the A11 standard for the construction of the Internet of Things system in oil and gas production. Byte8-bit unsigned data format is selected through the HR hold register, and more than 180 data points such as storage addresses and acquisition addresses are established. Through the database configuration data points can establish the connection with the corresponding data items in RTU, and display the relevant data in real time. The sample information of the corresponding child node name in the data configuration is shown in Table I below.

C. Monitoring System Module Design

The monitoring system is divided into the following six functional modules: polling control module, data acquisition module, data management module, feedback control module, output module and alarm module. The six modules have a division of labor, and work together to complete the collection of data, processing data and output data functions. Its basic composition and function are shown in Fig. 3.

TABLE I. EXAMPLES OF DATA POINT NAMES

Numbering	NAME	DESC	%I/OLINK	%HIS
1	I_A		PV=RTU....	PV=1s
2	I_B		PV=RTU....	PV=1s
3	I_C		PV=RTU....	PV=1s
4	V_A		PV=RTU....	PV=1s
5	V_B		PV=RTU....	PV=1s
6	V_C		PV=RTU....	PV=1s
7	yougonggonghao		PV=RTU....	PV=1s
8	wugonggonghao		PV=RTU....	PV=1s
9	P_W		PV=RTU....	PV=1s
10	P_R		PV=RTU....	PV=1s
11	P_fanxiang		PV=RTU....	PV=1s

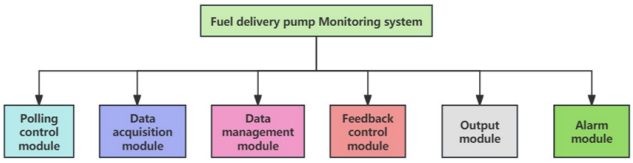

Fig. 3. Composition of monitoring system module of oil pump.

1) Polling control module: This module can detect online devices, implement polling device management, and configure multiple acquisition commands.Now the automatic input function of RTU and other equipment parameters is used to collect and control data. PING each IP to be connected before the polling check operation can reduce the error message interference caused by the network delay. As a communication protocol, the PING command can check whether the network is connected, which helps us analyze and determine whether there is a network fault [12]. After the PING command is used to determine whether the IP address is normal, the IP address that cannot be pinged can enter the polling program. The system records the IP address that cannot be pinged, and PING the IP address again after the network environment recovers. In this way, the target IP address is restored to the normal polling process and the next IP address polling is performed.

2) Data acquisition module: This module mainly realizes data monitoring functions such as automatic collection of operating parameters, automatic monitoring of production environment, automatic monitoring of IoT equipment status, automatic monitoring of production process and remote control of start-stop operation. Through the connection between the RTU equipment and the host computer and the feedback setting of the sampling frequency, the system can automatically collect different types of parameters, such as oil pressure, oil temperature, electrical parameters, load, displacement and stroke, which are closely related to each link of production.

The real-time data collected by the monitoring system are displayed on the monitoring screen in the way of numerical value or real-time curve display, and the information of any four different oil pump can be monitored at the same time on the main page interface, which is convenient to compare different working conditions. Users can read and print the values and real-time curves [13]. The relevant requirements for RTU data storage are specified in the manual of Construction Specification for Internet of Things System in Oil and Gas Production (QSY1722-2014). The relevant parameters of remote terminal unit system property data storage address and oil pump alarm function parameter control command storage address are shown in Table II and Table III below.

TABLE II. REMOTE TERMINAL UNIT SYSTEM PROPERTIES DATA STORE ADDRESS

No.	Data item Description	Storage address	Data type
1	Apply the type of oil and gas terminal	40001H	Integer type
2	System time	40005-40007.	BCD Code
3	System date	40008-40010.	BCD code
4	RAM battery voltage	40011	Whole shape
5	RTU cabinet temperature	40012	Integer shape

TABLE III. STORAGE ADDRESS OF OIL PUMP ALARM FUNCTION PARAMETER CONTROL INSTRUCTION

No.	Data item Description	Storage address	Data type
1	AI1 Instrument-shaped signal form	43001	Integer type
2	AI1 Meter range lower limit	43002-43003.	Solid type
3	AI1 meter range upper limit	43004-43005.	Solid type
4	AI1 Meter alarm Lower limit	43006-43007.	Solid type
5	AI1 meter alarm upper limit	43008-43009.	Solid type

3) Data management module: The function of data management module is mainly divided into data screening and data storage. Data screening is the index data management module through the induction and sorting of the original data to achieve the standardization and structure of the data, so as to get meaningful performance indicators that can be identified by users in the original data, and these effective performance indicators into the database that has been established [14]. Data warehousing means that after the data management module realizes the specific functions of viewing, deleting, modifying and statistical analysis of the management data, the establishment and storage of the real-time database can be completed.

The source data collected by RTU is processed by the control layer data conversion controller and stored in the configuration database. At present, the data that needs to be called by the user can be displayed in the front end of the upper computer in real time. The obtained data type is projected to the output module according to the user's command, and the specific data or report content is directly displayed. The data that does not need to be displayed in real time is stored in the database, waiting for the next command.

4) Feedback control module: The operation logic of feedback control module is mainly divided into three steps. The details are shown in Fig. 4 below.

a) Operation status judgment: First of all, the system will screen the data points collected by RTU, discard the data points with large errors, and then convert the reasonable

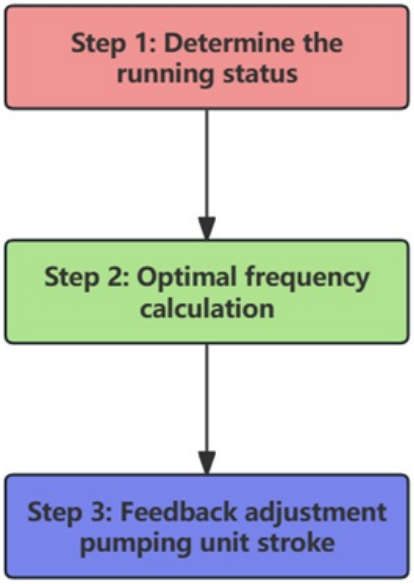

Fig. 4. Feedback control module Operation logic diagram.

data points after screening into the indicator diagram curve that can express the quantitative relationship between load and displacement [15]. The indicator diagram will transfer the relevant data to the pre-programmed Matlab platform for simulation and identification, through the shape, area and other information of the indicator diagram, with the help of the classification discriminator for logical verification, so as to show the corresponding working conditions and fault types reflected in the diagram, and further provide reference and judgment basis for adjusting the frequency and stroke of the oil pump.

b) Optimal frequency calculation: According to the electrical parameters, stroke, stroke and other information of the oil pump site, the quantitative relationship between the amount of liquid produced and the stroke and frequency can be calculated, and the frequency obtained through this quantitative relationship is the frequency corresponding to the maximum amount of liquid produced under a certain working condition, that is, the best frequency.

c) Feedback adjustment impulse times: After calculating the best stroke and the best frequency of the oil pump, combined with the fault type determined by the indicator diagram, the feedback control module can change the stroke of the oil pump by controlling the output frequency of the inverter, so that the oil pump works in an efficient state.

5) Output module: The output module can display the temperature, voltage, current, active/reactive power, power factor and other parameters of the oil pump in real time. The history record shows the data uploaded by a certain RTU in a certain period of time, and supports the export of text in Excel format [16]. At the same time, it supports the output of indicator diagram and fault identification function, and can edit and beautify the image.

6) Alarm module: Detect the electrical parameters and the temperature of the oil pump, set different alarm labels, and alarm is realized when the maximum range is exceeded. Set the specific alarm value, then the variable below the low value or higher than the high value will produce the alarm over the limit value. The monitoring software has a memory function, when there is an alarm or failure occurs, or when an accident occurs, there will be a detailed record in the "Event display bar" of the monitoring main interface. When a certain oil pump through the remote data monitoring alarm and other serious abnormal situation, you can remote stop the abnormal oil pump.

V. System Testing

Build a simulated test environment in the laboratory to check whether the functional modules of the developed intelligent monitoring system software for oil pump production meet the expected requirements, test the connection between the data acquisition and management modules and other modules, and focus on the test data management and the monitoring of the connection status of the oil field and the monitoring of the product receiving status.

A. Configuration of Network Environment

Set up the environment of IP polling mode, and test it in the designed system. At the same time, after connecting RTU to the computer, start to set the relevant operations of RTU configuration. Select the MODBUS(TCP) device with I/OManager monitor, debug the TCP standard serial port of MODBUS connecting RTU to the upper computer, and the RTU standard serial port of MODBUS connecting RTU to RTM, connect RTU to the external 5V power supply and then connect it to the computer [17]. At the same time, I/O Tester is used to monitor the connectivity status of RTU. The real RTU is shown in Fig. 5 below.

Fig. 5. RTU Physical map.

B. System Application Test

1) Data acquisition and storage: In the main interface of the system, the operation status of four different oil pump

can be displayed at the same time, which is convenient for customers to monitor the safety of operation at a glance. In addition, the buttons on the left side of the main interface correspond to different functions such as data collection and data query. The data acquisition module is shown in Fig. 6.

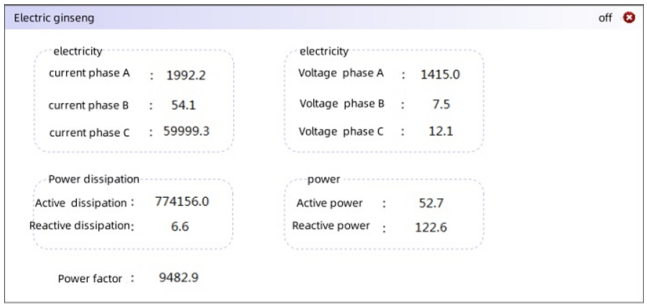

Fig. 6. Data acquisition module icon.

The system can display real-time data and historical data. The system can collect and store data such as three-phase current, three-phase voltage, reactive power and power factor by generating different types of random numbers (all data are random numbers generated by the system, one decimal point is reserved, and do not represent any actual meaning).

At the same time, the system can also display the data stored in a certain period of time in the past for the user to view [18]. History report as a collection of browsing, printing, statistics and other functions in one tool, can be used from the database historical data of one or more points, one time period or multiple time periods can be obtained by the setting of the user, and the data can be displayed visually in the form of a table and supported by output.

2) The Reading and processing of indicator diagram of production data: Manually set the measuring interval and number of points of indicator diagram collection point, and can directly generate real-time indicator diagram curve or indicator diagram curve of a certain period in history, as shown in Fig. 7. And through the connection with Matlab directly determine the type of fault, in order to carry out the next step of fault alarm and processing.

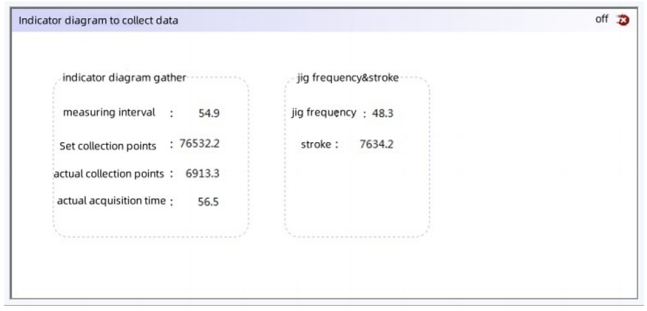

Fig. 7. Data acquisition output module icon.

VI. Conclusion

As a powerful integrated environment software, force control configuration software has a relatively mature configuration of various system parameters, create project screen, script compilation and animation Settings and other rich functions. Users can realize various monitoring requirements through it. Through the force control configuration software, various I/O devices and database components can be invoked to complete the reading, collection and management of production site data. In addition, using the various controls of the force control configuration software, you can fully call the related reports, functions and trend curves after editing the function. In this paper, the requirements of intelligent monitoring system for oil pump production are analyzed comprehensively and deeply, and the overall design of monitoring system software is completed. Then, based on the force control configuration software, the development of each functional module of the oil pump production monitoring system software is completed, and the data collection and management, data analysis and diagnosis, alarm processing and other functions are preliminarily equipped. Finally, the indoor test environment is built, and each function module is measured and tested, and the main functions are basically completed.

Due to the time limit, the intelligent monitoring system software of oil pump production developed in this paper has only completed the indoor coordination and testing, and has not been installed, debuted and run in the oil pump site, and the functions of the system can not be verified. The function of the system still needs to be checked, improved and perfected in the actual field.

***Abstract*—In the field of innovative design of Huizhou bamboo weaving patterns, traditional deep learning algorithms cannot fully capture the fine structure and subtle changes of patterns, resulting in distorted or blurred results, and require a lot of computing resources and time during the training process. This paper constructs an improved ViT (Vision Transformer) model to collect diverse Huizhou bamboo weaving pattern data covering different styles and forms. In the data enhancement stage, common enhancement techniques such as rotation, scaling, flipping, and color perturbation are used to increase the diversity of training data. Based on the traditional ViT model, a local self-attention mechanism is applied to replace the traditional global self-attention mechanism. Mixed precision training and distributed training strategies are used to effectively accelerate the training process while maintaining high accuracy. The model automatically generates innovative designs by learning the style and structural characteristics of Huizhou bamboo weaving patterns, and adds a detail repair module in the generation process to enhance the detail expression of the pattern. The experimental results show that the improved ViT model tends to 0.95 after 50 training rounds, indicating that it performs well in detail preservation and structural similarity; with a sample data volume of 5000, the training time of the improved ViT model is 47.4 seconds, and the GPU memory usage is 37.1GB, providing higher computing efficiency. The experimental results prove the effectiveness of this paper's research on the innovative design algorithm of Huizhou bamboo weaving patterns.**

***Keywords*—Deep learning; Huizhou bamboo weaving; bamboo weaving pattern; vision transformer; local self-attention mechanism**

I. INTRODUCTION

This template, modified in MS Word 2007 and saved as a "Word 97-2003 Document" for the PC, provides authors with most of the formatting specifications needed for preparing electronic versions of their papers. Huizhou bamboo weaving art, with its unique patterns and exquisite craftsmanship, occupies an important position in traditional Chinese crafts. As an important carrier of Huizhou culture, bamboo weaving patterns carry rich local characteristics and historical and cultural connotations [1-2]. With the diversification of modern design needs, how to realize the innovative design of Huizhou bamboo weaving patterns on the basis of inheriting traditional crafts has become an urgent issue to be solved. The advantages of deep learning technology in image generation and optimization provide new possibilities for innovation in this field.

In the design of Huizhou bamboo weaving patterns, the challenges faced by traditional methods have affected its innovation and development in modern applications. Traditional design methods mainly rely on manual creation. Designers need to conceive and arrange patterns based on experience and intuition. This old method can maintain the uniqueness of handicrafts, but it has limitations in design efficiency and diversity [3-4]. The manual design process is time-consuming and labor-intensive, and it is difficult to quickly respond to the market's demand for personalized and diversified patterns. Traditional design methods are difficult to adapt to modern consumers' high requirements for personalization and innovation [5-6]. Traditional computer-aided design (CAD) can improve design efficiency to a certain extent, but it has obvious shortcomings when dealing with the complex structure and details of Huizhou bamboo weaving patterns [7-8]. Traditional CAD systems rely more on the combination and transformation of geometric figures and cannot deeply capture the delicate changes and microstructures in the patterns. The designed patterns lack detail levels and cultural depth. This limitation makes the bamboo weaving patterns generated by traditional computer technology lack artistic quality and cultural transmission [9-10], and cannot truly show the unique charm of Huizhou bamboo weaving [11]. In recent years, deep learning technology has been applied to the field of image generation. The application of existing CNNs (Convolutional Neural Networks) and Transformer deep learning models in pattern design still faces some challenges [12-13]. In terms of the balance between detail expression and model training efficiency, traditional deep learning methods require a lot of computing resources and long training time, and their ability to process complex patterns is limited. In terms of the expression of pattern details, traditional deep learning methods cannot effectively process the complex features of bamboo weaving patterns that are highly dependent on local details, resulting in distortion or blurring of the generated patterns, making it difficult to achieve the ideal design effect [14]. How to improve design efficiency while ensuring the expression of design details has become a key issue in promoting the innovative design of Huizhou bamboo weaving patterns.

This paper constructs an improved ViT deep learning model to achieve innovative design of Huizhou bamboo weaving patterns. Traditional design methods can ensure the uniqueness of handicrafts, but have significant limitations in efficiency and innovation. This paper uses the ViT model to break through the bottleneck of traditional design methods and improve the automation, refinement, and innovation of Huizhou bamboo weaving pattern design. A diverse training dataset is constructed, covering Huizhou bamboo weaving patterns of different styles and forms, and data enhancement technology is

*Corresponding Author.

used to expand the diversity of training data. In view of the problem of detail loss that the traditional ViT model is prone to when processing complex patterns, a local self-attention mechanism is applied to optimize the global self-attention mechanism, enhance the ability to obtain local details, and ensure that the complex structure and delicate changes of bamboo weaving patterns can be precisely restored during the generation process. The study also focuses on solving the problem of training efficiency and adopting mixed precision training and distributed training strategies to improve the training speed and greatly reduce the demand for computing resources while ensuring model accuracy. The research goal is to realize an innovative design generation system that can automatically generate new patterns that conform to the artistic style of Huizhou bamboo weaving, and further enhance the artistic expression of the patterns through the detail repair module, providing a new solution for the modernization of traditional bamboo weaving crafts.

II. Related Work

The research on bamboo weaving pattern design has gradually attracted the attention of academia and industry. Many studies have used deep learning technology to optimize the design and generation of patterns. In view of the limitations of traditional generation methods, some studies are based on CNN [15-16] methods to capture the basic morphological characteristics of bamboo weaving patterns and generate corresponding designs. Rustandi D created an automatic recognition system for bamboo stems based on anatomical structure. The bamboo recognition algorithm was developed using macro images of cross-sectional bamboo stems, and CNN was used to identify bamboo species. The designed automatic recognition application had a high accuracy rate in detecting bamboo species [17]. However, CNN has difficulty maintaining the delicacy and clarity of the pattern when processing patterns with high detail complexity. To overcome this problem, some scholars have proposed using generative adversarial networks (GANs) for pattern design, which can effectively generate diverse patterns [18-19]. Kang X connected the deep convolutional neural network and the deep convolutional generative adversarial network. The deep convolutional neural network constructed a product image recognition model and enhanced the image recognition performance. The deep convolutional generative adversarial network learned intermediate features and automatically generated product shapes that resonated with customers' emotions, and finally generated bamboo furniture designs that met customers' emotional needs [20]. However, there is a certain degree of distortion or blur in the generated results, and the demand for computing resources during the training process is high. These studies provide innovative ideas for pattern generation, but there is still a problem of how to strike a balance between detail expression and generation efficiency, and they fail to fully utilize the advantages of modern ViT models in image processing.

Mohanarangan Veerappermal Devarajan (2022) proposed an improved Backpropagation neural network algorithm to optimize forecasting accuracy and training efficiency in intelligent cloud computing. We adopt their optimization strategies to enhance the learning performance of our deep learning model for recognizing and generating Huizhou bamboo weaving patterns which improves accuracy and faster convergence [21]. A cloud-based big data analytics framework using deconvolutional neural networks for detailed face recognition was developed to demonstrate the effectiveness of CNN architectures in extracting complex visual features, as presented by Swapna Narla (2022), we leverage this CNN-based approach to capture the intricate structural elements of bamboo weaving, enabling high-fidelity pattern recognition [22]. Venkata Surya Bhavana (2025) applied CNNs for automated skin cancer classification, highlighting CNN's ability to differentiate subtle texture variations in high-resolution images. Building on this foundation, their CNN techniques is used in our work to classify diverse weaving textures, preserving traditional aesthetic qualities while enabling innovative design variations. Our proposed study adopts the t-distributed stochastic neighbor embedding (t-SNE) and hierarchical clustering methods introduced by Rahul Jadon (2022) for enhanced machine learning pattern analysis through dimensionality reduction and clustering which supports for the systematic exploration [23-24]. Dinesh Kumar Reddy Basan (2024) presented a multi-scale fusion neural network for fault diagnosis in IoT systems, which effectively captures features across multiple granularities. Inspired by this, our method integrates multi-scale feature extraction to represent the hierarchical and multi-textured nature of Huizhou bamboo weaving, leading to more accurate feature representation [25].

In the field of image generation, the ViT model has become a research hotspot in recent years due to its strong feature extraction and long-distance dependency modeling capabilities. Compared with traditional convolutional neural networks, ViT can capture complex relationships and details in patterns in a larger range and shows unique advantages in image generation tasks [26-27]. Some studies have proposed image recognition models based on ViT, applied a global self-attention mechanism, and improved the model's understanding of global structure [28-29]. However, this may lead to poor processing results for pattern designs with rich details and frequent local changes. Drawing on existing methods, this paper proposes a new ViT model that integrates local self-attention and mixed precision training to effectively address the shortcomings of existing methods.

III. Methods

A. Data Collection and Enhancement

Diverse Huizhou bamboo weaving pattern data is collected, covering different styles and forms, to improve the model's generalization ability. In the data enhancement stage, common enhancement techniques such as rotation, scaling, flipping, and color perturbation are used to increase the diversity of training data and avoid overfitting.

1) Data collection: The data collection process focuses on bamboo weaving patterns covering various styles and forms to ensure that the improved ViT model can learn the diversity and complexity of Huizhou bamboo weaving patterns. The study collects a large number of handmade bamboo weaving patterns from multiple bamboo weaving craft museums and inheritors in the Huizhou area, including samples from different historical

periods and design styles. Using digital scanning and high-resolution photography technology, detailed image acquisition of each pattern is carried out to ensure that every detail and structure of the pattern is clearly displayed. In the process of constructing the dataset, attention is paid to maintaining the diversity of the data, including different types of bamboo weaving patterns from simple geometric forms to complex natural patterns. These samples not only cover basic morphological features but also include texture details, hierarchical structures between patterns, and color distribution, ensuring the comprehensiveness of the dataset for model training.

The study also captures bamboo weaving pattern images of similar styles and forms from multiple e-commerce platforms and design websites, and labels them to improve the diversity of the data. The diverse design backgrounds and styles of these images give the dataset a stronger generalization ability. The integration of multi-source datasets ensures that the model can extract effective features from diverse and highly variable pattern images, enhancing the model's adaptability to different design styles. The study also annotates and clarifies the artistic style, historical background, and specific region of each pattern, increasing auxiliary information in the model training process.

Table I lists the data collection of various styles and forms of Huizhou bamboo weaving patterns. The number of images and data sources under each style category are counted, covering a variety of designs such as traditional, modern, retro, natural, geometric, and animal. These data mainly come from multiple channels such as traditional craft museums, design platforms, and museums, ensuring the diversity and representativeness of the training data. These collected images provide a solid foundation for subsequent pattern generation and innovative design.

TABLE I. DATA COLLECTION STATISTICS

Category	Style/Form	Image Count	Data Source	Description
Traditional	Traditional Bamboo Weaving Patterns	500	Traditional Craft Museums, Folk Artists	Classic geometric patterns with fine details, representing centuries-old craftsmanship.
Modern	Creative Modern Bamboo Weaving Patterns	400	Design Platforms, E-commerce Websites	Simplified geometric shapes combined with modern elements for innovative expressions.
Retro	Vintage Bamboo Weaving Patterns	450	Museums, Handicraft Exhibitions	Rich in historical and traditional cultural flavor, representing ancient styles.
Nature	Nature-Inspired Bamboo Weaving Patterns	550	Bamboo Craft Museums, Nature Collections	Focuses on natural elements like plants and animals, emphasizing organic forms.
Geometric	Geometric Bamboo Weaving Patterns	350	Design Platforms, Craft Companies	Features regular geometric shapes and modern minimalist design.
Animal	Animal Motif Bamboo Weaving Patterns	300	Folk Artists, Bamboo Weaving Exhibitions	Animal-themed designs, with intricate details and lifelike representations.

2) Data enhancement: Data enhancement technology is used to expand the scale of the training dataset, increase its diversity, and avoid overfitting problems caused by insufficient samples. A series of enhancement methods such as rotation, scaling, flipping, and color perturbation are used. In the process of rotation enhancement, the original image is rotated at multiple angles to generate patterns in different directions, which increases the model's adaptability to directional changes. The image scaling method randomly changes the size of the pattern image, so that the pattern structure can be effectively recognized by the model at different scales. The use of image flipping operations can not only increase the diversity of the dataset, but also effectively avoid the model from over-relying on image features in a specific direction and improve the model's generalization ability for the performance of pattern structures in different directions. During the color perturbation process, the image is randomly adjusted in hue, saturation, and brightness, which not only enhances the visual diversity of the dataset but also simulates the possible changes in pattern color in actual applications. With these enhancement operations, the diversity of the dataset is greatly increased; overfitting caused by insufficient sample size is avoided; the robustness of the model is enhanced.

For the complexity of Huizhou bamboo weaving patterns, especially the details and texture parts, local cropping, and local enhancement techniques are used. Local cropping is to crop the pattern image in a small range to generate different local area images. This technology simulates the local feature variation in pattern design and ensures the retention and diversity of local details. Local enhancement performs a separate rotation, scaling, or color perturbation on each cropped area, so that each local area has independence and diversity in the pattern generation process, so that the local features of the bamboo weaving pattern can be effectively learned, especially those details that may be ignored in the full image mode. The data enhancement effect is shown in Fig. 1.

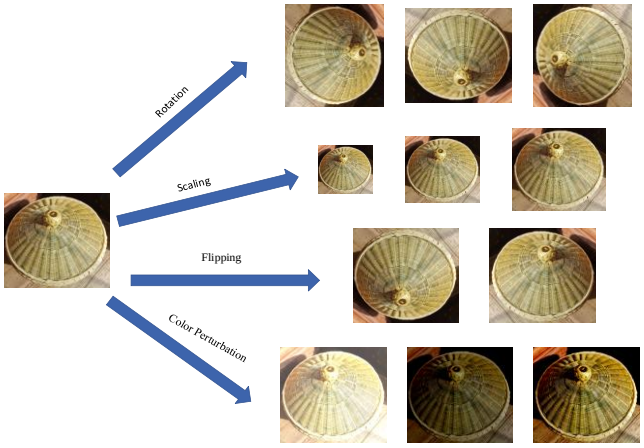

Fig. 1. Data enhancement effect.

B. Improved ViT Model Design

1) Application of local self-attention mechanism: In the traditional ViT model, the image is divided into blocks of fixed size. Each block is linearly embedded and then input into the self-attention mechanism for global calculation. This calculation model can capture the long-range dependencies in the image, but the accuracy of local detail processing is insufficient. In the Huizhou bamboo weaving pattern design with rich details and complex structure, subtle changes in the pattern may be lost. This study proposes an improved solution of the local self-attention mechanism to solve this problem. The local self-attention mechanism is applied to replace the global attention in the traditional ViT model with self-attention calculation in the local area, which can effectively enhance the ability to capture local pattern details. Unlike the global self-attention mechanism that calculates the entire image block, this method calculates in the local area, and each image block only establishes a connection with its neighboring image blocks. This method improves the accuracy of detail capture and reduces the computing complexity. The calculation formula of local self-attention is as follows:

$$\text{Attention}(Q,K,V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (1)$$

In the formula, d_k is the dimension of the key matrix, and QK^T represents the attention weight calculated by the similarity between the query and the key. The local self-attention mechanism limits the calculation scope, enhances the capture of the local structure of the pattern, and ensures the clear presentation of the details in the generated pattern.

TABLE II. HYPERPARAMETER SETTINGS OF THE LOCAL SELF-ATTENTION MECHANISM

Parameter	Value	Description	Unit
Local Block Size	16x16	Size of each block for local self-attention, controls the attention region	Pixel
Self-Attention Window Size	3x3	Size of the self-attention window, affects the precision of capturing local features	Image block
Number of Attention Heads	8	Number of attention heads in each self-attention layer, controls the model's learning ability	-
Local Region Coverage	40%	Proportion of the region focused on in each computation, controls computing complexity	Percentage

In Table II, the local block size determines the size of the image area that is focused on each time the calculation is performed. Smaller blocks can capture local features more finely, but increase the amount of calculation; larger blocks reduce the efficiency of calculation. The study sets it to 16x16 pixels to balance the efficiency of calculation and the ability to capture details. The self-attention window size is 3x3, which can help the model focus on capturing subtle local changes. The number of attention heads is set to eight, which can learn different local features in multiple subspaces and improve the expressiveness of the model. The local area coverage ratio is 40%. By limiting the area involved in each calculation, the consumption of computing resources can be effectively reduced; sufficient local information can be maintained; resource waste during the calculation of the global self-attention mechanism can be avoided.

2) Mixed precision training and distributed training strategy: In terms of improving training efficiency and reducing the consumption of computing resources, this paper adopts mixed precision training and distributed training strategies. The mixed precision training method combines 16-bit floating point and 32-bit floating point calculations to reduce the computing overhead while ensuring training accuracy. Mixed precision training adjusts the calculation accuracy of each layer in the model and selects appropriate numerical representation. When the weight update process uses 32-bit floating point numbers, forward propagation and back propagation use 16-bit floating point numbers, which reduces memory usage and speeds up the training process. By automatically optimizing numerical precision, mixed precision training reduces the demand for GPU (graphics processing unit) memory and avoids numerical instability problems. The loss calculation formula for mixed precision training is:

$$\mathcal{L}_{mixed} = \mathcal{L}_{float32} + \lambda \cdot \mathcal{L}_{float16} \quad (2)$$

In the formula, $\mathcal{L}_{mixed}$ represents the loss function under mixed precision; $\mathcal{L}_{float32}$ and $\mathcal{L}_{float16}$ represent the losses using 32-bit and 16-bit floating point numbers, respectively; λ is the balance coefficient. Using this method, training stability can be ensured, and the demand for computing resources can be greatly reduced.

TABLE III. HYPERPARAMETERS RELATED TO MIXED PRECISION TRAINING

Parameter	Value	Description	Unit
Precision Type	16-bit/32-bit	Precision type used in mixed precision training	Floating Point
Learning Rate	0.0001	The learning rate used by the optimizer, controlling the step size of gradient descent	Learning Rate
Batch Size	64	The number of samples used per training step	Samples
Number of Epochs	50	The total number of training epochs	Epochs

In Table III, the Precision Type parameter determines the numerical precision used, and 16-bit or 32-bit floating point numbers can be selected. Using 16-bit floating point numbers can significantly reduce memory usage and computing time, but in some cases it may affect the model accuracy. It is dynamically adjusted during training to balance performance and accuracy. Learning Rate is the learning rate of the optimizer, which controls the pace of the gradient descent algorithm to update the model parameters. A lower learning rate helps avoid excessive gradient updates during training and improves stability. Batch Size specifies the number of samples used for each training. A larger batch size can improve training efficiency and also increase memory burden. Number of Epochs indicates the rounds of model training. The more training cycles, the stronger

the model's fitting ability, but it also requires more computing resources and time.

Distributed training strategies are used to improve training efficiency. A combination of data parallelism and model parallelism is used to distribute training tasks among multiple computing nodes. Data parallelism divides the training data into multiple batches and passes them to different GPUs in parallel, while model parallelism distributes different levels or modules of the model among multiple GPUs for parallel training. This method can effectively improve training speed, reduce training time, and improve the stability and accuracy of the training process. The basic optimization formula for distributed training is as follows:

$$\text{Loss}_{total} = \sum_{i=1}^{N} \text{Loss}_i \quad (3)$$

In the formula, Loss_{total} represents the total loss; Loss_i is the local loss on each GPU node; N is the number of GPUs participating in the training. By using distributed training, this paper can significantly accelerate the convergence process and maintain efficient computing performance when training the improved ViT model on a large-scale dataset.

Combining the local self-attention mechanism, mixed precision training, and distributed training strategy, the improved ViT model can efficiently capture the details of Huizhou bamboo weaving patterns, and can also significantly shorten the training time and reduce the consumption of computing resources while maintaining high accuracy. These innovative optimization methods effectively solve the computing bottleneck problem of the traditional ViT model when processing complex patterns, and provide reliable technical support for large-scale pattern design tasks.

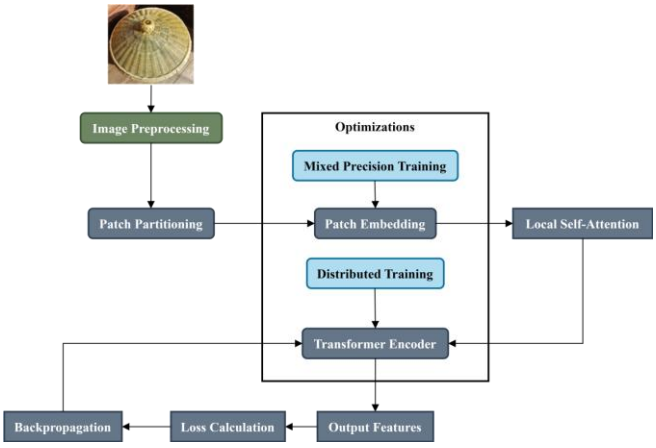

Fig. 2. Improved ViT model processing flow.

Fig. 2 shows the complete processing flow of the improved ViT model. The input image undergoes a preprocessing stage to remove noise and standardize it to ensure that the image data is suitable for model processing. The image is cut into several small blocks, each of which is converted into a vector of fixed dimension through an embedding layer as the input of the Transformer model. The core improvement is the application of a local self-attention mechanism, which significantly reduces the amount of computation brought by the global self-attention mechanism, while focusing more on capturing local features, improving the efficiency and accuracy of the model. After the local self-attention processing, the image block enters the Transformer encoder for more complex feature extraction to generate the final output features. The loss function calculation reflects the difference between the model prediction and the true label, and the network weights are adjusted through back propagation. To accelerate the training process and save computing resources, the improved model adopts mixed precision training and distributed training strategies. These optimization methods speed up the model training speed and maintain high accuracy. With this series of optimization measures, the improved ViT model improves the ability to process large-scale data while ensuring computing efficiency.

C. Innovative Pattern Generation and Detail Restoration

In the process of pattern generation, the improved ViT model first learns the style characteristics and structural layout of Huizhou bamboo weaving patterns through the self-attention mechanism to form an overall understanding of the pattern.

The model adds a detail restoration module in the design stage. The core purpose of this module is to solve the shortcomings of traditional generative models in the expression of pattern details, especially the restoration of blurred areas and missing parts of details. This measure makes the generated patterns both innovative and maintain high-quality restoration of details.

The detail restoration module is optimized based on the GAN architecture. In the generator part of the model, the improved ViT model is responsible for extracting high-level features of the pattern from the input design framework and mapping it to the innovative structure of the pattern. In the generation process, deep residual learning is applied, and the model can make detailed adjustments to the detail areas of the pattern to avoid over-smoothing or distortion in the generation of complex patterns. The loss function is designed as:

$$\mathcal{L}_{detail} = \mathcal{L}_{content} + \lambda_1 \mathcal{L}_{style} + \lambda_2 \mathcal{L}_{smoothness} \quad (4)$$

In the formula, $\mathcal{L}_{content}$ represents the content loss of the pattern; $\mathcal{L}_{style}$ is the style loss; $\mathcal{L}_{smoothness}$ is the smoothness loss; λ_1 and λ_2 are adjustment coefficients. By optimizing these losses, the generator can generate patterns similar to the training data, enhance the detail fidelity of the generated results, and avoid oversimplification of structure and texture.

During the optimization of the detail repair module, a specific region attention mechanism is applied to enhance the model's sensitivity to the pattern detail area. An adaptive weight mechanism is designed so that the model can automatically identify and focus on the key detail areas in the pattern, such as the complex bamboo weaving parts or the fine pattern boundaries during the generation process. The core of this mechanism is to calculate the feature differences of local regions, dynamically adjust the repair strategy according to the size of the difference, and achieve accurate repair of blurred areas and missing parts. The mathematical expression of the repair is:

$$\mathbf{S}_{repair} = \sum_{i=1}^{N} \omega_i \cdot \mathbf{S}_i \quad (5)$$

$\mathbf{S}_{repair}$ is the repaired pattern; $\mathbf{S}_i$ is the feature of the i-th local region; ω_i is the adaptive weight associated with the region; N is the total number of detail regions. Using the weighted summation method, the model can select the most appropriate solution from multiple repair strategies to achieve fine optimization of pattern details.

During the generation process, the artistic and structural consistency of the pattern is ensured, and the style transfer technology is used to adjust the artistic style of the generated results to be consistent with the training data. In the process of style transfer, the high-level artistic features of the pattern are guided by the style term in the loss function, so that the generated pattern has both creative design and the style characteristics of the traditional Huizhou bamboo weaving craft. The style loss calculation formula is as follows:

$$\mathcal{L}_{style} = \sum_{k=1}^{K} \|G_k - A_k\|_2 \quad (6)$$

In the formula, G_k and A_k represent the Gram matrix of the generated pattern and the real pattern at the k-th layer, respectively, and K is the number of layers. This loss compares the low-order features and high-order texture structure of the pattern, so that the generated pattern meets the morphological requirements and retains the original artistic style.

The pattern optimized by the detail restoration module uses this series of technical processing to restore the blurred areas and missing details, inject more artistic expression into the innovative design, and ensure that the pattern achieves a balance between accuracy and creativity. This optimization process improves the quality of the generated pattern, allowing it to have a deep inheritance of traditional culture and meet the aesthetic needs of modern design.

TABLE IV. DETAIL RESTORATION PARAMETERS FOR PATTERN GENERATION AND ENHANCEMENT

Parameter Name	Value	Description	Application Scenario
Detail Repair Module Weight	0.8	Controls the strength of the repair effect	Detail Repair Phase
Pattern Detail Loss Weight	0.75	Balances pattern details with overall design	During Generation
High-frequency Detail Recovery Coefficient	1.5	Enhances the recovery of high-frequency details	Detail Repair Process
Repair Image Resolution	512×512	The resolution of the output pattern	Post-repair Image
Detail Repair Iteration Count	10	The number of iterations for detail repair	During Detail Optimization
Module Activation Threshold	0.05	Threshold for activating the repair module	Repair Activation Standard

In Table IV, the weight of the detail repair module and the weight of the pattern detail loss determine the intensity and balance of the impact of detail repair on the overall design, so that the pattern has the best match between creative expression and detail accuracy. The setting of the high-frequency detail recovery coefficient can enhance the detail performance of the pattern, especially in the high-frequency area, to avoid detail loss. The repaired image resolution ensures high-quality output after the pattern is repaired, which is suitable for further application. The number of detail repair iterations controls the fineness of the repair process and increases the repair accuracy.

IV. METHOD EFFECT EVALUATION

A. Pattern Detail Retention

To evaluate the ability of the improved ViT model in capturing the details of Huizhou bamboo weaving patterns, the structural similarity index (SSIM) is used as the main evaluation indicator. SSIM is used to quantify the structural similarity between the generated pattern and the original pattern, and can comprehensively reflect the detail retention of the image in terms of brightness, contrast, and structure. An SSIM value close to 1 indicates that the pattern has a high degree of detail retention. The calculation formula for a more precise generation effect is as follows:

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \quad (7)$$

x and y represent the images of the original pattern and the generated pattern respectively; μ_x and μ_y are the means of images x and y, respectively; σ_x^2 and σ_y^2 are their respective variances; σ_{xy} is the covariance of the two images; c_1 and c_2 are constants to avoid the denominator being zero.

During the evaluation process, the original Huizhou bamboo weaving pattern is compared with the pattern generated by the improved ViT model, and the SSIM value between each pair of images is calculated. At the same time, to ensure the comprehensiveness of the evaluation, the improved model is compared horizontally with the traditional ViT model and the GAN method. Through this comparison, the performance differences of the improved ViT model in detail retention, pattern complexity, and structural restoration are comprehensively analyzed, and the effectiveness of the model in improving detail expression is verified.

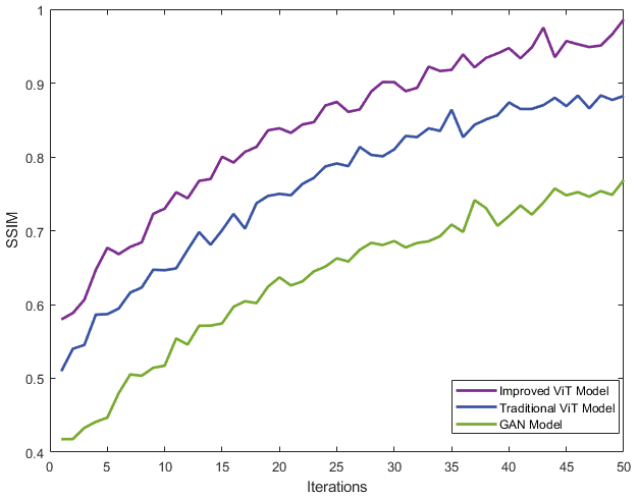

Fig. 3. Changes in SSIM values during different model training iterations.

Fig. 3 shows the changes in SSIM values of the improved ViT, traditional ViT, and GAN models at different training iterations. The improved ViT model improves rapidly in the early stage and converges stably in the later stage, tending to

0.95, indicating that it performs well in detail retention and structural similarity. The traditional ViT model tends to 0.88, showing that its ability in detail extraction is weak. Although the GAN model improves in the early stage of training, the final SSIM value is low and is not as stable as the ViT model in detail restoration. These changes reflect the differences in detail retention among different models, further verifying the superiority of the improved ViT model.

B. Computing Efficiency and Resource Consumption

To evaluate the advantages of the improved ViT model in terms of computing efficiency and resource consumption, training time and GPU memory usage are used as key indicators. Training time measures the time required for the model to complete optimization from the beginning of training, and GPU memory usage reflects the model's demand for hardware resources during training. In the comparative experiment, the same dataset and training conditions are used to train the improved ViT model, the traditional ViT model, and the GAN model, respectively, to generate Huizhou bamboo weaving patterns of the same quality, and the training time and GPU memory usage of each model at different data volumes are recorded to evaluate the computing efficiency of different models. The training time record is obtained by accurately timing the start and end of each training to ensure that the experimental results are repeatable and consistent. The GPU monitoring tool is used to collect the GPU memory usage during the training of each model in real-time. By comparing and analyzing these data, it can be determined whether the improved ViT model has advantages over the traditional ViT and GAN models in large-scale training, and whether it can effectively reduce the computing cost and improve the training efficiency.

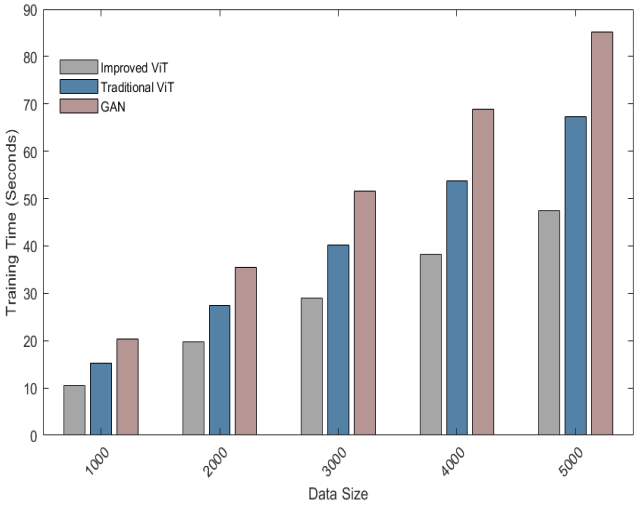

Fig. 4. Comparison of model training time under different data volumes.

Fig. 4 shows the comparison of the training time of the three models under different data volumes. As the data volume increases, the training time of all models shows an upward trend. The improved ViT model has the shortest training time, which is 47.4 seconds at a data volume of 5000. The training time of the traditional ViT model and the GAN model is relatively long, and the growth rate is large as the data volume increases. Using these data, it can be seen that the improved ViT model can effectively reduce the training time while generating high-quality patterns, and can reduce the computing cost in large-scale training, which reflects its advantage in computing efficiency.

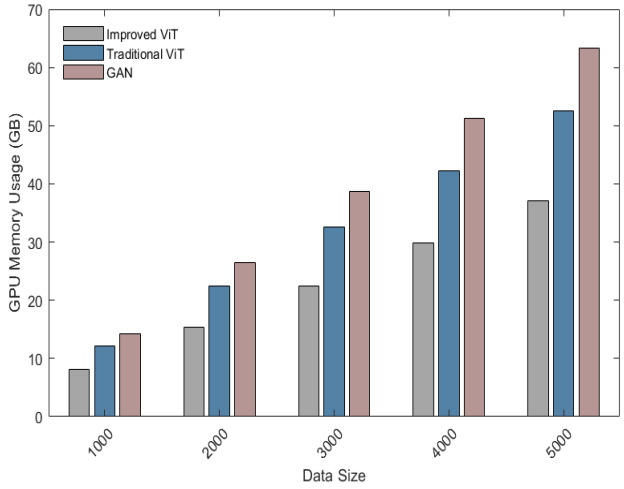

Fig. 5. Comparison of GPU memory usage of models under different data volumes.

Fig. 5 shows the GPU memory usage of the improved ViT, traditional ViT, and GAN models under different data volumes. As the data volume increases from 1000 to 5000 samples, the memory usage of the three models shows an upward trend, but the increase rate is different. The memory consumption of the improved ViT model in the entire data volume range is significantly lower than that of the traditional ViT and GAN models. When the data volume is 5000, the GPU memory usage is 37.1GB, and the memory usage advantage is more obvious. The improved ViT model can significantly reduce memory consumption and improve computing efficiency by optimizing the computing structure and applying the local self-attention mechanism.

V. CONCLUSION

This study constructs an improved ViT model and applies it to the generation and detail restoration tasks of Huizhou bamboo weaving patterns. By applying optimization methods such as local self-attention mechanism and mixed precision training, the improved ViT model guarantees the artistic creativity and detail expression of the generated patterns to a certain extent, and improves the performance in terms of computing efficiency and resource consumption. The experimental results show that the improved ViT model is superior to the traditional ViT and GAN models in many aspects.

From the perspective of pattern detail retention, the improved model has a significant advantage in improving the SSIM value, which tends to 0.95 after 50 training rounds, and can better retain the details of Huizhou bamboo weaving patterns, showing a relatively stable training process. In terms of computing efficiency and resource consumption, with a sample data volume of 5000, the training time of the improved ViT model is 47.4 seconds, and the GPU memory usage is 37.1GB. Under the premise of generating patterns of the same quality, the training time is reduced, providing a more efficient solution for

large-scale data processing. The improved ViT model has shown strong capabilities in pattern generation and detail restoration, and has also achieved satisfactory results in optimizing computing resources. These advantages give the model broad application prospects in art design, cultural heritage protection, and other visual generation tasks. In future research, more efficient attention mechanisms and training strategies can be further explored to further improve the model's performance and scalability.

FUNDING

This work was supported by Philosophy and Social Science Research Project of Colleges and Universities in Anhui Province. (Item Number：2023AH050876).

CONFLICTS OF INTERESTS

Authors do not have any conflicts.

DATA AVAILABILITY STATEMENT

No datasets were generated or analyzed during the current study.

CODE AVAILABILITY

Not applicable.

AUTHORS' CONTRIBUTIONS

Jinjin Rong, is responsible for designing the framework, analyzing the performance, validating the results, and writing the article. Xin Fang, is responsible for collecting the information required for the framework, provision of software, critical review, and administering the process.
